2:54PM X11.00003 Wrinkling instability in graphene supported on nanoparticle-patterned SiO₂ , WILLIAM CULLEN, MAHITO YAMAMOTO, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742-4111, OLIVIER PIERRE-LOUIS, LPMC, Université Lyon 1, France, THEODORE EINSTEIN, MICHAEL FUHRER, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742-4111 — Atomically-thin graphene is arguably the thinnest possible mechanical membrane: graphene's effective thickness (the thickness of an isotropic continuum slab which would have the same elastic and bending stiffness) is significantly less than 1 Å, indicating that graphene can distort out-of-plane to conform to sub-nanometer features. Here we study the elastic response of graphene supported on a SiO₂ substrate covered with SiO₂ nanoparticles. At a low density of nanoparticles, graphene is largely pinned to the substrate due to adhesive interaction. However, with increasing nanoparticle density, graphene's elasticity dominates adhesion and strain is relieved by the formation of wrinkles which connect peaks introduced by the supporting nanoparticles. At a critical density, the wrinkles percolate, resulting in a wrinkle network. We develop a simple elastic model allowing for adhesion which accurately predicts the critical spacing between nanoparticles for wrinkle formation. This work has been supported by the University of Maryland NSF-MRSEC under Grant No. DMR 05-20471 with supplemental funding from NRI, and NSF-DMR 08-04976.

3:06PM X11.00004 Molecular Dynamics Study of Ripples in Graphene and Bilayer Graphene , ARUNIMA SINGH, RICHARD G. HENNIG, Department of Materials Science and Engineering, Cornell University — Transmission electron microscopy experiments have shown that suspended graphene is not perfectly flat, but displays ripples such that the surface normal of graphene varies by several degrees [1,2]. For multi-layered graphene, the ripples are suppressed with increasing numbers of layers. Recent experiments demonstrated that ripples in suspended graphene can also be controlled by mechanical and thermally induced strain [3]. Knowledge of and control over the ripples in graphene is desirable for fabricating and designing of strain-based devices. We show using molecular dynamics simulation that thermally induced ripples in suspended single and multi-layer graphene at room temperature result in deviations of the local surface normal by $\pm 7^\circ$ and $\pm 4^\circ$ for single and bilayer graphene, respectively. These angular deviations are in excellent agreement with transmission electron microscopy results [2] and confirm that these ripples can be dynamic and thermally induced. We also study how these angles change as a function of applied tensile and shear strain. [1] Meyer J. C., Geim A. K., et al. Solid State Communications, 143, 101 (2007). [2] Meyer J.C., Geim A.K., et al. Nature, 446, 60 (2007). [3] Bao W., Miao F., et al. Nature Nanotechnology, 4 (9), 562 (2009).

3:18PM X11.00005 Ideal strength of graphene¹ , SUNGJONG WOO, YOUNG-WOO SON, Korea Institute for Advanced Study — We have investigated the ideal strength of graphene by calculating the response under strain based on density functional theory. The strength of materials with usual contaminations and impurities is typically weaker than the ideal one. However, we have considered realistic factors and calculated several electromechanical properties of perturbed graphene showing that under certain conditions graphene can endure more strain than the pristine one. The interpretation of our result will be presented in the context of competitions among different energy scales under mechanical strains that eventually leads to the structure failure.

¹Computational resources have been provided by KISTI Supercomputing Center (Project No. KSC-2011-C1-21).

3:30PM X11.00006 Determination of Young's Modulus of Graphene by Raman Spectroscopy , JAE-UNG LEE, DUHEE YOON, HYEONSIK CHEONG, Department of Physics, Sogang University, Seoul, Korea — The mechanical properties of graphene are interesting research subjects because its Young's modulus and strength are extremely high. Values of ~ 1 TPa for the Young's modulus have been reported [Lee et al. Science, 321, 385 (2008), Koenig et al. Nat. Nanotech. 6, 543 (2011)]. We made a graphene sample on a SiO₂/Si substrate with closed-bottom holes by mechanical exfoliation. A pressure difference across the graphene membrane was applied by putting the sample in a vacuum chamber. This pressure difference makes the graphene membrane bulge upward like a balloon. By measuring the shifts of the Raman G and 2D bands, we estimated the amount of strain on the graphene membrane. By comparing the strain estimated from the Raman measurements with numerical simulations based on the finite element method, we obtained the Young's modulus of graphene.

3:42PM X11.00007 Role of the effective tensile strain in the electromechanical response of helical graphene nanoribbons with open and closed edges , TRAIAN DUMITRICA, DONG-BO ZHANG, University of Minnesota — There is a growing need to understand the electronic properties of non-ideal graphene nanoribbons. Using objective molecular dynamics [1] and a density-functional based tight-binding model, we investigate the effects of torsion on the electromechanical properties of graphene nanoribbons with armchair edges. We propose to characterize with an effective tensile strain scalar [2] the torsional mechanical response, including a reverse Poynting effect, and the fundamental band gap modulations. The demonstrated utility of this concept in both the mechanical and electrical domains provides a perspective for understanding electromechanical response in a unified way, and for designing NEMS devices with graphene components. [1] T. Dumitric? and R.D. James, J. Mech. Phys. Sol. 55, 2206-2236 (2007). [2] D.-B. Zhang and T. Dumitric?, Small 7, 1023 (2011) .

3:54PM X11.00008 Failure mechanisms of graphene under tension , CHRIS MARIANETTI, Columbia University — Recent experiments established pure graphene as the strongest material known to mankind, further invigorating the question of how graphene fails. Using density functional theory, we reveal the mechanisms of mechanical failure of pure graphene under a generic state of tension at zero temperature. One failure mechanism is a novel soft-mode phonon instability of the K_1 -mode, whereby the graphene sheet undergoes a phase transition and is driven towards isolated hexagonal rings resulting in a reduction of strength. The other is the usual elastic instability corresponding to a maximum in the stress-strain curve. Our results indicate that finite wave vector soft modes can be the key factor in limiting the strength of monolayer materials.

4:06PM X11.00009 Characterization of strain in CVD graphene on copper substrates¹, RUI HE, University of Northern Iowa, LIUYAN ZHAO, NICHOLAS PETRONE, Columbia University, MICHAEL ROTH, University of Northern Iowa, JAMES HONE, PHILIP KIM, ABHAY PASUPATHY, ARON PINCZUK, Columbia University — Strain plays an important role in controlling graphene's properties and induces significant changes in the electronic band structure. Strain and morphology of CVD (chemical vapor deposition) graphene layers grown on Cu substrates are studied by Raman spectroscopy and scanning tunneling microscopy (STM). We find that CVD graphene on Cu surfaces are subject to strain which depends on the orientation of the underlying Cu surfaces. The strain is compressive on Cu (111) surface and estimated to be on the order of 0.5 percent by molecular dynamics (MD) simulations. For graphene grown on Cu (100) surface the strain is highly nonuniform and includes both compressive and tensile components. MD simulations of graphene on Cu (100) show highly nonuniform strain patterns including linear superstructures, consistent with the patterns seen in STM. For graphene grown on Cu foil the strain is partially released after graphene is removed from Cu surfaces and transferred onto oxidized Si substrate.

¹Supported by ONR and NSF

4:18PM X11.00010 Local nanoscale frictional variations of graphene investigated with lateral force microscopy¹, PATRICK HUNLEY, TYLER FLYNN, TOM DODSON, ABHISHEK SUNDARARAJAN, DOUGLAS STRACHAN, University of Kentucky — Lateral force microscopy is used to investigate the local nanoscale frictional variations on single- and multi-layered graphene films. Employing novel calibration methods, quantitative frictional measurements are taken for a range of normal loads. The coverage of specific high-friction regions with a single layer of graphene shows a significant reduction in the frictional characteristics.

¹Supported in part by the Kentucky NSF EPSCoR program through award EPS-0814194 and the University of Kentucky Center for Advanced Materials.

4:30PM X11.00011 Adsorption-induced Pore Expansion and Contraction in Activated Carbon, MATTHEW CONNOLLY, CARLOS WEXLER, University of Missouri Physics Department — Adsorbent materials such as activated carbon and Metal-Organic Frameworks (MOFs) have received significant attention as a potential storage material for hydrogen and natural gas. Typically the adsorbent material is assumed to consist of rigid slit- or cylindrical-shaped pores. Recent work has revealed the importance of the mechanical response of the adsorbent in the presence of an adsorbate. Here, we first demonstrate the flexibility of pore walls in activated carbon and the effect this has on the pore structure of the bulk samples. The interaction is modeled as a competition between Van der Waals interactions between neighboring walls and a resistance to bending due to the rigidity of graphene. Minimal energy configurations were calculated analytically for a simplified potential and numerically for a more realistic potential. The pore structures are discussed in the context of pore measurements on activated carbon samples. Following recent work by Cole and Neimark, large pressures due to an adsorbed film are predicted in the narrow pores of activated carbon. The coverage-dependent nature of adsorbed-film pressure, indicating a pressure-variant pore structure, is discussed in terms of adsorption isotherms.

4:42PM X11.00012 Hierarchical graphene materials: from monolayers to papers and nanocomposites, ZHIPING XU, Tsinghua University — Macroscopic graphene materials such as papers and nanocomposites consist of chemically modified graphene sheets and intersheet crosslinks of various types, which hold great promises in high-performance, multifunctional and light-weighted applications. In this talk, we will present a multiscale approach (density functional theory, molecular dynamics and continuum mechanics) to understand simultaneously atomistic mechanisms, microscale structures and microscopic performance of these hierarchical graphene materials, and provide general principles for materials design that are supported by experimental evidence. Hierarchical structures of graphene-based materials will be also discussed comparably with biological materials that are widely studied recently, such as bones, nacre and collagen fibrils, which possess similar materials hierarchies and inspire many novel concepts in new materials development.

4:54PM X11.00013 Layer Effects in Graphene NEMS Resonators, BRITTON BAUGHER, TCFEOR NDUKUM, KEVIN FISCHER, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — In this talk we will present new data on mono, bi, and tri-layer graphene nanoelectromechanical (G-NEMS) resonators. G-NEMS resonators utilize graphene's high mobility, high Young's modulus, Dirac-like dispersion relation, and other unique qualities to produce unusual physical phenomena at the intersection of electronics and mechanics on the quantum scale. We extend the work done on these devices with a study into the effects of layer number on temperature dependence, quality factor, tunability, and frequency amongst others.

5:06PM X11.00014 Ultrastrong Adhesion of Graphene Membranes, STEVEN P. KOENIG, NARASIMHA G. BODDETI, MARTIN L. DUNN, J. SCOTT BUNCH, Department of Mechanical Engineering, University of Colorado at Boulder — As mechanical structures enter the nanoscale regime, the influence of van der Waals forces increases. Graphene is attractive for nanomechanical systems because its Young's modulus and strength are both intrinsically high, but the mechanical behavior of graphene is also strongly influenced by the van der Waals force. For example, this force clamps graphene samples to substrates, and also holds together the individual graphene sheets in multilayer samples. Here we use a pressurized blister test to directly measure the adhesion energy of graphene sheets with a silicon oxide substrate. We find an adhesion energy of 0.45 ± 0.02 J m⁻² for monolayer graphene and 0.31 ± 0.03 J m⁻² for samples containing two to five graphene sheets. These values are larger than the adhesion energies measured in typical micromechanical structures and are comparable to solid-liquid adhesion energies. We attribute this to the extreme flexibility of graphene, which allows it to conform to the topography of even the smoothest substrates, thus making its interaction with the substrate more liquid-like than solid-like.

5:18PM X11.00015 Graphene coatings: An efficient protection from oxidation, MEHMET TOPSAKAL, HASAN SAHIN, SALIM CIRACI, UNAM-Institute of Materials Science and Nanotechnology — We demonstrate that graphene coating can provide an efficient protection from oxidation by posing a high energy barrier to the path of oxygen atom, which could have penetrated from the top of graphene to the reactive surface underneath. Graphene bilayer, which blocks the diffusion of oxygen with a relatively higher energy barrier provides even better protection from oxidation. While an oxygen molecule is weakly bound to bare graphene surface and hence becomes rather inactive, it can easily dissociate into two oxygen atoms adsorbed to low coordinated carbon atoms at the edges of a vacancy. For these oxygen atoms the oxidation barrier is reduced and hence the protection from oxidation provided by graphene coatings is weakened. Our predictions obtained from the state of the art first-principles calculations of electronic structure, phonon density of states and reaction path will unravel how a graphene can be used as a corrosion resistant coating and guide further studies aiming at developing more efficient nanocoating materials.

Thursday, March 1, 2012 2:30PM - 5:30PM –

Session X12 DMP: Focus Session: Graphene: Growth, Mechanical Exfoliation, and Properties - Morphology and Interactions 210C

2:30PM X12.00001 Atomic Scale Properties of Chemically Doped Graphene, ABHAY PASUPATHY, Columbia University — In monolayer graphene, substitutional doping during growth can be used to alter its electronic properties. We used scanning tunneling microscopy, Raman spectroscopy, x-ray spectroscopy, and first principles calculations to characterize individual nitrogen dopants in monolayer graphene grown on a copper substrate. Individual nitrogen atoms were incorporated as graphitic dopants, and a fraction of the extra electron on each nitrogen atom was delocalized into the graphene lattice. The electronic structure of nitrogen-doped graphene was strongly modified only within a few lattice spacings of the site of the nitrogen dopant. These findings show that chemical doping is a promising route to achieving high-quality graphene films with a large carrier concentration. Ref: L. Zhao et al, *Science* **333**,999 (2011).

3:06PM X12.00002 Quantum Hall Effect in Graphene Bilayers Grown on Copper by Chemical Vapor Deposition¹, BABAK FALLAHAZAD, The Microelectronics Research Center, The University of Texas at Austin, YUFENG HAO, The University of Texas at Austin, KAYOUNG LEE, SEYOUNG KIM, The Microelectronics Research Center, The University of Texas at Austin, RODNEY RUOFF, The University of Texas at Austin, EMANUEL TUTUC, The Microelectronics Research Center, The University of Texas at Austin — We report an investigation of quantum Hall effect in graphene bilayers grown on Cu substrates by chemical vapor deposition. Raman spectroscopy of the as grown graphene bilayers reveals a position dependent full width half maximum of the 2D peak, ranging from 22 to 55 cm⁻¹, suggesting the bilayer is a mixture of Bernal stacked and decoupled graphene monolayers. Using scanning Raman spectroscopy we identify areas with either wide (45-55 cm⁻¹), as well as narrow (22-26 cm⁻¹) 2D peaks, in order to fabricate back-gated Hall bars on such grains. Magnetotransport measurements in bilayer regions characterized by a wide 2D peak reveal quantum Hall states (QHS) at filling factors $\nu = \pm 4, 8, 12$ consistent with a Bernal stacked bilayer, which develop at magnetic fields higher than 15 T. In contrast, magnetotransport measurements in bilayer regions defined by a narrow 2D peak shows QHSs down to 3 T, and with a sequence consisting of the superposition of the QHSs of two independent monolayers. We compare the QHS energy gaps extracted from activation measurements with the theoretical Landau level (LL) separation, and estimate the LL broadening.

¹We appreciate support from the SWAN NRI and the ONR.

3:18PM X12.00003 Layer Number and Stacking Order Imaging of Few-layer Graphenes by Transmission Electron Microscopy, JINGLEI PING, MICHAEL FUHRER, Center for Nanophysics and Advanced Materials, University of Maryland, College Park — A method using transmission electron microscopy (TEM) selected area electron diffraction (SAED) patterns and dark field (DF) images is developed to identify graphene layer number and stacking order by comparing intensity ratios of SAED spots with theory. Graphene samples are synthesized by ambient pressure chemical vapor deposition and then etched by hydrogen in high temperature to produce samples with crystalline stacking but varying layer number on the nanometer scale. Combined DF images from first- and second-order diffraction spots are used to produce images with layer-number and stacking-order contrast with few-nanometer resolution. This method is proved to be accurate enough for quantitative stacking-order-identification of graphenes up to at least four layers. This work was partially supported by Science of Precision Multifunctional Nanostructures for Electrical Energy Storage, an Energy Frontier Research Center funded by the U.S. DOE, Office of Science, Office of Basic Energy Sciences under Award Number DESC0001160.

3:30PM X12.00004 Metal surface melting effect on the formation of graphene wrinkles, TEREZA PARONYAN, ELENA PIGOS, AVETIK HARUTYUNYAN, Honda Research Institute, USA Inc., Columbus, OH, 43212, USA, HONDA RESEARCH INSTITUTE TEAM — The synthesis of high quality large area graphene is a significant challenge that needs to be overcome for practical applications of this material. Therefore, understanding the growth mechanism of graphene is crucial in order to explain the origin of defects on it. Different thickness of Copper and Nickel films deposited on silica substrates, and foils with various degrees of purity were used in this study. We investigated the changes in the surface morphology of the thin films and foils with temperature at 860-1100°C with and without growth of graphene by Chemical Vapor Deposition method. Detailed investigation by Raman spectroscopy, SEM and AFM analysis revealed that thermal treatment of the metal substrates at high temperatures ~1000°C causes formation of dendritic like structures on the surface. We attributed these structures to the non-equilibrium solidification of the melted surface of the metal during the cooling, which are also present in the case of graphene growth. We concluded that the reconstruction of the metal surface morphology in the case of graphene growth, due to the surface melting, significantly affects on the final topography of the graphene wrinkles and, thereby on the quality of graphene.

3:42PM X12.00005 Growth and Characterization of Graphene-Boron Nitride Heterostructures¹, PETER SUTTER, Brookhaven National Laboratory — Graphene has been used to explore the fascinating properties of two-dimensional sp² carbon, and shows great promise for applications. Heterostructures of graphene (G) and hexagonal boron nitride (h-BN) have the potential for extended functionality, e.g., providing high carrier mobilities in graphene devices supported on h-BN and giving rise to emergent electronic behavior near in-plane G/h-BN junctions. While significant progress has been made recently in separate graphene and boron nitride growth on transition metals, the controlled synthesis of high-quality G/h-BN heterostructures poses new challenges. We discuss the fundamental growth mechanisms underlying the synthesis of G/h-BN heterostructures, studied by a combination of in-situ surface microscopy methods. Real-time low-energy electron microscopy (LEEM) provides a mesoscale view of the nucleation and growth of h-BN in the presence of graphene, and vice-versa. LEEM imaging together with diffraction and angle resolved photoemission spectroscopy (micro-ARPES) gives insight into the interaction between graphene and h-BN. Scanning tunneling microscopy has been used to probe intermixing and the atomic-scale structure of interfacial boundaries. Combining real-time and atomic-resolution imaging, we identify successful approaches for achieving atomically sharp G/h-BN junctions.

¹Research carried out at the Center for Functional Nanomaterials, Brookhaven National Laboratory, supported by the U.S. Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-98CH10886.

4:18PM X12.00006 Physical and electrical properties of graphene folds grown by Chemical Vapor Deposition, WENJUAN ZHU, TONY LOW, YU ZHU, AGEETH BOL, HUGEN YAN, XUESONG LI, YU-MING LIN, YANQING WU, FENGNIAN XIA, VASIL PEREBEINOS, PHAEDON AVOURIS, IBM T.J. Watson Research Center — We found that there is a large density of wrinkles on CVD graphene transferred to a SiO₂/Si substrate. At these graphene wrinkles, the SEM signal intensity is lower, the AFM height is higher, and the Raman G-band intensity is stronger as compared to the surrounding single-layer graphene, due to extra layers of graphene at the wrinkles. TEM images confirmed that wide wrinkles are folds instead of ridges. The channel resistance near the Dirac point along graphene folds is significantly lower than the resistance without folds. However, as the gate field or the carrier density is increased, the difference between graphene channel along the fold and without the fold is reduced, due to carrier screening.

4:30PM X12.00007 Superior Mobility in Chemical Vapor Deposition Synthesized Graphene by Grain Size Engineering, NICHOLAS PETRONE, CORY DEAN, INANC MERIC, AREND VAN DER ZANDE, Columbia University, PINSHANE HUANG, Cornell University, LEI WANG, Columbia University, DAVID MULLER, Cornell University, KENNETH SHEPARD, JAMES HONE, Columbia University — Chemical vapor deposition (CVD) offers a promising method to produce large-area films of graphene, crucial for commercial realization of graphene-based applications. However, electron transport in CVD grown graphene has continued to fall short of the performance demonstrated by graphene derived from mechanical exfoliation. Lattice defects and grain boundaries developed during growth, structural defects and chemical contamination introduced during transfer, and charged scatterers present in sub-optimal dielectric substrates have all been identified as sources of disorder in CVD grown graphene devices. We grow CVD graphene and fabricate field-effect transistors, attempting to minimize potential sources of disorder. We reduce density of grain boundaries in CVD graphene by controlling domain sizes up to 250 microns. By transferring CVD graphene onto h-BN utilizing a dry-transfer method, we minimize trapped charges at the interface between graphene and in the underlying substrate. We report field-effect mobilities up to 110,000 cm²V⁻¹s⁻¹ and oscillations in magnetotransport measurements below 1 T, confirming the high quality and low disorder in our CVD graphene devices.

4:42PM X12.00008 Transfer-Free, Wafer-Scale, and Patterned Synthesis of Graphene on Dielectric Substrates, HOSSEIN SOJOURDI, SAMUEL GRAHAM, Woodruff School of Mechanical Engineering, Georgia Institute of Technology, 771 Ferst Dr Atlanta, GA 30332-0405 — We report a method for the direct, wafer-scale synthesis of graphene on dielectric substrates using a solid carbon source. Graphene films were synthesized through the thermal decomposition of poly(methyl methacrylate) on copper coated quartz and Si/SiO₂ substrates in a low pressure H₂/Ar environment. The Cu film partially evaporated during growth, leaving a graphene layer directly on the dielectric substrate. Polyacrylamide was used for synthesis of N-doped graphene due to its nitrogen content. A similar method with process optimization was utilized to grow graphene without any external carbon source. Trace amounts of carbon in metal films result in direct formation of graphene on insulators through a segregation process. A wet etch step allowed complete removal of the metal film, leading to continuous graphene coverage of the surface. This technique utilized for patterned synthesis of graphene and can be used in Si-wafer compatible device fabrication.

4:54PM X12.00009 Transport studies of dual-gated ABA- and ABC-stacked trilayer graphene, K. ZOU, Department of Physics, The Pennsylvania State University, University Park, PA 16802, F. ZHANG, Department of Physics, The University of Texas at Austin, Austin, TX 78701, C. CLAPP, Department of Chemistry, Amherst College, Amherst, MA 01002, A.H. MACDONALD, Department of Physics, The University of Texas at Austin, Austin, TX 78701, J. ZHU, Department of Physics, The Pennsylvania State University, University Park, PA 16802 — We present electrical transport studies of dual-gated ABA- and ABC-stacked trilayer graphene field effect transistors. Employing high-quality thin HfO₂ layers as the top and back gate dielectrics, we independently tune the carrier density and control the band structure of trilayer graphene via the application of a perpendicular electric field E_{perp} . The large gating efficiency of the two gates (5.53×10^{12} /cm² per Volt) and their high breakdown voltage (> 6 V) enable us to reach exceedingly large carrier densities and E_{perp} values, which results in wide tuning of the conductivity of the trilayer devices. Results on ABA-stacked trilayer graphene confirm its semi-metallic nature and reveal evidence of the band structure changes induced by E_{perp} . The resistance at the charge neutrality point of ABC-stacked trilayer graphene increases by many orders of magnitude with increasing E_{perp} due to the gradual opening of a band gap. Our results suggest a saturation of the gap size at perpendicular displacement fields greater than 3.5 V/nm, in agreement with theoretical calculations.

5:06PM X12.00010 Graphene growth by CVD using liquid precursors, JESSICA CAMPOS DELGADO, ANDRÉS BOTELLO-MÉNDEZ, BENOIT HACKENS, JEAN-CHRISTOPHE CHARLIER, THOMAS PARDOEN, JEAN-PIERRE RASKIN, Université Catholique de Louvain — Chemical vapor deposition (CVD) represents an attractive route to synthesize large-area graphene. Its catalytic growth using metals has been studied in recent years, the most popular being nickel and copper. We have successfully grown graphene on copper by CVD at ambient pressure using alcohols as the carbon feedstock. The produced materials are analyzed by SEM, TEM, Raman spectroscopy and transferred onto Si/SiO₂ substrates using standard methods. Raman fingerprint of monolayer graphene is present in our samples. This technique represents a safer and more versatile alternative to the production of graphene compared to the synthesis of graphene using methane at low pressure.

5:18PM X12.00011 Vibrational properties in graphene-on-metal systems: A scanning tunneling microscopy study and density functional theory calculations, HAIGANG ZHANG, YUYANG ZHANG, WENDE XIAO, SHIXUAN DU, HONGJUN GAO, Institute of Physics, Chinese Academy of Science, PROF. HONGJUN GAO'S NANO RESEARCH GROUP TEAM — Combining inelastic electron tunneling microscopy (IETS) measured by scanning tunneling microscopy and quantum mechanical calculations based on density functional theory, we investigate and compare the vibrational properties of graphene on various transition metal substrates. The observed dI/dV spectra and mappings indicate there is a mode dependant spatial localization for graphene on Ru(0001) surface. In contrast, vibrations of graphene on Pt(111) surface and Ni(111) surface is homogeneous. Out-of-plane vibration modes of graphene are tuned by the different interactions on these three substrates. Vibrational density of states of graphene and graphene/Ni(111) system are calculated and make comparison to the IETS experiments. We also calculate the inelastic and elastic tunneling coefficients in Graphene/Ni(111) system to understand the missing peak in IETS experiments. Our results point to the importance of interfacial bonding on phonon properties and, consequently, electronic and thermal transport properties of graphene based devices.

Thursday, March 1, 2012 2:30PM - 5:30PM –

Session X13 DMP GMAG: Focus Session: Magnetic Nanostructures-Hard Magnetic Materials and Magnetocaloric Materials 211

2:30PM X13.00001 Thermal Fluctuation and Finite- Temperature Performance of Hard-Soft Composite Magnets¹, ALEXANDER BELEMUK, S.T. CHUI, University of Delaware — The demagnetization behavior of exchange-coupled hard/soft magnets was studied by finite temperature Monte Carlo simulation. Hard phase cube inclusions (Nd₂Fe₁₄B, SmCo₅ and Sm₂Fe₁₇N₃) into a soft matrix (FeCo) and hard/soft multilayer structure were studied. The easy axis of the hard and soft phase and the initial magnetization are parallel to the applied field. We found significant thermal fluctuations and lowering of the remnant magnetization with increasing soft magnet content than is anticipated from zero-temperature models, especially at higher temperatures. This greatly diminishes the expected performances of composites. For cube inclusions there is a boundary mismatch of the magnetization on the hard/soft interface. We investigated this mismatch as function of the soft phase content and temperature. The spin wave spectrum due to the mismatched dipolar interaction will be discussed.

¹Supported by ARPAE

2:42PM X13.00002 Control of Size and Magnetic Properties of L_{10} FePt islands by DC sputtering¹, XIAO CAO HU, Department of Materials Science and Engineering, University of DE, Newark, DE, 19716, USA, OZAN AKDOGAN, WANFENG LI, GEORGE HADJIPANAYIS, Department of Physics and Astronomy, University of DE, Newark, DE, 19716, USA — FePt particles with the tetragonal L_{10} structure are attractive for high density recording media. In this study, we have fabricated well-ordered and separated L_{10} FePt islands on MgO (100) substrates by DC sputtering at temperatures varying from room temperature to 700 °C. The dependence of particle size, degree of ordering and magnetic properties on sputtering time (5-20s), power (5-20W) and substrate temperature (300-1000K) were investigated. Electron diffraction patterns from TEM showed that the islands had the L_{10} tetragonal structure. TEM data revealed that a higher substrate temperature significantly increased the size of the islands from 2 to 20 nm whereas a higher sputtering power and longer sputtering times did not change the island size much but made the islands more connected with each other. Larger size islands and inter-connected islands showed a higher degree of ordering with an ordering parameter of 0.8 achieved at 600 °C. The magnetic properties are currently being measured and the results will be reported.

¹Work is supported by DOE ARPA-E DE-AR0000046.

2:54PM X13.00003 Nano-granular FePt thin films for thermally-assisted magnetic recording, TIFFANY SANTOS, OLEKSANDR MOSENDZ, SIMONE PISANA, JAMES REINER, GREGORY PARKER, BARRY STIPE, DIETER WELLER, Hitachi Global Storage Technologies — In order to extend the data storage density in hard disk drives beyond 1 Tb/in², nano-size grains of a high crystalline anisotropy (K_u) material are required to obtain these high densities and maintain thermal stability. A promising approach to recording using high- K_u materials is thermally-assisted magnetic recording (TAR), in which the media is locally heated above the Curie temperature while a magnetic field is applied in order to write a bit. FePt with L_{10} crystalline order is a potential candidate for TAR media. We deposit FePt nano-granular films with carbon as the segregant material, by co-sputtering on glass substrates at elevated temperature. Underlayer materials are selected for heat-sinking and to attain high out-of-plane L_{10} order. Characterization of the media by x-ray diffraction, magnetometry and transmission electron microscopy show that we can achieve properties that are promising for TAR media, such as an average grain size < 7.5nm, size distribution as low as 16%, coercivity as high as 5 tesla and $K_u > 4.5 \times 10^7$ erg/cm³. Recording densities exceeding 600 Gb/in² have been demonstrated for our FePt granular films using a static tester.

3:06PM X13.00004 Confined stripe structure in periodically grooved NdCo Films with perpendicular magnetic anisotropy¹, JOSE I. MARTIN, AURELIO HIERRO-RODRIGUEZ, ROSALIA CID, GABRIEL RODRIGUEZ-RODRIGUEZ, MARIA VELEZ, LUIS M. ALVAREZ-PRADO, JOSE M. ALAMEDA, Depto. Fisica, Universidad de Oviedo and CINN (CSIC - U.Oviedo - P.Asturias), Spain — Magnetic multilayers are broad research field with many interesting phenomena depending on interlayer coupling. Also, since the development of nanolithography techniques, magnetic nanowires and dots have been intensively investigated [1]. Recently, as a combination of these two fields, the concept of magnetic lateral superlattice has emerged: continuous magnetic films with a lateral modulation of their magnetic properties at submicrometric length scale [2]. In this work, we have fabricated amorphous Nd-Co films with perpendicular magnetic anisotropy and a periodic thickness modulation by e-beam lithography and ion milling. Lateral periods range from 2 μ m - 500 nm and groove depths from 10 to 30 nm. MFM and Kerr magnetometry have been used for characterization. Lateral patterning modifies the interplay between magnetostatic energy, perpendicular and in plane anisotropy and exchange interaction resulting in confined magnetic stripe structures. The different regimes that appear depending on the size of the periodic thickness modulation relative to the magnetic stripe period will be discussed. [1] J.I Martin et al, JMMM, 256 (2003) 449 [2] S. P. Li et al, PRL 88 (2002) 087202; N. Martin et al, PRB 83 (2010) 174423

¹Work supported by Spanish MICINN

3:18PM X13.00005 Intrinsic Magnetic Properties of fct FePt Nanocubes and Rods by Cluster Beam Deposition¹, OZAN AKDOGAN, WANFENG LI, GEORGE HADJIPANAYIS, Department of Physics and Astronomy, University of DE, Newark, DE, 19711 USA, RALPH SKOMSKI, DAVID SELLMYER, Department of Physics and Astronomy, University of Nebraska, Lincoln, NE 68588 USA — In this work, single crystal fct FePt nanocubes have been successfully produced by a cluster beam deposition technique without the need of post annealing. Particles have been deposited by DC magnetron sputtering using high Ar pressures (0.5 to 2 Torr) on both single crystal Si substrates and Au grids for the measurement of magnetic and structural properties, respectively. The nanocubes have a uniform size distribution with an average size of 6.5 nm. At 1 Torr, the particles have the fct structure with an order parameter of 0.5 and a RT coercivity of 2 kOe with high switching fields seen in the hysteresis loop. Particle size was controlled by changing the pressure and power and also by ex-situ annealing. In addition to these nanocubes, micron size rods (which consist of 20 nm nanoparticles) with the fct structure have been observed near the cluster gun. These particles show a room temperature coercivity of 8 kOe with an order parameter of 0.85. Intrinsic magnetic properties (Curie temperature, H_A , M_S and magnetic viscosity) of the nanocubes and the nanoparticles (separated from the rods) have been extensively studied and the results will be reported.

3:30PM X13.00006 Confinement Effect on the Phase Transformation of FePt from $A1$ to $L1_1$, ANDREW GALLAGHER, LEVENT COLAK, OZAN AKDOGAN, GEORGE HADJIPANAYIS, Department of Physics and Astronomy, University of DE, Newark, DE, 19711, USA — The major challenge for the application of chemically synthesized FePt nanoparticles (NPs) in magnetic storage media is the sintering problem encountered during the required high temperature annealing to obtain the high anisotropy L_{10} phase. In this work, we have used two methods to avoid sintering: coating the NPs with a protective layer of silica (SiO_2) and using porous aluminum oxide (Al_2O_3) as a template to hold the NPs. The NPs were synthesized via the synthesis method of Sun *et al.*^[1] The NPs were added to the Al_2O_3 by in-situ suctioning of the reaction solution into the porous Al_2O_3 template. Monodispersed FePt NPs with a size of 5.8 and 15 nm were coated with SiO_2 shells using a water-in-oil microemulsion method. High room temperature coercivities were only obtained after annealing the samples at 900 °C for long times (24-48 h) under forming gas flow as compared to the usual 600-700 °C. Values of 4.7 and 7.8 kOe were observed in SiO_2 and Al_2O_3 samples, respectively after annealing for 24 h at 900 °C. This behavior suggests that the restricted geometry of the samples suppresses the phase transformation drastically.

3:42PM X13.00007 Towards high strength nanocomposite magnets — Approaches from the bottom¹, J. PING LIU, University of Texas at Arlington — Exchange-coupled nanocomposite magnets are regarded as the next generation of permanent magnetic materials, based on the theoretical predictions. However, many fundamental questions and technical challenges remain in understanding the inter-phase exchange interactions and in processing bulk nanocomposite magnets with enhanced energy products. We will review recent advancements in both the fundamental research and the materials processing technologies. New findings about the effects of soft-phase properties and interface conditions on the hard/soft phase exchange interactions will be presented. Particularly, the development of the bottom-up approaches in materials processing will be discussed. Novel methodology for nanoparticle synthesis including the salt-matrix annealing, surfactant-assisted ball milling and severe plastic deformation will be described. Unconventional compaction techniques including warm compaction and dynamic compaction are recommended because they can be used to retain desired nanoscale morphology for effective exchange coupling in bulk nanocomposite magnets. A perspective on fabrication of anisotropic nanocomposite magnets will be also given.

¹Work supported by DoD/DARPA, MURI, ARO, and NSF.

4:18PM X13.00008 NdCo₅ Nanoflakes and Nanoparticles Produced by Surfactant-Assisted High Energy Ball Milling¹, NILAY GUNDUZ AKDOGAN, WANFENG LI, GEORGE HADJIPANAYIS, Department of Physics and Astronomy, University of Delaware, Newark, DE, U.S.A. — The study of size and surface effects in rare earth transition metal nanoparticles is scientifically very important. In this work our studies were focused on NdCo₅ which is interesting because of its complex magnetic ordering behavior at different temperatures. Anisotropic NdCo₅ nanoparticles have been produced by surfactant-assisted high-energy ball milling (HEBM) of nanocrystalline precursor alloys. A two-stage ball milling method has been employed to produce the NdCo₅ nanoflakes and nanoparticles. NdCo₅ flakes have a thickness below 150 nm and an aspect ratio as high as 10² - 10³; the nanoparticles have an average size of 7 nm. Both the nanoparticles and nano-flakes showed high coercivities at low temperatures, with values at 50 K of 3 kOe and 3.7 kOe, respectively. The high values of coercivity observed in a planar anisotropy phase can be attributed to the large surface anisotropy of nanoparticles that leads to an effective uniaxial-type of behavior. The nanoparticles also showed spin reorientation temperatures which are lower when compared to the bulk values.

4:30PM X13.00009 Magnetic Studies on Nd₂Fe_{14-x}Mn_xB Nanoflakes and Nanoparticles Produced by Surfactant-Assisted High Energy Ball Milling¹, GEORGE HADJIPANAYIS, NILAY GUNDUZ AKDOGAN, WANFENG LI, Department of Physics and Astronomy, University of Delaware, Newark, DE, U.S.A. — High temperature magnetic ordering studies on rare earth transition-metal nanoparticles and nanoflakes present a great challenge due to the very high reactivity of these materials. It is well known that Mn substitution for Fe in Nd₂Fe₁₄B compound decreases the Curie temperature to a temperature range that allows for reliable measurements to be made. In this work, we have studied the magnetic properties of Mn substituted Nd₂Fe₁₄B particles in the temperature range of 50-400 K. Nd₂Fe_{14-x}Mn_xB nanoparticles and nanoflakes have been produced by surfactant-assisted high-energy ball milling (SA-HEBM). Different size nanoparticles have been obtained by varying the milling conditions. Anisotropic Nd₂Fe_{14-x}Mn_xB nanoparticles have been found with a size from 13 to 25 nm. Both the nanoparticles and nano-flakes showed high coercivities at low temperatures, with values at 50 K of 2.4 kOe and 5.5 kOe, respectively. The Curie temperature was determined from the temperature dependence of magnetization. We have observed a different magnetic ordering behavior in the nanoparticles with Curie temperatures that are higher when compared to the bulk values.

4:42PM X13.00010 Giant Coercive Fields of 2.5 Tesla in Nanostructured Mn_xGa Films¹, STEVEN BENNETT, THOMAS NUMMY, THOMAS CARDINAL, WELVILLE NOWAK, DON HEIMAN, Northeastern University — There is a growing interest in designing new magnetic materials that are free of rare-earth elements. The magnetism of the Heusler ferrimagnet Mn_xGa [1] was found to be enhanced when fabricated with nanoscale structural disorder. Films of Mn_xGa (x=2 to 3) with thicknesses of 20 to 40 nm were grown using molecular beam epitaxy at 100 °C then annealed at 400 °C. Disordered films were grown on lattice mismatched Si (001) substrates, then compared to epitaxially grown films on desorbed GaAs (001) substrates. While the epitaxial films have small hysteresis in the magnetization with coercive fields in the range $\mu_0 H_C = 10^{-2}$ - 10^{-1} T, the disordered films exhibited surprisingly wide hysteresis with record high coercive fields as large as $\mu_0 H_C = 2.5$ T. These magnitudes are comparable to those of rare-earth-based magnets. This hysteresis was also present in the anomalous Hall effect. The enhanced coercive field in the disordered material arises from a combination of the exceptionally large magnetocrystalline anisotropy and nanoscale structural disorder. These results point out a new opportunity for developing rare-earth-free magnetic materials. Discovery of this unusually high coercive field is outlined and its sources discussed. [1] J. Winterlik, et al., Phys. Rev. B **77**, 054406 (2008).

4:54PM X13.00011 Tunable exchange length in laminate exchange coupled composite media, B.J. KIRBY, National Institute of Standards and Technology, HAO-CHENG HOU, CHIH-HUANG LAI, National Tsing Hua University, Taiwan — Exchange coupled composites - with a hard layer (HL) to anchor against thermal instabilities, and a soft layer (SL) to assist magnetization reversal - have been proposed for advanced recording applications. The reversal assist relies on a non-coherent rotation between the HL and SL, - the exchange-spring (ES) - in which the interfacial domain wall traverses the hard/soft interface, and promotes switching. Typically, the soft region is a single layer, with the emergent composite properties mainly determined by the choice of soft material. We are pursuing a more sophisticated approach, using a hard CoPtCr-SiO₂ layer adjacent to a multilayer of the same material, [CoPtCr-SiO₂/Pt]N, softened by lamination with Pt layers. Simulations predict that when the SL thickness exceeds a critical exchange length, a significant portion should decouple from the HL, becoming a domain wall nucleation site. Thus, ES behavior should be tunable via the Pt thickness. To test this, we have used polarized neutron reflectometry to measure the field-dependent magnetic depth profiles - and directly characterize ES formation - for a series of samples with varying Pt laminate thickness. The experimentally determined relationship between laminate thickness and ES formation will be discussed.

5:06PM X13.00012 Impact of Size Reduction on the Magnetocaloric Effect in Single- and Multi-Phase Manganites¹, N.S. BINGHAM, P. LAMPEN, A. PURI, S. CHANDRA, M.H. PHAN, H. SRIKANTH, University of South Florida, C.L. ZHANG, S.W. CHEONG, Rutgers University, T.H. HOANG, H.D. CHINH, Hanoi University of Technology — Mixed-valent manganites of the form $R_{1-x}M_x\text{MnO}_3$ ($R=\text{La, Pr, Nd, Sm}$ and $M=\text{Sr, Ca, Ba, Pb}$) are of interest as low-cost materials for potential application in the area of active magnetic refrigeration (AMR). An important parameter to optimize for AMR is the refrigerant capacity (RC), which depends on both the magnitude and breadth of the magnetic entropy change peak. Reducing the dimensions of a system to the nanoscale has the potential to enhance the RC by broadening a transition, but can also lead to a drop in entropy change. In this study, we contrast the impact of size reduction on the magnetic and magnetocaloric properties of single-phase $\text{La}_{0.4}\text{Ca}_{0.6}\text{MnO}_3$ (LCMO) and phase-separated $\text{La}_{0.35}\text{Pr}_{0.275}\text{Ca}_{0.375}\text{MnO}_3$ (LPCMO). Nanoparticles of LCMO and LPCMO were prepared by a sol-gel method; single crystals were grown in an optical floating zone furnace. XRD, SEM, and TEM were used to characterize the samples and DC magnetometry measurements were performed using a Quantum Design VSM. We find that size reduction negatively impacts both magnetization and the magnetocaloric properties in LCMO, while enhancing RC and entropy change simultaneously in LPCMO.

5:18PM X13.00013 Enhancement of magnetic refrigerant capacity in nanocrystalline LaMnO_3 ¹, ANIS BISWAS, SAYAN CHANDRA, M.H. PHAN, H. SRIKANTH, University of South Florida, FUNCTIONAL MATERIALS LABORATORY TEAM — Manganites are considered as potential magnetic refrigerants owing to their large magnetocaloric effect (MCE). However, the effective temperature span of large MCE (δT) is quite small in their bulk form resulting in small refrigerant capacity (RC). We have studied the magnetocaloric property of LaMnO_3 in its polycrystalline bulk and nanocrystalline form with particle size $\sim 50\text{nm}$. MCE is quantified as the change in magnetic entropy ($-\Delta S_M$), which is calculated from the isothermal magnetization curves using Maxwell relation. The samples exhibit large $-\Delta S_M$ associated with their paramagnetic to ferromagnetic transition. Relative to the bulk sample, δT increases significantly in the nanocrystalline form giving rise to more than 63% enhancement in RC. The calculated values of $-\Delta S_M(\text{RC})$ for bulk and nanocrystalline samples are $\sim 2.6\text{J/KgK}$ (173J/Kg) and 2.4J/KgK (282J/Kg) respectively for magnetic field change of 50 kOe. From present study, it can be inferred that reduction of particle size to the nanoscale may be an effective way to increase δT and hence improve RC of a material.

Session X14 GMAG DMP FIAP: Focus Session: Spins in Semiconductors - Spin-Orbit Interaction and Relaxation in Si and Ge 212

2:30PM X14.00001 Field-induced negative differential spin lifetime in silicon, JING LI, University of Maryland, LAN QING, HANAN DERY, University of Rochester, IAN APPELBAUM, University of Maryland — Using experimental measurements of spin transport in undoped silicon, we show that the electric field-induced thermal asymmetry between the electron and lattice systems substantially impacts the identity of the dominant spin relaxation mechanism. In contrast to the Elliott-Yafet theory where intraband phonon absorption leads to spin relaxation, here we induce phonon *emission* during which electrons are scattered between conduction band valleys that reside on different crystal axes. This leads to anomalous behavior, where reduction of the transit time between spin-injector and spin-detector with larger electric field is accompanied by a counterintuitive reduction in spin polarization and an apparent *negative* spin lifetime.

Work at UMD is supported by the Office of Naval Research and the National Science Foundation. We acknowledge the support of the Center for Nanophysics and Advanced Materials and Maryland NanoCenter and its FabLab. Work at UR is supported by AFOSR and NSF (No. FA9550-09-1-0493 and No. DMR 1124601).

2:42PM X14.00002 Decrease of electron spin lifetime in external electric field due to intervalley phonon scattering in silicon¹, LAN QING, HANAN DERY, University of Rochester, Rochester, New York 14627, JING LI, IAN APPELBAUM, University of Maryland, College Park, Maryland 20742 — We derive a simple approximate expression of the spin lifetime of drifting electrons in silicon. This expression agrees well with elaborate Monte Carlo simulations of the charge transport and spin relaxation of conduction electrons heated by the electric field. Already at low temperatures, the drifting electrons become hot enough to undergo *f*-processes (scattering between valleys of different crystal axes following emission of a shortwave phonon). Such a process involves a direct coupling of valence and conduction bands and dominates the spin relaxation. A sharp decrease of spin lifetime can then be expected in intermediate electric fields in between $\sim 100\text{V/cm}$ and $\sim 1\text{kV/cm}$. When electrons are transported between a spin injector and a spin-resolved detector, the decrease of both transit time and spin lifetime results in a non-monotonic behavior of the detected spin polarization with the electric field. The theory shows excellent agreement with empirical results.

2:54PM X14.00003 Spin-Polarized Luminescence Across the Indirect Band-Gap of Strained Ge, Si and Their Alloys¹, DHARA TRIVEDI, Department of Physics & Astronomy, University of Rochester, PENGKE LI, HANAN DERY², Department of Electrical and Computer Engineering, University of Rochester — We study optical orientation and circularly polarized photoluminescence in germanium, silicon and their alloys. We focus on phonon-assisted optical transitions across the indirect band-gap under conditions of biaxial strain (either compressive or tensile). The signature of strain on the band structure and phonon dispersion is observed in the luminescence spectra where spin properties are better resolved from the change in intensity ratio between left and right circularly polarized emission. The spectra is simulated using the combined results of a spin-dependent empirical pseudopotential method, adiabatic bond charge model, electric-dipole approximation, and rigid-ion model. An additional strain tensor has been introduced in calculating the strain effect. We have used group theory extensively to account for all possible transitions and to provide concise selection rules.

3:06PM X14.00004 Spin-orbit interaction and spin relaxation of conduction band electrons in Si and Ge¹, PENGKE LI, University of Rochester — Group IV element semiconductors, silicon and germanium, are promising material candidates in spintronics due to their intrinsic long electron spin lifetimes. To describe the spin properties of conduction electrons in these indirect band-gap multivalley semiconductors, the method of invariants is employed to build 8×8 (for Si) and 10×10 (for Ge) spin-dependent Hamiltonians that capture the symmetries of the zone edge states (X-point of Si [1] and L-point of Ge) and their spin dependent parameters. Concise expressions of the energy bands, and more importantly, of the spin mixed states are derived and verified by numerical results of an empirical pseudopotential method. These analytical state expressions are powerful tools to study the behavior of electron spins similar to the way that the Kane model in being used in direct band-gap semiconductors. Mechanisms of spin relaxation by electron-phonon scattering are studied based on this model. We reveal fundamental differences between spin and momentum relaxation mechanisms. In the case of silicon, intravalley spin flipping is governed by scattering with transverse acoustic (TA) phonons via the interband deformation potential that couples the upper and lower conduction bands (this deformation potential would also break the degeneracy of the conduction band at the X point if off-diagonal stress is applied). The intervalley g-process spin flipping couples the lowest conduction bands of different irreducible representations in opposite valleys via acoustic phonons; the intervalley f-process spin flipping, which is the dominant contribution of spin relaxation in a wide temperature range, couples the conduction and valence band components of the states by scattering with Σ_1 and Σ_3 phonons. In the case of germanium, intervalley spin-flip scattering, which is also the main contribution of spin relaxation, couples the lowest and upper conduction bands of different valleys by X-phonons. The intravalley spin flip scattering, which is about two orders of magnitude smaller, couples the conduction and valence bands mostly via TA phonons.

3:42PM X14.00005 Group theory analysis of phonon-induced spin relaxation in silicon¹, YANG SONG, Department of Physics and Astronomy, University of Rochester, HANAN DERY², Department of Electronic and Computer Science, University of Rochester — Selection rules and leading order matrix element expressions are derived for all important spin flip processes in the multivalley conduction band of bulk silicon. All results are generalized to arbitrary spin orientation directions. Intervalley *f*-process scattering induced by all phonon modes are analyzed using double group irreducible representation matrices of the Δ axis and independent integrals are identified for transitions between states of either spin. Intervalley *g*-process and intravalley spin flips are analyzed using the *X* point single group and detailed selection rules are derived using a four-band basis. Together with electronic states obtained by a spin-dependent *k*-*p* expansion, wavevector dependent spin-flip matrix elements are derived for all phonon modes in intravalley and for the leading order phonon mode in *g*-process scattering. Higher order matrix elements are qualitatively studied. Comparison with deformation potential theory in momentum scattering is made. Integrations for spin relaxation rate are carried out. Symmetry breaking mechanisms such as stress and electric field are discussed and quantified. We benchmark all of our analysis with numerical results of strain-dependent empirical pseudopotential and adiabatic-bond-charge models.

²also at Department of Physics and Astronomy

3:54PM X14.00006 Influence of spin polarization on resistivity of a two-dimensional electron gas in Si MOSFET at metallic densities¹, I. SHLIMAK, A. BUTENKO, D.I. GOLOSOV, Dept. of Physics, Bar-Ilan University, Israel, K.-J. FRIEDLAND, Paul Drude Institute, Berlin, Germany, S.V. KRAVCHENKO, Physics Dept., Northeastern University, Boston, MA, U. S. A. — Positive magnetoresistance (PMR) of a silicon MOSFET in parallel magnetic fields *B* has been measured at high electron densities $n \gg n_c$ where n_c is the critical density of the metal-insulator transition (MIT). It turns out that the normalized PMR curves, $R(B)/R(0)$, merge together when the field is scaled according to $B/B_c(n)$ where B_c is the field in which electrons become fully spin polarized. The values of B_c have been calculated from the simple equality between the Zeeman splitting energy and the Fermi energy taking into account the experimentally measured dependence of the spin susceptibility on the electron density. This extends the range of validity of the scaling all the way to a deeply metallic regime far away from MIT. The subsequent analysis of PMR for low $n \gtrsim n_c$ demonstrated that the merging of the initial parts of curves can be achieved only with taking into account the temperature dependence of B_c . It is shown that the shape of the PMR curves at strong magnetic fields is affected by a crossover from a purely two-dimensional (2D) electron transport to a regime where out-of-plane carrier motion becomes important (quasi-three-dimensional regime).

¹Supported by the BSF under grant 2006375

4:06PM X14.00007 Spin phase coherence of donor nuclear spins in silicon: the influence of electrical readout, DANE MCCAMEY, School of Physics, University of Sydney, Australia, JOHAN VAN TOL, National High Magnetic Field Laboratory and Florida State University, Tallahassee, GAVIN MORLEY, Department of Physics, University of Warwick, UK, CHRISTOPH BOEHME, Department of Physics and Astronomy, University of Utah — Storing information in spin underpins the operation of a wide range of emerging technologies. However, the ability to interact with, and thus control electron spin implies a reasonable coupling to the environment, and a correspondingly limited spin coherence time. This problem can be overcome by using nuclear spins for long term information storage, and significant experimental progress in this direction has been seen recently. Readout of stored information can be achieved in a variety of ways, with electrical approaches offering substantial benefit with regard to integration of spintronic and classical electronic applications. Here, we discuss electrical readout of coherent nuclear spin states of donor nuclei in silicon. By utilizing nuclear Hahn echo sequences, we are able to demonstrate that nuclear spin phase coherence can exceed 3 ms with electrical readout. We find that the spin phase coherence is in this case limited by the spin lifetime of the donor electron which mediates our readout scheme, and discuss approaches to ameliorate this effect.

4:18PM X14.00008 ABSTRACT WITHDRAWN —

4:30PM X14.00009 Optical Orientation and Spin Relaxation of electrons and holes in Strained Germanium Quantum Wells¹, FABIO PEZZOLI, Università degli Studi di Milano-Bicocca, FEDERICO BOTTEGONI, FRANCO CICCACCI, STEFANO CECCHI, Politecnico di Milano, EMANUELE GRILLI, MARIO GUZZI, GIOVANNI ISELLA, Università degli Studi di Milano-Bicocca, DHARA TRIVEDI, PENGKE LI, YANG SONG, HANAN DERY, University of Rochester — We demonstrate optical orientation in strained Ge/SiGe quantum wells and study their spin properties. The energy proximity between the center of the Brillouin zone to its edge allows us to achieve high spin-polarization efficiency and to resolve the spin dynamics of holes and electrons. The circular polarization degree of the direct-gap photoluminescence is 37% and 86% for transitions with heavy and light holes states, respectively. Considering the ultrafast transition of electrons to L valleys, the extracted spin lifetime of holes at the top of the valence band is found to be 0.5 ps. This lifetime is governed by transitions between heavy and light hole states. The indirect-gap photoluminescence via the no-phonon line and its LA phonon replica allows us to study spin properties of electrons at the bottom of the conduction band. Taking into account the recombination lifetime of electrons (radiative and non-radiative channels), we find that their spin lifetime exceeds 5 ns below 150 K. Theoretical analysis of the electrons spin relaxation indicates that phonon-induced intervalley scattering by the X point phonon modes dictates the spin lifetime.

4:42PM X14.00010 Infrared Kerr measurements in ferromagnetic silicon carbide, ALOK MUKHERJEE, CHASE ELLIS, NADA TESAROVA, JOHN CERNE, Physics Dept., University at Buffalo, Buffalo, NY, YU LIU, SHUNCHONG WANG, GANG WANG, Institute of Physics, Chinese Academy of Sciences, China — We measure the infrared (100-1000 meV) polar Kerr angle in ferromagnetic silicon carbide (SiC). The Kerr angle is sensitive to the Hall conductivity σ_{xy} and measures the difference of optical responses for left and right circularly polarized light, which makes it a sensitive spectral probe for small changes in the symmetry of the system due to magnetic order. Both neutron-irradiated and Al-doped samples are studied in the 10-300K temperature range. This study provides new insights into the mechanisms by which non-magnetic impurities and defects can produce magnetic order. Strong frequency dependence and hysteresis are observed in the Kerr measurements. Work supported by NSF-DMR1006078.

4:54PM X14.00011 Low-temperature scattering-Scanning Near-field Optical Microscopy of Strongly Correlated Materials, MOLLY MAY, JOANNA ATKIN, MARKUS RASCHKE, University of Colorado at Boulder — Strongly correlated electron materials display diverse complex phenomena such as metal-insulator transitions and ferroelectric and ferromagnetic ordering, with characteristic lengths on the nanometer scale. In order to directly access and study the associated nano-phase behavior and domains for a wide range of materials, we have developed a low temperature tip-enhanced scattering-type scanning near-field optical microscope (s-SNOM). A microscopy flow cryostat reservoir is coupled to a shear-force atomic force microscope, with illumination of electrochemically etched Au tips provided by an on-axis high numerical aperture parabolic mirror. We will discuss the use of this system for the study and imaging of ferroic ordering in multiferroic and ferroelectric materials through the symmetry selectivity provided by tip-enhanced second harmonic generation (SHG) and nano-Raman crystallography via the tensor based selection rules.

Thursday, March 1, 2012 2:30PM - 5:18PM –
Session X15 DMP FIAP GMAG: Focus Session: Spin and Dynamics in Metal, Resonance Phenomena II: FMR in Magnetic Nanostructures 213

2:30PM X15.00001 Two dimensional spectroscopic imaging of individual ferromagnetic nanostripes, ROBERT MCMICHAEL, HAN-JONG CHIA, Center for Nanoscale Science and Technology, NIST, Gaithersburg MD, LYUBA BELOVA, Dept. of Matls. Science & Eng., Royal Institute of Technology, Stockholm — We report on high resolution imaging of the center and edge modes of individual Permalloy nanostripes using ferromagnetic resonance force microscopy (FMRFM). Fabrication of future spintronic devices requires an understanding of how edge damage affects a device's magnetic properties, and the highly localized edge modes of a nanostripe provide a direct method to investigate edge properties. While previous studies have measured spectra of the edge modes in large arrays of stripes, in this work we use FMRFM to image and probe the center and edge modes in individual NiFe stripes, 400 and 700 nm in width and 20 nm in thickness. Our spectroscopic measurements reveal different resonance fields for opposite edges of a stripe, which also exhibit different structural profiles. 2-D spatial imaging of the bulk and edge mode resonances demonstrates the inhomogeneity of the edge modes along their lengths with a resolution of 300 nm.

2:42PM X15.00002 Size dependent nonlinear effects of magnetization dynamics in Permalloy disks, FENG GUO, HAN-JONG CHIA, National Institute of Standards and Technology, University of Maryland, LYUBA BELOVA, Royal Institute of Technology, ROBERT MCMICHAEL, National Institute of Standards and Technology — We use ferromagnetic resonance force microscopy (FMRFM) to probe nonlinear magnetization dynamics in individual $\text{Ni}_{80}\text{Fe}_{20}$ disks with diameters ranging from 100 nm to 500 nm. The nonlinear behavior of magnetic nanostructures has important implications for rapid switching of memory devices and for frequency stability of spin torque oscillators. In the studied size range, micromagnetic modeling predicts a transition from complex power dependent behavior in the larger disks to simple behavior in the smallest disks where only a few modes are observed. At low power levels in the measurements, precession produces a force-detected signal that is linear in power and that displays a Lorentzian line shape. At higher powers, we observe nonlinear effects, including asymmetric line shapes and foldover where the resonance shifts with power. In addition, complex, jagged line shapes appear at high powers. We report that the onset power level of the nonlinear regime was found to be size dependent. In smaller disks, higher microwave power is required to drive nonlinear precession, and we see fewer complex peaks. Furthermore, the direction of foldover also depends upon the disk size. We have modeled our results using micromagnetic simulations and they display good correspondence with our experimental data.

2:54PM X15.00003 Electrically Detected Broadband Ferromagnetic Resonance in Individually Defined Permalloy Nanowires, ZHENG DUAN, CARL BOONE, ILYA KRIVOROTOV, UC Irvine, NATHALIE RECKERS, SVEN STIENEN, JUERGEN LINDNER, University of Duisburg-Essen, UC IRVINE TEAM, UNIVERSITY OF DUISBURG-ESSEN TEAM — We report measurements of electrically detected broadband ferromagnetic resonance (FMR) in lithographically defined Permalloy nanowires. For these measurements, the Permalloy nanowire is placed in close proximity to the short of a gold coplanar strip waveguide. The microwave power applied to the waveguide drives the magnetization precession in the wire and the four-point resistance of the wire is measured as a function of DC external magnetic field. The time-averaged resistance of the wire depends on the amplitude of the magnetization precession via anisotropic magnetoresistance (AMR), and thus peaks and dips with resistance dependence on the bias magnetic field arise from resonant excitation of spin wave modes in the wire. Using this electrically detected FMR technique, we measure the frequency and linewidth of the quasi-uniform mode of magnetization precession as well as bulk modes and edge modes that exist for the magnetic field applied in the plane of the sample perpendicular to the wire. We will present measurements of the resonance frequency and linewidth of various modes for several values of the wire width and compare our results to theoretical predictions of the field dependence of the mode frequency.

3:06PM X15.00004 Spin torque phenomena originating from the spin Hall effect: resonance, magnetic switching, and magnetic dynamics¹, LUQIAO LIU, Cornell University — The spin Hall effect (SHE) generates a transverse spin current with the passage of a current through a non-ferromagnetic metal (NM) film. Quite different results have been obtained for the magnitude of this effect. Here I will discuss a new technique where, by applying an RF current to a NM/FM thin film bilayer, the spin current onto the FM layer can induce a spin torque ferromagnetic resonance (ST-FMR). This enables the determination of the SHE strength with precision and without the need to assume the values of unmeasured parameters. The large magnitude of the SHE that we have established in several types of NM is sufficient to reversibly switch the magnetic orientation of a FM layer and I will discuss two different implementations of this. In the first the FM layer has a perpendicular-to-plane magnetic moment at equilibrium and the SHE injected spins are orthogonal to the moment. The spin torque can overcome the anisotropy (coercive) field restoring torque, with the polarity of the current-induced switching being determined by the sign of a small external field applied along the current direction. In the second approach, the FM moment lies in plane and the spins injected by the SHE exert a negative damping just as in conventional ST switching of a spin valve or magnetic tunnel junction (MTJ). We have fabricated three-terminal devices that incorporate a MTJ and a SHE layer to induce in-plane reversal switching. The simple architecture of this three terminal device and the high efficiency of the SHE induced switching made it a promising technique for future memory and non-volatile logic applications. We have also used this three terminal device to demonstrate DC induced dynamics in the magnetic layer due to the SHE.

3:42PM X15.00005 Magnetostatics and magnetodynamics in single crystal Ni on MgO¹, MICHAEL PECHAN, BRIAN KASTER, MICHAEL SINKO, Department of Physics, Miami University, DAN DAHLBERG, Department of Physics and Astronomy, University of Minnesota, C.A. ROSS, GYE HYUN KIM, CARL V. THOMPSON, Department of Materials Science and Engineering, Massachusetts Institute of Technology — We present an investigation of the magnetic properties of 120 nm thick (100) and (110) oriented single crystal Ni films grown on MgO via evaporative deposition. X-ray diffraction analysis was used to confirm the single crystal nature and crystallographic orientations of the films. Magnetization measurements reveal anisotropy and magnetic moment consistent with bulk Ni values. Ferromagnetic resonance measurements have been made as a function of in-plane angle and temperature at 36 GHz. Resonance field maps confirm the anisotropy expected for high quality single crystal films. Both the anisotropy and damping are presented at temperatures ranging from 50 K to room temperature. Additional FMR results at 10 GHz are also presented from 4 K to room temperature. These results are discussed in the context of the temperature-dependent magnetocrystalline anisotropy of Ni and magnetoelastic anisotropy resulting from thermal mismatch between the Ni and MgO.

3:54PM X15.00006 Localized Edge Modes in Permalloy Square Antidot Arrays, J.B. KETTERSON, J. SKLENAR, Northwestern University, V.S. BHAT, L. DELONG, University of Kentucky, Lexington, O. HEINONEN, Northwestern University, Argonne National Laboratory — We have carried comprehensive experiments on and simulations of the ferromagnetic resonance spectrum of various thin films of permalloy patterned with a periodic array of holes on a square lattice. These so-called antidot lattices show a rich multi-line spectrum covering a wide range of frequencies and magnetic fields; they also exhibit striking angular dependences. One mode that is predicted in our simulations is highly localized at the edges of the holes. Our simulations further show that for a fixed field or excitation frequency the angular dependence of this mode strongly depends on the shape of the holes in the antidot array. It has been suggested¹ that, in comparison to other more extended modes, this localized mode would be difficult to find experimentally due to: i) the effects of varying shape and roughness present in an actual array, and ii) the fact that the mode is concentrated within a small fraction of the unit cell of the sample. Our experiments, performed with a broadband meanderline-based ferromagnetic resonance (FMR) spectrometer,² show a very weak resonance (requiring extensive signal averaging) that is in rough agreement with the simulations, which we propose as a candidate for this elusive edge mode.

4:06PM X15.00007 Topological Localization of FMR Modes by Antidot Arrays Patterned into Permalloy Thin Films¹, VINAYAK BHAT, JUSTIN WOODS, LANCE DE LONG, University of Kentucky, JOSEPH SKLENAR, JOHN KETTERSON, Northwestern University, OLLE HEINONEN, Argonne National Laboratory — We have observed novel broad-band FMR spectra for 25-nm-thick Permalloy films patterned with square arrays of diamond antidots with axes $D_x = 1430$ nm and $D_y = 860$ nm. The y-axis lattice spacing was held constant at $d_y = 2000$ nm, and variable x-axis lattice spacings $d_x = 1730, 2000, 2267$ and 2730 nm. The applied DC magnetic field H (in-plane at angle θ with respect to x-axis) spanned the hysteretic regime $|H| \leq 150$ Oe, to $|H| = 3$ kOe in the saturated regime, corresponding to mode frequencies $f \approx 250$ MHz to 14 GHz. In spite of hysteretic evolution of domain walls in the low-field regime, highly reproducible absorption peaks appear at $f < 3$ GHz. Static and dynamic micromagnetic simulations agree with DC magnetization and FMR dispersion curves, and show domain pinning by the antidot edges is responsible for the reproducible spectra in the hysteretic regime. For $H = 1$ kOe along the x-axis, we observe two localized modes: one ($f = 9$ GHz) in a narrow gap between the acute vertices, and another ($f = 10.25$ GHz) between the oblique vertices, of adjacent diamonds. For $\theta = 45^\circ$, one mode ($f = 8.7$ GHz) extends along the (-1,1) direction with strong angular variation of f , and a standing mode ($f = 9.87$ GHz) is localized between nearly parallel edges of adjacent antidots.

4:18PM X15.00008 Ferromagnetic Resonance Studies of Individual Ferromagnetic Nanowires, ROHAN ADUR, INHEE LEE, The Ohio State University, STEFAN PHILIPPI, THOMAS MUHL, IFW Dresden, DENIS V. PELEKHOV, P. CHRIS HAMMEL, The Ohio State University — We investigate magnetization dynamics in ferromagnetic nanowires using two techniques: Ferromagnetic Resonance Force Microscopy (FMRFM) and Vector Network Analyzer Ferromagnetic Resonance (VNA-FMR). Using FMRFM we report our attempts at scanned probe FMR imaging of individual ferromagnetic nanowires. By placing ferromagnetic nanowires on permalloy we can use the capability of localized mode imaging (I. Lee et. al, Nature 2010) to measure local fields both in and around the ferromagnetic nanowire. In addition, we use VNA-FMR to study dipolar interactions in densely packed nanowire arrays. The dipolar fields between neighboring nanowires introduce an anisotropy field that can dominate over the shape anisotropy expected for isolated nanowires, and this effect is observed in the angular dependence of VNA-FMR spectra.

4:30PM X15.00009 Damping Dependence in Microwave Assisted Magnetization Reversal, YUNPENG CHEN, XIN FAN, QI LU, JOHN XIAO, University of Delaware — Microwave assisted magnetization reversal (MAMR) is one possible technique to mitigate the writability problem in ultrahigh density magnetic recording. In the presence of microwaves, the magnetization reversal of a magnetic recording material could be triggered at significantly reduced switching field. The damping constant is one of the critical parameters in magnetization switching for the magnetization precession spiraling down to the direction along the external field. We demonstrate microwave assisted magnetization reversal (MAMR) in a CoFeB film and the damping dependence in MAMR through the measurement of ferromagnetic resonance (FMR). Spin-pumping in non-ferromagnetic/ferromagnetic films provides a large range variation of Gilbert damping constants in magnetic samples when changing the thickness of non-ferromagnetic layers without changing the ferromagnetic film. An evident dependence of switching fields on the damping constant is observed in the presence of microwaves. The trend of the experiment data is well reproduced by a numerical simulation based on the Landau-Lifshitz-Gilbert equation. The result indicates that the large damping decreases the efficiency of microwaves in reducing the magnetization switching field.

4:42PM X15.00010 Theory of the ac spin valve effect: a new method to measure spin relaxation time¹, DENIS KOCHAN, MARTIN GMITRA, JAROSLAV FABIAN, University Regensburg — Parallel (P) and antiparallel (AP) configurations of FNF junctions have, in a dc regime, different resistivities ($R_{AP} > R_P$), giving rise to the giant magnetoresistance (GMR) effect, which can be explained within the spin injection drift-diffusion model. We extend the model to include ac phenomena and predict new spin dynamical phenomenon; the resonant amplification and depletion of spin accumulation in the P and AP configurations, respectively. As the major new effect, the spin valve magnetoimpedance of the FNF junction oscillates with the driving ac frequency, which leads to negative GMR effect ($|Z_{AP}| < |Z_P|$). We show that from the spin-valve oscillation periods, measured all electrically in the GHz regime, the spin relaxation times could be extracted without any magnetic field and sample size changes (contrary to other techniques). For thin tunnel junctions the ac signal becomes pure Lorentzian, also enabling one to obtain the spin relaxation time of the N region from the signal width. This work, was published in Physical Review Letters,¹⁰, 176604 (2011).

4:54PM X15.00011 Vortex Resonance in Coupled Ferromagnetic Disks, SHIKHA JAIN, HELMUT SCHULTHEISS, JOHN PEARSON, FRANK FRADIN, SAMUEL BADER, VALENTYN NOVOSAD, Argonne National Laboratory — Advances in nanolithography and thin film growth techniques offer the unique opportunity to prepare a variety of laterally confined nanostructured magnets. Of particular interest are lithographically patterned micron and submicron disk-shaped particle arrays. The magnetic ground state in confined geometries consists of a curling spin configuration, known as a vortex state. Studies of vortex dynamics have mainly focused on circular or elliptical dots at remanence. In this work, we investigate the dynamic response of vortex gyration in interacting systems where two circular dots are statically exchange coupled. The induced coupling due to the interacting area forces the disks to have antiparallel chirality of magnetization. Apart from different vortex polarity combinations, various frequency modes were observed as a function of external magnetic field and contact length. Moreover, due to the induced configurational anisotropy in the system, vortex resonance in the two disks was found to be strongly dependent on the orientation of the static magnetic field.

5:06PM X15.00012 Study of the coupling of vortices in magnetic nanodisks, ALBERTO GUIMARAES, Brazilian Center for Physical Research (CBPF), Rio de Janeiro, Brazil, GABRIEL FIOR, FLAVIO GARCIA, LNLs, Campinas, Brazil — There is a marked interest nowadays in the dynamic behavior of magnetic nanodisks that present magnetic vortices [1]. The tailoring of vortex features, including their gyrotropic frequency, critical vortex core switching velocity and strength of the coupling between nanodisks, is very desirable for future applications, such as vortex magnetic memories (VRAMs) and spin transfer nanooscillators (STNOs) [2]. An original way to tune some of the static vortex properties (specially the vortex core diameter) is simply to introduce a uniaxial perpendicular magnetic anisotropy, as has been recently shown [3]. Here we have studied the coupling between vortices as a function of the magnetic properties of the disks and their separation, using micromagnetic simulations. We analyzed the motion of a vortex core caused by the motion of the second one, excited by static or rotating magnetic fields. A splitting of the gyrotropic frequency is also observed. Exciting one of the disks, it is possible to switch the core polarity of the other. These results open new possibilities for applications of magnetic vortices.

2:30PM X16.00001 Persistence of Jahn-Teller Distortion up to the Insulator to Metal Transition in LaMnO_3 , MARIA BALDINI, HpSynC, Carnegie Institution of Washington, Argonne, Illinois USA, VIKTOR STRUZHNIKIN, ALEX GONCHAROV, Geophysical lab. Carnegie Institution of Washington, Washington D.C. USA, PAOLO POSTORINO, Dipartimento di Fisica, Università "Sapienza," Roma Italy, WENDY MAO, Geological and Environmental Science, Stanford University, California USA — High pressure, low temperature Raman measurements performed on LaMnO_3 up to 34 GPa provide the first evidence for the persistence of the Jahn-Teller distortion over the entire stability range of the insulating phase. This result resolves the ongoing debate about the nature of the pressure driven insulator to metal transition (IMT), demonstrating that LaMnO_3 is not a classical Mott insulator. The formation of domains of distorted and regular octahedra, observed from 3 to 34 GPa, suggests that LaMnO_3 becomes metallic when the fraction of undistorted octahedra domains increases beyond a critical threshold. In this scenario, it is interesting to consider whether or not the CMR effect may be induced in LaMnO_3 by applying pressure. Preliminary results obtained performing high pressure resistivity measurements in a magnetic field will be reported.

2:42PM X16.00002 Influence of Gd-doping in $\text{La}_{0.7}\text{Ca}_{0.3}\text{MnO}_3$ on its structural and Magnetoelectrical Properties, SEVGI POLAT ALTINTAS, Abant Izzet Baysal University, ABDERREZAK AMIRA, Université de Jijel, CABIR TERZIOGLU, Abant Izzet Baysal University — We present a study of the structural and electrical properties of lanthanum-based manganite, $\text{La}_{0.7}\text{Ca}_{0.3}\text{MnO}_3$ with $x=0.0$ and 0.1 . The samples synthesized by the conventional solid state reaction method. The samples are characterized by X-ray diffraction, scanning electron microscope and energy dispersive X-ray spectrometer. The electrical and magneto-transport properties of bulk samples have been investigated in the temperature range 5-300 K and a magnetic field up to 7 T. Although the replacement of La ion by Gd results a decrease in metal-insulator transition temperature TMI, the magnetoresistance and resistivity are found to be increased. The electrical resistivity in the entire temperature range fit well with the phenomenological percolation model, which is based upon an approach that the system consists of the phase separated ferromagnetic metallic and paramagnetic insulating regions.

2:54PM X16.00003 Size control of Magnetism, Charge and Orbital Order in Half-Doped Manganite, $\text{La}_{0.5}\text{Ca}_{0.5}\text{MnO}_3$ ¹, TANUSRI SAHA-DASGUPTA, S.N.Bose National Centre for Basic Sciences, HENA DAS, Cornell University, G. SANGIOVANNI, A. VALLI, K. HELD, Institute for Solid State Physics, Vienna University of Technology, 1040 Wien, Austria — Motivated by recent experimental results, we study the effect of size reduction on half-doped manganite, $\text{La}_{0.5}\text{Ca}_{0.5}\text{MnO}_3$, using the combination of density functional theory (DFT) and dynamical mean field theory (DMFT). We find that upon size reduction, the charge-ordered antiferromagnetic phase, observed in bulk, to be destabilized, giving rise to the stability of a ferromagnetic metallic state. Our theoretical results, carried out on defect-free nanocluster in isolation, establish the structural changes that follow upon size reduction to be responsible for this. Our study further points out the effect of size reduction to be distinctively different from application of hydrostatic pressure. Interestingly, our DFT+DMFT study, additionally, reports the correlation-driven stability of charge-orbitally ordered state in bulk $\text{La}_{0.5}\text{Ca}_{0.5}\text{MnO}_3$, even in absence of long range magnetic order.

¹To appear in Physical Review Letters

3:06PM X16.00004 Measuring Coexisting Phases in $\text{La}_{0.35}\text{Pr}_{0.275}\text{Ca}_{0.375}\text{MnO}_3$ ¹, MARK H. BURKHARDT, SIMES, SLAC National Accelerator Laboratory and Stanford University, M.A. HOSSAIN, S. SARKAR, H.A. DÜRR, J. STÖHR, SIMES, SLAC National Accelerator Laboratory, Y.-D. CHUANG, A.G. CRUZ GONZALEZ, A. DORAN, A. SCHOLL, A.T. YOUNG, Advanced Light Source, Lawrence Berkeley National Laboratory, Y.J. CHOI, S.-W. CHEONG, Rutgers Center for Emergent Materials and Department of Physics & Astronomy — Manganite compounds in the $\text{La}_{0.625-y}\text{Pr}_y\text{Ca}_{0.375}\text{MnO}_3$ series are known for exhibiting phase separation over a large temperature range. We combined the x-ray photoemission electron microscopy (PEEM) and resonant elastic soft x-ray scattering (RSXS) techniques to study the interplay between the low-temperature ferromagnetic and intermediate temperature charge-ordered/antiferromagnetic phases, respectively, in $\text{La}_{0.35}\text{Pr}_{0.275}\text{Ca}_{0.375}\text{MnO}_3$. We found that the system is driven by glassy polarons, which are present above the curie temperature T_C in many ferromagnetic metallic manganites. They stunt the growth of the ferromagnetism on cooling: we clearly observe the onset of small, strained ferromagnetic domains almost 30 K above the temperature where ferromagnetism fully sets in, and the ferromagnetism has a very unconventional temperature dependence even below T_C . This relationship could explain the need for such high magnetic fields to induce colossal magnetoresistance.

¹This research and the ALS are supported by U.S. Department of Energy, Office of Basic Energy Science.

3:18PM X16.00005 Oxygen Vacancy Induced Metal Insulator Transition in Epitaxial $\text{Pr}_{0.7}\text{Ca}_{0.3}\text{MnO}_3$ Thin Films¹, JINGDI ZHANG, KEBIN FAN, Boston University, RYUHEI KINJO, WEIMING XU, IWAO KAWAYAMA, MASAYOSHI TONOUCHI, Osaka University, XIN ZHANG, RICHARD AVERITT, Boston University — We report the metal-insulator transition in epitaxial $\text{Pr}_{0.7}\text{Ca}_{0.3}\text{MnO}_3$ thin film by introducing oxygen vacancies, which assist the nucleation of ferromagnetic metallic domains in an antiferromagnetic insulating matrix. The hysteresis of the resistivity indicates the transition is first-order, and covers a broad temperature range from 80K to 220K. Such novel transport properties of the $x=0.3$ doped manganite may result from strong spin-lattice coupling which stabilizes the system to a metallic metastable state at low temperature.

¹We acknowledge DOE BES support.

3:30PM X16.00006 Search for Multi-Ferroic Manganites with Elongated Mn-O bonds, BOGDAN DABROWSKI, JAMES MAIS, STANISLAW KOLESNIK, Department of Physics, Northern Illinois University, DeKalb, IL — Development of multi-ferroic materials, where magnetism and ferroelectricity are strongly coupled near room temperature, is of fundamental technological and theoretical importance. Typically, both phenomena tend to be mutually exclusive because ferroelectricity is usually present for d^0 and magnetism for non- d^0 transition metals. By analogy to perovskite $\text{Ba}^{2+}\text{Ti}^{4+}\text{O}_3$ (d^0) for which [Ti-O] bonds are highly elongated beyond their equilibrium lengths resulting in Ti distortion out of the center of the TiO_6 octahedral unit, resulting in $T_F \sim 400$ K ferroelectricity, we have projected that similar effect should be observed for the non- d^0 insulating and antiferromagnetic ($T_N \sim 240$ K) perovskites of Mn^{4+} (d^3). I will describe our search for such compounds guided by our “tolerance factor design rules” in the (Sr,Ba)MnO₃ system for which strong multi-ferroic behavior was achieved near room temperature.

3:42PM X16.00007 Formation of mesoscopic metallic filaments in manganite thin films imaged by microwave impedance microscopy, WORASOM KUNDHIKANJANA, KEJI LAI, YONGLIANG YANG, YUE MA, MICHAEL KELLY, ZHI-XUN SHEN, Stanford University, MASAO NAKAMURA, ZHIGAO SHENG, MASASHI KAWASAKI, YOSHI TOKURA, RIKEN, Japan, STANFORD UNIVERSITY COLLABORATION, RIKEN, JAPAN COLLABORATION — We study the ferromagnetic metallic domains from the charge-order insulating background at mesoscopic length scale in a $\text{Pr}_{0.55}\text{Ca}_{0.75}\text{Sr}_{0.25}\text{MnO}_3$ thin film using a variable temperature microwave impedance microscope (MIM). The metallic state in this compound can be easily induced at a moderate magnetic field as low as 2 T observed by both the transport and MIM. The temperature dependent transport under 1.2 T shows a large hysteresis loop. MIM allows us to observe the formation and melting of metallic domains at different temperatures during the cooling and warming processes. At higher temperatures, the metallic domains first emerge in small isolated filaments along certain crystal axes of the LSAT(110) substrate, suggesting that the local strain plays an important role. Surprisingly, small insulating islands remain in the metallic ground state and persist up to very high magnetic fields, indicating strong pinning sites. Lastly, the sizes of the insulating islands at the ground state increase when the film is field cooled at lower speeds, suggesting a glassy order in this compound.

3:54PM X16.00008 Imaging of nano domain fluctuations in manganites¹, MIRIAN GARCIA FERNANDEZ, STUART WILKINS, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, New York 11973, USA, HONG ZHENG, JOHN MITCHELL, Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439, USA — We present a soft x-ray resonant diffraction study of the electronic spatial nano-scale domains present in manganites. We explain the details of our new set up that allow us to perform this diffraction contrast microscopy in the nano regime. We will present preliminary results on the nanoscale domains in the bilayer manganite $\text{LaSr}_2\text{Mn}_2\text{O}_7$. The structural reflection (002) and the A-type antiferromagnetic reflection (001) have been investigated with soft x-rays in the vicinity of the manganese L_3 edge. A resolution of ~ 150 -200 nm has been achieved by implementing a zone plate focusing optic in our diffraction set up. These two reflections have been mapped in the same region of the sample. This region has dimensions of 20×20 microns. We will present measurements comparing the magnetic nano scale domains in $\text{LaSr}_2\text{Mn}_2\text{O}_7$ probed directly by measuring the (001) antiferromagnetic reflection, with crystallographic inhomogeneities that are observed in the mapping of the (002) crystallographic reflection. Finally, future directions using this setup will be discussed for the study of strongly correlated systems.

¹Work performed at BNL was supported by the US Department of Energy, Division of Materials Science, under Contract No.DEAC02-98CH10886.

4:06PM X16.00009 Fragile Magnetic Ground State in Half-Doped Manganite $\text{LaSr}_2\text{Mn}_2\text{O}_7$: Orbital Instability, J.-S. LEE, C.-C. KAO, SSRL/SLAC, C.S. NELSON, BNL, S.B. KIM, Y.J. CHOI, S.-W. CHEONG, Rutgers Univ., S. SMADICI, P. ABBAMONTE, UIUC, H. JANG, K.-T. KO, J.-H. PARK, POSTECH — Recently, a careful doping control study, however, reported that the $\text{La}_{2-2x}\text{Sr}_{1+2x}\text{Mn}_2\text{O}_7$ material has an exotic phase diagram very near the half doping with extremely narrow antiferromagnetic phase boundaries at $x \approx 0.5 \pm 0.005$ — the CE-type within the boundaries but the A-type outside.¹ To understand a complexity on this material's phase diagram, we investigated the orbital and antiferromagnetic ordering behaviors of the half-doped bilayer manganite $\text{La}_{2-2x}\text{Sr}_{1+2x}\text{Mn}_2\text{O}_7$ ($x \approx 0.5$) by using Mn $L_{2,3}$ -edge resonant soft x-ray scattering. We confirmed the predicted CE-type antiferromagnetic order for the true half-doped ($x = 0.5$) case. Moreover, we found that such a narrow phase boundary is due to the close competition of the two antiferromagnetic ordering phases via 3d Mn e_g orbital instability. Our study reveals the spin and orbital orders of electrons in the sample as well as information about their ground states.²

4:18PM X16.00010 Bilayer manganites reveal polarons in the midst of a metallic breakdown¹, F.

MASSEE, S. DE JONG, Y. HUANG, W. K. SIU, I. SANTOSO, A. MANS, Van der Waals-Zeeman Institute, University of Amsterdam, 1018XE Amsterdam, The Netherlands, A. T. BOOTHROYD, D. PRABHAKARAN, Clarendon Laboratory, Oxford University, OX1 3PU Oxford, UK, R. FOLLATH, A. VARYKHALOV, BESSY GmbH, Albert-Einstein-Strasse 15, 12489 Berlin, Germany, L. PATTHEY, M. SHI, Paul Scherrer Institute, Swiss Light Source, CH-5232 Villigen, Switzerland, J.B. GOEDKOOP, M.S. GOLDEN, Van der Waals-Zeeman Institute, University of Amsterdam, 1018XE Amsterdam, The Netherlands — Just what tips the balance between the wealth of competing phases and textures in spin, charge and orbital degrees of freedom in the CMR manganites such as $\text{La}_{2-2x}\text{Sr}_{1+2x}\text{Mn}_2\text{O}_7$ (LSMO)? Combining ARPES and STM/S measurements on bilayered LSMO ($0.30 \leq x < 0.5$), we arrive at a compelling explanation for the seemingly contradictory data on the electronic structure of bilayered LSMO that has appeared in the literature. We show that the true signature of bilayered ($N=2$) LSMO is that of a gapped non-metal on the verge of a metallic breakdown. All the former confusion stems from the intrinsic presence of stacking faults leading to either more gapped single layer ($N=1$) LSMO or sharply peaked, $N>2$ slabs displaying true metallic double-exchange.

¹This work is part of the research program of the Foundation for Fundamental Research on Matter (FOM), which is part of the Netherlands Organisation for Scientific Research (NWO).

4:30PM X16.00011 The intrinsic electronic structure of bilayer manganites from Angle Resolved Photoemission, S.

SANNE DE JONG, SLAC National Accelerator Laboratory/ LCLS, R. KUKREJA, M.A. HOSSAIN, SLAC National Accelerator Laboratory/ SINES, M.S. GOLDEN, E. VAN HEUMEN, F. MASSEE, Y. HUANG, University of Amsterdam, WZI, A.T. BOOTHROYD, P. PAB-HAKARAN, University of Oxford, Dept. Phys., A. WALTER, A. BOSTWICK, E. ROTENBERG, ALS, Lawrence Berkeley National Laboratory, H.A. DURR, SLAC National Accelerator Laboratory/ PULSE, SINES — The Colossal MagnetoResistant (CMR) manganites are one of the most studied condensed matter physics systems since decades. Yet, the mechanism behind the CMR effect and their electronic structure are still under hot debate. Recent angle resolved photoemission (ARPES) studies on the bilayer manganite $\text{La}_{(2-2x)}\text{Sr}_{(1+2x)}\text{Mn}_2\text{O}_7$, LSMO327, reported contradictory results [1]. Here we present an ARPES study unveiling the intrinsic k - and temperature dependent electronic structure of LSMO327, while carefully steering away from the recently reported sample inhomogeneities [2] that have caused all the confusion.

4:42PM X16.00012 Unconventional response of acoustic phonons to the onset of charge order in a bilayer manganite, S.

ROSENKRANZ, Argonne National Laboratory, F. WEBER, Karlsruhe Institute of Technology, J.P. CASTELLAN, R. OSBORN, H. ZHENG, J.F. MITCHELL, Argonne National Laboratory, S. CHI, J.W. LYNN, NIST Center for Neutron Research, D. REZNIK, University of Colorado, Boulder — The acoustic phonons in the 50% doped bilayer manganite $\text{LaSr}_2\text{Mn}_2\text{O}_7$ exhibiting CE type charge order were investigated using inelastic neutron scattering. At the onset of charge ordering, we observe an abrupt increase of the energies and a decrease of the linewidths of the transverse mode along (1,1,0), which crosses the CE ordering wavevector. This effect is however not localized to the CE ordering wavevector, but is observed over an extended range of momentum transfers for which the phonon energy is lower than 15 meV. These observations indicate a reduced electron-phonon coupling due to a partial removal of the Fermi surface and provide direct evidence for a link between electron-phonon coupling and charge order in manganites. However, the observed response of the phonons is not consistent with a standard CDW mechanism, clearly showing that the transition is unconventional. Work supported by US DOE BES-DMS DE-AC02-06CH11357.

4:54PM X16.00013 Magnetoelastic Spin Flip in $\text{La}_{1.4}\text{Sr}_{1.6}\text{Mn}_2\text{O}_7$, K.-T. KO, H. JANG, J.-H. PARK, Dept. Physics,

Pohang University of Science and Technology, Korea, B.-G. PARK, J.-Y. KIM, Pohang Accelerator Laboratory, SUNG BAEK KIM, The College of General Education, Konyang University, Korea, S.-W. CHEONG, Dept. Physics and Astronomy, Rutgers University, USA — The magnetoelastic coupling in a bilayer manganite was investigated by using x-ray absorption spectroscopy (XAS) and resonant soft x-ray scattering (RSXS) at Mn $L_{2,3}$ -edge. Huge occupation reversal of e_g level from $d_{3z^2-r^2}$ to $d_{x^2-y^2}$ was observed at the temperature and magnetic field induced phase transition in $\text{La}_{1.4}\text{Sr}_{1.6}\text{Mn}_2\text{O}_7$. The CI model calculation indicated that the direction of magnetocrystalline anisotropy is affected by the configuration of e_g level, and the sharp spin flip transition was expected. The field dependent RSXS measurements demonstrated a strong magnetoelastic coupling in $\text{La}_{1.4}\text{Sr}_{1.6}\text{Mn}_2\text{O}_7$, where the AFM spin axis was changed from out-of-plane to in-plane as a result of the field induced change of e_g orbital occupation. Finally, we discuss the spin-orbital-lattice coupling in bilayer manganites.

Session X17 DMP: Focus Session: Nanostructures and Metamaterials, Growth, Structure, and Characterization – Improved Materials and Applications II 252A

2:30PM X17.00001 Low-loss multilayered metamaterial exhibiting a negative index of refraction at visible wavelengths¹, CARLOS GARCIA-MECA, Universidad Politecnica de Valencia. Nanophotonics Technology Center. — Over the

last decade, metamaterials have attracted a great interest thanks to their potential to expand the range of electromagnetic properties found in natural materials. In particular, the possibility of achieving negative refractive index media (NIM) enables us to implement superlenses and optical storing devices. Since the first experimental demonstration at microwave frequencies, much effort has been put in extending negative refraction to the visible spectrum, where we can take full advantage of NIM properties. For instance, the superior imaging ability of NIM would be essential for visible microscopy. The desired features for NIM are low loss and isotropy. This last property includes polarization independence and negative-index behavior in all spatial directions. None of these features have been attained in previous experiments. Thus, the current challenge is to improve such aspects in order to make NIM suitable for practical applications. In this work, we experimentally demonstrate a low-loss multilayer metamaterial exhibiting a double-negative index in the visible spectrum, while presenting polarization independence at normal incidence. This has been achieved by exploiting the properties of a second-order magnetic resonance of the so-called fishnet structure, in contrast to previous works that used first-order magnetic resonances, both related to gap surface plasmon polariton (SPP) modes. The low-loss nature of the employed magnetic resonance, together with the effect of the interacting adjacent layers, results in a figure of merit as high as 3.34. A wide spectral range of negative index is achieved, covering the wavelength region between 620 and 806 nm with only two different designs. The fabricated metamaterials are the first experimental multilayer NIM in the visible spectrum, which entails an important step towards homogeneous NIM in this range. Finally, we found that the SPP modes determining the permeability resonance display weak angular dispersion.

3:06PM X17.00002 Photonic-Plasmonic Coupling and Near Field Engineering in Nanoparticle Necklaces, ALYSSA PASQUALE, Boston University Electrical and Computer Engineering Department, BJÖRN REINHARD, Boston University Chemistry Department, LUCA DAL NEGRO, Boston University Electrical and Computer Engineering Department — Particle clusters with different degrees of rotational symmetry consisting of circular loops of gold nanoparticles, dubbed nanoplasmonic necklaces, are proposed as a novel, reproducible platform for elastic and inelastic optical sensors with polarization insensitive behavior. Engineering of the necklaces allows for full control of the plasmonic hot-spot locations and near-field strength by coupling photonic resonances to the circular resonator structure. The polarization insensitivity of necklaces guarantees that the plasmonic hot-spots remain excited within the necklaces irrespective of the incident polarization of the excitation field, which is a significant advantage compared to hot-spots in dimer configurations. Near-fields can be further enhanced using radiative coupling in concentric necklaces having integer multiple diameters. Engineering design rules are determined for hot-spot formation, polarization insensitivity, and intensity distribution in necklaces using 3-dimensional Finite-Difference Time-Domain simulations. Plasmonic necklaces of different rotational axes were fabricated using electron-beam lithography and electron-beam deposition of gold films. Surface enhanced Raman scattering measurements were used to experimentally validate our near-field calculations.

3:18PM X17.00003 Probing Thermomechanics at the Nanoscale: Impulsively Excited Pseudo-surface Acoustic Waves in Hypersonic Phononic Crystals, D. NARDI, Q. LI, K. HOOGEBOOM-POT, M. MURNANE, H. KAPTEYN, JILA - University of Colorado at Boulder, USA, M. SIEMENS, Department of Physics and Astronomy - University of Denver, USA, M. TRAVAGLIATI, Center for Nanotechnology Innovation @NEST - IIT, Pisa, Italy, F. PARMIGIANI, Dipartimento di Fisica - Università degli Studi di Trieste, Italy, G. FERRINI, F. BANFI, Dipartimento di Matematica e Fisica - Università Cattolica, Brescia, Italy — Hypersonic-frequency surface acoustic waves can be generated by ultrafast laser excitation of nanoscale patterned surfaces and are of great interest because of their high sensitivity to the mechanical properties of the material in which they propagate. By modeling nanoscale thermomechanics from first principles, we can calculate a composite system's initial heat-driven response and follow its evolution in time. A spectral decomposition of the response on the calculated eigenmodes of the system allows evaluation of impulsively excited pseudosurface acoustic wave frequencies and lifetimes, expanding our understanding of surface waves scattering in mesoscale metamaterials, while providing crucial information about non-destructive photoacoustic characterization and imaging of nanostructures for nanoelectronics, nanomedicine and photovoltaic applications. The model is successfully benchmarked against time-resolved optical diffraction measurements performed on 1D and 2D surface phononic crystals, probed using extreme ultraviolet and near-infrared light. Reference: D. Nardi et al., Nano Lett. 11, 4126 (2011).

3:30PM X17.00004 Plasmonic nanotips for spectroscopy with nanometer-scale resolution, JOHANNES FEIST, ITAMP, Harvard-Smithsonian Center for Astrophysics, SEMION K. SAIKIN, Department of Chemistry and Chemical Biology, Harvard University, M.T. HOMER REID, Research Laboratory of Electronics, Massachusetts Institute of Technology, ALÁN ASPURU-GUZIK, Department of Chemistry and Chemical Biology, Harvard University, MIKHAIL D. LUKIN, Department of Physics, Harvard University — We theoretically investigate the use of metallic nanotips, i.e. nanowires with a sharp tip, as tools for spectroscopic applications such as surface-enhanced Raman scattering (SERS). Nanotips can provide strong coupling between guided plasmon modes and single emitters such as atoms or molecules. At the same time, the spatial localization of the plasmon response can potentially provide nanometer-scale spatial resolution in a scanning-tip setup. In particular, we will focus on the possibilities of transporting the electromagnetic field to the target through the surface plasmon mode on the wire, and on coupling the emitted radiation into the same mode. We compare the performance of such an approach with more conventional SERS setups, where localized surface plasmons are used to enhance the local field of an incoming laser beam and the emitted free-space radiation. Finally, we will discuss whether single-molecule sensitivity can be reached.

3:42PM X17.00005 Structural and Optical Properties of Metals in Photonic Semiconductor Devices, MENG-MU SHIH, University of Florida — Metals can play important roles in semiconductor photonics if properly incorporated and designed. The mode-coupling coefficient of the periodic waveguide in the device is the key parameter for analyzing optoelectronic performance. This work constructs a modified model to show how the metal gratings on the semiconductor surfaces and how the metal compositions inside the semiconductors can affect the coupling coefficients. Metal gratings with various materials and nano-structures can affect optical interactions at corrugated metal-semiconductor interfaces. Optical effects such as wavelength and wave polarization can affect the optical properties of metals and semiconductors. In addition, metal compositions in semiconductor compounds can change the optical properties of semiconductors. Semiconductors with different optical and structural properties can generate specific wavelengths. Consequently, the above factors related to optical properties and interactions of metals can affect the coupling coefficients. Computational results with physical interpretations provide insights into photonic devices for more applications.

3:54PM X17.00006 Cavity Resonances in Plasmonic Patch Nanoantennas, AYAN CHAKRABARTY, FENG WANG, FRED MINKOWSKI, QI-HUO WEI, Kent State University — Plasmonic nanoantennas allow for confining and detecting photons at very small length scales. This work presents our recent experimental and theoretical studies of two dimensional periodic arrays of elliptical metal nano-patches on a silver film with a dielectric gap layer. Simulation and theoretical results shows that various cavity modes can be excited with tilted or normal incident light, and that the azimuthal symmetry breaking makes the nanoantennas polarization sensitive due to different resonant frequencies of the even and odd cavity modes. Particularly, it is shown that the cavity modes can be well described by a product of Mathieu functions, providing good agreements with both simulations and experiments. The effects of coupling between the cavity modes and the propagating plasmons will be discussed.

4:06PM X17.00007 Efficient calculation for waveguides and for photonic crystal band structures using improved finite elements in 2D¹, C.R. BOUCHER, C.I. AHENG, L.R. RAM-MOHAN, WPI — We employ scalar, fifth-order Hermite interpolation polynomials to solve Maxwell's equations in two dimensions in the finite element method. We analyze homogeneous conducting waveguides, inhomogeneous waveguides, and photonic crystals. The Hermite interpolation functions provide greater accuracy than vector finite elements of equal polynomial order, while bypassing the issue of spurious modes observed when using Lagrange polynomials. The scalar Hermite elements offer a level of flexibility which is not seen with vector finite elements, as in multiphysics problems such as coupled Schrödinger-Maxwell problems. The use of Hermite elements is an attractive alternative to plane-wave methods for modeling photonic crystals, leading to sparse matrices due to local connectivity of the finite elements, greater flexibility in modeling, and lower computational costs.

¹This work has been supported by Quantum Semiconductor Algorithms, Inc., and by AFRL/DARPA under grant FA8650-10-1-7046. 1

4:18PM X17.00008 Diffusion of a Plasmon-Exciton Polaron¹, CHARLES CHERQUI, DAVID DUNLAP, Department of Physics and Astronomy, University of New Mexico, ANDREI PIYATINSKI, Center for Nonlinear Studies, Los Alamos National Lab — We consider the motion of an exciton constrained to a quasi-one-dimensional geometry in the vicinity of a metal interface. For weak coupling, the metal causes damping of the center of mass motion, leading to a decrease in the exciton diffusion constant. This can be modeled as non-contact dielectric friction between an oscillating dipole and a substrate, where the frictional force is related to the response of the metal through the fluctuation dissipation theorem [1]. When the exciton frequency is in the neighborhood of the plasma resonance, the interaction can no longer be described by linear response theory, for the exciton and plasmon form a quasiparticle, an exciton-plasmon polaron. We calculate the transmission and reflection coefficients for the exciton-plasmon polaron in the neighborhood of a metal interface, as well as the diffusion rate and radiative lifetime versus coupling strength.

¹Work supported by the Department of Energy and the Center for Nanointegrated Technologies

4:30PM X17.00009 Coherent interband transport in binary zigzag optical waveguide arrays¹, KIN CHUNG AU YEUNG, NAI JING DENG, CHEUNG WAI CHAU, SAI KIT YUNG, KIN WAH YU, The Chinese University of Hong Kong — We have studied the optical oscillation and Zener tunneling of light waves in binary zigzag optical waveguide arrays in which the evanescent coupling in the array is included up to the second order. By tuning the ratio of the first order and second order coupling strengths, there is a miniband-minigap structure in the dispersion diagram. Moreover, by adding a gradient in the propagation constant transverse to propagation, Bloch-Zener oscillation (BZO) and Zener tunneling between two bands can be realized. The occurrence of BZO and Zener tunneling is simulated by the field-evolution analysis using an input Gaussian beam. Through a visual band picture, the simulation results confirm the band structure of the waveguide arrays. A rate equation is proposed to understand the coherent transport behaviors between the two minibands across the gap.

¹Supported by the General Research Fund of the HKSAR Government

4:42PM X17.00010 Tunable rainbow trapped in a self-similar liquid crystal waveguide, QING HU, SI-HUI WANG, DI-HU XU, YU ZHOU, RU-WEN PENG, MU WANG, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University, Nanjing 210093, China — We have investigated the optical propagation through a self-similar dielectric waveguide, where a hollow core is surrounded by a coaxial Thue-Morse multilayer. It is found that due to the self-similar furcation feature in the photonic band structure, the transmission multibands are achieved. And different frequency ranges of the transmission modes can be selectively guided and spatially confined along the waveguide. Consequently, a rainbow can be trapped in the waveguide. Then by infiltrating liquid crystal into the cladding layers, the transmission modes and rainbow trapping can be tuned by altering the temperature. And transverse electric (TE) and transverse magnetic (TM) polarizations present different propagating features. The attenuation and energy density distributions of different modes in the waveguide are also discussed. The finding can be applied to designing miniaturized compact photonic devices, such as a spectroscopy on a chip, color-sorters on a chip, and photon sorters for spectral imaging. Reference: Qing Hu, Jin-Zhu Zhao, Ru-Wen Peng, Feng Gao, Rui-Li Zhang, and Mu Wang, Appl. Phys. Lett. (2010) 96, 161101; and Qing Hu, Ru-Wen Peng, Si-Hui Wang, and Mu Wang, manuscript prepared(2011).

4:54PM X17.00011 A New Strategy for Designing Broadband Epsilon-Near-Zero Metamaterials¹, HON PING LEE, KA SHING HUI, LEI SUN, KIN WAH YU, The Chinese University of Hong Kong — We have developed a new strategy for designing metamaterials in multi-layered film with permittivity being closed to zero over a broad frequency range, which is as known as broadband epsilon-near-zero (ENZ) materials. Milton representation, Bergman-Milton representation and electromagnetic representation of the effective permittivity (ϵ_{eff}) are used, and the strategy consist of the following 3 parts: choosing the operation frequency range, properly placing the poles and zeros into the range, and solving the inverse problem by equating different representations of ϵ_{eff} . Demonstration of the strategy is carried out by zeroth and first order design with several examples. The distribution of electric field inside the designed materials is investigated to reveal the physical principles of the broadband ENZ phenomenon. The study would be further extended to other geometries (e.g. multi-shell cylinder) through conformal transformation. The results obtained are useful for designing ENZ metamaterials.

¹Work supported by the General Research Fund of Hong Kong SAR Government

5:06PM X17.00012 Effective permittivity of ensemble-averaged waves in dense random plasmonic composites¹, SATVIK WANI, Department of Biomedical and Chemical Engineering, Syracuse University, Syracuse, NY 13244, USA, ASHOK SANGANI², National Science Foundation, Arlington, VA 22230, USA, RADHAKRISHNA SURESHKUMAR, Department of Biomedical and Chemical Engineering and Department of Physics, Syracuse University, Syracuse, NY 13244, USA — Random composites of metallic nanospheres (Ag, Au, Cu, etc.) in transparent media are highly opaque due to absorption resulting from plasmon resonance. A new technique for calculating the effective properties of such dense composites is described. The underlying physical motif is the separation of the space surrounding any inclusion into two regions, one immediately surrounding the particle with the properties of the matrix (the size of this region depends on the static structure factor) and an effective medium. Self consistent closure relations are found for the conditionally averaged fields by solving the vector Helmholtz equations for a layered sphere in an infinite matrix by utilizing a multipole expansion technique. For finitely large ϕ , the effective permittivity is given by $\epsilon_{eff}/\epsilon_m = 1 + 3\beta\phi + \frac{3}{4}(\beta+4)\beta^2\phi^2 + O(\phi^3)$ where ϵ_m is the permittivity of the medium and β is the particle polarizability per unit volume. For denser systems, the particle and effective medium fields interfere to give rise to a Fano-like line shape for $Im(\epsilon_{eff})$. The resonance conditions result in a ϕ dependent red-shift of the resonance peak. Effects of polydispersity and multiple particle species on ϵ_{eff} will be discussed.

5:18PM X17.00013 Microfabrication of highly absorbent THz metafilms tuned for specific frequencies¹, DRAGOSLAV GRBOVIC, FABIO ALVES, BRIAN KEARNEY, GAMANI KARUNASIRI, Naval Postgraduate School — THz imaging has gained increased attention in recent years. The main motivation is the property of THz radiation to penetrate through most non-metalic materials and fabrics, making it attractive for medical and security applications. In addition, the radiation is non-ionizing and therefore does not present a risk for human health. However, THz imaging requires external illumination, often by quantum cascade lasers (QCLs). Metafilm absorbers with nearly 100% absorption, at frequencies matched to appropriate QCLs, have been designed and fabricated using a periodic array of aluminum (Al) squares and an Al ground plane, separated by a thin SiO₂ dielectric film. All metafilms are below 2 μ m and are suitable for integration with microbolometers or bimaterial sensors for THz imaging. The THz spectral characteristics of structures were probed using FTIR spectrometer. Films with different dielectric layer thicknesses exhibited resonant absorption at close to 100% at respective frequencies. The measured THz reflection, from thin film of both broad-band and resonant metamaterial structures, exhibit excellent agreement with their respective finite element models.

Session X18 DMP DCMP: Growth and Properties of Nanoparticles and Nanowires 252B

2:30PM X18.00001 Electronic structures and adsorption configurations of gold nanoclusters on cerium oxide defect surfaces, LU WANG, WAI-NING MEI, Department of Physics, University of Nebraska at Omaha, Omaha, NE 68132, NEIL LAWRENCE, JOSEPH R. BREWER, JAMES WELLS-KINGSBURY, MARCELLA IHRIG, GONGHUA WANG, CHIN LI CHEUNG, Department of Chemistry, University of Nebraska-Lincoln, Lincoln, NE 68588, YUN-LIANG SOO, Department of Physics, National Tsing Hua University, Taiwan — Fluorite-structured cerium oxide (or ceria, CeO_{2-x} , $0 \leq x \leq 0.5$) has been shown to be an important material in catalysis, yet few study has investigated the effect of non-dopant introduced oxygen vacancy defect (OVD). In addition, we found experimentally that when doped with Au nanoclusters, the catalytic ability of ceria enhanced. In this work, we modeled and optimized an (111) fluorite-structured slab model of defective ceria with a chemical formula corresponding to $\text{CeO}_{1.5}$. The optimized surface structure of this model was found to contain both surface and sub-surface OVDs, similar to those observed in our HRTEM data for low pressure activated nanoceria. Significantly, the model captures comparable reduction in the average Ce-O bond distance and also atomic coordination numbers observed in our EXAFS data. To explore the roles of Au nanoclusters, we adsorbed flat clusters of 3, 4, 9, 10, and 19 Au atoms on ceria slabs, optimized their configurations, and computed the corresponding electronic structures applying first-principle approach. Consequently, we present the density of states results to elucidate the experimentally observed optical property change and $s-d$ hybridization.

2:42PM X18.00002 The Kirkendall Effect in Copper Nanocrystals, MARK STOYKOVICH, KATHERINE RICE, Department of Chemical and Biological Engineering, University of Colorado - Boulder, DEPARTMENT OF CHEMICAL AND BIOLOGICAL ENGINEERING, UNIVERSITY OF COLORADO - BOULDER TEAM — The study of copper nanocrystals, unlike nanocrystals of other noble metals such as gold and silver, has been limited due to challenges in the synthesis of monodisperse copper nanoparticles and their reactivity at ambient conditions. Copper is a material of broad interest, however, because of its unique optical and catalytic properties, as well as its non-toxic nature and relative abundance. Copper nanocrystals in the process of being oxidized are subject to the Kirkendall effect, which describes independent diffusion rates in a binary system (Cu and oxygen in this case) and that causes the formation of voids at the core of spherical nanocrystals. Previous studies have attributed the Kirkendall effect in Cu/Cu₂O nanocrystals to interactions between the organic passivation layer and the solvent. Here we will present our results on the kinetics of oxidation of Cu nanocrystals in solvent-less conditions as a function of temperature and show that void formation occurs at a relatively narrow range of temperatures. In-situ UV-vis spectroscopy, x-ray diffraction, and electron microscopy have been used to monitor the oxidation process in Cu nanocrystals and a model has been developed to describe hollow particle formation in the Cu/Cu₂O system.

2:54PM X18.00003 Systematic Study of Supported Ni, Pd, Pt Metal Nanocrystals for Catalytic Energy Conversion, VICKY DOAN-NGUYEN, University of Pennsylvania, MATTEO CARGNELLO, University of Trieste, THOMAS R. GORDON, KEVIN BAKHMUTSKY, University of Pennsylvania, PAOLO FORNASIERO, University of Trieste, RAYMOND GORTE, CHRISTOPHER B. MURRAY, University of Pennsylvania — Ni, Pd, and Pt nanocrystals ranging from 4-12 nm have been synthesized with great control in size and shape using a high-temperature chemical synthetic method for gas-phase catalytic testing. The tunability in size allows for controlled catalytic study of model reactions such as CO oxidation, CO hydrogenation and methane oxidation. The monodispersity of the particles allow for a systematic correlation between size and catalytic activity. There is consistent size dependence of CO oxidation for each of the metal systems on CeO₂ support as indicated by the lower temperatures needed for full conversion. Our calculated activation energy using the Arrhenius equation for each size and material correlated with surface-area-to-volume ratio. Consistent with the light-off studies, the smallest particles were the most catalytically active under differential conditions. The same trend was observed for CO hydrogenation amongst each system. This trend was inverted for the oxidation of methane. This current study aims to elucidate the size dependence of catalytic activity in model systems with supported uniform nanocrystals.

3:06PM X18.00004 Ab Initio Investigation of the Structures of Fe-Doped Carbon Clusters, CHRISTELLA LOVATO, CLIFTON BROWNRIGG, AJIT HIRA, Northern New Mexico College — We continue our interest in the theoretical study of carbon clusters to examine the effects of the doping of small carbon clusters (C_n , $n = 2 - 15$) with iron atoms. This work applies the hybrid ab initio methods of quantum chemistry to derive the different Fe_mC_n ($m = 1-3$) geometries. Of particular interest are linear, fan, and cyclic geometries. Electronic energies, rotational constants, dipole moments, and vibrational frequencies for these geometries are calculated. Exploration of the singlet, triplet, quintet, and septet potential energy surfaces is performed. The type of bonding in terms of competition between sp^2 and sp^3 hybridization is examined, with a view to addressing the possibility of the stabilization of the doped carbon nano-particles in a diamond type structure. The potential for the existence of new pathways to the fabrication of nanotubes is explored.

3:18PM X18.00005 Electrical Detection of Mechanical Resonance of ZnO Nanowhiskers, DEEPIKA SAINI, DOYL DICKEL¹, RAMAKRISHNA PODILA, HERBERT BEHLOW, MALCOLM SKOVE, APPARAO RAO, Clemson University — Here, we present the fundamental mechanism for the observation of electrically actuated resonances in semi-conducting ZnO nanowhiskers (NWs). Previous studies have claimed that various mechanisms including charge induction lead to a mechanical resonance in NWs. Many of such studies employ an electron beam to visualize the resonance of NWs. However, we find that the use of an electron beam changes the electrical character of the NWs making it difficult to understand fundamental actuation mechanism. In this article, we developed a novel, fully electrical harmonic detection of resonance (HDR) method that enables us to probe mechanical resonances of NWs even in the absence of an electron beam. In contrast to the traditional optical detection scheme, the HDR method allows us to successfully decouple the effects of the electron probe beam from the actual driving force. Interestingly, we find that the observed mechanical resonance of ZnO NWs is dominated by their interactions with the electron probe beam. Importantly, ZnO NWs exhibit strong (weak) mechanical resonance only in presence (absence) of the electron probe beam suggesting that the observed behavior originates from dynamically induced (static) charges.

¹First and second author contributed equally

3:30PM X18.00006 Direct growth of vertically aligned long ZnO nanowires on FTO substrates and their application for dye sensitized solar cells, LIYOU LU, JIAJUN CHEN, WENYONG WANG, Department of Physics and Astronomy, University of Wyoming — In this research we report a direct growth of vertically aligned ZnO nanowires on fluorine-doped-tin-oxide (FTO) coated substrates for dye sensitized solar cell (DSSC) applications. ZnO nanowires with length of more than 30 μm were synthesized using a fine-tuned chemical vapor deposition method at temperatures as low as 550 °C. The nanowires grew along the [0001] direction and exhibited a needle-like shape with a wurtzite single crystal structure. Compared to the ZnO nanowires fabricated by solution based methods, the nanowires synthesized in this study have much longer length, thus could increase the amount of dye loading and improve DSSC performance. Furthermore, since the nanowires were directly synthesized on FTO substrates, DSSCs could be fabricated using the as-grown nanowires without the usual wire transfer processing that caused nanowire breaking and created additional transport barriers and recombination possibilities for photo-generated carriers. DSSCs fabricated in this study showed attractive performance with short-circuit current density of 5.1 mA/cm^2 and power conversion efficiency of 1.66%. Dependence of the DSSC performance on nanowire length and annealing processing was also examined in this research.

3:42PM X18.00007 Competing gas phase reactions during vapor transport deposition of ZnO nanowires, ERIC DRISCOLL, Lock Haven University, KEVIN RANGE, Lock Haven University, Department of Chemistry, MARIAN TZOLOV, Lock Haven University, Department of Physics — We present results illuminating some of the major chemical processes in the vapor deposition of ZnO nanowires. The analysis of our deposition experiments indicates that carbon dioxide is a major oxidizing agent rather than carbon monoxide as previously thought. Additionally, we present evidence that carbon monoxide will etch zinc oxide at high temperatures. Zinc oxide nanowires have been prepared by using chemical vapor deposition on silicon (100) substrates with a 10-15nm layer of gold as a catalyst. Zinc oxide and graphite powders were heated to approximately 1000°C in a tube furnace in a flow of argon. We have delivered oxygen gas specifically in the growth zone to facilitate the formation of high aspect ratio nanowire growth. Thermodynamics calculations were used to justify the growth and etching processes. Imaging of samples was performed with scanning electron microscopy. Chemical composition was determined by energy dispersive x-ray spectroscopy. Photoluminescence spectroscopy was used to characterize the emission properties of the zinc oxide samples.

3:54PM X18.00008 Study on Pure Phase Formation of Lead Oxide Nanowires by Oxidation of Lead Nanowires, KUO HAI, XIAOGANG WANG, Hunan Normal University, DEPARTMENT OF PHYS., HUNAN NORMAL UNIVERSITY TEAM — Lead-oxide nanowires were synthesized by oxidizing lead metal nanowires. The phase structures, sizes and morphologies of the nanowires were investigated by atomic force microscopy and x-ray diffraction, and the band gap of the nanowires was determined by UV-Vis-NIR reflectance diffusion spectrums. The thermodynamic environment for the pure phase formation has been studied. The first-principle computation has been done to help understand the phase formation. Our results reveal that the pure phase formation strongly relies on both the process temperature and the oxygen flow/oxygen partial pressure, and the pure phase γ -PbO nanowires can be obtained only in a narrow, low temperature range under a low oxygen flow.

4:06PM X18.00009 Formation of metallic gold chain on patterned hydrogen terminated Si(001)-2×1 surface: Density functional study, BIKASH GUPTA, PURUSOTTAM JENA, Department of Physics, Virginia Commonwealth University, Richmond, VA 23284 — Metal adsorption on silicon surface for the formation of linear metallic chain is one of the important research areas for the advancement of nanotechnology. Due to the presence of dangling bonds all over the surface of bare Si(001), metals when deposited, generally do not tend to form stable wire structures. However, patterned hydrogen terminated Si-surface may be a good choice for the formation of atomic chain structures of metals. Since patterned hydrogen terminated Si(001):2×1 surface is very stable, we consider patterning it by removing desired hydrogen atoms and adsorbing gold atoms. We have examined the structure, energetic and electrical properties of such gold adsorbed surface by varying gold coverage. We have found that linear gold chain structures may be formed by controlling gold coverage. Some of these gold chain structures are metallic in nature. We hope that our results will motivate synthesis of gold chains on patterned hydrogen terminated Si(001): 2×1 surface.

4:18PM X18.00010 Catalytic role of Au nanoparticle in GaAs nanowire growth¹, PETER KRATZER, SUNG SAKONG, VOLKER PANKOKE, University Duisburg-Essen, Germany — The energetics of Ga, As and GaAs species on the Au(111) surface (employed as a model for Au nanoparticles) is investigated by means of density-functional calculations. Apart from formation of the compound Au₇Ga₂, Ga is found to form a surface alloy with Au, with comparable $\Delta H \sim 0.5$ eV for both processes. Dissociative adsorption of As₂ is found to be exothermic by more than 2 eV on both clean Au(111) and AuGa surface alloys. The As-Ga species formed by reaction of As with the surface alloy is sufficiently stable to cover the surface of an Au particle *in vacuo* in contact with a GaAs substrate. Concerning the Au-catalysed growth of GaAs nanowires, we conclude that impingement of As₂ or As₄ molecules on the Au particle suffices as supply of arsenic to the growth zone. We identify a regime of temperatures and As₂ partial pressures suitable for Au-catalysed nanowire growth in molecular beam epitaxy.

4:30PM X18.00011 Engineering Enhanced Optical Properties of Near-IR Upconverting Nanoparticles, DANIEL GARGAS, ALEXIS OSTROWSKI, EMORY CHAN, DELIA MILLIRON, BRUCE COHEN, P. JAMES SCHUCK, The Molecular Foundry, Lawrence Berkeley Laboratory — Due to their unique properties in converting low energy light into higher energy electronic transitions, upconverting nanoparticles (UCNPs) have garnered considerable interest in bio-imaging, photovoltaic, and opto-electronic applications. In particular, lanthanide-doped UCNPs have demonstrated a host of functionalities due to their nanoscale dimensions, wide range in transition-metal doped compounds, and high photostability in both aqueous and ambient environments.¹ In addition, their mixed electric and magnetic dipole transitions make them ideal materials for study of plasmon-enhanced properties with metal nanostructures in which tunable surface properties can mediate energy transfer processes. Here we report on the luminescence properties of Er³⁺, Yb³⁺-doped NaYF₄ UCNPs with diameters ranging from 5 – 50 nm in both core and core-shell architectures. Optical characterization of the luminescence lifetime and spectral emission from both UCNP films and single particles reveal a strong dependence on particle size and surface functionalization. Furthermore, by utilizing the large shift (anti-stokes) in absorption energy versus transition energy, we investigate the interaction of energy transfer across metal-semiconductor nano-interfaces whereby the intrinsic luminescence lifetimes are probed for Purcell enhancement and emission rate modification.

¹P.J. Schuck, et al *Proc. Nat. Acad. Sci.* **106**, 10917, 2009

4:42PM X18.00012 Tuning the parameters to establish Quenching and enhancement regimes in hybrid Gold nanoparticles and CdSe Quantum dots monolayer¹, LAXMINARAYAN TRIPATHI, PRAVEENA M., J.K. BASU, Department of Physics, Indian Institute of science, Bangalore, India — The multi-component nanomaterials combine the individual properties and give rise to emergent phenomenon. Optical excitations in such hybrid nonmaterial's (for example Exciton in semiconductor quantum dots and Plasmon in Metal nanomaterials) undergo strong weak electromagnetic coupling. Such exciton-plasmon interactions allow design of absorption and emission properties, control of nanoscale energy-transfer processes, and creation of new excitations in the strong coupling regime. This Exciton plasmon interaction in hybrid nanomaterial can lead to both enhancement in the emission as well as quenching. In this work we prepared close-packed hybrid monolayer of thiol capped CdSe and gold nanoparticles. They exhibit both the Quenching and enhancements the in PL emission. The systematic variance of PL from such hybrid nanomaterials monolayer is studied by tuning the Number ratio of Gold per Quantum dots, the surface density of QDs and the spectral overlap of emission spectrum of QD and absorption spectrum of Gold nanoparticles. Role of Localized surface Plasmon which not only leads to quenching but strong enhancements as well, is explored.

¹Indian Institute of science, Bangalore, India

4:18PM X19.00004 Electronic and structural correlations at 2DEG oxide heterointerfaces¹, M.S. RZCHOWSKI, Physics Dept., University of Wisconsin-Madison — The formation of a two-dimensional electron gas (2DEG) at complex oxide interfaces is directly influenced by the rich electronic and structural characteristics of the bulk oxides, as well as new phenomena arising at the interface. We investigated how local correlations control oxide 2DEGs by inserting a single atomic layer of a rare-earth oxide (RO) [(R is lanthanum (La), praseodymium (Pr), neodymium (Nd), samarium (Sm), or yttrium (Y))] into an epitaxial SrTiO₃ matrix using pulsed-laser deposition with atomic layer control [1]. We find that structures with La, Pr, and Nd ions result in conducting 2DEGs at the inserted layer, whereas the structures with Sm or Y ions are insulating. Our local spectroscopic results, and our theoretical results, indicate that the interfacial conductivity is dependent on electronic and structural correlations that decay spatially into the SrTiO₃ matrix and are determined by the local rare-earth ion. We also find that at least the structural correlations play a role in the properties of the 2DEG at LaAlO₃/SrTiO₃ interfaces. We used different lattice constant single-crystal substrates to produce LaAlO₃/SrTiO₃ interfaces with controlled levels of biaxial epitaxial strain [2], finding that tensile-strained SrTiO₃ destroys the conducting 2DEG, while compressively strained SrTiO₃ retains the 2DEG, but with reduced carrier concentration. In addition, the critical LaAlO₃ overlayer thickness for 2DEG formation increases with SrTiO₃ compressive strain. Our first-principles calculations suggest that a strain-induced electric polarization in the SrTiO₃ layer, stabilized by the LaAlO₃ overlayer, is responsible for this behavior. This work was done in collaboration with H.W. Jang, C.W. Bark, D.A. Felker, T. Hernandez, Y. Wang, M.K. Niranjan, C.T. Nelson, Y. Zhang, D. Su, C.M. Folkman, S.H. Baek, S. Lee, K. Janicka, H. Zhou, Y. Zhu, X.Q. Pan, D.D. Fong, E.Y. Tsymlal, C. B. Eom. This work was supported by the National Science Foundation through grant DMR-0906443.

4:54PM X19.00005 Electronic structure and two-dimensional electron gas at the surface of SrTiO₃¹, ANDRES FELIPE SANTANDER-SYRO, CSNSM, Universite Paris-Sud, Bat. 108, 91405 Orsay, France — Similar to silicon that is the basis of conventional electronics, strontium titanate (SrTiO₃) is the bedrock of the emerging field of oxide electronics. SrTiO₃ is the preferred template to create exotic two-dimensional (2D) phases of electron matter at oxide interfaces, exhibiting metal-insulator transitions, superconductivity, large magnetoresistance, or coexistence of superconductivity and ferromagnetism. However, the physical nature of the electronic structure underlying these 2D electron gases (2DEGs) remains elusive, although its determination is crucial to understand their remarkable properties. In this talk, we present our angle-resolved photoemission spectroscopy (ARPES) results showing that there is a highly metallic universal 2DEG at the vacuum-cleaved surface of SrTiO₃, independent of bulk carrier densities over more than seven decades, including the undoped insulating material [A. F. Santander-Syro *et al.* *Nature* **469**, 189-193 (2011)]. Our data unveil a remarkable electronic structure consisting on multiple subbands of heavy and light electrons. We find that the 2DEG is confined within a region of ~5 unit cells and has a sheet carrier density of ~0.33 electrons per a^2 (a is the cubic lattice parameter). The similarity of this 2DEG with those reported in SrTiO₃-based heterostructures and field-effect transistors suggests that different forms of electron confinement at the surface of SrTiO₃ lead to essentially the same 2DEG. Our discovery provides thus a model system for the study of the electronic structure of 2DEGs in SrTiO₃-based devices and a novel route to generate 2DEGs at surfaces of other functional oxides.

Thursday, March 1, 2012 2:30PM - 5:30PM – Session X20 FIAP: Invited Session: Physics of Color Reflective Displays 253C

2:30PM X20.00001 Bio-Inspired Adaptive Coloration – Knowledge Gained by Comparison of Nature and Man-Made Technologies, JASON HEIKENFELD, University of Cincinnati — Adaptive coloration, achieved through the use of pigments and reflective surfaces, is used by biological organisms to resemble natural surfaces and/or vividly communicate information. The key to this approach is that light incident on the organism is manipulated to perform the adaptive coloration (i.e., no light is created in the process). Only recently have man-made display technologies (E-paper) attempted to achieve similar adaptive reflective properties. For biological organisms, as well as display technologies, the following features must be controlled simultaneously while minimizing optical losses: pattern, texture, multiple colors, diffuseness, reflectance, and polarization. Many e-Paper technologies have attempted to duplicate optical effects that are utilized in nature. However, to date, they fail in comparison to the optical performance of biological systems. Thus, engineers working on adaptive reflective surfaces may benefit by examining equivalent biological systems in greater detail than previously achieved. On the other hand, intense research and development into adaptive reflective surfaces has given us a mature understanding of the optics of man-made surfaces, and the advanced measurement standards required for scientific involvement. Although this framework currently exists, it is underutilized for the analysis of biological coloration. To advance the field of adaptive coloration, the gap between biology and engineering must be bridged by developing a consistent framework of scientific metrics important to the performance of all platforms of adaptive reflective surfaces. In this presentation, the optics of adaptive coloration are presented in detail. Biological and technological methods are compared based on the construction, physics, and optical performance of each type of adaptive coloration. These comparisons are discussed at the system (organism), device (organ), and pixel/materials (cellular) levels. The main outcomes of this investigation are: display engineers gain insight from techniques perfected in nature; biologists benefit from an understanding of the types of characterization and metrics that could be extracted from biological organisms; and all scientists gain a clearer picture of the long-term prospects for adaptive reflective technologies.

3:06PM X20.00002 Hewlett-Packard's Approaches to Full Color Reflective Displays, GARY GIBSON, Hewlett-Packard Laboratories, Hewlett-Packard — Reflective displays are desirable in applications requiring low power or daylight readability. However, commercial reflective displays are currently either monochrome or capable of only dim color gamuts. Low cost, high-quality color technology would be rapidly adopted in existing reflective display markets and would enable new solutions in areas such as retail pricing and outdoor digital signage. Technical breakthroughs are required to enable bright color gamuts at reasonable cost. Pixel architectures that rely on pure reflection from a single layer of side-by-side primary-color sub-pixels use only a fraction of the display area to reflect incident light of a given color and are, therefore, unacceptably dark. Reflective devices employing stacked color primaries offer the possibility of a somewhat brighter color gamut but can be more complex to manufacture. In this talk, we describe HP's successes in addressing these fundamental challenges and creating both high performance stacked-primary reflective color displays as well as inexpensive single layer prototypes that provide good color. Our stacked displays utilize a combination of careful light management techniques, proprietary high-contrast electro-optic shutters, and highly transparent active-matrix TFT arrays based on transparent metal oxides. They also offer the possibility of relatively low cost manufacturing through roll-to-roll processing on plastic webs. To create even lower cost color displays with acceptable brightness, we have developed means for utilizing photoluminescence to make more efficient use of ambient light in a single layer device. Existing reflective displays create a desired color by reflecting a portion of the incident spectrum while absorbing undesired wavelengths. We have developed methods for converting the otherwise-wasted absorbed light to desired wavelengths via tailored photoluminescent composites. Here we describe a single active layer prototype display that utilizes these materials along with an innovative optical out-coupling scheme. Further benefits of our approach include means for highly power-efficient back-lighting under low ambient light conditions and the possibility of video rate operation.

3:42PM X20.00003 Opalux Photonic Ink: Full-color, bistable, reflective displays, ANDRE ARSENAULT, Opalux Inc. — No abstract available.

4:18PM X20.00004 Cholesteric Liquid Crystal Based Reflex Color Reflective Displays, ASAD KHAN, Kent Displays, Inc. — Bistable color cholesteric liquid crystal displays are unique LCDs that exhibit high reflectivity, good contrast, extremely low power operation, and are amenable to versatile roll-to-roll manufacturing. The display technology, now branded as Reflex™ has been in commercialized products since 1996. It has been the subject of extensive research and development globally by a variety of parties in both academic and industrial settings. Today, the display technology is in volume production for applications such as dedicated eWriters (Boogie Board™), full color electronic skins (eSkin), and displays for smart cards. The flexibility comes from polymerization induced phase separation using unique materials unparalleled in any other display technology. The blend of monomers, polymers, cross linkers, and other components along with nematic liquid crystals and chiral dopants is created and processed in such ways so as to enable highly efficient manufacturable displays using ultra thin plastic substrates – often as thin as 50μm. Other significant aspects include full color by stacking or spatial separation, night vision capability, ultra high resolution, as well as active matrix capabilities. Of particular note is the stacking approach of Reflex based displays to show full color. This approach for reflective color displays is unique to this technology. Owing to high transparency in wavelength bands outside the selective reflection band, three primary color layers can be stacked on top of each other and reflect without interfering with other layers. This highly surprising architecture enables the highest reflectivity of any other reflective electronic color display technology. The optics, architecture, electro-topics, and process techniques will be discussed. This presentation will focus on the physics of the core technology and color, it's evolution from rigid glass based displays to flexible displays, development of products from the paradigm shifting concepts to consumer products and related markets. This is a development that spans a wide space of highly technical development and fundamental science to products and commercialization to enable the entry of the technology into consumer markets.

Session X21 DCMP: Fluctuation Phenomena (noise, nonequilibrium effects, localization effects)

254A

2:30PM X21.00001 Fluctuoscopia of Disordered Two-Dimensional Superconductors¹, ANDREAS GLATZ, Argonne National Laboratory, ANDREY VARLAMOV, University of Rome, Tor Vergata, VALERII VINOKUR, Argonne National Laboratory — In this talk I will present our results for the fluctuation conductivity (FC) in disordered two-dimensional superconductors placed in a perpendicular magnetic field. In our works [1,2] we finally derived the complete solution in the temperature-magnetic field phase diagram. The obtained expressions allow both to perform straightforward (numerical) calculation of the FC surface $\delta\sigma(T, H)$ and to get all 27 asymptotic expressions in the seven qualitatively different domains of the phase diagram. This surface becomes in particular non-trivial at low temperatures, where it is trough-shaped and close to the quantum phase transition non-monotonic, in agreement with experimental findings. I will show our main results and demonstrate how these can be used as a high precision tool (fluctuoscope) to determine the critical temperature, critical magnetic field, and dephasing time from experimental data in superconducting films.

2:42PM X21.00002 Majorana modes in a superconducting wire with quasiperiodic and, WADE DEGOTTARDI, University of Illinois at Urbana-Champaign, MANISHA THAKURATHI, DIPTIMAN SEN, Centre for High Energy Physics, Indian Institute of Science, SMITHA VISHVESHWARA, University of Illinois at Urbana-Champaign — We present a systematic study of the role quasiperiodic and disordered potentials play in the topology of 1D *p*-wave superconducting systems based on a lattice model which we analyze using a transfer matrix approach. We employ a similarity transformation to demonstrate that the existence of Majorana modes is intimately connected to the band structure of the corresponding normal state system (i.e one which, though otherwise identical, lacks superconducting order). We illustrate this correspondence using the case of an electron moving in a quasiperiodic potential. The Hamiltonian of this system is the so-called “almost Mathieu operator” whose bulk spectrum (for a certain choice of parameters) is described by a fractal known as Hofstadter's butterfly. Specifically, we prove that states belonging to this spectrum host end Majoranas for arbitrarily weak superconductivity and that increasing the magnitude of the superconducting gap causes these topologically non-trivial regions of the phase diagram to expand and fill in the butterfly. We show that similar considerations give us excellent theoretical control over the topological phase diagram of systems with disordered potentials.

2:54PM X21.00003 A Preformed Pair Approach to Diamagnetism in the Cuprates, VIVEK MISHRA, DAN WULIN, K. LEVIN, James Franck Institute, University of Chicago — Enhanced diamagnetism extending beyond the critical regime is associated with the pseudogap. It has been one of the key experiments supporting the precursor superconductivity scenario for this normal state gap. In this talk we demonstrate how non-condensed pairs (rather than normal state vortices) yield a large low field diamagnetic signal. Our work is based on a 3d BCS-BEC crossover scenario where the diamagnetic susceptibility calculation is well controlled and built on a sum-rule compatible correlation function approach. We demonstrate reasonable semi-quantitative agreement with experiment, with no adjusted parameters.

3:06PM X21.00004 Transport theory of superconductors in paramagnetic limit, MAXIM KHODAS, University of Iowa, ALEX LEVCHENKO, Michigan State University, GIANLUIGI CATELANI, Yale University — We report on the study of the quantum phase transition from metastable normal to superconductive state in thin films driven by in-plane magnetic field. In this system resistivity exhibits hysteresis at low temperature when the strong Zeeman field is gradually turned off and on. Quantum fluctuations smear the transition from the metastable normal state to paramagnetically limited superconductivity. The typical energy scale for fluctuations is $\bar{\Omega} = \sqrt{E_z^2 - \Delta^2}$, where E_z is the Zeeman energy and Δ is zero temperature gap. At the onset of the transition $\bar{\Omega} \rightarrow 0$ quantum fluctuations cause non-analytic corrections to the conductivity. The most singular corrections are presented. The result is strongly sensitive to the strength of the spin-orbit scattering. We argue that our theory qualitatively agrees with experimental findings provided the spin-orbit scattering is taken into account.

3:18PM X21.00005 Proliferation of mesoscopic effects in transport of superconductors, MENGJING ZHANG, ALEX LEVCHENKO, Michigan State University — Universality of conductance fluctuations is the hallmark of mesoscopic physics. This phenomenon emerges from the quantum coherence of electron trajectories and is sensitive to changes in external magnetic field or gate voltage. There exists compelling physical evidence, ranging from the experiments in sub-micron scale superconducting rings to granular films driven across superconductor-insulator transition, that the role of mesoscopic fluctuations proliferate in the presence of superconducting correlations. We thus study theoretically the fate of universality of mesoscopic fluctuations in superconductors focusing on the kinetic characteristics such as conductance, thermopower, NMR relaxation rate, spin susceptibility etc.

3:30PM X21.00006 Superconducting fluctuation regime in the cuprates revealed by torque magnetometry¹, GUICHUAN YU, University of Minnesota — The extent of the superconducting fluctuation regime in the normal state of the cuprate superconductors has remained unclear. For the single-CuO₂-layer compounds La_{2-x}Sr_xCuO₄ (LSCO) and Bi₂(Sr,La)₂CuO_{6+δ} (Bi2201), one class of experiments indicates characteristic temperatures as high as 2-3 times T_c at optimal doping, whereas a second class reveals superconducting fluctuations in a relatively narrow temperature range above T_c . Here we report a systematic torque magnetometry study of the superconducting fluctuation regime in three single-layer compounds, LSCO, Bi2201 and HgBa₂CuO_{4+δ}. We find in all three cases that the regime of fluctuating diamagnetism is narrow and closely tracks the doping dependence of T_c , consistent with the second class of experiments [1]. The seemingly controversial results can be understood if short-range phase correlations develop only in the vicinity of T_c , whereas local pair formation appears at a relatively high temperature that is universal among all single-layer cuprates.

3:42PM X21.00007 The potential for persistent current measurements in mesoscopic rings of underdoped cuprates, THOMAS LIPPMAN, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, 2575 Sand Hill Road, Menlo Park, CA 94025, USA, ILYA SOCHNIKOV, Geballe Laboratory for Advanced Materials, Stanford University, Stanford, California 94305-4045, USA, KATHRYN MOLER, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, 2575 Sand Hill Road, Menlo Park, CA 94025, USA — Dimensionality, disorder, order parameter symmetry, competing phases, quantum critical points, thermal phase fluctuations, and quantum phase fluctuations all play a role in the physics of the underdoped cuprates. Measurements of the persistent current in mesoscopic rings near phase transitions can provide valuable information about underlying coherent states. We evaluate the prospects for such measurements in the underdoped cuprates, considering both likely signatures of various theoretical scenarios and experimental feasibility in terms of fabrication and signal levels.

3:54PM X21.00008 Cantilever torque magnetometry study of multiply connected BSCCO arrays near T_c ¹, GRIGORIY POLSHYN, RAFFI BUDAKIAN, University of Illinois at Urbana-Champaign — The goal of this work is to study the superconducting coherence length in the fluctuation regime in cuprate superconductors. In this work we present cantilever torque magnetometry measurements of micron-size BSCCO flakes patterned with arrays of nanometer scale rings or holes. Using ultrasensitive dynamic torque magnetometry, oscillations in magnetization are observed near T_c as a function of the applied magnetic flux threading the array. Special effort was made to detect the oscillations in magnetization at temperatures above T_c , where the Nernst effect and magnetization measurements suggest the possibility of pairing. To constrain the magnitude of the coherence length in the fluctuation regime, we will present the dependence of the amplitude of the $h/2e$ period oscillations as a function of temperature and hole size.

¹This work was supported by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. DOE, Office of Science, under Award No. DE-AC0298CH1088.

4:06PM X21.00009 Properties of ultrathin Bi₂Sr₂CaCu₂O_{8+x} films grown by pulsed laser deposition, MICHAEL HINTON, JIE YONG, STANLEY STEERS, ADAM AHMED, JOHN DRASKOVIC, TOM LEMBERGER, Ohio State University — Thermal and quantum fluctuations in superconductors are expected to grow as film thickness decreases. Such behavior has been observed in YBa₂Cu₃O_{7-δ} (YBCO) films as thickness is reduced to two unit cells. In particular, a Kosterlitz-Thouless like drop in superfluid density appears and shows that 2D fluctuations are correlated through the YBCO film thickness. Since Bi₂Sr₂CaCu₂O_{8+x} (Bi-2212) plays such a prominent role in important ARPES and Scanning Probe measurements of the superconducting gap, it is important to see how this compound behaves in reduced dimensions. To that end, we are working to grow films of Bi-2212 as thin as possible, by pulsed laser deposition in on-axis and off-axis geometries. One goal is to look for the KT transition in the superfluid density, to see whether 2D fluctuations are correlated layer-to-layer even in this highly anisotropic compound, and complement the cuprate picture dominated by the wealth of YBCO data. This requires films to be quite homogeneous. To effectively improve homogeneity, we focus the ac magnetic field of our two-coil measurement system by masking the film of interest with a thick superconducting film with a hole etched through it. Thus, the film area probed is greatly reduced and transition widths are narrowed.

4:18PM X21.00010 Ghost critical field and weak localization phenomena in superconducting Tantalum Nitride films, NICHOLAS BREZNAY, AHARON KAPITULNIK, Stanford University — We study the appearance of superconducting fluctuations and weak localization effects in disordered conducting thin films using magnetotransport measurements. At temperatures above T_c , we observe a positive magnetoresistance that is 4 orders of magnitude larger than the predicted classical effect. Well above T_c this behavior is consistent with the magnetic field dependence of localization quantum corrections to the conductivity in the presence of strong spin-orbit scattering. Close to T_c the observed magnetoresistance is well described by theories that describe both localization and superconducting fluctuations effects. This analysis allows for careful study of the so-called ghost critical field and inelastic scattering rates close to T_c .

4:30PM X21.00011 Coexistence of superconducting gap and pseudogap above and below T_c in cuprates, JEFFERY TALLON, JAMES STOREY, MacDiarmid Institute, Industrial Research, JOHN LORAM, Cavendish Lab., Cambridge University — We develop a new method to calculate the full T -dependent superconducting (SC) gap from thermodynamic measurements and apply to the cuprates. We find that the SC gap persists high above T_c due to strong SC fluctuations and coexists there with the pseudogap. This allows the (disputed) phase diagram to be mapped more accurately than previously. We apply the results below T_c to understand the doping and temperature evolution of critical currents in practical conductors.

4:42PM X21.00012 On-chip detection of photon-assisted shot noise and photocurrent of quantum point contact, Y. JOMPOL, P. ROULLEAU, F. PORTIER, P. ROCHE, D.C. GLATTLI, SPEC, CEA/Saclay, France, I. FARRER, D.A. RITCHIE, Cavendish Laboratory, University of Cambridge, England — We present the first experimental realization of on-chip shot noise detection in capacitively-coupled quantum point contacts (QPCs). The detection is based on the photon-assisted effects. A dc voltage biased QPC: the emitter generates broad frequency current shot noise, inducing voltage fluctuations on the second QPC: the detector. This yields photon induced electron-hole pairs whose partitioning between left and right contact causes a current noise called photon-assisted shot noise (PASN). Alternatively, the electron-hole pairs may also generate a photon-assisted current for energy-dependent transmission. Both the photocurrent and PASN are proportional to the product $D(1-D)$, where D is the transmission of a QPC. Our sample is realized using a set of quantum point contacts positioned onto two separate mesas of a two-dimensional electron gas. The QPC emitter is DC biased and emits high-frequency shot noise that is converted into voltage fluctuations at the QPC detector via an interdigital capacitor, C . Two additional QPCs next to the emitter and the detector serve as tunable quantum resistors and are used to control impedance of the circuit. We show that by varying both the emitter and detector transmissions, D^E , D^D , the measured current at the QPC detector is proportional to $D^D(1-D^D) D^E(1-D^E)$ for a given V_{ds} , which is in good agreement with the theoretical prediction. This new way of detection should find fundamental applications in electronic quantum physics.

4:54PM X21.00013 Direct access to quantum non-Gaussian noise through cross-correlation measurements, IURI CHERNII, EUGENE SUKHORUKOV, University of Geneva — Detection of quantum non-Gaussian fluctuations is often difficult since they are dominated by the classical Gaussian noise, and requires the use of high frequency amplifiers. In our work we investigate the possibility to employ the cross-correlation technique in order to overcome these difficulties. We propose to measure the cross-correlator of outputs of a pair of two-level detectors, coupled to the source of fluctuations via an electric circuit. In the weak coupling regime, the noise induces rare stochastic transitions in the detectors, that allows one to perform the long time measurement. The transition rates can be derived from the evolution of the density matrix, calculated to the fourth order in level mixing of the two-level detectors. We express the cross-correlator in terms of these rates, and demonstrate that there is a range of parameters, where the main contribution to the cross-correlator is proportional to the intensity of the quantum non-Gaussian noise.

5:06PM X21.00014 Interferometric and Noise Signatures of Majorana Fermion Edge States in Transport Experiments, WOLFGANG BELZIG, University of Konstanz, GREGORY STRUEBLI, University of Basel, MAHN-SOO CHOI, Korea University, CHRISTOPH BRUDER, University of Basel — Domain walls between superconducting and magnetic regions placed on top of a topological insulator support transport channels for Majorana fermions. We propose to study noise correlations in a Hanbury Brown-Twiss type interferometer and find three signatures of the Majorana nature of the channels. First, the average charge current in the outgoing leads vanishes. Furthermore, we predict an anomalously large shot noise in the output ports for a vanishing average current signal. Adding a quantum point contact to the setup, we find a surprising absence of partition noise which can be traced back to the Majorana nature of the carriers.

Thursday, March 1, 2012 2:30PM - 5:18PM –
Session X22 DMP DCOMP: Focus Session: Fe-based Superconductors - Exchange Coupling Theory 254B

2:30PM X22.00001 Strong Versus Weak Coupling Pairing in Iron-Based Superconductors¹, B. ANDREI BERNEVIG, Princeton University — We use the functional renormalization group as well as strong-coupling methods to analyze the phase diagram of several of the iron-based superconductors. As in the previous studies by F. Wang, D.H. Lee et. al., we observe a nodeless sign-changing order parameter to be favored over a sizable part of the parameter space, but the physics quickly develops peculiarities depending on the doping, shape, size and orbital content of the Fermi surfaces in the different superconducting compounds. Using several new one-body models available in the literature (due to Kuroki, Graser and Raghu), we analyze the orbital content of the superconducting gap, which should be observable in spin-polarized ARPES experiments. We find that the effective theory of the iron-based superconductors is a $J_1 - J_2$ model in orbital space with $J_2 > |J_1|$ and antiferromagnetic, and analyze the behavior of the physical properties such as superconducting gap for systems ranging from electron overdoped $(K, Cs)Fe_{2-x}Se_x$ to hole-doped $K_xBa_{1-x}Fe_2As_2$.

¹NFS, Packard

3:06PM X22.00002 Hund's metal physics in iron-based superconductors, GABRIEL KOTLIAR, ZHIPING YIN, KRISTJAN HAULE, Department of Physics and Astronomy, Rutgers University — The role of Hubbard U and Hund's J in a material depends on the energy scale of the crystal field splitting. In transition metal oxides, the crystal field splitting is usually considerably larger than Hund's J thus Hubbard U plays the dominating role. However, the crystal field splitting in iron-based superconductors is substantially smaller and the physics in this family is governed primarily by Hund's rule. In this talk, we will show that the combination of density functional theory and dynamic mean field theory properly incorporates the Hund's physics as well as realistic band structure thereby is well suited to capture and predict a wide range of physical properties and their trends in iron pnictides and chalcogenides, such as optical conductivity, x-ray spectroscopy, Fermi surface, magnetic ordering and moments, spin excitations, effective masses and so on. We will demonstrate two important mechanisms operating in this family, namely, Hund's blocking and Kinetic frustration. The importance of electronic correlation caused by the Hund's physics and its relation to various experimental observations will also be discussed.

3:18PM X22.00003 Consistent theory of magnetism and superconductivity in iron pnictides, MICHAEL KATSNELSON, Radboud University Nijmegen, Netherlands, VLADIMIR ANTROPOV, LIQIN KE, Ames Laboratory, USA, MARK VAN SCHILF-GAARDE, Kings College, London, UK — We show that iron pnictide systems possess unusual quantum spin fluctuations which strongly affect their magnetic properties and may be relevant in the mechanism of superconductivity. These fluctuations represent highly non-linear anharmonic excitations and have both transversal and longitudinal components which may contribute differently to the observed properties. From the point of view of magnetism, these fluctuations are responsible for the stability of the observed magnetic ground states, and thus determine the spin-wave spectra. The anharmonic character of the excitations under consideration provides a strong coupling with electron degrees of freedom which may be relevant for the appearance of high-temperature superconductivity. We discuss a mechanism of superconductivity related to spin fluctuation which uses the same pool of fluctuations to explain the Cooper pairing. Theory predicts some correlations between superconductivity temperature and magnetic characteristics and they seem to be in agreement with the available experimental data for pnictides and selenides. We discuss also other materials where one can expect a similar behavior.

3:30PM X22.00004 Giant spin zero-point fluctuations in iron superconductors, VLADIMIR ANTROPOV, Ames Laboratory, USA, PAWEŁ BUCZEK, FRANK ESSENBERGER, ARTHUR ERNST, LEONID SANDRATSKII, E.K.U. GROSS, MPI Halle, Germany — We analyze the strength of quantum spin fluctuations in novel iron superconductors. By using linear response calculations and the density functional approach, we show that many of these materials can be classified as highly responsive magnetic materials with very strong non-linear quantum spin fluctuations. Furthermore, by using the newly developed theory of magnetic instabilities in systems with strong spin zero-point motion, we show that the inclusion of fluctuations dramatically improves an agreement with the experiment for systems such as $CaFe_2As_2$, $LiFeAs$ and $FeSe$, while for $FeTe$, the results are less affected by fluctuations. We demonstrate how spin fluctuations influence the criteria of local magnetic moment and long range magnetic order existence. In addition to iron superconductors, several other groups of materials with possible giant quantum spin fluctuations are identified.

3:42PM X22.00005 Spectral and magnetic properties of the iron-based superconductors: The role of electronic correlation, ALESSANDRO TOSCHI, Vienna University of Technology, P. HANSMANN, Centre de Physique Theorique, Ecole Polytechnique, R. ARITA, Department of Applied Physics, University of Tokyo, S. SAKAI, Centre de Physique Theorique, Ecole Polytechnique, G. SANGIOVANNI, K. HELD, Vienna University of Technology — Electronic correlation plays a subtle role in Fe-based superconductors. In fact, due to the presence of several moderately correlated bands close to the Fermi level, one observes the formation of localized magnetic moments driven by the Hund's exchange interactions, which takes place, however, in a mainly metallic background ("Hund's metal" [1]). This physical scenario provides the key to understand [2,3] the discrepancies observed between experimental estimates of the magnetic moments in the magnetically ordered phase and those obtained via standard LSDA calculations. The magnitude of the discrepancy observed in different compounds would be hence related to the efficacy of the metallic screening, which is decreasing when going from the 1111 (e.g., $LaFeAsO$) to the 122 class, and eventually to the 11 materials (like $FeTe$). Also important to be considered for the interpretation of the ARPES experiments and of the symmetry of the superconducting pairing within the Hund's exchange scenario is the interplay between the electronic correlations and the details of the band-structure of the specific compound considered.

3:54PM X22.00006 *Ab initio* Evidence of Strong Correlation Associated with Mott Proximity in Iron-Based Superconductor, TAKAHIRO MISAWA, KAZUMA NAKAMURA, MASATOSHI IMADA, Dept. of Applied Physics, Univ. of Tokyo — Recently discovered iron-based superconductors have attracted much interest because of their high superconducting critical temperatures (T_c). Although it is believed that electron correlations play key roles in the unconventional high- T_c superconductivity, their roles are not fully understood yet. To clarify electron correlation effects from a microscopic point of view, we study the *ab initio* low-energy effective models for iron-based superconductors by using multi-variable variational Monte Carlo (mVMC) method. From the *ab initio* calculations, we show that the iron-based superconductors found around d^6 configuration (namely, five Fe $3d$ orbitals filled by 6 electrons on average) are under the umbrella of an unexpectedly large-scale dome of correlated-electron matter centered at the Mott insulator at d^5 (namely, half filling). This proximity of the large-dome of strong electron correlations yields a variety with bad insulating (or incoherent metallic) states, quantum criticality of antiferromagnetism, orbital fluctuations and differentiations arising from interplay between the Hund's rule coupling and Mott physics.

4:06PM X22.00007 Two-orbital quantum spin model of magnetism in the iron pnictides¹, CHEN LIU, Boston University, DAO-XIN YAO, Sun Yat-Sen University, ANDERS SANDVIK, Boston University — We study a two-orbital spin model to describe $(\pi, 0)$ stripe antiferromagnetism in the iron pnictides. The “double-spin” model has an on-site Hund's coupling and inter-site interactions extending to second neighbors on the square lattice. Using a variational method based on a cluster decomposition, we optimize wave functions with up to 8 cluster sites (up to 2^{16} variational parameters). We focus on the anomalously small ordered moments in the stripe state of the pnictides. To account for it, and large variations among different compounds, we show that the second-neighbor cross-orbital exchange constant should be ferromagnetic, which leads to “partially hidden” stripe order. In a different parameter region, we confirm a canted state previously found in spin-wave theory.

¹NSF DMR-1104708

4:18PM X22.00008 Spin waves of 2D J_1 - J_2 model and single hole dynamics via nearest neighbor hole hopping, SATYAKI KAR, University of North Florida — We study the two dimensional J_1 - J_2 model using the spin wave approximation and find the spin wave modes at different values of parameter $\lambda = J_2/J_1$. Competing antiferromagnetic (π, π) and $(\pi, 0)$ (or, $(0, \pi)$) orders preferred by the J_1 and J_2 terms respectively creates frustration in such a system and the spin wave excitations about different vacuum states are observed for different values of λ . We investigate the stability of different zero spin deviation states as λ is varied from 0 to 1.5. We discuss the band folding of the super-lattice structure that appears with the emergence of the J_2 term and study the different spin wave modes that the system inherits. Dynamics of a foreign hole put in such a system is studied using a t - J_1 - J_2 model and the hole spectra obtained by solving the Dyson's equation self-consistently within the non-crossing approximation are compared with the ARPES spectra from the newly discovered FeAs superconducting compounds.

4:30PM X22.00009 An unified minimum effective model of magnetism in iron-based superconductors, JIANGPING HU, Department of Physics, Purdue University, West Lafayette, Indiana 47907, USA, BAO XU, WUMING LIU, NINGNING HAO, YUPENG WANG, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, P. O. Box 603, Beijing 100190, China — Since 2008, many new families of iron-based high temperature (high- T_c) superconductors have been discovered. Unlike all parent compounds of cuprates that share a common antiferromagnetically (AF) ordered ground state, those of iron-based superconductors exhibit many different AF ordered ground states, including collinear-AF (CAF) state in ferropnictides, bicollinear-AF (BCAF) state in 11-ferrochalcogenide FeTe, and block-AF vacancy (BAFv) order state in 122-ferrochalcogenide $K0.8Fe1.6Se2$. While the universal presence of antiferromagnetism suggests that superconductivity is strongly interrelated with magnetism, the diversity of the AF ordered states obscures their interplay. Here we show that all magnetic phases can be unified within an effective magnetic model. This model captures three incommensurate magnetic phases as well, two of which have been observed experimentally. The model characterizes the nature of phase transitions between the different magnetic phases and explains a variety of magnetic properties, such as spin-wave spectra and electronic nematism. Most importantly, by unifying the understanding of magnetism, we cast new insight on the key ingredients of magnetic interactions which are critical to the occurrence of superconductivity.

4:42PM X22.00010 Spin dynamics of the J_1 - J_2 Model with Biquadratic Spin Interactions for the Paramagnetic Phase of the Iron Pnictides, ZHENTAO WANG, RONG YU, Rice University, PALLAB GOSWAMI, Florida State University, ANDRIY NEVIDOMSKYY, QIMIAO SI, Rice University, ELIHU ABRAHAMS, UCLA — The parent compounds of the iron pnictides are bad metals, and are hence interpreted as being located at the boundary of localization and itinerancy. As such, the effective exchange interactions will naturally include more than two spin components. Here we study the $J_1 - J_2$ antiferromagnetic Heisenberg model with a biquadratic spin-spin coupling $-\kappa(\vec{S}_i \cdot \vec{S}_j)^2$ to explore the spin excitations in the paramagnetic phase of the iron pnictides which has a $(\pi, 0)$ collinear antiferromagnetic ground state. By using the modified spin wave theory and Schwinger Boson mean field theory, we determine the spin dynamics at finite temperatures. We show that a moderate biquadratic coupling κ can induce sizable anisotropy in the spin excitation spectrum. The calculated dynamical structure factor $S(\vec{q}, \omega)$ shows anisotropic elliptic features near $(\pi, 0)$, which expand with increasing frequency (ω), in a way that agrees with recent experiment on $BaFe_2As_2$ above its Neel transition temperature (L. W. Harriger *et.al.*, PRB **84**, 054544, 2011).

4:54PM X22.00011 Dimensional crossover in the quasi-two-dimensional Ising-O(3) model, NAOIKI KAWASHIMA, Institute for Solid State Physics, University of Tokyo, YOSHITOMO KAMIYA, CRISTIAN BATISTA, Theoretical Division, Los Alamos National Laboratory — We present results of our Monte Carlo simulation of the Ising-O(3) model on the two-dimensional (2D) and quasi-2D lattices. This model is an effective classical model for the stacked square-lattice J_1 - J_2 Heisenberg model where the nearest neighbor (J_1) and next-nearest neighbor (J_2) couplings are frustrated and we assume that J_2 is dominant. We find an Ising ordered phase where the O(3) spins remain disordered in a moderate quasi-2D region. There is a single first order transition for a sufficiently large 3D coupling in agreement with a renormalization group treatment. The subtle region where the single transition splits into two transitions is also discussed and compared against recent measurements of two very close transitions in $BaFe_2As_2$. Our results can provide a qualitative explanation on the experiments on ferropnictides, namely observed sequence and orders of the structural and magnetic transitions, in terms of the ratio between the inter-layer and intra-layer coupling.

5:06PM X22.00012 Are Spinwaves Glue for Cooper Pairs in Iron-Pnictide High- T_c Superconductors?¹, JOSE RODRIGUEZ, California State University at Los Angeles — We study the 2-orbital t-J model over the square lattice via Schwinger-boson-slave-fermion mean-field theory and by exact numerical diagonalization of two holes over a 4×4 grid. The two orbitals in question are the degenerate $d_{\pm} = 3d_{(x \pm iy)z}$ ones, which maximize the Hund's Rule coupling. The mean-field theory predicts the existence of a quantum critical point (QCP) that separates a commensurate spin-density-wave (cSDW) metal at strong Hund's Rule coupling from a hidden half metal at weak Hund's Rule coupling. Holes in the hidden half metal hop through a $\backslash_{d+} \backslash_{d-}$ spin background without much hopping across orbitals. Mean-field theory further predicts a critical spin-wave spectrum that shows hidden low-energy excitations at zero momentum, and that shows observable low-energy excitations at cSDW momenta. We find that the virtual exchange of such spin-waves by mobile holes can be attractive, and that it can result in the formation of hole pairs. We seek to corroborate this by exact diagonalization of two holes in the 2-orbital t-J model.

Thursday, March 1, 2012 2:30PM - 5:30PM – Session X23 GMAG: Magnetic Field Effects: Experimental II 255

2:30PM X23.00001 Investigating the field evolution of four-fold anisotropy in the basal plane of $\text{TmNi}_2\text{B}_2\text{C}$ ¹, P. DAS, C. RASTOVSKI, K. SCHLESINGER, M.R. ESKILDSEN, University of Notre Dame, IN, USA, J.M. DENSMORE, Lawrence Livermore National Laboratory, CA, USA, S.L. BUD'KO, P.C. CANFIELD, Ames Laboratory and Iowa State University, IA, USA — The superconductor $\text{TmNi}_2\text{B}_2\text{C}$ possesses a significant 4-fold in-plane anisotropy originating from the Fermi surface and possibly also from the superconducting pairing. However, unlike other members of the borocarbide superconductors, the anisotropy appears to decrease with increasing field, attributed to strong Pauli paramagnetic effects (PPE) and a vortex core expansion close to H_{c2} . We have investigated the field evolution of the four-fold anisotropy by small-angle neutron scattering (SANS) of the vortex lattice (VL), measuring several higher order Bragg peaks which allow a real space reconstruction of the VL field modulation. The measurements are possible due to the PPE which lead to a large field modulation (e.g. $\sim 65\%$ of the applied field at 0.2 T). Our results present the first *direct* demonstration of the decreasing anisotropy and furthermore, allows this to be measured quantitatively. This provides an explanation for the reentrant square VL phase observed in $\text{TmNi}_2\text{B}_2\text{C}$.

2:42PM X23.00002 Vortex Lattice Anisotropy in Sr_2RuO_4 with $H \parallel a^1$, M.R. ESKILDSEN, C. RASTOVSKI, University of Notre Dame, IN, USA, C.D. DEWHURST, Institut Laue-Langevin, France, W.J. GANNON, Northwestern University, IL, USA, D.C. PEETS, H. TAKATSU, Y. MAENO, Kyoto University, Japan — We have studied the vortex lattice (VL) in superconducting Sr_2RuO_4 using spin-polarized small-angle neutron scattering (SP-SANS) and with magnetic fields (H) close to, but not perfectly aligned with, the crystalline basal plane. In this configuration the VL possesses a large transverse field component, due to the large anisotropy of Sr_2RuO_4 , which greatly increases the spin-flip SANS scattered intensity. Bragg reflections indicative of a highly distorted hexagonal VL were observed, and an analysis of the magnitude of the scattering vector yielded an anisotropy of 50–60, roughly two times the H_{c2} anisotropy. We discuss implications of this result in relation to theoretical predictions of Pauli paramagnetic effects in Sr_2RuO_4 with $H \perp c$ [K. Machida and M. Ichioka, Phys. Rev. B **77**, 184515 (2008)].

2:54PM X23.00003 Influence of intrinsic superconducting parameters on the vortex dynamics and critical currents of different superconductor materials¹, N. HABERKORN, JEEHOON KIM, I. USOV, B. MAIOROV, M. WEIGAND, L. CIVALE, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — Vortex physics became a major field in condensed matter and statistical physics since the discovery of the oxide high temperature superconductors (HTS). Although the rich HTS vortex phenomenology arises from the large influence of thermal fluctuations, there is no hard boundary between HTS and conventional low temperature superconductors. The discovery of the iron-based superconductors provided a chance to study vortex matter in a new family of materials with broad ranges of superconductor transition temperature and crystalline anisotropy, where the small coherence length in some of them results in large fluctuation effects similar to those found in the oxide HTS. In this presentation, we will discuss the vortex dynamics of iron arsenide and oxide HTS by performing magnetization measurements of the critical current density (J_c) and flux creep rate (S). We will analyze the different creep regimes and crossovers that appear in the different samples and their relations to intrinsic superconducting parameters.

3:06PM X23.00004 Electrostatic manipulation of magnetic flux quanta at the nanoscale, ARNAUD CRASSOUS, ROZENN BERNARD, STEPHANE FUSIL, KARIM BOUZEHOUE, JAVIER BRIATICO, MANUEL BIBES, AGNES BARTHELEMY, JAVIER VILLEGAS, Unite Mixte de Physique CNRS/THALES — The electrostatic tuning of physical properties in materials offers significant potential in a large variety of systems. For example, the application of an electric field allows depressing or enhancing superconductivity in certain oxides. Using heterostructures that combine a large-polarization ferroelectric (BiFeO_3) and a high-temperature superconductor ($\text{YBa}_2\text{Cu}_3\text{O}_{7-x}$), we demonstrate here the nanoscale modulation of the superconducting condensate via ferroelectric field effects [1]. The ability to design the ferroelectric domain structure at will enables us to create nanoscale “patterns” of normal regions within the superconductor, in a reversible and modifiable way. This produces an energy landscape for magnetic flux quanta and, in turn, couples the local polarization in the ferroelectric to the local magnetic induction in the superconductor. This new form of magnetoelectric coupling allows the electrostatic manipulation of magnetic flux quanta.

3:18PM X23.00005 Strong periodic flux pinning in oxygen-ion-irradiated high- T_c superconductors¹, JAVIER VILLEGAS, I. SWIECICKI, J. BRIATICO, R. BERNARD, A. CRASSOUS, Unite Mixte de Physique CNRS/Thales, France, T. WOLF, N. BERGEAL, J. LESUEUR, LPEM, CNRS-ESPCI, France, C. ULYSSE, G. FAINI, CNRS, Phynano Team, LPN, France, X. HALLET, L. PIRAUX, Universite Catholique de Louvain, Belgium — We used oxygen ion irradiation to transfer into high- T_c superconducting thin films the nanoscale pattern of different types of masks (alumina [1] and [2] PMMA templates with ordered arrays of holes). This causes a nanoscale spatial modulation of superconductivity, and strongly affects the magneto-transport in the mixed-state. By tuning the irradiation dose and the array parameters, it is possible to engineer vortex energy landscapes sufficiently strong to govern flux dynamics. This is evidenced by a periodic series of strong magneto-resistance oscillations, the well-known fingerprint of periodic flux pinning. Interestingly, this irradiation technique allows tuning the *geometry* and the *strength* of the pinning potential wells at the nanoscale. This allows the observation of unusually strong matching effects at relatively high fields (up to several kOe). We show that the amplitude of the magneto-resistance oscillations is intimately connected with vortex channeling effects. [1] J.E. Villegas et al. Nanotechnology **22** 075302 (2011). [2] I. Swiecicki et al. submitted

3:30PM X23.00006 Single vortex manipulation in superconducting $\text{NdFeAsO}_{1-x}\text{F}_x$, MAGDALENA HUEFNER, JEEHOON KIM, Harvard University, MATT TILLMAN, PAUL CANFIELD, Ames Laboratory and Iowa State University, JENNIFER HOFFMAN, Harvard University — Vortex pinning challenges have severely hampered attempts to incorporate cuprate high T_c superconductors into technology. Understanding and improving the pinning of quantized magnetic vortices in high T_c superconductors remains an important challenge. We use a homebuilt low temperature magnetic force microscope to image and manipulate individual vortices in single crystal $\text{NdFeAsO}_{1-x}\text{F}_x$ ($T_c=50\text{K}$). By exerting a large force on a single vortex we can deliberately depin it from its original position and permanently move it to a different, predetermined position. We can also drag the top of a single vortex for a short distance without permanently depinning its full length. By dragging individual vortices along different directions, we observe a 4-fold anisotropy of the dragging distance, with the easy-drag direction along the Fe-Fe axis. Our results shed light on the questions of anisotropy and pinning mechanisms in iron pnictides.

3:42PM X23.00007 Anisotropy and Vortex Pinning of Heavy Ion irradiated $\text{SmFeAsO}_{0.8}\text{F}_{0.15}$ and $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$ Crystals¹, WAI-KWONG KWOK, LEI FANG, CARLOS CHAPARRO, YING JIA, ULRICH WELP, ALEXEI KOSHELEV, SHAOFEI XU, Argonne National Laboratory, GEORGE CRABTREE, Argonne National Laboratory and University of Illinois at Chicago, JANUSZ KARPINSKI, ETH, Zurich — We report specific heat and magnetization measurements on $\text{SmFeAsO}_{0.8}\text{F}_{0.15}$ and $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$ single crystals irradiated with high energy heavy ions of 1.4 GeV Pb to dose matching fields up to 4 Tesla. We find a nearly one half reduction in the superconducting anisotropy and doubling of the irreversibility field in $\text{SmFeAsO}_{0.8}\text{F}_{0.15}$ after irradiation and virtually no change in the zero-field superconducting transition temperature. In both $\text{SmFeAsO}_{0.8}\text{F}_{0.15}$ and $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$ crystals, we find a substantial increase in the critical current determined from SQUID and micro-Hall probe magnetization measurements. Pinning force analysis on proton and heavy ion irradiated pristine overdoped $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$ crystals indicates presence of induced ΔT_c -type pinning defects in these samples.

3:54PM X23.00008 High Dose Heavy-Ion Irradiation Effects on the Multiband Superconductor $(\text{Ba}_{0.6}\text{K}_{0.4})\text{Fe}_2\text{As}_2$ ¹, LEI FANG, CARLOS CHAPARRO, GOUTAM SHEET, YING JIA, SHAO-FEI ZHU, Argonne National Laboratory, HE-FEI HU, JIAN-MIN ZUO, University of Illinois at Urbana-Champaign, HAI-HU WEN, Nanjing University, China, ULRICH WELP, ALEXEI KOSHELEV, GEORGE CRABTREE, WAI-KWONG KWOK, Argonne National Laboratory — Optimal doped crystals of $(\text{Ba}_{0.6}\text{K}_{0.4})\text{Fe}_2\text{As}_2$ were irradiated with 1.4 GeV Pb ions to dose-matching fields ranging from 4 Tesla to 21 Tesla. Plan-view transmission electron microscopy shows creation of defects with diameters of $2 \sim 5$ nm. Post-irradiation characterization shows that the superconducting anisotropy is reduced to near unity, probably due to the increase in intra-band scattering. In addition, the critical current density J_C determined from magnetization measurements shows systematic enhancement up to ~ 5 MA/cm² at T=5K. We show that the decay of the critical current with magnetic field can be greatly mitigated with dense defects with approximately 20nm spacing produced by a dose matching field irradiation of 21T. Remarkably, the superconducting transition temperature remain unchanged for all matching field irradiation, suggesting that inter-band scattering due to non-magnetic impurity does not play a dominant role in pair-breaking.

¹ Work supported by the US DOE-BES funded Energy Frontier Research Center (LF, CC, YJ, GWC), and by Department of Energy, Office of Science, Office of Basic Energy Sciences (WKK, UW, AEK, SFZ), under Contract No. DE-AC02-06CH11357

4:06PM X23.00009 Angular dependence of magneto-transport properties in $\text{Ba}_{1-x}\text{K}_x(\text{FeAs})_2$ and $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$ single crystals, GOUTAM SHEET, ULRICH WELP, YING JIA, WAI-KWONG KWOK, Materials Science Division, Argonne National Laboratory, Argonne, USA, E.C. BLOMBERG, M.A. TANATAR, N. NI, S.L. BUD'KO, P.C. CANFIELD, R. PROZOROV, Iowa State University, Ames, Iowa, USA, H.H. WEN, University of Nanjing, Nanjing, China — We find unexpectedly sharp minima in the angular dependence of the flux-flow resistance of a series of $\text{Ba}_{1-x}\text{K}_x(\text{FeAs})_2$ and $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$ crystals when the magnetic field is applied parallel to the FeAs-planes. These minima are too sharp to be accounted for by effective mass anisotropy. Furthermore, since the c-axis coherence length is substantially larger than the FeAs layer spacing, intrinsic pinning mechanisms are ruled out. However, high-resolution cross-sectional SEM reveal the presence of plate-like inclusions of 50 - 100 nm thickness, which in a natural way can account for the enhanced pinning for $H \parallel ab$. On crystals that have been irradiated with heavy ions along the c-axis we observe additional resistance minima for $H \parallel c$, indicating the correlated nature of the irradiation induced defects.

4:18PM X23.00010 Combination of strong natural and artificial pinning centers in Co-doped BaFe_2As_2 films¹, BORIS MAIOROV, Los Alamos National Laboratory, NM 87545, T. KATASE, Tokyo Institute of Technology, Yokohama, Japan, M. WEIGAND, I. USOV, N. HABERKORN, Los Alamos National Laboratory, NM 87545, H. HIRAMATSU, H. HOSONO, Tokyo Institute of Technology, Yokohama, Japan, L. CIVALE, Los Alamos National Laboratory, NM 87545 — Studying the angular dependence of the critical current density (J_c) as a function of temperature in superconductors with complex pinning landscapes is very important from technical and fundamental points of view. The low anisotropy found in the $\text{BaFe}_2\text{As}_2(\text{Ba122})$ family together with strong naturally grown pinning make Ba122 films very attractive. We present results on Ba122 superconducting films with naturally grown correlated defects with the addition of different amounts of random defects produced by consecutive irradiations with 3MeV protons. We analyze the changes of J_c , H_{irr} and H_{c2} as a function of field, angle and temperature. Irradiations produce a small decrease in critical temperature (T_c) of 0.5 K per 1×10^{16} cm⁻² dose. After the irradiation, the pinning near the c-axis remains almost unchanged (except for the effects from the decrease of T_c). On the other hand, an increase of J_c is observed for other field orientations indicating and stronger random pinning contribution, particularly at high fields.

¹Work at Los Alamos was supported by the US Department of Energy (Division of Materials Sciences and Engineering)

4:30PM X23.00011 Highly Mobile In-plane Vortex Arrangement in $\text{SmFeAs}(\text{O},\text{F})$ ¹, PHILIP MOLL, Laboratory for Solid State Physics, ETH Zurich, Switzerland, LUIS BALICAS, National High Magnetic Field Laboratory, Tallahassee, FL, USA, JANUSZ KARPINSKI, NIKOLAI D. ZHIGADLO, BERTRAM BATLOGG, Laboratory for Solid State Physics, ETH Zurich, Switzerland — We observed a strong enhancement of flux flow dissipation for current flowing along the inter-planar direction in single crystals of the iron pnictide high- T_c superconductor $\text{SmFeAs}(\text{O},\text{F})$ ($T_c \sim 50\text{K}$) in high magnetic fields precisely aligned with the FeAs planes. The dissipation reaches significant fractions of the resistance in the normal state at all temperatures and fields, far below $H_{c2} \parallel ab$, estimated to be well above 100T at low temperatures. Even slightest field misalignments from the FeAs planes ($< 0.1^\circ$) restore the dissipation free state characterized by very high critical current densities ($\sim 10^6 \text{ A/cm}^2$) at low temperatures. We attribute this feature to vortices arranging themselves between the FeAs layers, accompanied by a reduced effectiveness of pinning. The qualitative features are reminiscent of the well-known lock-in effect in the cuprates, yet there are clear differences evident: The angular range of enhanced dissipation is reduced upon cooling in $\text{SmFeAs}(\text{O},\text{F})$, whereas in the cuprates it significantly broadens as H_{c1} increases at lower temperatures. Furthermore, the lock-in effect is most pronounced in strongly anisotropic materials, while $\text{SmFeAs}(\text{O},\text{F})$ is moderately anisotropic ($\gamma \sim 6-8$), becoming more isotropic at low temperature.

4:42PM X23.00012 Meissner holes in iron-based superconductors¹, TSUYOSHI TAMEGAI, SHYAM MOHAN, YUJI TSUCHIYA, YASUYUKI NAKAJIMA, Department of Applied Physics, The University of Tokyo — Magnetic flux penetrates into a superconductor in the form of quantized vortices. This process is usually described by the Bean model, and the flux front forms a regular pattern reflecting the shape of the sample. However, a novel form of flux penetration accompanying wiggling fronts between vortices and antivortices has been observed in $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$ upon remagnetization [1]. Such a phenomenon is ascribed to the presence of special arrangements of vortices at the front accompanying flux free regions and excess current around it. The flux free region is called as 'Meissner hole'. We have performed extensive magneto-optical imagings of iron-based superconductor single crystals and found similar anomalous features for the first time in superconductors other than 123-type cuprates [2]. Implications of this finding will be discussed with possible origins of the anomalous vortex arrangements. [1] V. K. Vlasko-Vlasov *et al.*, Phys. Rev. B **56**, 5622 (1997). [2] S. Mohan, Y. Tsuchiya, Y. Nakajima, and T. Tamegai, Phys. Rev. B **84**, 18050X (2011).

4:54PM X23.00013 Thermo-magnetic stability of NbN films with controlled nano-granularity, VITALIY YURCHENKO, University of Oslo, KONSTANTIN ILIN, Karlsruhe Institute of Technology, PAVLO MIKHEENKO, University of Oslo, M. SIEGEL, Karlsruhe Institute of Technology, YURI GALPERIN, TOM HENNING JOHANSEN, University of Oslo, UNIVERSITY OF OSLO TEAM, KARLSRUHE INSTITUTE OF TECHNOLOGY TEAM — The critical state in superconductors (SC) is metastable and can be destructed either by flux creep or by abrupt massive flux avalanches. The avalanches are associated with thermo-magnetic instability (TMI) of superconductors, which appears when the heat generated by the moving vortices is greater than the heat released into an environment. In that sense NbN films are known to be unstable, i.e. even the smallest increase of the external field may trigger a massive flux avalanche. Most theories developed to formulate the criteria of TMI operate in terms of intrinsic parameters of SC, such as heat capacity, critical current etc., and disregard the origins and the nature of the triggering mechanisms of the avalanches. We will present the most recent results of magneto-optical visualizations of flux dynamics in a series of NbN films with nano-scale disorder (ND) introduced in a well controlled fashion. We will demonstrate that not only do ND stipulate increase of the critical current but also promote correlated motion of large vortex bundles - micro jumps, which in turn trigger the macro avalanches.

5:06PM X23.00014 Quasi-1D intermittent flux dynamics in superconducting films, TOM H. JOHANSEN, ATLE J. QVILLER, VITALIY V. YURCHENKO, JORN I. VESTGARDEN, Dept. of Physics, University of Oslo, Norway, PETER B. MOZHAEV, JORN B. HANSEN, Dept. of Physics, Technical University of Denmark, Lyngby, Denmark, YURI M. GALPERIN, Dept. of Physics, University of Oslo, Norway — The stability of pinned vortex systems is constantly challenged in superconductors. In this work, magneto-optical imaging was used to reveal a new type of intermittent flux behavior in films of $\text{YBa}_2\text{Cu}_3\text{O}_x$. Films were grown on tilted NdGaO_3 substrates, where the terrace structure creates a high density of planar defects. The flux penetration along the terrace steps consists of numerous 1-dimensional avalanches, some starting at the film edge, some fully internal. In spite the vivid dynamics the flux front advances in accordance with the critical state model. Analysing more than 10000 avalanche events, we find a power-law size distribution and finite-size-scaling with the depth of the flux front as crossover length. The intermittent behaviour shows no threshold value in the applied field. These new characteristics largely contrast those of the thermo-magnetic avalanches observed in many superconducting films, and suggest that a different mechanism is responsible for the 1-dimensional avalanches.

5:18PM X23.00015 Investigation of the magnetic field angle dependence of resistance, irreversibility field, upper critical field and critical current density in DC sputtered Bi-2223 thin film¹, MURAT ERDEM, MUSTAFA AKDOGAN, GURCAN YILDIRIM, SEVGİ POLAT ALTINTAS, AHMET VARILCI, CABIR TERZIOGLU, Abant İzzet Baysal University — We measured resistivity and transport critical current density as a function of DC magnetic field and the angle between the surface of the film and the magnetic field on ex-situ annealed, c-axis oriented Bi-2223 thin films fabricated by DC sputtering method. Irreversibility field and upper critical field were determined from the resistivity vs. the applied magnetic field graph. It is observed that the superconducting properties of the films strongly depend on the direction and strength of the field. Penetration depths and coherence lengths were also determined from the irreversibility field and upper critical field versus temperature graphs, respectively. The anisotropic J_c behavior of the film is found to be intrinsic. We provided a theoretical analysis of the obtained results in the framework of intrinsic pinning theory of superconductors. Microstructural properties of the produced films were investigated by XRD and SEM measurements. XRD patterns indicate that the films are c-axis oriented based on the prominent (00l) peaks. SEM images show needle-like grain structures dominate the surface morphology of the films.

Thursday, March 1, 2012 2:30PM - 5:30PM – Session X24 DCOMP: Electronic Structure: Quantum Monte Carlo 256

2:30PM X24.00001 The Homogeneous Electron Gas: Beyond Fixed Nodes, JAMES SHEPHERD, GEORGE BOOTH, ANDREAS GRUNEIS, ALI ALAVI, The University Chemical Laboratory, University of Cambridge — The ground state energy of the homogeneous electron gas (HEG) still presents a significant challenge to Quantum Chemical methods, in spite of being a model Hamiltonian that has been studied for many decades and is often regarded as the archetypal system in solid state physics and in Fermi liquid theory. To date the only truly successful methods to yield accurate ground state energies at a range of densities have been quantum Monte Carlo techniques, in particular Diffusion Monte Carlo (DMC). Attempts to go beyond the fixed-node approximation have been met with some success, however elimination of this error all-together has not been achieved. Full Configuration Interaction (FCI) would provide an exact solution to this problem in the limit of an infinite basis set, which can be approached in a systematically improvable way. However, this is prohibitively expensive, scaling exponentially in the electron number and the size of the underlying one-electron basis with very large pre-factors. We present the application of a new method, FCI Quantum Monte Carlo, which stochastically samples the exact wavefunction producing FCI accuracy at a greatly improved computational cost, to the high-density HEG.

2:42PM X24.00002 Simulation of the Warm-Dense Homogeneous Electron Gas¹, ETHAN BROWN, DAVID CEPERLEY, University of Illinois at Urbana-Champaign, JONATHAN DUBOIS, Lawrence Livermore National Laboratory — Warm-dense matter (WDM), where both the Coulomb coupling parameter ($\Gamma \equiv q^2/(r_s k_B T)$) and the electron degeneracy parameter ($\Theta \equiv k_B T/\epsilon_F$) are approximately unity, exists in systems as disparate as planetary interiors and along the pathway to inertial confinement fusion. Attempts to characterize this regime through the use of Density Functional Theory (DFT) require an accurate equation of state. Here we present results for a first-principles simulation of the homogeneous electron gas (HEG) in the warm-dense regime through Restricted Path Integral Monte Carlo (RPIMC). These results could be used as a benchmark for improved functionals, as well as input for orbital-free DFT formulations.

¹DOE DE-F652-06NA26170

2:54PM X24.00003 Improved Full Configuration Interaction Monte Carlo for the Hubbard Model¹, HITESH CHANGLANI, ADAM HOLMES, FRANK PETRUZIELO, GARNET CHAN, C.L. HENLEY, C.J. UMRIGAR, Cornell University — We consider the recently proposed full configuration interaction quantum Monte Carlo (FCI-QMC) method and its “initiator” extension, both of which promise to ameliorate the sign problem by utilizing the cancellation of positive and negative walkers in the Hilbert space of Slater determinants. While the method has been primarily used for quantum chemistry by A.Alavi and his co-workers [1,2], its application to lattice models in solid state physics has not been tested. We propose an improvement in the form of choosing a basis to make the wavefunction more localized in Fock space, which potentially also reduces the sign problem. We perform calculations on the 4x4 and 8x8 Hubbard models in real and momentum space and in a basis motivated by the reduced density matrix of a 2x2 real space patch obtained from the exact diagonalization of a larger system in which it is embedded. We discuss our results for a range of fillings and U/t and compare them with previous Auxiliary Field QMC and Fixed Node Green's Function Monte Carlo calculations.

3:06PM X24.00004 Semi-stochastic full configuration interaction quantum Monte Carlo¹, ADAM HOLMES, FRANK PETRUZIELO, MIHIR KHADILKAR, HITESH CHANGLANI, Laboratory of Atomic and Solid State Physics, Cornell University, M.P. NIGHTINGALE, Department of Physics, University of Rhode Island, C.J. UMRIGAR, Laboratory of Atomic and Solid State Physics, Cornell University — In the recently proposed full configuration interaction quantum Monte Carlo (FCIQMC) [1,2], the ground state is projected out stochastically, using a population of walkers each of which represents a basis state in the Hilbert space spanned by Slater determinants. The infamous fermion sign problem manifests itself in the fact that walkers of either sign can be spawned on a given determinant. We propose an improvement on this method in the form of a hybrid stochastic/deterministic technique, which we expect will improve the efficiency of the algorithm by ameliorating the sign problem. We test the method on atoms and molecules, e.g., carbon, carbon dimer, N₂ molecule, and stretched N₂.

3:18PM X24.00005 Excited state calculations in solids by auxiliary-field quantum Monte Carlo¹, FENGJIE MA, SHIWEI ZHANG, HENRY KRAKAUER, Dept. of Physics, College of William & Mary — We have studied electronic excitations in solid systems using the phaseless auxiliary-field quantum Monte Carlo (AFQMC) method.² Trial wave functions for excited states are simply constructed from the corresponding density functional theory (DFT) ground state orbitals by promoting electrons to conduction bands. The post-processing finite size (FS) correction method³ is applied to remove the many-body FS effects. By fitting the calculated excitation energies at various crystal momentum values, a many-body electronic band structure is obtained. Our results for prototypical semiconductors such as silicon are compared to those from the GW approximation⁴ and diffusion Monte Carlo calculations.⁵

3:30PM X24.00006 Frozen core method in auxiliary-field quantum Monte Carlo¹, WIRAWAN PURWANTO, SHIWEI ZHANG, HENRY KRAKAUER, Department of Physics, College of William and Mary, Williamsburg, VA — We present the implementation of the frozen-core approach in the phaseless auxiliary-field quantum Monte Carlo method (AFQMC). Since AFQMC random walks take place in a many-electron Hilbert space spanned by a chosen one-particle basis, this approach can be achieved without introducing additional approximations, such as pseudopotentials. In parallel to many-body quantum chemistry methods, tightly-bound inner electrons occupy frozen canonical orbitals, which are determined from a lower level of theory, e.g. Hartree-Fock or CASSCF. This provides significant computational savings over fully correlated all-electron treatments, while retaining excellent transferability and accuracy. Results for several systems will be presented. This includes the notoriously difficult Cr₂ molecule, where comparisons can be made with near-exact results in small basis sets, as well as an initial implementation in periodic systems.

¹Supported by DOE, ONR, and NSF. Calculations were performed at OLCF Jaguar and CPD.

3:42PM X24.00007 Tests on novel pseudo-potentials generated from diffusion Monte Carlo data.¹, FERNANDO REBOREDO, Oak Ridge National Laboratory, RANDOLPH HOOD, Lawrence Livermore National Laboratory, MICHAL BAJDICH, Lawrence Berkeley National Laboratory — Since Dmitri Mendeleev developed a table in 1869 to illustrate recurring (“periodic”) trends of the elements, it has been understood that most chemical and physical properties can be described by taking into account the outer most electrons of the atoms. These valence electrons are mainly responsible for the chemical bond. In many ab-initio approaches only valence electrons are taken into account and a pseudopotential is used to mimic the response of the core electrons. Typically an all-electron calculation is used to generate a pseudopotential that is used either within density functional theory or quantum chemistry approaches. In this talk we explain and demonstrate a new method to generate pseudopotentials directly from all-electron many-body diffusion Monte Carlo (DMC) calculations and discuss the results of the transferability of these pseudopotentials. The advantages of incorporating the exchange and correlation directly from DMC into the pseudopotential are also discussed.

¹Research supported by the Materials Sciences and Engineering (MSE) Division of the Office of Science U.S. DOE

3:54PM X24.00008 A diffusion Monte Carlo study of sign problems from non-local pseudopotentials, NORM TUBMAN, University of Illinois at Urbana-Champaign, MIGUEL MORALES-SILVA, JONATHAN DUBOIS, RANDOLPH HOOD, Lawrence Livermore National Lab — Difficulties can arise in simulating various Hamiltonian operators efficiently in diffusion Monte Carlo (DMC) such as those associated with non-local pseudopotentials which require the introduction of an approximate form. The locality approximation and T-moves are two widely used techniques in fixed-node diffusion Monte Carlo (FN-DMC) that provide a tractable approach for treating non-local pseudopotentials, however their use introduces an uncontrolled approximation. Exact treatment of the non-local pseudopotentials in FN-DMC introduces a sign problem with the associated Green's function matrix elements which take on both positive and negative values. Here we present an analysis of the nature of the sign problem that non-local operators introduce into the Green's function. We then consider the feasibility of running DMC simulations in which the non-local pseudopotentials are treated exactly and demonstrate the algorithm on a few molecular systems.

4:06PM X24.00009 Variational and diffusion quantum Monte Carlo methods for spin-orbit interactions in heavy element systems¹, LUBOS MITAS, RENE DERIAN, SHI GUO, North Carolina State University — In most electronic structure quantum Monte Carlo calculations spins of individual electrons have fixed values which are determined by the spin and spatial symmetries of the desired eigenstate. However, for heavy atoms the spin-orbit interaction becomes important and its influence on electronic structure becomes comparable to the electron exchange, correlations or other many-body effects. In such cases the simplest antisymmetric wave function based on one-particle states is a determinant of spinors, while the simplest pairing wave function is a pfaffian. We will present calculations using variational and diffusion Monte Carlo for heavy atoms systems with spin-orbit operators. We eliminate the atomic cores by effective core potentials (pseudopotentials) which are formulated so as to include also effective spin-orbit operators. We test both discrete spin sampling as well as continuous spin representation in the variational and diffusion Monte Carlo methods. Corresponding generalizations of the fixed-node/fixed-phase methods will be discussed as well.

