12:51PM J24.00009 The chemical trends of a new defect cluster: DDX centers, JIE MA, SU-HUAI WEI, national renewable energy laboratory — DX center is a major “killer” defect limiting n-type doping in group II-VI and III-V semiconductors. It converts a shallow donor to deep one, which is a major reason for the saturation of free-electron carriers in the doping process. Several structure models of isolated DX centers have been proposed in the literatures, such as the broken-bond model (BB-DX), and the α and β cation-cation bond model (CCB-DX). All these DX centers can be stabilized with hydrostatic pressure or reduced dimensionality and size. In group III-V and II-VI semiconductors, it has been common believe that cation-site induced DX centers are easier to form than anion-site induced ones. Because DX centers trap an extra electron, therefore, another defect in the system must donate the electron and form a positive charged defect. We show, using GaAs as an example, that in heavily doped semiconductor, the negative charged DX center and positive charged donor can couple strongly through the Coulomb interaction, forming the dominant DDX center. The DDX centers are still deep level defects. However, unlike the DX center, the DDX centers have different chemical trends, i.e., anion-site DDX center is easier to form than cation-site DDX centers. A simple model is proposed to explain the new trends.

1:03PM J24.00010 Valence state manipulation of single Fe impurities in GaAs, PAUL KOENRAAD, JUANITA BOCQUEL, Eindhoven University of Technology, VICTORIA KORTAN, MICHAEL FLATTE, University of Iowa, RICHARD CAMPION, BRYAN GALLAGHER, University of Nottingham — Cross-sectional STM was used to characterize Fe doped GaAs. We show that, by controlling the tip-induced band bending, Fe atoms can be brought from their isoelectronic state (Fe^{3+})-3d5 state into their (Fe^{2+})-3d6 ionized acceptor state. This STM-induced valence manipulation that involves the (de)population of the d-shell of the Fe atom differs from our previous experiments on Mn-acceptors and Si-donors where we changed its charge state by adding or removing a valence band hole or a conduction band electron respectively that is bound by the impurity. In addition for specific tunneling conditions a peculiar contrast is observed under which Fe atoms appear as dark anisotropic features.

1:15PM J24.00011 Local Environment Effects on Single Zn and Mn Acceptors in Gallium Arsenide, NANCY SANTAGATA, DONGHUN LEE, JAY GUPTA, The Ohio State University — The ability to precisely control the properties of single dopants in semiconductors is of interest not only for the improvement of current technologies but also for the development of next generation devices. Recent work in our group has exploited the single atom precision afforded by a scanning tunneling microscope to explore how the properties of dopants in gallium arsenide depend on their local environment. Specifically, we have shown that Zn dopants located within the same layer and occupying identical binding sites exhibit dissimilarities that are dependent upon the proximity to neighboring subsurface Zn acceptors.(1) Further, we demonstrated control of the ionization state of single Mn acceptors by both defect- and tip-induced band bending.(2) Finally, we achieved tunable control over the binding energy of Mn acceptors by varying the proximity to charged As vacancies.(3) This talk will review these findings and elaborate on the application of these techniques to characterize defects in wide bandgap materials, where the origin of properties like ferromagnetism are not yet well understood. 1. Appl. Phys. Lett. 99, 053124 (2011). 2. Nano Lett. 11, 2004 (2011). 3. Science 330, 6012 (2010).

1:27PM J24.00012 Recombination dynamics of excitons bound to nitrogen isoelectronic centers in GaAs, PHILIPPE ST-JEAN, GABRIEL ÉTHIER-MAJCHER, École Polytechnique de Montréal, JOHN F. KLEM, Sandia National Laboratories, SÉBASTIEN FRANCOEUR, École Polytechnique de Montréal — Using time-resolved photoluminescence, we have studied the radiative recombination dynamics of excitons bound to single nitrogen dyads in GaAs. For in-plane dyads of C_{2v} symmetry considered in this work, the lifetime of all four allowed optical transitions, polarized either along or perpendicular to the dyad, decreases with temperature. Over the temperature range studied, the lifetimes of transitions of same polarization remain highly similar, but they are sensitively longer for transitions polarized along the dyad. These results indicate that 1) the spatial orientation of the exciton wavefunction is an important factor in the recombination dynamic, 2) the transfer dynamics between bright states appears negligible, and 3) the transfer to or from dark states is not significant for temperature over 5 K. These findings enhance the understandings of isoelectronic centers which are promising candidates for the implementation of atomic size memories based on a single charge or spin.

1:39PM J24.00013 First-principles study of InX (X=P,Sb) semiconductors, OSCAR D. RESTREPO, ROHAN MISHRA, WOLFGANG WINDL, The Ohio State University — III-V semiconductors are gaining increasing interest for applications due to the possibility of engineering their electronic properties by choosing and combining different elements. Additional design parameters can come from confinement effects which have led to intensified research on nanowires for electronic applications. Among the lesser studied III-V semiconductors with large technological potential are indium-based compounds, where InSb with an extremely small band gap in the infrared range is the staple material for infrared detector devices and InP (with a larger band gap of 1.42 eV) is considered as a promising material for nanowire-based applications. For these materials, many basic questions that have been answered for more-mainstream semiconductors are still unanswered, these include effective masses, optical properties, and the influence of defects on their properties. In order to address some of these questions, we have performed an exhaustive exploration of the defect energetics of InP using first-principles calculations. We also report a detailed comparison of calculated effective masses and optical properties of InSb with experiments. We have used both GGA and HSE06 to treat exchange-correlations. This work was supported by NSF MRSEC DMR-0820414.

1:51PM J24.00014 Simple intrinsic defects in GaP and InP, PETER A. SCHULTZ, Sandia National Laboratories, Albuquerque, NM — To faithfully simulate evolution of defect chemistry and electrical response in irradiated semiconductor devices requires accurate defect reaction energies and energy levels. In III-Vs, good data is scarce, theory hampered by band gap and supercell problems. I apply density functional theory (DFT) to intrinsic defects in GaP and InP, predicting stable charge states, ground state configurations, defect energy levels, and identifying mobile species. The SeqQuest calculations incorporate rigorous charge boundary conditions removing supercell artifacts, demonstrated converged to the infinite limit. Computed defect levels are not limited by a band gap problem, despite Kohn-Sham gaps much smaller than the experimental gap. As in GaAs, [P.A. Schultz and O.A. von Lilienfeld, Modeling Simul. Mater. Sci. Eng. 17, 084007 (2009)], defects in GaP and InP exhibit great complexity—multitudes of charge states, bistabilities, and negative U systems—but show similarities to each other (and to GaAs). Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Company, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

2:03PM J24.00015 Defects in GaSb and InAs/GaSb superlattices¹, JIANWEI WANG, YONG ZHANG, Electrical and Computer Engineering, University of North Carolina at Charlotte — Unintentionally doped GaSb is known to be p-type. One possible explanation for the p-type conductivity is due to the existence of Ga on Sb anti-site defects that behave as acceptors. Such an acceptor-like defect state could potentially impact the performance of an IR detector based on a type II superlattice InAs/GaSb. We use pseudopotential density functional theory to investigate this defect state in both bulk GaSb and the superlattice. We calculate the defect levels with and without spin-orbit interaction and with the p-d band separation and bandgaps corrected. Although the defect might be acceptor-like, its energy level does not necessarily follow the GaSb band edge that is shifted in the superlattice due to quantum confinement.

Session J25 DCOMP GSCCM DMP: Focus Session: Simulation of Matter at Extreme Conditions: Shock Compression and Other High-Strain-Rate Phenomena 257A

11:15AM J25.00001 Single two-zone elastic-plastic shock waves in solids, VASILY ZHAKHOVSKY, MIKALAI BUDZEVICH, University of South Florida, NAIL INOGAMOV, Landau Institute for Theoretical Physics, Russian Academy of Sciences, IVAN OLEYNIK, University of South Florida, CARTER WHITE, Naval Research Laboratory — A new regime of shock wave propagation in solids, corresponding to a single two-zone elastic-plastic shock-wave, was discovered using a novel moving window molecular dynamics technique. Both leading low-pressure elastic and trailing high-pressure plastic fronts move with the same speed and have a fixed separation that can extend to several microns. The material in the elastic zone is in a metastable state, having a pressure that substantially exceeds the critical shock strength characteristic of the onset of the well-known split-elastic-plastic, two-wave regime. The single two-zone elastic-plastic shock wave is a quite general phenomenon observed in our simulations for a broad class of crystalline materials, including aluminum, nickel, diamond, and Lennard-Jones crystals. It is the existence of the two-zone, elastic-plastic regime that allows for a consistent explanation of the anomalously high elastic wave amplitudes observed in recent experiments.

11:27AM J25.00002 The Role of Shock Induced Defect Structure in Spall Failure, JUSTIN WILKERSON, K.T. RAMESH, The Johns Hopkins University — Spall failure is a complex multiscale, multirate process. On the macroscale the process involves a period of shock compression followed by dynamic tension set up by the stress wave interactions. During the shock compression, the material undergoes a myriad of shock stress magnitude and pulse duration dependent microscopic processes that may include dislocation multiplication, nucleation, trapping, pile-up, annihilation, recovery, cell evolution, as well as vacancy generation and clustering. In addition to shock hardening the material, this new shock induced defect structure seeds the material with potential void nucleation sites that may be activated during the proceeding period of dynamic tensile loading. Upon nucleation, the voids undergo dynamic growth to coalescence, constrained by inertia and viscoplastic resistance to deformation. A multiscale predictive framework is developed to analyze the role of these time-dependent processes in the experimentally observed spall strength dependence on initial microstructure, preheated temperature, tensile loading rate, pulse duration, and shock stress magnitude.

11:39AM J25.00003 Physics of hyper-velocity impacts of micrometer and sub-micrometer sized particles, ANNA MOCKER, IRS, University of Stuttgart, Germany, KLAUS HORNUNG, Universitaet der Bundeswehr Muenchen, Germany, ZOLTAN STERNOVSKY, KEITH DRAKE, SASCHA KEMPF, CCLDAS, University of Colorado at Boulder, EBERHARD GRÜN, MPI-K, Heidelberg, Germany, FIEGE FIEGE, University of Heidelberg, Germany, RALF SRAMA, IRS, University of Stuttgart, Germany — The phenomena occurring during hypervelocity microparticle impact are manifold and the basis for the variety of applications. The processes of interest are particle fragmentation, impact ionization, impact flashes, and TOF mass spectrometry. To relate the parameters of individual particle impacts with the resulting measured values, a comprehensive program of impact experiments under well known experimental conditions for a wide variety of impact parameters is needed. For this, dust particles are accelerated to hypervelocity speeds with an electrostatic accelerator and the resulting plasma cloud is analyzed with suitable instruments. A detailed investigation using latest analyzing techniques like high-speed cameras and sensitive high-resolution spectrometers promises new instrument concepts and insights into short timescale high-pressure states of matter. Linear TOF mass spectroscopy provides the opportunity to measure the dynamic and thermodynamic properties of the impact ions. Together with a deeper theoretical understanding of the impact process and the subsequent expansion and other experimental approaches, this method can be a powerful tool to investigate the state of the hot compressed matter due to the related residual ion species.

11:51AM J25.00004 Shock Ejecta Entrainment in Gas¹, MICHAEL FURNISH, Sandia National Laboratories — In a continuation of earlier work, paired metal shock ejecta experiments, with and without helium fill, are used to measure shock ejecta motion in gas. The vacuum ejecta experiments use Asay foils and PDV to characterize ejecta properties, and the gas ejecta experiments use PDV. FFT analysis of the PDV signals gives a qualitative indication of the presence of such ejecta and of its motion; this can be “calibrated” via the Asay foil data. For modest amounts of ejecta (allowing enough light to reach the free surface and return to the probe to give a strong free surface velocity signal), the FFT amplitudes are roughly proportional to the ejecta areal density, where the proportionality constant depends on the shape and size distribution of the ejecta particles. We assume these are consistent for the two samples in each experiment pair, although limitations to this assumption (e.g. ejecta disruption by the gas) are discussed. An additional caveat is that PDV only measures the motion of ejecta with particle sizes exceeding the 1550 nm light wavelength. Experiments to assess optimal generators of shock ejecta detectable by PDV are also presented. Indium was found to work well in the pressure regime studied.

12:03PM J25.00005 Why nano-projectiles work differently than macro-impactors- role of plastic flow¹, E.M. BRINGA, CONICET and Instituto de Ciencias Basicas, Universidad Nacional de Cuyo, Mendoza, 5500 Argentina, CHRISTIAN ANDERS, GEROLF ZIEGENHAIN, Fachbereich Physik und Forschungszentrum OPTIMAS, Universitat Kaiserslautern, Germany, GILES GRAHAM, Mineralogy Department, The Natural History Museum, London SW7 5BD, United Kingdom, J. FREDDY HANSEN, Lawrence Livermore National Laboratory, Livermore CA 94550, USA, NIGEL PARK, AWE, Plc Aldermaston, Reading, UK, NICK TESLICH, Lawrence Livermore National Laboratory, Livermore CA 94550, USA, HERBERT URBASSEK, Fachbereich Physik und Forschungszentrum OPTIMAS, Universitat Kaiserslautern, Germany — Hypervelocity impacts provide a way to take localized regions of a target to extreme pressure and temperature conditions. Resulting crater features can be challenging for hydrocode simulations and test the validity of constitutive models. We will present atomistic simulation data on crater formation due to hypervelocity impact of nanoprojectiles of up to 55 nm diameter and with targets containing up to ten billion atoms, and compare them to available experimental data on micron-, mm-, and cm-sized projectiles. We show that previous scaling laws do not hold in the nano-regime and outline the reasons: within our simulations we observe that the cratering mechanism changes, going from the smallest to the largest simulated scales, from an evaporative regime to a regime where melt and plastic flow dominate, as it is expected in larger micro-scale experiments. The importance of strain-rate dependence of strength and of dislocation production and motion under these extreme conditions will be discussed.

12:15PM J25.00006 Elastic-plastic response and polymorphic phase transition in shock-compressed diamond, YOU LIN, ROMAIN PERRIOT, VASILY ZHAKHOVSKY, Department of Physics, University of South Florida, XIANG GU, Department of Applied Physics, Aalto University, CARTER WHITE, Naval Research Laboratory, IVAN OLEYNIK, Department of Physics, University of South Florida — Shock wave propagation in diamond along the $\langle 110 \rangle$ crystallographic direction was simulated by molecular dynamics (MD) using the reactive empirical bond order (REBO) potential. In addition to known regimes of shock wave propagation, such as single elastic, split elastic-plastic, and single plastic shock wave, two new regimes were observed: 1) a split elastic-elastic shock wave associated with a polymorphic phase transition; 2) a single two-zone elastic-plastic shock wave with the leading elastic zone followed by the plastic zone. In the case of the split elastic-elastic shock wave, the onset of phase transition occurs at a pressure below the Hugoniot elastic limit (HEL); therefore, the solid-solid transformation takes place in the uniaxially compressed material in the absence of plasticity. Within the single two-zone elastic-plastic shock wave, the material in the elastic zone is in a metastable state at a pressure exceeding the HEL. The metastable elastic state decays into the plastic state within the plastic zone, both elastic and plastic fronts moving with the same speed.

12:27PM J25.00007 ABSTRACT WITHDRAWN —

12:39PM J25.00008 The Shock Response of Granular and Consolidated Ta₂O₅¹, TRACY VOGLER, SETH ROOT, WILLIAM REINHART, Sandia National Laboratories, GREGG FENTON, DENNIS GRADY, Applied Research Associates — The dynamic behavior of granular and nearly fully dense tantalum pentoxide (Ta₂O₅) has been explored through planar impact experiments. The experiments span from the compaction regime to the ultra-high pressure range utilizing gas guns and the Z machine. These data provide a valuable data set for the extension of the P- λ model to the high-pressure regime. A thermodynamic approach due to Rice and Walsh is employed in the model to treat highly distended materials that can display anomalous compressibility. When the model is calibrated to the gas gun and Z data, we test its applicability against the data of Miller et al. from laser experiment on low-density aerogels. Even in these very different conditions, the model does a credible job of predicting the material behavior, suggesting that the approach may be useful as a general modeling tool for the high-pressure regime.

¹Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin company, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

12:51PM J25.00009 Optical emission from $\text{Gd}_3\text{Ga}_5\text{O}_{12}$ single crystals shock compressed from 40 to 300 GPa, XIANMING ZHOU, National Key Laboratory of Shock Wave and Detonation Physics, Institute of Fluid Physics, China, WILLIAMS NELLIS, Physics Department, Harvard University, JIABO LI, JUN LI, XUN LIU, XIUXIA CAO, WANGUANG ZHAO, QIANG WU, National Key Laboratory of Shock Wave and Detonation Physics, Institute of Fluid Physics, China, TSUTOMU MASHIMO, Shock Wave and Condensed Matter Research Center, Kumamoto University, CAEP, PR CHINA TEAM, HARVARD UNIVERSITY COLLABORATION, KUMAMOTO UNIVERSITY COLLABORATION — The question of the shock pressure at which a strong material reaches thermal equilibrium is an important one that depends on strength and has never been answered for any strong material. To answer the range of shock pressures in which shock dissipation is dominated by entropy (damage and disorder) or by shock heating (T), we have performed time-resolved optical emission and transmission measurements on strong GGG single crystals under wide-range uniaxial compression from ~ 40 GPa to ~ 300 GPa with a sixteen-wavelength pyrometer. Temperatures T and emissivities ϵ were derived from gray-body fits up to 300 GPa. These data: (i) determine shock pressures at which GGG reaches thermal equilibrium and melting, (ii) essentially confirm previously calculated shock temperatures of GGG, (iii) demonstrate the complete transition from heterogeneous shock heating at lower pressures (small ϵ) to thermally-equilibrated bulk heating (large ϵ) at higher pressure (never before been done in strong materials), and (iv) characterize GGG as an anvil for use in studying metallic fluid hydrogen.

1:03PM J25.00010 Laser-driven focusing shock waves in a thin liquid layer¹, DAVID VEYSSET, THOMAS PEZERIL, GAGAN SAINI, STEVEN KOOI, ALEX MAZNEV, KEITH NELSON, Massachusetts Institute of Technology — Direct real-time visualization of converging shock waves in a few micron thick liquid layer is demonstrated in an all-optical experiment. The set-up includes an axicon that focuses an intense picosecond excitation pulse into a ring-shaped pattern in a water layer. Optical excitation induces a shock wave that propagates in the plane of the sample and converges toward the center resulting in cylindrical focusing of the shock front. Streak-camera images with a quasi-cw probe beam yield real-time records of the entire shock propagation. Talbot imaging and interferometry with a femtosecond probe pulse are used to obtain full field images at variable delays. Shock pressure values calculated from the velocity of the shock front demonstrate the effect of shock focusing and agree with density profiles obtained by quantitative analysis of interferometric images. The configuration of the experiment provides ample access for optical diagnostics of the shocked material and can be combined with a wide range of spectroscopic probes.

1:15PM J25.00011 From fingering to fracture in a complex fluid, BAUDOUIN SAINTYVES, CEA-Saclay — We present a novel experiment – a specific Hele-Shaw cell with mobile sides which can be pulled at a prescribed velocity - with which both liquids and solids can be loaded with the same boundary conditions, beyond the small deformation regime. With such a system, one can examine quantitatively the response of a viscoelastic material when the loading rate is varied. In the case of viscous Newtonian liquids, an air bubble is shown to destabilize in a Saffman-Taylor manner, forming a finger which elongates in the direction in which the mobile sides are pulled. In contrast, in a Maxwell liquid, we observe a different kind of instability, which gives rise to more complex patterns. This instability leading to local stress concentrations, it is immediately followed by fracture. The displacement field is evaluated in each case by using tracers and image correlations.

1:27PM J25.00012 Nonlinear Elasticity as a Guide for Exploring High Pressure/Shear Stability, T.W. WRIGHT, Johns Hopkins University — Recent constitutive representation theorems for nonlinear anisotropic elasticity, Wright [2011], show the characteristics of elastic response for materials in any point group. All anisotropic representations consist of a sum of six terms, and each term consists of a scalar function of anisotropic invariants times a “tensor generator,” which has the same invariance under group transformations as the stress itself. Knowledge of these representations shows promise as a guide for exploring material stability under extreme loading conditions. Although much is known both experimentally and theoretically about material stability under high pressure, far less is known about the effect of large shear stress superimposed on high pressure. Stress has six independent components, so study of the effects of pressure alone leaves the other five dimensions unexplored. Rather than random DFT calculations in the five dimensional deviatoric space, the known structure of the six term representations suggests that systematic study of just one additional dimension at a time could be accomplished by following changes in just one additional term in the representation at a time. These ideas will be illustrated in the context of a program designed to explore the effect of shear on amorphization in B4C, a ceramic often used for ballistic protection. *T.W. Wright, Bootstrap elasticity: From linear to nonlinear constitutive representations, accepted for publication, J. Elasticity.*

1:39PM J25.00013 Multi million-to-Billion Atom Molecular Dynamics Simulations of Cavitation-Induced Damage on a Silica Slab, ADARSH SHEKHAR, KEN-ICHI NOMURA, RAJIV KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, Collaboratory for Advanced Computing and Simulations, University of Southern California — Cavitation bubble collapse causes severe damage to materials. For example, cavitation erosion is a major threat to the safety of nuclear power plants. The cavitation bubbles may also be utilized for preventing stress corrosion cracking with water jet peening technology. We have performed multi million-to-billion atoms molecular dynamics simulations to investigate the shock-induced cavitation damage mechanism on an amorphous silica slab in water. The system consists of a 60nm thick silica slab immersed in water in an MD box of dimension $285 \times 200 \times 200$ nm³. A nanobubble is created by removing water molecules within a sphere of radius 100 nm. To apply a planar shock, we assign a uniform particle velocity v_p on the entire system towards a planar momentum mirror. We have performed the simulation with two kinds of bubbles, an empty bubble and a bubble filled with inert gas. The simulation results reveal nanojet formation during bubble collapse causing damage on the silica surface; however, the damage was significantly reduced in the case of the filled bubble. We will discuss the effect of the presence of inter gas inside the nanobubble on the pressure distribution, the extent of damage, and collapse behavior corresponding the shock front.

1:51PM J25.00014 Akrology; the physics of the extreme behaviour of metals and energetics, NEIL BOURNE, AWE — Structures designed for extreme environments must be designed not only for the magnitude of the load that they will experience, but also the time for which that load acts upon them. At the core of the problem lies the loading impulse experienced by materials and the operating deformation mechanisms that are excited. Our experience of materials' physics, gathered by investigating response to mechanical loads, has suggested a series of descriptive constructs within which we build our picture of behaviour. At the highest loadings and the shortest loading times this perception is coloured by experience gathered from historical considerations. This paper suggests a framework by which to interpret data collected on the response of metals and explosives. It suggests that strength is a quantity that decays over time and that fundamentally approaches zero in the limit of infinite time. Controlling this decay is the business of engineering to design structures that will survive in the environments our times of interest define.

2:03PM J25.00015 Equation of State of a Solid: Potts-Percolation Model, MIRON KAUFMAN, Cleveland State University, H.T. DIEP, Universite de Cergy-Pontoise, France — We include stress and strain in a Potts-percolation model of a solid, see J. Phys.: Condens. Matter 20, 075222 (2008) and Phys Rev E80, 031116 (2009). Neighboring atoms are connected by a bond of Lennard-Jones energy. If the energy is larger than a threshold the bond is more likely to fail, while if the energy is lower than the threshold the bond is more likely to be alive. We compute the equation of state: stress as function of strain and temperature by using renormalization group and Monte Carlo simulations. The phase diagram and the equation of state are determined. When the Potts heat capacity is divergent the continuous transition is replaced by a weak first-order transition through the van der Waals loop mechanism. When the Potts transition is first order the stress exhibits a large discontinuity as function of the strain.

Session J26 DCOMP: Focus Session: What is Computational Physics? 257B

11:15AM J26.00001 Aneesur Rahman Prize for Computational Physics Lecture: Photonic Crystals and Genetic Algorithms: Adventures of a Computational Physicist¹, KAI MING HO², Department of Physics and Astronomy and Ames Laboratory, Iowa State University — I will review some of our work in the computation of photonic crystals, focusing on our discovery of the photonic band gap in diamond structures. I will also describe our conception of the cut-and-paste genetic algorithm in materials discovery structure search and discuss applications of the algorithm from early studies of atomic clusters geometries to more recent applications for structures of surfaces, interfaces, nanowires, and bulk crystals.

¹Support from the U. S. Department of Energy Basic Energy Sciences Office is gratefully acknowledged.

²Ho 31310 APS Aneesur Rahman Prize Winner

11:51AM J26.00002 Computational Science as a Data and Compute Intensive Environment: How do we Prepare the Future for it?, NORA SABELLI, SRI International — Much has been said about the data- and compute-driven transformations that science is undergoing. Much has also been said about the impacts this transformation will have in society, impacts that are not limited to science professionals. But not much has been said about the transformations that will have to take place for this impact on society to be positive. This talk will ask if we know enough about what the multiple institutions that educate society's members should be doing to serve the new needs, and discuss some challenging questions that could inform future action.

12:27PM J26.00003 New Approaches for Microscopic Hydrodynamics for the Study of Fluid-Structure Interactions Subject to Thermal Fluctuations¹, PAUL ATZBERGER, UC Santa Barbara — Many problems in fluid mechanics involve the interaction of a hydrodynamic flow with an elastic structure. Recent advances in biology and engineering further motivate such studies at small length and time scales. At such scales traditional continuum mechanics descriptions must be augmented to take into account microscopic phenomena, such as spontaneous thermal fluctuations. This presents a variety of challenges both in formulating appropriate physical models and in computational simulation. In the context of fluid-structure interactions, additional challenges arise from the often subtle interplay between elastic mechanics, hydrodynamic coupling, and thermal fluctuations. In this talk, we present a set of new approaches which address central mathematical, physical, and computational issues for how to incorporate in the description of such fluid-structure interactions thermal fluctuations. We also address important numerical issues in the approximation of the resulting stochastic partial differential equations. We also discuss results for specific illustrative applications including studies of polymeric fluids, vesicles, gels, and lipid bilayer membranes.

¹NSF CAREER Award : NSF-DMS-0956210

12:39PM J26.00004 Extending the Flux Operator with the Husimi Projection, DOUGLAS MASON, MARIO BORUNDA, ERIC HELLER, Harvard University — A common tool among physics in the transport community is the probability flux operator, but connecting this operator to measurement has not received much attention. We have extended the definition of flux by using coherent states, rendering it both measurable and infinitely more useful. For instance, we can use our extended definition to study closed systems and the classical dynamics of individual quantum states, and then connect these dynamics to resonant states interacting with an environment. This analytical technique, based on semi-classics, brings new tools to bear on wavefunction analysis and visualization

12:51PM J26.00005 Finite Element Modeling of Open Domain Quantum Scattering¹, A.V. ILYASHENKO, A.G. GIANFRANCESCO, C.R. BOUCHER, L.R. RAM-MOHAN, Worcester Polytechnic Institute — We study quantum scattering in the open domain in 2D using the finite element method. We solve the Schrödinger equation in a circular region using an arbitrary triangular mesh with a plane wave source and an arbitrary (finite) scattering potential. We employ perfectly matched layers (PML) around the region of interest to simplify the derivative Cauchy BCs to Dirichlet BCs. With PML, fewer resources are needed to account for the open domain without going to the asymptotic region as is usually done, while obtaining the “near-field” evanescent solutions when they are present. The scattering total cross-section, the differential cross-section, and the phase shifts can be determined by performing a partial wave analysis on the computed solution. Examples of this technique and results on multi-component, spin dependent scattering for spintronics will be presented.

¹This work was supported by the NSF under grant #ECS-0725427 and by AFRL/DARPA under grant #FA8650-10-1-7046.

1:03PM J26.00006 Solution of a Schroedinger equation containing a general non local potential, JOSEPH POWER, GEORGE RAWITSCHER¹, University of Connecticut — The non locality is given by an integral kernel $K(r,r')$ that is general. We solve the corresponding Lippmann-Schwinger integral equation a) by expanding the wave function into a Fourier series (Galerkin method), and b) by a spectral method involving Chebyshev polynomials (CP). We apply them to the case of the much used Perey-Buck kernel [1], and find that, by using 50 sine functions, method a) requires an hour of computing time, while method b) using 50 CP's takes less than one second and is precise to $1:10^5$. Previously the spectral method could be applied only to a kernel of rank 1, representing for example the knock-on exchange process [2], but with our new procedure we will be able to compare relatively easily the effect of several types of non localities [3].

1:15PM J26.00007 Accurate and fast numerical solution of Poisson's equation for arbitrary, space-filling convex Voronoi polyhedra: near-field corrections revisited¹, AFTAB ALAM, Ames Laboratory, Ames IA, BRIAN G. WILSON, LLNL, Livermore California, DUANE D. JOHNSON, Ames Laboratory, Ames IA — We present an accurate and rapid solution of Poisson's equation for space-filling, arbitrarily-shaped, convex Voronoi polyhedra (VP); the method is $O(N)$, where N is the number of distinct VP representing the system. In effect, we resolve the longstanding problem of fast but accurate numerical solution of the near-field corrections (NFC), contributions to each VP potential from nearby VP – typically involving multipole-type conditionally-convergent sums, or fast Fourier transforms. Our method avoids all ill-convergent sums, is simple, accurate, efficient, and works generally, i.e., for periodic solids, molecules, or systems with disorder or imperfections. We demonstrate the method's practicality by numerical calculations compared to exactly solvable models.

1:27PM J26.00008 Sonoluminescence and Vacuum Radiation , JUSTIN MELUNIS, EDUARDO FLORES, Rowan University — Sonoluminescence is the generation of light from sound. Our goal is to understand why a bubble trapped in water could generate light from sound. In our work we investigate the contribution of the dynamical Casimir effect to this phenomenon. In previous work researchers have approached this problem as a semi static Casimir effect and have not been able to show a significant contribution of the Casimir effect to sonoluminescence. In our approach, we treat the surface of the bubble as a highly reflecting surface, thus, the electric field of the zero-point modes at the surface is zero. Thus, when the bubble collapses the zero-point modes inside and outside are disturbed. Since the dynamics of zero-point mode fields obey Maxwell equations we can simulate their dynamics using programs like Mathematica. We study the radiation of the excited zero-point mode field.

1:39PM J26.00009 Second harmonic generation in three-dimensional metamaterials based on homogeneous centrosymmetric spheres , JINYING XU, Beijing Computational Science Research Center — The theory of second harmonic generation in three-dimensional metamaterials consisting of arbitrary distributions of spheres made of centrosymmetric materials is developed by means of the multiple scattering method. The electromagnetic field at both the fundamental frequency and second harmonic, as well as the scattering cross section, are calculated in a series of particular cases such as a single metallic sphere, two metallic spheres, chains of metallic spheres, and other periodic distributions of the metallic spheres. It is shown that the linear and nonlinear optical response of all ensembles of metallic spheres is strongly influenced by the excitation of surface plasmon-polariton resonances. The physical origin for such a phenomenon has also been analyzed. A new class of SHG devices made of such materials is anticipated.

1:51PM J26.00010 Characterizing the frequency response curve of large rooms in the short and long time regimes¹ , ANNA KLALES, SUZANNE PITTMAN, MATTHEW BARR, MARIO BORUNDA, ERIC HELLER, Harvard University — Room acoustics can be modeled by real Gaussian statistics, corresponding to randomized ray trajectories and characterized for instance by the reverberation time T60 (free field to decay by 60 decibels) which is independent of position or source point in a room. In his 1954 paper, Manfred Schroeder found universal statistical features of the steady state frequency response curve of large rooms, based upon the assumption of Gaussian probability distributions of the pressure. For example, he found the standard deviation from the mean level is 11 decibels for any concert hall, regardless of the shape of the room or its T60, within reasonable limits. Using semi-classical and numerical methods, we find non-universal (room dependent) corrections to Schroeder's universal results for the statistics of the frequency response curve. Along with corrections to the steady-state frequency response, we present the behavior of the frequency response curve for short to intermediate times.

Session J27 FIP GERA: Invited Session: International Energy Perspectives 258AB

11:15AM J27.00001 Energy production and use in China , MARK LEVINE, Lawrence Berkeley National Laboratory
— No abstract available.

11:51AM J27.00002 Economics of energy Alternatives , CARMINE DIFIGLIO, US Department of Energy — No abstract available.

12:27PM J27.00003 Future Trends and Issues in Nuclear Power , RICHARD LESTER, Massachusetts Institute of Technology — No abstract available.

1:03PM J27.00004 Science for Sustainable Energy: Recommendations of the 2010 BESAC Report , ALEXIS MALOZEMOFF, AMSC, 64 Jackson Rd, Devens MA 01434 — In August 2010, DOE's Basic Energy Sciences Advisory Committee issued a major report on Science for Energy Technology. The report identified opportunities for science to help overcome roadblocks to progress in emerging clean energy technologies and thus to have much needed near-term impact on our energy infrastructure. The report covered diverse areas including solar electricity from photovoltaics, advanced nuclear energy, carbon sequestration, electrochemical energy storage, power grid technologies including power electronics and superconductors, solid state lighting, biofuels, building efficiency, fuel cells and wind power. In addition, mechanisms were suggested to facilitate progress, in particular, by strengthening the link between basic research and industry. The talk will review the highlights of this report.

Session J28 FIAP DCOMP: Focus Session: Frontiers in Computational Thermodynamics of Materials 258C

11:15AM J28.00001 The role of Wang-Landau sampling in materials development¹ , DAVID LANDAU, Center for Simulation Physics, University of Georgia — An understanding of the thermodynamic behavior of materials as well as the prediction of the properties of "materials by design" often depends upon knowledge of the free energy of the system under study. Computer simulations offer a powerful tool for such investigations, but traditional methods often suffer from long time scales and metastable states due to the roughness of the free energy landscape. Wang-Landau sampling² is a powerful alternative to traditional Monte Carlo algorithms which can alleviate many such problems. We will review the Wang-Landau algorithm and discuss various implementations as well as possible application to materials development.

¹Supported by the National Science Foundation.

11:51AM J28.00002 Dissolving the Periodic Table in Zirconia: Data Mining for Insight, BRYCE MEREDIG, CHRIS WOLVERTON, Northwestern University — A standard approach to understanding physical phenomena in materials is to manually search for clear trends or correlations in data (i.e., descriptors) governing those materials. Pettifor maps are a classic example of such empirically constructed models. But what if a data set is too large and/or chemically diverse to explain by straightforward human inspection? We present such a case by calculating from first principles the solubility thermodynamics of 70 dopant cations in cubic zirconia. This data set, spanning three charge states and most non-synthetic metals in the periodic table, defies simple “manual” explanation. Instead, we employ data mining algorithms and statistical methods to cluster the dopants into distinct classes, and then to build intuitive models for each class’ thermodynamics in zirconia. Thus, we show that formal data mining techniques are a powerful means of elucidating meaningful property relationships in complex data sets.

12:03PM J28.00003 High-throughput discovering half-metals from materials magnetic properties database, JUNKAI XUE, SHIDONG WANG, KESONG YANG, Department of Mechanical Engineering and Materials Science, Duke University, CHAITANYA DAS PEMMARAJU, STEFANO SANVITOS, School of Physics and CRANN, Trinity College, Dublin-2, Ireland, STEFANO CURTAROLO, Department of Mechanical Engineering and Materials Science, Duke University — Half-metal materials have been found by investigating their magnetism data, such as band gap and spin polarization around the Fermi level. An efficient algorithm has been implemented to create a database to aid discovering materials magnetism properties. With this tool, a series of new half-metals has been obtained. We present this magnetism data as well as how the online database is used.

12:15PM J28.00004 First Principles Modeling of the Temperature Dependent Ternary Phase Diagram for the Cu-Pd-S System, WILLIAM HUHN, MICHAEL WIDOM, Carnegie Mellon University — A method for the prediction of temperature dependent phase diagrams using first principles calculations combined with thermodynamics principles will be discussed. Our method allows us to model the phase diagram without any empirical fitting parameters. Due to the importance of sulfidation when dealing with hydrogen separation using copper palladium membranes, we have chosen as our test case the Cu-Pd-S ternary phase diagram which has been experimentally determined. By applying thermodynamic principles and a simple solid solution model, temperature-dependent features of the Cu-Pd-S system can be explained, specifically solubility ranges for substitutions in select crystalline phases. We have also performed electronic density of states calculations to determine the physical origin of the favorability of select substitutions at T=0K. Work is currently underway to use this method to create phase diagrams where no known experimental results exist, specifically the P-Pd-S system.

12:27PM J28.00005 Wang-Landau Without Binning, G. BROWN, Oak Ridge National Laboratory / Florida State, D. NICHOLSON, KH. ODBADRAKH, M. EISENBACH, A. RUSANU, Oak Ridge National Laboratory — Results are presented for Wang-Landau calculations on a Heisenberg model of BCC Fe that describe the density of states as function defined for all accessible energies instead of a function tabulated at discrete values of the energy. The density of states function described here is an analytic result valid near the ground state supplemented by a polynomial expansion. The probability density of Wang-Landau random walkers is sampled for a fixed density of states, and that probability density can be used to improve the estimated density of states. Methods for evaluating the convergence of the density of states are discussed along with the diffusion behavior of the random walkers. This work was performed at the Oak Ridge National Laboratory, which is managed by UT-Battelle, LLC under Contract No. DE-AC05-00OR22725, and sponsored by the Laboratory Directed Research and Development Program (ORNL), by the Mathematical, Information, and Computational Sciences Division; Office of Advanced Scientific Computing Research (US DOE), and by the Division of Materials Sciences and Engineering; Office of Basic Energy Sciences (US DOE). Computer resources provided by Florida State University.

12:39PM J28.00006 Thermodynamic Stability of Actinide-Dioxide Solid Solutions and Surface Interactions with Water¹, MARK ASTA, Department of Materials Science and Engineering, University of California, Berkeley — Fluorite-structured actinide dioxides are the most common forms of fuel used in nuclear energy production worldwide. This talk will provide an overview of insights into the energetics of these compounds derived through the combination of density-functional-theory-based computational studies (including Hubbard-U corrections) and calorimetric measurements. The talk will focus on two main topics: the mixing energetics of cation solid solutions, and the energetics of water adsorption on the surfaces of these compounds. For the first topic, we present results for ThO₂ and UO₂ based solid solutions, highlighting the roles of elastic energy arising from cation size mismatch, electrostatic interactions, and charge-transfer reactions, in governing the sign and magnitude of the mixing energetics. For water adsorption, we contrast results for surface and adsorption energies on two fluorite-structured compounds, ThO₂ and CeO₂, that are relevant for understanding the behavior of water on actinide oxide surfaces more generally. Through a comparison between calorimetric measurements and computational results we assess the level of accuracy achieved in the computational modeling, and suggest areas where further experimental studies would be particularly useful.

¹This work was supported as part of the Materials Science of Actinides, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Basic Energy Sciences under award number DE-SC0001089.

1:15PM J28.00007 Structure and stability of Al₂Fe and Al₅Fe₂, MICHAEL WIDOM, Carnegie Mellon University, MAREK MIHALKOVIC, Slovakian Academy of Sciences — We employ first principles total energy and phonon calculations to address the structure and stability of Al₂Fe and Al₅Fe₂. The observed structure of Al₂Fe, which is reported as stable in the assessed Al-Fe phase diagram, is distinguished by an unusually low triclinic symmetry. The initial crystallographic structure determination additionally featured an unusual hole large enough to accommodate an additional atom. Our calculations indicate the hole must be filled, but predict the triclinic structure is unstable relative to a simpler tetragonal structure based on the prototype Mo Si₂. This tetragonal structure is interesting because it is predicted to be nonmagnetic, electrically insulating and high density, while the triclinic structure is magnetic, metallic and low density. We reconcile this seeming contradiction by demonstrating a high vibrational entropy that explains why the triclinic structure is stable at high temperatures. Finally, we note that orthorhombic Al₅Fe₂ is also destabilized by the tetragonal structure but may be stabilized at high temperatures, again by vibrational entropy and partial occupancy associated with the diffusion of Al atoms along channels.

1:27PM J28.00008 Equation of state of paramagnetic CrN from ab initio disordered local moments molecular dynamics, IGOR ABRIKOSOV, PETER STENETEG, BJÖRN ALLING, IFM, Linköping University, Sweden — A first-principles method is suggested for the calculation of thermodynamic properties of magnetic materials in their high temperature paramagnetic phase [1]. It is based on ab-initio molecular dynamics and simultaneous redistributions of the disordered but finite local magnetic moments. We apply this disordered local moments molecular dynamics (DLM-MD) method to the case of CrN and simulate its equation of state. In particular the debated [F. Rivadulla et al., Nat Mater 8, 974 (2009); B. Alling et al., Nat Mater 9, 283 (2010)] bulk modulus is calculated in the paramagnetic cubic phase and is shown to be very similar to that of the antiferromagnetic orthorhombic CrN phase for all considered temperatures.

1:39PM J28.00009 Lattice dynamics of anharmonic solids from first principles, OLLE HELLMAN, IGOR ABRIKOSOV, SERGEI SIMAK, IFM, Linköping University, Sweden — An accurate and easily extendable method to deal with lattice dynamics of solids is offered. It is based on first-principles molecular dynamics simulations and provides a consistent way to extract the best possible harmonic—or higher order—potential energy surface at finite temperatures. It is designed to work even for strongly anharmonic systems where the traditional quasi-harmonic approximation fails. The accuracy and convergence of the method are controlled in a straightforward way. Excellent agreement of the calculated phonon dispersion relations at finite temperature with experimental results for bcc Li and bcc Zr is demonstrated. In addition to that the bcc-hcp phase diagram for Zr is calculated with high accuracy. arXiv:1103.5590v3 [cond-mat.mtrl-sci]

1:51PM J28.00010 Unified cluster expansion method applied to the configurational thermodynamics of cubic $\text{Ti}_{1-x}\text{Al}_x\text{N}$, BJÖRN ALLING, IFM, Linköping University, ANDREI RUBAN, MSE, Royal Institute of Technology, Sweden, AYAT KARIMI, IPMC, École Polytechnique Fédérale de Lausanne, Switzerland, LARS HULTMAN, IGOR ABRIKOSOV, IFM, Linköping University — We study the thermodynamics of cubic $\text{Ti}_{1-x}\text{Al}_x\text{N}$ using a unified cluster expansion approach for the alloy problem [1]. The purely configurational part of the alloy Hamiltonian is expanded in terms of concentration and volume-dependent effective cluster interactions. By separate expansions of the chemical fixed lattice, and local lattice relaxation terms of the ordering energies, we demonstrate how the screened generalized perturbation method can be fruitfully combined with a concentration-dependent Connolly-Williams cluster expansion method, getting the best out of both two schemes that are traditionally used separately. Utilizing the obtained Hamiltonian in Monte Carlo simulations we access the free energy of $\text{Ti}_{1-x}\text{Al}_x\text{N}$ alloys and construct the isostructural phase diagram. The results show striking similarities with the previously obtained mean-field results: The metastable c-TiAlN is subject to coherent spinodal decomposition over a large part of the concentration range, e.g., from $x \approx 0.33$ at 2000 K.

2:03PM J28.00011 Atomistic modeling of thermodynamic equilibrium of plutonium, TONGSIK LEE, STEVE VALONE, Los Alamos National Laboratory, MIKE BASKES, Los Alamos National Laboratory and University of California, San Diego, SHAO-PING CHEN, Los Alamos National Laboratory, ANDREW LAWSON, Retired — Plutonium metal has complex thermodynamic properties. Among its six allotropes at ambient pressure, the fcc delta-phase exhibits a wide range of anomalous behavior: extraordinarily high elastic anisotropy, largest atomic volume despite the close-packed structure, negative thermal expansion, strong elastic softening at elevated temperature, and extreme sensitivity to dilute alloying. An accurate description of these thermodynamic properties goes far beyond the current capability of first-principle calculations. An elaborate modeling strategy at the atomic level is hence an urgent need. We propose a novel atomistic scheme to model elemental plutonium, in particular, to reproduce the anomalous characteristics of the delta-phase. A modified embedded atom method potential is fitted to two energy-volume curves that represent the distinct electronic states of plutonium in order to embody the mechanism of the two-state model of Weiss, in line with the insight originally proposed by Lawson et al. [Philos. Mag. 86, 2713 (2006)]. By the use of various techniques in Monte Carlo simulations, we are able to provide a unified perspective of diverse phenomenological aspects among thermal expansion, elasticity, and phase stability.

Session J29 GQI: Focus Session: Quantum Information for Quantum Foundations - Informational Principles and Fundamental Structures 259A

11:15AM J29.00001 Information Causality as a physical principle, VALERIO SCARANI, Centre for Quantum Technologies and Department of Physics, National University of Singapore — It is known that the physical principle of “no-signaling” alone does not single out quantum correlations, and that the post-quantum no-signaling correlations share many of the features that are supposed to define quantum physics (intrinsic randomness, no-cloning, violation of Bell’s inequalities...). This talk focuses on the principle of Information Causality (IC), which generalizes no-signaling and has been proved to come close to singling out quantum correlations. I shall review the successes of IC and also the difficulties that the subsequent research is meeting. In particular, I shall emphasize how a generalization of the initial bipartite scenario to a multipartite one is a most urgent necessary step.

11:51AM J29.00002 Tensor network states for quantum foundations, JACOB BIAMONTE, CQT Singapore, ISI Foundation Torino — Penrose developed a graphical language to reason about networks of connected tensors and applied these techniques to quantum theory. Here we present the development of a framework and tool set based on Penrose tensor networks that enables one to address certain questions of a foundational nature in quantum theory. A quantum tensor theory is one in which a fixed collection of tensors with clearly defined composition laws defines a physical theory. We show that each element of a universal collection of such tensors gives rise to a physical operation, allowed by the rules of quantum mechanics. Although each of these (possibly) atemporal operations is indeed physical, certain sequences of them could represent processes that violate the rules of quantum theory. The question is to determine when this is the case and we arrive at some perplexing conclusions.

12:03PM J29.00003 On the Feynman Problem¹, GIACOMO D'ARIANO, Università di Pavia — Foundations of Quantum Field Theory can be connected to foundations of Quantum Theory if we can derive the former in terms of the latter with two additional postulates of locality and topological homogeneity of interactions between quantum systems, in the hypothesis that a quantum field is ultimately made of a numerable set of quantum systems that are unitarily interacting. But, in order to do that we need to be able to simulate quantum field by a quantum computer. In the paper “Simulating Physics with Computers” (Int. J. Th. Phys, 21 467 (1982)) Richard Feynman raised the problem whether it is possible to simulate Fermi fields by a quantum computer—in short if we can “qubit-ize” a Fermi field, keeping the field interaction local on qubits. In this talk I will show how this problem is solved for any space-dimension, upon introducing a new general Jordan-Wigner map between field and qubits, and by adding witnessing auxiliary qubits. I will also derive the unique vacuum for the Fermi fields and for the auxiliary fields. The solution of the Feynman problem allows us to simulate quantum fields by a quantum cellular automata, also providing a kind of Planck-scale version of quantum field theory. Computer simulations will be projected at the end of the talk

¹Founded by Coquit FP7 project, Italian PRIN and INFN.

12:15PM J29.00004 Origin of Feynman’s Rules of Quantum Theory and Complementarity, PHILIP GOYAL, SUNY Albany — Complex numbers are an intrinsic part of the mathematical formalism of quantum theory, and are perhaps its most mysterious feature. If one considers how to combine experimental arrangements to generate new experimental arrangements, a set of five simple symmetries involving two binary operators naturally arises. Recently, I have shown that these symmetries, together with the probabilistic nature of measurement outcomes and the principle of complementarity (formalized in a novel way as the Principle of Information Duality) naturally lead to Feynman’s rules of quantum theory (including their complex nature) [1]. In this paper, I present recent development of this work showing that the assumption of complementarity can be dropped, and, instead, a fundamental theorem from number theory—Frobenius’ theorem—can be applied to show that the only formalism compatible with the experimental symmetries are real and complex quantum theory. I shall conclude with a discussion of physical principles which can be used to rule out real quantum theory.

[1] Origin of Complex Quantum Amplitudes and Feynman’s Rules, P. Goyal, K. Knuth, J. Skilling, Phys. Rev. A 81, 022109 (2010)

12:27PM J29.00005 Partially Ordered Sets of Quantum Measurements and the Dirac Equation

, KEVIN H. KNUTH, SUNY Albany — Events can be ordered according to whether one event influences another. This results in a partially ordered set (poset) of events often referred to as a causal set. In this framework, an observer can be represented by a chain of events. Quantification of events and pairs of events, referred to as intervals, can be performed by projecting them onto an observer chain, or even a pair of observer chains, which in specific situations leads to a Minkowski metric replete with Lorentz transformations (Bahreyni & Knuth, 2011. APS B21.00007). In this work, we unify this picture with the Process Calculus, which coincides with the Feynman rules of quantum mechanics (Goyal, Knuth, Skilling, 2010, arXiv:0907.0909; Goyal & Knuth, Symmetry 2011, 3(2), 171), by considering quantum measurements to be events. This is performed by quantifying pairs of events, which represent transitions, with a pair of numbers, or a quantum amplitude. In the 1+1D case this results in the Feynman checkerboard model of the Dirac equation (Feynman & Hibbs, 1965). We further demonstrate that in the case of 3+1 dimensions, we recover Bialnycki-Birula's (1994, Phys. Rev. D, 49(12), 6920) body-centered cubic cellular automata model of the Dirac equation studied more recently by Earle (2011, arXiv:1102.1200v1).

12:39PM J29.00006 An Observer-Based Foundation of Geometry

, NEWSHAW BAHREYNI, Department of Physics, University at Albany, Albany NY 12222, KEVIN H. KNUTH, Department of Physics, University at Albany, Albany NY 12222, Department of Informatics, University at Albany, Albany NY 12222 — The fact that some events influence other events enables one to define a partially ordered set (poset) of events, often referred to as a causal set. A chain of events, called observer chain, can be quantified by labeling its events numerically. Other events in a poset may be quantified with respect to an observer chain/chains by projecting them onto the chain, resulting in a pair of numbers. Similarly, pairs of events, called intervals, can be quantified with four numbers. Under certain conditions, this leads to the Minkowski metric, Lorentz transformations and the mathematics of special relativity (Bahreyni & Knuth, APS March Meeting 2011). We exploit the same techniques to demonstrate that geometric concepts can be *derived* from order-theoretic concepts. We show how chains in a poset can be used to define points and line segments. Subsequent quantification results in the Pythagorean Theorem and the inner product as well as other geometric concepts and measures. Thus the geometry of space, which is assumed to be fundamental, emerges as a result of quantifying a partially ordered set. More importantly, this proposed foundation of geometry is entirely observer-based, which may provide a natural way toward integration with quantum mechanics.