¹Supported by DOE, NSF and ARO

4:18PM X24.00010 Progress in exact treatment of fermions at finite temperature¹, JONATHAN L. DUBOIS, BERNI J. ALDER, Lawrence Livermore National Lab — We will discuss some key features of the structure of permutation space for interacting Fermi systems. Exploiting these features, we will then demonstrate improved efficiency in the exact path integral Monte Carlo treatment of liquid ³He by using importance sampling to deemphasize the contribution of long permutation cycles to the partition function. Finally, a route to a polynomial scaling algorithm for homogeneous Fermi systems will be presented.

¹This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

4:30PM X24.00011 An energy density estimator for quantum Monte Carlo calculations, JARON KROGEL, University of Illinois at Urbana-Champaign, JEONGNIM KIM, University of Illinois at Urbana-Champaign; Oak Ridge National Laboratory, DAVID CEPERLEY, University of Illinois at Urbana-Champaign — We establish a physically meaningful representation of a quantum energy density for use in quantum Monte Carlo calculations. The energy density operator, defined in terms of Hamiltonian components and density operators, returns the correct Hamiltonian when integrated over a volume containing a cluster of particles. This property is demonstrated for a Helium-Neon "gas," showing that atomic energies obtained from the energy density correspond to eigenvalues of isolated systems. The formation energies of defects or interfaces are typically calculated as total energy differences. Using a model of delta doped Silicon (where dopant atoms form a thin plane) we show how interfacial energies can be calculated more efficiently with the energy density, since the region of interest is small. We also demonstrate how the energy density correctly transitions to the bulk limit away from the interface where the correct energy is obtainable from a separate total energy calculation.

4:42PM X24.00012 Metal-Insulator Transition in Low Density Atomic Hydrogen¹, JEREMY MCMINIS, University of Illinois, JEONGNIM KIM, Oak Ridge National Lab, DAVID CEPERLEY, University of Illinois — At low density BCC hydrogen undergoes a metal-insulator transition. We compute the zero temperature equation of state for the paramagnetic and anti-ferromagnetic phases using diffusion Quantum Monte Carlo. We predict the phase transition density, investigate the shape of the anti-ferromagnetic curve, and compare to previous results

¹The work supported by the National Science Foundation under No. 0904572 and EFRC - Center for Defect Physics sponsored by the US DOE, Office of Basic Energy Sciences.

4:54PM X24.00013 Quantum Monte Carlo of ThO₂¹, SHUMING HU, LUBOS MITAS, Physics Department, North Carolina State University — Thorium dioxide solid is a unique optical and heat-resistant actinide material with large gap and cohesion. It is a diamagnet, unlike a number of other similar actinide oxides. We investigate the electronic structure of ThO₂ using Density Functional Theory (DFT) and quantum Monte Carlo (QMC) methods. We adopt Stuttgart RLC and RSC effective core potentials (pseudopotentials) for the Th atom. In the DFT calculations, some of the properties are verified in all-electron calculations using the FLAPW techniques. Using the fixed-node diffusion Monte Carlo we calculate the ground state and several excited states from which we estimate the cohesion and the band gap. Simulation cells of several sizes are used to estimate/reduce the finite size effects. We compare the QMC results with recent DFT calculations with several types of functionals which include hybrids such as PBE0 and HSE. Insights from QMC calculations give us understanding of the correlations beyond the DFT approaches and pave the way for accurate electronic structure calculations of other actinide materials.

5:06PM X24.00014 Quantum Monte Carlo for the Spectroscopy of Core Excited States, DMITRY ZUBAREV, UC Berkeley — X-ray absorption spectroscopy is a powerful experimental tool that is capable of delivering valuable information about very delicate aspects of electronic structure and reveals details of the local chemical environment in many systems of fundamental and applied importance. The rigorous interpretation of core-level spectra requires very accurate quantum chemical simulations. The trade-off between feasibility of treatment of large systems and consistency in description of electron correlation tremendously hinders the generation of accurate theoretical results for many experimental studies. We show that the fixed-node diffusion Monte Carlo (FN-DMC) approach can be used straightforwardly for the accurate simulation of core-level spectra. Basic methodological aspects are addressed, including the strategy for the construction of adequate trial wave functions. Examples of FN-DMC calculations of core-level spectra of water and pyrrole are presented. The possibility of the simulation of X-ray absorption spectra of solvent-solute systems is discussed.

5:18PM X24.00015 Density Functional Monte Carlo: an efficient way to calculate the ground state density profile of nanostructures, FONS BROSENS, KATRIJN PUTTENEERS, University of Antwerpen — We present a method in which the Hohenberg-Kohn theorems are implemented directly by simulating the density profile using Bernoulli walkers and conserving the total number of particles during the Monte Carlo process. This leads to a much faster algorithm than, e.g., by solving the Kohn-Sham equations. The method is explained in detail and results are shown for a nanoshell which contains several millions of conduction electrons.

Session X25 DCOMP: Focus Session: Modeling of Rare Events: Methods and Applications II

257A

2:30PM X25.00001 Accelerated Molecular Dynamics of Rare Events with the Bond-Boost Method¹, KRISTEN FICHTHORN, Penn State University — A continuing challenge in materials simulation is to conduct long time and large length simulations of structural evolution, while accurately retaining atomic detail. For many materials, dynamical evolution occurs through a series of “rare events,” in which the system spends a long-time period in one free-energy minimum before escaping and moving on to another. To address the rare-event problem for materials evolution, we developed the bond-boost method, which is a variant of hyperdynamics. We will introduce the bond-boost method and demonstrate several applications of it to thin-film growth and surface kinetics. A significant problem that plagues rare-event simulations is the “small barrier problem” and we will discuss how this problem can be addressed within the bond-boost method. We will also discuss our recent efforts to combine this method with kinetic Monte Carlo simulations.

¹Supported by NSF DMR-1006452

3:06PM X25.00002 Generalizations of the string method, ERIC VANDEN-EIJNDEN, Courant Institute, NYU — Generalizations of the string method will be presented that permit to identify the saddle points by which the process escapes the basin of attraction of a minimum of the potential due to thermal noise, or to map out the volume of this basin. These methods will be illustrated via examples such as thermal reorganization of Lennard-Jones clusters and packings of soft-spheres.

3:42PM X25.00003 String method for the computation of minimum energy paths and saddle points, WEIQING REN, National University of Singapore and IHPC — Many problems arising from applied sciences can be abstractly formulated as a system that navigates over a complex energy landscape of high or infinite dimensions. The system is confined in metastable states for long times before making important transitions from one metastable state to another. For gradient systems driven by small noise, the transitions follow the minimum energy path, i.e. the heteroclinic orbit connecting the metastable states. I will talk about the zero-temperature string method for computing the minimum energy paths and the saddle points.

3:54PM X25.00004 Rare events in viscoelastic escape dynamics and subdiffusive transport¹, IGOR GOYCHUK, University of Augsburg — Anomalously slow relaxation, escape and transport processes become increasingly important in many research domains. This talk is focused on a profound question: Does anomalously slow subdiffusive dynamics imply rare events with a divergent mean time separating such events in multistable potentials? The answer depends on the underlying physical mechanism. It is shown that the subdiffusive dynamics originated due to the medium's viscoelasticity and described by a power law memory kernel within the non-Markovian generalized Langevin equation (GLE) approach does not imply such anomalously rare events [1]. Based on a Markovian multidimensional embedding of the GLE dynamics it is shown that the kinetics of subdiffusive Kramers escape is asymptotically stretched exponential for intermediate barriers. It is characterized by a finite mean escape time, and all the higher moments are also finite. Moreover, it approaches normal exponential kinetics for very high barriers which coexists with anomalously slow subdiffusion and transport in washboard potentials [1]. Rare escape events for such subdiffusive dynamics are not presenting the transport limiting step.

4:06PM X25.00005 Non-axisymmetric Deformations of Monovalent Metallic Nanowires: A Stochastic Field Theory Approach, LAN GONG, DANIEL STEIN, New York University, JEROME BUERKI COLLABORATION, CHARLES STAFFORD COLLABORATION — A stochastic Ginzburg-Landau field theory is used to describe the noise-induced transition of monovalent metallic nanowires. Here the transition consists of the nanowire changing from one locally stable radius to another (and thereby changing its conductance as well). The lifetime of a specific wire configuration is obtained from the Kramers rate formula in the limit of weak noise. We found a “phase transition” in the saddle state under general conditions, and have constructed a phase diagram of the activated transition. To study the transition process further, we employed a numerical approach called the string method in order to obtain in detail the complete transition path, crucial to solving the dynamics of wire deformation and transition under noise. We also discuss several interesting applications to lifetime calculations for real nanowires.

4:18PM X25.00006 Study of Evaporation Rate of Water in Hydrophobic Confinement using Forward Flux Sampling, SUMIT SHARMA, PABLO G. DEBENEDETTI, Princeton University — Drying of hydrophobic cavities is of interest in understanding biological self assembly, protein stability and opening and closing of ion channels. Liquid-to-vapor transition of water in confinement is associated with large kinetic barriers which preclude its study using conventional simulation techniques. Using forward flux sampling to study the kinetics of the transition between two hydrophobic surfaces, we show that a) the free energy barriers to evaporation scale linearly with the distance between the two surfaces, d; b) the evaporation rates increase as the lateral size of the surfaces, L increases, and c) the transition state to evaporation for sufficiently large L is a cylindrical vapor cavity connecting the two hydrophobic surfaces. Finally, we decouple the effects of confinement geometry and surface chemistry on the evaporation rates.

4:30PM X25.00007 Reaching extended length-scales with accelerated dynamics¹, BRADLEY HUBARTT, YUNSHI SHIM, JACQUES AMAR, University of Toledo — While temperature-accelerated dynamics (TAD) has been quite successful in extending the time-scales for non-equilibrium simulations of small systems, the computational time increases rapidly with system size. One possible solution to this problem, which we refer to as parTAD¹ is to use spatial decomposition combined with our previously developed semi-rigorous synchronous sublattice algorithm². However, while such an approach leads to significantly better scaling as a function of system-size, it also artificially limits the size of activated events and is not completely rigorous. Here we discuss progress we have made in developing an alternative approach in which localized saddle-point searches are combined with parallel GPU-based molecular dynamics in order to improve the scaling behavior. By using this method, along with the use of an adaptive method to determine the optimal high-temperature³, we have been able to significantly increase the range of time- and length-scales over which accelerated dynamics simulations may be carried out. 4:54PM X25.00009 Dislocation Cross-slip Mechanisms in Aluminum, YANG XIANG, Hong Kong University of Science and Technology, CONGMING JIN, Zhejiang Sci-Tech University, China, GANG LU, California State University Northridge — We have systematically studied dislocation cross-slip in Al at zero temperature by atomistic simulations, focusing on the dependence of the transition paths and energy barriers on dislocation length and position. We find that for a short dislocation segment, the cross-slip follows the uniform Fleischer (FL) mechanism. For a longer dislocation segment, we have identified two different cross-slip mechanisms depending on the initial and final positions of the dislocation. If the initial and final positions are symmetric relative to the intersection of the primary and cross-slip planes, the dislocation cross-slips via the Friedel-Escaig (FE) mechanism. However, when the initial and final positions are asymmetric, the dislocation cross-slips via a combination of the FL and FE mechanisms. The leading partial folds over to the cross-slip plane first, forming a stair-rod dislocation at the intersection with which the trailing partial then merges via the FL mechanism. Afterwards, constrictions appear asymmetrically and move away from each other to complete the cross-slip via the FE mechanism.

5:06PM X25.00010 The Effects of Hydrogen on the Potential-Energy Surface of Amorphous Silicon, JEAN-FRANCOIS JOLY, NORMAND MOUSSEAU, Université de Montréal — Hydrogenated amorphous silicon (a-Si:H) is an important semiconducting material used in many applications from solar cells to transistors. In 2010, Houssem et al. [1], using the open-ended saddle-point search method, ART nouveau, studied the characteristics of the potential energy landscape of a-Si as a function of relaxation. Here, we extend this study and follow the impact of hydrogen doping on the same a-Si models as a function of doping level. Hydrogen atoms are first attached to dangling bonds, then are positioned to relieve strained bonds of fivefold coordinated silicon atoms. Once these sites are saturated, further doping is achieved with a Monte-Carlo bond switching method that preserves coordination and reduces stress [2]. Bonded interactions are described with a modified Stillinger-Weber potential and non-bonded Si-H and H-H interactions with an adapted Slater-Buckingham potential. Large series of ART nouveau searches are initiated on each model, resulting in an extended catalogue of events that characterize the evolution of potential energy surface as a function of H-doping.

Thursday, March 1, 2012 2:30PM - 4:54PM – Session X26 DCOMP: Focus Session: Non-Adiabatic Dynamics in Irradiated Materials 257B

2:30PM X26.00001 First-principles calculation of electronic stopping power in metals and insulators via time-dependent DFT simulations, JORGE KOHANOFF¹, Atomistic Simulation Centre, Queens University Belfast, Belfast BT7 1NN, Northern Ireland, United Kingdom — Projectiles interacting with solid or liquid targets are subject to two main inelastic collision channels: electronic and nuclear. The end result is a slowing down – or stopping – of the projectile due to energy deposition onto electronic excitations or motion of the target nuclei. At high projectile velocities, cross sections for nuclear stopping are exceedingly small, thus leaving electronic stopping as the only relevant channel. At low velocities nuclear stopping becomes predominant. In metals, it coexists with electronic stopping, but in insulators the existence of an energy gap for electronic excitations translates into a velocity threshold for electronic stopping. In this presentation I will introduce a recently developed computational methodology designed to study electronic stopping at the first-principles level, by means of time-dependent density-functional (TDDFT) simulations. I will then discuss the results for a variety of systems, starting from the first application to the ionic crystal LiF, moving to metallic systems like Al and Au, and then to the insulating water ice. In all cases I will compare to available experimental data to emphasize the astonishing accuracy of TDDFT results. I will also discuss how these simulations provide further insight into open questions such as the difference in stopping between H and He projectiles, and I will focus on the interplay between electronic excitations and non-adiabatic forces on the nuclei. Finally, I will touch on computational methods to simulate the combined dynamics of nuclei and electrons.

3:06PM X26.00002 Nonadiabatic Molecular Dynamics with Trajectories , IVANO TAVERNELLI, École

Polytechnique Fédérale de Lausanne (EPFL) — In the mixed quantum-classical description of molecular systems, only the quantum character of the electronic degrees of freedom is considered while the nuclear motion is treated at a classical level. In the adiabatic case, this picture corresponds to the Born-Oppenheimer limit where the nuclei move as point charges on the potential energy surface (PES) associated with a given electronic state. Despite the success of this approximation, many physical and chemical processes do not fall in the regime where nuclei and electrons can be considered decoupled. In particular, most photoreactions pass through regions of the PES in which electron-nuclear quantum interference effects are sizeable and often crucial for a correct description of the phenomena. Recently, we have developed a trajectory-based nonadiabatic molecular dynamics scheme that describes the nuclear wavepacket as an ensemble of particles following classical trajectories on PESs derived from time-dependent density functional theory (TDDFT) [1]. The method is based on Tully's fewest switches trajectories surface hopping (TSH) where the nonadiabatic coupling elements between the different potential energy surfaces are computed *on-the-fly* as functionals of the ground state electron density or, equivalently, of the corresponding Kohn-Sham orbitals [2]. Here, we present the theoretical fundamentals of our approach together with an extension that allows for the direct coupling of the dynamics to an external electromagnetic field [3] as well as to the external potential generated by the environment (solvent effects) [4]. The method is applied to the study of the photodissociation dynamics of simple molecules in gas phase and to the description of the fast excited state dynamics of molecules in solution (in particular Ruthenium (II) tris(bipyridine) in water).

3:42PM X26.00003 Advances on Time-dependent DFT Simulations of Electronic Stopping¹ ,

ALFREDO CORREA, ANDRE SCHLEIFE, Lawrence Livermore National Laboratory, YOSUKE KANAI, University of North Carolina at Chapel Hill, JORGE KOHANOFF, Queen's University, Belfast, ALFREDO J. CARO, Los Alamos National Laboratory — Radiation damage of reactor materials is a topic of interest and continuous research in the nuclear industry. A single nuclear decay event (e.g. alpha) produces a cascade of collisions involving the displacement of thousands of atoms in a crystalline material. While atomistic-scale simulations would be the ideal tool to understand these processes, the fact that they currently work on the assumption that electrons respond adiabatically to the atomic motion does not provide valid answers, for example to the stopping power problem. An alternative approach to attacking this problem is a method which explicitly takes into account electron non-adiabatic dynamics. We will present results obtained by time-depending DFT on the electronic stopping power of channeling protons in prototypical metals and insulators obtained by recent implementations of non-adiabatic electron dynamics methods.

3:54PM X26.00004 Electronic stopping of slow H and He atoms in gold from first principles

, M. AHSAN ZEB, Cavendish Lab, Cambridge, UK, JORGE KOHANOFF, Physics, Queens U, Belfast, UK, DANIEL SANCHEZ-PORTAL, CFM-CSIC, San Sebastian, Spain, ANDRES ARNAU, J.I. JUARISTI, CFM-UPV, San Sebastian, Spain, EMILIO ARTACHO, Nanogune & Ikerbasque, San Sebastian, Spain, and Cavendish Lab, Cambridge, UK — In spite of a long history, the quantitative understanding of non-adiabatic processes in condensed matter and our ability to perform predictive theoretical simulations of processes coupling many adiabatic energy surfaces is very much behind what accomplished for adiabatic situations, for which first-principles calculations provide predictions of varied properties within a few percent accuracy. We will present here high-accuracy results for the electronic stopping power of H and He moving through gold, using time-evolving density-functional theory, thereby conveying usual first-principles accuracies to strongly coupled, continuum non-adiabatic processes in condensed matter. The two key unexplained features of what observed experimentally have been reproduced and understood: (i) The non-linear behavior of stopping power versus velocity is a gradual crossover as excitations tail into the *d*-electron spectrum; and (ii) the higher stopping for He than for H at low velocities is explained by the substantial involvement of the *d* electrons in the screening of the projectile even at the lowest velocities where the energy loss is generated by *s*-like electron-hole pair formation only.

4:06PM X26.00005 Golden Rule of Radiation Hardness: a Study of Strain Effect on Controlled Radiation Damage¹ ,

QING PENG, WEI JI, SUVRANU DE, Rensselaer Polytechnic Institute — Stain is widely presented in microstructures. Strain effect to radiation hardness is critical in understanding and engineering nano-materials. Here we studied the strain effect on the controlled radiation damage in monolayer hexagonal boron nitride (h-BN) through *ab initio* density functional theory calculations. We observed a general behavior of reduction in the radiation hardness by the strain, for both B-vacancy and N-vacancy configurations, in both compressive and tensile strain states, at the directions of zigzag, armchair and bi-axial. We proposed a golden rule of the radiation hardness states that any effort adding energy to the system will reduce the radiation hardness. Such golden rule of radiation hardness could be widely applied to material design and engineering for those devices working in irradiation-enrich environments, for example, electronic and optoelectronic devices in outer space.

¹The authors would like to acknowledge the generous financial support from the Defense Threat Reduction Agency (DTRA) Grant # BRBAA08-C-2-0130, and the U.S. Nuclear Regulatory Commission Faculty Development Program under contract # NRC-38-08-950.

4:18PM X26.00006 First-principles simulation of laser irradiation of graphene and graphane¹ ,

KALMAN VARGA, SERGIY BUBIN, Vanderbilt University — In the framework of real-time real-space time-dependent density functional theory complemented with classical molecular dynamics for ions, we have studied the behavior of graphene and graphane fragments irradiated with strong laser pulses. In particular, we have investigated how the response of graphene and graphane changes when laser pulses of different frequency (near IR, visible, and UV) are shot. Damage thresholds have been established and compared with existing experimental data.

4:30PM X26.00007 Electron-Phonon Coupling in a CdSe Nanowire¹ ,

CHRISTOPHER BARRETT, Department of Materials Science & Engineering, UC Berkeley, LIN-WANG WANG, Materials Sciences Division, Lawrence Berkeley National Laboratory — It is important to calculate the coupling between phonons and electrons in realistic nanostructures, e.g. to understand carrier cooling and dynamics in a nanowire. In this talk, we will present results of phonon spectrum calculations using a customized valence force field (VFF) method. This customized VFF method is developed to be fittable to the results of any *ab-initio* calculations, with density functional theory (DFT) results being used in this work. By fitting many different DFT calculations on different motifs and their perturbations, we have obtained in the custom VFF a very efficient method that closely reproduces DFT phonons for CdSe nanowires with (10-10) surfaces having Cd-Se dimerization. We have also combined the results of these phonon spectrum calculations with electronic structure calculations to obtain the electron-phonon coupling. We will present this result and show how the electron-phonon coupling affects the carrier dynamics in the nanowire.

4:42PM X26.00008 Deviational formulations for efficient simulation of multiscale phonon transport , JEAN-PHILIPPE PERAUD, NICOLAS HADJICONSTANTINO, Mechanical Engineering, MIT — We show that by simulating only the deviation from equilibrium, considerable computational savings can be realized in Monte Carlo solutions of the Boltzmann equation describing phonon transport at small scales. The computational savings manifest themselves in the form of significantly smaller statistical uncertainty compared to standard Monte Carlo solution methods in the limit of small deviation from equilibrium (e.g. small temperature differences). Additional computational savings are realized in multiscale problems where the degree of deviation from equilibrium varies considerably over the simulation domain. By developing rigorous evolution equations for the deviation from equilibrium from the governing kinetic equation, the resulting algorithm seamlessly bridges the near- and far-equilibrium regions without introducing any approximation. We also show that considering an energy-based Boltzmann equation lends itself naturally to algorithms that conserve energy exactly, thus improving the simulation fidelity. Application of the proposed methods to practical problems of current interest, such as a transient thermoreflectance experiment used to extract information about the mean free path of heat carriers in various materials, will be presented and discussed.

Session X27 DMP DCMP: Invited Session: Physics for Everyone: Innovative Materials for Energy 258AB

2:30PM X27.00001 Materials research needs for energy , ARUN MAJUMDAR, Advanced Research Projects Agency - Energy — No abstract available.

3:06PM X27.00002 Water Splitting with Materials and Sunlight , TOM JARVI, Sun Catalytix Corporation — Sun Catalytix has been developing technology for energy storage and the generation of renewable fuels in an ARPA-E sponsored program. The program has focused on the development and deployment of low-cost earth-abundant catalytic materials coupled to light-absorbing semiconductor systems to capture and convert solar energy into chemical species. This talk will focus on recent work done to couple cobalt-based water-oxidation and nickel-based hydrogen evolution catalysts with silicon-based solar cells. The results demonstrate direct wireless coupling of solar collection with catalytic materials and operate in relatively benign conditions at reasonable conversion efficiency. These results suggest development pathways for solar hydrogen generation using catalyzed particulate solar absorbing materials. Such pathways will be discussed as they may offer relevant means to generate solar-derived hydrogen as a cost-effective fuel for the future.

3:42PM X27.00003 Advanced materials manufacturing for solar energy , FRANK VAN MIERLO, 1366 Technologies Inc. — The US has a robust technical roadmap to get to a \$1/W total installed cost with several potential winners in the race. We dominate in the new technology arena and there is a good chance that tomorrow's winning technology will be from the current crop of contenders. One potential breakthrough is Direct WaferTM a new manufacturing technique to make silicon wafers at a fraction of the traditional cost. Current wafer manufacturing is a multi-step, energy- and capital-intensive process that wastes half of the valuable silicon feedstock. 1366's Direct Wafer technology forms a standard, 156mm multi-crystalline wafer directly from molten silicon in a semi-continuous, efficient, high-throughput process that eliminates silicon waste. Direct WaferTM cuts the amount of consumables by a factor of four and requires only half the capital per GigaWatt production capacity thus enabling solar to compete successfully with coal generated electricity.

4:18PM X27.00004 Genetically Engineered Materials for Biofuels Production , MICHAEL RAAB, Agrivida, Inc. — Agrivida, Inc., is an agricultural biotechnology company developing industrial crop feedstocks for the fuel and chemical industries. Agrivida's crops have improved processing traits that enable efficient, low cost conversion of the crops' cellulosic components into fermentable sugars. Currently, pretreatment and enzymatic conversion of the major cell wall components, cellulose and hemicellulose, into fermentable sugars is the most expensive processing step that prevents widespread adoption of biomass in biofuels processes. To lower production costs we are consolidating pretreatment and enzyme production within the crop. In this strategy, transgenic plants express engineered cell wall degrading enzymes in an inactive form, which can be reactivated after harvest. We have engineered protein elements that disrupt enzyme activity during normal plant growth. Upon exposure to specific processing conditions, the engineered enzymes are converted into their active forms. This mechanism significantly lowers pretreatment costs and enzyme loadings (>75% reduction) below those currently available to the industry.

4:54PM X27.00005 Innovative oxide materials for electrochemical energy conversion , ERIC D. WACHSMAN, University of Maryland — Research in functional materials has progressed from those materials exhibiting structural to electronic functionality. The study of ion conducting ceramics ushers in a new era of "chemically functional materials." This chemical functionality arises out of the defect equilibria of these materials, and results in the ability to transport chemical species and actively participate in chemical reactions at their surface. Moreover, this chemical functionality provides a promise for the future whereby the harnessing of our natural hydrocarbon energy resources can shift from inefficient and polluting combustion - mechanical methods to direct electrochemical conversion. The unique properties of these materials and their applications will be described. The focus will be on the application of ion conducting ceramics to energy conversion and storage, chemical sensors, chemical separation and conversion, and life support systems. Results presented will include development of record high power density (3 kW/kg) solid oxide fuel cells, NO_x/CO species selective solid-state sensors, high yield membrane reactors, and regenerative life support systems that reduce CO₂ to O₂ and solid C.

Session X29 GQI: Focus Session: Semiconductor Qubits - Managing or Eliminating Nuclei 259A

2:30PM X29.00001 Ultrafast optical coherent control of individual electron and hole spins in a semiconductor quantum dot, KRISTIAAN DE GREVE, E.L. Ginzton Laboratory, Stanford University — We report on the complete optical coherent control of individual electron and hole spin qubits in InAs quantum dots. With a magnetic field in Voigt geometry, broadband, detuned optical pulses couple the spin-split ground states, resulting in Rabi flopping. In combination with the Larmor precession around the external magnetic field, this allows an arbitrary single-qubit operation to be realized in less than 20 picoseconds [1,2]. Slow fluctuations in the spin's environment lead to shot-to-shot variations in the Larmor precession frequency. In a time-ensemble measurement, these would prevent a measurement of the true decoherence of the qubit, and instead give rise to ensemble dephasing. This effect was overcome by implementing a spin echo measurement scheme for both electron and hole spins, where an optical π -pulse refocuses the spin coherence and filters out the slow variations in Larmor precession frequency. We measured coherence times up to 3 microseconds [2,3]. Finally, our optical pulse manipulation scheme allows us to probe the hyperfine interaction between the single spin and the nuclei in the quantum dot. Interesting non-Markovian dynamics could be observed in the free-induction decay of a single electron spin, whereas the complete absence of such effects illustrates the reduction of the hyperfine interaction for hole spin qubits. We measured and modeled these effects, and explain the non-Markovian electron spin dynamics as involving a feedback effect resulting from both the strong Overhauser shift of the electron spin and spin dependent nuclear relaxation [2,4].

3:06PM X29.00002 Ultrafast optical control of interacting hole spins in coupled quantum dots, SAMUEL CARTER, Naval Research Laboratory, Washington, DC 20375, ALEX GREILICH, Naval Research Laboratory, Washington, DC 20375; University of Maryland, College Park, Maryland 20742, DANNY KIM, Naval Research Laboratory, Washington, DC 20375; University of Michigan, Ann Arbor, Michigan 48109, ALLAN BRACKER, DANIEL GAMMON, Naval Research Laboratory, Washington, DC 20375 — Recently, hole spins in quantum dots (QDs) have shown great promise as quantum bits due to a reduced hyperfine interaction with nuclear spins, the primary source of decoherence for electron spins. We have developed a system of two vertically stacked InAs QDs that can be charged with a number of holes. In this way, an isolated hole in one QD or two interacting holes in separate dots can be studied. We demonstrate ultrafast optical control of both systems and find a number of differences compared to electron spins. Complete control of the single hole qubit is obtained through optical initialization and single qubit rotations. These control measurements give a hole spin T_2^* of 20ns, an order of magnitude longer than electrons in similar QDs. Spin echo experiments extend the coherence time but are complicated by oscillations in the echo amplitude. For the case of two hole spins, we can observe and tune the coherent exchange interaction that acts as a two qubit gate. We also initialize and perform gates on an entangled spin state, taking a significant step toward a scalable platform for quantum information processing. [1] "Optical control of one and two hole spins in interacting quantum dots," A. Grelich, S. G. Carter, D. Kim, A. S. Bracker and D. Gammon. *Nature Photon.* **5**, 702 (2011).

3:18PM X29.00003 Electrical control of single hole spins in InSb nanowire quantum dots, VLAD PRIBIAG, STEVAN NADJ-PERGE, JOHAN VAN DEN BERG, SERGEY FROLOV, TU Delft, SEBASTIEN PLISSARD, TU Eindhoven, ERIK BAKKERS, LEO KOUWENHOVEN, TU Delft — The spin-orbit interaction provides an efficient handle for all-electric control of individual spins in quantum dots. Recently, III-V semiconductor nanowires, which have a strong spin-orbit coupling, have emerged as a promising platform for spin-based qubits. Previous work has been focused on the electrical control of electron spins in InAs nanowires. In contrast, spin-dependent quantum transport with holes has so far remained largely unexplored. Here, we demonstrate gate tuning from the few-electron double dot to the few-hole double-dot regimes in InSb nanowires and observe Pauli spin-blockade for both electrons and holes. We use electric-dipole spin resonance (EDSR) to determine the effective g-factors of the two types of carriers. EDSR control over the hole spins is promising for driving coherent rotations of hole-spin qubits. These hole qubits are expected to be less sensitive to hyperfine-mediated decoherence effects than electron-spin qubits as a result of the p-wave symmetry of the hole wavefunction.

3:30PM X29.00004 Theory of heavy-hole spin-echo decay, XIAOYA JUDY WANG, WILLIAM COISH, McGill University — Heavy-hole spin states have emerged as a robust new candidate for realizing a qubit. Nevertheless, the coupling of the hole spin to nuclei in the surrounding medium likely limits hole-spin coherence and has, until very recently, been overlooked. We describe the real-time spin decoherence of a heavy-hole in a semiconductor quantum dot, subject to spin echo pulses. We obtain an analytical expression which we compute numerically for an experimentally realistic number ($\sim 10^4$) of nuclear spins. Including the (previously neglected) nuclear Zeeman term in the Hamiltonian, we observe novel effects uniquely characterizing the decoherence mechanisms under study. In particular, we find a nontrivial dependence of the decay on the applied magnetic field, as well as novel predictions for motional narrowing and envelope modulation, which could significantly extend the hole-spin memory time in near-future experiments.

3:42PM X29.00005 High Quality Two-Dimensional Electron Gases (2DEGs) in Isotopically-Enriched Strained Silicon, JIUN-YUN LI, CHIAO-TI HUANG, Department of Electrical Engineering and Princeton Institute for the Science and Technology of Materials (PRISM), Princeton University, LEONID ROKHINSON, Department of Physics, Purdue University, JAMES OHLHAUSEN, MALCOLM CARROLL, Sandia National Laboratories, JAMES STURM, Department of Electrical Engineering and Princeton Institute for the Science and Technology of Materials (PRISM), Princeton University — Silicon quantum dots (QDs) formed in a Si/SiGe two-dimensional electron gas (2DEG) are a promising candidate for quantum computation. To capture a single electron in a QD, the dot must be very small, which requires a short distance from the surface to Si 2DEG layer for fine gating. Here we demonstrate a high quality modulation-doped Si 2DEG grown by chemical vapor deposition (CVD), with a distance of 65 nm from the surface to 2DEG layer. The electron mobility at 0.3K of 504,000 $\text{cm}^2/\text{V-s}$ (density $4.3 \times 10^{11} \text{ cm}^{-2}$) is the highest yet reported by CVD for ungated Si 2DEGs. Further, a Si 2DEG layer consists of isotopically-enriched ^{28}Si to minimize spin decoherence due to ^{29}Si . SIMS results show that in the Si 2DEG layer, ^{28}Si is enriched from natural abundance of 92.2% to 99.8% with ^{29}Si reduced from 4.7% to an upper limit of $\sim 0.24\%$ and ^{30}Si reduced from 3.1% to $\sim 63\text{ppm}$. Finally, effective Schottky gating requires a sharp turn-off slope in phosphorus from the doped layer to the surface for low electric fields near the surface. We have achieved ultra-sharp turn-off slope of $\sim 16 \text{ nm/dec}$, and demonstrate Schottky gating to fully deplete the 2DEG with extremely low leakage current.

3:54PM X29.00006 Implanted bismuth donors in 28-Si: Process development and electron spin resonance measurements, C.D. WEIS, C.C. LO, Lawrence Berkeley National Laboratory, V. LANG, R.E. GEORGE, University of Oxford, A.M. TYRYSHKIN, Princeton University, J. BOKOR, University of California at Berkeley, S.A. LYON, Princeton University, J.J.L. MORTON, University of Oxford, T. SCHENKEL, Lawrence Berkeley National Laboratory — Spins of donor atoms in silicon are excellent qubit candidates. Isotope engineered substrates provide a nuclear spin free host environment, resulting in long spin coherence times [1,2]. The capability of swapping quantum information between electron and nuclear spins can enable quantum communication and gate operation via the electron spin and quantum memory via the nuclear spin [2]. Spin properties of donor qubit candidates in silicon have been studied mostly for phosphorous and antimony [1-3]. Bismuth donors in silicon exhibit a zero field splitting of 7.4 GHz and have attracted attention as potential nuclear spin memory and spin qubit candidates [4,5] that could be coupled to superconducting resonators [4,6]. We report on progress in the formation of bismuth doped 28-Si epi layers by ion implantation, electrical dopant activation and their study via pulsed electron spin resonance measurements showing narrow linewidths and good coherence times.

4:06PM X29.00007 Isotopic enrichment and growth of material for quantum coherent devices

, KEVIN DWYER, NIST, University of Maryland, JOSHUA POMEROY, NIST — We demonstrate isotopic enrichment and growth of highly pure materials in support of quantum coherent devices. Efforts to produce devices capable of quantum computation rely on long coherence times of the electron or nuclear spin being used. Impurities with nuclear spin are a major cause of decoherence in such systems, and their elimination is essential towards longer T_2 realization. The produced material must be isotopically enriched as well as chemically pure and defect free, and we present an alternative method for achieving these goals. Unenriched material is ionized and filtered using a mass selecting magnet and then epitaxially deposited. As an initial check on enrichment, ^{22}Ne is implanted into Si demonstrating an isotopic selectivity over 1800:1 which extrapolates to a ^{28}Si enrichment better than 99.994%. In progression towards Si deposition from a silane precursor, methane is used as an analog to grow enriched ^{13}C on semiconductor grade silicon. Analysis of this material by SIMS and ESR as a check on estimated levels of isotopic and chemical purity is presented.

4:18PM X29.00008 Realization of a double quantum dot in an isotopically purified ^{28}Si 2DES

, ANDREAS WILD, JUERGEN SAILER, GERHARD ABSTREITER, Walter Schottky Institut, Technische Universitaet Muenchen, Germany, J.W. AGER, E.E. HALLER, Department of Materials Science and Engineering, University of California at Berkeley, USA, STEFAN LUDWIG, Fakultät für Physik, Ludwig-Maximilians Universitaet Muenchen, Germany, JOHANNES KIERIG, DOMINIQUE BOUGEARD, Institut für Experimentelle und Angewandte Physik, Universitaet Regensburg, Germany — The Si/SiGe material system shows great promise for the realization of electron spin qubits due to the weak hyperfine interaction in natural silicon [2]. The electron spin coherence time is expected to further increase for spins embedded in a nuclear spin-refined ^{28}Si host crystal. In this contribution, we report on the realization and characterization of a 2DES in a MBE grown hybrid ^{28}Si /SiGe heterostructure with a record mobility of $5.5 \cdot 10^4 \text{ cm}^2/\text{Vs}$ at an electron density of $3 \cdot 10^{11}/\text{cm}^2$ in which the electron-nuclear spin overlap is greatly suppressed [1]. Based on this heterostructure, we present the first double quantum dot device in isotopically purified silicon. Our device can be operated down to the few electron regime and by using an additional global topgate above the quantum dot gates, the overall charge noise performance can be optimized significantly. This recent progress is fundamental for further experiments towards e.g. measurements of spin relaxation times in ^{28}Si .

4:30PM X29.00009 Deterministic preparation of Dicke states of donor nuclear spins in silicon¹

, YU LUO, HONGYI YU, WANG YAO, Department of Physics and Center of Theoretical and Computational Physics, The University of Hong Kong, Hong Kong, China — We present a scheme to deterministically prepare various symmetric and asymmetric Dicke states for donor nuclear spins in silicon. The state preparation is realized by cooperative pumping of nuclear spins by coupled donor electrons, and the required controls are in situ to the prototype Kane's architecture for quantum computation. This scheme only requires a sub-gigahertz donor exchange coupling which can be achieved without atomically precise donor placement, hence it could be a practical way to prepare multipartite entanglement of spins in silicon with current technology. All desired Dicke states appear as the steady state under various pumping scenarios and therefore the preparation is robust and does not require accurate temporal controls. Numerical simulations with realistic parameters show that Dicke states of 10 - 20 qubits can be prepared with high fidelity in the presence of decoherence and undesired dynamics.

¹The work was supported by the Research Grant Council of Hong Kong under Grant No. HKU 706711P.

4:42PM X29.00010 Optical Patterning of Nuclear Polarization in Gallium Arsenide , JONATHAN

KING, University of California, Berkeley, YUNPU LI, CARLOS MERILES, City College of New York, JEFFREY REIMER, University of California, Berkeley — Large enhancements of nuclear spin polarization can quench weak electron-nuclear fluctuations, mitigate electron spin decoherence, and provide control of electron spins in devices for quantum information processing. Such enhancements might include spatially patterned regions of polarized nuclei so as to prepare a spatially-dependent effective Zeeman field acting on electron spins as well as coherently manipulate the spin state of drifting electrons. By exploiting two competing mechanisms for optical nuclear polarization in semi-insulating GaAs, we use high field stray-field NMR imaging to demonstrate all-optical creation of three-dimensional patterns of positive and negative nuclear polarization without the need for ferromagnets or lithographic patterning techniques. These patterns may be controlled on the micron length scale.

4:54PM X29.00011 Integrating MREV and XXYX Pulse Sequences to Decouple Dipolar Interactions in ESR Experiments , ALEXEI TYRYSKHIN, STEPHEN LYON, Princeton University — Dynamical decoupling (DD) techniques

employ a series of strong refocusing pulses to combat decoherence in quantum systems. A great number of the new improved DD sequences have been designed recently aiming to decouple from a specific kind of decohering noise, arising in the direction of an externally applied quantizing field. MREV-type pulse sequences have long been used in NMR community to decouple spins from another source of decoherence - the dipolar interactions between like spins. Here, we report on our experience while using MREV sequences in ESR experiments on donors in silicon. We find MREV sequences to be very sensitive to even small instrumental errors in the applied pulses. The errors accumulate upon repeating the MREV pulse sequence, destroying the coherence instead of protecting it. A possible solution to this pulse error problem is found by integrating an MREV pulse sequence with a self-correcting XXYX sequence. The new MREV-XXYX sequence appears to satisfy all the requirements of a "good" DD sequence: (1) providing a protection to an arbitrary coherent state with good fidelity (at least 95% after more than 17,000 pulses), (2) decoupling from dipolar interactions of like spins, and (3) cancelling the phase noise arising from fluctuations in the magnetic field.

5:06PM X29.00012 Master equation approach to the central spin decoherence problem¹ , EDWIN

BARNES, Condensed Matter Theory Center, Dept. of Physics, University of Maryland, LUKASZ CYWINSKI, Institute of Physics, Polish Academy of Sciences, SANKAR DAS SARMA, Condensed Matter Theory Center, Dept. of Physics, University of Maryland — The electron-nuclear hyperfine interaction is the leading source of decoherence for electron spin qubits in III-V semiconductor quantum dots. For sufficiently low external B-field, the dynamics is purely hyperfine-induced. Generalized master equations embody an attractive approach to this problem due to strong analytical control, but so far they have only been applied in the case of high magnetic fields where a standard perturbative treatment is reliable. In the low field regime where pure hyperfine effects are measurable, this standard treatment breaks down. We show how to overcome this problem by first arguing that the detailed shape of the electron wavefunction is irrelevant for the electron spin decoherence at low B-fields. We then employ a powerful technique involving so-called correlated projection operators to vastly improve the convergence of the perturbative master equation approach by taking advantage of the symmetries that arise when the electron wavefunction is coarse-grained. This brings the low B-field regime into the scope of the master equation description, paving the way for the development of a well-controlled theory of pure hyperfine decoherence that is relevant for current experiments. [E. Barnes, L. Cywinski, S. Das Sarma, Phys. Rev. B 84, 155315 (2011)]

5:18PM X29.00013 Two-electron-spin dephasing due to hyperfine interaction in a GaAs double dot, JO-TZU HUNG, Department of Physics, University at Buffalo, SUNY, LUKASZ CYWINSKI, Institute of Physics, Polish Academy of Sciences, XUEDONG HU, Department of Physics, University at Buffalo, SUNY, SANKAR DAS SARMA, Department of Physics, University of Maryland — We study hyperfine interaction induced pure dephasing of two electron spin states in a GaAs double quantum dot. We construct the effective pure dephasing Hamiltonian for the two electron spins, and apply the ring-diagram theory [1] to calculate the decoherence function of the double dot two-spin system. With a finite exchange coupling, singlet and triplet states are the electron spin eigenstates, and we focus on the dephasing between the singlet state S and the unpolarized triplet state T_0 . We find that the effective Overhauser fields for these two states are suppressed because of their state symmetries, leading to weaker effective coupling between the nuclear spins. On the other hand, the weaker Overhauser field also allows more nuclear spins to flip-flop with each other. We show that these competing effects lead to interesting two-spin decoherence dynamics. We calculate the coherence decay as functions of the external field, the exchange splitting, and the quantum dot size, and compare our results with those for a single spin and for two uncorrelated spins. [1] L. Cywinski, W. Witzel, and S. Das Sarma, Phys. Rev. B 79, 245314 (2009).

Session X30 GQI: Focus Session: Quantum Information for Quantum Foundations - Foundational Experiments and Experimental Proposals 259B

2:30PM X30.00001 Experimental violation of the Leggett-Garg inequality under decoherence¹, JIN-SHI XU, CHUAN-FENG LI, XU-BO ZOU, GUANG-CAN GUO, University of Science and Technology of China — Despite the great success of quantum mechanics, questions regarding its application still exist and the boundary between quantum and classical mechanics remains unclear. Based on the philosophical assumptions of macrorealism and noninvasive measurability, Leggett and Garg devised a series of inequalities (LG inequalities) involving a single system with a set of measurements at different times. Introduced as the Bell inequalities in time, the violation of LG inequalities excludes the hidden-variable description based on the above two assumptions. Here, we experimentally investigate the single photon LG inequalities in a dephasing environment simulated by birefringent media. By implementing an optical Controlled-Not gate on a single photon, the LG inequalities are shown to be maximally violated in a coherent evolution process. This disproves its classical realistic description with the two assumptions of the LG inequalities. With the increase of birefringent media, the violation of LG inequalities becomes weaker and is shown to be not violated anymore at some time. The ability to violate the LG inequalities can be used to set the boundary of the classical realistic description.

¹This work was supported by the National Basic Research Program of China (Grants No. 2011CB9212000), National Natural Science Foundation of China (Grant Nos. 60921091, 10874162, 11004185), China Postdoctoral Science Foundation (Grant No. 20100470836)

2:42PM X30.00002 A condition for macroscopic realism beyond the Leggett-Garg inequalities, JOHANNES KOFLER, Max Planck Institute of Quantum Optics — In 1985, Leggett and Garg have put forward the concept of macroscopic realism (macrorealism), stating that the properties of macroscopic objects exist independent of and are not influenced by measurement. In analogy to Bell's theorem, they derived a necessary condition in terms of inequalities, which are now known as the Leggett-Garg inequalities. In this talk, a mathematical condition is introduced which is not only necessary but also sufficient for macrorealism. More importantly, the structure of this condition intuitively encompasses the physical meaning of macrorealism and allows for its experimental test in situations where the paradigm of Leggett-Garg inequalities might not be applicable.

2:54PM X30.00003 A quantum delayed-choice *gedanken* experiment¹, RADU IONICIOIU, Institute for Quantum Computing, University of Waterloo, DANIEL TERNO, Department of Physics & Astronomy, Macquarie University, Sydney — *Gedanken* experiments are important conceptual tools in the quest to reconcile our classical intuition with quantum mechanics and nowadays are routinely performed in the laboratory. An important open question is the quantum behaviour of the controlling devices in such experiments. We propose a framework to analyse quantum-controlled experiments and illustrate the implications by discussing a quantum version of Wheeler's delayed-choice experiment. The introduction of a quantum-controlled device (i.e., quantum beamsplitter) has several consequences. First, it implies that we can measure complementary phenomena with a single experimental setup, thus pointing to a redefinition of complementarity principle. Second, a quantum control allows us to prove there are no consistent hidden-variable theories in which "particle" and "wave" are realistic properties. Finally, it shows that a photon can have a morphing behaviour between "particle" and "wave"; this further supports the conclusion that "particle" and "wave" are not realistic properties but merely reflect how we "look" at the photon. The framework developed here can be extended to other experiments, particularly to Bell-inequality tests.

3:06PM X30.00004 The Pauli Exclusion Principle for electrons – a high sensitivity test in Gran Sasso underground laboratory, JOHANN MARTON, Stefan Meyer Institute, Austrian Academy of Sciences, VIP COLLABORATION — One of the fundamental rules of nature and a pillar in the foundation of quantum theory and thus of modern physics is represented by the Pauli Exclusion Principle. We know that this principle is extremely well fulfilled due to many observations like the order of the elements and the stability of matter. Numerous experiments were performed to search for tiny violation of this rule in various systems. The experiment VIP at the Gran Sasso underground laboratory is searching for possible small violations of the Pauli Exclusion Principle for electrons leading to an "anomalous" X-ray transition in copper atoms. VIP is aiming at a test of the Pauli Exclusion Principle for electrons with unprecedented accuracy, down to the level of 10^{-29} - 10^{-30} , thus improving the previous limit by 3-4 orders of magnitude. The experimental method, the setup, results obtained so far and future plans to further increase the precision by 2 orders of magnitude will be presented.

3:18PM X30.00005 Quantum metamaterials as a tool for investigating the quantum-classical transition, SERGEY SAVELIEV, ALEXANDRE ZAGOSKIN, MARK EVERITT, RICHARD WILSON, Department of Physics, Loughborough University, Loughborough LE11 3TU, UK — Quantum metamaterials are optical media comprised of individually controllable unit elements (e.g., qubits), which maintain quantum coherence for periods sufficient for an electromagnetic wave to pass through the system. They represent macroscopic, spatially extended quantum scatterers, which can be put in a superposition of states with different properties (e.g., different refractive indexes) and can thus provide new ways of testing different scenarios of quantum-classical transition. We consider an inverse of the classic double-slit experiment, where a classical electromagnetic wave is scattered by a quantum metamaterial in a superposition of states, and discuss the possibilities of its experimental realization.

3:30PM X30.00006 Progress towards a loophole-free test of nonlocality¹, KEVIN MCCUSKER, BRADLEY CHRISTENSEN, PAUL KWIAT, University of Illinois at Urbana-Champaign, JOSEPH ALTEPETER, Northwestern University — We report on our progress towards a loophole-free test of nonlocality using spontaneous parametric down-conversion (SPDC). While the timing loophole can be easily closed in such a system by moving the detectors far apart [1], closing the detector loophole is significantly more difficult. In the standard Bell entangled states with the maximal violation of the CHSH inequality [2], an overall efficiency of 83% is required. This limit can be lowered to 67% by using non-maximally entangled states (although sensitivity to noise is greatly increased) [3]. We are carefully engineering our source to achieve maximal heralding efficiency, by optimizing both the spatial and spectral filtering, while keeping noise low using high-extinction-ratio polarizing beamsplitters. Combined with high-efficiency detectors, either optimized visible-light photon counters [4] or transition-edge sensors [5], closure of the detection loophole is within reach.

3:42PM X30.00007 Loophole-free Quantum Steering¹, SVEN RAMELOW, BERNHARD WITTMANN, FABIAN STEINLECHNER, NATHAN K. LANGFORD, VCQ, Faculty of Physics, Univ. of Vienna and IQOQI Vienna, NICOLAS BRUNNER, Wills Physics Laboratory, Univ. of Bristol, HOWARD WISEMAN, Centre f. Quantum Computation and Communication Technology (ARC), Griffith University, RUPERT URSIN, ANTON ZEILINGER, VCQ, Faculty of Physics, Univ. of Vienna and IQOQI Vienna — Experiments testing quantum mechanics have provided increasing evidence against local realistic theories. However, a conclusive test that simultaneously closes all major loopholes (the locality, freedom-of-choice, and detection loopholes) remains an open challenge. An important class of local realistic theories can be tested with the concept of “steering.” Schrödinger introduced this term for entanglement seemingly allowing to remotely steer the state of a distant system [1]. Einstein called this “spooky action at a distance.” Steering was recently formalized by deriving steering inequalities allowing experimental tests. Here, we present the first loophole-free steering experiment [2]. We use entangled photons shared between two distant laboratories and close all loopholes by a large separation, ultra-fast switching and quantum random number generation, and high, overall detection efficiency. Beside its foundational importance loop-hole-free steering is relevant for is relevant for device-independent certification of quantum entanglement.

3:54PM X30.00008 Conclusive quantum steering with superconducting transition edge sensors, MARCELO P. DE ALMEIDA, DEVIN H. SMITH, GEO GILLET, CYRIL BRANCIARD, ALESSANDRO FEDRIZZI, TILL J. WEINHOLD, School of Mathematics and Physics, University of Queensland, 4072 Brisbane, QLD, Australia, ADRIANA LITA, BRICE CALKINS, THOMAS GERTIS, SAE WOO NAM, National Institute of Standards and Technology, 325 Broadway, Boulder CO 80305, USA, ANDREW G. WHITE, School of Mathematics and Physics, University of Queensland, 4072 Brisbane, QLD, Australia — Quantum steering allows two parties to verify shared entanglement even if one measurement device is untrusted. A conclusive demonstration of steering through the violation of a steering inequality is of considerable fundamental interest and opens up applications in quantum communication. To date all experimental tests with single photon states have relied on post-selection, allowing untrusted devices to cheat by hiding unfavorable events in losses. Here we close this “detection loophole” by combining a highly efficient source of entangled photon pairs with superconducting transition edge sensors. We achieve an unprecedented ~62% conditional detection efficiency of entangled photons and violate a steering inequality with the minimal number of measurement settings by 48 standard deviations. Our results provide a clear path to practical applications of steering and to a photonic loophole-free Bell test.

4:06PM X30.00009 Experimental Violation of Heisenberg’s Precision Limit by Weak Measurements, ARDAVAN DARABI, LEE A. ROZEMA, DYLAN H. MAHLER, ALEX HAYAT, Centre for Quantum Information and Quantum Control, and Institute for Optical Sciences, Department of Physics, University of Toronto, YASAMAN SOUDAGAR, Ecole Polytechnique de Montreal, University of Toronto, AEPHRAIM M. STEINBERG, Centre for Quantum Information and Quantum Control, and Institute for Optical Sciences, Department of Physics, University of Toronto — Along with the uncertainty principle, Heisenberg postulated another set of relations, which set a lower limit on the disturbance caused by a measurement [1]. These relations were shown by Ozawa to be inaccurate [2], shedding doubt on widely accepted bounds on the information left in a system after a measurement, and offering new insights into the foundations of quantum physics and quantum information. A theoretical scheme for testing Ozawa’s precision-disturbance relations was proposed [3]. In this proposal the hurdle of destructive measurements is addressed by the weak value approach [4]. This scheme is based on a 3-qubit quantum circuit that requires two CNOT gates of variable strength with a common control qubit. Here, we present an experimental realization of Heisenberg’s precision limit violation based on weak value measurements. We implement a technique inspired by the one-way quantum computing using entanglement as the substrate for quantum gates. In this way, we demonstrate a violation of Heisenberg’s relation for measurement disturbance, confirming the revised bound due to Ozawa.

4:18PM X30.00010 The rise of long-distance entanglement within a linear chain of ions, THOMAS FOGARTY, Physics Department, University College Cork, Cork, Ireland, ENDRE KAJARI, BRUNO G. TAKETANI, Theoretische Physik, Universität des Saarlandes, D-66123 Saarbrücken, Germany, ALEXANDER WOLF, Institute of Quantum Physics, Ulm University, D-89069 Ulm, Germany, THOMAS BUSCH, Physics Department, University College Cork, Cork, Ireland, GIOVANNA MORIGI, Theoretische Physik, Universität des Saarlandes, D-66123 Saarbrücken, Germany — One stumbling block which limits our observation of quantum effects in the macroscopic world is decoherence. For this reason the study of decoherence and dissipation in open quantum systems has attracted a lot of attention. It has been shown that the generation of long distance entanglement is possible between oscillators via a harmonic crystal (Wolf et al, EPL, 95(2011) 60008). The aim of this current work is to propose an experimentally feasible setup to test the possibility of the creation of long distance entanglement. For this purpose we consider an ion chain in a linear Paul trap with two embedded impurities, whose transverse modes resemble the two degrees of freedom that we aim to entangle via the rest of the chain. With the aid of appropriately designed laser fields, the dynamics described in (Wolf et al, EPL, 95(2011) 60008) is reproduced. The resulting entanglement between the transverse modes of the impurities is analysed by means of the logarithmic negativity.

4:30PM X30.00011 Popper's Thought Experiment Reinvestigated, CHRIS RICHARDSON, JONATHAN DOWLING, Louisiana State University — Karl Popper posed an interesting thought experiment in 1934. With it, he meant to question the completeness of quantum mechanics. He claimed that the notion of quantum entanglement leads to absurd scenarios that cannot be true in real life and that an implementation of his thought experiment would not give the results that QM predicts. Unfortunately for Popper, it has taken until recently to perform experiments that test his claims. The results of the experiments do not refute QM as Popper predicted, but neither do they confirm what Popper claimed QM predicted. Kim and Shih implemented Popper's thought experiment in the lab. The results of the experiment are not clear and have instigated many interpretations of the results. The results show some correlation between entangled photons, but not in the way that Popper thought, nor in the way a simple application of QM might predict. A ghost-imaging experiment by Strekalov, et al. sheds light on the physics behind Popper's thought experiment, but does not try to directly test it. I will build the physics of Popper's thought experiment from the ground up and show how the results of both of these experiments agree with each other and the theory of QM, but disprove Popper.

4:42PM X30.00012 Positive Noise Cross Correlation in a Copper Pair Splitter., ANINDYA DAS, YUVAL RONEN, MOTY HEIBLUM, HADAS SHTRIKMAN, DIANA MAHALU, Weizmann Institute of Science, MOTY'S GROUP TEAM — Entanglement is in heart of the Einstein-Podolsky-Rosen (EPR) paradox, in which non-locality is a fundamental property. Up to date spin entanglement of electrons had not been demonstrated. Here, we provide direct evidence of such entanglement by measuring: non-local positive current correlation and positive cross correlation among current fluctuations, both of separated electrons born by a Cooper-pair-beam-splitter. The realization of the splitter is provided by injecting current from an Al superconductor contact into two, single channel, pure InAs nanowires - each intercepted by a Coulomb blockaded quantum dot (QD). The QDs impedes strongly the flow of Cooper pairs allowing easy single electron transport. The passage of electron in one wire enables the simultaneous passage of the other in the neighboring wire. The splitting efficiency of the Cooper pairs (relative to Cooper pairs actual current) was found to be $\sim 40\%$. The positive cross-correlations in the currents and their fluctuations (shot noise) are fully consistent with entangled electrons produced by the beam splitter.

4:54PM X30.00013 Scalable fiber integrated source for higher-dimensional path-entangled photons¹, ROBERT POLSTER, CHRISTOPH SCHAEFF, RADEK LAPKIEWICZ, ROBERT FICKLER, SVEN RAMELOW, ANTON ZEILINGER, University of Vienna — Higher dimensional Hilbert spaces are expected to show intriguing higher order effects. Examples are higher dimensional perfect correlations or the unsolved problem of finding a complete set of MUBs for dimension 6. Higher dimensional systems also have advantages for QKD protocols. Our approach is to build an easy to use platform to access these dimensions. We realized an in-fiber, high brightness and high fidelity source for path-entangled quNits in the telecom band. It is purely integrated in fiber and only standard off-shelf components are used. This results in high stability and scalability in terms of complexity with increasing dimension. In order to manipulate and transform the produced entangled states we implemented multiports in integrated optical technology, enabling us to perform any unitary transformation depending on its internal settings[1]. Results up to dimension 4 (ququarts) will be presented in the talk. [1] M. Reck, A. Zeilinger, H. J. Bernstein and P. Bertani, PRL 73, 1 (1994)

5:06PM X30.00014 New Near-Deterministic Teleportation Protocol with Linear Optics, MLADEN PAVICIC, University of Zagreb — We present a new near-deterministic method of separating all four photon Bell states by means of concatenated Mach-Zehnder interferometers. Realistic proposals for implementations of teleportation, superdense coding, and cryptographic ping-pong protocols will be presented. Discrimination of the Bell states is made possible by two two linear chains of concatenated Mach-Zehnder interferometers each fed with photons emerging from two opposite sides of a beam splitter. This amounts to detecting two Bell states $|\Phi^\pm\rangle$ while keeping the third one $|\Psi^+\rangle$ conditionally at bay—thus going around Vaidman-Lütkenhaus 50%-limit. Realistic implementation with an efficiency of 90% is feasible with today's technology. Channel capacity of 1.98 can be ideally achieved for superdense coding with 5 concatenated Mach-Zehnder interferometers but already with only two easily implementable ones we obtain 1.74 capacity. The setup is based on a revised and corrected method given in M. Pavičić, *Phys. Rev Lett.* **107**, 080403 (2011).

Thursday, March 1, 2012 2:30PM - 5:30PM –
Session X31 DMP: Focus Session: Topological Insulators: Synthesis and Characterization - Scanning Tunneling Spectroscopy 260

2:30PM X31.00001 Scanning tunneling spectroscopic studies of Dirac fermions and impurity resonances in the surface-state of a strong topological insulator Bi₂Se₃, H. CHU, M.L. TEAGUE, C.-C. HSU, N.-C. YEH, Caltech, L. HE, K.-L. WANG, UCLA, F.-X. XIU, Iowa State Univ. — Scanning tunneling spectroscopic studies of MBE-grown Bi₂Se₃ epitaxial films on Si (111) revealed surface-state (SS) characteristics of Dirac fermions and signatures of strong impurity resonances. The impurity resonances in this three-dimensional strong topological insulator (3D-STI) occurred near the Dirac energy (E_D) and diverged as the Fermi level (E_F) approached E_D . They were also highly localized within a region of radius ~ 0.2 nm, beyond which the SS spectra of the 3D-STI recovered quickly, suggesting robust topological protection against non-magnetic impurities. Similar spectral characteristics and separations between E_F and E_D were also observed in the MBE-grown Bi₂Se₃ films on CdS. For sufficiently thin samples, opening of an energy gap due to wave-function overlap between the surface and interface layers was observed. The Rashba-like spin-orbit splitting further gave rise to spin-preserving quasiparticle interferences. Finally, the effect of different impurities (e.g. Cr and Mn) on the SS spectra of Bi₂Se₃ as a function of magnetic field will be reported. This work was supported by FENA and DARPA.

2:42PM X31.00002 Scanning tunneling spectroscopy studies of Bi₂Te₂Se¹, ILYA DROZDOV, HAIM BAIDENKOPF, JUNGPIIL SEO, Department of Physics, Princeton University, SHUANG JIA, ROBERT CAVA, Department of Chemistry, Princeton University, ALI YAZDANI, Department of Physics, Princeton University — Topological insulators are a class of semiconductors characterized by the presence of current-carrying helical surface states lying within the bulk gap. The surface states of these materials possess massless Dirac-like dispersion. Helical spin texture of the surface states leads to suppression of backscattering in these materials. Results of scanning tunneling spectroscopy study of Bi₂Te₂Se (BTS) topological insulator will be presented. Similar to previously studied Bi₂Te₃ and Bi₂Se₃ the new material shows a relatively large band gap and a simple surface band structure. High bulk resistivity and high surface electron mobility make it a compound of interest for potential applications. Differential conductance mapping with scanning tunneling microscope is used to visualize surface states of this novel highest-bulk-resistivity topological insulator. These experiments enable us to assess the variation of local density of states in this compound under different growth conditions and to correlate the findings with transport properties

¹This work was supported by NSF, NSF-MRSEC, and DARPA

2:54PM X31.00003 Scanning tunneling spectroscopy of stripe induced spatial modulations in the electronic structure of $\text{Bi}_2\text{Te}_3+\text{d}$, YOSHINORI OKADA, WENWEN ZHOU, DANIEL WALKUP, CHETAN DHITAL, YING RAN, ZIQING WANG, STEPHEN WILSON, VIDYA MADHAVAN, Boston College — To take full advantage of the unique properties of topological insulators, a huge amount of effort has been spent in exploring the tunability of their charge carrier density or magnetism by chemical doping, creating an ever increasing need for probing and understanding the real-space electronic response. In this study, we investigate the effects of a 1D periodic modulation (stripes) on the electronic structure of $\text{Bi}_2\text{Te}_3+\text{d}$. Using a combination of spectroscopic mapping, Fourier transform spectroscopy and Landau level measurements we map out the energy-momentum dispersion of the surface state over a large energy range and show that the stripes have a non-trivial effect on the bulk and surface state band structure.

3:06PM X31.00004 Scanning tunneling microscopy study of ultrathin topological insulator Bi_2Te_3 nanoribbons, CAROLINA PARRA, DESHENG KONG, JASON C. RANDEL, ALEX W. CONTRYMAN, FRANCIS NIESTEMSKI, MING RUE D. THIAN, YI CUI, HARI C. MANOHARAN, Stanford University — Currently there is an increasing interest in the study of topological insulators (TI) nanostructures as a result of their large surface-to-volume ratio, which allows the manifestation of surface conduction states without masking by bulk carriers. We performed low-temperature scanning tunneling microscopy (STM) measurements of the surface of TI Bi_2Te_3 nanostructures grown on HOPG. Although surface states of TIs are inherently robust against almost any surface modifications, these materials are prone to various surface chemical reactions which are taken into account when preparing samples for devices and STM study. Our STM measurements reveal the presence of ultrathin nanostructures (nanoribbons and nanoplates) which show an important growth anisotropy, with lateral dimension growing much faster than the vertical thickness dimension. Nanoribbons group mainly in bunches, with an aspect ratio of 1:300 and thickness down to 6 nm (6 quintuple layers). Nanoplates with hexagonal morphology of lower than 20 quintuple layers thick were also found, suggesting both one- and two-dimensional preferential growth.

3:18PM X31.00005 The field dependence of quantized Landau levels on $\text{Bi}_2\text{Te}_3+\text{d}$ via scanning tunneling spectroscopy, DANIEL WALKUP, YOSHINORI OKADA, WENWEN ZHOU, CHETAN DHITAL, STEPHEN WILSON, VIDYA MADHAVAN, Boston College — Measurements of Landau level (LL) spectra by scanning tunneling spectroscopy can provide important information on quasi-particle lifetime, effective g-factor as well as the dispersion of surface state bands. We have studied the effect of magnetic fields on spatially inhomogeneous samples of the topological insulator $\text{Bi}_2\text{Te}_3+\text{d}$. Using spatial maps of Landau levels as a function of magnetic field, we show that the surface state electrons near the Dirac point are surprisingly sensitive to perturbations. The magnetic field dependence also allows us to obtain an upper limit to the effective g-factor for the surface state electrons.

3:30PM X31.00006 Landau quantization and the thickness limit of topological insulator thin films of Sb_2Te_3 , XUCUN MA, YEPEING JIANG, YILIN WANG, Institute of Physics, CAS, MU CHEN, Department of Physics, Tsinghua University, CANLI SONG, ZHI LI, LILI WANG, KE HE, Institute of Physics, CAS, XI CHEN, QI-KUN XUE, Department of Physics, Tsinghua University — We report the experimental observation of Landau quantization of molecular beam epitaxy grown Sb_2Te_3 thin films by a low-temperature scanning tunneling microscope. Different from all the reported systems, the Landau quantization in Sb_2Te_3 topological insulator is not sensitive to the intrinsic substitutional defects in the films. As a result, a nearly perfect linear energy dispersion of surface states as 2D massless Dirac fermion system is observed. We demonstrate that 4 quintuple layers are the thickness limit for Sb_2Te_3 thin film being a 3D topological insulator.

3:42PM X31.00007 Multiband quasiparticle interference in the topological insulator $\text{Cu}_x\text{Bi}_2\text{Te}_3$ ¹, ERIK VAN HEUMEN, van der Waals - Zeeman Institute, University of Amsterdam, S. JOHNSTON, IFW Dresden, Germany, E. RIENKS, A. VÁRYKHALOV, Helmholtz Institute Berlin, Germany, F. MASSEE, N. DE JONG, Y. HUANG, J. KAAS, J.B. GOEDKOOP, M.S. GOLDEN, van der Waals - Zeeman Institute, University of Amsterdam — One of the main interests in topological materials is their purported robustness against disorder. In the Bi_2X_3 family (X=Se,Te) cubic spin-orbit coupling terms play an important role through their effect on the dispersion of the surface states. The cubic terms are also responsible for the restoration of Friedel like oscillations around impurity sites, which may be important in surface transport processes. We have therefore investigated how impurity scattering affects the surface states using a combination of Fourier-transform scanning tunneling spectroscopy (FT-STs) and calculations of the charge density oscillations expected from the cubic spin-orbit coupling terms [1]. FT-STs allows us to map out the energy-momentum relation of the important scattering wave-vectors, which can be compared to scattering vectors predicted from a self-consistent single impurity scattering calculation. To fully explain the features observed in our experiments we need to take the conduction band into account. Namely, for energies where the surface states and the conduction band overlap, the dominant scattering process turns out to be interband impurity scattering.

3:54PM X31.00008 LT-STM study of the topological insulator Bi_2Se_3 with superconducting and/or magnetic over layers, RAMI DANA, ANITA ROYCHOWDHURY, University of Maryland, IREK MIOTKOWSKI, YONG P. CHEN, Purdue University, MICHAEL DREYER, University of Maryland — Superconducting and/or magnetic over layers structures on topological insulator (TI) surfaces were suggested as a potential candidate to create Majorana bound states and 1D Majorana fermions (spin $1/2$, particle = antiparticle). The latter can serve as a platform for topological quantum computation since two Majorana bound states equal one fermion bound state and two degenerate states (full/empty) forming one qubit. In this work we study the TI Bi_2Se_3 using a low temperature STM. The data shows the signature energy gap $\Delta \sim 0.3$ eV, metallic surface states and typical defects. Following the experimental challenges to create and detect Majorana bound or chiral edge states, we present our study of Nb and/or Fe films on the Bi_2Se_3 surface.

4:06PM X31.00009 Visualizing the inhomogeneous response of Dirac surface states to bulk disorder in topological insulators¹, HAIM BEIDENKOPF, PEDRAM ROUSHAN, JUNGPII SEO, LINDSAY GORMAN, ILYA DROZDOV, Joseph Henry Laboratory, Department of Physics, Princeton University, Princeton, New Jersey 08544, USA, YEW SAN HOR, ROBERT J. CAVA, Department of Chemistry, Princeton University, Princeton, New Jersey 08544, USA, ALI YAZDANI, Joseph Henry Laboratory, Department of Physics, Princeton University, Princeton, New Jersey 08544, USA — The Dirac dispersion and helical spin texture of surface states in topological insulators render them resilient to backscattering. This remarkable property, assured by time reversal symmetry, should give rise to enhanced surface conductivity as the Dirac states anti-localize in presence of disorder. We have used scanning tunneling microscopy (STM) and spectroscopy to study the response of the surface states to both magnetic and non-magnetic dopants [HB et al. Nat. Phys. doi:10.1038/nphys2108]. We find that helicity provides protection from scattering, irrespective of the magnetic nature of the individual scatterers and even of ferromagnetic correlations among them. However, the charged defects in the bulk induce pronounced fluctuations in energy, momentum and helicity of the surface states. Agreement with a theoretical model, derived for the response of Dirac states to charged disorder in graphene, further implies that such fluctuations limit the attainable surface mobility. Although we show that the potential energy landscape induced by the bulk defects does not localize the Dirac surface states, our results suggest that reducing charged defects content is essential for tuning the chemical potential to the Dirac energy and enhancing mobility of the novel surface states.

¹This work was supported by NSF, NSF-MRSEC, and DARPA

4:18PM X31.00010 Probing surface state conductance of topological insulator Bi_2Se_3 with scanning tunneling potentiometry, CHOCKALINGAM SUBBIAH, Department of Physics, Columbia University, NY, FRANCES ROSS, IBM T. J. Watson Research Center, Yorktown Heights, NY, MATTHEW BRAHLEK, SEONGSHIK OH, Department of Physics & Astronomy, Rutgers, The State University of New Jersey, ABHAY PASUPATHY, Department of Physics, Columbia University, NY — Topological insulators such as Bi_2Se_3 have unique surface states. How do electrons actually flow on the surface of a real Bi_2Se_3 sample? We study this question using scanning tunneling potentiometry. In this measurement, a lateral current flows in the sample while the local potential is mapped on the surface using a scanning tunneling microscope. This technique can be used to identify with atomic resolution the potential drops in the current-carrying pathways at the surface, and is ideally suited to measure the properties of quasi-2D materials such as graphene. Our topological insulator samples are MBE grown films of Bi_2Se_3 on a sapphire substrate. We will describe both the surface morphology and its effect on the current carrying pathways in the material.

4:30PM X31.00011 Probing high energy, unoccupied states on the surface of pristine and Fe doped Bi_2Te_3 by scanning tunneling spectroscopy, WENWEN ZHOU, YOSHINORI OKADA, DANIEL WALKUP, CHETAN DHITAL, Boston College, HSIN LIN, ARUN BANSIL, Northeastern University, STEPHEN WILSON, VIDYA MADHAVAN, Boston College — We probe the surface state of pristine and Fe-doped topological Insulator Bi_2Te_3 by using Fourier Transform Scanning Tunneling Spectroscopy (FT-STs). FT-STs allows us to probe the surface state dispersion far above the Fermi energy, a regime inaccessible to angle resolved photoemission spectroscopy. We report the observation of novel multi scattering channels that emerge at high energies along the ΓM and ΓK directions. The possible origins of these channels including spin-orbit scattering will be discussed.

4:42PM X31.00012 STS studies of the surface of Bi_2Se_3 , MEGAN ROMANOWICH, MAL-SOON LEE, S.D. MAHANTI, STUART TESSMER, Michigan State University, DUCK YOUNG CHUNG, JUNG-HWAN SONG, MERCOURI KANATZIDIS, Northwestern University; Argonne National Laboratory — We apply scanning tunneling spectroscopy to characterize the surface of the topological insulator Bi_2Se_3 . Spectroscopy reveals that the minimum in the local density of states (LDOS) does not actually vanish in the region where Dirac cone states exist. We demonstrate with density functional theory calculations that this can be understood in terms of an asymmetric addition to the LDOS associated with a contribution from the bulk valence band that overlaps in energy with the Dirac point. We will discuss the origin of the fluctuations in the LDOS seen in the experiment near 0.2 eV above the Dirac point, which are associated with tunneling into the lowest conduction band states.

4:54PM X31.00013 STM imaging of impurity resonances on Bi_2Se_3 , ZHANYBEK ALPICHSEV, Stanford University, RUDRO BISWAS, Harvard University, ALEXANDER BALATSKY, Los Alamos National Laboratory, JAMES ANALYTIS, JIUN-HAW CHU, IAN FISHER, AHARON KAPITULNIK, Stanford University — In this paper we present detailed study of the density of states near defects in Bi_2Se_3 . In particular, we present data on the commonly found triangular defects in this system. While we do not find any measurable quasiparticle scattering interference effects, we do find localized resonances, which can be well fitted by theory [1] once the potential is taken to be extended to properly account for the observed defects. The data together with the fits confirm that while the local density of states around the Dirac point of the electronic spectrum at the surface is significantly disrupted near the impurity by the creation of low-energy resonance state, the Dirac point is not locally destroyed. We discuss our results in terms of the expected protected surface state of topological insulators.

5:06PM X31.00014 Probing Dirac Fermions in Bi-based Semimetals by Cryomagnetic Scanning Tunneling and Point Contact Spectroscopy¹, J.Y.T. WEI, University of Toronto and Canadian Institute for Advanced Research, I. FRIDMAN, Y.T. YEN, University of Toronto, HECHANG LEI, KEFENG WANG, C. PETROVIC, Brookhaven National Laboratory — The topological semimetal Bi_2Se_3 is distinguished by the presence of two-dimensional Dirac fermions with strong spin-orbit coupling. The linear dispersion of Dirac fermions in Bi_2Se_3 was recently observed by scanning tunneling spectroscopy measurements of the Landau level spacing versus magnetic field. In this work we extend the field-dependent spectroscopy study of Dirac fermions to other Bi-based semimetals, for both topological and non-topological cases, using cryomagnetic scanning tunneling and point contact probes on single crystals down to 300 mK and up to 9 T. The spectral dependences on field strength and field direction are examined, in an effort to elucidate the role of spin-orbit coupling in each case.

5:18PM X31.00015 Thickness and Wave-Vector Dependence in the Inter-Surface Coupling of Topological Surface States of Sb(111) Films, GUANGGENG YAO, FENG PAN, ZIYU LUO, WENTAO XU, JIATAO SUN, ANDREW THYE SHEN WEE, YUANPING FENG, XUE-SEN WANG, Department of Physics, Faculty of Science, National University of Singapore — Sb is a semimetal but possesses topological surface states (SSs) [1]. Taking advantage of quantum confinement effect for bulk states and topological protection for SSs, an Sb thin film could be a topological insulator. We explore this possibility using Fourier-transform scanning tunneling spectroscopy (FT-STs) and *ab initio* calculations for Sb(111) films of thickness ≤ 30 bilayers (BL). Quasiparticle interference (QPI) patterns of SSs and calculated band structures exhibit dramatic dependence on film thicknesses, reflecting variation of inter-surface coupling of SSs with film thickness and wave vector $\mathbf{k}$. One Kramers-pair of SSs forming a Dirac point at $\mathbf{k} = 0$ exist on each surface for 6-BL or thicker films. The inter-surface coupling of SSs not far away from $\mathbf{k} = 0$ is significant in the QPI patterns at ~ 10 BL. Such coupling is due to a relative large penetration depth of these SSs results in unpolarized states with large wave function amplitude in the interior of the film. [1] D. Hsieh et al., Science 323, 919 (2009); K. K. Gomes et al., e-print arXiv:0909.0921 (2009); J. Seo et al., Nature 466, 343 (2010).

Session X32 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides - Elastic and Optical Properties 261

2:30PM X32.00001 Flexoelectricity in Nanoscale Ferroelectrics, GUSTAU CATALAN, ICREA and CIN2, Barcelona — All ferroelectrics are piezoelectric and thus have an intrinsic coupling between polarization and strain. There exists an additional electromechanical coupling, however, between polarization and strain gradients. Strain gradients are intrinsically vectorial fields and, therefore, they can in principle be used to modify both the orientation and the sign of the polarization, thanks to the coupling known as flexoelectricity. Flexoelectricity is possible even in paraelectric materials, but is generally stronger in ferroelectrics on account of their high permittivity (the flexoelectric coefficient is proportional to the dielectric constant). Moreover, strain gradients can be large at the nanoscale due to the smallness of the relaxation length and, accordingly, strong flexoelectric effects can be expected in nanoscale ferroelectrics. In this talk we will present two recent results that highlight the above features. In the first part, I will show how polarization tilting can be achieved in a nominally tetragonal ferroelectric (PbTiO_3) thanks to the internal flexoelectric fields generated in nano-twinned epitaxial thin films. Flexoelectricity thus offers a purely physical means of achieving rotated polarizations, which are thought to be useful for enhanced piezoelectricity. In the second part, we will show how the large strain gradients generated by pushing the sharp tip of an atomic force microscope against the surface of a thin ferroelectric film can be used to actively switch its polarity by 180° . This enables a new concept for “multiferroic” memory operation in which the memory bits are written mechanically and read electrically.

3:06PM X32.00002 Giant Flexoelectric Effect in Ferroelectric Epitaxial Thin Films, TAE WON NOH, DAESU LEE, Department of Physics and Astronomy, Seoul National University, A. YOON, M. KIM, Department of Materials Science and Engineering, Seoul National University, J.-G. YOON, Department of Physics, University of Suwon, J.-S. CHUNG, Department of Physics and CAMDRC, Soongsil University, J.F. SCOTT, Department of Physics, University of Cambridge, UK — The flexoelectric effect describes an electric field that is generated by a strain gradient. Owing to its universal nature, flexoelectricity has inspired broad scientific interest and has application potential, particularly in flexible systems. In solids, however, there has been little investigation into flexoelectricity, due to its minuscule magnitude by limited elastic deformation. In this presentation, we will develop a general framework for realizing and modulating the giant flexoelectric effect in epitaxial oxide thin films, emphasizing the key role of flexoelectricity in solids.¹ In epitaxial oxide thin films, a lattice mismatch between the film and the substrate can result in strain relaxation within tens of nanometers of the film/substrate interface, inducing a large strain gradient. We observed the nanoscale strain gradients in ferroelectric HoMnO_3 epitaxial thin films, which were 6 or 7 orders of magnitude larger than typical values reported for bulk oxides. Giant flexoelectric effect by the nanoscale strain gradient provides a means of tuning the physical properties of ferroelectric epitaxial thin films, such as domain configurations and hysteresis curves.²

3:18PM X32.00003 Thermal Stresses in Ferroelectric Thin Films and Their Role on the Dielectric, Pyroelectric, and Electrocaloric Properties, JIALAN ZHANG, S. PAMIR ALPAY, University of Connecticut — In-plane strains develop in thin films due to thermal stresses that arise from differences between the thermal expansion coefficients of the film and the substrate upon cooling from a growth temperature (T_G) to room temperature (RT). In ferroelectric (FE) films, there is a coupling between strain and polarization through electrostriction. Therefore, thermal strains may have profound effects on the dielectric, pyroelectric, and electrocaloric (EC) responses of FE films. We provide here a quantitative thermodynamic model to investigate the role of in-plane thermal strains on these properties. We show that there is a substantial degradation in the dielectric response and tunability of SrTiO_3 films on IC-friendly substrates such as Si and *c*-sapphire due to tensile thermal in-plane strains. Our analysis on (001)-textured polycrystalline $\text{Ba}_x\text{Sr}_{1-x}\text{O}_3$ (BST) films with different compositions indicates that for BST 60/40 and BST 70/30 films, the pyroelectric response does not display a significant dependence on T_G if the FE is in a paraelectric state. Furthermore, we show that for BaTiO_3 films on Si, the thermal stresses are sufficient to shift the zero-field Curie temperature to RT, resulting in a strong enhancement of the EC properties as compared to the bulk material.

3:30PM X32.00004 Polarization in Perovskite Manganites induced by Shear Stress¹, K. MIYANO, N. OGAWA, Y. IDA, R. TAMAKI, K. SHIMIZU, Y. NOMURA, R. ARITA, Univ. of Tokyo, Y. OGIMOTO, Univ. of Tokyo and Fuji Electr. Co. — We found static polarization in perovskite manganite films when they are under shear stress. The phenomenon is omnipresent in films deformed in (at least) monoclinic fashion due to the substrate-imposed strain, whereas it is absent in bulk crystals even though they are distorted in a similar manner in thermal equilibrium. The substrate stress of low symmetry is clearly the driving force for the appearance of the polarization. Optical second-harmonic generation (SHG) confirms the loss of inversion symmetry in strained films and pyroelectricity was detected in insulating films confirming the presence of the static polarization. DFT calculations show that the stable atomic positions in the experimentally observed structure is polar with the shift of the center of gravity of anions relative to that of cations as much as $10^{-2}\text{\AA}$. The calculated polar structure is consistent with the symmetry obtained from the SHG polarimetry.

¹JST-CREST

3:42PM X32.00005 Discovery of strain glass transition in non-metallic ferroelastic, PEI ZHANG, DEZHEN XUE, XIAOBING REN, MMRC, Frontier Institute of Science and Technology, Xi'an Jiaotong University, China, MMRC, FRONTIER INSTITUTE OF SCIENCE AND TECHNOLOGY, XI'AN JIAOTONG UNIVERSITY, CHINA TEAM, FERROIC PHYSICS GROUP, NATIONAL INSTITUTE FOR MATERIALS SCIENCE, TSUKUBA 305-0047, JAPAN COLLABORATION — Strain glass, a glassy state of lattice strain, has been identified in alloys with shuffle being the principle order parameter and strain being the secondary order parameter. However, it is well known that many non-metallic ferroelastic systems possess long range order with tilt being the first order parameter. But the existence of the glassy state of such strain caused by tilt remains unclear. In the present study, we report that the strain glass indeed exists in the non-metallic ferroelastic material, a Sr and Nb co-doped LaAlO_3 system, with randomly frozen tilt strain local order. With increasing defect concentration x in $\text{La}_{1-x}\text{Sr}_x\text{Al}_{0.95}\text{Nb}_{0.05}\text{O}_3$, the martensitic transition is gradually suppressed and finally strain glass transition occurs. The glassy transition is characterized by a typical frequency dispersion of modulus, a broken of ergodicity for static strain, as well as the formation of nano-domains with R local structure. Due to the strong local barrier caused by the randomly distributed point defects, the ideal freezing temperature T_0 of strain glass in this system increases with defect concentration, which can be well understood by a modified Landau free energy landscape.

3:54PM X32.00006 Enhanced Piezoelectricity in $\text{PbTiO}_3/\text{BaTiO}_3$ Superlattices, T. YUSUFALY, Rutgers University, B. ZIEGLER, University of Geneva, V.R. COOPER, Oak Ridge National Laboratory, S.J. CALLORI, J. SINSHEIMER, Stony Brook University, K.M. RABE, P. CHANDRA, Rutgers University, M. DAWBER, Stony Brook University — First-principles calculations by Cooper and Rabe predict an enhancement of the piezoelectric coefficient (d_{33}) in $\text{PbTiO}_3/\text{BaTiO}_3$ (PTO/BTO) superlattices for intermediate values of PTO concentration. PTO/BTO superlattices have been fabricated using an off-axis RF magnetron sputtering technique, enabling x-ray diffraction, electrical measurements and atomic force microscopy on this system. The experimental results agree with the calculated polarization, tetragonality and enhanced piezoelectricity as a function of PTO concentration. Additional first-principles calculations indicate that the enhancement in d_{33} is more pronounced in shorter-period superlattices. By applying a Landau-Devonshire model to this system, we find that the enhanced piezoelectricity is due to the combination of a bulk effect associated with the presence of finite electric fields in each layer and interfacial effects. Implications of our results for future experiments are discussed.

4:06PM X32.00007 Interpolation schemes for high-throughput prediction of new piezoelectric alloys, RICKARD ARMIENTO, Massachusetts Institute of Technology, BORIS KOZINSKY, Research and Technology Center, Robert Bosch LLC, MARCO FORNARI, Central Michigan University, GERBRAND CEDER, Massachusetts Institute of Technology — Systematic discovery of materials with optimized properties based on first principles methodologies requires well-defined descriptors, in addition to the automation infrastructure for calculations and data analysis. We have designed a set of computationally affordable descriptors for enhanced piezoelectric performances and analyzed the chemical space for oxides with the perovskite structure. Our results include phase stability for the most promising compositions and ad hoc interpolation schemes that have been exploited to identify 49 alloys with favorable properties.

4:18PM X32.00008 Piezoelectric characteristics of PZT thin films on polymer substrate, MIN-GYU KANG, YOUNH-HO DO, SEUNG-MIN OH, RHEZA RAHAYU, YIYEIN KIM, CHONG-YUN KANG¹, Korea Institute of Science and Technology, SAHN NAHM, Korea University, SEOK-JIN YOON, Korea Institute of Science and Technology — The goal of piezoelectric energy harvesting is to improve the power efficiency of devices. One of the approaches for the improvement of power efficiency is to apply the large strain on the piezoelectric materials and then many scientists approached using thin films or nano-structured piezoelectric materials to obtain flexibility. However, the conventional thin film processes available for the fabrication of piezoelectric materials as $\text{PbZr}_{0.52}\text{Ti}_{0.48}\text{O}_3$ (PZT) are not compatible with flexible electronics because they require high processing temperatures ($>700^\circ\text{C}$) to obtain piezoelectricity. Excimer laser annealing (ELA) is attractive heat process for the low-temperature crystallization, because of its material selectivity and short heating time. In this study, the amorphous PZT thin films were deposited on polymer substrate by rf-sputtering. To crystallize the amorphous films, the ELA was carried out with various conditions as function of the applied laser energy density, the number of pulse, and the repetition rate. To evaluate the piezoelectric characteristics, piezoelectric force microscopy (PFM) and electrometer are used. As a result, we obtained the crystallized PZT thin film on flexible substrate and obtained flexible piezoelectric energy harvester.

4:30PM X32.00009 Characterizing the Angular Frequency of Radiative Polaritons using Infrared Spectroscopy, ANITA VINCENT-JOHNSON, GIOVANNA SCAREL, James Madison University Dept. of Physics and Astronomy — Polaritons are important for understanding the optical properties of oxide films and possibly also for energy conversion. The two known types of polaritons: surface phonon polaritons (SPP) and radiative polaritons (RP), form when infrared (IR) photons enter a crystal lattice material and couple with the phonons present. While SPP's are largely studied for their heat transfer properties, RP's are typically not studied; therefore, much is still not understood about RP's. It is known, however, that RP's have a complex angular frequency, which includes a real part, $\text{Re}(\omega)$, and an imaginary part, $\text{Im}(\omega)$. Investigations done by our Group suggests that $\text{Im}(\omega)$ indicates the frequency of the radiated field. What is unknown is the relationship between $\text{Re}(\omega)$ and $\text{Im}(\omega)$. Therefore, we experimentally compare three different oxides deposited on silicon and aluminum by atomic layer deposition (ALD). This allows us to characterize proportionality between $\text{Re}(\omega)$ and $\text{Im}(\omega)$ with respect to oxide film thickness.

4:42PM X32.00010 Dielectric and optical properties of SrTiO_3 films deposited from metallo-organic solution, M. SPIES, L.S. ABDALLAH, S. ZOLLNER, NMSU, C.V. WEISS, J. ZHANG, S.P. ALPAY, U of Connecticut, M.W. COLE, Army Research Lab — SrTiO_3 thin films on Si were grown by metallo-organic solution deposition. Spectroscopic ellipsometry was used to determine the ellipsometric angles ψ and Δ in the 0.6 to 6.6 eV spectral range at three angles of incidence. From the region below 3.5 eV (where the films are transparent), we are able to determine the refractive index and the film thickness, which ranges from 140 to 340 nm for different films. The refractive index is similar for all of our films, but 25% lower than that of bulk SrTiO_3 . By contrast, the low-frequency dielectric constant of similar films grown on metalized Si substrates is about the same as bulk SrTiO_3 . Using a B-spline parametrization, we are able to determine the dielectric function of our films from the ellipsometric angles. We find an onset of absorption (band gap) of about 3.7 eV and similar interband electronic transitions of our films as for bulk SrTiO_3 . For our films, the interband peaks are broadened due to poly-crystalline disorder and have a lower amplitude. The reason for the discrepancy between the low-frequency (vibrational) and the high-frequency (electronic) dielectric constant is unclear.

4:54PM X32.00011 Nonlinear photonic crystals of BaTiO_3 and their electro-optic properties, BRUCE WESSELS¹, Department of Materials Science and Engineering and Materials Research Center, and Department of Electrical Engineering and Computer Science, JIANHENG LI, ZHIFU LIU, Department of Materials Science and Engineering and Materials Research Center, Northwestern University, Evanston, IL 60208, USA, ELECTRONIC AND PHOTONIC MATERIALS GROUP TEAM — Future optical systems will require electro-optic (EO) modulators with bandwidths of 100 GHz and low drive voltage. To achieve this, non-linear photonic crystals using epitaxial BaTiO_3 have been proposed. In our work two-dimensional photonic crystal (PhC) structures with a hexagonal array were fabricated from an epitaxial BaTiO_3 thin film using focused ion beam milling. The PhC waveguides were based on $\text{Si}_3\text{N}_4/\text{BTO}/\text{MgO}$ multilayer epitaxial thin film structure. Simulation shows that sufficient refractive index contrast is achieved at 1550 nm to form a bandgap in the PhC structure by milling through the Si_3N_4 and BTO layers. The measured transmission spectrum of the PhC waveguide exhibited a stop-band centered at 1550 nm with well-defined band edges. Photonic crystal electro-optic modulators with a bandwidth of greater than 50 GHz have now been realized. The question of what dielectric properties limit the ultimate bandwidth of the PhC will be addressed.

5:06PM X32.00012 Electro-optic contribution of optically generated small bound polarons in nominally undoped, thermally reduced LiNbO_3 ¹, MIRCO IMLAU, HAUKE BRUENING, Department of Physics, University of Osnabrueck, Germany — Recently we have shown that a spatial modulation of optically generated densities of small bound polarons can be applied for hologram recording in LiNbO_3 [1]. This new type of recording mechanism is of particular interest for the field of nonlinear and ultrafast photonics because of small bound polaron generation on the fs-scale. The grating recording via the photochromic response of small bound polarons was successfully applied to explain gratings recorded with a grating vector aligned orthogonal to the polar c-axis. In this contribution we study the relation of optically generated small bound polarons with pronounced index changes, that were found with values up to 10^{-4} and a grating vector parallel to the c-axis. The Pockels effect that must be driven by an internal electric space-charge field is taken into account. In contrast to the classical photorefractive effect, where slow and long-ranging transport mechanisms must be considered, we discuss the build-up of the space-charge field on the sub-ps-time scale in the model of optical absorption of small polarons, i.e., the optically generated polaron hopping to next-neighboring lattice sites.

5:18PM X32.00013 Dispersive properties of small polaron-based hologram recording in nominally undoped, thermally reduced LiNbO_3 ¹, HAUKE BRUENING, MIRCO IMLAU, Department of Physics, University of Osnabrueck, Germany — We recently discovered a new type of hologram recording in nominally undoped, thermally reduced LiNbO_3 by means of a single intense ns-laser pulse ($\lambda = 532 \text{ nm}$) yielding short-lived volume phase-gratings with unique features [1]: a diffraction efficiency of more than 20% in the NIR spectral range ($\lambda = 785 \text{ nm}$), a stretched-exponential relaxation behavior of the grating efficiency with a lifetime in the ms-range at room temperature and a pronounced dependence on the orientation of the grating vector with respect to the polar c-axis. This type of hologram recording could be successfully modeled by taking into account an optically generated spatial modulation of small electron bipolarons, small bound and free electron polarons. In this contribution we face the unique dispersive properties of this type of hologram recording and particularly present our results for probing light in the blue-green spectral range ($\lambda = 488 \text{ nm}$). We show that the further contribution of small bound hole polarons must be taken into account. Furthermore, we conclude that a considerable diffraction efficiency at the telecommunication wavelength ($\lambda = 1550 \text{ nm}$) can be expected.

Thursday, March 1, 2012 2:30PM - 5:18PM – Session X33 GIMS: Focus Session: X-ray, Gamma Ray, and Electron Diffraction 106

2:30PM X33.00001 First-principles study of γ -ray detectors: Cs-based compounds¹, HOSUB JIN, JINO IM, ARTHUR FREEMAN, Department of Physics and Astronomy, Northwestern University, BRUCE WESSELS, Department of Materials Science and Engineering, Northwestern University, MERCOURI KANATZIDIS, Department of Chemistry, Northwestern University — In an effort to find good candidate materials for γ -ray detectors, Cs-based compounds containing heavy elements, such as in $\text{Cs}_2\text{Hg}_6\text{S}_7$, were investigated. We performed *ab-initio* density functional theory calculations using the full-potential linearized augmented plane wave method². The screened-exchange local density approximation (sX-LDA) scheme was employed to correct the underestimation of the band gap in the LDA method. As a result, the band gap of $\text{Cs}_2\text{Hg}_6\text{S}_7$ is predicted to be 1.23 eV by sX-LDA, corrected from 0.51 eV by LDA. Therefore, $\text{Cs}_2\text{Hg}_6\text{S}_7$ seems to be useful as a γ -ray detecting material in terms of the high density and the band gap. Not only the pristine bulk but also several defect configurations were calculated, which affects the transport properties. Defect formation energy determinations allow us to predict which defect configuration is most likely in $\text{Cs}_2\text{Hg}_6\text{S}_7$.

2:54PM X33.00003 Resolving Interface Interactions in Layered Structures in 3 Dimensions¹, ROZALIYA BARABASH, JON TISCHLER, JOHN BIDAI, Oak Ridge National laboratory, WENJUN LIU, Advanced Photon Source — 3D micro-Laue diffraction was used to probe interface interactions in layered structures. Indented Cr/NiAl composite with alternating submicron size Cr and NiAl lamellae was chosen as a model material. Differential aperture microscopy revealed a twin orientation relationship at the interface between the Cr and NiAl lamellae in the as grown state. The indentation-induced alternation of compressive/tensile residual strains in the neighboring Cr and NiAl lamellae was observed. Line broadening analysis found a two orders of magnitude increase of dislocation density in the near-surface zone in the center of the indent.

3:06PM X33.00004 X-ray Studies of Quantum Fluctuations in SrTiO_3 across its Quantum Paraelectric Phase Transition, SHIH-CHANG WENG, University of Illinois at Urbana-Champaign, RUQING XU, AYMAN SAID, HAWOONG HONG, Argonne National Laboratory, TAI-CHANG CHIANG, Univ. of Illinois at Urbana-Champaign — Strontium titanate (SrTiO_3), with a simple cubic perovskite structure at room temperature, displays a number of interesting phase transitions as a function of temperature and pressure. It exhibits an antiferrodistortive transition at $T_c = 105 \text{ K}$, resulting in a cubic-to-tetragonal structural distortion. This transition has been studied in detail by M. Holt and H. Hong using thermal diffuse scattering and inelastic x-ray scattering methods. Another phase transition takes place at 37 K, below which the system assumes a quantum paraelectric phase. It is generally believed that the classical free energy of the system favors a ferroelectric phase, but this transition never fully develops because of quantum fluctuation. Despite a large number of prior investigations, this quantum phenomenon is still not well understood in terms of the underlying lattice dynamics. Using inelastic x-ray scattering, we have obtained new information about this classic system, including mode softening as a function of temperature.

3:18PM X33.00005 X-ray nanotomography study of insulator-coated tips with sub-micron conducting apex for the combination of scanning probe microscopy and synchrotron radiation¹, VOLKER ROSE, Argonne National Laboratory, TEYU CHIEN, Northwestern University, JOHN FREELAND, DANIEL ROSENMANN, ROBERT WINARSKI, Argonne National Laboratory — Hard X-ray nanotomography provides an important three-dimensional view of insulator-coated “smart tips” that can be utilized for modern emerging scanning probe techniques. Tips, entirely coated by an insulating SiO_2 film except at the very tip apex, are fabricated by means of electron beam physical vapor deposition, focused ion beam milling and ion beam-stimulated oxide growth. Although x-ray tomography studies confirm the structural integrity of the oxide film, transport measurements suggest the presence of defect-induced states in the SiO_2 film [1]. The development of insulator-coated tips can facilitate nanoscale analysis with electronic, chemical, and magnetic contrast by synchrotron-based scanning probe microscopy.

3:30PM X33.00006 Grazing-incidence coherent x-ray imaging in true reflection geometry¹

TAO SUN, ZHANG JIANG, JOSEPH STRZALKA, JIN WANG, Argonne National Laboratory, APS SECTOR 8 TEAM — The development of the 3rd and 4th generation synchrotrons has stimulated extensive research activities in x-ray imaging techniques. Among all, coherent diffractive imaging (CDI) shows great promise, as its resolution is only limited by the wavelength of the source. Most of the CDI work reported thus far used transmission geometry, which however is not suitable for samples on opaque substrates or in which only the surfaces are the regions of interest. Even though two groups have performed CDI experiments (using laser or x-ray) in reflection geometry and succeeded in reconstructing the planar image of the surface, the theoretical underpinnings and analysis approaches of their techniques are essentially identical to transmission CDI. Most importantly, they couldn't obtain the structural information along sample thickness direction. Here, we introduce a reflection CDI technique that works at grazing-incidence geometry. By visualizing Au nanostructures fabricated on Si substrate, we demonstrate that this innovative imaging technique is capable of obtaining both 2D and 3D information of surfaces or buried structures in the samples. In the meanwhile, we will also explain the grazing-incidence-scattering based-algorithm developed for 3D phase retrieval.

3:42PM X33.00007 Soft x-ray absorption spectroscopy measurement methods with using x-ray scattering techniques

H. JANG, Department of Physics, POSTECH, Korea, J.-S. LEE, SSRL, SLAC, USA, W.-S. NOH, K.-T. KO, K.-B. LEE, Department of Physics, POSTECH, Korea, B.-G. PARK, J.-Y. KIM, PAL, POSTECH, Korea, S.H. CHUN, K.H. KIM, Dept. of Physics and Astronomy, Seoul National University, Korea, J.-H. PARK¹, Department of Physics, POSTECH, Korea — Methodology via x-ray absorption spectroscopy (XAS) has been actively employed for exploring the microscopic aspects of materials. In particular, such method within soft x-ray energy range is very useful for investigating strongly correlated systems, such as high T_C superconductor, and multiferroic, including heterostructures. While XAS approach on such materials has been used, however we sometimes confront a few of experimental difficulties; electron motion distortion under external fields, charging effect, and saturation effect. In this presentation, we introduce an alternative approach for overcoming the difficulties in conventional XAS measurement, which uses soft x-ray scattering techniques, i.e., reflection and diffraction. Due to photon-in and photon-out nature, probing depth becomes longer and possible to reduce several problems in conventional total electron yield method. The results of demonstrations on simple monoxide CoO and multiferroic Y-type hexaferrites will be given.

3:54PM X33.00008 Structure uncovering from fluctuation x-ray scattering of randomly oriented nanoparticles¹

GANG CHEN, Lawrence Berkeley National Laboratory, MIGUEL MODESTINO, University of California, Berkeley, BILLY POON, ANDRE SCHIROTZEK, STEFANO MARCHESINI, Lawrence Berkeley National Laboratory, RACHEL SEGALMAN, University of California, Berkeley, ALEXANDER HEXEMER, PETER ZWART, Lawrence Berkeley National Laboratory — We have carried out a fluctuation x-ray scattering experiment on platinum coated gold nanoparticles randomly oriented on a substrate. A complete algorithm for determining the electron density of an individual particle from diffraction patterns of many particles, randomly oriented about a single axis is demonstrated. This algorithm operates on angular correlations among the measured intensity distributions and recovers the angular correlation functions of a single particle from measured diffraction patterns. Taking advantage of the cylindrical symmetry of the nanoparticles, we proposed a cylindrical model to reconstruct the structure of the nanoparticle by fitting both the experimental ring angular auto-correlation and the small angle scattering data. The physical meaning of the resulted structure is discussed in terms of their statistical distributions of the shape and electron density profile.

4:06PM X33.00009 ABSTRACT WITHDRAWN —

4:18PM X33.00010 Hard X-ray resonance in sapphire crystal cavities using back diffraction

Y.-H WU, Y.-W TSAI, Y.-Y CHANG, Dept of Physics, National Tsing Hua University, C.-H CHU, National Synchrotron Radiation Research Center, DAVID G. MIKOLAS, C.-C FU, Institute of Nano Engineering and Microsystems, National Tsing Hua University, S.-L. CHANG, National Synchrotron Radiation Research Center & Dept of Physics, National Tsing Hua University, DEPT OF PHYSICS, NATIONAL TSING HUA UNIVERSITY TEAM, NATIONAL SYNCHROTRON RADIATION RESEARCH CENTER COLLABORATION, INSTITUTE OF NANO ENGINEERING AND MICROSYSTEMS, NATIONAL TSING HUA UNIVERSITY TEAM — The Fabry-Perot type resonators using back diffraction from sapphire crystals for hard X-ray was investigated. On the basis of its less absorption and hexagonal structure, the resonator in sapphire crystals underwent a pure 2-beam diffraction which could enhance the resonance interference and improve finesse compared with the one in silicon crystals. The resonators were manufactured from sapphire crystals using microelectronic lithography process with thickness of a few tens μm . With synchrotron radiation of energy resolution $\Delta E=0.82$ meV at 14.315 keV, X-ray back diffraction from two monolithic sapphire crystal plates shows resonance fringes clearly resulting from coherent interaction inside the energy gap of the (0 0 30) reflection. These experimental results of sapphire cavities imply the potential application for X-ray optics.

4:30PM X33.00011 X-ray wave guiding using three-beam Bragg-surface diffraction

SHIH-LIN CHANG, NSRRC, YAN-ZONG ZHENG, NTHU, WU TAI-SING TEAM, CHEN YI-CHUN TEAM, WU YU-HSIN TEAM, CHEN HSIN-YI TEAM, CHU PEI-CI TEAM — A diffraction-type of X-ray wave guide, in contrast to refraction-type, is proposed using three-beam diffraction geometry to generate a surface diffracted beam propagating along the direction of the wave guide. The three-beam Bragg-surface diffraction involves a symmetric Bragg reflection and a surface diffraction. The former is used to guide a wide-angle incident beam into a silicon crystal. The simultaneously occurring surface diffraction then guides the diffracted beam propagating along the direction of the wave guide that is parallel to the crystal surface. A wave guide with a shallow ditch is then manufactured along the direction of the surface diffraction using the conventional lithographic technique. As a whole the wave guide consists of a three-layer structure of tantalum/photon resist (PMMA)/tantalum, on the Silicon substrate. The surface diffracted X-rays can then be confined in and guided along the layer of photon resist. Details of the design of the wave guide and synchrotron diffraction experiments will be reported.

4:42PM X33.00012 Combined surface plasmon resonance and X-ray absorption spectroscopy¹

MIGUEL ANGEL GARCIA, Institute for Ceramic and Glass CSIC & IMDEA Nanociencia, AIDA SERRANO, Institute for Ceramic and Glass CSIC, Madrid, Spain, OSCAR RODRIGUEZ DE LA FUENTE, Dpt. Material Physics, Univ. Complutense at Madrid, Spain, GERMAN R. CASTRO, Spline Spanish CRG beamline at ESRF, Grenoble, France & ICMM CSIC — We present a system for the excitation and measurement of surface plasmons in metallic films based on the Kretschmann-Raether configuration that can be installed in a synchrotron beamline. The device was mounted and tested in a hard X-ray Absorption beamline, BM25 Spline at ESRF. With this device it is possible to carry on experiments combining surface plasmon and X-ray absorption spectroscopies. The surface plasmons can be used to monitor in situ changes induced by the X-rays in the metallic films or the dielectric overlayer. Similarly, the changes in the electronic configuration of the material when surface plasmons are excited can be measured by X-ray absorption spectroscopy. The resolution of the system allows to observe changes in the signals of the order of 10^{-3} to 10^{-5} depending on the particular experiment and used configuration. The system is available for experiments at the beamline.

¹This work was supported by the Spanish Ministry of Science and Education through the project FIS-2008-06249. We acknowledge the ESRF for provision of synchrotron radiation facilities and the SpLine beamline staff for assistance during XAS experiments.

4:54PM X33.00013 Probing of Strain Mediated Hybrid Multiferroic Devices, EDWIN FOHTUNG, J. KIM, M. MARSH, Department of Physics, University of California-San Diego, NA LEI, Institut d'Electronique Fondamentale, Universit Paris-Sud, S. CHEN, S. SINHA, Department of Physics, University of California-San Diego, D. RAVELOSONA, Institut d'Electronique Fondamentale, Universit Paris-Sud, ERIC FULLERTON, Center for Magnetic Recording Research, University of California-San Diego, OLEG SHPYRKO, Department of Physics, University of California-San Diego — Smart materials for sensor technology, (non) volatile device memories for information technology, and ultrasound generators in medical imaging have one thing in common, their active elements consist of ferroelectrics (FE) driven by voltages or ferromagnetics (FM) driven by magnetization. In the quest to design high functionality devices to meet today's consumer technological demands, high focus has been given to multiferroic [1]. However, the coexistence of magnetic order and ferroelectric polarization combined in a single-phase material has proven to be rare as most of these materials tend to have low magnetic ordering temperatures and are often antiferromagnets, in which the magnetoelectric (ME) coupling effect is intrinsically small. We utilize an alternative approach to design multiferroic-hybrid devices based on FE-FM composites where the ME coupling emerges from strain-mediated interaction between individual phases [2]. We develop a nonlinear thermodynamic theory for strain-mediated direct ME effect and Bragg Ptychographic Coherent Diffraction Imaging (BCDI) serves as the unique tool of choice for sub-nanometer resolution nondestructive probing of the order parameters in the devices [1] N. Spaldin and M. Fiebig, Science 309, 391 (2005). [2] E. Fohntung et al., submitted (2012)

5:06PM X33.00014 First-Principles Modeling for Low-Energy Electron Diffraction Spectra¹, JOHN MCCLAIN, University of New Hampshire, JIEBING SUN, Michigan State University, JAMES HANNON, IBM Thomas J. Watson Research Center, KARSTEN POHL, JIAN-MING TANG, University of New Hampshire — We present a computational method to incorporate density-functional theory (DFT) into the calculation of the reflectivity in low-energy electron diffraction (LEED). Rapid and accurate analysis of diffraction spectra will facilitate the development of low-energy electron microscopy. The dynamical analysis of the electron reflectivity is traditionally carried out using multiple scattering theory with spherically symmetric (muffin-tin) potentials. However, for directionally bonded materials, such as semiconductors, the actual crystal potentials in the interstitial region can be significant, particularly for very low energy electrons. DFT with nonlocal pseudopotentials yields the low-energy electronic structure more accurately. In typical DFT calculations for surfaces, a finite slab is set up in a large unit cell with periodic boundary conditions. By matching the plane waves representing the LEED beams to the Kohn-Sham wave functions at the boundaries of the supercell, we determine the diffraction intensities. To demonstrate that our matching approach is not limited by the finite size of the supercell, we first consider trial models with exact solutions. We then use this approach to analyze the electron diffraction from graphene and compare with features in the band structure.

¹ We acknowledge funding support from NSF DMR-1006863.

Thursday, March 1, 2012 2:30PM - 5:30PM – Session X34 DCP: Focus Session: Nano VI: Junctions and Transport 107A

2:30PM X34.00001 Electronic transport through a light-driven azobenzene molecule switch: A revisit by density functional theory study¹, YAN WANG, HAI-PING CHENG, Dept. of Physics and QTP, University of Florida, USA — Azobenzene, a molecule that changes conformation between *trans* and *cis* configurations, is a candidate light-driven molecule switch. Recent experiments showed that the “on” state with larger measured conductance is associated with the *cis* isomer, which is in contrast with our previous theoretical prediction. Here we reconsider the issue of the molecule-electrode and electrode-electrode coupling by performing a first-principles study of the electronic structures and transport properties of Au-azobenzene-Au molecule junctions. Specifically, we investigate the dependence of the conductance and the current-voltage characteristics in two types of Au electrode, 2-D Au(111) surface and 1-D Au STM tip. We find that, not only the *trans* to *cis* transformation of the molecule, but also the electrode-electrode coupling plays a critical role in determining the conductance near the Fermi level.

¹Supported by US/DOE/BES/DE-FG02-02ER45995.

2:42PM X34.00002 Reliable anchoring groups for single-molecule junctions, M. TERESA GONZÁLEZ, EDMUND LEARY, IMDEA-Nanoscience, CHARALAMBOS EVANGELI, CARLOS ARROYO, GABINO RUBIO-BOLLINGER, Universidad Autonoma de Madrid, NICOLÁS AGRAÏT, Universidad Autonoma de Madrid and IMDEA-Nanoscience — In the field of molecular electronics, thiols have been extensively used as the most common anchoring groups to bind molecules to gold electrodes. However, other anchoring groups as amines can provide interesting advantages. Recently, C60 has been also proposed as a possible very efficient binding group. In this talk, I will present our studies on molecular junctions formed by thiol-, amine-, and C60-terminated molecules. We use a STM (scanning tunneling microscope) break-junction technique to create and characterized single-molecule junctions both in ambient and liquid environment. We compare thiols and amines on the alkane family and an oligo(phenylene ethynylene). Our study of the molecular-junction stretching length allows us to conclude that thiols affect atomic rearrangement at the electrodes significantly more than amines. Using C60-terminated molecules, we have recently introduced a new technique for controllably wiring one molecule at a time. We first get STM images to located isolated molecules on a gold substrate, which are then specifically targeted and contacted using a STM gold tip. This technique offers a significant improvement over other techniques, as it guarantees that one and only one molecule is contacted at a time between the electrodes.

2:54PM X34.00003 Novel quantum interference effects in transport through molecular radicals, JUSTIN BERGFELD, Department of Chemistry, Northwestern University, GEMMA SOLOMON, NanoScience Center and Department of Chemistry, University of Copenhagen, CHARLES STAFFORD, Department of Physics, University of Arizona, MARK RATNER, Department of Chemistry, Northwestern University — In molecules with an unpaired electron (radicals), we predict a correlation-induced ‘Mott-node’ in the transmission spectrum arising from destructive interference between transport contributions from different charge states of the molecule. This class of quantum interference effect has no single-particle analog and cannot be described by effective single-particle theories. Large errors in the thermoelectric properties and nonlinear current-voltage response of molecular radical junctions are introduced when the complementary wave and particle aspects of the electron are not properly treated. A method to accurately calculate the low-energy transport through a radical-based junction using an Anderson model is given.

3:06PM X34.00004 Electron Transport through Porphyrin in Nanoscale Junctions, SWATILEKHA SAHA, GUOQUANG QIAN, KIM M. LEWIS, Rensselaer Polytechnic Institute — As electronic devices become exceedingly small, incorporation of molecules as circuit elements is an attractive option due to their small size and the new functions that molecules can bring to the existing microelectronics. To realize such devices we have fabricated nanogaps of size 2-3 nm on gold wires and positioned porphyrin molecules in the gap. I-V characteristics with and without molecules in the junction is performed and signatures of molecular transport has been identified. We measure inelastic electron tunneling spectra (IETS) from molecular junctions at 4K in ultra-high vacuum to study its vibrational modes. These measurements will be compared to Raman spectra. We discuss how IETS can provide valuable insight to the metal-molecule coupling and the role ligated atoms can play in electron transport properties.

3:18PM X34.00005 Modeling Surface and Stress-Anisotropy Effects on Transformations in Lead Sulfide Nanocrystals Under Pressure, CLIVE BEALING, RICHARD HENNIG, Cornell University — The semiconductor PbS, which displays a small band gap and large excitonic Bohr radius, presents an ideal candidate material for such devices as infrared photon detectors and nanocrystal solar cells.¹ This has motivated a number of studies into the effect of pressure on bulk PbS and PbS nanocrystals (NCs), which organize into highly periodic superlattices with interesting mechanical properties.² The ambient-pressure NaCl-type structure of PbS undergoes a transformation to an orthorhombic structure close to 2.5 GPa, which itself transforms to the CsCl-type structure at 21.5 GPa. We have identified competitive minimum energy paths between the different modifications of PbS using density-functional calculations, and have calculated the associated enthalpy barriers over a range of pressures. In empirical molecular dynamics simulations of the PbS NC transformation under pressure, the effect on the transformation of anisotropic stresses, applied perpendicular to the {100}- and {111}-type facets of the NC, has been investigated. The effect of the NC surface on the stability of metastable modifications in PbS NCs is also considered.

3:30PM X34.00006 Compositional Distribution and Electronic Structure of Ternary Compound Semiconductor Nanocrystals, SUMEET PANDEY, DIMITRIOS MAROUDAS, Department of Chemical Engineering, University of Massachusetts Amherst, MA 01003 — We present a first-principles-based theoretical study of compositional distribution and the resulting electronic structure of ternary quantum dots (TQDs) of compound semiconductor nanocrystals. The analysis is based on first-principles Density Functional Theory (DFT) calculations of atomic and electronic structure and on Monte Carlo (MC) simulations of compositional distribution according to DFT-parameterized valence force field models. We report results for $\text{ZnSe}_{1-x}\text{S}_x$ (type-I), $\text{ZnSe}_{1-x}\text{Te}_x$ (type-II), and $\text{In}_x\text{Ga}_{1-x}\text{As}$ (Reverse type-I) TQDs with nm-scale diffusion lengths and large surface-to-volume ratios. The equilibrium compositional distribution is predicted as a function of overall composition (x) and TQD diameter and its impact on the electron density distribution, electronic density of states, and band gap of the TQDs is analyzed. We find that thermodynamically stable atomic distributions allow for optimal band-gap tunability and wave function confinement in TQDs. Our findings explain the possibility for compositional redistribution that may cause, over time, favorable or adverse changes of the TQD electronic properties with far reaching implications for the synthesis and applications of such nanostructures in devices.

3:42PM X34.00007 The Role of morphology and interface in photoluminescent properties in CdSe/CdS Heterostructure Nanocrystals¹, ARNAUD DEMORTIERE, CHUNXING SHE, Argonne National Laboratory, DONOVAN N. LEONARD, Oak Ridge National Laboratory, SOMA CHATTOPADHYAY, MATTHEW PELTON, ELENA SHEVCHENKO, Argonne National Laboratory — Semiconductor core/shell colloidal nanocrystals (NCs) are promising materials for many applications such as luminescent solar concentrators and lasing media, due to their high PL quantum yield (PLQY) and their charge separation effect. The role of interface in PLQY and in band alignment type is studied in this nanoscale heterojunction. Rod-shaped CdSe/CdS NCs have been synthesized by colloidal chemical approach via epitaxial process, which gives us a fine-tuning of both the spherical core size and rod-like shell length. The modification of the relative morphology changes the effective core/shell band alignment, which impacts the electron and hole delocalization into the nanorods. The evolution of the PLQY and PL lifetimes has been studied as a function of the relative core/shell sizes. High PLQY of up to 80% and PL lifetime of 36 ns have been obtained for a shell-excitation wavelength of 450 nm with a large quasi-Stokes shift (~100nm). Radiative decay rates have been correlated with the rod volume and the band alignment type has been identified as being core size dependent. Finally, UltraSTEM and EXAFS analyses have been used to characterize the crystalline configuration at the core/shell interface and the lattice strain.

3:54PM X34.00008 Electrostatic gating and single-molecule Raman spectroscopy, YAJING LI, JOSEPH HERZOG, DOUGLAS NATELSON, Rice University — SERS(surface enhanced raman spectroscopy) is a useful tool for single molecule spectroscopic investigations. We fabricated nanoscale Au bowtie structures to function as SERS substrates. Following electromigration, these metal nanostructures possess nanometer-scale interelectrode gaps that support highly localized surface plasmon resonances, resulting in SERS electromagnetic enhancements sufficient for single-molecule studies. These structures have also proven suitable for single-molecule electronic transport experiments, in which the underlying substrate can function as a gate electrode to shift molecular electronic levels relative to the metal source and drain. We will present preliminary results of the effect of gate modulation on the SERS and electrical properties of molecules in such junctions.

4:06PM X34.00009 Thermoelectricity and transmission eigenchannels in buckyball junctions¹, MICHAEL STEFFERSON, JARRED HUDSON, JOSHUA BARR, Department of Physics, University of Arizona, JUSTIN BERGFELD, Department of Chemistry, Northwestern University, CHARLES STAFFORD, Department of Physics, University of Arizona — Transmission through nanoscale junctions consisting of a single Buckminsterfullerene molecule between two Pt or Au electrodes is investigated in the Coulomb blockade regime using the nonequilibrium Green's function approach. The Green's function of the buckyball is calculated in the isolated-resonance approximation, including the degenerate HOMO and LUMO orbitals. Electron-electron interactions were included in a constant-interaction model derived from π -electron effective field theory. For junctions with Pt electrodes, we find two transmission channels (despite the 5-fold degenerate HOMO and 3-fold degenerate LUMO resonances) and a positive thermopower. For Au electrodes, the thermopower is strongly affected by quantum interference, and we find just one transmission channel.

¹This material is based upon work supported by the Department of Energy under Award Number DE-SC0006699.

4:18PM X34.00010 Study of Raman Stark Effect in Self-Aligned Nanojunctions, JOSEPH HERZOG, Rice University, DANIEL WARD, University of Wisconsin, DOUGLAS NATELSON, Rice University — Plasmonically-active nanojunctions have been used to study the electrical and optical properties of single molecules by using surface-enhanced Raman spectroscopy (SERS). A new, "self-aligned" fabrication technique has been developed to mass-produce more robust nanojunctions. Similar to nanogaps made by electromigration, these self-aligned nanojunctions have been shown to exhibit strong SERS signal. In addition to having the capabilities of fabricating SERS substrates on a massive scale, the self-aligned technique also produces devices with a longer shelf-life than those fabricated by electromigration. Preliminary studies of the electromigrated devices have demonstrated Raman Stark shifts under DC bias. This work aims to study the Stark effect more in-depth and with the self-aligned nanogaps geometry by integrating the self-aligned structures into electrical circuits. Initial findings and current progress of these simultaneous optical and electrical measurements of a single molecule's vibrational modes will be discussed.

4:30PM X34.00011 Hopping And Trapping of F4TCNQ on h-BN Nanomesh¹, HUANYAO CUN, SILVAN ROTH, ARI SEITSONEN, HAIFENG MA, JURG OSTERWALDER, THOMAS GREBER, None, PHYSICAL-CHEMISTRY INSTITUTE @ UZH COLLABORATION — A single layer of hexagonal boron nitride (h-BN) on Rh(111) (nanomesh) [1] is an excellent template for trapping and self-assembly of molecules. This hexagonal structure has a periodicity of 3.22 nm and an appearance with strongly bound h-BN regions called “pores” of about 2 nm in diameter surrounded by h-BN regions called “wires.” The trapping mechanism traces back to a corrugated electrostatic potential at the surface [2]. We have investigated the adsorption behavior of an electron acceptor molecule, tetrafluoro-tetracyano-quinodimethane (F4TCNQ) on nanomesh by combining XPS, UPS, STM and DFT calculation. The work function increase upon F4TCNQ adsorption indicates electron transfer to the molecules, and is in good agreement with the DFT result. At room temperature, F4TCNQ adsorbs on the “wires” and in the “pores” because of a high mobility. STM measurements allow us to detect the hopping rate of molecules. Upon cooling, molecules are trapped inside of pores, which gives insight into the behavior of a negatively charged molecule, compared to neutral species, in the trapping potential of h-BN nanomesh.

¹The project is supported by the Sinergia Program of the Swiss National Science Foundation.

4:42PM X34.00012 Quantum-Enhanced Thermoelectric Effects in Polycyclic Molecular Junctions¹, JOSHUA BARR, CHARLES STAFFORD, University of Arizona — We calculate the thermoelectric response of a polycyclic molecular junction including electron-electron interactions. To do this, the molecular Green's function is determined via a Lanczos-based technique and π -electron effective field theory is used to model the degrees of freedom most relevant to transport. In these junctions we find that the presence of multiple rings leads to higher order quantum interference features giving rise to dramatic enhancements of molecular thermoelectric effects, consistent with previous predictions based on Hückel theory, which neglected electron correlations.

¹This material is based upon work supported by the Department of Energy under Award Number DE-SC0006699.

4:54PM X34.00013 Decoherence Assisted Single Electron Trapping at Room Temperature, AHMED ELHALAWANY, MICHAEL LEUENBERGER, University of Central Florida — In this work, we theoretically investigate electron transport in heterostructure semiconductor nanowire (NW). We develop a new mechanism to trap an electron in a quantum dot (QD) by means of decoherence. There are six QDs in the NW. Bias voltage (V_b) is applied across the NW and gate voltage (V_g) is applied to the auxiliary QD to control single charge tunneling. The single electron dynamics along the NW is calculated by means of the generalized master equation based on the tight binding model taking into account electron LO phonon interaction (ELOPI) and thermal broadening inside the QDs. It is shown that the decoherence, which is in the pico-second (ps) regime, speeds up the trapping of the electron in the central QD with probability of 70% in less than 2 ps. Our results can be used for the implementation of high temperature single photon source (SPS) or single electron transistor (SET). We acknowledge support from NSF (Grant No. ECCS-0725514), DARPA/MTO (Grant No. HR0011-08-1-0059), NSF (Grant No. ECCS-0901784), AFOSR (Grant No. FA9550-09-1-0450), and NSF (Grant No. ECCS-1128597).

5:06PM X34.00014 First-Principles Studies on Photoinduced Charge Transfer in Functionalized Carbon Nanotubes¹, IEK-HENG CHU, DMITRI KILIN, HAI-PING CHENG, Department of Physics and the Quantum Theory Project, University of Florida, Gainesville, Florida — We have studied the binding energy, electronic structure, optical excitation, and relaxation of dinitromethane molecules ($\text{CH}_2\text{N}_2\text{O}_4$) on semiconducting carbon nanotubes (CNTs) of chiral index ($n, 0$) ($n=7,10,16,19$). The electronic structures calculated from density functional theory (DFT) show that the dinitromethane introduces a localized state inside the band gap of CNT systems of $n=10,16$ and 19 , which indicates that the state can trap an electron when the CNT is photoexcited. The dynamics of intra-band relaxations in such systems has been investigated using reduced density matrix formalism combined with DFT. For pristine CNTs, we have found that the calculated charge relaxation time constants agree well with the experimental time scales. Upon adsorption, these constants are modified and there is not a clear trend for the direction and magnitude of the change. However, our calculations predict that electron relaxation in the conduction band is faster than hole relaxation in the valence band, for CNTs with and without molecular adsorbates.

¹This work is supported by DOE/BES-DE-FG02-02ER45995. The computation is performed using facilities at NERSC.

5:18PM X34.00015 Understanding Crosstalk Between Parallel Molecular Wires, MATTHEW REUTER, Computer Science and Mathematics Division, Oak Ridge National Laboratory, TAMAR SEIDEMAN, MARK RATNER, Department of Chemistry, Northwestern University — Cooperative effects between molecular wires affect conduction through the wires, and studies have yet to clarify the conditions under which these effects enhance (diminish) conduction. Using a simple but general model, we attribute this crosstalk to the duality of energetic splitting and phase interference between the wires' conduction channels. In most cases, crosstalk increases (decreases) conductance when the Fermi level is far from (close to) an isolated wire's resonance. Finally, we discuss strategies for controlling crosstalk between parallel molecular wires.

2:30PM X39.00001 ABSTRACT WITHDRAWN –

3:06PM X39.00002 Designing super-selectivity in multivalent nano-particle binding¹, FRANCISCO MARTINEZ-VERACOECHEA, DAAN FRENKEL, University of Cambridge — A key challenge in nano-science is to design ligand-coated nano-particles that can bind selectively to surfaces that display the cognate receptors above a threshold (surface) concentration. Nano-particles that bind monovalently to a target surface do not discriminate sharply between surfaces with high and low receptor coverage. In contrast, “multivalent” nano-particles that can bind to a larger number of ligands simultaneously, display regimes of “super-selectivity” where the fraction of bound particles varies sharply with the receptor concentration. We present numerical simulations that show that multivalent nano-particles can be designed such that they approach the “on-off” binding behavior ideal for receptor-concentration selective targeting. We propose a simple analytical model that accounts for the super-selective behavior of multi-valent nano-particles. We propose a simple rule of thumb to predict the conditions under which super-selectivity can be achieved. We validate our model predictions against the Monte Carlo simulations. Finally, we investigate the role of multi-component ligand-receptor interactions in the enhancement of targeting selectivity.

¹This work was supported by the ERC (Advanced Grant agreement 227758). Research partially carried out at the Center for Functional Nanomaterials, BNL, which is supported by the US DOE, Office of BES, under Contract No. DE-AC02-98CH10886.

3:18PM X39.00003 Nano-Engineered Cubic Zirconia for Orthopaedic Implant Applications¹

F. NAMAVAR, University of Nebraska Medical Center, A. RUBINSTEIN, University of Nebraska at Omaha, R. SABIRIANOV, UNO, G. THIELE, J. SHARP, U. POKHAREL, R. NAMAVAR, K. GARVIN, UNMC — Osseointegration failure of the prosthesis prevents long-term stability, which contributes to pain, implant loosening, and infection that usually necessitates revision surgery. Cell attachment and spreading in vitro is generally mediated by adhesive proteins such as fibronectin and vitronectin. We designed and produced pure cubic zirconia (ZrO₂) ceramic coatings by ion beam assisted deposition (IBAD) with nanostructures comparable to the size of proteins. Our ceramic coatings exhibit high hardness and a zero contact angle with serum. In contrast to Hydroxyapatite (HA), nano-engineered zirconia films possess excellent adhesion to all orthopaedic materials. Adhesion and proliferation experiments were performed with a bone mesenchymal stromal cells cell line (OMA-AD). Our experimental results indicated that nano-engineered cubic zirconia is superior in supporting growth, adhesion, and proliferation. We performed a comparative analysis of adsorption energies of the FN fragment using quantum mechanical calculations and Monte Carlo simulation on both types of surfaces: smooth and nanostructured. We have found that the initial FN fragment adsorbs significantly stronger on the nanostructured surface than on the smooth surface.

3:30PM X39.00004 Computational characterization of DNA/peptide/nanotube self assembly for bioenergy applications

VANESSA ORTIZ, RURIKO ARAKI, GALEN COLLIER, Department of Chemical Engineering, Columbia University — Multi-enzyme pathways have become a subject of increasing interest for their role in the engineering of biomimetic systems for applications including biosensors, bioelectronics, and bioenergy. The efficiencies found in natural metabolic pathways partially arise from biomolecular self-assembly of the component enzymes in an effort to avoid transport limitations. The ultimate goal of this effort is to design and build biofuel cells with efficiencies similar to those of native systems by introducing biomimetic structures that immobilize multiple enzymes in specific orientations on a bioelectrode. To achieve site-specific immobilization, the specificity of DNA-binding domains is exploited with an approach that allows any redox enzyme to be modified to site-specifically bind to double stranded (ds) DNA while retaining activity. Because of its many desirable properties, the bioelectrode of choice is single-wall carbon nanotubes (SWNTs), but little is known about dsDNA/SWNT assembly and how this might affect the activity of the DNA-binding domains. Here we evaluate the feasibility of the proposed assembly by performing atomistic molecular dynamics simulations to look at the stability and conformations adopted by dsDNA when bound to a SWNT. We also evaluate the effects of the presence of a SWNT on the stability of the complex formed by a DNA-binding domain and DNA.

3:42PM X39.00005 Engineering upconverting nanophosphors as biosensors and biotherapeutic agents

SHUANG FANG LIM, North Carolina State University — Contrast agents play an important role in the study of biological tissues and whole organisms, since they enable visualization of functional structures. Fluorescent contrast agents also enable specific targeting in therapeutic approaches. Developing optimized contrast agents is central to optimizing the performance of both imaging and therapy. Upconversion nanophosphors (UCNPs) are a class of nanoparticles which enable efficient 2-photon fluorescence. Their intrinsic properties of low toxicity, low excitation intensity, narrow fluorescence line width, multiplexing capability, zero fluorescent background, and absence of bleaching and blinking make them strong candidates as a contrast agent with wide applicability. I am working to develop these nanomaterials with biological significance as contrast agents in biolabels, in biosensors and as therapeutic agents in photodynamic therapy. This will be combined with the enhancement of brightness of the UCNPs through coupling to resonant gold nanostructures. The study is necessary in order to bring about a break through in upconversion luminescence enhancement, particularly at ever decreasing nanoparticle sizes necessary for biological applications.

4:18PM X39.00006 Optically Trappable Single Wall Carbon Nanotubes

SAMANTHA ROBERTS, Department of Physics, Cornell University, Ithaca NY, ARTHUR BARNARD, School of Applied and Engineering Physics, Cornell University, Ithaca NY, JOSHUA KEVEK, Department of Physics, Cornell University, Ithaca NY, ALEXANDER RUYACK, Materials Science and Engineering, Cornell University, Ithaca NY, IVE SILVESTRE, RODRIGO LACERDA, Department of Physics, Universidade Federal de Minas Gerais, Brazil, PAUL MCEUEN, Department of Physics, Kavli Institute at Cornell for Nanoscale Science, Cornell University, Ithaca NY — We are developing a single walled carbon nanotube (NT) force probe which would utilize an optical trap to manipulate NTs fitted with micron scale dielectric handles. With its nanometer diameter and micron length a NT harnessed in this way may eventually allow us to probe a cell's membrane and interior. In pursuit of this goal we have developed a method to create parallel arrays of aligned NT cantilevers. In this process we transfer highly aligned NTs to a substrate composed of alternating regions of Si separated by SiO₂. Patterning the NTs and etching away the oxide leaves behind ridges supporting arrays of NT cantilevers 0.7nm-2nm in diameter and up to 700nm in length with densities of over one cantilever per micron. We will discuss our work modifying this technique to pattern and release micron scale NT cantilever probes into solution. We have designed and optically tested lithographically patterned SiO₂ and SU-8 handles, shaped such that they can be manipulated with an optical trap in predictable orientations. We will focus on our current efforts in attaching these optically trappable dielectric handles to individual nanotubes so they can be implemented to make direct force measurements.

4:30PM X39.00007 Self-assembled peptide nanowires on single-layer graphene and MoS₂ with biomolecular doping effect¹

YUHEI HAYAMIZU, CHRISTOPHER R. SO, MEHMET SARIKAYA, Genetically Engineered Materials Science and Engineering Center, Materials Science and Engineering, University of Washington — Developing elegant hybrid systems of biological molecules on atomic single layers (ASLs), such as graphene, is a key in creating novel bio-nanoelectronic devices, where versatile biological functions are integrated with electronics of ASLs. Biomolecules self-assembling into ordered structures on ASLs offer a novel bottom-up approach, where organized supramolecular architectures spatially govern the ASL electronics. Despite the potential in bridging nano- and bio-worlds at the molecular scale, no work has yet realized a way to control electronic and optical properties of ASLs by the biomolecular structures. Here, we demonstrate that engineered dodecapeptides self-assemble into supramolecular networks of peptide nanowires on single-layer graphene and MoS₂. Peptide nanowires introduce electric charge into these ASLs via biomolecular doping. Abrupt boundaries of nanowires create electronic junctions in graphene, which manifest themselves within the single-layer as a self-assembled electronic network. Furthermore, the designed peptides modify both conductivity and photoluminescence of single-layer MoS₂. Controlling nano-electronics through engineered peptides potentially opens up new avenues in self-assembly of nanodevices for future bioelectronics.

4:42PM X39.00008 *Ab initio* Calculations of Electronic Fingerprints of DNA bases on Graphene¹

TOWFIQ AHMED, JOHN J. REHR, Univ. of Washington, SVETLANA KILINA, North Dakota State University, TANMOY DAS, JASON T. HARALDSEN, ALEXANDER V. BALATSKY, Los Alamos National Laboratory — We have carried out first principles DFT calculations of the electronic local density of states (LDOS) of DNA nucleotide bases (A,C,G,T) adsorbed on graphene using LDA with ultra-soft pseudo-potentials. We have also calculated the longitudinal transmission currents $T(E)$ through graphene nano-pores as an individual DNA base passes through it, using a non-equilibrium Green's function (NEGF) formalism. We observe several dominant base-dependent features in the LDOS and $T(E)$ in an energy range within a few eV of the Fermi level. These features can serve as electronic fingerprints for the identification of individual bases from dI/dV measurements in scanning tunneling spectroscopy (STS) and nano-pore experiments. Thus these electronic signatures can provide an alternative approach to DNA sequencing.

¹Supported by the LANL CINT, DOE BES Grant DE-FG03-97ER45623, and DE-AC52-06NA25396

4:54PM X39.00009 Controlled Chemical Patterns with ThermoChemical NanoLithography (TCNL) , KEITH CARROLL, School of Physics, Georgia Institute of Technology, ANTHONY GIORDANO, School of Chemistry and Biochemistry, Georgia Institute of Technology, DEBIN WANG, Lawrence Berkeley National Laboratory, VAMSI KODALI, School of Physics, Georgia Institute of Technology, W.P. KING, Department of Mechanical Science and Engineering, University of Illinois Urbana-Champaign, S.R. MARDER, School of Chemistry and Biochemistry, Georgia Institute of Technology, E. RIEDO, J.E. CURTIS, School of Physics, Georgia Institute of Technology — Many research areas, both fundamental and applied, rely upon the ability to organize non-trivial assemblies of molecules on surfaces. In this work, we introduce a significant extension of ThermoChemical NanoLithography (TCNL), a high throughput chemical patterning technique that uses temperature-driven chemical reactions localized near the tip of a thermal cantilever. By combining a chemical kinetics based model with experiments, we have developed a protocol for varying the concentration of surface bound molecules. The result is an unprecedented ability to fabricate extremely complex patterns comprised of varying chemical concentrations, as demonstrated by sinusoidal patterns of amine groups with varying pitches ($\sim 5\text{--}15\ \mu\text{m}$) and the replication of Leonardo da Vinci's *Mona Lisa* with dimensions of $\sim 30 \times 40\ \mu\text{m}^2$. Programmed control of the chemical reaction rate should have widespread applications for a technique which has already been shown to nanopattern various substrates including graphene nanowires, piezoelectric crystals, and optoelectronic materials.

5:06PM X39.00010 Interface-Limited Spherulitic Growth of Hydroxyapatite/Chondroitin Sulfate Composite Enamel-like Films¹ , GUOBIN MA, YIFEI XU, XIYAN WANG, MU WANG, National Laboratory of Solid State Microstructures, and Department of Physics, Nanjing University, Nanjing 210093, China — Understanding and mimicking the growth of hard tissues such as tooth enamel may lead to innovative approaches toward engineering novel functional materials and providing new therapeutics. Up to now, *in vitro* growth of enamel-like materials is still a great challenge, and the microscopic formation mechanisms are far from well understood. Here we report synthesis of large-scale hydroxyapatite (HAP) and chondroitin sulfate (ChS) composite films by an efficient solution-air interface growth method. The products have the characteristic hierarchical prism structures of enamel and the mechanical properties comparable to dentin. We demonstrate that the films are assembled by spherulites nucleated at the solution surface. The growth of the spherulites is limited by the interfaces between them as well as between the solution and air, leading to the ordered prism structure. The results are beneficial for a clearer understanding of the fundamentals of tooth enamel formation.

5:18PM X39.00011 Biomimetic Calcium Phosphate Crystallization: Synchrotron X-ray Studies¹ , AHMET UYSAL, BENJAMIN STRIPE, PULAK DUTTA, Physics and Astronomy, Northwestern University, BINHUA LIN, MATI MERON, CARS, The University of Chicago — The nucleation and growth of calcium phosphate by organic templates attract great attention due to its relevance to bone biomineralization. In spite of the vast studies in the field, the role of the organic templates in the process is still not well understood. One reason for this drawback is the lack of experimental tools to probe the organic template structure during the process. We studied the nucleation and growth of calcium phosphate under floating Langmuir monolayers, at the air/water interface, using two complementary X-ray scattering methods. We show that Grazing Incidence X-ray Diffraction (GID) and Grazing Incidence X-ray off-Specular Scattering (GIXOS) can reveal the organic-inorganic interface properties *in situ*. By using GID and GIXOS together, we can simultaneously determine the lateral interface structure and the electron density profile normal to the interface. Combined with *ex situ* methods, these techniques can improve our understanding of the role of the organic template during biomineralization.

2:30PM X40.00001 From force-fields to photons: MD simulations of dye-labeled nucleic acids and Monte Carlo modeling of FRET¹ , LORI GOLDNER, Physics Department, University of Massachusetts, Amherst — Fluorescence resonance energy transfer (FRET) is a powerful technique for understanding the structural fluctuations and transformations of RNA, DNA and proteins. Molecular dynamics (MD) simulations provide a window into the nature of these fluctuations on a different, faster, time scale. We use Monte Carlo methods to model and compare FRET data from dye-labeled RNA with what might be predicted from the MD simulation. With a few notable exceptions, the contribution of fluorophore and linker dynamics to these FRET measurements has not been investigated. We include the dynamics of the ground state dyes and linkers in our study of a 16mer double-stranded RNA. Water is included explicitly in the simulation. Cyanine dyes are attached at either the 3' or 5' ends with a 3 carbon linker, and differences in labeling schemes are discussed.

Work done in collaboration with Peker Milas, Benjamin D. Gamari, and Louis Parrot.

3:06PM X40.00002 Quantifying screening ion excesses surrounding stretched, charged polymers , JONATHAN LANDY, Materials Dept., UCSB, DUSTIN MCINTOSH, Physics Dept., UCSB, OMAR SALEH, Materials Dept., UCSB — We present the results of a combined theoretical/experimental study in which we have applied thermodynamic identities to infer – from single molecule force-extension curves taken at different salt concentrations – how the number of screening ions associated with a charged polymer changes as a function of its end to end extension. This number, which can change only through non-linear screening mechanisms, turns out to depend non-trivially on both the concentration of salt and the inherent rigidity of the polymer. In the case of a flexible polymer, such as ssDNA, our data indicates that the excess can change substantially between the fully extended and globule states. The effect is reduced for semi-flexible polymers, such as dsDNA, at physiologically-relevant salt concentrations, but it can again become substantial at lower salt concentrations. Based on these findings, we argue that small ion entropic effects should often contribute substantially to free energy differences between the competing conformational states of charged polymers – both *in vivo* and in certain polymer-based materials systems.

3:18PM X40.00003 Euler buckling and nonlinear kinking of double-stranded DNA , ALEXANDER FIELDS, KEVIN AXELROD, ADAM COHEN, Harvard University — Bare double-stranded DNA is a stiff biopolymer with a persistence length of roughly 53 nm under physiological conditions. Cells and viruses employ extensive protein machinery to overcome this stiffness and bend, twist, and loop DNA to accomplish tasks such as packaging, recombination, gene regulation, and repair. The mechanical properties of DNA are of fundamental importance to the mechanism and thermodynamics of these processes, but physiologically relevant curvature has been difficult to access experimentally. We designed and synthesized a DNA hairpin construct in which base-pairing interactions generated a compressive force on a short segment of duplex DNA, inducing Euler buckling followed by bending to thermally inaccessible radii of curvature. The efficiency of Förster resonance energy transfer (FRET) between two fluorophores covalently linked to the hairpin indicated the degree of buckling. Bulk and single-molecule measurements yielded distinctly different force-compression curves for intact DNA and for strands with single nicks, base pair mismatches, and damage sites. These results suggest that changes in local mechanical properties may play a significant role in the recognition of these features by DNA-binding proteins.

3:30PM X40.00004 Measuring fluctuations in shear stretched DNAs using site specific labeling

, ALLEN PRICE, Emmanuel College, Boston, MA, THOMAS GRAHAM, JOSEPH LOPARO, Harvard Medical School, Boston, MA, JOEL EAVES, University of Colorado, Boulder, CO — We report a new technique for measuring the internal dynamics of surface tethered DNAs in shear flow. Previous studies have used end labeling or intercalating dyes which label the entire length of the DNA. Neither prior method can resolve the internal longitudinal fluctuations of the DNA. Our technique accomplishes this by site specific labeling of five sites in lambda phage DNA using EcoRI labeled with fluorescent quantum dots. We used our technique to determine the two point cross correlation functions of the longitudinal and transverse fluctuations of the DNA under shear flow. Our technique allows us to test current models of the non-equilibrium fluctuations of DNA in shear flow in a way previously inaccessible.

3:42PM X40.00005 Electric-field Assisted Deposition of the DNA on Polymer Surface

, JUNHWAN RYU, Loomis Chaffee School, KE ZHU, JULIA BUDASSI, JONATHAN SOKOLOV, Stony Brook University — Recently, the interaction of DNA with surfaces has been widely studied for its range of applications, including mapping, sequencing and analyzing DNAs. In this study, the Lambda DNA molecules were aligned in 6:50(0.1M NaOH:0.02M MES) buffer solution with different electric fields and deposited onto polymethylmethacrylate (PMMA) surfaces by dipping and retracting PMMA coated silicon wafers into the solution. Electric field was set up with platinum wire and gold plated Si wafer. The DNA strands were dyed with YoYo-1 and observed using a fluorescence microscope. The efficiency of deposition was optimized with respect to DNA concentration, DNA length and electric field. The results indicate that the density and possibly the lengths of the DNA deposited on surface can be controlled by this method. Enhancement of adsorption density of greater than twenty-fold were found using electric field strengths of 10v/cm. This study is supported by NSF-DMR-MRSEC program.

3:54PM X40.00006 Using Microcontact Printing as a Novel Method for Patterned Dyeing of Surface-adsorbed DNA¹

, EMILY SHEA, Smithtown High School East, JULIA BUDASSI, KE ZHU, JONATHAN SOKOLOV, Stony Brook University — We use microcontact printing (MCP)¹ to stain individual DNA molecules adsorbed and combed onto a polymer-coated silicon surface. Polydimethylsiloxane (PDMS) stamps with micron-sized features have been used to selectively stain lambda DNA molecules with SyBr Gold dye. DNA was deposited out of dilute solution onto polymethylmethacrylate (PMMA) layers, 70nm thick, spun-coated on Si wafers, producing linearly stretched and aligned molecules. The stamps were soaked in dye solutions for one minute, followed by wiping of excess solution with a swap. The stamp was pressed onto the surface, varying the pressure and time of application (typically 5-10 minutes) to control the staining. The DNA molecules were imaged with a fluorescence microscope equipped with a cooled CCD camera. Single molecules of DNA were successfully dyed and imaged with stamps having a grating pattern either parallel to or perpendicular to the DNA orientation. Supported by NSF-DMR MRSEC program.

4:06PM X40.00007 Stretching DNA Molecules on a Polymer Surface¹

, JONATHAN ROSENBERG, Torah Academy of Bergen County, KE ZHU, JULIA BUDASSI, JONATHAN SOKOLOV, Stony Brook University — DNA's stretched form is one of great importance to the study of its structural characteristics and sequence. In our experiment, we studied the effects of stretching on lambda DNA, deposited onto Polydimethyl siloxane (PDMS, silicone) using the evaporating drop method. The DNA was dyed with SyBr Gold dye, or YOYO dye, which does not drastically affect the stretching properties of the DNA molecules while being deposited. Different DNA concentrations were used to optimize the density of the DNA on the surface. Once deposited, the DNA was imaged using a confocal microscope, for further measurements and to image stretching, in situ. To stretch the DNA molecules after deposition onto PDMS, the PDMS sample was placed onto a modified linear stage, pinched at the ends. The DNA length was measured throughout stretching. The result shows we successfully stretched DNA strands by 68% without breakage of the strands and without the strands coming off of the PDMS surface. This study is supported by NSF-DMR-MRSEC program.

¹NSF-DMR MRSEC

4:18PM X40.00008 Polarization and Angle Dependence of Fluorescence from Aligned DNA¹

, ASHISH SRIDHAR, Brophy College Preparatory, SURI BANDLER, Ramaz Upper School, KE ZHU, YINGZHAN GU, JULIA BUDASSI, JONATHAN SOKOLOV, Stony Brook University — DNA molecules can be deposited and aligned on various surfaces and imaged by confocal microscopy when labeled with fluorescent dyes. SyBr Gold dye, is known to possess a high angle and polarization dependence. We measured the emission intensity for various incident angles as a function of incident polarization angle. Samples were created by means of dipping PMMA-coated silicon wafers into dyed DNA solutions with DC electric field setup or drop evaporation. The blue laser as the imaging light source was mounted on an optical rail with a polarizer with rotatable half wave plate to change the incident polarization relative to the DNA molecular orientation. When applied to samples dyed using SyBr Gold, a clear change in the intensity of imaged DNA strands was observed though a range of input polarization angle. We have shown that it is possible to optimize the conditions in which aligned DNA is imaged using confocal microscopy by varying the polarization and angle of incidence of laser light on the sample. This study is supported by NSF-DMR-MRSEC program.

4:30PM X40.00009 Calorimetric and Low-Frequency Dielectric Studies of Mesoscopic Ordering in Solutions of Engineered DNA Hairpin Fragments

, K. KASHURI, H. KASHURI, G.S. IANNACCHIONE, WPI — Calorimetry (both AC and MDSC) from 20 to 100 °C, as well as low-frequency (0.1 to 100 kHz) isothermal dielectric measurements have been performed on solutions of DNA fragments as a function of concentration. Custom hairpin DNA fragments were obtained with 13-base unit length and samples made in solution at various concentration. Results show a reproducible heat capacity C_p signature on heating and cooling scans. This thermal behavior of a diluted oligonucleotide chain is very different from that seen for mesoscopic ordering of liquid crystals. The AC C_p peak vanishes and new features are revealed as the temperature scan rate is lowered to 0.017 K min⁻¹. The observed real, ϵ' , and imaginary, ϵ'' , permittivity of the suspended DNA show features indicating low-frequency dynamics that in turn suggests large-scale ordering or agglomeration of the DNA hairpin loops.

4:42PM X40.00010 Modeling of DNA zipper reaction rates

, PRESTON LANDON, CASEY SANCHEZ, ALEXANDER MO, RATNESH LAL, University of California, San Diego — DNA zippers are a thermodynamically driven system consisting of three DNA oligonucleotides. Two of the strands are designed to create a small helix the third is designed to invade and separated the helix. A zipper system consisting of a normal strand (N), a weak strand (W), and an opening strand (O). N is made up of normal DNA bases, while W is engineered with inosine bases substituted for guanine. Inosine forms one less hydrogen bond with cytosine than guanine. By varying the number and order of inosine, W is engineered to provide less than natural bonding affinities to N in forming the [N:W] helix. When O is introduced (a natural complement of N), it competitively displaces W from [N:W] and forms [N:O]. DNA zippers have been used to create new DNA devices such as springs and tweezers and to create functionalized DNA origami structures. Currently, The basic principles and interactions of DNA zippers are not well understood. Here we will report the results on an investigation of several different DNA zipper constructs designed to aid in the creation of a mathematical prediction of the reaction rate for DNA zippers.

4:54PM X40.00011 Moving Beyond Watson-Crick Models of Coarse Grained DNA, KEVIN DORFMAN, MARGARET LINAK, University of Minnesota - Twin Cities, RICHARD TOURDOT, University of Pennsylvania — DNA structure possesses several levels of complexity, ranging from the sequence of bases (primary structure) to base pairing (secondary structure) to its three-dimensional shape (tertiary structure) and can produce a wide variety of conformations in addition to canonical double stranded DNA. By including non-Watson-Crick interactions in a coarse-grained model, we developed a system that not only can capture the traditional B-form double helix, but also can adopt a wide variety of other DNA conformations. In our experimentally parameterized, coarse-grained DNA model we are able to reproduce the microscopic features of double-stranded DNA without the need for explicit constraints and capture experimental melting curves for a number of short DNA hairpins. We demonstrate the utility of the model by simulating more complex tertiary structures such as the folding of the thrombin aptamer, which includes G-quartets, and strand invasion during triplex formation. Our results highlight the importance of non-canonical interactions in DNA coarse-grained models.

5:06PM X40.00012 Direct comparison of the theory of molecular solvation with molecular dynamics and experiment, TYLER LUCHKO, IN SUK JOUNG, GEORGE GIAMBASU, BioMaPS Institute, Rutgers University, DARRIN YORK, DAVID A. CASE, BioMaPS Institute and Chemistry & Chemical Biology, Rutgers University — The reference interaction site model (RISM) provides complete equilibrium sampling of bulk solvent and solvent around a solute of arbitrary shape and size at a fraction of the computational cost of explicit solvent molecular dynamics (MD). Though based on first principles, approximations must be made to achieve numerical solutions. In this study, we first compare RISM to MD and experimental results for bulk solutions of aqueous monovalent ions using the Joung-Cheatham parameters with SPC/E and TIP3P water subject to several approximate closures. Then, using the same parameters and approximations, we evaluate the distribution of water and ions around a 24 base pair strand of DNA, once again, comparing to MD results and experimental observables. In both cases RISM gives the correct qualitative behavior and, often, the correct quantitative behavior. However, this strongly depends on the closure relation used, with higher order, HNC-like closures usually giving better results.

5:18PM X40.00013 Information-based measure of chirality for biomolecules, KAROL BACA LOPEZ, Faculty of Sciences, Autonomous University of the State of Mexico, B. ROY FRIEDEN, College of Optical Sciences, The University of Arizona, ROBERTO LOPEZ, MIGUEL MAYORGA, Faculty of Sciences, Autonomous University of the State of Mexico, ENRIQUE HENANDEZ LEMUS, Computational Genomics Department, National Institute of Genomic Medicine — Homochirality is a common property of biomolecules such as DNA, RNA and proteins. In particular, D-ribose and D-deoxyribose enantiomers are found within living cells, while their mirror images, the L-enantiomers, are not known to occur naturally even though the configurations are highly stable. On the other hand, proteins are formed by L-amino acids, not by their mirror images. Why? In this work, we propose the use of Fisher Information (FI) I as a measure of chirality or dissimilarity between enantiomers. We performed Hartree-Fock (HF) and Density Functional Theory (DFT) calculations to obtain the electronic wave function $\Psi(x, y, z)$ and corresponding density function $\rho(x, y, z)$ for each of the natural and synthetic forms of oligoribonucleotides and alanine amino acid. The four wave functions $\Psi(x, y, z)$ are used to compute the FI evaluated from two different viewpoints: a coherent viewpoint, which includes the phase part of each $\Psi(x, y, z)$, and an incoherent or classical viewpoint, which ignores the phase. Our goal is to describe the extent to which the information content in chiral molecules (D- and L-) plays a role in selecting one or the other isomer in nature.

Session X41 DBIO DPOLY DCOMP: Focus Session: Physics of Proteins II: Folding and Structure 156B

2:30PM X41.00001 Simulations of the folding/unfolding of biomolecules under solvent, and pressure perturbations¹, ANGEL GARCIA², Rensselaer Polytechnic Institute — Proteins exhibit marginal stability, determined by the balance of many competing effects. This stability can be perturbed by changes in temperature, pH, pressure, and other solvent conditions. Osmolytes are small organic compounds that modulate the conformational equilibrium, folded (F) and unfolded (U), of proteins as cosolvents. Protecting osmolytes such as trimethylamine N-oxide (TMAO), glycerol, and sugars that push the equilibrium toward F play a crucial role in maintaining the function of intracellular proteins in extreme environmental conditions. Urea is a denaturing osmolyte that shifts the equilibrium toward U. We will describe calculations of the reversible folding/unfolding equilibrium, under various solution conditions that include urea, high pressure, and different charge states of the Trp-cage miniprotein. The folding/unfolding equilibrium is studied using all-atom Replica exchange MD simulations. For urea, the simulations capture the experimentally observed linear dependence of unfolding free energy on urea concentration. We find that the denaturation is driven by favorable direct interaction of urea with the protein through both electrostatic and van der Waals forces and quantify their contribution. Though the magnitude of direct electrostatic interaction of urea is larger than van der Waals, the difference between unfolded and folded ensembles is dominated by the van der Waals interaction. We also find that hydrogen bonding of urea to the peptide backbone does not play a dominant role in denaturation. The unfolded ensemble sampled depends on urea concentration, with greater urea concentration favoring conformations with greater solvent exposure.

3:06PM X41.00002 Accurate prediction of explicit solvent atom distribution in HIV-1 protease and F-ATP synthase by statistical theory of liquids, DANIEL SINDHIKARA, NORIO YOSHIDA, FUMIO HIRATA, Institute for Molecular Science — We have created a simple algorithm for automatically predicting the explicit solvent atom distribution of biomolecules. The explicit distribution is coerced from the 3D continuous distribution resulting from a 3D-RISM calculation. This procedure predicts optimal location of solvent molecules and ions given a rigid biomolecular structure. We show examples of predicting water molecules near KNI-275 bound form of HIV-1 protease and predicting both sodium ions and water molecules near the rotor ring of F-ATP synthase. Our results give excellent agreement with experimental structure with an average prediction error of 0.45-0.65 angstroms. Further, unlike experimental methods, this method does not suffer from the partial occupancy limit. Our method can be performed directly on 3D-RISM output within minutes. It is useful not only as a location predictor but also as a convenient method for generating initial structures for MD calculations.

3:18PM X41.00003 Analysis and Interpretation of Single Molecule Protein Unfolding Kinetics

, HERBERT LANNON, JASNA BRUJIC, New York University — The kinetics of protein unfolding under a stretching force has been extensively studied by atomic force microscopy (AFM) over the past decade [1]. Experimental artifacts at the single molecule level introduce uncertainties in the data analysis that have led to several competing physical models for the unfolding process. For example, the unfolding dynamics of the protein ubiquitin under constant force has been described by probability distributions as diverse as exponential [2,3], a sum of exponentials, log-normal [4], and more recently a function describing static disorder in the Arrhenius model [5]. A new method for data analysis is presented that utilizes maximum likelihood estimation (MLE) combined with other traditional statistical tests to unambiguously rank the consistency of these and other models with the experimental data. These techniques applied to the ubiquitin unfolding data shows that the probability of unfolding is best fit with a stretched exponential distribution, with important implications on the complexity of the mechanism of protein unfolding.

3:30PM X41.00004 Investigating protein structure and folding with coherent two-dimensional infrared spectroscopy

, CARLOS BAIZ, CHUNTE PENG, MICHAEL REPPERT, KEVIN JONES, ANDREI TOKMAKOFF, Massachusetts Institute of Technology — We present a new technique to quantitatively determine the secondary structure composition of proteins in solution based on ultrafast two-dimensional infrared (2DIR) spectroscopy. The percentage of residues in alpha-helix, beta-sheet, and unstructured conformations is extracted from a principal component analysis of the measured amide-I 2DIR spectra. We benchmark the method against a library of commercially-available proteins by comparing the predicted structure compositions with the x-ray crystal structures. The new technique offers sub-picosecond time resolution, and can be used to study systems that are difficult to study with conventional methods such as gels, intrinsically disordered peptides, fibers, and aggregates. We use the technique to investigate the structural changes and timescales associated with folding and denaturing of small proteins via equilibrium and transient temperature-jump 2DIR spectroscopy.

3:42PM X41.00005 Protein Folding and Functional Dynamics

, FENG GAI, University of Pennsylvania — Proteins are intrinsically flexible and dynamic objects. Thus, protein dynamics are intimately coupled to their function. In many cases, however, it is difficult to directly probe protein conformational dynamics occurring on either very fast or very slow timescales with high spatial resolution. In this talk, several examples will be discussed to show how ensemble and single-molecule spectroscopic methods can be used to follow protein folding events taking place on the nanosecond timescale and slow conformational dynamics associated with function.

4:18PM X41.00006 Folding a protein with equal probability of being helix or hairpin¹

, CHUNG-YU MOU, CHUN-YU LIN, National Tsing Hua University, Taiwan, ROC, NAN-YOW CHEN, National Center for High-Performance Computing, Taiwan, ROC — We explore the possibility for the native state of a protein being inherently a multi-conformation state in an ab initio coarse-grained model. Based on the Wang-Landau algorithm, the complete free energy landscape for the designed sequence 2D4X: INYWLAHAKAGYIVHWT A is constructed. It is shown that 2DX4 possesses two nearly degenerate native states: one has a helix structure, while the other has a hairpin structure and their energy difference is less than 2% of that of local minimums. Furthermore, the hydrogen-bond and dipole-dipole interactions are found to be two major competing mechanisms in transforming one conformation into the other. Our results indicate that degenerate native states are stabilized by subtle balance between different interactions in proteins; furthermore, degeneracy only happens for small proteins of sizes being around 18 amino acids or 40-50 amino acids. These results provide important clues to the study of native structures of proteins.

¹We acknowledge support of National Science Council of Taiwan.

4:30PM X41.00007 Generic transition hierarchies of lattice HP protein adsorption: A Wang-Landau study¹

, YING WAI LI, D.P. LANDAU, Center for Simulational Physics, University of Georgia, T. WÜST, Swiss Federal Research Institute — We have applied Wang-Landau sampling with appropriate trial moves² to investigate the thermodynamics and structural properties of the HP lattice protein model³ interacting with an attractive substrate. The conformational “phase transitions” of several benchmark HP sequences have been identified by a comprehensive canonical analysis of the specific heat and structural observables, e. g. radius of gyration and thermal derivatives of number of surface contacts. Three major “transitions”: adsorption, hydrophobic core formation, and “flattening” of adsorbed structures, are observed. Depending on the surface attractive strength relative to the intra-protein attraction among the H monomers, these processes take place in a different order upon cooling. We identify a small number of generic categories that are sufficient to classify the folding hierarchies for different HP chains consisting of assorted sequences and chain lengths, regardless of the monomer type that the surface attracts. We thus believe that this classification scheme is generally applicable to lattice protein adsorption problems.

4:42PM X41.00008 Elucidating Structure and Catalytic Cycles of Anti- or Ferro-magnetic Iron Enzymes from Spin Density Functional Theory¹

, JORGE H. RODRIGUEZ, Department of Physics, Purdue University — Nature uses metal-containing enzymes to catalyze important biochemical reactions. Some enzymes, such as methane monooxygenase hydroxylase (MMOH), contain (anti)ferromagnetic binuclear iron centers that interact with dioxygen and/or other substrates to facilitate biochemical functions. We have studied the electronic and magnetic structures of several enzyme binuclear iron centers and predicted their spectroscopic properties. We have used spin density functional theory (SDFT) to predict ⁵⁷Fe Mössbauer and other spectral parameters of MMOH and structurally related iron-containing enzymes. Upon dioxygen binding, the diiron center of MMOH undergoes a ferromagnetic to antiferromagnetic transition which may play an important role in its catalytic activity. In addition, based on our ability to predict spectroscopic data, we have been able to predict the structure of a key reaction intermediate in the MMOH catalytic cycle for which there is no X-ray structure.

4:54PM X41.00009 AWSEM-MD: Coarse-grained Protein Structure Prediction Using Physical Potentials and Bioinformatically Based Local Structure Biasing, ARAM DAVTYAN, University of Maryland at College Park, WEIHUA ZHENG, NICK SCHAFER, University of California at San Diego, CECILIA CLEMENTI, PETER WOLYNES, Rice University, GAREGIN PAPOIAN, University of Maryland at College Park, PAPOIAN GROUP TEAM, WOLYNES GROUP COLLABORATION — The Associative memory, Water mediated, Structure and Energy Model (AWSEM) is a coarse-grained protein model. When combined with a sequence alignment method, AWSEM can be used to perform de novo protein structure prediction. Herein we present structure prediction results for a particular choice of sequence alignment method based on short residue sequences called fragments. We demonstrate the model's structure prediction capabilities for three variants on a standard sequence alignment protocol, all of which assume that the structure of the target sequence is not known. We show that the inclusion of structures from homologous sequences in the fragment memory search improves structure prediction only marginally. However, when the fragment search is restricted to only homologous sequences, AWSEM can perform high-resolution structure prediction.

5:06PM X41.00010 Combining first principles and replica exchange for the structure of two large peptides: Ac-Ala₁₉-LysH⁺ vs. Ac-LysH⁺-Ala₁₉¹, FRANZISKA SCHUBERT, MARIANA ROSSI, CARSTEN BALDAUF, VOLKER BLUM, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, D-14195 Berlin — Predicting the structure of peptides requires a high accuracy for “weak” interactions. We here focus on the predominant structure types of two alanine-based peptides *in vacuo* from first principles and in comparison to experimental IR spectroscopy¹: Ac-Ala₁₉-LysH⁺, which is expected to be α -helical [1,2], and Ac-LysH⁺-Ala₁₉, where globular monomers, helical dimers, and helices with non-standard protonation sites are expected [2]. Despite supposedly very different conformers, Ac-LysH⁺-Ala₁₉ and Ac-Ala₁₉-LysH⁺ yield very similar experimental IR spectra in the ≈ 1000 -2000 cm⁻¹ wavenumber range. We utilize a two-stage structure search approach: we begin by a force-field based replica exchange molecular dynamics (REMD) scan followed by further REMD scans based on density functional theory with the van der Waals corrected [3] PBE functional. We suggest plausible candidates for all likely structure prototypes. Helix-turn-helix motifs emerge as the most likely candidates and explain a subtle peak shift in experiment. [1] M. Rossi *et al.*, JPCL **1**, 3465 (2010); [2] M. Jarrold, PCCP **9**, 1659 (2007); [3] A. Tkatchenko, M. Scheffler, PRL **102**, 073005 (2009).

5:18PM X41.00011 Enhanced Wang Landau Sampling of Adsorbed Protein Conformations, MITHUN RADHAKRISHNA, Columbia University, SUMIT SHARMA, Princeton University, SANAT K. KUMAR, Columbia University — Using computer simulations to model the folding of proteins into their native states is computationally expensive due to the extraordinarily low degeneracy of the ground state. In this paper, we develop an efficient way to sample these folded conformations using Wang Landau sampling coupled with the configurational bias method (which uses an unphysical “temperature” which is between the collapse and folding transition of the protein). This method speeds-up the folding process by roughly an order of magnitude over existing algorithms. We apply this method to study the adsorption of HP protein fragments on a hydrophobic surface, a model which is a close analog of one presented recently by Shea and coworkers. We are able to readily capture the fact that these fragments, which are unstructured in the bulk, acquire secondary structure upon adsorption onto a strong hydrophobic surface. Apparently, the presence of a hydrophobic surface allows these random coil fragments to fold by providing hydrophobic contacts that were lost in protein fragmentation.

3:06PM X42.00002 Polymer-nematic textures in spherical confinement: a coarse-grained model of DNA packing¹, GREGORY GRASON, Dept. of Polymer Science & Engineering, University of Massachusetts Amherst, HOMIN SHIN, Dept. of Materials Science & Engineering, University of Illinois at Urbana-Champaign — Inspired to understand the complex spectrum of space-filling organizations the dsDNA genome within the capsid of bacterial viruses, we study a minimal, coarse-grained model of single chains densely-packed into a finite spherical volume. We build the three basic elements of the model—i) the absence of chain ends ii) the tendency of parallel-strand alignment and iii) a preference of uniform areal density of chain segments—into a polymer nematic theory for confined chains. Given the geometric constraints of the problem, we show that axially symmetric packings fall into one of three topologies: the coaxial spool; the simple solenoid; and the twisted-solenoid. Among these, only the twisted-solenoid fills the volume without the presence of line-like disclinations, or voids, and are therefore generically preferred in the incompressible limit. An analysis of the thermodynamic behavior of this simple model reveals a rich behavior, a generic sequence of phases from the empty state for small container sizes, to the coaxial spool configuration at intermediate sizes, ultimately giving way, via a second-order, symmetry-breaking transition, to the twisted-solenoid structure above a critical sphere size, which we estimate to be within the range of bacteriophage capsid dimensions.

3:18PM X42.00003 Conformational Fluctuations of Chromosomal DNA in *E. coli*, CLARISSA FREEMAN, JENS-CHRISTIAN MEINERS, University of Michigan — We measured the conformational fluctuations of the bacterial chromosome in *E. coli* *in vivo* using fluorescence correlation spectroscopy (FCS). The chromosomal DNA was randomly decorated with a cell-permeable intercalating dye. Conformational fluctuations of the DNA move the fluorophores stochastically into the diffraction-limited excitation volume of a focused laser beam. The time correlation function of the fluorescence intensity reflects the underlying dynamics of the DNA on length scales down to ~ 200 nm. A comparison between live cells and dead yet structurally intact cells shows identical fluctuation spectra for short time scales, yet substantial differences for frequencies below 100 Hz. Live cells show much stronger fluctuations in this regime. This observation points to the crucial importance of active molecular motor action, as opposed to passive thermal noise, in driving larger conformational fluctuations in the chromosomal DNA, in particular on length scales exceeding ~ 500 nm.

3:30PM X42.00004 Spatial organization and dynamics of interphase yeast chromosomes¹ , BARIS AVSAROGLU, Dept of Physics, Brandeis Uni, Waltham MA, SUSANNAH GORDON-MESSER, Dept of Biology, Brandeis Uni, Waltham MA, MIRIAM FRITSCHKE, Inst fur Theoretische Physik, Heidelberg University, Heidelberg Germany, JUNGOH HAM, Dept of Biology, Brandeis Uni, Waltham MA, DIETER W. HEERMANN , Inst fur Theoretische Physik, Heidelberg University, Heidelberg Germany, JAMES E. HABER , Dept of Biology and Rosenstiel Center, Brandeis Uni, Waltham MA, JANE KONDEV, Dept of Physics, Brandeis Uni, Waltham MA — Understanding how the genome is spatially organized is an important problem in cell biology, due to its key roles in gene expression and DNA recombination. Here we report on a combined experimental and theoretical study of the organization and dynamics of yeast chromosome III which has a functional role in the yeast life cycle, in particular, it is responsible for mating type switching. By imaging two fluorescent markers, one at the spindle pole body (SPB) and the other proximal to the HML locus that is involved in DNA recombination during mating type switching, we measured the cell to cell distribution of distances and the mean square displacement between the markers as a function of time. We compared our experimental results with a random-walk polymer model that takes into account tethering and confinement of chromosomes in the nucleus, and found that the model recapitulates the observed spatial and temporal organization of chromosome III in yeast in quantitative detail. The polymer model makes specific predictions for mating-type switching in yeast, and suggests new experiments to test them.

3:42PM X42.00005 Reverse-engineering Chromatin Folding via The Gaussian Polymer Model , MANJUL APRATIM, Physics and Astronomy, Rutgers, The State University of New Jersey, SWAGATAM MUKHOPADHYAY, Cold Spring Harbor Labs, ANIRVAN SENGUPTA, Physics and Astronomy, and BioMaPS Institute, Rutgers, The State University of New Jersey — Recent technological advancements in techniques exploring chromatin conformation, such as 3C and its derivatives, provide us with information about contact frequency between chromatin segments. There is an urgent need for systematic methods of reconstructing folding patterns of the chromatin from such data. Dekker et al have previously summarized this experimental data in the form of a so-called 'spatially averaged' conformation around which fluctuations occur. This would be accurate for regions where the chromatin is mostly frozen around one structure, but rather misleading for more dynamic euchromatin. To address the ill-posed problem of reconstruction of probability distribution from pairwise contact data, we propose a minimum relative entropy approach, which reduces to finding an interacting polymer model that reproduces the contact strengths, and allows for both very dynamic as well as frozen structures depending upon the indicated degree of interaction. While comparing contact frequencies computed from this model to observed data, we introduce the minimal number of interactions required as determined by criteria controlling model complexity. This technique allows us to reproduce known interactions for several biologically important regions like the beta-globin locus.

3:54PM X42.00006 Electrohydrodynamics of DNA in confinement , JONATHAN K. WHITMER, Department of Chemical and Biological Engineering, University of Wisconsin–Madison, JUAN P. HERNANDEZ-ORTIZ, Dept. of Materials, Universidad Nacional de Columbia, JUAN J. DE PABLO, Department of Chemical and Biological Engineering, University of Wisconsin–Madison — New methods of DNA sequencing aim to exploit the direct reading of individual DNA molecules. Such methods require one be able to elongate DNA molecules so that individual base-pairs may be accessed. In turn, this requires a detailed understanding of the mechanical and thermodynamic behavior of DNA, so that external manipulation and confinement successfully stretch the molecule. We aim to study the interplay between electrostatic and hydrodynamic interactions on the conformations of coarse-grained DNA through use of computer simulations with the general geometry Ewald-like method (GGEM), both in bulk and under geometric confinement.

4:06PM X42.00007 Susceptibilities to DNA Structural Transitions within Eukaryotic Genomes , DINA ZHABINSKAYA, CRAIG BENHAM, SALLY MADDEN, University of California at Davis — We analyze the competitive transitions to alternate secondary DNA structures in a negatively supercoiled DNA molecule of kilobase length and specified base sequence. We use statistical mechanics to calculate the competition among all regions within the sequence that are susceptible to transitions to alternate structures. We use an approximate numerical method since the calculation of an exact partition function is numerically cumbersome for DNA molecules of lengths longer than hundreds of base pairs. This method yields accurate results in reasonable computational times. We implement algorithms that calculate the competition between transitions to denatured states and to Z-form DNA. We analyze these transitions near the transcription start sites (TSS) of a set of eukaryotic genes. We find an enhancement of Z-forming regions upstream of the TSS and a depletion of denatured regions around the start sites. We confirm that these findings are statistically significant by comparing our results to a set of randomized genes with preserved base composition at each position relative to the gene start sites. When we study the correlation of these transitions in orthologous mouse and human genes we find a clear evolutionary conservation of both types of transitions around the TSS.

4:18PM X42.00008 Mechanics of DNA Sticky End Joints , EHSAN BAN, CATALIN PICU, Rensselaer Polytechnic Institute — Cohesive DNA sticky ends along with synthesis of stable branched DNA molecules have enabled self assembly of versatile new DNA structures including DNA crystals. Sticky end joints are formed by pairing of complimentary unpaired bases at the end of two DNA molecules. In this work mechanics of the DNA sticky end joints is investigated by using molecular dynamics simulations. Effects of base sequence, joint length, and salt concentration on the mechanical behavior of the joints is studied. The results have implications in understanding the mechanics of DNA crystals and other structures containing sticky end joints.

4:30PM X42.00009 Statistical physics of nucleosome positioning and chromatin structure¹ , ALEXANDRE MOROZOV, Department of Physics and Astronomy, Rutgers University — Genomic DNA is packaged into chromatin in eukaryotic cells. The fundamental building block of chromatin is the nucleosome, a 147 bp-long DNA molecule wrapped around the surface of a histone octamer. Arrays of nucleosomes are positioned along DNA according to their sequence preferences and folded into higher-order chromatin fibers whose structure is poorly understood. We have developed a framework for predicting sequence-specific histone-DNA interactions and the effective two-body potential responsible for ordering nucleosomes into regular higher-order structures. Our approach is based on the analogy between nucleosomal arrays and a one-dimensional fluid of finite-size particles with nearest-neighbor interactions. We derive simple rules which allow us to predict nucleosome occupancy solely from the dinucleotide content of the underlying DNA sequences. Dinucleotide content determines the degree of stiffness of the DNA polymer and thus defines its ability to bend into the nucleosomal superhelix. As expected, the nucleosome positioning rules are universal for chromatin assembled in vitro on genomic DNA from baker's yeast and from the nematode worm *C.elegans*, where nucleosome placement follows intrinsic sequence preferences and steric exclusion. However, the positioning rules inferred from in vivo *C.elegans* chromatin are affected by global nucleosome depletion from chromosome arms relative to central domains, likely caused by the attachment of the chromosome arms to the nuclear membrane. Furthermore, intrinsic nucleosome positioning rules are overwritten in transcribed regions, indicating that chromatin organization is actively managed by the transcriptional and splicing machinery.

5:06PM X42.00010 Interrogating Nucleosome Positioning Through Coarse-Grain Molecular Simulation¹, GORDON S. FREEMAN, DANIEL M. HINCKLEY, University of Wisconsin-Madison, VANESSA ORTIZ, Columbia University, JUAN J. DE PABLO, University of Wisconsin-Madison — Nucleosome positioning plays a crucial role in biology. As the fundamental unit in chromosome structure, the nucleosome core particle (NCP) binds to approximately 147 DNA base pairs. The location of bound NCPs in the genome, therefore, affects gene expression. The specific positioning of NCPs has been experimentally probed and competing viewpoints have been presented in the literature. Models for nucleosome positioning based on sequence-dependent flexibility (a genomic “code” for nucleosome positioning) have been demonstrated to explain available experimental data. However, so do statistical models with no built-in sequence preference; the driving force for NCP positioning therefore remains an open question. We use a coarse-grain model for the NCP in combination with advanced sampling techniques to probe the sequence preference of NCPs. We present a method for determining the relative affinity of two DNA sequences for the NCP and use this method to compare high- and low-affinity sequences. We discuss several coarse-grain protein models with varying level of detail to examine the impact of model resolution on the agreement of our results with experimental evidence. We also investigate the dynamics of the NCP-DNA complex and their dependence on system characteristics.

¹This work was supported by the National Science Foundation through the University of Wisconsin-Madison Nanoscale Science and Engineering Center, DMR-0832760.

5:18PM X42.00011 Dynamics of Histone Tails within Chromatin¹, MORGAN BERNIER, JUSTIN NORTH, MICHAEL PAGE, The Ohio State University Physics Department, CHRISTOPHER JARONIEC, The Ohio State University Chemistry Department, CHRISTOPHER HAMMEL, MICHAEL POIRIER, The Ohio State University Physics Department, CENTER FOR EMERGENT MATERIALS PROTO-INTERDISCIPLINARY RESEARCH GROUP COLLABORATION — Genetic information in humans is encoded within DNA molecules that is wrapped around histone octamer proteins and compacted into a highly conserved structural polymer, chromatin. The physical and material properties of chromatin appear to influence gene expression by altering the accessibility of proteins to the DNA. The tails of the histones are flexible domains that are thought to play a role in regulating DNA accessibility and compaction; however the molecular mechanisms for these phenomena are not understood. I will present CW-EPR studies on site directed spin labeled nucleosomes that probe the structure and dynamics of these histone tails within nucleosomes.

Thursday, March 1, 2012 2:30PM - 5:30PM – Session X43 DBIO DFD: Invited Session: Bacterial Swimming and Chemotaxis 157AB

2:30PM X43.00001 Bacterial Swimming and Accumulation at the Fluid Boundaries, JAY TANG, Physics Department, Brown University — Micro-organisms often reside and thrive at the fluid boundaries. The tendency of accumulation is particularly strong for flagellated bacteria such as *Escherichia coli*, *Vibrio alginolyticus*, and *Caulobacter crescentus*. We measured the distribution of a forward swimming strain of *Caulobacter crescentus* near a solid surface using a three-dimensional tracking technique based on darkfield microscopy and found that the swimming bacteria accumulate heavily within micrometers from the surface, even though individual swimmers are not trapped long enough to display circular trajectories. We attributed this accumulation to frequent collisions of the swimming cells with the surface, causing them to align parallel to the surface as they continually move forward. The extent of accumulation at the steady state is accounted for by balancing alignment caused by these collisions with the rotational Brownian motion of the micrometer-sized bacteria. We performed simulations based on this model, which reproduces the measured results. Additional simulations demonstrate the dependence of accumulation on swimming speed and cell size, showing that longer and faster cells accumulate more near a surface than shorter and slower ones do. Our ongoing experimental effort also includes observation of similar phenomena at the interfaces of either water-oil or water-air, noting even stronger trapping of the swimming bacteria than near a solid surface. These studies reveal a rich range of fluid physics for further analysis.

3:06PM X43.00002 Bacterial Motility Patterns and Their Chemotaxis Behaviors, XIAOLUN WU, University of Pittsburgh — No abstract available.

3:42PM X43.00003 Periplasmal Physics: The Rotational Dynamics of Spirochetal Flagella, GREG HUBER, University of Connecticut Health Center, and University of Connecticut Storrs — Spirochetes are distinguished by the location of their flagella, which reside within the periplasm: the tiny space between the bacterial cell wall and the outer membrane. In *Borrelia burgdorferi* (the causative agent of Lyme Disease), rotation of the flagella leads to cellular undulations that drive swimming. Exactly how these shape changes arise due to the forces and torques acting between the flagella and the cell body is unknown. By applying low-Reynolds number hydrodynamic theory to the motion of an elastic flagellum rotating in the periplasm, we show that the flagella are most likely separated from the bacterial cell wall by a lubricating layer of fluid. We obtain analytical solutions for the force and torque on the rotating flagellum through lubrication analysis, as well as through scaling analysis, and find results are in close agreement numerical simulations. (Joint work with J. Yang and C.W. Wolgemuth.)

4:18PM X43.00004 Microfluidics for bacterial chemotaxis, MINGMING WU, Biological and Environmental Engineering Department, Cornell University, Ithaca, NY 14853 — The emerging microfluidic technology opens up new opportunities for bacterial chemotaxis studies. In this talk, I will present our efforts in correlating molecular level events with cellular phenotypes in bacterial chemotaxis using microfabricated device. I will present results of bacterial chemotaxis in both single and dual chemical gradients. In single gradient experiments, we demonstrated that bacteria sense the chemical concentration at a logarithmic scale, similar to sensory system in higher organism. In dual gradient experiments, we showed that the number ratio of the two different types of receptor plays a critical role in bacteria's chemotactic decision making process. Experimental results based on single cell analysis will be presented. This work is supported by the National Science Foundation and the Cornell Nanobiotechnology Center.

4:54PM X43.00005 Directional swimming in bacteria: active and passive gradient responses, ROMAN STOCKER¹, MIT — The ability to swim directionally is paramount for bacteria, in their quest for nutrients and favorable microhabitats. This ability depends on both active and passive responses to gradients. Here we bring an example from each case, based on novel microfluidic experiments that quantify the swimming behavior of bacteria. First, we describe their active response to oxygen gradients - or aerotaxis - and show the unexpected consequences of competing oxygen gradients with nutrient gradients. Then, we present the first observations of directional swimming by bacteria in response to fluid velocity gradients - or rheotaxis. Combining experiments with mathematical modeling we demonstrate that, unlike in larger organisms such as fish, rheotaxis in bacteria is passive, resulting from a previously undetected torque that originates from the chirality of the bacterial flagellum.

Thursday, March 1, 2012 2:30PM - 4:54PM –
Session X44 DPOLY: Focus Session: Directed Assembly of Hybrid Materials - Nanoparticles in Micelles 157C

2:30PM X44.00001 Multigeometry nanoparticles and higher-order assemblies from block copolymer blends via kinetic control and chemical modification, JIAHUA ZHU, Department of Materials Science and Engineering, University of Delaware, SHIYI ZHANG, KAREN WOOLEY, Department of Chemistry, Texas A&M University, DARRIN POCHAN, Department of Materials Science and Engineering, University of Delaware — Multigeometry micellar structures, due to segregation of unlike hydrophobic domains trapped within the same micelle core, have been produced via self-assembly of block copolymer mixtures in tetrahydrofuran/water solution. The mixture is composed of two block copolymers with distinctive hydrophobic blocks but the same poly(acrylic acid) (PAA) hydrophilic block. By taking advantage of the complexation in the hydrophilic corona between the acid side chains of the PAA block and added organoamine molecules, unlike hydrophobic blocks can be trapped in the same micelle core. Locally, the unlike hydrophobic blocks can segregate into compartments and even express different interfacial curvatures, or geometries, within the same nanoparticle. Through controlled kinetic pathways, block copolymer design and mixing ratios, both micelle compartment size and shape can be controlled to generate sphere-sphere, sphere-cylinder, cylinder-cylinder, cylinder-bilayer, and bilayer-bilayer blended multigeometry nanoparticles. Furthermore, higher order assembly behavior of the micelles has been investigated by taking advantage of chemical modification on the hydrophilic PAA shells. New mixtures using functionalized-PAA-containing block copolymers produce nanoparticles with a compartmentalized surface. These patchy surfaces can be used as templates for asymmetric hybrid nanoparticles, but also as building blocks for hierarchical assembly of the nanoparticles to produce one-dimensional arrays or three dimensional networks.

2:42PM X44.00002 Polymer nano-particle hybrid micelles: Encapsulation of POSS into semi-fluorinated polymer micelles, DILRU RATNAWEERA, DVORA PERAHIA, Clemson University, SCOTT IACONO, Patrick Air Force Base, FL, JOSEPH MABRY, Edwards Air Force Base, CA, DENNIS SMITH, University of Texas, Dallas — Self-assembly of block copolymers in selective solvents was used to form a nanoparticle (NP)/polymer hybrid micelles. These micelles can be used as a cargo vehicle for other substances such as drug delivery, and as building blocks for polymer-nanocomposites with controlled NP distribution. Association of NPs into specific blocks of the copolymer depends on the compatibility between the NPs and the block as well as their preference to the solvent that micellization takes place. The current work introduces a small angle neutron scattering study of association of Polyhedral Oligomeric Silsesquioxane (POSS) NPs into micelles of a highly segregating random copolymer, Biphenyl Perfluorocyclobutane (BPh-PFCB), in toluene, which is a good solvent for BPh. Incompatibility between the blocks drives copolymer into micelles with PFCB in the core and BPh in swollen corona. Modification of NPs with polymer chains drives POSS cages into the micelle core and prevents the micelle dissociation at higher temperatures.

2:54PM X44.00003 Efficient Encapsulation of Gold Nanorods into Block Copolymer Micelles, DAE HWAN KIM, YOU-YEON WON, Purdue University — Gold nanorods (GNRs) have the potential to be used as an imaging and/or hyperthermia agent for cancer theragnosis. Clinical applications of as-synthesized GNRs (i.e., CTAB-coated CNRs) are currently limited by their cytotoxicity and insufficient colloidal stability. With an aim to address these problems, we developed a self-assembly processing technique for encapsulation of GNRs in block copolymer (BCP) micelles. This technique uses simple steps of solvent exchange processes designed based on the known principles of block copolymer self-assembly. It will be demonstrated that BCP-encapsulated GNRs are stable against aggregation under physiological conditions and non-toxic to cells.

3:06PM X44.00004 Kinetic pathways to organized polymer/nanoparticle assemblies, RYAN HAYWARD, University of Massachusetts Amherst — Processes that allow for controlled access to kinetically trapped non-equilibrium states have the potential to significantly expand the range of structures and properties that may be achieved by self-assembly. We will describe several recent examples from our group wherein new types of polymer/nanoparticle assemblies are enabled by designed processing pathways. In the first case, we study the formation of amphiphilic polymer micelles through hydrodynamic instabilities of solvent/water interfaces induced during emulsion processing. We show that this route allows for efficient co-encapsulation of multiple types of hydrophobic nanoparticles within the micelle cores. Second, we consider the influence of nanoparticles on spinodal decomposition of a polymer blend and find that the inclusion of aggregating particles provides a route to kinetically stabilize co-continuous structures through particle gelation in one of the polymer phases. Finally, we show how the structures of hybrid nanoparticle/conjugated polymer nanowires can be tuned using solution-state crystallization.

3:42PM X44.00005 A coarse-grained molecular dynamics approach to shear-directed assembly of nanoparticle arrays in amphiphilic block copolymer solutions, BRYAN ROLFE, Cornell University, JAEHUN CHUN, Pacific Northwest National Laboratory, YONG JOO, Cornell University, ENERGY AND ENVIRONMENT DIRECTORY PACIFIC NORTHWEST NATIONAL LABORATORY COLLABORATION — Experiments by Pozzo and Walker (2007) demonstrated shear ordering of binary nanoparticle block copolymer micelle crystals and its potential in the development of new nanostructured materials. Specifically, they have shown that nanoparticles occupying interstitial sites within the micelle crystal affect a low-shear, long-range order and that the shear type and rate are important to the crystal structure. However, the connection between macroscopic variables and resulting crystal structure is yet to be understood. We present results which elucidate the underlying mechanisms governing shear-directed assembly of these binary nanocrystals. Our approach employs a coarse-grained molecular dynamics model (CGMD) that includes the hydrodynamics of the solvent and preserves dynamic effects by making no assumptions regarding the micelle structure. In fact, micelle self-assembly of the amphiphilic block copolymers occurs in-situ with the nanoparticles along with the shear ordering of the binary crystal. Tunability of the crystal structure is determined by varying shear rates/types, nanoparticle size/concentration, and block copolymer chemistry as simulation parameters. The simulation predicted results of shear-directed assembly of nanoparticles will be compared to the experimental results.

3:54PM X44.00006 Nanoparticle Polymer Suspensions: Structure and Dynamics, SAMANVAYA SRIVASTAVA, LYNDEN ARCHER, Cornell University — We present structure and rheology measurements for model nanoparticle suspensions, which comprise of silica nanoparticles, densely grafted with small polyethylene glycol (PEG) chains and suspended in PEG oligomers. Structure characterization, using electron microscopy and X-ray scattering, reveals well-dispersed nanoparticles leading to stable suspensions across a range of particle volume fractions. At the same time, X-ray photon correlation spectroscopy studies reveal arrested dynamics and extremely small nanoparticle diffusivities in the high volume fraction suspensions, consistent with the expectations for a soft glass. The liquid-soft glassy solid transition is found to occur at strikingly low core volume fractions and the glassy suspensions are found to exhibit a range of unique features including strong shear thinning, presence of a zero shear Newtonian plateau, strain accelerated relaxation and prominent stress overshoots in flow startup. Comparisons of our experimental findings with the SGR model are provided and on this basis, we propose our suspensions as model systems for understanding the jamming transition and other properties of soft glasses. Further, we elucidate the form of particle interactions and compare them with models for spherical polymer brushes.

4:06PM X44.00007 Pristine graphene dispersions and solution-cast composites, SRIYA DAS, FAHMIDA IRIN, AHMED WAJID, ABEL CORTINAS, MICAH GREEN, Department of Chemical Engineering, Texas Tech University — Graphene holds potential as strong, conductive fillers in polymer nanocomposites; however, difficulties in dispersion quality and interfacial strength between filler and matrix have been a persistent problem for graphene-based nanocomposites, particularly for pristine, unfunctionalized graphene. We utilize a triphenylene based molecule (C10) to stabilize pristine graphene in water with a high graphene/stabilizer ratio. C10 molecules pi-pi stack with the graphene surface and prevent reaggregation. This dispersion can be reversibly destabilized based on pH and is stable against heat and lyophilization. Solution cast poly (vinyl alcohol) (PVA) composites prepared from these dispersions have enhanced mechanical and electrical properties (percolation threshold: 0.26 vol % graphene). Also, for the first time, pristine graphene/PVA dispersions are electrospun to form graphene/polymer composite nanofibers.

4:18PM X44.00008 Simulation of viscoelastic suspensions using regularized singularities, RONALD PHILLIPS, RYOTA AOKI, Chemical Engineering and Materials Science, UC Davis — Particles interacting through viscoelastic fluids exhibit behavior that differs qualitatively from corresponding systems with Newtonian suspending fluids. Depending on the type of fluid involved, the polymer contribution to the stress can induce clustering or particle chaining, and impede efforts to form a homogeneous suspension. We are using regularized singularities in conjunction with the finite volume method to calculate velocity fields, stress fields, and particle displacements in viscoelastic suspensions. These singularities consist of Stokelets and stresslets, or regions of enhanced body forces and stresses, and provide a simple model of suspensions of weakly deformable, non-neutrally buoyant particles. Simulations of hundreds of two-dimensional particles in multimode viscoelastic fluids show behavior similar to what is seen experimentally, and provide insight into the physical causes of particle aggregation in complex fluids.

4:30PM X44.00009 Polymer mediated solution self-assembly of nanorods, MIGUEL A. MODESTINO, RACHEL A. SEGALMAN, University of California, Berkeley — Control over the self-assembly of nanorods in polymer composites enables the design of hybrid materials in which the anisotropic properties of the nanocrystals can be harnessed efficiently. Here, we demonstrate that a delicate balance between entropic and enthalpic interactions controls the self-assembly behavior of nanorods in solutions and can lead to the formation of ordered nanorod arrays. Small angle X-ray scattering techniques were used to elucidate the phase behavior of CdSe nanorods in polymer solutions and to identify the concentration space that allows for the formation of nanorod superlattices. Furthermore, this work demonstrates that enthalpic interactions have strong effects on the nanorod self-assembly, and that the presence of reversible thermal transitions can allow for the growth of large nanorod arrays. The solution self-assembly behavior discussed in this study allows for the fabrication of solution processable composite thin films with vertically aligned nanorods over large areas.

4:42PM X44.00010 Quantifying the Thermodynamic Interactions in Carborane Nanoparticle Solutions, MARY MUTZ, University of Tennessee, ERIC EASTWOOD, Honeywell Kansas City Plant, MARK DADMUN, University of Tennessee and Oak Ridge National Laboratory — The dissolution of nanoparticles, particularly those containing boron, is an important area of interest for polymer nanocomposite formation and material development (1-2). In this work, the solubility of four boron cage molecules are quantified in toluene, THF, and methyl ethyl ketone with static light scattering, refractometry, UV-Vis spectroscopy, and physical observations. UV-Vis spectroscopy provides a method to determine the concentration and solubility limits of the solutions tested. Using light scattering, the second virial coefficient, A_2 , was determined and used to calculate χ , the solute-solvent interaction parameter. The Hildebrand solubility parameter, δ , was then extracted from this data using the Hildebrand-Scatchard solution theory (3-4). A list of potential good solvents based on the extracted δ value is provided for each nanoparticle. Of the systems tested, 1,3-di-o-carboranylpropane was shown to be a thermodynamically stable in toluene, with a χ less than 0.5, a solubility limit of 2.47 mg/mL, and all solutions remaining clear with no visible particle settling.

Session X45 DPOLY: Focus Session: Soft Matter Physics of Drops, Bubbles, Foams, and Emulsions - Droplet spreading, colliding, wetting 159

2:30PM X45.00001 Ultrafast interference of splashing dynamics: where is the air?, MICHELLE DRISCOLL, University of Chicago — A drop impacting a solid surface with sufficient velocity will splash and emit many small droplets. While liquid and substrate properties obviously are important for determining the splashing threshold, it has also been shown that the surrounding gas is a crucial control parameter [1]. The mechanism underlying how the surrounding gas affects splashing remains unknown. One suggestion [2,3] has been that upon impact the liquid spreads outwards over a thin layer of gas that has been trapped beneath it during impact. In a sufficiently viscous liquid, splashing occurs at the edge of the drop several tenths of a millisecond after impact [4]. This large separation between impact and splashing, in both time and space, creates an ideal system in which to test whether the initial air pocket remains to influence splashing dynamics. We develop high-speed interference imaging to measure the air beneath all regions of a spreading viscous drop [5]. Although an initial air bubble is created on impact, no significant air layer persists up to the time a splash is created. This suggests that splashing in our accessible range of viscosities is not caused by the presence of a layer of air beneath the liquid, but rather it is initiated at the edge of the drop as it encroaches into the surrounding gas.

3:06PM X45.00002 The drop impact dynamics of complex fluids on textured surfaces, KYOO-CHUL PARK, VIVEK SHARMA, ROBERT COHEN, GARETH MCKINLEY, Massachusetts Institute of Technology — The deposition of aqueous drops on non-wetting surfaces is an important canonical problem for many applications, including suppressing splash or rebound of sprayed herbicides on intrinsically hydrophobic plant leaves. The addition of a small amount of high molecular weight polymer has been demonstrated to suppress drop rebound on smooth hydrophobic surfaces. The high extensional viscosity of polymer solutions and the increased viscous dissipation near the receding contact line are cited as two distinct anti-rebound mechanisms. Using drop impact experiments on both micro- and nano-textured surfaces with controlled wetting characteristics we examine the roles of viscosity, elasticity and inertia on expansion, retraction, and rebound of well-characterized viscoelastic fluids. By adopting a stick-slip flow model on textured surfaces with various topographic length scales and solid area fractions, we rationalize the dynamics leading to complete rebound following drop impact on nanotextured surfaces even for highly viscoelastic fluids.

3:18PM X45.00003 Influence of nanoscale surface roughness on mechanism of dropwise water condensation¹, KONRAD RYKACZEWSKI, Material Measurement Laboratory, National Institute of Standards and Technology — Adversely to most potential applications of superhydrophobic coatings, only a few natural and artificial surfaces retain their superhydrophobic characteristics during water condensation. This work addresses the key question of why condensation on such surfaces leads to self-propelled dropwise condensation but causes wetting of other surfaces with water contact angles above 150 degrees. The effects of gradually varying nanoscale roughness of a hydrophobic surface on the mechanism of drop growth and coalescence are observed using electron and light microscopy. It is demonstrated that increasing the nanoscale surface roughness confines the base diameter of the nucleating droplets causing them to grow by increasing their contact angle. The increase in the nanoscale surface roughness also decreases triple line pinning during coalescence, thus allowing formation of nearly spherical drops after merging of two high contact angle drops. The role of the nanoscale roughness in the diameter confinement effect is explained through thermodynamic calculations. Lastly, confined base diameter growth model is derived and compared with experimental results.

¹This research was performed while K. Rykaczewski held a NRC ARRA fellowship at NIST. The author acknowledges J. Chinn from Integrated Surface Technologies Inc. for providing samples of superhydrophobic surfaces.

3:30PM X45.00004 Effect of Nano-Scale Roughness on Particle Wetting and on Particle-Mediated Emulsion Stability, ADRIANA SAN MIGUEL, SVEN BEHRENS, Georgia Institute of Technology — Colloidal particles can strongly adsorb to liquid interfaces and stabilize emulsions against droplet coalescence, the effectiveness of which depends crucially on the particle wettability. From the study of macroscopic solids, surface wetting is known to be influenced strongly by nano-scale roughness (as seen *e.g.* in the “Lotus effect” or in anti-fog coatings); similarly, strong effects of particle roughness on particle-stabilized emulsions should be expected. Here we report the first experimental study of particle wetting and particle-mediated emulsion stability in which particle roughness could be varied continuously without varying the surface chemistry. We demonstrate an enabling method for preparing particles and macroscopic substrates with tunable nano-roughness and correlate the extent of roughness quantitatively with surface wetting (measured *via* the three-phase contact angle) and with emulsion stability (quantifiable *via* the maximum capillary pressure). Our results confirm a dramatic influence of roughness on wetting, emulsion stability, and even the type of emulsion formed (o/w vs. w/o) upon mixing oil with an aqueous particle dispersion. Whether particle roughness benefits emulsion stability or not is seen to depend on both the size and shape of the surface features.

3:42PM X45.00005 ABSTRACT WITHDRAWN —

3:54PM X45.00006 Life Underneath a Leidenfrost Drop, AARON SHARPE, JUSTIN BURTON, ROELAND VAN DER VEEN, ANDRES FRANCO, SIDNEY NAGEL, The University of Chicago — Liquid drops deposited on a hot surface undergo a dramatic transition from boiling to levitating, a phenomena known as the Leidenfrost effect. The drops float on an insulating layer of evaporated vapor, which forms a pocket of high pressure underneath the drop and distorts the liquid-vapor interface. Experiments [1] have examined the lifetime and maximum size of such levitated drops. However, the interface beneath the drop has not been visualized or characterized. Using high-speed laser-light interference, we measure the geometry and fluctuations of the liquid-vapor interface. The interference fringes produced between the bottom surface of the liquid and the hot substrate provide information about the curvature of the vapor pocket beneath the drop as well as the azimuthal undulations along the rim that resides closest to the surface. We measure the speed, wavelength, and amplitude of the fluctuations as a function of the temperature of the substrate, as well as compare our results to recent theoretical predictions concerning the size of the vapor pocket for large drops [2].

4:06PM X45.00007 Voltage Bursting Drops in Solids, QIMING WANG¹, DUKE UNIVERSITY, ZHIGANG SUO², HARVARD UNIVERSITY, XUANHE ZHAO³, DUKE UNIVERSITY — Droplets in air or liquids under electrical voltages appear in diverse processes from thunderstorm cloud formation, ink-jet printing, electrospinning nanofibers to electrospray ionization. In these processes, the electrostatic energy competes with surface energy of the drops and causes sharp tips to form on the ends of the drops. Here, we report a physically distinct scenario for droplets in solid matrices under voltages. We show that water drops in elastic polymers can form sharp tips and surprisingly burst into long tubes under applied voltages. The new phenomenon is governed by the elasticity and fracture of the solids, instead of the drops' surface energy as in previous cases. A new scaling is derived for the critical electrical field of the voltage-induced instability of drops in solids. The observations and analyses have significant practical impacts, as they illustrate the mechanism of a major failure mode, defect-induced breakdown, of dielectric polymers, which are widely used as insulating cables and polymer capacitors and transducers.

4:18PM X45.00008 Spreading dynamics of a water droplet on a soluble polymer: glass transition effects, EMILIE VERNEUIL, JULIEN DUPAS, PPMD-SIMM, CNRS, UPMC, ESPCI ParisTech -Paris, France, MARCO RAMAIOLI, LAURENT FORNY, Nestlé Research Center, Lausanne - Switzerland, LAURENCE TALINI, FRANCOIS LEQUEUX, PPMD-SIMM, CNRS, UPMC, ESPCI ParisTech - Paris, France — We study the wetting dynamics of a droplet of solvent spreading on a soluble polymer coating. The complexity arises from the transfers of solvent and of soluble material through 3 processes: liquid evaporation and recondensation on the substrate, diffusion of the liquid in the substrate from the droplet, and substrate dissolution within the droplet. Indeed, when completely dry, the substrate, although soluble, is initially poorly wetting. Hydration enhances the wettability of the coating and the contact angle is found to decrease at higher humidity or at lower spreading velocity. In this paper, we explore experimentally the situation where hydration itself induces a sharp change in the diffusion coefficient of water in the polymer: this is what happens when the polymer undergoes a glass transition in water content. Diffusion coefficient changes by orders of magnitude upon glass transition, and we show that it results in a sharp effect on the course of the spreading as the hydration will be affected by the change in diffusion in the coating. We validate the previously derived model describing the various spreading regimes observed, and we expand it to account for the glass transition effects. It also successfully describes the results we obtain with other solvents and substrates.

4:30PM X45.00009 Water droplet spreading on a soluble polymer: what happens close to the contact line?, LAURENCE TALINI, JULIEN DUPAS, EMILIE VERNEUIL, FRANCOIS LEQUEUX, UPMC/CNRS/ESPCI, LAURENT FORNY, MARCO RAMAIOLI, Nestlé — We have studied the spreading of a water droplet on a water soluble substrate. Numerous coupled transfer processes are involved in such a situation, leading to complex wetting dynamics. In particular, previous studies have shown the major role of water evaporation from the droplet associated with water uptake by the substrate. However, the processes at stake close to the contact line, where the substrate properties set the wetting angle, have not been understood. We present an experimental study of the phenomena occurring within distances ranging from 10 to 1000 μm from the contact line of a water droplet spreading on a food polymer layer. We have evidenced a wrinkling pattern inside the droplet close to the contact line, and suggest it results from the swelling of the constrained polymer layer before it dissolves. In addition, using an optical method based on the analysis of Newton's rings, we have measured the hydration profile of the substrate ahead the contact line. We show that the profiles can be understood as a result of the evaporation/water uptake process through air combined with direct water diffusion in the substrate from the liquid wedge.

4:42PM X45.00010 Contact angle dependence of the resonant properties of sessile drops¹, JAMES SHARP, University of Nottingham — A simple optical deflection technique was used to monitor the vibrations of microlitre sessile drops of glycerol/water mixtures with glycerol compositions ranging from 0% to 75%. A photodiode was used to detect time dependent variations in the intensity of laser light reflected from the droplets. The intensity variations were Fourier transformed to obtain information about the resonant properties of the drops (frequency and width of the resonance). These experiments were performed on a range of different substrates where the contact angle formed by the droplets varied between $38 \pm 2^\circ$ and $160 \pm 4^\circ$. The measured resonant frequency values were found to be in agreement with a recently developed theory of vibrations which considers standing wave states along the profile length of the droplet. The widths of the resonances were also compared with theories which predict the influence of substrate effects, surface contamination effects and bulk viscous effects on the damping of capillary waves at the free surface of the droplets. These experiments indicate that the dominant source of damping in sessile liquid droplet is due to bulk viscous effects but that for small contact angles damping due to the droplet/substrate interaction becomes more important.

4:54PM X45.00011 Interfacial Effects on Droplet Dynamics in Poiseuille Flow, STEVEN HUDSON, NIST, JONATHAN SCHWALBE, MITRE, KENDRA ERK, FREDERICK PHELAN JR., NIST, PETIA VLAHOVSKA, Brown University — Many properties of emulsions arise from interfacial rheology. Here we advance theoretical understanding and experimental observation of the dynamics of isolated drops suspended in Poiseuille flow. Stokes flow is assumed in the bulk phases, and a jump in hydrodynamic stress at the interface is balanced by Marangoni forces (linearized with respect to local deviations of interfacial surfactant concentration) and surface viscous forces according to the Boussinesq–Scriven constitutive law. Interfacial diffusion is also included. Our analysis predicts slip, cross-stream migration and droplet-circulation velocities. These results and the corresponding interfacial parameters are separable, enabling a new droplet-based interfacial rheology method to determine interfacial viscosities and Marangoni elasticity. We illustrate such measurements by particle tracking velocimetry of surfactant-stabilized droplets in the Poiseuille flow of a microfluidic device. Small molecule and block copolymer surfactants are examined. This droplet-based interfacial rheology method is attractive since it mimics the natural geometry and length scale of practical emulsions and suspensions.

5:06PM X45.00012 Impact of liquid droplets on granular media, GILES DELON, DENIS TERWAGNE, STEPHANE DORBOLO, NICOLAS VANDEWALLE, HERVE CAPS, GRASP, Physics department B5, Université de Liège, Belgium — The crater formation due to the impact of a water droplet onto a granular bed has been experimentally investigated. Three parameters have been tuned: the impact velocity, the size of the droplet and the size of the grains. The shape of the crater depends on the Weber number at the moment the droplet starts to impact the bed. From the dynamical point of view, the spreading and the receding of the liquid during the impact have been carefully analyzed using image analysis of high speed video recordings. The different observed regimes are characterized by the balance between the impregnation time of the granular bed by the water contained in the droplet and the capillary time responsible for the receding of the drop.

5:18PM X45.00013 Droplet Rearrangement in a Sheared Dense Emulsion¹, S.K. DUTTA, D.L. BLAIR, Department of Physics, Georgetown University — The constituent particles of disordered colloidal dispersions compressed above the threshold for jamming flow with highly heterogeneous dynamics. Though this leads to the rich viscoelastic behavior that makes these materials so widespread, a clear description at the microscopic level has yet to emerge. We investigated the non-affine motion in a dense oil-in-water emulsion using a confocal rheometer, which can image individual droplets while applying a precisely controlled shear to the system. From these images, we identify the very fast rearrangements that accompany flow and determine the spatial and temporal distributions of the events as a function of the droplet volume fraction. In addition, it is possible to characterize the regions of the emulsion which are most susceptible to rearrangement.

¹This work is funded by the NSF through Grant DMR 0847490.

5:30PM X45.00014 Wetting Colloidal Particles at a Curved Interfaces, COLM KELLEHER, PAUL CHAIKIN, New York University Center for Soft Matter Research — At scales much smaller than the capillary length, surface tension plays a predominant role in the interactions that occur at an oil-water interface. When a spherical colloidal particle is adsorbed onto such an interface, two surface-tension-related effects occur: the adsorbed particle reduces the area of the interface, and the interface deforms in order to satisfy the requirement of constant contact angle at the three-phase contact line. If the interface is not flat or spherical, these effects depend on the position of the particle on the interface. In other words, the particle experiences an effective potential induced by the shape of the interface. [A. Wurger, PRE, 74, 041402 (2006).] We present results from an experiment in which a capillary bridge creates an interface of varying Gaussian curvature, onto which a colloidal particle is introduced. The shape of this interface is obtained by using confocal microscopy. We demonstrate that a shape-induced effective potential exists for this system, which attracts the wetting particle to the most curved regions. By tracking the motion of the particle in 3D, we are able to calculate the effective spring constant of this potential. We then compare our result to numerical and analytical predictions based on the geometry of the droplet.

Session X46 DPOLY: Invited Session: Deformation and Fracture of Soft Materials 160AB

2:30PM X46.00001 Responsive Gel-Gel Phase Transitions in Artificially Engineered Protein Hydrogels, B.D. OLSEN, Massachusetts Institute of Technology — Artificially engineered protein hydrogels provide an attractive platform for biomedical materials due to their similarity to components of the native extracellular matrix. Engineering responsive transitions between shear-thinning and tough gel phases in these materials could potentially enable gels that are both shear-thinning and tough to be produced as novel injectable biomaterials. To engineer a gel with such transitions, a triblock copolymer with thermoresponsive polymer endblocks and an artificially engineered protein gel midblock is designed. Temperature is used to trigger a transition from a single network protein hydrogel phase to a double network phase with both protein and block copolymer networks present at different length scales. The thermodynamics of network formation and resulting structural changes are established using small-angle scattering, birefringence, and dynamic scanning calorimetry. The formation of the second network is shown to produce a large, nonlinear increase in the elastic modulus as well as enhancements in creep compliance and toughness. Although the gels show yielding behavior in both the single and double network regimes, a qualitative change in the deformation mechanism is observed due to the structural changes.

3:06PM X46.00002 Direct probes of molecular interactions at buried interfaces¹, ALI DHINOJWALA, The University of Akron — The molecular interactions at buried interfaces play an important role in adhesion, friction, and wetting. In my talk, I will discuss the use of interface-sensitive sum frequency generation (SFG) spectroscopy to study acid-base interactions at solid-liquid and solid-solid interfaces. The shift of the sapphire hydroxyl peak in contact with several polar and non-polar liquids and polymers can be used to determine the interaction energy. The magnitude of the interaction energies cannot be predicted based on measuring water contact angles. Molecular rearrangements at the sapphire interface, to maximize the interaction of the acid-base groups, play a dominant role and these effects are not accounted for in the current theoretical models. The importance of these interactions in controlling segregation of polymer blends and friction and adhesion of soft substrates will be discussed.

¹Funded by National Science Foundation

3:42PM X46.00003 Adhesion of hydrogels under water by hydrogen bonding: from molecular interactions to macroscopic adhesion¹, COSTANTINO CRETON, ESPCI ParisTech - UPMC - CNRS — Hydrogels are an essential part of living organisms and are widely used in biotechnologies, health care and food science. Although swelling properties, cell adhesion on gel surfaces and gel elasticity have attracted much interest, macroscopic adhesion of hydrogels on solid surfaces in aqueous environment is much less well understood. We studied systematically and in aqueous environment, the reversible adhesion by hydrogen bonding of macroscopic model hydrogels of polydimethylacrylamide (PDMA) or of polyacrylamide (PAAm) on solid surfaces functionalized with polyacrylic acid (PAA) polymer brushes. The hydrogels were synthesized by free radical polymerization and the brushes were prepared by grafting polytertbutyl acrylate chains and converting them by pyrolysis into polyacrylic acid. A new adhesion tester based on the flat punch geometry was designed and used to control the contact area, contact time, contact pressure and debonding velocity of the gels from the surface while the samples were fully immersed in water. The adhesion tests were performed at different pH and temperatures and the modulus of the gel and grafting density and molecular weight of the brushes was varied. Macroscopic adhesion results were compared with phase diagrams in dilute solution to detect molecular interactions. While the PDMA/PAA pair behaved very similarly in solution and in macroscopic adhesion tests, the PAAm/PAA pair showed an unexpectedly high adhesion level relatively to its complexation ability in dilute solution. Surprisingly, time dependent experiments showed that the kinetics of H-bond formation and breakup at interfaces was very slow resulting in adhesion energies which were very dependent on contact time up to one hour of contact. At the molecular level, neutron reflectivity showed that the equilibrium brush conformation when in contact with the gels was more extended at pH2 (H-bonds activated) than at pH9 (H-bonds deactivated) and that a certain applied pressure was necessary to bring the brush and the gel in contact. These combined results suggest that the mechanisms of formation and breakup of interactions at surfaces are more complex and cannot be understood from bulk interactions in solution alone.

4:18PM X46.00004 Self-healing polymers and mechanochemistry¹, STEPHEN CRAIG, Department of Chemistry, Duke University — The forces that accompany macroscopic deformation and material failure are many orders of magnitude larger than the forces between the individual atoms of a molecule. The magnitude of macroscopic forces, in combination with the fact that they are directional, creates an opportunity to direct new, stress-responsive chemistry on demand in polymer materials. This talk will present studies of reactions under large, directional forces, and their applications in new classes of stress-responsive polymers, including a class of self-healing polymers in which mechanical activation of chemical reactions leads to improved structure and properties under conditions that are typically destructive to both.

¹This material is based on work supported by the U.S. Army Re-search Laboratory and the Army Research Office under Grant W911NF-07-1-0409.

4:54PM X46.00005 Soft active materials—when mechanics meets chemistry, ZHIGANG SUO, Harvard University — Soft materials, such as elastomers and gels, can mimic a salient feature of life: deformation in response to diverse stimuli. For example, an electric field can cause an elastomer to stretch several times its length. As another example, a change in pH can cause a gel to swell many times its volume. The deformation is large and reversible. These soft active materials are being developed for soft robots, adaptive optics, self-regulated fluidics, and programmable haptic surfaces. This talk describes recent work in my group on the mechanics of soft active materials. We formulate theories to answer commonly asked questions. How do mechanics, chemistry, and electrostatics work together to generate large deformation? What is the maximal energy that can be converted by a material? We also develop experimental methods to characterize nonlinear time-dependent mechanical behavior. Also described in this talk are hydrogels of exceptional toughness and stretchability.

Thursday, March 1, 2012 2:30PM - 5:18PM –

Session X47 DPOLY: Focus Session: Polymers for Energy Storage and Conversion - Nanostructures and Phase Separated Morphologies 160C

2:30PM X47.00001 Nanostructured Organometallic Polymers for Enzymatic Bioenergy, MOON JEONG PARK, JUNGPHIL LEE, Department of Chemistry, Division of Advanced Materials Science (WCU), Pohang University of Science and Technology (POSTECH) — The development of efficient enzymatic biofuel cell is a subject of considerable studies in past decades for potential applications such as biomedical devices and microchip systems. One of the key challenges in advancing the technology lies in the power densities of the system. Limitations have been arisen from the buried redox active sites within enzyme structure and poor interplay between redox reactions. In present study, a glucose oxidase is employed as a model enzyme and ferrocene-containing organometallic block copolymers are chosen for the electron mediators. Wiring of glucose oxidase into electrode surface was successfully achieved by cross-linked networks of organometallic polymers and remarkably, catalytic current densities of the fabricated electrodes have proven be a sensitive function of the morphologies of electron mediators. Different nanoscale morphologies, i.e., bicontinuous structure, nanowires, and nanoparticles, have been derived and the use of bicontinuous morphology confirms 2-50 times improved catalytic current response than the values obtained from other morphologies. The bio-sensing ability of the fabricated electrode with structural optimization was also exploited and good sensitivity is obtained at the physiological concentration of glucose in blood.

2:42PM X47.00002 Comparison of polymer-fullerene heterojunction morphology to bimolecular recombination kinetics, DEAN DELONGCHAMP, DEANNA RODOVSKY, NIST, JEFF PEET, Konarka, TRACEY CLARKE, ATTILA MOZER, University of Wollongong, LEE RICHTER, ANDREW HERZING, JOSEPH KLINE, NIST — One of the most important physical processes limiting the practical power conversion efficiency of bulk heterojunction (BHJ) organic photovoltaic devices is the bimolecular recombination of holes and electrons. Reduced recombination would permit the use of thicker BHJ layers, enabling greater light absorption without a penalty in device current. A few polymer light absorbers, when combined in a BHJ with a fullerene electron acceptor, exhibit recombination that is slower than Langevin-type, but the origins of this behaviour are not understood. This talk will describe our effort to determine whether slower-than-Langevin recombination can be attributed to features of the nanoscale morphology or crystalline microstructure within the BHJ film. In comparing BHJ films made from two silole-based monomers, one with Langevin recombination and one with slower-than-Langevin, we find many aspects of the BHJ material structure such as order, orientation, and nanoscale domain size and shape, to be surprisingly similar. We will compare the two materials and emphasize opportunities in data analysis and new measurements to determine whether a morphological basis underlies different recombination kinetics.

2:54PM X47.00003 Confinement effects on P3HT-PCBM Morphology for Bulk Hetero-Junction Polymer Solar Cells¹, ABUL HUQ, Department of Polymer Engineering, The University of Akron, DHARMARAJ RAGHAVAN, Department of Chemistry, Howard University, JOLANTA MARSZALEK, Department of Polymer Engineering, The University of Akron, DAVID BUCKNALL, Materials Science and Engineering, Georgia Institute of Technology, ALAMGIR KARIM, Department of Polymer Engineering, The University of Akron — Controlling morphology of the bulk hetero-junction in solar cell development is the key aspect for higher efficiency. We controlled the morphologies of phenyl-C61-butyric acid methyl ester (PCBM) and poly(3-hexylthiophene) (P3HT) blend thin films by tunable surface energy polydimethylsiloxane (PDMS) elastomer confinement. The advantages of replacing air-polymer interface with PDMS-polymer interface are its flexibility, easy detachability, facile tunability of surface energy by UVO exposure. We hypothesize that the confined annealing will suppress PCBM crystallinity, control crystallinity of P3HT, direct the vertical segregation of P3HT-PCBM blend, and thus influence the composition distribution of P3HT and PCBM at the interfaces. The annealed films were characterized by dark field optical microscopy, GISAXS, GIWAXS, AFM, and SANS. PCBM crystallization was indeed suppressed in the films during confinement annealing. On the other hand the phase separated interpenetrating network and favorable crystallinity of the P3HT evolved. The optimum surface energy of the confining PDMS yields the best structural features of the film. The morphology developed under different PDMS surfaces is an important step towards improvement of efficiency of OPV's.

¹DOE and BES

3:06PM X47.00004 The Role of P3HT Crystallization in the Morphological Development in P3HT/PCBM Thin Films Using Neutron Scattering, MARK DADMUN, WEN YIN, University of Tennessee — Small angle neutron scattering (SANS) provides an important method to characterize the morphology of PCBM/P3HT organic photovoltaics (OPVs), which is essential to improving the efficiency of plastic solar cell devices. Our recent SANS results indicate that fullerene derivatives and conjugated polymers employed in OPVs are significantly miscible, up to ~20%. In this work, the morphology of PCBM/P3HT composite *thin films* is investigated via SANS and analyzed to document their morphology and miscibility. These results indicate that both 20 and 50 vol% PCBM as-cast films exhibit relatively small low-Q scattering, suggesting an overall homogeneous mixture. After annealing at 150 °C for 30 minutes, P3HT undergoes further crystallization in both mixtures. However, the low-Q scattering of the 20 vol% PCBM sample remains low, indicating the film remains homogenous. On the other hand, 50% PCBM sample undergoes phase separation between amorphous PCBM and P3HT. These results therefore exemplify the importance of P3HT crystallization in the structure development of OPV active layers, showing that the crystallization of P3HT is not sufficient to induce phase separation.

3:18PM X47.00005 Understanding the Behavior of Poly(3-hexylthiophene) at Liquid/Vacuum Interfaces¹, YENENEH YIMER, MESFIN TSIGE, Department of Polymer Science, University of Akron, Akron, Ohio — Among semiconducting polymers used in opto-electronic devices, poly(3-hexylthiophene) (P3HT) is one of the better candidates because of its good electrical properties and ease of processing. The performance of these devices strongly depends on the structural, morphological, dynamic and interfacial properties of P3HT. Using molecular dynamics simulation and utilizing two different models - all-atom and united-atom - we have studied the dynamic and structural properties of free-standing P3HT thin films at liquid/vacuum interfaces. To quantify these properties, the temperature and chain-length dependence of surface roughness, interfacial width, surface tension, torsional defects, and several other surface properties have been investigated. The results we obtained from all-atom and-united atom models are in reasonable agreement.

¹This work is supported by the NSF (DMR0847580).

3:30PM X47.00006 Understanding Schroeder's Paradox, ADAM WEBER, AHMET KUSOGLU, Lawrence Berkeley National Laboratory — Schroeder's paradox is a well known, but not fully understood, phenomenon that exists in many polymers and gels. Essentially, the uptake of solvent in the polymer depends on the interaction with the boundary phase. Nafion, a polymer of interest for many electrochemical energy applications, is a classic example where the water uptake almost doubles by placement in liquid water versus saturated water vapor. In this talk, we examine the origin of this paradox through examination of Nafion morphology and water-uptake time constants using experiments in various solvents, vacuum, and small-angle X-ray scattering techniques. The results show that the interface controls the water uptake (even in bulk membranes) and that the interfacial morphology depends on the interactions of the different polymer moieties with the external environment including its density and dielectric constant. In addition, interactions with solid phases will be discussed which show similar impact on water uptake depending on whether they are hydrophilic or hydrophobic. Understanding the morphological changes and their associated impact on membrane properties is critical for optimizing polymers for use in energy applications.

3:42PM X47.00007 Ions in block copolymers: Effects on thermodynamics, structural changes and electric field induced alignment., THOMAS THURN-ALBRECHT, Martin-Luther-Universität Halle-Wittenberg — Block copolymers with added ions which selectively dissolve in one block are of interest as nanostructured polymeric ion conductors. In the microphase separated state such a system offers the possibility to simultaneously optimize different properties which would normally exclude each other. One block, being in the solid state, can give mechanical strength while the other block, typically in the liquid state, could be designed to achieve good ion transport. Oriented structures are especially interesting. We present two sets of experiments dealing with fundamental ion induced effects in block copolymers. It is generally observed that the addition of salt to a block copolymer leads to a strong increase of the order-disorder transition temperature and an increased domain spacing, i.e. conformational changes of the polymers. Based on a detailed analysis of small angle scattering data of two different copolymers (PS-b-PEO, PS-b-PVP) close to the order-disorder transition three contributions to the structural changes can be distinguished: an increased incompatibility between the different monomers, the additional volume of the added salt, and chain stretching due to coordination between polymer and salt. At the phase transition, i.e. at constant incompatibility χN , for low concentrations the increase in domain size is quantitatively explained by the volume of the added salt, at higher concentrations in addition chain stretching sets in. Structural and thermodynamic effects are considerably stronger in PEO than in P2VP. In a second experiment we study the effects of electric field induced interfacial polarization caused by the added salt. Impedance spectroscopy combined with orientation experiments at high fields enable a quantitative analysis of ionic polarization and a direct demonstration of its aligning effect on the interfaces. Field induced orientation effects are much stronger if the ionic charges come into play in comparison to much weaker dielectric effects. We present a physical model accounting for the differences.

4:18PM X47.00008 Does filler surface chemistry impact filler dispersion, polymer dynamics and conductivity in nanofilled solid polymer electrolytes?, LALITHA GANAPATIBHOTLA, JANNA MARANAS, The Pennsylvania State University — We study the impact of nanofiller surface chemistry on filler dispersion, polymer dynamics and ionic conductivity in acidic α -Al₂O₃ filled PEO+LiClO₄ solid polymer electrolytes (SPEs). SPEs are the key to light-weight and high energy density rechargeable Li ion batteries but suffer from low room temperature ionic conductivity. Addition of ceramic nanofillers improves conductivity of SPEs and their surface chemistry influences extent of conductivity enhancement. The ionic conductivity of acidic α -Al₂O₃ filled SPE is enhanced for salt concentrations at and below eutectic, while neutral γ -Al₂O₃ filler enhances conductivity only at eutectic composition. Li ion motion is coupled to segmental mobility of polymer and we study how this is affected by addition of α -Al₂O₃ using quasi-elastic neutron scattering. Aggregation extent of nanoparticles in SPE matrix, a less explored factor in filled SPEs, can affect segmental mobility of polymer. This can vary with surface chemistry of particles and we quantify this using small angle neutron scattering. All measurements are performed as a function of Li concentration, nanoparticle loading and temperature.

4:30PM X47.00009 Regular Arrays of Germanium Nanoparticles Assisted by Thermoset Polymer Composites for High Capacity Lithium Ion Battery, GYUHA JO, Pohang University of Science and Technology (POSTECH), MOON JEONG PARK, POSTECH (Pohang University of Science and Technology) — In recent years Li-batteries have attracted significant interests for a variety of applications such as portable electronics and electric vehicle (EV) batteries due to their high energy densities. Key challenges in advancing the technology lie in specific energy density, the long term cycle properties, and durability at elevated temperature. In present study, we were motivated to prepare high capacity Li-battery by creating regular arrays of germanium nanoparticles (GeNPs, 1600 mAh/g) to replace commercial graphite anode (370 mAh/g). Thermoset polymers were employed to prepare GeNPs/polymer composites with tunable NP loadings and spacings, followed by carbonization process to prepare GeNPs/carbon composite anode material. Due to the large volume change of GeNPs with charge/discharge cycles, the regular arrays of GeNPs are turned out to be a crucial parameter in obtaining enhanced cyclability. The GeNPs/carbon anode materials were cycle tested in a half cell configuration using Lithium foil as a counter electrode and lithium salt doped PS-PEO block copolymers as electrolytes. High capacity and rate capability were achieved, which demonstrate the role of nano-sized and regularly-arrayed anode active materials in obtaining the improved battery performance.

4:42PM X47.00010 Disorder – Order Transitions in Humidified Block Copolymer Electrolytes Studied by *In Situ* SAXS, KEITH BEERS, University of California, Berkeley, ANDREW JACKSON, European Spallation Source, NITASH BALSARA, University of California, Berkeley — The relationship between water uptake, proton conductivity and morphology in the dry and hydrated state for a series of poly(sulfonated styrene-*block*-ethylene) was investigated. Specifically, the disorder-to-order transition (DOT) and hydrated morphology was characterized by *in situ* humidity controlled small angle X-ray scattering (SAXS). The enhanced resolution afforded by SAXS allows for better characterization of the DOT than previous studies which have relied upon neutron scattering. The transition to an ordered state is found to display a coexistence of ordered and disordered states over a broad range of relative humidity values.

4:54PM X47.00011 Effects of lithium salts on the lamellar phase of diblock copolymers, ISSEI NAKAMURA, ZHEN-GANG WANG, California Institute of Technology — We study the effects of lithium salts on the lamellar phase of AB diblock copolymers by means of the self-consistent field theory. We consider a model in which the A and B blocks have different dielectric constants and account for the tight binding of Li^+ to one of the blocks, the preferential solvation energy of anions in the higher-dielectric polymer domain, the translational entropy of anions, and change in the χ parameter due to the binding of Li^+ . We study the effect of the strong polymer- Li^+ binding on the distribution of the salt ions. In particular, we show that local charge separation near the interface of the higher- and lower- dielectric polymers largely arises from the effect of the Born energy. We also examine the relationship between two definitions of the effective χ parameter, one based on the lamellar spacing and one based on the structure factor in the disordered phase, and show that these two definitions generally do not coincide.

5:06PM X47.00012 Structure of Block Copolymer Hydrogel Formed by Complex Coacervate Process, SOOHYUNG CHOI, JULIA ORTONY¹, DANIEL KROGSTAD, JASON SPRUELL, NATHANIEL LYND, SONGI HAN, EDWARD KRAMER, University of California, Santa Barbara — Complex coacervation occurs when oppositely charged polyelectrolytes associate in solution, forming dense micron-sized droplets. Hydrogels with coacervate block domains were formed by mixing two ABA and A'BA' triblock copolymer solutions in water where the A and A' blocks are oppositely charged. Small-angle neutron scattering (SANS) was used to investigate the structure of hydrogels formed by ABA triblock copolymers (A block: poly(allyl glycidyl ether) functionalized with guanidinium (A) or sulfonate (A'), B block: poly(ethylene oxide)). By using an appropriate fitting model, structural information such as coacervate core block radius and water volume fraction w can be extracted from SANS data. The results reveal that w in the coacervate core block was significantly higher than in conventional triblock copolymer hydrogels where microphase separation is driven by the hydrophobicity of the core-forming blocks.

Thursday, March 1, 2012 2:30PM - 5:42PM –
Session X48 DPOLY DBIO: Focus Session: Statistical Physics of Active Systems Away From Detailed Balance: Cytoskeleton, Flagella, and All That 161

2:30PM X48.00001 The Role of Dynein in Microtubule Mechanics, TONY LADD, University of Florida, GAURAV MISRA, Stanford University, JUN WU, ROBERT RUSSELL, TANMAY LELE, RICHARD DICKINSON, University of Florida — Experiments in Lele's group have shown that microtubules severed by laser ablation do not straighten, as would be expected from the large bending moments along their lengths. Instead, segments near newly created minus ends typically increased in curvature following severing, while segments near new microtubule plus ends depolymerize before any observable change in shape. However, in dynein-inhibited cells, segments near the cut straightened rapidly following severing. These observations suggest that microtubules are subject to significant tangential forces, and that lateral motion of the microtubule is primarily opposed by frictional rather than elastic forces. To interpret the experimental results, we have developed a numerical model for intracellular microtubule mechanics, accounting for dynein-generated forces on the microtubules. We have supplemented the Kirchhoff model for an elastic filament with the stochastic growth and collapse of microtubules, and by a model for dynein generated forces. I will present simulations of the dynamics of individual microtubules that show how motor forces result in the localization of short-wavelength buckles near the cell periphery. Our results suggest that microtubule shapes *in vivo* reflect a dynamic force balance, where bending moments are opposed by dynein-motor forces that include a large effective friction from the stochastic binding and unbinding of the motors. Simulations of the motion of the centrosome are consistent with a mechanism for centrosome centering driven by pulling forces exerted by dynein motors. I will explain how tension on the centrosome can be reconciled with buckled filaments near the cell periphery.

2:42PM X48.00002 Processivity and collectivity of molecular motors pulling membrane tubes, FRANCISCO FONTENELE ARAUJO, CORNELIS STORM, Eindhoven University of Technology — In every cell, directed transport involves proteins that convert chemical energy into mechanical work. Molecular motors responsible for this vital task are mostly too weak to carry biological cargo by themselves and some cannot even take more than a single step before unbinding from their cytoskeletal track. By acting collectively, however, they can muster the required forces. In this talk, we discuss interactions among motors and their collective effects on the extraction of membrane nanotubes. Via a force balance coupled to binding kinetics, we sketch the phase diagram of tube formation. Three regimes are identified: (1) tip clustering, in the sense that the driving force is concentrated at the tip of the tube, (2) viscous extraction, in which motors axially drag membrane, and (3) hybrid extraction, such that tip clustering and axial drag are equally important. Comparison with experiments indicates that synthetic membranes mostly fall into regime (1), while biological membranes tend to fall into regime (2). Our model suggests a unifying picture of tube extraction by both processive and nonprocessive motors.

2:54PM X48.00003 Carbon nanotubes as mechanical probes of equilibrium and non-equilibrium cytoskeletal networks, NIKTA FAKHRI, Third Institute of Physics - Biophysics, Georg-August-Universitaet, Goettingen, Germany, MATTEO PASQUALI, Department of Chemical and Biomolecular Engineering, Rice University, Houston, TX, USA, FREDERICK C. MACKINTOSH, Department of Physics and Astronomy, Vrije Universiteit, Amsterdam, The Netherlands, CHRISTOPH F. SCHMIDT, Third Institute of Physics - Biophysics, Georg-August-Universitaet, Goettingen, Germany — Networks of filamentous proteins underlie the mechanics of cells. The activity of motor proteins typically creates strong fluctuations that drive the system out of equilibrium. Understanding the behavior of such networks requires probes that ideally span the characteristic length-scales, from nanometers to micrometers. Single-walled carbon nanotubes (SWNTs) are nanometer-diameter filaments with micrometer length and tunable bending stiffness. On a Brownian energy scale they have persistence lengths of about 20-100 micrometers and show significant thermal fluctuations on the cellular scale of a few microns. Diffusive motion and local bending dynamics of SWNTs embedded in an active polymeric network reflect forces and fluctuations of the embedding medium. We study the motion of individual SWNTs in equilibrium and non-equilibrium networks by near infrared fluorescence microscopy. We show that SWNTs reptate in the network. We will discuss the possibility of using SWNTs as multi-scale probes relating their local dynamic behavior to the viscoelastic properties of the surrounding network.

3:06PM X48.00004 ABSTRACT HAS BEEN MOVED TO C1.00231 —

3:18PM X48.00005 The metaphase and anaphase dynamics is dominated by the physical and mechanical properties of both microtubules and chromatin, LUCA GRISA, MARIA KILFOIL, University of Massachusetts, Amherst — One of the most interesting problems in biophysics involves the physical separation of chromosomes and the mechanical properties of both microtubules (MT's) and chromatin. This process involves the polymers MT's and chromatin, each of which has unique physical properties that have been determined extensively in vitro. Of further interest for physicists is the out-of-equilibrium nature of this process involving several force generators from motor proteins and MT depolymerization. We follow the dynamics of spindle pole bodies and centromeres of yeast cells during mitosis in three-dimensions at high spatial resolution. Using this novel approach, we are able to observe spindle oscillations during metaphase, and the three-dimensional dynamics of spindle elongation and chromosome separation during anaphase. With these data, we can separate the dynamics caused by MT depolymerization from those caused by the motors. This allows us to determine the depolymerization rate of the kinetochore MT's in vivo. Furthermore, we determine the temporal profile of the chromatin extension during anaphase we combine with the known force-extension curve of chromatin in vitro, to infer the expected force-velocity curve of the collective motors in vivo, which has never been measured in vivo or in vitro.

3:30PM X48.00006 Effective temperature and spontaneous collective motion of active matter¹, SHENSHEN WANG, University of California, San Diego, PETER WOLYNES, Rice University — Spontaneous directed motion, a hallmark of cell biology, is unusual in classical statistical physics. Here we study, using both numerical and analytical methods, organized motion in models of the cytoskeleton in which constituents are driven by energy-consuming motors. Although systems driven by small-step motors are described by an effective temperature and are thus quiescent, at higher order in step size, both homogeneous and inhomogeneous, flowing and oscillating behavior emerges. Motors that respond with a negative susceptibility to imposed forces lead to an apparent negative temperature system in which beautiful structures form resembling the asters seen in cell division.

¹We gratefully acknowledge the financial support from the Center for Theoretical Biological Physics sponsored by the National Science Foundation via Grant PHY-0822283.

3:42PM X48.00007 An active matter analysis of intracellular Active Transport, BO WANG, KEJIA CHEN, SUNG CHUL BAE, STEVE GRANICK, University of Illinois Urbana-Champaign — Tens of thousands of fluorescence-based trajectories at nm resolution have been analyzed, regarding active transport along microtubules in living cells. The following picture emerges. Directed motion to pre-determined locations is certainly an attractive idea, but cannot be pre-programmed as to do so would sacrifice adaptability. The polarity of microtubules is inadequate to identify these directions in cells, and no other mechanism is currently known. We conclude that molecular motors carry cargo through disordered intracellular microtubule networks in a statistical way, with local cellular "noise" both in directionality and speed. Programmed random walks describe how local 1D active transport traverses crowded cellular space efficiently, rapidly, minimizing the energy waste that would result from redundant activity. The mechanism of statistical regulation is not yet understood, however.

3:54PM X48.00008 ABSTRACT WITHDRAWN —

4:06PM X48.00009 Constant torque in flagellar bacterial motors optimizes space exploration, CARLOS A. CONDAT, MARIO E. DI SALVO, IFEG-CONICET and National University of Cordoba, Cordoba, Argentina — Experiments indicate that the torque provided by the bacterial rotary motor is approximately constant over a large range of angular speeds. Constant torque implies that the power spent in active motion is proportional to the instantaneous bacterial speed, if the relation between angular speed and swimming speed is linear. Here we show that a constant torque maximizes the volume of the region explored by a bacterium in a resource-depleted medium. Given that nutrients in the ocean are often concentrated in separate, ephemeral patches, we propose that the observed constancy of the torque may be a trait evolved to maximize bacterial survival in the ocean. We also discuss the dependence of the explored volume with the particular features of the bacterial propulsion mechanism.

4:18PM X48.00010 Interplay between motor contractility and mechanical stability of active biopolymer networks, CHASE BROEDERSZ, Princeton University — The mechanical properties of cells are regulated in part by internal stresses generated actively by molecular motors in the cytoskeletal filamentous actin network. On a larger scale, collective motor activity allows the cell to contract the surrounding extracellular matrix, consisting also of biopolymer networks. Experiments show that such active contractility dramatically affects the networks' elasticity, both in reconstituted intracellular F-actin networks with myosin motors as well as in extracellular gels with contractile cells. We provide insight into this remarkable behavior with a model for the mechanics of contractile disordered networks consisting of simple straight fibers with linear bending and stretching elasticity. We find that these networks exhibit a low-connectivity rigidity threshold governed by fiber-bending elasticity and a high-connectivity threshold that controls a crossover between bending and stretching dominated network elasticity. Owing to their low connectivity, typical biopolymer networks fall below this upper threshold and their mechanical stability thus relies on the fibers' bending rigidity. The macroscopic elasticity of such networks is governed by soft fiber bending deformations. However, we find that motor-generated contractile forces can "pull out" these soft bending modes, thereby inducing a crossover to a mechanically more stable regime governed by stiff fiber stretching modes. Using scaling arguments and mean field theory, we show that this transition—induced by motor contractility—can be understood from the stress-dependence of the mechanical stability thresholds. These results suggest a physical principle by which active contractility can control biopolymer network mechanics, even when the fiber constituents are linear elastic elements.

4:54PM X48.00011 Propulsion of microorganisms by a helical flagellum, CHIH-HUNG CHEN, BRUCE RODENBORN, HARRY SWINNEY, Department of Physics and Center for Nonlinear Dynamics, University of Texas at Austin, BIN LIU, School of Engineering, Brown University, Providence Rhode Island, HEPENG ZHANG, Department of Physics and Institute of Natural Sciences, Shanghai Jiao Tong University — Many bacteria (e.g. *E. coli* and *Salmonella*) swim by rotating rigid helical flagella, which are typically several μm long and $0.4 \mu\text{m}$ in diameter. We investigate this propulsion in laboratory measurements on macroscopic rotating helices (typical diameter, 12 mm) in a fluid with viscosity 10^5 times that of water; thus the Reynolds number in the experiments is much less than unity, just as for bacteria. We measure the propulsive force and torque generated by a rotating flagellum, and the drag force on a translating flagellum; thus we can determine all elements of the propulsion matrices along the axial direction. We also compute force, torque and drag using the regularized Stokeslets method of Cortez et al. (2005). Our experimental and numerical results are in excellent agreement. However, these results differ significantly from the predictions of resistive force theories developed by Gray and Hancock (1953) and Lighthill (1975). The difference between our measurements and resistive force theory is especially large for helices with small pitch/diameter ratios, which is the regime of many bacteria.

5:06PM X48.00012 Energy Consumption of Actively Beating Flagella¹, DANIEL CHEN, Department of Physics, Brandeis University, DANIELA NICASTRO, Department of Biology, Brandeis University, ZVONIMIR DOGIC, Department of Physics, Brandeis University — Motile cilia and flagella are important for propelling cells or driving fluid over tissues. The microtubule-based core in these organelles, the axoneme, has a nearly universal “9+2” arrangement of 9 outer doublet microtubules assembled around two singlet microtubules in the center. Thousands of molecular motor proteins are attached to the doublets and walk on neighboring outer doublets. The motors convert the chemical energy of ATP hydrolysis into sliding motion between adjacent doublet microtubules, resulting in precisely regulated oscillatory beating. Using demembrated sea urchin sperm flagella as an experimental platform, we simultaneously monitor the axoneme's consumption of ATP and its beating dynamics while key parameters, such as solution viscosity and ATP concentration, are varied. Insights into motor cooperativity during beating and energetic consequences of hydrodynamic interactions will be presented.

¹We gratefully acknowledge support from the WM Keck Foundation.

5:18PM X48.00013 A particle based computational model for eukaryotic flagella, RAGHUNATH CHELAKKOT, MICHAEL HAGAN, Brandeis University — The structure of the eukaryotic flagella is very complex and the exact mechanisms responsible for flagellar beating are not clearly understood. Here we present a minimal model to study flagellar beating in two dimensions, which demonstrates that regular beating with a well defined characteristic frequency can arise spontaneously in the absence of external control. In this model, the flagella is represented by two stiff filaments clamped on a surface, on which model “molecular motors” take directed steps on one of the filaments and thereby apply a local force. The fluid medium is simulated using Multiparticle Collision dynamics (MPC), which is a particle based method for hydrodynamic simulations. Within a certain range of motor concentrations, large amplitude periodic oscillations with a well defined frequency are observed; other qualitatively different beating patterns arise outside of this range. We present a phase diagram that characterizes the beating behaviour as a function of relevant parameters such as filament length, motor density on the filament and motor velocity.

5:30PM X48.00014 Force generation in a regrowing eukaryotic flagellum¹, MARCO POLIN, DAMTP, University of Cambridge, BASTIEN BRUNEAU, Ecole Polytechnique, Paris, France, THOMAS JOHNSON, University of Birmingham, RAYMOND GOLDSTEIN, DAMTP, University of Cambridge — Flagella are whip-like organelles with a complex internal structure, the axoneme, highly conserved across eukaryotic species. The highly regulated activity of motor proteins arranged along the axoneme moves the flagellum in the surrounding fluid, generating forces that can be used for swimming or fluid propulsion. Although our understanding of the general mechanism behind flagellar motion is well established, the details of its implementation in a real axoneme is still poorly understood. Here we explore the inner working of the eukaryotic flagellum using a uniflagellated mutant of the unicellular green alga *Chlamydomonas reinhardtii* to investigate in detail the force and power generated by a moving flagellum during axonemal regrowth after deflagellation. These experiments will contribute to our understanding of the inner working of the eukaryotic flagellum.

Session X49 DMP DPOLY: Focus Session: Organic Electronics and Photonics - Polymer Di-
electrics and Charge Transport 162A

2:30PM X49.00001 Inhomogeneous deformation and instability in soft dielectric transducers, TIEFENG LI, SHAOXING QU, Zhejiang University, CHRISTOPH KEPLINGER, Johannes Kepler University, ZHIGANG SUO, Harvard University, WEI YANG, Zhejiang University — Dielectric elastomer (DE) is assembled by sandwich an elastomeric membrane with compliant electrodes on both sides. They are capable of converting mechanical into electrical energy (generator) or electrical into mechanical energy (actuator). The large actuation strain of DE has inspired intense development of dielectric elastomers as applications as actuators and generators. DE transducers are lightweight, compliant, rust-free, and can convert higher energy than those of conventional transducers. DE transducers often undergo inhomogeneous deformation and instability during operation. Inhomogeneous deformation can cause the DE membranes to have inhomogeneous fields distribution and fail locally. Instability during actuation highly affects the performance and safety of the DE transducer. We present an analytical model of a dielectric elastomer transducers undergoing inhomogeneous deformation and snap-through instability during operation.

2:42PM X49.00002 Dielectric Properties of Carbon, Silicon and Germanium Based Polymers: A First Principles Study, CHENCHEN WANG, GHANSHYAM PILANIA, CHUNSHENG LIU, RAMPI RAMPRASAD, University of Connecticut — The field of high energy density capacitors would benefit from the discovery of new insulating polymers with high dielectric constant, low loss, large band gap and high breakdown strength. The current standards for capacitive energy storage applications are polypropylene and polyethylene which have large band gap and high breakdown strength, but a small dielectric constant. As an initial step aimed at the discovery of new polymers with better dielectric properties, we consider a class of chemically-modified polymers based on polyethylene. These polymers are composed of $-XY_2-$ building blocks, with $X = C, Si$ or Ge , and $Y = H, F$ or Cl . We use density functional perturbation theory and exchange-correlation functionals that include van der Waals and/or nonlocal exchange interactions to accurately predict the structure, dielectric constant (electronic and ionic) and band gap of this class of polymers. The computed properties have been correlated to the underlying electronic structure and phonon modes, and tradeoffs between the band gap and dielectric constant are established. The time-consuming dielectric computations have been optimized using a new “single-chain” method to allow for future extensive explorations of the polymer chemical space via automated high-throughput computations.

2:54PM X49.00003 Paraelectric Crystalline Polymers for High Energy Density and Low Loss Dielectrics¹, LEI ZHU, Department of Macromolecular Science and Engineering, Case Western Reserve University, Cleveland, Ohio 44106-7202, RUN SU, College of Polymer Science and Engineering, Sichuan University, Chengdu, Sichuan 610065, JUNG-KAI TSENG, MAO-SHENG LU, Department of Macromolecular Science and Engineering, Case Western Reserve University, Cleveland, Ohio 44106-7202 — It is known that the high temperature phase above the Curie temperature (T_c) in poly(vinylidene fluoride-co-trifluoroethylene) [P(VDF-TrFE)] is a typical paraelectric phase. Frequency-dependent electric displacement-electric field (D-E) loop tests are used to study the dielectric/ferroelectric properties of this paraelectric phase. It is observed that normal ferroelectric hysteresis loops are observed at a poling frequency of 1 Hz, while narrow paraelectric loops are observed at a high poling frequency of 1000 Hz. The poling mechanism is revealed by an in-situ electric field-dependent Fourier transform infrared study. From this study, we consider that paraelectric crystalline polymers are good candidates for high energy density and low loss dielectrics.

3:06PM X49.00004 Influence of Aqueous Electrolytes on Electrical Insulating Properties of Polyethylene, ADAM TORNHEIM, TOM DEVINE, UC Berkeley — Polyethylene is commonly used as electrical insulation in high voltage (3-35 kV), underground electrical distribution cables. During service conditions the insulation “ages” and may fail. One method of ageing is a consequence of long-time exposure of the polyethylene to humidity and groundwater. Chemical analyses by other researchers indicated iron was frequently detected in degraded areas of aged cable. In the current research we examine the effect of a ferric chloride electrolyte on the electrical insulating character of polyethylene. In earlier research we discovered that in the presence of high DC voltages (approximately 3kV-6kV) ferric chloride electrolytes markedly enhance electron injection into and subsequent electron transport through polyethylene. The present research shows that ferric chloride complexes in solution are likely responsible for electron injection. The effect of exposure to ferric chloride solution was permanent, causing an increase in current density when the polyethylene was subsequently exposed to other electrolytes. The effect of FeCl_3 exposure was observed in additive free polyethylene as well as commercially processed polyethylene.

3:18PM X49.00005 Theoretically guided design of efficient polymer dielectrics¹, PHILIP TAYLOR, ELSHAD ALLAHYAROV, Case Western Reserve University — We have used theory and molecular dynamics simulation as an aid to the development of polymeric materials with favorable properties for energy storage with low dielectric losses. We build on the principle that the stored energy in a capacitor is a sum of the intrinsic energy of the electric field and the energy of distortion of the molecular bonds within the dielectric. We have attempted to maximize the energy of bond distortion by increasing the polarization without introducing large losses. In this initial study we simulate the behavior of a system consisting of parallel chains of the antiferroelectric α phase of polyvinylidene fluoride that has been modified to increase the separation between chains through crosslinks that prevent chain rotation. By varying the crosslink density, we identify the optimum length of unlinked chain such that the polar entities that rotate when subject to a strong electric field will be neither so long that they rotate collectively with little stored energy, nor so short that the large distortion of bond angles necessary for dipole rotation reduces the polarizability. We have adopted a combined-atom model in order to make feasible the study of systems comprising up to 100 chains, each consisting of up to 500 monomers.

3:30PM X49.00006 Interface conductivity contribution in Co-Phthalocyanines capacitive type devices, CARLOS MONTON, ILYA VALMIANSKY, IVAN SCHULLER, Department of Physics and Astronomy, University of California San Diego, 9500 Gilman Dr., San Diego, La Jolla, CA 92093, U.S.A — Metal Phthalocyanines are flat organic semiconductors which exhibit interesting magnetotransport properties. Recent experimental studies in a particular system together with theoretical calculations have shown that the temperature and thickness dependence of the ohmic conductivity can be universally described by two independent contributions: the organic film and the electrode-film interface [1]. In order to explore the implications of this model we performed transport measurements in sandwich devices with different bottom electrodes materials. These devices are grown in-situ by Organic Molecular Beam Epitaxy to assure ultra clean electrode-film interfaces. A combination of structural and transport studies are used to investigate the reason for the drastic change in ohmic conductance at metallo-organic film thickness around 100nm.

3:42PM X49.00007 Nanoscale Correlation of Heterogeneous Morphology and Electrical Transport in Nanostructured Organic and Hybrid Solar Cells, JIEBING SUN, SEAN WAGNER, XIAOYU LIU, PHILLIP DUXBURY, PENG PENG ZHANG, Michigan State University — The knowledge of correlation between morphology and electrical properties is essential both to understand fundamental physics and to facilitate device optimization. We report a systematic study of the organic blend of PCBM particles and P3HT fibers formed via the thermal annealing method. We use conductive atomic force microscopy (c-AFM) to simultaneously map the surface morphology and collect the electrical current. Cross-section AFM is attempted to get the internal 3D morphology so as to establish its correlation with the electrical properties. The obtained heterogeneity in the current map with a resolution up to 20 nm is attributed to the formation of cross-linked three dimensional fiber network, which is further supported by a three dimensional device model incorporating the geometry of nanowire and the c-AFM tip. Results on the hybrid cell of ZnO nanowires infiltrated with P3HT will also be discussed.

3:54PM X49.00008 Gigahertz Probing of Poly(3-hexylthiophene) With A Kilohertz Detection Scheme¹, JEFF WORNE, Department of Electrical and Computer Engineering, Rice University, COREY SLAVONIC, Department of Physics and Astronomy, Rice University, KEVIN KELLY, Department of Electrical and Computer Engineering, Rice University, DOUGLAS NATELSON, Department of Physics and Astronomy, Rice University — Organic semiconducting polymers have been well studied at DC and low-frequencies, giving important information about charge transport and metal-polymer interaction. However, comparatively little is known about the operation of these polymers at radio frequencies (1 GHz). RF frequencies can be a useful tool to investigate high-frequency mobility and charge carrier dynamics relevant for the possibility of using these polymers in RF applications. We present a novel technique that probes poly(3-hexylthiophene) (P3HT) response in the RF regime but allows for detection in the kHz regime. We show transport data of P3HT and discuss a theoretical framework for inferring behavior at GHz frequencies.

4:06PM X49.00009 Thickness dependence of hole mobility in regioregular poly(3-hexylthiophene) thin films, BINGYUAN HUANG, EMMANOUIL GLYNOS, BRADLEY FRIEBERG, PETER GREEN, University of Michigan-Ann Arbor — Methods of time of flight (TOF) and charge extraction by linearly increasing voltage (CELIV) are used to investigate the hole mobility in regioregular poly(3-hexylthiophene) (RR-P3HT) thin films. The film thickness was varied by changing the RR-P3HT solution concentration and spin-coating speed. The hole mobility is found to monotonically increase from 10^{-4} cm^2/Vs to 10^{-3} cm^2/Vs along with film thickness from 100 nm to 700 nm and saturate at 10^{-3} cm^2/Vs beyond 700 nm. X-ray diffraction and ellipsometry data showed that the film morphology changes with the thickness. The structural change supports the weak dependence of energetic and positional disorder on thickness analyzed by the Gaussian Disorder Model (GDM).

4:18PM X49.00010 Contribution of Increased Extraction Efficiency to Increased Photo-Luminescence in Strained Polymer Films, PO-JUI CHEN, Dept. of Photonics Engineering, Yuan Ze University, ARNOLD CHANG-MOU YANG, Dept. of Materials Science and Engineering, National Tsing Hua University, JUI-HUNG HSU, Dept. of Material Science and Opto-electronic Science, National Sun Yat-sen University, JONATHON D. WHITE, Dept. of Photonics Engineering, Yuan Ze University — Potential applications of Luminescent Conjugated Polymers in thin film diodes, solar cells and flat panel displays have been limited by low efficiency. Craze formation in MEH-PPV/polystyrene thin film leads to a factor of 2 or 3 increase in collected photo-luminescence (PL) due to a combination of factors such as MEH-PPV chain conformation and increased extraction efficiency of PL. In order to determine the contribution of the latter effect, we used Monte Carlo based Ray Tracing to analyze the trajectory of photons generated in the thin film under different strain conditions. Our results indicate that increased PL extraction due to the existence of crazes contributes ~15% of the observed increase in PL, the majority of this being due to light emitted near the craze edges.

4:30PM X49.00011 Modeling charge and energy transports in π -conjugated systems, YONGWOO SHIN, XI LIN, Boston University — A generic 3D model Hamiltonian is developed to simulate the charge and energy transports in π -conjugated composite materials. The intrachain interactions are described by our recently developed adapted Su-Schrieffer-Heeger Hamiltonian and the interchain $\pi\pi$ interactions are modeled using distance-dependent hopping integrals. Excellent agreements in their binding energetics and geometries with post-Hartree-Fock ab initio methods and experiments are found in the cases of a benzene dimer, graphene bi-layer, and poly(*p*-phenylene vinylene) (PPV) crystal. The computed photoinduced charge separated states and associated adsorption spectra of the PPV-C₆₀ and PPV-C₆₀-graphene agree perfectly with experimental measurements.

4:42PM X49.00012 NMR, magnetic susceptibility, and electrical conductivity investigation of doped poly-3-methylthiophene¹, W.G. CLARK, G. GAIDOS, UCLA Physics and Astronomy, K.J. SINGH, R. MENON, K.P. RAMESH, Physics, IISc Bangalore, India, A.P. REYES, P. KUHNS, NHMFL, Tallahassee, FL, J.D. THOMPSON, LANL, Los Alamos, NM — We report ¹H and ¹⁹F NMR spin-lattice relaxation rate (1/*T*₁) measurements over a wide range of temperature (3 K < *T* < 300 K) and magnetic field (0.9 T < *B* < 23.4 T for ¹H and 9.0 T for ¹⁹F) in the organic conductor poly-3-methylthiophene (P3MT) doped with hexafluorophosphate (PF₆). Also included are measurements of the electrical conductivity (σ) at *B* = 0 and 77 K < *T* < 300 K and the magnetic susceptibility (χ) at *B* = 0.1 T and 2 K < *T* < 350 K. The doping level has been varied to tune the conductivity value at 300 K in the fully doped sample to $\sigma \sim 120$ S/cm and in the dedoped one to $\sigma \sim 5$ S/cm. This range enables investigation of the roles of carrier density and electron-electron interactions in the mechanisms for 1/*T*₁. A correlation between χ and the relaxation mechanisms is observed in these samples. The results are analyzed using the modified Korringa relation. Also, the proton and fluorine spin relaxation data give insight into the role of both inter-chain and intra-chain conduction mechanisms.

¹This work was supported by the DST and NSF in Grants DMR-0334689 and OISE-0225578, at LANL from the DOE Office of Science, and at the NHMFL from NSF Grant DMR-0084173 and the State of Florida.

4:54PM X49.00013 Improving Order and Mobility in MEH-PPV Films by Reducing Polydispersity¹, JONATHON WHITE, Yuan Ze University — The effect of polydispersity on morphology and charge transport in drop cast films of poly[2-methoxy-5-(2'-ethylhexyloxy)-*p*-phenylene vinylene] (MEH-PPV) was investigated using grazing incidence X-ray diffraction and time-of-flight respectively. Morphologically, reducing polydispersity by removing short chain segments promoted the capability of crystallization. This resulted in higher hole mobility and non-dispersive transport down to lower temperatures for the lower polydispersity sample. The slope for the Poole-Frenkel relationship at 298 K was increased, and its change with temperature decreased, indicating reduced spatial inhomogeneity. Analysis using Bassler's Gaussian disorder model (GDM), found that the value for energy disorder ($\sigma \sim 53$ meV for both films) and infinite temperature zero field mobility ($\mu_0 \sim 3 \times 10^{-6}$ cm²/Vs) were similar for both films. However, a good fit for hopping site separation and spatial disorder was only possible for the lower polydispersity device, suggesting that the lower polydispersity films have less mesoscopic inhomogeneity.

5:06PM X49.00014 Charge Transport in Amorphous Polythiophene-Fullerene Blends, KIARASH VAKHSOURI, DEREK KOZUB, Department of Chemical Engineering, Pennsylvania State University, CHENCHEN WANG, ALBERTO SALLEO, Materials Science and Engineering, Stanford University, ENRIQUE GOMEZ, Department of Chemical Engineering and Materials Research Institute, Pennsylvania State University — Energy-filtered transmission electron microscopy studies revealed that amorphous mixed phases are ubiquitous within mesostructured polythiophene/fullerene mixtures. Nevertheless, the role of mixing within nanophases on charge transport of organic semiconductor mixtures is not fully understood. We have examined the electron mobility in amorphous blends of poly(3-hexylthiophene) and phenyl-C₆₁-butyric acid methyl ester. Our studies reveal that the miscibility of the components strongly affects electron transport within amorphous blends. Immiscibility promotes efficient electron transport by promoting percolating pathways within organic semiconductor mixtures. As a consequence, partial miscibility may be important for efficient charge transport in polythiophene/fullerene mixtures and organic solar cell performance.

5:18PM X49.00015 Modeling energy transport in π -conjugated dendrimers containing triple bonds, PAK KAU LIM, YONGWOO SHIN, XI LIN, Department of Mechanical Engineering and Division of Materials Science and Engineering, Boston University — An accurate, transferrable, and computational efficient adapted Su-Schrieffer-Heeger model Hamiltonian is developed to describe triple bonds in linear and fractal-dimensional π -conjugated systems. Chemical accuracy in the computed optical gaps is found for the cases of poly-(thiophene-ethynylene) and poly-phenylacetylene of arbitrary lengths, with all errors less than 3% as compared to existing UV-visible adsorption spectra. The computed exciton migration processes in the phenylacetylene dendrimers indicates that such conjugated Bethe tree structures are efficient energy transduction funnels.

Thursday, March 1, 2012 2:30PM - 5:30PM –

Session X50 DPOLY DFD: Focus Session: Micro and Nano Fluidics II: Structured or Active Surfaces and Electrotransport 162B

2:30PM X50.00001 Dynamics of self-oscillating cilia designed from active polymer gels, PRATYUSH DAYAL, AMITABH BHATTACHARYA, OLGA KUKSENOK, ANNA C. BALAZS, University of Pittsburgh — Using theory and simulations, we design active synthetic surfaces which are capable of replicating functionalities of biological cilia. In order to design such exquisite biomimetic systems we harness unique properties of polymer gels that undergo photosensitive Belousov-Zhabotinsky (BZ) reaction. Powered by internalized BZ reaction these polymer gels swell and de-swell autonomously by chemo-mechanical transduction and therefore are ideal materials for designing our system. In order to simulate the dynamics of the BZ cilia in surrounding fluid we have developed a nonlinear hybrid 3D model which captures elasto-dynamics of polymer gel and diffusive exchange of BZ reagents between the gel and the fluid. Here we show that the geometrical arrangement of cilia and the distribution of BZ activator in the fluid determine the dynamic response of the cilia. We further show that using light as an external stimulus we can sequentially modulate height of individual cilium and thereby create the “piano effect”. Finally, we demonstrate that synchronized oscillations in the cilia result from the distribution of BZ-activator in the surrounding fluid. Our findings can be used to design active surfaces which can be remotely tuned depending upon the magnitude of external stimuli.

2:42PM X50.00002 Using actuated synthetic cilia to enhance microscale heat transport, ZACHARY G. MILLS, ALEXANDER ALEXEEV, Georgia Institute of Technology — We used three dimensional computer simulations to examine heat transport in a microchannel that encompasses a periodic array of actuated synthetic cilia. The channel was filled with a viscous fluid and its walls were maintained at different temperatures. Elastic synthetic cilia were attached to the bottom channel wall and were actuated by a periodic external force applied horizontally to their free ends. To model this multi-component system, we employed a thermal lattice Boltzmann model coupled with the lattice spring model. We probed how the beating cilia affect the heat transfer between channel walls, and how the thermal transport coefficient changes depending on the oscillating frequency and the relative distance between actuated filaments. Our findings could be useful for developing new methods for temperature control in microscale devices.

2:54PM X50.00003 Transport of Micro-particles by Active Cilia Arrays, AMITABH BHATTACHARYA, Department of Chemical Engineering, University of Pittsburgh, GAVIN BUXTON, Department of Science, Robert Morris University, O. BERK USTA, Center for Engineering in Medicine, Massachusetts General Hospital, ANNA. C. BALAZS, Department of Chemical Engineering, University of Pittsburgh — Biological organisms are known to use hair-like filaments called cilia to manipulate and transport particles. The coordinated motion of cilia is known to be effective at propelling surrounding fluid. In this work, we show that adhesive interaction between the actuated cilia and particulates can be crucial towards controlling particle transport. We model transport of a microscopic particle via a regular array of beating elastic cilium, whose tips experience an adhesive interaction with the particle's surface. At optimal adhesion strength, the average particle velocity is maximized. Using simulations spanning a range of cilia stiffness, particle radius, and cilia-particle adhesion strength, we explore the parameter space over which the particle can be “released,” “propelled” or “trapped” by the cilia. We use a low-order model to predict parameters for which the cilia are able to attach themselves to the particle. We also study the effect of varying the particle size and stiffness on its transport properties. This is the first study that shows how both stiffness and adhesion strength are crucial for manipulation of particles by active cilia arrays.

3:06PM X50.00004 Fluid flows around nanoelectromechanical resonators, O. SVITELSKIY, V. SAUER, N. LIU, D. VICK, K.M. CHENG, M.R. FREEMAN, W.K. HIEBERT, University of Alberta Physics Department and National Institute for Nanotechnology, Edmonton AB Canada — To explore properties of fluids on a nanosize scale, we fabricated by a standard top down technique a series of nanoelectromechanical resonators (cantilevers and bridges) with widths w and thicknesses t from 100 to 500 nm; lengths l from 0.5 to 12 micron; and resonant frequencies f from 10 to 400 MHz. For the sake of purity of the experiment, the undercut in the widest ($w=500$ nm) devices was eliminated using the focused ion beam. To model the fluidic environment the devices were placed in the atmosphere of compressed gases (He , N_2 , CO_2 , Ar , H_2) at pressures from vacuum up to 20 MPa, and in liquid CO_2 ; their properties were studied by the real time stroboscopic optical interferometry. Thus, we fully explored the Newtonian and non-Newtonian flow damping models. Observing free molecular flow extending above atmospheric pressure, we find the fluid relaxation time model to be the best approximation throughout, but not beyond, the non-Newtonian regime, and both, vibrating spheres model and the model based on Knudsen number, to be valid in the viscous limit.

3:18PM X50.00005 Dynamic Similarity Principle for Nanoscale Resonant Devices in Gaseous Environments, CARYN BULLARD, MICHAEL ROUKES, California Institute of Technology, JOHN SADER, JIANCHANG LI, PAUL MULVANEY, The University of Melbourne — The mechanical performance of cantilevers on the nanoscale operating in atmosphere is dominated by gas damping. However, theoretical modeling of gas-solid interactions on the nanoscale is non-trivial due to the non-continuum nature of the gas flow. In addition, these gas-structure interactions can significantly affect the sensitivity of these devices. Instead of using numerical simulations to determine the gas flow and consequently, gas damping, of a nanoscale device, we used a general dynamic similarity principle to determine the gas damping of a nanoscale device by measuring the gas damping of a scaled up prototype device.

3:30PM X50.00006 Computational modeling of traveling wave electrophoresis¹, ROBERT CORRELL, JARROD SCHIFFBAUER, LLOYD CARROLL, West Virginia University — Traveling wave electrophoresis (TWE) is a microfluidic separation technique in which electrodes flanking a microchannel apply a traveling potential wave along the channel. Charged particles, including small molecules, proteins, and nanoparticles are differentially transported along the channel at a rate dependent on their mobility. TWE is ideally suited for application in lab-on-a-chip and field deployed sensor systems. In order to fully exploit this technology, a series of computational models have been developed, including 1-dimensional and 2-dimensional models. These models allow for testable predictions of single-particle motion, and the effects of factors such as pH and concentration upon separation efficiency. Efforts to include diffusive components within the model, and to consider the motion of bands, rather than single particles will be discussed.

¹This work is funded through NSF CBET-1066730 and the NSF RII award EPS-1003907, for which the WV EPSCoR Office and the WVU Research Corporation provided matching funds.

3:42PM X50.00007 Activated wetting dynamics in the presence of mesoscopic surface disorder, KRISTINA DAVITT, Laboratoire de Physique Statistique - ENS, MICHAEL PETTERSEN, Washington and Jefferson College, ETIENNE ROLLEY, Laboratoire de Physique Statistique - ENS — Although disorder is commonly used to explain contact angle hysteresis, it is often neglected when considering wetting dynamics. When viscous forces are negligible, contact-line velocity is modelled by the Molecular Kinetic Theory [1], which predicts an activated motion driven by molecular jumps on preferential adsorption sites. We believe that in the presence of mesoscopic disorder, this model can be reinterpreted and that the activation length is no longer molecular-sized but is related to depinning events on the surface. This hypothesis is supported by a study of the wetting of cesium by liquid hydrogen in which it was shown that the activation length is of the order of the expected roughness [2]. However, no systematic study between the activation area and the length scale of the disorder has previously been made. We study wetting dynamics on metal films evaporated under different conditions, allowing us to obtain films with lateral grain sizes ranging from 10 to 200 nm. We find that the activation area deduced from wetting experiments is coherent with these sizes; however, its precise relation to the scale of disorder is not clear.

3:54PM X50.00008 Experimental test of Schrodinger's first-passage-time theory using colloids in micro-channels, SUNGCHEOL KIM, XINSHENG LING, Brown University — We report an experimental study of the first-passage-time problem of driven diffusion in micro-channels. Fluorescent microspheres of 190nm diameter are confined in channels of 1.0 micron in width and 1.0 micron depth and driven by an applied longitudinal electric field. The images are acquired by a fluorescent microscope. The time dependence of the particle positions is tracked using particle tracking algorithms. The first passage times at different electric field values are extracted from the real-time data and compared with the exact solution given by Schrodinger for the 1D biased diffusion equation with one absorbing boundary condition.

4:06PM X50.00009 Liquid-impregnated surfaces: overcoming the limitations of superhydrophobic surfaces for robust non-wetting and anti-icing surface, J. DAVID SMITH, RAJEEV DHIMAN, ERNESTO REZA-GARDUNO, GARETH MCKINLEY, ROBERT COHEN, KRIPA VARANASI, None — In this work we address fundamental limitations of superhydrophobic surfaces for non-wetting and anti-icing applications by impregnating them with a hydrophobic liquid. The impregnating liquid serves as a barrier to the penetration of impinging water droplets and forces preferential condensation and frost formation on texture tops. We predict the thermodynamically stable wetting states based on a free energy analysis, and model the behavior of rolling droplets on liquid-impregnating surfaces. We conducted droplet impact and roll-off experiments to assess the robustness of liquid-impregnated micro- and nano-scale textured surfaces and found that their ability to shed droplets was improved dramatically. Furthermore, environmental scanning electron microscope experiments demonstrated that frost formation as well as condensation occurs preferentially on these surfaces thereby limiting ice contact to texture tops only. Ice adhesion strength was quantified using a custom-built adhesion testing apparatus to demonstrate greatly enhanced anti-icing performance of the liquid-impregnating surfaces compared to superhydrophobic surfaces.

4:18PM X50.00010 Using Superhydrophobic Surfaces and Optical Caustics to Detect Nanoparticle Aggregation, ANTONIO GARCIA, JAMES LINDSAY, ERIC GILMORE, None — A 3-D envelope of refracted light known as an optical caustic, can be formed by shaping an aqueous drop on a superhydrophobic surface which is used to generate a signal that is very sensitive to changes in particle size. When the sample being detected is suspended in the drop, slow evaporation induces movement that segregates smaller from larger particles, enhancing the speed of detection via induced aggregation. While the unique properties of optical caustics have been used in engineering science to evaluate stress distributions and contact between material components, they have not been widely used in diagnostics or biological analyses. This paper demonstrates how this method can track aggregation of gold nanoparticles for rapid detection of molecular disease markers using immunoassays.

4:30PM X50.00011 Droplet condensation and growth on nanotextured surfaces impregnated with an immiscible liquid, SUSHANT ANAND, ADAM PAXSON, JONATHAN SMITH, RAJEEV DHIMAN, KRIPA VARANASI, Massachusetts Institute of Technology — For effective dropwise condensation, a surface that sheds droplets easily is desirable due to the enhancement in accompanying heat transfer. Incorporating nano-textures on the surface can enhance the droplet shedding or spreading. We demonstrate that droplet shedding can be further influenced by impregnating the nano-textured surface with a liquid which is immiscible with respect to the droplet. In this study, the dynamics of dropwise condensation on such immiscible liquid impregnated nano-textured surfaces have been investigated in pure quiescent water vapor conditions. Condensation experiments were conducted using an Environmental Scanning Electron Microscope by controlling the chamber water vapor pressure and substrate temperature. We show preferential sites for condensation and different modes under which droplets grow, depending upon the surface chemistry, surface texture, and the impregnating liquid properties. Concurrently, we show an evolution of apparent contact angles during the condensation process on the impregnated surfaces.

4:42PM X50.00012 Molecular diffusion and tensorial slip at surfaces with periodic and random nanoscale textures¹, NIKOLAI PRIEZJEV, Michigan State University — The influence of periodic and random surface textures on the flow structure and effective slip length in Newtonian fluids is investigated by molecular dynamics (MD) simulations. This study is motivated by the possibility to generate transverse flows in microfluidics devices to enhance mixing and separation processes. We consider a situation where the typical pattern size is smaller than the channel height and the local boundary conditions at wetting and nonwetting regions are characterized by finite slip lengths. In case of anisotropic textures, the interfacial diffusion coefficient of fluid molecules near heterogeneous surfaces correlates well with the effective slip length as a function of the shear flow direction with respect to the texture orientation. In addition, it was found that the angular dependence of the effective slip length obtained from MD simulations is in good agreement with hydrodynamic predictions provided that the pattern size is larger than several molecular diameters. These findings lend support for the microscopic justification of recently introduced tensor formulation of the effective slip boundary conditions in the case of noninertial flows of Newtonian fluids over smooth surfaces with nanoscale anisotropic textures.

¹Funding from NSF (CBET-1033662) is gratefully acknowledged.

4:54PM X50.00013 Wetting as a basis for a highly selective colorimetric indicator for organic liquids¹, IAN BURGESS, School of Engineering and Applied Sciences, Harvard University, KEVIN RAYMOND, NATALIE KOAY, Wyss Institute for Biologically Inspired Engineering, Harvard University, ANNA SHNEIDMAN, MATHIAS KOLLE, MARKO LONCAR, JOANNA AIZENBERG, School of Engineering and Applied Sciences, Harvard University — We present a colorimetric indicator for organic liquids that couples distinct macroscopic color patterns to minute differences in liquids' intrinsic wettability to a surface. We find that when a liquid percolates through the pores of large-area, defect-free silica inverse-opal films, a highly consistent re-entrant geometry leads to sharply defined threshold wettability for liquid infiltration, occurring at intrinsic contact angles near 20°. The structure also acts as a 3D photonic crystal, producing bright iridescent color that disappears when infiltrated with liquid, coupling the highly selective wetting observed to an easy-to-visualize colorimetric response. Combining a percolation model and FDTD optical simulations, we estimate the selectivity of the colorimetric response. In addition, we present a technique to generate precisely controlled spatial patterns of surface chemistry throughout the porous network. This lets us tailor the wettability threshold to specific liquids across a continuous range. Using these techniques, we demonstrate the applicability of this indicator to colorimetrically distinguish: i) ethanol-water mixtures varying by only 2.5% in concentration; ii) hexane, heptane, octane, nonane, and decane; and iii) samples of gasoline (regular unleaded) and diesel.

5:06PM X50.00014 Drag Measurements in Laminar Flows over Superhydrophobic Porous Membranes, OZGUR OZSUN, VICTOR YAKHOT, KAMIL L. EKINCI, Boston University — An anomalous hydrodynamic response has recently been observed in oscillating flows on mesh-like porous superhydrophobic membranes.¹ This effect was attributed to a stable Knudsen layer of gas at the solid-liquid interface. In this study, we investigate laminar channel flow over these porous superhydrophobic membranes. We have fabricated surfaces with solid area fraction ϕ_s , which can maintain intimate contact with both air and water reservoirs on either side. Typical structures have linear dimensions of 1.5 mm $\times$ 15 mm $\times$ 1 μ m and pore area of 10 μ m $\times$ 10 μ m. The surfaces are enclosed with precisely machined plastic microchannels, where pressure driven flow of DI water is generated. Pressure drop across the microchannels is measured as a function of flow rate. Slip lengths are inferred from the Poiseuille relation as a function of ϕ_s and compared to that of similar standard superhydrophobic surfaces, which lack intimate contact with an air reservoir.

5:18PM X50.00015 Thermo-super-hydrophobic effect, JERZY M. FLORYAN, The University of Western Ontario — Super-hydrophobic effect involves capture of gas bubbles in pores of solid wall. These bubbles separate moving liquid from the solid surface resulting in a substantial reduction of shear drag experienced by the liquid. The super-hydrophobic effect requires presence of two phases and thus drag reduction can be accomplished only for liquids. Thermo-super-hydrophobic effect takes advantage of the localized heating to create separation bubbles and thus can work with single phase flow systems. Analysis of a simple model problem shows that this effect is very strong in the case of small Re flows such as those found in micro-channels and can reduce pressure drop down to 50% of the reference value if the heating pattern as well as the heating intensity are suitably chosen. The thermo-super-hydrophobic effect becomes marginal when Re increases above a certain critical value.

Thursday, March 1, 2012 2:30PM - 5:18PM –
Session X52 GSNP DFD: Focus Session: Extreme Mechanics - Fracture, Friction, and Frequencies 153C

2:30PM X52.00001 Geometry of Tearing: crack propagation in brittle sheets¹, BENOIT ROMAN, JOSE BICO, PMMH CNRS/ESPCI/UPMC/Paris7 - Paris France, ENRIQUE CERDA, EUGENIO HAMM, FRANCISCO MELO, VICTOR ROMERO, Departamento de Física, Universidad de Santiago de Chile — We experiment the fracture of thin object everyday when trying to open a packaging. From a physics point of view, the propagation of cracks in thin brittle elastic sheets appears to be remarkably reproducible, with very regular crack path. We will present some examples where the crack path can be predicted using classical arguments in fracture and geometrical tools: this is another example where geometry plays a central role in the mechanics of thin sheets.

¹We thank ANR MecaWet

2:42PM X52.00002 Spiral and croissant crack in drying thin films, JOEL MARTHELOT, BENOIT ROMAN, JOSE BICO, PMMH ESPCI ParisTech, ETIENNE BARTHEL, JEREMIE TEISSEIRE, DAVY DALMAS, SVI CNRS Saint Gobain, FRANCISCO MELO, USACH — Drying mud or crazing in ceramics glaze leads to familiar hierarchical cracks network where a new crack connects perpendicularly to older ones. We report unusual spirals and croissants crack patterns in methylsiloxane drying thin films moderately adhering on a substrate. Such cracks are also observed in a very different situation when magnetron sputtering multilayers are under external tension. The amplitude and wavelength of the pattern are robust and are orders of magnitude larger than the thickness of the layer. The propagation of the spiral and croissant cracks occurs in a narrow range of adhesion energy between the film and the substrate and strain in the film. We will show how the propagation is driven by a cooperation between fracture and adhesion.

2:54PM X52.00003 Rupture of a highly stretchable acrylic dielectric elastomer, GEORGE PHARR, Harvard University, JEONG-YUN SUN, Seoul National University and Harvard University, ZHIGANG SUO, Harvard University — Dielectric elastomers have found widespread application as energy harvesters, actuators, and sensors. In practice these elastomers are subject to large tensile stretches, which potentially can lead to mechanical fracture. In this study, we have examined fracture properties of the commercial acrylic elastomer VHB 4905. We have found that inserting a pre-cut into the material drastically reduces the stretch at rupture from $\lambda_{rup} = 9.43 \pm 1.05$ for pristine samples down to only $\lambda_{rup} = 3.63 \pm 0.45$ for the samples with a pre-cut. Furthermore, using “pure-shear” test specimens with a pre-crack, we have measured the fracture energy and stretch at rupture as a function of the sample geometry. The stretch at rupture was found to decrease with sample height, which agrees with an analytical prediction. Additionally, we have measured the fracture energy as a function of stretch-rate. The apparent fracture energy was found to increase with stretch-rate from $\Gamma \approx 1500 \text{ J/m}^2$ to $\Gamma \approx 5000 \text{ J/m}^2$ for the investigated rates of deformation. This phenomenon is due to viscoelastic properties of VHB 4905, which result in an apparent stiffening for sufficiently large stretch-rates.

3:06PM X52.00004 How does adhesion impact the formation of telephone cord buckles?, ETIENNE BARTHEL, JEAN-YVON FAOU, SERGEY GRACHEV, CNRS / Saint-Gobain, GUILLAUME PARRY, SIMAP — Compressively stressed thin films with low adhesion frequently buckle into telephone cords. Although telephone cord buckles have been studied for decades, no complete understanding of their origin and propagation has so far been presented. Here, using Finite Element Analysis, we have coupled non-linear plate deformation with a cohesive zone model to simulate the kinematics of a propagating telephone cord buckle. On the experimental side, we have developed model thin films with a precise adjustment of both adhesion and residual stresses. From the comparison of the simulations with some experimental observations, we propose a generic mechanism for the formation of telephone cord buckles. Proper inclusion of the dependence of interfacial toughness upon mode mixity proved to be central to the success of the approach so that this clarification of the mechanism of telephone cord formation promises better understanding of interfacial toughness through the analysis of buckle morphology.

3:18PM X52.00005 Nonlinear modal interactions in a microcantilever¹, HIDDE WESTRA, HERRE VAN DER ZANT, WARNER VENSTRA, Kavli Institute of Nanoscience, Delft University of Technology — We study the nonlinear interactions between vibrational modes in a microcantilever. The flexural-flexural, torsional-torsional and torsional-flexural modal interactions are investigated theoretically and experimentally. In a cantilever, the nonlinearity arising from geometrical and inertial effects couples the different modes. The motion of one mode influences the resonance frequency of the other modes. We show that depending on the amplitude of one mode, both frequency stiffening and weakening of the other mode occurs. The modal interactions in clamped-clamped beam resonators is recently studied, and several applications have been proposed. Microcantilevers are frequently used in instrumentation, and the modal interactions presented here enable such schemes, including Q-factor tuning and self-detection.

3:30PM X52.00006 Effects of Roughness and Inertia on Precursors to Frictional Sliding¹, MARK O. ROBBINS, K. MICHAEL SALERNO, Johns Hopkins University — Experiments show that when a PMMA block on a surface is normally loaded and driven by an external shear force, contact at the interface is modified in discrete precursor slips prior to steady state sliding.[1] Our simulations use an atomistic model of a rough two-dimensional block in contact with a flat surface to investigate the evolution of stress and displacement along the contact between surfaces. The talk will show how local and global stress conditions govern the initiation of interfacial cracks as well as the spatial extension of the cracked region. Inertia also plays an important role in determining the number and size of slips before sliding and influences the distribution of stresses at the interface. Finally, the geometry of surface asperities also influences the interfacial evolution and the total friction force. The relationship between the interfacial stress state and rupture velocity will also be discussed. [1] S.M. Rubinstein, G. Cohen and J. Fineberg, PRL 98, 226103 (2007)

3:42PM X52.00007 Scratch test as a fracture process: from soft to hard materials, ANGE-THERESE

AKONO, Dept of Civil and Environmental Engineering, Massachusetts Institute of Technology, Cambridge, MA, USA, PEDRO MIGUEL REIS, Dept of Civil and Environmental Engineering & Dept of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, MA, USA, NICHOLAS XAVIER RANDALL, CSM Instruments, Needham, MA, USA, FRANZ-JOSEF ULM, Dept of Civil and Environmental Engineering, Massachusetts Institute of Technology, Cambridge, MA, USA — The scratch test consists of driving a probe, at a certain depth, through a material and is most likely the oldest technique for the mechanical characterization of materials. Although it is widely used in strength testing, the presence of residual chips during the process suggests that a fracture mechanism is at play. We investigate the link between the material fracture properties, the probe geometry and the resulting forces using a combination of precision experiments and Linear Elastic Fracture Mechanics analysis. An analytical model is developed that is applicable both at the macro and micro scale, and that can take into account different probe geometries. Rationalizing the mechanics involved allows us to introduce a novel experimental technique to accurately determine the fracture toughness from scratch tests. Application of this technique to mechanical testing on metals, polymers and ceramics yields values for the fracture toughness that are in excellent agreement with conventional methods such as the three-point bending test, albeit in a way that is less destructive and more scalable. As such, our method to determine materials fracture properties represents an important new development in the field of mechanical micro-characterization.

3:54PM X52.00008 Sliding on a Nanotube: Interplay of Friction, Deformations and Defects, HSIANG-CHIH CHIU, SUENNE KIM, School of Physics, Georgia Institute of Technology, ERIO TOSATTI, International School for Advanced Studies (SISSA), and CNR-IOM Democritos, CHRISTIAN KLINKE, Institute of Physical Chemistry, University of Hamburg, ELISA RIEDO, School of Physics, Georgia Institute of Technology — Carbon nanotubes (CNT) have applications as composite material reinforcements and components in nanodevices due to their exceptional physical properties. However, CNTs have structural defects that can change their mechanical properties. For applications, CNTs have to be in contact with other surfaces, thus it is important to understand how defects change their frictional properties. Here, we show that defects can impact the frictional properties of supported Arc Discharge (AD) and Chemical Vapor Deposition (CVD) grown CNTs by sliding an AFM tip along (longitudinal) and across (transverse) the CNT axis. Larger friction coefficient is found during transverse sliding due to a lateral CNT deformation (called hindered rolling) that causes extra friction dissipation which is absent during longitudinal sliding.[1] A friction anisotropy, defined as the ratio of shear strength measured during both sliding directions, can be as high as 13.7 for AD CNTs but less than 6 for CVD CNTs. Extra defects in CVD CNTs couple both sliding motions, resulting in more energy dissipation and higher longitudinal friction. A simple analytical model is developed to explain the observed experimental behavior. Our finding provides a better understanding of tribological properties of individual CNT at the nanoscale. [1] M. Lucas et al., Nature Mater. 8, 876 (2009)

4:06PM X52.00009 Graphene Morphology on Nano-Patterned Electronic Substrates, GUANGXU LI, CIHAN YILMAZ, XIAOHONG AN, SIVASUBRAMANIAN SOMU, SWASTIK KAR, AHMED BUSNAINA, KAI-TAK WAN, Northeastern University, DEPARTMENT OF MECHANICAL AND INDUSTRIAL ENGINEERING COLLABORATION, NSF NANOSCALE SCIENCE AND ENGINEERING CENTER FOR HIGH-RATE NANOMANUFACTURING COLLABORATION, DEPARTMENT OF PHYSICS COLLABORATION — In order to get high quality of graphene for the application in electronic devices, good transfer of graphene prepared by mechanical exfoliation or chemical vapor deposition is always required and substrate with flat surface is preferred to avoid the crack and destruction of the thin sheets. Here, we studied the graphene morphology on nano-patterned electronic substrates by transferring graphene grown from chemical vapor deposition onto the gold nano pillar patterns on silicon substrate. The adhesion between the graphene and the gold surface makes the flexible thin membrane conform to the substrate geometry and form a series of blisters. By measuring the blister radius and height, the adhesion energy of graphene and gold substrate can be deduced. In the meantime, the morphology of graphene on the pillar patterns was found to strongly related to the adhesion energy, the height and separation of pillars. By changing these parameters, the blisters may decrease size or expand to coalesce. The critical separation between pillars and the critical height of pillars were predicted to avoid the coalescence of the blisters when the adhesion energy was fixed. The results obtained here can be useful to increase the performance and the durability of the graphene based device.

4:18PM X52.00010 Graphene Blister Adhesion Mechanics¹, NARASIMHA BODETTI, STEVEN KOENIG, JIAN-LIANG XIAO, SCOTT BUNCH, MARTIN DUNN, University of Colorado — We describe graphene blister configurations to study the elasticity of mono- and multi-layer graphene as well as the adhesion of the blister to an SiO₂ substrate. We create blisters by depositing graphene on a chip containing etched cavities of a prescribed volume. The chip is placed in a high-pressure chamber where the cavities are charged to a prescribed pressure. When the chip is removed from the chamber the pressure difference across the membrane causes it to bulge, while the number of gas molecules in the chamber remains constant. As the pressure is increased the membrane continues to bulge and at a critical pressure can delaminate (in a stable or unstable manner) permitting extraction of the adhesion energy from a combination of theory and measurements of the deformed blister configuration. We describe these experiments and develop a thermodynamic model of the system that identifies interesting nonlinear effects as the membranes deform including instabilities, delamination, and adhesion hysteresis, depending on the configurational parameters. We use the theory and experiments together to determine for the first time the adhesion energy between graphene and SiO₂, as well as explore the interesting mechanics that occur.

¹National Science Foundation, DARPA

4:30PM X52.00011 Novel method for simulation of structural post buckling, RACHMADIAN WULAN-DANA, Dept. of Mechanical Engineering and Materials Science, University of Pittsburgh, Pittsburgh, PA, SACHIN VELANKAR, Dept. of Chemical and Petroleum Engineering, University of Pittsburgh, Pittsburgh, PA — A new FEM-based method for simulating the onset of buckling instabilities and the post-buckling evolution is developed. The method consists of creating a random spatial perturbation of the elastic modulus and applying a step-by-step loading to approach the critical state and beyond. Prior to buckling, the non-uniform modulus triggers micro bending and lateral deformation. As the compressive load progresses, the micro displacement grows non-linearly causing the system to be biased toward the mode that minimizes energy. The system buckles in that mode and the post-buckling deformation can be examined. The technique has been applied to several buckling cases. The results show quantitative agreement with theory and experiments. For problems with continuously-distributed buckling modes and critical values that are close from one to another, the method is able to automatically select the correct critical configuration. Unlike other perturbation methods that are inspired by either Eigen vectors or experimental data, the current method does not need a priori knowledge of the expected buckling mode. This is especially useful in complex problems (e.g. wrinkling of stretched films) for which linear eigenvalue analysis cannot predict the critical conditions.

4:42PM X52.00012 Buckling morphologies of crystalline shells with frozen defects, EE HOU YONG, Harvard University, PROF. L. MAHADEVAN (HARVARD UNI.) COLLABORATION — The crumpling of spherical crystalline lattices where the topological defects are frozen is studied. The geometry of the crumpled membrane is found to depend on the set of topological defects and more exotic defect sets can result in crumpled shapes resembling that of the Platonic and Archimedean solids. The phase diagram of the crumpled spheres can be categorized by two dimensionless numbers h/R (aspect ratio) and R/a (lattice ratio), where h is the thickness of the shell, R is the radius of the initial sphere and a is the average bond length of the triangulation. The shapes of the crumpled membrane can be understood using rotationally invariant quantities formed from spherical harmonics coefficients and a Landau free energy can be written, involving quadratic and cubic rotational invariants. Shells with different topological defects have qualitatively different hysteresis behaviors and the transitions appear to be first order in general.

4:54PM X52.00013 Do tidal stresses trigger large earthquakes early? , BRADEN BRINKMAN, MICHAEL LEBLANC, University of Illinois at Urbana-Champaign, JONATHAN UHL, None, YEHUDA BEN-ZION, University of Southern California, KARIN DAHMEN, University of Illinois at Urbana-Champaign — The effect of tidal or other periodic stresses on the timing of large earthquakes is a hotly debated topic in geophysics and rock-friction or granular physics communities. I discuss a simple probabilistic model which captures the main qualitative features of several rock-friction or granular experiments and may resolve some outstanding discrepancies between different experimental results. With sufficiently accurate measurements, quantitative predictions for real experiments are possible, including the number of measured events needed to detect correlations between periodic stresses and large slip events for given amplitudes and frequencies.

5:06PM X52.00014 Tattoo-Like Strain Gauges Based on Silicon Nano-Membranes , NANSHU LU, University of Texas at Austin, LU RESEARCH GROUP TEAM — This talk reports the in vivo measurement of tissue deformation through adhesive-free, conformable lamination of a tattoo-like elastic strain gauge consisted of piezoresistive silicon nano-membranes strategically integrated with tissue-like elastomeric substrates. The mechanical deformation in soft tissues cannot yet be directly quantified due to the lack of enabling tools. While stiff strain gauges for structural health monitoring have long existed, biological tissues are soft, curvilinear and highly deformable in contrast to civil or aerospace structures. An ultra-thin, ultra-soft, tattoo-like strain gauge that can conform to the convoluted surface of human body and stay attached during locomotion will be able to directly quantify tissue deformation without affecting the mechanical behavior of the tissue. While single crystalline silicon is known to have the highest gauge factor and best elastic response, it is intrinsically stiff and brittle. To achieve strain gauges with high compliance, high stretchability and reasonable sensitivity, single crystalline silicon nano-membranes will be transfer-printed onto polymeric support through carefully engineered stamps. The thickness and length of the Si strip will be chosen according to theoretical and numerical mechanics analysis which takes into account for the tradeoff between stretchability and sensitivity.

Thursday, March 1, 2012 2:30PM - 5:42PM –
Session X53 GSNP: Focus Session: Common Features of Soft Materials: Polymers, Colloids and Granular Media II 153B

2:30PM X53.00001 Shear thickening and jamming in suspensions of different particle shapes , ERIC BROWN, University of California, Merced, HANJUN ZHANG, NICOLE FORMAN, DOUGLAS BETTS, JOSEPH DESIMONE, University of North Carolina, Chapel Hill, BENJAMIN MAYNOR, Liquidia Technologies, HEINRICH JAEGER, The University of Chicago — We investigated the role of particle shape on shear thickening and jamming in densely packed suspensions. Various particle shapes were fabricated including rods of different aspect ratios and non-convex hooked rods. A rheometer was used to measure shear stress vs. shear rate for a wide range of packing fractions for each shape. Each suspensions exhibits qualitatively similar Discontinuous Shear Thickening, in which the logarithmic slope of the stress vs. shear rate has the same scaling for each convex shape and diverges at a critical packing fraction ϕ_c . The value of ϕ_c varies with particle shape, and coincides with the onset of a yield stress, a.k.a. the jamming transition. This suggests the jamming transition controls shear thickening, and the only effect of particle shape on steady state bulk rheology of convex particles is a shift of ϕ_c . Intriguingly, viscosity curves for non-convex particles do not collapse on the same set as convex particles, showing strong shear thickening over a wider range of packing fraction. Qualitative shape dependence was only found in steady state rheology when the system was confined to small gaps where large aspect ratio particle are forced to order.

2:42PM X53.00002 Fluctuations and Avalanche Statistics in Sheared Systems of Elliptical Particles¹ , SOMAYEH FARHADI, ROBERT P. BEHRINGER, Duke University — We have performed a series of 2D Couette shear experiment on a system of granular particles near jamming. In these experiments, the particles, which are photoelastic ellipses with aspect ratio 2, are confined between an inner rotating wheel and a fixed outer ring. The inner wheel rotation rate was varied between 0.01 and 0.1 rpm. Using photoelastic properties of the particles and two synchronized cameras, we are able to track the position, orientation and contact forces of each particle through the entire experiment. We determined the local mean, fluctuations, and correlations for various system properties, such as density (Voronoi volume), pressure, orientational order parameter and shear rate. A striking finding of this study is the fact that near jamming, the system can exist in an effectively shear jammed metastable state for very long times before relaxing to an unjammed state. We have also studied the dynamics of avalanches by analyzing the time series of global stress. This study gives us insight to the nature of failure in sheared systems of asymmetrical particles.

2:54PM X53.00003 Mapping From Soft to Hard-Core Disks Near the Athermal Shear Driven Jamming Transition¹ , PETER OLSSON, Department of Physics, Umeå University, 90187 Umeå, STEPHEN TEITEL, Department of Physics and Astronomy, University of Rochester, Rochester, NY 14627 — We examine the rheology of soft-core, bidisperse, frictionless disks in two dimensions at zero temperature with overdamped dynamics. For shear driven flow at a uniform strain rate $\dot{\gamma}$, we find a simple expression for an effective hard-core packing fraction, ϕ_{eff} , such that the pressure equivalent to the shear viscosity, $p/\dot{\gamma}$, for different shear rates, packing fractions, and different contact interactions all collapse onto a common curve when plotted as a function of ϕ_{eff} . This function is a characteristic of the hard-core limit as it describes the system in the limit of vanishing particle overlaps. This mapping recovers all the critical behavior found in earlier scaling analyses. We use this mapping to derive a duality relation that gives the exponent of the non-linear Herschel-Bulkley rheology *above* jamming in terms of the exponent of the diverging viscosity *below* jamming.

¹Work supported by Energy Grant No. DE-FG02-06ER46298 and Swedish Research Council Grant No. 2010-3725. Simulations were performed on resources provided by the Swedish National Infrastructure for Computing (SNIC) at PDC and HPC2N.

3:06PM X53.00004 Hot spots in an athermal system , JEROME CRASSOUS, AXELLE AMON, IPR UMR 6251, Université Rennes 1, France, VAN BAU NGUYEN, PMMH, ESPCI, UMR CNRS 7636 and Université Paris 6 & Paris 7, 75005 Paris, France, ARY BRUAND, ISTO, UMR 6113, 45000 Orléans, France, ERIC CLEMENT, PMMH, ESPCI, UMR CNRS 7636 and Université Paris 6 & Paris 7, 75005 Paris, France — We study experimentally the dynamical heterogeneities occurring at slow shear, in a model amorphous glassy material i.e. a 3D granular packing. The deformation field is resolved spatially using a Diffusive Wave Spectroscopy technique. The heterogeneities show up as localized regions of strong deformations spanning a mesoscopic size of about 10 grains and called the 'hot spots'. The spatial clustering of hot-spots is linked to the subsequent emergence of shear bands. Quantitatively, their apparition is associated with the macroscopic plastic deformation and their rate of occurrence gives a physical meaning to the concept of "fluidity," recently used to describe the local and non-local rheology of soft glassy materials.

3:18PM X53.00005 Effect of Inertial Mass on Velocity Correlations of Shear Driven Soft-Core Disks Approaching the Athermal Jamming Transition¹

, DANIEL VÅGBERG, PETER OLSSON, Umeå University, 90187 Umeå, Sweden, STEPHEN TEITEL, University of Rochester, Rochester, NY 14627 — It was found numerically that overdamped, frictionless, soft-core disks undergoing uniform shear driven flow, show differences in behavior depending on how the viscous dissipation is introduced into the numerical simulation. When dissipation is with respect to a sheared external reservoir (the so-called “mean-field” approximation), velocity correlations are found to determine a finite length scale ξ that diverges as the jamming transition is approached[1]. However, when dissipation is modeled by inter-particle inelastic collisions, the velocity correlations show no characteristic length other than the length of the system[2]. To study the relation between these two models of dissipation, we remove the overdamped constraint and consider particles with finite inertial mass m , and study how velocity correlations behave as the overdamped limit $m \rightarrow 0$ is approached.

3:30PM X53.00006 Stretching dense colloidal suspensions: from flow to fracture

, MICHAEL SMITH, University of Nottingham, RUT BESSELING, ANDREW SCHOFIELD, University of Edinburgh, JAMES SHARP, University of Nottingham, MIKE CATES, University of Edinburgh, VOLFANGO BERTOLA, University of Liverpool — Concentrated suspensions of particles are commonly used in the pharmaceutical, cosmetic and food industries. Manufacture of these products often involves flow geometries that are substantially different from those studied by conventional shear rheology. Using a capillary break-up extensional rheometer we stretch fluids of different volume fraction at strain rates just below, at and above the critical rate required to induce jamming. We show that the jamming of a stretched colloidal column is closely related to that observed during shear rheology. However, fascinating additional effects due to the geometry are also observed. High speed photography of the filament shows evidence of dilatancy and granulation, leading finally to fracture at a critical strain rate. We also investigate an intriguing aspect of thin fluid filaments of the colloidal suspension, when stretched below the critical strain rate required to produce jamming. These filaments are observed to thin to a critical diameter before rupturing and displaying visco-elastic recoil. Finally, using fluorescent particles we visualise the flow fields inside these filaments to understand the dynamics.

3:42PM X53.00007 Fluctuations for Hopper Flow with Circular and Elliptical Particles¹

, JUNYAO TANG, Duke University — Recent studies have shown the importance of particle-scale fluctuations in granular flow, e.g. “stick-slip” and jamming. In this talk, we consider 2-D hopper flow, where we investigate how the mean and fluctuations of stress, velocity and density fields depend on hopper geometry (e.g. opening size and wall angle) and material properties (e.g. particle shape and initial filling height of materials). A particularly interesting observation is that the mean stress is a decreasing function of the filling height, even though the flux is nearly constant over the same range of material heights. We also find strong negative correlations between stress and velocity fluctuations. Also of interest is the effect of the particle orientation in the flow of elliptical particles. Related MD/DEM studies (supported by IFPRI and NSF) by Shattuck, Kondic and McCarthy et al. have found that good agreement between models and experiments for these flows.

¹This work is funded by IFPRI and the grant NSF-CBET-1010008

3:54PM X53.00008 Rheology and Jamming in Soft Colloidal System¹

, ANINDITA BASU, TIM STILL, Department of Physics and Astronomy, University of Pennsylvania, PAULO ARRATIA, Mechanical Engineering and Applied Mechanics, University of Pennsylvania, KERSTIN NORDSTROM, Department of Physics and Astronomy, University of Pennsylvania, JERRY GOLLUB, Department of Physics and Astronomy, Haverford College, DOUGLAS DURIAN, ARJUN YODH, Department of Physics and Astronomy, University of Pennsylvania — Recent simulations have proposed that the jamming transition can be understood in the framework of critical phenomena, and thus can be described by various asymptotic scaling laws. We use thermosensitive colloidal suspensions and a commercially available rheometer to study the shear response of soft colloidal glass across the jamming transition. We carry out steady-state (viscometry) and time-dependent (oscillatory) rheology experiments in the vicinity of the jamming transition. Both viscometry and oscillatory stress data exhibit asymptotic scaling and presence of critical exponents reminiscent of second-order phase transition, as reported in recent simulations. Critical scaling of frequency indicates the presence of a diverging time-scale associated with the jamming transition. We attempt to understand these critical exponents based on the microscopic interactions of the colloidal systems.

¹MRSEC DMR11-20901

4:06PM X53.00009 Local interactions and global rheology in disordered media

, ERIK WOLDHUIS, BRIAN TIGHE, Universiteit Leiden, KERSTIN NORDSTROM, DOUG DURIAN, Haverford College, JERRY GOLLUB, Haverford College, University of Pennsylvania, MARTIN VAN HECKE, Universiteit Leiden — We generalize our scaling model for the rheology of soft, frictionless repulsive spheres to include general local viscous and elastic interactions and come to a prediction of the effect on the global behavior of these local interactions. As our scaling model combines elastic and geometric ingredients and a power balance that depends on the local viscous law, we predict that the global rheology of disordered media depends on the details of the local interactions in a universal but non-trivial manner. We compare our predictions for the effect of different *elastic* interactions to recent experimental results on the interactions and rheology of NIPA particles.

4:18PM X53.00010 Jammed by shear: a new perspective of the jamming transition in frictional granular materials¹

, DAPENG BI, BULBUL CHAKRABORTY, Brandeis University — In the jamming diagram (*Nature* **396** 21 (1998)) for athermal systems jamming is induced only through compression, and jammed states exist above a packing fraction ϕ_J . Recent experiments in frictional disks clearly show shear induced jamming (D. Bi et al, *Nature* doi:10.1038/nature10667 (2011)). A minimum shear stress, τ_0 , is needed to create robust, shear-jammed (SJ) states with a strong force network percolating along both the compressive and dilational directions. This percolation transition is controlled by the fraction of force-bearing grains, a parameter not previously discussed in the context of jamming. The minimum anisotropy of SJ states vanishes as $\phi \rightarrow \phi_J$ from below in a manner reminiscent of an order-disorder transition. To shed light on the origin of shear jamming we have constructed a lattice gas model of force-bearing grains with nematic interactions between the force tiles (objects that reflect force balance on each grain). We will show that there are clear signatures of nematic ordering in SJ states, and present analysis of the nature of the shear-induced jamming transitions as a function of ϕ . We will also present numerical simulation results of sheared frictional particles.

¹This work has been supported by NSF.

4:30PM X53.00011 Deformation of inherent structures to detect short- and long-range correlations in supercooled liquids, EMANUELA DEL GADO, MAJID MOSAYEBI, PATRICK ILG, HANS CHRISTIAN OETTINGER, ETH Zurich, MICROSTRUCTURE AND RHEOLOGY, ETH ZURICH TEAM, POLYMER PHYSICS, ETH ZURICH TEAM — We use deformation of inherent structures as a tool for detecting structural changes and the onset of cooperativity in supercooled liquids. The non-affine displacement (NAD) field resulting from the applied deformation shows characteristic differences between the high temperature liquid and supercooled state, that are typically observed in dynamic quantities and correlated to normal mode structure. The average magnitude of the NAD is very sensitive to temperature changes in the supercooled regime and is found to be strongly correlated with the inherent structure energy. We can rationalize such changes in terms of a crossover from a viscous liquid to a regime dominated by elastic effects. In addition, the NAD field is characterized by a correlation length that increases upon lowering the temperature towards the supercooled regime. By analysing different measures of correlations in the direction of the NAD field, we discuss their analogies with observations in the cooperative dynamics.

4:42PM X53.00012 Experiments on ordering transitions in mechanically stable structures of granular rods, VIKRANT YADAV, Clark University, JEAN-YONNEL CHASTAING, Ecole Normale Supérieure de Lyon, ARSHAD KUDROLLI, Clark University — We investigated the evolution of granular rods from mechanically stable disordered to crystalline states in response to vibrations. We obtained positions and orientations of the rods in three dimensions using micro-focus X-ray Computed Tomography. Above a critical aspect ratio, we find that rods align vertically in layers with hexagonal order within a layer, independent of the shape of the container and details of the form of vibration. We also quantitatively study the evolution of local and global ordering using density pair correlation function $g(r)$ and orientational order parameter q_6 as a function of aspect ratio. As the system compacts, local structures emerge and grow, their size and orientation being dependent on volume fraction. Although the initial nucleation of order occurs along the boundaries, we show that the geometry of boundaries have little overall effect on the observed ordering transition. Finally we show that configuration entropy arguments do not play a significant role in the observed ordering, and the system evolves towards increasing stability under small perturbations.

4:54PM X53.00013 Elasticity of floppy amorphous systems, GUSTAVO DÜRING, EDAN LERNER, MATTHIEU WYART, New York University — Simple amorphous solids made of repulsive particles display curious properties when they are barely mechanically stable, in particular near the unjamming transition where pressure vanishes. Here we focus on another class of materials, including granular flows, covalent glasses or gels of semi-flexible polymers. In such materials the coordination associated with the dominant interaction is too weak to guarantee mechanical stability. This fact implies the presence of floppy modes, collective motions of particles that have no or very little restoring force, and that strongly affect the properties of these materials. We use analytical methods to derive the response of these systems, their length scale and frequency dependence, and test these numerically. If time permits our results will be compared with numerical observations in simplified suspension flows.

5:06PM X53.00014 Granular Matter, Foams, and Beyond: Applications of the Granocentric Model, KATHERINE NEWHALL, Courant Institute NYU — We present a local stochastic model that predicts the statistical fluctuations in jammed packings of monodisperse and polydisperse spheres revealed by confocal microscopy. Moreover, we find that this model can account for the properties of looser and denser random packings that result from depletion attraction between the particles or compression by an applied load, respectively. Finally, we extend the model to space-filling packings of cells in tissues and biliquid foams by testing analytic predictions for the dependence of the number of neighbors of a given cell on its volume. Interestingly, the model distinguishes between scenarios in which size or positional disorder in the packing dominate, in good agreement with experimental data. This versatile model can be put into the statistical mechanics framework proposed by Edwards in order to compute the entropy and compactivity of each packing.

5:18PM X53.00015 Force landscape for particulate systems¹, LOU KONDIC, New Jersey Institute of Technology, MIROSLAV KRAMAR, Rutgers University, ARNAUD GOULLET, New Jersey Institute of Technology, KONSTANTIN MISCHAIKOW, Rutgers University — We discuss the properties of force landscape for isotropically compressed particulate systems characterized by a wide range of packing fractions. The computational methods used are based on persistence diagrams which allow for clear identification of mathematical properties of force landscapes and help their physical interpretation. We find that using this technique which previously has not been applied to particulate matter, a significant new information can be extracted, going much beyond separation into 'strong' and 'weak' force networks. One result of this analysis is clear indication that for small packing fractions, polydispersity is a crucial parameter that defines the landscape, while for large packing fractions, friction, if present, becomes dominant. Preliminary results for dynamical features of force networks obtained from time-dependent analysis of force landscapes will be presented as well.

¹Supported by NSF Grant DMS-0835611 and DTRA Grant 1-10-1-0021

5:30PM X53.00016 Rearrangements in flow of foam, VIJAYAKUMAR CHIKKADI, ERIK WOLDHUIS, Instituut-Lorentz, Universiteit Leiden, PETER SCHALL, Institute of Physics, University of Amsterdam, MARTIN VAN HECKE, Kamerlingh Onnes Laboratory, Universiteit Leiden — The nonaffine deformation of amorphous solids has attracted considerable attention. Recent simulations and experiments have shown that the non-affine particle rearrangements under an applied stress are localised, and they generate a long-ranged quadrupolar strain field. Here we have investigated the particle rearrangements in flows of soft, viscous spheres near the jamming point. The characteristics of the particle rearrangements are extremely different as we move away from the jamming point.

Friday, March 2, 2012 8:00AM - 11:00AM –
Session Y1 GIMS: Measurement Science from Optics through Thermodynamics 203

8:00AM Y1.00001 Robustness of holographic particle tracking and characterization against defects in illumination, HENRIQUE W. MOYSES, BHASKAR JYOTI KRISHNATREYA, DAVID G. GRIER, Department of Physics and Center for Soft Matter Research, New York University — Images obtained with holographic video microscopy can be interpreted with predictions of the Lorenz-Mie theory of light scattering to track individual colloidal particle's motions with nanometer resolution in three dimensions over ranges extending to hundreds of micrometers, to measure their radii with nanometer resolution, and to characterize their complex refractive indexes with part-per-thousand precision. In this work we numerically and experimentally investigate how defects in the illumination system, such as divergence and tilt of the illuminating laser beam, and spherical aberrations in the optical train affect the measured properties of the particles. We show that for the usual conditions where the experiments are performed divergence and tilt of the laser beam do not affect the measured parameters significantly, while spherical aberration can introduce significant errors.

8:12AM Y1.00002 Quantification of metallic nanoparticle morphology with tilt series imaging by transmission electron microscopy¹, ANIRUDDHA DUTTA, BIAO YUAN, CHRISTOPHER J. CLUKAY, CHRISTOPHER N. GRABILL, HELGE HEINRICH, ANIKET BHATTACHARYA, STEPHEN M. KUEBLER, University of Central Florida — We report on the quantitative analysis of electrolessly deposited Au and Ag nanoparticles (NPs) on SU8 polymer with the help of High-Angle Annular Dark-Field Scanning Transmission Electron Microscopy (HAADF-STEM) in tilt series. Au NPs act as nucleating agents for the electroless deposition of silver. Au NPs were prepared by attaching Au^{3+} cations to amine functionalized SU8 polymeric surfaces and then reducing it with aqueous NaBH_4 . The nanoscale morphology of the deposited NPs on the surface of polymer has been studied from the dark field TEM cross sectional images. Ag NPs were deposited on the cross-linked polymeric surface from a silver citrate solution reduced by hydroquinone. HAADF-STEM enables us to determine the distances between the NPs and their exact locations at and near the surface. The particle distribution, sizes and densities provide us with the data necessary to control the parameters for the development of the electroless deposition technique for emerging nanoscale technologies.

8:24AM Y1.00003 Novel Imaging and Nano Fabrication with a Focused Beam of Helium Ions, JOHN NOTTE, Carl Zeiss, Microscopy — A newly introduced commercial instrument can produce a focused beam of helium ions with a focused probe size of 0.35 nm, and an energy range from 5 to 35 keV. While using only small beam currents (0.1 to 10 pA), it provides a means of generating images with high lateral resolution and surface specific information. The imaging is based up the generation of detectable particles (such as secondary electrons) as the beam interacts with the sample. Although similar to the scanning electron microscope, this instrument offers several unique imaging advantages. In addition to imaging, the focused helium beam has also been used for fabrication at the nanometer scale. Recent result have shown that this beam can be very effective for sputtering away materials to produce fine patterns for applications in biosensors, graphene, and plasmonic devices. The helium beam has also been used for lithographic purposes, producing 7 nm features with no apparent proximity effects. In another application, when the beam interacts with adsorbed molecules, the molecules are fixed – permitting the fabrication of three dimensional nano-structures. A review of the recent work, and future plans will be presented.

8:36AM Y1.00004 Neutral Atom Microscopy: A New Surface Imaging Probe, PHILIP WITHAM, ERIK SANCHEZ, Portland State University — Recent advances have made microscopy using scanned neutral atom beams a practical reality. This technique is also called Atomic DeBroglie Microscopy, Neutral Beam Microscopy, and Scanning Helium Microscopy. Using thermal energy (under 70 meV) gas particles with neutral charge results in a probe beam that scatters from the first atomic layer of samples, with little chance of beam damage. The technique presented eliminates any need to focus the beam by using an aperture in close proximity to the sample, and has produced the first published images from gas scattering. Resolution has reached $0.6\ \mu\text{m}$ and much higher resolution is possible¹. Now that NAM is a reality, a great deal of research can be done to show what it is uniquely useful for, and to explain the image contrast mechanisms. Molecular beam experiments show a wide range of surface properties that may be possible to image with such a microscope, some that are difficult to see otherwise. For example, thermal helium has a strong scattering interaction with surface hydrogens. Imaging un-coated surfaces with high electric fields is possible and imaging through high magnetic fields has been demonstrated. Recent image results and the basic instrument design will be presented. ¹A simple approach to neutral atom microscopy, Rev. Sci. Instrum. 82, 103705 (2011)

8:48AM Y1.00005 Imaging the solar cell p-n junction and depletion region using secondary electron contrast¹, JENNIFER HEATH, Linfield College, CHUN-SHENG JIANG, MOWAFAK AL-JASSIM, National Renewable Energy Laboratory — We report on secondary electron (SE) images of cross-sectioned multicrystalline Si and GaAs/GaInP solar cell devices, focusing on quantifying the relationship between the apparent n^+-p contrast and characteristic electronic features of the device. These samples allow us to compare the SE signal from devices which have very different physical characteristics: differing materials, diffused junction versus abrupt junction, heterojunction versus homojunction. Despite these differences, we find that the SE image contrast for both types of sample, and as a function of reverse bias across the diode, closely agrees with PC1D simulations of the bulk electrostatic potential in the device, accurately yielding the depletion edge and width. A spatial derivative of the SE data shows a local maximum at the metallurgical junction. Such data are valuable, for example, in studying the conformity of a diffused junction to the textured surface topography. These data also extend our understanding of the origin of the SE contrast.

¹This work was partially supported by the Petroleum Research Fund of the American Chemical Society

9:00AM Y1.00006 Resonant excitation of Rayleigh waves in a narrow fluid channel clad between two metal plates¹, NAGARAJ NAGARAJ, ARKADII KROKHIN, Center for Nonlinear Science, Univeristy of North Texas, JOSÉ SÁNCHEZ-DEHESA, VICTOR M. GARCIA-CHOCANO, Wave Phenomena Group, Universitat Politècnica de València, Spain — We study extraordinary absorption of acoustic energy due to resonant excitation of Rayleigh waves in a narrow water channel clad between two unidentical metal plates with Brass plate on one side of the channel and Aluminium plate on the other. The extraordinary absorption is observed at discrete resonant frequencies. From the elastic properties of the metal plates we derive a dispersion equation for coupled Rayleigh waves. Two different types of resonances, corresponding to different polarizations of the coupled waves, are studied for different channel widths and are experimentally confirmed. We also present the experimental confirmation of coupling through measurements of change in transmission minima with channel aperture. Experimental, theoretical, and numerical results are in a good agreement.

¹This work was supported by US Department of Energy Grant No. DE-FG02-06ER46312

9:12AM Y1.00007 Probing Heat Transfer in the Nanoscale Using Optomechanical Sensors., BRIAN BURG, JONATHAN TONG, POETRO SAMBEGORO, ANASTASSIOS MAVROKEFALOS, GANG CHEN, Massachusetts Institute of Technology — The transition from heat conduction to radiation at extremely small gaps cannot be captured by current theories. Experimentally researchers are only slowly starting to learn how to approach this domain. To this end, the development of a measurement platform based on the picowatt sensitivity of optomechanical sensors will be presented. The bending of a custom designed bimorph cantilever accurately allows the absolute amount of transferred heat to be extracted and temperature to be determined based on the response from thermal inputs. The versatility of the platform permits thermal radiation and conduction measurements, as well as the characterization of material thermal conductivities and absorptivities in nearly identical configurations. Results of this measurement platform for fundamental heat transfer measurements will considerably improve the current understanding of nanoscale energy transport and conversion, as well as lead to advanced design guidelines for energy capture and conversion devices, in particular thermophotovoltaic cells, (solar) thermoelectric generators and waste heat recovery heat exchangers.

9:24AM Y1.00008 Heat Capacity Measurements by Simultaneous Relaxation and AC-Calorimetry, H. KASHURI, K. KASHURI, G.S. IANNACCHIONE, WPI — A high-resolution method for measuring the heat capacity C_p using simultaneously AC and Relaxation Calorimetry techniques has been developed. This technique is useful for both first and second-order phase transitions of liquids and complex fluids. The difference of the C_p 's measured by the Relaxation and AC calorimetry is a direct measurement of a phase transitions' latent heat. As a test, the C_p of two cyanobiphenyl liquid crystals, 5CB and 8CB, were measured using a square wave modulation pulse train over a base temperature range from 300 to 320 K in which 5CB exhibits a first-order phase transition and 8CB exhibits a first and second-order phase transition. Fourier transform analysis allows for the direct C_p measurement at the fundamental frequency of the square wave pulse train (as well as higher frequency orders) as function of temperature (i.e., AC-mode). The heating and cooling relaxations at the beginning and end of the square pulse heating allows for a relaxation analysis of C_p by applying the dual slope-method that includes all enthalpic conversions.

9:36AM Y1.00009 The State of the Unit: A documentary film about the kilogram, AMY YOUNG¹, University of Illinois at Urbana-Champaign — The definition of the SI unit of mass is based on the international prototype of the kilogram, created in 1879 [1]. In the next years, metrologists will redefine the kilogram in relation to fundamental physical constants [2]. Intended for a general audience, the forthcoming documentary, *The State of the Unit: The Kilogram*, presents the history of the kilogram, interviews with researchers at national metrology institutes in the U.S., France, and Germany, and everyday mass measurement activities at varying scales. Excerpts of the film will be shown, and followed by a discussion with the filmmaker about the project to date. This film is supported in part by the Materials Computation Center at the University of Illinois at Urbana-Champaign, the California Institute of the Arts, Valencia, California, and La Fémis, Paris, France.

9:48AM Y1.00010 Wall friction measurement in the absence of mean shear¹, STEFANUS STEFANUS, JAMES CASTIGLIONE, RORY CERBUS, WALTER GOLDBURG, University of Pittsburgh — The dimensionless frictional force f between a pipe wall and a flowing turbulent fluid is $f = \nu \bar{s} / U^2$, where U is mean flow speed in the x -direction, ν is kinematic viscosity, and $\bar{s} = \frac{\partial u}{\partial y}$, where the y axis is perpendicular to the flow direction. The derivative is evaluated at the wall, $y = 0$. Described here a scheme for measuring f in a turbulent fluid where $\bar{s}$ is close to zero. Hence the source of frictional dissipation is from *fluctuations* in the shear about its mean, namely $\bar{s}^2$. This type of shear is encountered in turbulence in a closed container such as a food mixer. The scheme, which involves photon correlation spectroscopy, averages the shear rate over a laser spot size $w \simeq 100 \mu\text{m}$ or smaller. The scheme yields the probability density function (PDF) of components of the shear rate tensor and the moments of the PDF. The theory will be described briefly and measurements will be presented where $\bar{s} \simeq 0$. In that limit f is redefined to be $f = u' \bar{s}_{ij} / \nu$, where $\bar{s}_{ij}$ is the dominant component being measured, and u' is the rms fluctuations of the velocity.

¹Supported by the U. of Pittsburgh and NSF grant 0604477.

10:00AM Y1.00011 Mid-Infrared Photothermal Response in a Liquid Crystal Using a Quantum Cascade Laser¹, ALKET MERTIRI, Dept. Material Science, Boston University, MI HONG, Dept. Physics, Boston University, JEROME MERTZ, Dept. Biomedical Eng., Boston University, HATICE ALTUG, Dept. Electrical Eng., Boston University, SHYAMSUNDER ERRAMILLI, Dept. Physics, Boston University — We report on a new technique to measure the mid-infrared photothermal response induced by a tunable Quantum Cascade Laser (QCL) in the neat liquid crystal 4-Octyl-4'-Cyanobiphenyl (8CB), without using any intercalated dye. The modulated pump QCL range spanned a weak combination absorption band centered at 1912cm^{-1} . The thermally induced modulation of a Ti:Sapphire probe laser operating at 800 nm was measured by lockin detection. Heterodyne measurement of the response in the solid, smectic, nematic(N) and isotropic(I) liquid crystal phases allows direct detection of a weak mid-infrared normal combination mode absorption using an inexpensive room temperature silicon photodetector. The sensitivity of the response exceeds that of a conventional FTIR spectrometer equipped with a liquid nitrogen cooled detector. At high pump power in the nematic phase close to the N-I phase transition, we observe an interesting peak splitting in the photothermal response. The advent of tunable lasers that can access still stronger modes suggests that the photothermal mid-infrared response has the potential to detect ultralow concentration of absorbers.

¹We thank Thomas Jeys and Vladimir Liberman (MIT-Lincoln Labs) for helpful discussion.

10:12AM Y1.00012 Optical detection of thermal noise modes in torsional microelectromechanical oscillators¹, VINCENT VLAMINCK, JEFFREY R. GUEST, DARIO ANTONIO, DANIEL LOPEZ, JOHN E. PEARSON, AXEL HOFFMANN, Argonne National Laboratory — We present the optical detection of the thermal noise spectrum for different torsional MEMS that will be implemented in a study of magnetomechanical coupling at the nanoscale. The interferometric measurement yields the differential dynamic displacement between two diffraction-limited spots on the surface to sub-pm precision, allowing us to identify the thermal modes in the low MHz frequency range. Flexion and torsional modes from thermal noise at room temperature can be distinguished by different amplitudes at different positions of the probe beam. The different mechanical eigenmodes are identified with the help of finite element simulations. This study of the thermal oscillation serves to identify the torsional mode frequencies that can be matched to low frequency magnetization dynamics of magnetic domain wall oscillators. At this point we have fabricated torsional oscillators with a resonance frequency of 6.53 MHz and a Q-factor of 1030, which are at the same time compatible with magnetic domain wall oscillators.

¹Supported by DOE-BES under contract No. DE-AC02-06CH11357.

10:24AM Y1.00013 Advances in Surface Plasmon Resonance Imaging allowing for quantitative measurement of laterally heterogeneous samples, ADAM RAEGER, KYLE REITER, Department of Physics, University of Guelph, ANTHONY CLARKE, Department of Molecular and Cellular Biology, University of Guelph, JACEK LIPKOWSKI, Department of Chemistry, University of Guelph, JOHN DUTCHER, Department of Physics, University of Guelph — The Surface Plasmon Resonance (SPR) phenomenon is routinely exploited to qualitatively probe changes to materials on metallic surfaces for use in probes and sensors. Unfortunately, extracting truly quantitative information is usually limited to a select few cases – uniform absorption/desorption of small biomolecules and films, in which a continuous “slab” model is a good approximation. We present advancements in the SPR technique that expand the number of cases for which the technique can provide meaningful results. Use of a custom, angle-scanning SPR imaging system, together with a refined data analysis method, allow for quantitative kinetic measurements of laterally heterogeneous systems. The degradation of cellulose microfibrils and bundles of microfibrils due to the action of cellulolytic enzymes will be presented as an excellent example of the capabilities of the SPR imaging system.

10:36AM Y1.00014 Use of Cavity Ring Down Spectroscopy to Characterize Organic Acids and Aerosols Emitted in Biomass Burning¹

, SOLOMON BILILIGN, Department of Physics and NOAA-ISET Center North Carolina A&T State University, Greensboro, NC, MARC FIDDLER, NOAA-ISET Center, North Carolina A&T State University, Greensboro, NC, SUJEETA SINGH, Energy and Environmental Systems, North Carolina A&T State University, Greensboro, NC — One poorly understood, but significant class of volatile organic compounds (VOC) present in biomass burning is gas-phase organic acids and inorganic acids. These acids are extremely difficult to measure because of their adsorptive nature. Particulates and aerosols are also produced during biomass burning and impact the radiation budget of the Earth and, hence, impact global climate. Use cavity ring down spectroscopy (CRD) to measure absorption cross sections for OH overtone induced photochemistry in some organic acids (acetic acid and peracetic acid) will be presented and planned measurements of optical properties of aerosols composed of mixtures of different absorbing and non-absorbing species using CRD will be discussed.

10:48AM Y1.00015 Modeling large screening length effects in Electrostatic Force Microscopy

, P.L. LANG, LPEM, ESPCI-ParisTech-UPMC-CNRS, Paris, France; School of Science, BUPT, Beijing, China, A. MOTTAGHIZADEH, LPEM, ESPCI-ParisTech-UPMC-CNRS, Paris, France, L. CUI, LPEM, ESPCI-ParisTech-UPMC-CNRS, Paris, France; IOP and Beijing National Laboratory for Condensed Matter Physics, CAS, Beijing, China, A. ZIMMERS, H. AUBIN, LPEM, ESPCI-ParisTech-UPMC-CNRS, Paris, France, J. LI, D.N. ZHENG, IOP and Beijing National Laboratory for Condensed Matter Physics, CAS, Beijing, China — Electrostatic Force Microscopy (EFM) and its variants such as Kelvin Probe Microscopy (KPM) are ordinarily used to image charged states or electrochemical surface potentials. However, EFM can also be used to measure the local capacitance between the tip and the substrate. For perfectly metallic substrates, this capacitance is purely geometrical, i.e. it is set by the tip shape and substrate geometry. In semi-metals with long screening length, the measured capacitance contains a “quantum” component, which is set by the electronic compressibility. Using finite element calculations, we demonstrate that this quantum capacitance component can be measured by EFM. We apply these calculations to the analysis of EFM data on magnetite nanoparticles presented by A. Mottaghizadeh during this meeting.

Session Y2 GMAG FIAP: Invited Session: Magnetic Materials and Magnetism Research for Energy Applications 204AB

8:00AM Y2.00001 Magnetic Materials in sustainable energy

, OLIVER GUTFLEISCH, Material Science, Technical University of Darmstadt Germany — A new energy paradigm, consisting of greater reliance on renewable energy sources and increased concern for energy efficiency in the total energy lifecycle, has accelerated research in energy-related technologies. Due to their ubiquity, magnetic materials play an important role in improving the efficiency and performance of devices in electric power generation, conversion and transportation. Magnetic materials are essential components of energy applications (i.e. motors, generators, transformers, actuators, etc.) and improvements in magnetic materials will have significant impact in this area, on par with many “hot” energy materials efforts. The talk focuses on the state-of-the-art hard and soft magnets and magnetocaloric materials with an emphasis on their optimization for energy applications. Specifically, the impact of hard magnets on electric motor and transportation technologies, of soft magnetic materials on electricity generation and conversion technologies, and of magnetocaloric materials for refrigeration technologies, will be discussed. The synthesis, characterization, and property evaluation of the materials, with an emphasis on structure-property relationships, will be examined in the context of their respective markets as well as their potential impact on energy efficiency. Finally, considering future bottle-necks in raw materials and in the supply chain, options for recycling of rare-earth metals will be analyzed.¹

8:36AM Y2.00002 Spintronics Device for Stand-by Power Free Nonvolatile CMOS VLSI¹

, HIDEO OHNO, CSIS/RIEC, Tohoku University, Sendai, Japan — Recent progress in perpendicular magnetic-easy axis magnetic tunnel junctions (MTJs), a spintronics device, offers a high potential building block for constructing not only stand-alone fast and nonvolatile RAMs in the 30 nm feature size and beyond but also nonvolatile CMOS VLSI employing logic-in-memory architecture [1]. The shift from in-plane to perpendicular is prompted by the need for a high crystalline anisotropy that is available in perpendicular materials for reducing the device size. In addition, current-induced switching is inherently more efficient with perpendicular easy axis. However, satisfying both high tunnel magnetoresistance (TMR) ratio over 100% and low switching current was a challenge, because of the mismatch between MgO (100) - CoFe(B) bcc (100) structure needed to obtain high TMR and the crystal structure of perpendicular materials. It was shown that a strong perpendicular interface anisotropy exists at the MgO-CoFeB interface [2, 3], strong enough ($K_i = 1.3 \text{ mJ/m}^2$) to overcome demagnetization energy and make the easy axis perpendicular when the ferromagnetic electrode thickness is thin enough. First principle calculation by Nakamura *et al.* showed that the perpendicular anisotropy is due to the oxygen-iron bond that reduces contribution of in-plane crystalline anisotropy [4]. By the use of this perpendicular easy axis, a 40 nm ϕ MgO-CoFeB MTJ with high TMR (>100 %) and low switching current of 49 μA was realized [2]. It was also pointed out that activation volume for reversal plays an important role in determining the thermal stability of the MTJs [5]. I will discuss how the MTJs are incorporated in CMOS VLSIs to make them nonvolatile and stand-by power free.

9:12AM Y2.00003 Optimized Magnetocaloric Materials¹ , VITALIJ PECHARSKY, Ames Laboratory US DOE and Department of Materials Science and Engineering, Iowa State University, Ames, IA 50011-3020 — The discovery of the giant magnetocaloric effect in $\text{Gd}_5\text{Si}_2\text{Ge}_2$ and other R_5T_4 compounds (R = rare earth metal and T is a Group 14 element) generated a broad interest in the magnetocaloric effect and magnetostructural transitions. Reports on the giant magnetocaloric effect in other systems soon followed. These include $\text{MnFeP}_x\text{As}_{1-x}$ and related compounds, $\text{La}(\text{Fe}_{1-x}\text{Si}_x)_{13}$ and their hydrides, $\text{Mn}(\text{As}_x\text{Sb}_{1-x})$, $\text{CoMnSi}_x\text{Ge}_{1-x}$ and related compounds, Ni_2MnGa and some closely related Heusler phases, and a few other systems. A common feature is the enhancement of the magnetic entropy effect by the overlapping contribution from the lattice, regardless whether it is a massive structural change like in R_5T_4 compounds, or only a phase volume change as in $\text{La}(\text{Fe}_{1-x}\text{Si}_x)_{13}$. Both the magnetic and lattice entropies are, therefore, important and each contribution must be maximized in order to have the optimum magnetocaloric effect. Both of these entropy terms and the potential pathways towards a further enhancement of the giant magnetocaloric effect will be discussed.

9:48AM Y2.00004 High-Performance Permanent Magnets for Energy-Efficient Devices , GEORGE HADJIPANAYIS, Department of Physics and Astronomy, University of Delaware, Newark, DE, U.S.A. — Permanent magnets (PMs) are indispensable for many commercial applications including the electric, electronic and automobile industries, communications, information technologies and automatic control engineering. In most of these applications, an increase in the magnetic energy density of the PM, usually presented via the maximum energy product $(BH)_{max}$, immediately increases the efficiency of the whole device and makes it smaller and lighter. Worldwide demand for high performance permanent magnets has increased dramatically in the past few years driven by hybrid and electric cars, wind turbines and other power generation systems. New energy challenges in the world require devices with higher energy efficiency and minimum environmental impact. The potential of 3d-4f compounds which revolutionized the PM science and technology is almost fully utilized, and the supply of 4f rare earth elements does not seem to be much longer assured. This talk will address the major principles guiding the development of PMs and overview state-of-the-art theoretical and experimental research. Recent progress in the development of nanocomposite PMs, consisting of a fine (at the scale of the magnetic exchange length) mixture of phases with high magnetization and large magnetic hardness will be discussed. Fabrication of such PMs is currently the most promising way to boost the $(BH)_{max}$, while simultaneously decreasing, at least partially, the reliance on the rare earth elements. Special attention will be paid to the impact which the next-generation high- $(BH)_{max}$ magnets is expected to have on existing and proposed energy-saving technologies.

10:24AM Y2.00005 Soft Magnetic Materials for Improved Energy Performance¹ , MATTHEW WILLARD, U. S. Naval Research Laboratory — A main focus of sustainable energy research has been development of renewable energy technologies (e.g. from wind, solar, hydro, geothermal, etc.) to decrease our dependence on non-renewable energy resources (e.g. fossil fuels). By focusing on renewable energy sources now, we hope to provide enough energy resources for future generations. In parallel with this focus, it is essential to develop technologies that improve the efficiency of energy production, distribution, and consumption, to get the most from these renewable resources. Soft magnetic materials play a central role in power generation, conditioning, and conversion technologies and therefore promoting improvements in the efficiency of these materials is essential for our future energy needs. The losses generated by the magnetic core materials by hysteretic, acoustic, and/or eddy currents have a great impact on efficiency. A survey of soft magnetic materials for energy applications will be discussed with a focus on improvement in performance using novel soft magnetic materials designed for these power applications. A group of premiere soft magnetic materials – nanocrystalline soft magnetic alloys – will be highlighted for their potential in addressing energy efficiency. These materials are made up of nanocrystalline magnetic transition metal-rich grains embedded within an intergranular amorphous matrix, obtained by partial devitrification of melt-spun amorphous ribbons. The nanoscale grain size results in a desirable combination of large saturation induction, low coercivity, and moderate resistivity unobtainable in conventional soft magnetic alloys. The random distribution of these fine grains causes a reduction in the net magnetocrystalline anisotropy, contributing to the excellent magnetic properties. Recently developed $(\text{Fe,Co,Ni})_{88}\text{Zr}_7\text{B}_4\text{Cu}_1$ alloys will be discussed with a focus on the microstructure/magnetic property relationship and their effects on the energy efficiency of these materials for AC applications.

Session Y3 DCMP: Invited Session: Competing Phases and Quantum Criticality in Strongly Correlated Systems 205AB

8:00AM Y3.00001 Correlated Electron State in $\text{Ce}_{1-x}\text{Yb}_x\text{CoIn}_5$ Stabilized by Cooperative Valence Fluctuations¹ , LEI SHU², University of California, San Diego — Heavy fermion superconductivity has continuously attracted broad scientific attention. One of the important issues in this study is the relationship between quantum criticality, non-Fermi-liquid behavior (NFL), and unconventional superconductivity. It is generally thought that critical fluctuations associated with a magnetic quantum critical point (QCP) can provide a mechanism for NFL behavior and unconventional superconductivity in a narrow dome around the QCP. However, the precise nature of the relationship between these phenomena remains to be understood, particularly since many compounds have been reported where the NFL behavior persists over an extended region of the phase diagram in the absence of any identifiable QCP. Recently, intermediate valence phenomena has been found in the heavy fermion superconductor system $\text{Ce}_{1-x}\text{Yb}_x\text{CoIn}_5$. X-ray diffraction, electrical resistivity, magnetic susceptibility, and specific heat measurements reveal that many of the characteristic features of the $x = 0$ correlated electron state are stable for $0 \leq x \leq 0.775$, and that phase separation occurs for $x > 0.775$. The stability of the correlated electron state is apparently due to cooperative behavior of the Ce and Yb ions, involving their unstable valences. Low temperature NFL behavior is observed which varies with x , even though there is no readily identifiable quantum critical point. The NFL state is tuned by valence fluctuations. The strongly intermediate-valence state of Yb in $\text{Ce}_{1-x}\text{Yb}_x\text{CoIn}_5$ has recently been verified by angle-resolved photoemission spectroscopy, extended x-ray absorption fine structure, and x-ray absorption near-edge structure measurements.

8:36AM Y3.00002 Tuning Correlations in Low-Dimensional Electron Systems: Fermi liquid versus non-Fermi-liquid behavior in organic conductors, MARTIN DRESSEL, 1. Physikalisches Institut, Universität Stuttgart — While the electronic properties of cuprates can be modified by electron or hole doping, organic conductors provide the opportunity to tune the strength of electronic correlations more directly. Varying the bandwidth by (physical or chemical) pressure, the κ -phase BEDT-TTF compounds cross over from a Fermi liquid to a Mott insulator by increasing effective correlations. We systematically investigate the electronic transport properties in organic conductors by dc resistivity and optical measurements in order to extract the temperature and frequency-dependent scattering rate $1/\tau = A(k_B T)^2 + B(\hbar\omega)^2$. We find corresponding temperature and frequency ranges in which the parabolic behaviors are observed. For the first time, we can quantitatively relate the two prefactors ($A/B = 56$) and their enhancement as correlations increase upon approaching the Mott transition. Conceptually low-dimensional organic conductors are also good candidates for quantum criticality because often an ordered state is located next to a metallic state when the system is tuned by pressure. Interestingly both are found, order in the spin as well as in the charge sector. Fermi-liquid behavior observed in the metallic state seems to be limited to certain regions of the phase diagram with non-Fermi-liquid properties evolving as the ordered phase is approached. It is not clear whether these deviations from Fermi liquid behavior are actually a signature of quantum criticality.

9:12AM Y3.00003 Superconducting condensation energy of CeCu₂Si₂ and theoretical implications, STEFAN KIRCHNER, Max Planck Institute for Physics of Complex Systems — Unconventional superconductivity occurs in a broad range of strongly correlated electron systems including the newly discovered iron pnictides and chalcogenides, various intermetallic rare earth metals, the cuprates and the organic superconductors. These systems are not only of varying effective dimensionality but their parent compounds out of which superconductivity emerges ranges from metals to bad metals and Mott insulators. The only unifying characteristic features seems that unconventional superconductivity occurs in close vicinity of zero-temperature instabilities which are most often magnetic in nature. Heavy fermion compounds represent prototype systems to address the interplay between quantum criticality and unconventional superconductivity [1]. In CeCu₂Si₂, the magnetic quantum phase transition and superconductivity occur at ambient pressure which allows for a detailed study of the energetics across the superconducting transition. Based on an in-depth study of the magnetic excitation spectrum of CeCu₂Si₂ in the normal and superconducting state we obtain a lower bound for the change in exchange energy [2]. The comparison with the superconducting condensation energy demonstrates that the built-up of magnetic correlations near the quantum critical point does drive superconductivity in CeCu₂Si₂. In addition, our comparison establishes a huge kinetic energy loss which we relate to the competition of Kondo screening and superconductivity as the opening of the gap weakens the Kondo effect [2,3]. We discuss the relation between kinetic energy loss and the nature of the underlying quantum critical point [1,3]. Our unexpected findings sheds further light on the emerging global phase diagram of heavy fermion compounds [4] and are believed to be relevant to other families of superconductivity which are also located in close proximity to magnetism.

9:48AM Y3.00004 Quantum critical scaling in beta-YbAlB₄ and theoretical implications, ANDRIY NEVIDOMSKYY, Rice University, Houston, TX — Emergent phenomena in quantum materials are subject of intense experimental and theoretical research at present. A wonderful example thereof are the sister phases of YbAlB₄ - a newly discovered heavy fermion material [1]. While one phase (α -YbAlB₄) is a heavy Fermi liquid, its sibling β -YbAlB₄ is quantum critical, supporting an unconventional superconductivity with a tiny transition temperature of ~ 80 mK. Latest experiments [2] uncover the quantum critical T/B -scaling in β -YbAlB₄ and prove that superconductivity emerges from a strange metal governed by an extremely fragile quantum criticality, which apparently occurs at zero field, without any external tuning. Here, we will present a theoretical perspective on the quantum critical scaling in β -YbAlB₄ and will show that the critical exponents can be derived from the nodal structure of the hybridization matrix between Yb f -band and the conduction electrons. It follows that the free energy at low temperatures can be written in a scaling form $F \propto [(k_B T)^2 + (g\mu_B B)^2]^{3/4}$, which predicts the divergent Sommerfeld coefficient γ and quasi-particle effective mass as $B \rightarrow 0$: $\gamma \sim m^*/m \propto B^{-1/2}$. This is indeed observed in the experiment [1,2], which places a tiny upper bound on the critical magnetic field $B_c < 0.2$ mT. We will discuss theoretical implications of this fragile intrinsic quantum criticality in β -YbAlB₄ and discuss the possibility of a quantum critical phase, rather than a quantum critical point, in this material.

10:24AM Y3.00005 Chromium at High Pressure, RAFAEL JARAMILLO, Harvard University — Chromium has long served as the archetype of spin density wave magnetism. Recently, Jaramillo and collaborators have shown that Cr also serves as an archetype of magnetic quantum criticality. Using a combination of x-ray diffraction and electrical transport measurements at high pressures and cryogenic temperatures in a diamond anvil cell, they have demonstrated that the Néel transition (T_N) can be continuously suppressed to zero, with no sign of a concurrent structural transition. The order parameter undergoes a broad regime of exponential suppression, consistent with the weak coupling paradigm, before deviating from a BCS-like ground state within a narrow but accessible quantum critical regime. The quantum criticality is characterized by mean field scaling of T_N and non mean field scaling of the transport coefficients, which points to a fluctuation-induced reconstruction of the critical Fermi surface. A comparison between pressure and chemical doping as means to suppress T_N sheds light on different routes to the quantum critical point and the relevance of Fermi surface nesting and disorder at this quantum phase transition. The work by Jaramillo *et al.* is broadly relevant to the study of magnetic quantum criticality in a physically pure and theoretically tractable system that balances elements of weak and strong coupling.

Friday, March 2, 2012 8:00AM - 10:48AM —
Session Y4 DAMOP: Cold Quantum Gases in Reduced Dimensions 205C

8:00AM Y4.00001 Tunneling-driven transitions in magnetization compressibility and density redistributions in a fermionic superfluid of cold atoms trapped in an array of one-dimensional tubes, KUEI SUN, C.J. BOLECH, University of Cincinnati — We study two-species fermion gases with attractive interactions in optical lattices that are made as an array of one-dimensional tube confinements. With the decrease in lattice depth, we find that the increase in tunneling between tubes leads to an incompressible-compressible transition in magnetization. The role of pair tunneling is considered, as well as the experimental implications.

8:12AM Y4.00002 Fermion Pairing in a One-Dimension Optical Lattice¹, ARIEL SOMMER, LAWRENCE CHEUK, MARK KU, WASEEM BAKR, MARTIN ZWIERLEIN, Department of Physics, MIT-Harvard Center for Ultracold Atoms, and Research Laboratory of Electronics, MIT, Cambridge, Massachusetts 02139, USA — Strongly correlated fermions in an array of two-dimensional planes coupled via tunneling serve as an important model system for high-temperature superconductors and layered organic conductors. We realize this model using ultracold fermionic ⁶Li atoms in a one-dimensional optical lattice near a Feshbach resonance. The depth of the lattice controls the interlayer coupling, and tunes the system between three and two dimensions. Pairing between fermions is studied using radio-frequency spectroscopy. The binding energy of fermion pairs is determined along the dimensional crossover and for different interaction strengths through the BEC-BCS crossover. Probes of superfluidity in the coupled layer system are also discussed.

8:24AM Y4.00003 ABSTRACT WITHDRAWN —

8:36AM Y4.00004 Entanglement-based perturbation theory for highly anisotropic Bose-Einstein condensates, ALEXANDRE TACLA, CARLTON CAVES, University of New Mexico — We investigate the emergence of three-dimensional behavior in a reduced-dimension Bose-Einstein condensate trapped by a highly anisotropic potential. We handle the problem analytically by performing a perturbative Schmidt decomposition of the condensate wave function between the tightly confined direction(s) and the loosely confined direction(s). The perturbation theory is valid when the nonlinear scattering energy is small compared to the transverse energy scales. Our approach provides a straightforward way, first, to derive corrections to the transverse and longitudinal wave functions of the reduced-dimension approximation and, second, to calculate the amount of entanglement that arises between the transverse and longitudinal spatial directions. Numerical integration of the three-dimensional Gross-Pitaevskii equation for different cigar-shaped potentials and experimentally accessible parameters reveals good agreement with our analytical model even for relatively high nonlinearities. In particular, we show that even for such stronger nonlinearities the entanglement remains remarkably small, which allows the condensate to be well described by a product wave function that corresponds to a single Schmidt term.

8:48AM Y4.00005 Phase Diagram of the Bose Hubbard Model with Weak Links, KALANI HETTIARACHCHILAGE, VALY ROUSSEAU, KA-MING TAM, JUANA MORENO, MARK JARRELL, DANIEL SHEEHY, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, Louisiana 70803, USA — We study the ground state phase diagram of strongly interacting ultracold Bose gas in a one-dimensional optical lattice with a tunable weak link, by means of Quantum Monte Carlo simulation. This model contains an on-site repulsive interaction (U) and two different near-neighbor hopping terms, J and t , for the weak link and the remainder of the chain, respectively. We show that by reducing the strength of J , a novel intermediate phase develops which is compressible and non-superfluid. This novel phase is identified as a Normal Bose Liquid (NBL) which does not appear in the phase diagram of the homogeneous bosonic Hubbard model. Further, we find a linear variation of the phase boundary of Normal Bose Liquid (NBL) to Superfluid (SF) as a function of the strength of the weak link. These results may provide a new path to design advanced atomtronic devices in the future.

9:00AM Y4.00006 The effective mass of ultracold atoms in one-dimensional optical lattices, FEDERICO DUQUE GOMEZ, J.E. SIPE, Department of Physics, University of Toronto — According to the effective mass theorem, in the presence of an external force the wavepacket associated with a crystal electron in one band accelerates as a particle with an effective mass. However, when the force is turned on suddenly, the expectation value of the acceleration initially behaves according to the electron's bare mass, and afterwards oscillates around the value given by the usual effective mass.¹ These oscillations are difficult to measure in typical solid state systems because they decay after a time of the order of femtoseconds.² We consider this oscillatory behaviour with ultracold atoms in a one-dimensional optical lattice where the time scale of the oscillations and the coherence times are much longer. Our theoretical analysis is based on a perturbation scheme that decouples the bands to any order in the external force.³ We check the validity of this perturbative approach, comparing its results with those obtained from a full numerical calculation. Experimental investigations are underway.⁴

9:12AM Y4.00007 Supercurrent decay via quantum nucleation of phase slips in one-dimensional lattice bosons¹, IPPEI DANSHITA, RIKEN, Wako, Saitama 351-0198, Japan, ANATOLI POLKOVNIKOV, Department of Physics, Boston University, Boston, MA 02215 — We study transport properties of one-dimensional (1D) Bose gases in a periodic potential. In 1D, superflow at zero temperature can decay via quantum nucleation of phase slips even when the flow velocity is much smaller than the critical velocity predicted by mean-field theories. We use instanton techniques to find that the decay rate G is algebraically increases with the flow momentum p as $G/L \propto p^{2K-2}$, where L is the system size, K the Luttinger parameter. We also discuss the relation between the nucleation rate and the quantum superfluid-insulator transition in order to present a physical interpretation of the scaling formula.

¹A. P. acknowledges support from NSF DMR- 0907039, AFOSR FA9550-10-1-0110, and the Sloan Foundation.

9:24AM Y4.00008 Compressibility and Entropy of One Dimensional Fermions in a combined Harmonic and Periodic Potential, ANDREW SNYDER, THEJA DE SILVA, Binghamton University — We solve the homogeneous Hubbard model for repulsively interacting fermions using thermodynamic Bethe ansatz method. Treating the harmonic potential in local density approximation, we calculate particle density, various compressibilities, double occupancy, and entropy as a function of temperature and interaction. These quantities show characteristic features that can be used to detect temperature, metal-insulator transition, and coexistence of metallic and insulating phases.

9:36AM Y4.00009 From GPE to KPZ: Finite temperature dynamical structure factor of the 1D Bose gas, MANAS KULKARNI, University of Toronto, AUSTEN LAMACRAFT, University of Virginia — Recent experiments on 1D Bose gases have raised interest in the investigation of dynamical properties at finite temperature such as the structure factor. For weak enough interaction and high enough temperature, we expect a classical description in terms of the Gross-Pitaevskii equation with thermally populated modes to be valid. Here, we present numerical results for the finite temperature dynamical structure factor and its universal anomalous scaling behavior, arising from resonant interactions between phonons. Our results are also relevant to sound damping in 1D classical fluids. Somewhat more surprisingly, there is a deep connection to systems in the Kardar-Parisi-Zhang universality class, describing growing fluctuating interfaces.

9:48AM Y4.00010 Photoinduced phase transition in one dimensional extended Hubbard model, HANTAO LU, SHIGETOSHI SOTA, Yukawa Institute for Theoretical Physics, Kyoto University, Kyoto, 606-8502, Japan, HIROAKI MATSUEDA, Sendai National College of Technology, Sendai, 989-3128, Japan, TAKAMI TOHYAMA, Yukawa Institute for Theoretical Physics, Kyoto University, Kyoto, 606-8502, Japan — We illustrate one interesting example of the photoinduced phase transitions due to a nonequilibrium process. The impact of laser pump on one dimensional half-filled extended Hubbard model in the spin-density-wave (SDW) phase is investigated by using time-dependent density-matrix renormalization group. With proper laser frequencies and strengths, we find that charge-density wave (CDW) can be observed during the pulse. Further, in some situations, for instance, near the boundary between SDW and CDW in the ground state, the CDW signature can be sustained even after the pulse turned off. The underlying physics and possible experimental realization are discussed.

10:00AM Y4.00011 Separation induced resonances in quasi-one-dimensional ultracold atomic gases, WENBO FU, Institute for Advanced Study, Tsinghua University, Beijing, 100084, ZHENHUA YU, Department of Physics, Ohio State University, Columbus, OH 43210, XIAOLING CUI, Institute for Advanced Study, Tsinghua University, Beijing, 100084 — We study the effective one-dimensional (1D) scattering of two distinguishable atoms confined individually by *separated* transverse harmonic traps. With equal trapping frequency for two s-wave interacting atoms, we find that by tuning the trap separations, the system can undergo *double* 1D scattering resonance, named as the separation induced resonance (SIR), when the ratio between the confinement length and s-wave scattering length is within $(0.791, 1.46]$. Near SIR, the scattering property shows unique dependence on the resonance position. Right at SIR, the universal property of a many-body system is manifested by studying the interaction effect of a localized impurity immersed in a Fermi sea of light atoms. The proposed SIR can be realized in cold atom experiment.

10:12AM Y4.00012 Boson pairing and unusual criticality in a generalized XY model, YIFEI SHI, University of Virginia — Motivated by the physics of condensates of boson pairs, we study the generalized XY model in two dimension, which has a term proportional to $\cos(2\theta)$ in addition to the normal XY Hamiltonian. This corresponds to having half vortices connected by solitons, as well as integer vortices. From both renormalization group analysis and Monte Carlo simulation using the worm algorithm, we find that the phase diagram includes Kosterlitz-Thouless transitions of half and integer vortices, together with an Ising transition. Remarkably, part of the Ising line is a direct transition from the quasi-long-ranged ordered state to the disordered state.

10:24AM Y4.00013 Pairing and pseudogap for ultracold fermions in two dimensions¹, J. TEMPERE², S.N. KLIMIN, J.T. DEVREESE, Theorie van Quantum en Complexe Systemen (TQC), Universiteit Antwerpen, Belgium — The T-matrix approach, straightforwardly applied to cold fermions in two dimensions, leads to a divergent fermion density for any finite temperature. We have shown that the Gaussian pair fluctuation theory, which is an improvement of the Nozières – Schmitt-Rink approach, provides a convergent density in the paired fermion state. In our work, special attention is paid to the pseudogap state above the BKT transition temperature. In the pseudogap state, the modulus of the order parameter is finite, while phase coherence is absent. The pairing crossover temperature in 2D has been determined. Owing to the fluctuations, this pairing temperature is considerably lower than the mean-field critical temperature. With increasing coupling strength, the pairing temperature behaves non-monotonically reaching a maximum before decreasing to a finite value. For an imbalanced Fermi gas, the fluctuations lower the critical value of the imbalance at which the superfluid or non-coherent paired state is formed. This effect exists even at zero temperature, where only the quantum fluctuations survive. The obtained pairing temperatures and spectral functions are in fair agreement with recent experimental results on pairing of fermionic atoms in strongly anisotropic optical lattices.

10:36AM Y4.00014 Excitation spectrum of two-dimensional cold fermionic gases in the dilute limit, C. BERTHOD, C. KOLLATH, T. GIAMARCHI, University of Geneva, Switzerland, M. FELD, B. FRÖHLICH, M. KOSCHORRECK, E. VOGT, M. KÖHL, University of Cambridge, United Kingdom — Two-dimensional gases of fermionic atoms have been recently realized, and cooled down to temperatures a few tenths of the Fermi temperature. Such ultracold atom systems are ideal tools to investigate the fundamental properties of Fermi ensembles subject to short-range interactions. One of the key questions is whether the interaction changes the ground state and excitation spectrum in a non-perturbative way, or whether the weak-coupling perturbation theory and Fermi-liquid idea remain valid in two dimensions. In contrast to condensed-matter systems, in atomic gases the perturbation theory must be carried out at finite temperature and far from the Fermi surface for a meaningful comparison with experiment. We have calculated the electronic self-energy of dilute two-dimensional Fermi gases at arbitrary temperature and momentum, using the ladder approximation. This scheme is expected to become exact (in a perturbative sense) in the low-density limit. For short-range attractive interaction, we study the evolution of the excitation spectrum as a function of temperature and interaction strength, and we compare our results with recent experiments.

Friday, March 2, 2012 8:00AM - 10:24AM – Session Y5 DCMF: Optical Properties and Excitations in Semiconductor Quantum Dots 206A

8:00AM Y5.00001 Elastic vs Inelastic Light Scattering from a Quantum Dot, K. KONTHASINGHE, J. WALKER, M. PEIRIS, University of South Florida, C.K. SHIH, University of Texas at Austin, Y. YU, M. LI, J. HE, L. WANG, H. NI, Z. NIU, Chinese Academy of Sciences, A. MULLER, University of South Florida — We spectrally resolve the light scattered by a single InAs semiconductor quantum dot and analyze in detail the contribution from elastic and inelastic scattering processes. The measurements are well described by the theoretical expression given by Mollow. High resolution measurements reveal that the elastically scattered light is highly phase coherent with the laser. Thus a quantum dot elastically scattering a pulsed laser may serve as a triggered single photon source. In this regime, spectral diffusion and other broadening mechanisms are not a bottleneck for obtaining transform-limited photons.

8:12AM Y5.00002 Polarized luminescence characterization of charged quantum dot molecules¹

, RAMANA THOTA, SWATI RAMANATHAN, KUSHAL C. WIJESUNDARA, ERIC STINAFF, Department of Physics and Astronomy, and Nanoscale and Quantum Phenomena Institute, Ohio University, Athens, Ohio - 45701 - 2979, USA, ALLAN BRACKER, DAN GAMMON, Naval Research Laboratory, Washington, DC 20375, USA — Polarization sensitive spectroscopy of self assembled quantum dots (QDs) has been shown to yield important information about spins associated with the charge carriers in various excitonic states. As pairs of quantum dots are brought together, and the formation of molecular states via tunneling becomes relevant, the interactions that determine the polarization state can be modified. In this talk we will present polarization dependent photoluminescence and photoluminescence excitation studies on vertically stacked InAs QDs grown by molecular beam epitaxy. We will discuss the characterization of the Stokes parameters of singly and doubly charged exciton states in these coupled QDs and compare with the results reported for single QDs. This study will help in identifying appropriate charge states for potential spin manipulation and entanglement measurements.

8:24AM Y5.00003 Exciton fine structure splitting in self-assembled semiconductor quantum dots: Intrinsic and extrinsic effects

, RANBER SINGH, GABRIEL BESTER, Max Planck Institute for Solid State Research — We investigate the excitonic fine structure splitting (FSS) in InGaAs/GaAs and GaAs/AlGaAs quantum dots (QDs) of different shapes and sizes using an atomistic pseudopotential approach [1,2]. We consider intrinsic effects originating from the atomistic symmetry of the structure. We highlight the effects of the growth direction and the repercussions it has on the point group symmetry and the FSS. We give predictions for the cases where the semiconductor alloy has a certain degree of atomic order, and for the case, where the QDs are influenced by charged point defects. These effects are contrasted to the extrinsic effect of applied stress.

8:36AM Y5.00004 Coulomb Enhanced Nonlinear Optical Properties of Strongly Confined Excitons in InAs/GaAs Quantum Dots

, HANZ RAMIREZ, JEFFERSON FLOREZ, ANGELA CAMACHO, Department of Physics, Universidad de los Andes — Nonlinear optical response in parametric crystals has become widely used in entanglement production; however, low generation rate is an undesirable feature of this technique. Self-assembled quantum dots arrays (QDAs) may be a promising alternative with a larger nonlinear coefficients respect to higher dimensionality systems. Previously, some works have dealt with nonlinear susceptibilities of InAs/GaAs quantum dots, studying intraband transitions of either electrons or holes. The second order susceptibilities found there, are substantially bigger than those in bulk samples, although interband excitations and Coulomb effects were not considered. In this work we study the effects of strong confinement and Coulomb interactions on exciton states in fully 3D axially symmetric QDs. By using partial CI approach, we obtain eigenenergies and envelope eigenfunctions. Second order optical susceptibilities and their dependence on quantum dot size and aspect ratio are calculated. As a main result, we observe a Coulomb related enhancement in the second order optical susceptibilities of exciton transitions as compared to those in bulk, 2D, and even 0D purely intraband systems. This increased nonlinear response suggests interband excited QDAs as efficient entanglement sources.

8:48AM Y5.00005 Diamagnetic Exciton Properties in Quantum Dot Molecules

, FINO PUERTO NELSON RICARDO, RAMIREZ HANZ YECID, Universidad de los Andes, CAMACHO ANGELA S, Profesor, GRUPO DE MATERIA CONDENSADA UNIVERSIDAD DE LOS ANDES TEAM — The magnetic properties of nanostructures like quantum dots and rings are the subject of intense research. In particular, magnetic control of coupled quantum dots (artificial molecules) has become subject of interest. The diamagnetic shift of confined excitons complexes has been used as a measured of the wave function spatial extent in semiconductor nanostructures. In weak magnetic field, the diamagnetic shift is expected to exhibit quadratic dependence. However, for exciton complexes the diamagnetic behavior is expected to exhibit more complicated features related to electron-hole asymmetry effects on Coulomb interactions. In this work we study the magnetic response of neutral and charged excitons in InAs/GaAs asymmetric artificial molecules By using a first order perturbation approach, and within the effective mass approximation, we calculate magnetic field dependent electronic structures of confined excitons and trions in vertically coupled quantum dots. These predicted regions, which show coexistence of crossing and anticrossing exciton states, because of allowing control of charge localization and polarization of emitted photons. .

9:00AM Y5.00006 ABSTRACT WITHDRAWN —

9:12AM Y5.00007 Observed Shifts in Unoccupied States for Cu Doped CdSe Quantum Dots Observed via Synchrotron Techniques

, JOSHUA JOSHUA, ROBERT MEULENBERG, University of Maine — Recent work has been targeted on examining the optical properties of guest ions in quantum dot (QD) lattice; however, very few studies have attempted to understand the effect the dopant has on the host electronic structure. In this talk, we will present data that suggests copper doping of CdSe QDs leads to trapped states below the conduction band (CB) minimum of the host CdSe particle. We propose that one possible reason for this could be hybridization between copper and cadmium, lowering the energy for the cadmium 5s states below the CB minimum of bulk CdSe. X-ray absorption near edge structure spectroscopy measurements at the Cd M_{3-} edge for bulk, undoped, and doped QDs are compared and an unexpected lowering in the CB minimum is observed. We also present a first order theoretical model, for describing our results considering the effects caused by confinement, doping, and hybridization. Numerical approximations for atomic interactions suggest the hybridization parameter can lead to a lowering of the CB minimum by as much as 1.5 eV, as observed experimentally. Future work will include more in depth modelling of hybridization starting from tight binding calculations, developing a predictive model, applicable to more than existing data.

9:24AM Y5.00008 Elementary electronic excitations in quantum wires made up of vertically stacked quantum dots

, M.S. KUSHWAHA, Rice University — We investigate the elementary electronic excitations in quantum wires made up of vertically stacked (self-assembled) InAs/GaAs quantum dots. The length scales (of a few nm) involved in the experimental setups prompt us to consider an infinitely periodic system of two-dimensionally confined (InAs) quantum dot layers separated by GaAs spacers. The resultant quantum wire is characterized by the Bloch functions and the Hermite functions. We make use of the Bohm-Pines' RPA in order to derive a general nonlocal, dynamic dielectric function. The theoretical framework is then specified to work within a two-subband model that enables us to scrutinize the single-particle as well as collective responses of the system. We also size up the importance of studying the inverse dielectric function in relation with the quantum transport phenomena. It is remarkable to notice how the variation in the barrier- and well-widths can allow us to tailor the excitation spectrum in the desired energy range. Given the foreseen applications in the single-electron devices and in the quantum computation, it is quite tempting to explore the electronic, optical, and transport phenomena in such systems.¹

9:36AM Y5.00009 Anomalous Suppression of Valley Splittings in Lead Salt Nanocrystals, ALEXANDER Poddubny, MIKHAIL NESTOKLON, Ioffe Institute, Russian Academy of Sciences, SERGUEI GOUPALOV¹, Jackson State University — Atomistic $sp^3d^5s^*$ tight-binding theory of PbSe and PbS nanocrystals is developed. It is demonstrated, that the valley splittings of confined electrons and holes strongly and peculiarly depend on the geometry of a nanocrystal. When the nanocrystal lacks a microscopic center of inversion and has T_d symmetry, the splittings are strongly suppressed as compared to the more symmetric nanocrystals with O_h symmetry, having an inversion center. This effect is quite unusual because typically a higher symmetry of a physical system implies a higher degeneracy of its energy levels, while in our case the suppression of the splittings occurs in NCs having lower symmetry. Nevertheless, we were able to explain this puzzling behavior using mathematical apparatus of the group theory.

9:48AM Y5.00010 First-principles spectroscopic characterization of PbSe nanoparticles passivated with Fe complexes, KEITH GILMORE, AARON HAMMACK, APRIL SAWVEL, EVELYN ROSEN, D. FRANK OGLETREE, JEFFREY URBAN, DELIA MILLIRON, BRETT HELMS, BRUCE COHEN, DAVID PRENDERGAST, Lawrence Berkeley National Lab, THE MOLECULAR FOUNDRY TEAM — Given that defining characteristics of nanoparticles – morphology, catalytic reactivity, optical and electronic properties – are often dictated by their surfaces, it is informative to investigate how surface chemistry and structure change as different ligands are introduced to the surface. Starting with oleate-passivated PbSe nanoparticles, we remove the oleate ligands and replace them with an organometallic complex: cyclopentadienyl iron dicarbonyl. Measured and calculated x-ray photoemission core-level shifts indicate a charge transfer between surface Pb atoms and Fe atoms. We investigate the nature of this charge transfer in more detail through analysis of x-ray absorption spectra (XAS) at the Fe L-edge. Fe XAS are calculated from first-principles using a GW-based Bethe-Salpeter approach. The spectra reveal that the extent to which pi-backbonding is possible between the Fe and associated carbonyls varies with the charge density on the Fe atom.

10:00AM Y5.00011 Preservation of the optical properties of small Si quantum dots in the face of oxidation¹, HUASHAN LI, ZHIGANG WU, MARK LUSK, Department of Physics, Colorado School of Mines — Rapid oxidation occurs when small, unpassivated Si quantum dots are subjected to ambient conditions, and it may at first seem that complete oxidation of 1-3 nm QDs is inevitable, since their initial oxidation rate is expected to be greater than that for bulk Si for a more open surface structure, and the oxide layers on bulk Si tend to be thicker than the dot radii. We use computations based on density functional theory show that sufficiently small, appropriately terminated dots might actually be able to resist oxidation better than their larger brethren. This is because, on well-passivated bulk surfaces, oxygen attacks silicon through vulnerable sites and defects, and defects are much less likely to be present as dot size decreases. Although the more open surface structure of these small dots does leave certain key sites more vulnerable to oxidation than their bulk counterparts, the oxygen atoms absorbed there are essentially immobile due to large hopping barriers. Furthermore, computations employing the many-body Green function perturbation theory show that the oxidation of these QDs has a relatively small impact on optical character. Therefore, the best defense against oxidation is to eliminate defects; a strategy that becomes increasingly reasonable as dot size decreases.

10:12AM Y5.00012 Confinement effects on the vibrational properties of colloidal quantum dots, PENG HAN, GABRIEL BESTER, Max Planck Institute for Solid State Research — We present a first-principles study of the confinement effects on the vibrational properties of colloidal III-V and II-VI nanoclusters with thousand atoms and radii up to 16.2 Å. We describe the connection between the vibrational properties including surface-optical and -acoustic modes, coherent acoustic modes and the structural changes induced by the surface. We highlight the qualitative difference between III-Vs and II-VIs. We can clearly ascribe most of the observations to the large relaxation of the clusters dominated by an inward relaxation of the surface penetrating deep inside the cluster in case of the III-Vs and a large distribution of bond length at the surface of II-VIs. These strong confinement effects tend to disappear for clusters with more than 1000 atoms, where a small red shift of the Raman peaks remains, due to a softening in response to undercoordination. The coherent acoustic phonons are identified and found to be in good agreement with results from the Lamb model and experiment. We explain why the simple model by Lamb gives an accurate description in case of the breathing modes while the vibrational properties of small NCs are poorly described by continuum models in general.

Friday, March 2, 2012 8:00AM - 11:00AM –

Session Y6 DMP: Carbon Nanotubes: Devices, Capacitors and Other Applications 206B

8:00AM Y6.00001 The Ultimate Electron Sources Using Millimeter Long Carbon Nanotubes¹, N. PEREA, Department of Physics, The Pennsylvania State University, USA, B. REBOLLO, J.A. BRIONES, A. MORELOS, D. HERNANDEZ, E. MUNOZ, F. LOPEZ-URIAS, Advanced Materials Department, IPICYT, Mexico, A.R. BOTELLO, J.C. CHARLIER, ICMN, Université Catholique de Louvain, Belgium, V. MEUNIER, Department of Physics, Rensselaer Polytechnic Institute, USA, G.A. HIRATA, CNYN-UNAM, Mexico, B. MARUYAMA, AFRL, Materials and Manufacturing Directorate, USA, M. TERRONES, Department of Physics, The Pennsylvania State University, USA and Exotic Nanocarbon Research Center, Shinshu University, Japan, H. TERRONES, Department of Physics, The Pennsylvania State University, USA — We are reporting the fabrication of a very efficient electron source using long and crystalline carbon nanotubes. These devices start to emit electrons at fields as low as 0.10 V/μm and reach threshold emission at 0.164 V/μm. In addition, these electron sources are very stable for long operation periods up to 200 hrs and can achieve peak current density of 2 Acm⁻² at only 0.28 V/μm. To demonstrate intense electron beam generation, these devices were used to produce white light by cathodoluminescence. Finally, to rationalize the measured properties in open carbon nanotubes of different lengths we used density functional theory. The modeling establishes a clear correlation between length and field enhancement factor.

¹JST-Japan, AFRL FA9550-08-1-0204, CONACYT: 63001, S-3908, 3072, S-3909, 60218-F1, 48300.

8:12AM Y6.00002 One-dimensional nature in transport property of SWNT thin film electrochemical transistor, HIDEKAZU SHIMOTANI, SATOSHI TSUDA, Tohoku Univ., HONGTAO YUAN, The Univ. of Tokyo, YOHEI YOMOGIDA, Tohoku Univ., RIEKO MORIYA, Tokyo Metropolitan Univ., TAISHI TAKENOBU, Waseda Univ., KAZUHIRO YANAGI, Tokyo Metropolitan Univ., YOSHIHIRO IWASA, The Univ. of Tokyo — Recent success in isolating single-walled carbon nanotubes (SWNTs) of narrow chirality distribution enabled making pure metallic (m-) and semiconducting (s-) SWNT films. Such films are expected to reflect the nature of individual SWNTs, that is their one dimensional subband structure. Therefore, it is interesting to investigate electronic transport in m- and s-SWNT films by controlling their Fermi level (E_F). Chemical doping or FET is unsuitable for the purpose because of the lack of precise and reversible E_F controllability, and the narrow controllable E_F range, respectively. The problems are solved by our electric double layer transistor technique,¹ where the gate voltage (V_G) is applied through an electrolyte. The conductance and optical absorption spectra of the resistance of s- and m-SWNT films were measured at various V_G . The conductance of the s-SWNT film showed stepwise change against V_G . The absorbance spectra indicate the steps correspond to reaching of the E_F to a vHs. Furthermore, even m-SWNT films showed steep increases of conductance, demonstrating that the conductance strongly depend on the subband filling. ¹ H. Shimotani et al., Appl. Phys. Lett. 88, 073104 (2006).

8:24AM Y6.00003 A general approach for high yield fabrication of CMOS compatible all semiconducting carbon nanotube field effect transistor, MUHAMMAD R. ISLAM, KRISTY KORMONDY, ELIOT SILBAR, SAIFUL KHONDAKER, Nanoscience Technology Center, Department of Physics, University of Central Florida, Orlando, Florida — We report strategies of achieving both high assembly yield of carbon nanotubes at selected position of the circuit via dielectrophoresis (DEP) and field effect transistor (FET) yield using semiconducting enriched single walled carbon nanotube (s-SWNT) aqueous solution. When the DEP parameters were optimized for the assembly of individual s-SWNT, 97% of the devices show FET behavior with a maximum mobility of $210 \text{ cm}^2/\text{Vs}$, on-off current ratio $\sim 10^6$ and on conductance up to $3 \mu\text{S}$, however with an assembly yield of only 33%. As the DEP parameters were optimized so that 1-5 s-SWNTs are connected per electrode pair, the assembly yield was almost 90% with $\sim 90\%$ of these assembled devices demonstrating FET behavior. Further optimization gives an assembly yield of 100% with up to 10 SWNT/site, however with a reduced FET yield of 59%. Improved FET performance including higher current on-off ratio and high switching speed were obtained by integrating a local Al_2O_3 gate to the device. Our 90% FET with 90% assembly yield is the highest reported so far for carbon nanotube devices. Our study provides a pathway which could become a general approach for the high yield fabrication of CMOS compatible carbon nanotube FETs.

8:36AM Y6.00004 Scanning Photocurrent Characterization of Absorption Resonances and Photocarrier Generation in Single-Walled Carbon Nanotubes, TRISTAN DEBORDE, TAL SHARF, Oregon State University, JOSHUA W. KEVEK, Cornell University, ETHAN D. MINOT, Oregon State University — We use a scanning photocurrent microscope (SPCM) in conjunction with a supercontinuum laser source to study resonant absorption in individual single-walled carbon nanotubes (SWNTs). Characterization by spectrally-resolved SPCM is much faster than using resonant Raman scattering. The technique also complements existing Rayleigh scattering techniques because measurements can be performed on SWNTs in a standard field-effect transistor geometry. The broad band light source (0.67 eV to 2.76 eV) is monochromated and then focused onto the SWNT. Resonant absorption is manifested as peaks in photo-induced conductivity as a function of excitation energy. The wide range of photon energies gives us access to the excitonic transitions E11 to E44 in typical semiconducting SWNTs. This allows us to access information about the diameter/chirality of the nanotube, as well as probing phenomena associated with photogenerated carriers in SWNTs at room temperature.

8:48AM Y6.00005 Local and broadband photovoltaic response of aligned carbon nanotube films, SEBASTIEN NANOT, DARIUS MORRIS, LISA A. HENDRICKS, JUNICHIRO KONO, ECE and Physics and Astronomy Department, Rice University, CARY PINT, ROBERT H. HAUGE, Smalley Institute, Rice University, FRANCOIS LEONARD, Sandia National Laboratories, Livermore — Although individual semiconducting single-walled carbon nanotubes (SWCNT) have exhibited clear photovoltaic responses, it remains unclear whether macroscopic films of carbon nanotubes can also behave this way. While some groups have explained finite photovoltages as Schottky barrier effects, other groups have proposed photo-thermoelectric effects in suspended films. Here, we have studied highly aligned SWCNT films that work well as photovoltaics. SWCNTs grown by CVD were transferred onto a SiO_2 substrate. There was a broad diameter distribution in the films to obtain a large wavelength range of interband absorption. The films were top-contacted with various metals. We made a systematic scanning photocurrent study of such samples at 660 and 1350 nm. A strong local photovoltage appeared at electrode-SWCNT interfaces. Detailed comparison with theoretical calculations of the dependence of photo-response on the nanotube orientation, metal electrode type, and temperature unambiguously revealed the photovoltaic nature of the observed photovoltage. We assign these effects to the doping of both metallic and semiconducting SWCNTs under the electrodes, in a similar fashion to graphene, its lineshape being determined by the diffusion of photoexcited carriers. Finally, to obtain a finite net signal under global illumination, we utilized different electrode combinations and studied their photoresponses from the visible up to mid-infrared and terahertz.

9:00AM Y6.00006 Separated Carbon Nanotube Macroelectronics for Active Matrix Organic Light-Emitting Diode Displays, YUE FU, JIALU ZHANG, CHUAN WANG, POCHIANG CHEN, CHONGWU ZHOU, University of Southern California — Active matrix organic light-emitting diode (AMOLED) display holds great potential for the next generation visual technologies due to its high light efficiency, flexibility, lightweight, and low-temperature processing. However, suitable thin-film transistors (TFTs) are required to realize the advantages of AMOLED. Pre-separated, semiconducting enriched carbon nanotubes are excellent candidates for this purpose because of their excellent mobility, high percentage of semiconducting nanotubes, and room-temperature processing compatibility. Here we report, for the first time, the demonstration of AMOLED displays driven by separated nanotube thin-film transistors (SN-TFTs) including key technology components such as large-scale high-yield fabrication of devices with superior performance, carbon nanotube film density optimization, bilayer gate dielectric for improved substrate adhesion to the deposited nanotube film, and the demonstration of monolithically integrated AMOLED display elements with 500 pixels driven by 1000 SN-TFTs. Our approach can serve as the critical foundation for future nanotube-based thin-film display electronics.

9:12AM Y6.00007 Semiconducting Enriched Carbon Nanotube Aligned Arrays of Tunable Density and Their Electrical Transport Properties¹, SAIFUL I. KHONDAKER, Nanoscience Technology Center, Department of Physics, School of Electrical Engineering and Computer Science, University of Central Florida, BIDDUT K. SARKER, SHASHAK SHEKHAR, Nanoscience Technology Center, and Department of Physics, University of Central Florida — Many proposed applications of semiconducting single walled carbon nanotubes (s-SWNT) require massively parallel array as they can average out inhomogeneity of individual tubes, provide larger on- currents and better transistor properties. Here, we report assembly of solution processed semiconducting enriched (99%) SWNT in an array with varying linear density via ac-dielectrophoresis and investigate electronic transport properties of the fabricated devices. We show that (i) the quality of the alignment varies with frequency of the applied voltage and that (ii) by varying the frequency and concentration of the solution, we can control the linear density in the array from 1 to 25 s-SWNT/ μm . We found that with increasing nanotube density the device mobility increases while the current on-off ratio decreases dramatically. For the dense array, the device current density was $16 \mu\text{A}/\mu\text{m}$, on-conductance was $390 \mu\text{S}$, and sheet resistance was $30 \text{ k}\Omega/\square$. These values are the best reported so far for any semiconducting nanotube array. Our study will have important implications in fabricating high quality devices for digital and analog electronics.

¹This work is partially supported by the U.S. National Science Foundation under Grant ECCS- 0748091 (CAREER).

9:24AM Y6.00008 Fully Transparent Separated Carbon Nanotube Based Thin-film Transistors and their Application in Display Electronics, JIALU ZHANG, CHUAN WANG, CHONGWU ZHOU, University of Southern California — Transparent electronics have attracted numerous research efforts in recent years due to its great potential to make significant commercial impact in a wide variety of areas such as transparent displays. High optical transparency as well as good electrical performance is required for this kind of applications. Pre-separated, semiconducting enriched carbon nanotubes are excellent candidates for this purpose due to their excellent mobility, high percentage of semiconducting nanotubes, and room-temperature processing compatibility. Here in this paper, we report fully transparent high-yield transistors based on separated carbon nanotube random network. High electrical performance is achieved by using large work function thin metal layer and indium-tin oxide (ITO) as contacts and all devices show excellent transparency ($\sim 82\%$). Furthermore, OLED control circuit has been demonstrated with transparent separated nanotube thin-film transistors and large range output light intensity modulation has been observed. Our results suggest the promising future of separated carbon nanotube based transparent electronics and can serve as the critical foundation for the next generation transparent display applications.

9:36AM Y6.00009 Fabrication of Carbon nanotube TFTs for pressure-sensing device by printing method, HIROYUKI ENDOH, NEC Corporation, FUMIYUKI NIHEY, HIDEAKI NUMATA, KAZUKI IHARA, Technology Research Association for Single Wall Carbon Nanotubes, TSUYOSHI SEKITANI, TAKAO SOMEYA, The University of Tokyo — Printing technology is very promising from many advantages, for example, low cost, flexible etc. We previously have developed a high-performance printed thin-film transistor (TFT) using single-walled carbon nanotube (CNT). A simple ink-jet printing system was used for drawing the device patterns. The maximum temperature was 200 degrees during nano-silver electrode fabrication. The temperature of CNT-channel patterning is under 50 degrees. The widths of the source and drain electrodes were about 1 mm and the channel length were about 150 μm . The thickness of the gate insulator was about 650 nm. The estimated mobilities using over 95% purified semiconductive-CNT were $\sim 5.1 \text{ cm}^2/\text{Vs}$ for the TFTs whose on/off ratio were more than 5,000. This time we fabricated CNT-TFT arrays for pressure-sensing sheet devices, using the printed-process on a plastic film. CNT-TFT sheet has a dimension of 16 x 16 TFTs. The average mobility of the TFTs is 4.6 cm^2/Vs . The pressure-sensing cell was prepared to combine Printed-TFT, a conductive rubber sheet and a film with a copper foil. Drain current changes in response to pressure applied to the current changes were observed up to 100nA from 10pA. These results were very promising for CNT-TFT applications to printable electronics.