12:51PM J29.00007 Quantum state space as a maximal consistent set¹

, GELO NOEL TABIA, University of Waterloo, Perimeter Institute for Theoretical Physics, and Institute for Quantum Computing — Measurement statistics in quantum theory are obtained from the Born rule and the uniqueness of the probability measure it assigns through quantum states is guaranteed by Gleason's theorem. Thus, a possible systematic way of exploring the geometry of quantum state space expresses quantum states in terms of outcome probabilities of a symmetric informationally complete measurement. This specific choice for representing quantum states is motivated by how the associated probability space provides a natural venue for characterizing the set of quantum states as a geometric construct called a maximal consistent set. We define the conditions for consistency and maximality of a set, provide some examples of maximal consistent sets and attempt to deduce the steps for building up a maximal consistent set of probability distributions equivalent to Hilbert space. In particular, we demonstrate how the reconstruction procedure works for qutrits and observe how it reveals an elegant underlying symmetry among five SIC-POVMs and a complete set of mutually unbiased bases, known in finite affine geometry as the Hesse configuration.

¹This work was supported in part by the U. S. Office of Naval Research (Grant No. N00014-09-1-0247).

1:03PM J29.00008 SIC-POVMs and Lie Algebras¹

, HOAN DANG, Perimeter Institute for Theoretical Physics and University of Waterloo, MARCUS APPLEBY, CHRISTOPHER FUCHS, Perimeter Institute for Theoretical Physics — A symmetric informationally complete positive operator valued measure (SIC-POVM) is usually thought of as a highly symmetric structure in quantum state space. However Appleby, Flammia and Fuchs (J. Math. Phys. 52, 022202, 2011) have shown that the existence of a SIC-POVM in dimension d is equivalent to a proposition concerning the Lie Algebra $\mathfrak{gl}(d, \mathbb{C})$. Related to this they show that there is, associated to each SIC-POVM, a rich and intricate geometric structure in the adjoint representation space of $\mathfrak{gl}(d, \mathbb{C})$. In this talk we present a deeper exploration of this structure.

¹This work was supported in part by the U. S. Office of Naval Research (Grant No. N00014-09-1-0247) and by the Natural Sciences and Engineering Research Council of Canada.

1:15PM J29.00009 The Galois Group of Symmetric Measurements

, MARCUS APPLEBY, Perimeter Institute, 31 Caroline St N, Waterloo, Ontario, Canada, HULYA YADSAN-APPLEBY, University College, Gower St, London WC1E 6BT, UK, GERHARD ZAUNER, None — The problem of proving (or disproving) the existence of symmetric informationally complete positive operator valued measures (SICs) has been the focus of much effort in the quantum information community during the last 12 years. In this talk we describe the Galois invariances of Weyl-Heisenberg covariant SICs (the class which has been most intensively studied). It is a striking fact that the published exact solutions (in dimensions 2–16, 19, 24, 35 and 48) are all expressible in terms of radicals, implying that the associated Galois groups must be solvable. Building on the work of Scott and Grassl (J. Math. Phys. 51, 042203 (2010)) we investigate the Galois group in more detail. We show that there is an intriguing interplay between the Galois and Clifford group symmetries. We also show that there are a number of interesting regularities in the Galois group structure for the cases we have examined. We conclude with some speculations about the bearing this may have on the SIC existence problem.

1:27PM J29.00010 Quantum Nonlocal Boxes Exhibit Stronger Distillability

, JIBRAN RASHID, PETER HOYER, University of Calgary — Given the apparent limited distillability of nonlocal boxes (NLBs), we initiate a study of the distillation of correlations for NLBs that output quantum states rather than classical bits. We propose a new non-adaptive protocol for nonlocality distillation which asymptotically distills correlated quantum nonlocal boxes to the value 3.098, whereas in contrast, the optimal non-adaptive parity protocol for classical NLBs asymptotically distills to the value 3.0. The protocol is also proven to be an optimal non-adaptive protocol for 1, 2 and 3 copies by formulating nonlocality distillation as a semi-definite programming optimization problem. Even if we restrict our attention to non-adaptive protocols, qNLBs offer improved distillation over NLBs. A generalization of our SDP approach that allows for adaptive protocols may reveal a similar improvement in general. This may imply distillability for nonlocal correlations that are currently not known to be distillable. As a consequence of the work on nonlocality distillation we provide numerical evidence that correlations with non-trivial marginals which are not known to satisfy the macroscopic locality principle may be distillable even when corresponding correlations with trivial marginals are not.

1:51PM J29.00012 ABSTRACT WITHDRAWN —

2:03PM J29.00013 The necessity of entanglement and the equivalency of Bell's theorem with the second law of thermodynamics¹, IAN DURHAM, Saint Anselm College — We demonstrate that both Wigner's form of Bell's inequalities as well as a form of the second law of thermodynamics, as manifest in Carathéodory's principle, can be derived from the same assumptions. The results suggest that Bell's theorem is merely a well-disguised statement of the second law. It also suggests that entanglement is necessary for quantum theory to be in full accord with the second law.

¹Work partially supported by a grant from FQXi.

Tuesday, February 28, 2012 11:15AM - 2:15PM – Session J30 GQI: Open Quantum Systems and Decoherence 259B

11:15AM J30.00001 Heisenberg scaling of time-limited quantum metrology with realistic decoherence, MAXIME HARDY, WILLIAM A. COISH, Department of Physics, McGill University, Montreal, Quebec, Canada H3A 2T8 — The prospect of using entanglement to improve various metrology tasks is one of the most promising avenues for a near-term real-world benefit from genuine quantum phenomena [1]. However, in the standard scenario, history-independent Markovian dephasing removes the quantum advantage [2]. We revisit the problem of quantum metrology using the model of trapped ions subject to non-Markovian phase damping decoherence caused by Gaussian noise with finite correlation length and time (a slight generalization of the model used in Ref. [3]). Assuming a fixed available measurement time shorter than the noise correlation time (the non-Markovian limit) and a noise source that is local in space, we recover Heisenberg scaling ($\sim 1/N$). This allows one to measure an "instantaneous" frequency to a higher precision than the time-averaged noise amplitude and moreover to a higher precision than classically allowed. Interestingly, for this protocol we show that the optimal number of measurements to be performed within the measurement time is three.

11:27AM J30.00002 ABSTRACT WITHDRAWN –

11:39AM J30.00003 Entanglement and diffusive behavior of a driven Floquet system coupled to noise¹, BENJAMIN M. FREGOSO, JUSTIN WILSON, VICTOR GALITSKI, JQI, UMD — Attempting to improve the persistence of quantum effects in systems interacting with a bath, we consider a periodically-driven quantum system and focus on its quantum dynamics in the Floquet space. As a toy model, we first consider a harmonic oscillator interacting with a bath and investigate the diffusive behavior in the statistics of observables in the presence of a periodic driving force and analyze the system within the Floquet theory. We then extend this analysis to look at the entanglement of two oscillators interacting with a bath, and investigate whether a periodic driving force can improve the persistence of entanglement between the two systems. We discuss possible experimental realization of our exactly-solvable model with trapped ions. We discuss a Lie-algebraic contraction scheme to map the oscillator properties to spin the systems in an environment. Extensions of our theory to more complicated driven quantum systems will also be discussed. This research is supported by JQI-PFC.

11:51AM J30.00004 A Lie-algebraic approach to decoherence in a quantum spin system¹, JUSTIN WILSON, BENJAMIN FREGOSO, VICTOR GALITSKI, Joint Quantum Institute, University of Maryland, College Park — Quantum spin systems interacting with environment lose quantum coherence and information due to the debilitating effects of the noise. Quantitative description of decoherence even in the simplest spin-1/2 systems is technically complicated and the conventional approach (e.g., calculating T_1 and T_2) involves a number of strong approximations. In order to go beyond this approximation scheme and identify its regime of validity, we use the Lie-algebraic contraction, which reduces the $su(2)$ algebra into the solvable oscillator algebra to connect the two dynamical systems. We take advantage of the general exact solution to the latter and build a regular expansion in the contraction parameter to describe dissipative quantum dynamics of the spin. This procedure allows for a controlled non-perturbative treatment of the non-Markovian effects. New interesting effects include deviations from pure diffusion due to bath spectrum and non-Markovian effects in both systems. Our approach could shed light on the spin decoherence problem and noise characterization in experiments relevant for quantum computing.

12:03PM J30.00005 Quantum simulator of an open quantum system using superconducting qubits: exciton transport in photosynthetic complexes, SARAH MOSTAME, PATRICK REBENTROST, ALEXANDER EISFELD, Harvard University, ANDREW J. KERMAN, Lincoln Laboratory - Massachusetts Institute of Technology, DIMITRIS I. TSOMOKOS, University of London, ALAN ASPURU-GUZIK, Harvard University — In the initial stage of photosynthesis, light-harvested energy is transferred with remarkably high efficiency to a reaction center, with the vibrational environment assisting the transport mechanism. It is of great interest to mimic this process with present-day technologies. Here we propose an analog quantum simulator of open system dynamics, where noise engineering of the environment has a central role. In particular, we propose the use of superconducting qubits for the simulation of exciton transport in the Fenna-Matthew-Olson protein, a prototypical photosynthetic complex. Our method allows for a single-molecule implementation and the investigation of energy transfer pathways as well as non-Markovian and spatiotemporal noise-correlation effects.

12:15PM J30.00006 Quantum signatures of chaos in quantum tomography¹, VAIBHAV MADHOK, CARLOS RIOFRIO, IVAN DEUTSCH, University of New Mexico — We study the connection between quantum chaos and information gain in the time series of a measurement record used for quantum tomography. The record is obtained as a sequence of expectation values of a Hermitian operator evolving under repeated application of the Floquet operator of the quantum kicked top on a large ensemble of identical systems. We find an increase in information gain and hence higher fidelities in the process when the Floquet maps employed increase in chaoticity. We make predictions for the information gain using random matrix theory in the fully chaotic regime and show a remarkable agreement between the two. Finally we discuss how this approach can be used in general as a benchmark for information gain in an experimental implementation based on nonlinear dynamics of atomic spins measured weakly by a the Faraday rotation of a laser probe.

¹CQUIC (Center for Quantum Information and Control)

12:27PM J30.00007 Non-Markovian behavior of small and large complex quantum systems, CARLOS PINEDA, Instituto de Fisica, Universidad Nacional Autonoma de Mexico, Mexico D.F. 01000, Mexico, MARKO ZNIDARIC, Physics Department, Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, Slovenia, IGNACIO GARCÍA-MATA, Instituto de Investigaciones Fisicas de Mar del Plata (IFIMAR-CONICET), Funes 3350, 7600 Mar del Plata, Argentina — The channel induced by a complex system interacting strongly with a qubit is calculated exactly under the assumption of randomness of its eigenvectors. The resulting channel is represented as an isotropic time dependent oscillation of the Bloch ball, leading to non-Markovian behavior, even in the limit of infinite environments. Two contributions are identified: one due to the density of states and the other due to correlations in the spectrum. Prototype examples, one for chaotic and the other for regular dynamics are explored.

12:39PM J30.00008 Quantum correlation of an optically controlled open quantum system¹, CHING-KIT CHAN, L.J. SHAM, Department of Physics, Center for Advanced Nanoscience, University of California San Diego — A precise time-dependent optical control of an open quantum system relies on an accurate account of the quantum interference among the system, the photon control and the dissipative environment. In the spirit of the Keldysh non-equilibrium Green's function approach, we develop a diagrammatic technique to precisely calculate this quantum correlation for a fast multimode coherent photon control against slow relaxation, valid for both Markovian and non-Markovian systems. We demonstrate how this novel formalism can lead to a better accuracy than existing approximations of the master equation. We also describe extensions to cases with controls by photon state other than the coherent Glauber state.

12:51PM J30.00009 Effects of counter rotating terms on quantum discord and entanglement between two atoms in a dissipative cavity, FERDI ALTINTAS, RESUL ERYIGIT, Abant Izzet Baysal University — We have investigated the role of counter-rotating interaction terms in the Rabi Hamiltonian on the creation and dynamics of entanglement and quantum discord between two identical atoms interacting with a lossy single mode cavity field for a system initially in different product states. For some initial states, the counter-rotating terms are found to lead to steady states in the long time limit which can have high quantum discord, but have no entanglement. The effect of cavity decay rate on these steady states quantum discord has been also investigated, surprisingly the increase in cavity decay rate is found to enhance the steady state quantum discord. Moreover, for certain initial states the effect of counter rotating terms are found to be detrimental to the quantum correlations when counter rotating terms in interaction Hamiltonian are taken into account.

1:03PM J30.00010 Pointer state engineering in open quantum systems¹, LORENZA VIOLA, KAVEH KHODJASTEH, Dartmouth College, VIATCHESLAV DOBROVITSKI, Ames Laboratory — Pointer states have a long history in fundamental quantum theory and a practical relevance as long-lasting high-fidelity states in open quantum systems. For generic dissipative dynamics, however, pointer states need not exist or, when they do, need not coincide with states of interest. I will show how open-loop control procedures may be used to engineer dissipation in such a way that any desired initial pure state can be guaranteed to survive with high minimum fidelity over time and retrieved on demand. Quantitative fidelity bounds and constructive control protocols will be presented, and validated through simulation in paradigmatic single- and two- qubit dissipative scenarios. I will also argue that the state selectivity observed in recent dynamical decoupling experiments can be naturally understood within the pointer state engineering framework.

1:15PM J30.00011 Crossover from adiabatic to antiadiabatic quantum pumping with dissipation¹, GIUSEPPE ERNESTO SANTORO, FRANCO PELLEGRINI, SISSA and CNR/IOM, CARLOTTA NEGRI, FABIO PISTOLESI, Laboratoire d'Ondes et Matière d'Aquitaine, CNRS and Université de Bordeaux, NICOLA MANINI, ETSF and Dipartimento di Fisica, Università degli Studi di Milano, ERIO TOSATTI, SISSA and CNR/IOM — Quantum pumping, in its different forms, is attracting attention from different fields, from fundamental quantum mechanics, to nanotechnology, to superconductivity. We investigate the crossover of quantum pumping from the adiabatic to the anti-adiabatic regime in the presence of dissipation, and find general and explicit analytical expressions for the pumped current in a minimal model describing a system with the topology of a ring forced by a periodic modulation of frequency ω . The solution allows following in a transparent way the evolution of pumped DC current from much smaller to much larger ω values than the other relevant energy scale, the energy splitting introduced by the modulation. We find and characterize a temperature-dependent optimal value of the frequency for which the pumped current is maximal.

¹Research supported by the Italian CNR through ESF Eurocore/FANAS/AFRI, by the Italian Ministry of University and Research, through PRIN 20087NX9Y7, and by the French ANR, contract QNM ANR10-BLAN-0404-03.

1:27PM J30.00012 Open Quantum Walks and Dissipative Quantum Computing, FRANCESCO PETRUCCIONE, University of KwaZulu-Natal — Open Quantum Walks (OQWs) have been recently introduced as quantum Markov chains on graphs [S. Attal, F. Petruccione, C. Sabot, and I. Sinayskiy, E-print: <http://hal.archives-ouvertes.fr/hal-00581553/fr/>]. The formulation of the OQWs is exclusively based upon the non-unitary dynamics induced by the environment. It will be shown that OQWs are a very useful tool for the formulation of dissipative quantum computing and quantum state preparation. In particular, it will be shown how to implement single qubit gates and the CNOT gate as OQWs on fully connected graphs. Also, OQWs make possible the dissipative quantum state preparation of arbitrary single qubit states and of all two-qubit Bell states. Finally, it will be shown how to reformulate efficiently a discrete time version of dissipative quantum computing in the language of OQWs.

1:39PM J30.00013 Non-Markovian dynamics of a solid-state charge qubit measured by a quantum point contact, CHUNG-CHIN JIAN, PO-WEN CHEN, HSI-SHENG GOAN, Department of Physics, National Taiwan University, NTU TEAM — We study a system of a charge qubit consisting of an electron in two coupled quantum dots (CQD's) detected by a quantum point contact (QPC). We derive perturbatively the non-Markovian quantum master equation for the CQD's system and calculate the transport current through the QPC (considered as a reservoir) to second order in the system-reservoir interaction. The non-Markovianity of the whole system comes from the energy-dependent tunneling amplitudes and energy-dependent densities of states of the QPC, which are modeled as a spectral density with a Lorentzian shape. In the non-Markovian case, the decay coefficients in the derived master equation and transport current are time-dependent and involve the real and imaginary parts of the contributions from the QPC reservoir correlation functions. In the wide-band limit (WBL), the various Markovian master equations in different parameter regimes are recovered, and the contributions of the imaginary parts are found to vanish. However, in the non-Markovian regime, the contributions of the imaginary parts significantly influence the dynamics of the charge qubit and thus the transport current. Especially, the non-Markovian transient currents through QPC differ significantly from the WBL Markovian counterparts and thus may serve as a witness for the non-Markovian behavior in the QPC-qubit system.

1:51PM J30.00014 Hierarchical equations of motion: A fundamental theory for quantum open systems¹, YIJING YAN, Hong Kong University of Science and Technology — As a powerful alternative to the influence functional path integral formalism, HEOM has been exploited in the study of various systems. In this talk, I will present some recent advancement on the HEOM-based nonlinear/nonequilibrium response theory and efficient implementation methods. Numerical demonstrations include coherent two-dimensional spectroscopy signals of light-harvesting model systems, and transport current noise spectrums through Anderson model quantum dots, operated in high-order co-tunneling regime.

¹Supported partially by the Hong Kong UGC (AoE/P-04/08-2) and China NNSF (No.21033008).

2:03PM J30.00015 Fidelity of the ground state in adiabatic quantum computation, QIANG DENG, DMITRI AVERIN, Department of Physics and Astronomy, Stony Brook University, MOHAMMAD AMIN, PETER SMITH, D-Wave Systems Inc., Canada — The energy gap between the ground and excited states of a qubit register performing an adiabatic quantum computation (AQC) algorithm is expected to provide additional stability against decoherence by environmental noise. However, the precise quantitative magnitude of this effect is still an open question. In this work, we show that fidelity of the ground state provides the ultimate quantitative measure of the AQC stability against decoherence. Even if the qubit register is not driven out of the ground state by the time evolution of the algorithm, the ground state is deformed by the qubit-environment interaction. The extent of this deformation can be characterized by the same noise correlators that determine the relaxation rates in the gate-model QC. We derive finite-temperature expression for the ground-state fidelity and calculate it numerically for the 16-qubit instances of adiabatic quantum optimization.

Tuesday, February 28, 2012 11:15AM - 2:15PM –
Session J31 DMP: Focus Session: Topological Insulators: Synthesis and Characterization -
Transport 260

11:15AM J31.00001 Transport in Topological Insulator Thin Films, VALLA FATEMI, HADAR STEINBERG, JEAN-BAPTISTE LALOE, FERHAT KATMIS, LUCAS ORONA, JAGADEESH MOODERA, PABLO JARILLO-HERRERO, MIT — We report on electronic transport measurements on Bi₂Se₃ thin-film devices and show that an ambipolar modulation can be achieved via the electric field effect by using a top-gate with a high- κ dielectric insulator. By analyzing the evolution of the weak anti-localization magnetoconductance behavior with respect to gate voltage and temperature, we find that we are able to modulate the effective number of channels, demonstrating that the coherent coupling between the surface and the bulk is tunable. Moreover, we investigate the formation and behavior of tunable p-n junctions on thin-film devices with multiple local top-gates.

11:27AM J31.00002 Bi₂Se₃ and Bismuth: A comparison of transport in topological and trivial materials¹, ANTHONY RICARDELLA, Penn State University, MICHEL VAN MAASAKKERS, Eindhoven University of Technology, DUMING ZHANG, JOON SUE LEE, NITIN SAMARTH, Penn State University — The simple surface state structure of Bi₂Se₃ has made it one of the most promising materials for harnessing transport through topologically protected surface states. Identifying unambiguous signatures of transport through these states is difficult however due to residual bulk conductivity and the formation of 2D electron gases near the surface due to band bending. As in bulk bismuth these non-topological states are subject to strong-spin orbit coupling. Very thin films of bismuth are predicted to be 2D topological insulators and thus are interesting themselves for a topological to non-topological transition as a function of thickness. Analysis of signatures such as weak anti-localization and linear magnetoresistance are compared between high quality MBE grown films of these materials to determine what can and cannot be ascribed to transport through protected surface states.

¹Supported by DARPA and NSF-MRSEC.

11:39AM J31.00003 Low-temperature magnetoresistance in electrically gated Bi₂Se₃ thin films, J.S. LEE, A.M. DASILVA, A. RICARDELLA, D.M. ZHANG, J.K. JAIN, NITIN SAMARTH, Dept. of Physics, Penn State University, University Park PA 16802 — Although transport in samples of 3D topological insulators often has a large contribution from bulk conduction, the surface transport can be studied by electrical gating of topological insulator thin films. We have measured thin films of Bi₂Se₃ grown by molecular beam epitaxy and subsequently photolithographically patterned with a high- κ gate dielectric (HfO₂) using atomic layer deposition. Gate voltage-dependent Hall effect and magnetoresistance were measured over a temperature range $0.5\text{K} \leq T \leq 20\text{K}$ in both perpendicular and parallel magnetic fields up to 6 T. Applying a negative gate voltage forms a depletion layer at the top of the thin film and decouples the surface from bulk carriers. We use the weak antilocalization effect at low magnetic field to study the transport contribution of surface and bulk channels. We also discuss scattering mechanisms contributing to surface and bulk conduction. Supported by ONR and NSF-MRSEC.

11:51AM J31.00004 Thickness Independent Surface Transport of Bi₂Se₃ on Al₂O₃(0001) Substrates, NAMRATA BANSAL, Rutgers University, YONG SEUNG KIM, 3Graphene Research Institute, Sejong University, South Korea, MATTHEW BRAHLEK, ELIAV EDREY, SEONGSHIK OH, Rutgers University — The key requirement for exploiting the newly emerging three-dimensional (3D) topological insulators (TI) as a novel platform for coherent spin-polarized electronics is TI thin films with dominant surface transport properties. So far, while researchers have been able to observe the existence of surface states locally *in situ*, verification over a wide thickness range outside the growth chamber has not yet been reported. Here, we report large signature of surface transport in TI Bi₂Se₃ thin films. The Bi₂Se₃ films used for this study were grown on c-axis Al₂O₃ substrates with MBE. Hall-effect measurements in the standard Van der Pauw geometry provided clear evidence of two conducting channels for 4QL-2750QL thick samples, with the transport properties for one of the channel being thickness independent and the other varying with thickness. This thickness independent carrier density of $\sim 1.5 \times 10^{13} \text{ cm}^{-2}$ has been observed over the entire thickness range down to 2 QL, clearly suggesting that this is due to surface states. Furthermore, another surface transport property directly related to the topological protection mechanism, the weak-antilocalization (WAL) effect, exhibited similar thickness- and bulk-independent characteristics.

12:03PM J31.00005 Electronic transport in MBE-grown Bi₂Se₃ topological insulator thin film field effect devices, TAI-LUNG WU, JIFA TIAN, HELIN CAO, YI XUAN, Department of Physics and Birck Nanotechnology Center, Purdue University, West Lafayette, IN 47907, XINYU LIU, JACK FURDYNA, Department of Physics, University of Notre Dame, Notre Dame, IN 46556, YONG P. CHEN, Department of Physics and Birck Nanotechnology Center, Purdue University, West Lafayette, IN 47907, QMD TEAM — Topological insulators (TI), such as Bi₂Se₃ and Bi₂Te₃, have attracted a lot of attention due to their exotic electronic properties. Bi₂Se₃ TI films grown by molecular beam epitaxy (MBE) are promising for studying the nature of topologically protected surface states due to their large size, high quality, the capability to tune the thickness and interface with various semiconductor substrates. In this study, thin films of Bi₂Se₃ have been grown on GaAs (001) semi-insulating substrates in a III-V/II-VI dual chamber MBE system. To study the electronic properties, micrometer scale Hall-bar devices with high- κ dielectric (Al₂O₃) top gates have been fabricated. Systematical measurements of temperature dependent and electrical field modulated magnetotransport are performed to exam the conduction contributed by the surface states.

12:15PM J31.00006 Weak anti-localization behavior in Bi₂(SeTe)₃ grown on GaAs (001) substrate, JOSEPH HAGMANN, JACEK FURDYNA, MALGORZATA DOBROWOLSKA, XINYU LIU, University of Notre Dame — A series of Bi₂(SeTe)₃ thin films were grown by molecular beam epitaxy on GaAs(001) substrates in order to obtain ternary Te-Bi-Se-Bi-Te alloys with large bulk resistivities. X-Ray diffraction data reveals many reflections from only the {003}-type lattice planes, indicative of highly directed c-axis growth of these films despite the very different crystal symmetries of the film and the substrate along the film growth direction. The X-ray data reveal that a wide spectrum of mixed Bi₂(SeTe)₃ alloys can be obtained by this method [1]. Our studies show that the alloy films are highly uniform, and the crystallinity is comparable to that of films grown on substrates with hexagonal surface structure. In this work, we have carried out comprehensive magneto-transport measurements on a series of Bi₂(SeTe)₃ thin films. We find that the conductivities of the films are strongly affected by alloy composition, and that insulating samples can be obtained at Se concentrations of ~30%. Moreover, we observe weak anti-localization behavior in all samples, which is also composition-dependent. In order to understand diffusive transport in these topological insulator alloys, both disorder and electron-electron interaction effects are considered in our analysis. [1] X. Liu et al, J. Vac. Sci. Tech. B (submitted).

12:27PM J31.00007 Transport in topological insulator films¹, JIAN WANG, International Center for Quantum Materials, Peking University, Beijing 100871, ASHLEY DASILVA, MEENAKSHI SINGH, JOON SUE LEE, JAINENDRA JAIN, NITIN SAMARTH, MOSES H.W. CHAN, The Center for Nanoscale Science and Department of Physics, The Pennsylvania State University, University Park, PA 16802, USA, CUI-ZU CHANG, KE HE, XU-CUN MA, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, QI-KUN XUE, Department of Physics, Tsinghua University, Beijing 100084, China, HANDONG LI, MAOHAI XIE, Physics Department, The University of Hongkong, Pokfulam Road, Hongkong, China — The prediction and the subsequent confirmation of topological insulators is one of the most exciting discoveries in condensed matter physics. In the transport study of topological insulator films, we demonstrate that an excellent agreement between theory and experiment is achieved when both disorder and interaction are taken into account. In addition, measurements under an in-plane magnetic field, along and perpendicular to the bias current show opposite magnetoconductance. Furthermore, Bi₂Se₃ topological insulator thin films contacted by superconducting (In, Al and W) electrodes show an abrupt resistance upturn when the electrodes become superconducting. Concomitant with the upturn in resistance, there is a significant weakening of the superconductivity of the electrodes.

¹This work was financially supported by the Penn State MRSEC under NSF grant DMR-0820404, the National Natural Science Foundation of China (No. 11174007), and NBRP of China (No. 2012CB921300).

12:39PM J31.00008 Magneto-transport study of the topological insulator Bi₂Te₃¹, PRAMOD KUMAR, ARUNA RAMANAYAKA, RAMESH MANI, Georgia State University — Topological insulators are electronic materials that have a bulk band gap like an ordinary insulator, but have protected surface or edge states. Many materials have been realized as topological insulators, including the HgTe/CdTe superlattice, Bi_{1-x}Sb_x, Bi₂Se₃, Sb₂Te₃ and Bi₂Te₃. Topological insulators are interesting not only because of their fundamental importance but also their great potential for future applications. Here, we examine the magneto-transport properties of exfoliated Bi₂Te₃ specimens prepared from Bi₂Te₃ single crystals using the scotch tape method. Indium and silver paint contacts were applied to the exfoliated specimens and magneto-transport was examined at liquid helium temperatures at moderate magnetic fields. The results of these experiments will be described here within the context of the ongoing interest in topological insulators.

¹ARO: W911NF-07-01-0158, DOE: DE-SC0001762

12:51PM J31.00009 Theoretical study of carrier transport and screening in topological insulator Bi₂Se₃¹, SHAFFIQUE ADAM, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Gaithersburg, MD, E.H. HWANG, Condensed Matter Theory Center, University of Maryland, College Park, MD, M.D. STILES, CNST, NIST, Gaithersburg, S. DAS SARMA, CMTc, UMD, College Park — This theoretical work is motivated by two recent experiments on Bi₂Se₃ examining the charge inhomogeneity [1-2] close to the topologically protected crossing point of surface bands in these bulk topological insulators. Reminiscent of graphene close to charge neutrality [3-4], the energy landscape becomes highly inhomogeneous, forming a sea of electron and hole puddles, which determine the properties at low carrier density. Here, we show that the induced carrier density fluctuations are of order 1 % of the impurity density, providing a small-parameter with which we can perform a controlled perturbation theory. Analytic results are obtained for the minimum conductivity and puddle auto-correlation length. We also find that the band asymmetry between electron and holes states is a necessary ingredient to understand the aforementioned experiments. **References:** [1] H. 1:03PM J31.00010 Minimum conductivity and charge inhomogeneity in Bi₂Se₃ in the topological regime¹, DOHUN KIM, SUNGJAE CHO, NICHOLAS BUTCH, PAUL SYERS, KEVIN KIRSCHENBAUM, JOHNPIERRE PAGLIONE, MICHAEL FUHRER, University of Maryland — Using electrolytic and dielectric dual gating method, we report charge transport measurements of mechanically exfoliated Bi₂Se₃ in the topological insulator (TI) regime. We show that the surfaces of thin, low-doped Bi₂Se₃ crystals are strongly electrostatically coupled, and a gate electrode can be used to completely remove bulk charge carriers and bring both surfaces through the Dirac point nearly simultaneously with well-defined ambipolar electronic conduction of gapless surface states. In particular, we focus on linear carrier density dependent conductivity away from the Dirac point and a charge-inhomogeneous minimum conductivity region similar to that observed in graphene. An extension of the theory of charge disorder in graphene to Bi₂Se₃ explains well the mobility at high carrier density and the doping level at zero gate voltage. We show that the observed minimum conductivity is governed by induced carrier density that is self-consistently determined by the screened, charged impurity potential, as experimentally observed in recent STM study on surfaces of TIs.

¹The authors acknowledge support from Center for Nanophysics and Advanced Materials (CNAM).

1:15PM J31.00011 Gate-tunable electronic transport in topological insulator Bi₂Te₃ thin films synthesized by metal-organic chemical vapor deposition, HELIN CAO, Physics department, Birck Nanotechnology Center, Purdue University, West Lafayette, IN 47907, RAMA VENKATASUBRAMANIAN, JONATHAN PIERCE, Center for Solid State Energetics, RTI International, Research Triangle Park, NC 27709, TAI-LUNG WU, JIFA TIAN, ISAAC CHILDRES, Physics department, Birck Nanotechnology Center, Purdue University, West Lafayette, IN 47907, YONG CHEN, Physics department, Birck Nanotechnology Center, School of Electrical and Computer Engineering, Purdue University, West Lafayette, IN 47907 — Topological insulator is a new state of matter with a nominally insulating gap in the bulk and non-trivial metallic states on the surface. One of the proto-type topological insulator materials, Bi₂Te₃, can be synthesized in the form of high quality, wafer scale thin films by metal-organic chemical vapor deposition (MOCVD). Here we present an experimental study of Bi₂Te₃ thin films with thickness ranging from a few nm's to 1 μm synthesized by MOCVD on semi-insulating GaAs (001) substrates. Hall bar shaped devices using atomic layer deposition (ALD) high-k Al₂O₃ or HfO₂ as gate dielectric have been fabricated. We have measured the magneto-transport (including both R_{xx}, 4-terminal longitudinal resistance, and R_{xy}, the Hall resistance) at various temperatures and gate voltages to probe the possible transport signatures of the topological surface states. We have also studied gate-tunable weak anti-localization in R_{xx}(B) for ultra-thin films.

1:27PM J31.00012 Ambipolar field effect in the ternary topological insulator $(\text{Bi}_x\text{Sb}_{1-x})_2\text{Te}_3$ by composition tuning, YULIN CHEN, DESHENG KONG, JUDY CHA, QIANFAN ZHANG, JAMES ANALYTIS, KEJI LAI, ZHONGKAI LIU, SEUNG-SAE HONG, KRISTIE KOSKI, Stanford University, SUNG-KWAN MO, ZAHID HUSSAIN, Lawrence Berkeley National Lab, IAN FISHER, ZHI-XUN SHEN, YI CUI, Stanford University, STANFORD UNIVERSITY COLLABORATION, LAWRENCE BERKELEY NATIONAL LAB COLLABORATION — Topological insulators exhibit a bulk energy gap and spin-polarized surface states that lead to unique electronic properties, with potential applications in spintronics and quantum information processing. However, transport measurements have typically been dominated by residual bulk charge carriers originating from crystal defects or environmental doping, and these mask the contribution of surface carriers to charge transport in these materials. Our recent work demonstrates that the ternary sesquichalcogenide $(\text{Bi}_x\text{Sb}_{1-x})_2\text{Te}_3$ is a tunable topological insulator system. By tuning the ratio of bismuth to antimony, we are able to reduce the bulk carrier density by over two orders of magnitude, while maintaining the topological insulator properties. As a result, we observe a clear ambipolar gating effect in $(\text{Bi}_x\text{Sb}_{1-x})_2\text{Te}_3$ nanoplate field-effect transistor devices, similar to that observed in graphene field-effect transistor devices. The manipulation of carrier type and density in topological insulator nanostructures demonstrated here paves the way for the implementation of topological insulators in nanoelectronics and spintronics.

1:39PM J31.00013 Signature of Topological Insulators in Conductance Measurements, SEOKMIN HONG, VINH DIEP, SUPRIYO DATTA, Purdue University — Following the discovery of spin-polarized states at the surface of three-dimensional topological insulators (TI) like Bi_2Te_3 and Bi_2Se_3 , there are intense interests in possible electrical measurements demonstrating unique signatures of these unusual states. A recent interesting proposal suggests that a signature of TI material should be a change in the conductance measured between a normal contact and a magnetic contact when the magnetization of the latter is reversed. However, the generalized Onsager relation suggests that no such change is expected in two-terminal setups and a multi-terminal set up is needed to observe the proposed effect. We present numerical results using a Non-Equilibrium Green Function (NEGF) based model capable of covering both ballistic and diffusive transport regimes seamlessly. Simple expressions based on a semi-classical picture describe some of the results quite well. Finally, we estimate the magnitude of signal expected in realistic samples that have recently been studied experimentally and have shown evidence of surface conduction.

1:51PM J31.00014 Coupling between 3-D topological insulator and superconductor¹, VLADIMIR ORLYANCHIK, MARTIN STEHNO, CHRISTOPHER NUGROHO, DALE VAN HARLINGEN, University of Illinois at Urbana-Champaign, NAMRATA BANSAL, MATTHEW BRAHLEK, SEONGSHIK OH, Rutgers, The State University of New Jersey — Topological insulators are band insulators in the bulk with gapless topologically protected surface states. Recently it has been predicted that 3-D topological insulators (TI) can host zero energy modes called Majorana fermions. Many theoretical proposals for observation of the zero energy excitations involve coupling between the surface states of TI and s-wave superconductors (SC). A prerequisite for such experiments is a highly tunable surface which is decoupled from the residual bulk carriers and well established coupling between TI and superconductor. Here we present transport measurements performed in high quality MBE grown thin films of Bi_2Se_3 . Along with presenting evidence for significant contribution of the surface states to the electrical transport, we discuss the dependence of TI-SC coupling on temperature, gate voltage and thickness of TI films.

¹Supported by Microsoft Station-Q program

2:03PM J31.00015 Aging effect on carrier density and mobility of thin film Bi_2Se_3 and Bi_2Te_3 grown on Al_2O_3 , NIKESH KOIRALA, MATTHEW BRAHLEK, Rutgers University-Department of Physics and Astronomy, NAMRATA BANSAL, Rutgers University- Department of Electrical and Computer Engineering, SEONSHIK OH, Rutgers University-Department of Physics and Astronomy — Topological Insulators (TI) are materials with topologically protected metallic surface states and insulating bulk states. Bi_2Se_3 and Bi_2Te_3 are viable TI material as they possess bulk band gap as well as continuous surface band. However, there is bulk conduction as well in these materials due to Fermi surface lying in the bulk conduction band. Natural n-type doping due to ambient oxygen and water vapor and/or creation of Se/Te vacancies create bulk contamination, leading to change in carrier density and mobility. We report transport measurement data on epitaxially grown thin films of these materials which show the dependence of charge carrier density and mobility on environmental exposure time of these samples. In addition, we will present our data on samples capped with various materials.

Tuesday, February 28, 2012 11:15AM - 2:15PM –

Session J32 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides - Domain Structures and Switching 261

11:15AM J32.00001 Superdomains and Flux Closure Patterns in Ferroelectrics¹, MARTY GREGG, Queens University Belfast — Microstructural complexity has been a recognized feature of ferroelectric materials since the earliest optical microscopy studies on BaTiO_3 over 60 years ago,^{2,3} in which rich patterns of domain states were observed. Arlt and Sasko⁴ famously highlighted the existence of bands of domain structures forming herringbone patterns and, in so doing, helped to establish the notion that domain architectures exist over a number of different length scales: hierarchies naturally develop in which coarse-scale “superdomains” are themselves composed of sets of finer-scale “subdomains.” What was not widely recognised, was that these “superdomains” could act as functional entities in their own right, with net polarisation and spontaneous strain being the vector sum of these quantities from constituent “subdomains”. In this talk, we will explore the dominant role that superdomain functionality can have on the behaviour of ferroelectrics, at least at the meso and nanoscales. Observations made on single crystal thin film sheets and nanodots of BaTiO_3 (machined using a Focused Ion Beam Microscope) will be presented and several key points will be made: (i) that boundaries between superdomains generally adhere to the same constraints as those seen in subdomains (for example, that the divergence in the net superdomain polarisation across boundaries is zero); (ii) that superdomains demonstrate the same scaling laws (Landau-Kittel scaling) as were originally developed for simple subdomains; (iii) that ferroelectric switching can be entirely mediated by superdomains rather than subdomains; (iv) that flux closure objects, which extend beyond the nanoscale, require the existence of superdomains. The dynamics of flux closure formation, due to depolarising fields, has also been mapped and will be presented.

11:51AM J32.00002 Superdomain dynamics in single-crystal BaTiO₃ lamellae, RAYMOND MCQUAID, LEO MCGILLY, Queens University Belfast, PANKAJ SHARMA, ALEXEI GRUVERMAN, University of Nebraska, Lincoln, MARTY GREGG, Queens University Belfast — In the 1950's early studies pioneered by Merz established that 180° domain reversal in bulk BaTiO₃ could be described by a 3-stage switching process [see H. L. Stadler, *Ferroelectrics* 137, 1992]. This involved formation of a reversed domain nucleus, forward growth of a needle shaped domain towards the opposite electrode followed finally by sideways expansion. In a recent study [R. G. P. McQuaid, *Nat. Comms.* 2, 2011] we used Piezoresponse Force Microscopy (PFM) to monitor the switched domain states that developed in single-crystal BaTiO₃ slices machined (by Focused Ion Beam) to thin film thicknesses and incorporated into a coplanar geometry. We found that switched states are constrained to exist within a rigid framework of ordered ferroelastic stripe domains. Surprisingly, we see that switching occurs solely by the movement of a complex 180°-type boundary which separates 'bundles' of these domain stripes. We see that it is at the collective 'superdomain' level, rather than for individual domains, where the classic Merz nucleation and growth modes are observed. We use PFM imaging to track the realtime boundary position during switching and attempt model fits to understand its field driven dynamics.

12:03PM J32.00003 Theoretical study of ferroelectric switching of Pt/BaTiO₃ Slabs, KURT FREDRICKSON, ALEX DEMKOV, The University of Texas at Austin — BaTiO₃(BTO) is a well known ferroelectric perovskite, which is tetragonal at room temperature. The energy barrier for polarization switching is small at 9.7 meV; however, its energy barrier clamped between two metal electrodes is an open question. It has been shown (Junquera & Ghosez, *Nature* 422, 506 (2003)) that the ferroelectric behavior is highly thickness dependent. We examine thin slabs of BTO sandwiched between electrodes of Pt and calculate the polarization barriers using density functional theory to see whether the barrier should be surmountable. We have found that the energy barrier/unit cell reaches the bulk value at only 10 unit cells of BTO. We also examine the polarization of the relaxed slabs and compare them to bulk BTO, and find that the center of the slab exhibits bulk rumpling at 20 unit cells of BTO.

12:15PM J32.00004 Probing Nanoscale Ferroelectric Domain Switching Mechanisms with Scanning Probe Microscopy¹, VASUDEVA RAO ARAVIND, Clarion University of Pennsylvania, SENLI GUO, AMIT KUMAR, STEPHEN JESSE, SERGEI KALININ, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, TN, VENKATRAMAN GOPALAN, Pennsylvania State University, University Park, PA, CLARION UNIVERSITY COLLABORATION, CENTER FOR NANOPHASE MATERIALS SCIENCES COLLABORATION, PENNSYLVANIA STATE UNIVERSITY COLLABORATION — Ferroelectric domains and domain walls have been a focus topic for research, owing to their applications in memory devices, ultrasonic imaging devices, etc. Recently, ferroelectric domain walls have been demonstrated to exhibit a rich panoply of nanoscale switching behaviors (V. R. Aravind *et al*, *Physical Review B* 82, 024111 (2010)). In this presentation, we report our study of domain reversal and polarization relaxation behavior of ferroelectric domain walls under localized electric field provided by a scanning probe microscope tip. Our studies show the relaxation behaviors differs at different distances from a 180 degree domain wall, throwing light on the microscopic mechanisms of polarization reversal.

12:27PM J32.00005 In situ TEM studies of interaction between ferroelastic and ferroelastic domains during ferroelectric switching, PENG GAO, CHRISTOPHER NELSON, JACOB JOKISAARI, Department of Materials Science and Engineering, University of Michigan, SEUNG-HYUB BAEK, CHUNG WUNG BARK, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of WisconsinMadison, XIAOQING PAN, Department of Materials Science and Engineering, University of Michigan — Dynamic interaction between ferroelastic (90 degree) and ferroelectric (180 degree) domains in lead zirconate titanate during ferroelectric switching was investigated by in situ TEM. It was found that 90 degree domain walls were immobile under applied bias and act as obstacles to 180 degree domain wall motion. Pinning of the incident 180 degree domain wall occurs directly at the leading 90 degree domain wall and results in a charged head-to-head polarization vector configuration and thereby a large surface energy. This causes the roughening of the domain wall which was atomically sharp before switching. Subsequent switching occurs through the nucleation of a new domain on the opposite 90 degree domain wall and ultimately results in 180 degree switching across the film with the 90 degree domain wall still present. Although they were immobile, the 90 degree domains could sometimes be erased by an external electrical field parallel to the normal axis polarization and would return when the field was removed. This suggests that a pre-pulse opposite to the desired writing direction which momentarily erases these domains may improve switching efficiency.

12:39PM J32.00006 Vortex polarization, strain induced phase transitions and dielectric response in ultra-thin PbTiO₃ nanowires from first principles¹, GHANSHYAM PILANIA, R. RAMPRASAD, University of Connecticut — Nature of ferroelectricity in nanostructures and the resulting dielectric response are of both fundamental and applied interest. Here, using density functional theory (DFT) based computations, we investigate polarization configurations as a function of axial strain in ultra-thin PbTiO₃ [001] nanowires. Our computations involved relaxed and axially strained free-standing nanowires with varying sidewall terminations and diameters. While stress-free nanowires with their sidewalls terminated by PbO surfaces displayed purely rectilinear axial polarization at all sizes, the TiO₂-terminated nanowires, at a critical diameter of 16 Å, display a non-rectilinear vortex polarization transverse to the nanowire axis. We discuss the origins of such behavior. We also predict the existence of novel stress-induced phase transitions between the mutually exclusive vortex and the axial polarization states in both the PbO- and TiO₂-terminated nanowires. Normal mode vibrational frequency analysis of these nanowires further confirms these results. Furthermore, by employing density functional perturbation theory in combination with effective medium dielectric theory we calculate dielectric permittivity of the ferroelectric nanowires and compare it with the corresponding bulk results.

12:51PM J32.00007 Domain Wall Nucleation and Propagation within Ferroelectric Nanowires in High Strength Electric Fields¹, KEVIN MCCASH, University of South Florida, ARVIND SRIKANTH, University of Illinois at Urbana-Champaign, INNA PONOMAREVA, University of South Florida — Ferroelectric nanowires have attracted a lot of attention recently, thanks to their ability to develop electric polarization at the nanoscale [1]. Such a unique feature could potentially lead to the use of such nanowires in nanoscale, ultra fast, high-density memory elements. Here we take advantage of accurate first-principles-based simulations to study ultra fast polarization reversal in ultra thin ferroelectric nanowires made of PbTi_{0.6}Zr_{0.4}O₃ alloy. Our computational experiments reveal that polarization reversal in such nanowires is both qualitatively and quantitatively different from their bulk counterparts and exhibits unique features that could find potential use in nanoscale ferroelectric memory elements. 1:03PM J32.00008 Terahertz Frequency Dynamics of Ferroelectric Nanowires¹ , RYAN HERCHIG,

University of South Florida, KIMBERLY SCHULTZ, Carthage College, KEVIN MCCASH, INNA PONOMAREVA, University of South Florida — A thorough understanding of ferroelectric nanostructures is imperative considering their utility in creating nanoscale devices for the technology of the future. One such ferroelectric nanostructure which may prove useful in the design of nanosensors is the nanowire. We report our study on ferroelectric nanowires of $\text{Pb}(\text{Zr}_{0.4}\text{Ti}_{0.6})\text{O}_3$ alloy done using classic molecular dynamics with first-principle-based effective Hamiltonian[1] and Evans-Hoover thermostat. We found that 1) the polarization of such nanowires can be reversed and 2) that the nanowires temperature can be controlled by the application of a terahertz electric field pulse. The dependence of these properties on the frequency, width, and amplitude of the pulse is explored and discussed in addition to a possible energy dissipation mechanism. [1] L. Bellaiche *et al*, Phys. Rev. Lett. 8, 5427 (2000).

¹The present work is supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under award DE-SC0005245 (computational studies) and by the Army Research Office under contract 57787-EL.c

1:15PM J32.00009 Origin of 90° Domain Wall Pinning in $\text{Pb}(\text{Zr}_{0.2}\text{Ti}_{0.8})\text{O}_3$ Heteroepitaxial Thin

Films , DONG SU, Center for Functional Nanomaterials, Brookhaven National Lab, QINGPING MENG, MMYUNG-GEUN HAN, CMPMS, Brookhaven National Lab, CARLOS VAZ, YARON SEGAL, MATTHEW MARSHALL, FRED WALKER, Department of Applied Physics and CRISP, Yale University, MONICA SAWICKI, CHRISTINE BROADBRIDGE, Department of Physics, Southern Connecticut State University, CHARLES AHN, Department of Applied Physics and CRISP, Yale University — Researchers have studied the effect of ferroelectric fields in controlling the spin state via electric fields in multiferroic composite structures. For instance, in a bilayer system composed of a ferroelectric perovskite ($\text{PbZr}_{0.2}\text{Ti}_{0.8}\text{O}_3$) and a colossal magnetoresistive (CMR) manganite ($\text{La}_{0.8}\text{Sr}_{0.2}\text{MnO}_3$, LSMO), the spin state in the CMR film can be controlled by switching the ferroelectric polarization state, thereby generating a large magnetoelectric coupling. For this system, the domain's structure and switchability is critically important to the device's performance. We describe transmission-electron-microscopy study of the ferroelectric domains in an epitaxial $\text{Pb}(\text{Zr}_{0.2}\text{Ti}_{0.8})\text{O}_3$ (PZT) film grown on $\text{La}_{0.8}\text{Sr}_{0.2}\text{MnO}_3/\text{SrTiO}_3$ (001). We directly observe the pinning of 90° domain walls by pairs of misfit dislocations with Burgers vectors $\mathbf{a}[100]$ and $\mathbf{a}[001]$. Model calculations based on the elastic theory confirm our finding that, in addition to the depolarization field surrounding the dislocation, the strain field of misfit dislocation-pairs plays the primary role in the formation and pinning of a domains.

1:27PM J32.00010 Dynamics of Nanowalls In Ferroelectric Ultrathin Films¹ , QINGTENG ZHANG,

RYAN HERCHIG, INNA PONOMAREVA, Department of Physics, University of South Florida — Nanoscale ferroelectric films can exhibit nanostripes that are nanoscopic regions of “up” and “down” polarizations, hence forming domain walls which separate nanodomains with different polarization directions. The dynamical properties of domain walls are of technological importance since they are at the heart of ultradense ferroelectric memory technology and may play an important role in nanoscale ferroelectric sensors, actuators, and others. Here [1] we take advantage of accurate first-principle-based simulations to reveal the intrinsic dynamics of nanodomains in ultra-thin $\text{PbTi}_{0.6}\text{Zr}_{0.4}\text{O}_3$ films with thickness ranging from 2 to 20 nm. We first demonstrate that the nanodomain walls oscillate under driving AC-field of sub-switching amplitude. Secondly, we reveal that nanowalls can exhibit two types of intrinsic dynamics (resonance and relaxation) at the same frequencies. Thirdly, we prove that at nanoscale the dynamics is determined by the domain size which manifests itself via a unique size-driven transition from relaxational to resonance dynamics.

1:39PM J32.00011 Nanoscale Ferroelectric Switching in Thin Films by in-situ TEM for Magnetoelectric Applications , CHRISTOPHER NELSON, PENG GAO, JACOB JOKISAARI, University of Michigan, COLIN HEIKES, CAROLINA ADAMO, ALEXANDER MELVILLE, Cornell University, SEUNG-HYUB BAEK, CHAD FOLKMAN, University of Wisconsin-Madison, BENJAMIN WINCHESTER, YIJIA GU, Penn State University, YUANMING LIU, University of Washington, KUI ZHANG, University of Michigan, ENGE WANG, School of Physics, Peking University, China, JIANGYU LI, University of Washington, LONG-QING CHEN, Penn State University, CHANG-BEOM EOM, University of Wisconsin-Madison, DARRELL SCHLOM, Cornell University; Kavli Institute at Cornell for Nanoscale Science, Ithaca, XIAOQING PAN, University of Michigan

— The ferroelectric switching along the low-dimensional axis of nanoscale multiferroic BiFeO_3 thin films is studied in this work using in-situ transmission electron microscopy. With this technique, the atomic scale polarization distribution and the controlling influence of defects on growth kinetics are observed. Despite the inhomogeneous external field applied by a surface probe, nucleation sites are determined by the built-in fields formed within carrier depletion regions at the electrode interfaces. Homogenous full-film switching is often impeded by the pinning of domain growth by such features as point defect assemblies and from independent switching in the near-interface region. This inhomogeneity along the normal film axis has significant implications for the interpretation of surface probe ferroelectric switching measurements and for magnetoelectric applications which require ferroelastic switching at the interface.