9:48AM Y6.00010 Flexible Single-wall Carbon Nanotube Membrane Symmetric Aqueous Double Layer Electrochemical Capacitor¹, PRALAV SHETTY, Mechanical Engineering Department, The Pennsylvania State University, University Park, PA 16802, USA, JIM KAPULSON, RAMAKRISHNAN RAJAGOPALAN, Materials Research Institute, The Pennsylvania State University, University Park, PA 16802, USA, KOFI ADU, Department of Physics, The Pennsylvania State University, Altoona College, Altoona, PA 16601, USA — We present preliminary results on an aqueous symmetric double layer electrochemical capacitor (EDLC) constructed with flexible binder-free single wall carbon (SWCNTs) membrane as electrodes. The capacitors were cycled from 0 to 1V @ 10 A/g for 10,000 cycles with 99.9% coulombic efficiency and 94% energy efficiency, and 100% depth of discharge. The power performance of the aqueous symmetric SWCNTs membrane capacitor is almost 100 –1000 times better than commercial non-aqueous EDLC capacitors.

¹This Work is Funded by The Pennsylvania State University Materials Research Institute

10:00AM Y6.00011 Optimizing Efficiency in Conducting Polymer/Single-walled Carbon Nanotube Hybrids for Organic Photovoltaics, JOSH HOLT, Chemical & Materials Science Center, National Renewable Energy Laboratory, 1617 Cole Blvd., Golden, CO 80401 (USA), FRITZ PREHN, Department of Materials Science and Engineering, University of Wisconsin-Madison, 1509 University Ave., Madison, WI 53706 (USA), MARTIN HEENEY, Department of Chemistry, Imperial College London, South Kensington, SW7 2AZ, UK, NIKOS KOPI-DAKIS, GARRY RUMBLES, JEFFREY BLACKBURN, Chemical & Materials Science Center, National Renewable Energy Laboratory, 1617 Cole Blvd., Golden, CO 80401 (USA) — Several unique properties of single-walled carbon nanotubes (SWCNTs) have motivated their investigation as potential replacements for fullerene derivatives as the acceptor phase of organic photovoltaic (OPV) devices. Although replacement of the ubiquitous fullerene acceptors by SWCNTs in OPV devices has shown limited success thus far, better understanding of charge transfer between SWCNTs and conjugated polymers has promoted its viability. We provide experimental evidence that m-SWNTs limit the generation efficiency and lifetime of the charge-separated state in these composites. We also probe the photo-carrier generation and decay dynamics in poly(3-hexylthiophene) (P3HT) paired with a broad diameter range of SWCNTs. We witness electron transfer from the polymer to SWCNT and *selective* hole transfer from the SWCNT to polymer by varying the nanotube HOMO via its diameter. We finally extend our investigation to additional semi-conducting polymers that have contributed to high OPV efficiencies, pBTTT and PCDTBT.

10:12AM Y6.00012 Ultra-high density aligned Carbon-nanotube with controlled nano-morphology for supercapacitors, MEHDI GHAFARI, RAN ZHAO, YANG LIU, YUE ZHOU, JIPING CHENG, penn state univeristy, ROBERTO GUZMAN DE VILLORIA, B.L WARDLE, MIT, Q.M. ZHANG, penn state univeristy — Recent advances in fabricating controlled-morphology vertically aligned carbon nanotubes (VA-CNTs) with ultrahigh volume fraction create unique opportunities for developing unconventional supercapacitors with ultra-high energy density, power density, and long charge/discharge cycle life. Continuous paths through inter-VA-CNT channels allow fast ion transport, and high electrical conduction of the aligned CNTs in the composite electrodes lead to fast discharge speed. We investigate the charge-discharge characteristics of VA-CNTs with >20 vol% of CNT and ionic liquids as electrolytes. By employing both the electric and electromechanical spectroscopies, as well as nanostructured materials characterization, the ion transport and storage behaviors in porous electrodes are studied. The results suggest pathways for optimizing the electrode morphology in supercapacitors using ultra-high volume fraction VA-CNTs to further enhance performance.

10:24AM Y6.00013 Capacitance of highly ordered nanocapacitors arrays: Model and microscopy¹, ANDREA CORTES, CARLOS CELEDON, PABLO ULLOA, PATRICIO HABERLE, Departament of Physics, Universidad Tecnica Federico Santa Maria — It is described briefly the process used to build an ordered porous array in an anodic aluminum oxide (AAO) template, filled with multiwall carbon nanotubes (MWCNTs). The MWCNTs were grown directly inside the template through chemical vapor deposition (CVD). The role of the CNTs is to provide narrow metal electrodes with contact with a dielectric surface barrier, hence, forming a capacitor. This procedure allows the construction of an array of 10^{10} parallel nano-spherical capacitors/ cm^2 . A central part of this contribution is the use of physical parameters obtained from processing high-resolution transmission electron microscopy (HRTEM) images, to predict the specific capacitance of the AAO arrays. Electrical parameters were obtained by solving Laplace's equation through finite element methods

10:36AM Y6.00014 Gecko inspired carbon nanotube based thermal gap pads¹, SUNNY SETHI, ALI DHINOJWALA, The University of Akron — Thermal management has become a critical factor in designing the next generation of microprocessors. The bottleneck in design of material for efficient heat transfer from electronic units to heat sinks is to enhance heat flow across interface between two dissimilar, rough surfaces. Carbon nanotubes (CNT) have been shown to be promising candidates for thermal transport. However, the heat transport across the interface continues to be a challenging hurdle. In the current work we designed free standing thermal pads based on gecko-inspired carbon nanotube adhesives. The pads were made of metallic carbon nanotubes and the structure was designed such that it would allow large area of intimate contact. We showed that these adhesive pads can be used as electrical and thermal interconnects.

¹Funded by Airforce Research Laboratory and NSF

10:48AM Y6.00015 Stiff and Multifunctional Carbon Nanotube Composites, YUNTIAN ZHU, XIN WANG, North Carolina State University, QINGWEN LI, Suzhou Institute of Nanotechnology and Nanobionics, PHILIP BRADFORD, FUH-GWO YUAN, North Carolina State University, DENNIS TUCKER, NASA Marshall Space Flight Center, WEI CAI, HSIN WANG, Oak Ridge National Laboratory — It has been a challenge for two decades to assemble the extremely strong carbon nanotubes (CNTs) into macroscopic CNT composites that break the strength ceiling of carbon fiber composites. Here we report the fast incorporation of long CNTs into polymer matrix using a novel approach, stretch-winding, to produce composites that are much stronger than any current engineering composite. The CNT composites reach a strength of 3.8 GPa, an excellent electrical conductivity and a high thermal conductivity. These superior properties are primarily derived from the long length, high volume fraction, good alignment and reduced waviness of the CNTs that are produced. The combination of high strength and excellent electrical and thermal conductivities makes CNT composites a promising enabler of new aerospace technologies and adventures.

Friday, March 2, 2012 8:00AM - 11:00AM – Session Y7 DCMP: Glassy Metallic, Semiconductor, Oxide and Chalcogenide Systems 207

8:00AM Y7.00001 Ion irradiation induced suppression of shear banding in amorphous ZrCuAl nanowires under simulated compression, QIRAN XIAO, Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, HOWARD SHENG, School of Physics, Astronomy and Computational Sciences, George Mason University, YUNFENG SHI, Department of Materials Science and Engineering, Rensselaer Polytechnic Institute — Metallic glasses (MG) are amorphous metallic solids which exhibit extraordinary mechanical properties including large elastic strain limit and high tensile strength; at the same time, MGs are generally brittle due to catastrophic failure of shear banding. Controversy remains, however, as to whether shear banding is size-dependent in MG nanopillar samples prepared using Focused Ion Beam (FIB) technique. Here we modeled Zr₅₀Cu₄₀Al₁₀ MG nanopillars under irradiation via molecular dynamic simulations (MD) and found a transition in deformation mode from dominant shear-banding to homogeneous shear-flow. Our results call for careful consideration of irradiation damage as a result of FIB sample-preparation-technique. In addition, we also show the amorphization of icosahedral structures as a result of irradiation, which might be responsible for the homogeneous deformation mode of irradiated MG nanowires upon compression tests.

8:12AM Y7.00002 Two Level Systems in Amorphous Silicon¹, DANIEL QUEEN, JULIE KAREL, University of California, Berkeley, XIAO LIU, Naval Research Laboratory, GREGORY HOHENSEE, DAVID CAHILL, University of Illinois, Urbana-Champaign, FRANCES HELLMAN, University of California, Berkeley — The specific heat of e-beam evaporated a-Si thin films prepared at various growth temperatures was measured from 2-300K. Below 20K, films with low density have a specific heat in excess of the predicted Debye value while higher density films do not. The excess heat capacity is typical of a glass with a linear contribution that is characteristic of two-level systems (TLS) and a T³ contribution that is in excess of the Debye specific heat calculated from the measured sound velocity. The excess specific heat is independent of the elastic properties of the materials as determined by shear modulus and sound velocity measurements but depends on film density. The density dependence suggests that the low energy excitations form in voids or low density regions and are not intrinsic to the amorphous silicon network. A correlation is found between the density of TLS and the excess T³ specific heat suggesting that they have a common origin. Comparisons will be made between the specific heat and internal friction.

¹This work supported by the NSF under Grant No. DMR-0907724

8:24AM Y7.00003 First principles calculations of the Urbach tail in the optical absorption of silica glass¹, BABAK SADIGH, Lawrence Livermore National Laboratory, PAUL ERHART, Chalmers University of Technology, DANIEL ABERG, ERIC SCHWEGLER, JEFF BUDE, Lawrence Livermore National Laboratory, OPTIC DAMAGE MODELING TEAM — We present density-functional theory calculations of the optical absorption spectra of silica glass for temperatures up to 2400 K. The calculated spectra exhibit exponential tails near the fundamental absorption edge that follow the Urbach rule, in good agreement with experiments. We also discuss the accuracy of our results by comparing to hybrid exchange correlation functionals. By deriving a simple relationship between the exponential tails of the absorption coefficient and the electronic density-of-states, we establish a direct link between the photoemission and the absorption spectra near the absorption edge. This relationship is subsequently employed to determine the lower bound to the Urbach frequency regime. Most interestingly, in this frequency interval, the optical absorption is Poisson distributed with very large statistical fluctuations. Finally, We determine the upper bound to the Urbach frequency regime by identifying the frequency at which transition to Poisson distribution takes place.

8:36AM Y7.00004 Substrate- and interface-mediated photocrystallization in a-Se films and multi-layers, G.P. LINDBERG, R.E. TALLMAN, B.A. WEINSTEIN, SUNY Buffalo, NY 14260-1500 USA, S. ABBASZADEH, K.S. KARIM, Univ. of Waterloo, Ontario, N2L 3G1 CA, A. REZNIK, TBRI, Thunder Bay, Ontario P7B 5E1 CA — Photocrystallization in a-Se films and layered a-Se structures is studied by Raman scattering as a function of temperature for photon energies near or slightly below the band gap. The samples are ~16.5 μm thick films of a-Se grown i) directly on glass, ii) on indium tin oxide (ITO) coated glass, iii) on glass that is spin coated with 800nm polyimide, and iv) on a Capton sheet. A low As-concentration (< 0.2 %) is present in several of the a-Se films. We compare the results on these samples to prior findings on a-Se HARP targets, and on a polymer-encapsulated a-Se film [1]. We observe strong evidence that the interface between the a-Se film and the underlying substrate and/or multi-layers plays an important role in the onset time and growth rate of photocrystallized Se domains. In some samples a discontinuous increase in the onset time with increasing temperature occurs near the glass transition (~310K), and there is a surprising "dead zone" of no crystallization in this region. Other samples merely show a minimum in the onset time at similar temperatures, but no discontinuity and no region where crystallization is absent. Soft intermediate layers appear to increase stability against crystallization in an overlying a-Se film. The competing effects of substrate shear strain and thermal driving forces on the photocrystallization process are considered to account for these findings.

8:48AM Y7.00005 Lattice irreversibility and enhanced fragility under fatigue in amorphous solids, DESPINA LOUCA, PENG TONG, University of Virginia, GONGYAO WANG, PETER LIAW, University of Tennessee, YOSHIHIKO YOKOYAMA, Tohoku University, ANNA LLOBET, Los Alamos National Laboratory, YIMING QIU, NIST Center for Neutron Research — The enhanced brittleness observed in glassy ZrCuAl metallic alloys under mechanical cyclic fatigue loading is linked to a local atomic structure reorganization and suppression of atomic fluctuations. From the analysis of neutron scattering and the pair density function technique, an atomic cluster restructuring is observed that intensifies with increasing the compression cycles ex-situ. This is accompanied by an attenuation of the extended phonon-like lattice dynamics, beyond the region in the momentum space where the Boson peak appears, observed by inelastic neutron scattering. Together both effects most likely render the glass more fragile. These findings provide a direct link between the plasticity and the internal structure of metallic glasses under fatigue.

9:00AM Y7.00006 Probing the liquid behavior in La-based metallic glasses using NMR spectroscopy, MAGDALENA SANDOR, University of North Carolina, WEI XU, Huazhong University of Science and Technology, HAI-BO KE, XUE-KUI XI, Chinese Academy of Sciences, YUE WU, University of North Carolina, WEI-HUA WANG, Chinese Academy of Sciences — The nature of liquid structure and its temperature and/or pressure dependent behavior is currently an active area of scientific investigation. Temperature dependent ^{27}Al nuclear magnetic resonance (NMR) experiments were carried out above the liquid temperature in La-based metallic glasses. The strong coexistence of two liquid states was observed in addition to nonlinear liquid behavior. NMR results also provide thermodynamic insight for the structural changes observed.

9:12AM Y7.00007 Chemical ordering in Cu-Zr and Cu-Hf liquids and glasses, NICHOLAS MAURO, ADAM VOGT, MATT BLODGETT, JAMES BENDERT, KENNETH KELTON, Washington University, WASHINGTON UNIVERSITY DEPARTMENT OF PHYSICS TEAM — Evidence for chemical ordering in Cu-Zr and Cu-Hf metallic liquids and glasses is presented. High-energy X-ray diffraction data has been taken using the Beamline Electrostatic (BESL) technique and stationary scattering methods up to a high momentum transfer. From this data, we obtained the total pair-correlation functions. By examining the structural evolution in the equilibrium and undercooled liquid, and the glassy state, we find that ordering occurs, increasing the Cu-Zr (Cu-Hf) and Zr-Zr (Hf-Hf) correlations over a wide composition and temperature range. This ordering is evident by a judicious choice of scattering lengths and compositions. Growth is observed at two distinct r -space coordinates in the pair-correlation function, unique to these two metallic systems. These results will be discussed in the context of previous experiments which indicate that this ordering is chemical and topological in nature, likely due to the development of Cu-centered icosahedral clusters.

9:24AM Y7.00008 Molecular structure of $\text{Si}_x\text{Ge}_x\text{Te}_{100-2x}$ glasses¹, K. GUNASEKERA, P. BOOLCHAND, University of Cincinnati, S. MAMEDOV, Horiba Jobin Yvon Inc., New Jersey — Bulk glasses of the titled ternary have been synthesized in the $8\% < x < 16\%$ range by melt quenching. Glass transition temperatures, $T_g(x)$, increase linearly from 140°C at $x = 8\%$ to 200°C at $x = 12\%$, then decrease steadily to 160°C thereafter. The non-reversing enthalpy of relaxation at T_g shows a broad minimum near 9% but a maximum near 12% . Glasses appear to be fully polymerized at $x < 12\%$, but segregate as $x > 12\%$. The broad minimum near 9% , most likely, represents the opening of an Intermediate Phase. Raman scattering, excited using 785 nm radiation of a glass at $x = 10\%$, shows two modes, a broad one near 160 cm^{-1} and a narrow one near 127 cm^{-1} . A mode near 157 cm^{-1} has been previously² identified with polymeric Te_n chains of a-Te. Tentatively, we assign the 127 cm^{-1} mode with face-sharing³ GeTe_4 , and a mode near 170 cm^{-1} with edge-sharing SiTe_4 tetrahedra in these glasses. The nature of glass structure evolution with composition will be elucidated.

9:36AM Y7.00009 The sharpness of thermally reversing windows as a measure of glass network homogeneity¹, S. BHOSLE, K. GUNASEKERA, P. BOOLCHAND, University of Cincinnati, M. MICOULAUT, University of Paris IV, C. MASSOBRIO, University of Strassbourg — Reversibility windows(RWs) have been observed² in Chalcogenides, modified- and unmodified-oxides, and solid electrolytes. These are identified with isostatically rigid networks formed in narrow compositional windows between flexible and stressed-rigid elastic phases. Until recently, we found RWs in oxides and solid electrolytes to be sharper than in chalcogenides. Recently we introduced³ a Raman profiling method to track homogeneity of melts during synthesis, and found that the kinetics of homogenization of chalcogenide melts are slow. The enthalpy of relaxation at T_g measured in binary $\text{Ge}_x\text{Se}_{100-x}$ glasses show the RW to be intrinsically square-well like with sharp edges in homogeneous samples ($\Delta x \sim 0$), and becomes trapezoidal ($\Delta x = 1.5\%$), then triangular ($\Delta x = 3\%$) and eventually disappears as glass heterogeneity increases. The heterogeneity deduced from Raman profiling experiments provides the Ge-stoichiometry variation (Δx) across a batch composition, which can be used to predict the observed RWs.

9:48AM Y7.00010 Boson mode, Medium Range Structure and Intermediate Phase (IP) in $(\text{Na}_2\text{O})_x(\text{B}_2\text{O}_3)_{1-x}$ glasses¹, K. VIGNAROUBAN, P. BOOLCHAND, Univ of Cincinnati, M. MICOULAUT, Univ of Paris, M. MALKI, Univ of Orleans — Raman scattering of titled glasses are examined using a T64000 Dispersive system. Scattering strengths of the Boson mode (40 cm^{-1} , 70 cm^{-1}) and the Boroxyl ring (BR) mode (808 cm^{-1}) are found to decrease with increasing x at the same rate in the $0 < x < 20\%$ soda range. Apparently, the 2D character of BRs embedded in a 3D network gives rise to the Boson mode.² The triad of modes (705 , 740 , 770 cm^{-1}) near the 808 cm^{-1} mode are found to display a maximum in scattering strength near $x = 37\%$ (705 cm^{-1}), 33% (740 cm^{-1}) and 25% (770 cm^{-1}), suggesting that these are also ring modes of Na-tripentaborate (STPB), Na-diborate (SDB) and Na-triborate (STB) super-structures. Variations in Raman scattering strengths also suggest that STB percolate near $x = 20\%$, the *stress* transition, while the STPB and SDB percolate near $x = 40\%$, the *rigidity* transition. These transitions were inferred from m-DSC experiments that show an intermediate phase in the $20\% < x < 40\%$ range in dry and homogeneous glasses.

²M. Flores-Ruiz and G. Naumis, PRB, 2011. **83**: p. 184204

10:00AM Y7.00011 Boson mode, Intermediate Phase, and glass molecular structure of heavy metal Oxides¹, S. CHAKRABORTY, P. BOOLCHAND, U. of Cincinnati — We have synthesized bulk glasses of $(\text{B}_2\text{O}_3)_5(\text{TeO}_2)_{95-x}(\text{V}_2\text{O}_5)_x$ ternary and examined their thermal and optical properties as a function of composition “ x .” The enthalpy of relaxation at T_g shows a global minimum in the Vanadia concentration of $24\% < x < 26.5\%$, which we identify² as the intermediate phase (IP) with compositions at $x < 24\%$ to be in stressed-rigid and those at $x > 26.5\%$ in the flexible phase. Raman scattering reveals a rich lineshape including a Boson mode, whose scattering strength steadily decreases with increasing x , possibly due to bifurcation of weak (Te-O_{axial}) and strong ($\text{Te-O}_{equatorial}$) springs characteristic of TeO_2 building blocks.³ Vanadia alloying brings in isostatic building blocks, pyramidal $\text{V}(\text{O}_{1/2})_3$ and quasi-tetrahedral $\text{O}=\text{V}(\text{O}_{1/2})_3$ as suggested by present Raman scattering and recent ^{51}V NMR data.⁴ We describe the structure evolution of these glasses in terms of the Te-centered and V-centered local structures.

10:12AM Y7.00012 Identification of strong and weak interacting two-level systems in KBr:CN
 , ALEJANDRO GAITA-ARINO, Instituto de Ciencia Molecular, University of Valencia, MOSHE SCHECHTER, Department of Physics, Ben Gurion University of the Negev — Tunneling two-level systems (TLSs) are believed to be the source of phenomena such as the universal low temperature properties in disordered and amorphous solids, and $1/f$ noise. The existence of these phenomena in a large variety of dissimilar physical systems testifies for the universal nature of the TLSs, which however, is not yet known. Following a recent suggestion that attributes the low temperature TLSs to inversion pairs [M. Schechter and P.C.E. Stamp, arXiv:0910.1283] we calculate explicitly the TLS-phonon coupling of inversion symmetric and asymmetric TLSs in a given disordered crystal. Our work (a) estimates parameters that support the theory in M. Schechter and P.C.E. Stamp, arXiv:0910.1283 in its general form, and (b) positively identifies the relevant TLSs in a given system. Consequences to the understanding of the microscopic structure of amorphous solids will be discussed. A. Gaita-Arino and M. Schechter, Phys. Rev. Lett. **107**, 105504 (2011)

10:24AM Y7.00013 ABSTRACT WITHDRAWN —

10:36AM Y7.00014 Coulomb Glass: a Mean Field Study, SALVATORE MANDRA, MATTEO PALASSINI, Universitat de Barcelona — We study the Coulomb glass model of disordered localized electrons with long-range Coulomb interaction, which describes systems such as disordered insulators, granular metals, amorphous semiconductors, or doped crystalline semiconductors. Long ago Efros and Shklovskii showed that the long-range repulsion induces a soft Coulomb gap in the single particle density of states at low temperatures. Recent works suggested that this gap is associated to a transition to a glass phase, similar to the Almeida-Thouless transition in spin glasses. In this work, we use a mean field approach to characterize several physical properties of the Coulomb glass. In particular, following a seminal work of Bray and Moore, we show that the Edward-Anderson parameter q_{EA} and the spin glass susceptibility χ_{SG} are directly related to spectrum distribution of the Hessian matrix around free energy minima. Using this result, we show that no glass transition is associated to the gap formation.

10:48AM Y7.00015 Non-linear dielectric response of glass formers under oscillating temperature, TAKASHI ODAGAKI, MASATOSHI KURODA, HIDEAKI KATOH, Tokyo Denki University, YASUO SARUYAMA, Kyoto Institute of Technology — Exploiting a simple model we investigate linear and non-linear dielectric responses of glass formers under oscillating temperature. We demonstrate that three characteristic temperatures, Vogel-Fulcher, glass transition and cross-over temperatures, can be determined from the analysis of the dielectric response. We first show that the real part of the linear susceptibility at the static limit becomes a cusp below the cross-over temperature and its curvature changes at the glass transition temperature. We also analyze the non-linear susceptibility under oscillating temperature which contains information of the response of the system, in particular of the free energy landscape, against the temperature modulation. We find that the real part of the non-linear susceptibility shows anomalies at the characteristic temperatures similar to the linear susceptibility.

Friday, March 2, 2012 8:00AM - 10:36AM —

Session Y8 DMP GMAG: Focus Session: Frustrated Magnetism - Experiment 208

8:00AM Y8.00001 Magnetic ordering in SrEr_2O_4 and SrHo_2O_4 , O.A. PETRENKO, T.J. HAYES, O. YOUNG, G. BALAKRISHNAN, University of Warwick, UK, L.C. CHAPON, A. WILDES, ILL, Grenoble, France, P. MANUEL, ISIS, RAL, UK, P.P. DEEN, ESS, Lund, Sweden — Single crystal neutron diffraction reveals two distinct components to the magnetic ordering in geometrically frustrated compounds SrEr_2O_4 and SrHo_2O_4 . One component, a long-range ordered $\mathbf{k} = 0$ structure, is associated with the appearance of resolution limited Bragg peaks below the ordering temperature. Another component is a quasi 1D short-range structure which manifests itself by the presence of a strong diffuse scattering signal forming *planes* in reciprocal space. On cooling from higher temperatures down to 0.06 K, the partially ordered component develops gradually and does not undergo a pronounced phase transition. The magnetic moments in the long-range structure are pointing along the [001] axes in both compounds. In the short-range structure (which is incommensurate in SrEr_2O_4 and $\mathbf{k} \approx 1/2$ in SrHo_2O_4) the moments are predominantly pointing along the [001] and [010] axes in these two compounds respectively. The unusual coexistence of two magnetic structures is probed using XYZ-polarised neutron scattering techniques [1,2]. [1] T.J. Hayes *et al.*, to appear in Phys. Rev. B (2011). [2] O. Young *et al.*, in preparation (2011).

8:12AM Y8.00002 Magnetic order in GdBiPt studied by x-ray resonant magnetic scattering, A. KREYSSIG, M.G. KIM, Ames Laboratory, Dept. of Physics and Astronomy, Iowa State University, Ames, IA, J.W. KIM, Advanced Photon Source, ANL, Argonne, IL, S.M. SAUERBREI, S.D. MARCH, G.R. TESDALL, S.L. BUD'KO, P.C. CANFIELD, R.J. MCQUEENEY, A.I. GOLDMAN, Ames Laboratory, Dept. of Physics and Astronomy, Iowa State University, Ames, IA — Rare earth (*R*) half-Heusler compounds, *R*BiPt, exhibit a wide spectrum of novel ground states.[1] We have employed x-ray resonant magnetic scattering to elucidate the microscopic details of the magnetic structure in GdBiPt below $T_N = 8.5$ K. Experiments at the Gd L_2 absorption edge show that the Gd moments order in an antiferromagnetic stacking along the cubic diagonal [1 1 1] direction satisfying the requirement for an antiferromagnetic topological insulator as proposed previously[2] where both time-reversal symmetry and lattice translational symmetry are broken, but their product is conserved. The work at the Ames Laboratory was supported by US DOE, Office of Basic Energy Sciences, DMSE, contract DE-AC02-07CH11358. [1] P. C. Canfield *et al.*, J. Appl. Phys. **70**, 5800 (1991). [2] R. S. K. Mong *et al.*, Phys. Rev. B **81**, 245209 (2010).

8:24AM Y8.00003 X-ray resonance Exchange scattering study of Field induced meta-magnetic phases in TbNi_2Ge_2 ¹, R. DAS, Z. ISLAM, J.P.C. RUFF, Advanced Photon Source, Argonne National Laboratory, P.C. CANFIELD, Ames Laboratory, Iowa State University — Rare-earth inter-metallic compound, TbNi_2Ge_2 is an interesting material for its uniaxial anisotropy and the presence of a number of meta-magnetic phases (MP), which we have investigated using x-ray resonant exchange scattering techniques. Two distinct field induced MPs have been revealed at 5 K for fields below 3 T applied along the *c* axis. In zero field, the magnetic structure is characterized primarily by commensurate $q_1 = (0,0,0.75)$, $q_2 = (0.5,0.5,0)$ and $q_3 = (0.5,0.5,0.5)$ wave vectors, implying a complex sequence of FM and AFM planes. With increasing magnetic field, a weak (0,0,1) peak starts to evolve reaching a maximum in the first MP (1.2 T < H < 1.6 T) and sharply disappears on entering the second MP (H > 1.6 T). In the second MP, q_1 becomes incommensurate, (0,0,0.766), q_2 gets strongly suppressed, and q_3 peak splits into combination harmonics of q_1 and q_2 . The persistence of AF peaks imply that AF planes are quite robust to spin-flip transitions and MP phases are intricate in nature due to several competing interactions in this compound.

¹Use of the APS is supported by the DOE, Office of Science, under Contract No. DE-AC02-06CH11357, Ames Laboratory is operated for the U.S. Department of Energy by Iowa State University under Contract No. DE-AC02-07CH11358

8:36AM Y8.00004 Inelastic neutron scattering of the itinerant magnets Cr₂Te₃ and tr-Cr₅Te₈

, ADAM ACZEL, GARRETT GRANROTH, Oak Ridge National Lab, NIRMAL GHIMIRE, University of Tennessee, MICHAEL MCGUIRE, Oak Ridge National Lab, DAVID MANDRUS, University of Tennessee, STEVE NAGLER, Oak Ridge National Lab — Itinerant magnets based on transition metal chalcogenide compounds are of current interest, in part due to their relationship to the parent compounds of Fe-based superconductors. Two particularly interesting systems in this family are the chromium tellurides Cr₂Te₃ and trigonal (tr) Cr₅Te₈. These materials crystallize in layered structures with alternating partially and fully-occupied planes of Cr atoms stacked along the c-axis. Magnetization measurements along different crystallographic directions show a net ferromagnetic response and large magnetic anisotropy. In addition, the saturation moments are smaller than predicted by an ionic model; consistent with itinerant behavior. Previous neutron diffraction results for Cr₂Te₃ revealed an ordered moment of $< 0.2 \mu_B$ in the partially-occupied planes. We examined the magnetic excitations in these materials by powder neutron spectroscopy measurements using the SEQUOIA instrument at the SNS. We find similar moment sizes for the magnetic Cr atoms of both systems. However, despite their similar crystal structures, ordered moment sizes, and chemical compositions, their magnetic excitation spectra are strikingly different. We compare our data to the predictions of various models in an effort to determine the relevant exchange parameters, put constraints on their magnitudes, and understand the differences between the inelastic magnetic spectra. We find that exchange along the c-direction is critical to explain our data.

8:48AM Y8.00005 Magnetic structure and site occupancies in Fe containing μ -phases AFe (A=Ta, Nb, Mo)¹

, NIRMAL GHIMIRE, University of Tennessee, OVIDIU GARLEA, MICHAEL MCGUIRE, Oak Ridge National Laboratory, DAVID MANDRUS, University of Tennessee and Oak Ridge National Laboratory — Binary μ -phases are intermetallic compounds occurring in numerous systems combining heavy and light transition metals. They have compositions close to AM where A is a 4d or 5d element (Nb, Ta, Mo, W) and M is a 3d element (Fe, Co, Ni, Zn). The possibility of mixed site occupancies results in stoichiometries ranging from A_7M_6 to A_6M_7 . Interestingly, only the Fe containing compounds have been found to show magnetic ordering. NbFe and TaFe are known to be antiferromagnetic, with Neel temperatures near 280 and 320 K, respectively. It has been reported that in these materials ferromagnetic kagome planes stacked antiferromagnetically along the rhombohedral (111) direction, but the exact site occupancies in these layers remain unclear. In our investigation we have found μ -phase of MoFe also to be antiferromagnetic, but with a unique magnetic structure and significantly lower transition temperature about 110 K. Here we discuss in detail the crystallographic and magnetic structures of TaFe, NbFe and MoFe μ -phases based on our recent neutron diffraction studies and physical property measurements on polycrystalline samples.

¹Research sponsored by the U.S. Department of Energy, Assistant Secretary for Energy Efficiency and Renewable Energy, Office of Vehicle Technologies, as part of the Propulsion Materials Program, under Contract No. DE-AC05-00OR22725 with UT-Battelle, LLC.

9:00AM Y8.00006 Magnetic Excitations in the Nearly Localized, Itinerant Magnet Gd, Studied by Neutron Spectroscopy¹

, G.E. GRAROTH, A.A. ACZEL, J.A. FERNANDEZ-BACA, S.E. NAGLER, Oak Ridge National Laboratory — Many of the current questions about magnetic superconductors are present when these complex materials are in the normal state. Therefore studies of simpler itinerant magnets may help provide understanding of these phenomena. We chose to study an Itinerant magnet near to the fully localized limit. The system of choice, Gd has a total moment size of $\sim 7.6 \mu_B$ of which $\sim 0.6 \mu_B$ of that is itinerant. We used the SEQUOIA spectrometer, at the Spallation Neutron Source at Oak Ridge National Laboratory, to measure the magnetic excitations in a 12 gm ¹⁶⁰Gd single crystal. The fine resolution Fermi chopper was spun at 360 Hz and phased for $E_i = 50$ meV. The crystal was mounted with the $h0l$ plane horizontal and then rotated around the vertical axis in 1° steps. This method, and the large out of plane detector coverage of SEQUOIA, provided continuous coverage of a large region of reciprocal space allowing us to map the magnetic excitations. This map provides a measured structure factor for comparison to spin wave models with and without itinerancy effects. These measurements also more clearly resolve the excitations along the $h00$ direction than in previous studies (J. W. Cable, R. M. Nicklow and N. Wakabayashi Phys. Rev. B **32**, 1710 (1985)).

9:12AM Y8.00007 Magnetic and charge carriers properties of metamagnetic Fe₃Ga₄

, JOSHUA MENDEZ¹, YAN WU², BRADFORD FULFER³, JULIA CHAN⁴, JOHN DITUSA⁵, Louisiana State University — Single crystals of Fe₃Ga₄ were grown via an iodine vapor transport method. Previous investigations of arc-melted polycrystalline samples identify metallic conduction with a magnetic phase transition at 400 K and interesting temperature-dependent metamagnetic behavior. The single crystal samples allow a much fuller exploration of the magnetic properties and have yielded some interesting differences with the previous data. This includes a sharp reduction of the magnetization within the magnetically ordered phase associated with a sharp onset of the metamagnetic behavior in the field dependence near room temperature. A previously identified second phase transition occurs below 50 K where the metamagnetic behavior is replaced by a ferromagnetic magnetization with little hysteresis. We find substantial anisotropy in the magnetization which is particularly apparent between 50 and 300 K. Charge transport experiments are underway to explore the magnetoresistance and Hall effect of this magnet.

9:24AM Y8.00008 Structural and magnetic characterization of the complete delafossite solid solution (CuAlO₂)_{1-x}(CuCrO₂)_x

, PHILLIP BARTON, RAM SESHADRI, Materials Department and Materials Research Laboratory, University of California, Santa Barbara, ANDREA KNÖLLER, Institut für Materialwissenschaft, Universität Stuttgart 70569, Germany, MATTHEW ROSSEINSKY, Department of Chemistry, University of Liverpool, England, UK — We have prepared the complete delafossite solid solution between diamagnetic CuAlO₂ and the t_{2g}^3 frustrated antiferromagnet CuCrO₂. The crystal structure and magnetism were studied with powder x-ray diffraction and magnetometry. The unit cell parameters follow the Végard law and μ_{eff} is equal to the Cr³⁺ spin-only $S = 3/2$ value. Θ_{CW} is negative and its magnitude increases with Cr substitution. For dilute Cr compositions, J_{BB} was estimated by mean-field theory to be 3.0 meV. Despite the sizable Θ_{CW} , long-range antiferromagnetic order does not develop until x is almost 1, and is preceeded by glassy behavior. For all samples, the 5 K isothermal magnetization is sub-Brillouin and does not saturate in fields up to 5 T. A scaled inverse susceptibility plot reveals that significant short-range antiferromagnetic interactions occur in CuCrO₂ above its Néel temperature. Additionally, the Al-substituted samples exhibit uncompensated short-range behavior and $x = 0.75$ shows glassy characteristics. It is suggested that reduction in magnetic frustration due to the presence of non-magnetic Al does not have as dominant an effect on magnetism as do chemical disorder and dilution of magnetic exchange.

9:36AM Y8.00009 Quasi-Spin Glass in a Geometrically Frustrated Magnet, ARTHUR RAMIREZ, ANDREW LAFORGE, University of California, Santa Cruz, BENNY CHAN, The College of New Jersey, GAVIN LAWES, Wayne State University — A spin glass state is observed in the B-spinel $\text{ZnCr}_{2(1-x)}\text{Ga}_{2x}\text{O}_4$ for $x < 0.05$ via low-temperature magnetization and specific heat. The spin glass phenomenology is conventional. The degrees of freedom (quasi-spins) that undergo freezing are unconventional, however, both in structure as well as their mutual interactions. In particular, below $x = 0.05$, the freezing temperature is independent of quasi-spin density, yielding a strong violation of mean field theory.

9:48AM Y8.00010 Thermodynamic tuning in the dilute Ising magnet $\text{LiHo}_{0.045}\text{Y}_{0.955}\text{F}_4$, D.M. SILEVITCH, M.A. SCHMIDT, University of Chicago, G. AEPPLI, University College London, T.F. ROSENBAUM, University of Chicago — The $\text{LiHo}_x\text{Y}_{1-x}\text{F}_4$ family of dipole-coupled Ising magnets has been found to exhibit a rich variety of magnetic phases, ranging from ferromagnet to spin glass to decoupled spin clusters. We examine the behavior for $x=4.5\%$ at dilution refrigerator temperatures as a function of thermal coupling to a heat reservoir. We show that by cooling the sample in different thermodynamic limits, we can select qualitatively different low temperature magnetic states with different quantum characters. Furthermore, we demonstrate that an external transverse magnetic field, which acts to tune the rate of quantum tunneling, can be used to switch the system between the two states.

10:00AM Y8.00011 High Pressure ^{31}P -NMR Study of the 2D Frustrated Square-Lattice Compound $\text{BaCdVO}(\text{PO}_4)_2$ at Low Temperatures¹, B. ROY, Ames Laboratory, Dept. of Phys. and Astro., Iowa State Univ., Y. KOMAKI, Graduate School of Science, Dept. of Phys., Chiba Univ., R. NATH, D.C. JOHNSTON, Y. FURUKAWA, Ames Laboratory, Dept. of Phys. and Astro., Iowa State Univ. — $\text{BaCdVO}(\text{PO}_4)_2$ is a $S=1/2$ frustrated square-lattice (FSL) compound with a nearest neighbor exchange coupling $J_1 \sim -3.36$ K and a next-nearest neighbor exchange coupling $J_2 \sim 3.53$ K bearing $J_2/J_1 \sim 1.05$. Based on the J_2/J_1 ratio, the system is known to be located close to the disordered ground state (known as 'nematic state') regime of the phase diagram. We have carried out ^{31}P -NMR measurements under high pressure (~ 1 GPa) and at low temperatures using dilution refrigerator to investigate the pressure effects on the magnetic properties of the system. Under ambient pressure at $H=2.67$ T, we observed a sharp peak in ^{31}P spin lattice relaxation rate ($1/T_1$) at $T_N \sim 1.05$ K, which corresponds to the antiferromagnetic ordering temperature. On the other hand, under a pressure of 1 GPa, the peak in $1/T_1$ is suppressed and $1/T_1$ shows a sudden decrease below ~ 0.75 K. This indicates that T_N decreases with the application of pressure. We will report the temperature dependence of the NMR spectra and of the $1/T_1$ under different magnetic fields and pressures.

¹Supported by USDOE under the Contract No. DE-AC02-07CH11358.

10:12AM Y8.00012 Triplet state and in-gap scattering from the spin- $1/2$ quantum antiferromagnet Ba_2YMoO_6 , J.P. CARLO, Villanova University, J.P. CLANCY, University of Toronto, T. AHAREN, University of Ottawa, Z. YAMANI, National Research Council Canada, J.P.C. RUFF, Argonne National Laboratory, J.J. WAGMAN, G.J. VAN GASTEL, H.M.L. NOAD, McMaster University, G.E. GRANROTH, Oak Ridge National Laboratory, J.E. GREEDAN, H.A. DABKOWSKA, B.D. GAULIN, McMaster University — The double perovskite material Ba_2YMoO_6 is known to exhibit an absence of long-range and short-range magnetic order down to at least 2K, indicating a high degree of geometric frustration of its tetrahedrally-coordinated spin- $1/2$ Mo^{5+} moments, and NMR results have implied the existence of a spin-singlet ground state. Though geometric frustration in both 3D and quasi-2D systems has been of intense interest in recent years, comparatively little attention has been given to FCC systems, which may exhibit geometric frustration as the FCC lattice can be viewed as a network of edge-sharing tetrahedra. We have conducted inelastic neutron scattering measurements using triple-axis and time-of-flight instruments, revealing a band of scattering at 28 meV which disappears above ~ 125 K; we identify this scattering band as the triplet excitation out of a singlet ground state. We also identify a weaker population of in-gap states which are reminiscent of spin-polaron states induced by weak disorder.

10:24AM Y8.00013 Magnetothermal transport in monoclinic $\text{Nd}_2\text{Ti}_2\text{O}_7$ ¹, HUI XING, Department of Physics, University at Buffalo-SUNY, HONGWANG ZHANG, University at Buffalo-SUNY, HANJIE GUO, Department of Physics, Zhejiang University, CHUNMU FENG, GUANGHAN CAO, ZHUAN XU, Zhejiang University, HAO ZENG, University at Buffalo-SUNY — The monoclinic $\text{Nd}_2\text{Ti}_2\text{O}_7$ is an interesting material due to the existence of a novel field-induced slow spin relaxation (SSR) in the paramagnetic state. The SSR is attributed to the cooperative relaxation mode formed through the spin-spin interactions between partially polarized spins. Here we report the magnetothermal transport measurement on $\text{Nd}_2\text{Ti}_2\text{O}_7$ single crystals. The zero field thermal conductivity is dominated by the phonon contribution. The magnetothermal conductivity reveals significant field dependence. The field and temperature dependence is discussed in connection with the field-induced slow spin relaxation. .

Session Y9 DMP GMAG: Focus Session: Complex Bulk Oxide: Orbital Physics 209

8:00AM Y9.00001 Temperature dependence of Photoinduced dynamics in the orbital-ordered state of $\text{AV}_{10}\text{O}_{15}$ ($A = \text{Ba}, \text{Sr}$), AYAKA NOGAMI, YUYA ONISHI, KOU TAKUBO, TAKUROU KATSUFUJI, Dept. of Physics, Waseda University — In $\text{AV}_{10}\text{O}_{15}$ ($A = \text{Ba}, \text{Sr}$), the V ions with mixed-valence states, $\text{V}^{2+}/\text{V}^{3+}$ ($3d^3/3d^2$), are located on the triangular lattice. $\text{BaV}_{10}\text{O}_{15}$ exhibits a structural phase transition with V trimerization caused by the orbital ordering of V ions at $T_c = 123$ K, whereas $\text{SrV}_{10}\text{O}_{15}$ does not exhibit such a phase transition. We performed a femtosecond pump-probe reflection spectroscopy on $\text{BaV}_{10}\text{O}_{15}$ and $\text{SrV}_{10}\text{O}_{15}$ to clarify their photoinduced dynamics. For $A = \text{Ba}$, a photoinduced melting of V trimerization, i.e. a photoinduced phase transition, was observed at 10 K ($< T_c$). At $T = 200$ K ($>> T_c$), the photoinduced reflectivity change ($\Delta R/R$) for $A = \text{Ba}$ shows an oscillation with the period of several tens picoseconds, similarly to the behavior for $A = \text{Sr}$ at 10 K. This oscillation can be explained by assuming that the photoinduced state at the sample surface propagates into the inside of the sample. At $T = 135$ K, immediately above T_c , we found that $|\Delta R/R|$ for $\text{BaV}_{10}\text{O}_{15}$ increases with time, suggesting that the area of the photoinduced state on the sample surface increases with time.

8:12AM Y9.00002 Chemical pressure effects on structural, magnetic, and transport properties of $\text{Mn}_{1-x}\text{Co}_x\text{V}_2\text{O}_4$ ¹, ANDHIKA KISWANDHI, JAMES BROOKS, JUN LU, JEFFREY WHALEN, THEO SIEGRIST, HAIDONG ZHOU, National High Magnetic Field Laboratory — The low-temperature x-ray diffraction, susceptibility, specific heat, and resistivity of the single crystal $\text{Mn}_{1-x}\text{Co}_x\text{V}_2\text{O}_4$ have been investigated. With increasing Co-doping, the chemical pressure related to the decreasing V-V distance drives the system towards the itinerant electron limit, accompanied with the increase of the ferrimagnetic transition temperature and the suppression of the structural distortion. These effects are compared to the effects from the application of physical pressure, and show that the V-V distance is the critical parameter controlling the properties of AV_2O_4 .

8:24AM Y9.00003 Thermal conductivity of spinel MnV_2O_4 with doping, TAKURO KATSUFUJI, T. OMURA, T. ISHIKAWA, Y. ISHITSUKA, Department of Physics, Waseda University — Spinel MnV_2O_4 exhibits a structural phase transition and ferrimagnetic ordering simultaneously at 57 K. The crystal symmetry in the low-temperature phase obtained by the x-ray diffraction of a single crystal indicates an antiferro-orbital ordering of V t_{2g} states [1]. It was also found that Al doping into the V site suppresses the orbital-ordering temperature (T_{oo}) but barely affects the ferrimagnetic-ordering temperature (T_N); thus two transition temperatures are separated in the Al-doped samples. We measured the thermal conductivity of $\text{Mn}(\text{V}_{1-x}\text{Al}_x)_2\text{O}_4$, and found that thermal conductivity sharply increases (thermal resistivity decreases) below T_{oo} . It was also found that, with applied magnetic field, thermal resistivity increases above T_{oo} but decreases below T_{oo} . These results indicate that thermal conductivity is dominated by the fluctuation of orbital ordering. [1] T. Suzuki *et al.*, Phys. Rev. Lett. 98, 127203 (2007).

8:36AM Y9.00004 Magnetic properties driven by local structure in quasi-1D Ising chain system cobaltate system, BONGJAE KIM, BEOM HYUN KIM, KYOO KIM, HONG CHUL CHOI, SANG-YEON PARK, Y.-H JEONG, B. I. MIN, Department of Physics, POSTECH, Pohang, 790-784, Korea — Using *ab-initio* band structure method and the microscopic model calculation, the origins of the large orbital magnetic moment and unique magnetic anisotropy in the quasi-1D magnetic cobaltate, $\alpha\text{-CoV}_2\text{O}_6$, is investigated. Unique crystal electric field effect in $\alpha\text{-CoV}_2\text{O}_6$ is combined with the strong spin-orbit coupling, results in intriguing magnetic properties of the system. Based on the estimated strengths of the intra- and the inter-chain exchange interaction, experimentally found 1/3 magnetization plateau in the MH curve can be attributed to spin-flop mechanism. Origin of the reduced magnetic entropy behavior is found to be the strong uniaxial magnetic anisotropy in the quasi-1D Ising chain system.

8:48AM Y9.00005 A Comparative Study of Magnetic and Structural Transitions Focusing on Dielectric and RF Measurements¹, LAUREL WINTER, JAMES BROOKS, NHMFL/FSU, HAIDONG ZHOU, NHMFL — High frequency inductive and dielectric measurements were used to study the magnetic and structural transitions of a number of compounds, including a series of spinel vanadates of the form $\text{Mn}_{1-x}\text{Co}_x\text{V}_2\text{O}_4$. We then compared the results to those found using other measurement techniques, such as resistivity and specific heat. The high frequency inductive measurements were conducted using a tunnel diode oscillator (TDO), and proved to be an effective and simple way to observe the magnetic transitions. From capacitance and dissipation measurements we were able to observe both magnetic and structural transitions, but only in the more insulating samples.

¹NSF-DMR-0602859

9:00AM Y9.00006 MicroRaman study of orbitonphonon coupling in YbVO_3 , BENOIT ROBERGE, SERGE JANDL, Université de Sherbrooke, THOMAS T.M PALSTRA, A.A. NUGROHO, University of Groningen — Owing to their strong electron correlation, transition-metal oxides with perovskite related structures display a variety of interesting properties such as Mott transition, high- T_c superconductivity and colossal magnetoresistance. YbVO_3 belong to this family and exhibits magnetic and orbital orderings at low temperatures. In this communication, we present a study of its first order and multiphonon Raman active excitations as a function of temperature. Impact of various orbital, magnetic and structural transitions is analyzed and possibilities of orbiton-phonon coupling in the observed phonon combinations around 1400 cm^{-1} are discussed.

9:12AM Y9.00007 Controlling Magnetism in Multiferroic BiFeO_3 , VALERY KIRYUKHIN, Rutgers University — BiFeO_3 (BFO) is a room-temperature multiferroic combining large electric polarization with an antiferromagnetic structure with a superimposed long-wavelength (62 nm) cycloidal modulation. Large single crystals of BFO have become available recently, opening up new opportunities for experiments. In this talk, we discuss various ways of controlling magnetism in BFO single crystals using coupling between the ferroelectric and magnetic order parameters. Electric field can rotate the electric polarization and Fe spins simultaneously, and a chiral magnetic monodomain state can be obtained. Populations of the 3 equivalent cycloidal magnetic domains can be controlled by an electric field through piezoelectric coupling. Alternatively, they can be controlled via the inverse effect by applying uniaxial pressure. Very small (~ 50 bar) pressures producing tiny elastic strain ($\sim 10^{-5}$) are needed to move the magnetic domain walls. Using polarized small-angle neutron scattering, we show for the first time that the spins in the cycloid are tilted, producing local weak ferromagnetism ($0.06\ \mu_B$ rms value), confirming a long-standing theoretical prediction. This shows that intrinsic macroscopic ferromagnetism could be expected in strained BFO, in which the cycloid is suppressed. Combined with the ability to control the magnetic domains by an electric field or tiny deformation, this observation accentuates the potential of BFO for room-temperature applications involving magnetoelectric effects.

9:48AM Y9.00008 Pressure-driven changes in electronic structure of BiCoO_3 ¹, SUDIPTA KANUNGO, TANUSRI SAHA-DASGUPTA, S.N Bose National Centre for Basic Sciences — Using first-principles DFT based calculations, carried out on the recently measured crystal structure data [Oka *et al.* J. Am. Chem. Soc. 132, 9438 (2010)], we study the changes in the electronic structure of BiCoO_3 between the ambient-pressure and the high-pressure conditions. Our study shows that the application of high pressure drives the high-spin-to-low-spin transition at the Co site. The obtained results for the ambient pressure phase shows C-type AFM alignment of Co high spins, while the electronic structure at the high-pressure phase shows the presence of a finite energy gap at E_f in contrast with previously reported metallic or semimetallic character with low-spin state of Co. This semiconducting behavior in the nonmagnetic BiCoO_3 with LS state of Co is found to be driven by the presence of the GdFeO_3 type of orthorhombic distortion which arises due to finite mixing of Bi lone-pair states with O-p states, as opposed to previously predicted cubic or tetragonal symmetry of the high-pressure. The ambient pressure phase shows an order of magnitude larger energy gap arising due to the AFM alignment of Co in the high-spin state than the energy gap at the high pressure phase, explains the observed 3-order of magnitude jump in resistivity.

¹Ref: Sudipta Kanungo and T. Saha-Dasgupta, Phys.Rev.B 83,104104(2011)

10:00AM Y9.00009 Long Range Ordering in Oxygen Doped SrCoO_x ¹, F.J. RUECKERT, University of Connecticut, F.Z. HE, Canadian Light Source, H. MOHOTALLA, University of Hartford, J.I. BUDNICK, W.A. HINES, University of Connecticut, B. DABROWSKI, Northern Illinois University, B.O. WELLS, University of Connecticut — Recent investigations have shown magnetic phase separation in polycrystalline samples of SrCoO_x ($2.5 \leq x \leq 3.0$).² As the samples are oxidized electrochemically, distinct ferromagnetic phases are formed at $\text{SrCoO}_{2.75}$ ($T_C = 165\text{ K}$), $\text{SrCoO}_{2.88}$ ($T_C = 220\text{ K}$), and SrCoO_3 ($T_C = 280\text{ K}$). In the polycrystalline bulk samples, two magnetic phases are seen at oxygen concentrations between 2.875 and 3.0, always occurring in only a single structural phase. The distinct phases are also evident in epitaxial 100 nm films, but the mixed magnetic phase at intermediate concentrations is suppressed. The occurrence of separate magnetic phases at concentrations of 2.75 [3-1/4], 2.88 [3-1/8], and 3.0 imply an electronic ordering commensurate with the lattice. Using resonant x-ray diffraction in thin film samples, we have discovered the existence of a superlattice peak at (1/4, 1/4, 1/4), revealing a previously hidden order with a periodicity four times the basic perovskite cell in all directions.

²Xie *et al.* Appl. Phys. Lett 99, 052503 (2011)

10:12AM Y9.00010 Structural and magnetic properties of $\text{Nd}_{1-x}\text{Ca}_x\text{BaCo}_2\text{O}_{5.5}$, OMAR CHMAISSEM, Physics Department - Northern Illinois University and Materials Science Division - Argonne National Laboratory, IL USA, STANISLAW KOLESNIK, Physics Department - Northern Illinois University, IL USA, BOGDAN DABROWSKI, Physics Department - Northern Illinois University and Materials Science Division - Argonne National Laboratory, IL USA, SEVDA AVCI, Materials Science Division, Argonne National Laboratory, IL USA, MAXIM AVDEEV, Bragg Institute, ANSTO, Australia, JASON HODGES, Spallation Neutron Source, Oak Ridge National Laboratory, TN USA — $\text{R}_{1-x}\text{A}_x\text{BaCo}_2\text{O}_{5.5}$ (R = rare earth, A = alkaline metal) is a relatively new class of complex oxide materials that exhibit a wide range of magnetic attributes in addition to metal/insulator switching properties, structural transitions and superstructure order parameters. In many ways, this family exhibits behaviors similar to those of the famous colossal magnetoresistive manganites; however, more complex properties have also been identified owing to the fact that the oxidation state of the cobalt ions often behave in unpredictable ways depending on the chemical composition of the investigated material and the corresponding Co local environment. Thus, Co^{3+} and Co^{4+} ions with high, intermediate and low spin states may be produced offering an additional degree of freedom to be accounted for when designing new materials with tunable magnetic properties. In this talk, I will discuss the effects of calcium substitution at the Nd sites and the various structural and magnetic models as determined by neutron powder diffraction and complementary magnetic measurements.

10:24AM Y9.00011 Peculiarities of spin and charge degrees of freedom in strongly correlated layered cobaltates, FRANK LECHERMANN, LEWIN BOEHNKE, I. Institute for Theoretical Physics, University of Hamburg, Germany, ANTOINE GEORGES, Ecole Polytechnique, Centre de Physique Theorique (CPHT), Palaiseau, France, OLEG E. PEIL, CHRISTOPH PIEFKE, I. Institute for Theoretical Physics, University of Hamburg, Germany — The layered cobaltate systems stand for the rare case of metallic quasi-2D triangular lattices at doping x . While $x=0$ corresponds to a half-filled scenario, $x=1$ marks the band-insulating limit. Surprisingly, the phase diagram displays especially for $x > 0.5$ a rich competition between different spin-orderings as well as intriguing charge-ordering processes. Though already at high doping, strong electronic correlations are mainly responsible for the complex physics [1-4]. By means of combinations of band-structure techniques with many-body approaches it is shown that various cobaltate features may be tackled successfully. For instance the in-plane crossover from antiferromagnetic spin correlations towards the onset of ferromagnetism as well as charge ordering tendencies favoring an effective kagome lattice close to $x=0.67$ in agreement with experiment. The charge order also substantially effects the spectral and transport properties, giving rise to a specific low-energy scale susceptible to nonlocal correlations.

10:36AM Y9.00012 Stability of Multiferroic Transition in FeVO_4 against Transition Metal Doping, AKILA KUMARASIRI, Wayne State University, Detroit, MI, AMBESH DIXIT, Indian Institute of Technology, Rajasthan, India, GAVIN LAWES, Wayne State University, Detroit, MI — FeVO_4 is a recently discovered multiferroic material which undergoes successive antiferromagnetic phase transitions at $T_{N1} \sim 22$ K and $T_{N2} \sim 15$ K, with ferroelectricity developing at the T_{N2} transition. FeVO_4 is a type II multiferroic where the ferroelectricity is magnetically driven. We have studied the effect of transition metal doping on these two phase transitions in order to explore how the multiferroic order is affected by introducing perturbations into the lattice. We synthesized polycrystalline $\text{M}_x\text{Fe}_{1-x}\text{VO}_4$ samples (M = Zn, Mn, Cr) using a standard solid state reaction method, and we used magnetic, dielectric, and heat capacity measurements to track the transition temperatures. Both magnetic and heat capacity measurements show clear peaks at the two transitions, enabling us to map how the transitions are suppressed as the doping fraction is changed. On doping with non magnetic Zn, we find only a minimal suppression of both transition temperatures, indicating the magnetic interactions producing the multiferroic order are surprisingly robust against non-magnetic perturbations. We will also present preliminary results of the effects of magnetic dopants, specifically Mn and Cr.

10:48AM Y9.00013 ^{51}V single-crystal NMR Study on multiferroic FeVO_4 , JINSHAN ZHANG, School of Energy, Power and Mechanical Engineering, North China Electric Power University, Beijing, China, LONG MA, WEIQIANG YU, Department of Physics, Renmin University of China, Beijing, China, ZHANGZHEN HE, State Key Laboratory of Structural Chemistry, Fujian Institute of Research on the Structure of Matter, Chinese Academy of Science, Fujian, China — The multiferroicity in FeVO_4 is so far not well understood because its spin-orbit coupling is probably very weak. In this talk, we report our ^{51}V single crystal NMR study on FeVO_4 under zero field and a finite field. The double magnetic transitions with $T_{SDW} \approx 19$ K and $T_{helical} \approx 13$ K are clearly shown by NMR spectra and the spin-lattice relaxation rate $1/T_1$. Two nonequivalent ^{51}V sites are identified with different hyperfine couplings. Just below $T_{helical}$, a large RF enhancement is seen, which indicates rich magnetic domain walls formed in the helical state and not in the SDW state. Based on our results, we discuss the coupling between the magnetism and the ferro-electricity in FeVO_4 .

Friday, March 2, 2012 8:00AM - 11:00AM –
Session Y10 DCOMP: Invited Session: Modeling & Simulation of the Impact of Space Radiation on Electronic Systems (Avionic and Astronautic) 210A

8:00AM Y10.00001 Mitigation of Space Radiation Effects, WILLIAM ATWELL¹, The Boeing Company — During low earth orbit and deep space missions, humans and spacecraft systems are exposed to high energy particles emanating from basically three sources: geomagnetically-trapped protons and electrons (Van Allen Belts), extremely high energy galactic cosmic radiation (GCR), and solar proton events (SPEs). The particles can have deleterious effects if not properly shielded. For humans, there can be a multitude of harmful effects depending on the degree of exposure. For spacecraft systems, especially electronics, the effects can range from single event upsets (SEUs) to catastrophic effects such as latchup and burnout. In addition, some materials, radio-sensitive experiments, and scientific payloads are subject to harmful effects. To date, other methods have been proposed such as electrostatic and electromagnetic shielding, but these approaches have not proven feasible due to cost, weight, and safety issues. The only method that has merit and has been effective is bulk or parasitic shielding. In this paper, we discuss in detail the sources of the space radiation environment, spacecraft, human, and onboard systems modeling methodologies, transport of these particles through shielding materials, and the calculation of the dose effects. In addition, a review of the space missions to date and a discussion of the space radiation mitigation challenges for lunar and deep space missions such as lunar outposts and human missions to Mars are presented.

8:36AM Y10.00002 The Space Radiation Environment in Energetic Particles at the Earth ,

GARY ZANK, Center for Space Plasma and Aeronomic Research (CSPAR) and Physics Department, University of Alabama in Huntsville — Understanding the radiation environment in energetic particles at the Earth is critical to the stability, integrity, and longevity of satellite subsystems. The radiation environment comprises particles trapped in the Earth's radiation belts and magnetosphere, those generated by solar energetic particle events (SEPs), and galactic and anomalous cosmic rays. Of these different populations, the most highly variable, and consequently difficult to anticipate, is the SEP population. This is also the population that can often cause the most damaging effects. SEP events can be either impulsive or gradual (sometimes a mixture of the two) with the gradual events being larger, much longer lasting, and often with higher particle energies. Diffusive shock acceleration at a coronal mass ejection driven shock wave is generally invoked to explain gradual SEP events. The detailed [plasma] physics of the acceleration mechanism remains to be elucidated. We are fortunate in that very detailed observations of particle acceleration at shock waves, particularly in the guise of Space Weather, are providing considerable experimental insight into the basic physics of particle acceleration at a shock wave. Detailed interplanetary observations are not easily interpreted in terms of simple steady-state models of particle acceleration at shock waves. Three fundamental aspects make the interplanetary problem much more complicated than the typical astrophysical problem: the time dependence of the acceleration and the solar wind background; the geometry of the shock; and the long mean free path for particle transport away from the shock wave. An interplanetary shock is not steady, as it decelerates and expands into an expanding, temporal solar wind. Furthermore, the shock geometry varies from quasi-parallel to quasi-perpendicular along a shock front, and multiple shocks can be present simultaneously in the solar wind. Consequently, the shock itself introduces a multiplicity of time scales, ranging from shock propagation time scales to particle acceleration time scales at parallel and perpendicular shocks, and many of these time scales feed into other time scales (such as determining maximum particle energy scalings, escape time scales, etc.). We will discuss the basic physics of particle acceleration via scalings, their relationship to particle acceleration models, observations and geometry in both an astrophysical and space physics context. This will include discussing the physics of perpendicular and parallel shocks, upstream turbulence, particle spectra, and particle injection and the seed population. After acceleration of particles at an interplanetary shock, the transport of energetic particles is non-diffusive because of their large mean free path in the quiet solar wind. We will address the coupled acceleration and transport of heavy ions, Fe/O ratios, the variability among individual events, and seed particle populations. We will discuss theoretical models and address recent modeling efforts.

9:12AM Y10.00003 Monte Carlo Simulation of Radiation Effects in Microelectronics¹ , ROBERT

A. WELLER, Vanderbilt University — Microelectronic devices are susceptible to disruption by ionizing radiation, and with the scaling of devices to ever-smaller dimensions they are increasingly vulnerable to single event effects. Single event effects are transient errors in active devices, usually although not exclusively in digital logic, that are caused by the interaction of ionizing particles with the materials from which the devices are made. This presentation describes a Monte Carlo approach for predicting the rate of single event effects from knowledge of radiation environments and device structure. The approach combines detailed physical modeling of discrete radiation events, semiconductor device simulation to estimate charge transport and collection, and circuit simulation to determine the macroscopic electrical effects of collected charge. Details of the Monte Carlo simulation will be presented, and a mathematical analysis that establishes its relationship to earlier single event rate prediction methods will be discussed. Recent experimental and computational results on the rate of single event effects in highly scaled devices will be reviewed.

¹Work supported by NASA and the Defense Threat Reduction Agency Basic Research Program.

9:48AM Y10.00004 Data-driven Three-Dimensional (3D) Global Magnetohydrodynamic (MHD) Model with Radiation to Study the Solar Atmospheric Dynamics¹ , SHI WU, The University of

Alabama in Huntsville — In this presentation, we describe a self-consistent, three-dimensional, global compressible, and resistive magnetohydrodynamic (MHD) model together with time-dependent boundary conditions based on the projected method of characteristics at the source surface (photosphere) to accommodate the observations. The additional physics included in this model are differential rotation, meridional flow, effective diffusion, and cyclonic turbulence effects in which the complex magnetic field structure can be generated through the nonlinear interactions between the plasma flows and magnetic field. To illustrate the capability of this model, we selected GONG's global transverse velocity measurements of synoptic chart CR2009 near the photosphere and SOLIS full-resolution LOS magnetic field maps of synoptic chart CR2009 on the photosphere as the inputs to drive the model to simulate the equilibrium state and compute the energy transport across the photosphere. To show the advantage of using both measured magnetic field and transverse velocity data, we have investigated two cases: (1) with the inputs of the LOS magnetic field and transverse velocity measurements, and (2) with the input of only the LOS magnetic field. For these two cases, the simulation results presented here are a three-dimensional coronal magnetic field configuration, density distribution on the photosphere and 1.5 solar radii, and the solar wind in the corona. The deduced physical characteristics are the total current helicity and the synthetic emission.

10:24AM Y10.00005 Multi-Scale Modeling of the Plasma Flow and Magnetic Fields in the Entire Heliosphere , NIKOLAI POGORELOV, Physics Department, University of Alabama in Huntsville — Numerical model of the solar wind (SW)

interaction with the local interstellar medium (LISM), developed in UAHuntsville and implemented in the Multi-Scale Fluid-Kinetic Simulation Suite, treats ions with MHD equations while the transport of neutral atoms is performed kinetically by solving the Boltzmann equation. Pickup ions are treated as a separate fluid or kinetically. The evolution of SW turbulence is addressed on the differential equation level. Time-dependent, based on observational data, modeling of the SW in the entire heliosphere is critical for the space weather modeling and interpretation of the spacecraft data. We choose LISM properties using remote observations and appropriate numerical modeling which allows us to constraint them by matching the ribbon of the energetic neutral atom flux detected in different energy bands by the Interstellar Boundary Explorer. We used the Ulysses data to model the SW-LISM interaction during the period of the mission and matched rather well the timing of the termination shock crossing by Voyager 1 and Voyager 2. The SW boundary conditions include those provided by the interplanetary scintillation measurements and obtained by numerical modeling of the inner heliosphere from the Sun's surface to the Earth orbit. Numerical results are extracted as time series along real spacecraft trajectories and compared with in situ measurements.

Friday, March 2, 2012 8:00AM - 11:00AM –

Session Y11 DMP: Focus Session: Graphene Devices - Fabrication 210B

8:00AM Y11.00001 Lattice-Nanotomy for Large-Scale Production of Transferrable and Dispersible Graphene-Nanostructures of Controlled Shape and Size¹ , BALABALAJI PADAVALA, NIHAR MOHANTY,

Kansas State University, DAVID MOORE, University of Kansas, ZHIPING XU, Tsinghua University, ASHVIN NAGARAJA, ALFREDO A. RODRIGUEZ, VIKAS BERRY, Kansas State University, DR. MOORE'S TEAM TEAM, DR. XU'S TEAM TEAM — In this talk, we will present a novel graphite-lattice-nanotomy (nanoscale-cutting) process for high throughput production of monodispersed graphene nanostructures (GNs) with controlled shape (square, rectangle, ribbons and triangle), dimensions (sizes at 5 nm resolution with a range of 5–600 nm) and chemical-construct. We demonstrate that this versatile process enables the realization of unprecedented graphene-nanostructures, which exhibit the evolution of semiconductor-characteristics and electrical transport mechanism. Further, we will present in detail the size and shape-dependent electrical and optical properties of these GNs via various microscopic and spectroscopic techniques. This nanotomy process can provide access to virtually-infinite and unprecedented GNs for development of fundamental optical/electrical/structural correlations and novel applications.

¹NSF-CAREER, Office of Naval Research and KSU-Startup

8:12AM Y11.00002 Direct Writing of Graphene-based Nanoelectronics via Atomic Force Microscopy, MICHAEL HAYDELL, ELENA CIMPOIASU, US Naval Academy, Physics Dept., Annapolis, MD, 21402, WOO KYUNG LEE, RORY STINE, Naval Research Laboratory, Surface Nanoscience and Sensor Technology, Washington DC, 20375, WILLIAM P. KING, Univ. of Illinois at Urbana-Champaign, Dept. of Mech. Science and Eng., Urbana, IL, 61801, PAUL SHEEHAN, Naval Research Laboratory, Surface Nanoscience and Sensor Technology, Washington DC, 20375 — We use direct writing with an atomic force microscope (AFM) to fabricate simple, graphene-based electronic components to explore their electronic properties and the feasibility of manufacturing electronic devices via AFM. The process being studied, thermochemical nanolithography (TCNL), involves flowing current through an AFM cantilever to provide thermal energy to a chemically modified graphene (CMG) film, either graphene oxide or graphene fluoride. The heat reduces the insulating CMG film back into conductive graphene. Thus, these nanoribbons can be used to fabricate nano-scale electronic components such as resistors, capacitors, and transistors. The technique, as compared to other attempts to produce graphene-based devices, is simple, does not involve solvents or other complicated fabrication steps, and allows for the exact placement of the devices on the substrate. The electronic properties of the devices produced using the two materials, measured using current-voltage characteristics at various temperatures down to 2 K and in variable magnetic fields up to 9 T, will be discussed. This work was partially supported by the US Naval Academy Research Office and the Nanoscience Institute at NRL.

8:24AM Y11.00003 A study on tapered graphene nanoribbons with controlled angle: Fabrication and conductivity studies¹, SREEPRASAD THERUVAKKATTIL SREENIVASAN, BALABALAJI PADAVALA, PHONG NGUYEN, VIKAS BERRY, Kansas State University — Graphene, the newest member in the nanocarbon family, is a perfect single atom thick 2D sheet made up of carbon with exceptional electrical and mechanical properties. It is well-known that the band-gap of graphene nanoribbons (GNRs) can be controlled via their width. Here we demonstrate that GNRs with tapered morphology have semiconducting-to-metallic continuum along its length, and thus exhibit unique electrical properties. The device is fabricated from a single layer graphene grown on a Cu foil via the standard CVD process. Here, the graphene is transferred on a silica substrate and electron beam lithography etching is performed to produce a tapered graphene GNR device, followed by with Pd-Au electrode-deposition. We demonstrate the unique carrier transport properties, electrical rectification and carrier modulation in these novel devices.

¹Office of Naval Research, KSU-Start up

8:36AM Y11.00004 Toward graphene based electronics from homogeneous top-gated graphene devices, JINSEONG HEO, HYUNJONG CHUNG, HEEJUN YANG, DAVID SEO, HYUN JAE SONG, KYOUNG-EUN BYUN, SEONGJUN PARK, Samsung Advanced Institute of Technology, GRAPHENE TEAM — We report high quality top-gated graphene field effect devices integrated on 150mm substrate, which involves unprecedented homogeneous chemical vapor deposition growth of monolayer graphene on Ni/Cu. Statistics of maximum resistance, dirac voltage and also mobility over a thousand devices are shown for the first time, in which 5% of measurable devices are in 3,000~5,000 cm²/V·s of mobility. Furthermore, logic gates such as NOT and AND based on top-gated graphene devices were demonstrated. Our results imply a route toward graphene based electronics with complementary metal-oxide-semiconductor (CMOS) compatible process.

8:48AM Y11.00005 Gate-Tunable Superconductor-Insulator Transition in Bilayer-Graphene Josephson Junctions, DONGCHAN JEONG, GIL-HO LEE, Pohang University of Science and Technology, YONG-JOO DOH, Korea University, HU-JONG LEE, Pohang University of Science and Technology — Bilayer graphene shows opening of electric-field-induced band gap, the size of which is proportional to the intensity of the electric field. We report electronic transport measurements on superconducting proximity effect in planar dual-gated bilayer-graphene Josephson junction with Pb_{0.93}In_{0.07} (PbIn) electrodes ($\Delta_{PbIn} \sim 1.1$ meV, $T_c = 7.0$ K). The junction resistance along the charge-neutral point (CNP) increases as we modulate top- and back-gate voltages away from the zero-gap CNP. The resistive state near the CNP shows a variable-range-hopping-type insulating behavior in R - T curve with lowering temperature crossing the superconducting transition of PbIn electrodes. However, a highly doped regime shows metallic R - T behavior and junction becomes superconducting below T_c . Moreover, magnetic-field-induced Fraunhofer supercurrent modulation, microwave-induced Shapiro steps, and multiple Andreev reflection (MAR) are observed, which indicate the formation of genuine Josephson coupling across the planar junctions below T_c with sufficiently transparent superconductor–bilayer graphene interface. The separatrix of the superconductor-insulator transition corresponds to the square junction conductance of $G_{sq} \sim 6-8e^2/h$.

9:00AM Y11.00006 Characterization of graphene quantum dot hybrid structures¹, TING-FUNG CHUNG, JIUNING HU, LUIS A. JAUREGUI, LIANGLIANG CHEN, QING ZHAO, XIULIN RUAN, YONG P. CHEN, Purdue University — We report electrical transport, photo-electric response and Raman spectroscopy measurements in macroscopic samples of graphene decorated with inorganic quantum dots (CdSe QDs). QDs are deposited on chemical vapor deposition (CVD) graphene by spin-coating. Raman measurements of graphene decorated with QDs on Si wafer show very similar spectra with clear G and 2D peaks that reveal no degradation of graphene during the QDs deposition process. Furthermore, two types of device architectures (QDs-graphene and graphene-QDs-graphene) are fabricated with graphene as a transparent electrode and QD as a light absorbent for electrical photoresponse characterization. Upon application of either a broadband light source or a 532-nm monochromatic laser source, graphene-QDs-graphene devices demonstrate photoconducting response, but not in the case of QDs-graphene devices.

¹This work is partially supported by Day & Associate LLC.

9:12AM Y11.00007 Fabrication of nanometer-scale suspended graphene transistors, VAHID TAYARI, JOSHUA O. ISLAND, SERAP YİĞEN, JAMES PORTER, A.R. CHAMPAGNE, Department of Physics, Concordia University, Montreal, Quebec, Canada — We present a method to fabricate suspended ultra-short graphene transistors. We define narrow bowtie gold junctions on exfoliated graphene, and then use an oxygen plasma to etch away the graphene except under the gold junctions. The next step is to wet etch the SiO₂ under the junctions to suspend the devices. Finally, we use a feedback-control electromigration procedure to break the gold junctions and expose sections of graphene which are 100 to 300 nm wide and as short as ≈ 10 nm. Using electron transport, we show that these suspended graphene nanocrystals form ballistic two-dimensional Dirac electron gas systems. We study them as a function of temperature and charge carrier density. These ultra-short NEMS transistors offer the prospect of exploring the coupling between flexural vibrons and charge carriers in graphene.

9:24AM Y11.00008 Implementation of embedded-gate graphene field effect transistors on flexible substrates, JONGHO LEE, LI TAO, MILO HOLT, DEJI AKINWANDE, University of Texas at Austin — In this work we present embedded-gate graphene field effect transistors (GFETs) on flexible polyimide films for high frequency RF and sensor applications. Graphene transistors with gate lengths from 1μm to 4μm and width of 8μm have been realized by e-beam lithography. Chemical vapor deposited monolayer graphene with negligible defects is transferred to flexible polyimide substrates for device fabrication. The electrostatic measurement reveals that fabricated device shows a mobility of over 1000cm²/Vs at room temperature, the highest reported among graphene FETs implemented on flexible films. Surface roughness and impurity doping are of crucial importance in fabricating flexible graphene devices since its charge transport is limited by mobility degradation due to surface roughness and doping related with the chemical transfer process. The stack of atomic layer deposited Al₂O₃ as gate dielectric and gate pads underneath provides smooth surface for graphene to sit on as confirmed by atomic force microscopy. This results in a field effect mobility of an embedded gate GFET twice that of a top gated GFET on polyimide substrates. The minimum conduction point is close to zero, indicating the impurity induced doping for the device is negligible.

9:36AM Y11.00009 Molecular Layer-seeded Ultra-thin Top-gate Dielectrics for High Transconductance Graphene Transistors, VINOD SANGWAN, DEEP JARIWALA, HUNTER KARMEL, JUSTICE ALABOSON, LINCOLN LAUHON, Department of Materials Science and Engineering, Northwestern University, Evanston, Illinois 60208, TOBIN MARKS, Department of Materials Science and Engineering and Department of Chemistry, Northwestern University, Evanston, Illinois 60208, MARK HERSAM, Department of Materials Science and Engineering, Department of Chemistry and Department of Medicine Northwestern University, Evanston, Illinois 60208 — The potential of graphene in integrated analog and digital circuits can only be fully realized through incorporation of ultra-thin gate dielectrics to enable large-scale small-channel graphene field-effect transistors (GFETs). Atomic-layer deposition (ALD) is a viable technique to fabricate gate-dielectrics, however, it requires a seeding layer on otherwise inert graphene. Here, we demonstrate a single molecule thick perylene-3,4,9,10-tetracarboxylic dianhydride overlayer as an effective seeding layer to grow high- κ Al_2O_3 on mechanically exfoliated graphene for high-performance GFETs. Using an ultra-thin ($< 1\text{nm}$) seeding layer, in contrast to polymer films (5-10 nm), we demonstrate fabrication of the thinnest ALD-grown gate-dielectric (4 nm) reported to date in top-gated GFETs. This yields high performance GFETs with the intrinsic transconductance parameter approaching 2.4 mS and the field-effect mobility $\sim 3000\text{ cm}^2/\text{Vs}$. We also demonstrate generalization of this molecular layer seeded-ALD growth method to higher- κ gate dielectrics, yielding further enhanced GFET transconductance for possible application to radio-frequency circuits.

9:48AM Y11.00010 Conductance through two-terminal graphene junctions with wetting metal contacts, SALVADOR BARRAZA-LOPEZ, University of Arkansas, MARKUS KINDERMANN, MEI-YIN CHOU, Georgia Institute of Technology — Metallic contacts become a relevant factor for the behavior of nanoscale graphene devices. A thin layer of a wetting metal—a metal that forms covalent bonds to graphene—is customarily placed in between graphene and bulk leads. The most common choices for this wetting metal are Titanium, Chromium, and Palladium. We will present the equilibrium conductance through crystalline (defect- and impurity-free) two-terminal graphene junctions attached to normal, spin-unpolarized Titanium metal leads. In addition, we discuss the equilibrium potential profile across the junctions, and the presence of Fabry-Perot oscillations. The conductance shows pronounced noise, and the Fano factor near the Dirac point is seen to fluctuate, as in experiment [1]. The distribution of transmission eigenvalues is bimodal, indicating a disordered-metal-like charge transport through nanoscale two-terminal graphene junctions with wetting metals.

10:00AM Y11.00011 Fabrication of a tunable quantum point contact in bilayer graphene, PATRICK MAHER, CARLOS FORSYTHE, Columbia University, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS, PHILIP KIM, Columbia University — The realization of a quantum point contact (QPC) in graphene is of interest for both physical and technological reasons. Fabricating a tunable QPC thus far, however, has been technologically challenging due to the inability to electrostatically deplete graphene. Recent advances have allowed for the creation of high mobility dual-gated bilayer samples sandwiched in hexagonal boron nitride. These samples display a robust, tunable band gap, which opens the door to electrostatically defining the conductance channel. In this presentation, we report the fabrication and characterization of point contact structures in high mobility dual-gated bilayer graphene samples employing hBN as both the top and bottom dielectric layer.

10:12AM Y11.00012 Surperconducting Graphene Nanodevice in Ballistic Regime, JOEL I-JAN WANG, Harvard School of Engineering and Applied Sciences, Harvard University/ Department of Physics, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, PABLO JARILLO-HERRERO, Department of Physics, Massachusetts Institute of Technology — Superconductivity carried by Dirac fermion can be realized through induced superconductivity in graphene. Observation of novel phenomena anticipated by theories requires superconducting graphene devices with low disorder so that the transport is ballistic. In this talk we present the fabrication and characterization of superconducting graphene nanodevices that are built on hexagonal Boron Nitride. The ultra flatness and lack of dangling bond in the boron nitride substrate reduces the disorder in graphene, opening the door to the study of ballistic Dirac fermion in superconducting regime.

10:24AM Y11.00013 Scanning Tunneling Potentiometry Mapping of Electron Transport in Graphene on SiC^1 , KENDAL CLARK, SHENGYONG QIN, XIAO GUANG ZHANG, Oak Ridge National Laboratory, GUOWEI HE, Carnegie Mellon University, GONG GU, University of Tennessee, RANDALL FEENSTRA, Carnegie Mellon University, AN-PING LI, Oak Ridge National Laboratory — Single layers of graphene formed on SiC look to be a promising system for the realization of graphene electronics. To utilize the full potential of graphene on SiC a complete understanding of the physical and electronic properties of this system is needed. Scanning Tunneling Microscope (STM) images along with scanning tunneling spectroscopy is used to characterize the sample surface. STM images clearly show the distinction between 1 monolayer (ML) and 2ML regions and this transition is further confirmed by point spectroscopy and spectroscopic mapping across the boundary. Defects, grain boundaries, step edges and other potential scattering centers are thought to play a major role in the electronic properties, especially in transport, along the graphene sheets. Using a low temperature four-probe scanning tunneling microscope, potentiometry measurements are performed on the epitaxial graphene grown on 4H-SiC. Potentiometry maps spanning the transition from 1ML to 2ML graphene show a contrast change indicating a potential change at this interface. Preliminary results of the transport along this potentially revolutionary new electronic system will be presented.

¹This research was conducted at the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Office of Basic Energy Sciences, U.S. Department of Energy.

10:36AM Y11.00014 Atomic Force Microscopy-Based Local Tunable Oxidation of Graphene, SATORU MASUBUCHI, IIS University of Tokyo, INQIE University of Tokyo, MIHO ARAI, IIS, University of Tokyo, TOMOKI MACHIDA, IIS University of Tokyo, INQIE University of Tokyo, PRESTO-JST — We have fabricated graphene/graphene oxide/graphene (G/GO/G) junctions by local anodic oxidation lithography using atomic force microscopy (AFM). The conductance of the G/GO/G junction decreased with the bias voltage applied to the AFM cantilever V_{tip} . For G/GO/G junctions fabricated with large and small $|V_{tip}|$, GO was semi-insulating and semiconducting, respectively. AFM-based LAO lithography can be used to locally oxidize graphene with various oxidation levels and achieve tunability from semiconducting to semi-insulating GO [S. Masubuchi *et al.*, Nano Lett. 11, 4542 (2011).]

10:48AM Y11.00015 High mobility Single Layer Epitaxial Graphene on 4H-SiC (000-1), YIKE HU, ZELEI GUO, MING RUAN, JOHN HANKINSON, JAMES PALMER, BAIQIAN ZHANG, RUI DONG, JAN KUNC, CLAIRE BERGER, WALT DEHEER, Georgia Institute of Technology — Multi-layer Epitaxial Graphene on 4H-SiC (000-1) has demonstrated very high mobility up to $\sim 27,000\text{ cm}^2/\text{Vs}$ [1]. Recently single layer graphene grown by the Confinement Control Growth method [2] exhibits mobility up to $\sim 25,000\text{ cm}^2/\text{Vs}$ at 4K and $13,000\text{ cm}^2/\text{Vs}$ at 300K with $p=3 \times 10^{12}\text{ cm}^{-2}$. The relation between Raman G peak features (FWHM and position) and carrier density of Epitaxial Graphene on carbon face is revealed. Quantum Hall Effect [3] is observed both for p and n type carriers on top gated sample. This indicates that top gated single layer graphene can be produced on the Carbon face with high quality and high carrier mobility.

210C

8:00AM Y12.00001 Mapping Dirac Quasiparticles near a Single Coulomb Impurity on Graphene

, YANG WANG, VICTOR BRAR, Physics Department, UC Berkeley and LBNL, ANDREY SHYTOV, School of Physics, University of Exeter, QIONG WU, WILLIAM REGAN, Physics Department, UC Berkeley and LBNL, HSIN-ZON TSAI, Physics Department, UC Berkeley, ALEX ZETTL, Physics Department, UC Berkeley and LBNL, LEONID LEVITOV, Department of Physics, Massachusetts Institute of Technology, MICHAEL CROMMIE, Physics Department, UC Berkeley and LBNL, PHYSICS DEPARTMENT, UC BERKELEY TEAM, LBNL TEAM, SCHOOL OF PHYSICS, UNIVERSITY OF EXETER COLLABORATION, DEPARTMENT OF PHYSICS, MASSACHUSETTS INSTITUTE OF TECHNOLOGY COLLABORATION — We have locally mapped the response of charge carriers to a single Coulomb potential placed on a gated graphene device. Scanning tunneling microscopy and spectroscopy were used to fabricate a tunable charge impurity and to measure how Dirac fermions screen it. By mapping spatial variation in the electronic structure of graphene we have directly probed the strength of screened electronic interactions, obtaining a value of $\epsilon = 3$ for the intrinsic graphene dielectric constant. This small value suggests that microscopic electron-electron interactions contribute significantly to intrinsic graphene properties.

8:12AM Y12.00002 Graphene Tunneling Heterostructures

, BENJAMIN HUNT, JAVIER SANCHEZ-YAMAGISHI, PABLO JARILLO-HERRERO, R. C. ASHOORI, MIT — We have fabricated tunneling heterostructures comprising graphene on boron nitride (BN) substrates and tunnel barriers constructed of exfoliated BN or MoS_2 . We present measurements of the low-temperature tunneling spectrum as a function of the tunneling energy and the carrier density in the graphene, with the latter controlled by a back-gate voltage. We observe a series of tunneling resonances, reminiscent of those seen in STM and planar tunneling experiments on graphene, whose energies disperse with the back-gate voltage.

8:24AM Y12.00003 Scanning Tunneling Spectroscopy of Graphene on Hexagonal Boron Nitride

, MATTHEW YANKOWITZ, JIAMIN XUE, DANIEL CORMODE, Physics Department, University of Arizona, JAVIER SANCHEZ-YAMAGISHI, PABLO JARILLO-HERRERO, Department of Physics, Massachusetts Institute of Technology, K. WATANABE, T. TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, PHILIPPE JACQUOD, BRIAN LEROY, Physics Department, University of Arizona — Recent work has found hexagonal boron nitride (hBN) to be a good substrate for graphene devices due to its ability to screen charged impurities in the underlying substrate and increase graphene mobility. We investigated graphene on hBN heterostructures using scanning tunneling microscopy and spectroscopy. Because hBN has the same bond structure as graphene with a slightly longer lattice constant, a rotationally dependent Moiré pattern is formed in graphene on hBN heterostructures. The Moiré pattern creates a weak periodic potential for the charge carriers in graphene. We performed an experimental and theoretical investigation of its effect on the local density of states. We observed a Moiré wavelength dependent modification of the local density of states in good agreement with theory predictions.

8:36AM Y12.00004 Local spontaneous time-reversal symmetry breaking and interacting Dirac fermions in strained CVD-grown graphene on copper

, R.T.-P. WU, M.L. TEAGUE, H. CHU, D.A. BOYD, N.-C. YEH, Dept. of Physics, Caltech, Pasadena, CA 91125, M.W. BOCKRATH, Dept. of Physics and Astronomy, Univ. of California, Riverside, CA 92521 — Atomically resolved imaging and spectroscopy of CVD-grown graphene on Cu are studied using scanning tunneling microscopy and spectroscopy. Under strain-induced giant pseudo-magnetic fields (B_S), quantized Landau levels are manifested by peaks of density of states (DOS) at quantized energies. While global time-reversal symmetry is preserved, local spontaneous time-reversal symmetry breaking (TRSB) for the two inequivalent lattice sites due to opposite B_S directions is evidenced by the presence or absence of the zero-mode tunneling conductance peak, confirming theoretical predictions for gauge fields in graphene causing local TRSB while preserving the chiral symmetry. Additionally, the finding of both integer and fractional quantum Hall states due to strain-induced B_S may be attributed to significant short-range Coulomb interactions of Dirac fermions in graphene mediated by the underlying Cu substrate, which yields an onsite Coulomb interaction $U \sim 3.2$ eV larger than the nearest-neighbor hopping energy $t \sim 2.8$ eV. Finally, effects on the DOS of graphene due to pseudo-magnetic fields are compared with those due to applied fields. This work was supported by NSF.

8:48AM Y12.00005 Real-Space Magnitude and Spatial Extent of the Surface Charge Density of Graphene¹

, P. XU, Y. YANG, S.D. BARBER, M.L. ACKERMAN, J.K. SCHOELZ, SALVADOR BARRAZA-LOPEZ, I. BELLAICHE, P.M. THIBADO, Department of Physics, University of Arkansas, IGOR A. KORNEV, Propriétés et Modélisation des Solides, France — The discovery of graphene, a unique two-dimensional electron system with extraordinary physical properties, has ignited tremendous research activity in both science and technology. One such extraordinary property is its enormous current-carrying capacity of $1\mu\text{A}$ per atomic row. Fundamentally, this suggests that graphene possesses an unusually large electronic density of states (DOS). Surprisingly, a detailed atomic-scale investigation of the DOS has yet to be completed. Here we present, for the first time, variable-current scanning tunneling microscopy (STM) images, which reveal an unusual three-dimensional picture of graphene's orbitals. Furthermore, density functional theory was used to simulate the variable-current STM images. From this we found that the orbitals expand to fill the holes in the honeycomb structure, making atomic-resolution STM more difficult at lower currents. Also, we discovered that the wavefunctions expand into the vacuum an unusually large amount. Identical studies were performed on graphite, revealing that the DOS of graphene is 300% larger. Other significant differences found between graphite and graphene will be discussed.

¹Support provided by ONR N00014-10-1-0181, N00014-08-1-0915, NSF 0855358, 0701558, DoE 46612.

9:00AM Y12.00006 Direct Imaging of Intrinsic Molecular Orbitals Using Graphene-based Moiré Pattern¹

, HAITAO ZHOU, GENG LI, JINHAI MAO, YELIANG WANG, SHIXUAN DU, HONGJUN GAO, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES, BEIJING 100190, CHINA TEAM — Direct imaging of the intrinsic electronic structure at high resolution is of both fundamental and technological importance for investigating molecular interaction and mechanisms. Metallic or semiconducting materials are commonly used as substrates for molecular adsorption. Generally, the strong interactions between molecules and these substrates significantly change the intrinsic electronic and geometric structures of the adsorbed molecules. In order to overcome this problem, much effort has been made by passivating substrates with various buffer layers, for instance, thin organic films, NaCl, and oxides. We demonstrate the graphene grown epitaxially on Ru(0001) can be used as a buffer layer to study the intrinsic electronic properties of adsorbed molecules. The intrinsic molecular orbitals of C60, pentacene and perylene-3,4,9,10-tetracarboxylic dianhydride molecules were imaged by scanning tunneling microscope (STM). High resolution STM images of the molecules reveal that the graphene layer decouples the individual molecules electronically from the metallic substrate, which is also verified by density functional theory calculations.

¹This work was financially supported by the NSFC (10834011, 60976089) and MOST (2009CB929103, 2010CB923004) of China.

9:12AM Y12.00007 Tip Induced doping effects in the local tunnel spectra of graphene, ANJAN K. GUPTA, SHYAM K. CHOUDHARY, Physics Department, IIT Kanpur — We report on tip induced carrier density changes in local tunnel spectra of single layer graphene (SLG) with backgate using room-temperature scanning tunneling microscopy (STM) and spectroscopy. The SLG samples, prepared by exfoliation method and verified by Raman spectra, show atomically resolved honeycomb lattice. Local tunnel spectra show two minima with the two moving in opposite directions along the bias axis. One minimum shows nearly a square-root dependence, and the other shows a linear dependence on the gate voltage. We understand these features as arising from the STM tip induced and bias voltage dependent change in carrier density in SLG. Other than the tip induced doping we also see the effect of charge inhomogeneity on the local tunnel spectra of SLG. The charge inhomogeneity is also seen in bilayer graphene but no new features due to tip induced doping are observed in the local spectra.

9:24AM Y12.00008 Electronic Structures of Graphene on Ru(0001): Scanning Tunneling Spectroscopy Study, WON-JUN JANG, JEUNG-HUM JEON, JONG KEON YOON, SE-JONG KAHNG¹, Department of Physics, Korea University — Graphene has inspired remarkable advances in nanotechnology due to its unusual electronic band structures represented by massless Dirac cones. Graphene can be epitaxially grown on metal surfaces by chemical vapor deposition method. Due to the lattice mismatch, epitaxial graphene grown on Ru(0001) shows hexagonal Moiré patterns with subatomic height variations. We studied local electronic structures of the epitaxial graphene using low-temperature scanning tunneling microscopy (STM) and spectroscopy (STS). Different spectra were observed at top, bridge, and hollow regions of the Moiré patterns. Observed STS data will be explained with structural models.

9:36AM Y12.00009 Fourier transform-STM: signatures of impurity scattering in graphene ribbons, ANDERS BERGVALL, TOMAS LOFWANDER, Department of Microtechnology and Nanoscience - MC2, Chalmers University of Technology, SE-41296 Goteborg, Sweden — We report results of a theoretical investigation of the effects of impurity scattering on the Fourier transformed local density of states (FT-LDOS) in graphene ribbons. We derive analytic expressions, within the Dirac approximation, for the Green's functions for armchair ribbons. Utilizing these, we show that the FT-LDOS contains distinct features that can be understood in terms of intra- and intersubband scattering processes. The ribbon band structure can then be reconstructed from the FT-LDOS. This makes the FT-LDOS a valuable spectroscopic tool. These predictions can be directly confirmed by Fourier transform scanning tunneling microscopy.

9:48AM Y12.00010 Tunable gap graphene micro-ribbons for terahertz plasmonics, DANHONG HUANG, Air Force Research Laboratory, Space Vehicles Directorate, Kirtland Air Force Base, NM 87117 USA, GODFREY GUMBS, OLEKSIY ROSLYAK, Department of Physics and Astronomy, Hunter College of the City University of New York, 695 Park Avenue, New York, NY 10065 USA — Maxwell's equations are solved for an array of graphene micro-ribbons located at the interface between a vacuum half-space and a half-space of a dielectric substrate. Our calculations include mode-mixing in the optical-response function. A closed-form analytic expression is obtained for the nonlocal optical-response function of a graphene layer with an induced energy gap which is then employed in our calculations beyond the long-wavelength approximation. Both the reflectivity and transmissivity spectral functions are calculated. Specifically, we obtain their dependences on the period of the array, the ribbon width, chemical potential of doped graphene, energy gap between the valence and conduction bands, substrate refractive index, and incident angle of a plane-wave electromagnetic field. Additionally, a qualitative comparison is made between our calculated results in this paper and the recent experimental data given by Ju, *et al.*, [Nature Nanotechnology, 6, 630 (2011)].

10:00AM Y12.00011 Electron-phonon coupling effects in the (8-5-5) line defect of graphene nanoribbon, HENG LUO, YONGWOO SHIN, XI LIN, Boston University — A “metallic” line defect in graphene nanoribbon consisting of alternating units of octagon and a pair of pentagons (8-5-5) is modeled using the adapted Su-Schrieffer-Heeger model Hamiltonian to include explicit electron-phonon coupling effects. Our results indicate that the 8-5-5 line defect has a finite optical gap of 0.4 eV with a broken charge conjugation symmetry, the bottom conduction band state mimic the nanoribbon edge case and the top valence state identical to the polyacetylene case. Upon photoexcitation, a small self-localized polaron state is found along one zigzag side of the line defect and a soliton-antisoliton pair is found on the other side. When the line defect is sandwiched between two graphene nanoribbons, the finite optical gap and photo-induced self-localized states persist as long as the nanoribbon width is smaller than 2 nm.

10:12AM Y12.00012 One Dimensional Massless Dirac Fermions in Functionalized Graphene Nanoribbons¹, R. TUĞRUL SENER, OZAN ARI, Department of Physics, İzmir Institute of Technology, İzmir, Turkey — Low-energy excitations of graphene are massless Dirac fermions due to presence of linear bands crossing at the Fermi level. Zigzag-edged nanoribbons of graphene (ZGNR), however, being semiconducting, do not possess this property. Using ab initio density-functional theory calculations we find that it is possible to close the band gap of ZGNRs through edge-functionalization with Na atoms. Moreover, the resulting band structure displays tilted-v-shaped linear bands crossing at the Fermi level, corresponding to one-dimensional massless Dirac fermions. We discuss mechanism of formation of such a band structure and its consequences in terms of electronic and transport properties.

10:24AM Y12.00013 Band Structure Measurements of Bottom-up Fabricated Graphene Nanoribbons, CHRISTOPHER BRONNER, FELIX LEYSSNER, STEPHAN MEYER, Fachbereich Physik, Freie Universität Berlin, Berlin, Germany, MANUEL UTECHT, TILLMANN KLAMROTH, PETER SAALFRANK, Universität Potsdam, Institut für Chemie, Potsdam, Germany, PETRA TEGEDER, Fachbereich Physik, Freie Universität Berlin, Berlin, Germany — Along with the growing interest in graphene, other low-dimensional carbon nanostructures are currently in the focus of research since these materials offer a wide variety of properties interesting e.g. for nanotechnology application. Among these carbon systems, quasi-one-dimensional graphene nanoribbons (GNR) introduce a possibility to tune the electronic structure - for example, GNRs exhibit a band gap which is inversely proportional to their width and can thus be adjusted over a wide range. While many theoretical studies have been published on the band structure of GNRs, experiments are usually limited by the quality of the GNRs' fabrication, e.g. using lithography or unzipping of carbon nanotubes. In order to avoid defects and irregular edges that are inevitable in these methods, lately a surface-assisted bottom-up synthesis has been demonstrated which yields quasi-perfect GNR structures. [1] In the present study we employ complementary surface-sensitive spectroscopies to investigate occupied and unoccupied bands and the band gap in an armchair GNR which has been synthesized on the Au(111) surface. DFT calculations were performed to obtain a thorough understanding of the nature of the observed states.

10:36AM Y12.00014 Synthesis and characterization of nitrogen-doped graphitic nanoribbons, JOSUE ORTIZ, M. LUISA GARCIA, IPICT, Mexico, XIAOTING JIA, Massachusetts Institute of Technology, U.S.A., RAFAEL MARTINEZ, Universidad Autonoma de Barcelona, Spain, MIGUEL A. PELAGIO, Universidad Federal de Pernambuco, Brazil, DAVID SWANSON, Augustana College, U.S.A., A. LAURA ELIAS, HUMBERTO GUTIERREZ, The Pennsylvania State University, U.S.A., FERNANDO RODRIGUEZ, EMILIO MUNOZ, IPICT, Mexico, MILDRED DRESSELHAUS, Massachusetts Institute of Technology, U.S.A., HUMBERTO TERRONES, MAURICIO TERRONES, The Pennsylvania State University, U.S.A. — Nitrogen doping of carbon nanostructures such as nanotubes and graphene is a practical approach for tailoring their electronic and chemical properties. However, the doping of graphene nanoribbons still remains to be a challenge. Here we discuss a novel synthetic route to N-doped graphitic nanoribbons using chemical vapor deposition. The morphology of the new nanomaterial resembles the observed for the undoped graphitic nanoribbons, with particular differences specially at the ribbons' edges. We performed scanning and transmission electron microscopy as well as Raman and X-ray photoelectron spectroscopies in order to confirm the nitrogen presence within the nanoribbons. In addition, the electrical response for individual nanoribbons was obtained. We observed that N-doped nanoribbons exhibit a clear semiconductor-like behavior depending on the amount of nitrogen embedded in the hexagonal carbon network (undoped nanoribbons always showed a metallic response). These doped nanostructures could find applications in the fabrication of electronic devices.

10:48AM Y12.00015 Graphyne- and Graphdiyne-based Nanoribbons: Density Functional Theory Calculations of Electronic Structures¹, LIDA PAN, LIZHI ZHANG, BOQUN SONG, SHIXUAN DU, HONGJUN GAO, Institute of Physics, Chinese Academy of Sciences, Beijing — Graphdiyne, a carbon allotrope, which has the same symmetry as graphene and has butadiyne linkages between its nearest-neighbor hexagonal rings, has recently synthesized and fabricated on copper, showing experimentally the semiconductor property with conductivity of $2.516 \times 10^{-4} \text{ S m}^{-1}$, which is comparable to silicon. We investigate the configurations and electronic properties of graphyne and graphdiyne nanoribbons with armchair and zigzag edges by using first principles calculations. Our results show that all the nanoribbons are semiconductors with suitable band gaps similar to silicon. And their band gaps decrease as widths of nanoribbons increase. We also find that the band gap is at the Γ point for all graphdiyne ribbons and it is at the X point for all graphyne ribbons. Of particular interest, the band gap of zigzag graphyne nanoribbons show a unique "step effect" as the width increases. This property is good for tuning of the energy band gap, as in a certain range of the ribbon width, the energy gap remains constant and in reality the edge cannot be as neat as that in a theoretic model. Graphyne and graphdiyne with tunable gaps are promising candidates for future carbon-based electronic devices.

Session Y13 DMP GMAG: Focus Session: Low-Dimensional and Molecular Magnetism - Nano-
magnetism on Surfaces - Magnetic Adatoms and Clusters 211

8:00AM Y13.00001 Magnetism of single-vacancy defects in graphene and boron-nitride nanoflakes¹, SILVIA FERNANDEZ-SABIDO, CARLOS RAMOS, EDUARDO CIFUENTES-QUINTAL, ROMEO DE COSS, Department of Applied Physics, Cinvestav-Merida, Mexico — In this work we have used the hexagonal zigzag graphene and boron-nitride nanoflakes as a simple systems for studying the new class of magnetic materials obtained by structural vacancies in nonmagnetic s-p nanostructures. We have shown that for these systems, it is possible to predict the total spin moment from an electron counting analysis. Employing DFT calculations based on the LCAO approximation and the Fixed Spin Moment method, we have determinate the ground state spin multiplicity and the spin magnetic distribution for these structures. We have found that the ground state multiplicity of graphene nanoflakes is triplet, corresponding to a spin magnetic moment of $M = 2\mu_B$. Analyzing the spin orbital distribution we have determinate that the spin-polarized for the graphene nanoflakes is equally distributed in the sp^2 and p_z orbitals. For the boron-nitride nanoflakes we have obtained a quartet state ($M = 3\mu_B$) in the case of a boron vacancy, and a doublet state ($M = 1\mu_B$) for a nitrogen vacancy. We have found that for the boron-vacancy the spin-polarized is mainly localized on the sp^2 orbitals of nitrogen atoms. In contrast, for the nitrogen-vacancy the spin-polarized is concentrated at the p_z orbitals of boron atoms.

8:12AM Y13.00002 Dynamical magnetic excitations in adatoms and dimers on metallic surfaces¹, SAMIR LOUNIS, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, ANTONIO T. COSTA, ROBERTO B. MUNIZ, Instituto de Física, Universidade Federal Fluminense, 24210-340 Niterói, RJ, Brazil, DOUG L. MILLS, Department of Physics and Astronomy, University of California Irvine, Irvine, California, 92697 USA — There is hardly any method which has shaped nanoscience and nanotechnology more profoundly than the scanning tunneling microscope. Such a tool is used nowadays to probe spin-excitations in nano-objects[1,2,3,4]. A key quantity describing these excitations is the transverse dynamical magnetic susceptibility that we calculate using the Korringa-Kohn-Rostoker Green function method within the framework of time-dependent density functional theory[5]. The behavior of adatoms and dimers will be discussed and comparison to experimental works will be provided when available.

8:24AM Y13.00003 Real Space Observation of Inelastic Kondo Effect and Interorbital Spin-Coupling in Molecule-Metal Contacts, AITOR MUGARZA, CORNELIUS KRULL, Catalan Institute of Nanotechnology, ROBERTO ROBLES, NICOLAS LORENTE, RICHARD KORYTAR, Centre d'Investigacions en Nanociència i Nanotecnologia, CIN2 (ICN-CSIC), SEBASTIAN STEPANOW, GUSTAVO CEBALLOS, PIETRO GAMBARDILLA, Catalan Institute of Nanotechnology — We present a comparative scanning tunneling spectroscopy study of four different types of MPc complexes ($M = \text{Fe, Co, Ni, Cu}$) adsorbed on the Ag(100) surface. Their magnetic properties are studied via the Kondo interaction with the substrate. Whereas the spectra of FePc and CoPc near the Fermi level is featureless, CuPc and NiPc show a Kondo resonance arising from the interaction of a ligand spin with conduction electrons. The spin at the organic macrocycle is induced by charge transfer from the Ag substrate. In CuPc, the coexistence of ion and ligand spin gives rise to interorbital coupling and spin excitations. The latter are observed via inelastic tunneling, where the Kondo interaction appears coupled to spin and vibrational excitations. By using the tip as a mobile electron we find that each type of excitation occupy mutually exclusive regions within the molecule, and result in different spin relaxation dynamics, reflecting the need of an atomic control of the molecule-metal interface to obtain reproducible transport properties. Finally, we study the influence of intermolecular interactions on the electronic and magnetic properties by creating artificial clusters in a controlled manner by manipulation of individual molecules.

8:36AM Y13.00004 Emerging magnetic stability in atomically assembled spin arrays, SEBASTIAN LOTH, Max Planck Research Group - Dynamics of Nanoelectronic Systems, Hamburg, Germany, SUSANNE BAUMANN, CHRISTOPHER P. LUTZ, D.M. EIGLER, ANDREAS J. HEINRICH, IBM Research - Almaden, San Jose, CA, USA — Magnetic stability is usually created by the interaction of a large ensemble of atomically small magnetic moments that are themselves unstable. We make use of the Scanning Tunneling Microscope's ability to move individual atoms and construct arrays of interacting spins. Owing to their smallness, the magnetic states of these spin arrays are quantized and we probe their energies by inelastic electron tunneling spectroscopy [1]. To gain access to the equally important dynamical properties we employ an all-electronic pump-probe measurement scheme with which we follow the evolution between the spin states at nanosecond speed [2]. The combination of energetic and dynamical information allows identification of the relevant spin interaction and spin relaxation mechanisms at the atomic level. We design arrangements of atoms that suppress quantum tunneling of magnetization and drastically stabilize different spin configurations. Tracing the emergence of magnetic stability in the progression from individual atoms to arrays of spins points to new avenues for spintronic applications at atomic dimensions.

8:48AM Y13.00005 Magnetocrystalline anisotropy of 3d transition metal atoms on graphene, JUN HU, RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine, CA 92697-4575 — Graphene has attracted most attention in the field of condensed matter physics, chemistry and material science since the first day when it was produced in lab. It's an ideal material for two-dimensional electron gas (2DEG). Most intriguingly, the electronic and magnetic properties can be easily engineered by decorating with external elemental atoms ranging from nonmetal to transition metal. Especially, graphene is attractive for spintronics due to its long spin life time and high mobility. So far, ultrathin Co films have been deposited on graphene which exhibit perpendicular magnetic anisotropy. In this work, first-principles calculations are performed to systematically study the magnetic properties of graphene decorated by 3d transition metal atoms with several covering patterns. We find that Fe/graphene always exhibits in-plane anisotropy regardless the coverage, while Mn/graphene and Co/graphene tend to have perpendicular easy axis for most range of coverage. The spin moments of Ni atoms are largely quenched for Ni/graphene. Moreover, the Mn atoms on graphene prefer ferromagnetic exchange coupling which are totally different from the pure counterpart without graphene support. The strong hybridization between 3d orbitals of transition metal atoms and π states of graphene are responsible for the modification of magnetic properties. **Acknowledgement.** This work was supported by DOE Grant DE-FG02-05ER46237.

9:00AM Y13.00006 Exploring Kondo Phenomena in Physisorbed Nitric Oxide, RYAN REQUIST, SISSA, Trieste, Italy, ALEXANDER SMOGUNOV, CEA Saclay, France, PIERPAOLO BARUSELLI, MICHELE FABRIZIO, ERIO TOSATTI, SISSA, Trieste, Italy — The NO molecule is a $S=1/2$ system that can be physisorbed on gold surfaces. As there are presently no data indicating whether or not physisorbed NO retains its spin and displays an observable Kondo effect, we investigate that question by means of our ab-initio based DFT+NRG approach [1]. DFT calculations for NO/Au(111) confirm that at low coverage the on-top adsorption site is the most stable, with the NO molecule forming an angle of approximately 60 degrees with the surface normal. Spin-polarized DFT calculations reveal that the molecule retains one unpaired electron in an antibonding π orbital that hybridizes, albeit moderately, with the surface. Based on these ingredients, we discuss the possibility of observing a zero-bias Kondo anomaly in scanning tunneling spectroscopy above NO/Au(111). The influence of gold surface states and vibronic motion of the molecule are also investigated. [1] P. Lucignano et al., Nature Mat. 8, 563 (2009).

9:12AM Y13.00007 Magnetic Interaction between Surface Engineered Rare-earth Atomic Spins, BARBARA JONES, IBM Almaden Research Center, San Jose, CA, CHIUNG-YUAN LIN, National Chaio Tung University, Taiwan — We report an ab initio study of rare-earth adatoms (Gd) on a surface, where it has been demonstrated previously that the STM can build and manipulate spin-coupled transition-metal atoms on such a surface one atom at a time, and have their spin excitation measured to be antiferromagnetic. The present work is the first attempt of studying rare-earth spin-coupled adatoms, the geometry effect of spin coupling, and the underlying mechanism of ferromagnetic coupling. The exchange coupling between Gd atoms on the surface is calculated to be antiferromagnetic in one geometry and ferromagnetic in another, by considering their collinear spins and using the PBE+U exchange correlation. We also find the Gd dimer in these two geometries is similar to nearest-neighbor and next-nearest-neighbor Gd atom pairs in GdN bulk. We analyze how much direct exchange, superexchange, and RKKY interactions contribute to the exchange coupling for the ferromagnetic arrangement by additional first-principles calculations of alternative model systems. Our calculations also show that the Gd spin of these structures is $7/2$, the same as that of a GdN bulk.

9:24AM Y13.00008 Atom-by-atom engineering and atomic magnetometry of tailored nano-magnets with SP-STM¹, ALEXANDER A. KHAJETOORIANS, JENS WIEBE, BRUNO CHILIAN, Institute of Applied Physics, Hamburg University, Hamburg, Germany, SAMIR LOUNIS, STEFAN BLÜGEL, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, D-52425 Jülich, Germany, ROLAND WIESENDANGER, Institute of Applied Physics, Hamburg University, Hamburg, Germany — Nanomagnets, namely arrays of a few exchange coupled atomic magnetic moments, possess a rich variety of magnetic properties and are explored as constituents of nano-spintronics technologies. They have been realized as magnetic clusters or molecular nanomagnets. Individual nanomagnets, built from magnetic atoms adsorbed onto a non-magnetic surface (adatoms) coupled by Ruderman-Kittel-Kasuya-Yosida (RKKY) exchange, exhibit a high level of versatility resulting from distance-dependent interactions. Here, we combine spin-resolved scanning tunneling microscopy (SP-STs), atom manipulation and simulations to tailor nanomagnets ranging from linear chains to complex two-dimensional arrays and perform magnetometry in an atom-by-atom fashion. Distinct ground states of each chain, depending on even or odd numbers of constituent atoms, and magnetic frustration within the arrays have been observed directly. Our work demonstrates real space access to the magnetic states of tailored nanostructures providing an approach to tackling open fundamental questions in magnetism.

9:36AM Y13.00009 First-principles study of magnetic exchange interactions in scanning probe microscopy, STEFAN HEINZE, CESAR LAZO, PAOLO FERRIANI, Institute of Theoretical Physics and Astrophysics, University of Kiel, Germany — In the last years, spin-polarized scanning tunneling microscopy (SP-STM) has been established as a technique to resolve complex magnetic structures down to the atomic scale. More recently, it has even become possible to detect the exchange interactions between tip and sample by magnetic exchange force microscopy (MExFM). However, the interpretation of such measurements is non-trivial, especially on the atomic scale. Here, we use density functional theory in order to study the effect of exchange interactions in SP-STM and MExFM measurements. First, we demonstrate the occurrence of a spin-valve effect for single Co and Cr atoms on Fe islands on W(110) contacted by an SP-STM tip as a result of the spin-dependent orbital symmetry of the states in the vicinity of the Fermi energy [1]. We find that the exchange interaction between tip and adsorbed atoms affects the magnetoresistance in the tunneling regime. Second, we explain the quantitative measurement of the exchange interaction across a vacuum gap using MExFM applied to an Fe monolayer on W(001) [2]. We show how the chemical tip composition influences the magnitude and distance dependence of the exchange forces.

9:48AM Y13.00010 Evidence of Kondo effect in organic radical nanoassemblies, MOHAMMAD RASHIDI, STEFAN MULLEGER, MICHAEL FATTINGER, REINHOLD KOCH, Solid state physics division, Johannes Kepler University, Linz, Austria — The outstanding spatial resolution of low temperature (LT) scanning tunneling microscopy (STM) and spectroscopy (STS) enables to probe the frontier orbital electronic structure of single magnetic molecules and clusters adsorbed on substrates. Here, we study self-aligned nanostructures of (spin-1/2) hydrocarbon radicals on a metal surface by means of LT-STM and STS. Pronounced involvement of surface state electrons is observed in the frontier molecular orbital (MO) resonances. An empty hybrid state closely above the substrate Fermi level exhibits the characteristic properties of surface Kondo effect reported for similar systems in the literature. By identifying three electronic states as hybrids of molecular orbitals and surface state electrons (two of them directly related to the Kondo effect), we are able to present a modified picture of the surface Kondo effect. It is based on a valence-bond model, where the bonding state represents Kondo's virtual bound state and the antibonding state is the so called 'Kondo resonance' reported in STM studies of the surface Kondo effect. Furthermore, double occupation of the originally singly unoccupied MO by tunneling electrons leads to the third state well above the Fermi level due to Coulomb repulsion as described by the Anderson model.

10:00AM Y13.00011 Spin inelastic electron transport through magnetic nanostructures, AARON HURLEY, NADJIB BAADJI, STEFANO SANVITO, Trinity College Dublin — Recent experimental advances in scanning tunneling microscopy make the measurement of the conductance spectra of isolated and magnetically coupled atoms on nonmagnetic substrates possible. Notably, these spectra are characterized by a competition between the Kondo effect and spin-flip inelastic electron tunneling. In particular they include Kondo resonances and a logarithmic enhancement of the conductance at voltages corresponding to magnetic excitations, two features that cannot be captured by second order perturbation theory in the electron-spin coupling. We have now derived a third order analytic expression for the electron-spin self-energy, which can be readily used in combination with the non-equilibrium Green's function scheme for electron transport at finite bias. We demonstrate that our method is capable of semi-quantitative description of the competition between Kondo resonances and spin-flip inelastic electron tunneling at a computational cost significantly lower than that of other approaches. The examples of Co and Fe on CuN are discussed in detail. We also explain the theoretical origin of the conductance asymmetry that is present for both spin and non-spin polarized STM tips in the experimentally determined spectra of these atoms.

10:12AM Y13.00012 Real-space imaging of inelastic Kondo effect in a single O₂ molecule, YING JIANG, International Center for Quantum Materials, Peking University, Beijing 100871, China, WEI JI, Department of Physics, Renmin University of China, Beijing 100872, China, QING HUAN, ARTHUR YU, SHAOWEI LI, Department of Physics and Astronomy, University of California, Irvine, CA 92697-4575, WILSON HO, Department of Physics and Astronomy and Department of Chemistry, University of California, Irvine, CA 92697-4575 — Inelastic Kondo effect of the single O₂ molecule physisorbed on Ag(110) surface is investigated in real space using a low-temperature scanning tunneling microscope (STM) at 10 K. The O₂ molecule carries an unpaired spin, as supported by density functional theory, showing a Kondo resonance at the Fermi energy. The coupling between the vibrations and the unpaired electron in the O₂ molecule results in the inelastic Kondo effect, which is manifested as striking side peaks at finite biases in the dI/dV spectra, in clear contrast to the normal vibrational inelastic tunneling spectroscopy (IETS). Spectroscopic imaging shows that two vibrational modes are coupled to the Kondo resonance with different strengths, which arises from the symmetry match between the Kondo state and the vibrational modes.

10:24AM Y13.00013 Scanning Tunneling Microscopy and Spectroscopy of Fe[H₂B(Pz)₂]₂(bipy) Spin-Crossover Complex on Au(111)¹, ALEX PRONSCHINSKE, GEOFF LEWIS, YIFENG CHEN, North Carolina State University, ROBERT BRUCE, WEI YOU, University of North Carolina, MARCO BUONGIORNO-NARDELLI, DAVID SHULTZ, DANIEL DOUGHERTY, North Carolina State University — Spin crossover compounds have externally-tunable magnetic moments that will be useful for spintronic applications if they result in correspondingly tunable electronic properties. In order to assess this electronic tunability, we have performed variable temperature scanning tunneling microscopy and spectroscopy on a known Fe(II) spin crossover compound, Fe[H₂B(Pz)₂]₂(bipy), thermally-evaporated onto a single crystal Au(111) surface. We report on the surface assembly of this molecule in few layer films including imaging with submolecular resolution. In addition, we use STS to probe the local density of electronic states across a temperature range spanning the low spin to high spin transition and compare with first principles electronic structure calculations.

10:36AM Y13.00014 Frustration in the Magnetic Molecules W₇₂V₃₀ and Pr₁₃ Probed by NMR and Tunnel-diode Resonator, STEVEN YENINAS, M. LUBAN, R. PROZOROV, Y. FURUKAWA, The Ames Laboratory, C. SCHRÖDER, University of Applied Sciences, Bielefeld, Germany, J. SCHNACK, University of Bielefeld, Germany — The magnetic molecules Pr₁₃ and W₇₂V₃₀ have been studied by DC and AC magnetic susceptibilities and NMR. These molecules exhibit geometrical frustration resulting from antiferromagnetic intramolecular coupling of nearest neighbor paramagnetic ions. In Pr₁₃, 12 Pr^{III} ions (S=1) interact along edge sites of an icosahedron centered about an additional Pr^{III} ion. For W₇₂V₃₀, 30 V^{IV} ions (S=1/2) interact along corner sharing sites of a near perfect icosidodecahedron, a spherical representation of a 2-D Kagome Lattice. Characterizing the DC magnetic response requires a distribution of exchange constants for both molecules at low temperatures. Results are compared to similar frustrated systems which feature a variety of magnetic phenomena - metamagnetic phase transitions, magnetic hysteresis without anisotropy, spin glass behavior, and superparamagnetism.

10:48AM Y13.00015 Unification of ultrafast, laser-driven and slow, phonon-driven spin-flip scenarios in the three-magnetic-center cluster Ni₃Na₂, HONGPING XIANG, GEORGIOS LEFKIDIS, WOLFGANG HÜBNER, Dept. of Physics and Research Center OPTIMAS, University of Kaiserslautern — Recently the use of the three-magnetic-center Ni₃Na₂ on a fictitious, inert surface as a prototypical system for ultrafast, laser-driven spin manipulation and logic functionalization was reported [1]. Here we extend this investigation of spin dynamics on the same system by including vibronic motion and recalculating all electronic states for each structural distortion. The first immediate finding is that the system exhibits an unexpectedly rich set of magnetic phases (geometry sets with different orientations of the highly localized spin-density). Exploiting those phases allows us (a) to establish the combination of spin dynamics and phonons as an unprecedentedly accurate sensor of the bond length between metallic centers, and (b) to present for the first time a unified picture of ultrafast (fs), laser-driven and slow (ps), phonon-driven spin dynamics in molecular magnets.

Friday, March 2, 2012 8:00AM - 11:00AM —

Session Y14 DMP GMAG: Focus Session: Spins in Carbon - Organic Spintronics 212

8:00AM Y14.00001 A new twist on organic spintronics: Controlling transport in organic sandwich devices using fringe fields from ferromagnetic films¹, MARKUS WOHLGENANNT, University of Iowa, Department of Physics and Astronomy — Organic spintronics studies the physics of spin-injection and magnetic-field dependent transport phenomena in organic semiconductors, possibly leading to devices with added functionality. So far, studies have focused on spin-valve architectures as well as entirely non-magnetic devices that nevertheless show large room-temperature magnetoresistance through the so-called organic magnetoresistive effect. We demonstrate a new method of controlling the electrical conductivity of an organic film at room temperature, using the spatially-varying magnetic fringe fields of a magnetically-unsaturated ferromagnet. A large variation from hopping site to hopping site of the nuclear hyperfine field is known to dramatically affect electronic transport in organics, whose resistances are very sensitive to small applied magnetic fields, so the ferromagnet's fringe fields might act as a substitute either for the applied magnetic field or for the inhomogeneous hyperfine field. The size of the effect, magnetic field dependence, and hysteretic properties rule out a model where the fringe fields from the ferromagnet provide a local magnetic field that changes the electronic transport properties through the hyperfine field, and show our effects originate from electrical transport through the inhomogeneous fringe fields coming from the ferromagnet. Surprisingly these inhomogeneous fringe fields vary over length scales roughly two orders of magnitude larger than the hopping length in the organic materials, challenging the fundamental models of magnetoresistance in organic layers which require the correlation length of the inhomogeneous field to correspond roughly to the hopping length. Our devices, which do not rely on spin injection, tunneling anisotropic magnetoresistance or spin-valve behavior, may provide a simple approach to integrating magnetic metals and organics for hybrid spintronic devices. These devices may find application as high-voltage readouts of the magnetic state of low-impedance ferromagnetic films.

8:36AM Y14.00002 Magnetic Field Effects: Triplet-Charge Annihilation versus Triplet-Triplet Annihilation in Organic Semiconductors, BIN HU, MING SHAO, LIANG YAN, MINGXING LI, University of Tennessee — Triplet-charge reaction and triplet-triplet annihilation are two important processes in generating magnetic field effects in organic semiconductors. This presentation reports experimental studies on triplet-charge annihilation (TCA) versus triplet-triplet annihilation (TTA) in organic semiconductors. Specifically, we separately adjust the triplet-charge and triplet-triplet interactions towards the generation of TCA and TTA by changing triplet density, charge confinement, and charge/exciton ratio based on organic light-emitting diodes. We then use magnetic field effects of electroluminescence (MFE_{EL}) to study the TCA and TTA through spin interactions. We observe that the electroluminescence can clearly show negative response to applied magnetic field when triplets and charges are simultaneously confined within close proximity. On contrast, the electroluminescence only exhibits positive MFE_{EL} when triplets are confined within close proximity. Therefore, it can be concluded that the TCA is a major process to annihilate triplets through Coulomb interaction in organic semiconductors.

8:48AM Y14.00003 Electron Spin Relaxation: The Role of Spin-Orbit Coupling in Organic Semiconductors, M. WILLIS, L. NUCCIO, Queen Mary University of London, L. SCHULZ, University of Texas at Austin, USA, W. GILLIN, T. KREOUZIS, Queen Mary University of London, F. PRATT, J. LORD, ISIS Muon Facility, UK, M. HEENEY, Imperial London, UK, S. FRATINI, Institut Neel Grenoble, FR., C. BERNHARD, University of Fribourg, CH, A. DREW, Queen Mary University of London — Rapid development of organic materials has lead to their availability in commercial products. Until now, the spin degree of freedom has not generally been used in organic materials. As well as engineering difficulties, there are fundamental questions with respect to the electron spin relaxation (eSR) mechanisms in organic molecules. Muons used as a microscopic spin probe, localized to a single molecule, can access information needed to identify the relevant model for eSR. In this presentation I will introduce the ALC-MuSR technique describing how eSR can be extracted and the expected effects. I will show how the technique has been applied to small organic molecules such as the group III Quinolate series and functionalized molecules with a pentacene-like backbone. Lastly I will present the Z-number and temperature dependence in these organic molecules and show strong evidence for a spin-orbit based eSR mechanism.

9:00AM Y14.00004 Using quantum spin-phase to elucidate weakly coupled pair hopping rates in organic semiconductors, WILLIAM BAKER, University of Utah, DANE MCCAMEY, TOM KEEVERS, University of Sydney, JOHN LUPTON, University of Regensburg, CHRISTOPH BOEHME, University of Utah, UTAH SPIN ELECTRONICS GROUP COLLABORATION, LUPTON GROUP COLLABORATION, SYNDEY QUANTUM PHYSICS GROUP COLLABORATION — We have carried out electrically detected spin echo experiments on recombining electron-hole pairs (polaron pairs)¹ in MEH-PPV organic light emitting diodes at different temperatures and device currents. We find long spin-phase relaxation times [$T_2 = 324(18)$ ns] at room temperature and less than twice this value [$T_2 = 611(39)$ ns] at $T = 10$ K. Next to this very weak temperature dependency, we also observe nearly no dependency of T_2 on the free carrier density in the material. We attribute this coherence decay behavior to charge carrier hopping transitions between localization sites which are exposed to differing hyperfine fields. Although the nuclear spin relaxation times in our material are much longer than the time scale of our experiments, the stochastic movement through this random environment leads to a time dependent fluctuating field causing an irreversible phase loss. We have simulated the echo experiments with this hopping process incorporated, and find good agreement with experimental data. The results of our study contrast free polaron transport processes which show an Arrhenius-type activation in time-of-flight experiments.

9:12AM Y14.00005 Spin-flip induced magnetoresistance in positionally disordered organic solids¹, NICHOLAS HARMON, MICHAEL FLATTÉ, University of Iowa — A theory for magnetoresistance in positionally disordered organic materials is presented and solved using percolation theory. The model describes the effects of spin dynamics on hopping transport by considering changes in the effective density of hopping sites, a key quantity determining the properties of percolative transport. Faster spin-flip transitions open up 'spin-blocked' pathways to become viable conduction channels and hence produce magnetoresistance. Features of this percolative magnetoresistance can be found analytically in several regimes, and agree with previous measurements, including the sensitive dependence of the magnetic-field-dependence of the magnetoresistance on the ratio of the carrier hopping time to the hyperfine-induced carrier spin precession time. Studies of magnetoresistance in known systems with controllable positional disorder would provide an additional stringent test of this theory.

¹This research was made possible by an ARO-MURI

9:24AM Y14.00006 Magnetoresistance in organic spin-valve devices with low work-function metal, H.-JAE JANG, Semiconductor and Dimensional Metrology Div., NIST & Dept of Physics, WFU, KURT P. PERNSTICH, DAVID J. GUNDLACH, Semiconductor and Dimensional Metrology Div., NIST, OANA D. JURCHESCU, Dept. of Physics, Wake Forest Univ., CURT A. RICHTER, Semiconductor and Dimensional Metrology Div., NIST — Organic thin-films have recently generated interest for studies related to spin-based phenomena. Long spin transport through organic semiconductors has been predicted due to their weak spin-orbit and small hyperfine interactions. This property gives them great potential for spintronic applications. While magnetoresistance (MR) has been reported by multiple research groups, controversy still remains over whether the basic mechanism is the transport of spin-polarized carriers through the organic semiconducting thin films or transport via unintended tunneling paths through the devices. We investigate the MR of organic thin-film spin valve devices fabricated from tris[8-hydroxyquinoline]aluminum (Alq3), high Tc transition ferromagnetic metals, and low work-function metals. The devices are fabricated without the exposure to the air to minimize the oxidation. We observe the MR as large as 3 % at 4.5K in devices containing Alq3 as thick as 150 nm.

9:36AM Y14.00007 Origin of magnetoresistance in organic spin-injection structures, ZHI-GANG YU, SRI International — Spin injection into organic materials is usually inferred from the device resistance difference between antiparallel and parallel magnetic configurations (magnetoresistance, or MR) in an organic spin valve (OSV). The common features of the observed MR in OSVs include: 1) the MR is pronounced only at a low bias, where the device I-V characteristic is essentially linear; 2) the MR quickly decreases with bias and temperature while the decrease in device resistance is insignificant; 3) the MR is usually negative for OSVs with thick organic films, particularly when the two ferromagnets are similar in electronic structure. Despite superficial resemblance between OSVs and inorganic spin-injection structures, the MR in the former cannot be explained by theories developed for the latter. Here we show that the resistance of an OSV is controlled by the carrier density deep inside the organic and the MR is due to the difference in the carrier density for the two magnetic configurations. The sign of MR is determined by the electron spin polarization at a finite energy above the Fermi level in the electrodes. This picture explains common features of MR and suggests new strategies for probing and manipulating spin in organic spintronic structures.

9:48AM Y14.00008 Magnetoresistance in an all-organic-based spin valve, BIN LI, CHI-YUEH KAO, JUNG-WOO YOO, YU LU, MENGQI ZHOU, VLADIMIR PRIGODIN, ARTHUR EPSTEIN, The Ohio State University — We demonstrate spin injection and detection in an all-organic-based magnetic tunnel junction using two layers of organic-based magnet V[TCNE]_x (x~2, TCNE: tetracyanoethylene) as the magnetic contacts and organic semiconductor rubrene (C₄₂H₂₈) as the spacer. For the V[TCNE]_x film growth, we exploited two different growth techniques, chemical vapor deposition and molecular layer deposition, which result in different coercivities of V[TCNE]_x films. The spin valve devices show negative magnetoresistance (MR), the sign of which does not change with temperature and bias. To explain the unusual negative MR, we propose a simple phenomenological bias-enhanced selective tunneling (BEST) model based on the different spin polarizations of the molecular energy levels of V[TCNE]_x. Our results show the significance of bias induced energy level shift in organic spintronic devices due to relatively narrow spin polarized bandwidths. This work was supported in part by AFOSR Grant No. FA9550-06-1-0175, DOE Grant Nos DE-FG02-01ER45931, DE-FG02-86ER45271, NSF Grant No. DMR-0805220, the Center for Emergent Materials (an NSF-MRSEC; Award Number DMR-0820414) at The Ohio State University and the Institute for Materials Research at The Ohio State University.

10:00AM Y14.00009 Manganese Phthalocyanines on manganese surfaces: An ab-initio approach to the tunneling magnetoresistance, MARIA SORIANO, JUAN JOSE PALACIOS, Universidad Autonoma de Madrid — We have performed computational studies of spin polarized transport based on Density Functional Theory (DFT) using a non-equilibrium Green's functions formalism implemented in our ANT code [1] to compute tunneling magnetoresistance (TMR) on different manganese based systems. Specifically we present results for STM tips on a clean manganese surface, which is well known to show an antiferromagnetic coupling between layers when grown on an iron surface. In this system we have studied the dependence of the TMR on the tip-surface distance, the position of the tip, and on the bias voltage. Also we present a comparison between the Landauer formalism and the Tersoff-Hamman approach, usually used in this context. Finally we analyse the interaction between Manganese Phthalocyanine (MnPc) molecules on the manganese surface, focusing on the TMR signature and its dependence on the different adsorption sites.

10:12AM Y14.00010 Spin injection in cobalt and copper phthalocyanines¹, DAVID CIUDAD, Massachusetts Institute of Technology, MARCO GOBBI, CIC nanoGUNE Consolider, DARIO A. ARENA, National Synchrotron Light Source, Brookhaven National Lab, JAGADEESH S. MOODERA, Massachusetts Institute of Technology — An organic light emitting diode (OLED) is a heterojunction comprising two different organic semiconductors (OS): one for hole and another one for electron transport. Electrons and holes recombine at the interface between them. Depending on their total spin the recombination may (singlet state) or may not (triplet state) produce visible light. The efficiency of OLEDs could be doubled by injecting a spin-polarized current (Spin-OLED).² One obstacle to attain a spin-OLED is the lack of studies of spin diffusion lengths (λ_s) and injection efficiencies on hole-transport OS. We investigate spin injection in phthalocyanines (Pcs). The Pcs are ideal candidates to reach the above goal because: 1) of their high hole mobility; 2) Cu-Pc in particular is currently used in OLEDs; 3) their high thermal and chemical stability; 4) these molecules contain a single metal atom making them a unique system to study its effect on the spin injection. To determine λ_s we investigate multilayer structures having transition metal/ Cu-Pc or Co-Pc interfaces including magnetic tunnel junctions with OS as barriers. Further characterization of these interfaces has been performed by soft X-Ray measurements at the NSLS-BNL facility.

10:24AM Y14.00011 The role of thin MgO(100) epilayer for polarized charge injection into top-emitting OLED¹, TAE HEE KIM, NYUN JONG LEE, YU JEONG BAE, Department of Physics, Ewha Womans University, Seoul, South Korea, HYUNDUK CHO, CHANGHEE LEE, School of Electrical Engineering and Computer Science, Seoul National University, Seoul, South Korea, EISUKE ITO, Fluoro-Order Functions Research Team, RIKEN Advanced Science Institute, Wako, Saitama 351-0198, Japan — A new top-emitting OLED (TOLED) structure, which is formed on an Si(100) substrate and an epitaxial MgO(100)/Fe(100)/MgO(100) bottom electrode, was investigated. Our TOLED design included a semi-transparent cathode Al, a stack of conventional organic electroluminescent layers (α -NPD/Alq₃/LiF) and a thin Cu-Phthalocyanine (CuPc) film to enhance the hole injection into the luminescent layers. At room temperature (RT), magnetoluminescence of ~5 % was observed in low magnetic field up to 1 Tesla, which is obviously larger than that of the OLEDs with epitaxial and polycrystalline Fe anodes without MgO(100) covering layer. Our results indicate that the magnetic field effect on the electroluminescence could be strongly related to the magnetic properties of bottom electrode, more precisely the interfacial properties between CuPc layer and the anode. Therefore, we focused on understanding interface electronic states and energy alignment by using x-ray photoemission spectroscopy and ultraviolet photoemission spectroscopy. Our results showed that the use of appropriate oxide layers could represent a new interface engineering technique for improving reliability and functionality in organic semiconductor devices.

10:36AM Y14.00012 Spin Polarized Scanning Tunneling Microscopy of Alq₃ on Cr(001)¹, DANIEL DOUGHERTY, ZHENGANG WANG, ALEX PRONSHINSKE, Department of Physics, North Carolina State University — The field of organic spintronics has been strongly motivated in recent years by the observation of giant magnetoresistive effects in tris-(8-hydroxyquinoline) aluminum (Alq₃) films and nanostructures. It is crucial to understand the spin- dependent electronic structure at metal-Alq₃ interfaces. We have carried out spin polarized scanning tunneling microscopy to measure the local density of electronic states for submonolayer films of Alq₃ grown on the layered antiferromagnetic Cr(001) surface. We report an energy-dependent tunneling conductance asymmetry for single molecules adsorbed on differently magnetized (001) terraces and discuss its connection with metal-molecule hybridization and magnetoresistive effects in Alq₃ spintronic devices.

10:48AM Y14.00013 Ferroelectric control of the spin polarization in an organic spin valve, DALI SUN, Oak Ridge National Laboratory / The University of Tennessee, Knoxville, XIAOSHAN XU, Oak Ridge National Laboratory, LU JIANG, Oak Ridge National Laboratory / The University of Tennessee, Knoxville, HO NYUNG LEE, Oak Ridge National Laboratory, HANGWEN GUO, Oak Ridge National Laboratory / The University of Tennessee, Knoxville, PAUL C. SNIJDERS, T. ZAC WARD, Oak Ridge National Laboratory, ZHENG GAI, X.-G ZHANG, Oak Ridge National Laboratory / Center for Nanophase Materials Science, JIAN SHEN, Fudan University/ The University of Tennessee, Knoxville — Recently engineering the spin propagation in organic spin valves has shown increasingly interesting properties. In this work we demonstrate novel ferroelectric control of the spin polarization in an organic spin valve. By inserting a thin ferroelectric buffer layer between a bottom $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$ (LSMO) electrode and the organic Alq_3 layer, a controlled spin polarization through the ferroelectric interface is achieved. The spin valve exhibits both positive and negative magnetoresistance depending on the applied bias. We conclude that this results from the energy level shift by the ferroelectric dipoles between Alq_3 and LSMO (Research sponsored by the Laboratory Directed Research and Development Program of Oak Ridge National Laboratory, managed by UT-Battelle, LLC, for the U. S. Department of Energy).

Friday, March 2, 2012 8:00AM - 11:00AM –

Session Y15 DMP FIAP GMAG: Focus Session: Spins in Metals: Spin Torque Theory, Spin Dependent Transport 213

8:00AM Y15.00001 Newtonian reciprocity between spinmotive forces (SMF) and spin-torque-transfer (STT), STEWART BARNES, Physics Department, University of Miami, Coral Gables, FL — An SMF and the STT effect are reflected in definitions

$$\vec{p} = m\vec{v} + e\vec{A}_s \quad \text{and} \quad H = H_0 + e\Phi_s + eA_{0s},$$

valid beyond the adiabatic approximation, where the momentum $m\vec{v}$ is mechanical, while $\vec{p}$ is that conjugate to the position $\vec{r}$, H is the full Hamiltonian while H_0 is that for uniform magnet. Here $(\vec{A}_s, A_{0s})$ is the four vector which reflects the *linear* momentum of the magnetic system. The spin magnetic and electric fields

$$B_i = -\frac{im^2}{\hbar}\epsilon_{ijk}[v_j, v_k] \quad \text{and} \quad E_i = -\frac{im^2}{\hbar}[v_i, v_0]; \quad i = \{x, y, z\}$$

where $i\partial_t = mv_0 + eA_0$, and involve commutators. The Landau-Lifshitz equations are an *emergent*. They correspond to

$$[S_z, (H_0 + e\Phi_s + eA_{0s})] = 0$$

as required to separate the *slow* magnetic and *fast* electronic degrees of freedom. E.g. $L = (enAz - \dot{q})\frac{\hbar}{e}\phi + g\mu_B BnAx - q\mathcal{E}$ is the Lagrangian for simple domain wall connected to a battery emf $\mathcal{E}$. SMF-STT reciprocity reflects Newtonian third law and *not* an Onsager relationship between transport coefficients. Experiment for spin-valves and MTJs will be reviewed.

8:12AM Y15.00002 Theoretical investigation of the dynamics of a magnetic bilayer in the presence of spin transfer torque, LYDIA NOVOZHIOVA, Western Connecticut State University, SERGEI URAZHIDIN, Emory University — Magnetoelectronic nanodevices, such as magnetic memory cells and spin torque nano-oscillators, generally utilize at least two magnetic layers, the “reference” and the “free” layer. While most previous studies focused only on the behaviors of the “free” layer, the dynamics of the “reference” layer can also be important due to the coupling between the layers. We utilize Landau-Lifshitz-Slonczewski equations in the macrospin approximation to analyze the dynamics of a magnetic bilayer driven by a dc current. We show that even in the absence of magnetic or RKKY interactions, coupling between the layers is efficiently mediated by the spin transfer torque. We use an axially symmetric approximation to derive an analytical stability condition for the bilayer. The stability is determined by the physical characteristics of the bilayer and two control parameters - the dc current and the external time-independent magnetic field. Additionally, we use an averaging technique to find synchronized precessional motions of the two nanomagnets. Finally, we show that for some conditions, the dynamics of the bilayer becomes chaotic. Such chaotic dynamics is prohibited for a single macrospin due to the limitations imposed by the dimensionality of the system.

8:24AM Y15.00003 Interplay between conduction electron spin current and magnon spin current¹, SHULEI ZHANG, SHUFENG ZHANG, Department of Physics, University of Arizona — Spin current is a flow of angular momentum that can be carried by conduction electrons as well as magnons. In conducting ferromagnets, both electron spin currents and magnon currents are present. By using a semiclassical description for conduction electrons and magnons, we evaluate the distribution functions of the non-equilibrium electrons and magnons in the presence of electron-magnon interactions. In some interesting limiting cases, we have derived novel diffusion equations for both electrons and magnons. We then apply our formalisms to study the spin currents for various bilayer and trilayer systems. In particular, we predict how an electron spin current in a metallic layer can be converted into a pure magnon current in a ferromagnetic insulator layer at interface. We also discuss possible experimental realizations for non-equilibrium magnon currents.

8:36AM Y15.00004 A Unified Quantum Theory of Spin Transfer Torque and Electron Transport in Magnetic Nanostructures¹, YONG WANG, Department of Physics, The University of Hong Kong, Hong Kong — Dynamical control of nanoscale magnetization by spin-polarized current has attracted intensive studies due to its vast potential applications in spintronics. The magnetization dynamics driven by spin transfer torque is usually described by the semiclassical theory, where the quantum nature of the magnet is neglected. Here, we present a unified theory which describes the magnetization and the spin-polarized electrons at the full quantum level. The quantum state of the magnetization is given by the coherent state in angular momentum space, and is driven by the continuous scatterings with the electrons in the stochastic nature. Based on this picture, the Monte Carlo simulation is applied to get the mean trajectory and fluctuations of the magnetization, and also the electric current and the current shot noise. We also analyze the different sources which contribute to the magnetization noise and current noise, and show that the quantum noise due to the scattering can be comparable to the thermal noise at low temperature. An analytic theory is also formulated in terms of the density matrix technique. We obtain the master equation of the density matrix of the magnet driven by spin transfer torque, and find that it becomes a Fock-Planck equation in the coherent representation. Solutions from this approach is highly consistent with the results from the Monte Carlo method. We foresee that our theory will play an important role when the quantum nature of the nanomagnet emerges in the spintronics devices. For references, see [1] Yong Wang and L.J. Sham, Quantum Dynamics of a Nanomagnet driven by Spin-Polarized Current, arxiv : 1106.2359. [2] Yong Wang and L.J. Sham, A Quantum Theory of Spin Transfer Torque, to be submitted.

9:12AM Y15.00005 Spin-population inversion in magnetic point contacts under non-equilibrium conditions¹, TORSTEN PIETSCH, STEFAN EGLE, ELKE SCHEER, None — The creation of a novel type of spin-based electronics is one of the most intensively researched topics in current solid-state physics. The unifying characteristics in this advancing field is that the spin degree of freedom of the electron rather than its charge is exploited to achieve a specific device functionality. Recently, theoretical predictions suggest that spin-inversion in metallic point contacts under strong non-equilibrium conditions may enable the design of novel types of radiation sources. These radiation sources are highly tunable and of giant intensity compared to cutting-edge semiconductor devices, due to the much larger electron density in metals. Moreover, the accessible frequency range covers both, microwave (GHz) and THz radiation. Especially the later one is of great interest, since up to date there is no miniaturized, high intensity THz source available. Therefore, the experimental demonstration of this lasing effect in metallic systems is an important breakthrough in solid state physics. Presently the concept of spin-flip lasing in magnetic point contacts rests on theoretical predictions and first proof of principle studies. Herein we present detailed investigations on the magneto-transport properties of magnetic heterostructures and -point contacts. In particular, we study the complex interplay between magnetization, current density and the influence of high frequency (GHz and THz) fields on the magneto-transport properties of magnetic point contacts. The results illustrate that a successful spin-population inversion can be detected via transport spectroscopy.

9:24AM Y15.00006 Two-channel resonant tunneling in the presence of spin-orbit coupling¹, T.V. SHAHBAZIAN, L.S. PETROSYAN, Jackson State University — We study resonant tunneling through a pair of localized states independently coupled to two-dimensional electron gas (2DEG) in the leads. The shape of tunneling conductance is determined by the coherent coupling of localized states via electron continuum in the leads. We show that spin-orbit coupling (Rashba and Dresselhaus) in 2DEG leads to a splitting of the narrow (subtunneling) peak by the amount proportional to spin-orbit coupling constant. The conductance lineshape is highly sensitive to the magnitude and orientation of in-plane magnetic field.

9:36AM Y15.00007 Non-equilibrium coherent potential approximation for electron transport, ALAN KALITSOV, University of Puerto Rico, MAIRBEK CHSHIEV, SPINTEC, JULIAN VELEV, University of Puerto Rico — Treatment of disorder in extended systems presents essential difficulties because the disorder breaks the periodicity of the system. The coherent potential approximation (CPA) solves this problem by replacing the disordered medium with a periodic effective medium [1]. However, calculating the electron current within CPA requires summing scattering diagrams to infinite order, the so called vertex corrections. In this work we reformulate CPA for non-equilibrium electron transport (NE-CPA). This approach, based on the non-equilibrium Green function formalism, provides an efficient and precise way to solve the transport problems in the presence of disorder. We demonstrate that the NE-CPA current is equivalent to the CPA current with vertex corrections to infinite order. [1] B. Velicky, Phys. Rev. 184, 614 (1969).

9:48AM Y15.00008 Semiclassical dynamics of Bloch electrons to second order in electromagnetic fields, YANG GAO, SHENGYUAN YANG, QIAN NIU, University of Texas at Austin — Berry curvature appears in the semi-classical theory of Bloch electrons already to first order in electromagnetic fields, resulting in profound modification of the carrier velocity and phase space density of states. Here we derive the equations of motion for the physical position and crystal momentum to second order in the fields. The dynamics still has a Hamiltonian structure, albeit with noncanonical Poisson brackets between the physical variables. We are able to expand both the carrier energy and the Poisson brackets to second order in the fields with terms of clear physical meaning. To demonstrate the utility of our theory, we obtain with much ease the electromagnetic response and orbital magnetic susceptibility.

10:00AM Y15.00009 Zero bias STS Kondo anomalies of Co impurities on Cu surfaces: do ab initio calculations work?, PIER PAOLO BARUSELLI, SISSA, Via Bonomea 265, Trieste 34136, Italy, ALEXANDER SMOGUNOV, SISSA, Via Bonomea 265, Trieste 34136, Italy, CEA Saclay, MICHELE FABRIZIO, SISSA, Via Bonomea 265, Trieste 34136, Italy, ICTP Trieste, RYAN REQUIST, SISSA, Via Bonomea 265, Trieste 34136, Italy, ERIO TOSATTI, SISSA, Via Bonomea 265, Trieste 34136, Italy, ICTP Trieste — Transition metal atoms such as Co on Cu (111), (100), and (110) surfaces produce STS I-V spectra showing different zero bias Kondo anomalies [1] but these differences have been neither quantitatively predicted nor fully explained theoretically. We apply to this problem the DFT+NRG scheme of Lucignano et al [2], where one solves by NRG an Anderson model built from ab initio phase shifts provided by DFT. For Co/Cu(100) and Co/Cu(110) our calculations describe correctly the experimental trend of Kondo temperatures, and fairly the lineshapes too. By contrast, they fail to describe Co/Cu(111) where in particular the anti-lorentzian lineshape found in experiment remains unexplained. This failure underscores the role of surface states, probably relevant for Co/Cu(111) [3] but not correctly described by our thin slab calculations. Future efforts to quantitatively include Kondo screening by surface states are therefore called for. 1. N. Knorr et al PRL 88, 096804 (2002); M. Ternes et al 2009 J. Phys.: Cond. 10:12AM Y15.00010 ABSTRACT WITHDRAWN —

10:24AM Y15.00011 Linear magnetoresistance as a Berry phase effect, HUA CHEN, University of Tennessee at Knoxville, University of Texas at Austin, DI XIAO, Oak Ridge National Lab, ZHENYU ZHANG, University of Science and Technology of China, Harvard University, University of Texas at Austin, QIAN NIU, University of Texas at Austin — Conventional theory of charge carrier dynamics in metals and semiconductors predicts a quadratic field dependence in the magnetoresistance (MR) in the weak field limit. A linear dependence is usually explained as a quantum effect known as weak localization. However, in systems with time reversal symmetry breaking, a linear dependence can be observed even above room temperature, where quantum coherence is absent. Here we show that linear MR can arise from the Berry curvature modified semiclassical dynamics of the charge carriers, and evaluate its magnitude in several model systems and make preliminary comparisons with experimental results.

10:36AM Y15.00012 Theory of conducting electrons in textured antiferromagnets, RAN CHENG, QIAN NIU, The University of Texas at Austin — The dynamics of conducting electrons in antiferromagnetic texture is shown to exhibit an SU(2) geometric phase in the iso-spin that characterizes a locked spin-sublattice degree of freedom. The iso-spin rotation is purely geometrical and can be expressed in terms of the flux of a novel Berry curvature jointing the real and momentum space, a crucial quantity that has been overlooked in conventional transport theory. We provide an example of one dimensional domain wall, where the iso-spin rotation is topologically quantized. Scattering by skyrmion centers in two dimensions are also discussed, where a Mott like scattering of the iso-spins is predicted.

10:48AM Y15.00013 Exchange field induced large magnetoresistance in the correlated insulator phase of ultrathin Beryllium films¹, TIJIANG LIU, YIMING XIONG, SHANE STADLER, JOSEPH PRESTIGIACOMO, PHILIP ADAMS, Louisiana State University, LOUISIANA STATE UNIVERSITY COLLABORATION — We present a detailed study of low-temperature magnetotransport properties of ultrathin, amorphous Be films in the EuS/Be bilayers. Significant magnetoresistance (MR) of pure insulating Be films can only be observed in fairly high magnetic field ($> \sim 5$ tesla), but by depositing insulating ferromagnetic EuS on top of Be film, one can obtain the same value of MR at low magnetic field (~ 0.2 tesla). We argue that this shift of MR from high field to low field may be caused by the exchange field in the Be component of Be/EuS bilayers.

¹DOE under Grand No. DE-FG02-07ER46420

Friday, March 2, 2012 8:00AM - 11:00AM – Session Y16 DCMP: Strongly Correlated Electrons - Experiment and Theory 251

8:00AM Y16.00001 Electronic Excitations in CuO from a Many-Body Point of View, CLAUDIA RÖDL, FRANCESCO SOTTILE, LUCIA REINING, Laboratoire des Solides Irradiés, Ecole Polytechnique, 91128 Palaiseau cedex, France — The insulating transition-metal oxide CuO is considered a key to understanding the electronic structure of high-temperature superconducting cuprates, since it features similar bonding geometries. The photoemission spectra of this oxide, which is usually termed to be strongly correlated, have not been explained satisfactorily by first-principles calculations up to now. Special difficulties arise from the close entanglement of the structural and electronic degrees of freedom in this compound, which is due to the unoccupied Cu 3d orbitals. In contrast to the local-density approximation of density-functional theory (DFT), which predicts CuO to be a metal, we obtain finite band gaps by means of hybrid functionals containing screened exchange and the DFT+*U* method. Starting from these qualitatively correct band structures, we perform many-body calculations in the *GW* approximation. The various approaches to the one-particle excitation spectra are compared to experimental results. We discuss whether or not the peaks occurring in the photoemission data are quasiparticle excitations or satellite structures, respectively.

8:12AM Y16.00002 Pressure Effects on the Vanadium Oxides V₆O₁₁, V₇O₁₃, and V₈O₁₅¹, STELLA KIM, ESTELLE COLOMBIER, NI NI, SERGEY BUD'KO, PAUL CANFIELD, Iowa State University and Ames Laboratory — Members of the V_NO_{N-1} Magneli Series ($3 < N < 9$) exhibit metal to insulator transitions (MIT) as well as antiferromagnetic (AFM) transitions at ambient pressure, with the exception of V₇O₁₃ which remains metallic to lowest measured temperatures. In this talk we present pressure and temperature dependent measurements of electrical resistivity for V₆O₁₁, V₇O₁₃ and V₈O₁₅ samples. For V₆O₁₁ and V₈O₁₅ MIT can be suppressed by 4 and 1.3 GPa respectively. For V₇O₁₃ and V₈O₁₅ *T*_{SDW} can be suppressed by 3.5 GPa. Composite phase diagrams will be presented and low temperature data, focusing on the possibility of quantum criticality will be discussed.

¹Supported by U.S. DOE (DE-AC02-07CH11358)

8:24AM Y16.00003 Magnetic properties of Fe_{1-y}Co_ySi near insulator-metal transition¹, YAN WU, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, BRADFORD FULFER, JULIA CHAN, Department of Chemistry, Louisiana State University, Baton Rouge, LA 70803, DAVID YOUNG, JOHN DITUSA, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803 — FeSi is a nonmagnetic narrow gap insulator with interesting temperature-dependent magnetic and optical properties. When doped with Mn, holes are introduced to the FeSi system along with S=1 magnetic moments. As a result, a non-Fermi liquid metallic state is observed due to the underscreening of the S=1 moments. Here we investigate the effects of Co doping of FeSi (Fe_{1-y}Co_ySi, $0 \leq y \leq 0.03$) to explore the insulator-to-metal transition and to compare with Mn-doped effects. We find a systematic increase of the Curie constant and Weiss temperature of the impurity-induced low temperature susceptibility with *y*. The Curie constant and saturated magnetization indicates that there is an underlying competition between screening of the magnetic moments at low *y* and ferromagnetic ordering at higher Co-concentrations. Transport measurements are underway to explore the associated charge carrier properties in this semiconducting system on the verge of ferromagnetism.

8:36AM Y16.00004 Signatures of Correlation Effects and Thermopower in FeSi, JAN TOMCZAK, KRISTJAN HAULE, GABRIEL KOTLIAR, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — Correlated semiconductors have been studied intensively over the years, because they exhibit an unusual metalization process which is poorly understood. At low temperatures FeSi behaves as an ordinary semiconductor, while at high temperatures the system is a bad metal with a Curie like susceptibility. Analogies with heavy fermion Kondo insulators and mixed valence compounds, and anomalous electron phonon coupling have been invoked to account for this behavior, but lacking quantitative methodologies applied to this problem, a consensus remained elusive to date. Here, we use realistic many-body methods to elucidate the metalization of FeSi. Our methodology accounts for all substantial anomalies observed in FeSi: lack of conservation of spectral weight in optics, Curie susceptibility and an anomalous thermoelectric power. Having quantitatively validated our approach, we propose a new scenario. In correlated insulators such as FeSi the metalization is induced by the emergence of non-quasiparticle incoherent states in the gap. This coherence-incoherence crossover is accompanied by a massive reorganization of the spin excitations. Besides the fundamental interest of our theory, our work is relevant to the design of thermoelectric materials based on correlated insulators.

8:48AM Y16.00005 FeGa3 – a strongly correlated insulator?, MONIKA GAMZA, Brookhaven National Laboratory, MEIGAN ARONSON, Stony Brook University and Brookhaven National Laboratory — FeGa3 is one of few Fe-based nonmagnetic semiconductors, in which a small gap is produced by the hybridization of Fe 3d states with p states of a group 13 or 14 element. The role of strong electron-electron correlation effects in formation of the gap is unclear. In case of FeSi and FeSb2, a metal-insulator transition was observed at temperatures low relative to the gap energy, which is a hallmark of a Kondo nature of the gap. For FeGa3, a combination of photoemission data and DFT-based electronic structure calculations indicated a rather strong on-site effective Coulomb repulsion within the Fe 3d shell *U*_{eff}~3 eV and a sizable *U*_{eff}/*W* ~ 0.6 (*W* – band width) [1]. Interestingly, recent ARPES measurements revealed a Fe 3d derived state located around 0.4 eV away from the top of the valence band [1]. Thermodynamic and transport measurements do not give any sign of a metal-insulation transition up to 1000 K [2]. To get insight into the importance of e-e correlation effects in formation of the gap in FeGa3, we drive the system towards a metallic state by doping. The results of resistivity, specific heat and magnetization measurements on doped single crystals of FeGa3 grow by Ga-flux technique will be discussed.

9:00AM Y16.00006 Hybridization wave as the cause of the metal-insulator transition in rare earth nickelates¹, HYOWON PARK, Department of Physics, Columbia University, CHRIS A. MARIANETTI, Department of Applied Physics, Columbia University, ANDREW J. MILLIS, Department of Physics, Columbia University — The metal-insulator transition driven by varying rare earth (*Re*) ion in *ReNiO₃* has been a longstanding challenge to materials theory. Experimental evidence suggesting charge order is seemingly incompatible with the strong Mott-Hubbard correlations characteristic of transition metals. We present density functional, Hartree-Fock and Dynamical Mean field calculations showing that the origin of the insulating phase is a hybridization wave, in which a two sublattice ordering of the oxygen breathing mode produces two *Ni* sites with almost identical *Ni* *d*-charge densities but very different magnetic moments and other properties. The high temperature crystal structure associated with smaller *Re* ions such as *Lu* is shown to be more susceptible to the distortion than the high temperature structure associated with larger *Re* ions such as *La*.

9:12AM Y16.00007 Non-thermal dynamics of the spin and charge order in striped nickelates, WEI-SHENG LEE¹, SLAC National Accelerator Lab. — In the striped nickelate $\text{La}_{2-x}\text{Sr}_x\text{NiO}_4$, spin order coexists with charge order, whose periodicity is half of spin order. So far, most of the studies on the stripe phase were performed in the thermal equilibrium state by varying temperatures; the dynamics of stripe phase in the time domain when the system is driven-out-of-equilibrium has not yet been studied. Using the x-ray free electron laser (XFEL) at LCLS, we performed time-resolved optical-pump and resonant soft x-ray diffraction probe experiments to study the dynamics of the spin and charge order. Comparisons of charge and spin order dynamics will be discussed.

¹This work is a collective contributions of 33 researchers from several institute. Full list of the author will be acknowledged in the presentation.

9:24AM Y16.00008 The temperature evolution of NiO_6 octahedral tilts as a probe to study charge stripes in $\text{Ln}_{1.67}\text{Sr}_{0.33}\text{NiO}_4$ ($\text{Ln}=\text{La}/\text{Nd}$)¹, MILINDA ABEYKOON, EMIL BOZIN, GENDA GU, JOHN HILL, JOHN TRANQUADA, Brookhaven National Laboratory, SIMON BILLINGE, Brookhaven National Laboratory, Columbia University — $\text{Nd}_{1.67}\text{Sr}_{0.33}\text{NiO}_4$ and $\text{La}_{1.67}\text{Sr}_{0.33}\text{NiO}_4$ exhibit long range ordered (LRO) charge stripes below $T_{\text{co}} \sim 240\text{K}$. When the charge stripes are static and long-range ordered, they have been seen as superlattice Bragg peaks in single crystal neutron and x-ray diffraction. We used neutron atomic pair distribution function (NPDF) technique to investigate the possibility of existence of localized charges above T_{co} , where, the LRO of the stripes disappears. Rigid body type NiO_6 octahedral tilts were used as a probe to study the local and average structural response to charge order. The amplitude of rotation of the octahedral units was used to investigate the observed large apical oxygen thermal ellipsoids (anisotropic thermal displacement parameters) in the a-b crystal plane. We measured enhanced tilt amplitudes in the local structure, compared to the average. We will discuss the temperature dependence of the tilt amplitudes and of the correlation length of the local tilt order and explore the potential relationship to local stripe order.

9:36AM Y16.00009 Time-Dependent Recovery of Charge and Spin Order in Striped Nickelate¹, Y.F. KUNG, C.-C. CHEN, A.F. KEMPER, Stanford University, W.-S. LEE, B. MORITZ, Stanford University and SLAC National Accelerator Laboratory, A.P. SORINI, Lawrence Livermore National Laboratory, Z.-X. SHEN, T.P. DEVEREAUX, Stanford University and SLAC National Accelerator Laboratory — Using time-dependent Ginzburg-Landau theory, we study the melting and recovery of charge and spin order in the striped nickelate $\text{La}_{1.75}\text{Sr}_{0.25}\text{NiO}_4$ in response to an ultrashort pump pulse that destroys the order. Treating the behavior of both the amplitudes and phases of the order parameters, we examine their effects on the recovery time scales of the charge and spin order. We compare the temporal dynamics of our model to experimental observations at the Linac Coherent Light Source (LCLS).

¹National Defense Science and Engineering Graduate Fellowship

9:48AM Y16.00010 ARPES studies on metal-insulator-transition in $\text{NiS}_{2-x}\text{Se}_x$, GARAM HAN, Y.K. KIM, W.S. KYUNG, CHUL KIM, Y.Y. KOH, Institute of Physics and Applied Physics, Yonsei University, Korea, K.D. LEE, Department of Physics, Inha University, Korea, C. KIM, Institute of Physics and Applied Physics, Yonsei University, Korea — Understanding Metal insulator transition (MIT) is one of the most challenging issues in condensed matter physics. $\text{NiS}_{2-x}\text{Se}_x$ (NSS) is a well known system for band width controlled MIT studies while most of High- T_c superconductors (HTSCs) are described within band filling MIT picture. Cubic pyrite NiS_2 is known as a charge-transfer (CT) insulator and easily forms a solid solution with NiSe_2 , which is a good metal even though it is isostructural and isoelectronic to NiS_2 . MIT is induced by Se alloying and is observed at a low temperature for $x=0.5$. The important merit is that there is no structure transition which often accompanies MIT. In spite of the importance of the system, even the experimental band dispersion is not known so far along with many controversies. For this reason, we performed angle resolved photoemission spectroscopy on high quality single crystals and successfully obtained Fermi surface maps of $x=0.5$, $x=0.7$ and $x=0.8$ systems (the metallic side). By doping dependent systematic studies on NSS and comparison with LDA calculation, we try to explain the relationship between band width and the MIT.

10:00AM Y16.00011 Quantum criticality at a Mott-Hubbard Metal-Insulator Transition, ARNAB BANERJEE, DANIEL SILEVITCH, ALEXANDER PALMER, The University of Chicago, YEJUN FENG, The Argonne National Laboratory, THOMAS ROSENBAUM, The University of Chicago — The Mott insulator nickel disulfide undergoes an insulator to metal transition that can be driven by either hydrostatic pressure or doping-induced chemical pressure. Previously, NiS_2 doped with selenium to just below the quantum critical point showed anomalous critical exponents as a function of pressure. Doping, however, introduces positional disorder and charge transfer effects from the selenium orbitals, potentially altering the critical behavior. We report here on a set of transport experiments on pure NiS_2 , where the pressure and temperature scales for the critical regime require the use of a diamond anvil cell integrated with a helium dilution refrigerator, allowing us to compare the critical behavior of the pure and doped materials.

10:12AM Y16.00012 Redefining the metal/charge-transfer insulator paradigm in transition metal oxides¹, HUNG DANG, XINYUAN AI, Department of Physics, Columbia University, CHRIS MARIANETTI, Department of Applied Physics, Columbia University, ANDREW MILLIS, Department of Physics, Columbia University — The universality of the phase diagram in the variables of interaction strength and d-occupancy, shown for late transition metal oxides in Ref.[1], is examined for two series of early transition metal oxides: (SrVO_3 , SrCrO_3 , SrMnO_3) and (LaTiO_3 , LaVO_3 , LaCrO_3) using density functional theory (DFT), DFT+U and DFT+dynamical mean field theory methods. The interaction required to drive the metal-insulator transition is found to depend sensitively on the d-occupancy N_d , and beyond a threshold value of the d-occupancy an insulating state cannot be achieved for any practical value of the interaction. The critical N_d values are determined and compared to ab initio and experimental estimates where available. Additionally, the minimal model for the transition is determined and the crucial role played by the Hund's coupling is demonstrated.

10:24AM Y16.00013 Implementation of a dynamical cluster approximation within an augmented plane-wave framework, HUNPYO LEE, Institut fuer Theoretische Physik, Goethe Universitaet Frankfurt, 60438 Frankfurt, Germany, KATERYNA FOYEVTSOVA, JOHANNES FERBER, Institut fuer Theoretische Physik, Goethe Universitaet Frankfurt, 60438 Frankfurt, Germany, MARKUS AICHHORN, Institute of Theoretical and Computational Physics, TU Graz, Graz, Austria, HARALD O. JESCHKE, ROSE VALENTI, Institut fuer Theoretische Physik, Goethe Universitaet Frankfurt, 60438 Frankfurt, Germany — Even though the local density approximation in combination with dynamical mean field theory (LDA+DMFT) accounts for various and interesting physics such as Mott insulator and enhancement of effective mass for real compounds, the pseudo-gap and spin density wave behaviors are missed due to the absence of spatial correlations. In order to consider the short-range spatial correlations beyond the LDA+DMFT approach for real compounds, we introduce a combination of LDA with a dynamical cluster approximation (LDA+DCA) in the framework of the full-potential linear augmented plane-wave basis and show results for SrVO₃. We discuss how to implement the LDA+DCA approach in the WIEN2k density functional theory code and analyze the momentum spectral properties on SrVO₃ as a result. We compare our LDA+DCA results with LDA+DMFT as well as with angle-resolved photoemission spectra (ARPES). We find that LDA+DCA results compare better with ARPES than the LDA+DMFT results due to inclusion of spatial correlations.

10:36AM Y16.00014 Pressure induced insulator to metal transition and orbital dynamics in Sr₂VO₄, SUKANTA KARMAKAR¹, Bhabha Atomic Research Centre, Mumbai — The unusual ground states of transition metal oxides with layered perovskite structure (K₂NiF₄ type) are driven by a complex interplay between charge, orbital, spin and lattice degrees of freedom. The S=1/2 and 3d¹ system Sr₂VO₄, a Mott insulator, is of particular interest because of its vicinity to the insulator-metal boundary. The strong two-dimensionality along with a weak Jahn-Teller distortion (slightly elongated VO₆ octahedra along c-axis) causes splitting of t_{2g} orbitals (xy orbital and doubly degenerate yz and zx orbitals), pressure-tuning of which is expected to reveal interesting physical properties. Our recent high pressure Raman spectroscopic investigations at low temperature describe the orbital dynamical changes in this system. The anomalous pressure dependence of the strong magnetic excitations in Raman spectra confirms the unconventional spin-orbital composite nature (magnetic octupolar type order) of the dxy/zy levels [PRL **103**, 067205, (2009)]. The system transforms from high temperature orbital liquid like state to the low temperature orbital ordered state via a short range orbital order precursor at 150K. With increasing pressure the orbital ordering transition temperature decreases, predicting a QCP at ~8 GPa. At this pressure the system undergoes an insulator to metal transition (as observed from mid IR reflectance measurements as well as sharp rise in Raman intensity of phonon modes due to occurrence of intraband transitions).

10:48AM Y16.00015 ab-initio calculations of electronic structure and magnetism of O₂MF₆ (M=Sb, Pt) : Coulomb correlation and spin-orbit interaction effects in 2p and 5d electrons, MINJAE KIM, B. I. MIN, Department of Physics, Pohang University of Science and Technology — We have investigated electronic structures and magnetic properties of O₂MF₆ (M=Sb, Pt), which are composed of two building blocks of strongly correlated electrons: O₂⁺ dioxygenyls and MF₆⁻ octahedra, by employing the first-principles electronic structure band method. For O₂SbF₆, as a reference system of O₂PtF₆, we have shown that the Coulomb correlation of O(2p) electrons drives the Mott insulating state. For O₂PtF₆, we have demonstrated that the Mott insulating state is induced by the combined effects of the Coulomb correlation of O(2p) and Pt(5d) electrons and the spin-orbit (SO) interaction of Pt(5d) states. The role of the SO interaction in forming the Mott insulating state of O₂PtF₆ is similar to the case of Sr₂IrO₄ that is a prototype of a SO induced Mott system with J_{eff} = 1/2.

Friday, March 2, 2012 8:00AM - 10:48AM —

Session Y17 DCMP: Nanostructures and Interfaces: Electrons, Phonons, and Plasmons 252A

8:00AM Y17.00001 Transport and Kondo correlations in magnetic break junction devices, GAVIN D. SCOTT, Bell Laboratories, Alcatel-Lucent, 600 Mountain Ave, Murray Hill, NJ 07974, DOUGLAS NATELSON, Department of Physics and Astronomy, 6100 Main St, Rice University, Houston, TX 77005; Department of Computer and Electrical Engineering, Rice University — A single molecule transistor device fabricated with a break junction technique is utilized as a tunable model system for probing transport properties of the highly correlated Kondo state. The emergence of this collective phenomenon occurs due to an antiferromagnetic interaction between conduction electrons and a local magnet moment represented by an unpaired spin on the molecule. Low energy non-equilibrium conductance measured in the Kondo regime has been shown to obey a particular scaling relationship with respect to different perturbations. Devices are now fabricated with ferromagnetic and strongly paramagnetic electrodes, and the applicability of such scaling behavior is investigated in the presence of magnetic interactions and anomalous transport characteristics.

8:12AM Y17.00002 Phonon transmission across Si/Ge interface from first-principles by the Green's function method¹, ZHITING TIAN, KEIVAN ESFAJANI, GANG CHEN, MIT — Modeling phonon transmission as a function of phonon frequency and incidence angle is vital for multiscale modeling of heat transport in nanostructured materials. In this study, we calculate the phonon transmission in three-dimensions via Green's function method. It will be applied to silicon/germanium interface for which the force constants will be calculated from either the Stillinger-Weber semi-empirical potential, or from first-principles density functional methods. Both the perfect interface and the rough interface will be investigated. The transmission as a function of interface roughness will give us more guidance for surface engineering. Results between first-principles and the SW potential will be compared to see how reliable the predictions from SW potential are. The contribution of optical modes is illustrated by comparing the results with the prediction of the acoustic mismatch model (AMM) which is also harmonic and the long-wavelength limit of the general theory. It will now be possible to integrate the information on momentum and frequency-dependent transmission and the bulk mean free paths, both calculated from first-principles DFT, to accurately model heat transport in complex nanostructured materials.

¹This material is based upon work supported as part of the S3TEC, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DE-FG02-09ER46577

8:24AM Y17.00003 Ultrafast Characterization of Nanostructures in GaAs, STEPHANIE GILBERT, Vanderbilt University, JASON KAWASAKI, University of California Santa Barbara, ANDREW STEIGERWALD, JUSTIN GREGORY, Vanderbilt University, CHRIS PALMSTRØM, University of California Santa Barbara, NORMAN TOLK, Vanderbilt University — We combine ultrafast pump-probe and optoacoustic spectroscopy with magneto-optical Kerr rotation measurements to characterize embedded, self-assembled magnetically active nanostructures in a GaAs host matrix. We observe variations in the pump-probe and optoacoustic signals depending on the composition and growth characteristics of the embedded layers. Further, we observe (a) distinct behaviors in the femtosecond response of the composite structures when the probe photon energy is tuned near the GaAs band edge and (b) strong modulation of the optoacoustic signal inside the embedded layer. These results indicate an effective change in the transient femtosecond response of the composite structure, likely originating in strain effects due to the presence of nanoparticles within the host lattice. We additionally probe ultrafast magneto-optical interactions through time-resolved Kerr measurements. Finally, we present a potential method for high-resolution depth-dependent magnetic characterization by combining the Kerr rotation and optoacoustic experimental techniques.

8:36AM Y17.00004 Position-dependent Diffusion Coefficient as Localization Criterion in Non-Conservative Random Media, BEN PAYNE, ALEXEY YAMILOV, Missouri University of Science and Technology — Characterization of different regimes of electromagnetic wave transport in random media is an important area of research with ramifications in condensed matter physics. For passive systems, transport can be either ballistic, diffusive, or localized. Wave corrections to otherwise classical transport in a finite random media result in position-dependent diffusion coefficient $D(z)$. If media is active or dissipative (contains optical gain or absorption), then $D(z)$ can be used to distinguish a multitude of distinct wave transport regimes. Using a numerical model, we validate the existence of the position-dependent diffusion, including for media with absorption. We have previously developed a phase space enumerating all regimes exhibiting distinct transport behavior. Here we present recent results from our numerical simulations which demonstrate the ability to use $D(z)$ to distinguish between these regimes.

8:48AM Y17.00005 Probing phonon surface scattering in nanostructures, RICHARD ROBINSON, JARED HERTZBERG, OBAFEMI OTELAJA, Cornell University, Department of Materials Science and Engineering — In insulating materials, heat is transmitted by atomic vibrations ("phonons"). In nanostructured materials such as nanowires and nanosheets, the characteristic length scale of a material can be less than the mean free path of a phonon. The phonon transport is then drastically altered and becomes dominated by scattering from surfaces. We demonstrate a method to assess the scattering rate and transmission factor of phonons traversing a silicon nanosheet. Generation and detection of phonons is accomplished by a superconducting tunnel junction attached to the silicon nanostructure and operated at a temperature of 0.3K. Decay of excited states in the superconductor is employed as a tunable narrow-band source of phonons [1,2]. This tunable source enables investigation of the phonon mean free path as a function of phonon frequency and surface roughness, for frequencies from ~ 100 GHz to ~ 500 GHz in nanosheets 100 to 200 nm thick. This work is supported by DOE (DE-SC0001086).

[1] H. Kinder. Phys. Rev. Lett. 28, 1564 (1972)

[2] J. B. Hertzberg et al, Rev. Sci. Instr. 82, 104905 (2011).

9:00AM Y17.00006 Self-assembled, vertically aligned, epitaxial nanoscale $p-n$ heterojunctions for thin film based photovoltaic applications, DANIELA F. BOGORIN, TOLGA AYTUG, PARANS M. PARANTHAMAN, ANDREW A LUPINI, ADAM RONDINONE, KYLE WINTERS, Oak Ridge National Laboratory, Oak Ridge, TN 37831, OAK RIDGE NATIONAL LABORATORY, OAK RIDGE, TN 37831 TEAM — Using *rf*-sputtering technique we have exploited phase-separated self-assembly and developed epitaxial, nanostructured composite films composed of phase separated, and vertically oriented $p-n$ interfacial nanocolumns of Cu_2O (p type; 2eV bandgap) and TiO_2 (n type; 3.2 eV bandgap). The characteristic band gaps of these phases allow extension of the solar capture from ultraviolet to a visible wavelength. The composite films were grown on perovskite substrates and exhibit single crystalline epitaxy in both phases. We have investigated crystalline structure, interfacial quality and optical properties of the nanopillar arrays using XRD, TEM, SEM, AFM, and optical absorption techniques. Here, we show nearly complete atomic order at Cu_2O - TiO_2 interface (i.e., $p-n$ junction) and an absorption profile that captures a wide range of solar spectrum extending from ultraviolet to visible wavelengths. Compared to layered thin film architectures, the use of such vertically aligned nanostructures in solar cells can promote cost-effective fabrication of high efficiency PV devices by providing low defect concentrations, improved absorption and light trapping capabilities, and increased minority carrier diffusion lengths.

9:12AM Y17.00007 Ab initio calculation of the electron-phonon coupling for transport¹, NATHALIE VAST, JELENA SJAKSTE, PAOLA GAVA, IURII TIMROV, Laboratoire des Solides Irradiés - Ecole Polytechnique - CEA DSM - CNRS UMR7642 - France, VALERY TYUTEREV, Tomsk State Pedagogical University - Russia — We have developed an approach which enables us to compute matrix elements of the electron-phonon coupling within the density functional perturbation theory for the electronic interaction with short-wavelength phonons.² Combining this *ab initio* approach to the Boltzmann transport equation, we have obtained the thermoelectric coefficients of silicon.³ The lifetime of the $2p_0$ shallow impurity state in doped-silicon turns out to be shorter than expected.⁴ The lifetime of the exciton in germanium under pressure⁵ is found to be well described. Effect of the material nanostructuring on the electron-phonon coupling constants will be shown for small semiconducting superlattices. Finally, the calculation of deformation potentials for intravalley scattering will be discussed, and results shown for silicon and for bismuth, which is the prototype material for thermoelectricity.

9:24AM Y17.00008 ABSTRACT WITHDRAWN —

9:36AM Y17.00009 Effect of Interlayer Interaction on the Structural, Electronic, and Thermal Properties of Layered MS_2 ($M=\text{W}, \text{Mo}$) Structures, SEOUNG-HUN KANG, SORA PARK, YOUNG-KYUN KWON, Department of Physics and Research Institute for Basic Sciences, Kyung Hee University — Using density functional theory (DFT) supplemented with van der Waals interaction, we investigate the effect of interlayer interaction on the structural, electronic, and thermal properties of transition-metal disulfides MS_2 , such as MoS_2 and WS_2 . We calculate the relative stability of various layer-layer stacking configurations determined by considering relative positions and orientations between neighboring layers. We find that MS_2 layers may slide over each other with a small sliding barrier. We explore the effect of layer stacking on the electronic structure, and find an intriguing coupling effect. We also calculate their thermal properties including thermal expansion behavior especially along the direction normal to the plane. Such thermal expansion behavior is considered for our study of Li-intercalation into layered MS_2 , which may become a fundamental understanding for future development of Li-ion battery. We evaluate thoroughly the diffusion paths and barriers in between layers and compare them with those on the surface. Interestingly we find that the diffusion barrier between layers is ~ 100 meV smaller than that on a single layer, implying layered MS_2 may be a good candidate for Li-ion battery electrodes.

9:48AM Y17.00010 Surface plasmon modes management by Thompson plasmonics¹, NAI JING DENG, CHEUNG WAI CHAU, SAI KIT YUNG, KIN WAH YU, The Chinese University of Hong Kong — We have studied the dispersion and propagation of the surface plasmons in a structure consisting of a metal slab and a dielectric slab, the latter of which contains randomly distributed small metal particles. In our model, the metal material is characterized by the Drude model and the pudding structure is studied with Maxwell-Garnett effective medium theory. This construction of material can bring a new hybridized band in the dispersion relation where light has a relatively small group velocity. The geometric profile of volume fraction of metal balls in pudding structure can effectively change the behaviour of the plasmon propagation. For example, by adding a parabolic confinement, it is shown by the Hamiltonian optics that the light propagation is trapped, i.e., the light experiences an oscillation in a small space. Experimentally, the confinement condition can be achieved with various means, thus it may be useful in development of new mechanism of solar cell.

10:00AM Y17.00011 Tunable Propagation and Localization of Hybrid Surface Plasmon Polaritons in Chirped Metal-Dielectric Waveguides¹, CHEUNG WAI CHAU, SAI KIT YUNG, KIN WAH YU, The Chinese University of Hong Kong — We have studied the propagation of coupled surface plasmon polariton (SPP) waves in a metal-dielectric-metal (e.g. Au/MgF₂/Au) waveguide by the transfer matrix method. Due to the evanescent coupling of the SPP waves at the two interfaces in the dielectric layer, three hybridized surface plasmon polariton (HSPP) branches are achieved with a nearly flat branch at intermediate frequencies. The flat HSPP branch is tunable by varying the thickness and/or the permittivity of the dielectric layer. Moreover, by imposing a gradual variation of the permittivity (or thickness) of the dielectric layer along the propagation direction, it is possible to alter the local dispersion relation so that a localization of SPP waves can be realized. Under a parabolic confinement, Hamiltonian optics is used for simulating the propagation and localization of HSPP waves. We demonstrate that HSPP are localized at different locations at different frequencies, which is useful for achieving trapped SPP rainbow. The results of this research can have fruitful applications in optical computing, etc.

¹Supported by the General Research Fund of the HKSAR Government.

10:12AM Y17.00012 Energy concentration in plasmonic nanostructures: Green function formalism¹, SAI KIT YUNG, CHEUNG WAI CHAU, KIN WAH YU, The Chinese University of Hong Kong — We have developed the Green function formalism (GFF), which can be used to study the field distribution and electrostatic resonance of different nanostructures. In the GFF, a surface integral equation is formulated for the scalar potential for an arbitrary number of nanostructures of various shapes. This formalism has the advantage of avoiding matching the complicated boundary conditions on the surfaces of the nanostructure. In particular, we have studied the cases of two approaching metal cylinders and non-touching metal crescent under a uniform applied electric field. It is shown that there is an energy concentration within the air narrow gap and the metal narrow gap in the cases of approaching cylinders and non-touching crescent respectively. The numerical GFF results are compared with the analytic results by conformal transformation. The results are useful in designing plasmonic light-harvesting devices.

10:24AM Y17.00013 Circular Dichroism and Spin Polarization of Rashba Split Surface States on a Bi/Ag Surface Alloy, GUANG BIAN, LONGXIANG ZHANG, YANG LIU, T. MILLER, T.-C. CHIANG, University of Illinois at Urbana-Champaign — The Bi/Ag surface alloy possesses a huge Rashba splitting in its surface bands due to the prominent corrugation in the surface reconstruction and the large atomic spin-orbit coupling of the Bi atom. This system is an intriguing candidate to realize the 2D $p_x + ip_y$ superconductor and further, Majorana states. In this work, we study the electronic structure of the Bi/Ag surface alloy prepared by depositing Bi onto ultrathin Ag films followed by annealing. The electronic structure of the system is measured using circular angle resolved photoemission spectroscopy (CARPES). The results reveal two interesting phenomena: the hybridization of spin polarized surface states with Ag bulk quantum well states and the umklapp scattering by the perturbed surface potential. In addition, our CARPES spectra show clearly a unique dichroism pattern which is closely related to the spin texture of this 2D strongly spin-orbit coupled electron system.

10:36AM Y17.00014 Atomic structure, energetics, and dynamics of topological solitons in indium chains on Si(111) surfaces, HUI ZHANG, Hefei National Laboratory for Physical Sciences at Microscale and Department of Physics, USTC, JIN-HO CHOI, JUN-HYUNG CHO, Department of Physics, Hanyang University, CHANGGAN ZENG, ZHENYU ZHANG, JIANGUO HOU, ICQD, Hefei National Laboratory for Physical Sciences at Microscale and Department of Physics, USTC — Besides the presence of exotic ground states, potentially more intriguing are the elementary excitations of the One-dimensional charge density waves (1D-CDWs), including the nonlinear topological excitation or soliton. Solitons may possess spin-charge inversion properties, and act as the effective carriers that account for the high conductivity in conducting polymers. However, comprehensive quantitative study of topological solitary excitations at the atomic level remains a challenge. In this talk, I will present our recent work on the quantitative characterization of solitons in In chains grown on Si(111) surfaces at atomic scale. The precise atomic structure of the topological soliton in In/Si(111) is determined based on scanning tunneling microscopy and first-principles calculations. Variable temperature measurements of the soliton population allow us to determine the soliton formation energy to be ~ 60 meV, smaller than one-half of the band gap of ~ 200 meV. Once created, these solitons have very low mobility; the sluggish nature is attributed to the exceptionally low attempt frequency for soliton migration. We further demonstrate local electric field enhanced soliton dynamics, and the feasibility of aggregating solitons into soliton polymers.

Friday, March 2, 2012 8:00AM - 11:00AM –

Session Y18 DMP: Focus Session: Interfaces in Complex Oxides - Functional Interfaces 252B

8:00AM Y18.00001 Tunable ferroelectricity and magnetoelectricity at the interfaces of superlattices of antiferromagnets, CHRISTOS PANAGOPOULOS, Nanyang Technological University — In heterostructures composed of transition metal oxides, the disruption introduced even by an ideal interface can drastically upset the delicate balance of the competing interactions among electronic spins, charges and orbitals, leading to a range of exotic phenomena. These include interfacial conduction, magnetism, superconductivity but also improved ferroelectric properties. Possible incorporation of magnetoelectrics in these structures would further enable electrical control of magnetization as well as magnetic sensing of the polarization state. Naturally occurring magnetoelectrics are however, rare and generally with weak coupling. In this work we report a strategy and evidence for the emergence and control of ferroelectricity and strong magnetoelectric coupling in superlattices *consisting of solely non-ferroelectric antiferromagnetic layers*. By selecting appropriate yet abundant starting materials one may now design a plethora of low dimensional heterostructures with the desired relative arrangement of the oxide layers, of potential utility to miniature valves with electric and magnetic field tunable functions, promising to set new standards in future electronics.

8:36AM Y18.00002 Interfacial Properties of Ultra-thin YBCO/LCMO Superlattices¹, BENJAMIN GRAY, JIAN LIU, E.J. MOON, M. KAREEV, D.J. MEYERS, Physics Department, University of Arkansas, I.C. TUNG, M.J. BEDZYK, Department of Materials Science and Engineering, Northwestern University, M. VEENENDAAL, J.W. FREELAND, Advanced Photon Source, Argonne National Laboratories, J. CHAKHALIAN, Physics Department, University of Arkansas — The rational design of complex oxide heterostructures enables the investigation of novel materials with antagonistic order parameters. Our previous work using resonant x-ray spectroscopies has provided insight into the role of orbital reconstruction and covalent bonding at the interface of such heterostructures. In this talk, we will further address the intriguing interfacial electronic and magnetic properties and possible coupling between layers in superlattices composed of alternating superconductive YBa₂Cu₃O₇ and ferromagnetic La_{2/3}Ca_{1/3}MnO₃ layers upon approaching the ultra-thin limit, where a superconductor to insulator transition with increasing thickness N is observed in [YBCO (1 u.c.)/LCMO (N u.c.)] superlattices.

¹J.C. was supported by DOD-ARO under the Contract No. W911NF-11-1-0200 and NSF Contract No. DMR-0747808.

8:48AM Y18.00003 Scanning tunneling microscope investigation of the interfacial electronic properties of YBCO/LCMO , J.C. WANG, B.C. HUANG, Y.P. CHIU, Department of Physics, National Sun Yat-Sen University, Kaohsiung, 80424, Taiwan, Y.C. HUANG, Y.C. CHEN, Department of Physics, National Cheng Kung University, Tainan, 701, Taiwan, V.T. TRA, J.Y. LIN, Institute of Physics, National Chiao Tung University, Hsinchu, 300, Taiwan, J.C. YANG, Y.H. CHU, Department of Materials Science and Engineering, National Chiao Tung University, Hsinchu, 1001, Taiwan — Direct measurements of the interfacial electronic structures in YBCO/LCMO hetero-structures have been performed using cross-sectional scanning tunneling microscopy (STM) and spectroscopy (STS). Both scanning tunneling spectroscopy and analysis of the local electronic states across the interface of YBCO/LCMO reveal the evolution of the energy-band structures. Closely examining the recognition of the electronic structure by the unique combination of STM and STS reveals the direct information on the local interaction between superconductivity and magnetism in this work.

9:00AM Y18.00004 Quasiparticle dynamics in YBCO and YBCO/LSMO Using Femtosecond Optical Pulses , J. LEE, D. TALBAYEV, J. XIONG, CINT, Los Alamos National Laboratory, J. ZHU, Theoretical Division, Los Alamos National Laboratory, Q. JIA, A.J. TAYLOR, R.P. PRASANKUMAR, CINT, Los Alamos National Laboratory, CENTER FOR INTEGRATED NANOTECHNOLOGIES, LOS ALAMOS NATIONAL LABORATORY TEAM, THEORETICAL DIVISION, LOS ALAMOS NATIONAL LABORATORY TEAM — The properties of various complex oxide systems, such as multiferroics, high- T_c superconductors and colossal magnetoresistance manganites, have been extensively studied for the past ~25 years. In particular, the interplay between superconductivity (SC) and ferromagnetism (FM) is interesting from both academic and applied viewpoints. We have temporally resolved quasiparticle dynamics in multilayered films composed of the high-temperature superconductor YBCO and the ferromagnetic manganite LaSrMnO_3 (LSMO) by performing temperature-dependent UOS experiments. In YBCO alone, we observed two distinct decay relaxation channels that have previously been related to the pseudogap and superconducting gaps and can be explained with the phenomenological Rothwarf-Taylor (RT) model. However, the fast sub-picosecond relaxation related to the pseudogap was not observed in our YBCO/LSMO heterostructures, possibly due to the influence of FM order. These first UOS experiments on SC/FM heterostructures demonstrate the ability of UOS to quantify the influence of ferromagnetism on superconductivity through time domain measurements.