1:51PM J32.00012 Domain dynamics during ferroelectric switching , XIAOQING PAN, PENG GAO, CHRISTOPHER NELSON, JACOB JOKISAARI, Department of Materials Science and Engineering University of Michigan, Ann Arbor, Michigan 48109, SEUNG-HYUB BAEK, CHUNG-WUNG BARK, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin, Madison, Wisconsin 53706, DARRELL SCHLOM, Department of Materials Science and Engineering Cornell University, Ithaca, NY 14853

— Ferroelectric materials are characterized by a spontaneous polarization that can be reoriented by an applied electric field. The ability to form and manipulate domains at the nanometer scale is key to device applications such as nonvolatile memories. The ferroelectric switching is mediated by defects and interfaces. Thus, it is critical to understand how the domain forms, grows, and interacts with defects. Here we show the nanoscale switching of a tetragonal $\text{PbZr}_{0.2}\text{Ti}_{0.8}\text{O}_3$ thin film under an applied electric field using *in situ* transmission electron microscopy. We found that the intrinsic electric fields formed at ferroelectric/electrode interfaces determine the nucleation sites and growth rates of domains and the orientation and mobility of domain walls, while dislocations exert a weak pinning force on domain wall motion. We also show that localized 180° polarization switching initially form domain walls along unstable planes. After removal of the external field, they tend to relax to low energy orientations. In sufficiently small domains this process results in complete backswitching. Our results suggest that even thermodynamically favored domains are still subject to retention loss, which must be mitigated by overcoming a critical domain size.

2:03PM J32.00013 Modeling Micron Size Multi-domain Ferroelectric Switching using a Massively Parallel Time Domain Phase-Field Model , KHALID ASHRAF, SAYEEF SALAHUDDIN, UC Berkeley, LABORATORY OF EMERGING AD EXPLORATORY DEVICES TEAM

— For the study of devices incorporating multi-domain ferroelectric materials, it is necessary to extend the current capabilities of the phase field model up to the micron scale where experiments are typically performed. Also arbitrary electrical and mechanical boundary conditions need to be incorporated relatively easily. In this work, we report a time domain implementation of the 3D phase field model that can simulate multi-domain ferroelectric switching. This massively parallel implementation enables us to study the switching properties of micron size devices with $\sim 10^9$ degrees of freedom. We used a mixed finite difference and finite element grid, for calculating the nonlocal electrostatic and elastic interactions respectively. All the local and non-local interactions are shown to scale linearly up to thousands of processors. The model can take into account arbitrary electrical and mechanical boundary conditions suitable for the study of devices with arbitrary structures. Using this model, we report the simulation results of ferroelectric switching in devices incorporating the multi-ferroic material BiFeO_3 . We explain the domain growth mechanism observed in multiple experiments reported recently on various surfaces of BiFeO_3 .

Tuesday, February 28, 2012 11:15AM - 2:03PM – Session J34 DCP: Focus Session: Impact of Ultrafast Lasers III: Biophysics 107A

11:15AM J34.00001 Probing Electronic Excitations in Molecules by Coherent Multidimensional UV and X Ray Spectroscopy, SHAUL MUKAMEL, University of California, Irvine — Two-dimensional ultraviolet (2DUV) spectra of protein backbone (far UV) and side chains (near UV) provide new insights into the protein structures, dynamics and functions. Simulated chirality-induced 2DUV spectra reveal characteristic patterns of protein secondary structures and allow monitoring the aggregation mechanism of amyloid fibrils and predicting the aggregation propensity of peptides. Time-domain experiments that employ sequences of attosecond x-ray pulses in order to probe electronic and nuclear dynamics in molecules are made possible by newly developed bright coherent ultrafast sources of soft and hard x-rays. By creating multiple core holes at selected atoms and controlled times it should be possible to study the dynamics and correlations of valence electrons as they respond to these perturbations. The stimulated x-ray Raman spectrum of *trans*-N-methylacetamide and Cysteine at the Nitrogen, Sulfur and the Oxygen K-edges in response to two soft x-ray pulses is calculated by treating the core excitations at the Hartree-Fock static-exchange level (STEX) level. The signal is interpreted in terms of the dynamics of valence electronic wave packets prepared and detected in the vicinity of (either the nitrogen or the oxygen) atom. The evolving electronic charge density and as electronic coherences are visualized using a basis set of time-dependent natural orbitals. Effects of orbital relaxation upon core excitations are resolved. A two-dimensional extension of the technique that involves a sequence of three resonant Raman pulses will be presented. Extensions to multidimensional spectroscopy with photoelectron detection are proposed.

11:51AM J34.00002 Conformation of self-assembled porphyrin dimers in liposome vesicles by phase-modulation 2D fluorescence spectroscopy, ALEJANDRO PERDOMO-ORTIZ, Department of Chemistry and Chemical Biology, Harvard University, GEOFFREY A. LOTT, JAMES K. UTTERBACK, Department of Physics, Oregon Center for Optics, University of Oregon, JULIA R. WIDOM, Department of Chemistry, Oregon Center for Optics, Institute of Molecular Biology, University of Oregon, ALÁN ASPURU-GUZIĆ, Department of Chemistry and Chemical Biology, Harvard University, ANDREW H. MARCUS, Department of Chemistry, Oregon Center for Optics, Institute of Molecular Biology, University of Oregon — By applying a phase-modulation fluorescence approach to 2D electronic spectroscopy (PM-2D FS), we studied the conformation-dependent exciton coupling of a porphyrin dimer embedded in a phospholipid bilayer membrane. Our measurements specify the relative angle and separation between interacting electronic transition dipole moments and thus provide a detailed characterization of dimer conformation. PM-2D FS produces 2D spectra with distinct optical features, similar to those obtained using 2D photon-echo spectroscopy. Specifically, we studied magnesium meso tetraphenylporphyrin dimers, which form in the amphiphilic regions of 1,2-distearoyl-sn-glycero-3-phosphocholine liposomes. Comparison between experimental and simulated spectra show that although a wide range of dimer conformations can be inferred by either the linear absorption spectrum or the 2D spectrum alone, consideration of both types of spectra constrain the possible structures to a “T-shaped” geometry. These experiments establish the PM-2D FS method as an effective approach to elucidate chromophore dimer conformation.

12:03PM J34.00003 2-Dimensional Fluorescence Spectroscopy: Determining the Temperature-Dependent Conformations of Porphyrin Dimers and Nucleic Acids¹, JULIA WIDOM, University of Oregon, ALEJANDRO PERDOMO-ORTIZ, ALAN ASPURU-GUZIĆ, Harvard University, ANDREW MARCUS, University of Oregon — I will describe spectroscopic studies on a covalently-linked zinc tetraphenylporphyrin dimer embedded in a phospholipid bilayer membrane. Using phase-modulation 2-Dimensional Fluorescence Spectroscopy (2D FS, a fluorescence-detected version of 2D electronic spectroscopy) along with linear absorption and fluorescence spectroscopy, it was found that the dimer adopts two predominant conformations in the membrane, and that the relative populations of these two states change as a function of temperature. Simultaneously fitting the linear absorption spectrum and the 2D FS spectra at four different excitation wavelengths revealed a wealth of information about these two states, including their relative populations, relative fluorescence quantum yields, the strength of the exciton coupling present in each state, and the approximate angles between the electronic transition dipole moments of the two porphyrins. Ongoing analysis focuses on elucidating the relaxation and energy transfer dynamics of this system through the population time dependence of the 2D spectra. Finally, I will present preliminary results from experiments in which 2D FS was performed with ultraviolet excitation to study the conformations of DNA constructs labeled with a fluorescent analogue of guanine.

12:15PM J34.00004 Probing photosynthetic structure and function using multidimensional spectroscopy, JENNIFER OGILVIE, University of Michigan — No abstract available.

12:51PM J34.00005 Exploring Relaxation Processes in Components of DNA with UV Non-linear Spectroscopy, ANDREW MORAN, BRANTLEY WEST, JORDAN WOMICK, University of North Carolina — Underlying photoinduced relaxation in DNA is a complex world of solute-solvent interactions and fluctuations in the geometries of macromolecules. Electronic excitations are rapidly deactivated by nuclear motions through conical intersections, thereby suppressing the formation of lesions (e.g., thymine dimers) known to inhibit cellular function. At the instant following internal conversion, the bases are left in “hot” quantum states, wherein a subset of vibrational modes possess a highly non-equilibrium distribution of excitation quanta. The transfer of this energy to the surrounding also involves intriguing fundamental physics. We examine these processes in small components of DNA by conducting femtosecond laser spectroscopies at cryogenic temperatures. Our experiments utilize several recent advances in nonlinear optics. Parametric processes in argon gas are used to generate 25fs pulse durations at 265nm. These short pulses are employed in a variety of measurements (e.g., transient grating, 2D photon echo, fluorescence down-conversion) with the goal of understanding relaxation mechanisms. Our data suggest that excited state deactivation in DNA is quite sensitive to the exchange of vibrational energy between the bases and segments of the backbone.

1:03PM J34.00006 Early optical response of fluorescent molecules studied by synthetic optically delayed pulses¹, ARKAPRABHA KONAR, JAY SHAH, TAPAS GOSWAMI, VADIM LOZOVY, MARCOS DANTUS, Michigan State University — The early optical response of fluorescent molecules in solution is probed by pairs of collinear pulse replicas. Two approaches are followed. First approach mimics an interferometer, replicating interference as a function of time delay between the pulses. For the second approach, each pulse spans the entire laser bandwidth, sharing no common frequencies with the second pulse, thus no interference is observed between the pulses. In both cases, the pair of pulses is delayed with attosecond resolution to study IR 144. Both fluorescence at right angles or the stimulated emission along the output beam as a function of time delay is monitored. At high intensities when approximately 10% of the dye molecules are excited, the second pulse can stimulate emission from molecules excited by the first pulse, thereby giving rise to interference fringes every 2.66 fs. When the pulse replicas are generated by multiple independent comb shaping, it is evident that the interference fringes for stimulated emission bear an out of phase relationship with those observed from fluorescence and have a maxima at time zero. This is masked with conventional pulse replicas that interfere.

¹Department of Energy

1:15PM J34.00007 Quantum mechanical light harvesting mechanisms in photosynthesis, GREGORY SCHOLES, University of Toronto — More than 10 million billion photons of light strike a leaf each second. Incredibly, almost every red-coloured photon is captured by chlorophyll pigments and initiates steps to plant growth. Last year we reported that marine algae use quantum mechanics in order to optimize photosynthesis [1], a process essential to its survival. These and other insights from the natural world promise to revolutionize our ability to harness the power of the sun. In a recent review [2] we described the principles learned from studies of various natural antenna complexes and suggested how to utilize that knowledge to shape future technologies. We forecast the need to develop ways to direct and regulate excitation energy flow using molecular organizations that facilitate feedback and control—not easy given that the energy is only stored for a billionth of a second. In this presentation I will describe new results that explain the observation and meaning of quantum-coherent energy transfer.

1:51PM J34.00008 Temperature dependence of proton transfer kinetics in the green fluorescent protein¹, BRIDGET SALNA, ABDELKRIM BENABBAS, PAUL CHAMPION, J. TIMOTHY SAGE, Northeastern University, JASPER VAN THOR, ANN FITZPATRICK, Imperial College London — In green fluorescent protein (GFP), near UV photoexcitation leads to proton transfer from the chromophore phenolic oxygen along a proton “wire” consisting of an internal water molecule, Ser205 and Glu222. Using transient absorption kinetics, the complete cycle, including the picosecond excited-state proton transfer, the nanosecond radiative emission, and the slower ground state proton back-transfer reactions have been studied holistically as a function of temperature. This experiment was performed for both the hydrogenated and deuterated forms of GFP. We have extracted the Arrhenius prefactors and activation energy barriers for both the forward and back proton transfer kinetics. A large kinetic isotope effect for the ground state proton back-transfer has been observed at high temperatures suggesting that tunneling plays an important role. At lower temperatures the data suggest a cross-over to a different pathway for the back-transfer reaction. To investigate this hypothesis we studied the E222D mutant of GFP, which substitutes aspartate for glutamate on the proton wire. The H/D kinetics of this mutant explicitly test for the source of proton donors and indicate that proton transfer proceeds along the same pathway in the native protein at room temperature.

Tuesday, February 28, 2012 11:15AM - 2:03PM — Session J35 DCP: Liquids 107B

11:15AM J35.00001 Ion shape effect on dynamics of ionic liquids, HONGJUN LIU, EDWARD MAGINN, University of Notre Dame — Ionic liquids (ILs) are a group of salts composing of an organic cation and organic or inorganic anion with melting points below 100 °C and have many suitable properties, such as negligible vapor pressure, low flammability, high ionic conductivity and high thermal stability for various applications. Moreover, a great number of ILs with a variety of physical and chemical properties can be synthesized from a combination of different cations (most differently substituted imidazolium, pyridinium, and quaternary ammonium or phosphonium ions) and anions. One can judiciously select from a multitude of ILs to suit a specific application, where the concept of designer solvent comes from. To expedite the development process of target ILs, it is crucial to understand the relationship between ion shape and dynamics of ILs. We studied a wide range of ILs with different ion shape pairings and found the planar-planar paired ILs have a better dynamics as a whole.

11:27AM J35.00002 Thermodynamic Phase Diagram of Hydrogen in Nano-porous Silica, ELI VAN CLEVE, SERGEI KUCHEYEV, Lawrence Livermore National Laboratory — One of the major challenges faced by inertial confinement fusion (ICF) is spherical uniformity of fuel capsules. Most current ignition target designs call for spherically uniform layers of deuterium-tritium (DT) mix in a solid phase. Smooth solid DT layers of high-quality single crystals are necessary, requiring stringent layering protocols. Liquid DT confined in a low-density nano-porous scaffold layer is a possible alternative target, having greatly relaxed layering requirements. Hydrogen in vycor, which has a high density and a relatively uniform pore size distribution, has previously been studied. The porous materials used for this study are silica aerogels. These have ultralow densities and broad pore size distributions. We discuss the thermodynamic phase diagram of hydrogen and deuterium condensed in silica aerogels studied using relaxation calorimetry. We find that crystallization temperatures of both isotopes are suppressed inside the aerogel; however, the freezing takes place over a relatively wide range of temperatures and non-trivially depends on the hydrogen filling fraction. We discuss the correlation of freezing temperatures with the pore size distribution. This work was performed under the auspices of the U.S. DOE my LLNL under Contract DE-AC52-07NA27344.

11:39AM J35.00003 ABSTRACT WITHDRAWN —

11:51AM J35.00004 Quasi-free Electron Energy in Near Critical Point He, YEVGENIY LUSHTAK, SAMANTHA DANNENBERG, CHERICE EVANS, Department of Chemistry, Queens College – CUNY, Flushing, NY and Chemistry Department, the Graduate Center – CUNY, Manhattan, NY, GARY FINDLEY, Chemistry Department, University of Louisiana at Monroe, Monroe, LA — We present the quasi-free electron energy $V_0(\rho)$, where ρ is the density, in He from low density to the density of the gas/He-I/He-II triple point, at various noncritical temperatures and on an isotherm near the critical isotherm. These data, which were obtained using field enhanced photoemission, represent the first extended density overview of $V_0(\rho)$ for He, especially near the critical point. A novel critical point effect is observed and is accurately fitted to the local Wigner-Seitz model, thereby showing that this model, which was developed for attractive systems, can also be applied to repulsive systems.

The experimental measurements reported here were performed at the University of Wisconsin Synchrotron Radiation Center (NSF DMR-0537588). This work was supported by grants from the Petroleum Research Fund (45728-B6) and from the National Science Foundation (NSF CHE-0956719).

12:03PM J35.00005 COSMO-3D: Introducing Steric Effects into COSMO Solvation Models¹, ERIN MCGARRITY, Delft Technical University, JAN VAN DER EERDEN², Condensed Matter and Interfaces-Debye Institute for Nanomaterials Science, Utrecht University, Netherlands, GERARD KROOSHOF, DSM Research, Netherlands — We will present a modified COSMO-based thermodynamical model which can be used for the prediction of solvation in liquid mixtures. The method provides values for the surface-segment interactions and molecular contact areas as functions of the relative positions of all the segment pairings of the constituent molecules in a mixture. These expressions are obtained by placing the complete molecules into contact at each segment pair to determine if the molecules overlap, and using a probing particle to determine the total area of contact. The former expression can be used to discard terms from the COSMO-based segment sums which correspond to overlapping molecular configurations. The areas are used to determine the average contact energies based on Onsager's theory for dielectric screening. Our method allows us to remove three parameters from the original model without any loss of accuracy. We will show the results of our model as applied to binary mixture vapor-liquid equilibrium predictions.

12:15PM J35.00006 Charge induced hydrophobic/hydrophilic metallic surfaces, LUANA PEDROZA, ADRIEN POISSIER, MARIVI FERNANDEZ-SERRA, Stony Brook University — Understanding the interaction of water-metal systems in an atomic level is of fundamental importance in many areas, such as catalysis and materials science. We here present a detailed first-principles molecular dynamics study of bulk water molecules confined within Pd(111) surfaces. We show that there is a charge transfer between the substrate and the water inducing an asymmetry in the order of water molecules at Pd surfaces. Our results show that the hydrophobic/hydrophilic character of a metallic surface depend on its charge, which can be controlled by an applied voltage. We also propose a methodology to obtain the dipole moment of each water molecule and show how they are affected by the substrate induced polarization effects.

12:27PM J35.00007 Pulling adsorbed polymers at an angle: A low temperature theory, GERASIM ILIEV, University of Toronto/York University, STUART WHITTINGTON, University of Toronto — We consider several partially-directed walk models in two- and three-dimensions to study the problem of a homopolymer interacting with a surface while subject to a force at the terminal monomer. The force is applied with a component parallel to the surface as well as a component perpendicular to the surface. Depending on the relative values of the force in each direction, the force can either enhance the adsorption transition or lead to desorption in an adsorbed polymer. For each model, we determine the associated generating function and extract the phase diagram, identifying states where the polymer is thermally desorbed, adsorbed, and under the influence of the force. We note the different regimes that appear in the problem and provide a low temperature approximation to describe them. The approximation is exact at $T=0$ and models the exact results extremely well for small values of T . This work is an extension of a model considered by S. Whittington and E. Orlandini.

12:39PM J35.00008 Low-Energy Electron Induced Reactions in Condensed Methanol, MICHAEL BOYER, Clark University, MAVIS BOAMAH, KRISTAL CHAMBERLAIN, CHANMAYE MYAE SOE, Wellesley College, ANDREW BASS, LEON SANCHE, Université de Sherbrooke, CHRISTOPHER ARUMAINAYAGAM, Wellesley College — We investigate the dynamics of low-energy electron-induced reactions in condensed thin films of methanol (CH_3OH) through electron stimulated desorption (ESD) and post-irradiation temperature programmed desorption (TPD) experiments. ESD experiments indicate that the anions which desorb from the methanol thin film during electron irradiation are predominantly formed through the dissociation of temporary negative ions formed by electron capture by methanol molecules, a process known as dissociative electron attachment (DEA). However, based on investigation of reaction products remaining in the methanol thin film post-irradiation through TPD experiments, DEA is not the obvious primary mechanism by which methoxymethanol ($\text{CH}_3\text{OCH}_2\text{OH}$) and ethylene glycol ($\text{HOCH}_2\text{CH}_2\text{OH}$) are formed. Evidence indicates formation of these molecules may be driven by both DEA and electron impact excitation.

12:51PM J35.00009 The Widom line and noise power spectral analysis of a supercritical fluid¹, SUNGHO HAN, CLARE YU, Department of Physics and Astronomy, University of California, Irvine — In a typical pressure-temperature phase diagram for a fluid, there is a first order phase transition line between the liquid and the vapor phases that terminates at a critical point. Beyond this critical point lies the supercritical regime where one can go continuously between the liquid and vapor phases. In the supercritical region, there is a line of specific heat maxima, called the Widom line, which is often regarded as an extension of the liquid-vapor coexistence line. Using molecular dynamics simulations of a Lennard-Jones fluid, we find that the noise power spectrum of the density fluctuations on the Widom line of the liquid-vapor transition can be divided into 3 frequency regions. The intermediate frequency region with $1/f$ noise appears as the temperature approaches the Widom temperature from above or below. Furthermore, we find that the power spectra of both the density and potential energy fluctuations at low frequency have a maximum on the Widom line, suggesting that the noise power can provide an alternative signature of the Widom line.

1:03PM J35.00010 Disappearance of Widom Line for Liquid-Liquid Phase Transition with Horizontal Coexistence Line, JIAYUAN LUO, Boston University, LIMEI XU, Peking University, SERGEY BULDYREV, Yeshiva University, AUSTEN ANGELL, Arizona State University, GENE STANLEY, Boston University — The study of spherically symmetric two-scale Jagla model with both repulsive and attractive ramps has been very successful in demonstrating the anomalous behavior of liquids (especially water) and its relation with respect to the existence of a liquid-liquid (LL) critical point. However, the co-existence line of Jagla model shows a positive slope, which is opposite to what has been found in the simulations of water. To more convincingly link the result of the study on Jagla model with that of water, we applied discrete molecular dynamics to Gibson and Wilding's modified Jagla model and found that by shrinking both the attractive and repulsive ramps, the slope of the coexistence line can be reduced to zero. However, at these values of the parameters, the LL critical point becomes completely unstable with respect to crystal and glass. We further studied the Widom line, defined as extreme of response functions and also continuation of the coexistence line into one phase region, and found Widom line disappeared in the case of zero slope of the coexistence line, due to the equal enthalpy of low-density liquid (LDL) and high-density liquid (HDL).

1:15PM J35.00011 Effects of pressure on transitions between disordered phases in supercooled liquid Si¹, ALEX ANTONELLI, KARL GARCEZ, Universidade Estadual de Campinas — In the last 20 years, there has been an increasing interest in liquid-liquid transitions. Substances that exhibit negative melting slopes are considered to undergo such transitions. In this work, we study the pressure effects on the transitions between the disordered phases in supercooled liquid Si through Monte Carlo simulations and efficient methods to compute free energies. Our calculations, using a realistic interatomic potential for Si, indicate that at zero pressure the liquid-liquid phase transition, between the high density liquid and the low density liquid, occurs at a temperature 325 K below melting. We found that the liquid-liquid transition temperature decreases with increasing pressure, following the liquid-solid coexistence curve. As pressure increases, the liquid-liquid coexistence curve approaches the region where the glass transition between the low density liquid and the low density amorphous takes place. Above 5 GPa, our calculations show that the liquid-liquid transition is suppressed by the glassy dynamics of the system. We also found that above 5 GPa, the glass transition temperature is lower than that at lower pressures, suggesting that under these conditions the glass transition occurs between the high density liquid and the high density amorphous.

1:27PM J35.00012 Thermodynamics of Supercooled Water, VINCENT HOLTEN, CHRISTOPHER BERTRAND, MIKHAIL ANISIMOV, JAN SENGERS, Department of Chemical and Biomolecular Engineering and Institute for Physical Science and Technology, University of Maryland, College Park, MD 20742 — We present the currently available experimental information for the thermodynamic properties of supercooled ordinary and heavy water and the possibility of modeling these thermodynamic properties on a theoretical basis. Part of the interest into the thermodynamic behavior of supercooled water is caused by an anomalous temperature dependence of the heat capacity, the compressibility and the thermal expansivity. We show that by assuming the existence of a virtual liquid-liquid critical point in supercooled water, the theory of critical phenomena can give an accurate account of the experimental thermodynamic-property data up to a pressure of 150 MPa. In addition, we show that a semi-empirical extension of the theoretical model can account for all currently available experimental data in the supercooled region, up to 400 MPa. Critical-point thermodynamics describes the available thermodynamic data on supercooled water within experimental accuracy, thus establishing a benchmark for any further developments in this area.

1:39PM J35.00013 Diffusivity crossover and liquid-liquid transition in solutions of hard spheres in Jagla particles, DARIO CORRADINI, Center for Polymer Studies and Department of Physics, Boston University, 590 Commonwealth Avenue, Boston, Massachusetts 02215, USA, PAOLA GALLO, Dipartimento di Fisica, Universita' Roma Tre, Via della Vasca Navale 84, I-00146 Roma, Italy, SERGEY V. BULDYREV, Department of Physics, Yeshiva University, 500 West 185th Street, New York, New York 10033, USA, H. EUGENE STANLEY, Center for Polymer Studies and Department of Physics, Boston University, 590 Commonwealth Avenue, Boston, Massachusetts 02215, USA — We study by discrete molecular dynamics simulations the relation between the thermodynamics and the diffusive behavior in solutions of hard spheres in Jagla particles, close to their liquid-liquid critical point. For comparison, we also show the same properties in the bulk Jagla particles system. The hard spheres and the Jagla model are used as spherically symmetric potentials for small hydrophobic solutes in water. We find that the fragile to strong dynamic transition observed when studying the diffusive behavior is always coupled to the low density to high density liquid transition. Above the liquid-liquid critical pressure the diffusivity crossover happens exactly at the Widom line of the systems, where the thermodynamic response functions show maxima. Below the liquid-liquid critical pressure, the diffusivity crossover corresponds to the crossing of the limit of mechanical stability lines and it shows hysteresis when going from high to low temperatures or vice versa. These findings prove that the strong connection between dynamics and thermodynamics found for bulk Jagla particles persists in hydrophobic solutions for concentrations from low to moderate.

1:51PM J35.00014 Small-to-Large Polaron Transition in Water, SHAHRIAR SHADKHOV, ROBIJN BRUINSMA, Department of Physics and Astronomy, University of California, Los Angeles — Heavier charged particles, such as protons, dissolved in water form a hydration shell, which partially shields the charge and significantly increases their effective mass. On the other hand, electrons do not form a hydration shells in water. Leggett's path-integral formalism can be combined with Feynman's polaron theory to construct a theory for the effective mass of a charged particle in water in terms of the charge structure factor, $S(\mathbf{q}, \omega)$ of water, or alternatively, the frequency and wavefunction dependent dielectric function of water. Measurements of $S(\mathbf{q}, \omega)$ for density fluctuations indicate that water has a soft mode with a wave number in the range of an inverse Angstrom. By combining these experiments with analytical and numerical models of the dielectric function of water, we discuss the small-to-large polaron transition in water.

Tuesday, February 28, 2012 11:15AM - 2:15PM – Session J36 DCP: Focus Session: New Energy III 107C

11:15AM J36.00001 Tailoring Surface Chemical Properties Using Electronic Structure Theory, JENS NORSKOV, Stanford University — Electronic structure methods based on density functional theory have reached a level of sophistication where they can be used to describe complete catalytic reactions on transition metal surfaces. This opens the possibility that computational methods can be used to tailor surfaces with desired chemical properties. Recent progress in this direction for transition metal catalysts will be discussed. A series of concepts will be introduced to describe and understand trends in reactivity from one metal surface to the next. It is shown how these concepts can be used to identify the factors determining the catalytic activity of a given transition metal surface, and how this can form the basis for screening of a large number of metals and alloys for catalytic properties.

11:51AM J36.00002 Ab initio reaction pathways for dissociative adsorption of dioxygen on Al (111)¹, FLORIAN LIBISCH, CHEN HUANG, PEILIN LIAO, MICHELE PAVONE, EMILY CARTER, Dep. of Mechanical and Aerospace Engineering, Princeton University, Princeton, NJ — We investigate the interaction of dioxygen with a clean aluminum (111) surface. The theoretical description of this fundamental process is challenging due to the discrete, abrupt charge transfer (CT) from the metal surface to the molecule. Indeed, experimental investigations suggest a sizeable activation barrier not accounted for by a conventional DFT description, due to exchange-correlation functional errors. We adopt a different approach, embedding a small (12 atoms) aluminum cluster in a DFT-derived potential simulating the remainder of the Al surface. The interaction between this embedded cluster and an approaching O₂ molecule is treated using high-level correlated wave function methods (CASSCF, CASPT2) that allow for a correct description of the CT process involved. We map out the potential energy surface (PES) as a function of dioxygen bond length, orientation, and position. In agreement with experiment, we find an activation barrier of ~500 meV, which corresponds primarily to the cost to induce CT. Additionally, the PES is consistent with oxygen abstraction as the dominant process in the case of incident perpendicular orientation, confirming the mechanism proposed to explain the surprisingly large fraction of single oxygen atoms found in STM measurements.

12:03PM J36.00003 Alkane and CO₂ Activation by Modified Oxide Catalysts, HORIA METIU, University of California, Santa Barbara — I will present computational and experimental results concerning the effect of cation or anion doping on the catalytic activity of oxides. We are mainly interested in the activation of alkanes or of CO₂ and their conversion to useful products.

12:39PM J36.00004 First-principles calculations of Fischer-Tropsch processes catalyzed by nitrogenase enzymes¹, JOEL VARLEY, LARS GRABOW², JENS NORSKOV³, Stanford University — The nitrogenase enzyme system of the bacteria *Azotobacter vinelandii*, which is used in nature to catalyze ammonia synthesis, has been found recently to catalyze the efficient conversion of carbon monoxide (CO) into hydrocarbons under ambient temperature and pressure [1]. These findings indicate that nitrogenase enzymes could inspire more efficient catalysts for electrochemical CO and CO₂ reduction to liquid fuels. The nitrogenase variants, in which vanadium substitutes the molybdenum in the active site of the enzyme, show distinct features in their reaction pathways to hydrocarbon production. To compare and contrast the catalytic properties of these nitrogenase enzymes, we perform first-principles calculations to map out the reaction pathways for both nitrogen fixation and for the reduction of CO to higher-order hydrocarbons. We discuss the trends and differences between the two enzymes and detail the relevant chemical species and rate-limiting steps involved in the reactions. By utilizing this information, we predict the electrochemical conditions necessary for the catalytic reduction of CO into fuels by the nitrogenase active sites, analogous to a Fischer-Tropsch process requiring less extreme conditions.

12:51PM J36.00005 Low-temperature dehydrogenation catalysis of isophorone ($C_9H_{14}O$) on Pd(111), XINGUO REN, WEI LIU, ADITYA SAVARA, WIEBKE LUDWIG, KARL-HEINZ DOSTERT, SWETLANA SCHAUERMANN, ALEXANDRE TKATCHENKO, HANS-JOACHIM FREUND, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, Germany — Selective hydrogenation and dehydrogenation of hydrocarbons is one of the most extensively used processes in catalysis. In particular, it is important to design catalysis which can occur at or below room temperature. Here, we investigate the adsorption and dehydrogenation of a model organic/metal catalyst: isophorone ($C_9H_{14}O$) on the Pd(111) surface. Density-functional theory (DFT) calculations including van der Waals (vdW) interactions are carried out to elucidate the adsorbate geometry and reaction dynamics. The vdW interactions dramatically modify the potential-energy surface and enhance the binding energy by about 1 eV. The combination of our theoretical results with the analysis of infrared (IR) spectra and temperature-programmed desorption (TPD) experiments leads us to propose a dehydrogenation pathway from the weakly chemisorbed reactant ($C_9H_{14}O$) to the strongly chemisorbed product ($C_9H_{10}O$), which occurs after four C-H bond cleavages. The obtained low dehydrogenation temperature (130-150 K) from PBE+vdW barriers, including zero-point energy vibrations, is consistent with the TPD analysis.

1:03PM J36.00006 Interfacial binding in catalytic and photovoltaic materials, and the energetics of elementary surface processes during catalytic fuels production and utilization¹, CHARLES T. CAMPBELL², University of Washington — The fundamental understanding of reactivity trends in organic and inorganic chemistry has led to spectacular scientific advances over the past 50 years in synthetic chemistry. At the basis of this understanding is knowledge of the strengths of the relevant chemical bonds being broken and formed. In this regard, surface chemistry is several decades behind. Yet surface chemical reactivity dictates our choices of materials for energy technology, including catalysts for clean fuels production and utilization, fuel cell electrodes, photocatalysts and photovoltaics. This past decade has seen important advances in our ability to measure surface chemical bond energies and to use them to make predictions of relevance to energy technology. We will review those advances here, with a focus on: (1) the interfacial bonding strength between the metal and the support material in metal nanoparticle catalysts, with emphasis on the roles of particle size and the support in catalyst reactivity and stability, (2) the interfacial reactions that occur between the metal electrode and the semiconducting polymer in organic photovoltaic (OPV) devices, and the heats of those reactions, and (3) the adsorption energies of small molecules on Pt(111), with emphasis on intermediates in catalytic steam reforming, oxidation and dehydrogenation, which reveal a strong correlation between the strength with which adsorbates bond to the Pt(111) surface and their bond energy to the H atom in gas-phase molecules. These measurements provide important benchmarks for comparisons with new computational methods designed to improved energy accuracy beyond standard periodic DFT.

1:39PM J36.00007 Ab initio modeling of EXAFS spectra of nanoparticles, SAMUEL CHILL, The University of Texas, AARON YEVIK, ANATOLY FRENKEL, Yeshiva University, GRAEME HENKELMAN, The University of Texas — The structure of nanoparticles in the 1-3 nm range is often investigated using extended x-ray adsorption fine structure (EXAFS). Structural information for nanoparticles is typically determined from the fits to EXAFS data using the bulk structure for theoretical calculations. The average coordination numbers, interatomic distances, and their mean squared disorder can be found. The applicability of this procedure is less obvious when the particles are strongly disordered, i.e., when there are significant structural differences between the nanoparticles and the corresponding bulk structure. We use molecular dynamics (MD) simulations of 2 nm nanoparticles to construct EXAFS spectra ab initio, with the atom-by-atom approach, averaged over the time of the MD run. We obtain that the analysis of this data done by conventional procedures reveals significant differences between the actual (time- and configuration- average) structure of the simulated nanoparticles and what was determined from data analysis using a bulk reference. We demonstrate that EXAFS spectra calculated for a variety of theoretical models of nanoparticles can be directly compared to the experiment and thus used to determine the best-fit structure.

1:51PM J36.00008 Predicting the Catalytic Reactions using Random Phase Approximation, J. YAN, SUNCAT Center for Interface Science and Catalysis, SLAC, Stanford University, T. OLSEN, J.J. MORTENSEN, K.W. JACOBSEN, K.S. THYGESEN, Center for Atomic-Scale Materials Design, Department of Physics, Technical University of Denmark, F. ABILD-PEDERSEN, J.K. NORSKOV, SUNCAT Center for Interface Science and Catalysis, SLAC, Stanford University — Density functional theory has become the workhorse for simulations of catalytic reactions and computational design of novel catalysis. The generally applied semi-local exchange-correlation functionals have successfully predicted catalytic reaction trends over a variety of surfaces. However, in order to achieve quantitative predictions of reaction rates for molecule-surface systems, in particular where there is weak Van der Waals interactions or strong correlation, it is of vital importance to include non-local correlation effects. The use of random phase approximation (RPA) to construct the correlation energy, combined with the exact, self-interaction free exchange energy, offers a non-empirical way for accurately describe the adsorption energies [1] and dispersion forces [2]. We have recently implemented RPA in the GPAW code [3-4], an electronic structure package using projector augmented wave method and real space grids. In this talk I will present our initial results comparing RPA and generalized gradient functionals for the activation energies and reaction energies for transition metal or metal oxide surfaces.

[1] L. Schimka, et.al, Nature Mat. 9, 741 (2010) [2] T. Olsen, et.al, Phys. Rev. Lett. 107, 156401 (2011) [3] J. Yan, et.al, Phys. Rev. B 83, 245122 (2011). [4] J. Yan, et.al, Phys. Rev. Lett. 106, 146803 (2011)

2:03PM J36.00009 In situ XAS of Pt monolayer model fuel cell catalysts: balance of nanostructure and bimetallic interactions¹, DANIEL FRIEBEL, SLAC National Accelerator Laboratory, VENKAT VISWANATHAN, SUNCAT Center for Interface Science and Catalysis, ASK LARSEN, CAMD, Technical University of Denmark, DANIEL J. MILLER, HIROHITO OGASAWARA, SLAC National Accelerator Laboratory, TOYLI ANNIYEV, None, CHRISTOPHER P. O'GRADY, JENS NØRSKOV, SUNCAT Center for Interface Science and Catalysis, ANDERS NILSSON, SLAC National Accelerator Laboratory — The mechanism of the electrochemical oxygen reduction reaction (ORR) has been well understood based on DFT calculations, but there has been a lack of supporting experimental data, due to the difficulties of probing the electrocatalyst surface in situ. Our new approach using Pt monolayer model catalysts provides true surface sensitivity for - originally bulk sensitive - x-ray absorption spectroscopy (XAS) and, owing to the high resolution of the Bragg analyzer at SSRL beamline 6-2, allows for in situ detection of chemisorbed O and OH, whose stability can be used as a descriptor in predicting the activity of new ORR catalyst materials. Our ability to control the growth mode in the Pt/Rh(111) model system allows us to generate Pt nanostructures with highly different O affinities from identical starting materials.

11:15AM J37.00001 Life as a Hiltern¹, COURTNEY LEMON, California State Polytechnic University, Pomona — The Mather Policy Intern Program, conducted through the Society of Physics Students, is an innovative internship encouraging physics students to get involved in science policy. Funded by the John and Jane Mather Foundation for Science and the Arts and the American Institute of Physics, Mather Interns spend a summer at the Capitol, working as congressional interns for a representative or committee. As the first female student inducted into the Mather Policy Intern program, the author presents Life as a Hiltern, detailing her summer working with Representative Rush Holt, the only physicist currently serving in the U.S. House of Representatives.

¹Thank you to the John and Jane Mather Foundation for Science and the Arts for funding this project.

11:27AM J37.00002 Zinc Oxide Coated Carbon Nanotubes for Energy Harvesting Applications¹, AUSTIN MOHNEY, Lock Haven University, DAVID STOLLBERG, Georgia Institute of Technology — Small scale electrical devices depend on bulky batteries that require recharging or replacement. In biomedical monitoring, where sensors could be implanted inside the body, maintenance of batteries presents a problem. It would be beneficial if small scale devices could generate their own power and alleviate their dependence on batteries. Piezoelectric nanogenerators have proven themselves as a viable means for ambient energy harvesting. Piezoelectric materials, such as zinc oxide (ZnO), produce a voltage difference when subjected to mechanical strain. Manipulation of this voltage can allow for the storage of energy to power small scale devices. The objective of this research is to manufacture a piezo-generator that can transduce mechanical vibrations into electrical energy. Carbon nanotubes, selected for their strong, flexible, and conductive properties, are used as a structural backbone for a ZnO piezoelectric coating and a Ag electrode coating. A Schottky diode interface is used to rectify the current output of the device. The devices yielded an average current output of .79 microAmps. SEM imaging was used to characterize the fabrication process. A Keithley 2700 digital multimeter was used to characterize the current output of the devices.

¹Georgia Tech Research Institute & NSF SURF Program at Georgia Tech.

11:39AM J37.00003 Influence of carbon nanotubes diameter on thermal conductivity of polyester based nanocomposites, ROMEO DE COSS-MARTÍNEZ, GRACIELA INÉS QUIÑONES-WEISS, JAZMÍN ANELY DOPORTO-VALLADARES, Facultad de Ingeniería de la Universidad Autónoma de Yucatán, CARIDAD GUADALUPE VALES-PINZÓN, Department of Applied Physics, Cinvestav-Mérida, MIGUEL ÁNGEL ZAMBRANO-ARJONA, JOSÉ ÁNGEL MENDEZ-GAMBOA, RUBÉN ARTURO MEDINA-ESQUIVEL, Facultad de Ingeniería de la Universidad Autónoma de Yucatán, JUAN JOSÉ ALVARADO-GIL, Department of Applied Physics, Cinvestav-Mérida — Carbon nanotubes (CNTs) are considered good candidates to improve the physical properties of polymeric materials. It is well known that CNTs have one of the highest thermal conductivities in nature. However, it has been found that thermal resistance between polymer matrix and CNTs, at nanometric scale, could imply a disadvantage to obtain high thermal conductivity nanocomposites. In this work, the effect of CNTs diameter on the effective thermal conductivity of composites based on polyester resin is studied. In particular, the effects of CNT's diameter and volume fraction are analyzed. The thermal conductivity of the nanocomposites is obtained determining the thermal diffusivity by photothermal radiometry and from the values of their specific heat capacity.

11:51AM J37.00004 Electrical characterization of field effect transistors made from C-nanotubes covered with poly(3-hexylthiophene)¹, LUIS POMALES, NICHOLAS PINTO, University of Puerto Rico - Humacao, MITCHELL LERNER, ALAN JOHNSON JR., University of Pennsylvania — Organic transistors were fabricated using a thin film of regio-regular poly(3-hexylthiophene-2,5-diyl) spun from a 0.5 wt% solution in CHCl₃ on doped Si/SiO₂ substrates with and without CNT's. The performance of devices with percolating networks of CVD grown single-wall carbon nanotubes (SWNT's) between the source (S) and drain (D) electrodes and without SWNT's are compared. Nanotubes are used as a way to shorten the effective mean distance between the S/D terminals while retaining the wide spacing macroscopic shadow mask technique for S/D fabrication. We found that devices made with SWNT's do not exhibit S/D current saturation but have a charge mobility of 1.2×10^{-2} cm²/V-s and an on/off ratio of 9, while the device without SWNT's show clear saturation with a charge mobility of 8.6×10^{-4} cm²/V-s and an on/off ratio of 870. The devices made with nanotubes possess a larger off state current although they show a ~14X increase in the mobility which can thus be increased without using sophisticated lift-off techniques to shorten the S/D distance.

¹NSF

12:03PM J37.00005 Physical Manipulation of the Na/K Pump¹, DAVID EVE, Massachusetts College of Liberal Arts, CLAUSELL MATHIS, WEI CHEN, University of South Florida — It has been demonstrated that a well-designed oscillating electric field can synchronize and modulate the functions of the Na⁺/K⁺ ATPase pump, a ubiquitous active transporter in the cell membrane. Current work aims to improve this technique in order to synchronize the individual steps in the pumping cycle, allowing all of the individual pumps to run simultaneously. Using frog skeletal muscle fibers and the double Vaseline-gap voltage clamp technique, we are working to design wave pulses, which will isolate the voltage dependent steps of the active ion transport. This will improve the signal-to-noise ratio and provide insight into the protein conformation changes that occur during active transport.

¹This work was supported by NSF REU program (award No DMR-1004873)

12:15PM J37.00006 Characterization of the GaN-MgO Transistor Interface: More Power and Efficiency¹, JOSE SANCHEZ, University of Puerto Rico at Mayaguez, DIVINE KUMAH, FRED WALKER, Yale University — In this age of high-energy consumption, the development of more efficient and more reliable devices is indispensable. Gallium nitride (GaN)-based devices are an option in achieving this goal. GaN's wide bandgap of 3.4 eV allows the device to handle large amount of current before leakage makes its energy consumption inefficient. The characteristics of GaN, in conjunction with those of Magnesium oxide (MgO), would allow for improvement of different electronic applications such as mobile phone communication technology. In this work, the fabrication of the GaN/MgO device was done by Molecular Beam Epitaxy. This device was grown under a variety of parameters where the growth temperature, growth chamber pressure, and the rate of material deposition were changed. To determine the optimal growth parameters, current-voltage and capacitance-voltage measurements were conducted on to evaluate the effects of these growth conditions. Atomic Force Microscopy was also used in characterizing the crystallinity and morphology of the samples. A conclusion of the research is that by improving the roughness of the substrate, the breakdown voltage of the MgO layer and the overall performance of the device can be improve, yielding a device with very low energy loss in the current transmission process.

¹The research was conducted under the Leadership Alliance, The Summer Undergraduate Research Fellowship (SURF) Program at Yale University, and the Center for Research on Interface Structure and Phenomena (CRISP) REU programs.

12:27PM J37.00007 Generating more electricity from water¹, DANIEL MOSER, GUOPING ZHANG, Indiana State University: Department of Chemistry and Physics — The Kelvin water drop generator is an ingenious method of using naturally occurring water to induce charge separation in water droplets by allowing them to fall through cross-wired conductors. While being a simple and clean source of energy, the generator has never been considered practical due to its low current output. The goal of this experiment was to discover what conditions were required to obtain maximum voltage. Manipulating where a water stream breaks into droplets inside the conductor, we were able to take advantage of the conductor's geometry and electric field to induce the largest charge separation inside the water droplets. We also explored methods on how to reduce charge cancellation during the operation of the apparatus.

Tuesday, February 28, 2012 11:15AM - 1:51PM –
Session J39 DCMP: Exciton, Polariton, and Electron Dynamics in two-dimensional semiconductor structures 109B

11:15AM J39.00001 Valence-band Mixing in Strain-based Traps for Indirect Excitons in Coupled Quantum Wells¹, JEFFREY WUENSCHHELL, NICHOLAS SINCLAIR, DAVID SNOKE, University of Pittsburgh, LOREN PFEIFFER, KEN WEST, Princeton University — Excitons in a coupled quantum well system under an applied bias are spatially separated, with electrons and holes in opposite wells. The pair can interact via the Coulomb interaction, but recombination is suppressed. Indirect excitons exhibit a long (up to tens of microseconds), tunable lifetime and are of interest to those studying high density excitonic phase transitions in equilibrium. Recent experiments have revealed sharply temperature- and density-dependent transitions in the luminescence pattern of strain-trapped indirect excitons [1]. Localized strain shifts the valence and conduction bands, creating a trap for the case of hydrostatic stretching [2]. Two factors differentiate this technique from electrostatic traps, the splitting between the light- and heavy-hole exciton states varies with stress and the presence of shear strain modifies the symmetry of the ground state. Due to strong dependence of the radiative lifetime on the tunneling rate, the indirect heavy- and light-hole excitons have drastically different recombination rates; meaning that mixing sharply alters the luminescence pattern. We will discuss the modeling of the structure of the single-particle potential and the role that interband mixing plays in the appearance of high density phase transitions.

11:27AM J39.00002 Dark excitons and Bose-Einstein condensation in strain-trapped excitons in coupled quantum wells¹, NICHOLAS SINCLAIR, JEFF WUENSCHHELL, University of Pittsburgh, KENNETH WEST, LOREN PFEIFFER, Princeton University, DAVID SNOKE, University of Pittsburgh — It is possible to make excitons in coupled quantum wells with very long lifetime compared to their thermalization, allowing us to study equilibrium behavior. Using a localized stress to create traps for excitons in coupled quantum wells, we have demonstrated that at low temperature, high density, and large stress, the spatial pattern of photoluminescence (PL) from interwell excitons transitions to one with a dimmed center. This pattern emerges despite the center remaining the region of highest exciton density. This darkening is related to a strain-induced interaction between the light hole and heavy hole states. However, while this explanation provides a mechanism to explain many of the features, a few important predictions of this theory are not borne out by experiments. An alternate explanation is possible, utilizing an increasing population of dark ($J=2$) excitons and a separation of the dark and bright species. It has been proposed that a Bose-Einstein Condensate in this system would occur in a dark state, and this transition is consistent with the onset criteria of the pattern formation and explains how a slight bright/dark energy difference could lead to spatial separation of the species. Experiments employing a magnetic field to turn 'dark' excitons slightly 'bright' should allow the disambiguation of the role of dark excitons in this system. I will review this pattern formation and discuss data from experiments employing a magnetic field.

11:39AM J39.00003 Trapping Long-Lifetime Superfluid Polaritons Using a Laser-Generated Barrier¹, B. NELSEN, M. STEGER, G. LIU, D. SNOKE, University of Pittsburgh, K. WEST, L. PFEIFFER, Princeton University — We present results with new microcavity structures that have polaritons that live as long as 100 ps, about two orders of magnitude longer than in previous structures. We show that an exciton reservoir can be used to create a potential barrier for a superfluid polariton gas. In these experiments, we use a non-resonant laser to create a superfluid polariton gas at the same location as a population of excitons. The excitonic component of the polariton can coherently scatter with the excitons. Since the excitons have mass four orders of magnitude larger than the polaritons, they form essentially a static barrier for the polaritons. By resolving the polaritons both in real space and momentum space, we determine that the polaritons roll down the potential barrier created by the excitons. These results are consistent with numerical solutions of the Gross-Pitaevskii equation for the measured parameters of this system. The potential to use the exciton reservoir as a barrier/trap will allow exciting new ways to study macroscopic coherence phenomena such as Josephson oscillations and superfluid vortices.

¹This material is based upon work supported by the National Science Foundation under Grant No. 0706331.

11:51AM J39.00004 All Optical Switching Using Exciton-Polariton Renormalization in Microcavities¹, M. STEGER, B. NELSEN, C. GAUTHAM, D. SNOKE, University of Pittsburgh, L. PFEIFFER, K. WEST, Princeton University — We report on a method of all-optical switching based on resonantly pumped exciton-polariton microcavities. Depending on geometry, each optical transistor could be used to make an AND or an AND NOT gate. Optical switching in these samples may be limited by the lifetime of the polaritons, allowing for near THz frequency switching. These gates could be used for fast signal processing or optical computing. Where optical computing calls for signals and gates to be at the same wavelength, we can use a gate beam at an angle, since the dispersion relation of polaritons allows for the absorption of a gate higher in energy than the $k=0$ state. High exciton and free carrier densities lead to a renormalization of the lower polariton (LP) and increase its energy. If the $k=0$ LP becomes resonant with the signal beam, then the gate may be used to turn on transmission (or consequently turn off reflectivity) of that signal. We will present achievable on/off ratios and switching speeds as well as discuss modulating an intense signal with a weaker gate.

12:03PM J39.00005 Two-Dimensional Mott-Hubbard Electrons in an Artificial Honeycomb Lattice¹, V. PELLEGRINI, M. GIBERTINI, B. KARMAKAR, NEST-CNR, and Scuola Normale Superiore, Pisa, S. YUAN, Radboud University Nijmegen, Netherlands, M. POLINI, NEST-CNR, and Scuola Normale Superiore, Pisa, G. VIGNALE, University of Missouri, Columbia, USA, M. KATSNELSON, Radboud University Nijmegen, Netherlands, A. PINCZUK, Columbia University, USA, L.N. PFEIFFER, K.W. WEST, Princeton University, USA, A. SINGHA, Bose Institute, Kolkata, India. — Artificial crystal lattices can be used to tune repulsive Coulomb interactions between electrons. We trapped electrons, confined as a two-dimensional gas in a gallium arsenide quantum well, in a nanofabricated lattice with honeycomb geometry [1,2]. In our most recent studies [3] we probed the excitation spectrum of electrons in the honeycomb lattice with lattice spacing ranging down to 90nm in a magnetic field identifying collective modes that emerged from the Coulomb interaction in the artificial lattice, as predicted by the Mott-Hubbard model. These observations allow us to determine the Hubbard gap and suggest the existence of a Coulomb-driven ground state [3]. The proposed research promises to further expand current realms of study of quantum simulators. While the experiments are challenging, studies of electrons confined to artificial lattices should provide key perspectives on strong electron correlation in condensed matter science.

12:15PM J39.00006 Cooperative carrier dynamics in InGaAs/GaAs quantum wells in high magnetic fields, JI-HEE KIM, TIM NOE, Dept. of Electrical & Computer Engineering, Rice University, YONGRUI WANG, ALEKSANDER K. WOJCIK, Dept. of Physics and Astronomy, Texas A&M University, STEPHEN A. MCGILL, National High Magnetic Field Laboratory, ALEXEY A. BELYANIN, Dept. of Physics and Astronomy, Texas A&M University, JUNICHIRO KONO, Dept. of Electrical & Computer Engineering, Rice University — Ultrafast spectroscopy in strong magnetic fields provides a powerful means for studying quantum coherence in many-body systems. A high magnetic field leads to tunable energy quantization, which in turn results in a substantial enhancement of densities of states and suppression of scattering. Here, we study superfluorescence (SF), i.e., cooperative spontaneous emission of ultradense electron-hole plasmas in InGaAs quantum wells in a perpendicular magnetic field up to 17.5 T. We observe SF both through time-resolved photoluminescence and differential transmission (DT) measurements. We create an ultradense electron-hole plasma with an intense femtosecond laser pulse, and after a certain delay, an ultrashort burst of coherent radiation emerges. At the same time, an abrupt decrease in population from full inversion to zero was observed through DT measurements. Furthermore, the DT signals strongly depended on the probe energy, showing an anomalous negative DT signal (i.e., induced absorption) under certain circumstances.

12:27PM J39.00007 High-Order Sideband Generation in Quantum Wells Driven by Intense THz Radiation: Electron-Hole Recollisions¹, BENJAMIN ZAKS, Department of Physics and the Institute for Terahertz Science and Technology, University of California at Santa Barbara, REN-BAO LIU, Department of Physics and the Centre of Optical Sciences, The Chinese University of Hong Kong, MARK SHERWIN, Department of Physics and the Institute for Terahertz Science and Technology, University of California at Santa Barbara — Non-linear mixing of optical beams with intense terahertz beams has been observed in semiconductor heterostructures both as changes to the absorption spectrum and as sideband generation. Sidebands are generated when a material has a non-linear dielectric response that mixes the electric field of the two beams and produces radiation at the optical frequency plus or minus multiples of the THz frequency. Perturbatively generated sidebands have been observed up to fourth order when the optical beam resonantly excites excitons in GaAs quantum wells. We present here our observation of high-order sideband generation (HSG) from excitons in InGaAs QWs. Sidebands of up to 18th order are observed. From the THz intensity dependence and THz polarization dependence (linear-circular) of the sideband generation, we show that the observed phenomenon is non-perturbative. We note that the exciton system driven by an intense THz field is analogous to an atomic system driven by intense optical fields, as is the case for high-order harmonic generation (HHG). The recollision model used to describe HHG in atoms is then extended to describe HSG in excitons. Experimental results indicate that the recollision model is a valid description of the nature of HSG in excitons.

12:39PM J39.00008 Intersubband electrons coupled to zone-folded coherent acoustic phonons in a GaN/AlN superlattice, CYNTHIA AKU-LEH, KLAUS REIMANN, MICHAEL WOERNER, Max-Born Institut, Max-Born Strasse 2A, 12489 Berlin, Germany, EVA MONROY, CEA Grenoble, rue des martyrs 17, 38054 Grenoble, France, DANIEL HOFSTETTER, University of Neuchâtel, 1 Rue Abraham Louis Breguet, 2000 Neuchâtel, Switzerland — We present spectrally-resolved resonant pump-probe measurements on a strongly polar GaN/AlN superlattice. The transmitted and reference probe spectra are detected at the same read out rate. Analysis of the normalized probe spectra reveals electronic contributions as well as the first three folded longitudinal acoustic phonons, matching calculated frequency values predicted by the elastic continuum model. The observed modes couple strongly to intersubband electrons and modulate the spectral width and position of the intersubband absorption. We conclude that this electron-phonon coupling takes place via piezoelectric effects and a phonon-induced modulation of the subband effective mass.

12:51PM J39.00009 Intersubband polariton bleaching observed in ultrafast mid-infrared spectroscopy, SIMONE ZANOTTO, RICCARDO DEGL'INNOCENTI, JI-HUA XU, Scuola Normale Superiore and CNR-NANO, GIORGIO BIASIOL, Laboratorio TASC and CNR-IOM, LUCIA SORBA, ALESSANDRO TREDICUCCI, Scuola Normale Superiore and CNR-NANO — Strong coupling between intersubband transition in quantum wells and microcavity field leads to the concept of intersubband (ISB) polaritons. Their linear properties have been explored for several years, mainly focusing on optical spectra and electroluminescence. Among the implemented microcavity geometries, the one based on a photonic crystal (Zanotto et. al., Appl. Phys. Lett. 2010) is particularly interesting as it allows simultaneous access to both polariton branches at anticrossing. Here we report on the nonlinear response of ISB polaritons, investigating their bleaching, an effect already studied in the excitonic framework. When ISB polaritons are probed by an intense mid-infrared laser pulse, the typical double-peaked transmission spectrum is converted in a single-peaked one. By tuning the intensity of the femtosecond pulse that covers both polariton branches, the whole range between weak and strong coupling regimes has been swept. This study reveals that there is a threshold for pumping above which polariton states are destroyed, and restricts the pump intensity range that can be employed in an optically-pumped ISB polariton laser. Moreover, as a consequence of nonlinear optical properties, saturable absorbers and optically bistable devices could be implemented.

1:03PM J39.00010 Pump-probe experiment in LaMnO₃/SrTiO₃ superlattices and thin film, PUREVDORJ MUNKHBAATAR, Department of Physics, Chonbuk National University, Republic of Korea, B. TSERMAA, Department of Geophysics, National university of Mongolia, Mongolia, J.S. KIM, Department of Physics, Chonbuk National University, Republic of Korea, W.S. CHOI, S.S.A. SEO, H.N. LEE, Oak Ridge National Laboratory, K. MYUNG-WHUN, Department of Physics, Chonbuk National University, Republic of Korea — We present the time dependent transmittance of LaMnO₃ thin film and [(LaMnO₃)_n/(SrTiO₃)₈]₂₀ (n=2 and 8) superlattices grown on SrTiO₃ substrate. We used the laser pulse pump-probe technique. We observed two phonon oscillation in the LaMnO₃ film at 8 THz and at 15 THz. In the superlattices, 8 THz mode seemed obliterated. The phonon oscillation damping time constant was also different. In LaMnO₃ thin film, we could observe the oscillation until ~ 1.5 ps. In the superlattices, the damping time constant was smaller: ~ 0.7 ps for n=8 superlattice and ~ 0.3 ps for n=2 superlattice. We will discuss number of phonon mode and the damping time constant in terms of the sample geometry and the electronic structure.

1:15PM J39.00011 Excitonics of Hybrid Nanostructures Arranged with Mixed Dimensionality, PEDRO LUDWIG HERNANDEZ MARTINEZ, Bilkent University, Nanyang Technological University, ALEXANDER O. GOVOROV, Ohio University, HILMI VOLKAN DEMIR, Bilkent University, Nanyang Technological University — We present a complete study of the Förster-type nonradiative energy transfer in hybrid nanostructures composed of nanoparticles, nanowires and quantum wells, and investigate the effects of quantum confinement in different dimensions. We systematically consider all possible combinations in terms of dimensionality for exciton-exciton interactions in these hybrid architectures, and analyze the resulting energy transfer rates for item-to-item excitonic coupling as a function of dimensionality. We derive a full set of analytical expressions and show that the exciton transfer strongly depends on the dimensionality and geometry of the hybrid system. Arrangements of such nanostructures with mixed dimensionality ranging from the low dimensionality to the high offer important high-efficiency applications in photovoltaics [1,2], while in the reciprocal case (from the high dimensionality to the low) in light generation [3] and LEDs [4]. [1] J. Sambur, et al., Science 330, 63 (2010). [2] M. D. Kelzenberg, et al., Nature Materials 9, 239–244 (2010). [3] R. Yan, et al., Nature Photonics 3, 569–576 (2009). [4] H.V. Demir, et al., Nano Today (2011) doi:10.1016/j.nantod.2011.10.006

1:27PM J39.00012 Many-particle effects in the photoluminescent response of silicon quantum-dot solids, JOSEPH B. MILLER, AUSTIN R. VAN SICKLE, North Dakota State University, REBECCA R. ANTHONY, UWE R. KORTHSHAGEN, University of Minnesota, DANIEL M. KROLL, ERIK K. HOBBIE, North Dakota State University — Monodisperse colloidal suspensions of ligand-coated silicon nanocrystals (SiNCs), synthesized through a nonthermal low-pressure plasma reaction, are prepared through density-gradient ultracentrifugation in mixed organic solvents. The SiNC fractions are then self-assembled into close-packed quantum-dot “solids” and clusters, and photoluminescent properties of the resulting ordered ensembles are characterized through optical spectroscopy. We find striking manifestations of particle-particle interactions in the measured optical response, and we model these effects using Monte Carlo simulations of the photobleaching kinetics in dense SiNC packings.

1:39PM J39.00013 Spectral dependence of the Aharonov Bohm effect in the magneto-photoluminescence of layered ZnTe-ZnSe structures, BIDISHA ROY, Queens College of CUNY, The Graduate Center of CUNY, HAOJIE JI, SIDDHARTH DHOMKAR, Queens College of CUNY, The Graduate Center of CUNY, LE PENG, City College of CUNY, The Graduate Center of CUNY, RICHARD MOUG, City College of CUNY, UTTAM MANNA, Columbia University, MARIA TAMARGO, City College of CUNY, FRED CADIEU, Queens College of CUNY, IGOR KUSKOVSKY, Queens College of CUNY, The Graduate Center of CUNY — Aharonov-Bohm (AB) oscillations in the magneto-photoluminescence (PL) intensity of multilayered ZnTe/ZnSe structures grown via migration enhanced epitaxy (MEE) using three submonolayer deposition cycles of Zn-Te-Zn sandwiched between ZnSe barriers confirmed the presence of type-II ZnTe-based QDs. These co-exist with isoelectronic centers (ICs) as evident from the PL spectra. The spectral dependence of the transition magnetic field and the magnitude of the AB oscillation in intensity are investigated. A qualitative probing of distribution in the ensemble of QDs and ICs was done. The transition magnetic field changed from a lower value at the lower energy side of the PL emission to a higher value at the higher energy side which confirmed the lateral QD size distribution. AB oscillations at spectral positions dominated by emission from ICs were also observed suggesting that the presence of QDs also affects the ICs although the magnitude of the oscillation in the AB peak decreases at such spectral positions.

Tuesday, February 28, 2012 11:15AM - 2:15PM — Session J40 DBIO: Multi-cellular Processes and Development 156A

11:15AM J40.00001 A Quantitative Analysis of Axonal Growth and Connectivity in Cortical Neurons, JAMES WHITE, Physics and Astronomy and Biomedical Engineering, Tufts University, ELISE SPEDDEN, SAWYER BERNATH, Physics and Astronomy, Tufts University, DAVID KAPLAN, Biomedical Engineering and Chemical Engineering, Tufts University, TIMOTHY ATHERTON, CRISTIAN STAI, Physics and Astronomy, Tufts University — Developing neurons extend processes (axons and dendrites), which are led by a distally positioned growth cone. The growth cone both secretes and senses signaling molecules, that may either attract or repel nearby growing processes. While knowledge on the qualitative effects of several secreted growth factors on axon development (e.g. axon length and number of neurons developing processes) are known, a more detailed mathematical model describing the process of axonal guidance remains to be developed. Towards this end, we have collected time-lapse microscopy data of the axonal development of cortical neurons. Image analysis provides information on the rate of growth, arc length, and curvature of the processes as a function of time and the spatial positioning of the neurons. These results will be discussed in relation to theoretical studies that model axon growth in response to varying gradients of attractive forces, representative of the effect that signaling molecules may have on axon guidance.

11:27AM J40.00002 Collective cell migration in a periodic potential, THOMAS ANGELINI, JOLIE BREAUX, STEVEN ZEHNDER, University of Florida — The strength of cell-substrate adhesion can be modulated by the elasticity of substrate material. Thus, a cell culture surface with periodically varying elasticity is analogous to a periodic potential for cell adhesion. Rich collective dynamics emerge in systems of adatoms on crystal lattice surfaces due to the mismatch between the preferred spacing of adatoms and the periodic potential associated with the crystal lattice. Here we explore a biological analog of atoms in a periodic potential; we study the collective dynamics of cells on a substrate with periodically patterned elasticity. Preliminary results will be presented.

11:39AM J40.00003 Collective Cell Migration on Deformable Substrates, ADRIAN PEGORARO, Harvard University, ALLEN EHRLICHER, Harvard, MING GUO, Harvard University, THOMAS ANGELINI, University of Florida, DAVID WEITZ, Harvard University — In many biological processes, such as wound healing, tumor migration, or embryo development, cell migration is influenced by collective dynamics and coupling between cells. While cell-cell contact is one form of mechanical coupling, long-range interactions mediated by a deformable substrate lead to both spatial and temporal correlations during cell migration that extend over many cell lengths. While it is known that interactions between nearby but not contacted single cells are modified by substrate stiffness, it is not yet clear how changes to the substrate properties affect collective cell migration. This is especially important in the understanding of cancer cell migration since the mechanical properties of these cells change during disease progression; as such we expect that the influence of the substrate to change over time. To investigate this further, we study collective cell migration on deformable substrates of different stiffness to test whether changes in short range interactions between cells are correlated with changes in collective cell migration. Furthermore, we mix cells from different cancer stages and study their migration patterns to test whether correlations exist between different cell types during migration.

11:51AM J40.00004 Impact of jamming on collective cell migration, KENECHUKWU DAVID NNETU, MELANIE KNORR, STEVE PAWLIZAK, THOMAS FUHS, MAREIKE ZINK, JOSEF A. KÄS, Institut für Experimentelle Physik I, Universität Leipzig, D-04103, Leipzig, Germany — Multi-cellular migration plays an important role in physiological processes such as embryogenesis, cancer metastasis and tissue repair. During migration, single cells undergo cycles of extension, adhesion and retraction resulting in morphological changes. In a confluent monolayer, there are inter-cellular interactions and crowding, however, the impact of these interactions on the dynamics and elasticity of the monolayer at the multi-cellular and single cell level is not well understood. Here we study the dynamics of a confluent epithelial monolayer by simultaneously measuring cell motion at the multi-cellular and single cell level for various cell densities and tensile elasticity. At the multi-cellular level, the system exhibited spatial kinetic transitions from isotropic to anisotropic migration on long times and the velocity of the monolayer decreased with increasing cell density. Moreover, the dynamics was spatially and temporally heterogeneous. Interestingly, the dynamics was also heterogeneous in wound-healing assays and the correlation length was fitted by compressed exponential. On the single cell scale, we observed transient caging effects with increasing cage rearrangement times as the system age due to an increase in density. Also, the density dependent elastic modulus of the monolayer scaled as a weak power law. Together, these findings suggest that caging effects at the single cell level initiates a slow and heterogeneous dynamics at the multi-cellular level which is similar to the glassy dynamics of deformable colloidal systems.

12:03PM J40.00005 Self-rheology of cell monolayers, ROMARIC VINCENT, XAVIER SERRA-PICAMAL, VITO CONTE, ESTER ANON, XAVIER TREPAT, Institute for Bioengineering of Catalonia, University of Barcelona — Collective migration of cell sheets is a central feature of fundamental biological processes including morphogenesis, tissue regeneration, and cancer invasion. The dynamics of such processes are heavily determined by the rheology of the sheet and of the constituent cells. Such material properties have been extensively measured using a broad variety of rheological techniques, but none of these techniques has probed the ultraslow time scales that are central to collective cell migration, and exceed thousands of seconds. Here we present a novel approach we call 'Self rheology' that probes cell rheology using the pulses of strain rate that cells spontaneously generate. Using this approach, we show that stress and strain rate are in quadrature, thus indicating that the dominant stresses that govern collective cell migration are elastic. The monolayer's Young modulus is found to be an order of magnitude lower than the stiffness of single cells determined through active micro-rheology techniques at shorter time scales. This elastic behavior is followed by a fluidization regime at higher strains, which we interpret in terms of cell rearrangements. "Self-rheology" provides a new approach to study the dynamics of collective cellular processes at ultraslow time scales.

12:15PM J40.00006 Collective mechanics of undifferentiated cells drives ventral furrow formation in *Drosophila* embryo¹, ANA HOCEVAR, PRIMOZ ZIHERL, Jozef Stefan Institute, Ljubljana, Slovenia, MATTEO RAUZI, European Molecular Biology Laboratory, Heidelberg, Germany, MARIA LEPTIN, Universitaet zu Koeln, Koeln, Germany — We propose a 2D mechanical model of ventral furrow formation in *Drosophila* embryo that is based on undifferentiated epithelial cells of identical mechanical properties whose energy resides at their cortex. Depending on the relative tensions of the apical, basal, and lateral sides, the minimal-energy states of the embryo cross-section include circular and buckled furrow shapes. We discuss the possible shape transformation from a circular to an invaginated shape consistent with experimental observations, arguing that generic collective mechanics may contribute to the robustness of tissue shape changes in embryonic development. A small increase of the area of the mesoderm cells is sufficient to pin down the invagination. This agrees with experimental data which show that just before the outset of gastrulation, the apical, basal, and lateral sides of the mesoderm cells indeed are larger than in the rest of the embryo.

¹We thank the EMBL Advanced Light Microscopy Facility and Carl Zeiss for continuous support of the EMBL ALMF. This work was supported by the Slovenian Research Agency through Grant No. P1-0055 and by NSF Grant No. DMR05-47230.

12:27PM J40.00007 Collective Cell Mechanics in 3D Scaffolds, JOLIE BREAUX, STEVEN ZEHNDER, University of Florida, LUCAS OSTERBUR, JENNIFER LEWIS, University of Illinois, Urbana-Champaign, THOMAS ANGELINI, University of Florida — Mechanical cell behavior is influential in tissue health and dynamic cellular processes such as wound healing, and angiogenesis. Traction force microscopy (TFM) is often used to measure cell generated forces while mechanical testing methods such as atomic force microscopy (AFM) are employed to determine materials properties of cells. Extant cell mechanics methods including TFM and AFM are optimal for cells cultured on flat, 2D surfaces. However, the development of new cell mechanics techniques in 3D systems is essential to elucidate the behavior of tissues. In this presentation we introduce results from live-cell time-lapse measurements of mechanical cell behavior in highly ordered 3-D scaffolds. Preliminary data will be presented.

12:39PM J40.00008 Biomechanics of the endothelium substrate influences leukocyte transmigration¹, KIMBERLY STROKA, HELIM ARANDA-ESPINOZA, Fischell Department of Bioengineering, University of Maryland — The effects of shear flow and cytokines on leukocyte transmigration are well understood. However, the effects of substrate stiffness on transmigration remain unexplored. We have developed an in vitro model that allows us to study leukocyte transmigration as a function of varying physiological substrate stiffness. Interestingly, leukocyte transmigration increased with increasing substrate stiffness below the endothelium. Intercellular adhesion molecule-1 expression, stiffness, cytoskeletal arrangement, morphology, and cell-substrate adhesion could not account for the dependence of transmigration on substrate stiffness. We also explored the role of cell contraction and observed that (1) neutrophil transmigration caused large hole formation in monolayers on stiff substrates. (2) Neutrophil transmigration on soft substrates was increased by decreasing cell-cell adhesion. (3) Inhibition of myosin light chain kinase normalized the effects of substrate stiffness by reducing cell contraction on stiff substrates. These results demonstrate that neutrophil transmigration is regulated by MLCK-mediated generation of gaps at cell borders through substrate stiffness-dependent endothelial cell contraction.

12:51PM J40.00009 Growth variability in a tissue governed by stress dependent growth, KAREN ALIM, Harvard, AREZKI BOUDAUD, INRA, CNRS, ENS, Université de Lyon — Cell wall mechanics lie at the heart of plant cell growth and tissue morphogenesis. Conversely, mechanical forces generated at tissue level can feedback on cellular dynamics. Differential growth of neighboring cells is one eminent origin of mechanical forces and stresses in tissues where cells adhere to each other. How can stresses arising from differential growth orchestrate large scale tissue growth? We show that cell growth coupled to the cell's main stress can reduce or increase tissue growth variability. Employing a cell-based two dimensional tissue model we investigate the dynamics of a tissue with stress depending growth dynamics. We find that the exact cell division rule strongly affects not only the tissue geometry and topology but also its growth dynamics. Our results should enable to infer underlying growth dynamics from live tissue statistics.

1:03PM J40.00010 Emergent mechanical behavior in a minimal model for embryonic tissues, LISA MANNING, Department of Physics, Syracuse University, MARCOS LANIO, JARED TALBOT, EVA-MARIA SCHOETZ, Lewis-Sigler Institute for Integrative Genomics, Princeton University — We develop a minimal model for the mechanical properties of embryonic tissues that contains only three parameters and yet accurately reproduces many structural and dynamical features in zebrafish embryonic tissue explants. We verify model predictions for tissue surface tensiometer experiments and fusion assays, and contrast our model with existing models that are either difficult to constrain experimentally or insufficient to explain our experimental observations. The model tracks one degree of freedom per cell and introduces several types of interactions between cells to capture intracellular degrees of freedom, such as single cell viscoelasticity, adhesion, and active force generation. A key observation is that the motion of cells past one another, which must be generated by cells actively exerting tension on contacts, is best described by a special type of structured noise (both multiplicative and colored), instead of the white noise typically used in Brownian dynamics simulations. With such a noise term we can reproduce the glassy, viscoelastic dynamics in the bulk and explain how this new type of active "droplet" with very short-range interactions manages to have no "vapor pressure." We discuss how this well-calibrated model can be used to study morphogenesis and pattern formation in developing tissues.

1:15PM J40.00011 Spatially limited growth of an epithelium, MAXIME DEFORET, OLIVIER COCHET, AXEL BUGUIN, PASCAL SILBERZAN, Physico-Chimie Curie - UMR 168 - CNRS - Institut Curie, BIOLOGY INSPIRED PHYSICS AT MESO-SCALES TEAM — We present a study dealing with the growth of an epithelium on a spatially limited adhesive substrate. Adhesive patterns (typical size: 50 μ m to 500 μ m) are created by micro-fabrication techniques: A protein repellent polymeric gel homogeneously grafted on a coverslip is selectively ablated by plasma treatment through a thin layer of photoresist. The technique achieves a high resolution of patterning (around 2 μ m). After seeding cells (MDCK) on circular adhesive patterns, we let the monolayer grow for 30 hours after reaching the confluence. We use physical descriptors to describe migration and compaction. Two days after the confluence, we observe and characterize by confocal microscopy, the appearance of a tridimensionnal assembly of cells in the peripheral zone of the adhesive pattern (a "rim"). Moreover using other patterns, the existence of a tissue line tension and internal pressure is investigated.

1:27PM J40.00012 Information propagation and nutrient flow in *Physarum polycephalum* ,

GABRIEL AMSELEM, FRANCOIS PEAUDECEERF, KAREN ALIM, School of Engineering and Applied Sciences, Harvard University, JACQUES DUMAIS, ANNE PRINGLE, Department of Organismic and Evolutionary Biology, Harvard University, MICHAEL BRENNER, School of Engineering and Applied Sciences, Harvard University — Basal organisms such as slime mold and fungi grow as extended networks that can reach several square meters in size. Despite lacking a central coordination center, these organisms are able to globally reshape their morphology in response to local cues, such as the presence of a patch of nutrient. How are local signals integrated in these organisms, and how do they lead to an overall response? To answer this question, we focus on the flow of nutrients in the slime mold *Physarum polycephalum*. This slime mold exhibits internal flow oscillations, as well as periodic contractions of its veins. Using plastic masks, we constrain network growth to simple geometries. This allows for an experimental characterization of the relationship between the contractions and the flow. We next describe the change in the overall oscillation pattern when a food source is presented locally to the slime mold, and its implication on the internal flow. Internal flows are both inferred from the contraction pattern and experimentally measured using fluorescent markers.

1:39PM J40.00013 Scaling of Traction Stresses with Size of Cohesive Cell Colonies¹ , AARON F.

MERTZ, Yale University, SHILADITYA BANERJEE, Syracuse University, YONGLU CHE, Yale University, M. CHRISTINA MARCHETTI, Syracuse University, VALERIE HORSLEY, ERIC R. DUFRESNE, Yale University — We explore the mechanical properties of colonies of cohesive cells adherent on soft substrates. Specifically, we image the spatial distribution of traction stresses exerted by colonies of primary mouse keratinocytes on fibronectin-coated silicone gels. These cells have strong cell-cell adhesions mediated by E-cadherin. We observe that the work performed by a colony on its substrate is concentrated at the colony's periphery. The total work is strongly correlated to the geometrical size of the colony but not to number of cells. In other words, the mechanical output of a large single cell mimics that of a cohesive colony with the same overall size. We compare our findings to a recent theoretical model that treats the cohesive colony as an active gel.

¹This work was supported by NSF graduate fellowship to A.F.M., NSF grants to E.R.D. (DBI-0619674) and M.C.M. (DMR-0806511 and DMR-1004789), and NIH grants to V.H. (AR054775 and AR060295).

1:51PM J40.00014 Elasticity of adherent active cells on a compliant substrate¹ , SHILADITYA BANER-

JEE, Department of Physics, Syracuse University, AARON F. MERTZ, ERIC R. DUFRESNE², Department of Physics, Yale University, M. CRISTINA MARCHETTI, Department of Physics and Syracuse Biomaterials Institute, Syracuse University — We present a continuum mechanical model of rigidity sensing by living cells adhering to a compliant substrate. The cell or cell colony is modeled as an elastic active gel, adapting recently developed continuum theories of active viscoelastic fluids. The coupling to the substrate enters as a boundary condition that relates the cell's deformation field to local stress gradients. In the presence of activity, the substrate induces spatially inhomogeneous contractile stresses and deformations, with a power law dependence of the total traction forces on cell or colony size. This is in agreement with recent experiments on keratinocyte colonies adhered to fibronectin coated surfaces. In the presence of actomyosin activity, the substrate also enhances the cell polarization, breaking the cell's front-rear symmetry. Maximal polarization is observed when the substrate stiffness matches that of the cell, in agreement with experiments on stem cells.

2:03PM J40.00015 Wave transmission through cell-cell coupling , CHENLU WANG, MEGHAN DRISCOLL, SAGAR

CHOWDHURY, S.K. GUPTA, WOLFGANG LOSERT, University of Maryland-College Park — We previously found that waves of high boundary curvature travel from the front to the back of individual *D. discoideum* cells. We investigated the behavior of curvature waves in small groups of adherent cells, in particular, we investigated the transmission of the waves through cell-cell coupling. We analyzed the motion of individual cells in short streams of varying length, which are cells that follow one other. Furthermore, we developed a technique that uses holographic optical tweezers to grip cells indirectly and push them into one another, thereby forming artificial cell-cell contacts. Using that technique, we observed the affect of waves in coupled cells. We also compared the shape dynamics of groups of cells to the shape dynamics of cells within those groups. We extended these methods to suspended cells, which exhibit different wave dynamics.

Session J41 DFD: Vortex Dynamics, Turbulence and Geophysical Flows 156B

11:15AM J41.00001 Two point correlations between velocity sums and differences in turbu-

lence , NICHOLAS ROTILE, GREG VOTH, SUSANTHA WIJESINGHE, Wesleyan University — In turbulent flows, the universality of small scales has been a subject of ongoing investigation. Recent work has explored the degree to which small scales are independent of large scales by measuring correlations between velocity differences over a distance r (whose variance is dominated by scales near r) and velocity sums over the same distance (whose variance is dominated by large scales). Some correlations between velocity differences and sums are required by the Navier-Stokes equations (Hosokawa, Prog. Theor. Phys. Lett., 118:169, 2007.) This talk will focus on experimental measurements of correlations between velocity sums and velocity differences in a turbulent flow between oscillating grids. We find that these correlations provide an accurate way to measure the energy dissipation rate that complements existing methods based on the third order structure functions. The correlations which are required by Navier-Stokes dynamics do not appear to violate the assumption of independence between the large and small scales, however there are other correlations in our measurements that show clear dependence of the small scales on the large scales.

11:27AM J41.00002 Variance of scalar fluctuations using backwards relative dispersion in turbulent channel flows , CHIRANTH SRINIVASAN, DIMITRIOS PAPAVALASSIOU, The University of Oklahoma — Temperature fluctuations at a location in a turbulent flow field are brought about by the arrival of particle pairs with different scalar concentrations. Studying backwards relative dispersion can be an alternative way to describe the local variance in scalar fluctuation. This work uses a numerical approach that couples a direct numerical simulation with the tracking of scalar markers to obtain scalar statistics in an infinitely long turbulent channel flow. Focusing on the anisotropic direction perpendicular to the channel walls, the two-particle correlation coefficients are used to determine a Lagrangian material time scale as a function of distance from the wall. Introducing a model that follows Durbin's theory [1], the variance of the temperature fluctuation is calculated by assuming that particle pairs that arrive at a particular location carry with them the mean temperature acquired at the location they were at a previous time. This earlier location is determined by utilizing the Lagrangian backwards timescale. Results obtained from this model are tested at two different Reynolds numbers (at $Re_\tau = 150$ and 300) and for each Re case at several different Prandtl numbers (from 0.1 to 1,000). **References** [1] Durbin, P.A., J. Fluid Mech., 100, 279-302, 1980

11:39AM J41.00003 Measuring anisotropy as a function of scale in turbulence using 3D particle tracking, SUSANTHA WIJESINGHE, GREG VOTH, Department of Physics, Wesleyan University, Middletown, CT 06459 — We report the first full 3D experimental measurements of anisotropy as a function of scale in turbulence. From 3D particle tracks obtained with stereoscopic high speed video, we measure the Eulerian structure functions and decompose them into irreducible representation of $SO(3)$ rotation group. This method allows us to quantify the anisotropy in different sectors, specified by j and m of the spherical harmonics $Y_{jm}(\theta, \phi)$, at all scales in the flow. We study a turbulent flow between two oscillating grids in an octagonal tank filled with 1100 l of water with $Re_\lambda = 265$. An image compression system processes high-speed video from four cameras in real-time allowing us to acquire huge data sets required for full 3D measurement of anisotropy as a function of scale. Careful selection of a sample of measurements with isotropic orientations is necessary to ensure that anisotropy of the measurement system does not affect the measured anisotropy of the flow. Increasing j sectors show faster decay of anisotropy as scale decreases, consistent with the idea that the small scales should become isotropic at very high Reynolds number. However, conditioning the measured anisotropy on the instantaneous velocity reveals that characterization of anisotropy in an inhom

11:51AM J41.00004 Rotation rate of rods in turbulent flow, SHIMA PARSA, GREG VOTH, Wesleyan University — We present the first time resolved experimental measurements of the motion of small rod-like particles in turbulent flow. The orientation and position of rods are measured using Lagrangian particle tracking with images from multiple high speed cameras in a flow between two oscillating grids. We work at low particle density so rod-rod interaction can be ignored. The probability distribution of the rotation rate of the rods has extended tails indicating the presence of rare events with large rotation rate. Rods rotation rate is determined by the velocity gradients of the flow, so measurements of the rotation rate provide indirect access to statistics of the velocity gradient of the flow as well as the energy dissipation rate. However, tracer rods preferentially sample the flow since their orientation becomes correlated with the local axes of the velocity gradient tensor. The result is that the typical rotation rate of rods is much smaller than it would be if they were randomly oriented.

12:03PM J41.00005 Statistics of Macroturbulence from Flow Equations¹, BRAD MARSTON, THOMAS IADECOLA, WANMING QI, Brown University — Probability distribution functions of stochastically-driven and frictionally-damped fluids are governed by a linear framework that resembles quantum many-body theory. Besides the Fokker-Planck approach, there is a closely related Hopf functional method²; in both formalisms, zero modes of linear operators describe the stationary non-equilibrium statistics. To access the statistics, we generalize the flow equation approach³ (also known as the method of continuous unitary transformations⁴) to find the zero mode. We test the approach using a prototypical model of geophysical and astrophysical flows on a rotating sphere that spontaneously organizes into a coherent jet. Good agreement is found with low-order equal-time statistics accumulated by direct numerical simulation, the traditional method. Different choices for the generators of the continuous transformations, and for closure approximations of the operator algebra, are discussed.

12:15PM J41.00006 Motion of a Thread in Compressible Turbulence, RORY CERBUS, WALTER GOLDBURG, Department of Physics and Astronomy, University of Pittsburgh — Particles that float on a turbulent tank of water form a system that is compressible in the two dimensions on which they move. Here we study, with an overhead camera, the snake-like motion of a $10 \mu\text{m}$ thread that floats on the surface. The thread, of length much greater than the integral scale L_I of the underlying turbulence, cannot respond to the small-scale turbulent motions at the surface; its Young's modulus is too large. As a result, the mean curvature of the thread is of the order $1/L_I$. Measured properties include velocity structure functions of the thread $S_n(r)$ (including the third moment), the local curvature along the thread (a random variable), and "Richardson diffusion" of pairs of points along the thread separated by distances r . Supported by NSF Grant DMR 0604477 and the Okinawa Institute of Science Technology.

12:27PM J41.00007 Statistical Equilibria of Turbulence on Surfaces of Different Symmetry¹, WANMING QI, BRAD MARSTON, Brown University — We test the validity of statistical descriptions of freely decaying 2D turbulence by performing direct numerical simulations (DNS) of the Euler equation with hyperviscosity on a square torus and on a sphere. DNS shows, at long times, a dipolar coherent structure in the vorticity field on the torus but a quadrupole on the sphere². A truncated Miller-Robert-Sommeria theory³ can explain the difference. The theory conserves up to the second-order Casimir, while also respecting conservation laws that reflect the symmetry of the domain. We further show that it is equivalent to the phenomenological minimum-entropy principle by generalizing the work by Naso et al.⁴ to the sphere. To explain finer structures of the coherent states seen in DNS, especially the phenomenon of confinement, we investigate the perturbative inclusion of the higher Casimir constraints.

12:39PM J41.00008 Design and Evolution of Shaped Vortices, DUSTIN KLECKNER, WILLIAM T.M. IRVINE, University of Chicago — We present a novel method for generating vortex lines of arbitrary shapes. We then image their dynamics using a high speed scanning technique which provides three-dimensional information at up to 500 volumes per second. We create a variety of configurations and study the effect of geometry on their evolution.

12:51PM J41.00009 Insights into vortex merger using the core growth model, FANGXU JING, Georgia Institute of Technology, EVA KANSO, PAUL NEWTON, University of Southern California — We revisit the two vortex merger problem (both symmetric and asymmetric) for the Navier-Stokes equations using the core growth model for vorticity evolution coupled with the passive particle field and an appropriately chosen time-dependent rotating reference frame. Using the combined tools of analyzing the topology of the streamline patterns along with careful tracking of passive fields, we highlight the key features of the stages of evolution of vortex merger, pinpointing deficiencies in the low-dimensional model with respect to similar experimental/numerical studies. The model, however, reveals a far richer and delicate sequence of topological bifurcations than has previously been discussed in the literature for this problem, and at the same time points the way towards a method of improving the model.

1:03PM J41.00010 Entrainment of solid particles by energetic flow events, MANOUSOS VALYRAKIS, Virginia Tech — The focus of this research study is to investigate the utility and applicability of a recently proposed criterion for the prediction of incipient entrainment of sediment particles. Recently introduced theoretical frameworks and stochastic approaches are presented. At near incipient flow conditions the magnitude of energetic flow events follows a power law distribution, over a wide range of frequencies, similar to many other geophysical phenomena. This implies that highly energetic flow structures, which have a good potential of impinging on an exposed particle and displacing it downstream, occur less frequently. This is in agreement with the intermittent and episodic character of particle entrainment observed from mobile particle flume experiments at low flow stages. Further, analysis of synchronous time series of particle entrainment and local instantaneous flow upstream of it, allows for extraction and characterization of the scales and magnitudes that are relevant to the displacement of individual particles. In addition to having a sound theoretical basis, the modeling approach is shown to perform well in accurately defining the condition of incipient motion and various levels of probability of particle entrainment.

1:15PM J41.00011 Modeling and dynamics of sand bed vortex ripples, JUSTIN KAO, ABIGAIL KOSS, TAYLOR PERRON, Massachusetts Institute of Technology — Vortex ripples arise through the instability of a flat sand bed under oscillatory water flow, for example due to wave action at a beach or continental shelf. Fully developed vortex ripples display complex interactions through the mutual influence of fluid flow and bed topography on each other, via sediment transport. We discuss a mechanistic model of ripple dynamics in which the hydrodynamic influence is linearized, and show that this reduced model nonetheless captures many of the ripple dynamics observed in experiments. Cross-sectional profiles of experimentally generated ripples constrain the modeled sediment flux and provide support for our approximations.

1:27PM J41.00012 The statistics of wind driven ocean currents, YOSEF YOSEF, GOLAN BEL, Dept. of Solar Energy and Environmental Physics, Ben-Gurion University of the Negev — Ocean currents play an important role in the climate system, yet the properties and origin of their statistics is not fully understood. Using the Ekman layer model we show that the statistical properties of the depth integrated surface currents are associated with the temporal correlations of the wind driving the surface currents—when the temporal correlations of the wind are long the probability distribution of the current magnitude is proportional to that of the wind stress. When the temporal correlations of the wind are short the current approaches zero where each component of the current follows a Gaussian distribution such the current magnitude follows the Rayleigh distribution. Using two idealized cases we show that in between these two limits the second (and higher) moment of the current magnitude reaches a maximal value. The results are validated using an oceanic general circulation model.

1:39PM J41.00013 Modulation of Atlantic tropical cyclones by El Nino - Southern Oscillation, CONSTANTIN ANDRONACHE, Boston College — North Atlantic tropical cyclones (TC) usually form in the northern hemisphere summer and fall with a maximum of activity in September. El Nino–Southern Oscillation (ENSO) has been shown to impact seasonal levels of Atlantic basin TC activity. ENSO is the strongest year to year climate fluctuation on Earth. It originates in the tropical Pacific through coupled ocean-atmosphere interactions mediated by surface wind stress and sea surface temperature (SST) variations. Understanding the effects of ENSO on the seasonal variations of TC activity has important practical consequences for seasonal forecast of hurricanes in North Atlantic. In this study we use the NOAA Extended Reconstructed Sea Surface Temperature, the TC counts in North Atlantic, and the NCEP/NCAR reanalysis data to investigate the relationship between significant ENSO events and TC activity during the hurricane season. Model calculations show that forecasted ENSO SSTA can be used as predictors of TC in North Atlantic region. Such results are illustrated in the context of current efforts to understand climate predictability relevant to North Atlantic tropical storms.

1:51PM J41.00014 Fingers and Toes in Miscible Viscous Flows, RADHA RAMACHANDRAN, IRMGARD BISCHOF-BERGER, SIDNEY NAGEL, University of Chicago — The displacement of a more viscous fluid by a less viscous one in a porous medium produces complex fingering patterns. To study this phenomenon a Hele-Shaw geometry is used in which the gap-averaged equations for flow between two parallel plates has the same form as Darcy's law for flow in porous media. Our experiments use a radial Hele-Shaw cell as well as a two dimensional porous medium of densely packed granular beads between two circular glass plates, to study viscous fingering in miscible fluids. For immiscible fluids it is known that the most-unstable wavelength for interface growth depends on surface tension, viscosity difference, velocity and plate spacing. In contrast, we find that for *miscible fluids* the large-scale structure (i.e., the ratio of finger length to overall size of the pattern) is set entirely by the viscosity ratio rather than the viscosity difference of the two fluids. We further investigate the role played by other dimensionless parameters in determining the fine structure and evolution of these fingering patterns in the two geometries.

2:03PM J41.00015 Thermal plumes in locally heated vertical soap films, NICOLAS ADAMI, STÉPHANE DORBOLO, HERVÉ CAPS, Université de Liège, GRASP TEAM — A vertical soap film is maintained by injection of a soap solution from the top. The film is then locally heated. Thermal plumes may be observed to rise in the film, depending on the magnitude of the heating and injected flows. The nearly-2D nature of the system allows to visualize the motion of the plumes using an infrared camera. A model is proposed to describe the growth, emergence, and stationarity of the plumes in the film by taking into account both magnitudes of the heating ΔT and injected flow Q . Oscillatory behaviors of both the full-grown plumes size and direction with respect to the vertical direction may also be observed. Particular soap film thickness dynamics shows to be the origin of those phenomena.

Tuesday, February 28, 2012 11:15AM - 1:51PM –

Session J42 DBIO GSNP: Focus Session: Stochastic Population Dynamics I - Cyclic competition and population stability 156C

11:15AM J42.00001 Cyclic competition of four or more species: Results from mean field theory and stochastic simulations¹, R.K.P. ZIA, Physics Department, Virginia Tech, Blacksburg, VA 24061 — Population dynamics is a venerable subject, dating back two centuries to Malthus, Verhulst, Lotka, Volterra, and many others. Nonetheless, new and interesting phenomena are continually being discovered. For example, the recent discovery of "Survival of the Weakest" in cyclic competition between 3 species with no spatial structure (Berr, Reichenbach, Schottenloher, and Frey, Phys. Rev. Lett. 102, 048102 (2009)) attracted considerable attention, e.g., <http://www.sciencedaily.com/releases/2009/02/090213115127.htm>. Considering a similar system with 4 or more species, we find a more intuitively understandable principle which appears to underpin all systems with cyclically competing species. We will present several interesting aspects of the 4 species system – from non-linear dynamical phenomena in a deterministic mean-field approach to remarkable extinction probabilities in the stochastic evolution of a finite system. Some insights into the deterministic dynamics, gained from generalizing this system to one with any number of species with arbitrary pairwise interactions, will also be discussed.

¹Supported in part by NSF-DMR-0904999 and 1005417.

11:51AM J42.00002 Varieties of extinction scenarios when four species compete cyclically¹, S.O. CASE, C.H. DUNEY, M. PLEIMLING, R.K.P. ZIA, Virginia Tech — We study a stochastic system with N individuals, consisting of four species competing cyclically: $A + B \rightarrow A + A, \dots, D + A \rightarrow D + D$. Randomly choosing a pair and letting them react, N is conserved but the fractions of each species evolve non-trivially. At late times, the system ends in a static, absorbing state — typically, coexisting species AC or BD . The master equation is shown and solved exactly for $N = 4$, providing a little insight into the problem. For large N , we rely on simulations by Monte Carlo techniques (with a faster dynamics where a reaction occurs at every step). Generally, the results are in good agreement with predictions from mean field theory, after appropriate rescaling of Monte Carlo time. The theory fails, however, to describe extinction or predict their probabilities. Nevertheless, it can hint at many remarkable behavior associated with extinction, which we discover when studying systems with extremely disparate rates.

¹Supported in part by NSF-DMR-0705152, 0904999, 1005417.

12:03PM J42.00003 The effects of mobility on the one-dimensional four-species cyclic predator-prey model¹, DAVID KONRAD, MICHEL PLEIMLING, Virginia Tech — The dynamics of a one-dimensional lattice composed of four species cyclically dominating each other is very much dependent on the rates of mobility in the system. We realize mobility as the exchange of two particles located at two nearest neighbor sites with some species dependent rate s . Allowing for only one particle per site, the different species interact cyclically, with species dependent consumption rate k , such that $k + s \leq 1$. When varying the exchange rates, we see vastly different behavior when compared to the three-species model. The patterns of domain growth and decay still show an overall power law behavior, however the fundamental trend of domain growth does not follow the three-species case. We also look at the space-time diagrams to see precisely how the domains form, grow, and decay.

¹Supported in part by the US National Science Foundation through Grant DMR-0904999.

12:15PM J42.00004 Boundary conflicts and cluster coarsening: Waves of life and death in the cyclic competition of four species¹, AHMED ROMAN, MICHEL PLEIMLING, Virginia Tech — In the cyclic competition among four species on a two-dimensional lattice, the partner particles, which swap positions on the lattice with some probability, produce clusters with a length that grows algebraically as $t^{1/z}$ where z is the dynamical exponent. Further investigation of the dynamics at the boundary of the clusters is realized by placing one partner particle pair in the upper half of the system and the other pair in the lower half. Using this technique, results about the fluctuations of the interface are obtained. We also observe wave fronts in the case of non-symmetric reaction rates where extinction of a partner particle pair takes place.

¹Supported in part by the US National Science Foundation through Grant DMR-0904999.

12:27PM J42.00005 Discriminating the effects of spatial extent and population size in cyclic competition among species, DAVID LAMOUROUX, STEPHAN EULE, THEO GEISEL, JAN NAGLER, Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany — Quantifying and understanding the stability and biodiversity of ecosystems is a major task in biological physics as well as in theoretical ecology. From the perspective of game theory, this is highly relevant for questions pertaining to the emergence of cooperation or the coexistence of cyclically competing species. The latter has been recently proposed as a paradigm for biodiversity and it has been shown that the mobility of individuals can support the stability of biodiversity by the formation of spirals. In this contribution, we present a population model for species under cyclic competition that extends earlier lattice models to allow the single cells to accommodate more than one individual by introducing a per cell carrying capacity. We confirm that the emergence of spirals induce a transition from an unstable to a stable regime. This transition however does not appear to be sharp and we find a broad intermediate regime that exhibits an ambiguous behavior. The separation of the two regimes by the usual scaling analysis is thus hampered. The newly introduced carrying capacity offers an alternative way of characterizing the transition. We thus overcome the original limitations by separately analyzing the effect of spatial extent and population size.

12:39PM J42.00006 Stochastic extinction dynamics of HIV-1¹, IRA SCHWARTZ², US Naval Research Laboratory, ERIC FORGOSTON³, Montclair State University, LEOR WEINBERGER⁴, Gladstone Institute of Virology and Immunology and University of California, San Francisco — We consider an HIV-1 within host model in which T cells are infected by the virus. Due to small numbers of molecules, stochastic effects play an important role in the dynamical outcomes in that two states are observed experimentally: a replication state in which the virus is active, or a dormant state leading to latency in which the virus becomes active after a delay. The two states are conjectured to be governed by the Tat gene protein transcription process, which does not possess two stable attractors. Rather, the active state is stable, while the dormant state is unstable. Therefore the dormant state can only be achieved through the dynamics of stochastic fluctuations in which noise organizes a path to dormancy. Here we use optimal path theory applied to a Tat gene stochastic model to show how random fluctuations generate the dormant state by deriving a path which optimizes the probability of achieving the dormant state. We explicitly show how the probability of achieving dormancy scales with the transition rate parameters.

12:51PM J42.00007 Experimental observation of critical slowing down before population collapse, LEI DAI, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA., DAAN VORSELEN, Department of Physics and Astronomy, VU University, Amsterdam, The Netherlands., CARMEL DUDLEY, ONUR ORNEK, KIRILL KOROLEV, JEFF GORE, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA. — Tipping points marking population collapse and other critical transitions in natural systems (*e.g.* ecosystems, the climate) can be described by a fold bifurcation in the dynamics of the system. Theory predicts that the approach of bifurcations will result in an increasingly slow recovery from small perturbations, a phenomenon called critical slowing down. Here we demonstrate the direct observation of critical slowing down before population collapse using replicate laboratory populations of the budding yeast *Saccharomyces cerevisiae*. We mapped the bifurcation diagram experimentally and found a significant increase in both the size and timescale of the fluctuations of population density near a fold bifurcation, in agreement with the theory. We further confirmed the utility of theoretically predicted warning signals by observing them in two different slowly deteriorating environments. To extend the application of warning signals to spatially extended populations, we proposed and identified several indicators based on the emergence of spatial patterns. Our results suggest that generic temporal and spatial indicators of critical slowing down can be useful in predicting tipping points in population dynamics.

1:03PM J42.00008 Extinction of Bacterial Populations: A Change of Paradigm?¹, INGO LOHMAR, BARUCH MEERSON, Racah Institute of Physics, The Hebrew University, Jerusalem — It is now well-established that individual bacteria of many types switch stochastically between two phenotypes: fast-growing “normals” susceptible to antibiotics, and slowly-growing “persisters” hardly affected by the drug. In the competition of species during exponential growth, persisters are a burden, but they may become beneficial when introducing “stress” phases like drug treatment. We suggest to shift the focus to the *persistence* of an established population. Due to fluctuations, the population will (after a long time) eventually go extinct; persisters act as a life insurance against this. We study a simple stochastic model of these processes. Using a WKB approximation, we find the most likely path to extinction and quantify the extinction risk under both favorable and adverse conditions. Analytical results are obtained both in the biologically relevant regime when the switching is rare compared with the birth and death processes, and in the opposite regime of frequent switching. We explain how persisters strongly reduce the extinction risk and show that rare switches are most beneficial to this end. [I. Lohmar and B. Meerson, *Phys. Rev. E* **84** 051901 (2011)]

1:15PM J42.00009 Invasion, Coexistence, and Extinction Driven by Preemptive Competition and Sex Ratio¹, FERENC MOLNAR, Dept. of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, THOMAS CARACO, Dept. of Biological Sciences, University at Albany, GYORGY KORNISS, Dept. of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute — We investigate competitive invasion in a simple population dynamics model, where females can differ genetically in the sex ratio of their offspring, and males can differ in mortality. Analyzing of the mean-field dynamics, we obtain conditions for ecological stability of a given sex-ratio allele for any mortality rate parameters. We also found that stable coexistence of the two alleles is possible, but only males can differ; one female phenotype is present. Our results show that the success of invasion is determined by the female birth sex ratio. A lower female ratio never excludes a larger female sex ratio; in case of coexistence, the surviving female phenotype always has the greater female sex ratio. Finally, we identified an interesting invasion-to-extinction scenario: successful invasion followed by extinction occurs when the invader initially propagates with the resident allele, but after excluding the resident, cannot survive on its own.

¹Supported in part by NSF Grants Nos. DEB-0918392 and DEB-0918413.

1:27PM J42.00010 Vaccine enhanced extinction in stochastic epidemic models¹, LORA BILLINGS, Montclair State University, LUIS MIER-Y-TERAN, Johns Hopkins Bloomberg School of Public Health, IRA SCHWARTZ, U.S. Naval Research Laboratory — We address the problem of developing new and improved stochastic control methods that enhance extinction in disease models. In finite populations, extinction occurs when fluctuations owing to random transitions act as an effective force that drives one or more components or species to vanish. Using large deviation theory, we identify the location of the optimal path to extinction in epidemic models with stochastic vaccine controls. These models not only capture internal noise from random transitions, but also external fluctuations, such as stochastic vaccination scheduling. We quantify the effectiveness of the randomly applied vaccine over all possible distributions by using the location of the optimal path, and we identify the most efficient control algorithms. We also discuss how mean extinction times scale with epidemiological and social parameters.

1:39PM J42.00011 Fast stochastic algorithm for simulating evolutionary population dynamics¹, LEV TSIMRING, JEFF HASTY, WILLIAM MATHER, University of California, San Diego — Evolution and co-evolution of ecological communities are stochastic processes often characterized by vastly different rates of reproduction and mutation and a coexistence of very large and very small sub-populations of co-evolving species. This creates serious difficulties for accurate statistical modeling of evolutionary dynamics. In this talk, we introduce a new exact algorithm for fast fully stochastic simulations of birth/death/mutation processes. It produces a significant speedup compared to the direct stochastic simulation algorithm in a typical case when the total population size is large and the mutation rates are much smaller than birth/death rates. We illustrate the performance of the algorithm on several representative examples: evolution on a smooth fitness landscape, NK model, and stochastic predator-prey system.

Tuesday, February 28, 2012 11:15AM - 2:15PM – Session J43 GSNP DFD: Invited Session: Stochastic Geometry and Conformal Invariance in Non-Equilibrium and Disordered Systems 157AB

11:15AM J43.00001 Stochastic geometry of turbulence, GREGORY FALKOVICH, Weizmann Institute of Science — Geometric statistics open the window into the most fundamental aspect of turbulence flows, their symmetries, both broken and emerging. On one hand, the study of the stochastic geometry of multi-point configurations reveals the statistical conservation laws which are responsible for the breakdown of scale invariance in direct turbulence cascades. On the other hand, the numerical and experimental studies of inverse cascade reveal that some families of isolines can be mapped to a Brownian walk (i.e. belong to the so-called SLE class) and are thus not only scale invariant but conformally invariant. That means that some aspects of turbulence statistics can be probably described by a conformal field theory. The talk is a review of broken and emerging symmetries in turbulence statistics.