9:12AM Y18.00005 Ba and Sr templates on Ge(001) for epitaxial oxide growth , MIRI CHOI, AGHAM POSADAS, CHIH-KANG SHIH, ALEXANDER A. DEMKOV, The University of Texas at Austin — In the epitaxial growth of oxides on semiconductors, Ba and Sr templates are used as transition layers for perovskite deposition. Furthermore, the interface between complex oxides and semiconductors are relatively unexplored. The ability to control the interface between them can lead to new phenomena and new combinations of oxide-semiconductor heterostructures. In this work, we compare the differences between the Sr template with Ba templates on Ge(001) at various temperatures. The sub-monolayer coverage of Ba and Sr shows different morphology and nucleation behavior depending on the deposition temperature. For example, at higher deposition temperature, the electron diffraction pattern of Sr on Ge shows a 9×1 phase which was not observed at lower deposition temperature. We perform an atomic-scale study of Ba and Sr templates grown on Ge(001) by molecular beam epitaxy as a function of deposition temperature and coverage, using a combination of reflection high energy electron diffraction and *in situ* scanning tunneling microscopy (STM). An understanding of the behavior of Ba and Sr template formation on germanium can potentially be used as a means of better controlling the subsequent oxide growth.

9:24AM Y18.00006 Structure of SrTiO_3 films on Si , C. STEPHEN HELLBERG, Naval Research Lab, KRISTOPHER ANDERSEN, High Performance Technologies, Inc., HAO LI, Shenzhen New Degree Technology Co., PHILIP RYAN, Argonne National Laboratory, JOSEPH WOICIK, National Institute of Standards and Technology — The epitaxial deposition of oxides on silicon opens the possibility of incorporating their diverse properties into silicon-device technology. Deposition of SrTiO_3 on silicon was first reported over a decade ago, but growing the coherent, lattice-matched films that are critical for many applications has been difficult for thicknesses beyond 5 unit cells. Using a combination of density functional calculations and x-ray diffraction measurements, we determine the atomic structure of coherent SrTiO_3 films on silicon, finding that the Sr concentration at the interface varies with the film thickness. The structures with the lowest computed energies best match the x-ray diffraction. During growth, Sr diffuses from the interface to the surface of the film; the increasing difficulty of Sr diffusion with film thickness may cause the disorder seen in thicker films. The identification of this unique thickness-dependent interfacial structure opens the possibility of modifying the interface to improve the thickness and quality of metal oxide films on silicon.

9:36AM Y18.00007 Low kV Atomic Resolution and First Principles Study of the Structure and Bonding at $\text{SrTiO}_3/\text{GaAs}$ Hetero-interfaces¹ , QIAO QIAO, ROBERT KLIE, SERDAR OGUT, University of Illinois at Chicago — Ultrathin transition-metal oxide films on polar substrates have attracted increasing attention in recent years, due to the emergence of novel interfacial phases, not seen in the bulk of either material. In this study, we have combined aberration-corrected atomic-resolution Z-contrast imaging, electron energy loss spectroscopy (EELS) with first-principles density functional theory calculations to examine the atomic and electronic structures of epitaxially grown, ultrathin SrTiO_3 (100) films on GaAs (001). We find that the interface is atomically abrupt and no surface reconstruction of the GaAs (001) surface is observed. Using atomic-column resolved EELS, we show that Ti diffuses into the first few monolayers of GaAs and we will present evidence for the formation of As-oxides at the interface depending on the thin film growth conditions. First-principles DFT calculations will be used to analyze the formation energies of Ti-related impurity defects in the bulk and surface regions of GaAs, as well as the stability of any surface reconstruction at the $\text{SrTiO}_3/\text{GaAs}$ interface. These findings are used to explain transport behavior of the SrTiO_3 films as a function of deposition conditions.

¹Supported by NSF Grant No. DMR-0846748

9:48AM Y18.00008 Ultimate photovoltage in perovskite oxide heterostructures with critical film thickness , KUI-JUAN JIN, CONG WANG, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — One order larger photovoltage is obtained with critical thicknesses of $\text{La}_{0.9}\text{Sr}_{0.1}\text{MnO}_3$ films in both kinds of heterostructures of $\text{La}_{0.9}\text{Sr}_{0.1}\text{MnO}_3/\text{SrTiO}_3$ (0.8 wt % Nb-doped) and $\text{La}_{0.9}\text{Sr}_{0.1}\text{MnO}_3/\text{Si}$ fabricated at various oxygen pressures. Our self-consistent calculation reveals that the critical thickness of the $\text{La}_{0.9}\text{Sr}_{0.1}\text{MnO}_3$ film with the ultimate value of photovoltage is just the thickness of the depletion layer of $\text{La}_{0.9}\text{Sr}_{0.1}\text{MnO}_3$ in the $p-n$ heterostructures of $\text{La}_{0.9}\text{Sr}_{0.1}\text{MnO}_3/\text{SrTiO}_3$ (0.8 wt % Nb-doped) and $\text{La}_{0.9}\text{Sr}_{0.1}\text{MnO}_3/\text{Si}$, respectively.

10:00AM Y18.00009 Topological insulators from complex orbital order in transition-metal oxides heterostructures¹ , GREGORY FIETE, ANDREAS RUEGG, University of Texas at Austin — Topological band insulators which are dynamically generated by electron-electron interactions have been theoretically proposed in two and three dimensional lattice models. We present evidence that the two-dimensional version can be stabilized in digital (111) heterostructures of transition-metal oxides as a result of purely local interactions. The topological phases are accompanied by spontaneous ordering of complex orbitals and we discuss their stability with respect to the Hund's rule coupling, Jahn-Teller interaction and inversion symmetry breaking terms. As main competitors we identify spin-nematic and magnetic phases.

¹We gratefully acknowledge funding from ARO grant W911NF-09-1-0527 and NSF grant DMR- 0955778.

10:12AM Y18.00010 The electronic structure of epitaxially strained iridate thin films and superlattices from first principles, JOHANNES VOSS, CRAIG J. FENNIE, School of Applied and Engineering Physics, Cornell University, Ithaca, NY — Within the Ruddlesden-Popper iridates $\text{Sr}_{n+1}\text{Ir}_n\text{O}_{3n+1}$, strong spin-orbit interactions lead to the formation of a half-filled, narrow $J_{\text{eff}} = 1/2$ band and filled $J_{\text{eff}} = 3/2$ bands. This places the iridates in the vicinity of a Mott transition, which is sensitive to perturbations in crystal structure, despite relatively weak on-site Coulomb interactions [1]. For example, Sr_2IrO_4 ($n = 1$) is an antiferromagnetic Mott insulator that displays an almost rigid coupling between spin canting and IrO_6 octahedron rotations [2], while epitaxially stabilized SrIrO_3 ($n = \infty$) is a correlated metal. In this talk, we will discuss from first-principles within the LDA+SO+ U approach the possibility to engineer the electronic structure of SrIrO_3 and CaIrO_3 thin films using epitaxial strain and by creating superlattices of the form $(\text{AlrO}_3)_m(\text{A}'\text{BO}_3)_{m'}$ with $A, A' = \text{Ca}, \text{Sr}$. Park, C.S. Leem, J. Yu, T.W. Noh, C. Kim, S.-J. Oh, J.-H. Park, V. Durairaj, G. Cao, and E. Rotenberg, PRL 101, 076402 (2008).

10:24AM Y18.00011 The Structure of $\text{Y}_2\text{O}_3\text{:ZrO}_2$ / SrTiO_3 Layered Heterostructures, MATTHEW DYER, GEORGE DARLING, JOHN CLARIDGE, MATTHEW ROSSEINSKY, The University of Liverpool — Since the discovery of greatly increased conductivity in layered heterostructures of yttria stabilized zirconia (YSZ) and strontium titanate (STO) there has been considerable study and discussion regarding the origin of the high level of conductivity. The detailed atomic structure of layered YSZ-STO heterostructures is likely to be a crucial source of understanding, and as yet remains undetermined, particularly in the region of the buried interfaces between YSZ and STO. We present the results of density functional theory calculations on YSZ-STO heterostructures layered in the [001] direction, with different structures and compositions. We find that structures built using the terminations of the fluorite crystal structure of YSZ do not produce heterostructures which follow conventional solid state chemistry. These heterostructures contain Ti and Zr ions with unlikely O coordination geometries, reduced Ti^{3+} and Zr^{3+} ions and O-O bonding. In contrast, heterostructures built using a reconstructed YSZ termination, based on a rock-salt ordered ZrO layer, give more stable and more conventional atomic structures and are calculated to be electrically insulating. We describe these structures in detail, and the reasons behind the necessary reconstruction of YSZ at the interface.

10:36AM Y18.00012 Structural Rearrangement of Niobium Oxides from Lamellar Phases to Discrete Nanosheets and Nanoscrolls Probed by DFT Calculations, JHASHANATH ADHIKARI, LUIS J. SMITH, Clark University — Inorganic niobates $\text{ACa}_2\text{Nb}_3\text{O}_{10}$ ($A = \text{H}$ and K) with layered structures are good photocatalytic materials due to their high surface areas accommodating a larger number of active sites and ease of processing through soft chemical techniques like exfoliation and restacking. Alkali metal phases can be ion-exchanged to the acid phase, which in turn can be easily exfoliated to individual nanosheets. The nanosheets can change their form to nanoscrolls with a curled geometry instead of a flat surface. During these morphological transformations, the local structure at the Nb-atom, H-atom and the interface may undergo rearrangement which is responsible for the alteration of properties of the materials. This presentation highlights the preliminary results on these structural modifications (interface variation, stacking of layers, lattice contraction and space group settings) and the possible positions of the proton. Our calculations show that the protons in the acid form are non-bridging and bonded to the same layer oxygen atoms unlike the K-atoms in its parent compound. The Electric field gradient (EFG) is a parameter very sensitive to the electron density around a quadrupolar nucleus ^2H and ^{93}Nb that can be detected using NMR. Changes in its magnitude/sign can be correlated to the change in the local environment (bond lengths and angles) around the sites of interest. EFG values from DFT calculations based on the proposed structural models will be used for the characterization of surface O-H bond lengths, H-bonding and Nb-O bond lengths and can be used to interpret NMR studies.

10:48AM Y18.00013 Study of interface interactions in ZnO /Mesoporous silica nanocomposite, R.C. REDDY A, SOWRI BABU K, SUJATHA CH, V.G. REDDY K, National Inst. of Technology Warangal (A.P) 506004, India — The Photoluminescence (PL) properties of ZnO /Mesoporous silica (MPS) nanocomposite annealed under different temperatures were studied. A broad PL band at 395 nm has been observed in all samples and analysis was made by using Gaussian fitting. As the temperature increased, emission bands were blue shifted and the relative intensity ratio of the oxygen vacancies at ZnO - SiO_2 interface to the oxygen vacancies in inner ZnO crystallites was increased. The emission peaks at 363 nm and 384 nm are attributed to the near band edge emission (NBE) and to the phonon replica emission. At 550C the exciton confinement effect disappears due to the large amount of surface effects. The influence of porosity of host media on Si-O-Zn cross linking bonds was also investigated. ZnO nanoparticles were loaded into nanocrystalline silica (NCS) and silica gel (SG). The surface area increases monotonously from NCS to MPS through SG. Si-O-Zn cross linking bonds were almost absent in the sample prepared with NCS. It exhibits NBE emission at 360 nm which was found to be absent in other samples prepared with SG and MPS. It was also found that the emission intensity of the samples decreases with aging. This is due to diffusion of oxygen atoms from the atmosphere to interior of the sample.

Friday, March 2, 2012 8:00AM - 11:00AM –

Session Y19 DCMP: Invited Session: Novel Mechanisms of Multiferrocity 253AB

8:00AM Y19.00001 Multiferroicity due to Charge Ordering, JEROEN VAN DEN BRINK, IFW Dresden — In this contribution I discuss multiferroicity that is driven by different forms of charge ordering, presenting first the generic mechanisms by which charge ordering can induce ferroelectricity in magnetic systems. In type-I multiferroics [1], ferroelectricity and magnetism have different origins and occur at different temperatures. There is a number of specific classes of materials for which this is relevant. Discussed will be in some detail (i) perovskite manganites of the type $(\text{PrCa})\text{MnO}_3$ [2,3], (ii) the complex and interesting situation in magnetite Fe_3O_4 , (iii) strongly ferroelectric frustrated LuFe_2O_4 and (iv) an example of a quasi-one-dimensional organic system [4]. In type-II multiferroics [1], ferroelectricity is completely due to magnetism, but with charge ordering playing an important role [5], such as (v) multiferroic $\text{Ca}_3\text{CoMnO}_6$, (vi) possible ferroelectricity in rare earth perovskite nickelates of the type RNiO_3 [6,7], (vii) multiferroic properties of manganites of the type RMn_2O_5 [8], (viii) perovskite manganites with magnetic E-type ordering.

8:36AM Y19.00002 Soft X-ray Observation of electronic contribution to ferroelectric polarization, STUART WILKINS, Brookhaven National Laboratory — Multiferroic materials open up new interesting possibilities for devices by enabling the switching of an electric state by magnetic field or *vice-versa*. In addition to this functionality, multiferroics are intriguing from a fundamental physics perspective, raising interesting questions concerning coupling of the electric and magnetic order parameters. To date, most coupling mechanisms are understood to occur due to distortions in the crystal lattice. Here we present experimental evidence that in the multiferroics RMn_2O_5 (where R is a rare earth) there exists a new, purely *electronic* contribution to the ferroelectric polarization, which can exist in the absence of any lattice distortions. This contribution arises due to spin-dependent hybridization of O $2p$ and Mn $3d$ states and was observed through soft x-ray resonant scattering, which has proved to be a very useful tool in the study of the magnetic structure of multiferroics[1]. Through resonant x-ray scattering at the oxygen K-edge, we find that such spin dependent hybridization occurs in both TbMn_2O_5 [2] and YMn_2O_5 [3]. Remarkably, in YMn_2O_5 we find that the temperature dependence of the integrated intensity of the signal at the oxygen K-edge closely follows the macroscopic electric polarization [3], and hence is proportional to the ferroelectric order parameter. This is in contrast with the temperature dependence observed at the Mn L_3 edge, which reflects the Mn magnetic order parameter. Work performed at BNL was supported by the US Department of Energy, Division of Materials Science, under contract No. DE-AC02-98CH10886.

9:12AM Y19.00003 Dynamic magnetoelectric interaction in multi-orbital Mott insulators¹, MAXIM MOSTOVOY, Zernike Institute for Advanced Materials, University of Groningen — The control of spin textures in magnetic insulators with an applied voltage can be of great importance for dissipationless spintronics. The coupling between spin and charge degrees of freedom in Mott insulators originates from the fluctuations of electron occupancy of strongly correlated orbitals of transition metal ions. Several microscopic mechanisms resulting from the virtual hopping of electrons from a magnetic site to its neighbor, e.g. the “inverse Dzyaloshinskii-Moriya” and the Heisenberg exchange striction mechanisms, are responsible for the electric polarization induced by non-centrosymmetric magnetic orders, the excitation of spin waves with the oscillating electric field of a light wave, and other effects recently observed in multiferroic materials. I will discuss a new dynamic magnetoelectric interaction, which describes the electric polarization induced by time-dependent spin textures [1]. Simple symmetry arguments as well as the explicit derivation from an extended Hubbard model of multi-orbital Mott insulators are used to obtain the form of this interaction, which is the electric analogon of the coupling between the scalar spin chirality and magnetic field. It is closely related to the so-called spinmotive force exerted by spins on electrons in magnetic conductors. This interaction makes possible to displace spin textures in ferromagnetic insulators by applying a voltage. It couples the external electric field to the center-of-mass coordinates of topological spin textures in ferromagnetic thin films, such as Skyrmions and magnetic vortices. The effect of this coupling is dramatically amplified in the resonant absorption of circularly polarized light by spin vortices in nanodiscs.

9:48AM Y19.00004 Multiferroic vortices: arrested Kosterlitz-Thouless order¹, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials — The fascinating concept of topological defects permeates ubiquitously our understanding of the early-stage universe, hurricanes, quantum matters such as superfluids and superconductors, and also technological materials such as liquid crystals and magnets. Large-scale spatial configurations of these topological defects have been investigated only in a limited degree. Exceptions include the cases of supercurrent vortices or liquid crystals, but they tend to exhibit either trivial or rather-irregular configurations. Hexagonal REMnO_3 (RE= rare earths) with RE=Ho-Lu, Y, and Sc, is an improper ferroelectric where the size mismatch between RE and Mn induces a trimerization-type structural phase transition, and this structural transition leads to three structural domains, each of which can support two directions of ferroelectric polarization. We reported that domains in h- REMnO_3 meet in cloverleaf arrangements that cycle through all six domain configurations. Occurring in pairs, the cloverleaves can be viewed as vortices and antivortices, in which the cycle of domain configurations is reversed. Vortices and antivortices are topological defects: even in a strong electric field they won't annihilate. These ferroelectric vortices/antivortices are found to be associated with intriguing magnetism. The seemingly-irregular configurations of a zoo of multiferroic vortices and antivortices in h- REMnO_3 can be neatly analyzed in terms of graph theory and this graph theoretical analysis reflects the nature of self-organized criticality in complexity phenomena as well as the condensation and eventual annihilation processes of topological vortex-antivortex pairs. Furthermore, these numerous multiferroic vortices/antivortices can be understood as an arrested Kosterlitz-Thouless phase.

10:24AM Y19.00005 Interplay between trimerization, ferroelectric, and magnetic order in the hexagonal manganites¹, MANFRED FIEBIG, Department of Materials, ETH Zurich — The hexagonal manganites h- RMnO_3 with R = Sc, Y, In, Dy – Lu are a model system for multiferroics with pronounced magnetoelectric effects in which the magnetic and ferroelectric order emerge independently (so-called split-order-parameter or type-I multiferroics). In spite of many years of intense investigations the system never ceases to surprise us with novel, unexpected manifestations of its five-fold long-range order (antiferrodistortive, ferroelectric, antiferromagnetic Mn order, and rare-earth order on the 2a and 4b sites). Here I will discuss several such examples: (i) “Incompatible” magnetic order of the Mn and rare-earth sublattices according to different symmetry representations in combination with triggered ordering at the 4b site. (ii) The absence of ferroelectric order in h- InMnO_3 down to low temperatures in spite of its apparent similarities to, in particular, h- YMnO_3 . (iii) Observation of a direct and rigid coupling of the ferroelectric to the antiferrodistortive order in annealing experiments at 1300 K. In summary, all these experiments allow us to present a comprehensive model for the microscopic origin of the ferroelectric and the multiple magnetic (re-) ordering in this important group of compounds.

Friday, March 2, 2012 8:00AM - 11:00AM –
Session Y20 DCMP GSNP: Invited Session: New Anisotropy-Driven Phenomena in Colloidal Suspensions 253C

8:00AM Y20.00001 Entropically patchy particles: Shape-driven self assembly of hard colloids¹

, SHARON GLOTZER, Department of Chemical Engineering, University of Michigan, Ann Arbor, MI — Although the structural diversity of colloidal fluids and crystals has grown substantially in recent years, it still aspires to that of atomic and molecular systems. Ionic colloidal crystals and binary nanoparticle superlattices, by exploiting electrostatic interactions in mixtures of particles of opposite charge, have substantially broadened the diversity of structures beyond those obtainable in traditional hard sphere systems, but rely on energetic interactions as well as entropy for their stability. Likewise, “traditional” patchy particles with sticky interactions exploit explicit attractive interactions for assembly. Here we explore the role of shape and entropy in phase transitions of hard particle fluids, in the absence of all other interactions. Using computer simulations, we show that particle shape alone can suffice to produce a rich diversity of colloidal crystals, quasicrystals, glasses and mesophases through thermodynamic self-assembly whose complexity rivals that of atomic analogues. We compare self-assembled phases of hard polyhedra with their dense packings obtained from small unit cell compressions, and show the packings tend to be less structurally complex than the assemblies. Based on our findings, we present design rules for anisotropic hard, faceted colloids as “entropically patchy particles” for self assembly.

8:36AM Y20.00002 Lock-and-Key Colloids¹

, DAVID PINE, New York University — We have developed a new kind of colloidal particle that is spherical but with one or more spherical dimples in the particle surface. These dimples serve as docking points for colloidal spheres whose radius matches the radius of dimples. The attractive docking force is provided by the depletion interaction and can be controlled by changing the depletant concentration or, in some cases, the temperature. The docking is completely reversible and mimics the classic lock-and-key interaction often used to describe protein binding. The lock-and-key binding is size specific and can be used to assemble a number of interesting colloidal superstructures, including flexible jointed chains, dumbbells, trimers, tetramers, and other assemblies. A new synthetic method for making the dimpled particles can be generalized to make a number of other new structured colloidal particles, with different functionalities analogous to block copolymers.

9:12AM Y20.00003 Glass transitions in quasi-two-dimensional suspensions of colloidal ellipsoids

, YILONG HAN, Hong Kong University of Science and Technology — Colloidal glasses constitute of anisotropic particles were mainly studied by simulations in three dimensions with incomplete phase diagrams. Here we report the experiment about glass transitions in a colloidal suspension of micro-ellipsoids at the single-particle level. Video microscopy revealed a two-step glass transition corresponding to inter-domain freezing and inner-domain freezing respectively. The glass transition in the rotational degree of freedom was at a lower density than that in the translational degree of freedom. Between the two transitions, ellipsoids formed an “orientational glass” in the area fraction range $0.72 < \phi < 0.79$ for aspect ratio $p = 6$ ellipsoids and $0.60 < \phi < 0.72$ for $p = 9$. Such orientational glass is expected to be replaced by the rotator phase at small aspect ratios and the nematic phase at large aspect ratios. The observed decoupling between diffusion and relaxation for both of translational and rotational motions reflects the dynamic heterogeneity. Approaching the respective glass transitions, the rotational and translational fastest-moving particles in the supercooled liquid moved cooperatively and formed clusters with power-law size distributions. The mean cluster sizes diverge in power law as approaching the glass transitions. The translational and rotational fastest- and slowest-moving ellipsoids are all spatially anticorrelated: most translational fast-moving ellipsoids and rotational slow-moving ellipsoids formed at different areas within pseudonematic domains, while most rotational fast-moving ellipsoids and translational slow-moving ellipsoids formed at different areas around the domain boundaries.

9:48AM Y20.00004 Suppression of the coffee-ring effect by shape-dependent capillary interactions

, PETER YUNKER, Univ of Pennsylvania — No abstract available.

10:24AM Y20.00005 Glassy dislocation dynamics in colloidal dimer crystals

, SHARON GERBODE, Harvey Mudd College — Dislocation mobility is central to both the mechanical response and the relaxation mechanisms of crystalline materials. Recent experiments have explored the role of novel particle anisotropies in affecting the rules of defect motion in crystals. “Peanut-shaped” colloidal dimer particles consisting of two connected spherical lobes form densely packed crystals in 2D. In these “degenerate crystals,” the particle lobes occupy triangular lattice sites while the particle axes are randomly oriented among the three crystalline directions. One consequence of the random orientations of the dimers is that dislocation glide is severely limited by certain particle arrangements in the degenerate crystals. Using optical tweezers to manipulate single lobe-sized spherical intruder particles, we locally deform the crystal, creating defects. During subsequent relaxation, the dislocations formed during the deformation leave the crystal grain, either via annihilation with other dislocations or by moving to a grain boundary. Interestingly, in large crystalline grains this dislocation relaxation occurs through a two-stage process reminiscent of slow relaxations in glassy systems, suggesting the novel concept that glassy phenomena may be introduced to certain kinds of colloidal crystals via simple anisotropic constituents.

Session Y21 DCMP: Bi-based Cuprates – Experiment 254A

8:00AM Y21.00001 Phase Determination for Intra-unit-cell Fourier Transform STM – Picometer Registration of Zn Impurity States in $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$

, INES FIRMO, MOHAMMAD HAMIDIAN, KAZUHIRO FUJITA, SOURIN MUKHOPADHYAY, Cornell University; Brookhaven National Lab, JOSEPH ORENSTEIN, University of California, Berkeley, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology, Japan, SHIN-ICHI UCHIDA, University of Tokyo, Japan, MICHAEL LAWLER, EUN-AH KIM, Cornell University, J.C. DAVIS, Cornell University; Brookhaven National Lab; University of St. Andrews, Scotland; Kavli Institute at Cornell — By studying the real and imaginary components of the Bragg peaks in Fourier transforms of electronic structure images, distinct types of intra-unit cell (IUC) symmetry breaking can be studied using SI-STM [Lawler *et al.*, Nature **466** 347 (2010)]. However, establishing the precise r-space symmetry point of each unit cell is crucial in defining the phase for such analysis. Exemplary of this challenge is the high- T_c superconductor $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ for which the Bi atoms in the surface BiO layer are observable, while it is the invisible Cu atoms that define the relevant CuO_2 unit-cell symmetry point. We demonstrate, by imaging with pm precision the electronic impurity states at individual Zn atoms substituted at Cu sites, that the phase established using the Bi lattice produces a $\sim 2\%(2\pi)$ error relative to the Cu lattice. In this case, IUC C_{4v} symmetry breaking in the CuO_2 plane can be determined reliably using the phase assignment from the BiO layer. Moreover, impurity atom substitution at the relevant symmetry site can be of general utility in phase determination for Bragg-peak Fourier analysis of IUC symmetry.

8:12AM Y21.00002 Imaging broken symmetry in the electronic structure of Bi-doped cuprates by scanning tunneling microscopy¹, YANG HE, TESS WILLIAMS, ANJAN SOUMYANARAYANAN, MICHAEL YEE, Harvard University, TAKESHI KONDO, HIROSHI IKUTA, Nagoya University, ERIC HUDSON, Pennsylvania State University, JENNIFER HOFFMAN, Harvard University — The relationship between the mysterious pseudogap phase in the cuprate superconductors and the myriad broken symmetries observed by various experimental techniques is a source of much controversy. We use low-temperature scanning tunneling microscopy and spectroscopy to image electronic nematic order in the cuprate superconductor $\text{Bi}_{2-x}\text{Pb}_x\text{Sr}_2\text{CuO}_{6+\delta}$. We determine the robustness of the nematic order parameter to experimental conditions.

¹We acknowledge funding from NSF(DMR-0847433), NDSEG, A*STAR, and NSERC.

8:24AM Y21.00003 Investigating structural distortions in Bi based superconductors by scanning tunneling microscopy¹, MICHAEL M. YEE, ILIJA ZELJKOVIC, Department of Physics, Harvard University, ANJAN SOUMYANARAYANAN, Department of Physics, Massachusetts Institute of Technology, ELIZABETH MAIN, T. WILLIAMS, Department of Physics, Harvard University, TAKESHI KONDO, T. TAKEUCHI, HIROSHI IKUTA, Department of Crystalline Materials Science, Nagoya University, G.D. GU, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, E.W. HUDSON, Department of Physics, Pennsylvania State University, JENNIFER E. HOFFMAN, Department of Physics, Harvard University — We use scanning tunneling microscopy to image symmetry-breaking structural distortions in the bismuth-based high- T_c superconductors, $\text{Bi}_2\text{Sr}_2\text{Ca}_{n-1}\text{Cu}_n\text{O}_{2n+4+x}$ (BSCCO). To elucidate the structure, we have implemented a new algorithm that quantifies atomic distortions with picometer resolution. Using this algorithm, we have observed an in-plane inversion-symmetry-breaking orthorhombic structural distortion in the BiO layer. We have also quantified the lattice distortions resulting from the use of Pb substitution to suppress the supermodulation in BSCCO. Each of these structural distortions break point group symmetries of the CuO_2 plaquette, which may be generally relevant to understanding the broken symmetries of the mysterious pseudogap state in high- T_c cuprates.

¹We acknowledge support from NSERC (DMR-0847433), A*STAR, NDSEG and NSERC.

8:36AM Y21.00004 Exploring the Nature of the Electronic Scatters in $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$, EDUARDO CALLEJA, JIXIA DAI, University of Colorado at Boulder, GENDA GU, Brookhaven National Laboratory, KYLE MCELROY, University of Colorado at Boulder — The superconducting cuprates have been one of the most studied classes of materials over the last 20 years. While much progress has been made in understanding the strange electronic properties which govern their rich phase diagram, the interplay between coulomb interactions (which are thought to play a key role in their unconventional superconductivity) and the corresponding quasi particle scattering caused by coulomb interactions, are still the subject of debate among the community. We attempt to explore this issue by using spectroscopic imaging scanning tunneling spectroscopy (SI-STs) at variable temperatures which allows us to probe the Local Density of States (LDOS). The LDOS can be fitted with the theorized Dynes' formula allowing for the extraction of the quasi particle scattering rates. Furthermore, we seek to understand the scattering process by simulating the patterns produced by quasi particle interference (QPI) by either a pair potential impurity or a non-magnetic impurity. Extraction of these rates at various dopings and temperatures in the phase diagram will be presented.

8:48AM Y21.00005 Imaging the impact of single dopant atoms on the electronic order and disorder of $\text{Bi}_{2+y}\text{Sr}_{2-y}\text{CaCu}_2\text{O}_{8+x}$ ¹, ILIJA ZELJKOVIC, Harvard University, GENDA GU, Brookhaven National Laboratory, JENNIFER HOFFMAN, Harvard University — High- T_c cuprate superconductors display startling nanoscale disorder in essential properties such as critical temperature, pseudogap energy, and even band structure. The underlying cause of this disorder has remained mysterious; theoretical explanations have ranged from chemical inhomogeneity to spontaneous electronic phase separation. We extend the energy range of scanning tunneling spectroscopy, allowing the first-ever direct mapping of both types of interstitial oxygen dopants in $\text{Bi}_{2+y}\text{Sr}_{2-y}\text{CaCu}_2\text{O}_{8+x}$, as well as vacancies at the apical oxygen site. We show that a subset of these dopants are indeed the direct cause of the nanoscale disorder. We further explain how the spatial variations in electronic orders, such as the pseudogap and the charge order, are governed by the disorder in the dopant concentrations, particularly vacancies in the apical oxygen site.

¹We acknowledge the support from NSF Career (DMR-0847433).

9:00AM Y21.00006 Imaging Locally Oriented Charge Modulations in a Cuprate Superconductor, JENNIFER HOFFMAN, ELIZABETH MAIN, Harvard University, BENJAMIN PHILLABAUM, Purdue University, HIROSHI IKUTA, Nagoya University, ERIC HUDSON, Penn State University, KARIN DAHMEN, University of Illinois, Urbana-Champaign, ERICA CARLSON, Purdue University — We use scanning tunneling microscopy to image the local orientation of the static charge modulations in $\text{Bi}_{2-y}\text{Pb}_y\text{Sr}_{2-z}\text{La}_z\text{CuO}_{6+x}$, for samples spanning a wide range of doping. For each sample, we compute the size distribution of locally x -oriented and locally y -oriented clusters. We analyze the size distributions within a random field Ising model to obtain the fractal dimension and other critical exponents. We discuss the utility of scaling collapse to extract the critical doping x_c of the smectic charge order in $\text{Bi}_{2-y}\text{Pb}_y\text{Sr}_{2-z}\text{La}_z\text{CuO}_{6+x}$.

9:12AM Y21.00007 Structure of intra-unit cell C_{4v} symmetry breaking domains in $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ from SI-STM, MOHAMMAD HAMIDIAN, INES FIRMO, KAZUHIRO FUJITA, Cornell University; Brookhaven National Lab, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology, Japan, SHIN-ICHI UCHIDA, University of Tokyo, Japan, MICHAEL LAWLER, EUN-AH KIM, Cornell University, J.C. DAVIS, Cornell University; Brookhaven National Lab; University of St. Andrews, Scotland; Kavli Institute, Cornell — Mounting evidence from a number of experimental probes supports the idea that the electronic structure of the cuprate pseudogap phase breaks rotational symmetry. Furthermore, ARPES, neutron scattering and spectroscopic imaging scanning tunneling microscopy (SI-STM) data all point to an intra-unit cell origin. We present new findings for near optimally doped $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ (BSCCO) which elucidate the domains associated with intra-unit cell C_{4v} symmetry breaking in the electronic structure. The analysis method will be motivated by the preceding talk, 'Phase Determination of Intra-Unit Cell Fourier Transform STM – Picometer Registration of Zn Impurity States in $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8$ ' given by I. A. Firmo.

9:24AM Y21.00008 Optical conductivity of exfoliated $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ nanocrystals, LUKE SANDILANDS, VIKTORIYA BAYDINA, ALEXANDER SU, ANJAN REIJNDERS, University of Toronto, Canada, TOR PEDERSEN, FERENC BORONDICS, Canadian Light Source, Canada, GENDA GU, Brookhaven National Laboratory, USA, SHIMPEI ONO, University of Tokyo, Japan, YOICHI ANDO, Osaka University, Japan, KENNETH BURCH, Institute for Optical Sciences, University of Toronto, Canada — We report on infrared spectromicroscopy of mechanically exfoliated under-doped and optimally-doped $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ thin crystals on SiO_2/Si substrates. The infrared reflectance and transmission was measured for samples of various thicknesses and the optical conductivity extracted in the frequency range 0.15 eV to 1 eV. Trends in the optical conductivity with thickness are discussed. In particular, we observe that the conductivity of thicker (~ 100 nm) samples is comparable to bulk while that of thinner (~ 20 nm) samples is markedly suppressed.

9:36AM Y21.00009 Evidence of two-dimensional quantum critical behavior in the superfluid density of deeply underdoped $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+x}$, JIE YONG, MICHAEL HINTON, ANDY MCCRAY, Dept. of Physics, The Ohio State University, M. NAAMNEH, AMIT KANIGEL, Dept. of Physics, Technion, Israel, MOHIT Randeria, THOMAS LEMBERGER, Dept. of Physics, The Ohio State University — Evidence of two-dimensional (2-D) quantum critical fluctuations is observed in the superfluid density $n_s(T) \propto \lambda^{-2}(T)$ of deeply underdoped $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+x}$ (Bi-2212). Quantum critical behavior is indicated by the evolution of the T-dependence of $n_s(T)/n_s(0)$, which loses any evidence for thermal critical behavior and becomes quasi-linear when underdoping drops the transition temperature T_c below roughly 48K. Two-dimensionality is indicated by the linear scaling of transition temperature T_c with $n_s(0)$. The 2-D behavior contrasts with that of the less anisotropic $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$, which sustains 3D quantum critical fluctuations.

9:48AM Y21.00010 Coherent THz emission from isosceles-triangular mesas of $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8$, RICHARD KLEMM, ERICA LABERGE, CANDY REID, DUSTIN MORLEY, University of Central Florida, KAVEL DELFANAZARI, KAZUO KADOWAKI, University of Tsukuba — Using the standard emission patterns predicted for thin, isosceles triangular patch antennae, combined with a spatially uniform ac Josephson current source, we have performed two-parameter least-squares fits to our recently obtained unpublished experimental emission data from isosceles-triangularly-shaped $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ mesas. Our results support the notion that such irregular patch antennae shapes may be useful in constructing high-powered, tunable continuous-wave coherent sources of light in the sub-terahertz to terahertz regime.

10:00AM Y21.00011 Tunable sub-terahertz emission from intrinsic Josephson junctions in $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ enhanced by the internal cavity resonance¹, MANABU TSUJIMOTO, TAKASHI YAMAMOTO, KAVEH DELFANAZARI, RYO NAKAYAMA, TAKEO KITAMURA, MASASHI SAWAMURA, TAKANARI KASHIWAGI, HIDETOSHI MINAMI, MASASHI TACHIKI, University of Tsukuba, RICHARD KLEMM, University of Central Florida, KAZUO KADOWAKI, University of Tsukuba — Intense, continuous and coherent terahertz electromagnetic wave emission from the intrinsic Josephson junction system in cuprate high- T_c $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ with remarkably higher intensity [L. Ozyuzer *et al.*, Science **318**, 1291 (2007).] than previously generated from single or arrayed Josephson junctions has been understood by the enhancement of the output intensity by the internal cavity resonance. However, we have recently observed emission, which seems to have low enhancement due perhaps to the relatively low- Q factor, in a wide frequency range, covering almost all frequencies continuously as long as the ac Josephson effect is satisfied. This broadly tunable behavior is very different from that with the tunability found in the inner current-voltage branch region [M. Tsujimoto *et al.*, to be published in 2011.] and enables us to design useful and tunable sub-terahertz source devices. In the presentation, we will also discuss the possible high-power devices using the high- Q -electromagnetic cavity.

¹This work was supported in part by CREST-JST, WPI-MANA project (NIMS) and Strategic Initiative category (A) at the University of Tsukuba.

10:12AM Y21.00012 Effect of magnetic field on the coherent THz emission from mesas of single crystal $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$, TAKEO KITAMURA, TAKANARI KASHIWAGI, MANABU TSUJIMOTO, KAVEH DELFANAZARI, RYO NAKAYAMA, MASASHI SAWAMURA, TAKASHI YAMAMOTO, HIDEHIRO ASAI, HIDETOSHI MINAMI, MASASHI TACHIKI, KAZUO KADOWAKI, University of Tsukuba — Coherent and continuous electromagnetic (EM) waves radiation phenomena with a mesa structure of $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ single crystal have been investigated precisely in magnetic field up to only 200 Oe where the emission intensity decreases sharply expectedly for the field H parallel to the c -axis. The emission could not be observed above 20 Oe for $H//c$ -axis whereas it persisted up to 160 Oe for $H//ab$ plane [1]. These results indicate that both pancake vortices as well as Josephson vortices suppress the THz emission very strongly. On the other hand, the Josephson plasma resonance phenomena have been observed in both $H//ab$ and $H//c$ even in very high fields ($\sim$ Tesla). The emission processes are considered to be the reverse processes of the absorption. It is interesting to pose a question what happens in high fields in the EM waves emission. We show interesting experimental results of THz emission in high magnetic fields including low field region and will argue the mechanism of emission in high magnetic fields.

[1] K. Yamaki *et al.*, physica C **470** (2010) S804-805.

10:24AM Y21.00013 Quasiparticle dynamics in overdoped $\text{Bi}_{1.4}\text{Pb}_{0.7}\text{Sr}_{1.9}\text{CaCu}_2\text{O}_{8+\delta}$: Coexistence of superconducting gap and pseudogap below T_c , SARITHA K. NAIR, XINGQUAN ZOU, Nanyang Technological University, Singapore, JIAN-XIN ZHU, Los Alamos National Laboratory, CHRISTOS PANAGOPOULOS, Nanyang Technological University, Singapore, SHIGEYUKI ISHIDA, SHIN-ICHI UCHIDA, The University of Tokyo, ELBERT E.M. CHIA, Nanyang Technological University, Singapore — Photoexcited quasiparticle relaxation dynamics in overdoped $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ ($T_c=65$ K, hole doping $p=0.22$) single crystal is investigated as a function of temperature. We provide evidence of a ~ 22 meV pseudogap ($T^*\approx 100$ K) at this doping level. Moreover, this pseudogap vanishes at T^* . Our data support the scenario where both the superconducting gap and pseudogap coexist in the superconducting state. Our results also suggest an increased scattering rate between electrons and spin fluctuations as the sample enters the pseudogap phase. Phys. Rev. B **82**, 212503 (2010)

10:36AM Y21.00014 THz wave radiation from the triangular mesas in layered high- T_c superconductor $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ intrinsic Josephson junctions¹, KAVEH DELFANAZARI, MANABU TSUJIMOTO, TAKANARI KASHIWAGI, HIDEHIRO ASAI, TAKASHI YAMAMOTO, MASASHI SAWAMURA, TAKEO KITAMURA, RYO NAKAYAMA, KAZUYA ISHIDA, HIDETOSHI MINAMI, TOSHIAKI HATTORI, KAZUO KADOWAKI, University of Tsukuba — Recently, it has been reported that the mesa structures fabricated from single crystalline high- T_c superconductor $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ intrinsic Josephson junctions generate THz waves [1, 2]. However, most of radiations in the previous studies were observed either below the critical current where the junctions switched to the resistive state or around the retrapping region. We present here three types of emission for isosceles triangular mesas in which THz waves were also additionally detected above the critical current where the external current is increasing in the resistive branch structures. Furthermore, intense, coherent, monochromatic, continuous and tunable THz waves were observed in various triangular mesas fabricated by the focus ion beam (FIB) technique [3]. Moreover, elucidating the oscillating modes inside the mesas by precisely studying the IV characteristics, FT-IR spectrum and angular dependence of the emission intensity will be discussed in detail at meeting.

10:48AM Y21.00015 Particle-hole asymmetric QPI in the pseudogap phase of underdoped Bi-2212, CHUNG KOO KIM, Cornell, BNL, JHINHWAN LEE, KAIST, KAZUHIRO FUJITA, Cornell, HIROSHI EISAKI, AIST, SHINICHI UCHIDA, Tokyo University, J.C. SEAMUS DAVIS, Cornell, BNL, St. Andrews Univ., JINHO LEE, BNL — Quasi-Particle Interference (QPI) measured by STM revealed many interesting phenomena in Correlated Electron Systems. Particle-hole (p-h) symmetric QPI observed in the superconducting $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ disappears around the reduced zone boundary [1], while p-h asymmetric QPI's on non-superconducting $\text{Sr}_3\text{Ru}_2\text{O}_7$ [2] and $\text{Ca}(\text{Fe}_x\text{Co}_{1-x})_2\text{As}_2$ [3] identified dominant band structures, suggesting electronic nature of the nematic phases. In light of these discoveries, here we report the observation of p-h asymmetric QPI of underdoped $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ in the pseudogap phase continuously dispersing through E_F . The Fermi velocity measured from this dispersion is $\sim 0.12 \times 10^6$ m/s. We will discuss the possible origin and implications by comparing its symmetry and dispersion using theoretical model and currently available experimental data from other probes.

Friday, March 2, 2012 8:00AM - 11:00AM –
Session Y22 DMP DCOMP: Focus Session: Fe-based Superconductors - Crystal Growth and New Materials 254B

8:00AM Y22.00001 Single crystal growth and physical properties of SrCu_2As_2 , SrCu_2Sb_2 and BaCu_2Sb_2 ¹, V.K. ANAND, P.K. PERERA, A. PANDEY, R.J. GOETSCH, A. KREYSSIG, D.C. JOHNSTON, Ames Laboratory and Dept. Phys. Astron., Iowa State Univ., Ames, IA 50011 — We present the physical properties of self-flux-grown single crystals of SrCu_2As_2 , SrCu_2Sb_2 , $\text{SrCu}_2(\text{As}_{0.84}\text{Sb}_{0.16})_2$ and BaCu_2Sb_2 investigated by magnetic susceptibility χ , specific heat C_p and electrical resistivity ρ vs. temperature T measurements. Contrasting structures occur for SrCu_2As_2 (ThCr_2Si_2 -type), SrCu_2Sb_2 (CaBe_2Ge_2 -type) and BaCu_2Sb_2 (a distorted intergrowth of ThCr_2Si_2 -type and CaBe_2Ge_2 -type unit cells). The $\chi(T)$ data for all these compounds exhibit weakly anisotropic diamagnetic behaviors. For $1.8 \leq T \leq 300$ K, the $\rho(T)$ data show metallic character and are well-described by the Bloch-Grüneisen model, and the $C_p(T)$ data are well-fitted by metallic γT plus Debye lattice contributions. From the low- T $C_p(T)$ data, we infer Sommerfeld coefficients $\gamma = 2.2\text{--}3.9$ mJ/mol K² and Debye temperatures $\Theta_D = 204\text{--}246$ K. The electronic properties indicate that these compounds are *sp* metals containing Cu in a nonmagnetic $3d^{10}$ electronic configuration.²

8:12AM Y22.00002 Synthesis of Large Single Crystals Within the Zr - Fe - Si System¹, GREG SMITH, JACOB E. GROSE, J.W. SIMONSON, M.C. ARONSON, Physics and Astronomy Dept., Stony Brook University — The synthesis of large single crystals of intermetallic silicides from a metal flux is challenging, owing to the poor solubility of silicon in many of the traditional fluxes at low temperatures. Accordingly, single crystal syntheses of several compounds within the Zr - Fe - Si system from a gallium flux were investigated. $\text{Zr}_4\text{Fe}_4\text{Si}_7$, a member of the well-known V-phase family of compounds, forms as silver lustrous rods. Successful growths yielded crystals with dimensions up to 12.1 mm by 0.14 mm by 0.14 mm, large enough to perform the first transport measurements of this compound. We grew for the first time single crystals of the hexagonal Laves phase $\text{ZrFe}_{1.5}\text{Si}_{0.5}$, which has previously only been reported in the polycrystalline form. Two previously unreported phases, including the silver lustrous rods $\text{Zr}_{2-x}\text{Fe}_4\text{Si}_{12-y}$, have been discovered as single crystals within this system. The composition of all phases was verified with powder and single crystal x-ray diffraction. Our group is currently investigating the growth of similar compounds using the methods developed for this system.

¹Research supported by a DOD National Security Science and Engineering Fellowship via the AFOSR

8:24AM Y22.00003 Exploration of Superconductivity in Layered Structures¹, ATHENA SEFAT, Oak Ridge National Laboratory — Superconductivity at high temperatures is of great interest in terms of both basic science and applications. Although there are many findings on the chemistry and physics of superconductors, there are a lot of questions that remain unanswered. We will review experimental routes to possibly finding and identifying new superconducting materials.

¹This work is supported by the Department of Energy, Basic Energy Sciences, Materials Sciences and Engineering Division.

9:00AM Y22.00004 High T_c electron doped $\text{Ca}_{10}(\text{Pt}_3\text{As}_8)(\text{Fe}_2\text{As}_2)_5$ and $\text{Ca}_{10}(\text{Pt}_4\text{As}_8)(\text{Fe}_2\text{As}_2)_5$ superconductors¹, NI NI, JARED M. ALLRED, Chemistry department, Princeton University, BENNY C. CHAN, Department of Chemistry, The College of New Jersey, ROBERT J. CAVA, Chemistry department, Princeton University, NI NI, J. M. ALLRED, R. J. CAVA TEAM, B. C. CHAN COLLABORATION — In this talk, we will present the crystal structures and physical properties of two new iron arsenide superconductors, $\text{Ca}_{10}(\text{Pt}_3\text{As}_8)(\text{Fe}_2\text{As}_2)_5$ (the “10-3-8 phase”) which crystallizes in the triclinic structure and $\text{Ca}_{10}(\text{Pt}_4\text{As}_8)(\text{Fe}_2\text{As}_2)_5$ (the “10-4-8 phase”) which crystallizes in the tetragonal structure. They are very similar compounds for which the most important differences lie in the structural and electronic characteristics of the intermediary platinum arsenide layers. Electron doping through partial substitution of Pt for Fe in the FeAs layers leads to T_c of 11 K in the 10-3-8 phase and 26 K in the 10-4-8 phase. The anisotropic H_{c2} measurement indicates the multiband superconductivity in these compounds. The often-cited empirical rule in the arsenide superconductor literature relating T_c to As-Fe-As bond angles does not explain the observed differences in T_c of the two phases; rather, comparison suggests the presence of stronger FeAs interlayer coupling in the 10-4-8 phase due to the two-channel interlayer interactions and the metallic nature of its intermediary Pt_4As_8 layer. The interlayer coupling is thus revealed as important in enhancing T_c in the iron pnictide superconductors.

9:12AM Y22.00005 Influence of Cr-doping on the magnetic structure of the FeAs strip compounds CaFe_4As_3 : a single crystal neutron diffraction study, PASCAL MANUEL, ISIS Facility, STFC Rutherford Appleton Laboratory, Chilton, Didcot OX11 0QX, United Kingdom, LAURENT CHAPON, Institut Laue Langevin, 6 rue Jules Horowitz, BP156, Grenoble Cedex 9, France, ILLIYA TODOROV, DUCK Y. CHUNG, Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439, BACHIR OULADDIAF, Institut Laue Langevin, 6 rue Jules Horowitz, BP156, Grenoble Cedex 9, France, MERCOURI G. KANATZIDIS, Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439 & Department of Chemistry, Northwestern University — CaFe_4As_3 offers the unique opportunity to modify the topology of the Fe_2As_2 layers, key in the understanding of superconductivity in the new iron pnictide superconductors, from infinite layers to strips of finite width linked a rectangular cross pattern. Bulk measurement on CaFe_4As_3 indicate a magnetic ordering at 90K with a second transition seen at about 26K. Neutron diffraction allowed to ascribe the high temperature transition to a Spin Density Wave(SDW) with a propagation vector $\mathbf{k}=(0,\delta,0)$ eventually locking to $\delta=3/8$ at the lower transition. As expected a profound effect on the magnetic properties of CaFe_4As_3 can be obtained by chemically doping or applying pressure. We report here on the consequence of Cr-doping on the magnetic structure of CaFe_4As_3 derived from single crystal neutron diffraction.

9:24AM Y22.00006 Anisotropic H_{c2} curves determined up to 92 T and the signature of two-band superconductivity in the novel superconductor $\text{Ca}_{10}(\text{Pt}_4\text{As}_8)((\text{Fe}_{1-x}\text{Pt}_x)_2\text{As}_2)_5$, EUNDEOK MUN, VIVIEN ZAPF, OSCAR AYALA, ROSS MCDONALD, NEIL HARRISON, National High Magnetic Field Laboratory (NHMFL), Los Alamos National Lab (LANL), Los Alamos, NM, NI NI, JARED ALLRED, ROBERT CAVA, Department of Chemistry, Princeton University, Princeton, NJ 08544, USA — The upper critical fields, $H_{c2}(T)$, of single crystals of the novel superconductor $\text{Ca}_{10}(\text{Pt}_4\text{As}_8)((\text{Fe}_{1-x}\text{Pt}_x)_2\text{As}_2)_5$ with $x=0.02$ were determined over a wide range of temperatures down to $T = 1.42$ K and magnetic fields up to $H = 92$ T. The measurements of anisotropic $H_{c2}(T)$ curves are performed in pulsed magnetic fields using radio-frequency contactless penetration depth measurements for magnetic field applied both parallel and perpendicular to the ab-plane. Whereas a clear upward curvature in $H_{c2}^c(T)$ along $H||c$ is observed with decreasing temperature, the $H_{c2}^{ab}(T)$ along $H||ab$ shows a flattening at low temperatures. The rapid increase of the $H_{c2}^c(T)$ suggests that the superconductivity can be described by two dominating bands. The anisotropy parameter, $H_{c2}^{ab}(T)/H_{c2}^c(T)$, is ~ 7 close to T_c and decreases considerably to ~ 1 with decreasing temperature, showing rather weak anisotropy at low temperatures.

9:36AM Y22.00007 Direct measurement of the absolute value of the magnetic penetration depth in two-dimensional pnictide superconductor $\text{Ca}_{10}(\text{Pt}_3\text{As}_8)[(\text{Fe}_{1-x}\text{Pt}_x)_2\text{As}_2]_5$, JEEHOON KIM, FILIP RONNING, LANL, EVGENY NAZARETSKI, BNL, NI NI, J.M. ALLRED, R.J. CAVA, Princeton University, J.D. THOMPSON, R. MOVSHOVICH, LANL — We have measured the absolute value of the magnetic penetration depth λ in a single crystal of the $\text{Ca}_{10}(\text{Pt}_3\text{As}_8)[(\text{Fe}_{1-x}\text{Pt}_x)_2\text{As}_2]_5$ ("10-3-8") superconductor using low temperature magnetic force microscopy (MFM). We directly probed local values of λ in the "10-3-8" sample using Meissner response measurements and compared Meissner curves to those obtained in a Nb reference sample. The Meissner response measured at different locations on the sample shows similar behavior indicating homogeneity of the superconducting state, in accord with tunnel-diode resonator measurements. We also discuss larger values of λ in 10-3-8 relative to λ values measured in other pnictide systems.

9:48AM Y22.00008 Local Displacements, Magnetoelastic Coupling, and Bonding in Spin-Ladder Iron Selenides, JAMES NEILSON, JOSEPH CARON, DAVID MILLER, Johns Hopkins University, ANNA LLOBET, Los Alamos National Laboratory, TYREL MCQUEEN, Johns Hopkins University — The spin-ladder "1-2-3" compounds BaFe_2Se_3 and KFe_2Se_3 , built of double-chains of edge-sharing $[\text{FeSe}_4]$ tetrahedra, are localized-moment antiferromagnetic semiconductors. Total neutron scattering of BaFe_2Se_3 reveals local iron displacements coupled to long-range ordered antiferromagnetism comprised of ferromagnetic Fe_4 plaquettes. The magnitude of the iron displacements follow the antiferromagnetic order parameter: a manifestation of magnetoelastic coupling. These local displacements are essential for properly understanding the electronic structure of these systems, as local structural modulations necessarily perturb the ground state wavefunctions. Furthermore, while iron displacements from magnetoelastic coupling in FeX_4 -based materials are hypothesized to be important in the emergence of superconductivity, the spin-ladders remain insulating down to 1.8 K, even upon hole doping by substitution of K for Ba. As with the copper oxide superconductors two decades ago, our results highlight the importance of reduced dimensional spin-ladder compounds in the study of the coupling of spin, charge, and atom positions in superconducting materials.

10:00AM Y22.00009 Spin glass and semiconducting behavior of the flux grown $\text{BaFe}_{2-\delta}\text{Se}_3$ crystals¹, BAYRAMMURAD SAPAROV, STUART CALDER, BALAZS SIPOS, HUIBO CAO, SONGXUE CHI, DAVID SINGH, ANDREW CHRISTIANSON, MARK LUMSDEN, ATHENA SEFAT, Oak Ridge National Laboratory — In this talk, physical properties and crystal and electronic structures of $\text{BaFe}_{2-\delta}\text{Se}_3$ crystals, synthesized using tellurium flux, will be discussed. This phase is an iron-deficient derivative of the ThCr_2Si_2 -type and its structure is made of double chains formed from edge-sharing FeSe_4 tetrahedra. The semiconducting $\text{BaFe}_{2-\delta}\text{Se}_3$ with $\delta \approx 0.2$ does not order magnetically, however, there is evidence for short-range magnetic correlations of spin glass type below 50 K in magnetization, heat capacity and neutron diffraction results. The semiconducting behavior of $\text{BaFe}_{2-\delta}\text{Se}_3$ is in line with the detrimental influence of iron deficiency to the superconductivity in $A_x\text{Fe}_{1.8}\text{Se}_2$ (A = alkali metal) superconductors. The electronic structure calculations suggest that this compound can be considered as a low-dimensional (1D) ladder structure with a weak interchain coupling. Based on the survey of available data on BaFe_2Se_3 so far, lower concentrations of iron vacancies may lead to a long range antiferromagnetic order, whereas higher concentrations of iron vacancies may suppress long range order and then lead to a spin glass behavior.

10:12AM Y22.00010 $\text{Ba}_{1-x}\text{K}_x\text{Mn}_2\text{As}_2$: An Antiferromagnetic Local Moment Metal¹, ABHISHEK PANDEY, R.S. DHAKA, J. LAMSAL, Y. LEE, V.K. ANAND, A. KREYSSIG, R.J. MCQUEENEY, A. GOLDMAN, B.N. HARMON, A. KAMINSKI, D. C. JOHNSTON, Ames Laboratory and Dept. Phys. Astron., Iowa State Univ., Ames, IA 50011, T.W. HEITMANN, The Missouri Research Reactor, Univ. Missouri, Columbia, MO 65211 — The syntheses of K-doped single crystalline $\text{Ba}_{0.984}\text{K}_{0.016}\text{Mn}_2\text{As}_2$ and polycrystalline $\text{Ba}_{0.95}\text{K}_{0.05}\text{Mn}_2\text{As}_2$ with the tetragonal ThCr_2Si_2 structure are reported. Electrical resistivity, heat capacity, magnetic susceptibility, angle-resolved photoemission spectroscopy and neutron diffraction measurements and spin-polarized electronic structure calculations consistently establish that these hole-doped $\text{Ba}_{1-x}\text{K}_x\text{Mn}_2\text{As}_2$ samples are antiferromagnetic local-moment metals, in contrast to the parent BaMn_2As_2 [1-3] which is an antiferromagnetic local-moment semiconductor. This new class of materials bridges the gap between the iron pnictide and cuprate high T_c materials. Investigations of the phase diagram of the $\text{Ba}_{1-x}\text{K}_x\text{Mn}_2\text{As}_2$ system and other similar systems are underway.

10:24AM Y22.00011 Role of ruthenium in iron-based superconductors and related materials¹

, MICHAEL MCGUIRE, ATHENA SEFAT, BRAIN SALES, Oak Ridge National Laboratory — Ruthenium and iron share the same valence electron count, and form many isostructural compounds. However, the larger covalent radius and extent of the d-electrons of ruthenium lead to interesting and sometimes unexpected behavior when iron is partially or fully substituted by ruthenium. For example, “doping” layered iron compounds with ruthenium has been shown to produce superconductivity in some cases but not others, and ruthenium analogs of certain layered iron compounds do not form under similar conditions. We have investigated full and partial ruthenium substitution in several iron-based materials, including the superconducting 1111 and 122 families, and studied the effects on formation, crystal structures, and physical properties. Our new experimental findings and results from available literature will be used to discuss the unusual role that ruthenium plays in iron-based superconductors and related materials.

10:36AM Y22.00012 Neutron Diffraction Studies on $\text{Ba}_{0.95}\text{K}_{0.05}\text{Mn}_2\text{As}_2$, J. LAMSAL, Ames Lab and Dept.

Phys. Astron., Iowa State Univ, Ames, IA 50011, T.W. HEITMANN, The Missouri Research Reactor, Univ. of Missouri, Columbia, MO 65211, A. PANDEY, V.K. ANAND, Y. LEE, R.S. DHAKA, A. KAMINSKI, B.N. HARMON, D.C. JOHNSTON, R.J. MCQUEENEY, A. KREYSSIG, A.I. GOLDMAN, Ames Lab and Dept. Phys. Astron., Iowa State Univ, Ames, IA 50011 — There has been a great deal of interest in compounds, such as BaMn_2As_2 , which are closely related to the iron pnictide superconductors. Although undoped BaMn_2As_2 is an antiferromagnetic (AF) insulator[1, 2], recent studies of lightly doped $\text{Ba}_{1-x}\text{K}_x\text{Mn}_2\text{As}_2$ have shown a striking change to metallic behavior for $x > 0.01$ and, therefore, may offer a bridge between the high T_c cuprates and the iron-pnictide superconductors. We will present neutron diffraction measurements on polycrystalline $\text{Ba}_{0.95}\text{K}_{0.05}\text{Mn}_2\text{As}_2$ performed on the powder diffractometer at the Missouri Research Reactor. Our measurements reveal that the antiferromagnetism in the doped compound remains nearly the same as that found for undoped BaMn_2As_2 , characterized by a G-type collinear AF spin structure below $T_N \sim 607(2)$ K with an ordered moment of $4.21(6) \mu_B/\text{Mn}$ ion at 14 K. Research at Ames Lab was supported by the USDOE, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

10:48AM Y22.00013 Growth of parent and electron doped NaFeAs , YU SONG, University of Tennessee —

It has been found hole doping on Fe sites in BaFe_2As_2 does not induce superconductivity with Cr and Mn as dopants, but doping on Ba sites with K induces superconductivity as high as 38K. We have investigated hole doping with Titanium to be compared with other hole doping compounds. Single crystals of Titanium doped BaFe_2As_2 were grown by flux method. Transport and susceptibility measurements were done showing doping Titanium suppresses the Neel temperature but no superconductivity was found up to 4% doping. Susceptibility measurements also showed spin glass behavior. Phase diagrams of temperature vs doping concentration have been constructed from transport and Susceptibility measurements.

Friday, March 2, 2012 8:00AM - 11:00AM —

Session Y23 DCMP: Superconductor-Insulator Transitions 255

8:00AM Y23.00001 Theory of Giant Magnetoresistance Peak in InO Superconducting Films

, ANIRBAN GANGOPADHYAY, JOE MITCHELL, VICTOR GALITSKI, University of Maryland, College Park, MARKUS MUELLER, The Abdus Salam International Centre for Theoretical Physics — It has been suggested that the giant magnetoresistance peak seen on the insulating side of a superconductor-insulator transition in $\text{In}_2\text{O}_{3-x}$ films is a signature of remanent localized pairs which can participate in variable-range-hopping transport. A theory of pair-transport must necessarily take into account the bosonic nature of the pairs, as opposed to the fermionic nature of single-electron carriers. We show that this opposite statistical nature of the carriers alone can lead to opposite variations of the localization length with magnetic field and thus be a possible candidate for explaining the giant magnetoresistance peak. We further provide an explanation of the pairing mechanism in $\text{In}_2\text{O}_{3-x}$ films. We argue that the electron pairing mechanism here is non-BCS-type and is related instead to the local effect of electron pairs occupying Oxygen vacancies (with charge +2e). The neutral state of these defects may be more stable than the singly-charged defect, as supported by an ab initio analysis. This simple phenomenon leads naturally to a negative-U Hubbard model with strong disorder.

8:12AM Y23.00002 Broadband microwave study of 2D superconductor-insulator quantum phase transition , WEI LIU, LIDONG PAN, Johns Hopkins University, MINSOO KIM, SAMBANDAMURTHY GANAPATHY, SUNY-Buffalo, PETER ARMITAGE, Johns Hopkins University —

Using our broadband microwave spectrometer, we investigate the complex AC conductance of disordered InO_x films as a function of magnetic field through the 2D superconductor-insulator quantum phase transition. We have studied the behaviors of the frequency dependent complex response function of a particular InO_x sample near the critical point in the limit of $\hbar\omega < K_B T$ and $\hbar\omega > K_B T$ and compare our results to theoretical models. We discuss the possibility for a novel insulating state on the insulating side of the transition through the frequency dependent conductance.

8:24AM Y23.00003 Superconductor-insulator transition in amorphous indium oxide films: Role of in-plane magnetic field , MINSOO KIM, TAILUNG WU, GANAPATHY SAMBANDAMURTHY, SUNY Buffalo, Buffalo, NY 14260 —

We present experimental results from transport studies on amorphous indium oxide films that are driven through a superconductor-insulator transition by applying a pair-breaking magnetic field. The direction of the magnetic field is varied continuously from being perpendicular to the film plane to parallel to the film plane and we identify characteristically different transport regimes at different magnetic field values when the film is rotated in a magnetic field. We also study the evolution of these transport regimes as a function of disorder in these films. A distinctly clear magnetic field value, in the insulating phase, at which the sample resistance is independent of the angle and very weakly dependent on temperature and disorder is observed. Implications for our current understanding of the 2D superconductor - insulator transition will be presented.

8:36AM Y23.00004 Evolution of magnetoresistance peak on disordered systems¹ , YEONBAE LEE,

University of Minnesota, Minneapolis — Measurements of the electric and magnetic properties of amorphous indium oxide films are reported. The carrier densities of films have been tuned by employing electrostatic gating using electric double layer transistor (EDLT) configurations employing the ionic liquid DEME.TFSI. We have observed the emergence of the magnetoresistance peak as films are tuned from the insulating to the superconducting regimes, and its disappearance as the system is doped further with additional carriers. The result also demonstrates the reversible tuning of the superconductor-insulator transition with low gate voltages

¹This work was supported by the DOE under Grant No. DE-FG02-02ER46004

8:48AM Y23.00005 Superconductor-Insulator transition in long Mo-Ge nanowires, HYUNJEONG KIM, ANDREY ROGACHEV, University of Utah — We have studied transport properties of two series of long (1-25 μ m) and very narrow (9-20nm) homogenous amorphous Mo-Ge wires fabricated by advanced electron beam lithography. We observed that the wires undergo a superconducting-insulator transition that is controlled by the wire cross sectional area, i.e. by local physics. Reduction of mean-field critical temperature can be explained by the fermionic mechanism. We also observed an unusual zero-bias anomaly in the insulating state that has signatures of both Coulomb blockade and perturbative electron-electron interaction correction. In addition, some of our long superconducting wires appear to be localized superconductor, namely in these wires one-electron localization lengths is several times shorter than the length of a wires.

9:00AM Y23.00006 The extent of the Cooper pair insulator phase in amorphous $\text{Pb}_{0.9}\text{Bi}_{0.1}$ nanohoneycomb films¹, S.M. HOLLEN, J.C. JOY, A.H. BERG, Brown University, Department of Physics, G.E. FERNANDES, Brown University, Division of Engineering, J. SHAINLINE, Brown University, Department of Physics, J.M. XU, Brown University, Division of Engineering, J.M. VALLES, JR., Brown University, Department of Physics — Amorphous Bi nanohoneycomb (NHC) thin films, which contain a nanometer-scale array of holes and regular thickness undulations, exhibit an insulating phase made up of localized Cooper pairs (CPs) near their thickness-driven insulator to superconductor transition (IST). This Cooper pair insulator (CPI) phase includes a giant magnetoresistance peak, also observed in InO_x and TiN. We have now produced NHC films of a new material, $\text{Pb}_{0.9}\text{Bi}_{0.1}$, that show a qualitatively similar CPI phase. We will show the evolution of this CPI phase from deep in the insulating state to the IST using transport measurements. Throughout this regime, we will track the appearance, growth, and range of the magnetoresistance oscillations (which indicate CP transport) and giant magnetoresistance peak. Considering these observations, we will discuss the likely extent of CP transport in these insulators.

¹This work is supported by the AAUW, the NSF through Grant No. DMR-0605797 and No. DMR-0907357, by the AFRL, and by the ONR.

9:12AM Y23.00007 Superconductor-to-Insulator Transition in $\text{BaPb}_{1-x}\text{Bi}_x\text{O}_3$, PAULA GIRALDO-GALLO, Geballe Laboratory for Advanced Materials and Department of Physics, Stanford University, HAN-OH LEE, Geballe Laboratory for Advanced Materials, Stanford University and SLAC National Accelerator Laboratory, THEODORE GEBALLE, IAN FISHER, Geballe Laboratory for Advanced Materials and Department of Applied Physics, Stanford University — BaBiO_3 is a charge density wave (CDW) insulator. Hole doping with Pb, i.e. $\text{BaPb}_{1-x}\text{Bi}_x\text{O}_3$, eventually suppresses the CDW, leading to superconductivity, with a maximum critical temperature T_c of 10 to 13K for $x \approx 0.25$. The origin of the CDW state, its doping dependence, the nature of the pairing mechanism and the effects introduced by disorder remain open questions. Here we investigate the normal state properties in the vicinity of the metal-semiconductor transition. Single crystalline samples of the solid solution $\text{BaPb}_{1-x}\text{Bi}_x\text{O}_3$, with $0 < x < 0.35$ were grown using a flux technique, and studied via measurements of resistivity, magnetoresistance, magnetic susceptibility and heat capacity. For compositions near the optimal doping, the material exhibits a magnetic field tuned superconductor-to-insulator transition with a temperature independent crossing point in resistivity, scaling as $\rho(T, H) = \rho_c f(|H - H_{\text{cross}}|T^{-1/0.65})$ for fields around H_{cross} , the crossing point field. These results are discussed in the context of quantum phase transitions and compared to the results obtained in 2D disordered thin films of other novel materials.

9:24AM Y23.00008 Electrostatic doping of high T_c superconductors¹, JOSEPH KINNEY, JAVIER GARCIA-BARRIOCANAL, XIANG LENG, ALEXEY KOBRINSKII, BOYI YANG, STEPHEN SNYDER, ALLEN GOLDMAN, University of Minnesota — The application of field effect transistor concepts to electrostatically doped strongly correlated electron systems has been the focus of intense research during the last years [C. H. Ahn et al., Rev. Mod. Phys. 78, 1185 (2006)]. In this talk we will show our recent results on Electronic Double Layer Transistor (EDLT) techniques applied to high T_c cuprates. The EDLT configuration, which employs ionic liquids as gate dielectrics, has succeeded in achieving unprecedented charge transfers, of the order of 10^{15} carriers/cm². This large accumulation and depletion of carriers allows us to explore the phase diagram of $\text{YBa}_2\text{Cu}_3\text{O}_{7-x}$ and $\text{La}_2\text{CuO}_{4+\delta}$. We will focus on the physics of the superconductor to insulator transition [X. Leng et al., Phys. Rev. Lett. 107, 027001 (2011)] and discuss the magneto-transport properties of the underdoped and overdoped regions of the phase diagram [X. Leng, et al., arXiv:1108.0083v1].

¹NSF/DMR-0709584 and NSF/DMR-0854752

9:36AM Y23.00009 Dynamic charge order and superconductivity in lightly doped $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$ thin films¹, XIAOYAN SHI, D. POPOVIC, Dept. of Phys. & Natl. High Magnetic Field Lab., Florida State Univ., C. PANAGOPOULOS, Dept. of Phys., Univ. of Crete and FORTH & Div. of Phys. and Appl. Phys., Nanyang Tech. Univ., A. BOLLINGER, G. LOGVENOV, I. BOZOVIC, Brookhaven Natl. Lab. — Recent experiments have demonstrated the existence of a charge glass state at very low temperatures deep within the spin glass phase ($T \ll T_{SG}$) in lightly doped, insulating $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$ (LSCO) with $x = 0.03$. Here we use magnetotransport measurements in a series of high quality MBE-grown LSCO films ($x = 0.03, 0.05, 0.055$, and 0.06) to investigate the doping dependence of this dynamically inhomogenous, charge ordered state as the superconductor-insulator transition (SIT) is approached. We show that the charge glassiness is suppressed with doping. Nevertheless, close enough to the SIT on the insulating side, it coexists and competes with superconducting fluctuations (SCFs), leading to a suppression of SCFs at low T .

¹Supported by NSF DMR-0905843, NHMFL via NSF DMR-0654118, EURYI, MEXT-CT-2006-039047, the National Research Foundation of Singapore, US DOE, Basic Energy Sciences, Materials Sciences and Engineering Division, and the Center for Emergent Superconductivity.

9:48AM Y23.00010 Two component Coulomb glass in disordered superconducting films, JOE MITCHELL, ANIRBAN GANGOPADHYAY, VICTOR GALITSKI, University of Maryland, College Park, MARKUS MUELLER, The Abdus Salam International Center for Theoretical Physics — We propose a new two component Coulomb glass model which includes strong disorder, Coulomb interaction, and on-site electron pairing to investigate the effects of localized pairing in disordered films on the insulating side of a superconductor-insulator transition. In particular, we show how the density of states (DOS) changes with increasing on-site coupling between electrons, from an Efros-Shklovskii linear DOS for the electrons at weak coupling, to a strongly modified, non-monotonic DOS with nonuniversal Coulomb gap for electrons and on-site pairs at moderate coupling, and finally to an Efros-Shklovskii linear DOS for pairs at strong coupling. We discuss the effects of a spatially random coupling. We use a Miller Abrahams resistor network mapping to numerically calculate resistance for samples of this model, given temperature and localization length. With certain parameter choices, we can obtain a peak in resistance with respect to magnetic field, reminiscent of magnetoresistance peaks reported experimentally.

10:00AM Y23.00011 ABSTRACT WITHDRAWN —

10:12AM Y23.00012 Superconductor-insulator transition in Josephson junction arrays screened by a superconducting ground plane, JOSHUA PARAMANANDAM, MICHAEL GERSHENSON, Rutgers University — We have studied quantum phase transitions in unconventional Josephson arrays with a large number of interacting nearest-neighbour islands (typically, 10). The range of inter-island interactions was controlled by the presence/absence of a superconducting ground plane placed in close proximity to the array. We have found that the superconductor-to-insulator transition occurs in the arrays with both short- and long-range interactions at $E_J/E_C \sim 1$. Here E_J is the effective Josephson energy per island, E_C is its charging energy. However, the critical resistance for the arrays with short-range interactions greatly exceeds the quantum resistance, in contrast to the case of arrays with long-range interactions. These experiments clearly show that the ratio E_J/E_C is the only relevant (for the SIT) parameter, while the critical resistance can vary a great deal depending on the interaction range.

10:24AM Y23.00013 Strong quantum interference in strongly disordered bosonic insulators, SERGEY SYZРАНOV, Institut fuer Theorie der Kondensierten Materie, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany, ANDREAS MOOR, KONSTANTIN EFETOV, Theoretische Physik III, Ruhr-Universität Bochum, 44780 Bochum, Germany — We study the model of variable-range hopping of bosons in an array of sites with short-range interactions and a large characteristic coordination number, which describes conduction in a broad class of insulators, such as strongly disordered superconductive films, systems close to the Anderson transition, Josephson networks, etc. Large coordination number leads to strong quantum interference phenomena yet allows for their analytical study. We develop a functional renormalization group scheme that repeatedly eliminates high-energy sites properly renormalizing the tunneling between the low-energy ones. Using this approach we determine the temperature and magnetic field dependence of the hopping conductivity and find a large positive magnetoresistance. With increasing magnetic field the behaviour of the conductivity crossovers from the Mott's law to an activation behaviour with the activation gap proportional to the magnetic field.

10:36AM Y23.00014 Numerical identification of three distinct phases in a $(2+1)D$ array of quantum dissipative Josephson junctions, EINAR STIANSEN, IVER BAKKEN SPERSTAD, ASLE SUDBØ, Department of Physics, Norwegian University of Science and Technology, N-7491 Trondheim, Norway — We have performed large-scale Monte-Carlo simulations on a model describing a $(2+1)D$ array of quantum dissipative Josephson junctions. With the superconducting phases as our fundamental degrees of freedom we are able to identify three distinct phases as function of Josephson coupling and dissipation strength. Apart from the fully superconducting state, where fluctuations in both space and time are at bay, and the normal phase, characterized by wild fluctuations, we find an additional phase featuring spatial phase coherence coinciding with temporal disorder.

10:48AM Y23.00015 Metallic state in La-doped $\text{YBa}_2\text{Cu}_3\text{O}_y$ thin films with n-type charge carriers¹, S.W. ZENG, X. WANG, W.M. LV, Z. HUANG, M. MOTAPOTHULA, Z.Q. LIU, Y. L. ZHAO, A. ANNADI, S. DHAR, T. VENKATESAN, - ARIANDO, NUSNNI-Nanocore, National University of Singapore, Singapore — Through substitution of La for Ba and reduction of oxygen, we successfully doped n- and p-type charge carriers into La-doped $\text{YBa}_2\text{Cu}_3\text{O}_y$ thin films synthesized by pulsed laser deposition technique. The n-type samples demonstrated metallic behaviors and in-plane resistivity exhibited a quadratic temperature dependence within the metallic regime, and then evolved into a $\ln T$ -dependence insulating-like state. Furthermore, the doping evolution of temperature with minimum resistivity (T_{min}) and electron-electron rate were investigated and showed asymmetry between p- and n-side. The present results suggest the potential of obtaining n-type superconductivity in La-doped $\text{YBa}_2\text{Cu}_3\text{O}_y$ and investigating n-p asymmetry (symmetry) in cuprates with the same crystallographic structure.

¹We thank National Research Foundation (NRF) Singapore under the Competitive Research Program (CRP) "Tailoring Oxide Electronics by Atomic Control" NRF2008NRF-CRP002-024 and Ministry of Education (MOE) FRC-ARF Grant No. R-144-000-278-112.

Friday, March 2, 2012 8:00AM - 10:48AM – Session Y24 DCOMP: Quantum Many-Particle Systems: DMFT & DMRG 256

8:00AM Y24.00001 A New Lanczos-Based Low Rank Algorithm for Inhomogeneous Dynamical Mean-Field Theory¹, PIERRE CARRIER, YOUSEF SAAD, University of Minnesota, JAMES K. FREERICKS, Georgetown University — Inhomogeneous DMFT is used to approximately solve models of ultracold atoms in optical lattices. The intensive part of the IDMFT algorithm is the solution of the Dyson equation for the local Green's function, which involves the computation of the diagonal of the inverse of a sparse matrix. Our new algorithm for finding the diagonal of the inverse of a large sparse matrix is based on domain decomposition into interior and interface points. Since the number of interface points is much less than the interior points, it is a low-rank matrix. Using this matrix allows for a much smaller number of Lanczos steps to obtain the exact solution of the diagonal of the inverse and hence reduces the need for as many re-orthogonalization steps in Lanczos. We show that the problem of finding the diagonal of the inverse is transformed into a naturally parallel GMRES solver (based on the domain decomposition) solved at each of the Lanczos iterations. We successfully implemented a coarray fortran (CAF) program code of this new algorithm for the 2D Fermionic-Bosonic Falicov-Kimball Hamiltonian (mixture of light and heavy atoms). Results of parallel performance and advantages of using a CAF implementation are discussed, in terms of a 3D implementation which is planned for the Hubbard model.

¹Computations were performed on the Cray XE6 "Hopper", through a 2011 NISE-NERSC award (P. Carrier). This work is supported by NSF grants OCI-0904587 (Y. Saad) and OCI-0904597 (J.K. Freericks).

8:12AM Y24.00002 Continuum Numerical Renormalization Group, NANDAN PAKHIRA, Department of Physics, Georgetown University, Washington, DC 20057, USA, HULLIKEL KRISHNAMURTHY, Department of Physics, Indian Institute of Science, Bangalore 560012, India, JAMES FREERICKS, Department of Physics, Georgetown University, Washington, DC 20057, USA — The numerical renormalization group (NRG) has emerged as one of the most powerful techniques for calculating emergent renormalized low-temperature properties of strongly correlated systems. When applied as an impurity solver within the dynamical mean-field theory (DMFT), it allows one to directly find spectral functions and how they evolve with temperature. In spite of this success, the NRG method has a number of well-known shortcomings. It fails to properly produce the Fermi liquid state down to $T=0$ in DMFT and hence it does not properly calculate transport, and it produces only semiquantitative features of the spectral functions. We believe, this is mainly due to the fact that the spectral representation involves a discrete set of delta function peaks at logarithmically discretized frequency intervals which are broadened to the continuum. The broadening parameters are chosen in an *ad-hoc* basis. Here we formulate this problem as a discrete degree of freedom embedded in a continuum, which involves coupling the original semi-infinite NRG chain to another semi-infinite chain, arising from the neglected continuum degrees of freedom. This residual coupling can be solved perturbatively and provides an *ab initio* approach to constructing spectral functions from the NRG.

8:24AM Y24.00003 Nonequilibrium dynamical mean-field study of correlated electron systems driven by a mono-cycle pulse, NAOTO TSUJI, ETH Zurich, TAKASHI OKA, HIDEO AOKI, Department of Physics, University of Tokyo, PHILIPP WERNER, ETH Zurich — A few-cycle pulse can be generated and has been widely used in recent ultrafast optical experiments, but its potential application to correlated electron systems has remained unexplored in contrast to many-cycle pulses. What is characteristic of the few-cycle pulse is to induce a shift of electron's momentum dynamically. To reveal its effect on the electronic properties of the system, we study the single-band Hubbard model driven by half-cycle and mono-cycle pulses using the nonequilibrium dynamical mean-field theory. As an impurity solver, we employ the continuous-time quantum Monte Carlo method and the iterative perturbation theory. We show that when the momentum shift is nearly π (half of the Brillouin zone) the shifted population relaxes to a negative-temperature state, where the electron-electron interaction is effectively switched from repulsive to attractive. The shift is found to deviate from the dynamical phase $\phi = \int F(t)dt$ due to electron correlation effects, which suggests that one can generate the repulsion-to-attraction transition by a mono-cycle pulse with $\phi = 0$.

8:36AM Y24.00004 PIMC study of spin-polarized 1D trapped fermions with strong attractive contact interaction, CHANGMO YANG, University of Illinois — Spin imbalance in a trapped one-dimensional gas of ^6Li atoms ($F = 1/2$) is studied with continuous-space path-integral Monte Carlo simulation. This follows closely the experiment of Liao et al. [1], which aims to confirm the existence of the FFLO pairing predicted from the Bethe ansatz [2,3] and DMRG [4,5]. Algorithmic improvements [6] to the configuration-space sampling efficiency of a previous work [7] is made in order to explore the conditions where the attractive contact interaction between unlike-spin atoms can be stronger than in the previously accessible. Signatures of FFLO pairing is looked for in the pair momentum distribution.

8:48AM Y24.00005 Stability of Topological Quantum Phases at Zero Temperature, SPYRIDON MICHALAKIS, Caltech, JUSTYNA PYTEL, Oregon State University — We prove stability of the spectral gap for gapped, frustration-free Hamiltonians under general, quasi-local perturbations. We present a necessary and sufficient condition for stability, which we call *Local Topological Quantum Order* and show that this condition implies an area law for the entanglement entropy of the groundstate subspace. This result extends previous work by Bravyi et al, on the stability of topological quantum order for the groundstate subspace of Hamiltonians composed of commuting projections with a common zero-energy subspace. Moreover, our result implies that zero-temperature topological order is robust against quasi-local perturbations, for all topologically ordered subspaces that correspond to the groundstate space of a gapped, frustration-free Hamiltonian. Finally, even in the absence of topological order, we show that symmetry-protected sectors are also stable against perturbations respecting the same symmetries.

9:00AM Y24.00006 Recurrence relations and time evolution in the relativistic electron gas at long wavelengths¹, ERICA SILVA², Instituto de Física, Universidade Federal de Mato Grosso, Cuiabá, MT, Brazil — Some years ago M. Howard Lee developed the recurrence relations method to solve the Heisenberg motion equation in an exact way. The relaxation and memory functions, as other linear-response quantities, e.g., the density-density response function and the dynamic structure factor, were obtained for the two- and three-dimensional non-relativistic electronic systems at long wavelengths. In this work we study the time- and frequency-dependent behavior of the relativistic electron gas. As some applications, one can cite graphene, in two dimensions, and dwarf stars, in the three-dimensional case, since both systems have a relativistic electron gas in their compositions.

9:12AM Y24.00007 Combining Tensor Networks with Monte Carlo: Applications to the MERA, ANDY FERRIS, Université de Sherbrooke, GUIFRE VIDAL, Perimeter Institute for Theoretical Physics — Our recent understanding of the entanglement properties of ground states of many-body quantum systems has led to the development of a variety of variational wavefunctions based on tensor networks. The so-called *bond dimension* of the tensor network, χ , sets both the limit to the amount of entanglement allowed in the ansatz as well as the required computational power to contract the tensor network. Because the cost scales very strongly with χ in higher dimensions, these approaches are currently challenging in 2D and currently unusable in 3D. We present our efforts in combining Monte Carlo techniques with tensor networks to ease the computational bottleneck. Classical Monte Carlo sampling can be used to estimate the contracted value of the network, allowing one to sample expectation values and vary parameters to optimize ground states. In particular, we show a perfect sampling scheme can be efficient for tensor networks which are also unitary quantum circuits. We apply this to the Multi-scale Entanglement Renormalization Ansatz (MERA) in 1D, formally reducing the cost from $O(\chi^9)$ to $O(\chi^5)$ per sample, and demonstrate that we can optimize wavefunctions. We expect the advantages from Monte Carlo sampling will be stronger in 2D and 3D systems.

9:24AM Y24.00008 Recent Progress In Exactly Solvable Discrete Models for Topological Phases in Two Dimensions¹, YONG-SHI WU², YUTING HU, SPENCER D. STIRLING³, Department of Physics and Astronomy, University of Utah — The study of two-dimensional topological phases in condensed matter systems is a frontier in the field of condensed matter theory as well as topological quantum computation. Discrete or lattice models, which are exactly solvable have been proposed by Kitaev and by Levin and Wen, respectively, some years ago. Here we present a summary of recent progress in studying these models and their generalizations. The topics to be covered include 1) Duality between the Kitaev and Levin-Wen models in certain special cases; 2) General procedure for computing ground state degeneracy when the models are put on a topologically non-trivial surface; 3) More detailed study of the properties (exchange and exclusion statistics etc) of topological excitations (e.g. fluxons); 4) General framework for studying constraints of topological invariance on a wide class of discrete models on more general fluctuating graphs; 5) Generalization of these models to general graphs that incorporates more general degrees of freedom. Our approach, though closely related to topological field theory and tensor category theory, could be understood by physicists.

9:36AM Y24.00009 Time Evolution of Density Matrices Using BBGKY Hierarchy, ALI AKBARI, Nano-Bio Spectroscopy Group, Departamento de Física de Materiales, Universidad del País Vasco, San Sebastián, Spain, JAVAD HASHEMI, RISTO NIEMINEN, Department of Applied Physics, Aalto University, P.O. Box 11100, FI-00076 AALTO, Finland, ROBERT VAN LEEUWEN, Department of Physics, Nanoscience Center, FIN 40014, University of Jyväskylä, Jyväskylä, Finland, ANGEL RUBIO, Nano-Bio Spectroscopy Group, Departamento de Física de Materiales, Universidad del País Vasco, San Sebastián, Spain — Our work starts with the BBGKY hierarchy equations which can be straightforwardly derived from the time-dependent Schrödinger equation for each n -body reduced density matrices (n -RDM). The equations of the BBGKY hierarchy in each level, couple an n -RDM to the $(n + 1)$ -RDM. In order to make this set of equations tractable we need to truncate the hierarchy. While people usually truncate the hierarchy at the first level, one can also truncate it at the level of second equation by approximating 3-RDM in terms of 2-RDM and 1-RDM. Regardless of approximations that we choose, the total energy and momentum will be conserved if we solve the first and second equation together. However, we will show that most of the existing approximations are unstable and even diverging in time and ponder the reasons behind it.

9:48AM Y24.00010 Optimizing Matrix- and Tensor-Product Algorithms for Momentum-Space Hamiltonians using Quantum Entropy, REINHARD NOACK, Philipps-University Marburg, ÖRS LEGEZA, JENŐ SÓLYOM, Research Institute for Solid State Physics, Budapest — Momentum-space formulations of local models such as the Hubbard model are hard to treat using matrix- and tensor-product-based algorithms because they contain non-local interactions. Quantum entropy-based measures such as the single-site and block entropies and the mutual information can be used to map the entanglement structure in order to gain physical information and to optimize algorithms. In this contribution, we will discuss the optimization of density-matrix-renormalization-group and tree-tensor-network algorithms and their application to the two-dimensional Hubbard model.

10:00AM Y24.00011 Topological liquid nucleation induced by vortex-vortex interactions in Kitaev's honeycomb model, VILLE LAHTINEN, Nordita, ANDREAS LUDWIG, University of Santa Barbara, JIANNIS PACHOS, University of Leeds, SIMON TREBST, Station Q — We provide a microscopic understanding of the nucleation of topological quantum liquids for interacting non-Abelian anyons by making an explicit connection between the microscopics of the pairwise interactions - typically showing oscillations in sign, but decaying exponentially with distance - and the nature of the collective many-anyon state. We investigate this issue in the context of Kitaev's honeycomb lattice model, where non-Abelian vortex excitations can be arranged on superlattices. Depending on microscopic parameters such as the vortex-spacing, we observe the nucleation of several distinct Abelian topological phases. By reformulating the collective behavior of the interacting vortex superlattice in terms of an effective lattice model of tunneling Majorana fermion zero modes, we show that the pairwise interactions fully determine the phase diagram of the nucleated phases. We find that due to the oscillations longer-range interactions beyond nearest neighbor can influence the nature of the collective state and thus need to be included for a comprehensive microscopic picture. Corresponding results should hold for vortices forming an Abrikosov lattice in a p-wave superconductor or quasiholes forming a Wigner crystal in non-Abelian quantum Hall states.

10:12AM Y24.00012 Optimizing the Hartree-Fock orbitals by the DMRG, MINGPU QIN, Institute of Physics, The Chinese Academy of Sciences, HONGGANG LUO, Lanzhou University, P.R. China, TAO XIANG, Institute of Physics, The Chinese Academy of Sciences — We have proposed a density matrix renormalization group (DMRG) scheme to optimize the one-electron basis states of molecules. It improves significantly the accuracy and efficiency of the DMRG in the study of quantum chemistry or other many-fermion system with nonlocal interactions. For a water molecule, we find that the ground state energy obtained by the DMRG with only 61 optimized orbitals already reaches the accuracy of best quantum Monte Carlo calculation with 92 orbitals.

10:24AM Y24.00013 Determination of Boundary Scattering, Intermagnon Scattering, and the Haldane Gap in Heisenberg Chains¹, HIROSHI UEDA, KOICHI KUSAKABE, Graduate School of Engineering Science, Osaka University — Low-lying magnon dispersion in a $S = 1$ Heisenberg antiferromagnetic (AF) chain with boundary $S/2$ spins coupling antiferromagnetically ($J_{\text{end}} > 0$) is analyzed by use of the non-Abelian DMRG method. The Haldane gap Δ , the magnon velocity v , the inter-magnon scattering length a , and the scattering length a_b of the boundary coupling are evaluated. The length a_b , which represents the contribution of boundary effects, depends on J_{end} drastically, while Δ , v , and a are constant irrespective of J_{end} . Our method estimates the gap of the $S = 2$ AF chain as $\Delta = 0.0891623(9)$ using a chain length up to 2048, which is longer than the correlation length.

10:36AM Y24.00014 Fractional exclusion statistics: the paradigm to describe interacting particle systems¹, ANGHEL DRAGOS-VICTOR, Horia Hulubei National Institute of Physics and Nuclear Engineering — The thermodynamics and statistical mechanics calculations for systems of interacting particles represent in general a difficult task. Even in relatively simple cases, like systems described in the Fermi liquid theory or in the Hartree or Hartree-Fock approximations, the dependence of the quasiparticle energies on the population of all the quasiparticle energy levels makes it impossible to apply the standard formalism. This is because either the sum of quasiparticle energies is different from the total energy of the system or the typical Bose and Fermi populations do not maximize the partition function. The solution to this problem is provided by the application of the fractional exclusion statistics. In this presentation I will compare the standard treatment of systems of interacting particles, given in terms of the Bose or Fermi populations of the quasiparticle energy levels, with a method based on the fractional exclusion statistics. This method is the only paradigm for describing rigorously the interacting particle systems in terms of quasiparticles.

Friday, March 2, 2012 8:00AM - 11:00AM – Session Y25 DCOMP DMP: Focus Session: Multiscale Modeling 257A

8:00AM Y25.00001 The heterogeneous multiscale method: A ten-year review, WEINAN E, Peking University, Princeton University — The heterogeneous multiscale method (HMM) was proposed 10 years ago, as a unified framework for designing multiscale algorithms in different applications. It is a top-down strategy in the sense that it relies on a preconceived form of macroscale model. Missing data in the macroscale model are estimated on the fly using a reliable microscale model. In this talk, we will take a critical look at HMM. We will discuss applications to various problems, including dynamic fracture, complex fluids, transition pathways in complex systems and stochastic simulation algorithms. We will also examine areas where improvement are needed in order to make HMM more successful.

8:36AM Y25.00002 Progress Towards Atomistic Simulations that Reach Anthropological Timescale and Beyond¹

JU LI, MIT — Atomistic and first-principles modeling, which describe the world as assembly of atoms and electrons, provide the most fundamental answer to problems of materials. However, they also suffer the most severe timescale limitations. For instance, in molecular dynamics (MD) simulations, in order to resolve atomic vibrations, the integration time step is limited to hundredth of a picosecond, and therefore the simulation duration is limited to sub-microsecond due to computational cost. Although a nanosecond simulation is often enough (surprisingly) for many physical and chemical properties, it is usually insufficient for predicting microstructural evolution and thermo-mechanical properties of materials. In this invited talk I will discuss recent attempts at overcoming the timescale challenges of atomic-resolution simulations: (a) strain-boost hyperdynamics [Phys. Rev. B 82 (2010) 184114] for simulating primarily displacive events and associated issues of activation entropy and the Meyer-Neldel compensation rule, (b) diffusive molecular dynamics (DMD) [Phys. Rev. B 84 (2011) 054103] for microstructural evolution driven by repetitive diffusion events and coupled displacive-diffusive processes, and (c) a Markovian network statistical mechanical treatment of the energy-landscape basin connectivity and a formula for the viscosity of supercooled liquid and glass [PLoS ONE 6 (2011) e17909]. Challenges and future directions are discussed.

9:12AM Y25.00003 Adaptation of multiscale thermal modeling methods to general crystalline solids

BRENT KRACZEK, PETER CHUNG, Computational and Informational Science Directorate, US Army Research Laboratory — From the nano- to micro-scale, phonons act as the primary mechanism for energy transport and storage in most non-metallic, crystalline materials. While phonon properties are determined by interatomic interactions on the scale of the atomistic unit cell, phenomena and microstructures of interest are often at length and time scales that are too large for atomistic simulations. The phonon Boltzmann transport equation (pBTE) enables continuum-scale calculations that capture both atomistic- and continuum-scale thermal behavior, though so far pBTE-based methods have been limited primarily to silicon [1]. We have developed a pBTE-based method for general crystalline materials with up to hundreds of atoms per unit cell. We demonstrate its applicability in silica (9-atom unit cell) and RDX (168-atom unit cell), though presently limited to one dimension in k-space. We discuss the main challenges when moving to larger unit cells, including the automated untangling of phonon dispersion data, discretization of phonon modes and the treatment of high energy modes, including the omission and/or lumping of modes and the use of reservoir modes.

9:24AM Y25.00004 Extended Lagrangian Born-Oppenheimer Molecular Dynamics: quantum mechanical molecular dynamics for extended time and length scales¹

ANDERS NIKLASSON, MARC CAWKWELL, Los Alamos National Laboratory — Born-Oppenheimer molecular dynamics (BOMD) based on density functional theory offers a very accurate quantum mechanical approach to atomistic simulations that is more reliable and general compared to classical MD. Unfortunately, BOMD simulations are often limited by a high computational cost or by problems such as unbalanced phase space trajectories, numerical instabilities and a systematic long-term energy drift. These problems become particularly severe in combination with reduced complexity or linear scaling algorithms that are necessary for the study of large systems. We have recently taken some steps toward a new generation of first principles MD, which combines some of the best features of regular BOMD and Car-Parrinello MD, while avoiding their most serious shortcomings. The new dynamics is given in terms of an extended Lagrangian (XL), where auxiliary extended electronic degrees of freedom are added to the nuclear part. Our framework enables accurate geometric integration of both the nuclear and electronic degrees of freedom that provide a time-reversible and energy conserving dynamics on the ground state BO potential energy surface that is stable also under approximate SCF convergence. XL-BOMD provides a surprisingly simple and general framework for atomistic simulations

9:36AM Y25.00005 Multi scale modeling of atomic layer deposition¹

MAHDI SHIRAZI, SIMON D. ELLIOTT, Tyndall National Institute — Atomic layer deposition (ALD) is one of the techniques now used to grow conformal nanometer thin films with the quality required for electronic devices. ALD is a type of chemical vapor deposition that depends on self-limiting surface chemistry. Many aspects of chemical reactions and their effect on the stoichiometry of the film remain unclear. We have used therefore density functional theory (DFT) to explore those reactions. The growth of HfO₂ from H₂O and Hf(N(CH₃)₂)₄ was regarded as a sample ALD system. The process of densification was explained accurately. A new mechanism of multiple proton diffusion was propounded and DFT energetics showed it to be the most favourable path way. We also found that reaction rates are strongly coupled with the coordination number of Hf atoms at the surface. Then this complex chemistry was implemented in kinetic Monte-Carlo (KMC). The KMC calculation showed the effect of intermediate reactions on the growth rate. Furthermore the morphology of the film and the growth rate under different reaction conditions were compared with experimental data.

9:48AM Y25.00006 A unified approach to preserve structure and thermodynamics in a coarse-grained model of aqueous mixtures

PRITAM GANGULY, Center of Smart Interfaces, TU Darmstadt, Germany, DEBASHISH MUKHERJI, CHRISTOPH JUNGHANS, Max Planck Institute for Polymer Research, Mainz, Germany, NICO VAN DER VEGT, Center of Smart Interfaces, TU Darmstadt, Germany — Biological organizations depend on a sensitive balance of noncovalent interactions, in particular also those involving interactions of small molecules, including inorganic salts and urea, with biomolecules in aqueous solution. Computer simulations of these types of systems require simple-yet-specific models in order to cover all relevant time and length scales. We present a method to systematically coarse-grain liquid mixtures using Kirkwood-Buff theory of solution combined with an iterative Boltzmann inversion technique that infers single-site interaction potentials for the solution components from the pair correlation functions. Our method preserves both the solution structure at pair level and variations of solution components' chemical potentials with compositions within a unified coarse-graining framework. To test the robustness of our approach, we simulated urea-water and benzene-water systems over a wide-range of concentrations. We also observe the coarse-grained potentials to be reasonably transferable with varying concentrations.

10:00AM Y25.00007 Novel mesoscopic approach for modeling Carbon Nanotube System, IGOR OSTANIN¹, ROBERTO BALLARINI², TRAIAN DUMITRICA³, University of Minnesota, DAVID POTYONDY⁴, Itasca Consulting Group Inc, UNIVERSITY OF MINNESOTA/ITASCA CG COLLABORATION — We present a distinct spherical element concept for simulating morphologies and mechanical properties of carbon nanotube systems. The important interactions present at the microscopic level are encapsulated into two types of contact models that act simultaneously. Each individual nanotube is coarse-grained into a chain of spherical elements interacting by parallel contact bonds, representing the microscopic covalent bonding. An anisotropic model with aligning moments acts at the contact between elements located in different tubes to represent the van der Waals long-ranged interactions. The accuracy, computational efficiency, and capabilities of the created mesoscopic model are discussed along with illustrative examples, including self-folding of individual nanotubes, mechanical testing of nanotube ropes, self-assembly of a high-porosity nanotube paper, and mechanical testing of a low-porosity nanotube paper.

10:12AM Y25.00008 Structure formation of toluene around C60: Application of the Adaptive Resolution Scheme, CHRISTOPH JUNGHANS¹, Los Alamos National Laboratory, SEBASTIAN FRITSCH, KURT KREMER, Max Planck Institute for Polymer Research — In the adaptive resolutions scheme (AdResS) a local, typically all-atom cavity is coupled to a surrounding medium of coarse grained, simplified molecules. This methodology cannot only be used to reduce the CPU time demand of atomistic simulations but also to systematically investigate the relative influence of different interactions on structure formation. For this, we vary the thickness of the all atom layer of toluene around a C60, analyze the first toluene layers and compare the result to a full resolution simulation. With this system, we also introduce the implementation of AdResS for molecular simulations into GroMaCS.

¹Work was performed at the Max Planck Institute for Polymer Research

10:24AM Y25.00009 Characterization of phase behavior in assemblies of colloidal nanoparticles, RAY SEHGAL, Chemical Engineering, University of Massachusetts Amherst, DANIEL BELTRAN-VILLEGAS, MICHAEL BEVAN, Chemical and Biomolecular Engineering, Johns Hopkins University, DIMITRIOS MAROUDAS, DAVID FORD, Chemical Engineering, University of Massachusetts Amherst — We report results of a systematic investigation of the phase behavior of clusters of colloidal nanoparticles, which interact via a hard core and depletion attraction potential, as a function of system size and inter-particle interaction strength. To describe the various phases that may be present in such nanoparticle assemblies, we carry out a set of windowed Monte Carlo umbrella sampling (MC-US) simulations to generate free energy landscapes (FELs). For the MC-US generation of the FELs, we use the diffusion mapping method to identify the system's underlying dimensionality and define the dynamically relevant coarse variables. The resulting set of FELs samples broad ranges of the system size and interaction potential strength. These computed FELs describe the phase behavior of the nanoparticle assemblies and allow us to analyze the effects of interaction strength and system size as these assemblies approach the bulk thermodynamic limit. In very small clusters, only a single stable liquid-like phase exists. However, as the number of nanoparticles in the cluster increases, a second crystalline phase emerges in coexistence with the liquid-like phase. The corresponding critical cluster size marks the onset of nucleation of crystalline assemblies of colloidal nanoparticles.

10:36AM Y25.00010 New algorithms for field-theoretic block copolymer simulations: Progress on using adaptive-mesh refinement and sparse matrix solvers in SCFT calculations, SCOTT SIDES, BEN JAMROZ, ROBERT CROCKETT, ALEXANDER PLETZER, Tech-X Research — Self-consistent field theory (SCFT) for dense polymer melts has been highly successful in describing complex morphologies in block copolymers. Field-theoretic simulations such as these are able to access large length and time scales that are difficult or impossible for particle-based simulations such as molecular dynamics. The modified diffusion equations that arise as a consequence of the coarse-graining procedure in the SCF theory can be efficiently solved with a pseudo-spectral (PS) method that uses fast-Fourier transforms on uniform Cartesian grids. However, PS methods can be difficult to apply in many block copolymer SCFT simulations (eg. confinement, interface adsorption) in which small spatial regions might require finer resolution than most of the simulation grid. Progress on using new solver algorithms to address these problems will be presented. The Tech-X Chompst project aims at marrying the best of adaptive mesh refinement with linear matrix solver algorithms. The Tech-X code PolySwift++ is an SCFT simulation platform that leverages ongoing development in coupling Chombo, a package for solving PDEs via block-structured AMR calculations and embedded boundaries, with PETSc, a toolkit that includes a large assortment of sparse linear solvers.

10:48AM Y25.00011 Concurrent multiscale modeling of 3D granular systems, HOLGER MEIER, STEVEN MEIER, FUSHEN LIU, PETER GORDON, ExxonMobil Research and Engineering, TUAN TRAN, ExxonMobil Technical Computing — Large-scale granular mechanics simulations are often based on continuum approaches such as the finite element method (FEM). However, these approaches require continuum descriptions of the constitutive relationship between stresses and strains. As a result, grain-scale dynamics are not explicitly considered. Therefore, modeling of large-scale history dependent phenomena due to grain-scale rearrangement and strain localization remains a long-standing challenge. For small-scale studies, discrete element method (DEM) simulations model grain-scale interactions and thus capture history dependent phenomena. However, the application of this approach to large-scale systems is computationally expensive and impractical. We demonstrate a scalable multiscale approach where large-scale granular systems are discretized with the classical FEM simulation, while the necessary constitutive relation is calculated concurrently from DEM simulations of representative volume elements of grains subject to the loading and deformation prescribed by each finite element.

Friday, March 2, 2012 8:00AM - 11:00AM —
Session Y26 DCOMP: General Theory / Computational Physics I 257B

8:00AM Y26.00001 Computation of Collision-Induced Absorption by dense Hydrogen-Helium gas mixtures up to Thousands of Kelvin, for Astrophysical Applications¹, MARTIN ABEL, LOTHAR FROMMHOLD, The University of Texas at Austin, XIAOPING LI, KATHARINE L.C. HUNT, Michigan State University — The interaction-induced absorption by collisional pairs of H₂ molecules is an important opacity source in the atmospheres of the outer planets and cool stars. The emission spectra of cool white dwarf stars differ significantly in the infrared from the expected blackbody spectra of their cores, which is largely due to absorption by collisional H₂-H₂, H₂-He, and H₂-H complexes in the stellar atmospheres. Using quantum-chemical methods we compute the atmospheric absorption from hundreds to thousands of kelvin, as required, for example, in astrophysical analyses of objects, including cool white dwarf stars, brown dwarf stars, M dwarfs, cool main sequence stars, solar and extra-solar planets, and the formation of so-called first stars [1]. Comparisons of our calculations with laboratory measurements, which exist only at room temperature and below, show close agreement.

8:12AM Y26.00002 Microcanonical entropy inflection points and their relationship to cooperative behavior, MICHAEL BACHMANN, Center for Simulation Physics, The University of Georgia, Athens, GA 30602 — We discuss a method for the systematic classification of the analogs of phase transitions in finite systems. This completely general analysis, which is applicable to any physical system, is based on the microcanonical entropy and its energetic derivative, the inverse caloric temperature. Inflection points of this quantity signal cooperative activity and thus serve as distinct indicators of transitions. The microcanonical entropy as the logarithm of the density of states is the fundamental quantity of statistical mechanics and can directly be obtained by means of contemporary generalized-ensemble computer simulation methodologies. Nowadays, the statistics achieved by employing these methods is sufficiently high such that the accuracy of the data allows for a very precise microcanonical analysis of "phase" transitions, even in mesoscopic systems, where finite-size and surface effects are significant. This can hardly be achieved by the far more prevalent conventional canonical approach. We demonstrate the power of this method in exemplified applications to long-standing problems of polymer and protein nucleation transitions.

8:24AM Y26.00003 Improving Event Identification in the HF Calorimeter of CMS, CHRISTOPHER FRYE, University of Central Florida, JEREMIAH MANS, University of Minnesota, COMPACT MUON SOLENOID COLLABORATION — The Forward Hadron Calorimeter (HF) of the Compact Muon Solenoid (CMS) at the Large Hadron Collider (LHC) lies in a region not covered by an inner tracking system, and we can rely only on the shapes of showers that hit the HF to determine whether or not they are due to electromagnetic particles. We review the current method of distinguishing shower types in the HF, and we bring attention to a drawback that will become present as the luminosity of the LHC increases and creates a need for tighter shower-shape cuts. We provide a method to correct this drawback, and we analyze the effectiveness of various tight cuts at isolating signal from background.

8:36AM Y26.00004 The Effect of White Nonstationary and Colored Nonstationary Noise on Signal Detection¹, MAURICIO FLORES, MATTHEW BENACQUISTA, ALEXANDER STROEER, University of Texas at Brownsville — We analyze the effect of non-stationary noise on the detection of signals on unevenly sampled data. Initial frequency estimation is obtained from a Lomb-Scargle periodogram; which is followed by a global multi-start optimization, as working on a dense local Nelder-Mead iterator for parameter estimates. It has been found that a varying white noise level has no effect on the required relative signal-to-noise ratio for detection in the proposed algorithm, though affecting the absolute amplitude strength of the signal recording. Further analysis has been done on realistic colored noise. Different whitening routines have been incorporated to the proposed algorithm. Detection efficiency is compared for these different routines.

8:48AM Y26.00005 Deteriorated Quality of Phase Distorted Gaussian Beams, SERGIY MOKHOV, LEONID GLEBOV, BORIS ZELDOVICH, CREOL - the College of Optics and Photonics, Univ. of Central Florida — The divergence of coherent optical beam is often characterized by the parameter M^2 . For one transverse axis, this beam quality parameter is proportional to the product of the minimal observed beam size divided by the wavelength and multiplied by the divergence angle. Furthermore, M^2 is normalized such that its minimum value equals unity, which is achievable only by a Gaussian beam. An arbitrary phase distortion of a Gaussian beam increases M^2 . Self-phase modulation is a common distortion in which the phase difference across the beam aperture is proportional to the beam intensity profile. For self-phase modulation, the deterioration of the beam quality parameter will depend on only one parameter, the phase at the center of the beam. We have found this dependence analytically. A general phase distortion profile can be represented by higher-order radial phase modes. We have also found the analytical dependence of M^2 in this generalized case. In addition, we derived expressions for beam quality deterioration of super-Gaussian beams due to phase distortions. If the waists of Gaussian and super-Gaussian beams are defined by a residual power criterion, which means both beams outside the same radius have the same amount of residual power, then a super-Gaussian beam will better tolerate phase distortions. It is important that all of our results cannot be efficiently reproduced by the traditional approach, based on the polynomial representation of aberrations, due to the poor convergence of power series for Gaussian profiles.

9:00AM Y26.00006 Exponential tails near the band edges of a one-dimensional disordered exciton system in the Coherent Potential Approximation, ABDELKRIM BOUKAHIL¹, Physics Department, University of Wisconsin-Whitewater, NOUREDINE ZETTILI, Deptment of Physical and Earth Sciences, Jacksonville State University, 700 Pelham Road North, Jacksonville, AL 36265, USA, DAVID HUBER, Physics Department, University of Wisconsin-Madison, Madison, WI 53706, USA — We report the results of studies of the tails near the band edges of a one-dimensional Frenkel exciton system in the Coherent Potential Approximation (CPA). A Gaussian distribution of the transition frequencies with rms width σ ($0.1 \leq \sigma \leq 2.0$) is used. We found that the tails obey two different exponential power laws depending on the value of σ . In the weak disorder limit $0.1 \leq \sigma < 0.5$, the tails of the absorption line shape and the density of states behave like $\exp(-k|E|^{3/2}/\sigma^2)$, and in the strong disorder limit, $0.5 < \sigma \leq 2.0$, the tails behave like $\exp(-|E|^2/\sigma^2)$. In the weak disorder limit, our CPA results are in excellent agreement with previous investigations.

9:12AM Y26.00007 Elastic impurity scattering and relaxation in electronic lattice under finite electric-field¹, JONG HAN, SUNY Buffalo, WOO-RAM LEE, KWON PARK, Korean Institute for Advanced Study — From the birth of solid state physics, understanding electron transport in solids has been one of the central questions. Recently, rigorous quantum mechanical treatments of solid nonequilibrium have been sought by many groups. Here, we discuss electron transport in tight-binding lattice with disordered potential scatterers when driven by a finite electric field. Based on Floquet formalism with non-perturbative treatment of the electric field, we investigate how the spectral properties evolve when the system is non-dissipative, governed by a *closed* Hamiltonian. As the disorder becomes stronger, the spectra evolve from δ -peaks representing Bloch oscillations to a continuous spectral distribution which is distinctly different from the non-interacting limit. We investigate the fate of electric current in the steady-state nonequilibrium. Finally, we discuss an implementation of energy dissipation channels and the way that the conventional Drude picture is recovered within the Floquet method as a function of Bloch oscillation frequency and electron relaxation-time.

9:24AM Y26.00008 Universal resistance quantum in multichannel transport and dissipative field theory, PRASENJIT DUTT, Yale University, THOMAS SCHMIDT, Yale University, Basel University, KARYN LE HUR, Yale University, Ecole Polytechnique — The Landauer formula for coherent DC transport lies at the heart of nanoelectronics and embodies a startling prediction: the quantization of the conductance in one-dimensional metallic wires for ballistic transport, in steps of $R_q^{-1} = e^2/h$ for each channel. Scattering processes undergone by the electrons cause a deviation from this result. The resistance then depends on the transparency of the channel and assumes a nonuniversal value. Recently, the unit of resistance R_q has been shown to be a universal feature for AC transport through a single-channel quantum RC circuit with a large cavity. This result can be understood by mapping the system to the one-channel Kondo model and the emergent low-energy Fermi-liquid theory. In a different context R_q arises in a certain nonequilibrium setting for the multichannel quantum RC circuit. In this work, we study AC transport in the many-channel quantum RC circuit. Under certain well-defined conditions the charge relaxation resistance remains universal and equals R_q . We study the emergence of this universal resistance in the multi-channel limit by using the mapping with a dissipative particle on a ring and making an analogy with the Kondo model.

9:36AM Y26.00009 Holon-Doublon Dynamics in Hubbard Ladders¹, LUIS DIAS DA SILVA, University of Sao Paulo, GONZALO ALVAREZ, Oak Ridge National Laboratory (ORNL), ELBIO DAGOTTO, University of Tennessee/ORNL — Studies of the dynamics of holon-doublon pairs in Mott insulators have unveiled interesting and contrasting results with their band-insulator counterparts [1,2]. In the 1D Hubbard model, a paradigm for a Mott insulator, numerical evidence suggests that the mechanism for exciton decay into magnetic excitations is inefficient [1]. However, transition metal oxides are usually grown in layered superlattices and a real-time study of the holon-doublon propagation on ladders and other layered structures is therefore needed. In this talk, we present results for the real-time dynamics of holon-doublon pairs propagating in a *two-leg* Hubbard ladder, a more realistic model for several SCMs. We use the time-dependent density matrix renormalization group (tDMRG) algorithm with a time-step-targeting Krylov method. We find that the ladder geometry changes the dynamics of the holon-doublon pair. A “transfer” of the excitation between the ladder legs is seen, depending on the ratio between the couplings in the two leg directions. Furthermore, the time decay of the total double occupation is modified in the ladder as compared to the 1D case.

9:48AM Y26.00010 First principles study of the spin-orbit coupling effect on the Tl-Pb superconducting alloy¹, OMAR DE LA PEÑA-SEAMAN, Institute of Physics (IFUAP), Benemerita Universidad Autonoma de Puebla (BUAP), ROLF HEID, KLAUS-PETER BÖHNEN, Institute of Solid State Physics (IFP), Karlsruhe Institute of Technology (KIT) — We have studied the influence of spin-orbit coupling (SOC) on the phonon dispersion, the electron-phonon (e-ph) coupling and on the superconducting properties for the Pb-Tl alloy in the stable fcc-phase doping regime. This system have been studied within the framework of density functional perturbation theory, using a mixed-basis pseudopotential method and the virtual crystal approximation (VCA) for modeling the alloy. The Eliashberg spectral function ($\alpha^2F(\omega)$) and the electron-phonon coupling parameter (λ) have been calculated with and without SOC. The observed effects of SOC in the full phonon dispersion and $\alpha^2F(\omega)$ consist in a softening of the phonon frequencies and an increase of the e-ph coupling matrix elements, which become weaker on the Tl-rich side. SOC enhances λ by as much as 48% in some cases and improves its overall behavior as a function of the concentration for the alloy, leading to a very nice agreement with experimental data from tunneling measurements.

10:00AM Y26.00011 Critical point of phase transitions of fractional order at Superconductors, VLADIMIR UDODOV, Katanov Khakas State University, KATANOV KHAKAS STATE UNIVERSITY TEAM — This paper describes the behavior of thermodynamic values superconducting transition at temperature, tending to absolute zero. Using the thermodynamic arguments we demonstrate that superconductors can undergo third, fourth-, fifth- and higher (including fractional) order phase transitions (PT's) within the meaning of Baxter [1] (or Ehrenfest) as the temperature tending to zero. It is proved that the order of PT can be any real (fractional) number at some interval (from 2 to 8). It is established relation between critical exponent of specific heat and critical magnetic field for superconductor as the temperature tending to zero. It is proved that Ehrenfest classification of phase transitions does not work with a zero critical temperature. Note that the results are valid only in the case of thermodynamic equilibrium, making it difficult to reach experimentally at very low temperatures.

10:12AM Y26.00012 Numerical simulation of dynamical response in superconducting quantum detectors, YUKIHIRO OTA, Advanced Science Institute, RIKEN, KEITA KOBAYASHI, MASAHIKO MACHIDA, CCSE, Japan Atomic Energy Agency, TOMIO KOYAMA, Institute for Materials Research, Tohoku University, FRANCO NORI, Advanced Science Institute, RIKEN — We numerically study the dynamical response of superconducting quantum detectors such as a single-photon detector, using the time-dependent Ginzburg-Landau equation coupled with heat diffusion and Maxwell equations. Our simulation shows a dynamical transition to a resistive state via an incident particle with energy higher than T_c . We find that such a transition is associated with the generation of vortex-antivortex pairs and the occurrence of a normal-state region within the superconductor. We also discuss the applicability of this approach to a superconducting single-photon detector.

10:24AM Y26.00013 Quantitative examination of out-of-phase mixed holographic gratings¹

KAY-MICHAEL VOIT, HAUKE BRUENING, MIRCO IMLAU, Department of Physics, University of Osnabrueck, Osnabrueck, Germany — Modern holographic applications require advanced photosensitive materials that particularly obey alterations of the complex permittivity with pronounced amplitudes of both real and imaginary parts on the sub-ps-time scale. Promising candidates such as amorphous and crystalline materials remarkably show a mutual phase-shift between phase and absorption gratings that complicates the analysis of the underlying wave-coupling mechanisms. Hence, theoretical descriptions that are simply based on Kogelnik's coupled-wave theory can not be applied, i.e., a formal approach to systematically derive the full parameter space of the gratings from diffraction efficiency measurements is missing in literature. We revised the analysis of the wave-coupling theory omitting former approximations or applying them later. As a result we derived a formal description for mixed gratings allowing for a full description of beam-coupling experiments. Both the modulations of the refractive index and the absorption coefficient as well as the phase shift between these gratings can be determined through measurements of the angular dependent diffraction efficiency around the positive and the negative Bragg angle. Our approach and results are demonstrated along a mixed grating with a most common parameter set.

10:36AM Y26.00014 Extended phase diagram of ASEP with two types of particles¹

AYSE YESIL, M. CEMAL YALABIK, Bilkent University — First introduced by Evans et al. (PR E, 74 208, (1995)), the Asymmetric Simple Exclusion Process (ASEP) has become an important model in the field. The model is simple in structure, however it offers an opportunity to study some of the basic characteristics of nonequilibrium systems. We use mean field, Monte Carlo, and RG methods to present a detailed phase diagram of the ASEP with two types of particles moving in opposite directions. The nature of the spontaneous symmetry broken phases will also be discussed.

10:48AM Y26.00015 Non-Equilibrium Phase Transitions in the Baxter Model

BASAK RENKLIOGLU, M. CEMAL YALABIK, Department of Physics, Bilkent University — The Baxter model in equilibrium is an exactly solved model for which the universality of the static critical phenomena does not hold [1]. The free energy has a branch-point singularity at a phase transition. The exponent of this singularity can range continuously from one to infinity. That is to say, this model has non-universal equilibrium critical exponents [2]. In our study, the non-equilibrium critical dynamics of the Baxter model which is in contact with two thermal baths is analyzed. Monte Carlo methods are applied to the system in which one of the bath is fixed at infinite temperature. The Baxter model is formulated as two interlacing spin-1/2 Ising models on a square lattice, interacting through a four spin coupling. The dynamics of the system is taken to be driven by "spin exchanges" of the neighbor spins in each lattice. We focus on the phase transitions of the system under this spin exchange dynamics. Preliminary results on the universality class properties of the non equilibrium phase transitions is presented.

8:00AM Y27.00001 Formation and dynamics of Skyrmions in B20-type chiral magnets

NAOYA KANAZAWA, Department of Applied Physics, University of Tokyo — The topological stable spin texture called a Skyrmion, in which the directions of the spins wrap a sphere, has been attracting much attention as an arena for unconventional magneto-transport effects. Small angle neutron scattering (SANS) studies identify the formation of two-dimensional triangular Skyrmion lattice in B20-type transition-metal monosilicides, such as MnSi¹ and Fe_{1-x}Co_xSi.² In addition, novel transport properties due to its topological spin arrangement, namely the topological Hall effect³ and the current-induced rotation of the Skyrmion lattice⁴ are observed in MnSi. We have provided crucial evidence of the existence of Skyrmions in B20-type compounds by direct real-space observation using Lorentz transmission electron microscopy (TEM)^{5,6} and also found a large topological Hall effect in much wider temperature region in MnGe than other B20-type magnets.⁷ TEM observation reveals the detailed information on nucleation and fusion processes and topological defects besides the perfect hexagonal arrangement of Skyrmions. Furthermore, we have found that the Skyrmion lattice state is quite stabilized in a thin-plate formed sample with its thickness smaller than the skyrmion lattice constant. The orders of magnitude larger topological Hall effect in MnGe indicates the high-density Skyrmion crystal formation and distinguishable large responses in some novel electromagnetic phenomena. In addition, we have fabricated B20-type thin films where Skyrmions are more stabilized and applied electric current is more easily controlled than in bulk samples. This work was done in collaboration with X. Z. Yu, Y. Onose, J. H. Park, J. H. Han, N. Nagaosa, K. Kimoto, W. Z. Zhang, S. Ishiwata, Y. Matsui, T. Arima, D. Okuyama, K. Ohoyama, S. Wakimoto, K. 8:36AM Y27.00002 Magnetic Blue Phase in the Chiral Itinerant Magnet MnSi

DMITRY REZNIK, University of Colorado-Boulder — In MnSi with the cubic crystal structure B20, the lack of inversion symmetry induces a chiral Dzyaloshinsky-Moriya interaction between magnetic moments. It locally favors helical magnetic order. In addition to a long-range helical order with the well-defined propagation vector, other locally helical phases such as skyrmions and partial order appear in its phase diagram. These enigmatic phases are suspected to be behind many unusual properties of MnSi. I will report results of model calculations, which show that such phases should arise naturally as a result of the basic Dzyaloshinsky-Moriya Hamiltonian. Specifically, in the absence of an applied magnetic field, the free energy in MnSi should be minimized by the magnetic analogue of blue phases, which have previously been observed in chiral liquid crystals. This result is consistent with our recent neutron scattering measurements as well as those of others. The properties of this blue phase explain a number of previously reported puzzling features of MnSi such as partial magnetic order and a two-component specific-heat as well as, possibly, non-Fermi-liquid resistivity at high pressure.

9:12AM Y27.00003 Quasi-two-dimensional Skyrmion lattices and other exotic structures in confined chiral nematic liquid crystals¹, SLOBODAN ZUMER, University of Ljubljana and Jozef Stefan Institute — Skyrmions are localized particle-like topological entities in a number of continuous fields that play important roles in various condensed matter systems, including two-dimensional electron gases exhibiting the quantum Hall effect, Bose–Einstein condensates, and chiral ferromagnets [1, 2]. Here we are using Landau - de Gennes theoretical approach and numerical techniques to show that in a highly chiral nematic liquid crystal confined to a thin film between two parallel surfaces imposing normal alignment nematic director can exhibit thermodynamically stable states characterized by quasi-two-dimensional Skyrmion lattices of disclinations [3]. By confining a chiral nematic, that in bulk forms blue phases characterized by cubic lattices of nematic defect lines, to a layer with thickness comparable to the lattice constant of the blue phase [3-5], various quasi 2D defect lattices can be stable. Depending on the anchoring direction of the nematic director on confining surfaces, temperature, and layer thickness, beside skyrmion structures, lattices of double helical half-integer disclinations running along the layer [4], and lattices of ring defects [5] are the most interesting. A chiral nematic liquid crystal film can thus serve as a model system, allowing direct investigation of numerous defect lattices by a variety of optical techniques at conditions that are less demanding than used for other condensed matter Skyrmion systems.

9:48AM Y27.00004 Unusual Hall effect Anomaly in MnSi under pressure¹, MINHUEA LEE, University of Colorado at Boulder — Recent works in B20 type transition metal compounds have revealed a new topological object in spin systems – the skyrmion, a particle-like object in which spins point all directions to wrap around the sphere. While neutron scattering and scanning probe experiments^{2,3} confirmed the existence of individual skyrmions and skyrmion lattices in a particular part of the phase diagram, the interaction between skyrmions and electronic degrees of freedom remains to be unveiled. In this talk, we report the observation of a highly unusual Hall current in the helical magnet MnSi under pressure.⁴ In addition to the normal Hall effect and the anomalous part that arises from spontaneous magnetization, the Hall conductivity displays a distinctive stepwise field profile quite unlike any other Hall response observed in solids. This additional contribution was observed in a much larger range of temperature and applied field than the so-called *A*-phase, where the skyrmion lattice was observed in ambient pressure. It suggests that fluctuating, *i.e.* non-static, skyrmions might be present over a broad range of the phase diagram under pressure when the magnetic ordering becomes weakened.

10:24AM Y27.00005 Cosmic Strings Meet Multerroics: Understanding topological defects in spontaneous symmetry breaking phase transitions, SINEAD GRIFFIN, ETH Zurich — Jumping from the expanse of galactic scales to land in the laboratory might seem a gargantuan task. Common to both, however, is the concept of symmetry breaking and in particular the formation of topological defects. Here I discuss the formation of topological defects in multiferroic YMnO₃ whose ferroelectric behavior enables the direct imaging of these defects. I also show how this material can be used to study the Kibble-Zurek model of topological defect formation in the early universe and give quantitative insights on the number of domains formed during the spontaneous symmetry breaking phase transition.

Friday, March 2, 2012 8:00AM - 11:00AM –
Session Y29 GQI: Focus Session: Quantum Optics with Superconducting Circuits: Nonlinearity and Itinerant Microwave Photons 259A

8:00AM Y29.00001 Microwave Photon Counter Based on Josephson Junctions, GUILHEM RIBEILL, DAVID HOVER, UMESHKUMAR PATEL, University of Wisconsin-Madison Department of Physics, YUNG-FU CHEN, Department of Physics, National Central University, ROBERT MCDERMOTT, University of Wisconsin-Madison Department of Physics — We describe progress in the development of a microwave photon counter based on current biased Josephson junctions; absorption of a single photon causes the junction to switch to the voltage state, producing a large and easily measured classical signal. We have combined multiple junctions with a broad-band, on-chip microwave beam splitter to realize a multiplexed microwave photon detector. We discuss application of the Josephson microwave counter to the study of full counting statistics of the microwave emission from various mesoscopic conductors, and we describe alternative biasing schemes to enable operation in more traditional photon counting modes.

8:12AM Y29.00002 Quantum efficiency of a single microwave photon detector based on a current-biased Josephson junction¹, AMRIT POUDEL, ROBERT MCDERMOTT, MAXIM VAVILOV, University of Wisconsin-Madison — We analyze the quantum efficiency of a single microwave photon detector based on a current-biased Josephson junction. We consider the Jaynes-Cummings Hamiltonian to describe coupling between the photon field and the junction. We then take into account coupling of the junction and the resonator to the environment. Numerically solving the equation of motion of the density matrix of the resonator-junction system, we compute the quantum efficiency of the photon detector as a function of detection time, bias current and the junction's decay time. For current-biased Josephson junctions, the efficiency to detect a single photon with frequency in the microwave regime is around 50%. Our results also indicate that a highly efficient single microwave photon detector is feasible for a moderate improvement in the junction's decay time.

¹This work was supported by NSF and DOD

8:24AM Y29.00003 Backaction of Microwave Photon Detection by a Strongly Coupled Josephson Junction¹, EMILY PRITCHETT, Saarland University, LUKE GOVIA, University of Waterloo, SETH MERKEL, IBM T. J. Watson Research Center, FRANK WILHELM, Saarland University — We analyze the functionality of on-chip Josephson junctions as single microwave photon detectors, as has been demonstrated recently in Chen, *et al.*, arXiv:1011.4329. The Josephson junction device, which we refer to as a Josephson Photomultiplier (JPM), acts as a nearly perfect binary detectors of microwave photons by undergoing an observable switching event when there are one or more photons in an incident cavity. We analyze the backaction of this switching event on the state of incident light, including the energy dissipation and dephasing affecting an imperfect JPM. This analysis improves the efficiency and fidelity with which a JPM reconstructs the state of light in an incident transmission line 'cavity', which are commonly used to store and transfer quantum states in implementations of circuit-QED.

8:36AM Y29.00004 Cooperative effects for Qubits in a Transmission Line: Theory, K. LALUMIÈRE, A. BLAIS, Université de Sherbrooke, B.C. SANDERS, University of Calgary, A.F. VAN LOO, A. FEDOROV, A. WALLRAFF, ETH Zurich — Strong extinction of the transmitted power in a 1D transmission line coupled to an artificial atom has recently been achieved [1]. In contrast to the 3D case, large extinctions are made possible by the strong light-matter coupling occurring because of reduced dimensionality. Motivated by this, here we consider the situation where multiple artificial atoms (ie transmon qubits) are coupled to the 1D line. Following the work of Lehmberg for the 3D case [2], we obtain a master equation describing the dynamics of an arbitrary number of qubits coupled to the line. This master equation reveals interaction between the qubits mediated by the line. Using the input-output formalism, the model is compared to experimental results for multiple qubits coupled to the 1D line. [1] O. Astafiev *et al.*, Science 327, 840 (2010) [2] R. H. Lehmberg. Phys. Rev. A 2, 883 (1970).

8:48AM Y29.00005 Cooperative Effects for Qubits in a Transmission Line: Experiment, A.F. VAN LOO, A. FEDOROV, ETH Zurich, K. LALUMIÈRE, Université de Sherbrooke, B.C. SANDERS, University of Calgary, A. BLAIS, Université de Sherbrooke, A. WALLRAFF, ETH Zurich — The interaction probability between freely propagating photons and atoms or atom-like systems is greatly enhanced in one dimension. Thus a system of many atoms coupled to a one-dimensional continuum of electromagnetic modes is expected to reveal many interesting phenomena - the photons emitted by an atom can be absorbed by other atoms and coherently interact with propagating modes of the continuum. We implement three superconducting qubits coupled strongly to an open transmission line to investigate such light-matter interactions in one dimension. We characterize our system by scattering radiation off the qubits and measuring the transmitted and reflected field. For low driving powers, a single qubit reflects nearly all incident radiation resonant with its transition frequency [1]. When two qubits are tuned such that their emitted radiation has a wavelength close to twice the distance between the qubits we observe interference effects in the reflection and transmission spectra. At high driving powers resonance fluorescence is measured for single qubits and multiple qubits in resonance. These results present first steps towards investigating cooperative effects for multiple qubits in open one-dimensional space. [1] O. Astafiev *et al.*, Science, **327**, 840 (2010)

9:00AM Y29.00006 Hong-Ou-Mandel Interference in Circuit QED Experiments, MATTHEW WOOLLEY, Université de Sherbrooke, CHRISTIAN LANG, CHRISTOPHER EICHLER, ANDREAS WALLRAFF, ETH Zurich, ALEXANDRE BLAIS, Université de Sherbrooke — The Hong-Ou-Mandel (HOM) effect is a quantum interference effect whereby two indistinguishable photons incident at either side of a balanced beam splitter will be detected together at one output port or the other, but never with one photon at each output port. Such experiments have long been performed in the optical domain, but recent developments have raised the possibility of performing such experiments in the microwave domain, using linear amplifiers and quadrature amplitude detectors instead of photon counting [Bozyigit *et al.*, Nat. Phys. **7**, 154-158 (2010)]. Here we determine the signature of HOM interference in a system consisting of two independent circuit QED systems out-coupled into an on-chip microwave beam splitter. We have calculated the beam splitter output intensity auto- and cross-correlations for both trains of pulsed Lorentzian photons, and continuously-driven sources based on photon blockade. The HOM interference is manifest as antibunching in the output intensity cross-correlation. Controllable distinguishability may be introduced via a time delay in the pulsed case, or via a frequency offset in the continuously-driven case. The frequency offset leads to a quantum beat effect. Preliminary experimental results will be discussed.

9:12AM Y29.00007 Generating distributable and unconditional entanglement on-chip at microwave frequencies, W.F. KINDEL, H.S. KU, JILA and the University of Colorado, S. GLANCY, G.C. HILTON, K.D. IRWIN, E. KNILL, L.R. VALE, NIST, K.W. LEHNERT, JILA and the University of Colorado — Entanglement is a critical requirement for quantum teleportation protocols. In a strategy to generate entanglement between two separate microwave lines, we integrate two Josephson Parametric Amplifiers (JPAs) and a quadrature hybrid onto a single chip making the entangler circuit. When two squeezed states created by the JPAs are combined on the hybrid (microwave beam splitter), the two output modes are entangled. We observe entanglement using a quantum efficient two channel quadrature measurement device. In our initial tests, the degree of entanglement has been limited by undesirable coupling among the elements of our entangler circuit. We present our investigation of the undesired coupling along with design strategies to reduce it.

9:24AM Y29.00008 Quantifying distributable and unconditional entanglement at microwave frequencies, H.S. KU, W.F. KINDEL, JILA and University of Colorado at Boulder, S.C. GLANCY, E. KNILL, L.R. VALE, G.C. HILTON, K.D. IRWIN, NIST, K.W. LEHNERT, JILA, NIST and University of Colorado at Boulder — Unconditional and distributable entanglement can be created by combining a squeezed state and a vacuum state at a beam splitter. We create a single integrated circuit designed to pursue this strategy at microwave frequencies. The squeezed state is created with a Josephson Parametric Amplifier and then combined with a vacuum state in a hybrid (microwave beam splitter) producing entanglement of the output modes. In this talk, we will present the measurement and quantification of entanglement between separate microwave transmission lines. We quantify the entanglement and estimate the fidelity when applying this entangled state as a quantum teleportation channel.

9:36AM Y29.00009 Microwave photonics and Josephson junction arrays, JUAN J. MAZO, DAVID ZUECO, Instituto de Ciencia de Materiales de Aragon (CSIC-Universidad de Zaragoza), ENRIQUE SOLANO, IKERBASQUE and Universidad del Pais Vasco, JUAN J. GARCIA-RIPOLL, Instituto de Fisica Fundamental (CSIC) — We present an architecture for a photonic crystal in the microwave regime based on superconducting transmission lines interrupted by Josephson junctions. A study of the scattering properties of a single junction in the line shows that the junction behaves as a perfect mirror when the photon frequency matches the Josephson plasma frequency. We generalize our calculations to periodic arrangements of junctions, demonstrating that they can be used for tunable band engineering, forming what we call a quantum circuit crystal. As a relevant application, we discuss the creation of stationary entanglement between two superconducting qubits interacting through a disordered media.

9:48AM Y29.00010 Modeling of a Flying Microwave Qubit, KYLE KEANE, University of California, Riverside, Department of Physics and Astronomy, ALEXANDER N. KOROTKOV, University of California, Riverside, Department of Electrical Engineering — We investigate the transfer efficiency of sending a flying microwave qubit through a transmission line from one resonator to another resonator. Our model is based on the current technology of coupling superconducting phase qubits to microwave resonators and transmission lines. Analytical as well as numerical results are presented. Procedural imperfections have been modeled, including weak detuning, imperfect timing, and deviations from the ideal time dependence of the coupling modulation. The effects of multiple reflections within the transmission line and energy dissipation in the system are also considered.

10:00AM Y29.00011 A Four-wave Mixing Toolbox For Photon State Manipulation in Superconducting Resonators¹ , A.V. SHARYPOV, XIUHAO DENG, LIN TIAN, University of California, Merced — We present a circuit scheme to generate quantum operations on superconducting resonators by engineering effective interaction Hamiltonians. We show that both the linear Bogoliubov transformations, including the beam-splitter operation, the squeezing operation, and the phase shifter, and the nonlinear interactions such as the cross-Kerr interaction can be realized with one single circuit. Our circuit is composed of two superconducting qubits coupled with each other to form a quantum four-level system. Each qubit interacts directly with one superconducting resonator. We exploit the four-wave mixing (FWM) approach and use the circuit as a toolbox to generate the above-mentioned quantum operations by controlling circuit parameters with external sources. Using numerical simulations to study the error rates, we show that the transformations can be realized with high fidelity. Arbitrary quantum operations on the microwave photons can be realized by combining these effective interactions.

10:12AM Y29.00012 Dephasing and Kerr type interaction effects in circuit quantum electrodynamics , ERAN GINOSSAR, Advanced Technology Institute and Department of Physics, University of Surrey, STEVEN GIRVIN, Department of Physics, Yale University — There has been recently a significant advance in obtaining high quality factor resonators in superconducting circuit architectures. The reduction of the resonator line width motivates us to consider subtle Kerr type interaction effects in small clusters of cavities and transmon type qubits. The Kerr interaction leads to entanglement of cavities, which in the transient regime is manifested in collapse-revival dynamics. For longer time scales, the interaction of the system with its environment becomes important and we discuss how the entangled states are modified. The signal of this steady-state Kerr interaction is a multi-photon port-to-port scattering process which can be observed in homodyne measurements or in a spectral analysis (correlations). We discuss the relevance of these effects to the challenge of building quantum memories.

10:24AM Y29.00013 Dynamic quantum Kerr effect in circuit quantum electrodynamics , YI YIN, HAOHUA WANG, MATTEO MARIANTONI, RAMI BARENDTS, RADOSLAW C. BIALCZAK, YU CHEN, MIKE LENANDER, JULIAN KELLY, ERIK LUCERO, ANTHONY MEGRANT, PETER O'MALLEY, DANIEL SANK, JIM WENNER, TED WHITE, ANDREW CLELAND, JOHN MARTINIS, University of California, Santa Barbara — In the dispersive regime of circuit quantum electrodynamics (QED), where the qubit and resonator frequencies differ slightly, photons in the resonator exhibit induced frequency and phase shifts. The qubit-state dependent phase shift is usually measured by monitoring the resonator transmission spectrum at fixed qubit-resonator detuning. In this static scheme, the phase shift can only be monitored in the far-detuned, linear dispersion regime, in order to avoid measurement-induced demolition of the quantum state. By using a dynamic procedure to adiabatically drive the qubit frequency, here we are able to explore the dispersive interaction over a much broader range, and we further monitor the interaction using resonator Wigner tomography. Exotic non-linear effects on different photon states, e.g., Fock states, coherent states and Schrodinger cat states, are thereby directly revealed. Correspondingly, we demonstrate a quantum Kerr effect in the dynamic framework in circuit QED.

10:36AM Y29.00014 Shaping an Itinerant Quantum Field into a Multimode Squeezed Vacuum by Dissipation¹ , JUAN JOSE GARCIA-RIPOLL², Instituto de Fisica Fundamental, CSIC, DIEGO PORRAS³, Facultad de Ciencias Fisicas, Universidad Complutense de Madrid — This work shows how to create tunable continuous sources of single and multimode squeezed light by controlling single emitters coupled to propagating modes of the EM field. Our work builds on recent experiments that implement the main tools of cavity Quantum Electrodynamics (QED) using superconducting qubits coupled to microwave transmission lines, as well as quantum dots coupled to microcavity photons, or plasmons. The main results of this letter, presented in sequential order are: A multicolor driving of an artificial atom modifies its coupling to the EM field, inducing sidebands. Combining the sidebands with an auxiliary bath, a single qubit may cool a quantum field in a single mode cavity to a squeezed vacuum. If instead of a cavity, the driven qubit is placed in a waveguide, the high energy modes play the role of a dissipative bath and the result is tunable multimode squeezing of the propagating quantum field. Through the manuscript we will also discuss implementations, measurement schemes and further outlook.

10:48AM Y29.00015 Effects of nonlinearity in the emission spectrum of the driven nonlinear oscillator , MICHAEL MARTHALER, STEPHAN ANDRE, LINGZHEN GUO, Institut für Theoretische Festkörperphysik, Karlsruhe, VITTORIO PEANO, Department of Physics and Astronomy, Michigan State University, East Lansing, GERD SCHÖN, Institut für Theoretische Festkörperphysik, Karlsruhe — Motivated by many experiments on nonlinear driven systems realized using superconducting circuits we investigate the properties of a coherently driven nonlinear resonator. By using Josephson junctions in superconducting circuits, strong nonlinearities can be engineered, which lead to a relatively low number of photons in the resonator and the appearance of pronounced nonlinear effects. Based on a master equation approach, which takes into account the quantum nature of noise, we determine the emission spectrum and observe for typical circuit QED parameters, in addition to the primary side-peaks, second-order peaks not predicted by a linearized theory.

Session Y30 GQI: Quantum Computing, Quantum Algorithms, and Quantum Simulation 259B

8:00AM Y30.00001 Phase Slips in Topological Superconductor Wire Devices , SAMUEL GOLDBERG, DORON BERGMAN, DAVID PEKKER, GIL REFAEL, California Institute of Technology — We make a detailed study of phase slips in topological superconducting wires and devices based on topological wires. We begin by investigating a device composed of a topological superconducting wire connected to a non-topological wire (T-S). In the T-segment only slips of the phase by multiples of 4π are allowed, while in the S-segment slips by 2π are also allowed. We show that near the interface, 2π phase slips are also allowed and we comment on the consequences of such phase slips for the Aharonov-Casher effect. We also consider an implementation of a q-bit consisting of a T-S-T device, where the quantum information is stored in the parity of the two topological segments via the four Majorana modes. We show that the central S-segment of this type of device can support 2π phase-slips which result in the decoherence of the q-bit.

8:12AM Y30.00002 ABSTRACT WITHDRAWN —

8:24AM Y30.00003 String localization and delocalization in the disordered toric code¹, PEJMAN JOUZDANI, EDUARDO R. MUCCIOLO, Department of Physics, University of Central Florida — Topological quantum memories based on the toric code model have the ability to protect quantum information by self correcting a large class of errors. However, excitations such as a string of spin flips, when allowed to perform a quantum walk, can change the logical state encoded in the system every time they wind around the torus. It has been proposed that by adding randomness to the local spin exchange couplings, one can localize these string excitations and avoid logical errors. In our work, we investigate this proposal numerically through the use of an efficient time-dependent numerical quantum evolution method. We determine the dependence of the winding time on the torus size and on the amount of randomness. We study the effect of dephasing in the quantum evolution of the string excitations and show that a transition to delocalization can occur.

8:36AM Y30.00004 Implementing quantum gates through scattering between an electron and a magnetic impurity in a graphene nanoribbon, GUILLERMO CORDOURIER-MARURI, ROMEO DE COSS, Departamento de Física Aplicada, Cinvestav-Mérida, SOUGATO BOSE, Department of Physics and Astronomy, University College London — We study the feasibility of implementing quantum logic gates and generate entanglement when a ballistic electron is scattered by a magnetic impurity fixed in a graphene nanoribbon. Because electrons in graphene behaves like massless Dirac Fermions, we use the Dirac equation to describe the system. In our model we consider the ballistic electron spin as a relativistic flying qubit and the impurity spin as a static qubit. The interaction between spins is described by a Heisenberg - like operator. The interaction by electron scattering shows the advantage of a low control in the interaction, and the operation success can be measured by means the electron transmission probability. We show that is possible to implement quantum logic gates of the type SWAP, and partial SWAP with a physically feasible coupling strenght between spins. We also present the condition to generate states of maximum entanglement. The possible use of the graphene pseudospin as an additional degree of freedom is discussed.

8:48AM Y30.00005 Long-lived qubit constructed from three identical atoms, RUI HAN, Centre for Quantum Technologies, Singapore, HUI KHOON NG, Centre for Quantum Technologies, Singapore and DSO, National Laboratories, applied physics lab, Singapore, NIELS LÖRCH, Centre for Quantum Technologies, Singapore and Universitt Heidelberg, Philosophenweg 16-19, 69120 Heidelberg, Germany, JUN SUZUKI, National Institute of Informatics, 2-1-2 Hitotsubashi, Chiyoda ku, Tokyo 101-8430, Japan, BERGE ENGLERT, Centre for Quantum Technologies, National University of Singapore, Singapore — In this talk, I will present a scheme for constructing logical qubits from clusters of three identical atoms that are long-lived against decoherence from fluctuating magnetic fields, a limiting source of noise in many experiments. Each qubit is stored in a rotationally invariant subsystem of the total angular momentum states of the three atoms, and can persist with high fidelity for time-scales on the order of hours. This is to be compared with a fraction of a millisecond for an unprotected atomic qubit. I will first present the scheme of rotationally invariant subsystems in atomic systems and show that the information stored in the system is robust against decoherence. Then I will move on to discuss a proposal for an experiment to demonstrate the feasibility of the scheme. In our proposal, the state preparation is done with the help of Rydberg blockade for three atoms, where the atoms are localized in space and addressed by a sequence of laser pulses simultaneously. By carefully selecting the atomic levels addressed and tuning the parameters of the applied lasers, an arbitrary logical qubit state can be prepared. Lastly, the fidelity of state preparation will be discussed. Ref: R. Han, N. Lörch, J. Suzuki and B. G. Englert, Phys. Rev. A 84, 012322 (2011)

9:00AM Y30.00006 Deterministic and Cascadable Conditional Phase Gate for Photonic Qubits, CHRISTOPHER CHUDZICKI, ISAAC CHUANG, JEFFREY SHAPIRO, MIT — Cross-phase modulation (XPM) at the single-photon level, if strong enough, would enable a simple conditional π -phase gate for photonic qubits. Together with easily realized single-qubit rotations for such qubits, this would provide a universal gate set for quantum computation. However, previous analyses of photonic conditional ϕ -phase gates that treat XPM in a causal, multimode, quantum field setting suggest that a large ($\sim\pi$ rad) nonlinear phase shift is always accompanied by fidelity-degrading noise. We present a conditional phase gate that, for sufficiently small nonzero ϕ , has high fidelity. Moreover, our gate is cascable, in that it preserves the structure of the principal modes used to encode qubit information, and can therefore be cascaded to realize a high-fidelity conditional π -phase gate. The key components of our gate are: (1) an atomic $\mathcal{V}$ -system to create XPM; (2) a principal-mode restorer that compensates the evolution a principal-mode incurs when the $\mathcal{V}$ -system is driven by a single photon; and (3) a principal-mode projector that exploits the quantum Zeno effect to preclude the accumulation of fidelity-degrading departures from the principal-mode Hilbert space when both control and target photons illuminate the gate.

9:12AM Y30.00007 Dynamic Phases and Robust Quantum Gates¹, YASUSHI KONDO, TSUBASA ICHIKAWA, MASAMITSU BANDO, MIKIO NAKAHARA, Kinki University — We are interested in composite pulses widely employed in Nuclear Magnetic Resonance (NMR) and geometric phase gates (GQGs) with vanishing dynamic phases in Quantum Information Processing (QIP). A composite pulse in NMR is constructed with poor quality pulses but becomes more reliable than its components. We found: a composite pulse robust against pulse length error in NMR is always a GQG [1]. We then extended this observation to two-qubit operations. Let us consider the interaction $e^{-i\theta\sigma_z\otimes\sigma_z}$ and assume that there is a systematic error in θ . When we construct a “composite pulse” robust against this error, we obtain a two-qubit GQG [2]. We clarified that geometric phase gates are really useful in QIT.

9:24AM Y30.00008 Non-Adiabatic Holonomic Quantum Gates in an atomic system, VAHID AZIMI MOUSOLOU, CARLO M. CANALI, School of Computer Science, Physics and Mathematics, Linnaeus University, Kalmar, Sweden, ERIK SJOQVIST, Department of Quantum Chemistry, Uppsala University, Uppsala, Sweden — Quantum computation is essentially the implementation of a universal set of quantum gate operations on a set of qubits, which is reliable in the presence of noise. We propose a scheme to perform robust gates in an atomic four-level system using the idea of non-adiabatic holonomic quantum computation proposed in [1]. The gates are realized by applying sequences of short laser pulses that drive transitions between the four energy levels in such a way that the dynamical phases vanish.

9:36AM Y30.00009 Single-qubit gates by graph scattering¹, MICHAEL S. UNDERWOOD, BENJAMIN A. BLUMER, DAVID L. FEDER, IQIS, University of Calgary — Continuous-time quantum walkers with tightly peaked momenta can simulate quantum computations by scattering off finite graphs. We enumerate all single-qubit gates that can be enacted by scattering off a single graph on up to $n = 9$ vertices at certain momentum values, and provide numerical evidence that the number of such gates grows exponentially with n . The single-qubit rotations are about axes distributed roughly uniformly on the Bloch sphere, and rotations by both rational and irrational multiples of π are found.

9:48AM Y30.00010 Recent Results in Photonic Quantum Computations, Simulations and Quantum Networks, PHILIP WALTHER, University of Vienna — The applications of photonic entanglement manifold and reach from quantum communication [1] to quantum metrology [2] and optical quantum computing [3]. The advantage of the photon's mobility makes optical quantum computing unprecedented in speed, including feed-forward operations with high fidelity [4]. During the last few years the degree of control over photonic multi-particle entanglement has improved substantially and allows for not only overcoming the random nature of spontaneous emission sources [5], but also for the quantum simulation of other quantum systems. Here, I will also present the simulation of four spin-1/2 particles interacting via any Heisenberg-type Hamiltonian [6]. Moreover, recent experimental and theoretical progress, using the concepts of measurement-based quantum computation, indicates that photons are best suited for quantum networks. I will also present results for the realization for such a client-server environment, where quantum information is communicated and computed using the same physical system [7]. 10:00AM Y30.00011 Physics of an isolated electron puddle revealed via dephasing in thermal equilibrium, EMIL WEISZ, HYUNGKOOK CHOI, OKTAY GÖKTAŞ, MOTY HEIBLUM, YUVAL GEFEN, VLADIMIR UMANSKY, DIANA MAHALU, Weizmann Institute of Science — Low dimensional electron systems serve as a good setup for studying interactions among quantum systems. In our study, we examined a system comprised of an electron puddle, confined in a quantum dot, coupled to an electronic Mach-Zehnder interferometer via Coulomb interactions. Surprisingly, even when the electron puddle was in thermal equilibrium and nearly isolated, it induced full and robust dephasing in the nearby interferometer when the average puddle's occupation was $N+1/2$. We attribute this unexpected behavior to a unique manifestation of the Friedel Sum Rule, which connects the occupation of a system with its scattering phase. Furthermore, this phenomena allowed accessing various properties of the isolated electron puddle, such as its average occupation, in thermal equilibrium and under bias, and decoherence rate of the confined electrons.

10:12AM Y30.00012 Quantum trajectories for systems probed by fields in multimode Fock and Schrodinger cat states¹, JOSHUA COMBES, BEN Q. BARAGIOLA, Center for Quantum Information and Control, University of New Mexico, Albuquerque, NM 87131-0001, USA, AGATA M. BRANCZYK, Department of Physics and Centre for Quantum Information and Quantum Control, University of Toronto, Toronto ON M5S 1A7, Canada, ROBERT L. COOK, Center for Quantum Information and Control, University of New Mexico, Albuquerque, NM 87131-0001, USA, JOHN E. GOUGH, Institute for Mathematics and Physics, Aberystwyth University, SY23 3BZ, Wales, United Kingdom, MATTHEW R. JAMES, HENDRA I. NURDIN, Research School of Engineering, Australian National University, Canberra, ACT 0200, Australia — Using Gardiner and Collet's input-output theory we derive system and output field master equations for an arbitrary quantum system probed by a field in a non-classical state of light. Specifically the field states we study are arbitrary combinations (superpositions and / or mixtures) of continuous-mode Fock states or continuous mode-coherent states. We also unravel the master equations for the system state to get the conditional evolution (the stochastic master equation) for homodyne and photon counting measurements.

10:24AM Y30.00013 Optimal Experimental Detection and Characterization of SU(2) Decoherence, LEE A. ROZEMA, ARDAVAN DARABI, DYLAN H. MAHLER, AEPHRAIM M. STEINBERG, Centre for Quantum Information and Quantum Control, and Institute for Optical Sciences, Department of Physics, University of Toronto, ROBIN BLUME-KOHOUT, Theoretical Division, Los Alamos National Lab & CQULC, University of New Mexico — Quantum metrology is the art of measuring tiny forces by preparing quantum states, then measuring how much they get displaced by the force. The resulting precision often exceeds classical limits. The best state depends on what we want to detect. N00N states [1] are optimal for U(1) phase shifts. Measuring arbitrary dynamical shifts requires quantum process tomography (QPT)[3], in which the process is applied to a complete set of input states. In this work, we experimentally study the important intermediate case of SU(2) decoherence (SD), fluctuating SU(2) rotations, by probing it with biphotons [2]. We show that N00N states are optimal for detecting SD. Then, we turn to QPT, and examine how accurately SU(2)-covariant sets of states can identify SD. The set of spin-coherent states (generated by SU(2)-displacements of a "highest-weight" state) are sufficient for QPT [4], but exponentially insensitive to some parameters. We show that N00N states (though optimal at detecting SD) generate even less effective input sets, with zero sensitivity to some parameters. Finally, we show evidence that optimal input sets are 2-designs, which can be generated from a fiducial state and SU(2) rotations.

10:36AM Y30.00014 Complete characterization of linear amplifiers including the quantum limits for nongaussian noise¹, SHASHANK PANDEY, ZHANG JIANG, JOSHUA COMBES, CARLTON CAVES, Center for Quantum Information and Control, University of New Mexico — We characterize the quantum limitations on the entire probability distribution of added noise in a phase-preserving linear amplifier. Previously the quantum limits have been given entirely in terms of second moments, i.e., noise power or noise temperature [1]. As Josephson parametric amplifiers approach fundamental quantum limits on noise temperature [2,3,4], it becomes important to investigate the limits on higher moments of the amplifier noise. We prove that all phase-preserving linear amplifiers with arbitrary noise are formally equivalent to a parametric amplifier: $\rho_{out} = \text{tr}[S(r) \rho_{in} \otimes \sigma S^\dagger(r)]$, where the gain is $g^2 = \cosh^2(r)$, S is a two-mode squeeze operator, and σ is a physical state of an ancillary mode whose quantum noise determines the noise properties of the amplifier. We discuss generalization of these limits to the nondeterministic linear amplifiers proposed by Ralph and Lund [5]. [1] C. M. Caves, Phys. Rev. D **26**, 1817 (1982). [2] A. A. Clerk et al., Rev. 10:48AM Y30.00015 Playing the Aharon-Vaidman quantum game with a Young type photonic qutrit, PIOTR KOLENDESKI, URBASI SINHA, Institute for Quantum Computing, University of Waterloo, 200 University Ave. West, Waterloo, Ontario, Canada, YOUNING LI, Department of Physics, Tsinghua University, Beijing 100084, China, TONG ZHAO, MATTHEW VOLPINI, Institute for Quantum Computing, University of Waterloo, 200 University Ave. West, Waterloo, Ontario, Canada, ADAN CABELLO, Departamento de Fisica Aplicada II, Universidad de Sevilla, E-41012 Sevilla, Spain ; Department of Physics, Stockholm University, S-10691 Stockholm, RAYMOND LAFALMME, Institute for Quantum Computing, University of Waterloo, 200 University Ave. West, Waterloo, Ontario, Canada, THOMAS JENNEWEIN, Institute for Quantum Computing, University of Waterloo, 200 University Ave. West, Waterloo, Ontario, CA — The Aharon-Vaidman (AV) game exemplifies the advantage of using simple quantum systems to outperform classical strategies. We present an experimental test of this quantum advantage by using a three-state quantum system (qutrit) encoded in a spatial mode of a single photon passing through a system of three slits. The preparation of a particular state is controlled as the photon propagates through the slits by varying the number of open slits and their respective phases. The measurements are achieved by placing detectors in the specific positions in the near and far-field after the slits. This set of tools allowed us to perform tomographic reconstructions of generalized qutrit states, and implement the quantum version of the AV game with compelling evidence of the quantum advantage.

Friday, March 2, 2012 8:00AM - 10:36AM –

Session Y31 DMP: Focus Session: Topological Insulators: Synthesis & Characterization - Optical & THz Spectroscopy 260

8:00AM Y31.00001 Topological surface state dispersion measured using THz magneto-ellipsometry, JASON N. HANCOCK, J.L.M. VAN MECHELEN, ALEXEY KUZMENKO, DIRK VAN DER MAREL, University of Geneva, CHRISTOPHE BRUNE, ELENA NOVIK, GEORGY ASTAKHOV, HARTMUT BUHMANN, LAURENS MOLENKAMP, Universität Würzburg — We present a magneto-optical study of the three-dimensional topological insulator, strained HgTe. Using polarization-sensitive time-domain THz spectroscopy in a magnetic field, reliable information on the Drude weight and cyclotron resonance frequency severely constrain the details of surface state dispersion within 1meV of the Fermi level. Details of the technique and its prospect for future observation of axion electrodynamics using THz spectroscopy will also be discussed.

8:12AM Y31.00002 Terahertz Kerr Measurements of the Surface States on n- and p-type Bi₂Se₃ Topological Insulators¹, G.S. JENKINS, A.B. SUSHKOV, D.C. SCHMADEL, M.-H. KIM, K.M. BHAMIDIPATI, P. SYERS, J. PAGLIONE, H.D. DREW, CNAM, University of Maryland, College Park, N.P. BUTCH, Cond. Mat. and Matls. Div., Lawrence Livermore National Lab, J.G. ANALYTIS, I.R. FISHER, Dept. of Physics, Stanford University — We report terahertz magneto-optical characterization of a single surface state on bulk crystals of n-type Bi₂Se₃ and p-type Bi₂Se₃ doped with Mg as well as Sm, breaking time reversal symmetry and opening a gap at the Dirac point. A gate is used to apply an electric field which creates and modulates a small depletion layer. The modulated Fermi energy of the surface state produces differential optical signals with no contribution arising from bulk carriers. The real and imaginary parts of the differential Kerr angle yield the transport scattering rate, spectral weight, and mass of the surface state carriers. Comparison with ARPES and other transport measurements will be discussed.

¹This work supported by DOE grant #DESC0005436.

8:24AM Y31.00003 Nonlinear optical responses to circularly polarized lights of the surface state of a topological insulator, TETSURO MISAWA, TAKEHITO YOKOYAMA, SHUICHI MURAKAMI, Tokyo Institute of Technology — Recent photoelectron spectroscopy experiments have revealed the presence of the Dirac cone on the surface of the topological insulator and its spin-splitting due to the spin-orbit interaction. In general, on spin-orbit coupled systems, electric fields induce spin polarizations as linear and nonlinear responses. Here we investigate the inverse Faraday effect on the surface of the topological insulator. The inverse Faraday effect is a non-linear optical effect where a circularly polarized light induces a dc spin polarization. We employ the Keldysh Green's function method to calculate the induced spin polarization and discuss its frequency dependence. In particular, in the low frequency limit, our analytical result gives the spin polarization proportional to the frequency and the square of the lifetime. As for the finite frequency regime, we employ numerical methods to discuss the resonance due to interband transitions. We also discuss the photogalvanic effect, where an illumination of a circular polarized light generates the dc charge current. Lastly, we evaluate those quantities with realistic parameters.

[1] T. Misawa, T. Yokoyama, S. Murakami, Phys. Rev. B84, 165407 (2011).

8:36AM Y31.00004 Optical properties of highly resistive Bi₂Te₂Se, ANJAN REIJNDERS, S. Y. F. ZHAO, LOUISE NIEMEYER, RAPHAEL BOUSKILA, H. J. CHO, SEYEDYARA MOHAJERANI, LUKE J. SANDILANDS, University of Toronto, ROBERT J. CAVA, Princeton University, KENNETH S. BURCH, University of Toronto — Topological insulators are characterized by strong spin-orbit coupling, producing metallic surface states while the bulk remains insulating. Experimental observations of surface states in transport and optical measurements have been obstructed by bulk contributions due to sample defects, placing the Fermi level in the bulk energy gap. Bi₂Te₂Se (BTS), a three-dimensional topological insulator, has recently been shown to exhibit a bulk resistivity larger than any other topological insulator measured to date. However, quantum oscillations are still observed, and attributed to the surface states. In this talk I will present the optical properties of BTS, obtained by broadband FTIR spectroscopy combined with ellipsometry, over a range of 20 - 45,000 cm⁻¹, as well as the Raman spectrum of BTS.

8:48AM Y31.00005 Quasiparticle dynamics of topological insulator Bi₂Se₃ studied by time and angle-resolved photoemission spectroscopy, YIHUA WANG, DAVID HSIEH, EDBERT SIE, DILLON GARDNER, HADAR STEINBERG, YOUNG LEE, PABLO JARILLO-HERRERO, NUH GEDIK, MIT — Topological insulator is a new state of matter that hosts spin helical surface states that may be important for future spintronic applications. Even though the conical bandstructure of the helical Dirac fermions is well established, elastic and inelastic scattering rates of their excitations are less well known because conventional transport or optical techniques can not easily separate surface contribution from bulk effects. Here we use time and angle-resolved photoemission spectroscopy to study the surface electron time-domain dynamics of a prototypical topological insulator Bi₂Se₃. We observe non-Fermi liquid behavior of quasiparticles both above and below the Fermi level. Our result suggests that surface-bulk scattering can play an important role in the transport properties of topological insulator.

9:00AM Y31.00006 Ultrafast Bulk and Surface Dynamics of Bi₂Se₃ Measured by Time-Resolved ARPES, JONATHAN SOBOTA, SHUOLONG YANG, JAMES ANALYTIS, YULIN CHEN, Stanford University, IAN FISHER, Stanford University, PATRICK KIRCHMANN, Fritz Haber Institute of the Max Planck Society, ZHI-XUN SHEN, Stanford University — We investigated the nonequilibrium carrier dynamics of the topological insulator Bi₂Se₃ using femtosecond time- and angle- resolved photoemission spectroscopy. Optical excitation leads to a metastable population of bulk carriers due to the presence of the bandgap. We discuss the coupling of these carriers to the Dirac surface state, which results in a long-lived nonequilibrium surface carrier distribution. We will comment on the implications for topological insulator device applications.

9:12AM Y31.00007 Optical and magneto-optical spectra of Bi_{1-x}Sb_x with x = 0.015, M.S. WOLF, S.V. DORDEVIC, The University of Akron, N. STOJILOVIC, University of Wisconsin Oshkosh, S.S. VUJATOVIC, M.V. NIKOLIC, P.M. NIKOLIC, Serbian Academy of Arts and Sciences, L.C. TUNG, National High Magnetic Field Laboratory — Bismuth and its alloys with antimony have attracted attention in recent years due to possible realization of topological insulating state. In this study we have used infrared and magneto-optical spectroscopies to probe the electrodynamic response of bismuth doped with 1.5 % of antimony. The spectra will be presented for temperatures down to 5 K, and in magnetic fields as high as 18 Tesla. The results reveal strong magneto-optical activity, especially around the plasma minimum in reflectance. These findings will be compared and contrasted with magneto-optical results on pure bismuth.

9:24AM Y31.00008 Magneto-reflectance of Bi₂Se₃ in 18 Tesla fields, S.V. DORDEVIC, M.S. WOLF, The University of Akron, N. STOJILOVIC, University of Wisconsin Oshkosh, H. LEI, C. PETROVIC, Brookhaven National Laboratory, L.C. TUNG, National High Magnetic Field Laboratory — Magneto-optical measurements can provide valuable information in studies of topological insulators. We will report magneto-reflectance spectra of Bi₂Se₃ in magnetic fields up to 18 Tesla. Magnetic-field induced changes in reflectance are most pronounced around the plasma minimum and around the 60 cm⁻¹ mode. Such large magneto-optical activity is unusual for a phonon, and might indicate coupling to collective modes of magnetic origin. Model fits will provide deeper insight into evolution of optical functions with magnetic field.

9:36AM Y31.00009 Photo-induced Chiral Edge Current in the 3D Topological Insulator Bi_2Se_3 , RICKY ROY, University of Washington, MAO LI, Washington State University, GRANT AIVAZIAN, University of Washington, WANG YAO, University of Hong Kong, DAVID COBDEN, University of Washington, CHUANWEI ZHANG, Washington State University, XIAODONG XU, University of Washington — We perform scanning photocurrent (PC) microscopy measurements on the 3D topological insulator Bi_2Se_3 , and observe spatially separated PC peaks of opposite sign, localized along the sample edges. The physics origin of this experimentally observed two-way PC is attributed to the chiral nature of the TI surface states. We show that the coupling between the optical field and the topological surface states yields a spin population imbalance along the edges of the surface, leading to the first order chiral edge charge current observed in the experiment. Further experimental observations of the weak polarization and strong temperature dependence of the PC agree with the theoretical predictions. The PC fades away at a low temperature indicating a mean-free path of $\sim 3 \mu\text{m}$ for topologically protected surface spins.

9:48AM Y31.00010 Terahertz studies and colossal Kerr rotation in the topological insulator Bi_2Se_3 ¹, ROLANDO VALDÉS AGUILAR, A.V. STIER, L. WU, L.S. BILBRO, W. LIU, N.P. ARMITAGE, Department of Physics & Astronomy, Johns Hopkins University, Baltimore, MD 21218, N. BANSAL, M. BRAHLEK, S. OH, Department of Physics & Astronomy, Rutgers University, Piscataway, NJ 08854, D.K. GEORGE, J. CERNE, A.G. MARKELZ, Department of Physics, SUNY Buffalo, Buffalo, NY 14260 — We report a study of high quality MBE grown Bi_2Se_3 topological insulator thin films using time domain terahertz spectroscopy (TDS). We explicitly demonstrate the 2D character of the response by studying films of different thicknesses. In addition, we take advantage of a unique feature of TDS that allows to measure the time structure of the THz pulses. In this way we measure the Faraday and Kerr rotation angles in a single experiment. We find an unprecedentedly large value of the Kerr rotation that is due to the cyclotron resonance of the 2D Dirac fermions². We will also show results on the effect of exposure of the thin films to atmospheric conditions for prolonged periods of time.

10:00AM Y31.00011 Size effect in Bi_2Se_3 Topological Insulator micro and nanoparticles, FANGZE LIU, EUGEN PANAITESCU, SWASTIK KAR, Northeastern University — 3D Topological insulators are electronic materials that have a semiconducting bulk interior but a metal-like (zero-gap) surface. We present the investigations of optical transitions in bulk and nanoscale structures of the Topological Insulator Bi_2Se_3 , using optical absorption spectroscopy over a range of energies between 1.1 eV and 6.5 eV. Bi_2Se_3 micro and nanoparticles were obtained by a sequence of ultrasonication steps developed by our group for this purpose. Investigations were performed on particles of different size scales ranging from 10 microns to sub-25 nanometers. While the bulk samples demonstrated expected absorption properties, the smallest (sub-25 nm) particles showed the appearance of a number of new high-energy absorption edges. The fabrication, detailed characterization, and possible reasons for the appearance of the high-energy excitation states will be discussed within the framework of its electronic band-structure description

10:12AM Y31.00012 Temperature-Dependence in Optical Properties of Topological Insulator $\text{Bi}_{1.5}\text{Sb}_{0.5}\text{Te}_{1.8}\text{Se}_{1.2}$, CHI SIN TANG, XING QUAN ZOU, BIN XIA, MINGYI LIAO, LAN WANG, ELBERT E.M. CHIA, Nanyang Technological University — Topological Insulators are materials with insulating bulk states and conducting states on their edge or surface. Using Terahertz Time-Domain Spectroscopy (THz-TDS), we studied the temperature-dependence of the optical properties of $\text{Bi}_{1.5}\text{Sb}_{0.5}\text{Te}_{1.8}\text{Se}_{1.2}$ single-crystals from 5 K to 300 K in the terahertz regime (0.4 THz to 3.0 THz). We observed a spectral weight shift from low frequencies to frequencies above 1.0 THz in the real conductivity at temperatures below ~ 100 K.

10:24AM Y31.00013 Efficient THz emission from a topological insulator surface, LI-GUO ZHU, Case Western Reserve University; Tsinghua University, Beijing 100084, China, BRIAN KUBERA, Case Western Reserve University, KIN FAI MAK, Columbia University, JIE SHAN, Case Western Reserve University — Bi_2Se_3 is a 3D topological insulator (TI) recently confirmed by the ARPES.¹ Direct optical probe of its metallic surface states is, however, hindered by the remnant Drude response of the bulk material. Second-order nonlinear optical techniques with their surface specificity provide unique opportunities for studying surface electronic transitions in TIs such as Bi_2Se_3 with bulk inversion symmetry.² Here we demonstrate efficient THz emission from the surface of Bi_2Se_3 under the excitation of a femtosecond optical pulse. The emission arises from optical rectification of the optical pulse at the TI surface and the transient current within the surface depletion region. By spectrally resolving the emission under different pump and emission polarizations, we separate the different contributions. Effects arising from just a few atomic layers of the sample surface due to resonance enhancement of the quasi-real optical transitions between the surface electronic states will be discussed.

8:00AM Y32.00001 Z_Q topological invariants for identification of short range entangled states, ISAO MARUYAMA, Osaka University, SHO TANAYA, YASUHIRO HATSUGAI, Tsukuba University — Since the Berry phase is quantized as Z_2 value, i.e., 0 or π , due to the time-reversal, or lattice-inversion symmetry in any dimension, the quantized Berry phase[1] is useful for characterization of a topological or quantum order in various models including strongly correlated electron systems[2] and spin systems[3]. Recently, we have proved Z_Q quantization of Berry phases for the general lattice symmetry, where Z_Q ($Q = d+1$) Berry phases are defined for d -dimensional lattices: Polyacetylene, Kagome and Pyrochlore lattice respectively for $d = 1, 2$ and 3.[4]. We have also characterized the dimer-plaquette transition of the orthogonal dimer model in two dimension[5]. [1]Y.Hatsugai, J. Phys. Soc. Jpn, **75**, 123601 (2006). [2]IM, Y. Hatsugai, J. Phys. Soc. Jpn, **76**, 113601 (2007). [3]IM, T.Hirano, Y.Hatsugai, Phys. Rev. B, **79**, 115107 (2009)[4]Y.Hatsugai, IM, Euro. Phys. Lett., **95**, 20003 (2011) [5] I.Maruyama, S.Tanaya, M.Arikawa, Y.Hatsugai, J. Phys.:Conf. Ser., **320**, 01219 (2011)

8:12AM Y32.00002 Trace index and spectral flow in the entanglement spectrum of topological insulators, ARIS ALEXANDRADINATA, Princeton Physics Dept, TAYLOR HUGHES, UIUC Physics Dept, ANDREI BERNEVIG, Princeton Physics Dept — We investigate the entanglement spectra of topological insulators, which manifest edge states on a lattice with spatial boundaries. In the physical energy spectrum, a subset of the edge states that intersect the Fermi level translates to discontinuities in the trace of the single-particle entanglement spectrum, which we call a “trace index.” We find that any free-fermion topological insulator that exhibits spectral flow has a nonvanishing trace index, which provides us with a new description of topological invariants. In addition, we identify the signatures of spectral flow in the single-particle and many-body entanglement spectrum; in the process we present new methods to extract topological invariants and establish a connection between entanglement and quantum Hall physics.

8:24AM Y32.00003 Axions strings and Goldstone-Wilczek currents in quantum spin systems and topological insulators, AKIHIRO TANAKA, National Institute for Materials Science — Axion, originally a high-energy physics entity, has in recent years come into focus in the condensed matter community due to its incarnation in the physics of topological insulators. Much of the discussion so far has concentrated on the physics at the interface/junction of these insulators, which can be viewed as axion domain walls. Here we look into a slightly different situation: axion strings, which are vortex configurations of the axion fields. We discuss how these objects can arise in quantum spin systems and topological insulators, along with their electrodynamic and elastic implications. We also point to some novel Goldstone-Wilczek fermionic currents which can be relevant to the systems considered.

8:36AM Y32.00004 Casimir Interaction Between Topological Insulator Thin Films and Graphene Sheets¹, WANG-KONG TSE, A.H. MACDONALD, University of Texas at Austin — The Casimir effect is a peculiar manifestation of quantum vacuum fluctuations of the electromagnetic field, resulting in an attractive force between closely-spaced conductors. Because of the advent of new materials like graphene and topological insulators, it is of fundamental and potentially also of practical interest to investigate the Casimir effect between conductors described by two-dimensional Dirac models. In this work we study the Casimir effect between topological insulator thin films and graphene planes in the presence of a time-reversal breaking perturbation, most practically an external magnetic field, that gives rise to a half-quantized quantum Hall effect. We evaluate the Casimir energies and forces from the reflection properties of the double layer system. We demonstrate the essential role that is normally played by the Dirac system's dissipative longitudinal conductivity which is neglected in topological field theory descriptions of the Casimir effect. We also show that repulsive Casimir forces are possible in the presence of a magnetic field.

8:48AM Y32.00005 Exact duality between symmetry protected topological order and intrinsic topological order, ZHENGCHENG GU, MICHAEL LEVIN, Kavli Institute for Theoretical Physics — The discovery of topological insulator (TI) motivates the intensive study of symmetry protected topological (SPT) order. Different from the intrinsic topological order, SPT order is only distinguishable from a trivial disorder phase when certain symmetry is preserved. Indeed, SPT order has a long history in 1D, it has been shown the well known Haldane phase of $S=1$ Heisenberg chain belongs to this class. However, in higher dimensions, most of the previous studies focus on free electron systems with a time reversal symmetry. Until very recently, it was realized that SPT order also exists in interacting boson/spin systems in higher dimensions. In this talk, I will show in 2D boson/spin systems, there exists an interesting duality map between the intrinsic topological order and the SPT order. The duality map implies the SPT orders are stable and distinguishable against arbitrary perturbations if the symmetry is preserved. I will focus on a simplest exact solvable model with an Ising symmetry and discuss the nature of its symmetry protected low-lying edge excitations. The duality map can of course be generalized into arbitrary symmetry group G in any dimension. In principle, the duality map is also applicable for interacting fermion/electron systems.

9:00AM Y32.00006 Asymmetric spatial structure of zero modes for birefringent Dirac fermions¹, MALCOLM P. KENNETT, Simon Fraser University, BITAN ROY, NHMFL, Florida State University, PETER M. SMITH, Simon Fraser University — We study the zero energy modes that arise in an unusual vortex configuration involving both the kinetic energy and an appropriate mass term in a model which exhibits birefringent Dirac fermions as its low energy excitations. We find the surprising feature that the ratio of the length scales associated with states centered on vortex and anti-vortex topological defects can be arbitrarily varied but that fractionalization of quantum numbers such as charge is unaffected. We discuss this situation from a symmetry point of view and present numerical results for a specific lattice model realization of this scenario.

9:12AM Y32.00007 Location of Singularities in tight-binding wave function of loop-ordered states with Chern numbers, YAN HE, CHANDRA VARMA, University of California Riverside — As a pedagogic exercise, we consider time-reversal violating tight-binding wave-functions for Haldane states in the Graphene model and in a Copper-Oxide model. We locate the singularities in the wave-functions and derive the movement in their location as well as the change in the Berry phase with the choice of Gauge.

9:24AM Y32.00008 Effects of spin-orbit interaction on a triangular lattice potential patterned two-dimensional electron gas, CHON-SAAR CHU, WIE-LIN SU, RONGSING CHANG, Department of Electrophysics, National Chiao Tung University, Hsinchu 30010, Taiwan — We have studied theoretically the electronic states of a two-dimensional electron gas (2DEG) in the presence of a triangular lattice of muffin-tin potentials. In particular, spin-orbit interaction due to the in-plane potential gradient is included. At the K and K' points in the Brillouin zone, the Dirac cones open up a gap and their respective Berry curvatures are of the same sign which, in turn, depends on the electron spin. This contrasting feature, from that of graphene, is related to the fact that inversion symmetry is preserved in our case. The system thus exhibits Z_2 physics.

9:36AM Y32.00009 Smooth gauge for topological insulators, ALEXEY SOLUYANOV, DAVID VANDERBILT, Rutgers University — We develop a technique for constructing Bloch functions for Z_2 quantum spin-Hall insulators that are smooth functions of $\mathbf{k}$ on the whole Brillouin-zone torus. As the initial step, the occupied subspace of the insulator is decomposed into a direct sum of two "Chern bands," i.e., topologically non-trivial subspaces with opposite Chern numbers. This decomposition remains robust independently of underlying symmetries or specific model features. Starting with the Chern bands obtained in this way, we construct a topologically non-trivial unitary transformation that rotates the occupied subspace into a direct sum of topologically trivial subspaces. The possibility of using such a transformation is validated, and the entire procedure is illustrated, by applying it to the Kane-Mele model.

9:48AM Y32.00010 Stable nontrivial Z_2 topology in ultrathin Bi (111) films: a first-principles study¹, ZHENG LIU, Tsinghua University & University of Utah, CHAO-XING LIU, Wuerzburg Universitat, YONG-SHI WU, University of Utah, WEN-HUI DUAN, Tsinghua University, FENG LIU, University of Utah, JIAN WU, Tsinghua University — Recently, there have been intense efforts in searching for new topological insulator (TI) materials. Based on first-principles calculations, we find that all the ultrathin Bi (111) films are characterized by a nontrivial Z_2 number independent of the film thickness, without the odd-even oscillation of topological triviality as commonly perceived. The stable nontrivial Z_2 topology is retained by the concurrent band gap inversions at multiple time-reversal-invariant $\mathbf{k}$ -points and associated with the intermediate inter-bilayer coupling of the multi-bilayer Bi film. Our calculations further indicate that the presence of metallic surface states in thick Bi(111) films can be effectively removed by surface adsorption.

10:00AM Y32.00011 Breakdown of Landau-Ginzburg-Wilson Scheme by Spontaneous Orbital Currents in Zero-gap Semiconductors¹

, MOYURU KURITA, YOUHEI YAMAJI, Department of Applied Physics, University of Tokyo, MASATOSHI IMADA, Department of Applied Physics, University of Tokyo and JST CREST — Critical phenomena of phase transitions are classified into a small number of universality classes. For understanding such symmetry-breaking transitions, a Landau-Ginzburg-Wilson (LGW) scheme greatly helps us. Here, we study the critical phenomena of topological Mott insulator (TMI)[1] where spontaneous orbital currents induced by electron correlation bring the system to topological insulator by formally following the spirit of LGW. Then an unconventional criticality surprisingly emerges around the quantum critical point of TMI: It is governed not only by the symmetry as in the LGW framework but also by topology through electron dispersions and spatial dimension. We demonstrate it by studying an extended Hubbard model on several lattices such as honeycomb and pyrochlore lattice[2] within the Hartree-Fock mean-field level. Both fully numerical calculations and analytical calculations using effective band dispersions are performed.

10:12AM Y32.00012 Transition in topological phase of Ge-Sb-Te and Ge-Bi-Te heterostructures

, JEONGWOO KIM, JINWOONG KIM, Department of Physics, Pohang University of Science and Technology, KI-SEOK KIM, Asia Pacific Center for Theoretical Physics, Pohang University of Science and Technology, SEUNG-HOON JHI, Department of Physics, Pohang University of Science and Technology — We studied the transition of topological phase of ternary chalcogenide compounds using first-principles methods. Our calculations show that they undergo a transition between band insulator and topological insulator phases upon the variation of atomic composition and layer thickness. In order to understand the transition, we developed a model Hamiltonian of 1D Dirac fermionic superlattice. We introduced to the Hamiltonian an effective interaction between Dirac fermions that is mediated by the electrons from the band insulating layers. We obtained the phase diagram of the transition as a function of materials parameters including layer thickness, band gap, and Dirac fermionic mass gap. We also discussed the implication of our results to the conducting properties of chalcogenide compounds

10:24AM Y32.00013 Nontrivial topological effects on the surface of strong and weak topological insulators and superconductors

, CHING-KAI CHIU, MICHAEL STONE, University of Illinois at Urbana-Champaign — We investigate states on the surface of strong or weak topological insulators and superconductors that have been gapped by a magnetic material or by a charge density wave. The surface of a strong 3D topological insulator gapped by a magnetic material is well known to possess a half quantum Hall effect. Furthermore, a recent paper (arXiv:1110.3420) showed that the surface of a weak 3D topological insulator gapped by charge density wave has a half quantum spin Hall effect. We generalize these results to all classes of topological insulator and superconductors. We find that if, in d-1 dimension and that symmetry class, there is a Z or Z_2 topological invariant, then the resulting surface state may have a nontrivial topological phase.

8:00AM Y40.00001 Forces driving three-dimensional tissue patterning during morphogenesis

, HENG LU, ADAM SOKOLOW, U. SERDAR TULU, DANIEL KIEHART, GLENN EDWARDS, Duke University — Dorsal closure is an essential stage of *Drosophila* embryogenesis and is a model system for *in-vivo* investigations of cell sheet morphogenesis. During closure a system of four biological processes work collectively to close a gap in the epithelium, which initially is filled with a transient tissue. The geometry of the dorsal opening is similar to that of two intersecting circular arcs being pulled apart at a nearly constant rate. Substantial progress in understanding the dynamics has been made in the past by largely viewing closure as a two-dimensional process. However, tissue and cell dynamics are not confined to the embryo surface. We have been investigating the three-dimensional kinematics of dorsal closure by imaging the actomyosin purse strings at the periphery of the dorsal opening and by imaging the apical belts of DE-cadherin in each cell within the opening. We have analyzed the results with the methods of analytic geometry. In addition, in the past we have determined the relative magnitudes of the forces that drive dorsal closure. We have been using magnetic tweezers, time-resolved *in-vivo* microscopy, and biophysical modeling to measure the net force and to determine the magnitude of each force.

8:12AM Y40.00002 Cell Autonomous Shape Changes in Germband Retraction

, HOLLEY LYNCH, ELLIOTT KIM, ROBERT GISH, M. SHANE HUTSON, Vanderbilt University — Germband retraction involves the cohesive movement and regulated cellular mechanics of two tissues on the surface of fruit fly embryos, the germband and the amnioserosa. The germband initially forms a 'U' shape, curling from the ventral surface, around the posterior of the embryo, and onto the dorsal surface; the amnioserosa lies between the arms of this 'U'. Retraction straightens the germband and leaves it only on the ventral side. During retraction, the germband becomes clearly segmented with deep furrows between segments, and its cells elongate towards the amnioserosa, along what becomes the dorsal-ventral axis. To determine the importance of these changes for the overall movement of the tissues, we observed embryos that did not complete germband retraction due to targeted laser ablation of half the amnioserosa. Without the chemical and mechanical influence of the amnioserosa, germband furrows still formed and germband cells still elongated; however, this elongation was misaligned compared to unablated embryos. Thus, furrow formation and cell elongation in the germband are autonomous, but insufficient to drive proper tissue motion. These results suggest that part of the necessary role of the amnioserosa is proper orientation of germband cell elongation.

8:24AM Y40.00003 Wavefronts and mechanical signaling in early *Drosophila* embryos

, TIMON IDEMA, University of Pennsylvania, JULIEN DUBUIS, Princeton University, LISA MANNING, Syracuse University, PHILIP NELSON, ANDREA LIU, University of Pennsylvania — Mitosis in the early syncytial *Drosophila* embryo has a high degree of spatial and temporal correlations, visible as mitotic wavefronts that travel across the embryo. This mitosis wavefront is preceded by another wavefront which corresponds to chromosome condensation. The two wavefronts are separated by a time interval that is independent of cell cycle and propagate at the same speed for a given embryo in a given cycle. We study the wavefronts in the context of excitable medium theory, using two different models, one with biochemical signaling and one with mechanical signaling. We find that the dependence of wavefront speed on cell cycle number is most naturally explained via a mechanical signaling, and that the entire process suggests a scenario in which biochemical and mechanical signaling are coupled.

8:36AM Y40.00004 Passive cellular microrheology in developing fruit fly embryos , SARAH CREWS, XIAOYAN MA, STACEY LAWRENCE, M. SHANE HUTSON, Vanderbilt University — The development of fruit fly (*Drosophila*) embryos involves spatial and temporal regulation of cellular mechanical properties. These properties can be probed *in vivo* using laser hole drilling experiments; however, this technique only infers relative forces. Conversion to absolute forces requires measurement of cellular viscoelastic properties. Here, we use passive microrheology of fluorescently labeled cell membranes to measure the viscoelastic properties of amnioserosa cells. These dynamic epithelial cells play an important mechanical role during two developmental stages: germ band retraction and dorsal closure. Passive microrheology in this system is confounded by active contractions in the cytoskeleton. Thus, the fruit fly embryos are transiently anesthetized with CO₂, halting active cellular movements, leaving only passive Brownian motion. The power spectra of these fluctuations are well fit by a Lorentzian – as expected for Brownian motion – and allow us to extract cellular viscoelastic parameters at different developmental stages. These measured parameters inform previous hole-drilling experiments and provide inputs for quantitative computational models of fruit fly embryonic development.

8:48AM Y40.00005 Remodeling of cellular cytoskeleton drives tissue level morphogenesis , MADHAV MANI, KITP and UCSB Physics, THOMAS LECUIT, IBDML, BORIS SHRAIMAN, KITP and UCSB Physics — Mechanical stresses are central to morphogenesis, both as a cause that generates geometric and topological change, and as regulatory signals that couple cells. Live imaging of fluorescently tagged tissues gives us insight into the cellular processes underlying tissue dynamics during morphogenesis. Amongst these is the remodeling of the cytoskeleton and cellular adhesion. Here, following observations from *drosophila* germ band extension and ventral furrow formation, we a) investigate the mechanical state of the tissue b) perform a quantitative analysis and verification of the cell and tissue level stresses and c) determine how conserved cellular processes are regulated to generate tissue level stresses that drive morphogenesis.

9:00AM Y40.00006 Investigation of autonomous cell dynamics using holographic laser microsurgery , AROSHAN JAYASINGHE, M. SHANE HUTSON, Dept. of Physics & Astronomy, Vanderbilt University, Nashville, TN — Laser-microsurgery has emerged as a powerful technique for evaluating *in vivo* tissue mechanics. We extend this technique by using a spatial light modulator (SLM) to diffract a single UV laser pulse to simultaneously ablate multiple points in living tissue. Using this method, we can quickly and cleanly isolate a single cell by destroying all its nearest neighbors. The post-ablation dynamics of such an isolated cell are then largely dependent on autonomous intracellular forces. Here, we use this technique to investigate cell shape pulsations in amnioserosa cells in *Drosophila* embryos during dorsal closure – specifically to address the degree to which these pulsations are cell autonomous or driven by the contractions of neighboring cells. When cells are isolated at different points in the pulsation cycle, we find that the post-isolation dynamics are strongly dependent on the pre-isolation pulsation phase: cells in a contractile phase collapse immediately, but cells in an expansionary phase continue to expand – at least for 20-60 s before collapsing. These results are in conflict with previous pulsation models that place expanding cells under large extensional strain, and instead suggest that even the expansion phase has a significant cell autonomous component.

9:12AM Y40.00007 DBIO Best Thesis Award: Mechanics, Dynamics, and Organization of the Bacterial Cytoskeleton and Cell Wall , SIYUAN WANG, Harvard University — Bacteria come in a variety of shapes. While the peptidoglycan (PG) cell wall serves as an exoskeleton that defines the static cell shape, the internal bacterial cytoskeleton mediates cell shape by recruiting PG synthesis machinery and thus defining the pattern of cell-wall synthesis. While much is known about the chemistry and biology of the cytoskeleton and cell wall, much of their biophysics, including essential aspects of the functionality, dynamics, and organization, remain unknown. This dissertation aims to elucidate the detailed biophysical mechanisms of cytoskeleton guided wall synthesis. First, I find that the bacterial cytoskeleton MreB contributes nearly as much to the rigidity of an *Escherichia coli* cell as the cell wall. This conclusion implies that the cytoskeletal polymer MreB applies meaningful force to the cell wall, an idea favored by theoretical modeling of wall growth, and suggests an evolutionary origin of cytoskeleton-governed cell rigidity. Second, I observe that MreB rotates around the long axis of *E. coli*, and the motion depends on wall synthesis. This is the first discovery of a cell-wall assembly driven molecular motor in bacteria. Third, I prove that both cell-wall synthesis and the PG network have chiral ordering, which is established by the spatial pattern of MreB. This work links the molecular structure of the cytoskeleton and of the cell wall with organismal-scale behavior. Finally, I develop a mathematical model of cytoskeleton-cell membrane interactions, which explains the preferential orientation of different cytoskeleton components in bacteria.

9:48AM Y40.00008 Coupling of Active Motion and Advection Shapes Intracellular Cargo Transport , PHILIPP KHUC TRONG, Department of Physics, and Department of Applied Mathematics and Theoretical Physics, University of Cambridge, JOCHEN GUCK, Department of Physics, University of Cambridge, RAYMOND GOLDSTEIN, Department of Applied Mathematics and Theoretical Physics, University of Cambridge — Three different mechanisms can contribute to intracellular cargo transport: (1) passive diffusion, (2) active motor-driven transport along cytoskeletal filament networks and (3) passive advection by fluid flows. Active and advective transport are coupled because cytoplasmic flows can arise through entrainment of the fluid that surrounds actively moving cargo on cytoskeletal networks. Here, we report a reaction-advection-diffusion model for transport of a passive mass-conserved scalar that can cycle between a bound state, where advection represents active transport on a cytoskeletal network, and an unbound state, where the advecting fluid flow field is driven by forces from the cytoskeletal network. Cargo transport and localization patterns are explored for different cytoskeletal network topologies and for varying reaction kinetics. We find that for sufficiently low diffusion, localization of cargo to a target area is optimized either by low reaction kinetics and decoupling of bound and unbound state, or by a mostly disordered cytoskeletal network with only weak directional bias. The principles exemplified by this model likely have implications for our understanding and interpretation of transport patterns and cytoskeletal network structures.

10:00AM Y40.00009 Motion in partially and fully cross-linked F-actin networks , ELIZA MORRIS, ALLEN EHRLICHER, DAVID WEITZ, Harvard University — Single molecule experiments have measured stall forces and procession rates of molecular motors on isolated cytoskeletal fibers in Newtonian fluids. But in the cell, these motors are transporting cargo through a highly complex cytoskeletal network. To compare these single molecule results to the forces exerted by motors within the cell, an evaluation of the response of the cytoskeletal network is needed. Using magnetic tweezers and fluorescence confocal microscopy we observe and quantify the relationship between bead motion and filament response in F-actin networks both partially and fully cross-linked with filamin. We find that when the transition from full to partial cross-linking is brought about by a decrease in cross-linker concentration there is a simultaneous decline in the elasticity of the network, but the response of the bead remains qualitatively similar. However, when the cross-linking is reduced through a shortening of the F-actin filaments the bead response is completely altered. The characteristics of the altered bead response will be discussed here.

10:12AM Y40.00010 Measurements of the constituent contributions to the physical properties of fibroblast populated collagen microtissues with magnetic micro-tissue stretchers¹, RUOGANG ZHAO, ALAN LIU, Johns Hopkins University, THOMAS BOUDOU, CHRISTOPHER CHEN, University of Pennsylvania, DANIEL REICH, Johns Hopkins University — The mechanical properties of fibroblast populated collagen matrix (FPCM) provide important physical cues to regulate physiological and pathological processes of encapsulated cells. The mechanical strength of FPCM is arises from both of its constituents: the collagen matrix and the fibroblasts. Existing methods to separate the contribution of individual constituents by treating cm-scale tissue samples with decellularization drugs for prolonged periods have been shown to adversely affect the properties of the collagen matrix. To minimize such matrix damage, we have developed a magnetic microtissue stretching system that allows us to grow arrays of sub-mm scale microtissues that can be rapidly decellularized. This consists of arrays of paired micro-cantilevers that support the 3D FPCM and can be driven by incorporated magnetic material via externally applied magnetic fields. By measuring the tensile force applied to the FPCM and the tissue strain, we found the stiffness of the matured FPCM is 28.1 $\pm$ 1.8 kPa and that of the decellularized collagen matrix is 23.1 $\pm$ 3.1 kPa. These measurements of the stiffness of the intact collagen matrix in a remodeled FPCM can provide important clues on the mechanical environment that regulates the biological function of encapsulated cells.

10:24AM Y40.00011 Crowding of molecular motors determines microtubule depolymerization, LOUIS REESE, ANNA MELBINGER, ERWIN FREY, Arnold Sommerfeld Center for Theoretical Physics and Center for NanoScience, Department of Physics, Ludwig-Maximilians-Universitaet Muenchen — Assembly and disassembly dynamics of microtubules (MTs) is tightly controlled by MT associated proteins. Here, it is investigated how plus-end-directed depolymerases of the kinesin-8 family regulate MT depolymerization dynamics. We reproduce experimental findings within the framework of a totally asymmetric simple exclusion process with Langmuir kinetics (TASEP/LK). Thereby, crowding is identified as the key regulatory mechanism of depolymerization dynamics. The analysis gives two qualitatively distinct phases. For motor densities above a particular threshold, a macroscopic traffic jam emerges at the plus-end and the MT dynamics become independent of the motor concentration. Below this threshold, microscopic traffic jams at the tip arise which cancel out the effect of the depolymerization kinetics such that the depolymerization speed is determined by the motor density. Because this density varies over the MT length, length-dependent regulation is possible. The critical length at which MTs start to depolymerize in a length-dependent way is discussed. 10:36AM Y40.00012 Physics of the actin cortex in shape oscillations of dividing cells, GUILLAUME SALBREUX, Max Planck Institute for the Physics of Complex Systems, Dresden, EWA PALUCH LAB COLLABORATION¹ — During cytokinesis, a contractile actomyosin cortex is present at the poles of the dividing cell. For a large enough tension of the polar cortex, a physical symmetry-breaking instability of the cell shape can occur where one pole transfers its volume to the other. Such a shape instability can indeed be observed in control and treated dividing cultured cells where it results in cell shape oscillations and in some cases leads to cytokinesis failure. The cell oscillation properties can be accurately described with a theoretical model based on a competition between cortex turnover and contraction dynamics. Interestingly, our results indicate that a sufficiently large cell elasticity is needed to ensure successful cytokinesis.

10:48AM Y40.00013 Geometrical Reorganisation of the Cytoskeleton and Changes in Cellular Stiffness Following Stretch, HARIKRISHNAN PARAMESWARAN, BELA SUKI, Boston University — Cells in the lung and the vasculature are under a highly dynamic mechanical environment where they are constantly exposed to stretch. Cells adapt to these fluctuations in stretch by remodeling their cytoskeleton. However, the influence of these geometrical changes on cell stiffness is not well understood. We developed a computational model to simulate the geometrical reorganization of the actin by non-muscle myosin-II under conditions of monotonous cyclic stretch, where amplitude and frequency is constant from cycle to cycle and variable stretch, where the amplitude is varied from cycle-to-cycle and the frequency is inversely proportional to amplitude. With the monotonous cyclic-stretch, the network exhibited significant hysteresis in geometry, it reorganized itself into a more stable configuration and the internal prestress decreased after each cycle. In contrast, the more realistic variability in stretch amplitude prevented these stable configurations from forming and preserved the prestress. This behavior was dependent on the variability in stretch amplitude and the timing of the large amplitude stretches. We conclude that prestress is a consequence of cytoskeletal reorganization which exhibits structural hysteresis and is dependent on the nature of the stretch pattern.

8:00AM Y41.00001 Cancer Imaging, CHENGHANG ZONG, —

8:36AM Y41.00002 Optimality in the Development of Intestinal Crypts, ALEXANDER VAN OUDENAAR-DEN, MIT — Intestinal crypts in mammals are comprised of long-lived stem cells and shorter-lived progenies, maintained under tight proportions during adult life. Here we ask what are the design principles that govern the dynamics of these proportions during crypt morphogenesis. We use optimal control theory to show that a stem cell proliferation strategy known as a 'bang-bang' control minimizes the time to obtain a mature crypt. This strategy consists of a surge of symmetric stem cell divisions, establishing the entire stem cell pool first, followed by a sharp transition to strictly asymmetric stem cell divisions, producing non-stem cells with a delay. We validate these predictions using lineage tracing and single molecule fluorescent in-situ hybridization of intestinal crypts in newborn mice and find that small crypts are entirely composed of Lgr5 stem cells, which become a minority as crypts further grow. Our approach can be used to uncover similar design principles in other developmental systems.

9:12AM Y41.00003 Molecular Imaging System for Monitoring Tumor Angiogenesis, ESRA AYTAC, MEHMET BURCIN UNLU, None — In cancer, non-invasive imaging techniques that monitor molecular processes associated with the tumor angiogenesis could have a central role in the evaluation of novel antiangiogenic and proangiogenic therapies as well as early detection of the disease. Matrix metalloproteinases (MMP) can serve as specific biological targets for imaging of angiogenesis since expression of MMPs is required for angiogenesis and has been found to be upregulated in every type of human cancer and correlates with stage, invasive, metastatic properties and poor prognosis. However, for most cancers it is still unknown when, where and how MMPs are involved in the tumor angiogenesis [1]. Development of high-resolution, high sensitivity imaging techniques in parallel with the tumor models could prove invaluable for assessing the physical location and the time frame of MMP enzymatic activity. The goal of this study is to understand where, when and how MMPs are involved in the tumor angiogenesis. We will accomplish this goal by following two objectives: to develop a high sensitivity, high resolution molecular imaging system, to develop a virtual tumor simulator that can predict the physical location and the time frame of the MMP activity. In order to achieve our objectives, we will first develop a PAM system and develop a mathematical tumor model in which the quantitative data obtained from the PAM can be integrated. So, this work will develop a virtual tumor simulator and a molecular imaging system for monitoring tumor angiogenesis. 1.Kessenbrock, K., V. Plaks, and Z. Werb, MMP:regulators of the tumor microenvironment. Cell, 2010. 141(1)

9:24AM Y41.00004 Characterizing Spatial Organization of Cell Surface Receptors in Human Breast Cancer with STORM, EVAN LYALL, Department of Bioengineering, University of California, Berkeley, MATTHEW R. CHAPMAN, Biophysics Graduate Group, University of California, Berkeley, LYDIA L. SOHN, Department of Mechanical Engineering, University of California, Berkeley — Regulation and control of complex biological functions are dependent upon spatial organization of biological structures at many different length scales. For instance Eph receptors and their ephrin ligands bind when opposing cells come into contact during development, resulting in spatial organizational changes on the nanometer scale that lead to changes on the macro scale, in a process known as organ morphogenesis. One technique able to probe this important spatial organization at both the nanometer and micrometer length scales, including at cell-cell junctions, is stochastic optical reconstruction microscopy (STORM). STORM is a technique that localizes individual fluorophores based on the centroids of their point spread functions and then reconstructs a composite image to produce super resolved structure. We have applied STORM to study spatial organization of the cell surface of human breast cancer cells, specifically the organization of tyrosine kinase receptors and chemokine receptors. A better characterization of spatial organization of breast cancer cell surface proteins is necessary to fully understand the tumorigenesis pathways in the most common malignancy in United States women.

9:36AM Y41.00005 In Vivo Fluorescence Resonance Energy Transfer Imaging for Targeted Anti-Cancer Drug Delivery Kinetics¹, KEVIN WEBB, VAIBHAV GAIND, HSIAORHO TSAI, BRIAN BENTZ, VENKATESH CHELVAM, PHILIP LOW, Purdue University — We describe an approach for the evaluation of targeted anti-cancer drug delivery *in vivo*. The method emulates the drug release and activation process through acceptor release from a targeted donor-acceptor pair that exhibits fluorescence resonance energy transfer (FRET). In this case, folate targeting of the cancer cells is used - 40 % of all human cancers, including ovarian, lung, breast, kidney, brain and colon cancer, over-express folate receptors. We demonstrate the reconstruction of the spatially-dependent FRET parameters in a mouse model and in tissue phantoms. The FRET parameterization is incorporated into a source for a diffusion equation model for photon transport in tissue, in a variant of optical diffusion tomography (ODT) called FRET-ODT. In addition to the spatially-dependent tissue parameters in the diffusion model (absorption and diffusion coefficients), the FRET parameters (donor-acceptor distance and yield) are imaged as a function of position. Modulated light measurements are made with various laser excitation positions and a gated camera. More generally, our method provides a new vehicle for studying disease at the molecular level by imaging FRET parameters in deep tissue, and allows the nanometer FRET ruler to be utilized in deep tissue.

9:48AM Y41.00006 Exploring X-Ray Phase-Contrast Imaging using Photon Counting Detectors for Early Breast Cancer Detection¹, MINI DAS, Department of Physics, University of Houston, Houston, TX — X-ray attenuation-contrast (AC) imaging in the form of digital mammography (DM) is the current gold standard of screening for deep-set cancers like breast cancer. DM creates images based on the attenuation differences between normal and malignant breast tissue, but the extremely low attenuation contrast poses severe challenges for early cancer detection. In order to overcome these limitations posed by AC imaging, there is a growing interest in exploring phase changes in x-rays as they propagate through the tissue. Theoretical estimations show that the x-ray phase difference between normal and malignant breast tissue is three orders of magnitude higher than the corresponding absorption contrast. While x-ray attenuation is determined by the atomic number of the elements forming the tissue, the phase change is determined by the density or refractive index. Due to high energy of x-rays, absolute measurement of phase change is challenging. We will present our efforts to understand x-ray phase contrast in biological tissue using a photon counting detector (TIMEPIX), which is capable of energy and time resolved measurements with very high spatial resolution (about 50 microns). We are exploring novel methods, which will also be clinically feasible to extract phase information using a combination of PCDs and phase retrieval techniques. Phase changes and contrast details of various breast cancer types will also be investigated using the energy resolved measurements obtained using PCDs.

10:00AM Y41.00007 Uncovering cancer cell behavioral phenotype in 3-D *in vitro* metastatic landscapes, LIYU LIU, Physics, Princeton University, BO SUN, Mechanical & Aerospace Engineering, GUILLAUME DUCLOS, Physics, Princeton University, YOONSEOK KAM, ROBERT GATENBY, Moffitt Cancer Institute, HOWARD STONE, Mechanical & Aerospace Engineering, ROBERT AUSTIN, Physics, Princeton University, PHYSICS-MECHANICAL & AEROSPACE ENGINEERING, PRINCETON TEAM, PHYSICS, PRINCETON-MOFFITT CANCER INSTITUTE COLLABORATION — One well-known fact is that cancer cell genetics determines cell metastatic potentials. However, from a physics point of view, genetics as cell properties cannot directly act on metastasis. An agent is needed to unscramble the genetics first before generating dynamics for metastasis. Exactly this agent is cell behavioral phenotype, which is rarely studied due to the difficulties of real-time cell tracking in *in vivo* tissue. Here we have successfully constructed a micro *in vitro* environment with collagen based Extracellular Matrix (ECM) structures for cell 3-D metastasis. With stable nutrition (glucose) gradient inside, breast cancer cell MDA-MB-231 is able to invade inside the collagen from the nutrition poor site towards the nutrition rich site. Continuous confocal microscopy captures images of the cells every 12 hours and tracks their positions in 3-D space. The micro fluorescent beads pre-mixed inside the ECM demonstrate that invasive cells have altered the structures through mechanics. With the observation and the analysis of cell collective behaviors, we argue that game theory may exist between the pioneering cells and their followers in the metastatic cell group. The cell collaboration may explain the high efficiency of metastasis.

Friday, March 2, 2012 8:00AM - 11:00AM —
Session Y42 DBIO: Physics of Bacteria and Viruses 156C

8:00AM Y42.00001 Membrane-mediated interaction between retroviral capsids, RUI ZHANG, North-eastern State University, TOAN NGUYEN, Georgia Institute of Technology — A retrovirus is an RNA virus that is replicated through a unique strategy of reverse transcription. Unlike regular enveloped viruses which are assembled inside the host cells, the assembly of retroviral capsids happens right on the cell membrane. During the assembly process, the partially formed capsids deform the membrane, giving rise to an elastic energy. When two such partial capsids approach each other, this elastic energy changes. Or in other words, the two partial capsids interact with each other via the membrane. This membrane mediated interaction between partial capsids plays an important role in the kinetics of the assembly process. In this work, this membrane mediated interaction is calculated both analytically and numerically. It is worth noting that the differential equation determining the membrane shape in general nonlinear and cannot be solved analytically, except in the linear region of small deformations. And it is exactly the nonlinear regime that is important for the assembly kinetics of retroviruses as it provides a large energy barrier. The theory developed here is applicable to more generic cases of membrane mediated interactions between two membrane-embedded proteins.

8:12AM Y42.00002 Discrete fracture patterns of virus shells reveal mechanical building blocks

, IRENA L. IVANOVSKA, Biophysical Engineering Laboratory, University of Pennsylvania, Philadelphia, PA, ROBERTO MIRANDA, JOSÉ L. CARRASCOSA, Dept. Struct. Macromol., Centro Nacional de Biotecnología, Campus Universidad Autónoma de Madrid, GJIS J.L. WUITE, Dept. Physics and Astronomy, Vrije Universiteit Amsterdam, CHRISTOPH F. SCHMIDT, Third Institute of Physics, Georg-August-Universität Göttingen — Viral shells are self-assembled protein nanocontainers with remarkable material properties. They combine simplicity of construction with toughness and complex functionality. To date we know little about how virus structure determines assembly pathways and shell mechanics. We have used atomic force microscopy to study structural failure of the shells of the bacteriophage $\Phi 29$. We observed rigidity patterns following the symmetry of the capsid proteins and under prolonged force exertion, we see fractures along well-defined lines of the 2D crystal lattice. We found the mechanically most stable building block of the shells was a trimer. Our approach of “reverse engineering” the virus shells thus made it possible to identify stable structural intermediates. Such stable intermediates point to a hierarchy of interactions among equal building blocks correlated with distinct next-neighbor interactions. The results also demonstrate that concepts from macroscopic materials science, such as fracture, can be usefully employed in molecular engineering.

8:24AM Y42.00003 Pili-driven surface motility of *Myxococcus xanthus*

, MAXSIM GIBIANSKY, UCLA Bioengineering, WEI HU, UCLA School of Dentistry, KUN ZHAO, UCLA Bioengineering, HONGWEI PAN, WENYUAN SHI, UCLA School of Dentistry, KARIN DAHMEN, UIUC Physics, GERARD WONG, UCLA Bioengineering — *Myxococcus xanthus* is a common, rod-shaped soil-dwelling bacterium with complex motility characteristics. In groups, *M. xanthus* bacteria can move via social “S” motility, in which the Type IV Pili (TFP) attach to secreted exopolysaccharides (EPS). We examine this motility mechanism using high-frame-rate video acquisition, taking data on individual bacteria at 400 frames per second; using particle tracking algorithms, we algorithmically reconstruct the bacterial trajectories. The motion of a single bacterium as it is pulled by its TFP through the EPS layer on the surface is not smooth, but instead displays distinct plateaus and slips, with a wide range of plateau and slip lengths. The distribution of slips exhibits power law scaling, consistent with a crackling noise model; crackling noise has previously been used to model nonbiological systems such as earthquake dynamics and Barkhausen noise. We show quantitative agreement between mean field friction models and observed bacterial dynamics. We demonstrate that the crackling noise behavior of *M. xanthus* is strongly dependent on the presence of EPS, but is unaffected by the chemotactic behavior of the bacterium; we also demonstrate velocity coupling between pairs of bacteria in the early stages of social motility.

8:36AM Y42.00004 Pili-taxis: Clustering of *Neisseria gonorrhoeae* bacteria

, JOHANNES TAKTIKOS, Technical University Berlin, Germany, VASILY ZABURDAEV, Harvard University, NICOLAS BIAIS, Columbia University, HOLGER STARK, Technical University Berlin, DAVID A. WEITZ, Harvard University — The first step of colonization of *Neisseria gonorrhoeae* bacteria, the etiological agent of gonorrhea, is the attachment to human epithelial cells. The attachment of *N. gonorrhoeae* bacteria to surfaces or other cells is primarily mediated by filamentous appendages, called type IV pili (Tfp). Cycles of elongation and retraction of Tfp are responsible for a common bacterial motility called twitching motility which allows the bacteria to crawl over surfaces. Experimentally, *N. gonorrhoeae* cells initially dispersed over a surface agglomerate into round microcolonies within hours. It is so far not known whether this clustering is driven entirely by the Tfp dynamics or if chemotactic interactions are needed. Thus, we investigate whether the agglomeration may stem solely from the pili-mediated attraction between cells. By developing a statistical model for pili-taxis, we try to explain the experimental measurements of the time evolution of the mean cluster size, number of clusters, and area fraction covered by the cells.

8:48AM Y42.00005 The Psl economy in early *P. aeruginosa* biofilm development

, KUN ZHAO, University of California, Los Angeles, BOO SHAN TSENG, University of Washington, FAN JIN, MAX GIBIANSKY, University of California, Los Angeles, JOE HARRISON, MATTHEW PARSEK, University of Washington, GERARD WONG, University of California, Los Angeles — Psl from *P. aeruginosa* (PAO1) is a mannose- and galactose-rich exopolysaccharide (EPS). It has been shown that Psl plays an important role in bacterial surface adhesion. Here, we examine role of Psl in controlling motility and microcolony formation during early biofilm development, by translating video microscopy movies into searchable databases of bacterial trajectories. We use a massively-parallel cell tracking algorithm to extract the full motility history of every cell in a large community. We find that at early stages of growth, *P. aeruginosa* motility is guided by Psl and self-organize in a manner analogous to a capitalist economic system, resulting in a power law bacterial distribution where a small number of bacteria are extremely “rich” in communally produced Psl. By comparing overproducers and underproducers of Psl, we find that local Psl levels determine post-division cell fates: High local Psl levels drive the formation of sessile microcolonies that grow exponentially.

9:00AM Y42.00006 Roles of Pel and Psl in very early biofilm development

, B.J. COOLEY, TRAVIS THATCHER, GUILLAUME L'HER, ERIN REED, JAMIE STUART, APRIL KISSINGER, VERNITA GORDON, Center for Nonlinear Dynamics and Department of Physics, University of Texas at Austin — Biofilms are dynamic, multicellular communities of unicellular organisms. Biofilms cause many chronic infections; an important case is the opportunistic human pathogen *Pseudomonas aeruginosa*. Bacteria in biofilms produce an extracellular matrix that binds bacteria to each other and to a surface. The two primary extracellular matrix components produced by *P. aeruginosa* are the polysaccharides Pel and Psl. Here we examine the roles of Pel and Psl in the very early stages of biofilm development, just after initial surface attachment. We use high-throughput automated tracking and analysis to compare wild-type bacteria with mutants incapable of producing Pel, Psl, or both. We examine motion on a surface as well as inter-bacterial interactions. These results quantify the unique roles played by Pel and Psl and show an unexpected relationship between Pel expression and adhesion to a surface.

9:12AM Y42.00007 Quorum activation at a distance: spatiotemporal patterns of gene regulation from diffusion of an autoinducer signal

, GABRIEL DILANJI¹, JESSICA LANGEBAKE², PATRICK DELEENHEER³, STEPHEN J. HAGEN⁴, University of Florida — Bacteria in colonies coordinate gene regulation through the exchange of diffusible signal molecules known as autoinducers (AI). This “quorum signaling” often occurs in physically heterogeneous and spatially extended environments such as biofilms. Under these conditions the space and time scales for diffusion of the signal limit the range and timing of effective gene regulation. We expect that spatial and temporal patterns of gene expression will reflect physical environmental constraints as well as nonlinear transcriptional activation and feedback within the gene regulatory system. We have combined experiments and modeling to investigate how these spatiotemporal patterns develop. We embed engineered plasmid/GFP quorum sensor strains or wild type strains in a long narrow agar lane, and then introduce AI signal at one terminus of the lane. Diffusion of the AI initiates reporter expression along the length of the lane, extending to macroscopic distances of mm-cm. Resulting patterns are captured quantitatively by a mathematical model that incorporates logistic growth of the population, diffusion of AI, and nonlinear transcriptional activation. Our results show that a diffusing quorum signal can coordinate gene expression over distances of order 1cm on time scales of order 10 hrs.

9:24AM Y42.00008 Biofilm Formation in Microscopic Double Emulsion Droplets, CONNIE CHANG, DAVID WEITZ, Harvard University — In natural, medical, and industrial settings, there exist surface-associated communities of bacteria known as biofilms. These highly structured films are composed of bacterial cells embedded within self-produced extracellular matrix, usually composed of exopolysaccharides, proteins, and nucleic acids; this matrix serves to protect the bacterial community from antibiotics and environmental stressors. Here, we form biofilms encapsulated within monodisperse, microscopically-sized double emulsion droplets using microfluidics. The bacteria self-organize at the inner liquid-liquid droplet interfaces, multiply, and differentiate into extracellular matrix-producing cells, forming manifold three-dimensional shell-within-a-shell structures of biofilms, templated upon the inner core of spherical liquid droplets. By using microfluidics to encapsulate bacterial cells, we have the ability to view individual cells multiplying in microscopically-sized droplets, which allows for high-throughput analysis in studying the genetic program leading to biofilm development, or cell signaling that induces differentiation.

9:36AM Y42.00009 Atomic Force Microscope Investigations of Bacterial Biofilms Treated with Gas Discharge Plasmas¹, KURT VANDERVOORT, Physics Department, California State Polytechnic University, Pomona, CA, ANNA ZELAYA, Biological Sciences Department, California State Polytechnic University, Pomona, CA, GRACIELA BRELLES-MARINO, Biological Sciences Department, California State Polytechnic University, Pomona, CA and CINDEFI, Universidad Nacional de La Plata, Argentina — We present investigations of bacterial biofilms before and after treatment with gas discharge plasmas. Gas discharge plasmas represent a way to inactivate bacteria under conditions where conventional disinfection methods are often ineffective. These conditions involve biofilm communities, where bacteria grow embedded in an exopolysaccharide matrix, and cooperative interactions between cells make organisms less susceptible to standard inactivation methods. In this study, biofilms formed by the opportunistic bacterium *Pseudomonas aeruginosa* were imaged before and after plasma treatment using an atomic force microscope (AFM). Through AFM images and micromechanical measurements we observed bacterial morphological damage and reduced AFM tip-sample surface adhesion following plasma treatment.

¹Funding was provided by an NSF-NUE grant 0406533 and by an NIH-SCORE grant 1SC3GM088070-01. In addition, Anna Zelaya acknowledges support from the NIH MBRS Research Initiative for Scientific Enhancement (RISE) Program, grant 2R25GM061190-05A2.

9:48AM Y42.00010 High speed dynamic characterization of an *E. coli* population using advanced optical methods (DDM and DFM), RONGJING ZHANG, LAURENCE WILSON, Rowland Institute at Harvard University — The motility of microbes/bacteria in a complex environment, especially the average motility of the whole group of microorganisms, is directly related to behavior such as virulence, biofilm formation, etc. It is challenging to use traditional tracking methods to quantify the average motility of a large population. It is even more challenging when the environment is constantly changing. Two optical methods were developed to solve the problem: differential dynamic microscopy (DDM) and dark field flickering microscopy (DFM). The key features of bacteria motility were quantified automatically: average swimming speed, motile fraction, diffusion coefficient, cell body rotation speed and flagellar bundle rotation speed. This method is able to measure $\sim 10^4$ cells simultaneously. With the help of a high speed camera, the timescale of the dynamic measurement can be in a wide range from 10^{-4} s to 10^5 s. Using this tool, temperature effects on *E. coli* motility were studied. Potential biomedically-relevant applications will also be discussed.

10:00AM Y42.00011 Bacterial Swimming at Air/Water and Oil/Water Interfaces, MICHAEL MORSE, ATHENA HUANG, GUANGLAI LI, JAY TANG, Brown University, JAY TANG'S BIOPHYSICS GROUP TEAM — The microbes inhabiting the planet over billions of years have adapted to diverse physical environments of water, soil, and interfaces between water and either solid or air. Following recent studies on bacterial swimming and accumulation near solid surfaces, we turn our attention to the behavior of *Caulobacter crescentus*, a singly flagellated bacterium, at water/air and water/oil interfaces. The latter is motivated by relevance to microbial degradation of crude oil in light of the recent oil spill in the Gulf of Mexico. Our ongoing study suggests that *Caulobacter* swarmer cells tend to get physically trapped at both water/air and water/oil interfaces, accumulating at the surface to a greater degree than boundary confinement properties like that of solid surfaces would predict. At the water/air interface, swimmers move in tight circles at half the speed of swimmers in the bulk fluid. At the water/oil interface, swimming circles are even tighter with further reduced swimming speed. We report experimental data and present preliminary analysis of the findings based on low Reynolds number hydrodynamics, the known surface tension, and surface viscosity at the interface. The analysis will help determine properties of the bacterium such as their surface charge and hydrophobicity.

10:12AM Y42.00012 Bacterial thermotaxis by modulation of the swimming speed, MAHMUT DEMIR, HANNA SALMAN, Department of Physics and Astronomy, University of Pittsburgh, SALMAN LAB TEAM — It has been long established that random walkers such as bacteria can migrate in inhomogeneous environments, even without actively responding to changes they sense around them, by modulating their swimming speed and/or run time. We will show that *E. coli* bacteria migrate in shallow temperature gradients due to their speed dependence on temperature even without the presence of sensing receptors. Interestingly however, we find that the direction of their migration in the gradient depends on the serine concentration in the medium. This results from the fact that the bacterial swimming speed exhibits a two-state function of serine concentration and the difference between the two states increases with temperature. Our results show that the swimming speed of the bacteria increases monotonically with temperature when serine is present at high concentration, while it decreases for temperatures above 30 °C at low serine concentration. This observed difference in the speed dependence on temperature is found to be due to a change in the intracellular pH of the bacteria when serine is added to their surroundings, which occurs only in the presence of the serine receptor Tsr. We will discuss some details of the mechanism underlying this effect and its consequences for the bacterial behavior.

10:24AM Y42.00013 Role of cell bending and slime navigation in swarms of *M. xanthus*¹, CAMERON HARVEY, University of Notre Dame, DALE KAISER, Stanford University, MARK ALBER, University of Notre Dame — Many bacteria use motility described as swarming to colonize surfaces that allows them to optimize their access to nutrients. The swarming of the bacterium *M. xanthus* on surfaces is a remarkable interplay between motility mechanisms, cell flexibility, cell-cell adhesive interactions and directional reversals. The properties of individual cells from different mutant strains and density regimes will be demonstrated in this talk. Then, a computational model based on subcellular elements for cell representation and implemented on graphical processing units (GPUs) will be presented. High-quality high magnification movies of bacterial motility together with biologically justified computational simulations will be used for investigation of collective motion and order in swarming populations of bacteria. Collective motion will be shown to include the dynamical formation of cell clusters as well as streams of cells moving over networks of cell-generated slime tracks.

¹Research was partially supported by NIH grant 1R01GM100470-01.

10:36AM Y42.00014 Effect of Antimicrobial Agents on MinD Protein Oscillations in *E. coli* Bacterial Cells, COREY KELLY, MAXIMILIANO GIULIANI, JOHN DUTCHER, University of Guelph — The pole-to-pole oscillation of MinD proteins in *E. coli* cells determines the location of the division septum, and is integral to healthy cell division. It has been shown previously that the MinD oscillation period is approximately 40 s for healthy cells [1] but is strongly dependant on environmental factors such as temperature, which may place stress on the cell [2,3]. We use a strain of *E. coli* in which the MinD proteins are tagged with green fluorescent protein (GFP), allowing fluorescence visualization of the MinD oscillation. We use high-resolution total internal reflection fluorescence (TIRF) microscopy and a custom, temperature controlled flow cell to observe the effect of exposure to antimicrobial agents on the MinD oscillation period and, more generally, to analyze the time variation of the spatial distribution of the MinD proteins within the cells. These measurements provide insight into the mechanism of antimicrobial action. [1] Raskin, D.M.; de Boer, P. (1999) Proc. Natl. Acad. Sci. 96: 4971-4976. [2] Touhami, A.; Jericho, M; Rutenberg, A. (2006) J. Bacteriol. 188: 7661-7667. [3] Downing, B.; Rutenberg, A.; Touhami, A.; Jericho, M. (2009) PLoS ONE 4: e7285.

10:48AM Y42.00015 Residence and transit times of MinD in *E. coli* bacterial cells, MAXIMILIANO GIULIANI, COREY KELLY, JOHN DUTCHER, University of Guelph — A key step in the life of a bacterial cell is its division into two daughter cells of equal size. This process is carefully controlled and regulated so that an equal partitioning of the main cell components is obtained, which is critical for the viability of the daughter cells. In *E. coli* this regulation is accomplished in part by the Min protein system, that determines the localization of the division machinery. Of particular interest is the MinD protein that exhibits an oscillation between the poles in the rod shaped bacteria. The oscillation relies on a ATP mediated dimerization of the MinD protein that allows its insertion into the inner membrane at one of the poles of the cell, followed by an interaction with the MinE protein, which releases the MinD from the membrane, allowing it to travel to the other pole of the cell where the cycle is repeated. We have studied the spatio-temporal characteristics of the MinD oscillation from which we extract the average times for the two main processes that determine the oscillation period: the residence time in the membrane and the transit time to travel the length of the cell. Additionally, we explore how these two timescales are affected by stresses on the bacterial cells due to unfavorable physiological conditions.

Session Y43 DBIO: Invited Session: Physical Organizing Principles for Amyloid Matter: Prediction, Structure, Function 157AB

8:00AM Y43.00001 Prions, From Structure to Epigenetics and Neuronal Functions¹, SUSAN LINDQUIST, Whitehead Institute for Biomedical Research, Howard Hughes Medical Institute, Department of Biology, MIT — Prions are a unique type of protein that can misfold and convert other proteins to the same shape. The well-characterized yeast prion [PSI⁺] is formed from an inactive amyloid fiber conformation of the translation-termination factor, Sup35. This altered conformation is passed from mother cells to daughters, acting as a template to perpetuate the prion state and providing a mechanism of protein-based inheritance. We employed a variety of methods to determine the structure of Sup35 amyloid fibrils. First, using fluorescent tags and cross-linking we identified specific segments of the protein monomer that form intermolecular contacts in a "Head-to-Head," "Tail-to-Tail" fashion while a central region forms intramolecular contacts. Then, using peptide arrays we mapped the region responsible for the prion transmission barrier between two different yeast species. We have also used optical tweezers to reveal that the non-covalent intermolecular contacts between monomers are unusually strong, and maintain fibril integrity even under forces that partially unfold individual monomers and extend fibril length. Based on the handful of known yeast prion proteins we predicted sequences that could be responsible for prion-like amyloid folding. Our screen identified 19 new candidate prions, whose protein-folding properties and diverse cellular functions we have characterized using a combination of genetic and biochemical techniques. Prion-driven phenotypic diversity increases under stress, and can be amplified by the dynamic maturation of prion-initiating states. These qualities allow prions to act as "bet-hedging" devices that facilitate the adaptation of yeast to stressful environments, and might speed the evolution of new traits. Together with Kandel and Si, we have also found that a regulatory protein that plays an important role in synaptic plasticity behaves as a prion in yeast. Cytoplasmic polyAdenylation element binding protein, CPEB, maintains synapses by promoting the local translation of mRNAs. We postulate that the self-perpetuating folding of the prion domain acts as a molecular memory. Thus yeast prions have provided evidence for the surprising possibility that amyloid protein folds can serve as the basis for memory and inheritance.

8:36AM Y43.00002 Exploring the Amylome: Predicting Amyloidogenic proteins & mapping their roles, functional or not, ROLAND RIEK, ETH Zurich — No abstract available.

9:12AM Y43.00003 Toxic β -Amyloid ($A\beta$) Alzheimer's Ion Channels: From Structure to Function and Design, RUTH NUSSINOV, NCI-Frederick, SAIC-Frederick, Inc. — Full-length amyloid beta peptides ($A\beta_{1-40/42}$) form neuritic amyloid plaques in Alzheimer's disease (AD) patients and are implicated in AD pathology. Recent biophysical and cell biological studies suggest a direct mechanism of amyloid beta toxicity – ion channel mediated loss of calcium homeostasis. Truncated amyloid beta fragments ($A\beta_{11-42}$ and $A\beta_{17-42}$), commonly termed as non-amyloidogenic are also found in amyloid plaques of Alzheimer's disease (AD) and in the preamyloid lesions of Down's syndrome (DS), a model system for early onset AD study. Very little is known about the structure and activity of these smaller peptides although they could be key AD and DS pathological agents. Using complementary techniques of explicit solvent molecular dynamics (MD) simulations, atomic force microscopy (AFM), channel conductance measurements, cell calcium uptake assays, neurite degeneration and cell death assays, we have shown that non-amyloidogenic $A\beta_{9-42}$ and $A\beta_{17-42}$ peptides form ion channels with loosely attached subunits and elicit single channel conductances. The subunits appear mobile suggesting insertion of small oligomers, followed by dynamic channel assembly and dissociation. These channels allow calcium uptake in APP-deficient cells and cause neurite degeneration in human cortical neurons. Channel conductance, calcium uptake and neurite degeneration are selectively inhibited by zinc, a blocker of amyloid ion channel activity. Thus truncated $A\beta$ fragments could account for undefined roles played by full length $A\beta$ s and provide a novel mechanism of AD and DS pathology. The emerging picture from our large-scale simulations is that toxic ion channels formed by β -sheets are highly polymorphic, and spontaneously break into loosely interacting dynamic units (though still maintaining ion channel structures as imaged with AFM), that associate and dissociate leading to toxic ion flux. This sharply contrasts intact conventional gated ion channels that consist of tightly interacting α -helices that robustly prevent ion leakage, rather than hydrogen-bonded β -strands. Moreover, in comparison with β -rich antimicrobial peptide (AMP) such as a protegrin-1 (PG-1), both $A\beta$ and PG-1 are cytotoxic, and capable of forming fibrils and dynamic channels which consist of subunits with similar dimensions. These combined properties support a functional relationship between amyloidogenic peptides and β -sheet-rich cytolytic AMPs, suggesting that PG-1 is amyloidogenic and amyloids may have an antimicrobial function.

9:48AM Y43.00004 Predicting Amyloid Structure Without Bioinformatic Support: Threading the Left Handed Beta Helix, ALEXANDER KLUBER, UC-Davis — No abstract available.

10:24AM Y43.00005 Functional Hydrogel Materials Inspired by Amyloid, JOEL SCHNEIDER, National Cancer Institute — Protein assembly resulting in the formation of amyloid fibrils, assemblies rich in cross beta-sheet structure, is normally thought of as a deleterious event associated with disease. However, amyloid formation is also involved in a diverse array of normal biological functions such as cell adhesion, melanin synthesis, insect defense mechanism and modulation of water surface tension by fungi and bacteria. These findings indicate that Nature has evolved to take advantage of large, proteinaceous fibrillar assemblies to elicit function. We are designing functional materials, namely hydrogels, from peptides that self-assembled into fibrillar networks, rich in cross beta-sheet structure. These gels can be used for the direct encapsulation and delivery of small molecule-, protein- and cell-based therapeutics. Loaded gels exhibit shear-thinning/self-healing mechanical properties enabling their delivery via syringe. In addition to their use for delivery, we have found that some of these gels display antibacterial activity. Although cytocompatible towards mammalian cells, the hydrogels can kill a broad spectrum of bacteria on contact.

Session Y44 DPOLY: Focus Session: Directed Assembly of Hybrid Materials - Particle Organization and Arrays 157C

8:00AM Y44.00001 Simulations of nanoparticle ionic and organic hybrid materials¹, ATHANASSIOS

Z. PANAGIOTOPOULOS, Princeton University — We have used molecular dynamics simulations over microsecond time scales to study the structure and dynamics of coarse-grained models for nanoparticle-based ionic and organic hybrid materials [1]. The systems of interest consist of particles with charged surface groups and linear or three-arm counterions, which also act as the solvent. A comparable uncharged model of nanoparticles with tethered chains is also studied. The pair correlation functions display a rich structure resulting from the packing of cores and chains, as well as electrostatic effects. Even though electrostatic interactions between oppositely charged ions at contact are much greater than the thermal energy, we find that chain dynamics at intermediate time scales are dominated by chain hopping between core particles. We have also used molecular dynamics simulations and density functional theory to investigate the structure of solvent-free oligomer-grafted nanoparticles [2,3]. At low temperatures and moderate to high oligomer lengths, the qualitative features of the core particle pair probability, structure factor, and the oligomer brush configuration obtained from the simulations can be explained by a density-functional theory that incorporates the configurational entropy of the space-filling oligomers. In particular, the structure factor at small wave numbers attains a value much smaller than the corresponding hard-sphere suspension, the first peak of the pair distribution function is enhanced due to entropic attractions among the particles, and the oligomer brush expands with decreasing particle volume fraction to fill the interstitial space. At higher temperatures, the simulations reveal effects that differ from the theory and are likely caused by steric repulsions of the expanded corona chains.

8:36AM Y44.00002 Reverse-engineering the anisotropic assembly of grafted nano-particles ,

BEHNAZ BOZORGUI, SANAT KUMAR, Columbia University — We use computer simulations to study the self assembly and directed phase separation of nanoparticles grafted with polymeric chains in an implicit solvent. The formation of anisotropic clusters from building blocks that are symmetric (both in shape and interactions) has been the subject of recent studies. This anisotropy has roots in many body physics, which manifests itself as a directional assembly. Here we apply both full and coarse-grained simulations to get a better insight of the physics behind the assembly of such systems.

8:48AM Y44.00003 Crystalline assembly of hard polyhedra via directional entropic forces¹ ,

PABLO F. DAMASCENO, MICHAEL ENGEL, SHARON C. GLOTZER, University of Michigan — Entropic forces are effective forces that result from a system's statistical tendency to increase its entropy. Hard rods and disks spontaneously align and can assemble into layers and columns if those structures increase the configurational space available to the particles. Hard spheres, cubes and even tetrahedra order for the same reason. Here we extend those findings by showing that hard polyhedra can self-assemble into a variety of complex phases, most of them never before reported in systems of single-component hard particles. The role of shape and directional entropic forces in stabilizing these structures will be discussed. Our results suggest new possibilities for self-assembling complex target structures from colloidal building blocks.

9:00AM Y44.00004 Facile Fabrication of 3-D Nanoparticle Arrays in Thin Films toward Photonic Materials ,

JOSEPH KAO, SEONG-JUN JEONG, VIVIAN PENG-WEI CHUANG, PETER JIN BAI, UC Berkeley, ZHEN ZHANG, CHENG SUN, Northwestern University, TING XU, UC Berkeley — 3-D hierarchical assemblies of nanoparticles in thin films enable one to exploit their collective properties to generate functional electronic, magnetic, and photonic materials. Among many templates, block copolymer-based supramolecules is one of the most promising candidates since they combine solution processibility and high precision in nanoparticle spatial distribution. Herein, we report a facile way of fabricating 3-D nanoparticle arrays in thin films of diblock copolymer-based supramolecules exhibiting bandgap in the visible regime. The entropy-dominant assembly drives the formation of 3-D lattice of nanoparticle arrays with precise inter-array spacings in thin films. The coupling effect between the precisely positioned nanoparticle arrays with adjustable lattice spacings in the hierarchically-structured nanocomposites allows potentially interesting optical properties.

9:12AM Y44.00005 Creating Opal Templated Continuous Conducting Polymer Films with Ultralow Percolation Thresholds Using Thermally Stable Nanoparticles ,

D.J. KANG, T. KWON, M.P. KIM, B.J. KIM, KAIST, H. JUNG, J. BANG, Korea Univ. — We propose a novel and robust strategy for creating continuous conducting polymer films with ultralow percolation thresholds using polymer-coated gold nanoparticles (Au NPs) as surfactant. Continuous poly(triphenylamine) (PTPA) films of high internal phase polymeric emulsions were fabricated using an assembly of crosslinked polystyrene (PS) colloidal particles as template. Polymer-coated Au NPs localize at the PS/PTPA interface and function as surfactant to efficiently produce a continuous conducting PTPA polymer film with very low percolation thresholds. The volume fraction threshold for percolation of the PTPA phase with insulating PS colloids was found to be 0.20. In contrast, with the addition of an extremely low volume fraction of surfactant Au NPs, the volume fraction threshold for percolation of the PTPA phase was dramatically reduced to 0.05. The SEM and TEM measurements clearly demonstrated the formation of a continuous PTPA phase within the polyhedral phase of PS colloids. To elucidate the influence of the nanoparticle surfactant on the blend films, the morphology and conductivity of the blends at different PS colloid/PTPA volume ratios were carefully characterized as a function of the Au NP concentration.

9:24AM Y44.00006 Magnetic fields in long-range alignment of functional hybrid soft materials¹

, PAWEŁ MAJEWSKI, MANESH GOPINADHAN, CANDICE PELLIGRA, Yale University, SHANJU ZHANG, California Polytechnic State University, LISA PFEFFERLE, CHINEDUM OSUJI, Yale University — We present a magnetic field-based method to impose long range order in self-assembled soft materials including polymer-nanowire composites, block copolymers and surfactant mesophases. We discuss the broad utility of this approach, indicating its advantages and limitations. Our method yields highly anisotropic materials with quality of alignment in many cases comparable to that of single crystals as assessed by X-ray scattering techniques. We take advantage of the high fidelity of alignment to systematically explore and characterize the anisotropic properties of these materials. We present a perspective for improving electron and hole transport, as well as exciton utilization in magnetically doped ZnO nanowire-polythiophene composites for photovoltaic applications by global alignment of the nanowires. For block copolymers, we focus on enhancing Li-ion transport in membranes with self-assembled cylindrical and lamellar morphology by alignment of the Li-conducting PEO domains.

¹NSF support (DMR-0847534 and DMR-0934520) is gratefully acknowledged.

9:36AM Y44.00007 ²H NMR study of the Assembly of Gold Nanoparticles Dispersed in Nematic Liquid Crystal¹, LINDA REVEN, J MILETTE, R. BRUCE LENNOX, ALEJANDRO REY, McGill University, Montreal, Qc, Canada, EZEQUIEL SOULE, Institute of Materials Science and Technology (INTEMA), University of Mar del Plata, Argentina — Gold nanoparticles (AuNP) with mesogenic ligands, tailored to be highly miscible in the liquid phase of 4-n-pentyl-4'-cyanobiphenyl (5CB) liquid crystal (LC), form reversible, micron-scale cellular networks upon cooling to the nematic phase. The network topology and LC director field orientation are controlled by the cooling rate, film thickness, ligand shell composition and AuNP concentration. Isotopically labeled samples allow selective probing of the orientational order of the NP ligands and host LC by ²H NMR. The ²H NMR spectra of AuNPs dispersed in nematic 5CB display isotropic and doublet peaks assigned to disordered and field aligned ligands respectively. The intensity of the ligand doublet signal increases relative to the isotropic peak with decreasing temperature and NP concentration. Conversely an isotropic peak along with the expected doublet is observed for the host 5CB in the nematic phase. The intensity of the host 5CB isotropic peak, which persists far into the nematic phase and decreases with NP concentration, shows the coexistence of isotropic and nematic phases. The NP ligand and host LC orientational orders are related the formation of the cellular network and theoretical phase diagrams of NP-LC dispersions.

¹Centre for Self-Assembled Chemical Structures (CSACS-CRMAA)

9:48AM Y44.00008 Organization of Gold Nanorods in Cylinder-Forming Block Copolymer Films¹, GUOQUAN JIAN, ROBERT RIGGLEMAN, RUSSELL COMPOSTO, University of Pennsylvania — The addition of gold nanorods (AuNRs) to copolymer films can impart unique optical and electrical properties. To take full advantage of this system, the AuNRs must be dispersed in a self-organizing copolymer that directs the orientation of the anisotropic particle. In the present work, AuNRs with aspect ratio 3.6 (8 nm x 29 nm) are grafted with poly(2-vinyl pyridine) (P2VP) brushes and dispersed in a cylindrical forming diblock copolymer of polystyrene-b-P2VP (180K-b-77K, 29.6 wt% P2VP). Films are spun cast and solvent annealed in chloroform to produce a perpendicular cylindrical morphology at the surface. Using TEM and UV-ozone etching combined with AFM, the AuNRs are well dispersed and co-locate (top down view) with the P2VP cylinders, ~50nm diameter. However, the AuNRs mainly lie parallel to the surface indicating that they likely locate at the junction created at the intersection between P2VP cylinders and P2VP brush layer adjacent to the silicon oxide surface. Self-consistent field calculations of the Au:PS-b-P2VP morphology as well as the effect of adding P2VP homopolymer to the nanocomposite will be discussed.

¹NSF Polymer and MRSEC programs

10:00AM Y44.00009 Nanopatterned poly(ethylene glycol) brushes: A route for highly tunable assembly of Au nanoparticles, M. SERDAR ONSER, PAUL F. NEALEY, University of Wisconsin-Madison — Assembly of metallic nanoparticles (NPs) on surfaces offers many interesting opportunities for scientific studies as macroscopic properties of the assemblies depend on organization of the particles at the nanometer length scale. On the other hand, new/improved functionalities of the assemblies are promising in the potential technological applications such as chemical sensing and metamaterials. Chemical patterning of surfaces for directed assembly of ex-situ synthesized NPs is advantageous due to controllable substrate-particle interaction and applicability to a range of different size and type of particles. Here we present assembly of Au NPs (15-50 nm) on lithographically patterned poly(ethylene glycol) (PEG) brushes. The density of NPs on the patterns can be controlled with the molecular weight of PEG brush and the size of particles. The ability to pattern PEG brushes with high chemical contrast and resolution (sub 50 nm) with the interesting particle brush interaction provides routes for highly controllable assembly of NPs. For example, number of particles per spot can be precisely controlled with high yields (single 95% and dimer 70% for 30 nm Au NP) and NPs of two different sizes (heterostructures) can be assembled on patterned spots.

10:12AM Y44.00010 Distribution of POSS Nanoparticles in Symmetric Diblock Copolymer Thin Films, UMESH SHRESTHA, DILRU RATNAWEERA, Clemson University, STEPHEN CLARSON, University of Cincinnati, DVORA PERAHIA, Clemson University — The distribution of Polyhedral Oligomeric Silsesquioxanes (POSS) nanoparticles in thin films of symmetric diblock copolymer polystyrene-b-poly dimethyl siloxane (PS-b-PDMS) was studied by neutron reflectometry. Blending of nanoparticles (NPs) with polymers provide a pathway to tune properties of the polymer such as conductivity, mechanical strength, optical activity as well as dewetting, where the properties depend on the distribution of the NPs. Controlling the distribution of NPs in polymers thin films however, remains a challenge where entropic contributions drive segregation of the NPs to the interface. Different approaches were taken including modifying the interfacial interactions of the NP. The current study investigates effects of the relative size of the NP with respect to that of the polymer layers following distribution of POSS cages which consist of a silicon cage in a symmetric PS-PDMS. The temperature was varied from room temperature to 150°C, investigating the distribution above and below the glass transition temperature of the styrene blocks. The distribution of the NPs as well as structural changes for two molecular weights of the diblock 10kg/mol and 50kg/mol within the films will be discussed.

10:24AM Y44.00011 Long-range Ordering of Symmetric Block-copolymers by Chaining of Superparamagnetic Nanoparticles in External Magnetic Fields, V. RAMAN, M.I.T, A. BOSE, University of Rhode Island, B.D. OLSEN, T.A. HATTON, M.I.T — Chaining of superparamagnetic nanoparticles is numerically investigated as a new method to align the block copolymer without additional lithographic processing. The method relies on the chaining of superparamagnetic nanoparticles, sequestered preferentially in one of the blocks, in the direction of in-plane external magnetic fields to achieve long-range order in the block copolymer. Effects of nanoparticle size, concentration, and magnetization strength are explored using Hybrid-Particle-Field technique (Sides et al, 2006). The 2D simulations reveal that, for the same nanoparticle loading, the nanoparticle sizes commensurate with the domain sizes yield defect-free alignment. While small sizes lead to jamming and kinetic trapping of defects, larger sizes lead to swelling of domains and break the symmetry of the lamellar phase. A window of optimal nanoparticle concentrations exists over which orientational order is achieved. For low concentrations, only local alignment is observed, while high concentrations lead to order-order phase transition from lamellae to cylindrical phase. Scaling calculations corroborate the effect of high magnetization strengths in lowering the equilibrium defect density for such nematic-isotropic phase transitions observed in monolayers.

10:36AM Y44.00012 Highly Ordered Superstructures of Single-Walled Carbon Nanotubes in Polymeric Systems, SUNG-MIN CHOI, HYOUNG-SIK JANG, CHANGWOO DOE, TAE-HWAN KIM, Department of Nuclear and Quantum Engineering, KAIST, Daejeon, Republic of Korea — Fabrication of highly ordered arrays of single-walled carbon nanotubes (SWNTs) has been of great interest for a wide range of potential applications. Block copolymers exhibit rich phase behavior and have been extensively used as excellent templates for highly ordered nanostructure materials with various architectures. Therefore, utilization of the rich phase behavior of block copolymers may provide a general and inexpensive way for fabricating a large variety of self-assembled and highly ordered arrays of SWNTs without going through complicated preparative procedures. Here, we investigated the cooperative self-assembling behavior of functionalized isolated SWNTs in Pluronic block copolymer systems using small angle neutron and x-ray scattering techniques, which show highly ordered superstructures of SWNTs with different symmetries.

10:48AM Y44.00013 Block copolymer modified epoxies: Role of localized network damage¹

CARMELO DECLET-PEREZ, ERICA REDLINE², LORRAINE FRANCIS, FRANK BATES³, Department of Chemical Engineering and Materials Science, University of Minnesota — Adding block copolymers to epoxy resins has proven to be an effective approach to toughening these materials while retaining commercially relevant properties such as high modulus and glass transition temperature. When properly designed, block copolymers self-assemble into spherical micelles that disperse in the monomer resin. These structures survive curing into a dense network. At this point, a complete description of the toughening mechanism for block copolymer modified epoxies is still lacking. Here we present new experimental evidence that challenges the current understanding in this area. We compared the toughening effect of spherical micelle forming block copolymers with rubbery and glassy cores. Consistent with previous reports rubbery cores produced significant toughening, but surprisingly the glassy core micelles also imparted some toughness. These results suggest that the block copolymer/epoxy interface plays a significant role during deformation. We propose that the micelles compromise the integrity of the glassy matrix by damaging or plasticizing the crosslinked network in contact with the corona blocks, thereby facilitating shear yielding.

Session Y45 DPOLY: Focus Session: Soft Matter Physics of Drops, Bubbles, Foams and Emulsions - Bubbles, Films, Foams 159

8:00AM Y45.00001 Mechanical properties of surface modified microbubbles by Atomic Force Microscopy (AFM), JONATHAN MCKENDRY, COLIN GRANT, STEPHEN EVANS, None — Atomic force microscopy has been used to investigate the mechanical properties of phospholipid coated microbubbles and to quantify their stiffness. The mechanical properties were investigated using tipless AFM cantilevers to compress microbubbles attached to a gold surface in aqueous conditions. The phospholipid microbubbles were produced by microfluidic flow focusing and were found to have a stiffness of 25 mN/m. The attachment of a streptavidin coating increased the microbubble stiffness by a factor of 30 to around 750 mN/m. Further, the effect of temperature on the mechanical and time dependent properties of bubbles has been studied, the results of which have demonstrated that increasing temperature leads to a decrease in microbubble stiffness and an increase creep-displacement. The standard linear model was used to extract the visco-elastic parameters at different temperatures, this allowed the first determination of the activation energy for creep for a microbubble.

8:12AM Y45.00002 Cylindrical bubbles and blobs from a Class II Hydrophobin¹, PAUL RUSSO, MICHAEL PHAM, BRAD BLALOCK, Louisiana State University, HYDROPHOBIN COLLABORATION — *Cerato ulmin* is a class II hydrophobin. In aqueous suspensions, it easily forms cylindrical air bubbles and cylindrical oil blobs. The conditions for formation of these unusual structures will be discussed, along with scattering and microscopic investigations of their remarkable stability. Possible applications in diverse fields including polymer synthesis and oil spill remediation will be considered. Acknowledgment is made to Dr. Wayne C. Richards of the Canadian Forest Service for the gift of *Cerato ulmin*.

8:24AM Y45.00003 The collapse and the folding of a particle rafts under compression¹, CHIN-CHANG KUO, MICHAEL DENNIN, Department of Physics & Astronomy, University of California, Irvine — Compressing a single-layer of particles or bubbles that are confined to the air-water interface results in a range of interesting collapse dynamics. We report on the collapse modes of two systems: (1) a single layer of gas bubbles at the surface and (2) a single layer of polypropylene beads. Under compression, both systems exhibit a critical areal density beyond which there is a transition to a multi-layered structure. Generally speaking, the transformation is characterized by localized submergence into the subphase of bubbles or beads. For both systems, we observe single bubbles/beads being pushed underneath surrounding particles. However, for sufficiently small beads, we observe a folding mode, which corresponds to the long-ranged one dimensional wrinkling of the monolayer surface. In this talk, we will report on the transition between single particle submergence and folding, as well as general characterization of the collapse as a function of compression speed and initial structure of the particle raft.

8:36AM Y45.00004 Falling drops skating on a film of air, SHMUEL RUBINSTEIN, Dept. of Physics of Complex Systems, Weizmann Institute of Science — When a raindrop hits a window, the surface immediately becomes wet as the water spreads. Indeed, this common observation of a drop impacting a surface is ubiquitous in our everyday experience. I will show that the impact of a drop on a surface is a much richer, more complex phenomenon than our simple experience may suggest: To completely wet the surface the drop must first expel all the air beneath it; however, this does not happen instantaneously. Instead, a very thin film of air, only a few tens of nanometers thick, remains trapped between the falling drop and the surface as the fluid spreads. The thin film of air serves to lubricate the drop enabling the fluid to skate laterally outward at strikingly high velocities. Simultaneously, the wetting fluid spreads inward at a much slower velocity, trapping a bubble of air within the drop. However, these events occur at diminutive length scales and fleeting time scales; therefore, to visualize them we develop new imaging modalities that are sensitive to the behavior right at the surface and that have time resolution superior to even the very fastest cameras. These imaging techniques reveal that the ultimate wetting of the surface occurs through a completely new mechanism, the breakup of the thin film of air through a spinodal like dewetting process that breaks the cylindrical symmetry of the impact and drives an anomalously rapid spreading of a wetting front. These results are in accord with recent theoretical predictions and challenge the prevailing paradigm in which contact between the liquid and solid occurs immediately, and spreading is dominated by the dynamics of a single contact line.

9:12AM Y45.00005 Compression of multiwall microbubbles, NATALIA LEBEDEVA, SAM MOORE, University of North Carolina at Chapel Hill, ANDREY DOBRYNIN, University of Connecticut, MICHAEL RUBINSTEIN, SERGEI SHEIKO, University of North Carolina at Chapel Hill — Optical monitoring of structural transformations and transport processes is prohibited if the objects to be studied are bulky and/or non-transparent. This paper is focused on the development of a microbubble platform for acoustic imaging of heterogeneous media under harsh environmental conditions including high pressure (<500 atm), temperature (<100 °C), and salinity (<10 wt%). We have studied the compression behavior of gas-filled microbubbles composed of multiple layers of surfactants and stabilizers. Upon hydrostatic compression, these bubbles undergo significant (up to 100×) changes in volume, which are completely reversible. Under repeated compression/expansion cycles, the pressure-volume P(V) characteristic of these microbubbles deviate from ideal-gas-law predictions. A theoretical model was developed to explain the observed deviations through contributions of shell elasticity and gas effusion. In addition, some of the microbubbles undergo peculiar buckling/smoothing transitions exhibiting intermittent formation of faceted structures, which suggest a solid-like nature of the pressurized shell. Preliminary studies illustrate that these pressure-resistant microbubbles maintain their mechanical stability and acoustic response at pressures greater than 1000 psi.

9:24AM Y45.00006 The life cycle of individual boiling bubbles: Insights from beyond optical imaging, SCOTT PARKER, SUNG CHUL BAE, DAVID CAHILL, STEVE GRANICK, University of Illinois — With a high-speed camera, we have investigated the dynamics of individual vapor bubbles boiling on a laser-heated surface. Their sizes and shapes as they grow and depart from a surface are correlated with simultaneous thermal imaging measurements of the boiling surface using thermoreflectance-based microscopy to measure temperatures of individual stochastic events. Analysis of both the thermal profiles and the bubble shapes suggests the presence of an evaporating liquid microlayer under the developing bubble. Tuning surface and heating properties, we control the shapes of bubbles, ranging from regular periodic growth and departure to stochastic bubbles which exhibit rapid cavitation-like expansion and collapse. Unlike typical cavitation bubbles which collapse and form jets pointed towards the surface, jets from bubbles observed during boiling were observed to be directed away from the surface. By tuning the wettability of the substrate, we will report on how wettability affects the strength and direction of these jets.

9:36AM Y45.00007 Nonclassical Thermomigration of an Air Bubble, DOMINIK MICHLER, RUDOLF SPRIK, PETER SCHALL, DANIEL BONN, Soft Matter, Van der Waals-Zeeman Instituut, Universiteit van Amsterdam, SHELL COLLABORATION — We study air bubbles confined in capillaries with a temperature gradient. Classically, air bubbles move in a temperature gradient due to decreased surface tension at higher temperatures, creating a net surface traction towards the cold pole, pushing the bubble towards the hot pole for mass conservation. Here we report non-classical thermo-migration of confined air bubbles: in the presence of surfactant the bubbles can go the other way.

9:48AM Y45.00008 Two-Dimensional Microfluidics: Stable Island Emulsions in Freely Suspended Smectic Liquid Crystal Films¹, CHEOL PARK, ZOOM NGUYEN, CHANEY CRANFILL, SARAH RADZIHOVSKY, JOE MACLENNAN, MATT GLASER, NOEL CLARK, University of Colorado at Boulder, LCMRC TEAM — Islands (circular regions of greater thickness) in smectic films are easily created and manipulated, but are generally unstable, tending to grow or shrink over time. We have recently created stable emulsions of smectic islands by “work hardening” of the smectic film using shear and extensional flow to form a dense, mechanically stable network of edge dislocations. In this talk, we discuss this novel type of two-dimensional colloidal system, in particular the island size distribution, network of edge dislocations and topological defects that form stable two-dimensional emulsions.

¹Work supported by NSF MRSEC Grant DMR- 0820579 and NASA Grant NAG No. NNX07AE48G

10:00AM Y45.00009 Spherical and Non-Spherical Double Emulsions with Multiple Components, LAURA ADAMS, THOMAS KODGER, Harvard University, JACY BIRD, MIT, SHIN-HYUN KIM, LOUISE JAWERTH, VINOTHAN MANOHARAN, DAVID WEITZ, Harvard University — Monodispersed double emulsions, drops inside of drops, with multiple and tunable components are generated using microfluidics. A fluid dynamic model based on fast camera images of the single step emulsification technique is being developed to determine the critical separation between channels in the injection capillary; this model addresses the maximum number of distinct drops that can be controllably loaded inside a double emulsion for a given diameter capillary. New stable, non-spherical emulsions with two and three different components, Janus and Cerberus emulsions, are also reported.

10:12AM Y45.00010 Stability of thin liquid films: Influence of interfacial viscoelasticity¹, GERALD FULLER, LIAT ROSENFELD, Stanford University — Lipid layer spreading and liquid film dewetting are important variables influencing numerous processes, including the stability of the tear film. The viscoelasticity of insoluble monolayers may govern thin liquid film dewetting phenomena. The purpose of this work is to gain insight into the effects of surface viscoelasticity elasticity by insoluble monolayers on dewetting of thin films of water with a particular attention paid to materials, such as meibum, that stabilize the tear film. For this purpose an experiment has been devised wherein monolayers of known surface pressure and surface rheology are introduced atop thin, liquid films that would normally spontaneously dewet. The results reveal that monolayers of viscoelastic surfactants are able to stabilize thin films against spontaneous dewetting. As the surface pressure and surface rheology of these layers is increased, their effectiveness is enhanced. Meibum is particularly effective in stabilizing thin films. These results suggest that the role of the meibum is to offer the tear film enhanced stability and not only to suppress evaporation.

¹Alcon Corporation

10:24AM Y45.00011 Light-controlled air-water interfaces and thin liquid films using photosurfactants, ELOISE CHEVALLIER, ESPCI, CHRISTOPHE TRIBET, ENS Paris, FRANCOIS LEQUEUX, CECILE MONTEUX, ESPCI — We study the interfacial behavior of photosurfactants containing an azobenzene moiety in the apolar tail –which switch from cis to trans conformation depending on the wavelength of light. We present here results on the effect of stimulation on the interfacial dynamics of such photosurfactants upon illumination. First, without light stimulus, the trans isomers is found to desorb more slowly than the cis, this leads to a fast enrichment of the interface with trans. Under light, adsorbed trans convert to their cis form which quickly desorb resulting in an important decrease of the surface excess and an increase of the surface tension. Besides, we stimulate thin-liquid films stabilized by such surfactants. Several types of hydrodynamical instabilities in the thin-liquid films are generated. We show that these instabilities are due to a strong rise of concentration in-situ but also a light-induced variation of DLVO interactions that usually stabilize the films.

10:36AM Y45.00012 Supercritical Carbon Dioxide Assisted Processing of Silica/PMMA Nanocomposite Foams¹, DENIZ RENDE, LINDA S. SCHADLER, RAHMI OZISIK, Rensselaer Polytechnic Institute — Polymer nanocomposite foams receive considerable attention in both scientific and industrial communities. These structures are defined as closed or open cells (pores) surrounded by bulk material and are widely observed in nature in the form of bone structure, sponge, corals and natural cork. Inspired by these materials, polymer nanocomposite foams are widely used in advanced applications, such as bone scaffolds, food packaging and transportation materials due to their lightweight and enhanced mechanical, thermal, and electrical properties compared to bulk polymer foams. The presence of the nanosized fillers facilitates heterogeneous bubble nucleation as a result, the number of bubbles increases while the average bubble size decreases. Therefore, the foam morphology can be controlled by the size, concentration, and surface chemistry of the nanofiller. In the current study, we used supercritical carbon dioxide as a foaming agent for silica/poly(methyl methacrylate), PMMA, foams. The silica nanoparticles were chemically modified by fluoroalkane chains to make them CO₂-philic. The surface coverage was controlled via tethering density, and the effect of silica surface coverage and concentration on foam morphology was investigated through scanning electron microscopy and image processing. Results indicated that nanofiller concentration and filler surface chemistry (CO₂-philicity) had tremendous effect on foam morphology but surface coverage did not have any effect.

10:48AM Y45.00013 Drainage dynamics of aqueous foams generated by sparging and turbulent mixing, MATTHEW J. KENNEDY¹, MICHAEL W. CONROY, RAMAGOPAL ANANTH, JAMES W. FLEMING, Naval Research Laboratory — We investigate the effect of bubble size on the drainage dynamics of aqueous fire-suppression foams using laboratory-scale foam generators and theoretical modeling. We generate foams over a wide range of bubble sizes using two foam generation methods—sparging using fritted sheets of steel, and turbulent mixing using high-pressure T-junctions. The sparged foams comprise bubbles of mean diameter 0.5 mm or larger and begin draining immediately whereas the turbulently mixed foams comprise bubbles of mean diameter 0.15 mm or smaller and begin draining after induction times of 5-15 minutes. We study two proprietary fire-suppression foam solutions: a non-fluorinated surfactant solution containing viscous additives intended for use as a wet foam, *i.e.* liquid fraction > 0.1, and a sodium dodecyl sulfate surfactant solution intended for use as a dry foam, *i.e.* liquid fraction < 0.005. The change in liquid retention time due to change in mean bubble size differs between these two solutions. We compare our experimental results with theoretical models to examine the reasons for the difference in liquid retention time.

Session Y47 DPOLY: Soft Matter Physics of Biological Systems 160C

8:00AM Y47.00001 Antiviral activity of squalamine: Role of electrostatic membrane binding, BERNARD BECKERMAN, WEI QU, Northwestern University, ABHIJIT MISHRA, UCLA, MICHAEL ZASLOFF, Georgetown University, GERARD WONG, UCLA, ERIK LUIJTEN, Northwestern University — Recent work¹ has demonstrated that squalamine, a molecule found in the liver of sharks, exhibits broad-spectrum antiviral properties. It has been proposed that this activity results from the charge-density matching of squalamine and phospholipid membranes, causing squalamine to bind to membranes and displace proteins such as Rac1 that are crucial for the viral replication cycle. Here we investigate this hypothesis by numerical simulation of a coarse-grained model for the competition between Rac1 and squalamine in binding affinity to a flat lipid bilayer. We perform free-energy calculations to test the ability of squalamine to condense stacked bilayer systems and thereby displace bulkier Rac1 molecules. We directly compare our findings to small-angle x-ray scattering results for the same setup.

8:12AM Y47.00002 Simulating ligand receptor binding at a membrane interface with graphics processing accelerated coarse-grained molecular dynamics, SHARON M. LOVERDE, Department of Chemical and Biomolecular Engineering, University of Pennsylvania, DAVID N. LEBARD, Department of Chemistry, Temple University, ZHENGYU MA, Penn Institute for Immunology, University of Pennsylvania, MICHAEL L. KLEIN, Department of Chemistry, Temple University, DENNIS E. DISCHER, Department of Chemical and Biomolecular Engineering, University of Pennsylvania — Motivated by a deeper understanding of the immunological synapse, we develop a molecular-based model to understand receptor-polymer/ligand binding at a membrane interface. We examine the case of weak ligand binding in the limit of confined polymer chains as a function of chain length, binding constant, and system size. We utilize a coarse-grained (CG) model of poly(ethylene oxide) and dimyristoylphosphatidylcholine (DMPC) previously developed by the Klein group and mimic weak binding with a sticky potential. This work employs graphics processing units (GPU) to accelerate the CG-MD simulations, where each simulation is run with multiple random-walker replicas to enhance sampling and facilitate statistical convergence of physical observables. Our results demonstrate that such an aggressive combination of GPU acceleration with CG modeling can yield accurate and precise data on polymer-DMPC binding, and, more importantly, hints at the mechanism behind empirical data of polymer binding to a T-cell receptor protein.

8:24AM Y47.00003 Stabilization of concentration fluctuations in mixed membranes by hybrid lipids, BENOIT PALMIERI, SAMUEL SAFRAN, Weizmann Institute of Science — Finite-size domains have been observed at the surface of cells. These lipids “rafts” are stable nanodomains enriched in saturated lipids and cholesterol. While line tension favors macrodomains, one explanation for raft stabilization suggests that the membrane composition is tuned close to a spinodal temperature. From this point of view, rafts are long-lived concentration fluctuations in the mixed phase. We propose a ternary mixture model for the cell membrane that includes hybrid lipids which have one saturated and one unsaturated hydrocarbon chain. Finite amount of hybrid lipids reduces the packing incompatibility at the saturated/unsaturated lipid interface and stabilizes the concentration fluctuations. Hybrid-Hybrid interactions are included in the model and further increase the life-time of the rafts and decrease their length-scales. Moreover, the hybrid has extra orientational degrees of freedom that may lead to modulated phases.

8:36AM Y47.00004 Cooperativity in cholesterol-induced demixing of saturated and unsaturated lipids, JAMES KINDT, Emory University — The ternary DPPC/DOPC/cholesterol system exhibits a phase separation between liquid-ordered and liquid-disordered domains that may capture some features of demixing believed to occur in biomembranes. Using semi-grand canonical ensemble Monte Carlo approaches on a model with atomistic detail, we have investigated the degree of non-ideality of mixing of DPPC and DOPC as influenced by cholesterol. While the signature of phase separation is observed, more surprising is that in the region of composition space characterized by low DPPC and low cholesterol content, the mixing is approximately ideal. Through simple models we have shown that this behavior is inconsistent with a simple nearest-neighbor description of the interactions between these membrane components.

8:48AM Y47.00005 Steric Repulsion and Compressibility of Protein Resistant Brushes, MARIA SANTORE, Department of Polymer Science and Engineering University of Massachusetts — End-grafted polymer brushes, such as polyethylene glycol, have become commonplace as biocompatibilizers for medical devices and diagnostic surfaces. Key to their non-fouling character is the brush's steric repulsion towards biomolecules and cells. By functionalizing the substrate with small (order 10 nm) bioadhesive features around which the brush is placed, we gain insight into the repulsion between biomolecules and cells with the brush itself. While approximately exponential compression profiles are to be expected, some features of protein interactions with these brushes are unexpected, especially for small proteins whose dimensions are within a factor of 2 or 3 of the brush persistence length. The scaling of the compressive force, for example inferred from series of studies that vary the amounts and spacings of the adhesive elements, is weakly dependent on protein size, while one might expect a proportionality between this force and the effective protein footprint. These results are consistent with entropically inexpensive chain reconfigurations around the smaller proteins and the penetration of these proteins at least partially into the brush.

9:00AM Y47.00006 Topological defects induced by the retina's curvature improve vision , JOHNNATAN ALJADEFF, TATYANA SHARPEE, Computational Neurobiology Laboratory, The Salk Institute; Center for Theoretical Biological Physics and Department of Physics, UCSD — The theory of disclinations and dislocations on curved surfaces predicts the length and density of grain boundary scars on a sphere. These predictions were successfully tested with colloids on droplets for systems satisfying $5 \leq R/a \leq 20$ (R - sphere radius, a - lattice constant). The foveal cone mosaic is another realization of this problem, for which $R/a \sim 10^4$. New theories are needed to extend current predictions for scar length and density to this regime. We present a method of introducing the effect of irregularities that changes the prediction in the relevant regime. We do so by deriving a noise induced disclination density which truncates the scars: the cone density is mapped to an effective displacement h_{eff} from the sphere; then the deviation from the constant curvature is computed to first order in h_{eff} ; and finally the effective curvature is compared to a threshold above which noise induced disclinations appear. We compare stimuli projected on mosaics and on jittered lattices and show that the curvature induced correlations in the mosaics reduce aliasing by a factor of up to 50. This reduction increases with spatial frequencies, meaning that anti-aliasing is maximal in the visual acuity limit.

9:12AM Y47.00007 Exploring the low temperature thermodynamics of lattice proteins and polymers with chain lengths > 1000 , THOMAS WUEST, Swiss Federal Institute for Forest, Snow and Landscape Research WSL — Coarse-grained (lattice-) models have a long tradition in aiding to decipher the physical or biological complexity of polymers and proteins. Despite their simplicity however, numerical simulations of such models are often computationally very demanding and the quest for efficient algorithms is as old as the models themselves. I present a computational method based on Wang-Landau sampling in combination with suitable trial move sets which is particularly effective to study models such as the hydrophobic-polar (HP) lattice model of protein folding or its counterpart in polymer physics, the interactive self-avoiding walk (ISAW) at low temperatures. The approach provides a versatile and powerful mean for both the ground state search and the determination of the entire energy density of states (DOS) yielding reliable estimates of thermodynamic quantities for chain lengths > 4000 (ISAW) even in the very dense collapsed phase. The appearance of multiple low temperature pseudo-transitions for ISAWs will be elucidated. Further methodological improvements will be discussed.

9:24AM Y47.00008 Long-range mechanical force in epithelial tubule self assembly , CHIN-LIN GUO, None — In vivo, epithelial cells can respond to extracellular matrix (ECM) molecules, type I collagen (COL), and switch their morphology from a lobular lumen (100-200 micron) to a tubular lumen (1mm-1cm). However, the mechanism is unclear. Using a temporal control of cell-ECM interaction, we find that epithelial cells, in response to a fine-tuned percentage of COL in ECM, develop various linear patterns. Remarkably, these patterns allow cells to self-assemble into a tubule of length ~ 1 cm and diameter ~ 400 micron in the liquid phase. In contrast with conventional thought, the linear patterns arise through bi-directional transmission of traction force, but not through diffusible biochemical factors secreted by cells. In turn, the transmission of force evokes a long-range (~ 600 micron) intercellular mechanical interaction. A feedback effect is encountered when the mechanical interaction modifies cell positioning and COL alignment. Micro-patterning experiments further reveal that such a feedback is a novel cell-number-dependent, rich-get-richer process, which allows cells to integrate mechanical interactions into long-range (> 1 mm) linear coordination.

9:36AM Y47.00009 Bottom-up study of flaw tolerance properties of protein networks¹ , ZHAO QIN, MARKUS BUEHLER, Massachusetts Institute of Technology, LAMM TEAM — We study the material properties of an intermediate filament protein network by computational modeling using a bottom-up approach. We start with an atomic model of each filament's and obtain the mechanical behavior of them. We then use these parameters in setting up a mesoscale model of the network material at scales of micrometers. Using this multi-scale method, we report a detailed analysis of the associated deformation and failure mechanisms of this hierarchical material. Our modeling reveals that a structure transition that occurs at the proteins' secondary structure level is crucial for the networks' flaw tolerance property, which implies that the material retains its mechanical function despite the existence of large defects. We also examine the effect of crosslink strength on the failure properties. We discover that relatively weaker crosslinks lead to a more flaw tolerant network that is 23% stronger. This unexpected behavior is caused by that the crosslink strength functions as a switch to alter the failure mechanism. Weak crosslinks are able to efficiently diffuse the stress around the crack tip, making the crack more difficult to propagate. We compare our results to that of elastic and softening materials and find that the effect of crosslink strength is much smaller in those systems. These findings imply that the mechanical properties of both the filaments and interfaces among filaments are critical for bioinspired material designs, challenging the conventional paradigm in engineering design.

¹We acknowledge support from AFOSR, ONR-PECASE.

9:48AM Y47.00010 From Nano to Micro: Importance of Structure and Architecture in Spider Silk Adhesives¹ , VASAV SAHNI, ALI DHINOJWALA, The University of Akron — Spiders have developed outstanding adhesives over millions of years of evolution for prey capture and locomotion. We show that the structure and architecture of these adhesives play an important role in the adhesion. The adhesive produced by orb-weaving spiders to capture prey (viscid glue) is laid on a pair of silk fibers as micron-size glue drops composed of salts and glycoproteins. By stretching single drops, we show that viscid glue behaves like a viscoelastic solid and that elasticity is critical in enhancing adhesion caused by specific adhesive ligands by over 100 times. Comparing viscid glue with gumfoot glue, the glue produced by cob-weavers, the evolutionary descendants of orb-weavers, showed that, in spite of being produced in homologous aggregate glands, gumfoot glue behaves like a viscoelastic liquid. Moreover, gumfoot glue is humidity-resistant and viscid glue is humidity-sensitive. We use a synthetic strategy to spin beads-on-a-string (BOAS) architecture to mimic the adhesive properties of spider silk. Using these mimic threads, we show that the BOAS structure adheres more than a cylindrical structure during contact (collision of prey) and during separation (escape attempt of prey). These results inspire design of novel tunable adhesives.

10:00AM Y47.00011 Light scattering studies of human crystallin proteins and loss of transparency in cataracts , BENJAMIN MOHR, MURUGAPPAN MUTHUKUMAR, University of Massachusetts Amherst — The human lens derives its transparency and refractive index from the interactions between crystallin proteins (α -, β -, γ -crystallin). When the ordering of these crystallins is perturbed, insoluble macromolecular aggregates of crystalline proteins can occur resulting in cataracts. Using dynamic light scattering (DLS) and fast protein liquid chromatography (FPLC), we have conducted a detailed study of the formation of these aggregates. Our DLS results on γ -crystallin solutions exhibit the occurrence of slow and fast modes demonstrating the spontaneous formation of aggregates (hydrodynamic radius, $R_h \sim 200$ nm) in equilibrium with monomeric proteins ($R_h \sim 3$ nm). On the other hand, DLS results on α -crystallin solutions clearly demonstrate that α -crystallin molecules exist as a single population ($R_h \sim 18$ nm). Our results on mixtures of α - and γ -crystallin solutions show that the α -crystallin tends to demolish the clumps of γ -crystallin. Our exploration of environmental effects (temperature, pH, salt concentration) has revealed the macromolecular mechanism of dissolution of crystallin aggregates, providing a strategy for cataract prevention and insight into protein-protein interactions.

10:12AM Y47.00012 Quantifying the abnormal hemodynamics of sickle cell anemia¹ , HUAN LEI, GEORGE KARNIADAKIS, Brown University — Sickle red blood cells (SS-RBC) exhibit heterogeneous morphologies and abnormal hemodynamics in deoxygenated states. A multi-scale model for SS-RBC is developed based on the Dissipative Particle Dynamics (DPD) method. Different cell morphologies (sickle, granular, elongated shapes) typically observed in deoxygenated states are constructed and quantified by the Asphericity and Elliptical shape factors. The hemodynamics of SS-RBC suspensions is studied in both shear and pipe flow systems. The flow resistance obtained from both systems exhibits a larger value than the healthy blood flow due to the abnormal cell properties. Moreover, SS-RBCs exhibit abnormal adhesive interactions with both the vessel endothelium cells and the leukocytes. The effect of the abnormal adhesive interactions on the hemodynamics of sickle blood is investigated using the current model. It is found that both the SS-RBC - endothelium and the SS-RBC - leukocytes interactions, can potentially trigger the vicious “sickling and entrapment” cycles, resulting in vaso-occlusion phenomena widely observed in micro-circulation experiments.

10:24AM Y47.00013 The energetics of tightly bent DNA: a composite elastica model including local melting , ARTHUR EVANS, ALEX LEVINE, UCLA Department of Chemistry and Biochemistry — Melting transitions are well-known to be affected by the application of mechanical stress. Motivated by the experiments of Zocchi and collaborators (Qu and Zocchi 2011, EPL **94** 18003), we explore the effect of the application of mechanical stress on DNA melting in a particular composite of a stiff double stranded piece of DNA (dsDNA), shorter than its own persistence length, whose ends are linked by a flexible single stranded piece of DNA (ssDNA). The flexible ssDNA acts as a Gaussian polymer coil bending the stiff dsDNA through an elastic force that is controllable by the length of the ssDNA chain. In this talk we present theoretical predictions for two experimentally accessible features: the degree of local dsDNA melting and the local elastic energy of the dsDNA/ssDNA construct both as a function of the length of the attached ssDNA. We also address the effect of introducing a nick (broken covalent bond) in the dsDNA backbone on these results and discuss the implications of such data on the relative importance of backbone elasticity versus base stacking and base pairing interactions in determining the elasticity of dsDNA. This work also addresses open questions in the nonlinear elasticity of DNA in tightly bent curves.

10:36AM Y47.00014 Dispersion-relation phase spectroscopy of neuron transport , RU WANG, ZHUO WANG, Beckman Institute, University of Illinois at Urbana and Champaign, LARRY MILLET, MARTHA GILLETTE, Cell and Developmental Biology, University of Illinois at Urbana and Champaign, JOSEPH ROBERT LEIGH, NAHIL SOBH, National Center for Supercomputing Applications, University of Illinois at Urbana and Champaign, ALEX LEVINE, Department of Chemistry and Biochemistry, UCLA, GABREIL POPESCU, Beckman Institute, University of Illinois at Urbana and Champaign — Molecular motors move materials along prescribed biopolymer tracks. This sort of active transport is required to rapidly move products over large distances within the cell, where passive diffusion is too slow. We examine intracellular traffic patterns using a new application of spatial light interference microscopy (SLIM) and measure the dispersion relation, i.e. decay rate vs. spatial mode, associated with mass transport in live cells. This approach applies equally well to both discrete and continuous mass distributions without the need for particle tracking. From the quadratic experimental curve specific to diffusion, we extracted the diffusion coefficient as the only fitting parameter. The linear portion of the dispersion relation reveals the deterministic component of the intracellular transport. Our data show a universal behavior where the intracellular transport is diffusive at small scales and deterministic at large scales. We further applied this method to studying transport in neurons and are able to use SLIM to map the changes in index of refraction across the neuron and its extended processes. We found that in dendrites and axons, the transport is mostly active, i.e., diffusion is subdominant.

Session Y48 DPOLY DBIO: Focus Session: Statistical Physics of Active Systems Away From Detailed Balance: Swimmers and All That 161

8:00AM Y48.00001 Flow-controlled densification of E. Coli through a constriction , GASTÓN MIÑO, PMMH, UMR 7636 CNRS-ESPCI-Universités Paris 6 and 7, ERNESTO ALTSHULER, CARLOS PÉREZ-PENICHET, LENIN DEL RÍO, Henri Poincaré Group of Complex Systems and Superconductivity Laboratory, University of Havana, ANKE LINDNER, ANNIE ROUSSELET, ERIC CLÉMENT, PMMH, UMR 7636 CNRS-ESPCI-Universités Paris 6 and 7 — Bacterial suspensions are examples of “active matter.” Each bacteria can be regarded as a self-propelled particle that interacts hydrodynamically with its environment, including the surrounding “passive” fluid, the boundaries and other bacteria. In this presentation, we show a new phenomenon concerning E. Coli suspensions flowing through a funnel-like constrictions in micro-fluidic channels. The dynamics of bacterial suspensions flowing in confined spaces is relevant to understand their behavior in scenarios such as porous materials, soil, microbiology, water purification, and biomedical research. The applied flow induces a counter-intuitive symmetry breaking in the bulk bacteria concentration, which is found to increase past the funnel. The concentration enhancement persists over large distances and its amplitude increases linearly with the flow rate and disappears at large flow values. We show that the effect is reversible when the flow direction is reversed. We explain the observed effects on the interactions between the active bacteria and the channel boundaries. This experiment opens the possibility to control the concentration bacterial suspensions in microfluidic channels by simply tuning the flow of liquid.

8:12AM Y48.00002 Bidirectional sorting of flocking particles in the presence of asymmetric barriers , JEFFREY DROCCO, CHARLES REICHHARDT, CYNTHIA REICHHARDT, Los Alamos National Laboratory — We numerically demonstrate bidirectional sorting of flocking particles interacting with an array of funnel-shaped barriers. The particles choose a swimming direction by averaging the headings of their neighbors according to the Vicsek model, and experience additional steric interactions as well as repulsion from the fixed barriers. We show that particles preferentially localize to one side of the barrier array over time, and that the direction of this rectification can be reversed by adjusting the particle-particle exclusion radius or the noise term in the equations of motion. These results provide a conceptual basis for isolation and sorting of single- and multi-cellular organisms which move collectively according to flocking-type interaction rules.

8:24AM Y48.00003 Microfluidic one-way streets for algae , JORN DUNKEL, VASILY KANTSLE, MARCO POLIN, RAYMOND E. GOLDSTEIN, DAMTP, University of Cambridge — Controlling locomotion and transport of microorganisms is a key challenge in the development of future biotechnological applications. Here, we demonstrate the use of optimized microfluidic ratchets to rectify the mean swimming direction in suspensions of the unicellular green alga *Chlamydomonas reinhardtii*, which is a promising candidate for the photosynthetic production of hydrogen. To assess the potential of microfluidic barriers for the manipulation of algal swimming, we studied first the scattering of individual *C. reinhardtii* from solid boundaries. High-speed imaging reveals the surprising result that these quasi-spherical “puller”-type microswimmers primarily interact with surfaces via direct flagellar contact, whereas hydrodynamic effects play a subordinate role. A minimal theoretical model, based on run-and-turn motion and the experimentally measured surface-scattering law, predicts the existence of optimal wedge-shaped ratchets that maximize rectification of initially uniform suspensions. We confirm this prediction in experimental measurements with different geometries. Since the mechano-elastic properties of eukaryotic flagella are conserved across many genera, we expect that our results and methods are applicable to a broad class of biflagellate microorganisms.

8:36AM Y48.00004 Concentrating bacterial cells using a ratchet system: a lattice Monte Carlo simulation study, YUGUO TAO, GARY SLATER, Department of Physics, University of Ottawa — Rectification of motile *E. coli* bacteria has been observed in the presence of funnel-like channels. We present a lattice Monte Carlo model which takes into account both the size and the mechanical and thermodynamic properties of autonomous bacterial cells. The motion of the cells is composed of alternating run and tumble periods. We show that the rectification effect of the funnels is strongly dependent upon the effective random walk step length of the run/tumble cycle as well as the size of the funnel's aperture. Our results agree with experimental observations, and also confirm some conclusions from a previous simulation model of point-like bacteria. We also explore series of funnels as a means to pump and concentrate cells. We observe deviations from theoretical predictions when the size of the cells is comparable to that of the aperture of the funnel. The current model can be extended to study cells with different shapes, e.g. cigar-shape bacteria.

8:48AM Y48.00005 Spontaneous Segregation of Self-Propelled Particles with Different Motilities¹, SAMUEL MCCANDLISH, APARNA BASKARAN, MICHAEL HAGAN, Brandeis University — We study mixtures of self-propelled and passive rod-like particles in two dimensions using Brownian dynamics simulations. The simulations demonstrate that the two species spontaneously segregate to generate a rich array of dynamical domain structures whose properties depend on the propulsion velocity, density, and composition. In addition to presenting phase diagrams as a function of the system parameters, we investigate the mechanisms driving segregation. We show that the difference in collision frequencies between self-propelled and passive rods provides a driving force for segregation, which is amplified by the tendency of the self-propelled rods to swarm or cluster. Finally, both self-propelled and passive rods exhibit giant number fluctuations for sufficient propulsion velocities.

¹We gratefully acknowledge support from the NSF Brandeis MRSEC DMR-0820492. Computational support was provided by Brandeis HPC.

9:00AM Y48.00006 Active Brownian Particles with Active Fluctuations, PAWEŁ ROMANCZUK, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany, ROBERT GROSSMANN, LUTZ SCHIMANSKY-GEIER, Department of Physics, Humboldt University Berlin, Germany — We study the effect of different types of noise on the dynamics of self-propelled particles with variable speed (active Brownian particles). We distinguish between passive and active fluctuations. Passive fluctuations are considered independent of the direction of particle's motion (e.g., thermal fluctuations). In contrast, active ones are assumed to be intrinsically connected with the propulsion mechanism of the active particle and, as a result, correlated with its time-dependent orientation. We calculate the stationary speed and velocity probability density functions of non-interacting active Brownian particles in the presence of both fluctuation types and discuss the generic signature of active fluctuations [1]. Furthermore, we discuss a model of active Brownian particles interacting via a velocity-alignment force [2]. We show, based on the results of a corresponding mean-field theory, how the type of fluctuations has a strong impact on the onset and stability of collective motion.

9:12AM Y48.00007 Run and tumble, run and reverse, or run reverse and flick - who wins the chemotaxis race?, VASILY ZABURDAEV¹, School of Engineering and Applied Sciences, Harvard University, SERGEY DENISOV², Institute of Physics, Augsburg University, DAVID WEITZ³, School of Engineering and Applied Sciences, Harvard University — Run and tumble of *E. coli* bacteria is a well understood example of the stochastic cell motion that is alternated in the presence of signaling chemicals. By regulating the tumbling frequency bacteria are able to navigate toward the food sources. Another bacteria that use twitching to move on a surface, *M. xanthus*, utilize a different strategy - at the end of the run they completely reverse the direction of motion and continue moving in the opposite direction. The frequency of reversals was shown to be connected to the chemotactic response of the cell. Recently yet another pattern was discovered in marine bacteria *V. alginolyticus* which alternate sharp reversals with flicks - making a turn to an angle with a broad distribution and centered around 90 degrees. In this work we are presenting a theoretical framework that describes all above motion patterns. As a highlight of the developed approach we find the exact analytical expressions for the mean squared displacement of moving cells for arbitrary distribution of run times. That allows us to quantitatively compare the performance of bacteria exploring the environment with and without signaling chemicals and, therefore, to find the winner of the chemotactic race.

9:24AM Y48.00008 Kinetic theory for systems of self-propelled particles, YEN-LIANG CHOU, THOMAS IHLE, North Dakota State University — Models of self-driven particles similar to the Vicsek model [Phys. Rev. Lett. 75 (1995) 1226] are studied by means of kinetic theory. In these non-equilibrium models, particles try to align their travel directions with the average direction of their neighbors. At strong alignment a global flocking state forms. The alignment is defined by a stochastic rule, not by a Hamiltonian. The corresponding interactions are non-additive and are typically of genuine multi-body nature. The theory [1] is based on a Master equation in 3N-dimensional phase space, which is made tractable by means of the molecular chaos approximation. The phase diagram for the transition to collective motion is calculated and compared to direct numerical simulations. A stability analysis of a homogeneous ordered state is performed, which reveals a long wave length instability for some of the considered models. The mean-field calculations of one of the models show a tricritical point where the flocking transition changes its character from continuous to discontinuous.

9:36AM Y48.00009 Diffusional Variation in Autonomously Motile Catalytic Janus Particles¹, R. LLOYD CARROLL, SHENGRONG YE, ZACHARY JONES, West Virginia University Department of Chemistry — Recently, we and others have studied the motion of Janus particles that undergo catalytically-induced motion in an appropriate chemical environment. Published studies indicate particles move with reduced rotational diffusion, resulting in enhanced effective diffusion coefficient - motile particles move longer distances between each random rotation, resulting in much greater overall motion. We undertook to study the effective diffusion coefficient of janus particles with various structural designs (symmetric and asymmetric anisotropy, angular dislocation of catalytic regimes) and under environmental stresses (external fields, imposed gradients). We find that structural features have a strong effect on the characteristics of observed motion and effective diffusion, and that environmental stresses can change particle dynamics, suppressing rotational diffusion and enhancing correlated motion. These results are consistent, with some caveats, as particles grow smaller, and the effects of Brownian motion become more pronounced. Deeper understanding of the statistical behavior of the systems results in particles with practical applications in transport on a microfluidic scale.

9:48AM Y48.00010 Emergent Collective Behavior of Microscopic Swimmers¹, GUILLAUME LAMBERT, New York University — The individual components of a biological system often express simple behaviors that lead to the spontaneous emergence of order and high levels of complexity; the whole is greater than the sum of its parts. Emergent complexity may arise spontaneously or, more interestingly, in response to external forces present in the surrounding environment. Here, we study the emergence of the emergent collective behavior of swimming *Escherichia coli* bacteria inside microfabricated environments. We first demonstrate how the swimming dynamics of single bacterium cells inside jagged, funnel-shaped geometries leads to the emergence of complex migratory patterns. In particular, by creating ratchet-like barriers that redirect the motion of single *E. coli* cells, we demonstrate that while a single bacterium is unable to “escape” an array of ratchets, a *population* of cells are able to collectively navigate against these motion-rectifying barriers. We then investigate the collective behavior of cells at increasing densities and witness the emergence of multicellularity in bacteria. As the local density of cell increases to reach physiologically relevant concentrations, individual swimming cells respond to the cell-cell interactions and collectively assemble into biofilms. We describe the physiological development of such biofilms inside microfluidics devices and, using in situ measurements, study the physical properties of various biofilms from their motion and deformation.

10:24AM Y48.00011 Active crystallization of Artificial Microswimmers, JEREMIE PALACCI, STEFANO SACANNA, JOYCE LAINE, CSMR, NYU, USA, ASHER PRESKA STEINBERG, Brandeis University, USA, DAVID PINE, PAUL CHAIKIN, CSMR, NYU, USA, CSMR, NYU, USA TEAM — A novel type of light activated microswimmers is used to drive the system far from equilibrium. For sufficient concentrations they spontaneously assemble in crystalline clusters of particles. These clusters are mobile, with complex dynamics –explosion, self healing...– and can reversibly melt down if the activity is shut down. The origin of the attraction between the active particles as well as the crystallization mechanism and the complex dynamics will be presented and rationalized quantitatively.

10:36AM Y48.00012 Collective motility of cells on deformable substrates¹, ARVIND GOPINATH, MICHAEL HAGAN, BULBUL CHAKRABORTY, APARNA BASKARAN, Martin Fisher School of Physics, Brandeis University, BRANDEIS UNIVERSITY TEAM — We consider a simple model for motile cells on deformable substrates. The cells interact through contact interactions and medium-mediated elastic interactions arising due to the adhesion of the cells to the substrate. Using Brownian dynamics simulations and systematic coarse graining of the microscopic model, we characterize the collective velocity field of such a collection of cells by calculating the velocity autocorrelation function and identify the role of elastic interactions in the emergent motility of cell sheets. Our findings include suppression of diffusivity due to the attractive part of the elastic interaction and a growing length scale in the velocity correlations.

¹We acknowledge funding from MRSEC Brandeis.

Session Y49 DMP DPOLY: Focus Session: Organic Electronics and Photonics - Small Molecules and General Advances 162A

8:00AM Y49.00001 Charge transport calculations of organic semiconductors by the time-dependent wave-packet diffusion method¹, HIROYUKI ISHII, NOBUHIKO KOBAYASHI, University of Tsukuba, KENJI HIROSE, NEC corporation — Organic materials form crystals by relatively weak Van der Waals attraction between molecules, and thus differ fundamentally from covalently bonded semiconductors. Carriers in the organic semiconductors induce the drastic lattice deformation, which is called as polaron state. The polaron effect on the transport is a serious problem. Exactly what conduction mechanism applies to organic semiconductors has not been established. Therefore, we have investigated the transport properties using the Time-Dependent Wave-Packet Diffusion (TD-WPD) method [1]. To consider the polaron effect on the transport, in the methodology, we combine the wave-packet dynamics based on the quantum mechanics theory with the molecular dynamics. As the results, we can describe the electron motion modified by (electron-phonon mediated) time-dependent structural change. We investigate the transport property from an atomistic viewpoint and evaluate the mobility of organic semiconductors. We clarify the temperature dependence of mobility from the thermal activated behavior to the power law behavior. I will talk about these results in my presentation. [1] H. Ishii, N. Kobayashi, K. Hirose, Phys. Rev. B, 82 085435 (2010).

8:12AM Y49.00002 Investigation of Interfaces between Sub-Phthalocyanine and C60 using First-Principles Calculations¹, HOSSEIN HASHEMI, XIAO MA, JOHN KIEFFER, STEVEN E. MORRIS, MAX SHTEIN, Materials Science and Engineering Department, University of Michigan, Ann Arbor, Michigan 48109, USA, SHAOHUI ZHENG, EITAN GEVA, BARRY DUNIETZ, Department of Chemistry, University of Michigan, Ann Arbor, Michigan 48109, USA — The structure and electronic properties of a boron subphthalocyanine (SubPc) adsorbed on buckminsterfullerene (C60) and of C60 on SubPc surfaces, mimicking reverse orders of deposition, have been studied using density-functional theory (DFT) including long-van der Waals. Total-energy calculations are used to elucidate the initial adsorption of SubPc on C60 low index surfaces and also C60 on SubPc surfaces. The energetics of crystalline substrates with different surface terminations were mapped out using a single molecule of the partnering species. Accordingly, the interfacial structure and properties are different depending on whether the substrate is SubPc or C60, due to the incongruity between lattices and the disorder that develops in the contact layers of C60 and SubPc, respectively. The dependence of the charge transfer energies on the interface morphology is studied using range separated hybrid functionals. The stabilization of charge transfer states to below the absorbing state, needed to optimize the fill factor, also depends on the order of layer deposition. These results are discussed in the context of experiments performed on organic solar cells, showing trade-offs in the short circuit current and open circuit voltage with varying deposition order of the organic layers.

¹DoE-BES Award # DE-SC0000957

8:24AM Y49.00003 First principles study of the electrical and optical properties of SubPc single crystal¹, XIAO MA, HOSSEIN HASHEMI, JOHN KIEFFER, Materials Science and Engineering, University of Michigan, Ann Arbor, Michigan, 48109 — We studied the electrical and optical properties of the single crystal of boron subphthalocyanine chloride (SubPc), a popular donor material used in organic photovoltaic (OPV) devices within the framework of density-functional theory (DFT) with added van der Waals long range interactions to deepen our understanding of its performance in light absorption and charge transport. We calculated the frequency-dependent dielectric response, refractive index, extinction coefficient, and intrinsic charge mobility. The complex dielectric constant was computed using first-order perturbation theory, using the electronic wave functions and eigenvalues obtained from supercell DFT calculations. This was done for wave propagation in the (001), (010), (100) directions of optimized SubPc crystal with DFT calculations, revealing significant anisotropy in both electrical and optical properties. Comparison with experimental results allows us to draw conclusions regarding the structural organization of SubPc molecules deposited on a variety of substrates, as well as the conditions for thin film growth and property optimization.

¹DoE-BES Award # DE-SC0000957

8:36AM Y49.00004 Density-functional Theory and Beyond for Donor-Acceptor Complexes: The Example of TTF/TCNQ¹, VIKTOR ATALLA, Fritz-Haber-Institut der MPG, MINA YOON, Oak Ridge National Laboratory, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG — We study the performance of density-functional theory (DFT) with various exchange-correlation (XC) functionals in describing electronic and structural properties of the prototypical donor/acceptor complex TTF/TCNQ. We find that the binding energetics and the amount of electron transfer between TTF and TCNQ depends strongly on the functional. In particular, all semilocal functionals give rise to significant, artificial electron transfer due to a wrong ordering of Kohn-Sham (KS) levels. We consider the HSE [1] "family" of XC functionals using the fraction of exact exchange (α) as adjustable parameter. The optimum XC functional is then identified as that for which the G_0W_0 quasiparticle correction to the energy gap of the KS LUMO of the acceptor and the HOMO of the donor is minimized. We obtain $\alpha \sim 0.8$ which gives an electronic level alignment that is consistent with experiment and free from spurious asymptotic charge transfer. We conclude that the proposed scheme improves the KS spectrum, and that the investigated TTF-TCNQ dimer exhibits intra-molecular electron-density rearrangement rather than electron transfer.

¹Research sponsored by the Max Planck Society and the US Department of Energy, Basic Energy Sciences, Materials Sciences and Engineering Division.

8:48AM Y49.00005 Understanding the high device efficiency of a class of solution-processed small-molecule solar cells, ANDRIY ZHUGAYEVYCH, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, OLENA POSTUPNA, Department of Chemistry, University of Rochester, Rochester, NY 14627, USA, SERGEI TRETIKOV, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, GUILLERMO BAZAN, Department of Chemistry and Biochemistry, University of California, Santa Barbara, CA 93106, USA — We perform a first principles study of light absorption, exciton and charge carrier transport for two recently synthesized molecular crystals which in bulk heterojunction solar cells with PC70BM acceptor show up to 6.7% power conversion efficiency. Our results distinguish the following factors important for this high efficiency. The large conjugation length facilitates strong light absorption with low-energy absorption edge. The crystalline ordering of properly oriented molecules leads to exciton delocalization over the typical size of the crystallites. The tightly packed pi-stacks allow for fast disorder-resistant hole transport along these stacks. Nevertheless the microscopic characteristics of the considered crystals are typical and comparable with other materials used in photovoltaics. Therefore we conclude that the main factors of the high device efficiency should be searched at the mesoscale including interfaces and grain boundaries.

9:00AM Y49.00006 Relating Molecular-Scale Structure to Spectroscopy in Pentacene-Perfluoropentacene Donor-Acceptor Assemblies from First-Principles, SAHAR SHARIFZADEH, Molecular Foundry, LBNL, LEEOR KRONIK, Weizmann Institute of Science, JEFFREY NEATON, Molecular Foundry, LBNL — Using van der Waals-corrected density functional theory and many-body perturbation theory, we compute the spectroscopic properties of the archetypal organic semiconductors pentacene (PEN), perfluoropentacene (PFP), and their composite donor-acceptor blends. Band structures, bulk crystal densities of states, and low-energy optical excitations are computed for the isolated bulk crystals and their composite assemblies. For the individual crystals, transport and optical gaps are in good agreement with experiment, and the nature and orientation of the excitonic wavefunctions is found to be sensitive to the degree of co-facial packing. For the PEN-PFP systems, different molecular arrangements and compositions are considered in an effort to connect to thin film measurements. The relationship between packing in these structures, the transport gap, and the nature and binding energies of low-lying excitons are explored. We acknowledge DOE-BES, NSF, and US-Israel BSF for support, and NERSC for computational resources.

9:12AM Y49.00007 Quantitative structural analysis of organic thin film deposition: a real time synchrotron X-ray scattering study, ISHVIENE COUR, Materials Science Program, Department of Physics, University of Vermont, Burlington, VT-05405, CHRISTIAN SCHLEPUETZ, YONGSOO YANG, Department of Physics, University of Michigan, Ann Arbor, MI- 48109, SONGTAO WO, Materials Science Program, Department of Physics, University of Vermont, Burlington, VT-05405, RON PINDAK, National Synchrotron light source, Brookhaven National Laboratory, Upton, NY-11973, RANDALL HEADRICK, Materials Science Program, Department of Physics, University of Vermont, Burlington, VT-05405 — Direct writing gives us the ability to deposit films from solution with controlled thickness, grain structure and orientation. We have investigated TIPS-Pentacene films deposited from toluene solution at various speeds via a combination of real time synchrotron x-ray scattering and polarized-light video microscopy. Through video microscopy we observe a well-defined crystallization front that becomes less defined as the writing speed is increased. In synchrotron x-ray scattering we observe that the ordering process is an order of magnitude slower than what is seen under the optical microscope. This discrepancy in the apparent crystallization rate raises questions such as, which part of the film actually rotates the polarized light and becomes visible under crossed polarizers? Observation with varying speeds and substrate temperatures suggest that the crystallization first occurs near the top surface of the drying film, while subsurface regions remain in a disordered state for up to several seconds.

9:24AM Y49.00008 Diindenoperylene as donor and acceptor for organic photovoltaic cells, ANDREAS WILKE, BEN BRÖKER, JOHANNES FRISCH, PATRICK AMSALEM, JENS NIEDERHAUSEN, Humboldt Universität zu Berlin, ANTJE VOLLMER, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, NORBERT KOCH, Humboldt Universität zu Berlin, HUMBOLDT UNIVERSITÄT ZU BERLIN TEAM, HELMHOLTZ-ZENTRUM BERLIN FÜR MATERIALIEN UND ENERGIE GMBH TEAM — In organic photovoltaic cells (OPVCs) typically two organic materials with electron acceptor and donor character are sandwiched between anode and cathode, forming heterojunctions where charge separation occurs. To improve the efficiency of charge separation, understanding the mechanisms of the energy level alignment at these heterojunctions is crucial. We report on ultraviolet photoelectron spectroscopy (UPS) measurements on three different organic-diindenoperylene (DIP) heterojunctions formed on PEDT:PSS electrodes. The measurement reveal that the energy level alignment of C₆₀ on DIP/PEDT:PSS corresponds to a type II heterojunction, with DIP acting as donor. The offset between the highest occupied molecular orbital (HOMO) of DIP and the lowest unoccupied molecular orbital (LUMO) of the acceptor C₆₀, an estimate for the maximum achievable open circuit voltage, is 1.35 eV. In contrast, the energy level alignment of DIP on sexithiophene (6T) and poly(3-hexylthiophene) (P3HT) is of type II as well, but DIP acting as acceptor. The offset between the HOMO of the donors 6T and P3HT and the LUMO of DIP is found to be 1.75 eV and 1.6 eV, respectively.

9:36AM Y49.00009 Gradual thickness change of CuPc on MoO_x on Oxygen Plasma Treated ITO¹, CHENGGONG WANG, IRFAN IRFAN, YONGLI GAO², Department of Physics and Astronomy, University of Rochester — The thickness dependence of copper phthalocyanine (CuPc) interlayer on molybdenum trioxide (MoO₃) and conducting indium tin oxide (ITO) has been investigated with ultraviolet photoemission spectroscopy (UPS). We also investigated the air exposure effect on the CuPc/MoO₃/ITO interlayers. It was found that the MoO₃ interlayer substantially increased the substrate work function (WF). With the deposition of CuPc the WF decreased and saturated at the thickness of 80 Å. We also found that 3x10⁶ Langmuir (L) air exposure decreased both the MoO₃ WF and the interface dipole between CuPc/MoO₃ interface.

9:48AM Y49.00010 Voltage dependence of the electric double layer structure at an ionic liquid/Au interface, YUSUKE WAKABAYASHI, RYOSUKE YAMAMOTO, HAZUKI MORISAKI, Grad. Sc. of Eng. Sci., Osaka University, OSAMI SAKATA, National Institute for Materials Science, HIDEKAZU SHIMOTANI, Dept. of Phys., Tohoku University, HONGTAO YUAN, YOSHIHIRO IWASA, Dept. of Appl. Phys., Tokyo University, TSUYOSHI KIMURA, Grad. Sc. of Eng. Sci., Osaka University — Ionic liquids (ILs) have been studied extensively because of their unique characteristics. One of the utilization of them is applying a strong electric field to solids through the electric double layer. Using this field, one can reduce the gate voltage for an organic field effect transistors (FETs) to operate [1]. In order to clarify the microscopic structure of such IL-gated organic FETs, we have performed synchrotron x-ray scattering experiments at BL-13XU of the SPring-8, Japan. While the electric double layer structures at IL-solid interfaces have been studied by x-ray reflectometry [2], the electric double layer is stabilized by the natural polarity of the surface of the solid. In order to observe the electric field effect, we measured an electric double layer formed at the interface between an IL and a Au(111) single crystal under external electric field. The reflectivity profile was found to depend on the applied electric field, which reflects the formation of the electric double layer.

10:00AM Y49.00011 A critical assessment of thiolate self-assembled monolayers (SAMs) on platinum.¹, YENNY CARDONA QUINTERO, HONG ZHU, RAMPI RAMPRASAD, University of Connecticut — Thiolate SAMs have been successfully anchored on metal surfaces, but a critical assessment of the impact on the structural and electronic properties of the metal surfaces has remained elusive. CH₃S and CF₃S were selected as model systems in this work, because of their simple structures which can provide insights about how the composition and electronegativity of SAMs affect the properties of metal-SAM systems. Density functional theory calculations have been used in this work to study the adsorption of CH₃S and CF₃S molecules on the Pt (111) surface at different coverage (1/3, 1/4, 1/6, 1/9 and 1/12) and adsorption sites (fcc and hcp). The geometry, adsorption energy and the work function of the Pt-SAM systems have been determined. Several interesting observations could be made: (1) the optimized SAM is tilted with respect to the Pt surface and the tilted angle decreases with the molecular coverage on the Pt surface; (2) the adsorption energy of both systems are almost always lower at the fcc site compared to the hcp one and shows a coverage-dependence; (3) the work function of Pt-SAM also shows a dependence on coverage and hence controlling the molecular coverage is probably an effective technique to tune the work function.

10:12AM Y49.00012 Nonlinear light propagation in photopolymers: from self-trapped beams to 3-D optical lattices, KALAICHELVI SARAVANAMUTTU, McMaster University — While liquid crystals, surfactants and colloidal crystal systems assemble into ordered phases to attain free energy minima, strikingly complex patterns can also emerge when condensed matter systems are perturbed away from equilibria. This talk will be an overview of research in our group into the dynamics of light beams that propagate while simultaneously initiating free-radical polymerisation in photopolymers. The consequent nonlinear and reciprocal interactions between the optical field and self-induced refractive index changes in the medium elicit a rich assortment of three-dimensional spatial patterns. These include self-trapping bright and dark beams, beam filamentation due to modulation instability, diffraction rings due to self-phase modulation and the formation of 2-D and 3-D bright and dark optical lattices. The potential of these optical phenomena to spontaneously inscribe complex 3-D polymer architectures that are inaccessible through conventional lithographic techniques and that would have advanced optical applications such as nonlinear photonic crystals will also be described.

10:24AM Y49.00013 Enhancing sensing of nitroaromatic vapors by thiophene-based polymer films, G. NAGARJUNA, University of Massachusetts Amherst, ABHISHEK KUMAR, AKSHAY KOKIL, University of Massachusetts Lowell, KEDAR JADHAV, SERKAN YURT, University of Massachusetts Amherst, JAYANT KUMAR, University of Massachusetts Lowell, D. VENKATARAMAN, University of Massachusetts Amherst — Sensing of nitroaromatic-based explosives is important for homeland security and for the detection of landmines in war zones. These compounds are detected using fluorescence quenching of poly(phenyleneethynylene) (PPE). When compared with PPE, polythiophenes have several features that make them excellent candidates for sensing. However, due to strong $\pi - \pi$ aggregation in polythiophenes, the permeation of the analyte in the thin film is poor. Therefore polythiophenes have poor quenching efficiencies. We have addressed this problem by tuning the side chains on these polymers to disrupt the polymer aggregation, thereby enhancing the analyte diffusion into the polymer thin film. We have now developed a materials platform for next generation sensory materials based on polythiophenes. This talk will discuss our approach and the studies that showed enhanced sensing of nitroaromatics in polythiophene thin films.

10:36AM Y49.00014 Giant Electrocaloric Effect in Ferroelectric Polymers with Great Impact on Energy and Environment, XINYU LI, XIAOSHI QIAN, HAIMING GU, SHENGGUO LU, QIMING ZHANG, Electrical Engineering Department and Materials Research Institute, The Pennsylvania State University — Refrigeration and air conditioning overall consume around 20% of the energy budget in developed countries which necessitates a search for new approaches to increase the energy efficiency of these cooling technologies. Cooling technologies based on the electrocaloric effect (ECE) hold great potential and promise in realizing these goals. The electrocaloric effect (ECE) refers to the change in temperature and/or entropy of a dielectric material by an applied voltage. Recently, a class of P(VDF-TrFE) based ferroelectric polymers have been discovered that provide a giant electrocaloric effect with an adiabatic temperature change of $\Delta T \sim 20$ K and an isothermal entropy change $\Delta S > 90$ J/kgK at room temperature. This talk will review the earlier works in the ECE, as well as present the basic materials considerations and experimental results of the ECE in both normal and relaxor ferroelectric polymers. It will be shown he relaxor ferroelectric polymer displays a nearly flat ECE response over a broad temperature range, which is very attractive for practical cooling device applications. Furthermore, we will present our recent investigation, exploiting the giant ECE in these polymers for cooling devices with compact size, high cooling power and efficiency.

Session Y50 DPOLY DFD: Focus Session: Micro and Nano Fluidics III: Microtransport and Thermophysical Properties 162B

8:00AM Y50.00001 Cavitation in confined water: ultra-fast bubble dynamics, OLIVIER VINCENT, PHILIPPE MARMOTTANT, CNRS and University of Grenoble, Lab. Interdisciplinaire de Physique, France — In the hydraulic vessels of trees, water can be found at negative pressure. This metastable state, corresponding to mechanical tension, is achieved by evaporation through a porous medium. It can be relaxed by cavitation, i.e. the sudden nucleation of vapor bubbles. Harmful for the tree due to the subsequent emboli of sap vessels, cavitation is on the contrary used by ferns to eject spores very swiftly. We will focus here on the dynamics of the cavitation bubble, which is of primary importance to explain the previously cited natural phenomena. We use the recently developed method of artificial tress, using transparent hydrogels as the porous medium. Our experiments, on water confined in micrometric hydrogel cavities, show an extremely fast dynamics: bubbles are nucleated at the microsecond timescale. For cavities larger than 100 microns, the bubble “rings” with damped oscillations at MHz frequencies, whereas for smaller cavities the oscillations become overdamped. This rich dynamics can be accounted for by a model we developed, leading to a modified Rayleigh-Plesset equation. Interestingly, this model predicts the impossibility to nucleate bubbles above a critical confinement that depends on liquid negative pressure and corresponds to approximately 100 nm for 20 MPa tensions.

8:12AM Y50.00002 Multiphase flow within 3D porous media , SUJIT DATTA, DAVID WEITZ, Department of Physics, Harvard University — Multiphase flow through porous media is important for a diverse range of processes including aquifer remediation, CO₂ sequestration, and oil recovery. Despite its enormous importance, exactly how flow proceeds within a porous medium is unknown; the opacity of the medium typically precludes direct imaging of the flow. Here, we present an experimental technique to directly visualize multiphase flow within porous media. Using this approach, we show how heterogeneity strongly affects flow behavior during the drainage of porous media.

8:24AM Y50.00003 Modeling capillary filling of micropores with nanoparticle-filled binary fluid , YONGTING MA, AMITABH BHATTACHARYA, OLGA KUKSENOK, University of Pittsburgh, Pittsburgh, PA 15261, DENNIS PERCHAK, Kodak Research Laboratories, Rochester, NY 14650, ANNA C. BALAZS, University of Pittsburgh, Pittsburgh, PA 15261 — We examine the behavior of binary fluids containing nanoparticles that are driven by capillary forces to fill well-defined pores of microchannels. To carry out these studies, we use a hybrid computational approach that combines the lattice Boltzmann model for binary fluids and a Brownian dynamics model for the nanoparticles. The hybrid model allows us to capture the interactions between the binary fluids and the nanoparticles, as well as model the interactions among the fluid, the nanoparticles and the pore walls. We show that the nanoparticles dynamically alter both the interfacial tension between the two fluids and the contact angle on the pore walls; this, in turn, strongly affects the dynamics of the capillary filling. We demonstrate that by tailoring the properties of the nanoparticles, such as their affinity to the fluid components and their interaction with the pore walls, one can effectively control both the filling velocities and the deposition of nanoparticles on the pore walls. Our findings provide fundamental insights into the dynamics of this complex system, as well as potential guidelines for technological processes involving capillary filling with nanoparticles in microchannels with differing geometries.

8:36AM Y50.00004 Label-free Screening of Multiple Cell-surface Antigens Using a Single Pore , KARTHIK BALAKRISHNAN, UC Berkeley Department of Mechanical Engineering, MATTHEW CHAPMAN, UC Berkeley Biophysics Graduate Group, ANAND KESAVARAJU, UC Berkeley Department of Bioengineering, LYDIA SOHN, UC Berkeley Department of Mechanical Engineering — Microfluidic pores have emerged as versatile tools for performing highly sensitive measurements. Pore functionalization can result in slower particle transit rates, thereby providing insight into the properties of particles that travel through a pore. While enhancing utility, functionalizing with only one species limits the broader applicability of pores for biosensing by restricting the insight gained in a single run. We have developed a method of using variable cross-section pores to create unique electronic signatures for reliable detection and automated data analysis. By defining a single pore into sections using common lithography techniques, we can detect when a cell passes through a given pore segment using resistive-pulse sensing. This offers such advantages as 1) the ability to functionalize each portion of a pore with a different antibody that corresponds to different cell surface receptors, enabling label-free multianalyte detection in a single run; and 2) a unique electronic signature that allows for both an accelerated real-time analysis and an additional level of precision to testing. This is particularly critical for clinical diagnostics where accuracy and reliability of results are crucial for healthcare professionals upon which to act.

8:48AM Y50.00005 Tracking rotation and translation simultaneously in confined liquids , SUBHALAKSHMI KUMAR, SUNGCHUL BAE, STEVE GRANICK, University of Illinois, Urbana Champaign — At the same spatially-resolved spots when fluid is confined to molecularly-thin spacings between atomically-smooth mica crystals, we track simultaneously, using fluorescence correlation spectroscopy and time correlated single photon counting, the translational and rotational diffusion of small dyes suspended in octamethylcyclotetrasiloxane (OMCTS). The spatially-resolved quantification of both dynamical quantities gives insight, as it does in bulk glasses, into the origins of dynamical heterogeneity in confined fluids.

9:00AM Y50.00006 Neutron Scattering Applications for Characterizing Phase Behavior and Dynamics of Confined Fluids in Nanoporous Materials , YURI MELNICHENKO, Biology and Soft Matter Division, Oak Ridge National Laboratory — Fluid-solid interactions in natural and engineered porous solids underlie variety of technological processes, including sequestration of anthropogenic greenhouse gases, hydrogen storage, membrane separation, and catalysis. The size, distribution and interconnectivity of pores, the chemical and physical properties of the solid and fluid phases collectively dictate how fluid molecules migrate into and through the micro- and mesoporous media, adsorb and ultimately react with the solid surfaces. Due to the high penetration power and relatively short wavelength of neutrons, small-angle neutron scattering (SANS) as well as quasi elastic neutron scattering (QENS) techniques are ideally suited for *in situ* studies of the structure and phase behavior of confined fluids under pressure as well as for evaluating structure of pores in engineered and natural porous systems. It has been demonstrated recently that SANS and USANS can also be used for evaluating the volume of closed pores as a function of pore sizes in the range from micrometer to sub-nanometer pores. In this talk I will overview some recent developments in the SANS and QENS methodology and give several examples of how it can be used for in-situ studies of the adsorption and dynamics of carbon dioxide and methane in porous fractal silica and carbon aerogels as well as characterizing the abnormal densification of hydrogen in activated carbons at ambient temperatures.

9:12AM Y50.00007 A mathematical model for the transport of a solute through a porous-walled tube , IAN GRIFFITHS, REBECCA SHIPLEY, Mathematical Institute, University of Oxford — Predicting the distribution of solutes or particles in flows within porous-walled tubes is essential to inform the design of cross-flow filtration devices. Here we use Taylor-dispersion theory to derive a radially averaged model for solute transport in a tube with porous walls, where the wall Darcy permeability may vary both spatially and in time. Crucially, this model includes solute advection via both radial and axial flow components, as well as diffusion, and the advection, diffusion and uptake coefficients in the averaged equation are explicitly derived. The model is used to explore the specific example of a hollow-fibre membrane bioreactor for tissue engineering applications - here membrane fouling and cell population expansion mean that the effective membrane permeability is intrinsically coupled to both fluid flow and nutrient transport. We conclude by presenting design considerations that promote spatially uniform cell population growth.

9:24AM Y50.00008 Biased and flow driven Brownian motion in periodic channels¹ , S. MARTENS, A. STRAUBE, Humboldt-University Berlin, G. SCHMID, University Augsburg, L. SCHIMANSKY-GEIER, Humboldt-University Berlin, P. HÄNGGI, University Augsburg — In this talk we will present an expansion of the common Fick-Jacobs approximation to hydrodynamically as well as by external forces driven Brownian transport in two-dimensional channels exhibiting smoothly varying periodic cross-section. We employ an asymptotic analysis to the components of the flow field and to stationary probability density for finding the particles within the channel in a geometric parameter. We demonstrate that the problem of biased Brownian dynamics in a confined 2D geometry can be replaced by Brownian motion in an effective periodic one-dimensional potential $\Psi(x)$ which takes the external bias, the change of the local channel width, and the flow velocity component in longitudinal direction into account. In addition, we study the influence of the external force magnitude, respectively, the pressure drop of the fluid on the particle transport quantities like the averaged velocity and the effective diffusion coefficient. The critical ratio between the external force and pressure drop where the average velocity equals zero is identified and the dependence of the latter on the channel geometry is derived. Analytic findings are confirmed by numerical simulations of the particle dynamics in a reflection symmetric sinusoidal channel.

9:36AM Y50.00009 ABSTRACT WITHDRAWN —

9:48AM Y50.00010 Crossover from the Hydrodynamic to the Kinetic Regime in Confined Nanoflows¹, CHARLES LISSANDRELLO, VICTOR YAKHOT, KAMIL L. EKINCI, Department of Mechanical Engineering, Boston University — We present an experimental study of a confined nanoflow. The nanoflow is generated in a simple fluid by a sphere oscillating in the proximity of a flat solid wall. Varying the oscillation frequency, the confining length scale and the fluid mean free path over a broad range provides a detailed map of the flow. We use this experimental map to construct a scaling form, which seamlessly describes the nanoflow in both the hydrodynamic and the kinetic regimes. Furthermore, our scaling form unifies previous theories based on the slip boundary condition and the effective viscosity.

¹Support from the US NSF (through grants ECCS-0643178, CMMI-0970071, and DGE-0741448) is acknowledged.

10:00AM Y50.00011 Viscosity of ultrathin water films confined between oxide surfaces – ab initio and classical molecular dynamics simulations¹, PETER J. FEIBELMAN, GARY S. GREEST, Sandia National Laboratories, NEIL HARIA, CHRISTIAN D. LORENZ, King's College London — We compare estimates based on ab initio (DFT/PBE) and on classical molecular dynamics simulations of the viscosity of 2, 3 and 5-layer water films confined between hydrophilic kaolinite surfaces. Results were obtained by constraining the confining surfaces to move in +x and -x directions at equal speeds of 1-200 m/sec and loads up to 1 GPa. In neither simulation approach did the calculated viscosity of the confined water exceed that of bulk water by more than an order of magnitude. Thus neither supports the idea that nano-confinement dramatically enhances water's viscosity.

¹Supported by the DOE Office of Basic Energy Sciences, Division of Materials Science and Engineering. Sandia is operated by the Lockheed Martin Co. for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL8500

10:12AM Y50.00012 Submicron flows of polymer solutions, HUGUES BODIGUEL, AMANDINE CUENCA, Université de Bordeaux - LOF — We study flow properties of high molecular weight polymer solutions below the micron scale. Fluorescence photobleaching is used as a non-invasive technique to evaluate the velocity of pressure-driven flows in channels from 100 to 4000 nm height. We observe a striking reduction of the effective viscosity of polyacrylamide solutions in the semi-dilute regime. This effect increases with molecular weight and concentration. Using a Rabinovitch-like approach, we correlate the data at different thicknesses to obtain the wall slip velocity and the flow curve at sub-microscale. Those properties are also evaluated using particle imaging velocimetry close to similar surfaces and standard rheometry. Comparing the measurements in bulk and in confined geometries, we conclude that the observed viscosity reduction can not be solely explained by slippage. We discuss the possible reasons of this effect that are size-dependant filtration and shear-thinning enhancement due to the confinement.

10:24AM Y50.00013 Nanomechanics and dynamics of confined water and other liquids¹, PETER HOFFMANN, Wayne State University, SHAH KHAN, Wayne State University/ University of Peshawar — From oil recovery to molecular biology, nanoconfined water plays an important role in many areas of research. However, the mechanics and dynamics of nanoconfined water are not well understood. Over the last ten years, a number of groups have measured the mechanics of confined water using atomic force microscopy (AFM) or surface force apparatus (SFA) - often with contradictory results. At Wayne State University, we have developed high resolution AFMs for ultra-small amplitude, linear measurements of the mechanics and dynamics of confined liquids. We have shown that water shows a distinct slow-down in dynamics under confinement (PRB 2004), co-discovered a dynamic "solidification" in a model liquid (Langmuir 2006), and showed that normal and shear stiffness are closely related in confined liquids (Rev. Sci. Instr. 2008). Recently, we found dynamic solidification also in water layers (PRL 2010), a finding that explains the contradictory findings in earlier measurements and points to surprisingly complex behavior in this seemingly simple system. Here we will review these findings, as well as present new findings that show the profound effects of ion concentration on these dynamical effects, as well as measurements of colloidal systems, which illustrate that some findings at the molecular scale can be understood from purely geometric considerations and are not dependent on molecular-scale interactions.

10:36AM Y50.00014 Investigation of Nanoscale Structure Using Spin-Echo Small-Angle Neutron Scattering (SESANS), XIN LI, ROGER PYNN, ADAM WASHINGTON, Indiana University, WEI-REN CHEN, KUNLUN HONG, GREGORY SMITH, Oak Ridge National Laboratory, YUN LIU, National Institute of Standards and Technology — Spin-Echo Small-Angle Neutron Scattering (SESANS) is a new technique for probing structural correlations in real space over distances ranging from ~20 nm to several microns. The measured SESANS correlation function is a projection of the normal Patterson correlation function on to a particular spatial direction. A framework to theoretically calculate this correlation function is laid out, followed by a general discussion of the features of the SESANS correlation function for colloidal systems with different interaction potentials. Our calculations for a system of monodisperse spherical particles, show that SESANS is much more sensitive to the intercolloid potential than conventional Small Angle Neutron Scattering. We have used SESANS to study the correlations between 300-nm-diameter surfactant-stabilized poly(methyl methacrylate) (PMMA) spheres suspended in a good solvent, with and without an added polymeric depletant. Below a PMMA volume fraction of ~30% we find good agreement between the experimental data and theoretical prediction based on the Percus-Yevick approximation. With a small amount of polymer added to the suspension (less than 0.2% by weight of 110 kD polymer), the short-range correlations between PMMA spheres are enhanced because of the presence of polymer depletant. The magnitude of the change is roughly as expected on the basis of calculations of a mixture of spherical particles of different sizes.

10:48AM Y50.00015 Non local rheology and near wall fluctuations in microgel jammed suspensions, PATRICK TABELING, CHOONGYEOP LEE, FABRICE MONTI, MICHEL CLOITRE, ESPCI — We study flows of concentrated suspensions of soft nanoparticles in microchannels, over smooth hydrophilic and hydrophobic surfaces, using nano-PTV and μ PIV techniques. With hydrophobic walls, the flow curves are in good agreement with bulk rheology. With hydrophilic walls, substantial deviations from bulk rheology are observed. In the meantime, large velocity oscillations close to the wall are detected. We couple these observations by introducing a local rheology based on an energy barrier. As a whole, our work confirms the existence of non local rheological behavior in glassy systems.

Session Y52 GSNP: Focus Session: Spin Glasses: Advances, Algorithms, and Applications 153C

8:00AM Y52.00001 How the Edwards-Anderson Model reaches its Mean-Field Limit; Simulations in $d=3,\dots,7$ ¹, STEFAN BOETTCHER, STEFAN FALKNER, Physics Department, Emory University — Extensive computations of ground state energies of the Edwards-Anderson spin glass on bond-diluted, hypercubic lattices are conducted in dimensions $d = 3, \dots, 7$. Results are presented for bond-densities exactly at the percolation threshold, $p = p_c$, and deep within the glassy regime, $p > p_c$, where finding ground-states becomes a hard combinatorial problem. The “stiffness” exponent y that controls the formation of domain wall excitations at low temperatures is determined in all dimensions. Finite-size corrections of the form $1/N^\omega$ are shown to be consistent throughout with the prediction $\omega = 1 - y/d$. At $p = p_c$, an extrapolation for $d \rightarrow \infty$ appears to match our mean-field results for these corrections. In the glassy phase, ω does not approach the value of $2/3$ for large d predicted from simulations of the Sherrington-Kirkpatrick spin glass. However, the value of ω reached at the upper critical dimension *does* match certain mean-field spin glass models on sparse random networks of regular degree called Bethe lattices.

8:12AM Y52.00002 Ensemble Inequivalence in Spin Glasses, ZSOLT BERTALAN, HIDETOSHI NISHIMORI, KAZUTAKA TAKAHASHI, Tokyo Institute of Technology — We report on the ensemble inequivalence in many-body spin-glass models with Ising and integer spins. In the Ising case, for many-body interactions the transition between the ferromagnetic and paramagnetic phases is of first order, and the microcanonical and canonical ensembles give different results. The spin-glass transition is of first order for certain values of the crystal field strength in the integer-spin model and is dependent whether it was derived in the microcanonical or the canonical ensemble. We also discuss the ensemble inequivalence of random energy models, corresponding to the limit infinitely many-body interactions. This is the first systematic treatment of spin glasses with long-range interactions in the microcanonical ensemble using the replica approach, which shows how the two ensembles give different results.

8:24AM Y52.00003 Algorithms and long-range order in the two-dimensional $\pm J$ spin glass¹, A. ALAN MIDDLETON, Syracuse University, CREIGHTON K. THOMAS, Northwestern University, DAVID A. HUSE, Princeton University — Numerical methods and results of their application to the two-dimensional Ising spin glasses will be described. For a random mix of ferromagnetic and antiferromagnetic bonds of equal strength, long range correlations at zero-temperature are derived from scaling relations between computed exponents and are confirmed in numerical simulations. This long range order is stabilized by large entropy differences, as large domain walls often have zero energy cost. The order resembles that in higher-dimensional models at finite temperature. A publicly distributed implementation of the algorithms has been developed for computing partition functions and exactly sampling configurations according to their Boltzmann weight for the general spin-glass and related two-dimensional models.

8:36AM Y52.00004 Replica theory of partition-function zeros in spin-glass systems, KAZUTAKA TAKAHASHI, Tokyo Institute of Technology, TOMOYUKI OBUCHI, Osaka University — We study the phase transitions in spin-glass systems by analysing the partition-function zeros (Lee-Yang zeros) with respect to the complex temperature/field. For several models as the random energy and spherical models with many-body interactions, we extend the replica method and the procedure of the replica symmetry breaking ansatz to be applicable in the complex-parameter case. We derive the phase diagrams in the complex plane and calculate the density of zeros in each phase. We find that there is a replica symmetric phase having a large density near the imaginary axis away from the origin. In the spin-glass phase, the density is finite only when the chaos effect is present. This result indicates that the density of zeros is more closely connected to the chaos effect than the replica symmetry breaking. We also investigate the relevance of our result to the finite-dimensional systems by studying the renormalization group flow in the complex plane.

8:48AM Y52.00005 Aging behavior in disordered and frustrated spin systems¹, HYUNHANG PARK, MICHEL PLEIMLING, Virginia Tech — Using Monte Carlo simulations we investigate aging in three-dimensional Ising spin glasses as well as in two-dimensional Ising models with disorder quenched to low temperatures. The time-dependent dynamical correlation length $L(t)$ is determined numerically and the scaling behavior of various two-time quantities as a function of $L(t)/L(s)$ is discussed. For disordered Ising models deviations of $L(t)$ from the algebraic growth law show up. The generalized scaling forms as a function of $L(t)/L(s)$ reveal a generic simple aging scenario for Ising spin glasses as well as for disordered Ising ferromagnets.

9:00AM Y52.00006 Critical behavior of the 1D Lévy lattice spin-glass: from mean-field threshold to the effective lower critical dimension¹, LUCA LEUZZI, IPCF-CNR, Italy, GIORGIO PARISI, FEDERICO RICCI-TERSENGHI, Dept. Physics, Sapienza University of Rome, Italy, JUAN-JOSÉ RUIZ-LORENZO, Dept. Physics, University of Extremadura, Badajoz, Spain — By means of Monte Carlo numerical simulations we analyze the critical behavior of a one dimensional spin-glass model with diluted interactions decaying, in probability, as an inverse power of the distance: the Lévy lattice spin-glass. Varying the power ρ , corresponds to change the effective dimension from mean-field-like (small power $\rho < 4/3$) to finite dimensional-like short-range models ($4/3 < \rho < 2$) and, eventually, to 1D short-range models ($\rho > 2$), where no phase transition occurs. The bond diluteness drastically reduces the computational time and large sizes can be approached. The one dimensionality allows for studying long systems, e.g., long correlation lengths in the critical region. The spin-glass critical behavior can, therefore, be studied in and out of the range of validity of the mean-field approximation. After reviewing the main results in the Lévy lattice model about the spin-glass transition and the nature of the spin-glass phase for different values of the effective dimension, we will present new results on the critical behavior at $\rho = 2$, corresponding to the lower critical dimension, and compare them with old and recent renormalization group approaches in this limit.

9:12AM Y52.00007 Spin glasses: Still frustrating after all these years?, HELMUT G. KATZGRABER, Department of Physics and Astronomy, Texas A&M University and ETH Zurich — Spin glasses are archetypal model systems to study the effects of frustration and disorder. Despite ongoing research spanning several decades, there remain many fundamental open questions, such as the existence of a spin-glass state in a field or the low-temperature structure of phase space for short-range systems. Novel applications across disciplines, as well as progress in algorithms and the advent of fast and cost-effective computers, have recently revived interest in the study of spin glasses. First, an overview of spin glasses will be given, followed by recent novel applications to fields as diverse as structural glasses and quantum computing.

9:48AM Y52.00008 The de Almeida-Thouless line of the four-dimensional Ising spin glass, VICTOR MARTIN-MAYOR, Universidad Complutense de Madrid, JANUS COLLABORATION — We present the results of a large scale numerical simulation of the four dimensional Edwards-Anderson model in an external field. Using the Janus computer, as well as standard CPU clusters, we simulate lattices of size up to $L=16$ at several values of the external field. Our analysis method departs from the standard one. In fact, it has been previously noticed that the spin-glass susceptibility (i.e. the spin-glass propagator at zero external momentum) behaves anomalously. Instead, one should focus on the propagator at small but non-vanishing wave-vector. Starting from this observation, we obtain a simple and powerful finite-size scaling method. Clear evidence for a de Almeida-Thouless line is found. We compute critical exponents, widely differing from the zero field case, with an accuracy of five percent. The shape of the de Almeida-Thouless line in the (T, h) plane follows the Fisher-Sompolinsky scaling. Discrepancies with previous work are explained in terms of very strong scaling corrections.

10:00AM Y52.00009 Reentrance and ultrametricity in three-dimensional Ising spin glasses, HELMUT G. KATZGRABER, Department of Physics and Astronomy, Texas A&M University and ETH Zurich, CREIGHTON K. THOMAS, Department of Materials Science and Engineering, Northwestern University, ALEXANDER K. HARTMANN, Department of Physics, Oldenburg University, Germany — We study the three-dimensional Edwards-Anderson Ising spin glass with bimodal disorder with a fraction of 22.8% antiferromagnetic bonds. Parallel tempering Monte Carlo simulations down to very low temperatures show that for this fraction of antiferromagnetic bonds the phase diagram of the system is reentrant, in agreement with previous results. Furthermore, using a clustering analysis, we analyze the ultrametric properties of phase space for this model.

10:12AM Y52.00010 Replica exchange simulations of the three-dimensional Ising spin glass: static and dynamic properties¹, BURCU YUCESAY, JONATHAN MACHTA, Department of Physics, University of Massachusetts Amherst, HELMUT G. KATZGRABER, Department of Physics, Texas A&M University & ETH Zurich — We present the results of a large-scale numerical study of the equilibrium three-dimensional Ising spin glass with Gaussian disorder. Using replica exchange (parallel tempering) Monte Carlo, we measure various static, as well as dynamical quantities, such as the autocorrelation times and round-trip times for the replica exchange Monte Carlo method. The correlation between static and dynamic observables for 5000 disorder realizations ($N \leq 10^3$ spins) down to very low temperatures ($T \approx 0.2T_c$) is examined. Our results show that autocorrelation times are directly correlated with the roughness of the free energy landscape. We also discuss the size dependence of several static quantities.

10:24AM Y52.00011 Monte Carlo Simulations of Random Frustrated Systems on Graphics Processing Units, SHENG FENG, YE FANG, SEAN HALL, Louisiana State University, ARIANE PAPKE, University of Gottingen, CADE THOMAS-SON, KA-MING TAM, JUANA MORENO, MARK JARRELL, Louisiana State University — We study the implementation of the classical Monte Carlo simulation for random frustrated models using the multithreaded computing environment provided by the Compute Unified Device Architecture (CUDA) on modern Graphics Processing Units (GPU) with hundreds of cores and high memory bandwidth. The key for optimizing the performance of the GPU computing is in the proper handling of the data structure. Utilizing the multi-spin coding, we obtain an efficient GPU implementation of the parallel tempering Monte Carlo simulation for the Edwards-Anderson spin glass model. In the typical simulations, we find over two thousand times of speed-up over the single threaded CPU implementation.

10:36AM Y52.00012 Monte Carlo simulations of the $\text{LiHo}_x\text{Y}_{1-x}\text{F}_4$ diluted dipolar magnet, JUAN CARLOS ANDRESEN, Department of Physics, ETH Zurich, MOSHE SCHECHTER, Department of Physics, Ben Gurion University, HELMUT G. KATZGRABER, Department of Physics and Astronomy, Texas A&M University and ETH Zurich — Recent intriguing experimental results on $\text{LiHo}_x\text{Y}_{1-x}\text{F}_4$, a diluted dipolar magnet, along with new analytical insights, suggest that neither a mean-field treatment nor simulations using simplified versions of the underlying Hamiltonian adequately describe these materials. Not only does this imply that novel disordering mechanism might be present, it requires a detailed numerical analysis that incorporates all terms in the Hamiltonian. We present large-scale Monte Carlo simulations of the diluted dipolar magnet with competing interactions on a LiHo lattice with the inclusion of a random field term. For low concentrations of Ho atoms we reproduce the peculiar linear dependence of the transition temperature as a function of the random-field strength found in recent experimental results by Silevich *et al.* [Nature 448, 567 (2007)]. We then find a zero-temperature phase transition between the ferromagnetic and quasi-spin-glass phases, suggesting that it is the underlying spin-glass phase that dictates the above linear dependence of T_c on the random field. For large concentrations we recover the quadratic dependence of the critical temperature as a function of the random field strength.

10:48AM Y52.00013 Novel disordering mechanisms in dipolar spin glasses and ferromagnets, MOSHE SCHECHTER, Physics Department, Ben Gurion University of the Negev, JUAN CARLOS ANDERSEN, Department of Physics, ETH Zurich, HELMUT KATZGRABER, Department of Physics and Astronomy, Texas A&M University and ETH Zurich — At and below the critical dimension the disordering of an ordered phase by a random field occurs via a collective effect of large domains at infinitesimal random field [Imry & Ma, Phys. Rev. Lett. 35, 1399 (1975)]. At larger space dimensions the disordering requires a large random field, of the order of the interaction energy. In a random field, the lower critical dimension is 2 for Ising ferromagnets, whereas it is infinity for spin glasses. We have generalized the Imry-Ma argument for ferromagnets with competing interactions and an underlying spin-glass phase, and for dilute dipolar spin glasses. For dilute dipolar spin glasses we have found [EPL 88, 66002 (2009)] that the broad distribution of random fields dictates more efficient disordering of the glass phase, and domain sizes which depend explicitly on the concentration, i.e., do not obey simple scaling. Here we show that as a result of a competing spin-glass phase, the disordering of the ferromagnet occurs at a finite random field, which is yet much smaller than the interactions. Our results are verified numerically, explain the recently-observed peculiar linear dependence of T_c on the random field strength [Nature 448, 567 (2007)], and predict a zero-temperature random-field driven transition between a ferromagnetic and a quasi spin glass phase.

Friday, March 2, 2012 8:00AM - 10:48AM –
Session Y53 GSNP: Nonlinear Dynamics of Coupled Systems 153B

8:00AM Y53.00001 Frequency Enhancement in Coupled Noisy Excitable Elements¹, WEI-YIN CHIANG, PIK-YIN LAI, Dept. of Physics and Center for Complex Systems, National Central University, Chungli, Taiwan 320, R.O.C., C.K. CHAN, Institute of Physics, Academia Sinica, Nankang, Taipei, Taiwan 115, R.O.C. — The oscillatory dynamics of coupled noisy excitable FitzHugh-Nagumo elements is investigated as a function of the coupling strength g . For two such coupled elements, it is found that their frequencies are enhanced by the coupling and will synchronize at a frequency higher than the uncoupled frequencies of each element. As g increases, there is an unexpected peak in the mean of frequency distribution before reaching synchronization at the optimal coupling strength. This phenomenon can be understood with a simplified analytic model based on the excitation across a potential barrier whose height is controlled by g as well as the formation of temporary coherent cluster.

8:12AM Y53.00002 Ramification of stream networks, HANSJOERG SEYBOLD, OLIVIER DEVAUCHELLE, ALEXANDER PETROFF, ROBERT YI, DANIEL ROTHMAN, MIT — The geometric complexity of channel networks arises from their successive ramifications — the splitting of a single tip into two branches. Here we show that streams incised by groundwater seepage split at a characteristic angle of $\alpha = 2\pi/5 = 72^\circ$. Our theory represents streams as a collection of paths growing and bifurcating in a diffusing field, which can be described by Loewner dynamics. Analysis of thousands of bifurcations in a $\sim 100 \text{ km}^2$ stream network reveals that the mean branching angle is $72.5^\circ \pm 1.5^\circ$ (95% C.I.) and that the five fold symmetry induced by the branching of the tips is observed on all scales in the network. This consistency between theory and observation suggests that the network geometry is determined by the external flow field rather than flow within the streams themselves, contrary to assumptions made by models that relate geometry to internal dissipation.

8:24AM Y53.00003 Dynamical phyllotaxis: transition modes and Sine-Gorden-like solitons, YUANXI WANG, Penn State University, CRISTIANO NISOLI, T- Division, CNLS Los Alamos National Laboratory, VINCENT CRESPI, Penn State University — Repulsive particles constrained to a cylindrical surface generate a rich set of static spiral patterns known as phyllotaxis. The ground states and quasi-static transitions of phyllotaxis has been well understood based on the conventional hypothesis that particles always form a cylindrical lattice. We investigate inhomogeneous transition modes which break this helical symmetry to connect monojugate and multijugate patterns. Furthermore, traveling Sine-Gordon-like solitons in dynamical phyllotaxis are observed in numerical simulations and explained using a modified Frenkel-Kontorova model. We show that kinks propagate spirally along selected parastichies and carry an intrinsic dipole. Applications in different areas of physics are discussed.

8:36AM Y53.00004 Cascade of bifurcation type trajectories as a general type of attractors in fractional dynamical systems¹, MARK EDELMAN, Stern College at Yeshiva University, Courant Institute at NYU — Based on the results of computer simulations and analytical investigation of fractional maps, we present our latest results related to the existence and stability of the new type of attractors in the fractional dynamical systems: cascade of bifurcation type trajectories (CBTT). We show that in fractional Standard Map (FSM) this type of attractors appears in the area of parameters, where in the corresponding integer system (regular Standard Map) series of period doubling bifurcations and corresponding splitting of islands of stability leads to the disappearance of stability and transition to chaos.

¹ Author thanks Stern College and Courant Institute

8:48AM Y53.00005 Scale-free avalanches in disordered systems of localized charges with long-range Coulomb interaction¹, MATTEO PALASSINI, MARTIN GOETHE, Faculty of Physics, University of Barcelona, Spain — We study theoretically and numerically the charge avalanches created by a perturbation in disordered systems of localized charges with unscreened Coulomb interaction (the so-called electron glass model), in two and three dimensions. Starting from a low-lying local energy minimum, we perturb the system by inserting an extra charge or an extra dipole, and let it relax via one-particle hops until a new minimum is reached. We find that the size distribution of the avalanches created in this process displays generically a power-law tail with an exponent close to the mean-field value 3/2 both in 2D and 3D, without requiring any parameter tuning. We provide a qualitative explanation of these results in terms of the density of states of elementary charge and dipole excitations and the associated Coulomb gap, which shows that the power-law tail arises from arbitrarily long hops, without requiring to assume the existence of a glass phase. Finally, we discuss the experimental relevance of these results and compare our picture to similar scale-free avalanches observed in mean field spin glasses, in which they are associated to a marginal glass phase.

9:00AM Y53.00006 Cooperation-induced temporal complexity in networks of pulse-coupled units, ELVIS GENESTON, La Sierra University, PAOLO GRIGOLINI, University of North Texas — We study a network of stochastic pulse-coupled units generating bursts with the same size distribution as the neuronal avalanches in mature cultured neurons, recently revealed by the experimental observation. We prove that in addition to this form of complexity this model yields a form of phase transition generating also temporal complexity. This means that the distance from two consecutive bursts fits the prescription of a Mittag-Leffler (ML) function renewal theory. There exists a critical value of the cooperation parameter at which this description applies to the whole time regime. By increasing the cooperation parameter the ML theory breaks down and the sequence of bursts tend to become periodic with the same intensity. We make the conjecture that the analysis of this model may shed light into the theoretical foundation of neuronal burst leaders and that the recently discovered principle of complexity management may be conveniently applied to the neuro-physiological processes that are properly described by this model.

9:12AM Y53.00007 Time dependence of reprecipitation rates in heterogeneous media, DANIEL REEVES, DANIEL ROTHMAN, MIT — The analysis of spatial and temporal variations of the chemical and isotopic compositions of minerals in sedimentary systems provides a powerful tool for calculating dissolution and reprecipitation rates, and has previously been applied to find time-dependent rates in marine sediments. Dissolution and precipitation processes tend to shift the composition of the pore fluids toward that of the solid phase, and vice-versa. Current theory treats both the fluid and solid phases as well-mixed reservoirs, relying on mean-field theory that is inconsistent with the physical structure of the solid, as dissolution and precipitation occur only on the reactive surface of the solid. We present a model that accounts for the heterogeneity of the solid phase by adding and removing material only at the reactive surface. We therefore model the location of the surface with a 1-D random walk, in which the buried bulk of the solid phase can only be modified through repeated dissolution events. We approximate this physical scenario with a three-reservoir kinetic model and more detailed numerical simulations. We develop an understanding of two power-law scaling regimes, the second of which demonstrates 1/time aging in the rate constant, similar to those observed in marine sediment studies.

9:24AM Y53.00008 Properties of compacton-anticompacton collisions, BOGDAN MIHAILA, Los Alamos National Laboratory, ANDRES CARDENAS, New York University, FRED COOPER, ANDRÉS SAXENA, Los Alamos National Laboratory — We study the properties of compacton-anticompacton collision processes. We compare and contrast results for the case of compacton-anticompacton solutions of the $K(l,p)$ Rosenau-Hyman (RH) equation for $l=p=2$, with compacton-anticompacton solutions of the $L(l,p)$ Cooper-Shepard-Sodano (CSS) equation for $p=1$ and $l=3$. This study is performed using a Padé discretization of the RH and CSS equations. We find a significant difference in the behavior of compacton-anticompacton scattering. For the CSS equation, the scattering can be interpreted as “annihilation” as the wake left behind dissolves over time. In the RH equation, the numerical evidence is that multiple shocks form after the collision, which eventually lead to “blowup” of the resulting wave form.

9:36AM Y53.00009 Cardiac arrhythmias and degradation into chaotic behavior prevention using feedback control¹, ILIJA UZELAC, VENIAMIN SIDOROV, Vanderbilt University, Nashville TN, USA, MARC HOLCOMB, Hampden-Sydney College, Hampden-Sydney, VA, USA, JOHN WIKSWO, Vanderbilt University, Nashville TN, USA, RICHARD GRAY, Food and Drug Administration, MD, USA — During normal heart rhythm, cardiac cells behave as a set of oscillators with a distribution of phases but with the same frequency. The heart as a dynamical system in a phase space representation can be modeled as a set of oscillators that have closed overlapping orbits with the same period. These orbits are not stable and in the case of disruption of the cardiac rhythm, such as due to premature beats, the system will have a tendency to leave its periodic unstable orbits. If these orbits become attracted to phase singularities, their disruption may lead to chaotic behavior, which appears as a life-threatening ventricular fibrillation. By using closed-loop feedback in the form of an adjustable defibrillation shock, any drift from orbits corresponding to the normal rhythm can be corrected by forcing the system to maintain its orbits. The delay through the feedback network coincides with the period of normal heart beats. To implement this approach we developed a 1 kW arbitrary waveform voltage-to-current converter with a 1 kHz bandwidth driven by a photodiode system that records an optical electrocardiogram and provides a feedback signal in real time. Our goal is to determine whether our novel method to defibrillate the heart will require much lower energies than are currently utilized in single shock defibrillators.

9:48AM Y53.00010 Experiments on oscillator ensemble with global nonlinear coupling, MICHAEL ROSENBLUM, Potsdam University, AMIRKHAN TEMIRBAYEV, ZEINULLA ZHANABAEV, STANISLAV TARASOV, Kazakh National University, VLADIMIR PONOMARENKO, Institute of RadioEngineering and Electronics of Russian Academy of Sciences, Saratov Department — We experimentally analyze collective dynamics of a population of 20 electronic Wien-bridge limit-cycle oscillators with a linear or nonlinear phase-shifting unit in the global feedback loop. With linear unit we observe, with increase of the coupling strength, a standard Kuramoto-like transition to a fully synchronous state; the threshold of the transition depends on the phase shift. In case of nonlinear global coupling we first observe a transition to a state when approximately half of the population forms a synchronous cluster. With further increase of the coupling strength we observe destruction of this cluster and formation of a self-organized quasiperiodic state, predicted in [M. Rosenblum and A. Pikovsky, PRL, 98, 064101 (2007)]. In this state, frequencies of all oscillators are smaller than the frequency of the mean field, so that the oscillators are not locked to the mean field they create and their dynamics is quasiperiodic. The transition is characterized by a non-monotonic dependence of the order parameter on the coupling strength. We demonstrate a good correspondence between theory and experiment.

10:00AM Y53.00011 Dynamics of Confident Voting, DANIEL VOLOVIK, SIDNEY REDNER, Boston University — In the classical voter model, a voter has no intrinsic confidence in its current opinion. We introduce the confident voter model in which each voter can be in one of two opinions, and can additionally have two levels of commitment to an opinion — confident and vacillating. Upon interacting with an agent of a different opinion, a confident voter becomes less committed, or vacillating, but does not immediately change opinion. However, a vacillating agent changes opinion upon interacting with an agent of a different opinion. In the mean-field limit, a population of size N is quickly driven to a mixed state before consensus is eventually achieved in a time of order $\ln N$. In two dimensions, the distribution of consensus times is characterized by two distinct times — one that scales linearly with N and another that scales as $N^{3/2}$. The longer time arises from configurations that fall into long-lived stripe states, which are caused by an effective surface tension between domains of different opinion states, before consensus is finally reached.

10:12AM Y53.00012 Nonuniversal Effects in Mixing Correlation-Growth Processes with Randomness, ALICE KOLAKOWSKA, Valdosta State University, GA — In mixed-growth dynamical process $P = Y \vee X$ there are two dynamical processes: Y (in one universality class) and X (in another universality class). They *alternate* with each other: "*exclusively either Y (is active with probability q) or X (is active with probability p), $p + q = 1$.* When P models surface growth via deposition/desorption/adsorption with X building universal correlations and Y representing randomness (e. g., thermal effects), in order to correctly construct a continuum growth equation for P a distinction must be made *within a single universality class* of X between processes that do and do not create voids in the bulk of deposited material. Then, model-dependent prefactors in universal scaling of the surface roughness can be linked with the bulk morphology and determined from the bulk structures. This connection is essential to finding correct dynamical scaling and to interpretation of scaling laws for mixed-growth dynamical processes.

10:24AM Y53.00013 Non-equilibrium modulated phases in a system with local energy input¹, LINJUN LI, MICHEL PLEIMLING, Virginia Tech — The equilibrium phase diagram of the two-dimensional Ising model in contact with a single heat bath is well understood. We here study the properties of the two-dimensional Ising model with conserved dynamics where the two halves of the system are in contact with different heat baths. Using Monte Carlo simulations, we identify three different phases for this non-equilibrium system, as a function of the aspect ratio of the lattice and of the temperatures. The first phase is characterized by the complete disorder of the particles, while the second phase is characterized by the complete order of the particles. The third phase is the most interesting one as it displays stripes with widths that depend on the system parameters. The full phase diagram of our non-equilibrium system is determined through the study of the structure factor.

¹Supported in part by the US National Science Foundation through Grant DMR-0904999.

10:36AM Y53.00014 Nonequilibrium relaxation and critical aging for driven Ising lattice gases¹, GEORGE DAQUILA, UWE C. TAUBER, Department of Physics, Virginia Tech — We employ Monte Carlo simulations to study the non-equilibrium relaxation of driven Ising lattice gases in two dimensions. Whereas the temporal scaling of the density auto-correlation function in the non-equilibrium steady state does not allow a precise measurement of the critical exponents, these can be accurately determined from the aging scaling of the two-time auto-correlations and the order parameter evolution following a quench to the critical point. We obtain excellent agreement with renormalization group predictions based on the standard Langevin representation of driven Ising lattice gases, valid to all orders in the dimensional expansion.

Session Z1 DAMOP: General Atomic, Molecular and Optical Physics 203

11:15AM Z1.00001 The Timing of Sonoluminescence¹, THOMAS BRENNAN, West Virginia Weleyn College, GUSTAVE FRALICK, NASA Glenn Research Center — We measured the timing of the sonoluminescence flash by scattering laser light from the bubble. We performed this measurement on 17.8 kHz, 13.28 kHz and 7920 Hz systems and found that the flash typically occurs 100 nanoseconds before the minimum radius, contrary to previous claims that the flash always occurs within a nanosecond of the minimum radius. These results are important because they imply that previous *hot* models of sonoluminescence are wrong. We propose a new model: that the flash results from the discharge of an excited cold condensate, formed during the adiabatic expansion of the bubble.

¹We thank the Instrumentation Division at the NASA Glenn research center in Cleveland, Ohio for supproting this research.

11:27AM Z1.00002 Coherence Enhanced Transient Lasing, PANKAJ JHA, ANATOLY SVIDZINSKY, Texas A&M University, MARLAN SCULLY, Texas A&M University and Princeton University — We study the effect of a coherent drive on transient lasing with inversion in three-level Λ and Ξ configurations ($c \leftrightarrow a \leftrightarrow b$). We show that the presence of a resonant coherent drive on the $a \leftrightarrow c$ optical transition can yield substantial enhancement of the output laser energy on a $a \rightarrow b$ XUV or X-ray transition. We demonstrate the crucial role of coherence ϱ_{ac} for this laser power enhancement. Contrary to the forward direction, where forward gain can be enhanced for some choice of Ω_c , coherent drive on the ac transition always suppresses the backward gain. Thus, the use of a coherent drive at optical frequency could be a useful tool for increasing power of lasers in XUV and X-ray regions.

11:39AM Z1.00003 Variable Atomic Radius of Hydrogen Due to Vibrating Nucleus, STEWART BREKKE, Northeastern Illinois University (former grad student) — The H-atomic radius is variable because the H-nucleus is vibrating and the electric force field upon the electron is repeatedly changing due to the changing distance from the positive nucleus to the negatively charged electron. If the the distance from the nucleus to the electron is $d = r + A \cos 2\pi f t$ where $r = 5.29 \times 10^{-11} m$, the calculated Bohr radius, and $d = 2.5 \times 10^{-11} m$, the measured atomic radius of the H-atom, then the equation for the variable atomic radius of the H-atom is $5.29 \times 10^{-11} m + A \cos 2\pi f t = 2.5 \times 10^{-11} m$. If the RMS value for the average cosine is 0.707, solving for A, the average amplitude of nuclear vibration, $A = 3.95 \times 10^{-11} m$. Therefore, the oscillating orbit of the electron in an H-atom has an average amplitude of $A = 3.95 \times 10^{-11}$.

11:51AM Z1.00004 Strong Field Control of Atomic and Molecular Dynamics: An Attosecond Resolved Study, NIRANJAN SHIVARAM, HENRY TIMMERS, University of Arizona, XIAO-MIN TONG, University of Tsukuba, ARVINDER SANDHU, University of Arizona — Strong laser fields are routinely used in attosecond pump-probe studies of atomic and molecular phenomena. However, even a moderately strong field ($\sim 10^{12}$ W/cm²) can significantly alter the electronic structure. By understanding and quantifying the effect of strong fields, one can obtain a high degree of control over the photo-absorption and photo-fragmentation processes. Here, we study the atomic and molecular response to the simultaneous presence of XUV attosecond pulse trains and strong IR fields. We describe an IR laser-dressed atom using Floquet picture. We observe quantum interference between XUV excitation paths to the Fourier components of a given Floquet state, which leads to oscillations in the ion-yield. By measuring the phase of the ion-yield oscillations, we extract the quantum phase difference between the Fourier components of that Floquet state. We obtain a quantitative understanding of how Floquet ionization channels change with intensity and what is the phase associated with each channel. We also extend our studies to molecular fragmentation processes. Our work represents real-time measurement and control of dynamics using strong-field modification of the atomic and molecular structure. This work was support by NSF grant PHY-0955274.

12:03PM Z1.00005 Steady State Ab Initio Laser Theory: Generalizations, ALEXANDER CERJAN, YIDONG CHONG, Yale University, LI GE, Princeton University, A. DOUGLAS STONE, Yale University — We show that Steady-state Ab initio Laser Theory (SALT)¹ can be generalized to find the stationary multimode lasing properties of gain systems with N levels, and to include carrier diffusion. The former result is achieved by mapping the N -level rate equations to an effective two-level inversion equation of the type typically quoted in the Maxwell-Bloch equations.² The latter result is found by rewriting the SALT algorithm to non-linearly solve two coupled non-linear equations in the steady state, with one equation determining the modal field intensities, given the inversion and the other equation determining the inversion given the field intensities. In both cases we find excellent agreement with more computationally demanding Finite-Difference Time-Domain (FDTD) simulations for the steady state. These results generalize the SALT algorithm to handle more realistic lasing systems, including semiconductor lasers.

12:15PM Z1.00006 Dynamical mean-field theory for transition metal dioxide molecules¹, NAN LIN, DOMINIKA ZGID, Columbia University, Department of Physics, CHRIS MARIANETTI, Columbia University, Department of Applied Physics, DAVID REICHMAN, Columbia University, Department of Chemistry, ANDREW MILLIS, Columbia University, Department of Physics — The utility of the dynamical mean-field approximation in quantum chemistry is investigated in the context of transition metal dioxide molecules including TiO_2 and CrO_2 . The choice of correlated orbitals and correlations to treat dynamically is discussed. The dynamical mean field solutions are compared to state of the art quantum chemical calculations. The dynamical mean-field method is found to capture about 50% of the total correlation energy, and to produce very good results for the d-level occupancies and magnetic moments. We also present the excitation spectrum in these molecules which is inaccessible in many wave-function based methods. Conceptual and technical difficulties will be outlined and discussed.

12:27PM Z1.00007 Disalignment of the $Ne^*(2p_{10} [J=1])$ atoms induced by Helium atom collisions from 10K to 3000K, CRISTIAN BAHRIM, Department of Physics, Lamar University, VAIBHAV KHADILKAR, Department of Computer Science, UT Dallas — Quantum close-coupling many-channel calculations using the new model potential for the interaction between $Ne^*(2p_i [J=1])$ and He atoms proposed in [1] are performed in order to analyze the depolarization of $Ne^*(2p_i [J=1])$ atoms in a gaseous mixture at thermal equilibrium. For temperatures above 77 K we successfully explain measurements of disalignment done with a laser-induced fluorescence spectroscopy method and destruction of alignment using a technique based on the Hanle effect for all four $2p_i [J=1]$ states of the $2p^5 3p$ configuration of neon [1, 2]. Our interpretation of the experimental data is based on the anisotropy between collisional channels which asymptotically converge toward the same $2p_i [J=1]$ state [2]. Below 77 K our disalignment rate coefficients for the $Ne^*(2p_{10} [J=1])$ atoms are much larger than the experimental data [3] after the radiation re-absorption is subtracted from the disalignment rates. The calculations indicate that for the $2p_{10}$ state, at low collision energies, the nuclear rotation has a strong influence in the overall long-range interaction, while the experimental data suggests that below 16 meV, the intramultiplet transitions within the $(2p_i [J=1])$ state of neon are completely negligible. The discrepancy between theory and experiment is carefully analyzed.

12:39PM Z1.00008 Cold collisions of complex polyatomic molecules, ZHIYING LI, ERIC HELLER, Department of Physics, Harvard University — We introduce a method for classical trajectory calculations to simulate collisions between atoms and large rigid asymmetric-top molecules. Using this method, we investigate the formation of molecule-helium complexes in buffer-gas cooling experiments at the temperature of 6.5 K for molecules as large as naphthalene. Our calculations show that the mean lifetime of the quasi-bound collision complex is not long enough for the formation of stable clusters under the experimental conditions. Our results suggest that it may be possible to improve the efficiency of the production of cold molecules in buffer-gas cooling experiments by increasing the density of helium. In addition, we find that the shape of molecules is important for the collision dynamics where molecular vibrational motions are frozen. For some molecules, it is even more crucial than the number of accessible degrees of freedom. This indicates that by selecting molecules with suitable shape for buffer-gas cooling, one could cool molecules with a very large number of degrees of freedom.

12:51PM Z1.00009 Spin-boson models for periodic N -site systems, VICTOR V. ALBERT, Department of Physics, Yale University — The single/multi-mode spin-boson model provides a description for numerous two-level exciton-phonon and atom-cavity systems. Existing many-level extensions conserve symmetries but quickly become intractable due to the inclusion of multiple interacting modes. Other ad-hoc single-mode extensions contain arbitrary numbers of parameters and often ignore the symmetries of their respective systems. This work presents a simple model for the interaction of a periodic system of N coupled sites with one or more non-interacting boson modes using a minimal number of parameters [1]. A group theoretic approach allows one to partially diagonalize the Hamiltonian, providing numerical advantages, physical insight, and a gateway to accurate approximations. The single-mode two-site system reduces to the single-mode spin-boson model, also known as the Rabi Hamiltonian. Two higher dimensional generalizations are reviewed in the exciton-phonon/atom-field interpretations and related to a new integrability criterion [2]. The model predicts that $2N$ -level systems have parity symmetry and that the ground state of certain four-level atom-cavity systems will undergo parity change at large coupling.

1:03PM Z1.00010 Thermal Effects on Quantum Sticking¹, YANTING ZHANG, DENNIS CLOUGHERTY, University of Vermont — Many-body effects on the threshold law of quantum sticking of a particle coupled to an ohmic bosonic bath are examined for finite temperature surfaces. Generalizing a variational mean-field method² previously applied to zero temperature surfaces, we obtain an explicit expression for the sticking probability of a particle with incident energy E . We find that there is a critical particle energy below which the probability of its sticking to the surface discontinuously drops to zero. We show that this singularity, whose origin is rooted by analogy to the localization transition in the spin-boson model, is experimentally accessible for ultracold particles. We provide detailed numerical results for this effect.

1:15PM Z1.00011 Theory of Non-Markovian dynamics in resonance fluorescence spectra, ABHISHEK KUMAR, SIGURDUR I. ERLINGSSON, School of Science and Engineering, Reykjavik University, Iceland, BILL COISH, Department of Physics, McGill University, Canada — Robust quantum coherence is an important prerequisite for any system that may be used to perform quantum information processing tasks. For systems that can be probed optically, the resonance fluorescence spectrum may provide indirect evidence of coherence times when supplemented with an appropriate model of the decay process. A common approach is to assume a Markovian system, resulting in exponential decay of correlation functions and Lorentzian features in the associated spectrum. For physical systems with strongly history-dependent (non-Markovian) dynamics, there is currently no satisfying systematic theoretical approach to establish the associated spectrum. We present a detailed theoretical method to obtain the resonance fluorescence spectrum for a general system undergoing non-Markovian dynamics. This procedure can be used to systematically account for features in resonance-fluorescence spectra due to genuine non-Markovian dynamics. Our approach is based on a Nakajima-Zwanzig generalised master equation for the dynamics of the reduced density matrix. We apply this theory to study the resonance fluorescence in the non-Markovian dynamics of a three level lambda system, relevant to recent experiments on heavy-hole spin dynamics in a quantum dot.

1:27PM Z1.00012 Quantum Revivals of the Morse Oscillator in Position Space and Momentum Space, ALVASON ZHENHUA LI, Microelectronics and Photonics Program, University of Arkansas at Fayetteville, AR 72701, WILLIAM HARTER, Department of Physics, University of Arkansas at Fayetteville, AR 72701 — Analytical solutions for the Morse oscillator are applied to investigate the quantum revivals both in position and momentum spaces. The properties of this anharmonic oscillator came across interesting space-time phenomena. These findings include simple Farey arithmetic revival structures. Such dynamic systems may have applications for quantum information technology and quantum computing.

1:39PM Z1.00013 Trapping of particles in the ray optics regime using DNG materials, JOSEPH SHAHBAZIAN, Tufts University — Optical tweezers use to confine and manipulate microscopic objects including living cells and bacteria, with high accuracy. The objective is calibrating the force on targets using DPS-DNG layered structure. Using this layered structure which acts as a tunable optical band-pass filter would assist calibration of the force on the target(s). Here shown that the proposed DNG-DPS structure would help to have highly focused calibrated tweezers without worrying about the polarization of optical wave. Calculation can describe well the experimental results.

Session Z2 DCMP DBIO: Invited Session: Active Responses of Biological Materials to Mechanical Stress 204AB

11:15AM Z2.00001 Cellular Mechanics and Mechanotransduction, DANIEL FLETCHER, University of California at Berkeley — No abstract available.

11:51AM Z2.00002 Force Transmission in the Actin Cytoskeleton, MARGARET GARDEL, U. Chicago — The ability of cells to sense and generate mechanical forces is essential to numerous aspects of their physiology, including adhesion, migration, division and differentiation. To a large degree, cellular tension is regulated by the transmission of myosin II-generated forces through the filamentous actin (F-actin) cytoskeleton. While transmission of myosin-generated stresses from the molecular to cellular length scale is well understood in the context of highly organized sarcomeres found in striated muscle, non-muscle and smooth muscle cells contain a wide variety of bundles and networks lacking sarcomeric organization. I will describe the *in vitro* and *in vivo* approaches we use to study force transmission in such disordered actomyosin assemblies. Our *in vivo* results are showing that highly organized stress fibers contribute surprisingly little to the overall extent of cellular tension as compared to disordered actomyosin meshworks. Our *in vitro* results are demonstrating the mechanisms of symmetry breaking in disordered actomyosin bundles that facilitate the formation of contractile bundles with well-defined “contractile elements.” These results provide insight into the self-organization of actomyosin cytoskeleton in non-muscle cells that regulate and maintain cellular tension.

12:27PM Z2.00003 Environmental properties set cell mechanics and morphology, PAUL JANMEY, University of Pennsylvania — Many cell types are sensitive to mechanical signals that are produced either by application of exogenous force to their surfaces, or by the resistance that their surroundings place on forces generated by the cells themselves. Cell morphology, motility, proliferation, and protein expression all change in response to substrate stiffness. Changing the elastic moduli of substrates alters the formation of focal adhesions, the assembly of actin filaments into bundles, and the stability of intermediate filaments. The range of stiffness over which different primary cell types respond can vary over a wide range and generally reflects the elastic modulus of the tissue from which these cells were isolated. Mechanosensing depends on the type of adhesion receptor by which the cell binds, and therefore on both the molecular composition of the extracellular matrix and the nature of its link to the cytoskeleton. Many cell types can alter their own stiffness to match that of the substrate to which they adhere. The maximal elastic modulus that cells such as fibroblasts can attain is similar to that of crosslinked actin networks at the concentrations in the cell cortex. The precise mechanisms of mechanosensing are not well defined, but they presumably require an elastic connection between cell and substrate, mediated by transmembrane proteins. The viscoelastic properties of different extracellular matrices and cytoskeletal elements strongly influence the response of cells to mechanical signals, and the unusual non-linear elasticity of many biopolymer gels, characterized by strain-stiffening, leads to novel mechanisms by which cells alter their stiffness by engagement of molecular motors that produce internal stresses. Cell cortical elasticity is dominated by cytoskeletal polymer networks and can be modulated by internal tension. Simultaneous control of substrate stiffness and adhesive patterns suggests that stiffness sensing occurs on a length scale much larger than single molecular linkages and that the time needed for mechanosensing is on the order of a few seconds.

1:03PM Z2.00004 Molecular Mechanotransduction: how forces trigger cytoskeletal dynamics¹, ALLEN EHRLICHER, Harvard University — Mechanical stresses elicit cellular reactions mediated by chemical signals. Defective responses to forces underlie human medical disorders, such as cardiac failure and pulmonary injury. Despite detailed knowledge of the cytoskeleton's structure, the specific molecular switches that convert mechanical stimuli into chemical signals have remained elusive. Here we identify the actin-binding protein, filamin A (FLNa) as a central mechanotransduction element of the cytoskeleton by using Fluorescence Loss After photoConversion (FLAC), a novel high-speed alternative to FRAP. We reconstituted a minimal system consisting of actin filaments, FLNa and two FLNa-binding partners: the cytoplasmic tail of β -integrin, and FilGAP. Integrins form an essential mechanical linkage between extracellular and intracellular environments, with β integrin tails connecting to the actin cytoskeleton by binding directly to filamin. FilGAP is a FLNa-binding GTPase-activating protein specific for Rac, which in vivo regulates cell spreading and bleb formation. We demonstrate that both externally-imposed bulk shear and myosin II driven forces differentially regulate the binding of integrin and FilGAP to FLNa. Consistent with structural predictions, strain increases β -integrin binding to FLNa, whereas it causes FilGAP to dissociate from FLNa, providing a direct and specific molecular basis for cellular mechanotransduction. These results identify the first molecular mechanotransduction element within the actin cytoskeleton, revealing that mechanical strain of key proteins regulates the binding of signaling molecules. Moreover, GAP activity has been shown to switch cell movement from mesenchymal to amoeboid motility, suggesting that mechanical forces directly impact the invasiveness of cancer.

Session Z3 DCMP DCOMP: Invited Session: Frontiers of Non-Equilibrium Transport Theories
205AB

11:15AM Z3.00001 DFT treatment of transport through Anderson junction: exact results and approximations¹, KIERON BURKE, Departments of physics and chemistry, University of California, Irvine — Since the pioneering break-junction experiments of Reed and Tour measuring the conductance of dithiolated benzene between gold leads, many researchers in physics and chemistry have been calculating conductance for such systems using density functional theory (DFT). Off resonance, the predicted current is often 10-100 times larger than that measured. This error is often ascribed to the application of ground-state DFT to a non-equilibrium problem. I will argue that, in fact, this is largely due to errors in the density functional approximations in popular use, rather than necessarily errors in the methodology. A stark illustration of this principle is the ability of DFT to reproduce the exact transmission through an Anderson junction at zero-temperature and weak bias, including the Kondo plateau, but only if the exact ground-state density functional is used. In fact, this case can be used to reverse-engineer the exact functional for this problem. Popular approximations can also be tested, including both smooth and discontinuous functionals of the density, as well as symmetry-broken approaches.

11:51AM Z3.00002 Inelastic single-spin transport theory, STEFANO SANVITO, School of Physics, Trinity College Dublin — Spin-flip inelastic spectroscopy is a powerful tool for investigating the magnetic excitations of nano-scale magnets deposited on a metallic surface. In this talk I will present a perturbative approach to the calculation of the inelastic spin-flip spectra of magnetic adatoms, small magnetic clusters and magnetic molecules. The theory is based on the non-equilibrium Green's function formalism combined with a model spin Hamiltonian, where the conduction electrons are exchanged coupled to a system of quantum spins. By expanding the self-energy describing the electron-spin interaction to the third order we are able to capture both inelastic spin-flip events and the signature of Kondo resonances. Furthermore, when our approach is combined with a Master equation describing spin-relaxation, effects related to the spin-pumping at the single spin level can be described. In the talk I will demonstrate that the method offers an extremely good quantitative agreement with published experimental data. Importantly the formalism is amenable to be implemented together with highly accurate electronic structure methods.

12:27PM Z3.00003 Electron correlation effects on the diode properties and the local heating, YOSHIHIRO ASAI, Nanosystem Research Institute (NRI) "RICS," National Institute of Advanced Industrial Science and Technology (AIST) — Single molecular bridge junctions and atomic wires provide one of the best test fields for non-equilibrium transport theories whose progress gives benefits over wide range of physics. Experimental progresses in inelastic tunneling spectroscopy (IETS) and break junction techniques have played very important roles to make this possible. Inelastic scatterings between electrons and phonons give "local heating" of the junctions. The effective temperature due to the local heating was discussed successfully in terms of a fully self-consistent theory treating energy dissipation processes as well as inelastic heat generation on equal footing [1]. Recently, we found two cases where electron correlation gives distinct changes. The first case was found in the local heating problem in the resonant systems, where phonon damping due to its coupling with electron-hole excitation is suppressed by the correlation. The suppression enhances heat release to electrodes leading to the effective temperature suppression [2]. Another example is the single molecular rectifier. First principle NEGF-GGA calculation fails to explain the large rectification ratio (RR) at high bias voltage. Separate GW calculation based on Keldysh Green's function gives clear enhancement of RR over the mean field NEGF results suggesting that RR could be enhanced by the electron correlation effect [3]. Thus latest non-equilibrium transport theories enable us to treat the important physical processes accompanying electric conduction allowing us to make more direct comparisons with experimental phenomena at nano-scale.

1:03PM Z3.00004 Electron-ion correlations in electromigration: Coulomb's law and Landauer transport at the nanoscale, KIRK BEVAN, McGill University — Electromigration has gained increased prominence in recent years, as the rise of nanoelectronics has given way to higher current and power densities in computing interconnects and devices. In this context we address the fundamental materials question: what drives electromigration at the nanoscale? Our understanding of the forces that drive electromigration has remained at an uneasy juncture between the mesoscopic semi-classical and atomistic quantum mechanical regimes. At the nanoscale an atomistic understanding of materials is required. Through first-principles quantum transport calculations we show that a self-consistent Landauer transport framework provides much needed atomistic insight into the fundamental Coulombic forces which drive both current flow and electromigration at the nanoscale. These insights provide a general timely overview of the importance of electromigration in modern nanoelectronic devices and materials, not only from an operational perspective but also from a novel materials design perspective.

1:39PM Z3.00005 Probing DNA in nanopores via tunneling: from sequencing to "quantum" analogies, MASSIMILIANO DI VENTRA, University of California, San Diego — Fast and low-cost DNA sequencing methods would revolutionize medicine: a person could have his/her full genome sequenced so that drugs could be tailored to his/her specific illnesses; doctors could know in advance patients' likelihood to develop a given ailment; cures to major diseases could be found faster [1]. However, this goal of "personalized medicine" is hampered today by the high cost and slow speed of DNA sequencing methods. In this talk, I will discuss the sequencing protocol we suggest which requires the measurement of the distributions of transverse currents during the translocation of single-stranded DNA into nanopores [2-5]. I will support our conclusions with a combination of molecular dynamics simulations coupled to quantum mechanical calculations of electrical current in experimentally realizable systems [2-5]. I will also discuss recent experiments that support these theoretical predictions. In addition, I will show how this relatively unexplored area of research at the interface between solids, liquids, and biomolecules at the nanometer length scale is a fertile ground to study quantum phenomena that have a classical counterpart, such as ionic quasi-particles, ionic "quantized" conductance [6,7] and Coulomb blockade [8]. Work supported in part by NIH.

Friday, March 2, 2012 11:15AM - 2:03PM – Session Z4 DAMOP: Disorder and Pairing in Ultracold Systems 205C

11:15AM Z4.00001 Many Body Localization in Incommensurate Potentials, SHANKAR IYER, California Institute of Technology, DAVID HUSE, Princeton University, GIL REFAEL, California Institute of Technology — A long-standing problem concerns the survival of Anderson localization in a many body system with interparticle interactions. In recent years, this problem has resurfaced due to work by Basko, Aleiner, and Altshuler, who have argued that highly excited states of an interacting, many body system can be localized in Fock space. Consequently, a dynamical quantum phase transition may separate such a many body localized phase from a delocalized, ergodic phase, and there is now numerical evidence for the existence of such a transition in disordered 1D systems. Meanwhile, 1D lattice models that lack genuine disorder, but which instead contain a periodic potential that is incommensurate with the lattice spacing, are known to have a localization transition even in the absence of interactions. Here, we numerically investigate whether this transition survives the introduction of interactions and, if so, how it is modified. These questions are increasingly experimentally relevant, because ultracold atom experiments sometimes use incommensurate potentials in place of true disorder to probe localization physics.

11:27AM Z4.00002 Mobile impurities in one-dimensional cold gases: subdiffusive, diffusive and ballistic regimes, ADRIAN KANTIAN, THIERRY GIAMARCHI, University of Geneva — Advances in cold gases physics are beginning to enable experiments involving the direct manipulation and observation of single- or few-atom mobile impurities [1] within a many-body quantum system, a topic of longstanding interest for condensed matter theory, where it is related to studies of e.g. conductivity and the X-ray edge problem. Further progress in this direction is expected from the latest generation of experiments offering single-site addressability in optical lattices [2,3]. In light of these developments we study the dynamics of mobile impurities in 1D quantum liquids using a DMRG technique. We address the recently proposed subdiffusive regime of impurity motion [4], a class of excitations beyond those described by the standard Tomonaga-Luttinger theory. We study the conditions for observing this regime and its' crossover to the ballistic regime. We furthermore examine the possibilities to observe the intermediate diffusive motion of impurities in these systems.

11:39AM Z4.00003 Collective mode of an impurity and a Tonks-Girardeau gas¹, CHARLES MATHY, Institute for Theoretical Atomic, Molecular and Optical Physics, MIKHAIL ZVONAREV, EUGENE DEMLER, Physics Department, Harvard University — We investigate the quantum dynamics of an impurity immersed in a one-dimensional gas of strongly repulsive bosons, or equivalently fully-polarized fermions, interacting via a contact interaction. Using Bethe Ansatz we obtain essentially exact results at all timescales and for all couplings to the impurity. We find at strong coupling that if the impurity starts off with a momentum of the order of the Fermi momentum or higher a new type of collective mode is excited, corresponding to long lived oscillations of the impurity with respect to the background gas. We characterize this mode and discuss how it can be observed experimentally.

¹C.M. acknowledges support from the NSF through ITAMP at Harvard University and the Smithsonian Astrophysical Observatory.

11:51AM Z4.00004 Dynamics of mobile impurities in one-dimensional quantum liquids¹, MICHAEL SCHECTER, University of Minnesota, School of Physics and Astronomy, ALEX KAMENEV, University of Minnesota, School of Physics and Astronomy and Fine Institute for Theoretical Physics, DIMITRI GANGARDT, University of Birmingham, United Kingdom, AUSTEN LAMACRAFT, University of Virginia — We consider the dynamics of mobile impurities immersed in one-dimensional (1d) quantum liquids. Such systems have been realized experimentally in the context of ultracold atomic gases in optical lattices. We show that, on very general grounds, the dispersion relation of the impurity dressed by the liquid is a periodic function of momentum with period $2\pi\hbar n$, n being the 1d density. An impurity subject to a small external force thus exhibits the phenomenon of Bloch oscillations about a fixed point in real space, in the absence of a periodic potential. To compare with experiments, we set out to address the consequences of both finite temperature and finite force on the Bloch oscillation sequence. Our main results are as follows: (i) There exists a finite window of parameters where Bloch oscillations exist $F_{\min}(T) < F < F_{\max}$ (ii) The lower bound is fixed by thermal friction depending on temperature T , and interaction parameters. In particular, we show that $F_{\min} = 0$ for integrable impurity models. (iii) The upper bound $F_{\max}$ is set by friction associated with dipole radiation of phonons due to the accelerating impurity. The ensuing energy loss results in the uniform drift of the oscillation center.

12:03PM Z4.00005 Gapless superfluid phase with spin-dependent disorder, MI JIANG, RAVINDRA NANGUNERI, Physics Department, UC Davis, NANDINI TRIVEDI, Department of Physics, Ohio State University, GEORGE BATROUNI, INLN, Université de Nice-Sophia Antipolis, CNRS, RICHARD SCALETTAR, Physics Department, UC Davis — Motivated by the recent experimental development on spin-dependent optical lattices and disordered lattices, we show that the presence of a spin-dependent random potential on a superconductor or a superfluid atomic gas leads to distinct transitions at which the energy gap and average order parameter vanish, generating an intermediate gapless superfluid phase. This behavior is in marked contrast to the case of spin-symmetric randomness. The calculations are performed for a two dimensional attractive Hubbard model within Bogoliubov-de Gennes mean field theory. We characterize the different phases by correlating the local order parameter and the density of states.

12:15PM Z4.00006 Superdiffusive nonequilibrium transport of an impurity in a Fermi sea, HYUNGWON KIM, DAVID HUSE, Princeton University — We discuss a nonequilibrium transport of a single impurity atom immersed in a low-temperature Fermi sea with a short range interaction. We find that the impurity does a superdiffusive geometric random walk in which the characteristic momentum decay rate shows a quartic decrease in its momentum in three dimension. Then, we construct a master equation and its scaled form that governs the time evolution of the impurity. Next, we discuss two dimensional case in which the momentum decay rate decreases with the third power of its momentum.

12:27PM Z4.00007 Repulsive polarons in two-dimensional Fermi gases, VUDTIWAT NGAMPRIETIKORN, JESPER LEVINSSEN, University of Cambridge, MEERA PARISH, London Centre for Nanotechnology — We consider a single spin-down impurity atom interacting via an attractive, short-range potential with a spin-up Fermi sea in two dimensions (2D). Similarly to 3D, we show that the impurity can form a metastable state (the “repulsive polaron”) with energy greater than that of the non-interacting impurity. Moreover, we find that the repulsive polaron can acquire a finite momentum for sufficiently weak attractive interactions. Even though the energy of the repulsive polaron can become sizeable, we argue that saturated ferromagnetism is unfavorable in 2D because of the polaron’s finite lifetime and small quasiparticle weight.

12:39PM Z4.00008 Universal bound states of two atoms near a Feshbach resonance¹, SHINA TAN, Georgia Institute of Technology — The Efimov effect was traditionally thought to exist for three or more particles only. It will be shown how to make universal shallow bound states of TWO atoms only, which will exhibit a universal energy spectrum reminiscent of the Efimov effect, by using potentials to constrain the spatial motion of atoms. Several related types of such two-body states will be described. These diatomic “artificial molecules”, if isolated from each other, will be free from three-body recombination, and can have long lifetimes in principle.

12:51PM Z4.00009 Feshbach Correlations and Closed Channel Amplitudes, NICOLAS LOPEZ, SHAN-WEN TSAI, UC Riverside, EDDY TIMMERMAN, Los Alamos National Lab — The magnetically controlled Feshbach resonance is a prominent member of the cold atom toolkit. The ability to tune binary particle interactions in a quantum many body system has given access to collapsing BEC-physics in boson gases, to BEC-BCS crossover physics, to the unitarity regime, and to quantum phase transitions. The resonance is accessed by tuning the energy of a quasi-bound spin-rearranged molecular state near the vacuum of the interacting particles. Does the amplitude of the spin-rearranged or “closed channel” state play a significant role in the many body physics? We present a microscopic derivation of the Feshbach resonance interactions and obtain the parameters of the two-channel model in an optical lattice. We study two atoms interacting in a harmonic oscillator potential near a Feshbach resonance to derive the closed channel probability and to uncover the validity-range of the two channel lattice model.

1:03PM Z4.00010 Superfluid pairing in a mixture of a spin-polarized Fermi gas and a dipolar condensate¹, BEN KAIN, Department of Physics, College of the Holy Cross, Worcester, MA 01610, HONG LING, Department of Physics, Rowan University, Glassboro, NJ 08028 — We consider a mixture of a spin-polarized Fermi gas and a dipolar Bose-Einstein condensate in which s-wave scattering between fermions and the quasiparticles of the dipolar condensate can result in an effective attractive Fermi-Fermi interaction anisotropic in nature and tunable by the dipolar interaction. We show that such an interaction can significantly increase the prospect of realizing a superfluid with a gap parameter characterized by a coherent superposition of all odd partial waves. We formulate, in the spirit of the Hartree-Fock-Bogoliubov mean-field approach, a theory which allows us to estimate the critical temperature when the anisotropic Fock potential is taken into consideration and study how to prepare the mixture in order to optimize the critical temperature at which such a superfluid emerges before the system starts to phase separate.