11:51AM J43.00002 Stochastic geometry in disordered systems, applications to quantum Hall transitions, ILYA GRUZBERG, The University of Chicago — A spectacular success in the study of random fractal clusters and their boundaries in statistical mechanics systems at or near criticality using Schramm-Loewner Evolutions (SLE) naturally calls for extensions in various directions. Can this success be repeated for disordered and/or non-equilibrium systems? Naively, when one thinks about disordered systems and their average correlation functions one of the very basic assumptions of SLE, the so called domain Markov property, is lost. Also, in some lattice models of Anderson transitions (the network models) there are no natural clusters to consider. Nevertheless, in this talk I will argue that one can apply the so called conformal restriction, a notion of stochastic conformal geometry closely related to SLE, to study the integer quantum Hall transition and its variants. I will focus on the Chalker-Coddington network model and will demonstrate that its average transport properties can be mapped to a classical problem where the basic objects are geometric shapes (loosely speaking, the current paths) that obey an important restriction property. At the transition point this allows to use the theory of conformal restriction to derive exact expressions for point contact conductances in the presence of various non-trivial boundary conditions.

12:27PM J43.00003 Efficient SLE algorithms and numerical pitfalls of the method¹, TOM KENNEDY, Departments of Mathematics and Physics, University of Arizona — We consider a physical experiment or a numerical simulation of a physical phenomena that produces a random family of two-dimensional curves. We would like to know if there is a conformal invariance underlying this stochastic geometry. The Schramm-Loewner evolution (SLE) is a conformally invariant stochastic process which depends on a single parameter κ . For different values of κ it is known to describe the scaling limit of many conformally invariant 2d systems, e.g. percolation, the Ising model, self-avoiding walks and many more. So it is a natural candidate for describing the stochastic geometry of other physical systems. The classical Loewner equation provides a correspondence between curves in the plane and “driving functions,” and SLE is obtained by taking the driving function to be a Brownian motion. Given a collection of random curves in the plane one would like to determine if the curves come from an SLE process for some value of κ . One method is to compute the driving processes of the curves and test if they are a Brownian motion. We discuss algorithms for doing this efficiently and some of the pitfalls in this approach.

1:03PM J43.00004 Search for Conformal Invariance in Two-dimensional Compressible Turbulence, - STEFANUS, University of Pittsburgh — We present a viable way of experimentally testing for conformal invariance at the surface of a turbulent fluid. The theory being tested here is related to the behavior of random curves on a plane and is associated with the work of Loewner, Schramm and others. It is usually referred to as Schramm-Loewner evolution (SLE). The scalar random variables that are put to this test are the vorticity and the divergence of the surface flow. Both of these variables display certain characteristics of Brownian motion, but the divergence field does not exhibit the Gaussian behavior required by SLE.

1:39PM J43.00005 Schramm-Loewner (SLE) analysis of quasi two-dimensional turbulent flows, SIMON THALABARD, SPEC/IRAMI/CEA Saclay — Quasi two-dimensional turbulence can be observed in several cases: for example, in the laboratory using liquid soap films, or as the result of a strong imposed rotation as obtained in three-dimensional large direct numerical simulations. We study and contrast SLE properties of such flows, in the former case in the inverse cascade of energy to large scale, and in the latter in the direct cascade of energy to small scales in the presence of a fully-helical forcing. We thus examine the geometric properties of these quasi 2D regimes in the context of stochastic geometry, as was done for the 2D inverse cascade by Bernard et al. (2006). We show that in both cases the data is compatible with self-similarity and with SLE behaviors, whose different diffusivities can be heuristically determined.

Session J44 DPOLY: Focus Session: Dynamics of Polymers: Phenomena Due to Confinement

I 157C

11:15AM J44.00001 A closer look at the two-layer model, DONGDONG PENG, Boston University — Previously we have measured the viscosity of short-chain, unentangled polystyrene films coated on silicon covered with a 100 nm thick oxide layer. We found that a two-layer model, portraying the films as being made of a 3 nm thick mobile layer sitting on top of a bulk-like inner layer, was able to describe our data very well. More recently, we extended similar measurements to entangled films with a higher molecular weight of 212 kg/mol. We found that the same two-layer model was able to describe the viscosity measurements, but would imply an unphysically large stretching of the polymer chains in the films or else the near-surface chains would have to be oblate spheroids with an aspect ratio of about 4. In this talk, I will discuss new results we obtain from films with higher molecular weights of up to 2316 kg/mol and also films that are deposited on a different kind of substrate, namely hydrogen terminated silicon. Implications of these results on the two-layer model will be discussed.

11:27AM J44.00002 Inter- and intra-chain Proximity in PS and PMMA free-standing thin films Studied by Fluorescence NRET, JIE XU, GI XUE, Nanjing University — The reduction in glass transition temperature (T_g) for free-standing thin polymer film has attracted a long term discussion. We found that the inter- and intra-chain coupling/constraint restricts the molecular motion of polymer chains and thus results in the deviation in glass transition dynamics. To observe inter-chain proximity and control the inter-chain interaction, we attached carbazoyl probe (donor) and anthryl probe (acceptor) to some side groups of different chains respectively. Meanwhile, we also attached both donor and acceptor to one chain to characterize the intra-chain constraint. A close proximity of the donor to the acceptor results in a higher NRET efficiency. So the NRET results can provide information about chain proximity and packing density in polymer thin film. With decreasing film thickness h , the density of the films was reduced. The magnitude of the reduction in packing density for PS free-standing films was much larger than that in PMMA, resulted a larger reduction in T_g for PS film.

11:39AM J44.00003 Surface Dynamics of Partially Tethered Polymer Films, MARK FOSTER, JIN KUK LEE, Dept. of Polymer Science, The University of Akron, BULENT AKGUN, NIST Center for Neutron Research, ZHANG JIANG, SURESH NARAYANAN, X-ray Science Division, Argonne National Laboratory, SUSHIL SATIJA, NIST Center for Neutron Research — The surface dynamics of thin polystyrene (PS) melt films can be tailored by tethering some of the chains to a supporting substrate. The relaxation of surface height fluctuations for these films depends on the density of grafting, molecular weight of tethered chains, and extent to which tethered chains extend into the layer. The surface dynamics of “partially tethered” thin films have been studied using X-ray photon correlation spectroscopy (XPCS). PS chains have been grafted to substrates with low grafting densities untethered deuterated PS (dPS) chains spun cast on the tethered chains, and the films annealed to create layers containing both tethered and untethered chains. The degree to which the tethered PS extends into the untethered dPS chains has been measured by neutron reflectivity.

11:51AM J44.00004 Structural characterization of irreversibly adsorbed polymer layers at the polymer/solid interface - In-situ grazing incidence angle x-ray scattering studies¹, NAISHENG JIANG, FEN CHEN, XIAMENG CHEN, ZEXI HAN, CHEN LIANG, PETER GIN, Department of Materials Science and Engineering, Stony Brook University, MITSUNORI ASADA, Kurashiki Research Center, Kuraray Co., Ltd., Japan, MAYA ENDOH, TAD KOGA, Department of Materials Science and Engineering, Stony Brook University — In recent years, great attention has been paid to irreversibly adsorbed polymer layers formed on solid substrates since they can modify various properties of polymeric materials confined at the nanometer scale. In this talk, by the combined use of in-situ grazing incidence small angle x-ray scattering and x-ray reflectivity techniques, we aim to characterize the detailed structures of the adsorbed layers composed of different homopolymers (polystyrene, polybutadiene, poly (ethylene oxide), and poly (methyl methacrylate)) prepared on silicon substrates. We will highlight the generality/differences in the structures, leading to a better understanding of the formation process of the adsorbed layers at the impenetrable solid interfaces.

12:03PM J44.00005 Relaxation of Polyisoprene in Nanoscale Confinement , SUNG A. KIM, PRAVEEN AGARWAL, LYNDEN ARCHER, Cornell University — This talk introduces a simple model of confined polymers in polymer nanoparticle composites. Most studies about confined polymer dynamics have been investigated from the system of polymers in porous media or the polymer thin film structure. This new class of polymer nanoparticle hybrid materials, termed Nanoscale Ionic Materials (NIMs), is synthesized in bulk scale with convenient controllability of diverse properties to create the confined polymers in nanoscale. cis-Polyisoprene (PI), type A polymer whose dipole moments are parallel along the chain backbone, are synthesized by anionic polymerization and then tethered to spherical silica nanoparticles. Broadband Dielectric Spectroscopy measures responses to the applied electric field which are normal mode relaxation indicative of whole chain relaxation, and also segmental relaxation. We show that relaxations of PI are slower when simultaneously confined and tethered. We also show that molecular weight and grafting density have a profound effect on dynamics of the twice-confined PI chains.

12:15PM J44.00006 Molecular simulations of confined polymer glasses , ROBERT RIGGLEMAN, AMIT SHAVIT, University of Pennsylvania — For many technological applications ranging from semiconductor manufacturing to membranes for separations and flexible displays, the properties of glass-forming materials confined on the nanoscale are of critical importance. For example, common semiconductor manufacturing techniques rely on the mechanical integrity of amorphous polymer nanostructures. Experiments over the past several years have demonstrated that many of the properties of polymer glasses (e.g., the glass transition temperature, T_g , and the elastic constants) can change significantly and in unintuitive ways when confined to dimensions below approximately 100 nm. These confinement effects depend strongly on the detailed polymer chemistry. In this talk, I will describe our recent work using molecular simulations to study the effects of nanoscale confinement on both the dynamic and mechanical properties of a series of coarse-grained polymer models. Our coarse-grained models systematically explore the effects of polymer chemistry by gradually changing the polymer backbone stiffness and analyzing changes in various properties in free-standing thin films. We find that the confinement effects can vary drastically depending on the properties measured, and in some cases we observe significant ordering of our polymer chains

12:27PM J44.00007 Structure and Dynamics of Polymer / Single Wall Carbon Nanotube Nanocomposites , NIGEL CLARKE, ARGYRIOS KARATRANTOS, University of Sheffield, KAREN WINEY, RUSSELL COMPOSTO, University of Pennsylvania — We simulate the static¹ and dynamic² properties of monodisperse polymers in the presence of a SWCNT using molecular dynamics. The SWCNT has a large aspect ratio and radius smaller than the polymer radius of gyration. We find that although the local chain structure is significantly affected, the overall configuration, as characterized by the radius of gyration, is not perturbed by either the interaction strength between the polymer and the SWCNT or by variations in the SWCNT radius. In contrast, for the dynamics of entangled polymers, we find a significant heterogeneity, with the center of mass polymer diffusion being affected by the strength of the enthalpic interaction between monomers and the SWCNT, as well as the SWCNT radii. In addition, we find that the polymer chain diffusivity perpendicular to the SWCNT is smaller than that parallel to the SWCNT in the case of entangled polymers.

²Karatrantos A., Composto R.J., Winey K.I., Clarke N., in preparation.

12:39PM J44.00008 Polymer Conformations in SWCNT/Polystyrene Nanocomposites using SANS¹ , WEI-SHAO TUNG, University of Pennsylvania, NIGEL CLARKE, University of Sheffield, RUSSELL J. COMPOSTO, KAREN I. WINEY, University of Pennsylvania — Polymer conformations are a critical factor that affects the performance of polymer nanocomposites. Using small angle neutron scattering, we probe chain conformations and confinement of polymers in SWCNT/polystyrene nanocomposites. We established the contrast matching criteria by measuring nanocomposites with different dPS:PS ratios (79:21 to 63:37) for two different SWCNT loadings and found the best ratio of dPS:PS (72.5:27.5) which gives us a similar scattering strength as SWCNT. Therefore, the scattering signal from SWCNT are screened and contribute little to the total scattering intensity. By making contrast matched samples, we are able to focus on the scattering intensity from polymer chains and determine R_g by fitting the intensity data. We found that the R_g of the polymer chain increases weakly with 1 wt% (< 5%) nanotube and then strongly (>25%) with 3 wt% nanotube, while the chain conformation still follows Gaussian statistics.

12:51PM J44.00009 Structures and Dynamics of Polymers Adsorbed on Supported Cationic Lipid Membrane , CHEN-MING CHANG, YUK-GYN LAU, JIH-CHIANG TSAI, WEN-TAU JUAN, Institute of Physics, Academia Sinica, Taipei, Taiwan — The structures and dynamics of polymers adsorbed on various surfaces have received attentions not only as a subject concerning fundamental polymer physics, but also for their important roles in many industrial and biological processes. In this talk, I will discuss our recent work utilizing single-molecule imaging to study the conformation and dynamics of fluorescent dye labeled λ -DNA molecules adsorbed on supported cationic lipid membrane. High-magnification snapshots of individual molecules, combined with statistical analyses on their apparent size and anisotropy as well as dynamic analyses on their diffusions, reveal interesting details that could have been overlooked in measurements based on ensemble averaging and theories based on polymers in 2D.

1:03PM J44.00010 Structure and Dynamics in Hyperbranched Nanohybrids , K. CHRISOPOULOU, S. FOTIADOU, S.H. ANASTASIADIS, Foundation for Research and Technology-Hellas and Univ. of Crete, Greece, B. FRICK, ILL, France — The structure and dynamics of a hyperbranched polyester-amide (Hybrane[®] 1200, $M_n=1200$, $T_g=45^\circ\text{C}$) polymer and its nanocomposites with natural montmorillonite (Na^+ -MMT) are investigated to offer a detailed picture of its behavior in bulk and under confinement and reveal its potential use for various applications. The static properties were studied utilizing X-ray diffraction (XRD), while the dynamics using energy-resolved elastic and quasi-elastic neutron scattering (QENS). XRD reveals that the polymer chains reside within the galleries of the Na^+ -MMT producing an intercalated nanocomposite. The elastically scattered intensity for the polymer exhibits two distinct relaxation steps, which are attributed to the methyl group rotation and to the segmental motion. The intensity for the nanocomposite shows the first step broader than the respective of the pure polymer indicating restricted local motion whereas it indicates frozen dynamics under confinement at temperatures higher than the bulk polymer glass transition temperature, T_g . The QENS spectra measured at temperatures covering the regimes below and above T_g are in agreement with the elastic measurements. Sponsored by the Greek GSRT ($\Sigma\text{YNEPTA}\Sigma\text{IA}$; 09 $\Sigma\text{YN} - 42 - 580$) and by the EU (CP-IP 246095-2).

1:15PM J44.00011 Large Amplitude Shear Deformations of Nano-Filled Elastomers: Evidence of Glassy Dynamics in the Vicinity of the Fillers , DIDIER LONG, PAUL SOTTA, CNRS/Rhodia, SAMY MERABIA, CNRS/Universite Lyon I, AURELIE PAPON, ESPCI, FRANCOIS LEQUEUX, HELENE MONTES, CNRS/ESPCI, LAURENT GUY, Rhodia — Adding fillers in elastomers is known to increase the elastic modulus and the wear resistance of elastomers, but also to increase non-linear dissipation, a phenomenon known as the Payne effect. Indeed, when submitted to deformations of the order of a few per cents or more, the elastic modulus can decrease down to values much smaller than the initial one. On the other hand, when submitted to large amplitude oscillatory shear, frequency analysis shows that the contribution of higher harmonics to the response is quite small. This might appear somehow as a paradox since the non-linear behavior of filled elastomers can be strongly marked. We proposed a possible physical origin of these various features. We do it by comparing experimental results performed on model elastomers to the prediction of a model proposed recently, based on the presence of glassy bridges linking neighboring particles. The non-linear response is a consequence of a shift towards shorter time scales (as compared to the non-perturbed distribution) of the relaxation time distribution when a large amplitude periodic solicitation is applied. The non-harmonic response is the consequence of the fluctuation during one cycle of the distribution of relaxation times and is thus a much smaller effect.

1:27PM J44.00012 Polymer Diffusion Slows Down in Nanocomposites Containing Hard Nanospheres¹, RUSSELL COMPOSTO, SANGAH GAM, KAREN WINEY, University of Pennsylvania, NIGEL CLARKE, University of Sheffield, JEFFREY METH, E.I. DuPont de Nemours & Co. — Here, we present two experimental studies of tracer diffusion in polymer nanocomposites (PNCs). Tracer diffusion of deuterated polystyrene (dPS) in a PS matrix containing phenyl-grafted silica (13nm and 29nm) represents a PNC with a weak polymer/particle interaction [1]. However, tracer diffusion of deuterated poly(methyl methacrylate) (dPMMA) in a PMMA matrix containing hydroxyl-terminated silica (13 nm and 28nm) represents a PNC with a strongly attractive polymer/particle interaction. In the former case, the normalized diffusion coefficients fall on a master curve when plotted against the confinement parameter, namely the interparticle separation normalized by the probe size. However in the latter case, the reduced diffusion coefficients in the PMMA matrix with 13nm nanoparticles are less than those with 29nm nanoparticles, suggesting that enthalpic interactions play a role in slowing down diffusion. These experimental studies indicate that a successful model of polymer dynamics must include contributions due to constraints imposed by the nanoparticles as well as interactions between polymer and nanoparticles.

1:39PM J44.00013 Time and Temperature Dependent Surface Stiffness of Poly(alpha-methylstyrene)(PAMS) through Particle Embedment¹, TASKIN KARIM, GREGORY MCKENNA, Texas Tech University — In the present work, we have used the particle embedment technique with sub-micron particles to study the time dependence surface modulus of poly(alpha-methylstyrene)(PAMS) at different temperature ranging from room temperature to $1.1T_g$ of PAMS. The surface was found softer at room temperature and at $1.02T_g$ compared to the bulk film while at $1.1T_g$ the surface was found stiffer compared to the macroscopic modulus measured for the same PAMS. The embedment of the particle is determined from atomic force microscope measurements and the modulus was determined using the elastic analysis of Johnson, Kendall and Roberts (JKR) with surface energy estimates of the work of adhesion as the driving force for embedment. 1:51PM J44.00014 The Calorimetric Glass Transition of Polystyrene Ultrathin Films¹, SIYANG GAO, YUNG P. KOH, SINDEE SIMON, Texas Tech University — Although the glass transition behavior of polystyrene ultrathin films has been widely studied, calorimetric measurements are limited due to difficulties in sample preparation. Here we report the use of a rapid scanning calorimeter based on a membrane sensor to measure the rate-dependent glass transition temperature (T_g) for single ultrathin films. Both microtomed and spin-coated films are investigated. Preliminary results suggest that the magnitude of the T_g depression is similar to that observed for freely-standing films. The T_g depression also depends on the cooling rate such that at the highest rates used (1000 K/s), the depression is only a few degrees. The kinetics of dewetting are followed, with T_g values increasing as a function of time and finally reverting to the bulk values after several hours at 160 °C.

2:03PM J44.00015 Dynamics of anchored polymer chains in a tunable micelle confinement system, HENGXI YANG, CHELSEA CHEN, GA RAM JUN, PETER GREEN, University of Michigan — We investigated the dynamics of the polyisoprene (PI) component confined within micelles in the blends of polystyrene-*b*-polyisoprene (PS-*b*-PI) diblock copolymers and polystyrene (PS) homopolymers, using broadband dielectric spectroscopy (BDS). In these blend, the diameter of the PS-*b*-PI micelle cores, composed of the PI component, increased with increasing molecular weight of the PS host, P , and reached a plateau at high P regime. The BDS results show that the dynamics of the PI component were fastest within the smallest micelle cores. Additionally, the relaxation intensities were weakest within smallest micelle cores. The local glass transition temperature (T_g) of the PI component was 201 K when its core diameter is ~29 nm, while the T_g dropped to 193 K with a core diameter of ~21 nm. Although faster dynamics with confinement has been previously observed in several systems, few have examined confinement at length scales much greater than that of the typical cooperative rearranging region, which is normally a few nanometers. Therefore, our study may shed new light on understanding the dynamical behavior of confinement, especially in domains formed in microphase separated block copolymer structures.

11:15AM J45.00001 Field-Theoretic Studies of Nanostructured Triblock Polyelectrolyte Gels, DEBRA AUDUS, GLENN FREDRICKSON, University of California, Santa Barbara — Recently, experimentalists have developed nanostructured, reversible gels formed from triblock polyelectrolytes (Hunt et al. 2011, Lemmers et al. 2010, 2011). These gels have fascinating and tunable properties that reflect a heterogeneous morphology with domains on the order of tens of nanometers. The complex coacervate domains, aggregated oppositely charged end-blocks, are embedded in a continuous aqueous matrix and are bridged by uncharged, hydrophilic polymer mid-blocks. We report on simulation studies that employ statistical field theory models of triblock polyelectrolytes, and we explore the equilibrium self-assembly of these remarkable systems. As the charge complexation responsible for the formation of coacervate domains is driven by electrostatic correlations, we have found it necessary to pursue full “field-theoretic simulations” of the models, as opposed to the familiar self-consistent field theory approach. Our investigations have focused on morphological trends with mid- and end-block lengths, polymer concentration, salt concentration and charge density.

11:27AM J45.00002 Effect of Confinement on Proton Transport in Nanostructured Block Copolymer/Ionic Liquid Membranes, MEGAN L. HOARFROST, University of California, Berkeley, MADHU S. TYAGI, NIST Center for Neutron Research, RACHEL A. SEGALMAN, JEFFREY A. REIMER, University of California, Berkeley — Nanostructured membranes containing structural and proton-conducting domains are of great interest for a wide range of applications requiring high conductivity coupled with high thermal stability. Understanding the effect of nanodomain confinement on proton-conducting properties in such materials is essential for designing new, improved membranes. This relationship has been investigated for a lamellae-forming mixture of poly(styrene-*b*-2-vinylpyridine) (PS-*b*-P2VP) with ionic liquid composed of imidazole and bis(trifluoromethane)sulfonimide (HTFSI), where the ionic liquid selectively resides in the P2VP domains of the block copolymer. Quasi-elastic neutron scattering and NMR diffusion measurements reveal high levels of a fast proton hopping transport mechanism, which we hypothesize is due to changes in the hydrogen bond structure of the ionic liquid under confinement. This, in combination with unique ion aggregation behavior, leads to a lower activation energy for macroscopic ion transport compared to that in a mixture of ionic liquid with P2VP homopolymer. These results portend the rational design of nanostructured membranes having improved mechanical properties and conductivity.

11:39AM J45.00003 Controlling Au Nanorod Dispersion in Thin Film Polymer Blends¹, MICHAEL J.A. HORE, RUSSELL J. COMPOSTO, Dept. of Materials Science and Engineering, University of Pennsylvania — Dispersion of Au nanorods (Au NRs) in polymer thin films is studied using a combination of experimental and theoretical techniques. Here, we incorporate small volume fractions of polystyrene-functionalized Au NRs ($\phi_{rod} \approx 0.05$) into polystyrene (PS) thin films. By controlling the ratio of the brush length (N) to that of the matrix polymers (P), we can selectively obtain dispersed or aggregated Au NR structures in the PS-Au(N):PS(P) films. A dispersion map of these structures allows one to choose N and P to obtain either uniformly dispersed Au NRs or aggregates of closely packed, side-by-side aligned Au NRs. Furthermore, by blending poly(2,6-dimethyl-p-phenylene oxide) (PPO) into the PS films, we demonstrate that the Au nanorod morphology can be further tuned by reducing depletion-attraction forces and promoting miscibility of the Au NRs. These predictable structures ultimately give rise to tunable optical absorption in the films resulting from surface plasmon resonance coupling between the Au NRs. Finally, self-consistent field theoretic (SCFT) calculations for both the PS-Au(N):PS(P) and PS-Au(N):PS(P):PPO systems provide insight into the PS brush structure, and allow us to interpret morphology and optical property results in terms of wet and dry PS brush states.

11:51AM J45.00004 Influence of Charge and Network Inhomogeneities on the Swollen-Collapsed Transition in Polyelectrolyte Nanogels, PRATEEK JHA, JOS ZWANIKKEN, Northwestern University, FRANÇOIS DETCHEVERRY, LPMCN, Université de Lyon, JUAN DE PABLO, University of Wisconsin-Madison, MONICA OLVERA DE LA CRUZ, Northwestern University — Polyelectrolyte nanogels are sub-microscopic networks of solvent-permeated polyelectrolyte chains that undergo large reversible volume changes for a range of environmental stimuli. This volume phase transition behavior finds use in targeted drug delivery, optical switching in photonic crystals, and many other applications that require controlled tunability. Although the strength of electrostatic interactions have a strong influence on the nanogel response, these interactions are not well captured by the classical mean-field theories of macroscopic gels. We develop a simplified Poisson-Boltzmann model of spherical gels, that highlights the importance of charge inhomogeneities and the associated Coulomb interactions in determining the response of gels. Our analysis reveals that nanometer-sized gels, collapsed gels, and gels in media with low salinity or high dielectric constant, have large regions of excess charge, and show clear deviations from the classical Donnan picture of polyelectrolyte gels. The detailed swelling-collapse behavior is obtained using the theoretically-informed coarse-grained simulations, which includes the effects of network imperfections and thermal fluctuations. The simulations capture the universal features of volume phase transition in nanogels.

12:03PM J45.00005 Enhanced electron mobility of n-channel polymer thin film transistors by use of low-k polymer dielectric buffer layer, FELIX SUNJOO KIM, SAMSON JENEKHE, University of Washington — Understanding the factors that govern charge transport in polymer thin film transistors is of interest in developing high-performance polymer transistors and circuits. Engineering the dielectric properties of the gate insulator of a field-effect transistor represents one of the promising approaches to improving the performance of the devices. We show that insertion of a low-k polymer dielectric layer between a silicon dioxide gate dielectric and poly(benzobisimidazobenzophenanthroline) (BBL) semiconductor of n-channel organic transistors increases the field-effect electron mobility by two orders of magnitude. The enhanced electron mobility was accompanied by increased on/off current ratio, superior multicycling stability with negligible hysteresis, and enhanced durability in air. Systematic studies of a series of polymer dielectrics showed that the electron mobility increased exponentially with decreasing dielectric constant, which can be understood in terms of the reduced energetic expense of charge carrier/dipole interaction.

12:15PM J45.00006 Imaging three dimensional bicontinuous networks in bulk heterojunction solar cells, JAMES T. ROGERS, LOUIS A. PEREZ, ALAN J. HEEGER, UC Santa Barbara, HIROSHI JINNAI, Kyushu University, GUILLERMO C. BAZAN, EDWARD J. KRAMER, UC Santa Barbara — Highly efficient, solution processable, organic photovoltaics typically consist of a two component donor-acceptor type heterojunction structure comprised of a low bandgap conjugated polymer donor blended with a fullerene acceptor. Efficient charge extraction from these blends demands that donor and acceptor components form nanoscale phase separated percolating pathways to their respective electrodes. Although the existence of this bicontinuous interpenetrating network, termed a bulk heterojunction (BHJ), is hypothesized to be requisite for efficient device operation, attempts to characterize BHJ structures using conventional transmission electron tomography (TEM) techniques have failed. Energy filtered TEM (EF-TEM) is demonstrated to overcome the inadequacies of conventional TEM, enabling three-dimensional (3D) imaging of high efficiency BHJ structures with nanometer resolution. Considered in combination with x-ray scattering measurements, the 3D chemical maps derived from EF-TEM are used to offer a plausible mechanism of BHJ formation in devices reaching 7.1% efficiency.

12:27PM J45.00007 Single molecule dynamics of self-associating polymers, CHARLES SING, ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology — Recent progress has been made experimentally in understanding the importance of reversible interactions in polymer systems, with systems such as stimuli-responsive gels demonstrating tunable properties. We extend these ideas to single molecules, since this type of behavior is especially important in biological polymers where molecular interactions can be both reversible and long-lived. We have developed simulation models where a Bell-like association model is incorporated into a Brownian Dynamics simulation, so that we represent a self-associating polymer in a coarse-grained fashion. We find that there are exciting implications of these binding properties on the dynamics of polymers both in and out of equilibrium. The introduction of this extra time scale to a dynamic polymer system manifests itself in drastic changes in polymer properties under dynamic loading; in particular, self-associating polymers in shear flow demonstrate large non-monotonic effects and single-molecule pulling scenarios demonstrate pulling behaviors reminiscent of biological molecules. This thus represents a physical model that has intriguing implications in both biological and synthetic polymer systems.

Session J46 DPOLY: Invited Session: Electrostatic Interactions in Polymeric and Biological Systems 160ABC

11:15AM J46.00001 Ion Specific Effects at Interfaces, YAN LEVIN, Instituto de Física, Universidade Federal do Rio Grande do Sul — Availability of highly reactive halogen ions at the surface of aerosols has tremendous implications for the atmospheric chemistry. Yet neither simulations, experiments, nor existing theories are able to provide a fully consistent description of the electrolyte-air interface. In this talk a new theory will be presented which allows us to explicitly calculate the ionic density profiles, the surface tension, and the electrostatic potential difference across the solution-air interface [1,2]. The theory takes into account both ionic hydration and polarizability [3]. The theoretical predictions are compared to experiments and are found to be in excellent agreement. Finally, the implications of the present theory for stability of lyotropic colloidal suspensions will be considered [4], shedding new light on one of the oldest puzzles of physical chemistry — the Hofmeister effect.

11:51AM J46.00002 Solvation of ions in bulk and at interfaces: What can density functional theory teach us?¹, CHRISTOPHER MUNDY, Pacific Northwest National Laboratory — Insights from molecular simulation have influenced both experiment and theory regarding the understanding of the specific ion effect. Although there seems to be a consensus that large polarizable anions exist at the air-water interface, the understanding of the precise molecular interactions that give rise to surface adsorption remain elusive. I will present our work on the adsorption of iodide at the air-water interface using density functional theory (DFT) based interaction potentials. I will discuss similarities and differences of the results obtained using different descriptions of molecular interaction. Last, we are able to reconcile the results obtained with molecular simulation using standard empirical potentials with the dielectric continuum theory of Levin and co-workers.

In collaboration with Marcel Baer, Pacific Northwest National Laboratory; Douglas Tobias, Abe Stern, University of California, Irvine, CA; and Yan Levin, Instituto de Física, UFRGS, Porto Alegre, RS, 91501-970, Brazil.

12:27PM J46.00003 Simulation of single molecule stretching experiments on denatured ssDNA¹, MARK STEVENS, Sandia National Laboratories — We have performed simulations of stretching denatured ssDNA using a bead-spring model to compare with recent single molecule experiments. Each bead represents a singly charged base or monomer in the ssDNA. The salt and counterions are explicitly treated. An equal and opposite force is applied to the two terminal beads, and the force-extension curves are calculated at a range of forces. In denatured ssDNA, the bases of ssDNA are blocked from pairing making the flexible polyelectrolyte model applicable. The recent single molecule stretching experiments² on denatured ssDNA have studied the effect of added salt treating both 1:1 and 2:1 salts. These experiments found force-extensions curves exhibit two regimes: at low forces, the extension $R \sim f^\gamma$, where $\gamma = 0.60 - 0.69$ and a high force regime where $R \sim \log f$. The force-extension curves can be scaled to produce overlap for the salt dependence. The force at the crossover between the two regimes f_c scales as $c_s^{1/2}$ for 1:1 salt, but as I^3 for 2:1 salt, where I is the ionic strength. The simulation data reproduce the experimental overlap for both salt cases. The two regimes including the logarithmic behavior at large forces are present in the simulation results. The simulation results imply that the behavior is due to a competition between electrostatics, entropy and the applied force and that other molecular interactions can be neglected. Thus, the standard theoretical methods are not missing an important term in the free energy, although approximation level may be an issue. We will present simulation data on the conformations as a function of applied force and discuss the implications for analytic theory.

1:03PM J46.00004 Charge-regularization effects on polyelectrolytes, MURUGAPPAN MUTHUKUMAR, University of Massachusetts — When electrically charged macromolecules are dispersed in polar solvents, their effective net charge is generally different from their chemical charges, due to competition between counterion adsorption and the translational entropy of dissociated counterions. The effective charge changes significantly as the experimental conditions change such as variations in solvent quality, temperature, and the concentration of added small electrolytes. This charge-regularization effect leads to major difficulties in interpreting experimental data on polyelectrolyte solutions and challenges in understanding the various polyelectrolyte phenomena. Even the most fundamental issue of experimental determination of molar mass of charged macromolecules by light scattering method has been difficult so far due to this feature. We will present a theory of charge-regularization of flexible polyelectrolytes in solutions and discuss the consequences of charge-regularization on (a) experimental determination of molar mass of polyelectrolytes using scattering techniques, (b) coil-globule transition, (c) macrophase separation in polyelectrolyte solutions, (c) phase behavior in coacervate formation, and (d) volume phase transitions in polyelectrolyte gels.

1:39PM J46.00005 Effect of electrostatic interactions on lubrication in polymeric and biological systems¹, JAN-MICHAEL CARRILLO, Institute of Materials Science and Department of Physics, University of Connecticut — Many connective tissues, such as cartilage demonstrate excellent lubrication and wear characteristics. Cartilages in mammalian joints can withstand pressures of the order of ten atmospheres and have remarkably low friction coefficient in the range of 0.001-0.03. The surface of the cartilage is covered with bottle-brush-like polyelectrolyte layer consisting of glycoproteins. This brush layer, which faces a similar layer on the opposing cartilage, is sheared as two surfaces slide passing each other during joint motion. We have performed molecular dynamics simulations of charged and neutral bottle-brush macromolecules tethered to substrates to understand the role of the electrostatic and hydrodynamic coupling between brush layers on the lubricating properties in biological and polymeric systems. Glycoprotein layers were modeled as two opposing layers of highly charged bottle-brush macromolecules composed of Lennard-Jones particles grafted to a substrate. Simulations have shown that charged bottle-brush systems have lower friction under shear and weaker dependence of the disjoining pressure on substrate separation than neutral bottle-brush systems. This was explained by formation of lubricating layer with excess of counterions located in the middle between brush-bearing surfaces. In overlapping brush layers the disjoining pressure between brush-bearing surfaces is controlled by the bottle-brush bending rigidity. Under shear, the main deformation mode of the charged bottle-brush layers is associated with the bottle-brush backbone deformation resulting in backbone deformation ratio and shear viscosity being universal functions of the Weissenberg number. In the case of neutral bottle-brush systems there is coupling between backbone and side chain deformation. This violates universality in backbone deformation ratio and manifests itself in shear viscosity dependence on the shear rate. The shear viscosity as a function of the shear rate for the neutral bottle-brush systems has two plateaus and two shear thinning regimes.

Session J48 DPOLY: Focus Session: Gelation and Glass Transition in Colloids and Soft Matter Systems II 161

11:15AM J48.00001 Kinetic arrest and activated relaxation in dense suspensions of attractive nonspherical colloids, RUI ZHANG, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — The coupled translation-rotation activated dynamics in dense suspensions of uniaxial short-range attractive homogeneous (hDC) and Janus (JDC) colloids are studied using the microscopic nonlinear Langevin equation theory based on the concept of a dynamic free energy surface. For larger aspect ratios, three activated regimes, repulsive glass (RG), attractive glass (AG) and gel (G), are predicted where translation and rotation are always strongly coupled. Physical clustering in the JDC system suppresses the re-entrant RG-fluid(F) process. For hDCs of small enough aspect ratio, multiple kinetic arrest transitions, novel re-entrant phenomena, and a dynamical quadruple point emerge associated with F, G, RG, AG, and plastic glass (PG) states. Colloid translational and rotational motions are strongly coupled in the gel, but decoupled (slower translation) in the other activated regimes due to the presence of two distinct hopping processes. Both translation and rotation activated relaxation rates are non-monotonic functions of attraction strength at high volume fractions. Translation-rotation decoupling universally weakens as attraction strength grows, and exhibits a different volume fraction dependence at low, intermediate, and high attraction strengths.

11:27AM J48.00002 Rearrangements, Vibrations and Microscopic Glassy Dynamics and Structure in Quasi-2D Dense Colloidal Gels¹, MATTHEW LOHR, ARJUN YODH, University of Pennsylvania — In this work, we investigate the microscopic dynamics of quasi-2D dense attractive colloidal systems. We confine bidisperse polystyrene spheres between glass coverslips in a suspension of water and 2,6-lutidine; as we increase the temperature of the sample into a critical regime, lutidine wets the colloids, creating a strong attractive interaction ($> 4\text{ kT}$). We specifically study suspensions in the “dense gel” regime, i.e., at a volume fraction high enough that the attractive particles form a spanning cluster, yet just low enough that there exists some structural heterogeneity larger than the individual particle size. We track the particle locations via bright-field video microscopy and analyze the dynamics of both lower-volume-fraction gel states and higher-volume-fraction glassy states. Specifically, we make correlations between local structure, rearrangement-prone regions, and low-frequency vibrational modes. In doing so, we not only characterize the structural and dynamical differences and similarities between colloidal gels and glasses, but we also gain further insight into the origins of dynamic heterogeneity in glassy systems.

11:39AM J48.00003 Dynamical Phases and Rheology of Rod-Sphere Nanoparticle Mixtures, RYAN JADRIC, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — Colloidal mixtures involving sticky nonspherical particles that form glasses and gels are relatively unexplored compared to their single component analogs. We develop and apply a microscopic statistical dynamical approach (mode coupling and nonlinear Langevin equation theories) at the center-of-mass level for dense isotropic mixtures of spheres and rods as a function of (short range) attraction strength, aspect ratio, and composition. Based on the mixture structural pair correlations as input, up to seven dynamical phases (transiently localized states with activated dynamics) are predicted corresponding to fluid, repulsive glass, attractive glass, gel, a mixed coexisting glass-gel state, and several partially localized states. The dynamical complexity increases with aspect ratio, and reflects a rich competition between repulsive force caging, physical bond formation and rod interpenetration. Removal of the nanosphere attraction destroys the double gel state but otherwise has minor consequences. The elastic shear modulus and absolute yield stress are also studied, and order of magnitude changes are found along various trajectories in the dynamical phase diagram. Rods are found to generically impart greater bulk rigidity than spheres.

11:51AM J48.00004 Phonons and Rearrangements in Disordered Colloidal Glasses¹, ARJUN YODH, University of Pennsylvania — I will describe experiments which explore the behaviors of disordered particle suspensions at high packing fraction (e.g., see references [1-5]). Recent systems studied include two-dimensional glasses composed of temperature-sensitive microgel particles, and colloidal glasses in binary fluid which permit interaction potential to be switched from attractive to repulsive. Displacement correlation matrix techniques are employed to derive phonon modes and phonon density of states, and video microscopy is employed to study particle rearrangements. Connections between phonons and stress-induced rearrangements will be described, and detailed observations of the properties of cooperative rearrangement events in attractive versus repulsive glasses will be presented.

12:27PM J48.00005 Characterization of local shear zones that govern the deformation of colloidal glasses, KATHARINE JENSEN, Department of Physics, Harvard University, Cambridge, MA, NOBUTOMO NAKAMURA, Department of Mechanical Science and Bioengineering, Osaka University, Osaka, Japan, DAVID WEITZ, Department of Physics and School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, FRANS SPAEPEN, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA — Colloidal glass provides a unique experimental system with which to study the structure, defects, and dynamics of a generic amorphous material. We report experiments on 1.55- μm -diameter, hard-sphere silica colloidal glasses under conditions of uniform shear. We use confocal microscopy to follow the 3D, real-time trajectories of roughly 100,000 particles during homogeneous deformation and explore the roles of both glass density and applied strain rate. In this way, we probe the elastic, anelastic, and plastic response of the system, with particular focus on identifying specific mechanisms of deformation. In plastic deformation, we directly observe “shear defects” or “shear transformation zones” (STZs) as clusters of particles that behave as Eshelby inclusions, undergoing highly localized plastic strain. These clusters can be identified as regions that are best fits to the Eshelby strain field throughout the sample. We correlate the development of these regions with local density-related properties, including the Voronoi volume and the free volume of both individual particles and connected clusters of particles.

12:39PM J48.00006 Elasticity and microstructure of colloidal gels undergoing strain-induced yielding, LILIAN HSIAO, RICHMOND NEWMAN, SHARON GLOTZER, MICHAEL SOLOMON, University of Michigan — The mechanism of yielding in colloidal gels, particularly for high strain-rate deformations that are typical of materials applications, is not fully understood. Here, we examine the oscillatory response and stress relaxation of a colloidal gel formed by short-range depletion interactions to find a correlation between the macroscopic rheological behavior and their microstructural features. We use confocal laser scanning microscopy to directly observe the strain-dependent evolution of 3D gel structure within a shearing device. The gels are made up of monodisperse poly(methyl methacrylate) spheres of different sizes and volume fractions dispersed in refractive index matched solvents. We impose simple shear flows of various strains on the gel and observe the 3D structural change after deformation. This is done using a UV light-activated photopolymer, which allows particle configurations to be locked in place rapidly ($< 0.6\text{ s}$) after yielding. We characterize the transition from a dense network to interconnected clusters using the contact number distribution. Our results show that rigid, stress-bearing clusters play an important part in contributing to the gel elasticity at large strains.

12:51PM J48.00007 Complex oscillatory yielding in model hard sphere glasses, GEORGE PETEKIDIS, NICK KOUMAKIS, FORTH & Univ. of Crete, Greece, FORTH TEAM — The yielding behaviour of hard sphere glasses under large amplitude oscillatory shear has been studied by experimental rheology and Brownian Dynamics simulations. Here we focus on varying the frequency of oscillation probing the interplay between Brownian motion and shear-induced diffusion. Stress, structure and dynamics are followed by rheology and BD simulations. Two frequency regimes are revealed: At low frequencies Brownian motion is dominant, assisting particles to escape their cage during a single step yielding process, identified by a peak of G'' at around the $G' = G''$ crossover. At high frequencies shear induced particle collisions causes cage breaking with the maximum energy dissipation marked by the G'' peak taking place beyond the $G' = G''$ crossover. Intermediate frequencies present a complex yielding behaviour influenced by both mechanisms that leads to a double peak in G'' that has not been reported before in HS glasses. The nonlinear response is quantified by the higher harmonics present in the stress signal. While at low frequencies the strength of higher harmonics reaches a constant value at high strains, in the intermediate and high frequency regime a non-monotonic behaviour is detected with characteristic large amplitude strains exhibiting apparent harmonic response.

1:03PM J48.00008 Interactions of Dislocations with Twin Boundaries in Hard-Sphere Colloidal Crystals, MARIA PERSSON GULDA, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, United States, ERIC MAIRE, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, United States and MATEIS, INSA-Lyon, Villeurbanne, France, DAVID WEITZ, Department of Physics, Harvard University, Cambridge, MA, United States, FRANS SPAEPEN, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, United States — The interaction of dislocations with twin or grain boundaries is a key factor in understanding the strength and strain hardening of crystals. Confocal tracking of particles in a colloidal crystal allows a detailed look at the mechanisms of such interactions at the particle scale, analogously to what happens on the atomic scale in conventional crystals. The grain boundaries are prepared by sedimentation onto templates in the [110] $\Sigma 3$ orientation. A complex set of interactions is observed: additional twinning, the emission of a pair of partial dislocations, and the formation of kinks in the original twin boundary.

1:15PM J48.00009 Gel formation and aging in weakly attractive nanocolloid suspensions, JAMES HARDEN, Department of Physics, University of Ottawa, HONGYU GUO, Department of Physics, University of California, San Diego, SUBRAMANIAN RAMAKRISHNAN, Department of Chemical and Biomedical Engineering, Florida State University, ROBERT LEHENY, Department of Physics and Astronomy, Johns Hopkins University — We present combined x-ray photon correlation spectroscopy (XPCS) and rheometry studies of the evolution of concentrated suspensions of nanometer-scale colloids undergoing thermo-reversible gelation and aging. After a quench through the gel point, suspensions display a protracted latency period in which they remain fluid followed by a gelation regime in which the shear modulus grows rapidly. The XPCS intermediate scattering function displays two features, a plateau value that provides information about constrained local dynamics and a terminal decay related to relaxation of residual stress. From the wave-vector dependence of the plateau value, a localization length can be extracted. At intermediate colloidal volume fractions ($\phi \simeq 0.20$), the relationship between the localization length and the shear modulus agrees quantitatively with a prediction based on a simplified mode coupling theory, while deviations from the predicted scaling at a higher volume fraction ($\phi \simeq 0.43$) are observed near the gel point. While some features of slow strain from stress relaxation correlate with the evolving rheology, others appear decoupled from the macroscopic behavior.

1:27PM J48.00010 Phase-Change Dynamics in Attractive, Polydisperse Colloidal Suspensions¹, JOHN MERGO, Cornell University, School of Applied and Engineering Physics, ITAI COHEN, Cornell University, Department of Physics, ANTHONY DINS-MORE, University of Massachusetts Amherst, Department of Physics — Understanding the single-particle dynamics of phase changes in polydisperse suspensions is important for predicting the structures that arise in these systems. In this talk, we discuss the results of experiments on the melting and freezing of polydisperse colloidal particles. In these experiments, micron-sized colloidal particles are sedimented in water onto a glass coverslip to form a quasi two-dimensional gas. The particles experience an attractive interaction due to a size-tunable depletant added to the mixture. This allows both melting and freezing to be probed in the same experiment. Optical images with single-particle resolution are recorded and each particle is tracked through the duration of the experiment. Interestingly, we find that the increase in polydispersity may stabilize the fluid phase, which has previously been shown to be metastable in experiments on monodisperse particles. In particular, we explore the stability, structure, and dynamics of this fluid phase and how the structures in this phase solidify over time.

1:39PM J48.00011 The role of picosecond dynamics in relaxation of molecular glasses¹, MARCUS CICERONE, QIN ZHONG, FENG DING, JACK DOUGLAS, MADHUSUDAN TYAGI, DAVID SIMMONS, National Institute of Standards and Technology — The importance of the relative amplitude of elemental relaxation processes, specifically of the fast β relaxation process ($\langle u^2 \rangle$), to long-time relaxation processes have been emphasized in a number of theoretical models. In this talk I will focus on transport properties and their relationship to $\langle u^2 \rangle$ in supercooled liquids and glasses. In these studies we use antiplasticization to systematically tune molecular packing. These results provide insights into the role that localization and the concomitant emergence of an excess density of states plays in relaxation of and transport in molecular glasses.

¹This work was funded under NIH/NIBIB Grant R01 EB006398-01A1

1:51PM J48.00012 AC Impedance Study of the Structural Transformation of Graphite Suspensions¹, JIANJIAN WANG, GANG CHEN, Massachusetts Institute of Technology — Recently graphite suspensions have been demonstrated to possess very high thermal conductivity enhancements with high stability. However, the thermal conductivity is quite sensitive to the internal structures of the suspensions or the different states of the particulates in the liquids. At low graphite loadings, the graphite particulates can only form evenly distributed isolated clusters in the host material. As the graphite loading increases, the clusters will start merging together to form a 3D percolation network and the graphite suspension becomes gel-like. For the first time, we have observed a sharp kink behavior in the thermal conductivity of suspensions at the percolation threshold. Combined microstructural and AC impedance spectroscopy studies suggest that this kink arises from the change in the bonding strength between graphite flakes as the suspensions go through a transition from isolated clusters to percolated structures. Our studies shed light on the heat conduction mechanisms of nanofluids, suspensions and composites.

¹This work is supported by AFOSR.

2:03PM J48.00013 Large colloidal crystals grown by centrifugation onto a template, DANIEL PENNACHIO, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, KATHARINE JENSEN, Department of Physics, Harvard University, Cambridge, MA, DAVID WEITZ, Department of Physics, Harvard University, Cambridge, MA; School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, FRANS SPAEPEN, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA — Colloidal crystals are commonly formed by sedimenting a colloidal solution at 1g onto a patterned template. Slow sedimentation was previously believed to be a requisite for growing large, perfect crystals without crossover to an amorphous sediment. By increasing the relative gravitational force applied to a monodisperse sample of hard-sphere, 1.55 μm diameter silica colloids, we examined the effect of increased sedimentation velocity on the growth of face-centered cubic crystals on a (100) template. We varied relative centrifugal force up to 3000g, time of centrifugation, lattice parameter, and crystal thickness to assess their effect on crystal quality. Single crystals up to 52 μm thick were grown for all centrifugation speeds. Crystal defects were predominantly stacking faults (bounded by partial dislocations), most of which formed after the critical thickness was reached. The critical thickness, which is a function of the lattice mismatch between crystal and template, was measured directly by varying the crystal thickness. Final stacking fault and vacancy concentrations were independent of centrifugal force and time. We also examined samples centrifuged onto other templates to elucidate the critical role of the template design in directing crystal versus glass formation.

Session J49 DPOLY: Focus Session: Crystallization in Single-, Multicomponent, and Hybrid Systems | 162A

11:15AM J49.00001 Orientation of conjugated polymers: epitaxy versus mechanical rubbing¹, MARTIN BRINKMANN, Institut Charles Sadron, CNRS- University of Strasbourg, France — Orientation of conjugated polymers like regioregular poly(3-alkylthiophene)s (P3AT) is of high importance as it can be used to exploit their high intrinsic charge transport anisotropy in the elaboration of devices e.g. OFETs and OLEDs. Orientation has been achieved by two different approaches: i) epitaxy and ii) mechanical rubbing. Herein we describe and compare these two orientation methods. On the one hand side, a large palet of structures, nanomorphologies and orientations can be achieved by controlled epitaxial crystallization of polymers like P3HT, PBTTT or polyfluorenes. Not only can epitaxy afford highly oriented and crystalline films of P3ATs, but also highly oriented fibers with a characteristic shish-kebab morphology. The application of Electron Diffraction analysis (rotation-tilt) on highly oriented polymer layers is an original and powerful method to unravel the crystal packing of conjugated polymers. On the other hand side, mechanical rubbing of conjugated polymers, especially P3HT can also lead to highly oriented films without the use of an orienting substrate. The mechanism of thin film orientation has been analyzed in detail using Transmission Electron Microscopy, Grazing-Incidence X-ray diffraction and optical spectroscopy. It is demonstrated that the molecular weight Mw of the polymer impacts the maximum orientation achieved by rubbing. The Mw-dependence of orientation is explained in terms of chain folding and entanglements that prevent the reorientation and reorganization of the pi-stacked chains, especially for Mw ≥ 50kDa. Electron diffraction and HR-TEM show that epitaxially rubbed films differ in terms of *intra-lamellar* order within layers of pi-stacked chains. Whereas the epitaxially rubbed P3HT films show a semi-crystalline structure with crystalline domains bearing 3D order, the rubbed P3HT films exhibit rather a 2D nematic-like order.

11:51AM J49.00002 Solution Assembly of Hybrid Poly (3-hexyl thiophene) and Cadmium Selenide Nanowires, FELICIA BOKEL, EMILY PENTZER, TODD EMRICK, RYAN HAYWARD, University of Massachusetts Amherst — Optimizing morphology of self-assembled systems containing both electron carrying (n-type) and hole carrying (p-type) materials holds promise for the fabrication of improved devices, such as solar cells. In this talk, two routes to formation of hybrid p-n composite fibrils consisting of crystalline p-type poly(3-hexyl thiophene) (P3HT) nanowires with n-type cadmium selenide (CdSe) quantum dots and nanorods into well-defined structures will be discussed. The first method involves co-crystallization of freely soluble P3HT and P3HT-functionalized CdSe nanorods to form crystalline hybrid nanowires upon addition of a marginal solvent. Transmission electron microscopy reveals that nanorods preferentially orient parallel to and flank the sides of fibrils. In a second route to forming hybrid materials, chain-end functionalized P3HT is crystallized into fibrillar nanowires. Introduction of nanoparticles promotes binding at the fibril edge, forming parallel composite pathways or “superhighways.” These assembly approaches represent efficient means to organization of conjugated polymers and semiconducting nanostructures, thus offering new opportunities for optoelectronic device design.