1:15PM Z4.00011 Superfluid transition temperature and its zero density limit extrapolation in a unitary atomic Fermi gas on a lattice¹, QIJIN CHEN, Zhejiang University — The superfluid transition temperature T_c of a unitary Fermi gas has been of great interest. One way to study T_c in a 3D continuum is to study fermions on a lattice at finite densities and then extrapolate to the zero density limit, as has been done in quantum Monte Carlo (QMC) simulation studies. For this extrapolation to work, it is essential to probe the densities in the asymptotic regime. In this talk, we study fermions on a three-dimensional isotropic lattice with an attractive on-site interaction as a function of density n , from half filling down to 5.0×10^{-7} per unit cell, using a pairing fluctuation theory. As n decreases towards $n = 0$, T_c/E_F increases to the leading order linearly in $n^{1/3}$, and reaches the zero density limit $T_c/E_F = 0.256$, consistent with that calculated directly in the continuum for a contact potential. Inclusion of the particle-hole channel reduces T_c/E_F to 0.217, in agreement with experiment. However, except for very low n , T_c/E_F exhibits significant higher order nonlinear dependence on $n^{1/3}$. The densities accessed by QMC studies are still not low enough to be in the asymptotic regime. References: Q.J. Chen, arXiv:1109.5327; arXiv:1109.2307; Q.J. 1:27PM Z4.00012 Pair Condensation in a Finite Trapped Fermi Gas¹, CHRISTOPHER GILBRETH, YORAM ALHASSID, Center for Theoretical Physics, Yale University — Cold atomic fermi gases are widely studied examples of strongly interacting quantum systems. Examples include ^4K , ^6Li and neutron matter. In the unitary regime, where the scattering length is very large compared to the mean inter-particle distance, they are nonperturbative and exhibit universal behavior. Moreover, they can be created in the lab, providing an excellent testing ground for theory. In this talk I will describe quantum Monte Carlo calculations we have been performing to study the signatures of pairing and the superfluid phase transition in finite-size systems. Using the Auxiliary Field Monte Carlo (AFMC) method, we study the pairing gap, condensate fraction, pair wavefunction and density profile as a function of temperature. Defining the onset of condensation T_{cond} as the temperature when the condensate fraction crosses its (finite) noninteracting limit, we consider the question of whether pairing occurs prior to condensation in the unitary regime.

¹Supported in part by the U.S. DOE grant No. DE-FG02-91ER40608, by facilities and staff of the Yale University Faculty of Arts and Sciences High Performance Computing Center, and by the NSF grant No. CNS 08-21132.

1:39PM Z4.00013 Cooling across the superfluid-normal interface of a unitary Fermi gas - an analogue of a dilution fridge?, ARIJEET PAL, DAVID HUSE, Princeton University — Phase separation between paired superfluid and partially polarized normal phases has been observed by various experimental groups around the world using resonantly-interacting spin-imbalanced, hyperfine states of fermionic atoms. In this work we phenomenologically study the effect of the evaporation of atoms and explore the possibility of realizing a non-equilibrium steady state with chemical potential and temperature gradients in some of these experiments.

1:51PM Z4.00014 Upper Branch Bosons at High Temperatures, WEIRAN LI, TIN-LUN HO, the Ohio State University — We use a generalized Nozieres-Schmitt-Rink (NSR) approach, which excludes the molecule poles in the T-matrix, to study the “upper branch” Bose gases at high temperatures. We show that when we tune the scattering length from positive side across the resonance, the Bose system can remain stable even with attractive interactions at relatively high temperatures. The energy of this upper branch Bose gas has a maximum at negative scattering length, which indicates pair formations are enhanced by Bose statistics in a many body system, in contrast to the Fermionic case where the maximum occurs at positive scattering length.¹

Session Z5 DCMF: Synthesis, Transport, and Devices Based on Artificially Structured Materials
206A

11:15AM Z5.00001 Ultrasmall Silver Nanopores Fabricated by Femtosecond Laser Pulses¹, JIMIN ZHAO, F. BIAN, Y.C. TIAN, R. WANG, H.X. YANG, Institute of Physics, Chinese Academy of Sciences, HONGXING XU, Institute of Physics, CAS; Lund University, SHENG MENG, Institute of Physics, Chinese Academy of Sciences — Ultrasmall nanopores in silver thin films with a diameter of about 2 nm have been fabricated using femtosecond laser ablation in liquid [1]. Ultrafast laser pulse ablation generates highly nonequilibrium excited states, from which silver thin films emerge and progressively grow with the assistance of capping agent molecules. During this growth process, capping agent molecules are enclaves within the film, leaving individual ultrasmall pores in the thin film. Our first-principles calculations show that the pore size is critically determined by the dimension of the confined molecules. Furthermore, by using smaller capping agent molecules, we were able to fabricate smaller nanopores with 1.6nm diameter. Our approach advances the capability of optical methods in making nanoscale structures with potential applications in areas such as near-field aperture probes, imaging masks, magnetic plasmonic resonances, and biosensing with individual nanopores.

11:27AM Z5.00002 Effect of Li+3 Ion Irradiation on Properties of Ta and Dy Doped Bi_{1.5}Zn_{0.92}Nb_{1.5}O_{6.92} Pyrochlores, BILGEHAN YUMAK, Marmara University Department of Physics, MEHMET YUMAK, AY-HAN MERGEN, Marmara University Department of Metallurgical and Materials Eng, ANJUM QURESHI, Faculty of Engineering and Natural Sciences, Sabanci University — Pyrochlore compounds with a general formula of A₂B₂X₇ where A and B are B cations and X is anion exhibit a variety of interesting properties which allow for a broad range of applications, such as high-permittivity dielectrics, as cathode and electrolyte materials in solid electrolytes, host materials for the immobilization of fission products, catalysis, and thermal barrier coatings and fluorescence centers. Pyrochlore oxides can accommodate a wide range of solid solutions between BO₂ and A₂O₃ compounds. Radiation effects in a wide range of pyrochlore compositions have been extensively investigated due to the potential application of pyrochlores. In this study, Ta and Dy-doped Bi_{1.5}Zn_{0.92}Nb_{1.5}O_{6.92} (BZN) pyrochlore compounds were produced by mixed oxide technique. After determining the solubility limit of Ta and Dy in BZN by XRD, single phase Ta and Dy-doped BZN ceramics were irradiated with different fluences of Li³⁺ ion irradiation. The microstructures of sintered ceramics before and after irradiation were discovered by scanning electron microscopy. The effect of irradiation on dielectric properties at different frequencies and temperatures were also investigated.

11:39AM Z5.00003 Development of ZnO/Cu Nanolaminate Materials , SETH KING, LORALEE BILKE, JOSEPH KRUEGER, BENJAMIN OLESON, IAN SMITH, BENJAMIN STUROMSKI, University of Wisconsin - La Crosse — Promising materials to replace cost inhibitive indium-tin oxide as transparent conductive oxide layers are ZnO based alloys. Unlike In, Zn is cheap and abundant with a stable supply. Furthermore, ZnO is easily fabricated using standard industrial scale techniques. Therefore, the development of ZnO based materials may greatly advance modern electrical devices. The undoped bandgap of ZnO is 3.4 eV, and may be degenerately doped with donor species such as Al, B, or Ga. For pure ZnO, the electron mobility is ca. 200 cm²/V, but decreases significantly with doping due to impurity scattering. Recent studies have suggested that bilayers of doped ZnO and metal may offer low enough resistivity for industrial application. Therefore, it is a logical extension to investigate the properties of ZnO/metal nanolaminate films fabricated from multiple, thin, alternating layers of doped ZnO and a metal. We will present the preliminary results of the development of ZnO based nanolaminate materials consisting of alternating layers of ZnO and Cu fabricated by reactive DC sputter deposition. Our preliminary results suggest that these materials may have applications in photovoltaic devices as well as infrared mirrors.

11:51AM Z5.00004 Nano-structured Au surfaces by off-normal gas cluster ion beam technique , BUDDHI TILAKARATNE, DHARSHANA WIJESUNDERA, XUEMEI WANG, WEI-KÂN CHU, Department of Physics and Texas center for Superconductivity at University of Houston — Surface nano pattern formation has generated great interest in semiconductor, optoelectronics and bio-medical industries. For the past three decade cluster ion beam technology has developed significantly. A gas cluster ion consists thousands of atoms and usually energy per atom in the cluster is about 10eV and cluster ion surface penetration is minimum. Therefore, cluster ion impact form shallow depth modifications. When a cluster ion incident on to the surface off-normal beyond a certain angle from the normal surface target atoms gains forward momentum and creates clear surface nano-ripples between angles 40 to 60 degrees from surface normal. Even though many experiments have demonstrated cluster ion ripple formation, a mechanism of these formations has limited cluster ion beam industrial applications. We will discuss experimental results of surface evolution during the cluster ion off-normal incident irradiation and azimuthal sample rotation dependence of surface patterns, and compare results with a theoretical model.

12:03PM Z5.00005 Diamondoids enables 10nm resolution on X-ray PEEM , HITOSHI ISHIWATA, Stanford University, HENDRIK OHLDA, Stanford Synchrotron Radiation Laboratory, ANDREAS SCHOLL, Lawrence Berkeley National Laboratory, OLAV HELLWIG, Hitachi Global Storage Technologies, PETER SCHREINER, Justus-Liebig Universitaet, Institut fuer Organische Chemie, JEREMY DAHL, NICK MELOSH, Z.X. SHEN, Stanford University — Diamondoids are the smallest sp³ bonded carbon cage that can be found in different sizes and shapes, starting from single cage called adamantane that contain 10 carbons all hydrogen terminated on outside. While the electronic structure and material properties of diamondoids are based on bulk diamond, their nanostructure allows for tailoring their properties to a particular task. Diamondoids can be produced reliably and cost effective in different sizes and quantities. They exhibit a tremendous potential for real-world applications, e.g. as seed crystals in diamond growth, as robust mechanical coatings or as highly efficient electron cathodes. Here, we will focus on the latter, showing how diamondoid coating can be used to push the spatial resolution to the limit and significantly increasing the efficiency of an x-ray based cathode lens microscope (X-ray Photoemission Electron Microscope or XPEEM) by minimizing the effect of chromatic aberrations caused by the energy spread of the electrons emitted from the cathode. The unique feature of XPEEM microscopy is that it is capable of acquiring images with magnetic, chemical, structural as well as topographical contrast of surfaces and shallow interfaces. The capability to obtain such images with 10nm spatial resolution through simple, low-cost and readily available nanodiamond coating represents a major step forward towards real world application of these promising nano materials. (Presenting author: Z.X. Shen)

12:15PM Z5.00006 ABSTRACT HAS BEEN MOVED TO B17.00008 —

12:27PM Z5.00007 Quantum-Dot Cellular Automata On A Hydrogenated Silicon Surface: An Exact Diagonalization Study , BURKHARD RITTER, University of Alberta — Quantum-dot cellular automata (QCA) is an alternative computing paradigm for molecular-scale quantum devices. We present results from the first detailed exact diagonalization study of QCA systems using a richly extended Hubbard model. A controlled Hilbert space truncation alleviates the scaling problem and provides access to moderate system sizes. We characterize the static signal transmission for short wires and identify suitable material and system parameters for dangling bonds on a hydrogen-terminated silicon surface, a recent experimental realization. We discuss the challenges for a realistic, working implementation.

12:39PM Z5.00008 The chemical analysis about post annealing effect of HfO₂ on Si-passivated GaAs , SANG HAN PARK, HYO JIN KIM, DAE-KYONG KIM, MANN-HO CHO, Yonsei Univ., Sinchon-dong, Seodaemun-gu, Seoul, Korea, CHUNG YI KIM, LG Institute, Umyeong-dong, Seocho-gu, Seoul, Korea, HYOUNGSUB KIM, Sungkyunkwan Univ. Natural Sciences Campus, Cheoncheon-dong, Jangan-gu, Suwon-si, Gyeonggi-do, Korea — In order to develop a high performance MOS device, 3-5 based semiconductors as a high carrier transport semiconductors have been seriously considered. Especially, GaAs with HfO₂ as gate dielectric material attract as a candidate for future MOS FET device. Since, larger trap density at HfO₂/GaAs interface than for HfO₂/Si interface degrade device performance, Si interfacial layer was introduced to reduce interfacial trap. Moreover, Si reduces intrinsic defects at GaAs surface by reconstruct Ga or As homo bonds. In this study, we focused on changes in the chemical and structural characteristics of HfO₂/Si/GaAs film as a function of post annealing temperature. The interfacial reactions induced by post annealing were investigated by XPS, REELS, and XAS. The results show that Si layer decrease the diffusion and oxide formation of Ga and As. Also, the post nitridation significantly improve the diffusion barrier by forming the Ga-N layer. XAS result also consists with the fact that the post nitridation suppress Ga diffusion. The band offsets between GaAs and high-k gate dielectric were aligned using XPS and REELS.

12:51PM Z5.00009 Terahertz Generation Based on Gunn Oscillations in Unipolar Nanodiodes , MUBARAK ALI, AIMIN SONG, University of Manchester — A pressing concern in the terahertz (THz) deployment of technology is the lack of efficient, compact, solid-state THz emitters. Recently, self-switching devices (SSDs) have been demonstrated to offer a 2D planar technology with ultra-low parasitic capacitance, which enabled detection of microwave radiation up to 2.5 THz. Furthermore, it is possible to integrate a large array of SSDs in parallel in order to reduce overall impedance and hence reduce thermal noise. Monte Carlo simulations showed that the SSD can also emit radiation based on Gunn oscillations. In this work, we modeled using Silvaco Atlas to provide evidence of dipole domain formation in the channel and systematically study the dependence of emission frequency and intensity as a function of channel length and width as well as interface-charge density. The results showed that the fundamental oscillation frequency can reach as high as 400 GHz, whereas higher harmonics go well beyond 1.2 THz. By constructing an array that contains different geometries of SSDs placed in parallel, we expect to achieve frequency tuning in wide or narrow bands, which may have useful implications to practical applications.

1:03PM Z5.00010 Tuning electric and magnetic responses with structure evolution in a meta-material , XIANG XIONG, MU WANG, RUWEN PENG, Nanjing University — We demonstrated that in an assembly of double-layered metallic U-shaped resonators, magnetic and electric responses are realized respectively. The two different types of responses are realized at higher and lower frequency. When the U-shaped structure resonators evolve into H-shaped structure gradually, the electric and magnetic frequencies move forward to each other. In this case, when electric response and magnetic response are overlapped in frequency, negative refractive index can be realized.

1:15PM Z5.00011 Configuration interaction in a tunable wavelength shifter, ALEKSEJ MIALITSIN, National Renewable Energy Laboratory, ILIA SOLOV'YOV, Beckman Institute for Advanced Science and Technology, STEFAN SCHMULZ, Namlab, BRIAN FLUEGEL, ANGELO MASCARENHAS, National Renewable Energy Laboratory — It has recently been demonstrated how hybridized plasmon-phonon collective excitations in GaAs can be blue shifted by about 20 wavenumbers (0.6 THz) relative to the unperturbed longitudinal optical lattice vibration frequency as a function of excitation beam intensity [Fluegel et al., Nat. Phot. 1, 701 (2007)]. At beam intensities greater than 10 mW/cm^{-2} the wavelength shifted mode broadens and begins to exhibit a double-peak structure. We attribute this line-shape modification to configuration interaction of the named mode with the edge of the continuous background and discuss potential implications for coupled plasmon-phonon modes generated in semiconductor hetero-structures.

1:27PM Z5.00012 Secondary Electron Emission (SEE) Calculations, HAROLD P. HJALMARSON, RONALD P. KENSEK, Sandia National Laboratory, KENNETH E. KAMBOUR, Air Force Research Laboratory — Secondary electron emission (SEE) from solids is a consequence of energy loss by charged particles such as electrons. One important energy loss mechanism to be considered involves plasmon emission by the charged particle. Plasmons create electron-hole pairs when they decay. Under certain conditions, a sufficiently energetic electron, a secondary electron, may be emitted from the solid surface. In this presentation, results from two different approaches to this process will be presented. A particle-based Monte Carlo method and a continuum method will be used for these calculations. The results from the two different methods will be compared to each other to understand the effects of the various approximations in the two methods. The methods will be illustrated by an application to titanium dioxide (rutile). —Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

1:39PM Z5.00013 Dark Field Imaging of Plasmonic Resonator Arrays, ATILLA AYDINLI, SINAN BALCI, ERTUGRUL KARADEMIR, COSKUN KOCABAS, Bilkent University — We present critical coupling of electromagnetic waves to plasmonic cavity arrays fabricated on Moiré surfaces. The critical coupling condition depends on the superperiod of Moiré surface, which also defines the coupling between the cavities. Complete transfer of the incident power can be achieved for traveling wave plasmonic resonators, which have relatively short superperiod. When the superperiod of the resonators increases, the coupled resonators become isolated standing wave resonators in which complete transfer of the incident power is not possible. Dark field plasmon microscopy imaging and polarization dependent spectroscopic reflection measurements reveal the critical coupling conditions of the cavities. We image the light scattered from SPPs in the plasmonic cavities excited by a tunable light source. Tuning the excitation wavelength, we measure the localization and dispersion of the plasmonic cavity mode. Dark field imaging has been achieved in the Kretschmann configuration using a supercontinuum white light laser equipped with an acoustooptic tunable filter. Polarization dependent spectroscopic reflection and dark field imaging measurements are correlated and found to be in agreement with FDTD simulations.

1:51PM Z5.00014 Engineered Uniform Conduction Fronts in Memristive/Memcapacitive Systems, PATRICK MICKEL, CONRAD JAMES, Sandia National Laboratories — We introduce here a novel “memristor” design enabling the uniform propagation of the conduction front within the device, improving performance as well as device-to-device consistency. Typically, resistive switching in memristors occurs due to the localized formation of conductive filaments. Electric fields are magnified at filament tips (due to decreased separation, $E = V/d$), amplifying growth rates for select filaments and producing a localized and highly non-uniform conduction front. However, we show that by incorporating specifically spaced layers with alternating ionic mobilities the electric field magnification can be counterbalanced, resulting in a uniform conduction front. The uniform conduction front lowers device-to-device variability, improves analog tuning and significantly amplifies the memcapacitive properties of the device. These multilayered engineered nanostructures have potential applications in multi-bit memory storage and neuromorphic computing architectures.

Session Z6 DMP: Focus Session: Carbon Nanotube Electronics, Properties, and Devices 206B

11:15AM Z6.00001 ABSTRACT WITHDRAWN –

11:27AM Z6.00002 Exploring adiabatic/non-adiabatic phase transitions in suspended metallic carbon nanotubes, SHUN-WEN CHANG, Department of Physics and Astronomy, University of Southern California, ROHAN DHALL, Department of Electrical Engineering, University of Southern California, ZUWEI LIU, Department of Physics and Astronomy, University of Southern California, STEPHEN CRONIN, Department of Electrical Engineering, Physics and Astronomy, and Chemistry, University of Southern California, CRONIN'S GROUP TEAM — We investigate the non-adiabatic Kohn anomaly in suspended pristine metallic single-walled carbon nanotubes by studying the dependence of the Raman G band and $2D$ band frequency on Fermi energy. We find that by varying temperature, metallic nanotubes can switch between a regime in which the non-adiabatic Kohn anomaly is clearly observed, to a regime where the non-adiabatic Kohn anomaly is absent. Furthermore, we find that the non-adiabatic Kohn anomaly is always accompanied by a dramatic gate-induced modulation of the G band Raman intensity. By establishing a quantitative correlation between the strength of the non-adiabatic Kohn anomaly and the modulation of Raman intensity, we determine that the underlying mechanism that leads to both these effects is the same.

11:39AM Z6.00003 Current-Induced Cleaning of Adsorbates from Suspended Semiconducting Carbon Nanotube Diodes, ARGYRIOS MALAPANIS, EVERETT COMFORT, JI UNG LEE, College of Nanoscale Science and Engineering, SUNY, Albany, NY — Single-walled carbon nanotubes (SWNT) are prime candidates for future applications, including nanoelectronic and nanophotonic devices. Because of their large surface-to-volume ratio compared to that of a bulk semiconductor, however, SWNTs are very sensitive to their environment. Others have already established that their electronic properties can be dramatically changed by exposure to air, particularly oxygen or water. In this paper,¹ we show that the electronic and optical properties of $p-n$ diodes fabricated with suspended semiconducting SWNTs degrade over time with exposure to ambient conditions, mainly due to adsorption onto the tube's suspended part, which creates band-gap states. We provide the first correlation between adsorbate-generated electronic states and their impact on diode performance. Specifically, we show that the ideality factor, a fundamental parameter used to measure defect states in a $p-n$ diode, increases with the degree of adsorbate coverage. We also demonstrate a simple technique—current annealing—that can thermally reverse such degradation, returning device properties to their original characteristics.

11:51AM Z6.00004 Electronic performance of flexible single-wall carbon nanotube films: The role of electronic type, JOHN M. HARRIS, North Dakota State University, STEVEN D. HUDSON, JEFFREY A. FAGAN, NIST, ERIK K. HOBIE, North Dakota State University — Recent advances in the separation of single-wall carbon nanotubes (SWCNTs) by length and electronic type have made highly monodisperse SWCNT membranes a reality, opening up new realms of potential application in flexible electronics. By measuring the coupling between mechanical flexibility and electronic performance for thin transparent films of metallic and semiconducting SWCNTs assembled on elastic polymer substrates, we demonstrate a marked difference in the electronic manifestations of thin-film deformation for the two electronic SWCNT types. We relate these differences to mechanical and interfacial phenomena that stem from the distinct optical resonances characteristic of metallic or semiconducting nanotubes, and we evaluate the durability of each film type in response to repeated mechanical strain.

12:03PM Z6.00005 Origin of Capacitance Change in Semiconducting and Metallic Carbon Nanotubes, SEONG CHU LIM, DINH LOC DUONG, YOUNG WOO JO, TAE HYUNG KIM, SOO MIN KIM, Department of Energy Science, Sungkyunkwan University, JUNG HYUN YOON, HA RYONG HWANG, WISE CONTROL Inc., R&D Division, SLAVA ROTKIN, Department of Physics, Lehigh University, YOUNG HEE LEE, Department of Energy Science, Sungkyunkwan University, WISE CONTROL INC., R&D DIVISION COLLABORATION, DEPARTMENT OF PHYSICS, LEHIGH UNIVERSITY COLLABORATION — Different mechanisms are reported for the capacitance changes in metallic (m-) and semiconducting (s-) single-walled carbon nanotubes (SWCNTs) upon gas adsorption. The sensitivity, i.e., the change in capacitance, was high and reached approximately 2500% in the aligned s-SWCNT network, whereas the sensitivity was found to be low in the m-SWCNT network. The charge transfer/Fermi level shift and quantum capacitance related to the localized electronic density of states near the Fermi level were key contributors to sensitivity changes upon gas adsorption, although the polarization effect also played a role in the capacitance changes, particularly in the aligned CNTs, under a strong electric field.

12:15PM Z6.00006 Carbon based devices for molecular quantum spintronics¹, WOLFGANG WERNSDORFER, Institut Neel, CNRS, Grenoble — This presentation will address a new field called molecular quantum spintronics, which combines the concepts of spintronics, molecular electronics and quantum computing [1]. Various research groups are currently developing low-temperature scanning tunnelling microscopes to manipulate spins in single molecules, while others are working on molecular devices (such as molecular spin-transistors, spin valves and filters, and carbon-nanotube-based devices [1]) to read and manipulate the spin state and perform basic quantum operations. The talk will discuss the read-out of the spin states of single-molecule magnets using carbon based devices. In particular, carbon nanotube devices [2] and graphene nano-constrictions [3] will be discussed.

12:51PM Z6.00007 Poole-Frenkel emission by carbon nanotube defect sites, DENG PAN, BRAD CORSO, PHILIP COLLINS, Department of Physics and Astronomy, University of California Irvine — Single walled carbon nanotubes (SWCNTs) have a conductance that is particularly sensitive to the presence of defects and disorder. Here, we fabricate field effect devices out of individual SWCNTs in order to investigate this effect. The bias- and gate-dependent conductance of SWCNT devices is measured over a temperature range of 77 – 400 K. By performing these measurements on the same SWCNT before and after the incorporation of a point defect, we clearly discern the electronic consequences of the addition. Specifically, the initial recording of the pristine SWCNT determines the energy-dependent resistances of the SWCNT itself. After electrochemical point functionalization to introduce a defect site, the additional resistance and its energy-dependence is determined by properly accounting for the initial contributions. We find the defect scattering to be well fit by a Poole-Frenkel emission model, with the consequence that barrier widths and heights can be extracted for different defect types.

1:03PM Z6.00008 Scanning Probe Characterization of Electronic Scattering by Carbon Nanotube Defects, ELLIOT FULLER, STEVEN HUNT, BRAD CORSO, PHILIP COLLINS, Dept. of Physics and Astronomy, Univ. of California Irvine, Irvine, CA 92697 — Single-walled carbon nanotubes (SWCNTs) are quasi-ballistic, one-dimensional conductors with unique electronic properties. The controlled addition of a single covalent, sidewall defect interrupts this conduction pathway and produces a disproportionate change in the device properties. Here, we investigate the electronic effects in the immediate vicinity of a defect site using Kelvin force microscopy (KFM) and scanning gate spectroscopy (SGS). KFM images the local electrostatic surface potential along a SWCNT and thus can directly measure the potential drop at defects and other electronic surface features. Using KFM, we clearly observe the bias dependence of resistance at the site of defects and/or chemical attachments. The SGS technique provides complementary information by mapping their gate dependence. Combined, these two scanning probe techniques resolve the full energy dependence of scattering by a defect site and allow the determination of effective barrier widths and heights for different types.

1:15PM Z6.00009 Fundamental Limits of Current Flow in One-dimensional Carbon Nanomaterials, ALBERT LIAO, CHRISTOPHER NEUMANN, ERIC POP, Department of Electrical and Computer Engineering at the University of Illinois at Urbana-Champaign — Carbon nanotubes (CNTs) and graphene nanoribbons (GNRs) carry very high current densities given their strong sp² bonds and high carrier mobility. However, the fundamental limitations to their maximum current flow are still not well understood. We measured the maximum current flow of CNTs and GNRs in substrate-supported configurations in ambient air where devices break from Joule heating at ~600 C [1,2], revealing information about their power dissipation. Interestingly, thermal coupling with the substrate increases with CNT diameter but decreases with GNR width, due to competing roles of thermal boundary resistance and heat spreading into the substrate. To further study quasi-metallic single-wall CNTs at very high fields, we performed measurements in vacuum. We found some devices show current saturation as expected [3], but in many the current continues to increase with a constant slope of ~ 1 μ A/V at fields >10 V/ μ m. This is observed even in small-diameter (~1.2 nm) CNTs whose dimensions were verified by AFM and Raman spectroscopy. We suggest such behavior can be explained by a combination of better heat coupling with the substrate and higher subband conduction. [1] A. Liao *et al*, PRB **82**, 205406 (2010). [2] A. Liao *et al*, PRL **106**, 256801 (2011). [3] Z. Yao *et al*, PRL **84**, 2941 (2000).

1:27PM Z6.00010 Terahertz Detection in an Individual Single-Walled Carbon Nanotube¹, JOEL CHUDOW, DANIEL SANTAVICCA, Dept. of Applied Physics, Yale University, CHRIS MCKITTERICK, Dept. of Physics, Yale University, LUIGI FRUNZIO, Dept. of Applied Physics, Yale University, DANIEL PROBER, Dept. of Applied Physics and Physics, Yale University, PHILIP KIM, Dept. of Physics, Columbia University — Carbon nanotubes (CNTs) serve as a test experimental system for verification of physical models of one-dimensional (1-D) conduction. We aim to excite terahertz standing wave resonances on a CNT, which are predicted to display Luttinger-liquid behavior due to the lack of screening in 1-D. We describe measurements of terahertz (THz) absorption in individual single-walled carbon nanotubes and distinguish between two response mechanisms: bolometric detection due to heating a CNT with a temperature-dependent resistance and the response due to non-thermal electrical contact nonlinearities. This is the first frequency-domain demonstration of THz detection in an individual CNT. The effect of the contact nonlinearity is not decreased at THz frequencies and allows for analysis of the parallel contact capacitance to an individual CNT. Both detection mechanisms are expected to give evidence of the Luttinger-liquid resonant behavior. This experimental technique provides a method to study high-frequency charge excitations in the nanotube as a probe of the strength of the electron-electron interactions in this 1-D system.

¹This work supported by NSF-DMR.

1:39PM Z6.00011 Individual Single-Walled Carbon Nanotube Device Fabrication for Terahertz Detection¹, CHRIS MCKITTERICK, Physics Department, Yale University, JOEL CHUDOW, DANIEL SANTAVICCA, LUIGI FRUNZIO, Applied Physics Department, Yale University, DANIEL PROBER, Physics and Applied Physics Departments, Yale University, PHILIP KIM, Physics and Applied Physics Departments, Columbia University — We describe the fabrication process for the development of antenna-coupled single-walled carbon nanotube (CNT) terahertz (THz) detectors. This requires the development of a lithographically-defined gate electrode, as the device is fabricated on a THz-transparent insulating silicon substrate. Antenna development is geared towards accessing the largest possible bandwidth to facilitate the study of standing wave resonances in the CNT. These standing wave resonances are expected from the one-dimensional Tomonaga-Luttinger Liquid theory, which predicts collective charge oscillations, known as plasmons, which travel faster than the Fermi velocity. Using a Fourier transform interferometer, we excite the antenna-coupled CNT with a broadband blackbody source and probe the THz impedance of the CNT through Joule heating.

¹This work is supported by NSF-DMR and NSF-CHE.

1:51PM Z6.00012 In-situ TEM study of heat transfer between a carbon nanotube and contacting material, MERIJNTJE BRONGEEST, NORVIK VOSKANIAN, HANNA NILSSON, JOHN CUMINGS, University of Maryland — Due to their interesting intrinsic properties and 1D nature, carbon nanotubes may be (part of) the solution to the heat management challenge in nanoelectronics in multiple ways: e.g. as thermal interface material and/or interconnects in existing Si-based electronics, or as a building block in carbon-based electronics. Of crucial importance for any of these applications is the (in)ability to get heat in and out of the tube: the thermal contact resistance. Thermal contact resistance for carbon nanotubes is not fully understood yet, and theory is under construction. Measuring it is a challenge of its own as it is intimately connected to the thermal conductivity of the connected materials which are not necessarily known that well either. We study the thermal properties of carbon nanotubes with Electron Thermal Microscopy [T. Brintlinger et al., Nano Lett. 8, 582 (2008)], which allows for thermal imaging with a resolution of 150 nm, and combine that with finite-element modeling. With this approach we have already demonstrated that also on a substrate the CNT thermal conductivity is high, and that different heat transfer mechanisms (e.g. phonon-phonon, electron-surface polariton interaction) can be important. Our goal is to study and quantify thermal contact resistance between a carbon nanotube and its surroundings and we will present our latest results.

2:03PM Z6.00013 Remote Joule heating of crossed nanotube, NORVIK VOSKANIAN, KAMAL H. BALOCH, Materials Science and Engineering, University of Maryland, College Park, Maryland, MERIJNTJE S. BRONGEEST, Physics, University of Maryland, College Park, Maryland, JOHN CUMINGS, Materials Science and Engineering, University of Maryland, College Park, Maryland — The high thermal conductivity of carbon nanotubes makes them an excellent candidate for thermal management and thermal logic devices. We have studied the thermal characteristics of Joule-heated MWNTs in a crossed geometry, using an established thermal measurement technique that relies on the solid to liquid phase transition of indium islands [1]. Our experimental observations show the efficient transfer of heat from CNT to substrate but inefficient heat transfer past the crossing point. This supports the presence of a nonlocal joule heating phenomenon in which the hot electrons from the biased CNT directly transfer their energy to a nearby material. This talk will cover the developed thermal characterization technique, experimental results and simulations.

Session Z7 DCMP: Transport and Optical Properties of Non-Carbon Nanotubes and Nanowires

207

11:15AM Z7.00001 Exchange induced electron transport in heavily n-doped Si nanowires¹, JOONYEON CHANG, Korea Institute of Science & Technology, TAE-EON PARK, Yonsei University, Korea Institute of Science & Technology, BYOUNG-CHUL MIN, Korea Institute of Science & Technology, ILSOO KIM, Yonsei University, JAE-EUN YANG, MOON-HO JO, Postech, HEON-JIN CHOI, Yonsei University, KOREA INSTITUTE OF SCIENCE AND TECHNOLOGY TEAM, YONSEI UNIVERSITY TEAM, POSTECH TEAM — Silicon nanowires (Si NWs) have been used as building blocks in the “bottom-up” approach to nanoelectronics because of their excellent electrical properties. Despite the potential of Si NWs, unfortunately, there is little known about the electrical properties of heavily doped Si NWs. We have synthesized heavily doped *n*-type Si NWs and measured the electrical resistance using four-probe method. As we decrease the temperature, the resistivity of Si NWs decreases initially, shows a resistivity minimum around 60 K, and thereafter increases logarithmically. Below the resistivity minimum temperature (T_{min}), we have observed a dip around zero-bias in the differential conductance, and a negative magnetoresistance (MR) which depends on the angle between the applied magnetic field and current flow. These results are associated with the impurity band conduction and electron scattering by the localized spins at phosphorus donor states. The analysis on the MR reveals that the localized spins are coupled antiferromagnetically at low temperature via the exchange interaction.

¹Nano R&D and KIST Institutional program

11:27AM Z7.00002 Low-field mobility in ultrathin silicon nanowire junctionless transistors, BART SOREE, WIM MAGNUS, WILLIAM VANDENBERGHE, imec, UNIVERSITEIT ANTWERPEN COLLABORATION, KULEUVEN COLLABORATION — We theoretically investigate the phonon, surface roughness and ionized impurity limited low-field mobility of ultrathin silicon *n*-type nanowire junctionless transistors in the long channel approximation with wire radii ranging from 2 to 5 nm, as function of gate voltage. A few years ago, the junctionless nanowire transistor (JNT) or pinch-off nanowire was proposed by several research groups and was recently fabricated for the first time. The JNT is a uniformly doped nanowire with no junctions, i.e. source, channel and drain are doped with the same doping type. The main motivation for introducing this novel device concept are the absence of doping junctions which makes the fabrication easier, and the reduction of detrimental interactions occurring at the interface between the silicon body of the wire and the insulator (surface roughness). We investigate the case where due to quantum mechanical confinement the surface roughness scattering becomes again important and we report on the behavior of phonon, ionized impurity and surface roughness limited mobility as a function of radius and gate voltage.

11:39AM Z7.00003 Photovoltaic properties of axial in-situ doped SiGe heteronanowires, SON T. LE, Department of Physics, Brown University, A.D. MOHITE, D.E. PEREA, H. HTOON, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, P. JANNATY, A. ZASLAVSKY, School of Engineering, Brown University, S.T. PICRAUX, Center for Integrated Nanotechnologies, Los Alamos National Laboratory — We report on vapor-liquid-solid (VLS) growth and photovoltaic properties of axial in-situ doped Ge-Si heteronanowire (hetero-NW) solar cells. Modern VLS growth has recently demonstrated the growth of Si-Ge axial NWs with abrupt heterojunctions [1], and simultaneous control of both material composition and doping profiles. This advance allows for the integration of Ge with Si in a hetero-NW structure for broad-spectrum and high absorption efficiency solar cells. Our preliminary optical measurements on p -Ge/ i -Si/ n -Si wires provide important ingredients for a hetero-NW photovoltaic device. We achieved good rectification with $\sim 10^3$ ratio between forward and reverse bias currents at moderate voltage. Under laser illumination (532 nm), we measured a large open circuit voltage $V_{OC} \sim 0.54$ V and a high short-circuit current density $J_{SC} \sim 4 \times 10^3$ A/cm², comparable to state-of-the-art reported single NW results [2]. Additional optimization of separate Ge and Si pin NW structures and their integration in a combined Ge/Si tandem hetero-NW solar cell will be reported.

11:51AM Z7.00004 Strong Tuning of Spin Orbit Interaction in an InAs Nanowire by an Electrolyte Gate¹, DONG LIANG, XUAN P.A. GAO, Department of Physics, Case Western Reserve University — Manipulating electron spin in solid state devices has been the main target of spintronics. A key concept in many spintronic devices is to apply gate voltage or electric field (E) to tune spin precession via the Rashba spin orbit interaction (SOI). Quasi-one dimensional (1D) indium arsenide (InAs) nanowires are promising platforms in this regard due to InAs's strong intrinsic SOI and more effective control of Rashba SOI in 1D system with uni-directional momentum. Here, we demonstrate efficient control of Rashba SOI where E is created at the surface of InAs nanowire by solid electrolyte surrounding gate. Six-fold tuning of Rashba coefficient and 2.5 order of magnitude tuning of spin relaxation time are achieved within only 1 V of gate bias. Such a dramatic tuning of SOI paves a way towards quasi-1D nanowire spintronic devices with low power consumption.

¹The authors acknowledge ACS PRF (48800-DNI10) for partial funding support.

12:03PM Z7.00005 InAs/InSb axially heterostructured nanowires for small junction area semiconductor diodes, ALESSANDRO PITANTI, DANIELE ERCOLANI, LUCIA SORBA, STEFANO RODDARO, FABIO BELTRAM, NEST Scuola Normale Superiore & CNR NANO p.zza S. Silvestro 12 56127 Pisa Italy, LUCIA NASI, GIANCARLO SALVIATI, IMEM CNR parco Area delle Scienze 37/A 43010 Parma Italy, ALESSANDRO TREDICUCCI, NEST Scuola Normale Superiore & CNR NANO p.zza S. Silvestro 12 56127 Pisa Italy — Semiconductor nanowires are low-dimensional systems which appear as ideal candidates to enable ultra-fast electronic technology. Even if the realization of complex [1], nanowire-based electronic devices such as transistors and diodes has been demonstrated, the ultra-small axial electronic capacitance, related to the semiconductor tiny cross-section, is rarely exploited, due to the difficulty in creating homo/hetero-junctions within the nanowire itself. We propose a solution to produce axial, majority-carrier diodes, by employing growth interruption to create InAs/InSb heterojunction along the nanowire axis [2]. Despite being both InAs and InSb n -type materials, their broken gap band alignment produces strong asymmetry in the I-V characteristic, similarly to standard Schottky-barrier diodes. The band line-up determines a strong nonlinear current response at positive source-drain bias: when an additional InP barrier layer is inserted in-between the heterojunction, the maximum nonlinearity is drawn towards zero bias and the leakage current reduced, making these devices promising candidates for high cut-off frequency rectifying detectors/photomixers.

12:15PM Z7.00006 Growth and electrical properties of vertically oriented organic single-crystalline nanostructures¹, SAN THEINGI, Mount Holyoke College, TIM MIRABITO, ALEJANDRO BRISENO, University of Massachusetts (Amherst,MA), KATHERINE AIDALA, Mount Holyoke College — We present our growth of vertically oriented organic single crystalline nanowires of copper tetra-tertbutylphthalocyanine (t-butyl-CuPc) on highly ordered pyrolytic graphite (HOPG). The nanowires are grown by using physical vapor transport (PVT) method, with directed crystallization on ordered substrates. Single crystal nanostructures are free of grain boundaries and this promotes charge transport through the material. The pi-pi interactions between adjacent molecules of the single crystal provide a direct path for charge transfer, leading to high carrier mobility. Vertically oriented single-crystal nanostructures have applications as high surface area solar cells. We are studying the electrical conductivity of these nanostructures using conductive atomic force microscopy (CAFM). The AFM tip makes an electrical contact to an individual wire, and current is measured as a function of applied voltage.

12:27PM Z7.00007 Rectification in an idealized model junction of strongly correlated electrons¹, FLORIAN SABOU, NATALIE BODINGTON-ROSEN, BRAD MARSTON, Brown University — Junctions of oppositely doped Mott insulators offer the possibility of rectification at extremely high frequencies. To simulate an idealized junction we use a model of spinless electrons moving in one dimension, the t-V chain, and control the chemical potential on the two halves of the chain to create a p-n junction. For short chains the many-body Schrodinger equation can be integrated forward in time numerically exactly, and we find that when subjected to an oscillating electric field the system rectifies by transferring charge in a preferred direction. Dissipation can be included in a phenomenological way by rotating time slightly off the real axis. The time dependent density-matrix renormalization-group may be used to extend the simulation to longer chains with spinning electrons.

¹Supported in part by NSF grant no. DMR-0605619.

12:39PM Z7.00008 Temperature effects on the Raman lineshape of cupric oxide thin films and nanowires, SHRIVIDYA RAVI, ALAN KAISER, Victoria University of Wellington, CHRISTOPHER BUMBY, Industrial Research Limited — The Raman spectrum can be used as a fingerprint for a given material but the details of the Raman spectrum (e.g. the peak lineshape) can also impart considerable information about various environmental effects. In this study, we will describe the effects of heating on the Raman lineshape using a temperature-dependent model. Homogeneous heating (i.e. spatially uniform temperature) leads to symmetrically broadened lineshapes while asymmetric lineshapes can be associated with electron-phonon coupling in or phonon confinement effects. Recently, several groups have found that asymmetric lineshapes from nanoparticles and nanowires require an additional term that describes the inhomogeneous heating - temperature gradients within the sample - due to a gaussian laser beam. In our samples, phonon confinement does not play a role at all as nanowire dimensions are well above 20 nm. Hence, we have invoked a purely temperature-dependent model. This model has considerable flexibility as it can explain both the symmetrical and asymmetrical broadening of the lineshape. We have used it to describe and compare a thin film of cupric oxide (which mostly exhibits homogeneous heating effects) and a vertical forest of cupric oxide nanowires (which exhibit effects of inhomogeneous heating).

12:51PM Z7.00009 Nonlocal Response of the Plasmonic Nanowire Metamaterials, BRIAN WELLS, Department of Physics and Applied Physics, University of Massachusetts Lowell, ANATOLY ZAYATS, Department of Physics, King's College London, VIKTOR PODOLSKIY, Department of Physics and Applied Physics, University of Massachusetts Lowell — Nanowire metamaterials are a class of composite photonic media formed by an array of aligned plasmonic nanowires embedded in a dielectric matrix. Depending on exact composition, geometry, and excitation wavelength, nanowire structures are known to exhibit elliptical, hyperbolic, or epsilon-near-zero (ENZ) responses. In the ENZ regime optical response of the composite becomes strongly nonlocal. Excitation of an additional wave, caused by nonlocality, has been experimentally demonstrated in nanowire-based metamaterials. Here we present numerical and analytical studies of the nonlocal optical response of plasmonic nanowire metamaterials. Dispersion of photonic modes of plasmonic metamaterials has been studied in finite-element-method (FEM) simulations as a function of wavelength, geometry, and material parameters. Analytical description of nonlocal effective permittivity tensor has been developed. These analytical results are in agreement with FEM simulations and experimental data.

1:03PM Z7.00010 ABSTRACT WITHDRAWN —

1:15PM Z7.00011 Equilibration of Luttinger liquid and conductance of quantum wires¹, K.A. MATVEEV, Argonne National Laboratory, A.V. ANDREEV, University of Washington — Luttinger liquid theory describes one-dimensional electron systems in terms of non-interacting bosonic excitations. In this approximation thermal excitations are decoupled from the current flowing through a quantum wire, and the conductance is quantized. We show that relaxation processes not captured by the Luttinger liquid theory lead to equilibration of the excitations with the current and give rise to a temperature-dependent correction to the conductance. In long wires, the magnitude of the correction is expressed in terms of the velocities of bosonic excitations. In shorter wires it is controlled by the relaxation rate.

¹Work supported by the U.S. Department of Energy under Contracts No. DE-AC02-06CH11357 and No. DE-FG02-07ER46452.

1:27PM Z7.00012 Rectification in Y-junctions of Luttinger liquid wires¹, CHENJIE WANG, D.E. FELDMAN, Brown University — We investigate rectification of a low-frequency ac bias in Y-junctions of one-channel Luttinger liquid wires with repulsive electron interaction. Rectification emerges due to three scatterers in the wires. We find that it is possible to achieve a higher rectification current in a Y-junction than in a single wire with an asymmetric scatterer at the same interaction strength and voltage bias. The rectification effect is the strongest in the absence of the time-reversal symmetry. In that case, the maximal rectification current can be comparable with the total current $\sim e^2V/h$ even for low voltages, weak scatterers and modest interaction strength. In a certain range of low voltages, the rectification current can grow as the voltage decreases. This leads to a bump in the I - V curve.

1:39PM Z7.00013 Phonon scattering in a strongly-driven 1D electron system¹, KATHLEEN E. HAMILTON, LEONID P. PRYADKO, ALEXEY A. KOVALEV, UCR — We consider phonon relaxation kinetics of a non-equilibrium, one-dimensional electron system driven by a strong, high frequency electric field. For a single-band system, and assuming that the phonon scattering rate is small on the scale of the driving frequency ω , we derive and solve the coupled equations for the Keldysh Green's functions and self energies. In the presence of the periodic driving field, the electrons' energy is replaced by the Floquet quasienergy; in the single-band case it just equals the energy averaged over the period (modulo $\hbar\omega$). The energies of the phonons emitted or absorbed by the system correspond to transitions between the Floquet energy bands, and are strongly dependent on both the amplitude and the frequency of the driving field. Of note is a system in the regime of dynamical localization, where the average electron kinetic energy vanishes. Here, the phonon energies must be in resonance with harmonics of the driving frequency, and the stationary electron distribution function reduces to a constant, with infinite effective temperature.

1:51PM Z7.00014 Nonequilibrium transport through a spinful quantum dot with superconducting leads, JENS PAASKE, BRIAN MOELLER ANDERSEN, KARSTEN FLENSBERG, Niels Bohr Institute, University of Copenhagen, VERENA KOERTING, NBIA, Niels Bohr Institute, University of Copenhagen — We study the nonlinear cotunneling current through a spinful quantum dot contacted by two superconducting leads. Applying a general nonequilibrium Green function formalism to an effective Kondo model, we study the rich variation in the IV-characteristics with varying asymmetry in the tunnel coupling to source and drain electrodes. The current is found to be carried respectively by multiple Andreev reflections in the symmetric limit, and by spin-induced Yu-Shiba-Rusinov bound states in the strongly asymmetric limit. The interplay between these two mechanisms leads to qualitatively different IV-characteristics in the cross-over regime of intermediate symmetry, consistent with recent experimental observations of negative differential conductance and re-positioned conductance peaks in sub-gap cotunneling spectroscopy.

11:27AM Z8.00002 ESR studies of the quasi-2D frustrated Cs₂CuBr₄¹, S.A. ZVYAGIN, D. KAMENSKYI, J. WOSNITZA, HLD-HZDR, 01328 Dresden, Germany, M. IKEDA, T. FUJITA, M. HAGIWARA, KYOKUGEN, Osaka University, Toyonaka, Osaka 560-8531, Japan, O.A. STARYKH, Department of Physics and Astronomy, University of Utah, Salt Lake City, UT 84112, USA, *R. HU, H. RYU, C. PETROVIC, Condensed Matter Physics and Materials Science Department, BNL, Upton, NY 11973, USA — We report low-temperature electron spin resonance (ESR) studies of single-crystalline samples of Cs₂CuBr₄, a spin-1/2 antiferromagnet with a triangular spin-lattice structure. A remarkable angular dependence of the resonance field, including the splitting of the ESR line for some orientations of the magnetic field, and the presence of a gap in the ESR excitation spectrum at temperatures above $T_N \sim 1.3$ K have been revealed. Our observations suggest that uniform Dzyaloshinskii-Moriya interaction affects the low-energy excitation spectrum in this frustrated compound. The results are compared with that obtained recently for the isostructural material Cs₂CuCl₄ [Povarov et al., Phys. Rev. Lett. 107, 037204 (2011)].

11:39AM Z8.00003 NMR Spectra in 2D Anisotropic Triangle Lattice¹, ADAM FREES, VESNA MITROVIC, Brown University — The spin 1/2 Heisenberg antiferromagnet on the 2D anisotropic triangle lattice represents an important example of the frustrated quantum magnets. The materials Cs₂CuCl₄ and Cs₂CuBr₄ are relevant model systems of such a frustrated magnet. In these compounds magnetic fields can induce numerous exotic quantum states. The states are characterized by their spin texture, which can be measured by NMR. In this talk, we discuss how to model different spin arrangements, and compute the resulting NMR spectra.

¹Supported in part by NSF DMR-0547938

11:51AM Z8.00004 Distinct magnetic regimes through site-selective atom substitution in the frustrated quantum antiferromagnet Cs₂CuCl_{4-x}Br_x, KATERYNA FOYEVTSOVA, HARALD O. JESCHKE, Institut fuer Theoretische Physik, Goethe Universitaet Frankfurt, 60438 Frankfurt, Germany, P.T. CONG, B. WOLF, M. DE SOUZA, N. KRUEGER, A.A. HAGHIGHIRAD, F. RITTER, W. ASSMUS, M. LANG, Physikalisches Institut, Goethe Universitaet Frankfurt, 60438 Frankfurt, Germany, ROSER VALENTI, Institut fuer Theoretische Physik, Goethe Universitaet Frankfurt, 60438 Frankfurt, Germany — A good realization of a spatially anisotropic spin 1/2 triangular lattice is provided by the isostructural layered compounds Cs₂CuCl₄ and Cs₂CuBr₄. In this talk, we shall present electronic structure calculations and magnetic susceptibility measurements[1] for the mixed systems Cs₂CuCl_{4-x}Br_x. We shall discuss the existence of three distinct concentration regimes which are separated by critical concentrations $x_{c1} = 1$ and $x_{c2} = 2$. The role of frustration effects at the critical concentrations will be highlighted.

[1] Cong et al. Phys. Rev. B 83, 064425 (2011)

12:03PM Z8.00005 Two-stage orbital order and dynamical spin frustration in KCuF₃¹, JAMES C.T. LEE, Frederick Seitz Materials Research Laboratory (FSMRL), UIUC, SHI YUAN, FSMRL, UIUC, SIDDHARTHA LAL², FSMRL and Institute for Condensed Matter Theory (ICMT), UIUC, YOUNG-IL JOE, YU GAN, SERBAN SMADICI, FSMRL, UIUC, PAUL M. GOLDBART, FSMRL and ICMT, UIUC, S. LANCE COOPER, PETER ABBAMONTE, FSMRL, UIUC, KEN FINKELSTEIN, Cornell High Energy Synchrotron Source, Cornell University, YEJUN FENG, Advanced Photon Source, Argonne National Laboratory, ANDRIVO RUSYDI, National University of Singapore — Results from our x-ray and Raman scattering studies on KCuF₃, a model orbital order system, strongly link a low-temperature orbital order transition to a previously unidentified structural phase transition at 50 K. Raman scattering shows softening of phonon modes linked to F—ions that ceases upon a splitting of a degenerate E_g mode at 50 K. This, along with the emergence of diffuse scattering around an orbital order Bragg peak at low temperature, suggests an onset of GdFeO₃-like octahedral tilting, which serves to stabilize the Neel spin order at 39 K. To explain these effects, we have added to the Kugel-Khomskii model a term for direct orbital exchange driven by electron-electron interactions and ligand distortions. This term creates a near degeneracy, which dynamically frustrates the spin order at high temperature, that is lifted by orbital—lattice interactions at low temperature.

¹Funding provided by grants from US DOE and NSF.

²Now at IISER-Kolkata

12:15PM Z8.00006 Evidence for pressure-tuned quantum structural fluctuations in KCuF₃, S. YUAN, M. KIM, J. SEELEY, S. LAL, P. ABBAMONTE, S.L. COOPER, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, Urbana, IL 61801 — Frustrated magnetic systems are currently of great interest because of the possibility that these materials exhibit novel ground states such as orbital and spin liquids. We provide evidence in the orbital-ordering material KCuF₃ for pressure-tuned quantum melting of a static structural phase to a phase that dynamically fluctuates even near $T \sim 0$ K.[1] Pressure-dependent Raman scattering measurements show that applied pressure above $P^* \sim 7$ kbar reverses a low temperature structural distortion in KCuF₃, resulting in the development of a $\omega \sim 0$ fluctuational (quasielastic) response near $T \sim 0$ K. This pressure-induced fluctuational response is temperature independent and exhibits a characteristic fluctuation rate that is much larger than the temperature, $\Gamma \gg K_B T$, consistent with quantum fluctuations of the CuF₆ octahedra. We show that a previous developed model of pseudospin-phonon coupling qualitatively describes both the temperature- and pressure-dependent evolution of the Raman spectra of KCuF₃. Work supported by the U.S. Department of Energy under Award No. DE-FG02-07ER46453 and by the National Science Foundation under Grant NSF DMR 08-56321.

12:27PM Z8.00007 Bose metal phase in a simple honeycomb lattice model¹, CHRISTOPHER VARNEY, University of Massachusetts, Amherst / Georgetown University / University of Maryland, KAI SUN, VICTOR GALITSKI, University of Maryland, MARCOS RIGOL, Georgetown University — The existence of quantum spin liquids was first conjectured by Pomeranchuk some 70 years ago, who argued that frustration in simple antiferromagnetic theories could result in a Fermi-liquid-like state for spinon excitations. Here we present evidence that a simple quantum spin model on a honeycomb lattice hosts the long sought for Bose metal with a clearly identifiable Bose surface. The complete phase diagram of the model is determined via exact diagonalization and is shown to include four distinct phases separated by three quantum phase transitions. The stability of the Bose metal phase in the presence of other interactions is also discussed.

12:39PM Z8.00008 Spin liquid ground state on the honeycomb Heisenberg spin 1/2 model with nearest and next nearest neighbor interaction, ZHENYUE ZHU, STEVEN WHITE, University of California, Irvine, DAVID HUSE, Princeton University — We numerically investigate the $S=1/2$ Heisenberg model on the honeycomb lattice with nearest (J_1) and next-nearest neighbor (J_2) interactions with the density matrix renormalization group (DMRG). We are able to study open cylinders with widths up to 12 lattice spacings. For J_2/J_1 near 0.3, we find a spin liquid phase, bordered by an antiferromagnetic phase for smaller J_2 and a valence bond crystal for larger J_2 . For the spin liquid phase we find finite spin singlet and triplet gaps and short spin-spin and bond-bond correlation lengths. We also find that the energy splitting between the two different topological sectors decays exponentially with the system width, consistent with a gapped Z_2 spin liquid.

12:51PM Z8.00009 Exact Spin Liquid Ground States of the Quantum Dimer Model on the Square and Honeycomb Lattices, HONG YAO, Stanford University and Tsinghua University, STEVE KIVELSON, Stanford University — We study a generalized quantum hard-core dimer model on the square and honeycomb lattices, allowing for first and second neighbor dimers. At generalized Rohksar-Kivelson points, the exact ground states can be constructed, and ground-state correlation functions can be equated to those of interacting 1+1 dimensional Grassmann fields. When the concentration of second neighbor dimers is small, the ground state correlations are shown to be short-ranged corresponding to a (gaped) spin liquid phase. On a 2-torus, the ground states exhibit fourfold topological degeneracy. On a finite cylinder we have found a dramatic even-odd effect depending on the circumference, and propose that this can be used as a numerical diagnostic of the phase, more generally.

1:03PM Z8.00010 Physical solutions of the Kitaev honeycomb model¹, STEFANO CHESI, McGill University, FABIO L. PEDROCCHI, DANIEL LOSS, University of Basel — We have investigated the exact solution of the honeycomb model proposed by Kitaev and derived an explicit formula for the projector onto the physical subspace. The physical states are simply characterized by the parity of the total occupation of the fermionic eigenmodes. We consider a general lattice on a torus and show that the physical fermion parity depends in a nontrivial way on the vortex configuration and the choice of boundary conditions. In the vortex-free case with a constant gauge field we are able to obtain an analytical expression of the parity. For a general configuration of the gauge field the parity can be easily evaluated numerically, which allows the exact diagonalization of large spin models. We consider physically relevant quantities, as in particular the vortex energies, and show that their true value and associated states can be substantially different from the one calculated in the unprojected space, even in the thermodynamic limit.

1:15PM Z8.00011 An FRG approach to the Heisenberg-Kitaev model, JOHANNES REUTHER, Karlsruhe Institute of Technology, RONNY THOMALE, Stanford University, SIMON TREBST, University of California, Santa Barbara — We apply the Functional Renormalization Group (FRG) method to frustrated spin-1/2 systems on two dimensional lattices such as the Heisenberg-Kitaev model. In order to be able to perform diagrammatic approximations, we use the pseudo fermion representation of spin operators. The FRG provides a systematic scheme for infinite order resummations in different interaction channels and hence allows to treat magnetic order and disorder effects on an equal footing. Calculating the magnetic susceptibility we identify different magnetically ordered and paramagnetic phases. In particular, the Heisenberg-Kitaev model exhibits magnetically ordered states well beyond the isotropic Heisenberg limit as well as an extended gapless spin-liquid phase around the highly anisotropic Kitaev limit. From the RG flow of the magnetic susceptibility we extract both, the Curie-Weiss scale and the critical ordering scale (for the magnetically ordered states). The Curie-Weiss scale changes sign, indicating a transition of the dominant exchange from antiferromagnetic to ferromagnetic, deep in the magnetically ordered regime. We discuss our results in light of recent experimental susceptibility measurements for Na_2IrO_3 and Li_2IrO_3 .

1:27PM Z8.00012 DMRG study of the spin-1/2 J1-J2 Honeycomb Antiferromagnetic Heisenberg Lattice¹, SHOU SHU GONG, DONGNING SHENG, Department of Physics and Astronomy, California State University Northridge, Northridge, California, 91325, USA, MATTHEW FISHER, Department of Physics, University of California, Santa Barbara, California 93106, USA — A possible quantum spin liquid state has been revealed in the Hubbard model on the honeycomb lattice by Quantum Monte Carlo study, which has stimulated a lot of recent interest in the quantum spin models on honeycomb lattice. In a recent paper (Phys. Rev. B 84, 024406 (2011)), the J1-J2-J3 Heisenberg model has been studied by exact diagonalization (ED), establishing a rich phase diagram with the Neel and plaquette valence-bond crystal (VBC) phases depending on couplings J2 and J3, while it remains unclear if there is a featureless spin liquid phase exists in such a model. Here, by implementing DMRG method with the full rotational $SU(2)$ symmetry, we study the J1-J2 Heisenberg model on honeycomb lattice at larger sizes. We analyze the spin-spin and dimer-dimer correlation functions for different sizes and extrapolate the structure factors to the thermodynamic limit to determine the nature of the quantum state. Our results suggest that the intermediate phase (with $J_2/J_1 \sim 0.2-0.35$) may be a spin liquid phase with vanishing spin/dimer correlations at the large distance limit. The nature of such a phase will be explored based on comparison with variational wavefunctions.

1:39PM Z8.00013 Searching for the Topological Degeneracy in the Hubbard Model on a Honeycomb Lattice, BRYAN CLARK, Princeton Center for Theoretical Science, Princeton University — Recent quantum Monte Carlo calculations by Meng, et. al [1] have produced strong numerical evidence for a topological Z_2 spin liquid on the Hubbard model on the honeycomb lattice. One feature of these spin liquids is the presence of a ground state degeneracy that depends on the manifold on which the system lives. Using finite temperature QMC calculations, we identify what states can live in the low-lying spectra, constraining the options for topologically degenerate ground states. In this talk we discuss these bounds and the implications for the Z_2 spin liquid. [1] Z. Y. Meng, T. C. Lang, S. Wessel, F. F. Assaad, and A. Muramatsu, Quantum spin-liquid emerging in two-dimensional correlated Dirac fermions, Nature 464, 847 (2010).

1:51PM Z8.00014 Emergent critical phase in a 2D frustrated Heisenberg model, PETER P. ORTH, Karlsruhe Institute of Technology (KIT), PREMALA CHANDRA, PIERS COLEMAN, Rutgers University, JOERG SCHMALIAN, Karlsruhe Institute of Technology (KIT) — It is well-known that a discrete Ising (Z_2) order parameter emerges in the frustrated square lattice J_1 - J_2 -Heisenberg model, which may be broken at finite temperature. We ask whether a different discrete symmetry Z_q with $q > 2$ may be found in other frustrated Heisenberg models, giving rise to a different finite temperature phase transition. Indeed, we identify an emergent Z_6 symmetry at low temperatures in a frustrated Heisenberg model on a 2D lattice that contains both the sites of the triangular and its dual honeycomb lattice. Our analysis combines a spin-wave expansion, susceptible to short-distance physics, with renormalization group arguments of the corresponding long-wavelength non-linear sigma model. Our results are even more appealing since the Z_6 clock model has a rich finite temperature phase diagram with two distinct Berezinskii-Kosterlitz-Thouless (BKT) phase transitions separated by a massless critical phase. We also discuss possible realizations of this phenomenon using cold-atoms in optical lattices.

Session Z9 DMP GMAG: Focus Session: Complex Bulk Oxide: General Properties 209

11:15AM Z9.00001 Local atomic structure of the layered compound SrFeO_2 , KAZUMASA HORIGANE, Department of Physics, University of Virginia, ANNA LLOBET, Los Alamos National Laboratory, KEESEONG PARK, DESPINA LOUCA, Department of Physics, University of Virginia — SrFeO_2 exhibits several unexpected structural and physical properties. Its antiferromagnetic transition temperature $T_N=473\text{K}$ is unusually high for a two-dimensional layered structure. First-principle calculations on SrFeO_2 showed that the Fe 3d down-spin electrons occupy the nondegenerate d_{z^2} level rather than the degenerate (d_{xz} , d_{yz}) levels. This is in good agreement with the absence of a Jahn-Teller instability and the existence of the three dimensional antiferromagnetic ordering because the out-of plane direct Fe-Fe exchange is comparable in strength to the in-plane Fe-O-Fe superexchange. Therefore, it is expected that there is no structure instability in SrFeO_2 . Using the pair distribution function (PDF) analysis to characterize the local structure of SrFeO_2 , we observed that the local symmetry is lower than the average P4/mmm crystal symmetry. In particular, the FeO_2 planes are buckled, with two unique buckling angles along the a-axis. The buckling angle of Fe-O-Fe is reduced from 180° with increasing temperature, accompanied by a reduction of the Fe magnetic moment. Thus the local structure instability correlates with the magnetism where the distortions suppress orbital overlap.

11:27AM Z9.00002 Phonon anomalies and critical fluctuations associated with charge stripes in $\text{La}_{1.67}\text{Sr}_{0.33}\text{NiO}_4$, SVETLANA ANISIMOVA, DAN PARSHALL, DMITRY REZNIK, University of Colorado at Boulder, DANIEL LAMAGO, LLB, CEA Saclay, DOUGLAS ABERNATHY, SNS, Oak Ridge National Laboratory, KAROL MARTY, MARK LUMSDEN, HFIR, Oak Ridge National Laboratory, G. GU, J.M. TRANQUADA, Brookhaven National Laboratory — We will report inelastic neutron scattering measurements of the spectrum of charge excitations in the stripe-ordered phase of $\text{La}_{2-x}\text{Sr}_x\text{NiO}_4$ ($x = \frac{1}{3}$). We identified clear signature of charge stripes at low energies in the nickelates. Our results imply that dynamic stripes are critical fluctuations associated with the stripe-ordering transition. We also observed a phonon anomaly correlated with dynamic stripes above the static-ordering transition, which occurs at 241 K. Our results elucidate the nature of dynamic charge stripes and their signature in the neutron spectra.

11:39AM Z9.00003 Rare orbital glass state in single crystalline $\text{Y}_2\text{Mo}_2\text{O}_7$, HARLYN SILVERSTEIN, University of Manitoba, HAIDONG ZHOU, National High Magnetic Field Laboratory, ALANNAH HALLAS, University of Manitoba, JASON GARDNER, YIMING QIU, National Institute of Standards and Technology, GEORG EHLERS, ANDREI SAVICI, Oak Ridge National Laboratory, ZAHRA YAMANI, Chalk River Laboratories, MICHEL GINGRAS, University of Waterloo, BRUCE GAULIN, KATHARINA FRITSCHKE, KATE ROSS, McMaster University, CHRISTOPHER WIEBE, University of Winnipeg — Perhaps one of the most curious cases of frustrated pyrochlores, $\text{Y}_2\text{Mo}_2\text{O}_7$ was first classified as a spin glass in 1986. Conventionally, spin glasses must exhibit some sort of chemical disorder although oxygen vacancies and Y-Mo site mixing is virtually absent in all studies to date. NMR and neutron PDF experiments show the presence of local disorder. While other studies have shown a lattice deformation occurring near $T_g=22\text{K}$, these distortions cannot be detected globally and may not be enough to explain the spin glass behavior. For 25 years, researchers have struggled to resolve spin glass theory with the data; the problem lies in that, until now, scientists have been unable to grow single crystal samples due to the oxidation of Mo^{4+} to Mo^{6+} at low temperatures. Here, we report the synthesis and characterization of the world's first single crystalline sample of $\text{Y}_2\text{Mo}_2\text{O}_7$. Unlike powder samples, single crystalline $\text{Y}_2\text{Mo}_2\text{O}_7$ heat capacity measurements show a T^2 dependence. Neutron scattering experiments show isotropic, broad, liquid-like collective modes and high-Q diffuse scattering characteristic of an orbital liquid to orbital glass transition at T_g .

11:51AM Z9.00004 Anisotropic magnetic properties of the KMo_4O_6 , M. ANDRADE, M. L. MAFFEI, C. A. M. DOS SANTOS, B. FERREIRA, A. F. SARTORI, Escola de Engenharia de Lorena - USP — Electrical resistivity measurements in the tetragonal KMo_4O_6 single crystals show a metal-insulator transition (MIT) near 100K. Magnetization measurements as a function of temperature show no evidence of magnetic ordering at this MIT [1]. Single crystals of KMo_4O_6 were obtained by electrolysis of a melt with a molar ratio of $\text{K}_2\text{MoO}_4:\text{MoO}_3 = 6:1$. The process were carried out at 930°C with a current of 20-25mA for 52h in argon atmosphere. After that, electrodes were removed from the melt alloying the crystals to cool down to room temperature rapidly. Scanning Electron Microscopy (SEM) showed that the black single crystals were grown on the platinum cathode. Typical dimensions of the single crystals are $1 \times 0.2 \times 0.2 \text{ mm}^3$. X-ray diffractometry confirmed that the single crystals have KMo_4O_6 tetragonal crystalline structure with space group $P\bar{4}$. Magnetization measurements were performed parallel and perpendicular to the c-axis from 2 to 300K. The results show anisotropic behavior between both directions. Furthermore, the temperature independence of the magnetization at high temperature and the upturn at low temperature are observed in agreement with previous results [1]. MxH curves measured at several temperatures show nonlinear behavior and a small magnetic ordering. The magnetic ordering seems to be related to the MIT near 100K. This material is based upon support by FAPESP (2009/14524-6 and 2009/54001-6) and CNPq/NSF (490182/2009-7). M. Andrade is CAPES fellow and C.A.M. dos Santos is CNPq fellow.

12:03PM Z9.00005 $\text{Cu}_3\text{Nb}_2\text{O}_8$: A Multiferroic with Chiral Coupling to the Crystal Structure, ROGER JOHNSON, Clarendon Laboratory, Department of Physics, University of Oxford, Oxford, OX1 3PU, United Kingdom, SUNIL NAIR, IISER Pune, Sai Trinity Building, Garware Circle, Sutarwadi, Pashan, Pune, Maharashtra 411021, India, LAURENT CHAPON, Institut Laue-Langevin, BP 156X, 38042 Grenoble, France., ALESSANDRO BOMBARDI, CARLO VECCHINI, Diamond Light Source, Harwell Science and Innovation Campus, Didcot, OX11 0DE, United Kingdom, D. PRABHAKARAN, ANDREW BOOTHROYD, PAOLO RADAELLI, Clarendon Laboratory, Department of Physics, University of Oxford, Oxford, OX1 3PU, United Kingdom — We will present recent bulk properties, neutron powder diffraction, and non-resonant x-ray diffraction measurements on a new multiferroic material, $\text{Cu}_3\text{Nb}_2\text{O}_8$. We demonstrate that an electric polarization evolves simultaneously with a generalised helicoidal magnetic ordering. Contrary to conventional models of multiferroicity, the electric polarization was found to lie perpendicular to the common rotation plane of the magnetic moments. We present a new model applicable to a specific class of crystals; those that support a macroscopic "ferroaxial" vector and adopt a helicoidal magnetic structure. Our new interpretation, which may explain the multiferroic properties of a number of systems reported in recent literature, is based upon the well-understood inverse Dzyaloshinskii-Moriya interaction, but requires an altogether different interpretation.

12:15PM Z9.00006 THz and infrared excitation spectrum below the Jahn-Teller transition in $\text{Sr}_3\text{Cr}_2\text{O}_8$, ZHE WANG, MICHAEL SCHMIDT, AXEL GÜNTHER, SEBASTIAN SCHAIKE, NIKOLA PASCHER, FRANZ MAYR, YURII GONCHAROV, HANS-ALBRECHT KRUG VON NIDDA, ALOIS LOIDL, Experimental Physics V, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, D-86135 Augsburg, Germany, DIANA QUINTERO-CASTRO, A.T.M.N. ISLAM, BELLA LAKE, Helmholtz-Zentrum Berlin für Materialien und Energie, D-14109 Berlin, Germany, JOACHIM DEISENHOFER, Experimental Physics V, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, D-86135 Augsburg, Germany — We report on optical excitations observed recently in $\text{Sr}_3\text{Cr}_2\text{O}_8$ by THz and infrared spectroscopy. Low-energy excitations below 3 THz are detected by THz time domain spectroscopy. These excitations can be divided into two different classes according to the temperature-dependent properties. One is emergent right below the Jahn-Teller transition temperature, which is determined by specific heat measurement to occur at 285 K [1, 2]. The other appears only below 100 K, where the fluctuations are sufficiently suppressed, consistent with the temperature dependence of low-energy Raman modes [3]. Infrared transmission measurements reveal a broad crystal-field excitation, which can be associated with an electronic transition from E to T2 orbital states.

12:27PM Z9.00007 Magnetic and Orbital Excitations in $\text{Sr}_3\text{CuIrO}_6$ ¹, J.P. HILL, X. LIU, M. DEAN, W. YIN, A. TSVELIK, Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, NY 11973, J. KIM, D. CASA, M.H. UPTON, APS, Argonne National Laboratory, Illinois 60439, USA, H. GRETARSSON, Y.-J. KIM, Dept. of Physics, University of Toronto, Canada M5S 1A7, T. QI, G. CAO, Dept. of Physics and Astronomy, U. Kentucky, Kentucky 40506, L. HOZOI, V. KATUKURI, J. V.D. BRINK, Institute for Theoretical Solid State Physics, IFW Dresden, 01069 Dresden, Germany — We report resonant inelastic x-ray scattering studies of the one-dimensional $\text{Sr}_3\text{CuIrO}_6$ at the Ir L_3 edge, with $\Delta E=40$ meV. At high energies, we find peaks at 0.6 eV, 0.9 eV, 3 eV, 4 eV and 6 eV. These peaks are non-dispersive, well-defined excitations. On the basis of quantum chemistry calculations, we are able to identify the first two as excitations within the t_{2g} manifold and the next two as between the t_{2g} and e_g manifolds, together with charge transfer excitations from the O $2p$ to the Ir $5d$. The 6 eV feature is another $t_{2g} - e_g$ excitation. From these we are able to determine both the spin-orbit and non-cubic crystal field splittings. We find that they are of comparable strength. In addition, magnetic excitations are observed, corresponding to excitations of the $j_{1/2}$ isospin. We find these are highly dispersive along the chain direction with a bandwidth of 20 meV and a gap of 30 meV. These results allow a complete modeling of the spin and orbital degrees of freedom in this model compound and we conclude an atomic, spin-orbit coupled description works well.

¹Work performed at BNL was supported by US DOE, Office of Science, DMSE under contract no. DE-AC02-98CH10886.

12:39PM Z9.00008 Probing Spin-Orbit Coupling in Iridium 5d Compounds with X-ray Absorption Spectroscopy, J.P. CLANCY, University of Toronto, N. CHEN, W.F. CHEN, C.Y. KIM, Canadian Light Source, K.W. PLUMB, Y.J. KIM, University of Toronto — Iridium-based transition metal oxides have begun to attract considerable interest following recent proposals of exotic electronic and magnetic ground states (topological insulators, topological semi-metals, spin liquids, and spin-orbital Mott insulators) driven by large spin-orbit coupling effects. We have performed x-ray absorption spectroscopy (XAS) measurements on a series of iridium-based compounds (such as Ir, IrCl₃, IrO₂, Na₂IrO₃, Sr₂IrO₄, and Y₂Ir₂O₇) in order to investigate the magnitude of the spin-orbit interactions in these systems. By determining the branching ratio of the XAS white-line intensities at the Ir L₂ and L₃ absorption edges, we obtain a direct measure of the expectation value for the spin-orbit operator ($L \cdot S$). These measurements reveal remarkably strong spin-orbit interactions in almost all Ir-based compounds, with branching ratios up to several times larger than the statistical value. The branching ratio is found to be largely independent of electronic properties (metal or insulator), ionization state (Ir³⁺ [5d⁶] or Ir⁴⁺ [5d⁵]), and chemical composition (oxide or halide), although it does appear to be correlated with local Ir site symmetry and Ir-Ir bond distances.

12:51PM Z9.00009 Investigation of magnetic phase transitions in B-site disordered $\text{PbBxB}'\text{-xO}_3$ ($B = \text{Fe, Co}$ and $B' = \text{Nb, Ta}$), SHRAVANI CHILLAL, ETH Hoenggerberg, Switzerland, ELENA POPOVA, Saint Petersburg State University and Ioffe Physico-Technical Institute RAS, Russia, ERIK EULF, SEVERIAN GVASALIYA, ETH Hoenggerberg, Switzerland, TATIANA SHAPLYGINA, SERGEY LUSHNIKOV, Ioffe Physico-Technical Institute RAS, Russia, ANDREY ZHELUDEV, ETH Hoenggerberg, Switzerland, LABORATORY FOR NEUTRON SCATTERING AND MAGNETISM, ETH HOENGGERBERG, 8093 ZURICH, SWITZERLAND TEAM, IOFFE PHYSICO-TECHNICAL INSTITUTE RAS, 194021 ST. PETERSBURG, RUSSIA COLLABORATION, SAINT PETERSBURG STATE UNIVERSITY, DEPARTMENT OF CRYSTALLOGRAPHY, 199034, ST. PETERSBURG, RUSSIA COLLABORATION — Materials such as $\text{PbFe}_{0.5}\text{Nb}_{0.5}\text{O}_3$ (PFN-0.5)/ $\text{PbFe}_{0.5}\text{Ta}_{0.5}\text{O}_3$ (PFT-0.5) and $\text{PbCo}_{0.33}\text{Nb}_{0.67}\text{O}_3$ (PCN-0.33) are relaxor ferroelectrics. $\text{PbFe}_{0.5}\text{Nb}_{0.5}\text{O}_3$ (PFN-0.5) also shows anti-ferromagnetic order below ~ 143 K. Though multiferroicity is an important property of PFN-0.5, its uniqueness stems from coexisting anti-ferromagnetic and spinglass phases below ~ 12 K. Presently, it is the only known such case in a Heisenberg 3D spin system. We report a first systematic study of the H-T phase diagram of PFN-0.5 and discuss the results in the context of existing theories. In addition, we study the magnetic properties of PFT-0.5 and PCN-0.33. While PFN-0.5 and PFT-0.5 demonstrate similar behavior, PCN-0.33 does not show any anomalies that could signify magnetic ordering. We propose that the observed dramatic differences may result from partial B-site ordering.

1:03PM Z9.00010 Direct neutron scattering-based observation of spin excitons in LaCoO_3 ¹, S. EL-KHATIB, American University of Sharjah, D. PHELAN, University of Minnesota, J.A. BORCHERS, J. BARKER, P. BUTLER, NIST Center for Neutron Research, H. ZHENG, J.F. MITCHELL, Argonne National Laboratory, C. LEIGHTON, University of Minnesota — We report temperature-dependent small angle neutron scattering (SANS) results on undoped LaCoO_3 single crystals. The data reveal two main scattering components; a high q signal increasing with T above 50 K, and a low q component that turns on sharply below 60 K. The former is shown to be due to inelastic scattering quantitatively consistent with the excitations associated with the spin-state transition. Of greater interest, the low q scattering is shown to be of Guinier form, revealing scattering from a dilute assembly of magnetic objects of size approximately 15-20 nm. The abrupt onset of this scattering at 60 K, i.e. very close to the point at which prior work provided evidence of formation of interacting magnetic excitons, suggests that this represents the first direct scattering-based observation of magnetic excitons forming around O defects in LaCoO_3 .

¹Work supported by DOE (neutron scattering) and NSF

1:15PM Z9.00011 High-pressure studies on Ba-doped cobalt perovskites by neutron diffraction¹, HUIBO CAO, VASILE GARLEA, Oak Ridge National Laboratory, FANGWEI WANG, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, ANTONIO DOS SANTOS, Oak Ridge National Laboratory, ZHAOHUA CHENG, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences — Cobalt perovskite possess rich structural, magnetic and electrical properties depending on the subtle balance of the interactions among the spin, charge, and orbital degrees of freedom. Divalent hole-doped cobalt perovskites $\text{LaA}^{2+}\text{CoO}_3$ exhibit structural phase transitions, metal-insulator transitions, and multi-magnetic phase transitions. High-pressure measurement is believed to mimic the size effects of the doped ions. We performed neutron diffraction experiments on selected Ba-doped LaCoO_3 under pressures up to 6.3 GPa at SNAP at Spallation Neutron Source of ORNL. This work focuses on the high-pressure effects of the selected Ba-doped samples and the change of the phase diagram with pressure.

¹This research is supported by UT Battelle, LLC, Contract DE-AC05-00OR22725 for U.S. D.O.E., and the National Basic Research Program of China (973 Program, 2010CB833102).

1:27PM Z9.00012 Electric field tuning of the metal-magnetic transition in ionic liquid gated $\text{Ca}_3\text{Ru}_2\text{O}_7$ flakes, CONOR PULS, XINXIN CAI, Physics Department, The Pennsylvania State University, JIN PENG, ZHIQIANG MAO, Physics Department, Tulane University, YING LIU, Physics Department, The Pennsylvania State University — The recent application of ionic liquids in electric field-effect devices has provided for unprecedentedly high surface charge accumulations ($\approx 10^{14} \text{ cm}^{-2}$) due to the formation of an electronic double layer at their interface with various materials. This technique provides a tool to explore metal-insulator transitions and superconductivity in various materials including transition metal oxides. We extend this technique to the study of the physics of strongly correlated electrons in complex oxides such as the Ruddlesden-Popper (R-P) series $\text{Ca}_{n+1}\text{Ru}_n\text{O}_{3n+1}$, where $n = 1, 2, \dots \infty$. $\text{Ca}_3\text{Ru}_2\text{O}_7$, the $n = 2$ member of the R-P series, features antiferromagnetic ordering below 56 K and a first-order metal-insulator transition along with a structural transition at 48 K. We developed a technique for fabricating Hall bar devices on $\text{Ca}_3\text{Ru}_2\text{O}_7$ flakes prepared by mechanical exfoliation from bulk crystals, and performed low-temperature measurements using the ionic liquid DEME-TFSI in a top-gate configuration. We will discuss electrical transport results and the metal-magnetic transition with gate voltage tuning in these devices.

1:39PM Z9.00013 p-Electron Magnetism in anion doped BaTiO_{3-x}X_x (X=C,N,B), CHRISTOPH GRUBER, PEDRO OSVALDO BEDOLLA VELAZQUEZ, JOSEF REDINGER, PETER MOHN, Vienna University of Technology, MARTIJN MARSMAN, University of Vienna — We present VASP calculations using the HSE functional for carbon, nitrogen, and boron doped BaTiO_{3-x}X_x (X=C,N,B). We calculate a 40-atom supercell and replace one oxygen atom by C,N, or B. For all three substituents we find a magnetically ordered groundstate which is insulating for C and N and halfmetallic for B. The changes in the electronic structure between the undoped and the doped case are dominated by the strong crystal field effects together with the large band splitting for the impurity p-bands. Using an MO picture we give an explanation for the pronounced changes in the electronic structure between the insulating non-magnetic state and the as well insulating magnetic state for doped BaTiO₃. p-element doped perovskites could provide a new class of materials for various applications ranging from spin-electronics to magneto-optics.

1:51PM Z9.00014 Spin-dependent Optical Properties of Multiferroic EuO and GdN, CHUN-GANG DUAN, Key Laboratory of Polar Materials and Devices, Ministry of Education, East China Normal University — We present a first-principles study on the linear and non-linear optical properties of multiferroic EuO and GdN. In particular, we have decomposed the linear and non-linear optical spectra into spin-dependent terms, i.e., we could obtain optical spectra from individual spin channel. With the help of such method, a regular optical spectrum could present information of spin-dependent band structures, which is of great importance to the study of ferromagnetic insulators.

Friday, March 2, 2012 11:15AM - 2:15PM – Session Z11 DMP: Focus Session: Graphene Devices - Hybrid Structures 210B

11:15AM Z11.00001 Nano-patterning of fluorinated graphene by electron beam, SAVERIO RUSSO, FREDDIE WITHERS, THOMAS BOINTON, Centre for Graphene Science, University of Exeter, Exeter, United Kingdom, MARC DUBOIS, Clermont Université, UBP, Laboratoire des Matériaux Inorganiques, Aubière, France, MONICA CRACIUN, Centre for Graphene Science, University of Exeter, Exeter, United Kingdom — The development of transparent electronics is reliant on achieving high conductivity materials with a gate tuneable carrier mobility and low contact resistance at the interface with metals. Graphene — a layer of carbon atoms in a honeycomb lattice — offers just such a possibility. Functionalizing graphene with fluorine induces the opening of a band gap in the otherwise semimetallic graphene. Here we demonstrate that fluorinated graphene — a wide gap semiconductor with sp³ electron orbital hybridization — can be selectively reduced to graphene by electron-beam irradiation. We employ this functionality to pattern conductive nanostructures in a sheet of fluorinated graphene, realizing transparent graphene-based electronic devices such as nanoribbons without the need for etching of graphene. Electrical transport experiments over a wide range of temperatures (from 300K to 4K) of the ribbons show a transport gap whose size is inversely proportional to the width of the patterned ribbons. In this gap, electrons are localized, and charge transport is dominated by variable range hopping. Charging effects constitute a significant portion of the activation energy, and we find that the activation energy scales well with the width of the ribbons [Nano Lett. 11, 3912 (2011)].

11:27AM Z11.00002 Room-temperature gating of molecular junctions using few-layer graphene nanogap electrodes¹, AMELIA BARREIRO, FERRY PRINS, JUSTUS RUITENBERG, JOHANNES SELDENTHUIS, Kavli Institute of Nanoscience, TU Delft, NURIA ALIAGA-ALCALDE, ICREA, Universitat de Barcelona, LIEVEN VANDERSYPEN, HERRE VAN DER ZANT, Kavli Institute of Nanoscience, TU Delft, KAVLI INSTITUTE OF NANOSCIENCE, TU DELFT COLLABORATION — We report on a new method based on feedback controlled electroburning to controllably form nanogaps in few-layer graphene [1]. The gaps have separations on the order of 1-2 nm as estimated from a Simmons model for tunneling. Furthermore, molecules are deposited in the nanogaps. These molecular junctions display gateable IV-characteristics at room temperature. Gateable transport through molecules contacted between the electrodes demonstrates the potential of room-temperature operation of our molecular devices. Combined with the observed stability in time, our study shows that few-layer graphene nanogaps are an interesting alternative to metal electrodes. [1] Ferry Prins, Amelia Barreiro, Justus Ruitenber, Johannes Seldenthuis, Núria Aliaga-Alcalde, Lieven Vandersypen, Herre van der Zant, Nanoletters 11 (2011) 4607 - 4611

¹Fundamental Research on Matter (FOM)

11:39AM Z11.00003 Graphene Nanogap for Gate Tunable Quantum Coherent Single Molecule Electronics, TOMAS LOFWANDER, ANDERS BERGVALL, KRISTIAN BERLAND, PER HYLDGAARD, SERGEY KUBATKIN, Dep. of Microtechnology and Nanoscience - MC2, Chalmers University of Technology, SE-412 96 Goteborg, Sweden — We present atomistic calculations¹ of quantum coherent electron transport through fulleropyrrolidine terminated molecules bridging a graphene nanogap. We predict that three difficult problems in molecular electronics with single molecules may be solved by utilizing graphene contacts: (1) a back gate modulating the Fermi level in the graphene leads facilitate control of the device conductance in a transistor effect with high on/off current ratio; (2) the size mismatch between leads and molecule is avoided, in contrast to the traditional metal contacts; (3) as a consequence, distinct features in charge flow patterns throughout the device are directly detectable by scanning techniques. We show that moderate graphene edge disorder is unimportant for the transistor function.

11:51AM Z11.00004 The Role of Surfactant Adsorbates on Hysteresis and Carrier Mobility in Graphene Transistors, CHIH-JEN SHIH, GERALDINE PAULUS, QING HUA WANG, ZHONG JIN, MOON-HO HAM, DANIEL BLANKSCHTEIN, MICHAEL STRANO, Massachusetts Institute of Technology, MIT TEAM — Understanding the role of polar and ionic adsorbates on the transport characteristics of graphene transistors is important for the development of graphene-based sensor devices and printable electronics using graphene solutions. We have investigated the effects of commonly used surfactants for graphene dispersion in aqueous solution on transport characteristics of graphene transistors. The adsorbates are found to transfer electrons to graphene, scatter carrier transport, and induce more electron-hole puddles when the graphene is on an SiO₂ substrate. We relate the change in transport characteristics to specific properties of a series of anionic, cationic, and neutral surfactants using a modification of a self-consistent transport theory. To understand the effects of surfactant adsorbates trapped on either side of the graphene, suspended devices were fabricated. Strong hysteresis is observed when both surfaces were exposed to the surfactants, attributable to their function as charge traps. This work is the first to demonstrate the control of hysteresis, allowing us to eliminate it for sensor and device applications or enhance it for non-volatile memory applications.

12:03PM Z11.00005 Model results for graphene electrodes in molecular junctions, CARLO MOTTA, Dept. Materials Science, Università di Milano-Bicocca (Italy), MARIO ITALO TRIONI, CNR – National Research Council of Italy, ISTM (Italy), GIAN PAOLO BRIVIO, ETSF, Dept. Materials Science, Università di Milano-Bicocca (Italy), KIZHAKEYIL LUKOSE SEBASTIAN, IPC Department Indian Institute of Science, Bangalore (India), DANIEL SÁNCHEZ PORTAL, Centro Mixto CSIC-UPV/EHU and Donostia International Physics Center (DIPC) — Graphene is a material with a high potential for nanoelectronic applications as transparent conductive electrode. In view of a graphene-based electronics, a possible way to bridge graphene electrodes is by molecular linkers either organic molecules or graphene-derived systems such as graphene nanoribbons (GNR). In the present work, we investigated the electronic and conductive properties of such junctions for two different devices. First we modeled a photochromic switch based on diarylethene molecules, which can be activated/deactivated by light. We found a large on/off current ratio, which can be improved by modifying the functional groups of the molecule. We then investigated the properties of graphene/GNR/graphene junctions, showing that their conductive properties can be tailored by changing the length and width of the GNR. The calculations have been carried out by using the non-equilibrium Green's function method combined with density functional theory.

12:15PM Z11.00006 ABSTRACT WITHDRAWN —

12:27PM Z11.00007 Graphene Chemical sensors on Flexible Substrates, BENJAMIN MAILLY, ALLEN HSU, Massachusetts Institute of Technology, FRANCESCO PAPPALARDO, STMicroelectronics, DAWN NIDA, NSRDEC, ELIO GUIDETTI, LUIGI OCCHIPINTI, SALVATORE COFFA, STMicroelectronics, JING KONG, TOMAS PALACIOS, Massachusetts Institute of Technology, TOMAS PALACIOS TEAM — Thanks to its all-surface 2D structure combined with a very high carrier mobility, Graphene is a very promising candidate for high sensitivity and low noise chemical sensing. Indeed, graphene devices can perform electrical detection for chemical sensing in a wide variety of applications, including pH monitoring in electrolytes and glucose measurements in blood. Furthermore, the fabrication of low cost and flexible sensors can be made possible by enabling the integration of graphene on plastic substrates. Our group has developed the first solution-gated graphene field effect transistor (SGFET) on a flexible substrate, PolyEthylene Naphthalate (PEN). For this purpose, graphene grown by chemical vapor deposition is transferred on the PEN substrate, where the metal contacts had already been evaporated. The characterization of our devices in a phosphate buffer solution displays good transconductance around $0.9 \text{ mS} \cdot \text{mm}^{-1}$. pH measurements have been performed using these devices and a sensitivity as high as 22 mV/pH have been demonstrated. In addition, long term pH monitoring was demonstrated in these devices. Our on-going work focuses on studying the influence of the substrate as well as the presence of residues on the graphene surface in the pH sensing mechanism.

12:39PM Z11.00008 Graphene field-effect biosensor arrays, B. WANG, Department of Physics, Penn State University, K.L. LIDDELL, C.D. KEATING, Department of Chemistry, Penn State University, J. ZHU, Department of Physics, Penn State University — We report on the study of chemical and biological sensing using graphene field-effect transistor (GFET) arrays. Large-scale single layer graphene sheets are synthesized by low-pressure chemical vapor deposition on copper. We fabricate GFET arrays capable of operating in solutions by passivating the graphene channel with a thin oxide layer. This oxide layer also serves as the electrolyte gate dielectrics and the sensing surface. The GFET arrays exhibit an average field-effect mobility of $\sim 5000 \text{ cm}^2/\text{Vs}$ and small hysteresis in gate sweeps. We demonstrate the sensing operation of the GFET via measuring the pH value of phosphate buffer solutions. Gate sweeps indicate an approximately linear shift of the Dirac point with increasing pH, with an average slope of $+46 \text{ mV/pH}$. The viability of using GFETs to detect the specific binding of biomolecules will also be discussed.

12:51PM Z11.00009 A model of large volumetric capacitance in graphene supercapacitors based on ion clustering, BRIAN SKINNER, University of Minnesota, MICHAEL FOGLER, University of California, San Diego, BORIS SHKLOVSKII, University of Minnesota — Electric double layer supercapacitors are promising devices for high-power energy storage based on the reversible absorption of ions into porous, conducting electrodes. Graphene is a particularly good candidate for the electrode material in supercapacitors due to its high conductivity and large surface area. In this paper we consider supercapacitor electrodes made from a stack of graphene sheets with randomly-inserted “spacer” molecules. We show that the large volumetric capacitances $C > 100 \text{ F/cm}^3$ observed experimentally can be understood as a result of collective intercalation of ions into the graphene stack and the accompanying nonlinear screening by graphene electrons that renormalizes the charge of the ion clusters.

1:03PM Z11.00010 Morphology-controlled graphene aerogel for energy storage, SON TRUONG NGUYEN, Department of Mechanical Engineering - National University of Singapore, HOA TIEN NGUYEN, School of Chemical and Biomedical Engineering - Nanyang Technological University, HAI MINH DUONG, Department of Mechanical Engineering - National University of Singapore — The development of new anode/cathode materials with highly conductive, non-corrosive, high specific surface area and high porosity for energy storage devices is highly desirable. Graphene aerogels have been focused emergently recently due to novel properties of the graphene. However, the aerogel-based application performance strongly depends on the morphology and structure of the graphene aerogels. The graphene aerogels with low-density have thinner struts, a different distribution of particle sizes, and less internal connectivity. This, in turn, changes the way the material can transport electric charge. As a result, the highest surface area graphene aerogels end up having the worst electrical conductivity, and the most conductive graphene aerogels have lowest surface areas. So the best designs of the developed graphene aerogel nanostructures in terms of pore size, porosity, density and mechanical properties for energy storage devices are essential. In this work, we develop a new fabrication method of graphene aerogels with well-controlled morphology and high electrical conductivity from graphene oxide through the supercritical drying process. The morphology and electrical conductivity of the graphene aerogels are controlled by the precursor contents and the synthesis conditions. The experimental results are very useful for experimentalists deciding the best graphene aerogel nanostructures for their needs.

1:15PM Z11.00011 Electrostatic control of many-body interactions in graphene: Observation of the effects of doping on the saddle-point exciton, KIN FAI MAK, Columbia University, KELIANG HE, Case Western Reserve University, NICK PETRONE, JIM HONE, Columbia University, JIE SHAN, Case Western Reserve University, TONY HEINZ, Columbia University — Significant excitonic effects were recently identified in the optical response of graphene through the asymmetric resonance feature at 4.62 eV in the optical conductivity. The peak, which is red-shifted by nearly 600 meV from the predicted band-to-band transition energy,¹ can be considered as a saddle-point exciton. Here we report a systematic study of this excitonic feature as a function of the doping density, for densities extending up to the metallic regime² ($\sim 10^{14} \text{ cm}^{-2}$). With increasing density of either electrons or holes, the excitonic resonance is found to shift to the red and to become more symmetric in form. These experimental features agree very well with a recent ab-initio GW-Bethe-Salpeter calculation³ and can be understood as a consequence of enhanced “metallic” screening of the graphene dielectric function.⁴ In addition, analysis of the width of the excitonic peak provides information on the quasiparticle lifetime. Mechanisms for the inferred rapid quasiparticle decoherence will be discussed.

1:39PM Z11.00013 First-principles study of hybrid Graphene/MnO₂ bilayers, MIGUEL PRUNEDA, Centro de Investigación en Nanociencia y Nanotecnología (CIN2-CSIC) — Oxide nanosheets are an important and promising component for creating new materials. Their capacitance properties are particularly appealing for electric batteries. Manganese oxide nanosheets are abundant, environmental friendly, have low cost, and high electrochemical activity. However MnO₂ poor electrical conductivity and chemical stability limits its applicability as electrode material. Hybrid graphene/oxide nanostructures have been proposed to overcome these difficulties. Here, density functional theory calculations are performed to better understand the electronic properties of heterobilayers made from graphene and MnO_x monolayers. The charge transfer between graphene and MnO₂ monolayers are analyzed and related to the presence of oxygen vacancies in different concentrations, which are known to induce atomic reconstructions and phase transformations of the oxide. Magnetic properties of the heterobilayers will also be discussed.

1:51PM Z11.00014 Boron Nitride Nanoribbons: Synthesis and Future Directions¹, ASHLEY GIBB, KRIS ERIKSON, UC Berkeley, ALEX SINITSKII, University of Nebraska Lincoln, MICHAEL ROUSSEAS, NASIM ALEM, UC Berkeley, JAMES TOUR, Rice University, ALEX ZETTL, UC Berkeley, Lawrence Berkeley National Lab — Boron Nitride Nanoribbons (BNNR) have been theorized to have many interesting electrical and magnetic properties and edge states, but these characteristics have not been experimentally verified due to challenges in synthesis and purification. We have produced BNNRs by longitudinally splitting boron nitride nanotubes (BNNT) using potassium vapor as an intercalant. Due to the strong interactions between boron nitride sheets, separation of nanoribbons from their parent tubes is challenging. We have used various solvent systems to assist with separation of the ribbons with the goal of probing their properties.

¹Research supported in part by the National Science Foundation.

2:03PM Z11.00015 Electron-Hole Polarization Dynamics in Graphene Oxide¹, ANNEMARIE L. EXARHOS, MICHAEL E. TURK, ZHENG TANG LUO, A.T.C. JOHNSON, JAMES M. KIKKAWA, Department of Physics and Astronomy, University of Pennsylvania — Graphene oxide (GO) has been shown to emit broadband visible and near infrared photoluminescence (PL). Here we use polarization sensitive optical spectroscopy to study spectral diffusion and temporal dynamics of electron-hole polarization in this material. Steady state polarization memory measurements show strong polarization memory close to the excitation energy, which weakens gradually in moving toward lower emission energies. To understand the dynamics underlying this behavior, we also perform time-resolved PL studies using an optical Kerr gate with sub-picosecond temporal resolution. Polarization memories show ultrafast dynamics within the PL lifetime in solid GO preparations where the incident light lies fully in the plane of the GO flakes. Using additional knowledge gained from optical anisotropy measurements, we discuss the relevance of our polarization memory data to the origins of PL in these systems.

¹We gratefully acknowledge the primary support of NSF DMR-0907226. Construction of the Kerr gate system was supported by the Department of Energy Office of Basic Energy Sciences Award DE-SC0002158. Sample fabrication supported under NSF NSEC DMR08-32802

Friday, March 2, 2012 11:15AM - 2:15PM – Session Z12 DCMP: Graphene: Electronic Structure and Interactions - Spectroscopy 210C

11:15AM Z12.00001 Phonon self-energy corrections to non-zero wavevector phonon modes in single-layer graphene, PAULO ARAUJO, Massachusetts Institute of Technology, DANIELA MAFRA, Universidade Federal de Minas Gerais, KENTARO SATO, RICHIRO SAITO, Tohoku University, JING KONG, MILDRED DRESSELHAUS, Massachusetts Institute of Technology — Phonon self-energy corrections have mostly been studied theoretically and experimentally for phonon modes with zone-center ($q=0$) wave-vectors. Here, gate-modulated Raman scattering is used to study phonons of a single layer of graphene (1LG) in the frequency range from 2350 to 2750 cm⁻¹, which shows the G* and the G'-band features originating from a double-resonant Raman process with $q \neq 0$. The observed phonon renormalization effects are different from what is observed for the zone-center $q=0$ case. To explain our experimental findings, we explored the phonon self-energy for the phonons with non-zero wave-vectors ($q \neq 0$) in 1LG in which the frequencies and decay widths are expected to behave oppositely to the behavior observed in the corresponding zone-center $q=0$ processes. Within this framework, we resolve the identification of the phonon modes contributing to the G* Raman feature at 2450 cm⁻¹ to include the iTO+LA combination modes with $q \neq 0$ and the 2iTO overtone modes with $q=0$, showing both to be associated with wave-vectors near the high symmetry point K in the Brillouin zone.

11:27AM Z12.00002 Impact of Graphene-Metal Interfaces on the Raman and Transport Properties of Graphene Devices¹, ALLEN HSU, MARIO HOFMANN, WENJING FANG, KI KANG KIMG, JING KONG, TOMAS PALACIOS, MIT — Graphene is an amazing nano-material with many exciting properties and applications. However, due to its low dimensionality, the performance of this material is mainly limited by interfaces and surface properties. One of these interfaces, important for graphene field effect transistors and catalysts supported on graphene membranes, is that between the graphene and a metal layer. In this study, we experimentally examine the impact of various metals on graphene through Raman and Transmission Electron Microscopy. We find that strong graphene-metal interactions have significant impacts on the phonon structure in graphene. Furthermore, we observe changes in our Raman spectra relating to the crystallographic orientation between a metal and graphene.

¹Army Research Labs, MSD Focus Center, ONR Gate Muri, ISN

11:39AM Z12.00003 Raman spectroscopy of sputtered metal-graphene and metal-oxide-graphene interfaces, CHING-TZU CHEN, MARCIN GAJEK, MARCUS FREITAG, MARCELO KURODA, VASILI PEREBEINOS, SIMONE RAOUX, IBM TJ Watson Research Center — In this talk, we report our recent development in sputtering deposition of magnetic and non-magnetic metal and metal-oxide thin films on graphene for applications in spintronics and nanoelectronics. TEM and SEM images demonstrate homogeneous coverage, uniform thickness, and good crystallinity of the sputtered films. Raman spectroscopy shows that the structure of the underlying graphene is well preserved, and the spectral weight of the defect D mode is comparable to that of the e-beam evaporated samples. Most significantly, we report the first observation of graphene-enhanced surface excitations of crystalline materials. Specifically, we discover two pronounced dispersive Raman modes at the interface of graphene and the nickel-oxide and cobalt-oxide films which we attribute to the strong light absorption and high-order resonant scattering process in the graphene layer. We will present the frequency-dependent, polarization-dependent Raman data of these two modes and discuss their microscopic origin.

11:51AM Z12.00004 Effects of sliding on Raman spectrum of bilayer graphene¹, SEON-MYEONG CHOI, Korea Institute for Advanced Study, Seoul 130-722, Korea, SEUNG-HOON JHI, Department of Physics, Pohang University of Science and Technology, Pohang 790-784, Korea, YOUNG-WOO SON, Korea Institute for Advanced Study, Seoul 130-722, Korea — Electronic properties of graphene are changed by various external effects such as strain, doping, and defects, etc. Such effects can be measured by Raman spectroscopy. For example, doping and defects increase the intensities of D-peak of single layer graphene, while the external strains generate splitting of G- and 2D-peaks respectively. In bilayer graphene, sliding motions between two layers also can change its electric and optical properties. Based on the first principles calculation methods, the sliding between two layers of bilayer graphene is shown to change the electronic and phonon dispersions, thereby altering its Raman spectrum significantly.

¹Computational resources have been provided by KISTI Supercomputing Center (Project No. KSC-2011-C1-21).

12:03PM Z12.00005 Electronic Structure of Suspended Bilayer Graphene¹, PO-CHUN YEH, KEVIN KNOX, WENCAN JIN, JERRY DADAP, PHILIP KIM, RICHARD M. OSGOOD, Columbia University, ALEXEI BARINOV, ELETTRA TRIESTE — Bilayer graphene is an important medium for achieving band-gap tuning for graphene applications in digital electronics, such as in graphene nanoribbon FETs. ARPES is an important tool for measuring the electronic structure of crystals in the vicinity of the Dirac point. While accurate measurements have been made on the bilayer graphene band-structure on SiC, similar effort on free-standing graphene has not yet been reported. In this paper, we describe measurements of the band-structure of a $\sim 650 \mu\text{m}^2$ sample of exfoliated bilayer graphene suspended over $5\text{-}\mu\text{m}$ -diameter wells formed in SiO_2 on a Si substrate. The measurements, performed at the Spectromicroscopy Beamline at ELETTRA with photon energy of 27eV, show that this material is essentially undoped and we compare its band structure with that expected from tight-binding calculations.

¹Work is supported by DOE grant DE-FG 02-04-ER-46157. Sample preparation is supported by AFOSR MURI Grant FA9550-09-1-0705

12:15PM Z12.00006 Electrical transport between single-crystal domains in graphene: bigger is not always better, ADAM TSEN, LOLA BROWN, MARK LEVENDORF, Cornell University, FERESHTE GHAAHARI, Columbia University, PINSHANE HUANG, CARLOS RUIZ-VARGAS, DAVID MULLER, Cornell University, PHILIP KIM, Columbia University, JIWOONG PARK, Cornell University — Single-layer graphene can now be produced on the centimeter or even meter scale using chemical vapor deposition. These large-scale graphene films are polycrystalline, consisting of many separate single-crystal domains, as was recently identified using transmission electron microscopy. Understanding the electrical transport across these domains is relevant not only for device applications, but has also been the focus of many fundamental studies. Here, we first examine the structure of graphenes produced under different growth conditions using dark-field transmission electron microscopy (DF-TEM). We find three classes of grain boundaries—continuous, amorphous, and overlapped. Next, we study the electrical properties of graphene devices consisting of individual grain boundaries that have been first imaged by DF-TEM. We find that the grain boundaries exhibit an additional gate-dependent resistance that is keenly sensitive to growth conditions. Surprisingly, this resistance is an order of magnitude greater for growths with larger grain size due to more poorly-connected domains. Our results show that domain size is not the single most important parameter determining electrical performance of large-scale graphene films—the quality of inter-domain connections is just as crucial.

12:27PM Z12.00007 Trapping Image State Electrons on Graphene Layers and Islands¹, JERRY DADAP, Columbia University, DANIEL NIESNER, THOMAS FAUSTER, Universitat Erlangen-Nurnberg, NADER ZAKI, KEVIN KNOX, PO-CHI YEH, ROHAN BHANDARI, RICHARD M. OSGOOD, Columbia University, MARIN PETROVIC, MARKO KRALJ, Institut za Fiziku, Croatia — The understanding of graphene-metal interfaces is of utmost importance in graphene transport phenomena. To probe this interface we use time- and angle-resolved two-photon photoemission to map the bound, unoccupied electronic structure of the weakly coupled graphene/Ir(111) system. The energy, dispersion, and lifetime of the lowest three image-potential states are measured. In addition, the weak interaction between Ir and the smooth, epitaxial graphene permits observation of resonant transitions from an unquenched Shockley-type surface state of the Ir substrate to graphene/Ir image-potential states. The image-potential-state lifetimes are comparable to those of mid-gap clean metal surfaces. Evidence of localization of the excited image-state electrons on single-atom-layer graphene islands is provided by coverage-dependent measurements.

¹Columbia work supported by DOE grant DE-FG 02-04-ER-46157

12:39PM Z12.00008 Image potential states of Graphene/Ru(0001) interface, SHENGMIN ZHANG, XUEFENG CUI, LEIMING WANG, HRVOJE PETEK, Department of Physics and Astronomy, University of Pittsburgh, LABORATORY OF ULTRAFAST DYNAMICS TEAM — Graphene, the parent of all graphitic forms, has become one of the most exciting topics in condensed matter physics. It is now well understood that the low-energy electronic properties of graphene are described by two-dimensional Dirac equation for massless particles, but the unoccupied bands are hardly unexplored in experimental research. In this talk we will present new results on the unoccupied electronic structure, namely the image potential states (IPS), measured by two-photon photoemission spectroscopy (2PPS). The single layer graphene is prepared by thermal decomposition of ethylene on a Ru(0001) surface. Through low energy electron diffraction (LEED) and 2PPS, we verify formation of high-quality, single layer thick graphene samples. Based on the graphene/Ru(0001) system, we first measured the surface structure and IPS on Ru(0001) by angle-resolved 2PP. From the angle-resolved spectra, we obtain the effective mass $m_{eff} = 1.1m_e$, which is close to the expected value for a free electron state of $m_{eff} = 1m_e$. With the same method, we measured the IPS on the graphene/Ru(0001) surface. However, we observe complex structure consisting of two nearly degenerate states that reflect the mutual interactions between graphene and Ru(0001) substrate.

12:51PM Z12.00009 Energy loss spectroscopy of epitaxial and free-standing multilayer graphene, OLEKSIY ROSLYAK, GODFREY GUMBS, Department of Physics and Astronomy, Hunter College at the City University of New York, 695 Park Avenue New York, NY 10065, USA, DANHONG HUANG, Air Force Research Laboratory, Space Vehicles Directorate, Kirtland Air Force Base, NM 87117, USA — We present a formalism and numerical results for the energy loss of a charged particle scattered at an arbitrary angle from epitaxially grown multilayer graphene (MLG). It is compared with that of free-standing graphene layers. Specifically, we investigated the effect of the substrate induced energy gap on one of the layers. The gap yields collective plasma oscillations whose characteristics are qualitatively and quantitatively different from those produced by Dirac fermions in gapless graphene. The range of wave numbers for undamped self-sustaining plasmons is increased as the gap is increased, thereby substantially increasing and red-shifting the MLG stopping power for some range of charged particle velocity. We also applied our formalism to interpret several distinct features of experimentally obtained electron energy loss spectroscopy (EELS) data.

1:03PM Z12.00010 Interface Science in Graphene Materials: An Electronic Structure View of Soft X-Ray Spectroscopy , LIANG ZHANG, JUNFA ZHU, University of Science and Technology of China, WEI-CHENG WANG, CHINGLIN CHANG, Tamkang University, PER-ANDERS GLANS, JINGHUA GUO, Lawrence Berkeley National Laboratory — The ability to control the morphology of nanostructured carbon-based materials is of crucial importance for the applications of photovoltaic, energy storage such as Li-ion batteries, etc. The properties of matter at nanoscale dimensions are dramatically different from the bulk. The differences arise through quantum confinement, altered thermodynamics or changed chemical reactivity. In general, electronic structure ultimately determines the properties of matter, thus understanding of electronic structure is crucial for tailoring the properties of nanoscale systems. The graphene/Cu and SiO₂ composites have been studied using XAS, XES and RIXS. New electronic states in the conduction band are observed, which are ascribed to the monovacancy defect state and interfacial interaction. The polarized XAS spectra demonstrate that the graphene/Cu exhibits high alignment and weak corrugation. Significant intensity modulation of resonant XES spectral shape upon different excitation energies near the C K-edge, indicates that graphene preserves an intrinsic symmetry and the interaction between graphene and Cu has unique influence on the electronic structure of graphene. The broad RIXS features and subtle shifts are observed in the RIXS spectra of graphene/Cu, which can be attributed to the strong electron-phonon scattering, charge transfer from the Cu sites

1:15PM Z12.00011 Electron-Phonon Coupling and Large Intrinsic Bandgap in Highly-Screened Graphene , DAVID SIEGEL, University of California, Berkeley / Lawrence Berkeley National Lab, CHOONGYU HWANG, Lawrence Berkeley National Laboratory, ALEXEI FEDOROV, Advanced Light Source, Lawrence Berkeley National Laboratory, ALESSANDRA LANZARA, University of California, Berkeley / Lawrence Berkeley National Lab — The electron-electron and electron-phonon interactions are two of the most fundamental interactions in many-body physics, leading to Mott insulating behavior and superconductivity. In graphene, the pointlike Fermi surface and linear band dispersions give these interactions distinctive characteristics with respect to normal metals. Here we present data on the electron-phonon interaction in highly-screened graphene, which we have analyzed by angle-resolved photoemission spectroscopy (ARPES). In contrast with every previous ARPES study, the magnitude of our extracted electron-phonon coupling constants generally agree with theoretical predictions. We also demonstrate the presence of a 400 meV bandgap at the Dirac point in epitaxial graphene on a copper substrate. These results shed light on the nature of the electron-phonon interaction and the tunability of the Dirac quasiparticles in graphene.

1:27PM Z12.00012 Photoemission on highly-ordered arrays of structured epitaxial graphene , JEREMY HICKS, J. PALMER, H. TINKEY, K. SHEPPERD, Georgia Institute of Technology, A. TEJEDA, A. TALEB-IBRAHIMI, P. LE FÈVRE, Synchrotron SOLEIL, C. BERGER, Georgia Institute of Technology & CNRS-Institut Néel, W.A. DE HEER, E.H. CONRAD, Georgia Institute of Technology — We use the recently-demonstrated method of growing pre-patterned epitaxial graphene directly from structured silicon carbide (SiC) to produce dense, highly-ordered arrays of graphene nanoribbons suitable for macroscopic characterization methods. Specifically, we use angle-resolved photoemission spectroscopy (ARPES) to observe the ensemble-averaged band structure of nanoribbons with nominal widths of 10nm and 30nm. A Dirac-like cone is visible down to 10nm and, although the graphene is a single layer, it is undoped, in contrast to single layer graphene nanoribbons on either the Si- or C-terminated faces of SiC.

1:39PM Z12.00013 Spectroscopic Ellipsometry, Auger and STM Characterization of Epitaxial Graphene grown on 6H-SiC (0001) , FLORENCE NELSON, ALAIN C. DIEBOLD, College of Nanoscale Science and Engineering, University at Albany, ANDREAS SANDIN, DAN DOUGHERTY, DAVE ASPNES, JACK ROWE, Department of Physics, North Carolina State University — Graphene grown by the thermal decomposition of SiC has become of interest to the semiconductor industry due to its unique, high-mobility electronic structure. The growth is of a more scalable nature when compared to exfoliated flakes produced from the “scotch tape” method. The resulting film rests on a “buffer layer” separating the graphene from the underlying substrate, which is thought to consist of a mixture of sp² and non-sp² bonding due to the sp³ bonding of the SiC substrate. The mobilities of the graphene layer have previously been shown to differ from that of the interface layer. We investigate the difference in the optical response of the two layers using Spectroscopic Ellipsometry and find a red-shift of the ~4.5 eV absorbance found in graphene due to the exciton-dominated transition at the M point of the Brillouin Zone. The structural characterization of the films are performed through Auger and STM on substrates which were cleaned by CMP and chemical etching methods prior to the epitaxial growth in UHV.

1:51PM Z12.00014 Vibrational spectroscopy of molecules adsorbed on graphene , YAQING BIE, JASON HORNG, FENG WANG, UC Berkeley — Graphene, being a monolayer membrane, is extremely sensitive to the environment. Understanding how it interacts with adsorbed molecules and polymers is fundamental for improving graphene electronic devices. Previous studies show that electrons in graphene can couple efficiently to phonon vibrations of the substrate, which can become a limiting factor for graphene mobility. Here we investigate the interactions between vibrations of adsorbed molecules with graphene using vibrational spectroscopy. We performed the vibrational spectroscopy using a broadband tunable infrared laser source and a high precision spectrometer. We will discuss how the vibration frequencies of the adsorbed molecules get modified through their interactions with graphene.

2:03PM Z12.00015 Magneto-phonon resonance of shear modes of bilayer graphene , KOSTYANTYN KECHEDZHI, Department of Physics and Astronomy, Rutgers The State University of New Jersey, 136 frelinghuysen rd, Piscataway, 08854 NJ, USA, MARK OLIVIER GOERBIG, JEAN-NOEL FUCHS, Laboratoire de Physique des Solides, Université Paris-Sud, CNRS UMR 8502, F-91405 Orsay, France, VLADIMIR FAL'KO, Department of Physics, Lancaster University, Lancaster, LA1 4YB, UK — We describe the frequency renormalization of the recently observed shear phonon mode of bilayer graphene due to electron-phonon coupling. In presence of a relatively strong magnetic field resonances with electronic inter-Landau level transitions are possible. When the resonance condition is satisfied a fine structure of the Raman line corresponding to the shear mode arises which is linear in electron-phonon coupling constant. This effect can be used to measure the strength of the electron-phonon coupling for the shear mode.

Session Z13 DMP GMAG: Focus Session: Magnetic Nanostructures-Nanoparticles and Granular Systems 211

11:15AM Z13.00001 Unexpected magnetization in highly pure metal oxide nanoparticles , C.B. HANNA, GORDON ALANKO, BOONE BEAUSOLEIL, JORDAN CHESS, AARON THURBER, ALEX PUNNOOSE, Boise State University — We report the synthesis and characterization of a large set of highly pure metal oxide (CeO₂, SnO₂ and ZnO) nanoparticles of ultra-small size (2-10 nm). While the metal oxide systems in this study are non-magnetic as bulk materials, our prepared nanoparticles possess an unexpected small room-temperature ferromagnetic magnetization on the order of 0.001 emu/g. This magnetization is shown to not be a result of magnetic impurities, and is discussed in terms of modification of the electronic structure and crystal lattice. These nanoparticles were thoroughly characterized in their size and phase by x-ray diffraction, morphology by transmission electron microscopy, chemical state and elemental purity by x-ray photoelectron spectroscopy, electronic bandgap by UV-vis absorption spectroscopy, and magnetic properties by vibrating sample magnetometry and electron paramagnetic resonance.

11:27AM Z13.00002 Magnetic Transitions in Granular FeRh¹, B. KAESWURM, F. JIMÉNEZ-VILLACORTA, R. BARUA, D. HEIMAN, L.H. LEWIS, Northeastern University — The relationship between the crystallographic lattice and magnetism in materials undergoing first order thermodynamic phase transitions, where structural and magnetic phase transitions occur simultaneously, are not fully understood. Nanostructuring of such materials offers a route to tailor these transitions through alteration of free energy terms dependent upon the surface area and volume of finite systems. Previous studies in melt spun ribbons of FeRh nanoprecipitates in a Cu matrix have shown a reduced phase transition compared to bulk [1]. In this study nanostructured FeRh films were obtained by RF sputter deposition in nonmagnetic matrices of Cu, Si and alumina. After vacuum annealing, the structure and magnetism of the samples were studied. Preliminary results highlight the relationships between chemistry, nanostructuring and magnetic response in the FeRh system.

11:39AM Z13.00003 Investigation of Local Structures and Magnetism in Mn-doped Y₂O₃ Nanocrystals¹, T.S. WU, S.L. CHANG, Y.L. SOO, National Tsing Hua University — Nanocrystals of Mn-doped Y₂O₃ were prepared by thermal decomposition method and alternately annealed in oxygen and forming gas to vary the oxygen deficiency. X-ray diffraction (XRD), high-resolution transmission electron microscopy (HR-TEM), x-ray absorption fine structures (XAFS), and superconducting quantum interference device (SQUID) techniques were applied before and after each annealing to monitor structural and magnetic variations of the sample. The XRD data show that these annealing treatments do not appreciably change the average particle size of the sample. An amorphous-to-crystalline long-range-order structural change was observed for the first annealing applied to the as-made samples. The short-range-order structure exhibited by XAFS reveals that O vacancies surrounding magnetic impurity atoms were appreciably increased by forming-gas-annealing and decreased by oxygen-annealing in the samples. The increase and decrease of O vacancies are accompanied by enhanced and reduced saturation magnetization as demonstrated by SQUID, respectively. Our experimental results demonstrate clear correlation between magnetism and O vacancies around magnetic ions and therefore strongly support the bound magnetic polaron model in these nanocrystal DMO samples.

11:51AM Z13.00004 Preparation and Characterization of Mg Substituted NiCuZn Nano Ferrites for Multilayer Chip Inductors, R.C. REDDY A, SUJATHA CH, VENUGOPAL REDDY K, SOWRI BABU K, National Inst. of Technology Warangal - 506004 (A.P) India, H.RAO K, Andhra University Visakhapatnam - 530003 (A.P) India — The present paper examines the effect of magnesium substitution on structural and magnetic properties of NiCuZn nano ferrites synthesized by sol - gel method. Formation of single phase spinel structure was confirmed both from XRD and FTIR. The initial permeability shows decreasing trend with increasing Mg concentration due to reduced magnetization, grain size and increased magneto - crystalline anisotropy constant. At the same time, the cut off frequency increases with increasing Mg content. This is attributed to domain wall pinning arising due to the presence of non magnetic magnesium ions. Also the permeability is observed to be constant up to 10MHz frequency range showing compositional stability and quality of the material. The magnetic loss factor shows very low values at higher frequencies. It is concluded that even though both zinc and magnesium are non magnetic ions, substitution of one cation by another prone to influence the magnetic properties due to their change in dimension and cation distribution among the two available sites of a spinel system. These samples have advantages of low sintering temperature find applications in multilayer chip inductors due to their high and constant permeability even at higher frequencies.

12:03PM Z13.00005 Ferromagnetic Resonance on Micro- and Nanoferrites in Millimeter Waves, KONSTANTIN KOROLEV, Tufts University, JOHN MCCLOY, Glass and Materials Science Team, Pacific Northwest National Laboratory, Richland, WA, USA, MOHAMMED AFSAR, Tufts University, TUFTS UNIVERSITY TEAM, GLASS AND MATERIALS SCIENCE TEAM TEAM, EXTREMELY HIGH FREQUENCY MEDICAL AND TECHNICAL ASSOCIATION TEAM — Complex magnetic permeability and dielectric permittivity of micro- and nano-sized powdered barium ferrite (BaFe₁₂O₁₉) and strontium ferrite (SrFe₁₂O₁₉) have been studied in a broadband millimeter wave frequency range for the first time. Transmittance measurements have been performed using a free space quasi-optical millimeter wave spectrometer, equipped with a set of high power backward wave oscillators. Backward wave oscillators have been used as sources of tunable coherent radiation at each individual *Q*-, *V*- and *W*- frequency bands. Real and imaginary parts of dielectric permittivity for both types of micro- and nanoferrites have been calculated using analysis of recorded high precision transmittance spectra. Frequency dependences of the magnetic permeability have been obtained from Schlömann's equation for partially magnetized ferrites. Tunable millimeter wave absorber, based on micro- and nano-sized powdered ferrite materials is presented.

12:15PM Z13.00006 Polarized Magnetic Induced Broadening of Plasmon-photonics in Fe₃O₄-Silicone Elastomer Composite Films¹, DANHAO MA, DEREK CAPLINGER, DUSTIN HESS, KOFI ADU, Department of Physics, The Pennsylvania State University, Altoona College, Altoona, PA 16601, RICHARD BELL, Department of Chemistry, The Pennsylvania State University, Altoona College, Altoona, PA 16601 — We report systematic studies of polarization dependence of magneto-optical response of Fe₃O₄-silicone elastomer composite. The Fe₃O₄ particles were aligned in the elastomer matrix with static magnetic field. The optical response of two composites containing 5wt% and 15wt% of 20nm-30nm diameter Fe₃O₄ particle aligned in- and out-of-plane were measured with an absorption spectrometer. We observed a systematic redshift in the optical response of the out-of-plane samples with increasing static magnetic field. Furthermore, the observed redshift increases with increasing weight percent of Fe₃O₄ in the composite; obtaining a maximum shift of ~ 174 nm at 600 Gauss in the 15wt% Fe₃O₄-elastomer composite films. The observed redshift in the optical response of the out-of-plane composite is attributed to the effect of magnetic field strength and the metal particle/cluster size in the elastomer. However, there were no observable shifts in the in-plane samples, suggesting that the orientation (polarization) of the magnetic dipole and the induced electric dipole play a crucial role in the optical response.

¹This Work is Funded by Penn State Altoona Undergraduate Research Grant.

12:27PM Z13.00007 Precipitation of coherent FeRh nanoparticles with highly suppressed magnetostructural transition temperatures in rapidly solidified (FeRh)₅Cu₉₅ alloys¹, RADHIKA BARUA, Department of Chemical Engineering, Northeastern University, XIUJUAN JIANG, JEFF SHIELD, Department of Mechanical Engineering, University of Nebraska, DON HEIMAN, Department of Physics, Northeastern University, LAURA LEWIS, Department of Chemical Engineering, Northeastern University — Magnetostructural phase transitions have the capability of delivering large functional effects in response to small excursions in magnetic field, temperature and strain; this potential might be amplified in nanostructured systems by virtue of large surface:volume ratios. Nanoprecipitates (~10nm) of FeRh, a well-known magnetostructural material, were studied with structural and magnetic probes in a rapidly solidified phase-separated system of (FeRh)₅Cu₉₅. Magnetization studies indicate a dramatic reduction in the magnetostructural phase transition temperature (T_t) of the nanoscaled FeRh phase relative to the bulk value ($\Delta T = T_{t,Bulk} - T_{t,Nano} = 220$ K). Transmission electron microscopy (TEM) and selected area electron diffraction (SAED) reveals a coherent orientational relationship between the FeRh ($a_{FeRh} = 3.09$ Å) and Cu ($a_{Cu} = 3.78$ Å) phases. At the matrix/precipitate interface a constrained misfit strain of $\epsilon = 0.18$ is observed. The reduction of the magnetostructural phase transition temperature and evolution of the magnetic properties with system annealing is analyzed in the context of the strain between the FeRh nanoparticles and the Cu matrix.

¹Research conducted under the auspices of U.S. Department of Energy (DOE Grant DE-SC0005250)

12:39PM Z13.00008 Biomimetic Control of Magnetite Shape and Morphology using Polyaminoacids, CEM LEVENT ALTAN, SEYDA BUCAK, T.C. Yeditepe University, NICO SOMMERDIJK, Eindhoven University of Technology — Inspired by nature, this work explores the use of randomly sequenced poly(amino acids) to control the size, morphology and magnetic properties of magnetite via synthetic methods in a controlled manner as in the case of magnetotactic bacteria. Aqueous partial oxidation and chemical precipitation methods are employed for the synthesis of 7 - 50 nm iron oxide nanoparticles at room temperature. X-ray diffraction (XRD) and Transmission Electron Microscopy (TEM) revealed formation of iron oxide nanoparticles both in the presence and absence of poly(amino acids). In the presence of random poly(amino acid)s with different compositions consisting of E, K and A amino acids the mean particle size for the chemical precipitation method is decreased regardless of amino acid composition. For partial oxidation method, mean particle size is also decreased and nanoparticle strings are observed while synthesized in the presence of poly(aspartic acid). Magnetic properties of particles obtained via different routes are also investigated. This provides a bio-inspired route for control over size, morphology and magnetic properties of magnetite nanoparticles.

12:51PM Z13.00009 High Resolution Far Infrared Study of Antiferromagnetic Resonance Transitions in α -Fe₂O₃ (hematite), SHIN GRACE CHOU, DAVID F. PLUSQUELLIC, PAUL E. STUTZMAN, SHUANGZHEN WANG, EDWARD J. GARBOCZI, WILLIAM F. EGELHOFF¹, National Institute of Standards and Technology — In this study, we report high resolution optical measurements of the temperature dependence of the antiferromagnetic (AFM) transition in α -Fe₂O₃ (hematite) between (0.5 and 10) cm⁻¹. The absorption peak position, over a large temperature range, is found to be in agreement with a modified spin-wave model at both the high and low temperature phases, where the temperature is above and below the Morin transition temperature, respectively. The high spectral resolution optical measurements as demonstrated in this study allow unprecedented zero-field spectral analysis of the zone center AFM magnon in a previously challenging spectral region, giving insights into the role of temperature and strain on the exchange and anisotropy interactions in the system. The results also suggest that the frequency-resolved measurement platform could be extended for room-temperature non-destructive examination and imaging applications for antiferromagnetic materials and devices.

1:03PM Z13.00010 Mapping Nanomagnetic Fields Using a Radical Pair Reaction¹, HOHJAI LEE, Department of Chemistry and Chemical Biology, Harvard University, NAN YANG, School of Engineering and Applied Sciences, Harvard University, ADAM COHEN, Department of Chemistry and Chemical Biology and Department of Physics, Harvard University — We visualized the magnetic field around ferromagnetic nanostructures using a combination of a standard epifluorescence microscope and a fluorescence chemical indicator of magnetic field (H. Lee et al., Nano Lett. DOI: 10.1021/nl202950h). The indicator was a chain-linked electron donor-acceptor molecule, phenanthrene-(CH₂)₁₂-O-(CH₂)₂-dimethylaniline, that forms spin-correlated radical pairs upon photoexcitation. The magnetic field altered the coherence spin dynamics, yielding an 80% increase in exciplex fluorescence in a 0.1 T magnetic field. The magnetic field distributions were quantified to precision of 1.8×10^{-4} T by image analysis and agreed with finite-element nonmagnetic simulations.

1:15PM Z13.00011 Electrostatic Force Microscopy of Fe₃O₄ nanoparticles, A. MOTTAGHIZADEH, LPEM, ESPCI-ParisTech-UPMC-CNRS, Paris, France, P.L. LANG, LPEM, ESPCI-ParisTech-UPMC-CNRS, Paris, France; School of Science, BUPT, Beijing, China, L. CUI, LPEM, ESPCI-ParisTech-UPMC-CNRS, Paris, France; IOP and Beijing Nat. Lab. for Cond. Matt. Phys., CAS, Beijing, China, J. LESUEUR, A. ZIMMERS, H. AUBIN, LPEM, ESPCI-ParisTech-UPMC-CNRS, Paris, France, J. LI, D.N. ZHENG, IOP and Beijing Nat. Lab. for Cond. Matt. Phys., CAS, Beijing, China, V. REBUTTINI, Dept. of Chemistry, CICECO, University of Aveiro, Aveiro, Portugal, N. PINNA, Dept. of Chem., CICECO, Univ. of Aveiro, Portugal; WCU, C2E2, School of Chem. and Biological Engineering, College of Engineering, SNU, Seoul, Korea — The electronic compressibility is a fundamental property that characterizes the electronic properties of materials submitted to an external electric field. In metals (insulators), the electronic compressibility is large (small) and leads to a small (large) screening length. Variations of the screening length can be observed through measurements of the “quantum” capacitance between one material and a metallic counter-electrode. Using an Electrostatic Force Microscope (EFM), we measured maps of the local capacitance of 8 nm magnetite nanoparticles synthesized following the “benzyl alcohol route” deposited on a metallic substrate. Magnetite, an inverse spinel structure of composition Fe₃O₄, is a material with strongly correlated electronic properties and presents a metal-insulator transition at 120 K, the so-called Verwey transition. We present EFM measurements of these nanoparticles as a function of tip-sample distance and temperature.

1:27PM Z13.00012 Nano-scaled magnetic domains in CMR-manganites, YOSHIHIKO TOGAWA, Nanoscience and Nanotechnology Research Center, Osaka Prefecture University, TSUKASA KOYAMA, KEN HARADA, SHIGEO MORI, Department of Materials Science, Osaka Prefecture University — La_{1-x}Sr_xMnO₃ (LSMO) is one of interesting materials with strongly-correlated electrons, wherein a complex variety of ground states are generated depending on the Sr doping concentration x . In this work, we have microscopically investigated changes of the magnetic states by applying magnetic fields in single crystals of LSMO by using Lorentz transmission electron microscopy. In the specimen with $x = 0.175$, the magnetic stripe domains appear at regular intervals of about 200 nm as a magnetic ground state in zero magnetic field at 110 K. Importantly, we have clarified that magnetic domains as large as 100 nm are generated in the magnetic stripe domains in vertical magnetic fields and take a form of the magnetic vortex with tilted magnetic components. To the best of our knowledge, these magnetic domains are new kinds of magnetic ground states (spin textures) in manganites. In the presentation, we will explain detailed responses of magnetic vortices to various experimental parameters of external magnetic fields and discuss the nucleation and growth mechanism of magnetic vortices in the magnetic stripe domains and the expected functionality of magnetic vortices in manganites.

1:39PM Z13.00013 Anomalous thermal hysteresis in the high-field magnetic moments of magnetic nanoparticles embedded in multi-walled carbon nanotubes, GUO-MENG ZHAO, California State University, Los Angeles, JUN WANG, Ningbo University, YANG REN, Argonne National Lab, PIEDER BEELI, California State University, Los Angeles — We report high-temperature (300-1120 K) magnetic properties of Fe and Fe₃O₄ nanoparticles embedded in multi-walled carbon nanotubes. We unambiguously show that the magnetic moments of Fe and Fe₃O₄ nanoparticles are seemingly enhanced by a factor of about 3 compared with what they would be expected to have for free (unembedded) magnetic nanoparticles. What is more intriguing is that the enhanced moments were completely lost when the sample was heated up to 1120 K and the lost moments at 1120 K were completely recovered through several thermal cycles below 1020 K. The anomalous thermal hysteresis of the high-field magnetic moments is unlikely to be explained by existing physical models except for the high-field paramagnetic Meissner effect due to the existence of ultrahigh temperature superconductivity in the multi-walled carbon nanotubes.

1:51PM Z13.00014 Carbon Nanostraws with Novel Magnetic Properties for Microwave Devices and Biomedical Applications¹, K. STOJAK, S. CHANDRA, S. PAL, H. KHURSHID, M.H. PHAN, H. SRIKANTH, University of South Florida-Physics — Carbon nanotubes (CNTs) have stirred interest in many areas of current research because of their unique electrical properties and potential use in the biomedical field. Here, we report on the synthesis, structural, and magnetic characterization of “nanostraws,” which consist of nanoparticle-filled CNTs made by a template-assisted chemical vapor deposition method. In this study, the nanoparticle fillers are magnetite, cobalt ferrite, and nickel ferrite. These high-aspect ratio magnetic nanostructures have a tunable anisotropy in addition to enhanced magnetic interactions amongst the CNT-encapsulated magnetic nanoparticles. Enhanced magnetic interactions include higher saturation magnetization and higher blocking temperature. These properties are desirable for microwave devices and biosensing applications.

Friday, March 2, 2012 11:15AM - 2:03PM – Session Z16 DCMP: Disordered and other Strongly Correlated Systems 251

11:15AM Z16.00001 Composition-tuned smeared phase transitions, DAVID NOZADZE, FAWAZ HRAHSEH, CHRISTOPHER SVOBODA, THOMAS VOJTA, Missouri University of Science and Technology — Phase transitions in random systems are smeared if individual spatial regions can order independently of the bulk system. We study such smeared phase transitions (both classical and quantum) in substitutional alloys A_{1-x}B_x that can be tuned from an ordered phase at composition $x = 0$ to a disordered phase at $x = 1$. We show that the ordered phase develops a pronounced tail that extends over all compositions $x < 1$. Using optimal fluctuation theory, we derive the composition dependence of the order parameter and other quantities in the tail of the smeared phase transition. We also investigate the influence of spatial disorder correlations on smeared phase transitions. We compare our results to computer simulations of a toy model, and we discuss experiments.

11:27AM Z16.00002 Understanding zero-bias anomalies in disordered strongly-correlated electron systems: An atomic-limit perspective¹, RACHEL WORTIS, LISTER MULINDWA, Trent University — Many interesting phenomena arise in strongly-correlated electron systems which are disordered, either intrinsically or due to doping. In trying to understand these phenomena, the single-particle density of states provides a useful bridge between theory and experiment. Progress has recently been made in understanding the origins of the zero-bias anomaly that appears in these systems, and how this zero-bias anomaly differs from that studied by Altshuler and Aronov in weakly-correlated systems. Because both interactions and disorder reduce the importance of kinetic energy, the atomic limit provides a useful perspective. The case of long-range 1/r interactions in the atomic limit was addressed by Efros and Shklovskii, who showed the density of states is suppressed to zero at the Fermi level. However, the argument they used does not address screened interactions or the effect of double occupancy. This talk presents classical Monte Carlo results for the density of states in the atomic limit of the extended Anderson-Hubbard model. The origin of the zero-bias anomaly in this system is explained, and the results are compared both with those obtained when hopping is allowed and with those of Efros and Shklovskii.

11:39AM Z16.00003 Novel critical point in the random quantum Ashkin-Teller model, FAWAZ HRAHSEH, THOMAS VOJTA, Missouri University of Science and Technology — The first order phase transition of the quantum Ashkin-Teller model has been intensely studied over many decades. In this work, we study the effect of disorder on this quantum phase transition using a strong-disorder renormalization group approach. Specifically, we develop an implementation of the strong-disorder renormalization group that works for both weak and strong four-spin couplings. For large four-spin coupling, we find a novel type of infinite-randomness fixed point. We investigate the critical properties of this fixed point, and we discuss broader implications for the fate of the first-order quantum phase transitions in disordered systems.

11:51AM Z16.00004 Spectral function of two-dimensional disordered Hubbard model¹, OINAM NGANBA MEETEI, NANDINI TRIVEDI, The Ohio State University — We show that moderate disorder introduces extended states in the Mott gap which upon further increase of disorder strength become localized states [1]. We propose that the inverse of the Lorentzian broadening of the spectral function $A(\mathbf{k}, \omega=0)$ as a function of $\mathbf{k}$ can be used as an order parameter for describing the both the transition from a Mott insulator to an unusual metallic state and the transition from the metal to a localized insulator of spin singlets. We further track the evolution of $A(\mathbf{k}, \omega)$ as a function of disorder and interaction strength. We also obtain the screening length of an external Coulomb potential from the density-density correlation function and find that the screening length is shortest at intermediate disorder in the metallic region. Our calculations are performed within an exact eigenstate formalism that treats the disorder exactly. The single particle Green's function is calculated within self-consistent mean field theory. In real space the bubble diagrams for this on-site interaction are an exact representation of density-density correlation function.

12:03PM Z16.00005 Variational Monte Carlo Study of Anderson Localization in the Hubbard Model¹, WILLIAM ATKINSON, AVID FARHOODFAR, Trent University, ROBERT J. GOODING, Queen's University — We have studied the effects of interactions on persistent currents in half-filled and quarter-filled Hubbard models with weak and intermediate strength disorder. Calculations are performed using a variational Gutzwiller ansatz that describes short range correlations near the Mott transition. A persistent current is induced with an Aharonov-Bohm flux, and the Anderson localization length is extracted from the scaling of the current with system size. We find that, at half filling, the localization length grows monotonically with interaction strength, even though the current itself is suppressed by strong correlations. This supports earlier dynamical mean field theory predictions that the elastic scattering rate is reduced near the Mott transition.

12:15PM Z16.00006 Spin fluctuations near a spin-density-wave instability in periodic Anderson model studied by two-particle approach in dynamical mean field theory, WENHU XU, Department of Physics and Astronomy, Rutgers University, CEDRIC WEBER, Cavendish Laboratories, Cambridge University, United Kingdom, GABRIEL KOTLIAR, Department of Physics and Astronomy, Rutgers University — We study the magnetic properties of periodic Anderson model when the system approaches to the vicinity of a spin-density-wave(SDW) instability from paramagnetic phase. Static and dynamical Q -dependent susceptibility are calculated using a two-particle approach in dynamical mean field theory. The SDW instability at a critical value of hybridization V_c is identified by the divergence of static susceptibility at low temperature and at a wavevector Q_c which connects the “hot zones” of the conduction band. Away from V_c , spin fluctuations at Q_c is suppressed at low energy and at low temperature in the heavy Fermi liquid regime, while near V_c , spin fluctuations at Q_c are significantly enhanced as temperature decreases. This indicates that the SDW instability is due to the competition between RKKY interaction and Kondo coupling in the crossover regime.

12:27PM Z16.00007 Large Disorder Renormalization Group Study of Singularities in the Insulating Phase of the Anderson Model of Localization¹, SONIKA JOHRI, Department of Electrical Engineering, Princeton University, Princeton NJ 08544-5263, R.N. BHATT, Department of Electrical Engineering and Princeton Center for Theoretical Science, Princeton University, Princeton NJ 08544-5263 — A recent study² of Anderson's 1958 model of localization³ reveals singular behavior of electronic eigenstates, as displayed by the density of states and inverse participation ratio, as a function of energy. This behavior occurs inside the insulating phase and separates typical Anderson localized from rare configuration, resonant Lifshitz states. Here, we use the large disorder renormalization group (LDRG) approach to study this problem. In particular, we study, using the LDRG approach, how the singular behavior evolves as a function of system size, starting from a toy model with two-sites which can be solved analytically. We assess the accuracy of the LDRG approach in obtaining the singular behavior in the thermodynamic limit for different disorder strengths, by comparing with results obtained by exact numerical diagonalization.

12:39PM Z16.00008 Long-range spatial correlations in one-dimensional Anderson models¹, GREG PETERSEN, NANCY SANDLER, Ohio University, NQPI TEAM — The study of metal-insulator transitions (MIT) in one-dimensional (1d) Anderson disordered systems remains an active topic of research. Analytic and numerical results have confirmed the scaling prediction on the absence of MIT for short-range correlated disorder potentials. Solutions for long-range correlated potential models (i.e. the dimer model and those with power-law spectral densities) have shown MITs in 1d. However, long-range correlations remain poorly understood. In order to gain some insight, we study a 1d Anderson model with disorder potential correlations described by a power-law model with $\langle \epsilon_i \epsilon_0 \rangle = 1/(1 + r/a)^\alpha$. Here ϵ_i , r , a , and α are the on-site energy, position, lattice constant, and strength of the correlation respectively. We obtained results with various methods (wave packet diffusion, participation ratio, transfer matrix and Green's function) that support the absence of a MIT in these models in. We further show that an analysis of the beta function provides evidence for the validity of the same one-parameter scaling law valid for short-range correlated potentials.

12:51PM Z16.00009 Dispersive Impurities in one-dimensional Fermi Gases: From one to two Channel Kondo Polarons, KAREN HALLBERG, Centro Atomico Bariloche and Instituto Balseiro, CNEA, CONICET, Bariloche, Argentina, JULIAN RINCON, Oak Ridge National Laboratory, USA, DANIEL GARCIA, Centro Atomico Bariloche and Instituto Balseiro, CNEA, CONICET, Bariloche, Argentina, MATTHIAS VOJTA, Institut für Theoretische Physik, Technische Universität Dresden, 01062 Dresden, Germany — We consider the problem of a dispersive magnetic impurity interacting antiferromagnetically with a one dimensional fermionic gas. By combining general considerations and extensive numerical simulations we show that the problem displays a quantum phase transition between two-channel and one-channel Kondo behaviour upon increasing the Kondo coupling and construct a phase diagramme. We also discuss possible experimental realisations.

1:03PM Z16.00010 ABSTRACT WITHDRAWN —

1:15PM Z16.00011 Charge fractionalization on quantum Hall edges, MARIANNE RYPESTOEL, University of Oslo, MATS HORS DAL, University of Leipzig, HANS HANSSON, Stockholm University, JON MAGNE LEINAAS, University of Oslo — Interactions between edges of quantum Hall bars give rise to Luttinger Liquid behavior with a nontrivial interaction parameter g . This leads to fractionalization of localized charges that propagate along the edges. We focus on fractionalization in systems with variable g and the separation of a charge into a sharply defined front pulse and a broader tail. The possibility of detecting the front pulse through noise measurement is discussed and illustrated by numerical simulations of a simplified Hall bar model.

1:27PM Z16.00012 Study of spontaneous anomalous Hall effect in 2-D electron fluid by bosonization, WATHID ASSAWASUNTHONNET, EDUARDO FRADKIN, Department of Physics, University of Illinois at Urbana-Champaign — We explore spontaneous time-reversal symmetry breaking in two-dimensional electron fluids using the method of higher dimensional bosonization. We focus on a fluid phase in which time-reversal symmetry and chiral symmetry are broken, but the space inversion and the combination of chiral and time-reversal symmetries are intact. This phase exhibits non-quantized anomalous Hall effect in the absence of external magnetic fields which corresponds to the Berry curvature on the Fermi surface. Furthermore we investigate the Berry phase connection and its representation in terms of bosonized fields.

1:39PM Z16.00013 Non-chiral Bosonization of Fermions in One Dimension¹, GIRISH SETLUR², Associate Professor, Department of Physics, Indian Institute of Technology Guwahati 781039, India — An alternative to the conventional approach to bosonization in one dimension that invokes the Dirac equation in 1+1 dimension with chiral “right-movers” and “left-movers” is proposed that works directly with the bounded parabolic energy bands relevant to Condensed Matter problems. This technique allows us to use a basis different from the plane wave basis that makes this non-chiral approach ideally suited to study Luttinger liquids that have boundary or impurities that break translational symmetry. We provide a simple solution to the electron Green function for the problem of Luttinger liquid (LL) with a boundary and also for a LL with a single impurity. The present method is significantly easier than the g-ology based standard bosonization and other methods that require a combination of RG along with bosonization/refermionization techniques. Our results are broadly consistent with these more established approaches.

1:51PM Z16.00014 A Partially-ordered-set Based Approach to the Dirac Equation in 3+1 space-time¹, KEITH EARLE, KEVIN KNUTH, University at Albany (SUNY) — Recent work by Knuth and co-workers has shown how insights into Einstein's Theory of Special Relativity may be obtained by careful reasoning about consistent quantification of a poset. The Feynman Chessboard problem in 1+1 spacetime can be treated from this perspective, for example. Alternative methods of solution based on techniques borrowed from statistical mechanics have also been developed over the years to solve the Feynman Chessboard model in 1+1 spacetime. One particularly intriguing solution is based on a master-equation approach developed by McKeon and Ord for 1+1 spacetime. We will show how this model may be extended to 3+1 spacetime using techniques developed by Bialynicki-Birula, thus providing an alternative derivation of the Dirac equation. An external electromagnetic field can be accommodated very naturally in the formalism from which a pleasing pictorial representation of electromagnetic interactions in the lattice picture emerges.

Friday, March 2, 2012 11:15AM - 2:15PM – Session Z17 DCMP: 2D Crystals: Beyond Graphene 252A

11:15AM Z17.00001 Electronic and Transport Properties of Few-Layer MoS₂ Crystals, DORON NAVEH, Electrical & Computer Engineering, Carnegie Mellon University, Pittsburgh, PA, United States, ASHWIN RAMASUBRAMANIAM, Mechanical & Industrial Engineering, University of Massachusetts Amherst, Amherst, MA, United States, ELIAS TOWE, Electrical & Computer Engineering, Carnegie Mellon University, Pittsburgh, PA, United States — We investigate the electronic properties of few-layer MoS₂ flakes prepared by mechanical exfoliation. Field-effect transistors from MoS₂ flakes were fabricated and their properties were systematically characterized as a function of sample thickness. Scanning probe measurements are employed to characterize the interface between MoS₂ flakes and metal contacts. Transport properties of these devices and their correlation to electronic structure calculations are discussed.

11:27AM Z17.00002 Optical pump-probe studies of carrier dynamics in few-layer MoS₂, RUI WANG, BRIAN RUZICKA, NARDEEP KUMAR, MATTHEW BELLUS, HSIN-YING CHIU, HUI ZHAO, University of Kansas — Molybdenum disulfide is a transition metal dichalcogenide with an indirect band gap of 1.29 eV. Its layered structure allows fabrication of atomically-thin films where the quantum confinement can significantly modify the electronic and optical properties. We demonstrate that a femtosecond pump-probe technique can be used to study charge carrier dynamics in few-layer MoS₂ samples fabricated on Si/SiO₂ substrates by mechanical exfoliation. Carriers are injected by a 780-nm pump pulse via phonon assisted indirect absorption in bilayers or through edge states. Their dynamics are probed by measuring differential reflection of a probe pulse tuned to the excitonic transition near 670 nm. We found that the magnitude, the sign, and the decay time of the signal change dramatically as the probe wavelength is tuned within the excitonic resonance. With a fixed probe wavelength, the differential reflection signal is proportional to the carrier density. The decay time is independent of the carrier density. Besides providing quantitative information on the carrier dynamics in this promising two-dimensional material, our experiment may stimulate further optical studies of carrier dynamics in this material system.

11:39AM Z17.00003 Integrated circuits and logic operations with high room temperature voltage gain based on single-layer MoS₂, ANDRAS KIS, BRANIMIR RADISAVLJEVIC, MICHAEL WHITWICK, EPFL — Two-dimensional materials such as single-layer MoS₂ represent the ultimate limit of miniaturization in the vertical dimension, are interesting as building blocks of low-power nanoelectronic devices and are suitable for integration due to their planar geometry. Because they are less than 1 nm thin, 2D materials in transistors could also lead to reduced short channel effects and result in fabrication of smaller and more power efficient transistors. Here, we report on the first integrated circuit based on a two-dimensional semiconductor MoS₂. Our integrated circuits are capable of operating as inverters, converting logical “1” into logical “0”, with room-temperature voltage gain higher than 4.5, making them suitable for incorporation into digital circuits. We also show that electrical circuits composed of single-layer MoS₂ transistors are capable of performing the NOR logic operation, the basis from which all logical operations and full digital functionality can be deduced. We have also fabricated suspended single-layer MoS₂ membranes and have performed mechanical measurements using an atomic force microscope. Our results show that single-layer MoS₂ has a Young's modulus higher than steel and can withstand deformation up to 11%, making it suitable for integration with flexible electronic devices.

12:03PM Z17.00005 ABSTRACT WITHDRAWN —

12:15PM Z17.00006 Transient Photoluminescence in MoS₂ layered crystals, TUNG-WU HSIEH, CHIH-WEI LAI, Michigan State University — We report sub-10-ps transient exciton photoluminescence (PL) in mechanically exfoliated few- and mono-layered crystals of MoS₂. We characterize layered crystals with thickness of $\sim 1\mu\text{m}$, 100 nm, 10nm, and down to few-layers on SiO₂/Si and mica substrates using luminescence and Raman spectroscopy. A frequency shift of $\sim 2\text{ cm}^{-1}$ is observed on sub-10-nm-thick samples for the in-plane E_{2g}^1 and the out-of-plane A_{1g} Raman modes. The relative intensities of Stokes and Anti-Stokes Raman components are used to determine the lattice temperature under a laser excitation with a spot diameter of $1\mu\text{m}$ and an average power 0.5 to 20mW. PL spectra are measured for lattice temperatures from $\sim 70\text{K}$ to 500K. We observe two groups of luminescence emissions with comparable peak intensities centered at 1.85eV (VIS) and 1.35eV for samples of a thickness $1\mu\text{m}$ down to 10 nm under a cw laser excitation at a wavelength of 532nm (2.33eV). The VIS luminescence emissions are enhanced under a 2-ps pulsed laser excitation at a wavelength of 633nm (1.96eV). The rise and decay times of the luminescence are found to be less than 5 ps. Our results suggest that excitonic effects play a role in enhancing the luminescence quantum efficiency.

12:27PM Z17.00007 Quasiparticle self-consistent GW calculations of monolayer, bilayer and bulk MoS₂, TAWINAN CHEIWCHANHAMNANGIJ, WALTER LAMBRECHT, JIE SHAN, Department of Physics, Case Western Reserve University, 10900 Euclid Avenue, Cleveland, Ohio 44106 — Photoluminescence and absorption spectra of monolayer MoS₂ indicate a direct gap behavior while bulk MoS₂ is known to have an indirect gap. The details of these spectra and the band structure are not yet fully understood. Here, the quasiparticle self-consistent GW method is used to study the electronic structure of monolayer, bilayer, and bulk MoS₂. Band structures, effective masses, and dielectric functions are extracted from our calculations. In contrast to another recent GW calculation, we find the monolayer to have a direct gap of 2.84 eV at K, which is large compared to the photoluminescence energies. The exciton binding energy for this transition is estimated within an effective mass approximation using our calculated effective masses and dielectric constants and amounts to about 0.90 eV, leading to good agreement with the experimental data for the lowest direct transition. We find a second conduction band local minimum along Γ -K about 0.44 eV higher but do not find it to give rise to a bound state exciton. When spin-orbit coupling is included, we find a spin-splitting of the levels along Γ -K in the monolayer related to the absence of an inversion center. In the bilayer, we find an indirect gap from Γ -K and a splitting of the valence band at K, mainly due to the interlayer interaction but also increased by spin-orbit coupling. The splitting between the lowest two absorption features A and B is consistent with the slightly larger splitting calculated in the bilayer than the monolayer.

12:39PM Z17.00008 High Performance Two Dimensional MoS₂ MOSFET with ALD Al₂O₃ Gate Stacks, HAN LIU, KUN XU, PEIDE YE, Purdue University — We study the growth mechanism of atomic layer deposition (ALD) of Al₂O₃ on layered MoS₂. We demonstrate the feasibility of direct growth of Al₂O₃ on this 2D material by trimethylaluminum (TMA) and water as precursors. Atomic force microscopy study shows that the quality of the Al₂O₃ film is degraded at elevated temperatures, originated from impeded surface absorption of precursors. We also apply density functional theory (DFT) study of the reaction which is in good agreement with our experimental observations. In addition, we fabricate dual gate MoS₂ metal-oxide-semiconductor field effect transistors (MOSFET). From the transport study we find out the lowering the growth temperature will result in a huge negative threshold voltage shift, which can be improved by either forming gas anneal after Al₂O₃ deposition or insertion of an Al seeding layer which would facilitate higher growth temperature with better film quality. Further details will be provided in the presentation.

12:51PM Z17.00009 Novel valley and spin physics in monolayer MoS₂¹, DI XIAO, Oak Ridge National Laboratory, G.B. LIU, The University of Hong Kong, WENGUANG ZHU, University of Tennessee & Oak Ridge National Laboratory, XIAODONG XU, University of Washington, WANG YAO, The University of Hong Kong — We show that the valley Hall effect and valley-dependent optical selection rule can be realized in monolayer MoS₂, which is a direct bandgap semiconductor with non-central valleys. In addition, spin-orbit coupling in this materials is large, which gives rise to novel spin physics tied to the valley degree of freedom.

1:03PM Z17.00010 Enhanced thermal conductivity and isotope effect in single-layer hexagonal boron nitride¹, DAVID BROIDO, Boston College, LUCAS LINDSAY, Naval Research Laboratory — We have calculated the lattice thermal conductivity, k , of both naturally occurring and isotopically enriched single layers of hexagonal boron nitride (h-BN) as well as bulk h-BN using an exact numerical solution of the Boltzmann transport equation for phonons [1]. Good agreement is obtained with measured bulk h-BN data [2], and the stronger phonon-phonon scattering identified in these systems explains why their k values are significantly lower than those in graphene and graphite. A reduction in such scattering in the single layer arising mainly from a symmetry-based selection rule leads to a substantial increase in k , with calculated room temperature values of more than 600 W/m-K. Additional enhancement is obtained from isotopic enrichment, which exhibits a strong peak as a function of temperature, with magnitude growing rapidly with crystallite size. [1] L. Lindsay and D. A. Broido, Phys. Rev. B 84, 155421 (2011). [2] E. K. Sichel, R. E. Miller, M. S. Abrahams, and C. J. Buicocchi, Phys. Rev. B 13, 4607 (1976).

1:15PM Z17.00011 Two-dimensional Dirac fermions and quantum transport in (Sr/Ca)MnBi₂, KEFENG WANG, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory Upton, New York 11973 USA, D. GRAF, National High Magnetic Field Laboratory, Florida State University, LIMIN WANG, HECHANG LEI, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory Upton, New York 11973 USA, S.W. TOZER, National High Magnetic Field Laboratory, Florida State University, CEDOMIR PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory Upton, New York 11973 USA — We report two dimensional Dirac fermions and quantum transport behavior in single crystals of SrMnBi₂ and CaMnBi₂. The non-zero Berry's phase, small cyclotron resonant mass and first-principle band structure suggest the existence of the Dirac fermions in the Bi square nets. Angular dependent magnetoresistance and quantum oscillations suggest dominant two-dimensional (2D) Fermi surfaces. The in-plane transverse magnetoresistance exhibits a crossover at a critical field B^* from semiclassical weak-field B^2 dependence to the high-field unsaturated linear magnetoresistance ($\sim 120\%$ in 9 T at 2 K) due to the quantum limit of the Dirac fermions. The temperature dependence of B^* satisfies quadratic behavior, which is attributed to the splitting of linear energy dispersion in high field. Our results demonstrate the universal existence of two dimensional Dirac fermions in different materials with Bi square nets.

1:27PM Z17.00012 Field-induced polarization of Dirac valleys in bismuth, KAMRAN BEHNIA, ZENGWEI ZHU, AURELIE CALLAUDIN, BENOIT FAUQUE, ESPCI, WOUN KANG, Ewha Womans University — The principal challenge in the field of "valleytronics" is to lift the valley degeneracy of electrons in a controlled way. In graphene, a number of methods to generate a valley-polarized flow of electrons have been proposed, which are yet to be experimentally realized. In bulk semi-metallic bismuth, the Fermi surface includes three cigar-shaped electron valleys lying almost perpendicular to the high-symmetry axis known as the trigonal axis. The in-plane mass anisotropy of each valley exceeds 200 as a consequence of Dirac dispersion, which drastically reduces the effective mass along two out of the three orientations. We present a study of angle-dependent magnetoresistance in bismuth which shows that a flow of Dirac electrons along the trigonal axis is extremely sensitive to the orientation of in-plane magnetic field. The effect is visible even at room temperature. Thus, a rotatable magnetic field can be used as a valley valve to tune the contribution of each valley to the total conductivity. At high temperature and low magnetic field, the three valleys are interchangeable and the three-fold symmetry of the underlying lattice is respected. As the temperature is decreased or the magnetic field increased, this symmetry is spontaneously lost. This loss may be an experimental manifestation of the recently proposed valley-nematic Fermi liquid state.

1:39PM Z17.00013 STM measurements of Charge Density Waves in S-doped NbSe₂, ULRICH WURSTBAUER, ETHAN ROSENTHAL, ERICK F. ANDRADE, CARLOS ARGUELLO, SUBBAIAH P. CHOCKALINGAM, Dept. of Physics, Columbia University, SHUANG JIA, ROBERT J. CAVA, Dept. of Chemistry, Princeton University, ABHAY N. PASUPATHY, Dept. of Physics, Columbia University — Recent scanning tunneling microscopy (STM) measurements have shown that crystal defects have a profound influence on the nature of the charge density wave (CDW) transition in the transition-metal dichalcogenides (TMD). In order to examine this effect systematically, we employ low temperature STM to visualize the CDW transition in intentionally doped TMD crystals. We use a newly designed homebuilt ultra-low-loss, variable temperature STM to perform measurements on crystal samples of NbS_xSe_{2-x}. We describe the effect of the sulphur atoms on both the local and global charge order in this material.

1:51PM Z17.00014 Imaging Charge Density Wave Nucleation in NbSe₂, ETHAN ROSENTHAL, CARLOS ARGUELLO, SUBBAIAH CHOCKALINGAM, WOO CHANG CHUNG, LIUYAN ZHAO, CHRISTOPHER GUTIERREZ, JOON HO KANG, ABHAY PASUPATHY, Columbia University, SHUANG JIA, ROBERT CAVA, Princeton University — Understanding the effects of spatial inhomogeneity in complex materials is necessary to achieve a fundamental understanding of their quantum states. NbSe₂ serves as a clean and relatively simple system for understanding the emergence of one such state – the charge density wave (CDW) phase. Using variable temperature scanning tunneling microscopy (STM), we visualize the nucleation of CDWs about crystal defects at temperatures well above T_{CDW} . The CDW correlation length increases with decreasing temperature, until global order is reached below T_{CDW} . We also employ scanning tunneling spectroscopy in order to visualize the energy-dependent, spatial phase of the CDW state. With both topographic and spectroscopic data, we will provide a clear picture of the CDW transition and insight into the microscopic mechanisms at work.

2:03PM Z17.00015 Nature of Electronic States in Ultrathin MoS₂ Field Effect Transistor, SUBHAMOY GHATAK, ATINDRA NATH PAL, ARINDAM GHOSH, Indian Institute of Science, Bangalore, LOW TEMPERATURE NANO-ELECTRONICS GROUP TEAM — Molybdenum disulphide (MoS₂) is a layered transition metal dichalcogenide with a Mo layer sandwiched between two S layers (S-Mo-S), which forms its basic unit. Each basic unit is attached to other units only with weak Van der Waals force. This enables to make an atomically thin single layer of MoS₂ with a bandgap 1.9 eV. The presence of bandgap has made it an interesting material in thin film transistors. It has been reported [1] recently that very high on/off ratio ($\sim 10^8$) can be obtained in single layer MoS₂ transistor due to the presence of this bandgap. Though the on/off ratio is very high, mobility in these transistors are considerably low. Here we have investigated the origin of such low mobility. From our temperature dependent study we find that atomically thin MoS₂ layer becomes highly disordered in the presence of the substrate and electron got localised in the traps created by the charge impurities at substrate-MoS₂ interface. We propose that high mobility can be obtained in these transistors by removing the charge impurity background.

Friday, March 2, 2012 11:15AM - 2:15PM –
Session Z18 DCMP: Enhanced Optical Properties Using Plasmonics, Metamaterials, and Nanoparticles 252B

11:15AM Z18.00001 Nonresonant Broadband Funneling of Light via Ultrasubwavelength Channels¹, GANAPATHI SUBRAMANIA, Sandia National Laboratories, Albuquerque, NM, USA, STAVROULA FOTEINOPOULOU, School of Physics, University of Exeter, Exeter, UK, IGAL BRENER, Sandia National Laboratories, Albuquerque, NM, USA — Efficient control of light-matter interaction, which is key to many photonics applications such as detectors, sensors and novel light sources, can be achieved by enhancing and funneling light efficiently through deep subwavelength channels. Thus far, this has been accomplished by exciting the structural surface plasmon resonances of perforated nanostructured metal films, a phenomenon known as extraordinary optical transmission. The resonant nature of the phenomenon makes it inherently narrowband. Here, we introduce a new paradigm structure consisting of double-grooved metallic structure that possesses all the capabilities of extraordinary optical transmission platforms, yet operates nonresonantly and across broadband (Phys. Rev. Lett. 107, 163902(2011)). As a result, our proposed platform demonstrates efficient ultrabroadband funneling of optical power confined to an area as small as $\sim (\lambda/500)^2$, where optical fields are enhanced, thus exhibiting functional possibilities beyond resonant platforms. We explain the nonresonant mechanism underlying this phenomenon with a simple quasistatic picture that shows excellent agreement with our numerical simulations.

¹Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. DOE's National Nuclear Security Administration under contract DE-AC04-94AL85000.

11:27AM Z18.00002 Measurement of Near-Field Thermal Radiation through a Nanometer-Sized Gap, ANASTASSIOS MAVROKEFALOS, POETRO SAMBEGORO, GANG CHEN, Massachusetts Institute of Technology — Radiation heat transfer in nanostructures can differ significantly from that in macrostructures due to wave effects. Theory has predicted that thermal radiation heat transfer between two surfaces separated by tens of nanometers can exceed that of Planck's blackbody radiation law by several orders of magnitude. Our AFM-inspired heat flux sensor, comprising of a sphere attached to the tip of a bimetallic cantilever, can measure the radiation exchange across nanometer-scale gaps between a sphere and a flat surface. The objective of this work is to experimentally study thermal radiative transfer at very small separation gaps. In previous experiment, our group has successfully measured near-field radiative heat transfer through gap as small as 30 nm. In this work, we extend this technique to decrease the gap down to a few nanometers and show that existing fluctuating electrodynamics theory cannot predict experimental results in the extreme limit of small separation between two surfaces. Our experiments raise interesting question on the convergence of radiation heat transfer mechanism and interfacial heat conduction mechanism. Theoretical approaches bridging these two regimes will be discussed.

11:39AM Z18.00003 Making metals transparency for white light by surface plasmons¹, RU-WEN PENG, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University, Nanjing 210093, China, XIAN-RONG HUANG, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA, REN-HAO FAN, JIA LI, QING HU, MU WANG, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University, Nanjing 210093, China, NATIONAL LABORATORY OF SOLID STATE MICROSTRUCTURES COLLABORATION, ARGONNE NATIONAL LABORATORY COLLABORATION — We demonstrate both experimentally and theoretically that metallic gratings consisting of narrow slits become transparent for extremely broad bandwidths under oblique incidence. This phenomenon can be explained by a concrete picture in which the incident wave drives free electrons on the conducting surfaces and part of the slit walls to form surface plasmons (SPs). The SPs then propagate on the slit walls but are abruptly discontinued by the bottom edges to form oscillating charges that emit the transmitted wave. This picture explicitly demonstrates the conversion between light and SPs and indicates clear guidelines for enhancing SP excitation and propagation. Making structured metals transparent may lead to a variety of applications. References: Xian-Rong Huang, Ru-Wen Peng, and Ren-Hao Fan, Phys. Rev. Lett. 11:51AM Z18.00004 Fabrication of Broad Band Mid-Infrared Absorber based on Periodic Dielectric-Thin Metal Film Multilayer Structures, SHY-HAUH GUO¹, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20742, ANDREI B. SUSHKOV, Department of Physics, University of Maryland, College Park, MD 20742, TIMOTHY CORRIGAN, Department of Physical Sciences, Concord University, Athens, WV 24712, DONG PARK², Department of Electrical Computer Engineering, University of Maryland, College Park, MD 20742, H. DENNIS DREW³, Department of Physics, University of Maryland, College Park, MD 20742, PAUL KOLB, WARREN HERMAN, Laboratory for Physical Sciences, College Park, MD 20740, RAYMOND PHANEUF⁴, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20742 — We present results from measurements on periodic multilayer structure of alternating dielectric and thin metal layers to achieve a broadband absorber of mid-infrared radiation. We examine the effect on performance of a back-reflective metallic bottom layer, surface roughness at interfaces, the metal conductance, the thickness of dielectric layers, and a patterned anti-reflective layer. We determine optimum structure parameters for absorption of a 500 K-black body spectrum, and find that the numerical results agree well with the measured absorption spectra. We also investigate the possibility of fabricating a patterned anti-reflective layer to further increase the absorption.

12:03PM Z18.00005 Simultaneous Bulk and Surface Plasmon Resonance and Radiative Polaritons excited in RuO₂ films grown on glass and on TiO₂ (001)¹, L. WANG, C. CLAVERO, K. YANG, E. RADUE, College of William and Mary, G. SCAREL, James Madison University, I. NOVIKOVA, R. LUKASZEW, College of William and Mary — Conducting oxides, such as RuO₂, have a much lower carrier concentration as compared to metals, leading to a lower plasma frequency of 3.3eV which lies in the infrared (IR) region. This unique feature of conducting oxides allows for simultaneous observation of surface and bulk polariton modes in the IR range. Here we have investigated bulk and surface plasmons as well as radiative polaritons in RuO₂ thin films. The RuO₂ thin films investigated were grown using DC magnetron sputtering on glass and on TiO₂ (001). We have used X-ray Diffraction and Reflection High-Energy Electron Diffraction to characterize the microstructure of these samples. Four-point probe and ellipsometry were used to investigate the electrical conductivity and the optical properties. The optical measurements were carried out using HeNe red laser (632nm) and IR laser (1520nm) radiations to illuminate RuO₂ thin films. We will show that bulk plasmons can be excited in RuO₂ thin films in the visible red region, while simultaneous bulk plasmons as well as surface plasmons excitation are observed in the IR region. We also studied the substrate influence on the radiative polaritons in the middle IR region ($20\text{-}2.2\mu\text{m}$) by measuring films grown on glass and on TiO₂ (001).

12:15PM Z18.00006 Simulations of enhanced absorption in composite embedded, insulated metal nanopatterns for ultrathin film photovoltaics, XINYU LIU, FAN YE, MICHAEL J. BURNS, MICHAEL J. NAUGHTON, Department of Physics, Boston College, Chestnut Hill, 02467 — In recent work [1], a concept of employing embedded metallic nanopatterns (EMN) in ultrathin film solar cells was discussed. Elsewhere in this conference, Fan *et al.* advance this with a scheme for embedded insulated metallic nanopatterns (EIMN) that is designed to avoid deleterious carrier recombination as would result from bare metal inclusions in a PV film. However, a practical route to fabricating EIMNs of desired shapes for eventual scale production is nontrivial. Here, we introduce two notions toward that goal, nano-stamping and spin-coating, of compact arrays of metallic core/insulating shell nanoparticles (MNP). We show by simulations that optical absorption of an EIMN composed of arrays of core-shell MNPs having SiO₂ coatings is essentially the same as that of an EMN composed of solid metals without insulation, with absorption concentrated in the surrounding PV medium. These concepts may provide practical routes for scalability of EIMN-based ultrathin film plasmonic solar cells.

12:27PM Z18.00007 Embedded insulated metallic nanopatterns for enhanced optical absorption and photovoltaics, FAN YE, MICHAEL J. BURNS, MICHAEL J. NAUGHTON, Department of Physics, Boston College, Chestnut Hill, 02467 — Recently, we have shown embedded metallic nanopatterns (EMN) in ultrathin PV films to be candidates for high efficiency thin-film solar cells, owing to prominent metamaterial/plasmonic-enhanced light trapping, as compared to unpatterned, surface- or bottom-patterned [1]. We also showed that hot electron effects emerge in ultrathin a-Si-based solar cells [2]. The EMN in the semiconductor layer, however, can also serve as a source of recombination for photogenerated electrons and holes, leading to decreased current. Here, we propose the idea of an embedded insulated metallic nanopattern (EIMN) to efficiently avoid the recombination effect while maintaining high light absorption in an ultrathin film format in which hot electron physics can contribute. Simulations show that an EIMN with a 10 nm layer of dielectric insulation provides essentially the same absorption as its EMN counterpart. Measurements on several EMN structures will be presented. This EIMN architecture may provide a practical route to high efficiency, hot electron solar cell technology using ultrathin films.

[2]K. Kempa, M.J. Naughton, Z.F. Ren, A. Herczynski, T. Kirkpatrick, J. Rybczynski, Y. Gao, Appl. Phys. Lett. 95, 233121(2009)

12:39PM Z18.00008 An effective medium formulation to estimate the plasmonic dispersion of a randomly distributed gallium nanoparticle ensemble, YANG YANG, Physics Dept, Duke University, JOHN M. CALLAHAN, Nanogenesis Div, AEGIS Technology, TONG-HO KIM, APRIL S. BROWN, ECE Dept, Duke University, MARIA LOSURDO, GIANNI BRUNO, IMIP-CNR, HENRY O. EVERITT, Physics and ECE, Duke University; Army Aviation and Missile RD&E Center — Quantum confinement causes the dielectric function of nanometer-sized metal particles to depart from metallic bulk dispersion in a manner correlating with the size, shape, and spacing of the nanostructures. An improved effective medium approximation is formulated to reconcile angle-dependent ultraviolet/visible spectroscopy and spectroscopic ellipsometry measurements of the collective optical dispersion of randomly distributed hemispherical gallium nanoparticles deposited on a sapphire surface using ultra high vacuum molecular beam epitaxy. Atomic force microscopy and scanning electron microscopy analyze the size distribution of the nanoparticle ensembles to estimate their volume fraction. The optical constants are then estimated using a modified Maxwell-Garnett effective medium approximation that treats the ambient vacuum as a host and the bare sapphire substrate as a semi-infinite layer. The refined dielectric function improves estimates of the collective plasmonic response of the nanoparticle ensemble.

12:51PM Z18.00009 Plasmon responses and optical chirality of helical nanoparticle assemblies¹, ZHIYUAN FAN, ALEXANDER GOVOROV, Department of Physics and Astronomy, Ohio University, Athens, Ohio 45701, United States, OHIO UNIVERSITY TEAM — Helical gold nanoparticle assemblies exhibit strong circular dichroism (CD) in the plasmonic band. This CD effect comes from dipolar Coulomb and electromagnetic interactions between spherical gold nanoparticles. A typical CD spectrum of chiral plasmonic assembly includes positive and negative bands. The shape of CD spectra is sensitive to geometrical parameters of the assembly. In this study, we show that the CD signal is stable against structural defects, which makes experimental realizations of strong CD effect feasible. To date, several recent experimental papers reported CD effects in helical plasmonic systems. In addition, we found that the sign of CD signal can flip as a function of the inter-particle distance and, for very long helices, the long-range electrodynamic interactions become essential. These results are important for designing nanocomposite materials with strong optical chirality in the visible wavelength range.

1:03PM Z18.00010 Determining 3D Relative Orientation between Plasmonic Nanoparticles¹, FARBOD SHAFIEI, CHIHUI WU, PATRICK PUTZKE, YANWEN WU, AKSHAY SINGH, GENNADY SHVETS, XIAOQIN LI, University of Texas at Austin — Polarization resolved far-field scattering measurements were used to determine 3D relative orientation between plasmonic nanoparticles placed few nanometers apart. The metallic nanostructure was assembled using the atomic force microscope (AFM) nanomanipulation method. When a gold nanosphere (150 nm in diameter) was placed within a few nanometers to the end of a gold nanorod (20 nm in diameter and 180 nm in length), near field coupling between them introduced new features in the scattering spectra. Specifically, a Fano resonance emerged, due to the interference between a dark mode, corresponding to the quadrupole charge distribution on the rod, and the bright, dipole mode of the sphere. As linear polarizer in the path of the incident and emission light was rotated, the scattering spectra evolve systematically, enabling us to determine the 3D relative orientation between these two plasmonic nanoparticles. This orientation information cannot be accurately and dynamically obtained using other scanning probe techniques, especially when one nanoparticle is partially hidden under the other nanoparticles.

1:15PM Z18.00011 Plasmonic Circular Dichroism Effect in Nanomaterials¹, HUI ZHANG, ZHIYUAN FAN, ALEX GOVOROV, Ohio University — By employing a numerical solution of Maxwell's equations beyond the dipole limit, we studied the circular dichroism (CD) signal of a chiral molecule in the presence of a gold nanoparticle (NP) dimer. The CD signals come from two parts: The first one is Coulomb interaction within the molecule-dimer complex giving rise to the plasmon peak in the CD spectrum, while the other one is the plasmonic enhancement of the absorption process in a chiral molecule. Typically, the CD signals of chiral molecules are very weak in the visible range, but are strong in the UV range. In the presence of gold dimer, however, we found a strong CD signal emerges in the visible range of photon energies, where the plasmon effect makes the main contribution to CD signal at the plasmon frequency. Furthermore, we propose that, by using the plasmon-induced CD signals, one can design optical sensors to study chirality of biomolecules.

1:27PM Z18.00012 Metamaterial Enhanced Terahertz Spectroscopy of Biomolecules, LOGAN CHIEFFO, GEORGE KEISER, ANDREW STRIKWERDA, Boston University, Department of Physics, KEBIN FAN, Boston University, Department of Mechanical Engineering, SHYAMSUNDER ERRAMILLI, Boston University, Department of Physics, XIN ZHANG, Boston University, Department of Mechanical Engineering, RICHARD AVERITT, Boston University, Department of Physics — As the field of metamaterials experiences exponential growth, an increasing number of studies have focused on understanding near-field coupling between arrays of metamaterials and their local environment. Examples include a second array of metamaterials, phonon bands in semiconductors, and even small molecules. In this work, we demonstrate metamaterial coupling to a thin film of biomolecules. Protein films are deposited onto arrays of gold split ring resonators (SRRs) on thin silicon nitride substrates. As the LC resonance of the SRR is tuned across the low frequency terahertz (THz) modes of the biomolecule, hybridization results in mode splitting. The thin substrates (400nm) and the large electric field enhancement intrinsic to the SRRs provide ultrasensitive detection of the THz modes in the protein, allowing for the THz response to be measured from thin films which would otherwise not be observable.

1:39PM Z18.00013 Poynting vector in magnetic materials: from thermomagnetic effects to metamaterials, ANDREI SERGEEV, MICHAEL REIZER, VLADIMIR MITIN, SUNY at Buffalo — In a finite sample, besides the bulk currents given by the Kubo formula, additional charge and energy are transferred by surface magnetization currents. We show that for the energy current, the corresponding surface correction to the Kubo's current is expressed in terms of the magnetization component of the Poynting vector, $\mathbf{M} \times \mathbf{E}$. Magnetization currents, like persistent currents, are dissipationless and do not transfer entropy. Only in this way, one can obtain the Nernst and Ettingshausen coefficients that satisfy to the Onsager relation. In the microscopic transport theory, for maintaining gauge invariance in a magnetic field, the heat current operator should include the magnetic term. Both magnetization-related effects - the dissipationless nature and strong surface contribution to the energy transfer - have been also overlooked in the recent works on the Poynting vector in metamaterials. The paradoxes in this area are resolved, if one accurately considers a balance of electromagnetic energy transferred by bulk and surface magnetization currents.

1:51PM Z18.00014 Polarization Conversion Using the Cavity Resonances of Plasmonic Patch Nanoantennas, FENG WANG, AYAN CHAKRABARTY, Liquid Crystal Institute, Kent State University, FRED MINKOWSKI, Department of Physics, Kent State University, QI-HUO WEI, Liquid Crystal Institute, Kent State University — The control of light polarization is essential to all optical experiments and photonic devices. Here we propose and demonstrate a novel method to realize the polarization conversion by using an array of non-chiral plasmonic patch nano-antennas. The patch nano-antennas are composed of a 2D array of elliptical Ag nano-disks and a base Ag substrate spaced by an ultra-thin dielectric layer. The Ag nano-disks and the base metal substrate would form an array of plasmonic nanocavities with ultrasmall mode volumes. We will show the excitation of the fundamental mode of the plasmonic cavity resonance could introduce a 90° phase delay to the reflected light from the patch antenna. This phase delay can be utilized to realize the polarization conversion between linearly polarized light and elliptically or circularly polarized light.

2:03PM Z18.00015 Plasmonic nanowire transmission lines, YUN PENG, KRIS KEMPA, Physics Department, Boston College — Metallic nanowires could be used as nano-optical transmission lines. The important factors characterizing such lines are the subwavelength operation, long propagation length, and low penetration of the propagating modes into the environment outside wires. In this work we study these factors in silver nanowires operating as surface plasmon polariton (SPP) waveguides, by employing the finite difference time domain (FDTD) and the finite difference frequency domain (FDFD) simulations. In addition to the dispersion relation of the SPP mode, we investigate the inter-wire crosstalk, an important feature of the nano-optical circuits. We compare our results with the available experimental results.

Session Z19 DCMP: Invited Session: Non-Abelian States in the 1st Excited Landau Level: Experimental Status and Theoretical Outlook 253AB

11:15AM Z19.00001 Interferometric evidence for non-Abelian quasiparticles at filling factor $5/2$, ROBERT WILLETT, Bell Laboratories, Alcatel-Lucent — The $5/2$ fractional quantum Hall state charge $e/4$ excitations are proposed to follow non-Abelian statistics [1]. In edge state interference these purported non-Abelian quasiparticles should display period $e/4$ Aharonov-Bohm oscillations if the interfering quasiparticle encircles an even number of localized $e/4$ charges, but suppression of oscillations if an odd number is encircled [2-3]. To test this, we have performed swept area interference measurements at $5/2$ [4-5]. We observe an alternating pattern of $e/4$ and $e/2$ period oscillations in resistance for a large change in the interferometer area, with the area sweep changing the enclosed localized $e/4$ quasiparticle number. This observed aperiodic alternation is consistent with proposed non-Abelian $e/4$ properties: the $e/4$ oscillations occur for encircling an even number of localized quasiparticles over their aperiodic spatial distribution, and the lower amplitude $e/2$ oscillations are observed when encircling an odd number as the $e/4$ oscillations are suppressed, allowing observation of the persistent smaller Abelian $e/2$ oscillations. Importantly, adding localized quasiparticles to the encircled area by changing magnetic field can change the parity of the enclosed quasiparticle number and should induce interchange of the expressed $e/4$ and $e/2$ periods: such interchange is observed in these measurements. In further experiments with the goal of understanding specific $e/4$ edge propagation properties, a series of interferometers of different sizes have been tested. The range of device dimensions has allowed measurement of the $e/4$ quasiparticle propagation attenuation length, demonstrating that small interferometric pathlengths are necessary to observe the interference oscillations. The stability in phase and amplitude of the $e/4$ oscillations has been tested with respect to sample dimensions, time, and temperature using this set of interferometers, and these results will be discussed.

11:51AM Z19.00002 Observation of Braiding Statistics in the Fractional Quantum Hall Effect¹, WOOWON KANG, University of Chicago — It has been postulated that the quasiparticles excitations of fractional quantum Hall (FQH) states are Abelian anyons with fractional statistical angles. More interestingly, non-Abelian anyons have been predicted for certain FQH states such as that found at filling factors $\nu = 5/2$ and $12/5$. To date experimental detection of anyons and their braiding statistics in quantum interference experiments has remained controversial. In this talk I will present results from the study of Abelian and non-Abelian braiding statistics of anyons in the fractional quantum Hall (FQH) systems through Fabry-Perot interferometry. In the $\nu = 7/3$ FQHE state we confirm the anyonic braiding statistics by detecting the postulated statistical phase angle of $2\pi/3$. This result is consistent with a change of the anyon number by one. In the interference study of the $\nu = 5/2$ FQH state we observe phase slips $5\pi/4, \pi$, and $\pi/4$. These observed statistical phase slips agree with a theoretical model of braiding of Majorana modes of the $\nu = 5/2$ non-Abelian state that is strongly coupled to each other and to the edge modes of interferometer in presence of Coulomb interaction. Our results provide compelling support for the existence of non-Abelian anyons.

¹Work performed in collaboration with Sanghun An, P. Jiang, H. Choi, S.H. Simon, L.N. Pfeiffer, K.W. West, and K.W. Baldwin; supported by Microsoft and NSF MRSEC.

12:27PM Z19.00003 Quantum Hall interferometry in abelian and non-abelian states, ADY STERN¹, Weizmann Institute of Science — This talk deals with the theory of quantum Hall interferometers. I will first consider an idealized model of such interferometers and review how they may potentially identify anyonic quasi-particles, both abelian and non-abelian. I will then describe lessons learned from experiments regarding this idealized model, and how it should be amended to take into account effects of coupling between the bulk and the edge. In particular, I will describe how electron-electron interaction affects the outcome of interferometry experiments and distinguishes between “Aharonov-Bohm” and “Coulomb-dominated” regimes. These two regimes are characterized by different magnetic field periodicities and different directions of the equi-phase lines in the plane of magnetic field and voltage applied to a side gate. I will discuss how the contributions of the Aharonov-Bohm effect, the Coulomb interaction and the fractional statistics (abelian and non-abelian) may be distinguished from one another in the two regimes. Finally, I will address issues unique to non-abelian states, particularly the effect of bulk-edge tunnel coupling on the interference, and comment on experimental observations of interference in the $\nu = 5/2$ state.

¹The works I will describe have been carried out with B.I. Halperin (Harvard), I. Neder (Harvard & Tel-Aviv), Bernd Rosenow (Leipzig) and S.H. Simon (Oxford)

1:03PM Z19.00004 Plasma Analogy and non-Abelian Braiding Statistics in Ising-type Quantum Hall States, PARSA BONDERSOON, Microsoft Station Q — Quantum Hall systems are effectively two-dimensional and thus allow for quasiparticle excitations with exotic exchange statistics based on the braid group. These may be “anyons” with fractional statistics that lie somewhere between that of bosons and fermions, or, even more exotically, “non-Abelian anyons” with quasiparticle exchange represented by matrices. The quasiparticle statistics of candidate quantum Hall states (universality classes) is usually conjectured, but in some instances can be deduced from their representative trial wavefunctions. I will explain how this can be done for wavefunctions with a “plasma analogy” similar to Laughlin’s. Then I will construct a plasma analogy for the non-Abelian Ising-type states, e.g. the Moore-Read Pfaffian state. This provides the first complete proof of the non-Abelian braiding statistics of quasiparticles in these states, which are likely candidates to explain the observed Hall conductivity plateaus in the second Landau level, most notably the one at filling fraction $\nu = 5/2$.

1:39PM Z19.00005 Insights into the Nature of the Exotic Fractional Quantum Hall States from Ultra-low Temperature Transport, GABOR CSATHY, Purdue University — It is believed that the $\nu = 5/2$ and $12/5$ fractional quantum Hall states (FQHS) in the second Landau level of a two-dimensional electron gas support excitations with non-Abelian braiding statistics. Two outstanding questions concerning the nature of the both the odd and even denominator FQHS of the second Landau level as probed by transport measurements at temperatures as low as 5mK will be addressed. We report the discovery of a new odd denominator FQHS state at $\nu = 2 + 6/13$. The energy gaps of this and other states at $\nu = 2 + 1/3, 2 + 2/3$, and $2 + 2/5$ reveal a markedly different dependence on the effective magnetic field as compared to that of the corresponding lowest Landau level states at $6/13, 1/3, 2/3$, and $2/5$. If, in addition, we assume a Landau level-independent effective mass, we find that the $7/3$ and $8/3$ states are consistent, whereas the $2 + 2/5$ and the $2 + 6/13$ states show a strong deviation from the predictions of the model of free composite fermions. For the even denominator states at $\nu = 5/2$ and $7/2$ we extended measurements to the new regime of very low densities and to samples grown in two MBE chambers: one at Princeton and one at Purdue. Comparisons found in the literature of the experimentally measured intrinsic gaps at $\nu = 5/2$ with numerical results are confusing: three methods find a large difference whereas a fourth method finds a good agreement. Our data suggests that the former three methods have deficiencies and therefore cannot be used. Using the fourth and a new method we introduce we find an excellent agreement of the experimental and numerical intrinsic gaps at $\nu = 5/2$. These findings lend a strong support to the Pfaffian description of the $\nu = 5/2$ fractional state. Work done in collaboration with A. Kumar, N. Samkharadze, N. Deng, J. Watson, G. Gardner, M. Manfra, L. Pfeiffer, and K. West. G.A.C. has been supported by the NSF DMR-0907172 and DOE DE-SC0006671 grants.

Session Z20 DCMP: Invited Session: Optical Processes in Nitrides and Other Wide-Band-Gap Semiconductors 253C

11:15AM Z20.00001 Electronic Properties of ZnO: Reconciling Multiple Techniques¹, STEVEN M. DURBIN, University at Buffalo, The State University of New York — Significant progress has been made recently in our understanding of the electronic properties of ZnO and their physical origins, and yet we are far from being in possession of a complete picture despite decades of effort. Given the ultraviolet bandgap of this semiconductor (essentially the same as GaN), its easy synthesis using a wide variety of crystal growth techniques, the ready availability of high-quality single crystals, and intrinsic highly efficient luminescence, it is a material of great interest for a wide variety of device applications. Still, reliable p-type doping remains a considerable obstacle to realizing junction devices, and luminescence features often attributed to acceptor related transitions in fact have alternative physical origins. The role of impurities is reasonably well-understood, but a detailed understanding of dominant defects is somewhat elusive, although several techniques based directly and indirectly on Schottky contacts have provided some illumination on the topic. In this talk, I will summarize recent results in the field, and outline some of the key issues to which definitive answers are desirable if ZnO is going to be commercially competitive with GaN.

11:51AM Z20.00002 Loss mechanisms in nitrides¹, CHRIS VAN DE WALLE, Materials Department, University of California, Santa Barbara — Indium gallium nitride alloys are successfully being used for light emitting diodes (LEDs) and laser diodes (LDs) in the green to ultraviolet part of the optical spectrum. These devices are the key enablers to Solid-State Lighting, which promises to significantly cut electricity consumption. Applications are still limited, however, by the declining efficiency of LEDs at high currents ("droop") and by absorption losses of undetermined origin in LDs. Several mechanisms have been suggested as the cause of this efficiency loss, such as Auger recombination and free carrier absorption. Experimentally it is very difficult to discriminate between different nonradiative processes. We have therefore addressed the loss mechanisms based on state-of-the-art first-principles computational theory. We use ab initio wave functions and bands that are accurate throughout the entire Brillouin zone (as opposed to k.p band structures). For Auger recombination we find that both electron-electron-hole and hole-hole-electron processes contribute, and that indirect processes assisted by alloy scattering and by electron-phonon coupling dominate. The magnitude of the resulting Auger coefficient indicates that Auger recombination is indeed responsible for the efficiency reduction at high carrier densities. Strategies for overcoming this limitation will be discussed. For free-carrier absorption, the relevant optical processes are again indirect. We determine the optical absorption coefficient and the corresponding photon mean free path as a function of carrier concentration. The computed values indicate that the effect is weak in LEDs but constitutes an important loss mechanism in LDs.

¹Work performed in collaboration with E. Kioupakis, P. Rinke, K. Delaney, and D. Steiauf, and supported by DOE and by the UCSB SSLEC.

12:27PM Z20.00003 Carrier localisation mechanisms and efficiency droop in nitride quantum wells, COLIN HUMPHREYS, University of Cambridge — A variety of experimental evidence indicates that the carriers in InGaN quantum wells (QWs) in InGaN/GaN QW structures are localised at room temperature, for example the S-shape temperature dependence of the peak photoluminescence (PL) energy with increasing excitation power density, a key fingerprint of carrier localisation. This localisation is believed to be responsible for the high efficiency of light emission from InGaN QWs since it prevents the carriers from moving to non-radiative recombination centers such as dislocations. In-rich clusters in the InGaN QWs were widely believed to be responsible for the localisation of the carriers. However, careful electron microscopy (EM) and atom probe tomography (APT) have shown that such clusters do not exist in InGaN QWs, at least for In contents less than 25%, and hence such clusters cannot be responsible for the localisation of the carriers. So what mechanisms are localising the carriers? APT and EM have shown that the InGaN in the QWs is a random alloy, with the In atoms distributed at random on the Ga sites. They have also shown that the InGaN QWs have monolayer and bilayer thickness fluctuations. Quantum mechanical calculations show that the holes in the InGaN QWs are localised on a scale of 1-2nm by the random indium fluctuations, and the electrons are localised on a scale of about 5nm by the QW thickness fluctuations. This localisation prevents the carrier from diffusing to dislocations and hence results in a high efficiency of light emission at room temperature. At high carrier densities the localised states saturate with carriers and the additional non-localised carriers can then diffuse to defects and recombine non-radiatively. It is suggested that this is a significant contributory factor to the efficiency droop observed in InGaN/GaN QW structures at higher current densities.

1:03PM Z20.00004 Photoluminescence as a tool for characterizing point defects in semiconductors, MICHAEL RESHCHIKOV, Physics Department, Virginia Commonwealth University — Photoluminescence is one of the most powerful tools used to study optically-active point defects in semiconductors, especially in wide-bandgap materials. Gallium nitride (GaN) and zinc oxide (ZnO) have attracted considerable attention in the last two decades due to their prospects in optoelectronics applications, including blue and ultraviolet light-emitting devices. However, in spite of many years of extensive studies and a great number of publications on photoluminescence from GaN and ZnO, only a few defect-related luminescence bands are reliably identified. Among them are the Zn-related blue band in GaN, Cu-related green band and Li-related orange band in ZnO. Numerous suggestions for the identification of other luminescence bands, such as the yellow band in GaN, or green and yellow bands in ZnO, do not stand up under scrutiny. In these conditions, it is important to classify the defect-related luminescence bands and find their unique characteristics. In this presentation, we will review the origin of the major luminescence bands in GaN and ZnO. Through simulations of the temperature and excitation intensity dependences of photoluminescence and by employing phenomenological models we are able to obtain important characteristics of point defects such as carrier capture cross-sections for defects, concentrations of defects, and their charge states. These models are also used to find the absolute internal quantum efficiency of photoluminescence and obtain information about nonradiative defects. Results from photoluminescence measurements will be compared with results of the first-principle calculations, as well as with the experimental data obtained by other techniques such as positron annihilation spectroscopy, deep-level transient spectroscopy, and secondary ion mass spectrometry.

1:39PM Z20.00005 Numerical Simulation of III-Nitrides Materials and Light Emitting Devices¹, ENRICO BELLOTTI, Boston University — The versatility of III-Nitrides semiconductors has led to their use in an increasing number of technologically important applications. Their ability to operate over a wide spectral range from the infrared to the deep ultraviolet has propelled this material system into the field light emitters and detectors. Furthermore, their desirable high field transport properties make III-Nitrides an ideal platform for power semiconductor devices. Along with the experimental activity to fabricate and characterize optoelectronic and electronics devices, a number of significant theoretical efforts are underway to understand the novel properties of this material system. This presentation will discuss the unique characteristics that the III-Nitrides material presents from the point of view of the carrier transport and optical properties. The quantum mechanical processes that are responsible for breakdown at high fields will also be discussed. In particular it will be shown that these quantum mechanical effects have to be taken into account to reproduce a number of experimental results. Furthermore, an analysis of the non-radiative recombination processes that are relevant in analyzing the quantum efficiency data of III-Nitride based light emitters will be presented. Finally the model used and the results obtained for the direct and assisted (phonons and electrons) Auger recombination rates and their impact on the calculated quantum efficiency of III-Nitrides based LEDs will be presented.

Friday, March 2, 2012 11:15AM - 2:15PM –

Session Z22 DMP DCOMP: Focus Session: Fe-based Superconductors - Orbital Order and Chalcogenides 254B

11:15AM Z22.00001 Orbital Order and Orthorhombic Anisotropy in Iron Pnictides¹, CHENG-CHIEN CHEN, Stanford Institute for Materials and Energy Science, SLAC National Accelerator Laboratory — Orthorhombic anisotropy has been reported in iron-pnictide superconductors by a broad range of experiments, including neutron scattering, transport measurements, and a variety of spectroscopies. We explore the idea that these observed anisotropies of broken tetragonal symmetry stem from an ordering of the partially-filled iron d-orbitals. In particular, we will consider a model Hamiltonian that couples the spin and orbital variables, and show that this spin-orbital model captures several observed behaviors in the iron-pnictide materials. We will conclude the talk by discussing x-ray absorption linear dichroism and other recent experiments supportive of theories highlighting the orbital degrees of freedom.

¹Research supported by the U.S. Department of Energy under contract No. DE-AC02-76SF00515. Work in collaboration with the research groups of Thomas Devereaux and Rajiv Singh.

11:51AM Z22.00002 Orbital ordering in Ba(Fe_{1-x}Co_x)₂As₂ revealed by X-ray absorption Spectroscopy, Y.K. KIM, W.S. JUNG, G.R. HAN, C. KIM, Yonsei Univ., K.-Y. CHOI, Seoul National Univ., A.P. SINGH, J.Y. KIM, Pohang accelerator lab., J. MIYAWAKI, Y. TAKATA, A. CHAINANI, Excitation order research team, RIKEN SPing-8 Center — Recently, anomalous in-plane anisotropy was observed by various experiment in iron pnictide systems. To explain the anomalous in-plane anisotropic behavior observed in iron pnictide system, orbital ordering was suggested as an origin of it. Among the various possible ordering, Ferroorbital ordering was proposed which occurs unequal occupation number of d_{yz} and d_{zx} orbital. It was theoretically predicted that such orbital ordering could be observed by performing X-ray Linear Dichroism experiment. To figure out, we performed the experiment on the most studied iron pnictide system, Ba(Fe_{1-x}Co_x)₂As₂. We obtained linear dichroism signal which indicates different occupation number for different orbital. And we observed temperature and doping dependence of the dichroism signal. Our results support the existence of ferro-orbital ordering.

12:03PM Z22.00003 Non-Fermi Liquid due to Orbital Fluctuations in Iron Pnictide Superconductors, WEI-CHENG LEE, PHILIP PHILLIPS, University of Illinois at Urbana-Champaign — We propose that the quantum fluctuations associated with quasi-1D d_{xz} and d_{yz} bands could result in a non-Fermi liquid behaviour in iron-pnictide superconductors. Using a five orbital tight binding model with generalized Hubbard on-site interactions, we find that within a one-loop treatment, a branch of overdamped collective modes develops at low frequency in channels associated with quasi-1D d_{xz} and d_{yz} bands. When the critical point for the C₄ symmetry broken phase (structural phase transition) is approached, the overdamped collective modes soften, and acquire increased spectral weight, leading to a non-Fermi liquid behavior at the Fermi surface. We argue that this non-Fermi liquid behavior is responsible for the recently observed zero-bias enhancement in the tunneling signal in quantum point contact spectroscopy. A key experimental test of this proposal is the absence of the non-Fermi liquid behaviour in the hole-doped materials. Our result suggests that quantum criticality plays an important role in understanding the normal state properties of iron-pnictide superconductors.

12:15PM Z22.00004 Spin and orbital characters of excitations in iron arsenide superconductors revealed by simulated resonant inelastic x-ray scattering, TAKAMI TOHYAMA, Yukawa Institute for Theoretical Physics, Kyoto University, EIJI KANESHITA, Sendai National College of Technology, KENJI TSUTSUI, Synchrotron Radiation Research Center, Japan Atomic Energy Agency — We theoretically examine the orbital excitations coupled to the spin degree of freedom in the parent state of the iron-arsenide superconductor, based on the calculation in a five-band itinerant model [1]. The calculated Fe L₃-edge resonant inelastic x-ray scattering (RIXS) spectra disclose the presence of spin-flip excitations involving several specific orbitals. Magnon excitations predominantly composed of a single orbital component can be seen in experiments, although its spectral weight is smaller than spin-flipped interorbital high-energy excitations. The detailed polarization and momentum dependence is also discussed with predictions for the experiments. [1] E. Kaneshita, K. Tsutsui, and T. Tohyama, Phys. Rev. B **84**, 020511(R) (2011)

12:27PM Z22.00005 Orbital fluctuation mediated superconductivity and structure transition in iron-based superconductors, HIROSHI KONTANI, Nagoya University — The main features in Fe-based superconductors are summarized as (i) orthorhombic transition accompanied by remarkable softening of the shear modulus C₆₆, (ii) high-T_c superconductivity close to the orthorhombic phase, and (iii) stripe-type magnetic order induced by orthorhombicity. To understand them, we analyze the multiorbital Hubbard-Holstein model with Fe-ion optical phonons. In the random-phase-approximation (RPA), a small electron-phonon coupling constant ($\lambda \sim 0.2$) is enough to produce large orbital (=charge quadrupole) fluctuations. The most divergent susceptibility is the O_{xz}-antiferro-quadrupole (AFQ) susceptibility, which causes the s-wave superconductivity without sign reversal (s₊₊-wave state). ¹ The s₊₊-wave state is robust against impurities, ² consistently with experimental observations. At the same time, divergent development of O_{x²-y²}-ferro-quadrupole (FQ) susceptibility is brought by the “two-orbital process” with respect to the AFQ fluctuations.

²S. Onari and H. Kontani, Phys. Rev. Lett. **103**, 177001 (2009).

12:39PM Z22.00006 A Monte Carlo simulation study of phase transitions in spin-orbital models for iron pnictides¹, RYAN APPLGATE, RAJIV SINGH, Department of Physics, University of California, Davis, CHENG-CHIEN CHEN, THOMAS DEVEREAUX, Department of Physics, Stanford University, Stanford — The common phase diagrams of superconducting iron pnictides show interesting material specificities in the structural and magnetic phase transitions. In some cases the two transitions are separate and second order, while in others they appear to happen concomitantly as a single first order transition. We explore these differences using Monte Carlo simulations of a two-dimensional Hamiltonian with coupled Heisenberg-spin and Ising-orbital degrees of freedom. In this spin-orbital model, the finite-temperature orbital-ordering transition results in a tetragonal-to-orthorhombic symmetry reduction and is associated with the structural transition in the iron-pnictide materials. With a zero or very small spin space anisotropy, the magnetic transition separates from the orbital one in temperature, and the orbital transition is found to be in the Ising universality class. With increasing anisotropy, the two transitions rapidly merge together and tend to become weakly first order. We also study the case of a single-ion anisotropy and propose that the preferred spin-orientation along the antiferromagnetic direction in these materials is driven by orbital order.

¹Supported in part by NSF-DMR1004231 and US DOE DE-AC02-76SF00515

12:51PM Z22.00007 Local Quantum Criticality of an Iron-Pnictide Tetrahedron¹, TZE TZEN ONG, PIERS COLEMAN, Center for Materials Theory, Department of Physics & Astronomy, Rutgers University — Motivated by the close correlation between transition temperature (T_c) and the tetrahedral bond angle of the As-Fe-As layer observed in the iron-based superconductors, we study the interplay between spin and orbital physics of an isolated iron-arsenide tetrahedron embedded in a metallic environment. Whereas the spin Kondo effect is suppressed to low temperatures by Hund's coupling, the orbital degrees of freedom are expected to quantum mechanically quench at high temperatures, giving rise to an overscreened, non-Fermi liquid ground-state. Translated into a dense environment, this critical state may play an important role in the superconductivity of these materials.

¹This work is supported by DOE grant DE-FG02-99ER45790.

1:03PM Z22.00008 Hint of a condensate in $K_{0.8}Fe_{2-y}Se_2$ ¹, C.C. HOMES, J.S. WEN, Z.J. XU, G.D. GU, Condensed Matter Physics and Materials Science Dept., Brookhaven National Laboratory, Upton, New York — The optical properties of the iron-chalcogenide superconductor $K_{0.8}Fe_{2-y}Se_2$ with a critical temperature $T_c = 31$ K have been measured over a wide frequency range in the a - b planes above and below T_c . The conductivity is incoherent at room temperature, but becomes coherent (Drude-like) with $\omega_{p,D} \simeq 430 \pm 20$ cm⁻¹ and $1/\tau_D \simeq 70 \pm 5$ cm⁻¹ at $T \simeq T_c$; however, $\omega_{p,D}$ is an order of magnitude smaller than what is observed in other iron-based superconductors. The highly anisotropic nature of these materials suggests that the transport is best described by a sheet resistance $R_{\square} = \rho_{dc}/d \simeq 64$ k Ω (per sheet), well above the threshold for the superconductor-insulator transition at $R_{\square} = h/4e^2 \simeq 6.9$ k Ω . Below T_c , $\omega_{p,S} \simeq 220 \pm 20$ cm⁻¹ resulting in a superfluid density $\rho_{s0} \equiv \omega_{p,S}^2 \simeq 48 \times 10^3$ cm⁻², placing this material on the scaling line $\rho_{s0}/8 \simeq 4.4 \sigma_{dc} T_c$ observed for the cuprates, but in a region associated with Josephson coupling, suggesting this material is inhomogeneous and constitutes a Josephson phase.²

²C. C. Homes *et al.*, arXiv:1110.5529

1:15PM Z22.00009 Optical spectroscopy of $K_xFe_{2-y}Se_{2-z}S_z$ superconductors¹, CATALIN MARTIN, K. MILLER, University of Florida, Gainesville, FL 32611, HECHANG LEI, C. PETROVIC, Brookhaven National Laboratory, Upton, NY 11973, D. B. TANNER, University of Florida, Gainesville, FL 32611 — We measured the temperature dependent optical reflectivity $R(\omega)$ and extracted the complex optical conductivity $\sigma(\omega)$ of the $K_xFe_{2-y}Se_{2-z}S_z$ superconductors. At room temperature, both $R(\omega)$ and $\sigma_1(\omega)$ have semiconducting behavior. Upon cooling, at temperatures depending on the S-concentration, the low frequency reflectivity increases in absolute value and shows a sharp upturn, consistent with metallic behavior. The phonon spectrum of $\sigma_1(\omega)$, which is very different from similar Fe-based superconductors and also doping dependent will be explained in terms of the changes in occupancy of the Fe-sites with doping. An anomalous feature in optical reflectivity is observed in the superconducting state and its possible origin and association with the condensation of free carriers will be discussed.

¹Supported by US DOE under contract DE-FG02-02ER45984 and under contract DE-AC02-98CH10886

1:27PM Z22.00010 Electronic Structure of $K_{0.8}Fe_2Se_2$ High Temperature Superconductor, SHIZHONG YANG, RUI GUO, EBRAHIM KHOSRAVI, GUANG-LIN ZHAO, DIOLA BAGAYOKO, Southern University and A&M College, ELECTRONIC STRUCTURE TEAM, HPC TEAM — Since the synthesis of the first ones in 2008, iron-based high temperature superconductors have been the subject of many studies. This great interest is partly due to their higher, upper magnetic field, smaller Fermi surface around the Γ point, and a larger coherence length. This work is focused on $A_xFe_2Se_2$ structural superconductor (FeSe, 11 hierarchy; A=K, Cs) as recently observed. ARPES data show novel, electronic structure and a hole-free Fermi surface which is different from previously observed Fermi surface images. *Ab initio* density functional theory GW method was used to simulate the electronic structure of the novel superconductor $A_xFe_2Se_2$. We compare this electronic structure with those of other Fe-based superconductors. Possible explanations for the hole-free Fermi surface were discussed.

1:39PM Z22.00011 ARPES studies of the AFe_2Se_2 (A=K, Rb, Cs) iron-based superconductors, MING YI, Stanford University, D.H. LU, SLAC National Accelerator Laboratory, Z.K. LIU, S. RIGGS, J.-H. CHU, Stanford University, B. LV, University of Houston, S.-K. MO, Lawrence Berkeley National Laboratory, M. HASHIMOTO, SLAC National Accelerator Laboratory, R.G. MOORE, Stanford Institute for Materials and Energy Sciences, Z. HUSSAIN, Lawrence Berkeley National Laboratory, I.R. FISHER, Stanford University, C.W. CHU, University of Houston, Z.-X. SHEN, Stanford University — The AFe_2Se_2 (A=K, Rb, Cs) family is one of the newest iron-based superconductors that has attracted considerable attention in the pnictide community due to its many differences with the other iron pnictide compounds, including a very large magnetic moment indicative of strong electron correlation, insulating behavior in non-superconducting compounds, and even in superconducting compounds resistivity shows a bad metallic behavior that crosses over into insulating behavior at higher temperatures. Despite such marked differences with the other pnictides, T_c in AFe_2Se_2 can be as high as 30K. Such interesting properties suggest that the AFe_2Se_2 superconductors may be close to a Mott insulating state, and many theoretical efforts have followed in this regard. Here we present detailed angle-resolved photoemission studies of AFe_2Se_2 to address the issue of whether these materials are indeed close to a Mott insulating state.

1:51PM Z22.00012 One-Fe versus Two-Fe Brillouin Zone of Fe-Based Superconductors: Creation of the Electron Pockets via Translational Symmetry Breaking¹, CHIA-HUI LIN, Brookhaven National Laboratory/ Stony Brook University, TOM BERLIJN, LIMIN WANG, CHI-CHENG LEE, WEI-GUO YIN, Brookhaven National Laboratory, WEI KU, Brookhaven National Laboratory/ Stony Brook University — We investigate the physical effects of translational symmetry breaking in Fe-based high-temperature superconductors due to alternating anion positions [1]. In the representative parent compounds, including the newly discovered Fe-vacancy-ordered $K_{0.8}Fe_{1.6}Se_2$, an unusual change of orbital character is found across the one-Fe Brillouin zone upon unfolding the first-principles band structure and Fermi surfaces [2], suggesting that covering a larger one-Fe Brillouin zone is necessary in experiments. Most significantly, the electron pockets (critical to the magnetism and superconductivity) are found only created with the broken symmetry, advocating strongly its full inclusion in future studies, particularly on the debated nodal structures of the superconducting order parameter. [1] C.-H. Lin et al, arXiv:1107.1485 (2011). [2] Wei Ku et al, Phys. Rev. Lett. 104, 216401 (2010).

2:03PM Z22.00013 Metal-to-Insulator Transition in Multi-Orbital Models for $A_xFe_ySe_2$, RONG YU, QIMIAO SI, Department of Physics and Astronomy, Rice University, Houston, TX 77005 — The degree of electron correlations remains a central issue in the iron-based superconductors. Compared to other compounds, the newly discovered $A_xFe_ySe_2$ family is unique in some aspects: the Fermi surface consists of only electron pockets, while T_c is as high as 30 K; the superconducting compound is close to an antiferromagnetically insulating phase with a large magnetic moment. These features suggest that the $A_xFe_ySe_2$ system contains stronger electron correlations than pnictides. To investigate the correlation effects in $A_xFe_ySe_2$, we study the metal-to-insulator transition in multi-orbital models for this system using slave-spin mean-field method. We show that when electron correlations are tuned, the system undergoes a metal-to-Mott-insulator transition at commensurate electron filling. We also find that the Mott insulator is close to an orbital-selective Mott phase in the phase diagram.

Friday, March 2, 2012 11:15AM - 2:15PM –

Session Z23 DCMP: Superconductivity: Magnetic Field & Vortex Related (Experimental) 255

11:15AM Z23.00001 Flux avalanches triggered by microwave depinning of superconducting vortices, AHMAD AWAD, FARKHAD ALIEV, Universidad Autonoma de Madrid Spain, WELDESCLASSIE ATAKLTI, ALEJANDRO SILHANEK, VICTOR MOSHCHALKOV, Katholieke Universiteit Leuven Belgium, YURI GALPERIN, University of Oslo Norway, VALERI VINOKUR, Argonne National Laboratory USA — We observe abrupt changes in broadband microwave permeability of thin Pb superconducting films as functions of the microwave frequency and intensity, as well as of external magnetic field. These changes are attributed to vortex avalanches generated by microwave induced depinning of vortices close to the sample edges. We map the experimental results on the widely used theoretical model assuming reversible response of the vortex motion to a. c. drive. It is shown that our measurements provide an efficient method of extracting the main parameter of the model- depinning frequencies for different pinning centers. The observed dependences of the extracted depinning frequencies on the microwave power, magnetic field and temperature support the idea that the flux avalanches are generated by microwave induced thermomagnetic instabilities.

11:27AM Z23.00002 Free flux flow: a probe into the field dependence of vortex core size in clean single crystals¹, A.A. GAPUD, O. GAFAROV, S. MORAES, University of South Alabama, J.R. THOMPSON, University of Tennessee and Oak Ridge National Laboratory, D.K. CHRISTEN, Oak Ridge National Laboratory, A.P. REYES, National High Magnetic Field Laboratory — The free-flux-flow (FFF) phase has been attained successfully in a number of clean, weak-pinning, low-anisotropy, low- T_c , single-crystal samples as a unique probe into type II superconductivity that is independent of composition. The “clean” quality of the samples have been confirmed by reversible magnetization, high residual resistivity ratio, and low critical current densities J_c with a re-entrant “peak” effect in $J_c(H)$ just below the critical field H_{c2} . The necessity of high current densities presented technical challenges that had been successfully addressed, and FFF is confirmed by a field-dependent ohmic state that is also well below the normal state. In these studies, the FFF resistivity $\rho_f(H)$ has been measured in order to observe the field-dependent core size of the quantized magnetic flux vortices as modeled recently by Kogan and Zelezhina (KZ) who predicted a specific deviation from Bardeen-Stephen flux flow, dependent on normalized temperature and scattering parameter λ . The compounds studied are: V_3Si , $LuNi_2B_2C$, and $NbSe_2$, and results have shown consistency with the KZ model. Other applications of this method could also be used to probe normal-state properties, especially for the new iron arsenides, as will be discussed.

¹Funded by the Research Corporation and by an NSF-RUI grant.

11:39AM Z23.00003 Vortex exclusion transition¹, MILIND KUNCHUR, MANLAI LIANG, University of South Carolina, ALEXANDER GUREVICH, Old Dominion University — Ordinarily, Abrikosov vortices penetrate a type-II superconductor in a magnetic field larger than the lower critical field. However if the sample dimensions/s transverse to the applied magnetic field become smaller than some limit (found by Likharev to be $d < 4.4\xi$ for a film of thickness d where ξ is the coherence length), the formation of a parallel vortex in a film is excluded. We measured the transport response of a Molybdenum-Germanium superconducting film in parallel magnetic field and observed a sharp change in the V-I characteristics at a temperature which corresponds to the condition that $d \approx 4.4\xi(T)$. We present the evolution of the observed transport behavior as a function of temperature and magnetic field.

11:51AM Z23.00004 Vortex motion in superconducting single-crystal microstructures of $NbSe_2$ ¹, SHAUN MILLS, NEAL STALEY, CONOR PULS, The Pennsylvania State University, CHENYI SHEN, LINJUN LI, ZHUAN XU, Zhejiang University, YING LIU, The Pennsylvania State University — Superconducting microstructures prepared by advanced nanofabrication methods can be used to address long-standing, fundamental questions concerning vortex motion, including vortex tunneling and the Aharonov-Casher effect of vortices. The observation of these phenomena requires devices with minimal disorder and the fewest dissipative normal electrons. We have developed a process to fabricate superconducting microstructures from single-crystal ultrathin flakes of the layered Type II superconductor $NbSe_2$. Our process utilizes a multi-step electron beam lithography technique, whereby a $NbSe_2$ flake is cut into a desired microstructure with appropriate electrical leads. Despite the small device dimensions, which feature line widths less than 40 nanometers, our devices are superconducting. We are currently working on superconducting microstructures of $NbSe_2$ that involve integration of aluminum leads, aiming at the control and measurement of vortices in these novel structures.

¹Work supported by NSF under grant CMMI 09-00692

12:03PM Z23.00005 Evidence of Vortex Jamming in Abrikosov Vortex Flux Flow Regime¹, GORAN KARAPETROV, Physics Department, Drexel University, V. YEFREMENKO, G. MIHAJLOVIC, J.E. PEARSON, Argonne National Laboratory, M. IAVARONE, Temple University, V. NOVOSAD, S.D. BADER, Argonne National Laboratory — We report on dynamics of non-local Abrikosov vortex flow in mesoscopic superconducting Nb channels. Magnetic field dependence of the non-local voltage induced by the flux flow shows that vortices form ordered vortex chains. Voltage asymmetry (rectification) with respect to the direction of vortex flow is evidence that vortex jamming strongly moderates vortex dynamics in mesoscopic geometries. The findings can be applied to superconducting devices exploiting vortex dynamics and vortex manipulation, including superconducting wires with engineered pinning centers.

¹This work was supported by UChicago Argonne, LLC, Operator of Argonne National Laboratory. Argonne, a U.S. Department of Energy Office of Science Laboratory, is operated under Contract No. DE-AC02-06CH11357 and US DOE Grant No. DE-FG02-10ER46710

12:15PM Z23.00006 Vortex Pinning Enhancement in Patterned MoGe Thin Films Coated with Permalloy, MICHAEL LATIMER, ZHILI XIAO, Northern Illinois University, Argonne National Laboratory, RALU DIVAN, IL WOONG JUNG, WAI-KWONG KWOK, Argonne National Laboratory — Resistivity measurements on permalloy (Py) coated MoGe thin films containing periodic hole arrays were carried out to study the effects of magnetic material filling the hole array. Thin films of MoGe were patterned via focused-ion-beam (FIB) milling to create pinning sites for the vortex lattice. A Py layer was deposited onto the hole array using magnetron sputtering. We investigate periodic hole arrays coated with magnetic material to determine the change in transport properties with varying magnetic fields. Samples with and without a Py coating were tested to determine the effect of magnetic material filling the hole array on the vortex lattice. Significant pinning enhancement was found in the Py coated samples.

12:27PM Z23.00007 Vortex Confinement in Planar S/F Hybrid Structures¹, S. MOORE, Physics Department, Temple University, Philadelphia, PA 19122 USA, V. NOVOSAD, V.G. YEFREMENKO, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439 USA, G. KARAPETROV, Physics Department, Drexel University, Philadelphia, PA 19104 USA, M. IAVARONE, Physics Department, Temple University, Philadelphia, PA 19122 USA — We have investigated the effect of periodic stray fields of the ferromagnet on the vortex dynamics in superconductor/ferromagnet (S/F) systems. Magnetization measurements were performed using SQUID magnetometry for Permalloy/Niobium (Py/Nb) samples of varying Py domain widths and Nb thicknesses. The hysteresis loops show an increase of the critical current for some values of magnetic domain width and superconductor thickness in some portion of the H-T phase diagram. However, below a threshold temperature sudden jumps in magnetization are observed during a slow sweep of the external magnetic field, which indicate the occurrence of vortex avalanches. These avalanches have been confirmed by scanning probe microscopy and they can cause a collapse of the critical state below a threshold temperature. Static and dynamics of these systems will be discussed.

¹This work was supported by US DOE Grant No. DE-FG02-10ER46710 and UChicago Argonne, LLC, Operator of Argonne National Laboratory. Argonne, a U.S. Department of Energy Office of Science Laboratory, is operated under Contract No. DE-AC02-06CH11357.

12:39PM Z23.00008 Spatial resolution of MFM measurements of penetration depth, ERIC SPANTON, Stanford Institute for Materials and Energy Science, SLAC, LAN LUAN, Harvard, JOHN KIRTLEY, KATHRYN MOLTER, Stanford Institute for Materials and Energy Science, SLAC — The penetration depth and its temperature dependence are key ways to characterize superconductors. Measurements of the local Meissner response of a superconductor can determine the local penetration depth. To quantify the spatial resolution of such measurements, we seek to characterize the point spread function of magnetic force microscope (MFM) measurements of the penetration depth both numerically and experimentally. Modeling various geometries of MFM tips (pyramid, dipole, and long thin cylinder) in the presence of various geometries of spatial variation in the penetration depth (point variation, columnar defects, and planar defects or twin boundaries) shows the importance of the MFM tip geometry to achieving both excellent spatial resolution and quantitatively interpretable results. We compare these models to experimental data on pnictides and cuprates to set upper limits on the sub-micron-scale variation of the penetration depth. These results demonstrate both the feasibility and the technical challenges of submicron penetration depth mapping.

12:51PM Z23.00009 Direct observation of jamming of superconducting vortices in a funnel structure, VITALII VLASKO-VLASOV, TIM BENSEMAN, ULRICH WELP, WAI KWOK, Argonne National Laboratory — Arrest of the vortex dynamics at elevated temperatures is an imperative for using benefits of high T_c in cuprate superconductors. Here we explore experimentally a possibility of using funnel geometries for attenuation of the vortex motion. A single funnel structure is sculptured into a twin free single crystal of YBCO using laser lithography and ion milling. The magnetic field penetration patterns are studied using magneto-optical imaging technique at different temperatures below T_c . In ramping up fields we observe an increase of the vortex density in the throat of the funnel structure showing the jamming of vortices at the entry into narrow vortex channel. The effect is discussed using results of recent numerical simulations. This work was supported by UChicago Argonne, LLC, under contract No. DE-AC02-06CH11357.

1:03PM Z23.00010 Interplay between Superconducting Vortices in the Dynamic Regime and Magnetism in Borocarbides, MARCUS WEIGAND, CHRISTIAN BATISTA, LEV BULAEVSKII, SHIZENG LIN, FRANCISCO BACA, LEONARDO CIVALE, Los Alamos National Laboratory, SERGEY BUD'KO, PAUL CANFIELD, Ames Laboratory, BORIS MAIOROV, Los Alamos National Laboratory — In superconductors with coexisting magnetic order an interaction is expected between vortices moving above a certain speed and the intrinsic magnetic moments. It has been predicted that in this dynamic regime vortices emit energy through the radiation of spin waves, thus slowing down and reducing the dissipation associated with their movement.¹ While of potential interest for applications, this effect has not yet been proven experimentally. In order to elucidate the phenomenon, we have carried out electrical transport measurements on $\text{ErNi}_2\text{B}_2\text{C}$ single crystals, covering a broad range of temperatures, applied magnetic fields and field orientations. We observe a distinct change in the shape of current-voltage curves measured above and below the Néel temperature (T_N), which implies that the features seen below T_N are related to the material's antiferromagnetism. We complement these results with measurements of the irreversible magnetization, which also show significant anomalies around T_N . Angular critical current measurements have also been performed to investigate the influence of the material's intrinsic magnetic moments on its current-carrying capabilities.

1:15PM Z23.00011 Vortex pinning effects in the Corbino geometry¹, YANIV ROSEN, STEFAN GUÉNON, IVAN SCHULLER, Center for Advanced Nanoscience, University of California San Diego — We probed a dynamic system of superconducting vortices with an artificial pinning landscape in the Corbino geometry. Current was applied from the center of the disc and propagated radially outward to produce a circular force with strength proportional to $1/r$ on the vortices. For small injection currents the vortex lattice is rigid, however large currents can cause shearing of the lattice. In order to investigate the temperature, current, and pinning lattice dependencies in different samples, we have defined Nb discs with a diameter of $60\text{ }\mu\text{m}$ on a circularly symmetric lattice of magnetic dots. In particular we present data that show steps instead of minima in the magnetoresistance curves at the position of the matching field indicating an unexpected influence of the pinning array on the motion of the vortex lattice.

¹This work was supported by the US-NSF

1:27PM Z23.00012 Zero average and net flows of vortices in hybrid nanostructures with asymmetric pinning potentials¹, JOSE L. VICENT, Universidad Complutense and IMDEA-Nanociencia (Madrid), DAVID PEREZ DE LARA, IMDEA-Nanociencia and Universidad Complutense (Madrid), ALICIA GOMEZ, FERNANDO GALVEZ, Universidad Complutense (Madrid), MIGUEL A. GARCIA, CSIC and IMDEA-Nanociencia (Madrid), ELVIRA M. GONZALEZ, Universidad Complutense (Madrid) — We have fabricated hybrid nanostructures with superconducting film on top of an array of magnetic nanotriangles. In these structures, non-zero DC and AC voltages (V_{DC} , V_{AC}) are generated by alternating currents injected in the hybrid device. The V_{DC} and V_{AC} behaviors give us an overall picture of the vortex dynamics and the rectification effects in these superconducting devices.

¹Spanish MICINN, CM and Santander-Complutense

1:39PM Z23.00013 Vortex configurations and geometrical shapes of superconducting MoGe networks revealed by scanning SQUID microscope¹, TAKEKAZU ISHIDA, HO THANH HUY, TSUTOMU YOTSUYA, Osaka Prefecture University, MASAHIKO HAYASHI, Akita University — We prepared square networks of MoGe films by a standard photolithographic technique to observe vortex penetration into the network by means of a scanning SQUID microscope under different conditions of applied magnetic fields and temperatures. We found that vortex distribution in network evolves with applied magnetic field. At half matching field, vortices showed a checkerboard pattern, being in good agreement with theoretical predictions. We also investigated how vortices occupy network holes at different temperatures. Vortices tend to align in a “diagonal” direction at high temperatures while vortices repel each other to become isolated vortices at lower temperatures. Our results are consistent with theoretical calculation for nanoscopic superconducting network using the nonlinear Ginzburg-Landau equation. We also demonstrate that our data processing method appreciably improved a spatial resolution of the SQUID microscope.

¹This work was partly supported by a Grant-in-Aid for Scientific Research from the Ministry of Education, Culture, Sports, Science and Technology of Japan (Grant Nos. 19206104, 23246173, 23226019).

1:51PM Z23.00014 Threshold Critical Current Density to Trigger Flux Avalanches in Superconducting Thin Films, W.A. ORTIZ, DF/UFSCar, Brazil and Centre for Advanced Study, Norwegian Academy of Science and Letters, M. MOTTA, F. COLAUTO, DF/UFSCar, Brazil, R. ZADOROSNY, DFQ/UNESP, Brazil, T.H. JOHANSEN, Physics, Univ of Oslo and Centre for Advanced Study, Norwegian Academy of Science and Letters, R. DINNEN, M. BLAMIRE, Materials Science, Cambridge Univ, UK, G.W. ATAKLTI, V.V. MOSHCHALKOV, A.V. SILHANEK, K.U.Leuven, Belgium — Under certain conditions of temperature and magnetic field, sudden flux bursts (avalanches) develop into superconducting films, as a consequence of thermomagnetic instabilities, which occur when heat dispersion is slower than magnetic diffusion. Based on a systematic study of the magnetic response (including magneto-optical imaging) of two Nb films - one plain and the other decorated with a square array of square antidots - we have found the existence of a threshold critical current density above which vortex avalanches are triggered. The experimental results reveal that this threshold value is nearly constant within the whole range of temperatures and magnetic fields investigated. The fact that an avalanche is triggered once the critical current reaches the threshold is in close correspondence with the behavior of granular material in sandpiles, which slides down whenever the slope exceeds the threshold repose angle. Our results are in perfect agreement with the predictions of a model for thermomagnetic instabilities in superconducting films, published previously by Yurchenko and coworkers [PRB 76, 092504 (2007)].

2:03PM Z23.00015 Vortex-state electrodynamics in superconducting thin films studied by infrared spectroscopy¹, XIAOXIANG XI, D.B. TANNER, Department of Physics, University of Florida, G.L. CARR, Photon Sciences, Brookhaven National Laboratory, J.-H. PARK, D. GRAF, National High Magnetic Field Laboratory, Florida State University — In a type-II superconductor, a magnetic field above the lower critical field creates vortices and dramatically changes the superconductor's electrodynamic response. Such changes have been observed in thin film samples by our infrared magneto-spectroscopy experiments with field normal to the film surface. The complex optical conductivity was extracted, and was compared to existing models for the effective electrodynamic response of the vortex state. We found a good agreement between our optical data and a calculation using Maxwell Garnett theory, which treats the mixed state as having normal-metal disks (representing the vortex cores) surrounded by superconductor. Our data also show the effect of magnetic-field-induced pair breaking on the superconducting fraction outside of the vortices.

Friday, March 2, 2012 11:15AM - 12:39PM – Session Z26 DCOMP: General Theory / Computational Physics II 257B

11:15AM Z26.00001 Corrections to the geometrical interpretation of bosonization¹, MANFRED STEINER, BRAD MARSTON, Brown University — Bosonization is a powerful approach for understanding certain strongly-correlated fermion systems, especially in one spatial dimension but also in higher dimensions². The method may be interpreted geometrically in terms of deformations of the Fermi surface, and the quantum operator that effects the deformations may be expressed in terms of a bilinear combination of fermion creation and annihilation operators. Alternatively the deformation operator has an approximate representation in terms of coherent states of bosonic fields³. Calculation of the inner product of deformed Fermi surfaces within the two representations reveals corrections to the bosonic picture both in one and higher spatial dimensions. We discuss the implications of the corrections for efforts to improve the usefulness of multidimensional bosonization.

11:39AM Z26.00003 Uniform Approximation from Symbol Calculus on a Spherical Phase Space, LIANG YU, U.C. Berkeley — We use symbol correspondence and quantum normal form theory to develop a more general method for finding uniform asymptotic approximations. We then apply this method to derive a uniform approximation of the $6j$ -symbol in terms of the rotation matrices. The derivation is based on the Stratonovich-Weyl symbol correspondence between matrix operators and functions on a spherical phase space. The resulting approximation depends on a canonical, or area preserving, map between two pairs of intersecting level sets on the spherical phase space.

11:51AM Z26.00004 Searching for B-modes with QUIET: Latest results from the maximum-likelihood pipeline, INGUNN KATHRINE WEHUS, University of Oslo, QUIET COLLABORATION — The polarisation of the cosmic microwave background (CMB) gives us unique information about the existence of primordial gravitational waves and the energy scale of inflation. QUIET is a ground-based CMB polarisation experiment, taking advantage of the world's most sensitive microwave radiometers, to search for B-modes in the CMB polarisation. The pilot phase data taking was finished in December 2010, consisting of around 250 000 diode hours of Q-band data at 43 GHz and about ten times more W-band data at 94 GHz. The data are analyzed by two independent pipelines, the maximum-likelihood (ML) pipeline and the pseudo- C_ℓ (PCI) pipeline. I will present the ML pipeline and our latest results.

12:03PM Z26.00005 The Fourth Dimension and Transaction Line, PETER SCHICK, Columbia University — The fourth dimension is basically the depth between two objects or the depth between an object. It is the z compared to the length, width, height. When one looks at a few objects the depth in between them is the fourth dimension. The transaction line is a relationship between two objects that are falling. This line allows the relationship to form so that they fall at the same time, regardless how much they weigh.

12:15PM Z26.00006 Reconsidering Dark Matter, SOL AISENBERG, International Technology Group — There is a difference between (a) distances of remote standard candles, SN Type Ia, and (b) distances based upon their red shifts. It was believed that these galaxies had accelerated and used Dark Energy. There are 2 assumptions not supported by observations. The first is that the red shifts for remote galaxies are due to the Doppler Effect associated with receding velocity. Hubble only observed red shifts as a function of distances of known stars, and never measured receding velocities. He suggested the Doppler Effect as a cause, but expressed doubt about the suggestion. There are other causes for a red shift - gravity red shift of light from the sun, and loss of photon energy by gravity interaction of photons with dust and gas in interstellar space. The second assumption is that Hubble's linear relationship between the observed red shift and the distance will be valid at very large distances. Increasing red shift corresponds to a decrease of photon energy towards zero, and cannot be used for very remote stars - where the photon energy approaches zero and the red shift dependence becomes nonlinear and asymptotic to a constant value. This predicts the difference between the galaxy distances and the distances determined from their observed red shifts. The recent Nobel Prize (to Schmidt, Reis, and Perlmutter) needs reexamination. Two basic assumptions that are the foundation of their work may not be accurate. Details are in my earlier essays in "The Misunderstood Universe", © 2009. .

12:27PM Z26.00007 The Exact Solution of The Pioneer Anomaly According to The General Theory of Relativity and The Hubble's Law, AZZAM ALMOSALLAMI, University of Malaya — Radio metric data from Pioneer 10/11 indicate an apparent anomalous, constant, acceleration acting on the spacecraft with a magnitude $\sim 8 \times 10^{-10}$ m/s², directed towards the Sun[1,2]. Turyshev [7] examined the constancy and direction of the Pioneer anomaly, and concluded that the data a temporally decaying anomalous acceleration $-2 \times 10^{-11} \frac{m}{s^2 yr}$ with an over 10% improvement in the residuals compared to a constant acceleration model. Anderson, who is retired from NASA's Jet Propulsion Laboratory (JPL), is that study's first author. He finds, so "it's either new physics or old physics we haven't discovered yet." New physics could be a variation on Newton's laws, whereas an example of as-yet-to-be- discovered old physics would be a cloud of dark matter trapped around the sun[12]. In this paper I introduce the exact solution for the Pioneer anomaly depending on the general theory of relativity and the Hubble's law. According to my solution, there are two terms of decelerations that controls the Pioneer anomaly. The first is produced by moving the Pioneer spacecraft through the gravitational field of the Sun, which causes the velocity of the spacecraft to be decreased according to the Schwarzschild Geometry of freely infalling particle. This deceleration is responsible for varying behaviour of the Pioneer anomaly in Turyshev [7], depending on $1/r^{2.5}$ the distance from the sun. The second term is produced by the attractive force of the dark matter which is constant and equals to the Hubble's constant multiplied by the speed of light in vacuum.

Session Z27 DCMP: Invited Session: Interaction Driven Broken Symmetry States in Bilayer Graphene 258AB

11:15AM Z27.00001 Theoretical Approach to Many-body Instabilities in Bilayer Graphene¹, OSKAR VAFEK, National High Magnetic Field Laboratory and Florida State University — I will review current theoretical approach to electron-electron interaction driven many-body instabilities in bilayer graphene at the neutrality point. The role of competing interactions and the dependence of different ordering tendencies on the range of the interaction will be examined. In particular, I will argue that within the renormalization group approach, for longer range interaction giving predominantly forward scattering, the leading ordering tendency is towards a gapless electronic nematic state. For shorter range interactions giving additional back scattering comparable to the forward scattering, the leading ordering tendency is towards a gapped Neel antiferromagnet. These results will be discussed in the context of recent experiments reporting signatures of broken symmetry states in suspended bilayer graphene.

¹NSF CAREER Award under Grant no. DMR-0955561

11:51AM Z27.00002 Interaction-Driven Spectrum Reconstruction in Bilayer Graphene, KOSTYA NOVOSELOV, University of Manchester — The nematic phase transition in various two-dimensional electronic systems is a fascinating subject of an ongoing investigation. Driven by electron-electron interactions it represents a new class of strongly correlated electronic ground states. Thus it is extremely important and interesting to expand the list of materials where such transitions are observed to those with particularly unusual electronic dispersion. Here we show indications that bilayer graphene – a truly two-dimensional material with complex chiral electronic spectrum – undergoes such transition. This is especially surprising as no interaction effects have been observed so far in either mono- or bilayer graphene without a help of magnetic field. Gaining access to low-energy physics in bilayer graphene devices (by suspending our samples and achieving quasiparticle mobilities larger than 10^6 cm²/V.s) allowed us to observe strong spectrum reconstructions and electron topological transitions which we attribute being due to such nematic transition.

12:27PM Z27.00003 Spontaneous Quantum Hall Liquids, FAN ZHANG, (1) UT-Austin (2) UPenn — Driven by electron-electron interactions, bilayer graphene and its thicker cousins, chirally (ABC) stacked multilayers, exhibit a variety of distinct broken symmetry states in which each spin-valley flavor spontaneously transfers charge between layers, because of their flat touching bands and large pseudospin chiralities. These gapped states are accompanied by large momentum space Berry curvatures and different types of topological orders. These competing ground states are distinguished by their flavor Hall conductivities, orbital magnetizations, edge state properties, and response to external fields. These spontaneous quantum Hall (SQH) states at zero field smoothly evolve into quantum Hall ferromagnet states at finite field. Various phase transitions occur by tuning carrier densities, temperature, and external fields. Recently, SQH states have started to be observed and explored in transport and Hall experiments on suspended devices with dual gates.

1:03PM Z27.00004 Interaction-Driven Insulating States in Bilayer Graphene, CHUN NING LAU, University of California, Riverside — Bilayer graphene (BLG) at the charge neutrality point (CNP) is unstable to electronic interactions, and expected to host a ground state with spontaneously broken symmetries. Here I will present our transport spectroscopy measurements on singly- and dual-gated suspended BLG devices, which have field effect mobility values up to 250,000 and 100,000 cm²/Vs, respectively. We observe an insulating state at CNP with a gap ~2 meV, which can be closed by elevated temperature, finite doping or a perpendicular electric field of either polarity. For magnetic field B>1T, the gap increases linearly with B. Our work contributes towards understanding the rich interaction-driven physics in BLG.

1:39PM Z27.00005 Electronic structure of multilayer graphene¹, EDWARD MCCANN, Lancaster University — The single-particle low-energy Hamiltonian of bilayer graphene describes chiral quasiparticles with a dominantly parabolic dispersion exhibiting Berry phase 2π . This chiral Hamiltonian produces a doubly-degenerate zero-energy Landau level incorporating two different orbital states with the same energy. Taking into account spin and valley degeneracies, the zero-energy Landau level in a bilayer is eightfold degenerate, as compared to the fourfold degeneracy of other bilayer states and the fourfold degeneracy of all levels in a monolayer. Such levels can be split by interlayer asymmetry, due to the presence of an external gate or doping, or by interaction effects. This talk will describe the electronic behavior of multilayer graphene, focusing on three, four and five layers. The goal will be to identify features that are distinct from those observed in monolayers and bilayers, and to highlight effects - such as level splitting and crossing - that can be explained either within the single-particle picture or that require an understanding of electronic interactions. For example, the low-energy Hamiltonian of ABA-stacked multilayer graphene may be partially diagonalized into an approximate block-diagonal form, with each diagonal block contributing parabolic bands except for an additional block describing Dirac-like bands with a linear dispersion in a multilayer with an odd number of layers. By taking into account the symmetry of the crystal structure, it is possible to fully include the band parameters and to analyze their effect on the block-diagonal Hamiltonian. Next-nearest-layer couplings are shown to be particularly important in determining the low-energy spectrum and the phase diagram of the quantum Hall conductivity by causing energy shifts, level anti-crossings, and valley splitting of the low-lying Landau levels.

Session Z29 GQI: Focus Session: Superconducting Qubits: Noise and Anomalous Temperature
259A

11:15AM Z29.00001 Measurement-induced qubit state mixing from upconverted low frequency noise¹, D.H. SLICHTER, R. VIJAY, S.M. WEBER, I. SIDDIQI, UC Berkeley, QNL — We observe readout-induced qubit state mixing in a flux-tunable transmon qubit coupled to a planar resonator. Our results indicate that dephasing noise at the qubit-cavity detuning frequency Δ is upconverted by photons in the readout cavity, causing spurious qubit state transitions in agreement with theory [1]. Using a superconducting parametric amplifier to perform continuous high-fidelity qubit measurement, we characterize the transition rate dependence on cavity photon population and the intensity of added low frequency noise injected from a broadband fast flux excitation line. From the remnant excitation rate in the absence of added noise, we extract a noise spectral density at frequencies ~ 1 GHz. We also measure the noise spectral density from 0.02-0.5 Hz and 1-20 MHz using Ramsey fringes and Rabi oscillations, respectively. Postulating that flux noise is the dominant source of dephasing in our qubit, we fit the measured noise to a $1/f^\alpha$ power law, finding a slope $\alpha = 0.6$ and amplitude $(1.4\mu\Phi_0)^2/\text{Hz}$ at 1 Hz. These values are in agreement with other measurements of low-frequency flux noise. Our results suggest that $1/f$ flux noise persists to GHz frequencies.

11:27AM Z29.00002 $1/f$ Noise of Josephson Tunnel Junction Embedded Microwave Resonators at Single Photon Energies and Millikelvin Temperatures¹, I. SIDDIQI, KATER MURCH, STEVEN WEBER, ELI LEVENSON-FALK, R. VIJAY, UC Berkeley, QNL — We present measurements of the $1/f$ frequency noise of superconducting aluminum lumped and distributed element resonators in the low power, low temperature operating regime characteristic of superconducting qubits. A comparison was made between these devices and similar co-fabricated linear resonators to infer the level of critical current noise associated with the tunnel junctions. At 25 mK and in the single photon regime, the observed frequency fluctuations of junction embedded and linear resonators were comparable. Attributing all the observed noise to critical current fluctuations, we report an upper bound for $1/f$ critical current fluctuations in 0.5-2 μA junctions of $3 \times 10^{-8} (1/\sqrt{Hz})$ at 1 Hz. We note that for some samples we observed the activation of a single fluctuator above 50 mK which increased the level of noise significantly.

¹This research is supported by the IARPA CSQ program.

11:39AM Z29.00003 Flux Noise in SQUIDS Due to Hyperfine Interactions¹, JIANSHEG WU, CLARE YU, Department of Physics and Astronomy, University of California, Irvine, — Although there have been significant advances in superconducting qubits, they continue to be plagued by noise and decoherence. Low frequency $1/f$ flux noise in superconducting quantum interference devices (SQUIDS) is one of the dominant sources of noise in superconducting flux and phase qubits. Recent experiments implicate spins on the surface of metals as the source of flux noise in SQUIDS, and indicate that these spins are able to relax without conserving total magnetization. We present a model of $1/f$ flux noise in which electron spins on the surface of metals can relax via hyperfine interactions. Our results indicate that flux noise would be significantly reduced in superconducting materials where the most abundant isotopes do not have nuclear moments such as zinc and lead.

11:51AM Z29.00004 Pure dephasing in flux qubits due to flux noise with spectral density scaling as $1/f^{\alpha_1}$, STEVEN ANTON, UC Berkeley, C. MULLER, Univ de Sherbrooke, J.S. BIRENBAUM, S.R. O'KELLEY, A.D. FEFFERMAN, UC Berkeley, D.S. GOLUBEV, Karlsruhe Institute of Technology, G.C. HILTON, H.-M. CHO, K.D. IRWIN, NIST, Boulder, F.C. WELLSTOOD, Univ of Maryland, GERD SCHON, A. SHNIRMAN, Karlsruhe Institute of Technology, JOHN CLARKE, UC Berkeley — Magnetic flux noise is a major source of pure dephasing in superconducting flux qubits. This noise, common to SQUIDs, is believed to arise from localized electrons whose spins reverse randomly. We present representative measurements on dc SQUIDs over a range of temperatures showing, in general, $S_{\Phi}(f) = A^2/(f/(1 \text{ Hz}))^{\alpha}$. In our measurements, A is of the order of $1 \mu\Phi_0\text{Hz}^{-1/2}$ and $0.6 < \alpha < 1$. Motivated by these results, for arbitrary values of α we calculate pure dephasing times for both Ramsey and echo pulse sequences assuming linear coupling between the energy level splitting and the flux through the qubit. We find that the dephasing time τ_{ϕ} decreases dramatically as α is reduced. In addition, the frequency bandwidth to which the qubit is sensitive—defined by the infrared and ultra-violet cutoff frequencies—can significantly affect τ_{ϕ} in a manner depending on the type of sequence and value of α . For each sequence, τ_{ϕ} becomes independent of the ultra-violet cutoff frequency when its value exceeds $1/\tau_{\phi}$. Finally, we present calculated dephasing times corresponding to our measured spectra.

12:03PM Z29.00005 Very-low-frequency spectroscopy of both flux and tunnel-coupling noise in a flux qubit, JONAS BYLANDER, FEI YAN, SIMON GUSTAVSSON, Massachusetts Institute of Technology, FUMIKI YOSHIHARA, Institute of Physical and Chemical Research (RIKEN), Japan, DAVID G. CORY, IQC, University of Waterloo, and Perimeter Institute, Canada, YASUNOBU NAKAMURA, NEC Corp. and RIKEN, Japan, WILLIAM D. OLIVER, MIT and MIT Lincoln Laboratory — We inferred the very-low-frequency noise (0.01 to 100 Hz) of a superconducting flux qubit by repeatedly subjecting it to free induction during a fixed length of time and sampling the binary read-out signal. The excited-state probability varies as the qubit-transition frequency fluctuates due to noise, and we control the sensitivities to noise in the energy and tunnel coupling terms of the Hamiltonian by tuning the static flux (energy) bias. At low temperature, interestingly, both types of low-frequency noise follow the same $1/f$ -type power laws observed at much higher frequencies. We will further present the temperature dependence of both noises from 10 to 200 mK.

12:15PM Z29.00006 $T_{1\rho}$ experiment as a noise spectrum analyzer, FEI YAN, SIMON GUSTAVSSON, JONAS BYLANDER, Massachusetts Institute of Technology, FUMIKI YOSHIHARA, The Institute of Physical and Chemical Research, YASUNOBU NAKAMURA, The Institute of Physical and Chemical Research, NEC, DAVID CORY, University of Waterloo, WILLIAM OLIVER, MIT Lincoln Laboratory — We performed a $T_{1\rho}$ (spin-locking) experiment on a superconducting flux qubit, enabling us to resolve the environmental noise in the intermediate-frequency range. By driving the qubit along its state polarization, in the rotating frame, it is effectively spin-locked: the decohering effect of low-frequency noise is thereby dramatically reduced compared to Rabi oscillations. We measured the $T_{1\rho}$ relaxation rate in the rotating frame, under different driving amplitudes and flux biases. Relating this driven relaxation rate to the noise at the corresponding Rabi frequency, we extracted the noise power spectral densities of the energy-bias (flux) and tunnel-coupling terms of the qubit's Hamiltonian at frequencies ranging from 0.5 to 100 MHz. In the flux-noise spectrum, we observed features due to non-Gaussian noise, which can be modeled by a strong random-telegraph fluctuator, supporting observations in the decoherence of a spin-echo.

12:27PM Z29.00007 Characterization of critical-current noise in Josephson junctions and its implications for qubit dephasing¹, CHRISTOPHER D. NUGROHO, VLADIMIR ORLYANCHIK, DALE J. VAN HARLINGEN, University of Illinois at Urbana-Champaign — Critical-current noise in Josephson junctions may ultimately limit the coherence of superconducting qubits. Presently qubit coherence times are limited by energy relaxation or other dephasing mechanisms, but recent qubit advances may put the coherence times in the regime where critical-current noise play an important role. We report on the measurement of I_c -noise in Josephson junctions and compare them to fluctuations in the normal state resistance when superconductivity is suppressed in a magnetic field. We measure the noise scaling with the junction area, normal state resistance, and temperature. We will then discuss the implication of this noise to qubit decoherence.

¹Work supported by IARPA grant Army UCB-00006692.

12:39PM Z29.00008 Pure dephasing from quasiparticle tunneling in superconducting qubits, GIANLUIGI CATELANI, Yale University — Quasiparticles tunneling across Josephson junctions provide an intrinsic decoherence mechanism in superconducting qubits. The quasiparticle current spectral density $S_{qp}(\omega)$ determines both the relaxation rate and the pure dephasing rate. The latter is in general proportional to the spectral density evaluated at zero frequency. In the case of quasiparticle, however, $S_{qp}(\omega)$ diverges logarithmically as frequency goes to zero, potentially leading to very fast dephasing. Here we show how to regularize this divergence in a self-consistent way. This enable us to estimate the dephasing rate due to quasiparticle tunneling and to study its magnetic flux dependence for various qubit designs.

12:51PM Z29.00009 Anomalous Temperatures of Superconducting Qubits¹, K. GEERLINGS, S. SHANKAR, Z. LEGHTAS, M. MIRRAHIMI, L. FRUNZIO, R.J. SCHOEKOPF, M.H. DEVORET, Applied Physics Dept., Yale University — We present qubit temperature measurements on several superconducting transmon qubits coupled to compact resonators. By addressing multiple transitions of the artificial atom and cavity system, we measured the temperature as a function of qubit and cavity frequency and cavity Q. For high cavity Q and large detuning, qubit temperatures were found to be greater than 120mK, well in excess of the dilution refrigerator base temperature of 15mK. This unanticipated effect can be explained by the decoupling of the qubit to the cold load damping the cavity. We will present our attempts to produce lower qubit temperatures with additional filtering and dynamical cooling experiments.

¹Work supported by IARPA, ARO and the NSF.

1:03PM Z29.00010 Minimizing environmental decoherence for a superconducting phase qubit - transmon architecture, RAMI BARENDTS, J. WENNER, M. LENANDER, Y. CHEN, J. KELLY, J. BOCHMANN, B. CHIARO, E. LUCERO, P. O'MALLEY, M. MARIANTONI, A. MEGRANT, C. NEILL, D. SANK, P. ROUSHAN, A. VAINSENER, H. WANG, T. C. WHITE, Y. YIN, A. N. CLELAND, JOHN M. MARTINIS, UC Santa Barbara, J. J. A. BASELMANS, SRON Netherlands Institute for Space Research — The coherence of superconducting quantum systems is currently a major obstacle towards high gate fidelity and long-lived memory. We found that quasiparticle generation from stray infrared light is a significant source of energy relaxation. We show that resonator quality factors and phase qubit energy relaxation times are limited by a quasiparticle density of approximately $200 \mu\text{m}^{-3}$, induced by 4 K blackbody radiation from the environment. We demonstrate how this influence can be fully removed by isolating the devices from the radiative environment using multistage shielding. In addition, we analyze the decoherence due to circuitry in our new phase qubit-transmon architecture. This architecture - consisting of transmon qubits, resonators, and phase qubits using a frequency domain multiplexed readout - is less affected by Purcell decay. At present, fabrication of samples is ongoing.

1:15PM Z29.00011 Designs towards improved coherence times in superconducting qubits, ANTONIO CORCOLES, JERRY CHOW, JAY GAMBETTA, CHAD RIGETTI, JIM ROZEN, GEORGE KEEFE, MARY BETH ROTHWELL, STEFANO POLETTI, MARK KETCHEN, MATTHIAS STEFFEN, IBM TJ Watson Research Center — Coherence times for superconducting qubits in a planar geometry have increased drastically over the past 10 years with improvements exceeding a factor of 1000. However, recently these appeared to have reached a plateau around 1-2 microseconds, the limits of which were not well understood. Here, we present experimental data showing that one limit is due to infra-red radiation, confirming observations from other groups. We observe increased coherence times after appropriate IR shielding. Further improvements are shown to be possible by increasing the feature size of the interdigitated shunting capacitor, strongly indicating that surface losses at the metal/substrate interface are limiting qubit coherence times. In our experiments we kept the ratio of line width to gap size constant, but increased the overall feature size. We will discuss this and other similar design approaches towards better coherence in superconducting qubits.

Friday, March 2, 2012 11:15AM - 2:15PM –
Session Z30 GQI: Focus Session: Quantum Information for Quantum Foundations - Quantumness versus Classicality 259B

11:15AM Z30.00001 Nonequilibrium quantum correlations and Leggett-Garg inequalities¹, J.C. CASTILLO, F.J. RODRIGUEZ, L. QUIROGA, Universidad de los Andes — Theoretical guides to test 'macroscopic realism' in condensed matter systems under quantum control are highly desirable. We report the evaluation of Leggett-Garg inequalities (LGI) in an out-of-equilibrium set up consisting in two interacting qubits coupled to independent baths at different temperatures as can occur for two dipolar coupled spins or superconducting qubits in diverse solid-state environments. We find that LGI violations persist for a longer time in a thermal nonequilibrium scenario as compared with similar results at thermodynamic equilibrium. We contrast these findings with the behavior of non-locality-dominated quantum correlation measurements, such as concurrence, between the two qubits under similar temperature gradients.

¹Facultad de Ciencias Research Funds, Universidad de los Andes.

11:27AM Z30.00002 Quantum Correlations in Large-Dimensional States of High Symmetry, ERIC CHITAMBAR, University of Toronto — Multiparty quantum systems can possess non-classical correlations more general than those characterized by entanglement. In this talk, I will discuss various proposed measures of quantum correlations and investigate how these measures behave for the so-called Werner and isotropic families of states. In particular, I will provide closed expressions for the quantum discord (QD) and the relative entropy of quantumness (REQ) in these states for arbitrary dimensions. The QD and REQ will be shown to equal one another, as well as other well-known measures of quantum correlations. For all Werner states, the classical correlations are seen to vanish in high dimensions while the amount of quantum correlations becomes independent of whether or not the state is entangled. For isotropic states, nearly the opposite effect is observed with both the quantum and classical correlations growing without bound as the dimension increases and only as the system becomes more entangled.

11:39AM Z30.00003 Nonnegative subtheories of qubits: stabilizer states and more, STEPHEN BARTLETT, JOEL WALLMAN, The University of Sydney — Negativity in a quasi-probability representation is typically interpreted as an indication of nonclassical behavior. However, this does not preclude bases that are nonnegative from having interesting applications—the single-qubit stabilizer states have nonnegative Wigner functions and yet play a fundamental role in many quantum information tasks. We determine what other sets of quantum states and measurements of a qubit can be nonnegative in a quasi-probability distribution, and identify nontrivial groups of unitary transformations that permute such states. These sets of states and measurements are analogous to the single-qubit stabilizer states. We show that no quasi-probability representation of a qubit can be nonnegative for more than 2 bases in any plane of the Bloch sphere. Furthermore, there is a unique set of 4 bases that can be nonnegative in an arbitrary quasi-probability representation of a qubit. We provide an exhaustive list of the sets of single-qubit bases that are nonnegative in some quasi-probability distribution and are also closed under a group of unitary transformations, revealing two families of such sets of 3 bases with quasi-probability distributions defined on a space of 8 ontic states. We extend several of these results to higher dimensions.

11:51AM Z30.00004 Symmetric States on the Octonionic Bloch Ball¹, MATTHEW GRAYDON, University of Waterloo, Perimeter Institute for Theoretical Physics, Institute for Quantum Computing — Finite-dimensional homogeneous self-dual cones arise as natural candidates for convex sets of states and effects in a variety of approaches towards understanding the foundations of quantum theory in terms of information-theoretic concepts. The positive cone of the ten-dimensional Jordan-algebraic spin factor is one particular instantiation of such a convex set in generalized frameworks for quantum theory. We consider a projection of the regular 9-simplex onto the octonionic projective line to form a highly symmetric structure of ten octonionic quantum states on the surface of the octonionic Bloch ball. A uniform subnormalization of these ten symmetric states yields a symmetric informationally complete octonionic quantum measurement. We discuss a Quantum Bayesian reformulation of octonionic quantum formalism for the description of two-dimensional physical systems. We also describe a canonical embedding of the octonionic Bloch ball into an ambient space for states in usual complex quantum theory.

12:03PM Z30.00005 Magically, the negativity of the discrete Wigner function is useful, VICTOR VEITCH, CHRISTOPHER FERRIE, JOSEPH EMERSON, Institute for Quantum Computing and Department of Applied Mathematics, University of Waterloo — It is possible to represent d -dimensional quantum states as probability distributions over a phase space of d^2 points. However, to encompass the full quantum formalism we must allow negative representations. The well known magic state model of quantum computation gives a recipe for universal quantum computation using perfect Clifford operations and repeat preparations of a noisy ancilla state. It is an open problem to determine which ancilla states enable universal quantum computation in this model. In this talk we will show that for systems of odd dimension a necessary condition for a state to enable universal quantum computation is that it have negative representation in a particular quasi-probability representation. This representation is a natural discrete analogue to the Wigner function. This condition implies the existence of a large class of bound states for magic state distillation: states which cannot be prepared using Clifford operations but which are not useful for quantum computation. This settles in the negative the conjecture that all states not representable as a convex combination of stabilizer states enable universal quantum computation.

12:15PM Z30.00006 Anderson localization modeled by means of numerical solutions of the Schrödinger equation¹, NAGENDRA DHAKAL, SERGIO TAFUR, MICHAEL LEUNBERGER, UCF — We developed codes for simulating the Schrödinger equation based on the finite-difference time-domain (FDTD) method. We model the 2 dimensional free electron gas system using perfectly matched layers for the open surrounding space. We study the effect of localized impurities on the time evolution of the electron wave function, thereby observing dephasing introduced by the impurities. Our numerical simulations show the decoherence due to the impurities at moderate impurity densities and Anderson localization at high impurity densities. Our results are important for the implementation of quantum computing, quantum communication, and spintronics.

12:27PM Z30.00007 Quench dynamics in the Anderson impurity model, DEEPAK IYER, NATAN ANDREI, Department of Physics and Astronomy, Rutgers, The State University of New Jersey — We study the non-equilibrium behavior of an interacting quantum dot following a quench, where it is suddenly attached to a lead. The system is modeled by a single level Anderson impurity model with infinite on-site repulsion attached via tunneling to non-interacting leads. We use the open system Bethe Ansatz solution of the Anderson model and develop a formal framework to implement Yudson's contour integral formalism in the presence of a Fermi sea. This framework allows the calculation of the full time evolution of the multi-particle wave function and various observables of the system.

12:39PM Z30.00008 Consistent quantum prediction and decoherence in quantum cosmology, DAVID CRAIG¹, Le Moyne College and Perimeter Institute for Theoretical Physics — A complete "consistent histories" framework for certain symmetry-reduced models of quantum gravity is given, within which probabilities may be consistently extracted from quantum amplitudes. The decoherence functional for both a standard "Wheeler-DeWitt" quantization and a loop quantization of a flat Friedmann-Robertson-Walker cosmological model is constructed, from which consistent quantum predictions may be made in mathematically precise models of quantum cosmologies. Consistent (decoherent) families of histories are exhibited, with an emphasis on the crucial role played by the decoherence of histories in arriving at self-consistent quantum predictions for these closed quantum systems. By way of example, the problem of resolution of the classical "big bang" singularity is compared and contrasted in these two models. Special attention is given to consistent quantum predictions in these theories which are *certain i.e.* predictions for which the problem of interpretation of probabilities for a closed quantum system is not present.

¹Based in part on joint work with Parampreet Singh, LSU.

12:51PM Z30.00009 Wavefunction Collapse via a Nonlocal Relativistic Variational Principle, ALAN HARRISON, Los Alamos National Laboratory — We propose a relativistically covariant variational principle (VP) capable of describing wavefunction collapse. This produces a nonlinear, nonlocal, time-reversal-invariant theory; the hidden variable is the phase of the wavefunction. The VP is $\delta(A_1 + A_2) = 0$, in which A_1 and A_2 are positive definite integrals over all spacetime of functions of $\psi(t, \vec{x})$. A_1 is quadratic in deviations of the wavefunction from compliance with the standard quantum mechanical (SQM) wave equation. A_2 takes a minimum value when the wavefunction is a state of minimal uncertainty, penalizing certain kinds of superpositions and thus driving collapse. A multiplier sets the relative size of the terms so that (1) A_1 dominates in isolated microscopic systems, so they evolve according to the SQM wave equation; and (2) macroscopic superpositions cause A_2 to dominate, driving the system to collapse. Since any macroscopic measurement apparatus is entangled with the system being measured, process (2) explains the empirical observation that measurement collapses the wavefunction. We show that A_2 enforces the Born rule, under suitable assumptions and approximations. As an example, the theory predicts the results of the two-slit experiment, including the delayed-choice variant.

1:03PM Z30.00010 New proofs of the Kochen-Specker theorem for a system of three qubits, MORDECAI WAECELL, P.K. ARAVIND, Worcester Polytechnic Institute — In 1995 Kernaghan and Peres gave a transparent state-independent "parity proof" of the Kochen-Specker theorem by using a system of three qubits. They did this by using the observables of the 3-qubit system to construct a set of 40 rays in a real 8-dimensional space that formed 25 bases, and then picked out a subset of the bases that gave a parity proof. They showed that there are 320 different (but unitarily equivalent) versions of their proof in this 40-ray set. We extend their result in a number of ways. Firstly, we show that this 40-ray set contains five new types of parity proofs in addition to the one found by Kernaghan and Peres, and that the total number of versions of all six types of proofs under the symmetries of the system is $2^{11} = 2048$. Secondly, we point out the existence of a large number of state-independent KS proofs in the 3-qubit system that are structurally different from the Kernaghan-Peres proof, and we explore their features. The geometry of mutually unbiased bases (MUBs) in the 3-qubit system, which played a crucial role in the discovery of these new proofs, will be discussed.

1:15PM Z30.00011 New Algorithms for Generating Arbitrary Kochen-Specker Sets, NORMAN D. MEGILL, Boston Information Group, Lexington, MA 02420, USA, MLADEN PAVIČIĆ, University of Zagreb, Croatia — The Kochen-Specker (KS) sets (constructive proofs of quantum contextuality) have recently obtained a special significance as building blocks of quantum information protocols since quantum contextuality was revealed as property complementary to nonlocality and entanglement. [A. Cabello, *Phys. Rev. Lett.* **104**, 220401 (2010).] Thus, generating arbitrary KS sets becomes as needed as generating Bell states and this has been enabled by recent findings of a vast amount ($> 10^{20}$) of new KS sets—we call them a "KS sea." [N.D. Megill, K. Fresl, M. Waegell, P.K. Aravind, and M. Pavičić, *Phys. Lett. A*, **375** 3419 (2011); M. Waegell and P.K. Aravind, *Int. J. Phys. A* [to appear] (2011).] Here we present our newest algorithms and computer programs which enable us to obtain any desired KS set from the KS sea in a very short time without ever making a complete data base of KS sets—which would be an impossible task anyhow. This was made possible with the help of our representation of the KS sea as well as individual KS sets by means of MMP hypergraphs.

1:27PM Z30.00012 How Different Can Quantum States with the Given Fidelity Be?, VIKTOR DODONOV, MATHEUS HOROVITS, Institute of Physics, University of Brasilia, Brazil — We address the following question: how big can the relative energy difference between two states of a harmonic oscillator (field mode) with the fixed value of fidelity F be? Exact analytical bounds are found for several popular families of quantum states: coherent, squeezed, arbitrary (mixed) Gaussian, binomial and negative binomial. Numerical bounds are calculated for various superpositions of coherent states ("Schrödinger cat states") and their generalizations. The restrictions on the minimal admissible fidelity levels for quite arbitrary (unknown) states belonging to selected families appear rather strong. For example, one can find two squeezed states with $F = 0.9$ but with the relative mean energy difference exceeding 100%. To guarantee the relative energy difference less than 10% for arbitrary coherent states, the fidelity must exceed the level 0.995. For many other sets of states (e.g., squeezed and negative binomial) the restrictions can be much stronger.

1:39PM Z30.00013 Physical meaning of the de Broglie waves, JINGZHENG QIN, SIMON BERKOVICH, The George Washington University — Commonly regarded as an abstract entity, de Broglie waves represent a real thing making the wave-particle duality an operative factor with a wealth of consequences. Waves as probabilities in Schrödinger's quantum mechanics are due to interactive holography that builds up on top of the suggested cellular automaton model of the physical Universe [1]. This model implementing a rule of mutual synchronization produces a set of helicoidal solitons that corresponds exactly to the whole spectrum of elementary particles of matter, no more and no less. The particle-like behavior of the solitons exhibits periodic synchro activities that constitute a wave. The wavelength is inversely proportional to the momentum of these elementary particles, and they distinctly show characteristic qualities of the micro world. The condition of translation-rotation congruity foresees a very small decrease of photons speed with their frequency and polarization, while smoothness of this condition for neutrinos accounts for their already observed faster-than-light propagation. Helicoidal solitons create identical impacts from rotation resulting in the same value of spin for different particles irrespective of variations in mass and speed that are related to translational motion. For any given orientation, spin is either "up" or "down" since helicoidal solitons are flipping this way with every half-turn. Deep inelastic scattering performs sampling of the wave structure of the helicoidal solitons deceptively portraying the outcomes as isolated quarks. [1] S. Berkovich, "A comprehensive explanation of quantum mechanics," <http://www.cs.gwu.edu/research/technical-report/170>

1:51PM Z30.00014 No Drama Quantum Theory? , ANDREY AKHMETELI, LTASolid Inc. — Is it possible to offer a “no drama” quantum theory? Something as simple (in principle) as classical electrodynamics – a theory described by a system of partial differential equations (PDE) in 3+1 dimensions, but reproducing unitary evolution of a quantum field theory in the configuration space? The following results suggest an affirmative answer: 1. The scalar field can be algebraically eliminated from scalar electrodynamics; the resulting equations describe independent evolution of the electromagnetic field (EMF). 2. After introduction of a complex 4-potential (producing the same EMF as the standard real 4-potential), the spinor field can be algebraically eliminated from spinor electrodynamics; the resulting equations describe independent evolution of EMF. 3. The resulting theories for EMF can be embedded into quantum field theories. Another fundamental result: in a general case, the Dirac equation is equivalent to a 4th order PDE for just one component, which can be made real by a gauge transform. Issues related to the Bell theorem are discussed. A. Akhmeteli, Int'l Journal of Quantum Information, Vol. 9, Suppl., 17-26 (2011) A. Akhmeteli, Journal of Mathematical Physics, Vol. 52, 082303 (2011) A. Akhmeteli, quant-ph/1108.1588

2:03PM Z30.00015 Type 2 local realism is alive and well in the quantum world , JEFFREY BOYD, retired — It is often, but incorrectly said, that there is no local realism in the quantum world. This is wrong because there is a second type of local realism. Type two local realism is drastically different than how most people think of their world, including Einstein. It starts with the idea that we are immersed in a sea of invisible elementary waves, traveling in all directions, at all wavelengths. Whenever a photon or other particle moves, it follows one of these waves in the reverse direction. Although this may sound preposterous, this theory can explain several quantum experiments: Jacques (2007) Wheeler thought experiment with delayed choice, Kim (1999), Quantum eraser experiment with delayed choice, all the Bell test experiments with delayed choice, and the double slit experiment. Using the Theory of Elementary Waves (TEW), all these experiments can, surprisingly, be explained using this unconventional type of local realism, with time going forward.

Friday, March 2, 2012 11:15AM - 2:15PM – Session Z31 DCMP: Topological Insulators: Junctions and Interfaces 260

11:15AM Z31.00001 Topological p-n Junction , JING WANG, SHOU-CHENG ZHANG, Department of Physics, Stanford University — $(\text{Bi}_{1-x}\text{Sb}_x)_2\text{Te}_3$ is an ideal topological insulator with truly insulating bulk and tunable surface state across the Dirac point. We consider a junction between surface p-type and surface n-type on these ideal topological insulators in which carrier type and density in two adjacent regions are locally controlled by electrostatic gating or planar grade doping. Such junction setting on topological insulators are fundamental to device development. We find a gapless chiral edge state localized at the p-n interface arises when applying a magnetic field, which can be detected by scanning tunneling microscopy. The two-terminal conductance of such p-n junction in the quantum Hall regime will be $1/4$ times the quantum of conductance e^2/h , which signifies the half-quantum Hall effect of a topological insulator surface.

11:27AM Z31.00002 Andreev Reflection in two-dimensional Topological Insulators , AWADHESH NARAYAN, STEFANO SANVITO, Trinity College Dublin — A metal-superconductor interface may reflect an incident electron from the metal as a positively charged hole with opposite spin, while a Cooper pair is formed in the superconductor. This electron-hole conversion is Andreev reflection (AR) and has served as a useful probe for spin-polarized currents. In this work we study AR at topological insulator-superconductor interface, for both time-reversal symmetric (Z_2) and time-reversal broken (*Chern*) cases. We model Z_2 insulators using the proposal of Kane and Mele, while for *Chern* insulator we use a spinful version of the Haldane model. By employing Landauer-Büttiker scheme we find for both cases perfect AR, which is highly robust to disorder and persists as long as the edge states are present. Further, we propose an experiment to distinguish between the two types of topological insulators. The proposal involves a local doping with magnetic impurities at one of the edges of the two-dimensional material. This suppresses one of the channels for reflection and the AR coefficient drops by a factor of two. No such suppression is seen for the *Chern* insulator.

11:39AM Z31.00003 Theory of Odd-Parity Superconductivity: from Gap Function to Topological Invariants and Surface Andreev Bound States , YANG QI, Institute for Advanced Study, Tsinghua University, LIANG FU, Department of Physics, Massachusetts Institute of Technology — Three-dimensional superconductors with a nodeless pairing gap can be classified by an integer topological invariant, and gapless Andreev bound states exist on the surface when the topological invariant is nontrivial. In this letter we give a general criterion for determining the topological invariant for centrosymmetric superconductors with *odd-parity* pairing. We show that in a general system with spin-orbit coupling, the superconducting gap function can be expressed by a pseudospin d-vector, and the topological invariant can be determined from the total winding number of the pseudospin d-vector on the Fermi surfaces. We also discuss Andreev surface states, and we found gapless surface states when the topological invariant in the bulk is topologically nontrivial.

11:51AM Z31.00004 Current-phase relation for Josephson effect through helical metal , ERHAI ZHAO, George Mason University, CHRIS OLUND, University of Virginia — We compute the current-phase relation of Josephson junctions fabricated on the surface of three-dimensional topological insulators. The Josephson coupling between two superconductors is mediated by the two-dimensional helical metal. It gives rise to the so-called fractional Josephson effect. A short junction is previously known to be a quantum wire of Majorana fermions. We discuss the dependence of the current-phase relation on the length of the junction, the chemical potential of the helical metal, and temperature.

12:03PM Z31.00005 Interface engineering of quantum Hall effects in digital transition-metal oxide heterostructures¹ , SATOSHI OKAMOTO, DI XIAO, Materials Science and Technology Division, Oak Ridge National Laboratory, WEN-GUANG ZHU, Department of Physics and Astronomy, University of Tennessee & Materials Science and Technology Division, Oak Ridge National Laboratory, YING RAN, Department of Physics, Boston College, NAOTO NAGAO, Department of Applied Physics, The University of Tokyo & CMGR and CERG, RIKEN-ASI — Based on tight-binding modeling and first-principles calculations, we investigate possible quantum Hall effects in transition-metal oxide heterostructures. Bilayers of perovskite-type transition-metal oxides grown along the [111] crystallographic axis are found to be potential candidates for two-dimensional topological insulators. The topological band structure of these materials can be tune-tuned by changing dopant ions, substrates, and external gate voltages. We predict that LaAuO_3 bilayers have a topologically-nontrivial energy gap of about 0.15 eV, which is sufficiently large to realize the quantum spin-Hall effect at room temperature. We also discuss intriguing phenomena associated with the nearly flat topologically-nontrivial bands found in eg systems, such as fractional quantum Hall effect.

12:15PM Z31.00006 Proximity effects at semiconductor/topological insulator interfaces¹, GUFENG ZHANG, JIE WANG, Univ. of Sci. & Tech. of China, XIAOGUANG LI, Fudan Univ., Shanghai, China, U of Tennessee, Univ. of Sci. & Tech. of China, DIMITRIE CULCER, Univ. of Sci. & Tech. of China, ZHENYU ZHANG, Univ. of Sci. & Tech. of China, Harvard Univ. — Using phenomenological model Hamiltonians, we study the spatial distribution of topological surface states (TSS) in semiconductor/topological insulator (TI) heterostructures. Due to proximity effects induced by the TI substrate, the location of the TSS can be shifted perpendicularly to the interface. We show that both the direction and magnitude of the shift can be tuned by the cooperative effects of the spin-orbit coupling within the hybrid system, the bandgap of the overlayer, and the thickness of the overlayer. Potential technological applications of these salient properties of the TSS will also be discussed.

¹Supported by DMSE of USDOE, USNSF, and NNSF of China.

12:27PM Z31.00007 Abrikosov Vortex Lattice in 3D Topological Insulator – Superconductor Heterostructures¹, HSIANG-HSIUAN HUNG, Department of Electrical and Computer Engineering, the University of Illinois at Urbana-Champaign, TAYLOR HUGHES, Department of Physics, the University of Illinois at Urbana-Champaign, MATTHEW GILBERT, Department of Electrical and Computer Engineering, the University of Illinois at Urbana-Champaign — Majorana fermions have been predicted to exist on the surface of the three-dimensional (3D) topological insulator/s-wave superconductor heterostructures by proximity effects [Phys. Rev. Lett. **100**, 096407 (2008)]. In the diffuse vortex limit, the physics of these non-abelian anyons is theoretically well-understood c.f. Phys. Rev. B **84**, 144507 (2011). However, the dilute vortex limit is unlikely to be available in experimental systems. In this work, we study the dense vortex limit in 3D topological insulator/s-wave superconductor heterostructures using the self-consistent Bogoliubov-de Gennes (BdG) equations under the application of a uniform magnetic flux. We find that as we approach the dense limit of vortices on the surface, that the hybridization between the vortices leads to the formation of a “Majorana bandstructure” which exists within the superconducting gap. We describe the physics of the system as we move from the dilute limit to the dense limit as we vary the surface chemical potentials and the magnetic field magnitudes.

12:39PM Z31.00008 Quantum Hall Superfluids in Topological Insulator Thin Films, DAGIM TILAHUN, BYOUNGHAK LEE, Texas State Univ/ Univ of Texas at Austin, EWELINA HANKIEWICZ, Universitaet Wuerzburg, ALLAN MACDONALD, University of Texas at Austin — Three-dimensional topological insulators have protected Dirac-cone surface states. In this work we argue that gapped excitonic superfluids with spontaneous coherence between top and bottom surfaces can occur in the TI-thin-film quantum-Hall regime. We find that the large dielectric constants of TI materials increase the layer separation range over which coherence survives and decrease the superfluid sound velocity, but have little influence on the superfluid density or on the charge gap. The coherent state at total Landau-level filling factor $\nu_T = 0$ is predicted to be free of edge modes, qualitatively altering its transport phenomenology compared to the widely studied case of $\nu_T = 1$ in GaAs double quantum wells.

12:51PM Z31.00009 Junction between surfaces of two topological insulators¹, DIPTIMAN SEN, QINDRILA DEB, Indian Institute of Science, Bangalore, India — We study scattering from a line junction which separates the surfaces of two three-dimensional topological insulators; some aspects of this problem were recently studied in Takahashi and Murakami, Phys. Rev. Lett. **107**, 166805 (2011). The velocities of the Dirac electrons on the two surfaces may be unequal and may even have opposite signs; in the latter case, we find that the electrons must, in general, go into the two-dimensional interface separating the two topological insulators. We also study what happens if the two surfaces are at an angle ϕ with respect to each other. We find in this case that there are bound states which propagate along the line junction with a velocity and direction of spin which depend on the bending angle ϕ .

1:03PM Z31.00010 Dirac cones in the gapless interface states between two topological insulators, RYUJI TAKAHASHI, SHUICHI MURAKAMI, Department of Physics, Tokyo Institute of Technology — When two topological insulators are attached together, the states on the interface become gapped due to the hybridization between the surface states. We have shown that if the two topological insulators have the opposite signs for the Dirac velocities, there exist gapless interface states [1]. In the last March meeting we showed a general proof for the existence of the gapless states using the mirror Chern number, which fixes the chirality of the surface states. In this presentation, we report the dispersions of these gapless interface states. They are in general a collection of Dirac cones. For example, if the system has threefold rotational symmetry, the interface states have six Dirac cones. By using the Fu-Kane-Mele model, which is the tight-binding model on the diamond lattice with the spin-orbit interaction, we calculate the dispersion of this gapless interface states, and discuss the relationship with the mirror Chern number.

[1] R. Takahashi, S. Murakami, Phys. Rev. Lett. **107**, 166805 (2011).

1:15PM Z31.00011 Conductance through step junctions in 3D topological insulators¹, MIREIA ALOS-PALOP, RAKESH P. TIWARI, MIRIAM BLAAUBOER, Delft University of Technology, Kavli Institute of Nanoscience — An effective continuous model for low-energy surface states of a 3D topological insulator was presented by Zhang *et al.*, Nat. Phys. **5**, 438 (2009). We present a general solution for this 3D model in a surface different from the standard (111)-surface. In our solution, surface states consist of a single Dirac cone with a Fermi velocity different from the one in (111)-surfaces, and the energy has an elliptical dispersion in k -space. We then study transport through a step junction composed of a (111)-surface – side-surface – (111)-surface and predict that the conductance saturates at $2/3 G_0$, independent of eccentricity and velocity mismatch at the interfaces. We compare our model with a junction in a plane with only (111)-states where conductance saturation does depend on velocity mismatch. We also analyze the Fano factor and highlight experimentally relevant situations where our predictions could be tested.

1:27PM Z31.00012 Inter-band Tunneling between Doped Topological Insulator Surface States, GEN YIN, DARSHANA WICKRAMARATNE, ROGER LAKE, University of California Riverside — Thin films of 3D topological insulators (TIs) have been experimentally synthesized recently. Impurity doping of the TI surface has been reported to modify the position of the Fermi level and generate Rashba-like splitting of the surface band structure. Our research uses a Non-Equilibrium Green's Function (NEGF) method to simulate inter-surface transport properties for TI thin films. A tight-binding model is established by discretizing a 4×4 k.p Hamiltonian for 3D TIs. Because of confinement, thin TI slabs of several nanometers allows inter-surface tunneling at quantum number matching states. The tunneling intensity can be tuned by surface Coulomb impurity doping or applying an external bias. Unlike regular topologically trivial surface states, inter-band tunneling between TI surfaces presents a conduction minimum when the dispersions of the two surfaces align perfectly over each other. The suppression of transport originates from the momentum coupling with time reversal symmetry, leading to significant non-linear I-V properties for the P-N tunneling at forward bias. This leads to a NDR current minimum when an external bias completely compensates the built-in potential. The study on inter-surface tunneling in TI thin films benefits the understanding of the transport behavior of TI surface states, which calls for further experimental investigations in the future.

1:39PM Z31.00013 Spin Texture on the Fermi Surface of Strained HgTe, SAAD ZAHEER, STEVE YOUNG, University of Pennsylvania, DANIEL CELLUCCI, University of Georgia, JEFFREY TEO, CHARLES KANE, EUGENE MELE, ANDREW RAPPE, University of Pennsylvania — We present *ab initio* and $\mathbf{k} \cdot \mathbf{p}$ calculations of the Fermi surface of strained HgTe obtained by stretching the Zinc-Blende lattice along the (111) axis. Near the Fermi level, strained HgTe exhibits point-like accidental degeneracies between a two-fold degenerate and two non-degenerate bands along the (111) axis. The three bands disperse linearly in all directions about the degenerate points and their low energy physics is described by an effective four band $\mathbf{k} \cdot \mathbf{p}$ Hamiltonian. The Fermi surface consists of two ellipsoids which contact only at the point where the Fermi level crosses the two-fold degenerate band along the (111) axis. The spin expectation value on both ellipsoids is constrained to vanish along the (111) axis due to mirror symmetry about a plane that contains that axis. Furthermore the winding number of spins around the two ellipsoids changes from one end to the other indicating the existence of singular points in the spin texture. Indeed, the *ab initio* and $\mathbf{k} \cdot \mathbf{p}$ calculations confirm the existence of such spin singularities on the Fermi ellipsoids. We show that doping HgTe with Zinc atoms chemically strains the HgTe Zinc-Blende lattice and present *ab initio* calculations on HgZnTe that confirm the above results.

1:51PM Z31.00014 Spin-transfer torque and spin-polarization in topological-insulator-based magnetic tunnel junctions¹, FARZAD MAHFOUZI, Department of Physics and Astronomy, University of Delaware, Newark, DE 19716-2570, USA, NAOTO NAGAOSA, Department of Applied Physics, University of Tokyo, Tokyo 113-8656, Japan, BRANISLAV NIKOLIĆ, Department of Physics and Astronomy, University of Delaware, Newark, DE 19716-2570, USA, QUANTUM TRANSPORT THEORY GROUP COLLABORATION — We derive a nonequilibrium Green function-based formula for spin-transfer torque (STT) exerted by the conduction electrons on the magnetization of a free ferromagnetic (F) layer where *strong* spin-orbit coupling (SOC) is present either in the bulk or at the interface of the F layer. This nonequilibrium Born-Oppenheimer approximation-type formula is employed to predict unconventional STT in N|TI|F semi-magnetic tunnel junction (MTJ) containing a three-dimensional topological insulator (TI). The STT is driven by the SOC on the surface of TI, as well as by the charge current becoming spin-polarized in the direction of transport as it flows from the normal metal (N) through the bulk of the TI layer. The in-plane and perpendicular STT components in N|TI|F semi-MTJ are an order of magnitude larger than in conventional F|I|F MTJ, or N|I|F semi-MTJ with the strong Rashba SOC at the I|F interface, assuming comparable resistance of all three junctions.

¹F. M. and B. K. N. were supported by DOE Grant No. DE-FG02-07ER46374 and N. N. was supported by Grant-in-Aids for Scientific Research (21244053) from the Ministry of Education, Culture, Sports, Science and Technology of Japan.

2:03PM Z31.00015 Time reversal symmetric Kitaev model and topological superconductor, RYOTA NAKAI, Department of Physics, University of Tokyo, SHINSEI RYU, Department of Physics, University of Illinois, AKIRA FURUSAKI, Condensed Matter Theory Laboratory, RIKEN — We study a time reversal symmetric quantum spin model in two dimensions that is introduced as a higher spin extension of the Kitaev model and is exactly solvable [1]. The ground state of the topological phase of this model can be viewed as a time reversal symmetric topological superconductor in two dimensions. The helical Majorana edge modes which appear in time reversal pair in the topological phase are explained by topological argument. The correlation functions along the edge are derived from the gapless edge theory.

Friday, March 2, 2012 11:15AM - 1:39PM – Session Z32 DCMP: Topological Insulators: General Theory II 261

11:15AM Z32.00001 Room temperature quantum spin Hall thin film for buckled honeycomb structures of silicon, germanium, and tin, TAY-RONG CHANG, National Tsing Hua U., Hsinchu, Taiwan, HSIN LIN, Northeastern U., HORNG-TAY JENG, National Tsing Hua U., Hsinchu, Taiwan and Institute of Physics, Academia Sinica, Taipei, Taiwan, M.Z. HASAN, Princeton U., ARUN BANSIL, Northeastern U. — We have carried out first-principles calculations on buckled honeycomb structures of silicon, germanium and tin. When the spin-orbit coupling is included in the computations, these two dimensional (2D) systems are found to be in a quantum spin Hall phase with nontrivial topological invariant $Z_2 = -1$, and a band gap that increases with increasing atomic number. In particular, we predict that buckled honeycomb Sn thin film is a room temperature quantum spin Hall insulator with 0.25 eV band gap.

11:27AM Z32.00002 Topological order and semions in a strongly correlated quantum spin Hall insulator, ANDREAS RUEGG, GREGORY A. FIETE, University of Texas at Austin — We provide a self-consistent mean-field framework to study the effect of strong interactions in a quantum spin Hall insulator on the honeycomb lattice. We identify an exotic phase for large spin-orbit coupling and intermediate Hubbard interaction. This phase is gapped and does not break any symmetry. Instead, we find a four-fold topological degeneracy of the ground state on the torus and fractionalized excitations with semionic mutual braiding statistics. Moreover, we argue that it has gapless edge modes protected by time-reversal symmetry but a trivial Z_2 topological invariant. Finally, we discuss the experimental signatures of this exotic phase. Our work highlights the important theme that interesting phases arise in the regime of strong spin-orbit coupling and interactions.

11:39AM Z32.00003 Spontaneous breakdown of time reversal symmetry in the doped honeycomb lattice with enlarged unit cell, ADOLFO G. GRUSHIN, EDUARDO V. CASTRO, ALBERTO CORTIJO, MARIA A. H. VOZMEDIANO, BELÉN VALENZUELA, Instituto de Ciencia de Materiales de Madrid, CSIC, Spain, FERNANDO DE JUAN, Department of Physics, Indiana University, Bloomington, IN — Enlarging the unit cell of simple lattice models is proposed as a simple means to get spontaneous breakdown of time reversal symmetry (T) and to stabilize non trivial topological phases. As a case study we explore the nearest neighbor tight binding model for spinless fermions interacting through short range Coulomb interactions in the honeycomb lattice. Using a variational mean field approach and an enlarged six atom unit cell we obtain a very rich phase diagram as doping and interaction strength are varied. Two broken T phases, with orbital currents (fluxes) arranged in a Kekulé pattern, show up above the Van Hove filling. One of them realizes a topological Fermi liquid with a finite anomalous Hall conductivity. Instabilities towards charge modulated and superconducting phases are also discussed.

11:51AM Z32.00004 Synchronous and Asynchronous Mott Transitions in Topological Insulator Ribbons¹, AMAL MEDHI, VIJAY B. SHENOY, H.R. KRISHNAMURTHY, Center for Condensed Matter Theory, Indian Institute of Science, Bangalore 560012, India — We address how the nature of linearly dispersing edge states of two dimensional (2D) topological insulators evolves with increasing electron-electron correlation engendered by a Hubbard like on-site repulsion U . We consider finite ribbons of two systems of topological band insulators with local electronic interactions incorporated. Using an inhomogeneous cluster slave rotor mean-field method developed here, we show that electronic correlations drive the topologically nontrivial phase into a Mott insulating phase via two different routes. In a synchronous transition, the entire ribbon attains a Mott insulating state at one critical U . In the second, asynchronous route, Mott localization first occurs on the edge layers at a smaller critical value of electronic interaction which then propagates into the bulk as U is further increased until all layers of the ribbon become Mott localized.

12:03PM Z32.00005 Interaction-driven topological and nematic phases on the Lieb lattice, WEI-FENG TSAI, National Sun Yat-sen University, CHEN FANG, Purdue University, HONG YAO, Stanford University, JIANGPING HU, Purdue University — We investigate the interaction-driven instabilities of the band crossing point (BCP), which occurs in the band structure resulting from spinless/spinful fermions moving on the (extended) Lieb lattice. In the non-interacting limit, we show the topological stability of the BCP both from momentum and real space arguments, provided time reversal and C_4 point group symmetries are preserved. With short-range repulsive interactions, we find that at zero temperature this BCP is marginally unstable against infinitesimal repulsions and results in topological quantum anomalous/spin Hall, charge nematic, and nematic-spin-nematic phases, separately, depending on the interaction strengths. Possible physical realizations and the existence of a topological nearly flat band are also discussed.

12:15PM Z32.00006 Geometric effects on surface states in topological insulator Bi_2Te_3 nanowire, PARIJAT SENGUPTA, TILLMAN KUBIS, MICHAEL POVOLOTSKYI, GERHARD KLIMECK, Purdue University — Bismuth Telluride (BT) is a 3D topological insulator (TI) with surface states that have energy dispersion linear in momentum and forms a Dirac cone at low energy. In this work we investigate the surface properties of a BT nanowire and demonstrate the existence of TI states. We also show how such states vanish under certain geometric conditions. An atomistic model (sp3d5s* TB) is used to compute the energy dispersion in a BT nanowire. Penetration depth of the surface states is estimated by ratio of Fermi velocity and band-gap. BT possesses a tiny band-gap, which creates small localization of surface states and greater penetration in to the bulk. To offset this large spatial penetration, which is undesirable to avoid a direct coupling between surfaces, we expect that bigger cross-sections of BT nanowires would be needed to obtain stable TI states. Our numerical work validates this prediction. Furthermore, geometry of the nanowire is shown to influence the TI states. Using a combined analytical and numerical approach our results reveal that surface roughness impact electronic structure leading to Rashba type splits along z-direction. Cylindrical and square cross-sections are given as illustrative examples.

12:27PM Z32.00007 Spinless massless and massive Dirac fermions in a checkerboard lattice magnet¹, JORN VENDERBOS, MARIA DAGHOFER, JEROEN VAN DEN BRINK, IFW Dresden, SANJEEV KUMAR, Indian Institute of Science Education and Research (IISER) — We investigated the theory of the interplay of itinerant electrons and localized magnetic moments on the frustrated checkerboard lattice as function of the super-exchange interaction between the localized moments and the band filling of fermions. We find that at half filling a very robust magnetic “flux” phase is lowest in energy. The ordering of the localized spins induces an effective gauge field flux of π for the electrons. Consequently, this phase preserves time-reversal symmetry and the low-energy effective theory of the electrons is that of massless Dirac fermions, resembling the situation in graphene except that the spin degree of freedom is absent here. The robustness of this state originates from the geometrical frustration of the checkerboard lattice. In the crossover regime from this flux state and the saturated FM state at vanishing super-exchange coupling, these Dirac fermions become massive with opposite sign of the mass at the two degeneracy points. This chiral spin state is then equivalent to a time-reversal breaking anomalous Quantum Hall phase, precisely in the way once envisioned by Haldane in graphene.

¹Supported by DPG (Emmy Noether program) and the Dutch Science Foundation NWO/FOM (Interphase program)

12:39PM Z32.00008 Kondo lattice on the edge of a 2D topological insulator, JOSEPH MACIEJKO, Princeton Center for Theoretical Science — Much attention has been devoted recently to the experimental and theoretical study of the effect of magnetic impurities on the stability of the gapless boundary modes of topological insulators. When the quantum dynamics of the impurities is considered, those boundary modes constitute novel types of fermionic baths which may affect the nature of possible impurity phases and phase transitions. We study a regular one-dimensional array of quantum magnetic impurities interacting with the helical edge liquid of a two-dimensional time-reversal invariant topological insulator. Exact solutions at the special Toulouse and Luther-Emery points as well as a renormalization group analysis à la Anderson-Yuval allow us to construct a phase diagram in the space of Kondo coupling, electron-electron interaction strength, and electron density. We point out similarities and differences with the Kondo lattice in an ordinary one-dimensional electron gas.

12:51PM Z32.00009 Non-Abelian Berry transport, spin coherent states, and Majorana points, YUN LIU, ABHISHEK ROY, MICHAEL STONE, University of Illinois at Urbana-Champaign — We consider the adiabatic evolution of Kramers degenerate pairs of spin states in a half-integer spin molecular magnet as the molecule is slowly rotated, for which it is possible to encounter non-Abelian Berry's phase. To understand the full details of the adiabatic quantum evolution, we invoke Majorana's parametrization of a general spin- j state in terms of the $2j$ Majorana points. As an illustration we consider molecular magnets of the $j = 9/2$ Mn4 family and compute the frequency with which the magnetization varies. This frequency is generally different from the frequency of the rotation.

1:03PM Z32.00010 Exploring Diabolical points and Berry Phases in the Majorana Representation, ABHISHEK ROY, University of Illinois, Urbana-Champaign — Diabolical points or level crossings are often observed in spin hamiltonians, where they give rise to a Berry phase. We study their geometric structure using the Majorana representation which associates a spin state to a set of points on the Bloch sphere. Each crossing carries a Chern number which is found to be directly related to the wrapping of Majorana points around it. We apply our method to study model hamiltonians for molecular magnets in an external magnetic field, in which a rich pattern of diabolical points are seen. Our result enables a simple visualization of the Berry phases without the use of perturbation theory.

1:15PM Z32.00011 Quasiparticle effects in the bulk and surface-state bands of Bi_2Se_3 and Bi_2Te_3 topological insulators¹, OLEG V. YAZYEV, UC Berkeley/LBNL/EPFL, EMMANOUIL KIOUPAKIS, U of Michigan, JOEL E. MOORE, STEVEN G. LOUIE, UC Berkeley/LBNL — We investigate the bulk band structures and the surface states of Bi_2Se_3 and Bi_2Te_3 topological insulators using first-principles many-body perturbation theory based on the GW approximation. The quasiparticle self-energy corrections introduce significant changes to the bulk band structures, surprisingly leading to a decrease in the direct band gaps in the band-inversion regime as opposed to the usual situation without band inversion. Parametrized “scissors operators” derived from the bulk studies are then used to investigate the electronic structure of slab models which exhibit topologically protected surface states. The introduction of self-energy corrections results in significant shifts of the surface-state Dirac point energies relative to the bulk bands and in enlarged gap openings from the interactions between the surface states across the thin slab, both in agreement with experimental data.

1:27PM Z32.00012 Search for new topological insulators: ternary Li_2AgSb -class semiconductors and related compounds, HSIN LIN, Northeastern U., TANMOY DAS, LANL and Northeastern U., Y.J. WANG, Northeastern U., L.A. WRAY, LBNL and Princeton U., S.-Y. XU, M.Z. HASAN, Princeton U., ARUN BANSIL, Northeastern U. — Topological insulators host a rare quantum phase of electrons which is characterized by a topological invariant number of bulk states of combined spin-orbit and time-reversal symmetry origin. Despite recent progress the available classes of topological insulators are still quite limited for use in device applications and experimental exploration of exotic topological phenomena. For this reason, the search for new materials with greater structural flexibility and tunability in various local order broken symmetry phases is continuing worldwide with great intensity. Here we discuss our effort based on first-principles calculations to show that the adiabatic continuation method can provide a very powerful tool for predicting non-trivial topological phases with the example of ternary intermetallic series, $\text{Li}_2M'X$ ($M'=\text{Cu, Ag, Au, and Cd}$, $X=\text{Sb, Bi, and Sn}$) as well as other compounds with zinc-blende type sublattice. Friday, March 2, 2012 11:15AM - 1:51PM – Session Z40 DBIO: Biomechanics - Organismic Motion 156A

11:15AM Z40.00001 The mechanics of anisotropic cytoskeletal networks, TAO ZHANG, MOUMITA DAS, Syracuse University, D.A. QUINT, UC-Merced, J.M. SCHWARZ, Syracuse University — At the leading edge of a crawling cell, the actin cytoskeleton extends itself via a branched, crosslinked network of filaments, otherwise known as the lamellipodium. The filaments in this network have an average preferred orientation of around ± 30 degrees with respect to the normal of the leading edge. This preferred orientation of filaments leads to a material that is structurally anisotropic. To better understand the forces generated by the lamellipodium, we analytically and numerically study the mechanical properties of a model branched and crosslinked filamentous network where the filaments are preferentially oriented along one direction. We investigate the interplay between geometry, elasticity and anisotropy in the network. In particular, we show how anisotropy modulates the onset of rigidity and non-linear mechanical response of the network.

11:27AM Z40.00002 Self-Organized Cell Motility from Motor-Filament Interactions, XINXIN DU, KONSTANTIN DOUBROVINSKI, MIRIAM OSTERFIELD, Princeton University — Cell motility is driven primarily by the dynamics of the cell cytoskeleton, a system of filamentous proteins and molecular motors. It has been proposed that cell motility is a self-organized process; that is, local short-range interactions determine much of the necessary dynamics required for the whole-cell organization that leads to polarization and directional motion. Here we present a mesoscopic meanfield description of filaments, motors, and cell boundaries; this description gives rise to a dynamical system exhibiting multiple self-organized states. We discuss several qualitative aspects of the asymptotic states and compare them to those of living cells.

11:39AM Z40.00003 Modeling of a crawling *C. elegans* in a micro-structured environment¹, AMAR PATEL, VENKAT PADMANABHAN, DEEPAK SOLOMON, ZEINA KHAN, Texas Tech University, FRANK VAN BUSSEL, Max Planck Institute for Dynamics and Self-Organization, SIVA VANAPALLI, Texas Tech University, KENDRA RUMBAUGH, Texas Tech University Health Sciences Center, JERZY BLAWZDZIEWICZ, Texas Tech University — A simple curvature-based model is used to study crawling *C. elegans* in a micro-structured environment of periodic pillars. In our model system, the shape of the worm is described by a simple sinusoidal expression in curvature representation. The gait of the worm is determined by a set of parameters including the amplitude, frequency, and phase of the curvature. The moving worm is subject to the friction with the underlying substrate, and the forces due to interaction of the worm body with pillars. If the friction is isotropic the worm has to interact with the pillars to move forward. We find that only a narrow range of worm gaits leads to efficient propulsion in this case. To investigate how the worm adjusts its gait to the environment microstructure, we implement a simple control system that chooses the right set of parameters based on the past interactions of the worm with its surroundings. Results of our simulations of the worm motion are compared with our experimental observations of *C. elegans* crawling in an agar environment containing an array of fabricated pillars.

11:51AM Z40.00004 Fluctuations, Dynamics, and the Stretch-Coil Transition of Single Actin Filaments in Extensional Flows, VASILY KANTSER, RAYMOND E. GOLDSTEIN, DAMTP, University of Cambridge, DEPARTMENT OF APPLIED MATHEMATICS AND THEORETICAL PHYSICS TEAM — Semi-flexible polymers (actin filaments) subject to hydrodynamic forcing play an important role in cytoskeletal dynamics in the cell. The non-equilibrium problem of semi-flexible polymer dynamics is highly challenging due to the coupling between the objects deformations and the flow. This leads to a free-boundary hydrodynamic problem, where the object's shape is not given *a priori*, but determined by an interplay between the fluid stresses, bending energy and the length constrain of the actin filaments. We have investigated experimentally and analytically dynamics of actin filaments in elongational flow. Near hyperbolic stagnation points of the flow filaments experience a competition between bending elasticity and tension induced by the flow, and are predicted to display suppressed thermal fluctuations in the steady regime and a buckling instability under sudden change of the velocity gradient. Using a microfluidic cross-flow geometry we verify these predictions in detail, including a fluctuation-rounded stretch-coil transition of actin filaments.

12:03PM Z40.00005 Cell Shape Dynamics: From Waves to Migration, MEGHAN DRISCOLL, University of Maryland, College Park, COLIN MCCANN, University of Maryland, College Park and National Cancer Institute, National Institutes of Health, XIAOYU SUN, JOHN FOURKAS, University of Maryland, College Park, CAROLE PARENT, National Cancer Institute, National Institutes of Health, WOLFGANG LOSERT, University of Maryland, College Park — We observe and quantify wave-like characteristics of amoeboid migration. Using the amoeba *Dictyostelium discoideum*, a model system for the study of chemotaxis, we demonstrate that cell shape changes in a wave-like manner. Cells have regions of high boundary curvature that propagate from the leading edge toward the back, usually along alternating sides of the cell. Curvature waves are easily seen in cells that do not adhere to a surface, such as cells that are electrostatically repelled from surfaces or cells that extend over the edge of micro-fabricated cliffs. Without surface contact, curvature waves travel from the leading edge to the back of a cell at $\sim 35 \mu\text{m}/\text{min}$. Non-adherent myosin II null cells do not exhibit these curvature waves. At the leading edge of adherent cells, curvature waves are associated with protrusive activity. Like regions of high curvature, protrusive activity travels along the boundary in a wave-like manner. Upon contact with a surface, the waves stop moving relative to the surface, and the boundary shape thus reflects the history of protrusive motion. The wave-like character of protrusions provides a plausible mechanism for the ability of cells to both swim in viscous fluids and to navigate complex 3-D topography.

12:15PM Z40.00006 A curvature-based description for the kinematics of *C. Elegans*¹, VENKAT PADMANABHAN, ZEINA KHAN, DEEPAK SOLOMON, SIVA VANAPALLI, Texas Tech University, KENDRA RUMBAUGH, Texas Tech University Health Sciences Center, JERZY BLAWDZIEWICZ, Texas Tech University — *Caenorhabditis Elegans* is a free-living soil nematode that propels itself in various complex environments by producing undulatory body motion. Such nematodes display a rich variety of body shapes and trajectories during their locomotion. Here we show that the complex shapes and trajectories of *C. Elegans* have a simple analytical description in curvature representation. Our model is based on the assumption that the curvature wave is generated in the head segment of the worm body and propagates backwards. We have found that a simple sinusoidal function for the curvature can capture multiple worm shapes during the undulatory movement. The worm body trajectories can be well represented by piece-wise sinusoidal curvature with abrupt changes in amplitude, frequency, and phase.

¹We acknowledge financial support by NSF grant CBET 1059745.

12:27PM Z40.00007 Paramecia Swim with a constant propulsion in Solutions of Varying Viscosity¹, JAMES M. VALLES, JR., ILYONG JUNG, HARRY MICKALIDE, HOJIN PARK, THOMAS POWERS, Brown University — Paramecia swim through the coordinated beating of the 1000's of cilia covering their body. We have measured the swimming speed of populations of Paramecium Caudatum in solutions of different viscosity, η , to see how their propulsion changes with increased drag. We have found the average instantaneous speed, V to decrease monotonically with increasing η . The product ηv is roughly constant over a factor of 7 change in viscosity suggesting that paramecia swim at constant propulsion force. The distribution of swimming speeds is Gaussian. The width appears proportional to the average speed implying that both fast and slow swimmers exert a constant propulsion. We discuss the possibility that this behavior implies that the body cilia beat at constant force with varying viscosity.

¹This work was supported by NSF PHY0750360 and at the NHMFL by NSF DMR-0084173

12:39PM Z40.00008 Response of Swimming Paramecia to *in situ* changes in their apparent weight¹, ILYONG JUNG, HARRY MICKALIDE, JAMES M. VALLES, JR., Brown University — There is a class of marine micro-organisms that are small enough that low Reynold's number hydrodynamics dictates their swimming mechanics and large enough that the force of gravity exerts a noticeable influence on their motion. Experiments on populations of paramecia suggest that they exert a greater propulsion when swimming against gravity. This negative gravi-kinesis is surprising because it suggests that they sense their tiny apparent weight of about 80 pN. To understand this response in more detail, we are investigating how individual paramecia caudatum change their swimming speed and helical trajectories in response to changes in their apparent weight. We vary the apparent weight with the technique of Magnetic Force Buoyancy Variation employing a high field resistive magnet at the National High Magnetic Field Laboratory. We will present analysis of the swimming for apparent weight changes as large as a factor of 8.

12:51PM Z40.00009 Capillary Action may act as a cooling method in Plants and Animals, RICHARD KRISKE, University of Minnesota — A capillary tube in a plant may lead from its roots to the leaves. It takes no work for the column of water to rise from the roots to the leaves, and if there is capillarity in the soil, it takes no work for the water to flow through the ground to the roots. It does take work for a molecule of water to evaporate from the tube into the atmosphere. When a molecule of water evaporates another molecule travels through the soil and up the plant to replace it. The lost molecule creates a "hole" in the water column which like a signal is sent to the root and the sea of water in the soil replaces it. Since the water molecules are not unique this is the same situation as if the water vapor were condensed back to a liquid in a refrigeration cycle. Another interesting aspect of this sort of refrigeration is that the "hole" itself may be used to do work along the wall of the capillary tube, which may have Fermi Levels in it. An Hydraulic Semi Conductor, and in it is a method of cooling the Semi Conductor. This may be applicable to other similar systems using other liquids, or substances such as nanotube systems, where the hole signals,cools and performs chemical reactions involving not only orbitals but Fermi Levels, a transition between Quantum and Classical Mechanics, with surprises.

1:03PM Z40.00010 Data-Driven Classification of Animal Behavior, GORDON BERMAN, WILLIAM BIALEK, JOSHUA SHAEVITZ, Princeton University — The last decades have seen an explosion in our ability to characterize the molecular, cellular and genetic building blocks of life; the ingredients out of which we try to explain the rich and compelling behavior of living organisms. Our characterization of behavior itself, however, has advanced more slowly. Since modern ethology was founded over a century ago, behavioral experiments have focused largely on a restricted set of behaviors within the scope of a limited environment. Moreover, the set of behaviors to be examined is often user-defined, creating the potential for human bias and anthropomorphism. The research presented here describes a data-driven methodology for analyzing animal behavior, focusing on the fruit fly, *Drosophila melanogaster*, as a model system. Towards this end, we have built an imaging system that can track single flies as they move about a relatively unencumbered environment. Utilizing this capacity to generate large data sets of animal behavior, we have developed a method for automatically identifying behavioral states using techniques from image analysis, machine learning, and nonlinear dynamics. Identifying these states provides the starting point for many analyses and creates the possibility for automatic phenotyping of subtle behavioral traits.

1:15PM Z40.00011 Multiscale Analysis of Head Impacts in Contact Sports¹, MARK GUTTAG, Brown University, SUBHAM SETT, SIMULIA, JENNIFER FRANCK, KYLE MCNAMARA, EYAL BAR-KOCHBA, Brown University, JOSEPH CRISCO, Rhode Island Hospital, JANET BLUME, CHRISTIAN FRANCK, Brown University — Traumatic brain injury (TBI) is one of the world's major causes of death and disability. To aid companies in designing safer and improved protective gear and to aid the medical community in producing improved quantitative TBI diagnosis and assessment tools, a multiscale finite element model of the human brain, head and neck is being developed. Recorded impact data from football and hockey helmets instrumented with accelerometers are compared to simulated impact data in the laboratory. Using data from these carefully constructed laboratory experiments, we can quantify impact location, magnitude, and linear and angular accelerations of the head. The resultant forces and accelerations are applied to a fully meshed head-form created from MRI data by Simpleware. With appropriate material properties for each region of the head-form, the Abaqus finite element model can determine the stresses, strains, and deformations in the brain. Simultaneously, an in-vitro cellular TBI criterion is being developed to be incorporated into Abaqus models for the brain. The cell-based injury criterion functions the same way that damage criteria for metals and other materials are used to predict failure in structural materials.

1:27PM Z40.00012 The fern sporangium: an ultrafast natural catapult, XAVIER NOBLIN, LPMC, UMR 6622 CNRS-UNS, Parc Valrose, 06108 Nice cedex 2, France, MEDERIC ARGENTINA, LJAD, UMR 6621 CNRS-UNS, Parc Valrose, 06108 Nice cedex 2, France, JARED WESTBROOK, Department of Botany, University of Florida, Gainesville, FL, 32611 USA, CORALINE LLORENS, NICOLAS ROJAS, LJAD, UMR 6621 CNRS-UNS, Parc Valrose, 06108 Nice cedex 2, France, JACQUES DUMAIS, OEB, Harvard University, 16 Divinity Avenue, 02138 Cambridge, MA, USA — Plants have developed fascinating mechanisms to create ultra fast movements that often reach the upper limit allowed by physical laws. Inspiration for new technologies is one of the reasons for the strong interest for these mechanisms, along with the deep interest of understanding complex, natural systems. The fern sporangium is a capsule that contains the spores, it is surrounded by a row of cells called the annulus which acts as a beam. Due to the water evaporation from its cells, the annulus bends strongly and induces elastic energy storage during an opening phase. The tension in the cells breaks when cavitation bubbles appear in the cells, leading to a fast release of the elastic energy. The fern sporangium then acts as a catapult which ejects rapidly its spores by closing back to the initial closed shape. We have analyzed the slow opening motion and the fast catapulting mechanism. We found that the catapult motion involves two time scales, showing a very original behavior. In man-made catapults, the recoil motion needs to be arrested by a cross bar so that the projectile is released from the arm. We show here that the fern sporangium replaces the essential cross bar by an elegant poroelastic damping, leading to a completely autonomous, efficient device.

1:39PM Z40.00013 Hydrodynamics of Active Permeating Gels, ANDREW CALLAN-JONES, University of Montpellier II, FRANK JÜLICHER, Max Planck Institute for the Physics of Complex Systems — We present a hydrodynamic theory of active viscoelastic gels in which a polymer network is embedded in a background fluid. This work is motivated by active processes in the cell cytoskeleton in which motor molecules generate elastic stresses in the network which can drive permeation flows of the cytosol. Our approach differs from earlier ones by considering the elastic strain in the polymer network as a slowly relaxing dynamical variable. We discuss a specific case that illustrates the role of permeation in active gels: the self-propulsion of a thin slab of gel relative to a substrate driven by filament polymerization and depolymerization.

Session Z41 DBIO GSNP: Focus Session: Non-Covalent Protein Interactions 156B

11:15AM Z41.00001 Novel Aspects of Hydrogen Bonding in Protein Function: Active Site Ionic Hydrogen Bonds, WOUTER D. HOFF, Oklahoma State University — We use photoactive yellow protein (PYP), a bacterial photoreceptor, to explore novel aspects of the role of hydrogen bonding in protein function. PYP exhibits photochemical activity based on its ionized p-coumaric acid (pCA) chromophore, which is hydrogen bonded to Tyr42 and Glu46. We report that these active site ionic hydrogen bonding interactions cause unexpected molecular and functional properties of PYP. First, we describe a novel spectroscopic isotope effect (SIE) in which dissolving PYP in D₂O causes a red-shift in its electronic absorbance spectrum. We assign this SIE to the ionic hydrogen bond between pCA and Glu46, which—in contrast to standard hydrogen bonds—is weakened upon H/D exchange. These findings extend the effects of H/D exchange from kinetic isotope effects to include shifts in absorbance spectrum, and illustrate the biological relevance of ionic hydrogen bonding to protein active sites. Secondly, we examine how the protein environment achieves the unusual strong preference of the pCA to remain ionized in the protein interior. We use the rescue of the Y42F mutant of PYP by incorporation of a trans-locked analog of pCA to dissect the contributions of active site hydrogen bonding to the large down-shift in the pK_a of the pCA. Together, the Tyr42 and Glu46 hydrogen bonds to the pCA account for ~80% of this shift, which can be quantitatively explained by the loss of ionic hydrogen bonding upon pCA protonation from the solvent. Since ionic hydrogen bonds occur in many proteins, this mechanism of pK_a tuning is likely to be of general relevance.

11:51AM Z41.00002 Computational design of protein interactions: designing proteins that neutralize influenza by inhibiting its hemagglutinin surface protein, SAREL FLEISHMAN, Weizmann Institute of Science — Molecular recognition underlies all life processes. Design of interactions not seen in nature is a test of our understanding of molecular recognition and could unlock the vast potential of subtle control over molecular interaction networks, allowing the design of novel diagnostics and therapeutics for basic and applied research. We developed the first general method for designing protein interactions. The method starts by computing a region of high affinity interactions between dismembered amino acid residues and the target surface and then identifying proteins that can harbor these residues. Designs are tested experimentally for binding the target surface and successful ones are affinity matured using yeast cell surface display. Applied to the conserved stem region of influenza hemagglutinin we designed two unrelated proteins that, following affinity maturation, bound hemagglutinin at subnanomolar dissociation constants. Co-crystal structures of hemagglutinin bound to the two designed binders were within 1Å RMSD of their models, validating the accuracy of the design strategy. One of the designed proteins inhibits the conformational changes that underlie hemagglutinin's cell-invasion functions and blocks virus infectivity in cell culture, suggesting that such proteins may in future serve as diagnostics and antivirals against a wide range of pathogenic influenza strains. We have used this method to obtain experimentally validated binders of several other target proteins, demonstrating the generality of the approach. We discuss the combination of modeling and high-throughput characterization of design variants which has been key to the success of this approach, as well as how we have used the data obtained in this project to enhance our understanding of molecular recognition. References: Science 332:816 JMB, in press Protein Sci 20:753

12:27PM Z41.00003 The power of simple hard-sphere models in protein structure prediction¹, LYNNE REGAN, Yale University — There are several force-fields that are currently used to describe the potential energy of biological macromolecules such as proteins. These typically include many parameters, derived from a combination of statistical, experimental sources. These work on average to describe a protein, but the large number of parameters moves this description further away from a true physical understanding than is desirable. Our approach is to investigate to what extent simple hard sphere models can be used to model and predict the behavior of different aspects of protein structure. We present the results of specific calculations. The distributions of the side-chain dihedral angle χ_1 of Val and Thr in proteins of known structure show distinctive features: Val side chains predominantly adopt dihedral angle, χ_1 , of 180, whereas Thr side chains typically adopt a dihedral angle, χ_1 , of 60 or 300. Several hypotheses have been proposed to explain these differences, including inter-residue steric clashes and hydrogen-bonding interactions. In contrast, we show that the observed side-chain dihedral angle distributions for both Val and Thr can be explained using only local steric interactions in a dipeptide mimetic. Our results emphasize the power of a simple physics-based approaches and their importance for future advances in protein engineering and design.

1:03PM Z41.00004 Acetylation of LYS-16 of H4 Histone Tail May Sequester the Tail and Inhibit its Interactions with Neighboring Nucleosomes, DAVIT POTOYAN, GAREGIN PAPOIAN, University of Maryland — Histone tails are highly flexible N terminal protrusions of histone proteins, which help to fold DNA into dense superstructures known as chromatin. On a molecular scale histone tails are poly-electrolytes with high degree of conformational disorder, allowing them to function as bio-molecular “switches,” regulating various genetic regulatory processes via diverse types of covalent modifications. Because of being intrinsically disordered, the structural and dynamical aspects of histone tails are still poorly understood. Using multiple explicit solvent and coarse-grained MD simulations we have investigated the impact of the acetylation of LYS-16 residue on the conformational and DNA-binding propensities of H4 histone tail. The potential of mean force computed as a function of distance between a model DNA and histone tail center of mass showed a dramatic enhancement of binding affinity upon mono-acetylation of the H4 tail. The estimated binding free energy gain for the wild type is 2kT, while for the acetylated it reaches 4-5 kT. Additionally our structural analysis shows that acetylation is driving the chain into collapsed states, which get enriched in secondary structural elements upon binding to the DNA. We suggest a non-electrostatic mechanism that explains the enhanced binding affinity of the acetylated H4 tail. At last our findings lead us to propose a hypothesis that can potentially account for the celebrated chromatin “fiber loosening effects” observed in many experiments.

1:15PM Z41.00005 Exploring copper chelation in Alzheimer's disease protein, FRISCO ROSE, MIROSLAV HODAK, JERRY BERNHOLC, CHiPS/NCsu — Alzheimer's disease (AD) is a neurodegenerative disorder affecting millions of aging people in the U.S. alone. Clinical studies have indicated that metal chelation is a promising new approach in alleviating the symptoms of AD. Our study explores the as yet undetermined mechanism of copper chelation in amyloid- β , a protein implicated in AD. The structure of amyloid- β is derived from experimental results and incorporates a planar copper-ion-binding structure in a semi-solvated state. We investigate the chelation process using the nudged elastic band method implemented in our *ab initio* real-space multigrid code. We find that an optimal sequence of unbonding and rebonding events as well as proton transfers are required for a viable chelation process. These findings provide fundamental insight into the process of chelation that may lead to more effective AD therapies.

1:27PM Z41.00006 Transition-metal prion protein attachment: Competition with copper, MIROSLAV HODAK, JERRY BERNHOLC, North Carolina State University — Prion protein, PrP, is a protein capable of binding copper ions in multiple modes depending on their concentration. Misfolded PrP is implicated in a group of neurodegenerative diseases, which include "mad cow disease" and its human form, variant Creutzfeld-Jacob disease. An increasing amount of evidence suggests that attachment of non-copper metal ions to PrP triggers transformations to abnormal forms similar to those observed in prion diseases. In this work, we use hybrid Kohn-Sham/orbital-free density functional theory simulations to investigate copper replacement by other transition metals that bind to PrP, including zinc, iron and manganese. We consider all known copper binding modes in the N-terminal domain of PrP. Our calculations identify modes most susceptible to copper replacement and reveal metals that can successfully compete with copper for attachment to PrP.

1:39PM Z41.00007 Steric clashes determine differences in side chain dihedral angle distributions: A study of Thr versus Val¹, ALICE ZHOU, COREY O'HERN, LYNNE REGAN, Yale University — With the long-term goal to improve the design of protein-protein interactions, we develop a simple hard sphere model for dipeptides that can predict the side-chain dihedral angle distributions of Val and Thr in both the α -helix and β -sheet backbone conformations. We find that it is essential to include the non-polar hydrogens in the model; indeed interatomic clashes involving the non-polar hydrogens largely determine the form of side-chain dihedral angle distributions. Further, we are able to explain key differences in the side-chain dihedral angle distributions for Val and Thr from intra-residue steric clashes rather than inter-residue steric clashes or hydrogen bonding. These results are the crucial first step in developing computational models that can predict the side chain conformations of residues at protein-peptide interfaces.

Session Z42 DBIO: Focus Session: Physics of Biomaterials: Mechanics, Dynamics, and Transport 156C

11:15AM Z42.00001 Highly parallel computational study of amphiphilic molecules using the Wang-Landau method¹, THOMAS VOGEL, DAVID LANDAU, The Center for Simulation Physics, University of Georgia, Athens, GA, 30602, U.S.A. — The self-assembly process in amphiphilic solutions is a phenomenon of broad interest. Molecular dynamics simulations generally used to study micelle formation or lipid layer assembly in an explicit solvent are limited in time scale. Vast studies of structure formation processes via standard Markov-chain based Monte Carlo simulations are challenging, but the Wang-Landau method [1] provides a way to efficiently study such systems in a generalized thermodynamic ensemble. This makes it possible, for example, to get results over a broad temperature range from a single simulation. In an attempt to develop highly parallel applications using this method, we study the thermodynamic behavior of a generic coarse-grained model for amphiphilic molecules [2] as well as of a new coarse-grained lipid model specifically designed for dimyristoyl phosphatidylcholine (DMPC) [3]. Here, we focus on the design and the performance of our parallel Wang-Landau simulation on multi-CPU and GPU systems.

11:27AM Z42.00002 Spatial response variations within biosensor flow cells, NICOLA CANT, SARAH HARRISON, Dstl — Biosensors are currently being developed for the detection of a wide range of analytes in a variety of scenarios. One such area is that of environmental monitoring for the presence of biological threats, from toxins through to viruses and bacteria. The varying nature, and in particular disparate size, of such a variety of analytes poses a significant challenge in the development of effective high confidence instruments. Many existing biosensors employ functionalised flow cells in which spatially defined arrays of surface immobilised recognition elements are present to specifically capture their analyte of interest. Experimental data obtained using a grating coupled SPR instrument, the BIAcoreTM Flexchip, has revealed spatial dependency differences in response behaviours between proteinaceous and particulate analytes. In particular, the magnitude of responses seen with *Bacillus anthracis* spores across the instruments flow cell appear to be influenced by shear and gravitational effects whilst those from soluble proteins are more uniform. We have explored this dependence to understand its fundamental impact on the successful implementation of multi-analyte environmental biological detection systems.

11:39AM Z42.00003 Size-dependent mechanical properties of low-dimensional materials: coupling between deformation modes, YITING DING, ZHIPING XU, Computational Energetics Laboratory, Department of Engineering Mechanics & Center for Nano and Micro Mechanics — Coupling between deformation modes, such as tension, bending, shear, and twisting, are widely observed in low-dimensional materials, especially biological materials. In this talk we will present our study on microtubules (MT) mechanics, where significance of mode coupling leads remarkable size-dependence in structural and mechanical properties. Using molecular dynamics (MD) simulations, we find a distinct dependence of bending rigidity on the contour length of a MT that agrees well with experimental data. We develop a simple model by including basic parameters to explain and predict this interesting phenomenon. An extended discussion will be made to general low-dimensional materials, with focuses not only on the mechanism, but also applications in optimal materials design.

11:51AM Z42.00004 A QM/MM method for simulating the sequencing of DNA using graphene nanopores: solvent effects on nucleobase selectivity, ALEXANDRE ROCHA, GUSTAVO FELICIANO, Universidade Federal do ABC - Brazil, YUHUI HE, Osaka University - Japan, RALPH SCHEICHER, Department of Physics and Astronomy, Uppsala University - Sweden, MAURICIO COUTINHO, Universidade Federal do ABC - Brazil — The possibility of using graphene nanopores for DNA sequencing is driving a significant research effort with the aim of obtaining cheaper, more efficient, sequencing techniques. In this work we will present electronic transport calculations of graphene nanopores used for sequencing DNA strands. We consider both single layer and double layer graphene with different types of functionalization of the pore edges. The simulations were performed using a QM/MM method which allows us to treat the graphene sheet containing the nanopore and a segment of DNA within the pore via ab initio DFT methods (QM) whereas the effects of the water molecules, the counter-ions and the remainder of the DNA strand is taken into consideration using a classical potential (MM). The electronic transport properties along graphene are subsequently calculated using non-equilibrium Green's functions including the classical potential. Different time steps of classical molecular dynamics simulations of the DNA strand passing through the nanopore are considered in order to simulate the translocation process. This way we are able to address the effects of the solvent on the selectivity of the device to different nucleobases using atomistic methods.

12:03PM Z42.00005 First-Principles Study of Muon Trapping in Singlet and Triplet States of Oxyhemoglobin, ROGER PINK, S.R. BADU, T.P. DAS, Department of Physics, University at Albany, SUNY, N. SAHOO, UTMD Anderson, LEE CHOW, Department of Physics, University of Central Florida, R.H. SCHEICHER, Uppsala University, K. NAGAMINE, Department of Physics, UCR — There is great current interest in the possibility of magnetic character in oxyhemoglobin (OxyHb) due to the detection [1] of muon spin-lattice relaxation in OxyHb. First-Principles variational Hartree-Fock Many Body Perturbation Theory (VHFMBPT) technique investigations on the singlet and triplet states of pure OxyHb have shown² that the triplet state is considerably higher than the singlet state ruling out magnetic character. However the charge distribution obtained by the VHFMBPT procedure in both states show a number of sites that have negative charges where the trapping of muon is being investigated to examine if the energy gap in the ordering of singlet and triplet states can be reduced or reversed leading to magnetic effects. Other possible sources of magnetism in Oxyhemoglobin will also be discussed. 1. K. Nagamine et al. Proc. Japan. Acad. B-Physics 83, 120 (2007); 2. S.R. Badu et al. Reported at Third Joint HFI-NQI International Conference, CERN, Geneva, September 2010.

12:15PM Z42.00006 Branched Polymer Models and the Mechanism of Multilayer Film Buildup, PRADEEP WADUGE, DHAN KHADKA, DONALD HAYNIE, University of South Florida — The “in and out diffusion” hypothesis does not provide a sufficient explanation of the exponential buildup displayed by some polyelectrolyte multilayer film systems. Here, we report initial tests of an alternative view, on which the completion of each adsorption cycle results in an increase in the number of polymer binding sites on the film surface. Polycationic dendrimeric peptides, which can potentially bind several oppositely-charged peptides each, have been designed, synthesized and utilized in comparative film buildup experiments. Material deposited, internal film structure and film surface morphology have been studied by ultraviolet spectroscopy (UVS), circular dichroism spectroscopy (CD), quartz crystal microbalance (QCM) and atomic force microscopy (AFM). Polycations tended to contribute more to film buildup than did polyanions on quartz but not on gold. Increasing the number of branches in the dendrimeric peptides from 4 to 8 reproducibly resulted in an increase in the film growth rate on quartz but not on gold. Peptide backbones tended to adopt a β -strand conformation on incorporation into a film. Thicker films had a greater surface roughness than thin films. The data are consistent with film buildup models in which the average number of polymer binding sites will increase with each successive adsorption cycle in the range where exponential growth is displayed.

12:27PM Z42.00007 Reduction of Scattered Light by Müller Cells in the Human Retina, OLIVER BENDIX, RAGNAR FLEISCHMANN, THEO GEISEL, MPI for Dynamics and Self-Organization — It is a long standing question why in the mammalian eye photoreceptors are positioned at the back of the retina, forcing photons to travel through various neuronal layers of the retina before the light-sensitive rods and cones can detect them. Recent studies suggest that certain retinal glial cells—called Müller cells (MCs)—play an important role in answering that question. It has been experimentally shown that MCs extracted from the retina can act as optical fibers [1]. To understand the light guiding properties of the MC in the natural fluctuating optical environment, we developed a model to analyze the light reflection and transmission of MCs embedded in a random medium neuronal tissue. With these quantities and a simplified geometrical eye model we study how light is scattered in the eye. We found that MCs can lead to a substantial increase of the signal-to-noise ratio (SNR), the ratio of the intensity of direct incident light at a photoreceptor to the intensity of back-scattered light from other areas of the retina. The SNR is most pronounced in the vicinity of the fovea and can be more than an order of magnitude.

12:39PM Z42.00008 Quantifying the deformation of the red blood cell skeleton in shear flow¹, ZHANGLI PENG, Massachusetts Institute of Technology, QIANG ZHU, University of California San Diego — To quantitatively predict the response of red blood cell (RBC) membrane in shear flow, we carried out multiphysics simulations by coupling a three-level multiscale approach of RBC membranes with a Boundary Element Method (BEM) for surrounding flows. Our multiscale approach includes a model of spectrins with the domain unfolding feature, a molecular-based model of the junctional complex with detailed protein connectivity and a whole cell Finite Element Method (FEM) model with the bilayer-skeleton friction derived from measured transmembrane protein diffusivity based on the Einstein-Stokes relation. Applying this approach, we investigated the bilayer-skeleton slip and skeleton deformation of healthy RBCs and RBCs with hereditary spherocytosis anemia during tank-treading motion. Compared with healthy cells, cells with hereditary spherocytosis anemia sustain much larger skeleton-bilayer slip and area deformation of the skeleton due to deficiency of transmembrane proteins. This leads to extremely low skeleton density and large bilayer-skeleton interaction force, both of which may cause bilayer loss. This finding suggests a possible mechanism of the development of hereditary spherocytosis anemia.

12:51PM Z42.00009 Theoretical study of electron transport in DNA, BIKAN TAN, MIROSLAV HODAK, WENCHANG LU, JERRY BERNHOLC, CHIPS/NCSS — Multiple experiments have indicated high conductivity of DNA, but its origin has not yet been satisfactorily explained. In this work, we explore the conductivity of double stranded B-DNA using a nonequilibrium Green's function method based on density-functional theory. The DNA is sandwiched between metallic nanotube leads and we investigate the effect of various linkers connecting the DNA to the leads. Our results show that the alkane linker, $(CH_2)_n$, which is often used in experiments, dramatically decreases the conductivity due to its large band gap around the Fermi level. We also find that conductivity can be greatly enhanced by aligning the highest occupied molecule orbital energy of DNA with the Fermi level of the leads by applying a gate bias to the DNA. Finally, we examine the effects of misalignment and mismatches on conductivity of DNA.

Session Z43 GSNP DFD: Invited Session: Applications of Jamming 157AB

11:15AM Z43.00001 Robotics using sand, HEINRICH JAEGER, Univ of Chicago — No abstract available.

11:51AM Z43.00002 Shocks in fragile matter, VINCENZO VITELLI, Instituut Lorentz for Theoretical Physics — Non-linear sound is an extreme phenomenon typically observed in solids after violent explosions. But granular media are different. Right when they unjam, these fragile and disordered solids exhibit vanishing elastic moduli and sound speed, so that even tiny mechanical perturbations form supersonic shocks. Here, we perform simulations in which two-dimensional jammed granular packings are continuously compressed, and demonstrate that the resulting excitations are strongly nonlinear shocks, rather than linear waves. We capture the full dependence of the shock speed on pressure and compression speed by a surprisingly simple analytical model. We also treat shear shocks within a simplified viscoelastic model of nearly-isostatic random networks comprised of harmonic springs. In this case, anharmonicity does not originate locally from nonlinear interactions between particles, as in granular media; instead, it emerges from the global architecture of the network. As a result, the diverging width of the shear shocks bears a nonlinear signature of the diverging isostatic length associated with the loss of rigidity in these floppy networks.

12:27PM Z43.00003 Controlling the jamming transition of sheared hard spheres, THOMAS HAXTON, Lawrence Berkeley National Laboratory — Many applications require understanding how disordered materials flow under an external load such as a shear stress. Since external loads drive systems out of equilibrium, their behavior cannot be described solely in terms of equilibrium parameters like temperature and pressure. However, simulations and experiments show that sheared spherical particles possess an *effective* temperature that relates low-frequency fluctuations of various observable quantities to their associated response functions. Here, we show that the mobility of a mixture of sheared hard spheres is largely controlled by the dimensionless ratio of effective temperature to pressure, $T_{\text{eff}}/p\sigma^3$, where σ is the sphere diameter. We define the effective temperature as the consistent value that relates the amplitudes of low-frequency shear stress and density fluctuations to their associated response functions. We find that the relaxation time τ characterizing the mobility depends on $T_{\text{eff}}/p\sigma^3$ according to two distinct mechanisms in two distinct regimes. In the *solid response* regime, the behavior at fixed packing fraction ϕ satisfies $\tau\dot{\gamma} \propto \exp(-c\rho\sigma^3/T_{\text{eff}})$, where $\dot{\gamma}$ is the strain rate and c depends weakly on ϕ , suggesting that the effective temperature controls the average local yield strain. In the *fluid response* regime, τ depends on $T_{\text{eff}}/p\sigma^3$ as it depends on $T/p\sigma^3$ in equilibrium. This regime comprises a large part of the hard-sphere jamming phase diagram including both near-equilibrium conditions where T_{eff} is similar to the kinetic temperature T_{kin} and far-from-equilibrium conditions where $T_{\text{eff}} \neq T_{\text{kin}}$. In particular, the dynamic jamming transition is largely controlled by the fluid-response mechanism; like equilibrium hard spheres, sheared hard spheres can flow only if low-frequency fluctuations are large enough compared to the pressure. By presenting our results in terms of the dimensionless jamming phase diagram, we show how these mechanisms likely apply to systems with soft repulsive interactions.

1:03PM Z43.00004 Density-Temperature-Softness Scaling of the Dynamics of Glass-forming Soft-sphere Liquids¹, MAGDALENO MEDINA-NOYOLA, Instituto de Física, Universidad Autónoma de San Luis Potosí — We employ the principle of dynamic equivalence between soft-sphere and hard-sphere fluids [Phys. Rev. E **68**, 011405 (2003); Phys. Rev. Lett. **107**, 155701 (2011)] to describe the interplay of the effects of varying the density n , the temperature T , and the softness (characterized by a softness parameter ν^{-1}) on the dynamics of glass-forming soft-sphere liquids in terms of simple scaling rules. The main prediction is the existence of a dynamic universality class associated with the hard sphere fluid, constituted by the soft-sphere systems whose dynamic parameters, such as the α -relaxation time and the long-time self-diffusion coefficient, depend on n , T , and ν only through the reduced density $n^* \equiv n\sigma_{HS}^3(n, T, \nu)$, where the effective hard-sphere diameter $\sigma_{HS}(n, T, \nu)$ is determined by the Andersen-Weeks-Chandler condition for soft-sphere-hard-sphere structural equivalence. A number of scaling properties observed in recent experiments and simulations involving glass-forming fluids with repulsive short range interactions are found to be a direct manifestation of this general dynamic equivalence principle. The self-consistent generalized Langevin equation (SCGLE) theory of colloid dynamics [Phys. Rev. E **76**, 041504, 062502 (2007)] is shown to accurately capture these scaling rules. The non-equilibrium extension of this theory [Phys. Rev. E **82**, 061503, 061504 (2010)] is employed to describe the manifestation of this scaling on the aging of instantaneously-quenched soft-sphere liquids.

1:39PM Z43.00005 Active Jamming: Self-propelled particles at high density¹, SILKE HENKES, Syracuse University — What determines the mechanical properties of dense collections of active particles? The answer to this question is highly relevant to a wide range of physical and biological phenomena from tissue formation to the dynamics of vibrated granular layers. We present a numerical study of the phases and dynamics of a dense collection of self-propelled particles with soft repulsive interactions and polar alignment in a two-dimensional confined geometry. The phase diagram consists of a polar liquid phase at low packing fraction and high self-propulsion speed, and an active jammed phase at high density and low self-propulsion speed. The liquid phase exhibits local alignment and giant number fluctuations typical of the Vicsek class of models. The dynamics of the jammed phase is dominated by oscillations along the low frequency modes of the underlying packing. We show analytically that at long times the energy is carried entirely by the lowest available excitations of the system. Recent experiments on epithelial cell monolayers using force traction microscopy have revealed stress distributions that resemble those observed in granular materials. We measure and compare the local stresses in our active system, with added attraction, to both granular materials and the tissue experiments.

Session Z46 DPOLY DBIO: Invited Session: Self-Assembly of Proteins: From Capsids to Crystals 160AB

11:15AM Z46.00001 Experimental and theoretical studies of capsid self-assembly, ADAM ZLOTNICK, Indiana University — No abstract available.

11:51AM Z46.00002 Theoretical approach to crystallization: foundations and application to proteins¹, JAMES LUTSKO, Center for Nonlinear Phenomena and Complex Systems, Universite Libre de Bruxelles — A fundamental issue in the modern study of phase transitions is the description of the process of nucleation, i.e. the choices of nucleation pathways. Proteins, in particular, are well-known to sometimes crystallize by passing through a meta-stable amorphous state and simulation and theory have shown that this is also true of many other systems. The issue also arises in the important case of polymorphic materials. In all cases, the goal is to understand which pathway is favored and how this is affected by the external control parameters. In this talk, I discuss a theoretical description of nucleation that allows for the direct determination of nucleation pathways and of their relative probability of realization that takes into account both thermodynamics and kinetic effects. It is based on a formulation of nucleation as a fundamentally non-equilibrium process and fully incorporates the effect of free-energy landscapes, determined e.g. via Density Functional Theory, in a consistent manner.

12:27PM Z46.00003 Elasticity Theory of Viral Capsids, ROBIJN BRUINSMA¹, Department of Physics and Astronomy, University of California, Los Angeles — The continuum elasticity theory of icosahedral thin shells has been applied with success to shape transitions of the protein shell surrounding the viral genome, the capsid. The talk presents an extension of thin-shell elasticity theory that is applicable to aggregates of *functional biomolecules* at length scales comparable to that of the component molecules themselves. Unlike classical elasticity theory, the stress and strain fields have a network of *mathematical discontinuities* along the interfaces of the proteins, due to the conformational incompatibility of packing proteins as well as to conformational transitions of the proteins. The method is applied to the P-II to EI transition of the protein shell of the virus HK97 driven by hexon skewing. The combination of the intrinsic stresses of icosahedral shells and the conformational pre-stress turns the P-II state into a “critical” state whose shape is independent of the bending and Young’s moduli.

1:03PM Z46.00004 The Role of Multivalent Counterions in Protein Crystallization¹, FAJUN ZHANG, Institut für Angewandte Physik, Universität Tübingen, Germany — In this talk, I will give an overview of our recent studies on the phase behavior of model globular proteins in solution in the presence of multivalent counterions. We have shown that negatively charged globular proteins at neutral pH in the presence of multivalent counterions undergo a “reentrant condensation (RC)” phase behavior [1,2], i.e. a phase-separated regime occurs in between two critical salt concentrations, $c^* < c^{**}$, giving a metastable liquid-liquid phase separation (LLPS) [3]. This reentrant phase behavior corresponds to an effective charge inversion of proteins as confirmed by zeta-potential measurements and supported by Monte Carlo simulations [1,2]. Crystallization from the condensed regime follows different mechanisms. Near c^* , crystals grow following a classic nucleation and growth mechanism; near c^{**} , the crystallization follows a two-step mechanism, i.e. crystals growth follows a metastable LLPS [3,4]. Nucleation rate is faster from the protein-poor phase than that from the protein-rich phase, which cannot be explained by the recent theories. SAXS measurements demonstrate that protein clusters act as precursors for crystal growth, which reduce the energy barrier of nucleation [4]. X-ray diffraction analyses on the high quality single crystals provide direct evidence of the crystal structure and cation binding sites [3]. The bridging effect of the metal cations explains the cluster formation.

1:39PM Z46.00005 Self-assembly and Evolution from protein complexes to DNA nanostructures, ARD A. LOUIS, Rudolf Peierls Centre for Theoretical Physics, Oxford, UK — The remarkable ability of biological matter to robustly self-assemble into well defined composite objects excites the imagination, suggesting that these processes could perhaps be emulated through the judicious design of synthetic building blocks. We use statistical mechanics to uncover the design rules for self-assembly into well defined three dimensional composite objects. In Nature, the rules for self-assembly emerge from an evolutionary process. We show how some patterns in protein complexes can be explained by their evolutionary origin [1]. We also introduce a coarse-grained rigid nucleotide model of DNA that reproduces the basic thermodynamics of short strands: duplex hybridization, single-stranded stacking and hairpin formation, and also captures the essential structural properties of DNA: the helical pitch, persistence length and torsional stiffness of double-stranded molecules, as well as the comparative flexibility of unstacked single strands [2]. We apply the model to calculate the detailed free-energy landscape of one full cycle of DNA “tweezers,” a simple machine driven by hybridization and strand displacement. We also study other nanomachines as well as processes such as force-induced melting, cruciform formation and the self-assembly of DNA tetrahedra.

Friday, March 2, 2012 11:15AM - 1:51PM –
Session Z47 DPOLY: Self-Assembly and Polymer Composites 160C

11:15AM Z47.00001 Highly piezoelectric Biocompatible and Soft Composite Fibers, ANTAL JAKLI, JASON MORVAN, Kent State University Kent, OH 44242, EBRU BUYUKTANIR, Stark State College, North Canton, OH, 44720, JOHN WEST, Kent State University Kent, OH 44242 — We report the fabrication of highly piezoelectric biocompatible soft fibers containing Barium Titanate (BT) ferroelectric ceramic particles dispersed in electrospun poly lactic acid (PLA). These fibers form mats that have two orders of magnitude larger piezoelectric constant per weight than single crystal barium titanate films. We demonstrate that the observed super-piezoelectricity results from the electrospinning induced polar alignment of the ferroelectric particles and the increased surface area compared to single crystal films. Due to the biocompatibility of PLA that encases the ferroelectric particles, these mats can be applied even in biological applications such as bio-sensors, artificial muscles and energy harvesting devices.

11:27AM Z47.00002 Phase Behavior of Polymer Nanocomposites from Gravity-based Combinatorial Simulations, DONG MENG, SANAT KUMAR, Department of Chemical Engineering, Columbia University — The phase behavior of polymers mixed with nanoparticles, termed nanocomposites, has been of great current interest. Holding the promise of improved engineering properties, the property improvement is critically dependent on the spatial dispersion of nanoparticles, which is controlled by polymer-nanoparticle phase behavior. Enumerating the appropriate phase diagrams, however, still remain outside the realm of most simulation-based methods. The difficulty arises since inserting a large particle into a dense sea of small particles, critically for establishing phase equilibrium, is prohibitively difficult. Here we extend a gravity-based combinatorial method, first devised by Biben et al., and used primarily in the context of pure fluids to circumvent this insertion issue. Our results are validated against available simulations for colloid mixtures, but provide new insight into the phase behavior of polymers and nanoparticles.

11:39AM Z47.00003 Diffusive and re-orientation dynamics in lyotropic gels of self-assembled organic nanotubes, LUTZ WIEGART, Brookhaven National Laboratory, PIERRE WIEGART, CEA-Grenoble, UM5819, INAC-SPrAM, CHIARA CARONNA, SLAC National Accelerator Laboratory — It is known that dispersing lithocholic bile acid (LCA) in aqueous solutions of sodium hydroxide or ammonia leads to the formation of organic nanotubes with well-defined diameters on the nanometer scale. The suspensions appear to be tunable from liquid- to solid-like via the LCA concentration. The length of the tubes is decreasing as a function of temperature, favoring the formation of a phase where the tubes form hexagonally ordered bundles for an appropriate LCA concentration and temperature. In the present study, we have used X-ray Photon Correlation Spectroscopy (XCPS) to probe the diffusive dynamics of the nanotubes in these lyotropic gels under various conditions (concentration, counter ion, temperature). The multispeckle analysis of the coherent scattering pattern reveals domains in the sample with differing diffusive dynamics. The re-orientation process of different domains of nanotube bundles into a preferred parallel alignment has been observed.

11:51AM Z47.00004 Carbon Nanotube Liquid Crystals: Nematic Droplets and Coarsening Dynamics, NATNAEL BEHABTU, Rice University, BOHDAN SENYUK, IVAN SMALYUKH, University of Colorado Boulder, MATTEO PASQUALI, Rice University — On a fundamental basis, carbon nanotubes (CNTs) offer a new model molecule to explore the dynamics and phases of rigid rods and test theories. Their large aspect ratio (100 to 100,000) and persistence length (~ 100 microns) allow exploring the physics of nematic phases with high Frank elastic constant. Moreover, understanding of CNT liquid crystals is key to their rational processing into ordered materials such as fibers. Here we report the formation of elongated nematic droplets of CNTs in chlorosulfonic acid. In nematic droplets, a continuous transition from a homogeneous to bipolar nematic director field is expected theoretically, as a function of droplet volume; yet, experimental determination of such transition has been elusive. We show that CNT nematic droplets display such transition. We study the coarsening dynamics of positive and negative nematic droplets and observe that two or more droplets merge by matching their nematic director. Merging scenarios that lead to defect formation are not observed. Negative tactoids (isotropic phase in liquid crystalline continuum) merge through attractive forces induced by the nematic director distortion with quadrupolar symmetry.

12:03PM Z47.00005 Free volume in a granular nanocomposite, REGHAN J. HILL, AHMAD MOHADDESPOUR, McGill University — Free volume plays a determinative role in the unusual molecular sieving and rheological characteristics of nanocomposites. To help elucidate the nanoparticle influence on polymer-chain packing, we mixed acrylic spheres with aluminum ball-chains and ascertained from measurements of the bulk density the partial molar sphere volume at small but finite sphere volume fractions. This macroscopic mechanical model permits a systematic exploration of how the chain length, sphere size, and mixture composition influence free volume. We show that the nanoparticle radius to the chain loop size is the primary dimensionless parameter that bridges the solvent and continuum scaling regimes. In the intermediate regime, where the inclusion and polymer nanoscales are comparable, the primary sphere-chain interaction increases free volume—up to twice the intrinsic inclusion volume per particle—and the primary sphere-sphere interaction decreases free volume. Comparisons will be made with data gleaned from PALS and the bulk density of molecular nanocomposites reported in the literature.

12:15PM Z47.00006 Molecular packing in bone collagen fibrils prior to mineralization, BENJAMIN HSIAO¹, Stony Brook University, HONG-WEN ZHOU², Stony Brook University, CHRISTIAN BURGER³, BENJAMIN CHU⁴, Stony Brook University, MELVIN J. GLIMCHER⁵, Harvard Medical School — The three-dimensional packing of collagen molecules in bone collagen fibrils has been largely unknown because even in moderately mineralized bone tissues, the organic matrix structure is severely perturbed by the deposition of mineral crystals. During the past decades, the structure of tendon collagen (e.g. rat tail) — a tissue that cannot mineralize in vivo, has been assumed to be representative for bone collagen fibrils. Small-angle X-ray diffraction analysis of the native, uncalcified intramuscular fish bone has revealed a new molecular packing scheme, significantly different from the quasi-hexagonal arrangement often found in tendons. The deduced structure in bone collagen fibrils indicates the presence of spatially discrete microfibrils, and an arrangement of intrafibrillar space to form “channels”, which could accommodate crystals with dimensions typically found in bone apatite.

12:27PM Z47.00007 Understanding the self-assembly of meso-tetra(4-sulfonatophenyl)porphyrin (H_2TPPS^{4-}) in aqueous solutions¹, JAVORIS HOLLINGSWORTH, ALLISON RICHARD, GRACA VICENTE, PAUL RUSSO, Louisiana State University — The aggregation of meso-tetra(4-sulfonatophenyl)porphyrin (H_2TPPS^{4-}) in phosphate solutions was investigated as a function of pH, concentration, time, ionic strength, and solution preparation (either from dilution of a freshly prepared 2 mM stock or by direct preparation of μM solution concentrations) using a combination of complementary analytical techniques. UV-Vis and fluorescence spectroscopy indicated the formation of staggered, side-by-side (J-type) assemblies. Their size and self-associative behavior was determined using analytical ultracentrifugation and small angle X-ray scattering. Our results indicate that in neutral and basic solutions of H_2TPPS^{4-} , porphyrin dimers and trimers are formed at μM concentrations and in the absence of NaCl to screen any ionic interactions. At these low concentrations and pH 4, the protonated H_4TPPS^{2-} species self-assembles leading to the formation of particularly stable aggregates bearing 25 ± 3 macrocycles. At higher concentrations, these structures further organize or re-organize into tubular, rod-like shapes of various lengths which were imaged by cryogenic and freeze-fracture transmission electron microscopy. Micron-scale fibrillar aggregates were obtained even at μM concentrations at pH 4 when prepared from dilution of a 2 mM stock solution and/or upon addition of NaCl.

¹This research was partially funded by NIH R01 CA098902 and by NSF DMR-1005707.

12:39PM Z47.00008 Self-Assembly of Polystyrene Tethered Hydrophilic POSS/C60 Nanoparticles, XINFEI YU, STEPHEN Z.D. CHENG, Department of Polymer Science, The University of Akron — Self-assembly of nanobuilding block provides unique opportunities to arrange nanoparticles into larger, functional ensembles. Anisotropy or symmetry breaking will lead to the formation of specific hierarchical structures with novel properties. Polymer tethered particle is one of the approaches to break the symmetry of nanobuilding blocks, which are promise to become the elementary building blocks for self-assembled materials. Shape and interactions are two important factors to determine the self-assembly of these molecules. Although a few examples have been reported during the last decade, little is known about ordered self-assembly structures from these anisotropic building blocks in bulk or solution by experiments. To solve this problem, hydrophilic POSS and C60 have been designed and synthesized, to which hydrophobic polystyrene tail(s) was tethered with controlled topology. The designed molecules could form micelles and colloidal particles in solutions. The effects of PS tail length, solvent properties, and molecular topology on self-assembly morphologies have been studied. The designed molecules could form ordered nanophase separation structures in bulk state with the feature sizes of sub-22 nm, which has great potential applications in advanced lithography technologies.

12:51PM Z47.00009 Self-Assembly of Narrowly Dispersed Brush Diblock Copolymers with Domain Spacing more than 100 nm¹, WEIYIN GU, University of Massachusetts Amherst, BENJAMIN SVEINBJORNSSON, California Institute of Technology, SUNG WOO HONG, University of Massachusetts Amherst, ROBERT GRUBBS, California Institute of Technology, THOMAS RUSSELL, University of Massachusetts Amherst — Self-assembled structures of high molecular weight (MW), narrow molecular weight distribution brush block copolymers containing poly(lactic acid) (PLA) and polystyrene (PS) side chains with similar MWs were studied in both the melt and thin films. The polynorbornene-backbone-based brush diblock copolymers containing approximately equal volume fractions of each block self-assembled into highly ordered lamellae with domain spacing over 100 nm, as revealed by SAXS, GISAXS and AFM. The domain size increased approximately linearly with backbone length, which indicated an extended conformation of the backbone in the ordered state. The length of side chains also played a significant role in terms of controlling the domain size. As the degree of polymerization (DP) increased, the symmetric brush diblock copolymers with longer side chains tended to form larger lamellar microdomains in comparison to those that have the same DP but shorter side chains.

1:03PM Z47.00010 Non-Classical Ordering of Sphere Forming SISO Tetrablock Terpolymers

JINGWEN ZHANG, University of Minnesota, SCOTT SIDES, Tech-X Research Corporation, FRANK BATES, University of Minnesota — ABAC tetrablock terpolymers represent the simplest symmetry breaking multiblock extension of ABC triblocks. The model system poly(styrene-*b*-isoprene-*b*-styrene-*b*-ethylene oxide) (SISO) tetrablock terpolymers were synthesized in relatively monodisperse form and the resulting morphologies were characterized by small-angle X-ray scattering, transmission electron microscopy, differential scanning calorimetry and dynamic mechanical spectroscopy. Two non-classical sphere-based ordered phases have been established in these single component materials with P_6/mmm (simple hexagonal) and P_{42}/mnm (tetragonal sigma phase) symmetry. A third state, tentatively associated with quasicrystalline order, has been identified at temperatures between the hexagonal and sigma phases, which occur at low temperatures, and prior to disordering, respectively. This unusual set of morphologies will be discussed in the context of segregation under the constraints associated with the tetrablock molecular architecture. Self-consistent mean-field theoretical calculations, obtained using the PolySwift++ software package, provide valuable insights into the molecular configurations associated with these morphologies.

1:15PM Z47.00011 Tear rotation in reinforced natural rubber

PAUL SOTTA, BRICE GABRIELLE, ARNAUD VIEYRES, LPMA CNRS/Rhodia, LOIC VANEL, University of Lyon, DIDIER LONG, LPMA CNRS/Rhodia, OLIVIER SANSEAU, Rhodia, PIERRE-ANTOINE ALBOUY, LPS CNRS/Universite Paris-Sud — We analyze the impact of tear rotation, that is, an abrupt instability in the direction of propagation of a notch, on the tensile strength of natural rubber elastomers reinforced with carbon black or precipitated silica, in single edge notched samples stretched at constant velocity. As a consequence of tear rotation, the energy at break increases by a factor of 6 to 8 in some cases. We show how the tensile strength of a test sample is related to the presence of tear rotations and analyze semi-quantitatively this increase in tensile strength, based on energetic arguments, without entering into a detailed description of the elastic strain field in the vicinity of the tear tip. The proposed interpretation is based on the idea that tear rotations create a macroscopic tip radius, which relaxes the local strain (or stress) at the tear tip. Materials reinforced with carbon black or precipitated silica aggregates show similar behavior. The relation to strain-induced crystallization is discussed.

1:27PM Z47.00012 Quantification of Folding in Sheet-like Nanostructures

DURGESH RAI, GREGORY BEAUCAGE, RAMANTH RAMACHANDRAN, SIDDHARTH PRADHAN, University of Cincinnati — Two-dimensional nanostructures are of interest to a wide range of scientists from biologists interested in membranes to polymer scientists producing graphene reinforced nanocomposites. Considering two-dimensional structures as a class of nanomaterials, we could use the sheet thickness and lateral size as structural description. In addition to these parameters, two-dimensional structures are, at times, capable of folding or crumpling, largely depending on the interfacial chemistry and to some extent on thermodynamics. We have studied this crumpling behavior using small-angle neutron and x-ray scattering in a range of nano-materials, specifically, membrane bilayers, graphene oxide, as well as exfoliated nano-sheets of molybdenum sulfide, boron nitride, and tungsten sulfide. A new parameterization of crumpling in these two-dimensional nanostructures will be described with indications of how this quantification can lead to general categories of crumpling behavior that differ in the systems mentioned above. (A helpful discussion with Fyl Pincus assisted with this work.)

1:39PM Z47.00013 Rheology of cube shaped particles in a suspension

RAJESH MALLAVAJULA, DONALD KOCH, LYNDEN ARCHER, Cornell University — The rheological properties of suspensions of Brownian cube-shaped particles are interesting because of the greater increase in the translational freedom caused by layering relative to suspensions of Brownian spheres. Theoretical solutions for a simple shear flow around an isolated cube were obtained using the geometric properties of cubes. Since stress-strain relationship is anisotropic, the suspension viscosity in the limit of zero shear rate can be obtained from the orientational average of the stresslet acting on the cube. The value of intrinsic viscosity was found to be 3.1. Brownian dynamics simulations were carried out with the obtained anisotropic stress relationship to understand hydrodynamic interactions between cubes at low to moderate volume fractions and lubrication hydrodynamic interactions at higher volume fractions. Interesting transitions are observed in rheological properties as the volume fraction of particles in suspension rises above a critical value substantially lower than the minimum close-packing. We have also synthesized model cube-shaped particles with two different chemistries and sizes: Iron oxide, Fe_3O_4 , nanocubes (20nm and 100nm) and hollow Manganese Carbonate ($MnCO_3$) microcubes (1-2microns). $MnCO_3$ microspheres were also synthesized to compare their properties with the cubic particle suspensions. At low particle volume fractions, the experimentally determined intrinsic viscosity for the suspension of cubic particles is in excellent accord with expectations from theory. The talk will also compare results of rheological properties of spheres and cubes for both high and low volume fractions over a range of Peclet numbers.

Session Z48 DPOLY DBIO: Focus Session: Statistical Physics of Active Systems Away from Detailed Balance; Motors, Swimmers and All That 161

11:15AM Z48.00001 Mechanical manipulation and bifurcation dynamics of stereociliary bundles

SEUNG JI, LEA FREDRICKSON-HEMSING, ROBIJN BRUINSMA, DOLORES BOZOVIC, UCLA — We propose a numerical model for the mechanical response of hair cells of the inner ear. These mechanically sensitive cells have been described previously using systems of nonlinear differential equations, that captured the main features of the experimental phenomena. Here we extend the study to include the effects of static and time-dependent forcing, and show it to induce transitions across different types of bifurcations. We compare the theory to the experimental measurements of the phase-locked response of spontaneously oscillating hair cells of the bullfrog sacculus, under varying mechanical deflections. For a static deflection, when adaptation phenomena play an important role, the offset generates a critical point where the frequency but not the amplitude vanishes, as opposed to the expected Hopf bifurcation where the amplitude vanishes. On the other hand, for a periodic deflection, mode-locking of the spontaneous oscillations to the drive period can proceed via different types of bifurcations, depending on the degree of detuning. We will present a simple dynamic systems framework that captures the main features of the experimentally observed behavior in the form of an Arnold Tongue.

11:27AM Z48.00002 Towards an active hydrodynamic theory of the metaphase spindle

JAN BRUGUES, DANIEL NEEDLEMAN, Harvard University — The spindle is a dynamic steady-state structure composed of microtubules and a wide range of factors which control microtubule nucleation, growth, and motion. While many of the individual components of the spindle have been studied in detail, it is still unclear how these molecular constituents self-organize into this structure. Here I describe how we are using spatio-temporal correlations of microtubule density and orientation to formulate a continuum coarse grained theory for the spindle. Our results suggest that microtubule turnover plays a crucial role in stabilizing the giant density fluctuations predicted by traditional active hydrodynamic theories.

11:39AM Z48.00003 A phase transition between collective and individual dynamics in suspension of swimming bacteria¹

ANDREY SOKOLOV, IGOR ARONSON, Argonne National Laboratory — We present the experimental study of the onset of collective behavior in suspension of swimming bacteria *Bacillus Subtilis* in a liquid film. The system behavior is analyzed as the average swimming speed is varied in a wide range while the concentration of bacteria is constant. The average swimming speed was controlled by adjusting the concentration of dissolved oxygen in a fluid with bacteria. We obtained phase diagrams for the transition of the system between the state of collective swimming and the disordered state at different conditions.

11:51AM Z48.00004 Chemotaxis of Phoretic Swimmers, SUROPRIYA SAHA, SRIRAM RAMASWAMY, Indian Institute of Science, Bangalore, RAMIN GLOESTANIAN, Rudolf Peierls Centre for Theoretical Physics, University of Oxford — An artificial phoretic swimmer in a uniform bath of reactant propels itself in a direction dictated by the polarity of the enzymatic and mobility patterning on its surface. We have shown that a polar active particle of this type can also orient itself along an imposed gradient of reactant concentration. This amounts to a theoretical demonstration of a phoretic analogue of chemotaxis, that is, the ability of a self-propelled particle to align with respect to, and hence to move up or down, a chemical gradient. The nature of the chemotaxis depends on the shape of the particle, on the distribution of enzymatic sites on its surface, and on the surface mobility. We have also considered the type of motion that arises when the orientation time of the particle becomes comparable to the diffusion time of the cloud of reaction products around it. Lastly, we consider motion arising from the interaction of two or more such chemotactic particles.

12:03PM Z48.00005 Active viscosity of E-Coli suspensions¹, ERIC CLEMENT, JEREMIE GACHELIN, GASTON MINO, HELENE BERTHET, ANKE LINDNER, ANNIE ROUSSELET, PMMH-ESPCI - University Pierre et Marie Curie — Active suspension is the name borne by fluids laden with self-swimming entities such as bacteria, algae or artificial swimmers. Such fluids display emergent constitutive properties differing strongly from those of passive suspensions. Here, we present a recent work, where we measure the viscosity of a wild type E-Coli suspension in the dilute and semi-dilute limits. To this purpose, we use micro-fluidic device build as a Y shape micro-fluidic channel. On one side of the arm, the active suspension is injected and on the other arm, the suspending fluid is injected at the same flow rate. From the position of the interface between the pure fluid and the suspension, we extract the suspension relative viscosity. Varying bacteria density and flow rate, we show a regime specific to active fluids, where the relative viscosity is lower than the viscosity of the suspending viscous fluid. We discuss our results in the perspective of recent theoretical and experimental works.

12:15PM Z48.00006 Molecular Dynamics Study of Self-propelled Droplets on Solid Substrates, MURAT MÜLAYIM, MARCUS MÜLLER, Georg-August Universität — We study, by molecular simulation, the statics and dynamics of chemically driven polymer droplets on regularly and finely corrugated substrates. Droplets are driven by a self-induced wettability gradient, which is formed under the droplet by changing the strength of the polymer-substrate interaction when the polymer get into contact with a reactive substrate with a pre-defined probability. The effect of reaction rate on droplet profile, slip and motion are investigated in the quasi steady-state. Moreover wetting properties of heterogeneous, partially reacted, systems are studied and a connection to experiments in the literature and thin film theoretical results on driven droplets are drawn, via exploring velocity profiles and dissipation mechanisms in the system.

12:27PM Z48.00007 Self-assembled structures in immiscible systems of active, switchable nanocolloids¹, ANTONIO OSORIO-VIVANCO, University of Michigan, IGAL SZLEIFER, Northwestern University, SHARON GLOTZER, University of Michigan — We consider the synthesis and fabrication of active building blocks that can dynamically switch between two or more states and assemble into novel structures. We present novel steady-state structures predicted by computer simulation to assemble in systems of switchable, immiscible building blocks. We discuss the dynamics that stabilize these structures, explore approaches to analyze the dissipative nature of the system, and provide a mapping to experimental colloidal systems where these concepts could be implemented.

12:39PM Z48.00008 Collective motion in active solids and active crystals¹, CRISTIAN HUEPE, Unaffiliated, ELISEO FERRANTE, ALI EMRE TURGUT, IRIDIA, CoDe, Université Libre de Bruxelles — We introduce a minimal model for self-propelled particles with strong attraction-repulsion interactions, but no explicit alignment rules, that displays collective polar or rotational motion. We describe a novel elasticity-based mechanism responsible for such collective motion and compute analytically its required conditions in the continuous elastic sheet approximation. By studying the mechanism's dynamics numerically and analytically, we show that it supports collective motion even for finite noise levels if the coupling between individual self-propulsion and elastic modes transfers energy towards larger and larger wavelengths. We hypothesize that this elasticity-based mechanism could provide an alternative explanation for collective motion in some biological groups without explicit alignment interactions, given their natural cohesion.

12:51PM Z48.00009 Statistics and dynamics in an optical vortex¹, Yael Roichman, Yulia Sokolov, DEREK FRYDEL, Tel Aviv University, DAVID GRIER, New York University, HAIM DIAMANT, Tel Aviv University — When two identical particles are driven along a straight line by an identical force there are no attractions forces between them. Surprisingly, when the same two particles are driven along a ring of light, with identical force, they attract and form a pair. The pairing mechanism is a pure non-equilibrium phenomena and is a result of symmetry breaking due to the path's curvature. We use experiment, simulation and theory to demonstrate and explain this effect. We show that dynamic limit-cycles and structure emerge due to this pseudo-potential in many particle systems, and demonstrate how they depend on temperature and trapping stiffness.

1:03PM Z48.00010 Induced Motion by Asymmetric Enzymatic Degradation of Hydrogels, JENNIFER HOU, ADAM COHEN, Harvard University — Biological hydrogels are continuously turned over through secretion and degradation. This non-equilibrium flux is critical to understanding cellular and molecular transport through biogels such as mucus and the extracellular matrix. Gel-digesting enzymes can drastically change the physical and chemical properties of the hydrogel environment. We report that a spatial gradient in the degradation of two gel/enzyme systems—gelatin/trypsin and hyaluronan/hyaluronidase—leads to directional motion of particles embedded in the gel in the direction of higher enzyme concentration. We study the rate at which the degradation front propagates through the gel and the ensuing velocity of the embedded particles, as functions of enzyme and gel concentrations. We propose that asymmetric degradation leads to asymmetric swelling, which transports particles up the enzyme concentration gradient.

1:15PM Z48.00011 Possible mechanisms for initiating macroscopic left-right asymmetry in developing organisms¹, CHRISTOPHER L. HENLEY, RICKY CHACHRA, JIMMY X. SHEN, Cornell Univ. — Systematic left-right (L/R) asymmetry in development –i.e. body axes satisfying a “right-hand rule” – emerges at the organism level out of the microscopic handedness of biological molecules, not by the usual pattern-forming mechanisms of reactions (including regulation) plus diffusion, but rather (at the cell level) from the cytoskeleton and molecular motors – usually in collective two-dimensional states associated with the cell membrane ². I outline possible scenarios we are simulating for (i) snails and C. elegans, from a chiral shearing tendency in the actomyosin layer and/or (ii) for plant cells, from a precession of the nematic order direction in the microtubule array.

1:27PM Z48.00012 Activation of nanoscale allosteric protein domain motion revealed by neutron spin echo spectroscopy¹, ZIMEI BU, City College of New York, BELA FARAGO, Institut Laue Langevin, DAVID CALLAWAY, City College of New York — NHERF1 is a multi-domain scaffolding protein that assembles the signaling complexes, and regulates the cell surface expression and endocytic recycling of a variety of membrane proteins. The ability of the two PDZ domains in NHERF1 to assemble protein complexes is allosterically modulated by a membrane-cytoskeleton linker protein ezrin, whose binding site is located as far as 110 angstroms away from the PDZ domains. Here, using neutron spin echo (NSE) spectroscopy, selective deuterium labeling, and theoretical analyses, we reveal the activation of interdomain motion in NHERF1 on nanometer length scales and on sub-microsecond time scales upon forming a complex with ezrin. We show that a much simplified coarse-grained model is sufficient to describe inter-domain motion of a multi-domain protein or protein complex. We expect that future NSE experiments will benefit by exploiting our approach of selective deuteration to resolve the specific domain motions of interest from a plethora of global translational and rotational motions. The results demonstrate that propagation of allosteric signals to distal sites involves the activation of long-range coupled domain motions on submicrosecond time scales, and that these coupled motions can be distinguished and characterized by NSE.

1:39PM Z48.00013 Effector CD8⁺ T cells migrate via chemokine-enhanced generalized Lévy walks, EDWARD BANIGAN, Physics & Astronomy, University of Pennsylvania, TAJIE HARRIS, DAVID CHRISTIAN, Pathobiology, University of Pennsylvania, ANDREA LIU, Physics & Astronomy, University of Pennsylvania, CHRISTOPHER HUNTER, Pathobiology, University of Pennsylvania — Chemokines play a central role in regulating processes essential to the immune function of T cells, such as their migration within lymphoid tissues and targeting of pathogens in sites of inflammation. In order to understand the role of the chemokine CXCL10 during chronic infection by the parasite *T. gondii*, we analyze tracks of migrating CD8⁺ T cells in brain tissue. Surprisingly, we find that T cell motility is not described by a Brownian walk, but instead is consistent with a generalized Lévy walk consisting of Lévy-distributed runs alternating with pauses of Lévy-distributed durations. According to our model, this enables T cells to find rare targets more than an order of magnitude more efficiently than Brownian random walkers. The chemokine CXCL10 increases the migration speed without changing the character of the walk statistics. Thus, CD8⁺ T cells use an efficient search strategy to facilitate an effective immune response, and CXCL10 aids them in shortening the average time to find rare targets.

Session Z50 DPOLY DFD: Focus Session: Micro and Nano Fluidics IV: Emulsions and Complex Fluids 162B

11:15AM Z50.00001 Active Emulsions: Synchronization of Chemical Oscillators, SETH FRADEN, Brandeis University — We explore the dynamical behavior of emulsions consisting of nanoliter volume droplets of the oscillatory Belousov-Zhabotinsky (BZ) reaction separated by a continuous oil phase. Some of the aqueous BZ reactants partition into the oil leading to chemical coupling of the drops. We use microfluidics to vary the size, composition and topology of the drops in 1D and 2D. Addition of a light sensitive catalyst to the drops and illumination with a computer projector allows each drop to be individually perturbed. A variety of synchronous regimes are found that systematically vary with the coupling strength and whether coupling is dominated by activatory or inhibitory species. In 1D we observe in- and anti-phase oscillations, stationary Turing patterns in which drops stop oscillating, but form spatially periodic patterns of drops in the oxidized and reduced states, and more complex combinations of stationary and oscillatory drops. In 2D, the attractors are more complex and vary with network topology and coupling strength. For hexagonal lattices as a function of increasing coupling strength we observe right and left handed rotating oscillations, mixed oscillatory and Turing states and finally full Turing states. Reaction – diffusion models based on a simplified description of the BZ chemistry and diffusion of messenger species reproduce a number of the experimental results. For a range of parameters, a simplified phase oscillator model provides an intuitive understanding of the complex synchronization patterns.

“Coupled oscillations in a 1D emulsion of Belousov–Zhabotinsky droplets,” Jorge Delgado, Ning Li, Marcin Leda, Hector O. Gonzalez-Ochoa, Seth Fraden and Irving R. Epstein, *Soft Matter*, 7, 3155 (2011).

11:51AM Z50.00002 Double Emulsion Templated Celloidosomes¹, LAURA R. ARRIAGA, Department of Physics and Division of Engineering and Applied Science, Harvard University, Cambridge, MA 02138, SAMANTHA M. MARQUEZ, Maggie L. Walker Governor's School, 1000N. Lombardy St. Richmond, VA 23220, SHIN-HYUN KIM, CONNIE CHANG, JIM WILKING, Department of Physics and Division of Engineering and Applied Science, Harvard University, Cambridge, MA 02138, FRANCISCO MONROY, Department of Physical Chemistry, Complutense University, 28040 Madrid, Spain, MANUEL MARQUEZ, YNano LLC 14148 Riverdowns S. Dr. Midlothian, VA 23113, DAVID A. WEITZ, Department of Physics and Division of Engineering and Applied Science, Harvard University, Cambridge, MA 02138 — We present a novel approach for fabricating celloidosomes®, which represent a hollow and spherical three-dimensional self-assembly of living cells encapsulating an aqueous core. Glass- capillary microfluidics is used to generate monodisperse water-in-oil-in-water double emulsion templates using lipids as stabilizers. Such templates allow for obtaining single but also double concentric celloidosomes. In addition, after a solvent removal step the double emulsion templates turn into monodisperse lipid vesicles, whose membrane spontaneously phase separates when choosing the adequate lipid composition, providing the adequate scaffold for fabricating Janus-celloidosomes. These structures may find applications in the development of bioreactors in which the synergistic effects of two different types of cells selectively adsorbed on one of the vesicle hemispheres may be exploited.

12:03PM Z50.00003 Viscoelastic Flow Instabilities of Worm-like Micellar Solutions in Microfluidic Devices, THOMAS OBER, GARETH MCKINLEY, Massachusetts Institute of Technology — Worm-like micellar (WLM) fluids are a unique class of complex fluids whose large deformation rate rheology is not fully understood. By combining mechanical pressure measurements, μ -PIV and spatially-resolved measurements of flow-induced birefringence, we study the behavior of WLM solutions undergoing large deformation rates in microfluidic rectilinear and converging geometries, whose small characteristic dimensions facilitate experiments at high elasticity number (i.e. low inertia). In our experiments, we observe the extensional flow of a shear-banding WLM fluid in a planar hyperbolic contraction. We classify the flow regimes and observe the onset of spatio-temporally unsteady flow often referred to as “elastic turbulence.” We use pressure drop measurements to calculate the apparent extensional viscosity of both Newtonian fluids and WLM fluids. We also investigate the onset of elastically driven instabilities in flows nominally without streamwise curvature in a high aspect ratio straight channel. These latter experiments are aimed at determining if elastically-driven turbulence in dilute polymer solutions can be initiated and sustained in pressure-driven rectilinear flows.

12:15PM Z50.00004 Elastic instability in straight channels, ANNIE COLIN, HUGUES BODIGUEL, JULIEN BEAUMONT, University Bordeaux 1 — Polymer solutions exhibit purely elastic flow instabilities even in the absence of inertia. The almost ubiquitous ingredient of such an elastic instability is the curvature of streamlines: polymers that have been extended along curved streamlines are taken by fluctuations across shear rate gradient in the unperturbed state which, in turn, couples the hoop stresses acting along the curved streamlines to the radial and axial flows and amplifies the perturbation. It has been tacitly assumed for over 30 years that in line with this instability scenario, visco-elastic parallel shear flows are stable, since the streamlines are straight. Recently, Saarloos and coworkers [1] derived a general instability criterion, which shows that these flows invariably exhibit a nonlinear instability. At this stage only a few studies support and validate this analysis [2]. In this work, we take advantage of microfluidic devices and study the flow of highly elastic polymers and surfactant solutions in a straight microchannel located after a constriction. The velocity of the solution is measured using Particle Imaging Velocimetry. The amplitude of the perturbation is controlled by the shape of the constriction. Using such devices, we present a comprehensive flow diagram in the parameter plane amplitude of the perturbation, Weissenberg number. 1/ Bernard Meulenbroek at all J. Non-Newtonian Fluid Mech. 116 (2004) 235–268 2/ Daniel Bonn et al Phys Rev E 84, 045301(R) (2011)

12:27PM Z50.00005 Microfluidic Fabrication of Functional Capsules with ultra-thin membranes¹, SHIN-HYUN KIM, ALIREZA ABBASPOURRAD, DAVID WEITZ, Harvard University — We have developed a new emulsification technique to produce monodisperse double-emulsion drops with an ultra-thin middle layer through a one-step emulsification. A biphasic flow, consisting of sheath of one fluid flowing along the capillary wall and surrounding a second fluid flowing through center of the capillary, is created in a form of either a jet or drops, which is emulsified into double-emulsion drops with ultra-thin middle layer. The ultra-thin middle phases provide stability to the double-emulsion drops by putting the fluid in the middle phase in the lubrication regime. We have employed such stable double-emulsion drops to make functional microcapsules using evaporation-induced consolidation. Simplest form is microcapsules with homogenous membrane. Using biodegradable polymers such as PLA or PLGA as a membrane material, we can achieve a long-term release of various bioactives from the capsules as the membrane degrades by hydrolysis. Heterogeneous membrane can also be prepared by using polymer blends. For example, a polymer blend of PMMA and PLA with small interaction parameter makes heterogeneous structure at nanoscale, while a polymer blend of PS and PLA with large interaction parameter makes their phase separation at one micrometer scale.

12:39PM Z50.00006 Coupled oscillations in a 1D emulsion of Belousov–Zhabotinsky droplets¹, NING LI, Brandeis University, JORGE DELGADO, University of Guanajuato, HECTOR GONZALEZ OCHOA, San Luis Potosi Institute of Scientific Research and Technology (IPICYT), MARCIN LEDA, Institute of Physical Chemistry (Polish Academy of Science), SETH FRADEN, IRVING EPSTEIN, Brandeis University, BRANDEIS UNIVERSITY TEAM — We experimentally and computationally study the dynamics of interacting oscillating Belousov–Zhabotinsky (BZ) droplets of 100 micron diameter separated by perfluorinated oil and arranged in a one-dimensional array. A microfluidic chip is used for mixing the BZ reactants, forming monodisperse droplets by flow-focusing and directing them into a hydrophobized 100 micron diameter capillary. In order to make quantitative comparison with theory, we use photosensitive Ru(bipy)₃ catalyzed BZ droplets and set both boundary and initial conditions of arrays of small numbers of oscillating BZ droplets with a programmable illumination source. The coupling strength is a function of malonic acid concentration and varying coupling strength leads to the generation of different dynamical attractors. In many cases, simulations agree well with experiments.

¹Funded by MRSEC.

12:51PM Z50.00007 Double emulsion templated monodisperse phospholipid liposomes incorporating Doxorubicin hydrochloride, MINGTAN HAI, University of Science and Technology Beijing/Harvard University, DAVID WEITZ, Harvard University — We present a novel approach for fabricating monodisperse phospholipid liposomes incorporating water soluble anticancer drug Doxorubicin hydrochloride using controlled w/o/w double emulsions as templates. Glass-capillary microfluidics is used to generate monodisperse w/o/w double emulsion templates and double emulsion droplet size is from 20 to 100 μm according to different flow rates. We show that the high uniformity in size and shape of the templates are maintained in the final phospholipid liposomes after a solvent removal step by Nikon eclipse microscopy. The lipid bilayers encapsulating anticancer drug inside is retained after the emulsion drops are converted to vesicles. The liposomes vesicles are promising water soluble anticancer drug delivery vehicles.

1:03PM Z50.00008 Drops of Yield-Stress Liquid Impacting a Solid Surface, QIN XU, HEINRICH JAEGER, James Frank Institute and Department of Physics, The University of Chicago — We use high-speed video to investigate the drop impact process for yield-stress fluids under different initial conditions. Unlike Newtonian fluids, the impact dynamics of yield-stress liquids are greatly affected by their viscoelasticity, which can be attributed to either a surface stress or bulk material properties. To explore these two different mechanisms, we perform impact experiments for two model fluids: liquid metals and particle suspensions, which both exhibit significant yield-stress in rheology. By controlling surface oxidation (for liquid metals) and packing density (for suspensions), we quantitatively vary the yield-stress within several orders of magnitude. In this way, we draw a direct comparison between the two fluids at various impact velocities to clarify the role of different sources of yield stress. Also, we build up an approach to bridge impact dynamics with rheological measurements.

1:15PM Z50.00009 Oscillatory shear of non-colloidal fiber suspensions, ALEXANDRE FRANCESCHINI, EMMANOUELA FILIPPIDI, NYU, Dept Phys, Ctr Soft Matter Res, New York, NY 10003 USA, ELIZABETH GUAZZELLI, Aix Marseille Univ U1, IUSTI, CNRS, UMR Polytech Marseille 6595, F-13453 Marseille 13, France, DAVID PINE, NYU, Dept Phys, Ctr Soft Matter Res, New York, NY 10003 USA — Concentrated suspensions of non-colloidal fibers under slow periodic strain undergo a phase transition from an absorbing state to an active fluctuating state. Fiber trajectories are reversible in the absorbing state and irreversible in the fluctuating state. The activity, measured by the translational diffusivity between successive periods, vanishes in the absorbing state but reaches a finite value in the fluctuating state. We show that the transition is controlled by a collision cross-section, which is a function of the strain amplitude, concentration and fiber orientation. Over the course of an experiment, the activity drives the orientation toward the vorticity, subsequently reducing the cross section. We evaluate the influence of the control parameter decay on the phase transition and then focus on the fluctuating state dynamics.

1:27PM Z50.00010 Dynamics in Semidilute Rod Suspensions, PRAMUKTA KUMAR, DAN BLAIR, JEFFREY URBACH, Department of Physics, Georgetown University — While shear-thinning in semidilute suspensions of rod-like particles has been widely observed, the underlying mechanisms are often unclear. We have developed a model system of fluorescent SU-8 rods suspended in a Glycerol/Ethylene-Glycol solution. This model system exhibits an order of magnitude difference in apparent viscosity at low shear rates as compared to high shear rates while showing no discernible difference in structure. Using a coupled confocal microscope and rheometer instrument along with fiber identification and particle tracking routines, we directly image and quantify the 3D structure and dynamics of our model system under shear flow in order to determine how particle interactions could be generating the observed shear thinning. In particular we look at how interactions modify Jeffery's orbits in semidilute suspensions as compared to the motion of an isolated rod or ellipsoid.

1:39PM Z50.00011 The field effect on local temperature distribution in natural convection in a magnetic fluid , JUN HUANG, WEILI LUO, University of Central Florida — Previously, we have reported the magnetic field effect on the flow front of natural convection in magnetic fluids. In this work we present the local temperature distribution as a function of applied field, from which flow patterns are constructed. We will also report, and discuss the possible mechanism for, a crossover field, above which the field dependence diminishes.

1:51PM Z50.00012 Mixing dynamics of slurry in rotating drum , KIWING TO¹, Institute of Physics, Academia Sinica, CHUN CHUNG LIAO², SHU-SAN HSIAU³, Department of Mechanical Engineering, National Central University — We study the effects of interstitial fluid viscosity on the rates of dynamical processes in a thin rotating drum half-filled with monodisperse glass beads. The rotating speed is fixed at the rolling regime such that a continuously flowing layer of beads persists at the free surface. While the characteristic speed of a bead in the flowing layer decreases with the fluid viscosity, the mixing rate of the beads is found to increase with the fluid viscosity. These findings are consistent to a simple model related to the thickness of the flowing layer.

2:03PM Z50.00013 Bubble production using a Non-Newtonian fluid in microfluidic flow focusing device , YI-LIN WANG, National Taiwan University of Science and Technology, THOMAS WARD, CHRISTINE GRANT, North Carolina State University — We experimentally study the production of micrometer-sized bubbles using microfluidic technology and a flow-focusing geometry. Bubbles are produced by using a mixture containing aqueous polyacrylamide of concentrations ranging from 0.01-0.10% by weight and several solution also containing a sodium-lauryl-sulfate (SLS) surfactant at concentrations ranging 0.01-0.1% by weight. The fluids are driven by controlling the static pressure above a hydrostatic head of the liquid while the disperse phase fluid static pressure is held constant (air). In the absence of surfactant the bubble production is discontinuous. The addition of surfactant stabilizes the bubble production. In each type of experiment, the bubble length ℓ , velocity U and production frequency ω are measured and compared as a function of the inlet pressure ratio. The bubbles exhibit a contraction in their downstream length as a function of the polymer concentration which is investigated.