12:03PM J49.00003 Correlating crystallization and ionic conductivity of PEO/graphene oxide nanocomposite, SHAN CHENG, DERRICK SMITH, GRACE HSUAN, CHRISTOPHER LI, Drexel University — Polyethylene oxide (PEO) is one of the best candidates for solid state electrolyte due to its chemical stability and strong ability to form complex with lithium salts. Crystallization behavior of PEO directly affects the lithium ion transport, and in turn the ionic conductivity of the electrolyte. By adding two dimensional graphene oxide nanosheets into PEO matrix, mechanical property of the latter is significantly strengthened, while the crystallization behavior of PEO is also altered by the graphene oxide sheets. The crystallization of PEO/graphene oxide nanocomposites was studied by differential scanning calorimetry (DSC) and the orientations of graphene oxide and PEO crystal were studied by small angle X-ray scattering and wide angle X-ray diffraction. PEO/graphene oxide nanocomposite doped with lithium salt was further fabricated and characterized by electrochemical impedance spectroscopy. Anisotropic ionic conductivity was observed for the nanocomposite electrolyte due to the orientation of graphene oxide and directional growth of PEO crystals.

12:15PM J49.00004 Nucleation and Crystallization in nucleated Polymers, CHRISTOPH SCHICK, EVGENY ZHURAVLEV, ANDREAS WURM, University of Rostock — Crystallization is commonly considered as nucleation followed by a growth process. Here we apply the recently developed technique, differential fast scanning calorimetry (DFSC), for a unique, new look at the crystal growth of poly(epsilon-caprolactone) (PCL) and PCL carbon nanotube composites from 185 K, below the glass transition temperature, to 330 K, close to the equilibrium melting temperature. The DFSC allows temperature control of the sample and determination of its heat capacity during temperature treatments by employing cooling and heating rates from 50 to 50,000 K/s. First, the crystal nucleation and overall crystallization half times were determined simultaneously in the range of temperatures where crystallization of PCL occurs. After attempting to analyze the experiments with the classical nucleation and growth model a new methodology is described, which addresses the specific problems of crystallization of flexible linear macromolecules. The structures seem to range from having practically unmeasurable latent heats of ordering (nuclei) to being clearly-recognizable, ordered species with rather sharp disordering endotherms at temperatures from the glass transition to equilibrium melting (increasingly perfect and larger crystals). The mechanisms and kinetics of growth (if any) involve a detailed understanding of the interaction with the surrounding rigid amorphous fraction (RAF) in dependence of crystal size and perfection. E. Zhuravlev, J.W.P. Schmelzer, B. Wunderlich and C. Schick, Kinetics of nucleation and crystallization in poly(epsilon-caprolactone) (PCL), Polymer 52 (2011) 1983-1997.

12:27PM J49.00005 Spherulite Growth in Polymer-Nanoparticle Blends¹, GORAN UNGAR, Seoul National University and University of Sheffield, EUNWOO LEE, Seoul National University, RUIBIN ZHANG, University of Sheffield, JYONGSIK JANG, Seoul National University, SEOUL NATIONAL UNIVERSITY, WCU C2E2 TEAM, UNIVERSITY OF SHEFFIELD TEAM — Blends of polymers with inorganic nanoparticles (NP) were studied by polarized optical and fluorescence microscopy. Silica nanoparticles with a range of diameters from 7 to 100 nm were used. Neat NPs as well as NPs surface-functionalized with a range of groups from strongly to weakly interacting, were blended with poly(ethylene oxide). A purpose-built T-jump microscopy cell was used allowing rapid temperature equilibration at high supercoolings. Lautitzen-Hoffman type analysis revealed that, although the NPs slow down the standard growth rate G_0 in the order PEO - Me-treated SiO₂ - untreated SiO₂ - COOH-treated SiO₂ - NH₂-treated SiO₂, the surface free energy σ decreases in the same order. This suggests that the NPs reduce macromolecular mobility, but at the same time help reduce the secondary nucleation barrier to some extent. Other polymers and NP types, including quantum dots, were also studied. The work also examines the spatial distribution of NPs in the spherulitic polymer nanocomposites.

¹Supported by WCU program through the National Research Foundation of Korea (R31-10013).

12:39PM J49.00006 Synthesis and morphology of hydroxyapatite/polyethylene oxide nanocomposites with block copolymer compatibilized interfaces, JI HOON LEE, MEISHA SHOFNER, Georgia Institute of Technology — In order to exploit the promise of polymer nanocomposites, special consideration should be given to component interfaces during synthesis and processing. Previous results from this group have shown that nanoparticles clustered into larger structures consistent with their native shape when the polymer matrix crystallinity was high. Therefore in this research, the nanoparticles are disguised from a highly-crystalline polymer matrix by cloaking them with a matrix-compatible block copolymer. Specifically, spherical and needle-shaped hydroxyapatite nanoparticles were synthesized using a block copolymer templating method. The block copolymer used, polyethylene oxide-b-poly(methacrylic acid), remained on the nanoparticle surface following synthesis with the polyethylene oxide block exposed. These nanoparticles were subsequently added to a polyethylene oxide matrix using solution processing. Characterization of the nanocomposites indicated that the copolymer coating prevented the nanoparticles from assembling into ordered clusters and that the matrix crystallinity was decreased at a nanoparticle spacing of approximately 100 nm.

12:51PM J49.00007 Confined crystallization in compatibilized Polyamide 6/High Density Polyethylene blends, SIMONA CECCIA, ALEXANDRA ARGOUD, LISE TROUILLET-FONTI, DIDIER R. LONG, PAUL SOTTA, CNRS/Rhodia UMR5268, St.Fons (France) — Blending polymers can be considered the easiest way to obtain new materials with tuned properties thanks to the possibility to control blend morphologies. The blend characteristics depend on the properties of each component, on composition and on morphologies developed during polymers processing. In case of semi-crystalline blended polymers, mechanical performances are closely related to the crystalline morphology. Therefore, it is essential that crystallinity is maintained after blending in order to keep or enhance the properties. This may be a challenge when the blends exhibit multiphase morphologies with sub-micrometer domain sizes. In this work, we study the crystallization behavior of compatibilized Polyamide 6/High Density Polyethylene (PA6/PE) blends by means of the Differential Scanning Calorimetry technique. Blends with various morphologies (dispersed, stretched dispersed, fibrillar and co-continuous) are obtained by reactive extrusion and varying blend composition and processing parameters. Blend composition and morphology turn out to greatly affect the bulk crystallization temperatures of both PA6 and PE. When the polymer is confined in domains of a few micrometers the crystallization temperature peak shifts to lower temperatures. Thus, the smaller the domain size the lower the crystallization temperature in case of dispersed morphologies. Moreover, in multi-scale morphologies showing polymer droplets in the nanometer range, fractionated crystallization (multiple crystallization peaks) is observed.

1:03PM J49.00008 Crystallization and Microphase Separation in Chiral Block Copolymers, RONG-MING HO, Department of Chemical Engineering, National Tsing Hua University, Taiwan — Block copolymers composed of chiral entities, denoted as chiral block copolymers (BCP*s), were designed to fabricate helical architectures from self-assembly. A helical phase (denoted H*) was discovered in the self-assembly of poly(styrene)-*b*-poly(L-lactide) (PS-PLLA) BCPs*. To examine the phase behavior of the PS-PLLA, self-assembled superstructures resulting from the competition between crystallization and microphase separation of the PS-PLLA in solution were examined. A kinetically controlled process by changing non-solvent addition rate was utilized to control the BCP* self-assembly. Single-crystal lozenge lamellae were obtained by the slow self-assembly (i.e., slow non-solvent addition rate) of PS-PLLA whereas amorphous helical ribbon superstructures were obtained from the fast self-assembly (i.e., fast non-solvent addition rate). As a result, the formation of helical architectures from the self-assembly of the PS-PLLA reflects the impact of chirality on microphase separation, but the chiral effect might be overwhelmed by crystallization. Consequently, various crystalline PS-PLLA nanostructures in bulk were obtained by controlling the crystallization temperature of PLLA ($T_{c, PLLA}$) at which crystalline helices and crystalline cylinders occur while $T_{c, PLLA} < T_{g, PS}$ (the glass transition temperature of PS) and $T_{c, PLLA} \geq T_{g, PS}$, respectively. Anisotropic arrangement of the PLLA crystallites grown within the microdomains was identified. The formation of this exclusive crystalline growth is attributed to the spatial confinement effect for crystallization. While $T_{c, PLLA} < T_{g, PS}$, winding crystals with specific crystallographic orientation within the helical microdomains can be found. By contrast, while $T_{c, PLLA} \geq T_{g, PS}$, the preferential growth may modulate the curvature of microdomains by shifting the molecular chains to access the fast path for crystalline growth due to the increase in chain mobility. As a result, a spring-like behavior of the helical nanostructure can be driven by crystallization so as to dictate the transformation of helices and to result in crystalline cylinders.

1:39PM J49.00009 Chain conformation and crystallization in PEO / layered silicate nanocomposites, SPIROS H. ANASTASIADIS, K. CHRISOPOULOU, S. BOLLAS, Foundation for Research and Technology-Hellas and Univ. of Crete, Heraklion Crete, Greece, K.S. ANDRIKOPOULOS, S. FOTIADOU, Aristotle University of Thessaloniki, Greece, G.A. VOYIATZIS, Institute of Chemical Engineering & High Temperature Chemical Processes, Patras, Greece — The polymer chain conformation under confinement and the polymer morphology are investigated in hydrophilic PEO/Na⁺-montmorillonite nanohybrids synthesized by melt and/or solution intercalation. Intercalated hybrids with mono- and bi-layers of PEO chains are obtained for all compositions covering the complete range from pure polymer to pure clay. For low polymer concentrations, where all the polymer chains are intercalated, PEO is purely amorphous. As PEO concentration increases further, the polymer chains adsorbed on the outer surface of the clay particles remain amorphous as well. It is only when there is large amount of excess polymer outside the completely filled galleries that the bulk polymer crystallinity is abruptly recovered. The conformation of the confined or adsorbed polymer chains, as probed by Raman and FTIR spectroscopies, is found more disordered than the PEO melt even at higher temperatures; this is evident by the dramatic increase of the gauche conformations of the C-C bond along the chain backbone. Sponsored by the Greek GSRT (ΣΥΝΕΡΓΑΣΙΑ; 09ΣΥΝ – 42 – 580) and by the EU (CP-IP 246095-2).

1:51PM J49.00010 Lamellar Orientation Inversion under Dynamic Interplay between Simultaneous Crystallization and Phase Separation, CHARLES HAN, ICCAS, WEICHAO SHI, None, ICCAS TEAM — Crystallization dynamics and lamellar orientation may be affected under the dynamic interplay between crystallization and phase separation for a two component system. If phase separation is really weak, lamellae grow in the radial direction within spherulites. However, when strong phase separation intervenes, the lamellae growth could be oriented in the tangential direction in a concentric alternating concentration ring pattern. This lamellar orientation inversion is reflected by a birefringence inversion under optical microscopy and will be illustrated by a study of the PEO/PMMA system.

2:03PM J49.00011 Phase separation of DMDBS from iPP, and controlled crystalline orientation, K. SREENIVAS, NCL, Pune, India, GURUSWAMY KUMARASWAMY, NCL, R.S. BASARGEKAR, Reliance Industries Limited — We report an unexpected dependence of DMDBS phase separation temperature on the molecular weight of the matrix isotactic polypropylene (iPP). DMDBS crystallizes out at lower temperatures for iPP with decreasing molecular weight (and correspondingly lower tacticity). This molecular weight dependence is unique to iPP, and is not observed for either syndiotactic PP or for random ethylene-PP copolymers. We show that thermodynamic Flory-type arguments are unable to rationalize the observed results. We also report results on extrusion film casting of iPP containing DMDBS and show that flow-alignment of DMDBS networks template the orientation of PP crystals. The modulus and yield strength increase on addition of DMDBS, relative to the neat iPP. Tensile modulus and yield stress of drawn films increase with the degree of orientation, and we are able to achieve a substantial increase even at relatively low draw ratios.

Tuesday, February 28, 2012 11:15AM - 2:03PM –
Session J50 DPOLY DBIO: Focus Session: Translocation through Nanopores - Novel Devices and Computational Approaches 162B

11:15AM J50.00001 Integrated Nanopore Detectors in a Standard Complementary Metal-Oxide-Semiconductor Process¹, ASHFAQUE UDDIN, CHIN-HSUAN CHEN, SUKRU YEMENICIOGLU, KAVEH MILANINIA, ELLIE CORIGLIANO, Dept. of Electrical and Computer Engineering, UCSB, MADOO VARMA, Integrated Biosystems Lab, Intel Corporation, LUKE THEOGARAJAN, Dept. of Electrical and Computer Engineering, UCSB — High-bandwidth and low-noise nanopore sensor and detection electronics are crucial in achieving single-DNA base resolution. A potential way to accomplish this goal is to integrate solid-state nanopores within a CMOS platform, in close proximity to the biasing electrodes and custom-designed amplifier electronics. Here we report the development of solid-state nanopore devices in a commercial CMOS potentiostat chip implemented in On-Semiconductor's 0.5 micron technology. By using post-CMOS micromachining, a free-standing oxide membrane and electrodes are fabricated utilizing the N+ polysilicon/oxide/N+ polysilicon capacitor structure available in the aforementioned process. Nanopores with sub-5 nm diameter are drilled in the membrane using a Transmission Electron Microscope. The integrity of pores is validated by measuring current-voltage and noise characteristics. DNA translocation experiments are also performed utilizing these on-chip pores. In addition, electrical tests performed on the CMOS potentiostat circuitry show that the post-CMOS micromachining process does not have any detrimental effect on the CMOS circuitry.

11:27AM J50.00002 Graphene Gating of Solid State Nanopores for DNA Translocation, KIMBERLY VENTA, MATTHEW PUSTER, MARIJA DRNDIC, University of Pennsylvania — We report on ionic current measurements through gated solid state nanopores. Devices consist of Si_3N_4 membranes covered with a graphene sheet connected off-membrane to a gold contact pad. The graphene is insulated from solution with a TiO_2 layer deposited by atomic layer deposition, and the gold is exposed by an SF_6 etch. An electron-beam sculpted nanopore below 10 nm in diameter is drilled through the silicon nitride, graphene, and titania. Applying a voltage to the graphene modulates the ionic current through the pore. We measured the current-voltage characteristics for different gate potentials for our devices. We characterized the leakage current from the graphene as well as the ionic current noise in these pores to complement our current-voltage measurements. These results can lead to measurements of the influence on DNA translocation of a potential at the pore and set the groundwork for characterization of graphene-based sensing of DNA at a nanopore.

11:39AM J50.00003 Nanochannel Device with Embedded Nanopore: a New Approach for Single-Molecule DNA Analysis and Manipulation, YUNING ZHANG, WALTER REISNER, McGill University — Nanopore and nanochannel based devices are robust methods for biomolecular sensing and single DNA manipulation. Nanopore-based DNA sensing has attractive features that make it a leading candidate as a single-molecule DNA sequencing technology. Nanochannel based extension of DNA, combined with enzymatic or denaturation-based barcoding schemes, is already a powerful approach for genome analysis. We believe that there is revolutionary potential in devices that combine nanochannels with nanopore detectors. In particular, due to the fast translocation of a DNA molecule through a standard nanopore configuration, there is an unfavorable trade-off between signal and sequence resolution. With a combined nanochannel-nanopore device, based on embedding a nanopore inside a nanochannel, we can in principle gain independent control over both DNA translocation speed and sensing signal, solving the key draw-back of the standard nanopore configuration. We will discuss our recent progress on device fabrication and characterization. In particular, we demonstrate that we can detect - using fluorescent microscopy - successful translocation of DNA from the nanochannel out through the nanopore, a possible method to 'select' a given barcode for further analysis. In particular, we show that in equilibrium DNA will not escape through an embedded sub-persistence length nanopore, suggesting that the embedded pore could be used as a nanoscale window through which to interrogate a nanochannel extended DNA molecule.

11:51AM J50.00004 fd Virus as a Model Stiff Polymer for Translocation Experiments with Solid-State Nanopores¹, ANGUS MCMULLEN, XU LIU, MIRNA MIHOVILOVIC, DEREK STEIN, JAY TANG, Brown University — We report preliminary experimental results of the translocation of the filamentous virus fd through a solid-state nanopore. fd virus is suitable for translocation and detection in a voltage-biased nanopore because it is highly charged, 880 nm long, and 6.6 nm in diameter. Importantly, fd has a persistence length of $\sim 2 \mu\text{m}$, a forty-fold increase over dsDNA, making fd a model stiff polymer for testing theories of polymer translocation dynamics. fd cannot coil in solution, therefore the dispersion of fd translocation times can test a model by Lu et al. that ascribes DNA translocation velocity fluctuations to the distribution of initial conformations of the DNA coil. That picture is in contrast with an alternative model by Li et al., which attributes the spread of DNA translocation times to thermal velocity fluctuations. The physics of fd capture by a nanopore also differs significantly from DNA since the ends of the virus cannot diffusively search for the pore independently of the middle. As a result, the rate of fd capture from solution may not increase monotonically with the applied voltage across the pore; it is possible for fd to become kinetically trapped against the nanopore membrane by the electric field. We will compare the distribution of translocation times of fd virus to distributions for DNA and discuss the influence of the virus's orientation and interactions with the nanopore on the translocation speed and the measured current blockage. We will also examine the dependence of capture rate on the applied voltage.

¹Supported by NSF Grant No. CBET0846505 and IMNI at Brown Univ.

12:03PM J50.00005 Studies of DNA Translocation Dynamics Using Asymmetrical Nanopores¹, XU LIU, KARRI DIPETRILLO, JASON CHAN, DEREK STEIN, Brown University — Despite extensive studies of DNA translocations through voltage-biased solid-state nanopores, the influence of the DNA coil on the translocation dynamics remains poorly understood. We investigated this issue experimentally by controlling the separation between the DNA coil and the nanopore. We studied lambda DNA translocations through devices comprising a 400 nm-high, 2500 nm-wide, disc-shaped cavity bounded from above by a 20 nm-thin silicon nitride membrane with a 10 nm wide nanopore in the center, and from below by at 400 nm-thick silicon nitride membrane with a 300 nm-wide opening in the center. The asymmetric nanopore-cavity structure introduced an 800 nm gap between the initial DNA coil and the nanopore when a molecule translocated from below, but no gap when it translocated from above. Translocation times were longer and the integrated charge deficit was larger for molecules translocating from below. These results are explained by the viscous drag on the DNA outside the pore, whose importance relative to the drag inside the pore we quantify. We outline a consistent model of DNA translocation speeds that depends on the initial configuration of the DNA coil, similar to the velocity fluctuation model of Lu et al.

¹ This material is based upon work supported by the National Science Foundation under Grant No. CBET0846505.

12:15PM J50.00006 First-passage-time analysis of DNA translocation in solid-state nanopores¹, DANIEL LING, East Greenwich High School, Rhode Island, XINSHENG LING, Brown University — We report a DNA translocation experiment using solid-state nanopores and 48 kb lambda DNA samples. As reported previously, the DNA translocation dynamics in such standard solid-state nanopore experiments appear to be complex and multiple folded translocation pathways are observable. We use the translocation events with little or no detectable folded structures to construct a distribution function for the DNA translocation times. We find that the translocation time distribution can be fitted using the first-passage-time probability density function derived by Schrodinger for 1-D Brownian motion with a drift. The voltage dependence of the extracted DNA drift velocity shows excellent agreement with the Stokes' law at high voltages. Deviation from the Stokes' law is found at low voltages, but can be attributed to a systematic error in how different types of folded DNA translocations are sorted.

¹The measurements were carried out by D.L. in the lab of Prof. Derek Stein at Brown University with the supervision of Jason Chan, and assistance by Karri DiPetrillo and Xu Liu.

12:27PM J50.00007 Some aspects of polymer translocation dynamics through nanopore: comparison of recent the theories with simulation results¹, ANIKET BHATTACHARYA², University of Central Florida — Translocation of a flexible polymer chain through a narrow pore has still remained an active field of research. Earlier theoretical studies of Sung and Park,³ Muthukumar,⁴ Chuang, Kantor and Kardar, Kantor and Kardar⁵ for a flexible chain have been complemented by more recent theories of Sakaue⁶ where tension propagation (TP) along the chain backbone at the *cis* side resulting in a nonuniform stretching of the chain has been proposed to be a key input for theoretical studies. Recently these elements of the TP theory has been incorporated in to a Brownian dynamics (BDTP) scheme and numerical studies of the equations of motion are in excellent agreement with prior simulation studies.⁷ A driven translocating chain is essentially *out-of-equilibrium*⁸ which results in *cis-trans* asymmetries both in conformations and in dynamics. Therefore, results from theoretical studies should capture these features. In this talk first I will first present results from Langevin dynamics simulation citing several cases where how this *cis-trans* asymmetry affects the chain conformations and the translocation dynamics. Then I will discuss relevance of these results in the context of existing theories.

1:03PM J50.00008 DNA translocation measurements in solid-state nanopores fabricated using helium-ion microscope, LIPING LIU, Southeast University (Nanjing, China) and Brown University, WANG MIAO, Brown University, CHUONG HUYNH, Zeiss America, QUANJUN LIU, Southeast University, Nanjing, China, XINSHENG LING, Brown University — We report high-quality DNA translocation measurements in solid-state nanopores drilled in free-standing SiN membranes by using a helium-ion beam in a Zeiss helium-ion microscope (HIM). We show that the HIM nanopores have similar performance as the TEM-drilled pores.

1:15PM J50.00009 Dynamics of Simultaneous, Single Ion Transport through Two Single-Walled Carbon Nanotubes: Observation of a Three-State System, STEVEN SHIMIZU, WONJOON CHOI, CHANG YOUNG LEE, MOON-HO HAM, MICHAEL STRANO, Massachusetts Institute of Technology — The ability to actively manipulate and transport single molecules in solution has the potential to revolutionize chemical synthesis and catalysis. In previous work, we developed a nanopore platform using the interior of a single-walled carbon nanotube (diameter = 1.5 nm) for the Coulter detection of single cations of Li⁺, K⁺, and Na⁺. We demonstrate that as a result of their fabrication, such systems have electrostatic barriers present at their ends that are generally asymmetric, allowing for the trapping of ions. We show that above this threshold bias, traversing the nanopore end is not rate-limiting and that the pore-blocking behavior of two parallel nanotubes follows an idealized Markov process with the electrical potential. Such nanopores may allow for high-throughput linear processing of molecules as new catalysts and separation devices.

1:27PM J50.00010 Polymer Translocation through a Nanopore Modulated by a Sticky Site, HENDRICK W. DE HAAN, GARY W. SLATER, Department of Physics, University of Ottawa — We examine the translocation of a long polymer that has one “sticky site” where a single monomer experiences an attraction to the pore. Using a quasistatic model for the translocation dynamics and employing numerically exact methods to generate results, high precision values for the translocation times are obtained across a wide range of driving forces and sticky site well depths. It is found that the interplay between the sticky site well depth, the driving force, and entropic effects can lead to unexpected results such as a non-monotonic variation of the critical well depth with the driving force and abnormally long translocation times due to the generation of a metastable state at a critical driving force. The dynamics are also found to be strongly dependent on the location of the sticky site: a site near the head of the polymer increases the probability of successful translocation while a site in the middle acts merely as a “speedbump.” Treating the sticky site as a perturbation to an otherwise diffusive process (low driving forces) or driven process (high driving forces) yields good agreement with the numerical results.

1:39PM J50.00011 Translocation dynamics of a semi-flexible chain through a nano-pore¹, RAMESH ADHIKARI, ANDY W.C. LAU, Florida Atlantic University, ANIKET BHATTACHARYA, University of Central Florida — We study translocation dynamics of a semi-flexible chain through a nano-pore in two dimensions (2D) using Langevin dynamics simulation. Specifically, we show how the mean first passage time (MFPT) and the probability distribution of the MFPT are both influenced by the bending rigidity of the chain. Furthermore, we monitor the chain conformations both at the *cis* and the *trans* sides and relate these results with recent theories and experiments for a translocating chain through a nano-pore.

1:51PM J50.00012 Characterization of Idealized Helical Repeat Proteins in Silicon Nitride Nanopores¹, JIALI LI, BRADLEY LEDDEN, University of Arkansas, DAVID TALAGA, Montclair State University, AITZIBER CORTAJARENA, LYNNE REGAN, Yale University — In this work, we report the measurement of consensus tetratricopeptide repeat (CTPR) proteins with single silicon nitride nanopores. The CTPR proteins were measured in KCl solution at pH below and above its isoelectric point (pI), as well as with and without denaturing agent, Guanidine HCl. When a CTPR protein molecule transits through a nanopore driven by an applied voltage, it partially blocks the ions (K⁺ and Cl⁻) flow in the nanopore and generates a characteristic electric current blockage signal. The current blockage signal reveals information about the size, conformation, and primary sequence of the CTPR protein molecule. Previous translocation studies carried out with DNA have established that higher bias voltages result in shorter duration current blockages indicating that DNA translocates faster at a stronger electric field. However, our CTPR translocation studies show that longer duration current blockades were observed at higher bias voltages. We discuss how the inhomogeneous distribution of the primary charge sequence of the CTPR proteins predicts translocation barriers that are proportional to the bias voltage. Larger barriers at higher bias voltages will result in longer translocation times, consistent with our experimental results.

Tuesday, February 28, 2012 11:15AM - 2:03PM —
Session J51 DCMP DFD: Liquid Crystals: Smectic, Ferroelectric, Nanocomposites and DNA
Boston Conference Center 154

11:15AM J51.00001 Two-Dimensional Microfluidics: Hydrodynamic Interactions in Ultra-Thin Smectic Liquid Crystal Films¹, ZOOM NGUYEN, AARON GOLDFAIN, CHEOL PARK, JOE MACLENNAN, MATT GLASER, NOEL CLARK, Physics, University of Colorado at Boulder, LCMRC TEAM — Hydrodynamics is important in nature and has a wide range of applications in science and industry. Most studies of fluid dynamics have been carried out in 3D systems, but there is an increasing interest in the hydrodynamics in confined geometries. Smectics can form ultra-thin, stable fluid films of uniform but readily variable thickness, a structure which enables the quantitative study of 2D hydrodynamics. Hydrodynamic interactions in 2D extend much further across the fluid than in 3D, and all the dynamics is confined to a well-defined plane, facilitating clean, high-contrast and high-resolution experiments. Here, we explore the hydrodynamic interactions of disk-like smectic islands with other islands and with a straight film boundary acting as a 1D wall. High speed video microscopy confirms that the translational diffusion of an island is anisotropic in the vicinity of another island or the wall, and this anisotropy persists even at large separations many times the island radius.

11:27AM J51.00002 Two-Dimensional Microfluidics: hydrodynamics of drops and interfaces in flowing smectic liquid crystal channels¹, ZHIYUAN QI, ZOOM NGUYEN, CHEOL PARK, JOE MACLENNAN, MATT MACLENNAN, NOEL CLARK, Physics, University of Colorado at Boulder, LC TEAM — The quantization of film thickness in freely suspended fluid smectic liquid crystal film enables the study of the hydrodynamics of drops and interfaces in 2D. We report microfluidic experiments, in which we observe the hydrodynamics of 2D drops flowing in channels. Using high-speed video microscopy, we track the shape of 2D drops and interfaces, visualizing the deterministic lateral displacement-based separation and pinched flow separation phenomena previously observed only in 3D. Finally, we demonstrate techniques for 2D drop generation and sorting, which will be used for 2D microfluidic applications.

¹Work supported by NSF MRSEC Grant DMR- 0820579 and NASA Grant NAG No. NNX07AE48G

11:39AM J51.00003 Smectic liquid crystal cells with a “dirty” substrate, QUAN ZHANG, LEO RADZIHOVSKY, Department of Physics, University of Colorado, Boulder, CO 80309 — I will describe our recent studies of smectic liquid crystal cells with a “dirty” substrate. Acting as quenched disorder, such substrate heterogeneity destabilizes long-range smectic order on the surface and in the bulk for arbitrarily weak randomness. We analyze the statistics of the corresponding distortions, their decay into the bulk, topological defects and the role of nonlinear smectic elasticity. We will discuss our predictions in the context of recent experiments on ferroelectric smectic-C liquid crystals.

11:51AM J51.00004 Structural Reorganization of 4 - Cyano - 4' - octyloxybiphenyl (8OCB) revealed by Fast Scanning Calorimetry¹, DONGSHAN ZHOU, JING JIANG, ZHIJIE HUANG, WEI JIANG, GI XUE, Nanjing University, DONGSHAN ZHOU TEAM — 4-Cyano-4'-octyloxybiphenyl (8OCB) is a liquid crystal with a few crystalline polymorphic modifications, of which the square plate form is the most elusive. Square plate form was reported to be only solution grown at low temperature and transformed to metastable parallelepiped form immediately even at -20 OC. With the chip calorimeter, we got the smectic glass of 8OCB when it was quenched from the melt with cooling rate of 20, 000 K/s. In the subsequent reheating with rates ranged from 2,000 K/s to 7,000 K/s, we could find two melting peaks located at 310K and 320K, respectively. Under faster heating, the peak at 310K became dominating, while the peak at 320K weakening. At heating rate of 8000 K/s, there was only melting peak of 310K. If further increased the heating rate, the melting peak at 310K would become smaller again because the crystal growth was suppressed until basically invisible at heating rate of about 20,000 K/s. This work shows that the square plate form is the dominating form when grown from the smectic glass, but it starts transforming to the parallelepiped form at heating slower than 8000 K/s. At heating slower than 1000 K/s, the transformation is completed and there is no chance to capture the square plate form.

12:03PM J51.00005 A Biaxial Banana Liquid Crystal Phase with Short-range Layer Ordering¹, YONGQIANG SHEN, TAO GONG, DONG CHEN, RENFAN SHAO, CHENHUI ZHU, MATTHEW GLASER, JOSEPH MACLENNAN, DAVID WALBA, NOEL CLARK, Liquid Crystal Materials Research Center, University of Colorado at Boulder — W623, a single-tail, bent-core molecule with a polar termination on one end and a siloxane-terminated tail on the other, exhibits a ferroelectric, orthorhombic, fluid smectic liquid crystal phase, the SmAP_F. Powder x-ray diffraction (XRD) measurements reveal an exotic structural transition on cooling from the SmAP_F to a SmX phase, in which resolution-limited fluid smectic layering reflections give way to four much broader peaks, indicating short-range layer ordering. This behavior points to the kind of internal frustration that gives rise to our recently discovered helical nanofilament phases. We have performed two-dimensional XRD on aligned samples and discovered that one of the four peaks is from the in-plane order. Freeze-fracture transmission electron microscope (FFTEM) measurements confirm that there is two-dimensional short-range order in the SmX phase, with one periodicity in the layer plane and another normal to the layers. The in-plane periodicity can be measured directly from the packing of fibrils to be about 8 nm, consistent with the in-plane x-ray reflection peak. We will present depolarized transmission light microscopy, high-resolution XRD, and FFTEM studies of pure W623, and of mixtures of W623 with the calamitic liquid crystal 8CB.

12:15PM J51.00006 A Bent – Shape Leaning Smectic Liquid Crystal Material, CUIYU ZHANG, NICK DIORIO, Kent State University, S. RADHIKA, B.K. SADASHIVA, Raman Research Institute, ANTAL JAKLI, Kent State University — Liquid crystals of bent-shape molecules theoretically can form four types of fluid smectic layer structures: (a) A polar smectic phase (called SmAP) where both molecular plane and the line connecting the end of average molecules (director) are perpendicular to the layer normal; (b) A double tilted chiral polar structure; (c) A single tilted phase (SmCP) where only the molecular plane is tilted with respect to the layer normal. The fourth possibility, where the director is tilted with respect to the layer normal, the “leaning” SmLP phase, has never been verified experimentally. Here we present the first bent-core material that forms a SmLP structure, thus proving the reality of all theoretically predicted bent-core smectic phases.

12:27PM J51.00007 Effective Conductivity due to Continuous Polarization Reorientation in Fluid Ferroelectrics¹, JOSEPH MACLENNAN, YONGQIANG SHEN, TAO GONG, RENFAN SHAO, EVA KORBLOVA, DAVID WALBA, NOEL CLARK, Liquid Crystal Materials Research Center, University of Colorado at Boulder — In crystal ferroelectrics, the macroscopic polarization density $\mathbf{P}$ is stabilized to a set of discrete orientations by the underlying lattice, and ferroelectricity characterized by field-induced switching of $\mathbf{P}$ between these stable states. Fluid ferroelectrics exhibit $\mathbf{P}$ with no energy barriers to its reorientation. As a result, $\mathbf{P}$ can respond to applied electric field in a continuous fashion. We show here that, due to the reorientation of $\mathbf{P}$, an otherwise insulating fluid ferroelectric behaves electrically as a resistive medium, with conductivity in the semiconducting range. Measurements of cell dynamics are reported for the SmAP_F material W623, a bent-core liquid crystal (LC) with large macroscopic polarization that we find to exhibit nearly ideal field-induced block polarization reorientation. We have investigated theoretically the dynamic behavior of block polarization in the SmAP_F phase, finding that a reorienting LC polarization block behaves electrically as a resistor. Experimental studies of W623 confirm this behavior, revealing the low resistance of the block-reorienting LC and the corresponding characteristic flat-topped step in the current response.

¹This work is supported by NSF MRSEC Grant DMR-0820579 and by NSF Grant DMR-1008300.

12:39PM J51.00008 Microscopic origins of first-order SmA-SmC phase behavior and electro optics in de Vries smectic liquid crystals¹, Z. KOST-SMITH, M.A. GLASER, P.D. BEALE, N.A. CLARK, Dept. of Physics, University of Colorado — Many de Vries liquid crystals exhibit a first-order SmA-SmC phase transition. The original de Vries hollow cone model, in which molecules in the SmA phase are tilted with respect to the layer normal but are uniformly distributed in azimuthal orientation, ϕ , has been used successfully to model many properties of de Vries materials, but the microscopic origins of first-order behavior remain obscure. We describe a microscopic mechanism for first-order behavior in de Vries smectics based on the hollow cone model, embodied in a generalized planar spin model where effective interactions between tilted molecules in the smectic layer planes are represented by a nearest-neighbor pair potential, $u(\phi_{ij})$, with a minimum of variable width around $\phi_{ij} = \phi_i - \phi_j = 0$. Using mean-field theory and Monte Carlo simulation, we find that the SmA-SmC transition is second order for a relatively broad minimum in the potential, and becomes first-order as the minimum narrows. This reflects the expected behavior due to excluded volume interactions in a tilted smectic, in which increasing cone angle leads to a more steeply varying effective azimuthal potential. This model naturally explains the observed first-order behavior in the framework of a hollow cone model.

12:51PM J51.00009 Morphology and Dynamics of Liquid Crystalline Molecules Confined in Nano-pores, MALGORZATA JASIURKOWSKA, WILHELM KOSSACK, ROXANA ENE, CIPRIAN IACOB, WYCLIFFE KIPNUSU, PERIKLIS PAPADOPOULOS, JOSHUA SANGORO, University of Leipzig, Germany, MARIA MASSALSKA-ARODZ, Polish Academy of Sciences, Krakow, Poland, FRIEDRICH KREMER, University of Leipzig, Germany, UNIVERSITY OF LEIPZIG, GERMANY TEAM, POLISH ACADEMY OF SCIENCES, KRAKOW, POLAND COLLABORATION — Broadband dielectric and Infrared spectroscopy are combined to study the molecular dynamics of the liquid crystalline compounds belong isothiocyanatobiphenyl homologous series (abbreviated as nBT) confined in pores of mean diameters from 4 nm to 10.5 nm. In bulk, the studied substances show only one liquid crystalline phase: the SmE phase with orthorhombic arrangement within the molecular layers. In contrast to well-known bulk dielectric properties of nBTs, confinement leads to modification of the molecular dynamics. Two relaxation processes are detected. The slower process corresponds to molecular reorientation around short axis and it is faster in pores than in bulk. The second process is attributed to a librational motion of the molecules close to the walls. Both processes exhibit an Arrhenius-type temperature dependence. Detailed analysis of the temperature dependent infrared spectra indicates the different impact of confinement on the rigid and flexible molecular units of nBTs. Transition Moment Orientational Analysis is employed to explore the orientational order of molecules in pores.

1:03PM J51.00010 Temperature Dependence of Smectic Liquid Crystals Mixed With Magnetic Nanoparticles¹, JEFFERSON W. TAYLOR, University of Maryland - College Park, LYNN K. KURIHARA, Naval Research Laboratories, LUZ J. MARTINEZ-MIRANDA, University of Maryland - College Park — We investigate the properties of bulk liquid crystal mixed with a magnetic nanoparticle (CoFe) as a function of temperature. We compare our results to those of a heat capacity measurement of Cordoyiannis et al.² and compare the way the smectic as a function of temperature the way the nematic behaves. We study how the liquid crystal reorganizes in the presence of the functionalized nanoparticles as a function of temperature and compare it to how it behaves at room temperature.³ The X-rays give rise to three or four peaks whose evolution in temperature varies depending on their origin. In particular the second peak does not seem to vary much with temperature, and can be associated with the first several molecular layers attached to the nanoparticles.

1:15PM J51.00011 The Role of ZnO Particle Size, Shape and Concentration on Liquid Crystal Order and Current-Voltage Properties for Potential Photovoltaic Applications¹, LUZ J. MARTINEZ-MIRANDA, JANELLE BRANCH², ROBERT THOMPSON, JEFFERSON W. TAYLOR, LOURDES SALAMANCA-RIBA, University of Maryland - College Park — We investigate the role order plays in the transfer of charges in ZnO nanoparticle - octylcyanobiphenyl (8CB) liquid crystal system for photovoltaic applications as well as the role the nominally 7x5x5nm³ or 20x5x5nm³ ZnO nanoparticles play in improving that order. Our results for the 5nm nanoparticles show an improvement in the alignment of the liquid crystal with increasing weight percentage of ZnO nanoparticles¹. Our results for the 7x5x5 nm³ sample show that the current is larger than the current obtained for the 5 nm samples. We find that order is improved for concentrations close to 35% wt ZnO for both the 7x5x5 nm³ and 20x5x5 nm³. We have analyzed the X-ray scans for both the 7x5x5 and the 20x5x5 nm³ samples. The signal corresponding to the liquid crystal aligned parallel to the substrate is much smaller than the peak corresponding to the liquid crystal aligned approximately at 70° with respect to the substrate for the 7x5x5 nm³ sample whereas this same peak is comparable or more intense for the 20x5x5 nm³ sample. 1. 1:27PM J51.00012 ZnO Nanowire Arrays with Liquid Crystals for Photovoltaic Applications¹

, LOURDES SALAMANCA-RIBA, JOSHUA TAILLON, LUZ MARTINEZ-MIRANDA, Materials Science and Engineering Department, University of Maryland, College Park, MD — Liquid crystals are small monodisperse molecules with high mobilities and are easy and cheap to process. In addition, some of their phases exhibit molecular orientation that can provide a path for the electrons, or holes, to move from one electrode to the other. We have added a smectic A liquid crystal (8CB) to ZnO nanowire arrays of different diameters and have observed a photovoltaic effect as a function of the concentration of ZnO in the liquid crystal. The nanowire arrays are covered with 8CB liquid crystal for hole conduction. We have observed an increase in the light absorption of the PV cells as a function of wavelength of the light for the ZnO nanowire cells. We present a detailed study of the structure of the system.

1:39PM J51.00013 Ligation of Complementary Oligomers in Liquid Crystals of nanoDNA¹

GREGORY SMITH, DAVID WALBA, NOEL CLARK, LCMRC, CU Boulder, WEIXIAN XI, TAO GONG, CHRISTOPHER BOWMAN, Chemical Engineering, CU Boulder, TOMMASO FRACCIA, GIULIANO ZANCHETTA, TOMMASO BELLINI, University of Milan, LIQUID CRYSTAL MATERIALS RESEARCH CENTER, UNIVERSITY OF COLORADO, BOULDER COLLABORATION, DEPARTMENT OF CHEMICAL AND BIOLOGICAL ENGINEERING, UNIVERSITY OF COLORADO, BOULDER COLLABORATION, DIPARTIMENTO DI CHIMICA, BIOCHIMICA E BIOTECNOLOGIE, UNIVERSITY OF MILAN, MILAN COLLABORATION — The chromonic stacking mode of short oligomeric DNA upon forming liquid crystalline phases presents an intriguing possibility for liquid crystal autocatalysis, the promotion, by LC ordering, of chemical synthesis that stabilizes LC ordering. In such a scenario the concentration and physical organization of ligation reactants and the fluidity of the liquid crystal phase promotes the appropriate chemical ligation of oligomers. Because it is a mode of elongation free of other catalysts, this offers a tantalizing means of oligonucleotide self-elongation that might have implications in prebiotic life. We present here work toward elucidating possible catalytic enhancement by liquid crystalline phase formation. Ligation approaches based on water soluble carbodiimide base activation and photopolymerization will be presented.

1:51PM J51.00014 Liquid Crystal Ordering of Random DNA Oligomers

, TOMMASO BELLINI, GIULIANO ZANCHETTA, TOMMASO FRACCIA, ROBERTO CERBINO, University of Milan, Milan, ETHAN TSAI, MARK MORAN, GREGORY SMITH, DAVID WALBA, NOEL CLARK, LCMRC, University of Colorado, Boulder, DIPARTIMENTO DI CHIMICA, BIOCHIMICA E BIOTECNOLOGIE, UNIVERSITY OF MILAN, MILAN COLLABORATION, LIQUID CRYSTAL MATERIALS RESEARCH CENTER, UNIVERSITY OF COLORADO, BOULDER COLLABORATION — Concentrated solutions of DNA oligomers (6 to 20 base pairs) organize into chiral nematic (NEM) and columnar (COL) liquid crystal (LC) phases. When the oligomer duplexes are mixed with single strands, LC phase formation proceeds through macroscopic phase separation, as a consequence of the combination of various self-assembly processes including strand pairing, reversible linear aggregation, demixing and LC ordering. We extended our investigation to the case of LC ordering in oligonucleotides whose sequences are partially or entirely randomly chosen, and we observed LC phases even in entirely random 20mers, corresponding to a family of $4^{20} \approx 10^{12}$ different sequences. We have tracked the origin of this behaviour: random sequences pair into generally defected duplexes, a large fraction of them terminating with stretches of unpaired bases (overhangs); overhangs promote linear aggregation of duplexes, with a mean strength depending on the overhang length; LC formation is accompanied by a phase separation where the duplexes with longer overhangs aggregate to form COL LC domains that coexist with an isotropic fluid rich in duplexes whose structure cannot aggregate.

11:15AM J52.00001 Radial stretching of thin sheets: A prototypical model for morphological complexity

, BENNY DAVIDOVITCH, UMass Amherst — The complex morphologies of thin sheets consist of wrinkles, crumples, folds, creases, and blisters. These descriptive words may sound lucid — but do they carry any quantitatively distinguishable content? Following the classical approach of pattern formation theory, we seek to impart a universal meaning to these modes of deformation as distinct types of symmetry-breaking instabilities of a flat, featureless sheet. This idea motivates us to consider the general problem of *axisymmetric stretching* of a sheet. A familiar realization of this problem is the “map maker’s conflict”: projecting a flat sheet onto a foundation of spherical shape. Another representative realization is the ‘Lame’ set-up: exerting a radial tension gradient on a sheet, which may be free-standing or resting on a solid or liquid foundation. I will introduce a set of *generic parameters: bendability, confinement, stiffness, adhesiveness*, that span a phase space for the morphology of radially stretched sheets. In this phase space, wrinkling, crumpling, folding, creasing and blistering could be identified as primary and secondary symmetry-breaking instabilities.

11:27AM J52.00002 Bending of a surface with spontaneous curvature

, CATHERINE QUILLIET, PHILIPPE MARMOTTANT, ALEXANDRE FARUTIN, CHAOUQI MISBAH, LIPhy, Univ. Grenoble, France — We interest to curvature deformations that can be described by Helfrich’s energy: a quadratic mean curvature term, and a gaussian curvature term. When the surface is not strictly incompressible and presents a nonzero spontaneous mean curvature, we focus on simple cases to show that a priori determination of key features (spontaneous curvature, equilibrium area) may be biased according the expression taken for the energy.

11:39AM J52.00003 Deformations of 2D Random Elastic Networks

, HENDRIK FLORIJN, M. VAN DEEN, HENK IMTHORN, MARTIN VAN HECKE, Leiden University, GRANULAR & DISORDERED MEDIA TEAM — We study the linear and nonlinear behavior of random 2D elastic networks at the desktop scale. We demonstrate how to fabricate random networks and characterize them with the lattice coordination number Z . We investigate experimentally if there is a relation between the mechanical response and the lattice coordination number Z of the network.

11:51AM J52.00004 Packing with a twist: from Wrinkles to Scrolls

, ARSHAD KUDROLLI, JULIEN CHOPIN, Department of Physics, Clark University — We discuss an experimental investigation of a thin elastic sheet in the form of a ribbon with clamped boundary conditions at both ends which is then subjected to a twist by rotating the ends through a prescribed angle. We find that a wrinkling instability appears even at a small twist angle which depends on the aspect ratio of the ribbon, its bending modulus and initial tension. Using x-ray tomography, we show that the pattern of this first instability has an impact on the folding at larger twist angles which can result in ordered configurations including Fermat scrolls. Still further twisting results in a highly compressive packing as in wringing a towel without application of direct radial compression. Implications for developing yarns with novel mechanical and transport properties [Lima, et al., Science 331, 51 (2011)] will be discussed.

12:03PM J52.00005 Geometry and Mechanics of Chiral Pod Opening¹, ERAN SHARON, SHAHAF ARMON, The Hebrew University of Jerusalem, EFI EFRATI, University of Chicago, RAZ KUPFERMAN, The Hebrew University of Jerusalem — We study the geometry and mechanics that drive the opening of Bauhinia seeds pods. The pod valve wall consists of two fibrous layers oriented at $\pm 45^\circ$ with respect to the pod axis. Upon drying, each of the layers shrinks uniaxially, perpendicularly to the fibers orientation. This active deformation turn the valve into an incompatible sheet with reference saddle-like curvature tensor and a flat (Euclidean) reference metric. These two intrinsic properties are incompatible. The shape is, therefore, selected by a stretching-bending competition. Strips cut from the valve tissue and from synthetic model material adopt various helical configurations. We provide analytical expressions for these configurations in the bending and stretching dominated regimes. Surface measurements show the transition from minimal surfaces (narrow limit) to cylindrical ones (wide limit). Finally, we show how plants use these mechanical principles using different tissue architectures.

¹Supported by ERC “soft Growth” project and by BSF grant #2008432

12:15PM J52.00006 Flat-twisted-helical transition in composed gel sheets and self assembled chiral molecules¹, SHAHAF ARMON, ERAN SHARON, Hebrew University, Jerusalem, EFI EFRATI, University of Chicago, RAZ KUPFERMAN, Hebrew University, Jerusalem — We recently presented a new chirality creating mechanism in elastic strips. In such frustrated bodies, the chiral configuration is determined in a competition between bending and stretching energies, controlled by a dimensionless parameter $\tilde{w} = w\sqrt{k}/t$, in which w is the strip's width, t – its thickness and k – the spontaneous curvature. I will show the geometrical and mechanical equivalence between such elastic strips and self assembled molecules made of twisted elements. I will also show experiments in responsive gels, showing how a continuous variation in $\tilde{w}$ yields an ordered shape transition from flat to twisted and helical shapes and to tubes. Similar transitions have been observed in self assembled macromolecules.

12:27PM J52.00007 Curvature and defects in soft membranes with orientational order¹, THANH SON NGUYEN, JUN GENG, JONATHAN V. SELINGER, Liquid Crystal Institute, Kent State University — Previous research has demonstrated that soft membranes have a coupling between curvature and in-plane orientational order. Defects in the orientational order can induce curvature, and conversely, curvature leads to an effective geometrical potential acting on defects [1]. Recently, our group has done simulations which show that the interaction between curvature and defects depends on several important issues, including the baseline curvature of the membrane (flat, cylinder, sphere, torus), the phase of the defects (radial or tangential), and the relative contribution of in-plane (intrinsic) vs. out-of-plane (extrinsic) variations of the director [2]. To understand the simulations, we develop a theoretical approach that can address those issues. Using this approach, we calculate the energy of defect structures in curved geometries, and determine how the energy varies as a function of the defect position and separation and the membrane distortions. The interaction energy depends on the relative magnitude of intrinsic vs. extrinsic couplings, and on the mechanical properties of the membrane. This approach provides opportunities to design membranes that will relax into selected shapes. [1] AM Turner et al, Rev Mod Phys 82, 1301 (2010). [2] RLB Selinger et al, J Phys Chem B, in press.

12:39PM J52.00008 Capillary induced buckling of floating sheets, MIGUEL PINEIRUA, JOSE BICO, BENOIT ROMAN, PMMH-ESPCI, NARAYANAN MENON, UMass — When a water droplet is deposited over a thin floating sheet, radial wrinkles appear in the vicinity of the droplet as a result of capillary forces exerted at the contact line [1]. However, determining the stress state at the contact line is still challenging and limits the full description of the wrinkling pattern. In order to avoid this contact line ambiguities, we propose the experimental study of the buckling of a macroscopic annulus floating on the surface of water and submitted to a difference in surface tension between its inner and outer edges. This particular configuration allows to generate radial wrinkles on the membrane with well defined border conditions. The topography of the wrinkled patterns are precisely measured using a synthetic Schlieren technique. Based on the standard buckling theory, we develop scaling laws for the buckling threshold of the annulus as well as for the wave length and radial extension of the wrinkles, which are compared to our experimental results and numerical simulations.

[1] J. Huang, M. Juszkiwicz, W.H. de Jeu, E. Cerda, T. Emrick, N. Menon, and T.P. Russell. Capillary wrinkling of floating thin polymer films. Science, 317(5838):650-653, 2007.

12:51PM J52.00009 The wrinkle transition of a sheet on a drop, ROBERT SCHROLL, BENNY DAVIDOVITCH, HUNTER KING, NARAYANAN MENON, Physics Department, University of Massachusetts — A thin sheet subject to confinement will wrinkle in order to relieve compressive stress. We discuss the case of a circular sheet living on the surface of a liquid drop. The pressure of the drop forces the sheet to be non-planar, which may induce confinement along the outer edge of the sheet. We show that, in the limit of very thin, highly bendable sheets, the system is governed by a single confinement parameter. This parameter determines if and where wrinkles appear on the sheet. Comparison to experimental results provides the first detailed confirmation of a new far-from-threshold theory to describe such ultra-thin sheets. According to this model, the transition to the wrinkled state represents the loss of axisymmetry in the height field, while the stress field maintains its symmetry.

1:03PM J52.00010 Transition from Wrinkling to Crumpling in a Sheet Floating on a Drop¹, HUNTER KING, NARAYANAN MENON, ROBERT SCHROLL, BENNY DAVIDOVITCH, University of Massachusetts, Amherst — An ultrathin* circular polystyrene sheet floating on the surface of a water drop stretches radially and compresses along its circumference as the curvature of the drop increases. The compression is at first fully relaxed by a wrinkle pattern extending inward from the edge. When the wrinkles occupy too large a fraction of the area of the sheet, sharp, localized, crumpled features continuously emerge. We show that the onset of crumpling is a primary symmetry breaking transition of the stress field. We experimentally characterize this transition from wrinkling to crumpling by studying the distribution of gaussian curvature in the film, measured by optical profilometry. *Typical dimensions are tens of nanometers in thickness and millimeters in lateral size.

¹NSF DMR 0907245

1:15PM J52.00011 Supported conical defects, EFI EFRATI, University of Chicago — In this work we study the elastic equilibrium configurations of a hyperbolic conical defect (a flat disc with a single negative Gaussian curvature condensation), supported on a rigid plane. Originating from the study of strictureplasty, this problem which seems to be a natural extension to the D-cone problem displays a distinct behavior.

1:27PM J52.00012 Stamping and wrinkling of elastic plates, JEREMY HURE, JOSE BICO, BENOIT ROMAN, PMMH - ESPCI ParisTech — In classical Euler buckling a beam is found to buckle with the lowest mode as a compressive strain is applied. Higher modes are however observed if the amplitude of the out-of-plane displacement is bounded by geometrical constraints. What is the limit when the maximum amplitude prescribed is decreased to zero? We show that the wavelength tends towards a finite value dictated by the thickness of the beam. This one-dimensional model is used to describe the compression of a circular elastic plate into an hemispherical mold.

1:39PM J52.00013 Deterministic Wrinkling Patterns of Thin Polymeric Coatings on Soft Substrates, JIE YIN, Department of Mechanical Engineering, Massachusetts Institute of Technology, JOSE L. YAGUE, Department of Chemical Engineering, Massachusetts Institute of Technology, KAREN K. GLEASON, Department of Chemical Engineering, Massachusetts Institute of Technology, MARY C. BOYCE, Department of Mechanical Engineering, Massachusetts Institute of Technology — Wrinkling surface patterns in soft materials have become increasingly important for a broad range of applications including stretchable electronics, microfluidics, thin-film property measurement, wetting and adhesion, and other surface area and topology controlled phenomena. Thermal and swelling mismatch between the thin surface layer and the soft substrate lead to spontaneous formation of buckling-induced disordered labyrinth patterns, which exhibit a mechanistically-determined short wavelength, but an undetermined and highly varied long wavelength. In this paper, analytical and computational models are presented to create deterministic wrinkling patterns through directed buckling methods, which capture the physics of the instabilities governing the formation of multiple wavelength wrinkling patterns, providing a predictive tool for design of deterministic wrinkling patterns. The fabrication of the deterministic patterns is accomplished using novel chemical vapor deposition processes. The role of these patterns in providing multifunctional performance is illustrated and discussed.

1:51PM J52.00014 Wrinkles in reinforced membranes, ATSUSHI TAKEI, ESPCI, FABIAN BRAU, Université de Mons, BENOÎT ROMAN, JOSÉ BICO, ESPCI — We study, through model experiments, the buckling under tension of an elastic membrane reinforced with a more rigid strip or a fiber. In these systems, the compression of the rigid layer is induced through Poisson contraction as the membrane is stretched perpendicularly to the strip. Although strips always lead to out-of-plane wrinkles, we observe a transition from out-of-plane to in plane wrinkles beyond a critical strain in the case of fibers embedded into the elastic membranes. The same transition is also found when the membrane is reinforced with a wall of the same material depending on the aspect ratio of the wall. We describe through scaling laws the evolution of the morphology of the wrinkles and the different transitions as a function of material properties and stretching strain.

2:03PM J52.00015 Mechanics of Graphene Electronics¹, XUANHE ZHAO, Soft Active Materials Laboratory, Duke University — Graphene, a monolayer of tightly-packed carbon atoms, has demonstrated great academic and industrial promises for integrating superior properties of nanomaterials and nanostructures into novel macroscale devices. Here, we demonstrate a simple method to enable over 200% reversible deformation of continuous large-area graphene sheet (over 1cm × 1cm) on polymer substrates. By patterning large-area graphene on a pre-stretched polymer layer by 200%, the graphene film develops hierarchical patterns including wrinkles with wavelengths on the order 10~100 nm and delaminated buckles with wavelengths on the order of 1 μ m. If the polymer is stretched again (<100%), the wrinkled region relaxes and the graphene on this region becomes flat. As the stretch further increases (over 100%), the graphene on delaminated buckles slides toward the flat regions, decreasing the amplitude of the buckles. The relaxation of the wrinkles and buckles enables the large deformation of graphene electrode without fracture. We further demonstrate potential applications of the graphene electrodes capable of large deformation. For example, a polymer film can be sandwiched between two graphene electrodes. As a voltage is applied between the two graphene electrodes, the polymer can achieve an actuation strain over 200%.

Tuesday, February 28, 2012 11:15AM - 2:15PM – Session J53 GSNP: Disordered Systems: Jamming 153B

11:15AM J53.00001 The contact percolation transition¹, TIANQI SHEN, Physics Department at Yale University, COREY O'HERN, Department of Mechanical Engineering & Materials Science, Yale University, MARK SHATTUCK, Benjamin Levich Institute and Department of Physics, City College of New York of the City University of New York — Typical quasistatic compression algorithms for generating jammed packings of athermal, purely repulsive particles begin with dilute configurations and then apply successive compressions with relaxation of the elastic energy allowed between each compression step. It is well-known that during isotropic compression athermal systems with purely repulsive interactions undergo a jamming transition at packing fraction ϕ_J from an unjammed state with zero pressure to a jammed, rigid state with nonzero pressure. Using extensive computer simulations, we show that a novel second-order-like, contact percolation, which signals the formation of a system-spanning cluster of mutually contacting particles, occurs at $\phi_P < \phi_J$, preceding the jamming transition. By measuring the number of non-floppy modes of the dynamical matrix, the displacement field between successive compression steps, and the overlap between the adjacency matrix, which represents the network of contacting grains, at ϕ and ϕ_J , we find that the contact percolation transition also heralds the onset of nontrivial response to applied stress. Highly heterogeneous, cooperative, and non-affine particle motion occurs in unjammed systems significantly below the jamming transition for $\phi_P < \phi < \phi_J$.

11:27AM J53.00002 Constraint counting for frictional jamming, D.A. QUINT, University of California Merced, S. HENKES, J.M. SCHWARZ, Syracuse University — While the frictionless jamming transition has been intensely studied in recent years, more realistic frictional packings are less well understood. In frictionless sphere packings, the transition is predicted by a simple mean-field constraint counting argument, the isostaticity argument. For frictional packings, a modified constraint counting argument, which includes slipping contacts at the Coulomb threshold, has had limited success in accounting for the transition. We propose that the frictional jamming transition is not mean field and is triggered by the nucleation of unstable regions, which are themselves dynamical objects due to the Coulomb criterion. We create frictional packings using MD simulations and test for the presence and shape of rigid clusters with the pebble game to identify the partition of the packing into stable and unstable regions. To understand the dynamics of these unstable regions we follow perturbations at contacts crucial to the stability of the "frictional house of cards."

11:39AM J53.00003 Decoupling of Rotational and Translational Diffusion in a 2D Granular Experiment, NABIHA SAKLAYEN, GARY L. HUNTER, ERIC R. WEEKS, Emory University — We experimentally study the rotation and diffusion of granular clusters in a 2D binary granular system. Our apparatus vibrates a 2D system of densely packed granular bidisperse disks (to avoid crystallization) containing trackable 3-particle clusters. We use this system to mimic hard-sphere fluids and the clusters probe the system's local translational and rotational dynamics. As the area fraction of the bidisperse disks is increased, diffusion within the sample becomes slower, and above a critical area fraction, the sample behaves as a granular glass. We analyze the rotational and translational motions of the clusters to determine whether they decouple with changing area fraction of the system. As we approach the glass transition, we observe a decoupling between the two motions.

11:51AM J53.00004 Characterizing the clogging transition by individual grain behavior, CHARLES THOMAS, DOUGLAS DURIAN, University of Pennsylvania — Granular media clogs as it flows out of a hopper when the exit hole is appropriately small. However, when the hole is enlarged, the grains will never clog: there exists a well-defined transition between these two regimes at a particular critical hole size. To understand the origin of this clogging transition we follow the behavior of individual grains in the bulk. Using a quasi-2D hopper and a fast CCD, we can measure the positions of grains to sub-pixel accuracy. We then use this information to determine various local and global properties, including strain rate, velocity correlations, and dynamical heterogeneity time scales. We study how these quantities depend on the distance to the clogging transition, defined as the difference between the hole size and the critical hole size. This helps to explain the clogging transition and its relationship to the jamming transition.

12:03PM J53.00005 Jamming around fixed obstacles¹, AMY BUG, SAM BULLARD-SISKEN, Swarthmore College, CARL GOODRICH, University of Pennsylvania, LISA MANNING, Syracuse University, ANDREA LIU, University of Pennsylvania — Lattices of obstacles, such as microfluidic arrays, are capable of filtering or sorting particles like emulsion droplets, colloidal particles, and even cells. We study the jamming of soft, bidisperse discs placed within a lattice of fixed obstacles. Such obstacles provide a supporting structure for the jammed configuration, and their ability to alter a jamming threshold is of interest. Conjugate gradient methods are used to find minimum energy configurations, both with and without fixed obstacles. The likelihood of jamming as a function of disc volume fraction is calculated. If a configuration is jammed, the coordination number, energy, pressure, and other parameters of interest are calculated as a function of the obstacle size, number density, and configuration (hexagonal vs. square vs. random lattices).

12:15PM J53.00006 Frictional Jammed Packings: Classification, Protocol Dependence and the Phase Diagram, STEFANOS PAPANIKOLAOU, COREY O' HERN, Departments of Mechanical Engineering & Materials Science and Physics, Yale University, New Haven, Connecticut 06520, MARK D. SHATTUCK, Benjamin Levich Institute and Physics Department, The City College of the City University of New York, New York, New York 10031 — We probe the nature of the jamming transition in systems of frictional disks, where static friction is modeled geometrically using “bumpy-particles” with uniform circular asperities on the disks’ surface. First, we enumerate and classify the mechanically stable (MS) packings in small systems using exhaustive numerical simulations. We explicitly show that finite friction stabilizes packings that are unstable for frictionless particles, which causes the number of MS packings to increase strongly with the friction coefficient. MS packings for frictional particles are organized into low-dimensional geometric families in configuration space. We then calculate the critical behavior of the structural and mechanical properties near the jamming transition for frictional particles and as a function of protocol and show that friction drastically alters the nature of the transition.

12:27PM J53.00007 Jammed 2D circle packing reconsidered as a jigsaw puzzle, ERIC CORWIN, Department of Physics, University of Oregon, KENNETH DESMOND, ERIC WEEKS, Department of Physics, Emory University — Athermal random packings are inherently non-equilibrium structures. For a bidisperse jammed packing of N disks the global packing structure can be thought of as composed of N jigsaw pieces, each representing the local structure around a disk. We show that we can assign a unique identifier, termed a jigsaw number, to each local packing structure. We find that as the number of disks grows to infinity the number of different jigsaw numbers present in a packing remains finite. We report on the distribution of jigsaw numbers and find that certain local packing structures are more common than others, demonstrating that the non-equilibrium packing structure is incompatible with a flat measure over all configurations. We further report on the correlations present between jigsaw pieces.

12:39PM J53.00008 An experimental test of equilibration of temperature-like variables in jammed granular materials¹, JAMES PUCKETT, Dept. of Physics, North Carolina State University, BRIAN TIGHE, Process & Energy Laboratory, TU Delft, KAREN E. DANIELS, Dept. of Physics, North Carolina State University — Although jammed granular systems are athermal, a number of thermodynamic-like descriptions have been proposed which make predictions about the distributions of volume and stress fluctuations. We perform experiments with an apparatus designed to generate a large number of jammed two-dimensional configurations, which consists of a single layer of photoelastic disks supported by a layer of air driven through a microporous membrane. New configurations are automatically generated by alternately dilating the system (permitting large-scale rearrangements) and compressing it biaxially until a desired volume or pressure is reached. Within each configuration, a bath of $\gtrsim 10^3$ particles surrounds a smaller subsystem of particles with either the same or a different inter-particle friction coefficient than the bath. The use of photoelastic particles permits us to find all particle positions, and to numerically solve for the vector forces at each inter-particle contact. By comparing temperature-like quantities between subsystems, we test whether equilibration is observed under several proposed volume and stress ensembles.

¹We acknowledge support from NSF DMR-0644743.

12:51PM J53.00009 Energy decay of freely cooling granular gases in three dimensions, ZAHERA JABEEN, Department of Physics, University of Michigan, Ann Arbor, MI 48109-1040, SUDHIR N. PATHAK, RAJESH R., Institute of Mathematical Sciences, CIT Campus, Taramani Chennai-600 113, India — Freely cooling granular gases, wherein a dilute system of macroscopic particles with uncorrelated initial velocities lose energy through inelastic collisions, have been extensively studied both as a simple model for granular systems as well as a nonequilibrium system showing nontrivial coarsening at late times. As the system cools, inelasticity induces clustering, making the system inhomogeneous. While the form of energy decay ($E(t) \sim t^{-\theta}$) in the initial homogeneous regime is well established by Haff’s law ($\theta = 2$), the energy decay in the clustered regime is still unresolved in higher dimensions. Within mean field theory, $\theta = 2d/(d+2)$ (where d is the spatial dimension), while a correspondence to Burgers equation implies an exponent $\theta = 2/3$ ($d = 1$), $d/2$ ($d > 1$). In one and two dimensions, the two formulae predict the same exponents. By performing extensive event driven molecular dynamics simulations, we show that in three dimensions, the energy decays asymptotically with a power ≈ 1.2 , for all coefficients of restitution $r < 1$, consistent with the mean field exponent. However, we argue that the mean field arguments fail due to non local interactions between mass clusters.

1:03PM J53.00010 The Influence of Topology on Signal Propagation in Granular Force Networks¹, DANIELLE BASSETT, University of California Santa Barbara, ELI OWENS, KAREN DANIELS, North Carolina State University, MASON PORTER, Oxford University — Granular materials exhibit numerous rich and complex behaviours, which have been investigated from both continuum and particulate perspectives. In particular, sound propagation through granular materials is both heterogeneous and complicated, and understanding its features is important not only from the perspective of fundamental physics but also for practical applications such as the characterization and non-destructive testing of such materials. Unfortunately, continuum models of sound propagation have been unable to explain the full range of observed behaviours. Here we represent granular materials as spatially-embedded networks composed of nodes (particles) and weighted edges (contact forces between particles) located in Euclidean space, and we use network science to provide fundamental insights into how sound propagates. Using photoelastic particles, we quantitatively characterise the internal force structure and show that its meso-scale network structure plays a crucial role in sound propagation. These results might help to explain the failure of previous physical models, and illustrate that contact topology alone is insufficient to understand signal propagation in granular materials.

1:15PM J53.00011 Jamming of Brownian disks in a channel with a constriction¹, ALEJANDRO BILBAO, JERZY BLAWDZIEWICZ, Texas Tech University — We investigate jamming dynamics of an externally driven system of Brownian particles in a two-dimensional channel with an abrupt constriction. Our numerical simulations reveal a rich dynamical behavior that results from an interplay between external driving forces, thermal excitations, and geometrical constraints due to confinement. In particular, we have observed that channel blockage arising from particle accumulation at the constriction entrance alternates with sudden unjamming events originating from thermal fluctuations. We have also found that the dependence of the average particle flux on the channel width is non-monotonic as a result of strong spatial particle-wall correlations. Under some conditions there exist spontaneous particle ordering and dynamic switching between phases with square and hexagonal symmetry. We expect that similar phenomena can be observed in confined granular flows and in suspension flows in microchannels.

¹We acknowledge financial support by NSF grant CBET 1059745.

1:27PM J53.00012 To be or not to be jammed, SIMON DAGOIS-BOHY, Kamerling Ohnes Laboratory - Leiden University, BRIAN TIGHE, TU Delft - 3mE, JOHANNES SIMON, Kamerling Ohnes Laboratory - Leiden University, SILKE HENKES, Syracuse University, MARTIN VAN HECKE, Kamerling Ohnes Laboratory - Leiden University — When are packings of soft athermal spheres jammed? Any experimentally relevant definition must at least require a jammed packing to resist compression and shear. Numerical algorithms usually rely on a global compression monitored by a parameter (like pressure) that signals whether the packing is jammed or not. Here we show that compression is not sufficient to ensure properly jammed packings: some of those packings have positive pressures and bulk moduli, but negative shear moduli, and even for large systems, the number of these “bad apples” diverges as the jamming point is approached. We will discuss how to understand this situation and propose as a remedy the boundary relaxation, that is including the boundary shape parameters as variables in the equilibration process; finally we will compare the distribution of shear moduli obtained for both methods.

1:39PM J53.00013 Jamming, Yielding and Rheology of Weakly Vibrated Granular Media, GEERT WORTEL, JOSHUA DIJKSMAN, University of Leiden, OLIVIER DAUCHOT, CEA-Saclay, MARTIN VAN HECKE, University of Leiden, GRANULAR AND DISORDERED MEDIA TEAM, GROUPE INSTABILITÉS ET TURBULENCE TEAM — We establish that the rheological curve of dry granular media is nonmonotonic, both in the presence and absence of external mechanical agitations. In the absence of vibrations, the nonmonotonic flow curve governs the yielding behavior of granular media. In the presence of weak vibrations, the nonmonotonic flow curves govern a hysteretic transition between slow but steady and fast, inertial flows. For large agitations, the transition becomes non-hysteretic. We probe the fluctuations near the point where the 1st order transition becomes of 2nd order.

1:51PM J53.00014 Dynamics near shear-jamming for a dense granular system¹, JIE REN, JOSHUA DIJKSMAN, ROBERT BEHRINGER, Duke University — This talk will present several systematic experimental studies of a two-dimensional, frictional dense granular system subjected to simple shear deformation. The first experiment consists of linear shear for densities smaller than the isotropic jamming point, and examines both the evolution of the average stress and the evolution of force network. These measures reveal three distinguishable regimes of the granular system with increasing shear strain: unjammed, fragile, and shear-jammed regimes. The second experiment uses small amplitude cyclic shear to probe the dynamical response of the states from the first experiment. For fragile or jammed regimes, cyclic shear drives the system through transient states that evolve towards relatively stable forces networks and system-averaged stress. The timescale of the transient increases rapidly as the system moves deeper into the fragile, or shear-jammed regimes. These experiments also involve particle tracking (displacements and rotations) to search for and characterize non-affine motion and spatial heterogeneity. There is a clear increase in particle diffusion with increasing density and shear strain amplitude, even when the system is still unjammed and experiences only minimal stress. When the system is fragile or jammed, the heterogeneity of particle displacements reveals subtle correlations with the force network.

2:03PM J53.00015 Tricriticality in constraint percolation, L. CAO, J. M. SCHWARZ, Physics Department, Syracuse University — Constraint percolation goes beyond ordinary percolation to include constraints on the occupation of sites/bonds. For instance, k -core site percolation implements a geometric constraint requiring each occupied vertex on a network have at least k occupied neighboring vertices. It turns out that the percolation transition in such a model is essentially equivalent to the study of a dynamical glass transition in the Fredrickson-Andersen model, one of the models underlying the kinetically-constrained approach to the glass transition. We study heterogeneous k -core bond percolation on a random network with f denoting the probability of a $k = 2$ -core vertex and $1 - f$ the probability of a $k = 3$ -core vertex. This model corresponds to a heterogeneous extension of the Fredrickson-Anderson model. For $f = 1$, the percolation transition is continuous, while for $f = 0$, it is discontinuous. Using a master equation approach, we show that there exists a tricritical point at $f = 1/2$ with a new order parameter exponent of unity. Our results are consistent with other mean field results obtained via a different method. We also look for tricriticality beyond mean field by investigating another constraint percolation model dubbed force-balance percolation.

Session J54 GSNP: Focus Session: Complex and Co-evolving Networks - Empirical Studies of Social Networks 152

11:15AM J54.00001 Modeling users' activity on Twitter networks: validation of Dunbar's number, BRUNO GONCALVES, NICOLA PERRA, ALESSANDRO VESPIGNANI, Northeastern University — Microblogging and mobile devices appear to augment human social capabilities, which raises the question whether they remove cognitive or biological constraints on human communication. In this paper we analyze a dataset of Twitter conversations collected across six months involving 1.7 million individuals and test the theoretical cognitive limit on the number of stable social relationships known as Dunbar's number. We find that the data are in agreement with Dunbar's result; users can entertain a maximum of 100-200 stable relationships. Thus, the “economy of attention” is limited in the online world by cognitive and biological constraints as predicted by Dunbar's theory. We propose a simple model for users' behavior that includes finite priority queuing and time resources that reproduces the observed social behavior.

11:27AM J54.00002 Entropy of dynamical social networks, KUN ZHAO, Northeastern University, MARTON KARSAI, Aalto University, Finland, GINESTRA BIANCONI, Northeastern University — Dynamical social networks are evolving rapidly and are highly adaptive. Characterizing the information encoded in social networks is essential to gain insight into the structure, evolution, adaptability and dynamics. Recently entropy measures have been used to quantify the information in email correspondence, static networks and mobility patterns. Nevertheless, we still lack methods to quantify the information encoded in time-varying dynamical social networks. In this talk we present a model to quantify the entropy of dynamical social networks and use this model to analyze the data of phone-call communication. We show evidence that the entropy of the phone-call interaction network changes according to circadian rhythms. Moreover we show that social networks are extremely adaptive and are modified by the use of technologies such as mobile phone communication. Indeed the statistics of duration of phone-call is described by a Weibull distribution and is significantly different from the distribution of duration of face-to-face interactions in a conference. Finally we investigate how much the entropy of dynamical social networks changes in realistic models of phone-call or face-to-face interactions characterizing in this way different type human social behavior.

11:39AM J54.00003 The nature and perception of fluctuations in human musical rhythms¹, HOLGER HENNIG, Harvard University, and Max Planck Institute for Dynamics and Self-Organization (MPIDS), Goettingen, Germany, RAGNAR FLEISCHMANN, MPIDS, ANNEKE FREDEBOHM, Institute of Psychology, University of Goettingen, YORK HAGMAYER, Kings College, London, UK, JAN NAGLER, ANNETTE WITT, MPIDS, FABIAN THEIS, Institute for Bioinformatics and Systems Biology, Helmholtz Zentrum Munich, Germany, THEO GEISEL, MPIDS — Although human musical performances represent one of the most valuable achievements of mankind, the best musicians perform imperfectly. Musical rhythms are not entirely accurate and thus inevitably deviate from the ideal beat pattern. Nevertheless, computer generated perfect beat patterns are frequently devalued by listeners due to a perceived lack of human touch. Professional audio editing software therefore offers a humanizing feature which artificially generates rhythmic fluctuations. However, the built-in humanizing units are essentially random number generators producing only simple uncorrelated fluctuations. Here, for the first time, we establish long-range fluctuations as an inevitable natural companion of both simple and complex human rhythmic performances [1]. Moreover, we demonstrate that listeners strongly prefer long-range correlated fluctuations in musical rhythms. Thus, the favorable fluctuation type for humanizing interbeat intervals coincides with the one generically inherent in human musical performances. [1] HH et al., PLoS ONE, 6, e26457 (2011)

11:51AM J54.00004 Structural and social aspects of human mobility, JAMES BAGROW, Northwestern University, YU-RU LIN, Northeastern University — Research on human mobility has been revolutionized by cellular phone data, capturing activity patterns across extensive populations. A number of interesting features have been discovered, including the ultra-slow growth of human mobility patterns, which cannot be reproduced by traditional random-walk models. However, the spatiotemporal flows and detailed microstructure of human mobility have not been well studied. Inferring complex mobility networks from country-wide data from mobile phone data, we find that human mobility is dominated by a small group of frequently visited and dynamically close locations, forming a primary “habitat” that captures typical behavior, along with subsidiary habitats representing additional travel. These habitats are both well separated and spatially compact. We find that motion within habitats exhibits distinct temporal scaling and that the time delay to enter subsidiary habitats is a primary factor in the spatiotemporal growth of human travel. Mobility is also coupled with social activity. Interestingly, many phone users possess habitats that occupy single temporal and social contexts and display high temporal and social predictability when occupying subsidiary habitats, revealing new connections between human activity and mobility dynamics.

12:03PM J54.00005 Temporal and spatial regularity of mobile-phone data¹, PHILIPP HOEVEL, TU Berlin, Germany, ALBERT-LASZLO BARABASI, CCNR, Northeastern University — Network science is a vibrant, interdisciplinary research area with strong connections to a plethora of different fields. As the amount of empirically obtained datasets increases more and more, approaches from network sciences continue to enhance our understanding, for instance, of human dynamics. The available data often consist of temporal as well as spatial information. In our case they originate from anonymized mobile-phone traces, which include information about the timing of the connections between two mobile phones and also their positions. Thus, the data contains an additional social component. In this study, we evaluate patterns of human behavior identifying both temporal and spatial regularity. This leads to a detailed mobility analysis on various timescales and contributes to a general theory of synchronization in complex, real-world networks.

¹This work is supported by a postdoctoral fellowship of the Deutsche Akademische Austauschdienst (DAAD).

12:15PM J54.00006 Scale-free correlations in the geographical spreading of obesity, LAZAROS GALLOS, City College of New York, PABLO BARTTFELD, Buenos Aires University, SHLOMO HAVLIN, Bar-Ilan University, MARIANO SIGMAN, Buenos Aires University, HERNAN MAKSE, City College of New York — Obesity levels have been universally increasing. A crucial problem is to determine the influence of global and local drivers behind the obesity epidemic, to properly guide effective policies. Despite the numerous factors that affect the obesity evolution, we show a remarkable regularity expressed in a predictable pattern of spatial long-range correlations in the geographical spreading of obesity. We study the spatial clustering of obesity and a number of related health and economic indicators, and we use statistical physics methods to characterize the growth of the resulting clusters. The resulting scaling exponents allow us to broadly classify these indicators into two separate universality classes, weakly or strongly correlated. Weak correlations are found in generic human activity such as population distribution and the growth of the whole economy. Strong correlations are recovered, among others, for obesity, diabetes, and the food industry sectors associated with food consumption. Obesity turns out to be a global problem where local details are of little importance. The long-range correlations suggest influence that extends to large scales, hinting that the physical model of obesity clustering can be mapped to a long-range correlated percolation process.

12:27PM J54.00007 Mining networks of human contact with wearable sensors, ALAIN BARRAT, CPT Marseille, CNRS, France & ISI Foundation, Torino, Italy — Due to the development of sensors of various types and the use of digital media and computational devices, we increasingly leave digital traces of our daily activities. The scale at which such data can be gathered and analyzed makes possible a novel, data-driven approach to the investigation of various aspects of human behavior. In this talk, I will focus on the research done within the SocioPatterns project (www.sociopatterns.org), in which we have developed the SocioPatterns sensing platform to obtain longitudinal datasets on face-to-face contact events between individuals in a variety of contexts ranging from scientific conferences to museum, schools or hospitals. The gathered data sets consists in dynamic networks of human contacts, and their analysis reveal interesting similarities and differences of human interaction patterns across contexts. I will also consider the impact of the temporal resolution, which allows to take into account causality constraints, on dynamical processes occurring on networks, such as spreading processes.

1:03PM J54.00008 Are we in our travel decisions self-determined?, CHRISTIAN SCHNEIDER, MIT, THOMAS COURONNE, ZBIGNIEW SMOREDA, Orange Labs, MARTA GONZALEZ, MIT — Mobile phone data, as saved by every phone provider worldwide, allows us to extract information about human mobility. It can be mainly used to study the locations and routes of each mobile phone user during entire months. In order to gain deeper understanding of the inherent travel decisions of the daily trips measured by phone data, we compare them statically with those extracted from 10,000 trajectories reported in a travel diary survey. We identify and compare from both data sets the underlying trip decisions networks or motifs. Interestingly, although millions of different motifs are possible, in both data sets we found similar motif distributions. Hence, we develop a simple model, which could reproduce not only the size distribution of the motifs, but the motifs themselves and answer the opening question.

1:15PM J54.00009 A cross-section test of Cobb-Douglass production function between market capitalization and GDP, ADAM AVAKIAN, Boston University, Boston, MA 02215, USA, BORIS PODOBNIK, Faculty of Civil Engineering, University of Rijeka, 51000 Rijeka, Croatia, H. EUGENE STANLEY, Boston University, Boston, MA 02215, USA — Most classical economic theories imply that both (a) economies with lower output (GDP) per person tend to grow faster in per capita terms and (b) economies with lower capital per person tend to grow faster in per capita terms. It is well-known that the former was found to be wrong. Taking market capitalization as a proxy for physical capital, we analyze a cohort of countries over a 17-year period (1994-2010) and we find the latter statement in agreement with empirical data implying a contradictory result that while capital data worldwide tend to converge, GDP data tend to diverge. However, for the countries analyzed, for which we have both market capitalization and GDP data, we find that even economies with lower output (GDP) per person tend to grow faster in per capita terms. The result that for all countries one obtains divergence while for a group of countries having both market capitalization and GDP data we have convergence is in contrast with the refutation of (a) but our results only apply to countries that have an exchange market, and are thus participating in globalization, indicating the convergent effect of globalization.

1:27PM J54.00010 Statistical Analysis on the Korean Transportation System, OKYU KWON, National Institute for Mathematical Sciences, GABJIN OH, Chosun University, WOO-SUNG JUNG, POSTECH — We investigate the Korean transportation system including subway, highway and express bus systems. The network topology and traffic pattern of the Korean transportation system is studied. We find the transportation have many complexity features such as scale-free property. We also find the relationship between the traffic flow, and the population and the distance.

1:39PM J54.00011 The Growth Dynamics of Words: How Historical Context Shapes the Competitive Linguistic Environment, JOEL TENENBAUM, Center for Polymer Studies, Department of Physics, Boston University, Boston, MA, ALEXANDER PETERSEN, IMT Lucca Institute for Advanced Studies, Lucca 55100, Italy, SHLOMO HAVLIN, Minerva Center and Department of Physics, Bar-Ilan University, Ramat-Gan 52900, Israel, H. EUGENE STANLEY, Center for Polymer Studies, Department of Physics, Boston University, Boston, MA — Using the massive Google n-gram database of over 10^{11} word uses in English, Hebrew, and Spanish, we explore the connection between the growth rates of relative word use and the observed growth rates of disparate competing actors in a common environment such as businesses, scientific journals, and universities, supporting the concept that a language's lexicon is a generic arena for competition, evolving according to selection laws. We find aggregate-level anomalies in the collective statistics corresponding to the time of key historical events such as World War II and the Balfour Declaration.

1:51PM J54.00012 Voronoi Cell Patterns: Application of the size distribution to societal systems¹, RAJESH SATHIYANARAYANAN², DIEGO LUIS GONZÁLEZ³, ALBERTO PIMPINELLI⁴, T.L. EINSTEIN, U. of Maryland — In studying the growth of islands on a surface subjected to a particle flux, we found it useful to characterize the distribution of the areas of associated Voronoi (proximity or Wigner-Seitz) cells in terms of the generalized Wigner surmise⁵ and the gamma distributions. Here we show that the same concepts and distributions are useful in analyzing several problems arising in society.⁶ We analyze the 1D problem of the distribution of gaps between parked cars, assuming that successive cars park in the middle of vacant spaces, and compare with published data. We study the formation of second-level administrative divisions, e.g. French *arrondissements*. We study the actual distribution of *arrondissements* and the Voronoi tessellation associated with the chief town in each. While generally applicable, there are subtleties in some cases. Lastly, we consider the pattern formed by Paris Métro stations and show that near the central area, the associated Voronoi construction also has this sort of distribution.

K1.00002 Integrated High Switch Test System to Determine Time-Dependent Dielectric Breakdown, HEATHER PETROCCIA¹, Villanova University — As a 2011 SPS summer intern, I worked for NIST in the Semiconductor Division learning about characterizing defects in MOSFETs. The lifetime and reliability of a MOSFET is directly related to the projected lifetime of an electronic device. By applying an increased stress voltage to the gate oxide, the lifetime of the MOSFET within an electronic device can be simulated. From this simulation, the reliability of the device can be determined from a mathematical extrapolation which is derived from breakdown data. Although time dependent breakdown has been thoroughly studied in the past in silicon dioxides, large statistical studies are still necessary to confirm the already accepted models for extrapolating mean lifetimes as well as increasing the accuracy of the projected lifetime. By creating an integrated high switch test system to determine time dependent dielectric breakdown, we hope to create a more affordable and efficient system to test copious numbers of oxides. This system is composed of set of highly parallel switches which apply a stress voltage to a total of 48 oxides. By implementing LabVIEW, the level of the stress voltage as well as the break down voltage and time can be determined. From this data further statistical analysis can be applied.

K1.00003 ABSTRACT WITHDRAWN —

K1.00004 Out of the Box Thinking: Kinematics from a 163 Million-Year-Old Dinosaur Trackway, SCOTT LEE, University of Toledo — Dinosaurs always grab the interest of students. Information about dinosaur locomotion is accessible from the trackways they left. In a unique connection to kinematics, evidence of the acceleration of a meat-eating dinosaur (theropod) is evident in Trackway 13 in Ardley Quarry in Oxfordshire, UK. This particular trackway is described by J.J. Day, D.B. Norman, P. Upchurch and H.P. Powell in Vol. 415 of Nature on pages 494 and 495, published in 2002. This particular theropod underwent an acceleration of about $g/3$. This example provides a fun and engaging exercise for students studying kinematics.

K1.00005 Polyaniline-Carbon Nanotubes Composite Actuators¹, SABRINA ROSA, University of Puerto Rico at Humacao, Humacao, Puerto Rico, CARLOS CAMARGO, Centre Nacional de Microelectronica, Barcelona, Spain, EVA CAMPO, University of Pennsylvania, PA, JAUME ESTEVE, Centre Nacional de Microelectronica, Barcelona, Spain, IDALIA RAMOS, University of Puerto Rico at Humacao, Humacao, Puerto Rico — The understanding of photoactuation in Carbon Nanotubes (CNT)-polymer composites can contribute to the development of micro- and nano-optical-mechanical systems for applications that include intracellular motors, artificial muscles, and tactile displays for blind people. The integration of CNTs into polymers combines the good processability of polymers with the functional properties of CNTs. CNTs-polymer composite fibers were fabricated using the electrospinning technique. electrospinning process orients the CNTs along the precursor stream and can contribute to enhance photo actuation properties. The addition of polyaniline, an electroactive conductive polymer is expected to enhance the actuation strain of the composite. aim of this research is to study photoactuation in MWCNT-Polyaniline electrospun fibers. fibers were characterized using Scanning Electron Microscopy, Atomic Force Microscopy, and X-Ray Diffraction. Results demonstrate evidence of photo-actuation after irradiating the fibers with visible light. tests are being conducted to understand the mechanisms of the composites response to light stimulation.

¹Research Sponsored by Partnership for Research and Education in Materials (NSF-DMR 0934195).

K1.00006 Using the IPAD as a Pedagogical Tool: Focus on Angular Motion Analysis with Real-World Applications¹, LEAH BUSH, ANGELA GARRIOTT, ROBERTO RAMOS, Indiana Wesleyan University — The IPAD is a portable, novel interface that has the potential to create a more interactive learning environment in undergraduate physics education, particularly in the introductory physics laboratory setting. We report our experience in using this pedagogical tool in an algebra-based physics laboratory course, focusing on its application in analysis of angular motion. Taking advantage of its portability, we use it to analyze motion not only using standard physics laboratory equipment but using it for analyzing motion in real-world applications such as with exercise equipment such as an exercise bicycle and an elliptical machine. We report on student response to this learning tool.

¹We acknowledge Indiana Wesleyan University for providing an IPAD minigrant to R. Ramos

K1.00007 Why Physics Programs are Slimming Down, SAMINA MASOOD, University of Houston Clear Lake — We study the Physics enrollment in the light of the current financial situation. Role of the Physics program in the growth of several programs in a university and the importance of a successful Physics program to prepare for the future needs of the time are analyzed in detail. The effect of shutting down of Physics programs will also be discussed.

K1.00008 Student Autonomy and its Effects on Student Enjoyment in a Traditional Mechanics Course for First-Year Engineering Students¹, JANAKI I. PERERA, BRENDAN T. QUINLIVAN, JENNIFER A. SIMONOVICH, EMILY TOWERS, OREN H. ZADIK, YEVGENIYA V. ZASTAVKER, F. W. Olin College of Engineering — In light of recent literature in educational psychology, this study investigates instructional support and students' autonomy at a small technical undergraduate school. Grounded theory is used to analyze twelve semi-structured open-ended interviews about engineering students' experiences in *Introductory Mechanics* that includes *Lecture*, *Recitation*, and *Laboratory* components. Using data triangulation with each course component as a unit of analysis, this study examines students' course enjoyment as a function of instructional support and autonomy. The *Lecture* utilizes traditional instructor-centered pedagogy with predominantly passive learning and no student autonomy. The *Recitation* creates an active learning environment through small group work with a moderate degree of autonomy. The *Laboratory* is designed around self-guided project-based activities with significant autonomy. Despite these differences, all three course components provide similar levels of instructional support. The data reveal that students enjoy the low autonomy provided by *Lecture and Recitations* while finding the *Laboratory* frustrating. Analyses indicate that the differences in autonomy contribute to students' misinterpretation of the three course components' value within the context of the entire course.

K1.00009 Does requiring graded online homework improve physics exam performance?, NORMA CHASE, Massachusetts College of Pharmacy and Health Sciences — In a first experiment with using Mastering Physics in a first semester calculus-based course, homework and exam performance was tracked periodically during the semester. As expected, the use of novel technology (and its ability to track which students were persistently working at problem exercises) motivated many students to become more involved with work on assigned physics problems. Although there did appear to be a significant correlation between exam averages and homework scores in the upper half of the exam average distribution, individuals spanning the full range of exam averages (down to 45 percent) earned homework scores as high as those who had performed outstandingly well in exams. In this work, we present results and proposed plausible explanations for the apparent anomaly.

K1.00010 UNDERGRADUATE RESEARCH (SOCIETY OF PHYSICS STUDENTS ABSTRACTS) —

K1.00011 Preparation and characterization of optically-active metal probes for tip-enhanced Raman spectroscopy, JAE CHO, ISAAC RIISNESS, MICHAEL GORDON, University of California, Santa Barbara — Tip-enhanced Raman spectroscopy (TERS) has enabled spatially correlated topographic and chemical imaging of biomolecules, catalysts, photovoltaics, and materials on the nanoscale. Critical to the TERS experiment is the tip; tip size sets the spatial resolution, whereas tip material and shape determine how well far-field laser light couples to electron oscillations (plasmons) in the tip to create a tightly confined field that enhances Raman scattering of molecules in the tip-surface gap. Tips are typically prepared via electrochemical etching of metal wires in strong acid or base solutions. This etching process is not well understood, and the production of sharp, plasmonically active tips remains a key challenge in the TERS field. To address this issue, we developed an electrochemical etching cell with diagnostic system based on a tuning fork oscillator to evaluate the tip-etching process. We present initial study of oscillation dynamics during electrochemical tip etching under varying conditions.

K1.00012 Electrical and Magnetic Properties of Nanostructured Mo-Doped Yttrium Iron Garnet¹, S. KHANRA, A. LAUDARI, Department of Physics, Missouri State University, Springfield, MO 65897, Y. KOLEKAR, Department of Physics, Pune University, India, P. KAHOL, K. GHOSH, Department of Physics, Missouri State University, Springfield, MO 65897 — Yttrium Iron Garnet (YIG) is a synthetic garnet and ferromagnetic with the chemical formula $Y_3Fe_5O_{12}$. In YIG, five iron (III) ions occupy two octahedral and three tetrahedral sites, with yttrium (III) ions coordinated by eight oxygen ions in an irregular cube. The iron ions in the two coordination sites exhibit different spins, resulting in magnetic behavior. It is also transparent to infrared wavelengths over 600 nm. Nanostructured YIG has been synthesized systematically by solid state reaction method. The formation of pure YIG have been investigated through X-ray diffraction (XRD) beginning from weighing in molar proportions of Y_2O_3 and Fe_2O_3 , mixing and grinding, pre-sintering and final sintering at 1300 °C. XRD study shows that YIG exhibits cubic structure with lattice constant of about 12 Å. Magnetization with varying field and temperature has been measured using a SQUID magnetometer. Room temperature dielectric measurements indicate that the YIG shows the usual dielectric dispersion. Magnetic studies of Mo YIG has shown that it becomes diluted after doping and dielectric measurement have shown that dielectric constant of that sample has been reduced.

K1.00013 Water on a Hydrophobic Surface: Contact Angle vs. Depletion Layer, CAITLYN NEIDIG, JACOB BREZINSKY, MENGJUE ZHOU, ADELE POYNOR, Allegheny College — Hydrophobic surfaces repel water. When this occurs, a depletion layer is formed between the water and the hydrophobic surface. We will be studying the effects from the contact angle, the angle at which the water droplet meets the surface, on the depletion layer. Larger contact angles create thicker depletion layers, which has lead us to determine if there is a direct relationship between the contact angle and depletion layer. In order to do this, we will be coating gold slides with a hydrophobic ODT solution, a hydrophilic Mercapto solution, and various mixtures of both of these solutions to create a large range of contact angles. We will be using Surface Plasmon Resonance to study to any depletion layer created by water on these surfaces.

K1.00014 SPS Fabric of the Cosmos Cafe¹, ANISH CHAKRABARTI, Drury University — Hosted by Brian Greene and based on his best-selling book of the same title, *The Fabric of the Cosmos* is a new four- part NOVA series that explores the deepest mysteries of space and time. The program was kicked-off by 30 “Cosmic Cafes” being held around the country funded by an NSF grant which allows SPS-NOVA to fund SPS chapters for these events. During the summer I assisted in planning this kick-off, reviewing and suggesting revisions of resources related to the NOVA series to make them relevant to an SPS audience. I also got to organize and moderate the first “Cosmic Cafe.” The Cosmic cafe that I organized was discussion based, with our speaker Dr. James Gates starting with a short talk and then opening the floor up for questions. By organizing a “Cosmic cafe,” I got real hand experience about the challenges an SPS chapter would face while organizing a cafe themselves. Based on my experience I shall also discuss the effectiveness of the first ever themed science cafe blitz. A science café is an informal discussion with an expert in a very casual location, usually a restaurant, coffee shop, or a bar. A science cafe is mostly discussion based, but has a lot of freedom for the format. A “Cosmic” cafe is a science cafe which is based around the topics discussed in the documentary “The Fabric of the Cosmos.”

¹Society of Physics Students

K1.00015 Water on a Hydrophobic surface, RYAN SCRUGGS, MENGJUE ZHU, ADELE POYNOR, Allegheny College — Hydrophobicity, meaning literally fear of water, is exhibited on the surfaces of non-stick cooking pans and water resistant clothing, on the leaves of the lotus plan, or even during the protein folding process in our bodies. Hydrophobicity is directly measured by determining a contact angle between water and an objects surface. Associated with a hydrophobic surface is the depletion layer, a low density region approximately 0.2 nm thick. We study this region by comparing data found in lab using surface plasmon resonance techniques to theoretical calculations. Experiments use gold slides coated in ODT and Mercapto solutions to model both hydrophobic and hydrophilic surfaces respectively.

K1.00016 Correlation between acoustic emission and mechanoluminescence of rock cores under quasistatic compression¹, RACHEL A. MILLER, TIMOTHY W. DARLING, Physics, University of Nevada, Reno — When a rigid solid undergoes mechanical deformation, locally accumulated strain energy can be released through multiple avenues including acoustic emission (AE) and light emission known as mechanoluminescence (ML). In AE, events within a stressed rock such as defect movement, grain boundary shifting, and crack propagation create pressure waves which can be detected at the rock surface. While AE is used extensively for rock evaluation in geophysics, civil engineering, and mining, ML by comparison has received little attention from the geoscience community. ML from stressed and fracturing rock has been observed in mines, earthquakes, and the laboratory, but the underlying mechanism behind ML is poorly understood. Possible candidates include defect movement, creation of charged surfaces during fracture, piezoelectrification, and triboluminescence. Observing whether a correlation exists between ML and AE will help determine the source of ML. We have designed an apparatus for AE and ML detection of rock cores under quasistatic compression. Using photomultiplier tubes and piezoelectric transducers, AE and ML events can be spatially and temporally observed and correlated. We present apparatus design and preliminary results.

K1.00017 Harpoon-based sample Acquisition System, JAVIER BERNAL, Researcher, JOSEPH NUTH, DONALD WEGEL, Mentor — Acquiring information about the composition of comets, asteroids, and other near Earth objects is very important because they may contain the primordial ooze of the solar system and the origins of life on Earth. Sending a spacecraft is the obvious answer, but once it gets there it needs to collect and analyze samples. Conceptually, a drill or a shovel would work, but both require something extra to anchor it to the comet, adding to the cost and complexity of the spacecraft. Since comets and asteroids are very low gravity objects, drilling becomes a problem. If you do not provide a grappling mechanism, the drill would push the spacecraft off the surface. Harpoons have been proposed as grappling mechanisms in the past and are currently flying on missions such as ROSETTA. We propose to use a hollow, core sampling harpoon, to act as the anchoring mechanism as well as the sample collecting device. By combining these two functions, mass is reduced, more samples can be collected and the spacecraft can carry more propellant. Although challenging, returning the collected samples to Earth allows them to be analyzed in laboratories with much greater detail than possible on a spacecraft. Also, bringing the samples back to Earth allows future generations to study them.

K1.00018 AIP Career Pathways¹, AMANDA PALCHAK, University of Southern Mississippi — American Institute of Physics (AIP) Career Pathways is a new project funded by the National Science Foundation. One of the goals of AIP Career Pathways is to prepare students to compete for Science, Technology, Engineering, and Mathematics (STEM) careers with a bachelor's degree in physics. In order to do so, I reviewed and compiled useful resources on finding a STEM career with a bachelor's degree in physics. These resources not only supply the job seeker with job postings in STEM careers but also provide them with information on resumes, interviewing skills, and networking. Recently at the 2011 Industrial Physics Forum, I interviewed companies in the private sector to obtain a unique perspective on what types of skills potential employers expect an applicant to possess with a bachelor's degree in physics. Ultimately, these components will be used as supplements at student career workshops held at annual Society of Physics Students Zone Meetings.

¹National Science Foundation, American Institute of Physics

K1.00019 Simulation of a Tunable, Three-dimensional Resonant Cavity for Quantum Control and Measurement¹, RAVI NAIK, KATER MURCH, I. SIDDIQI, UC Berkeley, QNL — We present the design and simulation of a tunable, superconducting, three-dimensional resonant cavity for control and measurement of quantum systems. By adjusting the dimensions of the cavity appropriately, we create a photon resonant mode in the 4-8 GHz frequency band, typical of many current superconducting qubits. We simulate the resonance behavior of the cavity using a commercial three-dimensional finite-element solver to explore the effects of various modifications of the cavity boundaries and coaxial signal ports, as well as the insertion of dielectric materials and metallic control lines within the cavity. In particular, we find that the quality factor of the cavity resonance is exponentially dependent on the insertion depth of the port pins from the surface of the cavity. A weak dependence is observed for other modifications. By adjusting the pin depth, we can achieve a range of quality factors from a few hundred to a few million, as verified by experiment.

¹This research is supported by the IARPA CSQ program.

K1.00020 Suspended Particle Mass Determination from Transport Coefficients¹, DONOVAN MYERS, Louisiana State University Baton Rouge, PAUL RUSSO, Department of Chemistry, Louisiana State University — It has long been known that a suitable combination of transport coefficients can be used to determine particulate mass in suspensions. Advances in particle tracking make this straightforward and easier to apply to large numbers of particles. This poster will concern recent experiments along these lines, which are devoted to improved understanding of composite, hybrid, core-shell colloidal particles, without regard to shape.

¹Supported by NSF DMR 10055707

K1.00021 Electromagnetically Induced Transparency in a Four-Level W Scheme: Effect of Beam Intensity and Phase on Propagation, MATTHEW LEWIS, CHRISTOPHER NELSON, Department of Physics, Millersville University, Millersville, PA — Co-propagation of two circularly polarized lasers in an electromagnetically induced transparency four-level W scheme is investigated. Our four level system is produced using the ground state and three Zeeman levels of ultracold magnesium atoms. Parameters are determined such that co-propagation of the two incident optical fields will occur. Group velocities obtained by solving the density matrix master equation for the appropriate coherences are found to be periodic with respect to the phase angle of the Rabi frequency.

K1.00022 Fluorescent security markers on ZnO nanowires¹, KRISTY WARREN, MARIAN TZOLOV, None — Zinc oxide is an efficient emitter of light thanks to the large exciton binding energy of 60 meV. The narrow emission lines from ZnO nanowires can be used as an enhanced security feature in documents and can be easily recognized from the background originating from the paper itself. We have studied the emission properties of ZnO nanowires in the UV range and how they can be implemented into paper products for document security. The zinc oxide nanowires were synthesized by chemical vapor transport and postprocessed in solution. The nanowires were dispersed using a sonicator into nitric acid water solutions with a pH of 2 and 4, and ammonium hydroxide water solution with a pH of 5 and 7. The morphology of the dispersed ZnO nanowires was imaged under a scanning electron microscope. Fluorescence measurements have shown better light emission from the nanoparticles dispersed in the basic pH solution. This material was then implemented into crafted paper and viewed under UV lamps and with a spectrometer. We have studied the loading of the paper with ZnO nanoparticles. A comparison was done with equivalently processed material of ZnO in powder form. The implementation of zinc oxide nanowires into paper products can advance document security at a relatively low cost.

¹Lock Haven University of PA, Department of Physics

K1.00023 Noise correlations in quasi-1D conductors with different contact geometries¹, A. BELKADI, A.F. ISAKOVIC, Khalifa University - KUSTAR, Abu Dhabi, UAE — We nanofabricated end contacts to mesowires of NbSe₃ and tested for the presence of correlations in noise spectroscopy at various temperatures below Peierls transition temperature. We find that for $1/f$ -like, broadband noise (BBN), the degree of correlations in transport in two segments along a NbSe₃ mesowire can be tuned with electric field and temperature. For standard, bottom/top contacts geometries, we see a limited degree of correlations for narrow band noise (NBN) (typically 20-30%, except for a limited range of temperatures), but we also see that end contact geometry enhances the degree of correlations for NBN signal (closer to 50%). We believe this phenomenon is related to a better control of the CDW transport, such as weaker temperature dependence of condensate current. We also explore the issues of the overall energy transfer through such contacts.

¹The material growth and some of the measurements were done in Prof. R. E. Thorne lab at Cornell University. We acknowledge recent support from ATIC-SRC through contract 2011-KJ-2190 and KUSTAR.

K1.00024 Intensity dependent photoluminescence studies on zinc oxide nanowires, MARIAN TZOLOV, ANDREW EPPS, ERIC DRISCOLL, ZACHARY BARCIKOWSKI, Lock Haven University — The ZnO nanowires were grown by the chemical vapor transport method using a thin gold film as a catalyst. Their light emission in the visible and near UV spectral range was studied using excitation sources with large variation of the pump intensity, e.g. Xenon lamp, UV LEDs, nitrogen laser. The photoluminescence spectrum consists typically of the exciton emission band and a defect related band in the green spectral range. We have observed drastic change in the photoluminescence spectrum at high pump intensities with drastically decreased intensity of the defect related band. The results have been interpreted within a model accounting for the surface effects and associated band banding at the surface. Cathodoluminescence measurements of ZnO nanowires and bulk films were performed, which support the proposed model.

K1.00025 Specific Heat of Two-Gap Extreme Type-II Superconductors in High Magnetic Fields¹, TAMIRO VILLAZON, JULIAN IRWIN, SASHA DUKAN, Department of Physics and Astronomy, Goucher College, MD21204 — We present a numerical study of the quasiparticle contribution to the low-temperature specific heat of an extreme two-gap type-II superconductor at high magnetic fields. Within a T-matrix approximation for the self-energies in the mixed state of a homogeneous superconductor, the electronic specific heat is a linear function of temperature with a linear- T coefficient $\gamma(H)$ being a nonlinear function of magnetic field H . We compare our theoretical curve with available experimental data for the two-gap superconductors NbSe₂ and LuNi₂B₂C.

¹This work is supported by NSF grant no. DMR-0856415.

K1.00026 Changes in Ocean Color at Puerto Rico due to Tropical Storms¹, ANGELA FERRA, FERNADO GILBES, University of Puerto Rico at Mayaguez — In this research we analyze the impact of tropical storms in the ocean color of the Puerto Rico coast. The changes in ocean color are due to the absorption and scattering of light. It has been shown that remote sensing techniques are used as a fast and economical way to study the concentrations of phytoplankton and other water constituents at the ocean. Data from MODIS (Moderate Resolution Imaging Spectroradiometer) were used to generate images of ocean color. The images were downloaded from internet and processed using the program developed by NASA called SeaDAS. The processing involved the standard atmospheric correction and algorithm application. Dramatic changes in ocean color were detected due to tropical storms Earl and Jeanne. The results support the use of remote sensing in this type of assessments.

¹The research was done thanks for the support of the Physics Department at the University of Puerto Rico at Mayaguez.

K1.00027 High aspect ratio cell probes based on ZnO nanowires, MATTHEW KNARR, Lock Haven University, MARIAN TZOLOV, Lock Haven University, Department of Physics — ZnO is a useful and versatile material being used in nanotechnology and has many potential applications as a material in nanoscale biotechnological devices. The growth of ZnO nanowires using a gold catalyst has been extensively researched. In this project we propose an alternative growth method using electrophoretically deposited gold nanoparticles as a catalyst, rather than use of the more common gold thin film catalyst, in order to grow ZnO nanowires. Colloidal Au nanoparticles approximately 25 nm in diameter are used as the catalyst source and 0.003" diameter tungsten wire as the substrate. The gold nanoparticles were deposited on the tip of the tungsten wire by electrophoresis. The ZnO nanowires were deposited by chemical vapor transport process in a three zone tube furnace. Scanning electron microscopy was used to image the nanowires and energy dispersive X-ray spectroscopy to analyze the composition of the probes. We will illustrate our approach on electrically insulating the probe so that only the very tip can probe electrically the interior of biological cells.

**K1.00028 Laser Induced Fluorescence Studies of New Liquid Crystal C16-Fluorescent Dipyrri-
none** , SAMUEL BECK, DARREN NORTH, RICHARD RODE, CHRISTOPHER HEATH, AMY RENAUD, LOGAN TATE, Undergraduate, CHANDRA PRAYAGA, AARON WADE, MICHAEL HUGGINS, Faculty Advisor — A new liquid crystal, C-16 Fluorescent Dipyrri-
none, was synthesized and its absorption and fluorescence properties investigated near the phase transitions. A sample of the liquid crystal was dissolved in chloroform and deposited on a glass slide and housed in a temperature controlled environment. Fluorescence was induced by pumping the sample at 355nm from a frequency-tripled, pulsed ND:YAG laser and was analyzed using a monochromator and a 1GHz oscilloscope. The sample was held at each temperature, from 30 °C to 80 °C, with 1 mK precision before taking the spectra. The results show significant changes in the peak in the spectra near the phase transitions, allowing for precise measurement of the phase transitions. The samples were further characterized by measuring their absorption spectrum at different temperatures in the range of 30-60 °C was recorded over the spectral region 300-800 nm.

**K1.00029 Absorption and Fluorescence Study of New Liquid Crystal C14-Fluorescent Dipyrri-
none** , RICHARD RODE, SAMUEL BECK, DARREN NORTH, CHRISTOPHER HEATH, AMY RENAUD, LOGAN TATE, Undergraduate, CHANDRA PRAYAGA, AARON WADE, MICHAEL HUGGINS, Faculty Advisor — A new liquid crystal, C14-Fluorescent Dipyrri-
none, was synthesized and its fluorescence and absorption properties were studied near the phase transitions. A frequency-tripled, pulsed ND: YAG laser was used to induce fluorescence in the liquid crystal sample. The fluorescence spectra and decay times were studied as functions of temperature using a 1GHz oscilloscope, monochromator, and photomultiplier tube. This sample was tested over a temperature range of 30-60 °C with 1 mK resolution to allow precise determination of the phase transitions of the sample. The absorption spectra were recorded over the temperature range of 30 – 50°C using a HP 8453 UV-VIS spectrometer, on a sample of the liquid crystal dissolved in chloroform and dried on a quartz insert.

K1.00030 Resonance Circuit with a Nonlinear Liquid Crystal Capacitor , CHLOE RENFROE, SAMUEL BECK, Undergraduate, SAMI ALSHEIKH, Pensacola High School, CHANDRA PRAYAGA, TIM ROYAPPPA, Faculty Advisor — The liquid crystal 4'octyl-4-cyanobiphenyl (8CB) was injected into a commercially available liquid crystal capacitor cell (INSTEC, Inc). The cell was housed in a temperature-controlled environment constructed in the lab and a resonant circuit was assembled using the 8CB capacitor. The temperature of the capacitor was varied over the range 25 °C to 45 °C, covering the smectic, nematic, and isotropic phases. The sample was held at each temperature with a precision of 1mK before measuring the resonance curve with a network analyzer. The results showed a non-linearity in the resonance curve in the nematic phase, distorting the shape of the resonance curve. The corresponding curves for the smectic and isotropic phases were linear.

**K1.00031 Optical Absorption and Laser Induced Fluorescence Studies of Liquid Crystal C-
10 Fluorescent Dipyrri-
none** , DARREN NORTH, SAMUEL BECK, RICHARD RODE, CHRISTOPHER H, AMY RENAUD, LOGAN TATE, Undergraduate, CHANDRA PRAYAGA, AARON WADE, MICHAEL HUGGINS, Faculty Advisor — A newly synthesized liquid crystal C-10 Fluorescent Dipyrri-
none was dissolved in chloroform and allowed to dry on a glass slide. The slide was housed in a temperature controlled environment constructed in the lab. A frequency-tripled pulse ND: YAG laser (355 nm) was used to induce fluorescence in the liquid crystal sample, which was analyzed using a monochromator, photomultiplier tube, and a 1GHz oscilloscope. The sample was tested over a temperature range of 30-70°C. The temperature control was precise to within 1 mK, allowing precise determination of the phase transition temperatures. The area, fall time, and peak values of the fluorescence signal were studied as functions of wavelength and temperature. Absorption spectra in the spectral range 300 – 800 nm were also recorded using a commercial (HP8453) UV-VIS spectrometer.

**K1.00032 Analysis, Reconstruction, and Modeling of the Electrical Signal of the Weakly Elec-
tric Fish *Apteronotus Leptorhynchus*** , LORENZO SEWANAN, KENT DUNLAP, Trinity College — The weakly electric fish *Apteronotus leptorhynchus* uses approximately sinusoidal electrical signals to electrolocate and electrocommunicate. In particular, the complex electrical signals which are generated during dynamic interactions have been shown to impact the behavior and physiology of interacting fish. In order to study the specific features of these electrical signals that are biologically relevant, signals collected from fish under diverse conditions are analyzed using temporal and spectral techniques, specifically amplitude variation and frequency variation. Having characterized specific features of the signals, computational methods are then used to construct signals to mimic real electric fish signals. Constructed signals show close matching in relevant features when analyzed in the same manner as the original signals. From a different perspective, a two-dimensional dynamic model is formulated to simulate the generation of amplitude modulation in these signals based on the motion of a particle sampling a generalized field of time-varying points and found to generate some features of experimental electric fish signals. Work continues on both analysis, reconstruction, and modeling as well as actual playback experiments to determine the impact of these signals to influence fish neuroethology.

**K1.00033 The WASTED Resolutions: exploration of the spatial and energy limits of the
Webcam Alpha Spectrometer TEchnology Demonstrator** , JOSEPH FRYMAN, ARTHUR PALLONE, Northern Kentucky University — Scientists and engineers build simple, low-cost, webcam-based instruments for use in many disciplines. Analysis of the optical signal received through the three broadband color filters – red, green and blue – form the basis of many of those instruments. The CMOS sensors in webcam pixels also produce signals in response to ionizing radiations – such as alpha particles from a radioactive source. Simple alpha radiography has been demonstrated with an alpha source and a webcam modified to expose the sensors. The performance of the Webcam Alpha Spectrometer TEchnology Demonstrator (WASTED) built from such a modified webcam and a commercially available alpha source mounted to an optics rail is analyzed in terms of the energy upper-half-width-half-maximum and of the spatial modulation transfer function.

**K1.00034 Temperature and polarization dependent photoluminescence studies of WO₃ and
WO₃-x single crystals¹** , EMILY MAKOUTZ, Michigan Technological University, PRASENJIT DEY, DENIS KARAISKAJ, University of South Florida — WO₃ is an important material not only due to its interesting electronic properties but also due to applications in electrochromic devices and energy storage. The mechanism behind the electrochromic effect has been debated for several decades [1]. We have studied two WO₃ single crystals, a transparent and doped WO₃-x. A photoluminescence center around 865 nm is observed after sub-band gap excitation at 405 nm with relatively higher intensity in the crystal containing oxygen vacancies. The center appears as a broad transition of 35 nm FWHM and does not follow the band gap energy with temperature. However polarization dependent studies reveal at least two polarization dependent components of the center. To further investigate the polarization dependence for the two WO₃ crystals, we will use samples for which the orientation of the high axis of symmetry is known.

¹This work was supported by NSF REU program (award No DMR-1004873).

K1.00035 Raman spectroscopy investigation in the NWA 3118 meteorite: Implications for planet formation¹, BHUWAN GHIMIRE, The University of Utah and Westminster College MO, ANALÍA G. DALL'ASÉN, JORDAN M. GERTON, INESE I. IVANS, BENJAMIN C. BROMLEY, The University of Utah — Planet formation involves the coagulation of micron-scale dust into centimeter-meter scale objects. Explanation is sought of the adhesion property of the dust aggregates ultimately leading to the formation of structures like planetesimals. Confocal raman microscopy has been used to investigate carbon structures on the NWA 3118 meteorite. It is a carbonaceous type CV3 meteorite composed of micrometer scaled structures like chondrules and inclusions embedded in the matrix material. Raman mapping of meteorite samples with a laser of excitation wavelength 488nm was pursued, with a focus on the interfaces between chondrules and the matrix. Raman spectra of olivines and graphitic structures with corresponding optical and raman images of the spotted structures in the NWA 3118 are reviewed.

¹This work was supported by an internship grant from Nano-Optics lab at the Department of Physics and Astronomy, The University of Utah.

K1.00036 Formation of wave packets in electron diffraction on crystals, ROBERT LANNING, CRISTIAN BAHIRM, Department of Physics, Lamar University — Measurements of electron diffraction typically reveal the atomic structure of crystals and allow finding the length of chemical bonds. The effective electronic charge of each atom in the crystal acts upon the incident electron beam as a netting of narrow pinholes, and Fourier transforms the unique deBroglie wavelength of the projectile electron accelerated at fixed voltage into a wave packet. Using the uncertainty principle one can understand the mechanism that makes an incident electron to become a wave packet travelling inside the crystal at a group velocity identical with the initial speed of the projectile electron. Furthermore, the Pauli Exclusion Principle allows us to understand the fast passage of the projectile electron through the crystal and also, it allows the evaluation of the characteristic time for electron transmission. The project was sponsored by the STAIRSTEP program under the NSF-DUE grant# 0757057.

K1.00037 Exploring the limits of spin transport efficiency for spin ejection in spin photodiodes¹, K.P. SIMON, Olin College of Engineering, Needham, MA, USA, A. BELKADI, A.F. ISAKOVIC, Khalifa University - KUSTAR, Abu Dhabi, UAE — We examine several factors that affect the efficiency of the transport of optically excited, spin-polarized carriers in ferromagnet-semiconductor heterostructures. The process of optical excitation leads to the creation of the population of spin carriers in a III-V semiconductor [1], which faces a number of obstacles on its way out of the semiconductor. This poster addresses a hierarchy of problems that need to be addressed in order to improve the efficiency of spin ejection, with the goal of bringing it up to the efficiency level of the opposite process, the spin injection. Our approach is based on modeling the existing spin ejection data, in order to understand several spin relaxation processes and the transport across the interface between a semiconductor and a ferromagnet or other metal. Our results are based in part on Schokley-Queisser [2] approach for photodiodes efficiency. Our investigation shows that there is a considerable space for improvement of spin ejection transport efficiency, which opens up possibility of designing novel spintronics devices.

K1.00038 Testing of Unfolding Algorithm Using Blind Data, EMY RIVERA, University of Puerto Rico Mayaguez, NATALIE MILKE, Technische Universität Dortmund — The RooUnfold package currently has available several different algorithms for the numerical solution of inverse problems or unfolding. Time-dependent Regularized Unfolding for Economics and Engineering, also known as TRUEE is an algorithm used to unfold and with time will be integrated to the RooUnfold package. Tests using simulated data in TRUEE were made with the goal to let future users know which parameters are ideal for their data. To test the TRUEE algorithm we used simulated data, with a known distribution and two different resolutions. The number of degrees of freedom and knots were found for different bin sizes. Chi square was then used to compare the unfolded and real distribution. The bin sizes with the smallest chi square were then used to unfold the blind data along with its parameters. Smaller bin sizes were used as well and then re-binned to see if the distributions matched. These re-binned distributions matched the unfolded distribution but did not match the known distribution.

K1.00039 Reconfiguration of the Receiver System for Sodium Doppler Wind/Temperature Lidar, VARDAN SEMERJYAN, Student, Utah State University, TAO YUAN, Research Assistant Professor, Utah State University — The newly established USU Na Lidar has the capability to measure neutral temperature and horizontal winds in the mesopause region (80-110 km in altitude) under clear sky condition in full diurnal cycle. Current system setup allows the observations of zonal (east-west) and meridional (north-south) winds, but lacks the coverage of the wind speed in zenith direction, which is essential to estimate the vertical wind perturbations. Since such perturbations are most likely associated with the atmospheric gravity waves (bouncy waves) breaking events and the related energy, momentum transfer, this upgrade of the Na Lidar system will provide further detailed information to the ongoing studies of such gravity wave dynamics and the induced atmospheric instabilities in the MLT (mesosphere and lower thermosphere) region. The proposed addition of the fourth channel and the associated new design of the Lidar receiving system will not only enable the data acquisition of the zenith channel but, the same time, will produce a more compact and robust structure than the current design. The new design will accommodate four high quantum efficiency(40%) Hamamatsu PMTs in the Lidar receiver, therefore, increase the system signal/noise(S/N) ratio by a factor of two.

K1.00040 Surface adhesion and confinement variation of Escherichia coli on SAM surfaces¹, KARISA BOWERSOX, KRISTA SITLER, JOSEPH CALABRESE, Lock Haven University of Pennsylvania, RESHANI SENEVIRATHNE, Don's Food Products, INDRAJITH SENEVIRATHNE, Lock Haven University of Pennsylvania — Controlled surface adhesion of non - pathogenic gram negative bacterial strain, Escherichia coli, DH5 alpha is interesting as a model system due to possible development of respective biosensors for prevention and detection of the pathogenic strain Escherichia coli and further as a study in biological and monolayer interactions. Self Assembled Monolayers (SAM) with engineered surfaces of linear thiols on Au(111) were used as the substrate. Sub cultured E. coli were used for the analysis. The SAM layered surfaces were dipped in varying concentrations of 2 – 4 Log/ml E. coli solutions. Subsequent surface adhesion at different bacterial dilutions on surfaces will be discussed, and correlated with quantitative and qualitative adhesion properties of bacteria on the engineered SAM surfaces. The bacteria adhered SAM surfaces were investigated using intermittent contact, noncontact, lateral force and contact modes of Atomic Force Microscopy (AFM).

¹Lock Haven University Nanotechnology Program

K1.00041 Aligned Single-Walled Carbon Nanotube Cantilevers, ALEXANDER RUYACK, Materials Science and Engineering, Cornell University, Ithaca NY, SAMANTHA ROBERTS, Department of Physics, Cornell University, Ithaca NY, IVE SILVESTRE, Department of Physics, Universidade Federal de Minas Gerais, Brazil, ARTHUR BARNARD, School of Applied and Engineering Physics, Cornell University, Ithaca NY, RODRIGO LACERDA, Department of Physics, Universidade Federal de Minas Gerais, Brazil, PAUL MCEUEN, Department of Physics, Kavli Institute at Cornell for Nanoscale Science, Cornell University, Ithaca NY — Researchers are striving to make smaller cantilever sensors with higher resonant frequencies in an effort to enhance force, position and mass detection sensitivity. With its minimal mass and high Young's modulus, a single wall carbon nanotube (SWNT) cantilever is suggested to represent the ultimate limit of this trend. We will present a novel nanolithography method that has been developed utilizing highly aligned SWNT's grown via chemical vapor deposition which are then transferred to a silicon/silicon dioxide substrate planarized with chemical mechanical polishing. This method allows us to create arrays of ~ 1 nanometer diameter aligned SWNT cantilevers of tunable length (typically 75 to 700 nanometers) with densities on the order of one cantilever per micrometer. Details about the nanofabrication process analyzed via imaging techniques such as scanning electron microscopy and atomic force microscopy will be discussed. Our future work will include characterization of the mechanical properties of these cantilevers and possible applications in biological sensing.

K1.00042 Parallel Performance Analysis between Free Response Environments and the Force Concept Inventory in Introductory Mechanics Courses, NICOLE BOBBITT, AARON WADE, CHANDRA PRAYAGA, University of West Florida — This paper reports our attempts to: 1) find a way to model and predict common thought processes that cause typical misconceptions identified by the Force Concept Inventory (FCI), 2) create a problem solving situation that folds in both kinematics and force discussions, and 3) accurately assess the students' ability to interpret a kinematic graph. Two pen and paper test questions were designed with these goals in mind, both broken into specific elements, not only to allow for partial credit, but also to arrive at a quantifiable fragmentation of the necessary thought processes required to solve the problem. These results were compared to pre- and post-FCI data to analyze the common misconceptions as defined by FCI and their correlation to mistakes in the thought processes in answering the designed questions. Ultimately this, and any future questions, would become a tool in the classroom to pinpoint the critical ideas with which a typical student struggles during a mechanics course.

K1.00043 Surface engineering and adhesion modification of SAM surfaces of 1-mercaptopundecanoic acid 1-undecanethiol: confining *Bacillus subtilis*¹, ROSE PASQUALE, LAUREN SWIGER, JOSEPH CALABRESE, RESHANI SENEVIRATHNE, INDRAJITH SENEVIRATHNE, Lock Haven University of Pennsylvania — Engineering surfaces for adhesion and confinement of bacteria is interesting towards development of respective biosensors, and to understand the interactions between biological systems and molecular layers. Investigation was focused on modification of surfaces towards confinement and entrapment of the nonpathogenic strain *Bacillus subtilis* or *Bacillus pathogenic/non pathogenic* variants and to study surface engineering. Clean, flat Au(111) on mica surfaces were used for self assembly for Self Assembled Monolayers (SAM). 1-mercaptopundecanoic acid and 1-undecanethiol were used at total 5 mM solutions in varying ratios, in 200 proof Ethanol solution. Resulting SAM layers were investigated for surface corrugation, morphology and structure variation at different thiol ratios. Observations will be discussed, quantitatively and qualitatively. Eventual mixture ratios were so selected towards optimum conditions for confining *Bacillus subtilis* as a model system. SAM surfaces were investigated using intermittent contact, noncontact, lateral force and contact modes of Atomic Force Microscopy (AFM).

K1.00044 Light Scattering Characterization of Salt Dependent Thermoreversible Micelles Synthesized from Elastin-Like Polypeptides¹, KAITLIN VANDEMARK, ALI GHOORCHIAN, KIRIL STRELETZKY, NOLAN HOLLAND, Cleveland State University — Environmentally responsive nanoparticles synthesized from Elastin-Like Polypeptides (ELP) present a promising system for applications such as biosensors, drug delivery vehicles, and viscosity modifiers. These nanoparticles undergo a transition from a soluble state at T_{room} to micellar aggregates above the transition. The ELP micelles have been found to be sensitive to various outside stimuli including pH, salt concentration, and solvent. Dynamic and Static Light Scattering were used to study structure and dynamics of ELP nanoparticles below the transition and of formed ELP micelles above the transition. Micelles were found to generally depend strongly on solution pH, however, in the pH window of 10.1-10.4 their size stayed constant. The apparent radius and molecular weight of micelles in this pH range strongly depend on salt concentration with three apparent regimes. At low salt (0-15mM), largely spherical micelles were found with $R_h=15nm$, which corresponds to the size of folded ELP hydrophilic tail; and molecular weight of 5000-6000kg/mol. At the intermediate salt (15-30mM) the observed particles are spherical micelles that increase in size (by about 3 fold) and molecular weight (by about 50 fold) as salt concentration increases. At high salt concentrations (30-60mM), $R_g/R_h \sim 1.3$, indicating the micelles behave as elongated particles with $R_h \sim 75nm$ that corresponds to the size of a stretched ELP chain with an apparent molecular weight of 300000-600000kg/mol.

K1.00045 Fluorescence studies of gram-positive and gram-negative bacteria, BRITNI BLUST, None, TRACY SWINGER COLLABORATION¹, DR. MARIAN TZOLOV COLLABORATION², DR. JOSEPH CALABRESE COLLABORATION³ — Autofluorescence is a relatively unexplored technique for identification. It is nondestructive, noncontact, fast, and has the potential to be integrated in small handheld devices. On the other hand, the autofluorescent signal is sometimes very weak, or it can be overwhelmed by the emission of a surrounding medium. We are exploring the possibility to develop an optical method for identification of the Gram-type of bacterial cultures based on the autofluorescence. We have enhanced the detectivity of a standard fluorimeter using combination of bandpass and long pass filters. In this particular study, we are investigating if the previously observed difference in the autofluorescent spectra of Gram-positive and Gram-negative bacteria is dependent on the age of the culture. We have selected two types of bacteria, *Kocuria rhizophila* and *Alcaligenes faecalis*, and we have monitored in equal time intervals of their development the autofluorescence spectra. The stages of development were monitored separately by measuring the turbidity and creating a growth curve. The goal of this study is to find out if the previously observed difference in the autofluorescence spectra of Gram-positive and Gram-negative bacteria is dependent on the stage of the development of the bacterial culture.

K1.00047 Surface adhesion and confinement variation of Staphylococcus aureus on SAM surfaces, ALICIA AMROSKI, MORGAN OLSEN, JOSEPH CALABRESE, Lock Haven University of Pennsylvania, Lock Haven PA 17745, United States, RESHANI SENEVIRATHNE, Don's Food Products, Schwenksville, PA 19473, United States, INDRAJITH SENEVIRATHNE, Lock Haven University of Pennsylvania, Lock Haven PA 17745, United States — Controlled surface adhesion of non - pathogenic gram positive strain, Staphylococcus aureus is interesting as a model system due to possible development of respective biosensors for prevention and detection of the pathogenic strain methicillin resistant Staphylococcus aureus (MRSA) and further as a study for bio-machine interfacing. Self Assembled Monolayers (SAM) with engineered surfaces of linear thiols on Au(111) were used as the substrate. Sub cultured S. aureus were used for the analysis. The SAM layered surfaces were dipped in 2 – 4 Log/ml S. aureus solution. Subsequent surface adhesion at different bacterial dilutions on surfaces will be discussed, and correlated with quantitative and qualitative adhesion properties of bacteria on the engineered SAM surfaces. The bacteria adhered SAM surfaces were investigated using intermittent contact, noncontact, lateral force and contact modes of Atomic Force Microscopy (AFM).

K1.00048 Precipitant diffusion and surface segregation in Al Alloys near melting point: Al 2024¹, AUSTIN MOHNEY, INDRAJITH SENEVIRATHNE, Lock Haven University of Pennsylvania — Industrial Al alloys are precipitant hardened with an impurity phase. Micro precipitants introduce various novel physical properties to the systems system. The diffusion of these constituents under thermal gradient was studied by sequentially increasing temperatures near melting point as it was observed to better facilitate the migration of precipitants. Study is based on Al 2024, age hardened, high strength AL alloy, annealed at incremental temperatures near melting point of 500 C and was observed in Scanning Electron Microscopy (SEM) and Energy Dispersive X ray Spectroscopy (EDX). Solvent cleaned near surface region of the alloy was investigated with observation of differential migration of constituent Cu, Fe Mg and Zn precipitants. The migrations were modeled in terms of diffusion coefficients and established literature of the participating species. Study will attempt to correlate the elemental concentration variation with applied elevated heat stress in industrial settings.

K1.00049 Entanglement in Quantum Harmonic Chains¹, NOEL KLINGLER, NATHAN HARSHMAN, American University — We study interparticle entanglement in finite chains of coupled harmonic oscillators as a function of the vibrational mode, excitation number, and bipartition of oscillators. Harmonic chains are used as a model in quantum information theory for ion traps and simple solid state systems, and our results extend previous work for the Gaussian ground state to excited states. Entanglement is analyzed by calculating the purity of the reduced density matrix of the combined wavefunctions of the oscillators in the chain tracing, over subensembles. We present analytic and numerical results for a varying effective spring constants between the particles and number of particles in the chain. Our entanglement results show interesting correlations between the symmetries of the modes and the symmetries of the partitions.

K1.00050 Computational Design of Druglike Small Molecule Plk1 PBD Inhibitors, SEAN VANADIA, The College of New Jersey (TCNJ) Undergraduate — Polo-like Kinase 1 (Plk1) participates in regulation of the cell cycle and is often overexpressed in cancers. Inhibition of Plk1 was found to suppress cancer development. Most known kinase inhibitors interact with highly conserved ATP binding sites of the kinases. This makes the design of Plk1-specific inhibitors difficult. However, Plk1 has another active site, the Polo-Box Domain (PBD). PBD is not present in other kinases that were studied here. In this research, the PBD site of Plk1 was used as a target for designing small molecules that could potentially bind Plk1. A previously designed small molecule, Purpurogallin (PPG), was found to bind only the PBD of Plk1 and a highly similar site of LYN kinase, but no other kinases. The PPG structure was used as a template to design new putative Plk1-specific inhibitors. Druglike properties of the new molecules were evaluated with the Osiris Property Explorer program. Interactions of the molecules with Plk1, LYN, and eight other kinases were studied using the Argus Lab docking program. Further search for Plk1-specific inhibitors that could potentially target cancers with overexpressed Plk1 is discussed.

K1.00051 Experimental and Numerical Study of the Role of Disorder on Contact Angle Hysteresis¹, ANGELINA N. SAMS, VICTORIA E. MERTEN, MICHAEL S. PETTERSEN, Washington and Jefferson College — Hysteretic behavior of the contact angle of a liquid on a solid is often ascribed to topographic or chemical heterogeneity of the surface. Recent experiments by Rolley and Guthmann² on liquid hydrogen on cesium suggest that both the hysteresis and the contact line dynamics might be explained in terms of the mesoscale structure of the cesium surface. We have investigated a room temperature system with similar wetting and structural properties, tetradecane on dodecanethiol-treated evaporated gold films, and compare the results with a model of the expected hysteresis due to the topographical heterogeneity as measured by AFM, and reported disorder in the thiol film.³

K1.00052 Surface adhesion and confinement variation of *Bacillus subtilis* on SAM surfaces, LAUREN SWIGER, ROSE PASQUALE, JOSEPH CALABRESE, INDRAJITH SENEVIRATHNE, Lock Haven University — Controlled surface adhesion of non-pathogenic gram positive strain, *Bacillus subtilis* is interesting as a model system due to possible development of respective biosensors for prevention and detection of the pathogenic variants *B. anthracis* and *B. cereus*. Further as a study for bio-machine interfacing systems. Self Assembled Monolayers (SAM) with engineered surfaces of linear thiols on Au(111) were used as the substrate. Sub cultured *B. subtilis* were used for the analysis. The SAM layered surfaces were dipped in 2 – 5 Log/ml *B. subtilis* solution. Subsequent surface adhesion at different bacterial dilutions on surfaces will be discussed, and correlated with quantitative and qualitative adhesion properties of bacteria on the engineered SAM surfaces. The bacteria adhered SAM surfaces were investigated using intermittent contact, noncontact, lateral force and contact modes of Atomic Force Microscopy (AFM).

K1.00053 Micromechanical and structural study of ambient grown Au nanostructures on P doped Si(100)¹, INDRAJITH SENEVIRATHNE, JOSHUA TATHAM, Department of Geology and Physics, Lock Haven University, Lock Haven, PA — Au nanostructure have wide application potential due to their noble nature, plasmonic, catalytic and specific conductive properties. Such nanostructures grown on substrate support under ambient conditions are complex but provides unique opportunities in dirty systems. In this model system Au was self assembled on solvent cleaned P doped Si(100) surface giving rise to near spherical geometry. Self assembly was initiated by magnetron sputter deposited Au at RT (300K) under high vacuum, on Si(100) which subsequently exposed to atmosphere. The micromechanical properties of the structures were measured by contact mode force curves in Atomic Force Microscopy (AFM). Both the stiffness and young modulus was measured for the nanostructures assembled and annealed at different temperatures. Initial plasticity of the nano structures was observed to reduce at annealing. Au nano structures were likely Stranski - Krastanov growth mode. Observed structure and their variations when annealed at successively higher temperatures will also be discussed. All measurements were taken by the AFM in contact intermittent contact and non-contact modes.

K1.00054 Open-frame external cavity diode laser for teaching and research¹, JASEN SCARAMAZZA, TYLER DONATO, ZACHARY BUCK, BRITTANY CURRAN, MICHAEL LIM, Dept. of Physics and Astronomy, Rowan University — We have constructed an open-frame, low-power, tunable external cavity diode laser suitable for both teaching and research purposes. We adapt the design of [1, 2] to an open, 4-rod frame composed entirely of commercially available parts. The laser can be quickly disassembled and reassembled by undergraduate students, while its open architecture provides an intuitive demonstration for students learning about laser physics. The laser will be used for atomic absorption spectroscopy.

K1.00055 Surface engineering and adhesion modification of SAM surfaces of 1-hexanethiol and 1-decanethiol: confining *Staphylococcus aureus*¹, MORGAN OLSEN, ALICIA AMROSKI, Department of Chemistry, Lock Haven University, PA 17745, JOSEPH CALABRESE, Department of Biology, Lock Haven University, PA 17745, RESHANI SENEVIRATHNE, Don's Food Products, Schwenksville, PA 19473, INDRAJITH SENEVIRATHNE, Department of Geology and Physics, Lock Haven University, PA 17745 — Engineering surfaces for adhesion and confinement of bacteria is interesting towards development of respective biosensors, and bio machine interfacing. Investigation was focused towards modification of surfaces towards confinement and entrapment of the nonpathogenic strain *Staphylococcus aureus* or similar pathogenic strains and to study surface engineering. Clean, flat Au(111) on mica surfaces were used for self assembly for Self Assembled Monolayers (SAM). 1-hexanethiol, and 1-decanethiol were used at total 5 mM solutions in varying ratios, in 200 proof Ethanol solution. Resulting SAM layers were investigated for surface corrugation, morphology and structure variation at different thiol ratios. Observations will be discussed, quantitatively and qualitatively. Eventual mixture ratios were so selected towards optimum conditions for confining *Staphylococcus aureus* as a model system. SAM surfaces were investigated using intermittent contact, noncontact, lateral force and contact modes of Atomic Force Microscopy (AFM).

¹Lock Haven University Nanotechnology Program

K1.00056 Scanning electron microscopy studies of bacterial cultures¹, TRACY SWINGER, BRITTNI BLUST, JOSEPH CALABRESE, MARIAN TZOLOV, Lock Haven University — Scanning electron microscopy is a powerful tool to study the morphology of bacteria. We have used conventional scanning electron microscope to follow the modification of the bacterial morphology over the course of the bacterial growth cycle. The bacteria were fixed in vapors of Glutaraldehyde and ruthenium oxide applied in sequence. A gold film of about 5 nm was deposited on top of the samples to avoid charging and to enhance the contrast. We have selected two types of bacteria *Alcaligenes faecalis* and *Kocuria rhizophila*. Their development was carefully monitored and samples were taken for imaging in equal time intervals during their cultivation. These studies are supporting our efforts to develop an optical method for identification of the Gram-type of bacterial cultures.

K1.00057 Electrical Characterization of Temperature Dependent Resistive Switching in $\text{Pr}_{0.7}\text{C}_{0.3}\text{MnO}_3$, MELINDA LOPEZ, CHRISTOPHER SALVO, STEPHEN TSUI, California State University San Marcos — Resistive switching offers a non-volatile and reversible means to possibly create a more physically compact yet larger access capacity in memory technology. While there has been a great deal of research conducted on this electrical property in oxide materials, there is still more to be learned about this at both high voltage pulsing and cryogenic temperatures. In this work, the electrical properties of a PCMO-metal interface switch were examined after application of voltage pulsing varying from 100 V to 1000 V and at temperatures starting at 293 K and lowered to 80 K. What was discovered was that below temperatures of 150 K, the resistive switching began to decrease across all voltage pulsing and that at all temperatures before this cessation, the change in resistive switching increased with higher voltage pulsing. We suggest that a variable density of charge traps at the interface is a likely mechanism, and work continues to extract more details.

K1.00058 Preparation and Characterization of C-16 and C-10 Fluorescent Dipyrinone Liquid Crystal Langmuir-Blodgett Films , GIOVANNI DELUCA¹, ALEXANDER CARROLL², CHANDRA PRAYAGA³, AARON WADE⁴, Physics Department, University of West Florida, CHRISTOPHER HEATH⁵, AMY RENAUD⁶, MICHAEL HUGGINS⁷, Chemistry Department, University of West Florida — A new C-16 and C-10 Fluorescent Dipyrinone Liquid Crystal has been synthesized by the University of West Florida's Chemistry department. The liquid crystals have amphiphilic properties with their dipyrinone polar heads and long hydrocarbon nonpolar tails. This led to the preparation and characterization of their Langmuir and Langmuir-Blodgett Film, using a Nima Langmuir-Blodgett Trough. The influence of the length of the hydrocarbon tail on the behavior of the pressure-area isotherm of the Langmuir film is studied. There is considerable difference in the behavior of the C-16 and C-10 Fluorescent Dipyrinone Liquid Crystal Films prepared. Ellipsometric characterization of the films, using an ellipsometer built by the Physics department, is used to further study the Liquid Crystal films.

K1.00059 Characterization of Acryl amide Resins Using Static Light Scattering , SUMIT LIBI, DAVID NORWOOD, Southeastern Louisiana University — Our research is based on the use of light scattering technique for the characterization of known and unknown particles within a liquid. The research focused specifically on the detection of resin polymer that may be present in the given samples using static light scattering. The sample was delivered into a high performance liquid chromatography system with static light scattering, refractive index and viscosity detectors. Static Light scattering measures the intensity of the light scattered as the function of scattering angle and polymer sample concentration. Based on these results the molecular weight and radius of gyration of the given sample can be calculated.

K1.00060 SUPERCONDUCTIVITY —

K1.00061 Synthesis and properties of a new superconducting compound (ZrNi_xS₂) , ARTHUR SCARAMUSSA, Escola de Engenharia de Lorena - Universidade de Sao Paulo, ZACHARY FISK, Departments of Physics and Astronomy, University of California at Irvine, ANTONIO JEFFERSON MACHADO, Escola de Engenharia de Lorena - Universidade de Sao Paulo, DEPARTMENTS OF PHYSICS AND ASTRONOMY, UNIVERSITY OF CALIFORNIA AT IRVINE - IRVINE, CA 92697, USA COLLABORATION — Since the discovery of superconductivity in chalcogenides in Fe-Se system and in iron pnictides much attention have been give for synthesis of new materials which can exhibit superconductivity. Within this context in this work we show results which suggest that ZrNi_xS₂, where x can assume 0.3, 0.5 and 0.8 values, is a new superconductor material. This compound crystallizes in a new crystallographic structure with hexagonal symmetry belongs to the space group R – 32/m. Indeed this compound is a variation of the Zr₃S₄ which can be considered as the prototype structure of this new compound (ZrNi_xS₂). In this prototype structure zirconium atoms may occupy two different sites in the structure. Thus, nickel atoms substitute zirconium in a specific site of the structure. These results suggest that superconducting critical temperature is dependent of the nickel content in this new compound. The optimum Ni content yield to T_c ~ 9.8 K.

K1.00062 Superconductivity in the T₂ phase of the Ta-Ge-B system , LUCAS EDUARDO CORRÊA, CARLOS NUNES, GILBERTO COELHO, ANTONIO AUGUSTO SILVA, ZACK FISK, ANTONIO JEFFERSON MACHADO, None, UNIVERSITY OF CALIFORNIA AT IRVINE COLLABORATION — In the Ta-Ge system the α-Ta₅Ge₃ phase is not superconductor. Considering the high solubility of this phase for boron, in this work it has been evaluated the effect of boron doping in α-Ta₅Ge₃ on the electrical, heat capacity and magnetic properties of the produced materials. It has been shown that boron doping promoted superconductivity for some specific composition. The Ta₅GeB₂, also named T₂ phase, crystallizes in the tetragonal symmetry with Cr₅B₃ prototype structure. In this composition the sample presented the maximum superconducting critical temperature (3.4 K). Others systems that exhibit the existence of the T₂ phase present superconductivity such as Mo₅SiB₂ (T_c ~5.5 K), Nb₅Si_{3-x}B_x (T_{cmax} ~7.8 K) and W₅SiB₂ (T_c ~5.5 K). Thus, Ta₅GeB₂ is more one example.

K1.00063 Evidence of the superconductivity in the Zr-Pt-Te system , SERGIO RENOSTO, Escola de Engenharia de Lorena, Universidade de São Paulo, P.O. Box 116, Lorena, SP, Brasil, TED GRANT, ZACHARY FISK, Departments of Physics and Astronomy, University of California at Irvine, Irvine, CA 92697, USA, ANTONIO MACHADO, Escola de Engenharia de Lorena, Universidade de São Paulo, P.O. Box 116, Lorena, SP, Brasil — Layered transition metal dichalcogenides MetalX₂ are well-known CDW conductors, with low dimensionality properties. The structure of layered TMDC can be regarded as a stacking of covalent coupled M-X-X sandwiches, and the coupling between layers X-X is of weak van der Waals type. The intercalation of metallic atoms into the weak coupled region between the X-X layers leads to significant modification of electronic properties. In this work results suggest that the Pt intercalation is able to induce superconductivity in the matrix compound (ZrTe₂). The critical temperature at 6.5 K is revealed through of magnetization, resistivity and specific heat measurements. Heat-capacity measurements show unambiguously a bulk superconductivity behavior. However, the x-ray diffraction results reveal that ZrPt_xTe₂ can crystallize in the LiCrS₂ prototype structure. Thus, we had shown that the superconductivity is induced by intercalation of Pt atoms.

K1.00064 Superconductivity in Zr_{1-x}V_xB₂ , LUIS HENRIQUE CONSOLINE, SERGIO RENOSTO, Escola de Engenharia de Lorena, Universidade de São Paulo, ZACHARY FISK, Departments of Physics and Astronomy, University of California at Irvine, ALEX COSTA, ANTONIO JEFFERSON MACHADO, Escola de Engenharia de Lorena, Universidade de São Paulo, UNIVERSITY OF CALIFORNIA AT IRVINE COLLABORATION — Since the discovery of superconductivity in MgB₂, much attention has been give for research in new diboride with potential for exhibit superconductivity. There are many diboride of refractory metals which crystallize in the same prototype structure than MgB₂ (AlB₂ prototype structure). However, only NbB₂ can exhibit superconductivity with superconductor critical temperature close to 3.5 K on the optimum composition. Some authors have been reported superconductivity in ZrB₂ with critical temperature close to 5.5 K, but this result was not reproduced for other research groups. In this work we present results which show that small substitution of Zr by V in the Zr_{1-x}V_xB₂ is able to induce superconductivity in the matrix phase (ZrB₂). The best composition gives a superconducting critical temperature close to 8.5 K.

K1.00065 Superconductivity in ZrVGe and HfVGe compounds , ANTONIO JEFFERSON MACHADO, Escola de Engenharia de Lorena, Universidade de São Paulo, P.O. Box 116, Lorena, SP, Brazil, ZACHARY FISK, Departments of Physics and Astronomy, University of California at Irvine, Irvine, CA 92697, USA — In the Zr-V-Ge and Hf-V-Ge there are two ternary phases of ZrVGe and HfVGe compositions which crystallize in a tetragonal symmetry. Both structures crystallize in the UGeTe prototype with space group I4/mmm. The lattice parameters of the two compounds are a = 3.72 Å and c = 14.34 Å for HfVGe and a = 3.75 Å and c = 14.48 Å for ZrVGe. In this structure the elements are arranged in layers in which obey V-RM-Ge sequence, where RM represents the refractory metal like Zr or Hf. In this work we show that both compounds are bulk superconductor with superconducting critical temperature at 4.8 K for HfVGe and 6.0 for ZrVGe.

K1.00066 Superconductivity in ZrAg_xTe_2 , HELTON SANTANA, SERGIO RENOSTO, ANTONIO JEFFERSON MACHADO, Escola de Engenharia de Lorena, Universidade de Sao Paulo — Layered transition metal dichalcogenides of the type MX_2 (M is transition metal, X = S, Se, Te) have been studied for their electronic properties due to low dimensionality. In these materials each layer correspond to the hexagonal transition metal intercalated by two similar chalcogen sheets. In ZrTe_2 the prototype structure is CdI_2 . The interaction of layers is weak as van der Waals bonding between chalcogen element (X). In general charge density wave and superconductivity coexist in these of materials. Indeed, various compounds of this material class exhibits this coexistence such as 2H-TaS_2 , 2H-NbS_2 etc. Some results reported in literature about the electrical properties of ZrTe_2 show that this material presents metallic behavior at a temperature interval from 4.0 K to 300 K. In this work we present results about intercalation of silver in the ZrTe_2 compound. The results suggest that the intercalation of Ag also is able to induce superconductivity in this compound. The superconducting critical temperature close to 9.0 K is revealed through of magnetization and resistivity measurements. The x-ray result reveals a new compound, originating from Ag intercalation and crystallizes in the LiCrS_2 prototype structure.

K1.00067 Superconductivity in ZrCu_xTe_2 , NAIARA BAPTISTA, Escola de Engenharia de Lorena, Universidade de Sao Paulo, TED GRANT, University of California at Irvine, SERGIO RENOSTO, Escola de Engenharia de Lorena, Universidade de Sao Paulo, ZACK FISCH, University of California at Irvine, ANTONIO JEFFERSON MACHADO, Escola de Engenharia de Lorena, Universidade de Sao Paulo, UNIVERSITY OF CALIFORNIA AT IRVINE COLLABORATION — Layered transition metal dichalcogenides of the type MX_2 (M is transition metal, X = S, Se, Te) have been studied for their electronic properties due to low dimensionality. In these materials each layer correspond to the hexagonal transition metal intercalated by two similar chalcogen sheets. In ZrTe_2 the prototype structure is CdI_2 . The interaction of layers is weak as van der Waals bonding between chalcogen element (X). In general charge density wave and superconductivity coexist in these of materials. Indeed, various compounds of this material class exhibits this coexistence such as 2H-TaS_2 , 2H-NbS_2 etc. Some results reported in literature about the electrical properties of ZrTe_2 show that this material presents metallic behavior at a temperature interval from 4.0 K to 300 K. Thus, in this work we present results about intercalation of Cu in the ZrTe_2 compound. The results suggest that the intercalation of Cu is able to induce superconductivity in this compound. The superconducting critical temperature close to 10.2 K is revealed through of magnetization and resistivity measurements. The x-ray result reveals a new compound, originating from Cu intercalation and crystallizes in the LiCrS_2 prototype structure.

K1.00068 Synthesis and properties of a new superconducting compound (ZrCu_xSe_2) , ANA CAROLINA GENEROSO, NAIARA BAPTISTA, SERGIO RENOSTO, ANTONIO JEFFERSON MACHADO, Escola de Engenharia de Lorena, Universidade de Sao Paulo — Since the discovery of superconductivity in chalcogenides in Fe-Se system and in iron pnictides much attention have been give for synthesis of new materials which can exhibit superconductivity. Within this context in this work we show results which suggest the existence of a new selenite intercalate with copper atoms in the ZrCu_xSe_2 nominal composition, where x is $0.1 \leq x \leq 0.4$ interval. A superconductor behavior begins in the $\text{ZrCu}_{0.3}\text{Se}_2$ with superconducting critical temperature close to 9.0 K. ZrSe_2 is a compound which crystallize in the hexagonal symmetry with CdI_2 prototype structure belongs to the space group $P-32/m1$. Indeed, copper is intercalating between Se-Se which have van der Waals interaction in the ZrSe_2 compound. This intercalation with copper atoms, produce superconductivity in the matrix compound (ZrSe_2) which is not superconductor. The copper intercalation in the matrix compound crystallizes in a LiCrS_2 prototype structure.

K1.00069 Superconductivity in a new compound of Zr_2CuSb_3 composition , RAFAEL TEBECHERANI, SERGIO RENOSTO, LUCAS CORREA, Escola de Engenharia de Lorena, Universidade de Sao Paulo, ZACHARY FISK, Departments of Physics and Astronomy, University of California at Irvine, ANTONIO JEFFERSON MACHADO, Escola de Engenharia de Lorena, Universidade de Sao Paulo, UNIVERSITY OF CALIFORNIA AT IRVINE COLLABORATION — In the Zr-Cu-Sb system there is a phase of Zr_2CuSb_3 composition which represents a ternary compound. This phase crystallize in a new prototype structure Zr_2CuSb_3 which have a tetragonal symmetry with space group $P-4m2$. The lattice parameters are $a=3.9404 \text{ \AA}$ and $c=8.6971 \text{ \AA}$. This structure can be represented as sequence of $1\text{Zr}_4\text{Sb}_2\text{Cu}_2\text{Sb}$ and (4Sb) which form like layer compound. However, the literature is very poor in results about the properties of this compound. Thus, in this work we show results which suggest the existence of superconductivity with superconducting critical temperature close to 8.0 K. These conclusions were obtained through X-ray diffraction, magnetization, and resistivity measurements.

K1.00070 Microscopic description of vortices in nanoscale superconductors , LIVIU CHIBOTARU, BART DELOOF, VICTOR MOSHCHALKOV, University of Leuven — The results of Bogolyubov-de Gennes calculations for thin superconducting discs and squares in applied magnetic field will be presented. The paramagnetic effect is taken fully into account. The vortex phase diagrams for the samples of nanoscopic size will be constructed and compared with the predictions of the Ginzburg-Landau theory. The size limitations for the entering of one and several vortices as function of material parameters will be established. Several unusual vortex transformations during the vortex pattern evolutions as function of temperature and field will be discussed.

K1.00071 Hexagonal pnictide SrPtAs ; the role of spin-orbit interaction and locally broken inversion symmetry¹ , S.H. RHIM, Northwestern U., S.J. YOUN, Gyeong Sang Natl. U., M.H. FISCHER, LASSP and Cornell U., D.F. AGTERBERG, U. Wisconsin-Milwaukee, M. SGRIST, ETH-Zuerich, M. WEINERT, U. Wisconsin-Milwaukee, A.J. FREEMAN, Northwestern U. — The first hexagonal pnictide superconductor SrPtAs which consists of stacked PtAs layers has been studied using the FLAPW method² and tight-binding methods. The single PtAs layer forms a honeycomb structure that exhibits: (1) locally broken inversion symmetry despite the presence of the global inversion center, and (2) strong spin-orbit interaction, for which physical consequences are nontrivial. Based on these findings, we predict significant enhancement of both the spin susceptibility and the paramagnetic limiting field with respect to the usual s wave superconductors. Further, we suggest an increase of T_C by electron doping of a van Hove singularity.

¹DOE (DE-FG02-88ER45382)

²Wimmer, Krakauer, Weinert, and Freeman, Phys.Rev.B. **24**, 864 (1981)

K1.00072 Superconductivity and structural variation of the electron-correlated layer systems $\text{Sr}(\text{Pd}_{1-x}\text{Te}_x)_2\text{Ge}_2$ ($T = \text{Co, Ni, or Rh}$; $0 \leq x \leq 1$)¹ , H.C. KU, J.W. WANG, I.A. CHEN, Y.B. YOU, C.Y. LIN, C.H. HUANG, S.J. WANG, Department of Physics, National Tsing Hua University, Y.Y. HSU, Department of Physics, National Taiwan Normal University — Superconductivity variations in the pseudoternary $\text{Sr}(\text{Pd}_{1-x}\text{Te}_x)_2\text{Ge}_2$ layer system ($\text{Pd}(4d^8)$, $T = \text{Co}(3d^7)$, $\text{Ni}(3d^8)$, or $\text{Rh}(4d^7)$; $0 \leq x \leq 1$) are reported. For the BaFe_2As_2 -type tetragonal structure, the degenerate nd^7 or nd^8 orbital of transition metal T is splitted by c -axis squeezed $T\text{Ge}_4$ tetrahedral crystal field in the T -Ge layer. For the isoelectronic $\text{Sr}(\text{Pd}_{1-x}\text{Ni}_x)_2\text{Ge}_2$ system, superconducting transition temperature T_c decreases monotonically from 3.12 K for $4d$ -band SrPd_2Ge_2 to 0.92 K for $3d$ -band SrNi_2Ge_2 , where major contribution of conduction electrons was from the half-filled dispersive 3D-like upper-lying $nd_{xz,yz}$ bands. For the $\text{Sr}(\text{Pd}_{1-x}\text{Rh}_x)_2\text{Ge}_2$ system, T_c decreases to 2.40 K with 25% of $4d^7$ Rh substitution. For the $\text{Sr}(\text{Pd}_{1-x}\text{Co}_x)_2\text{Ge}_2$ system, T_c decreases sharply to 2.58 K with only 3% of $3d^7$ Co substitution. The lower T_c of the present electron-overdoped (nd^7 or nd^8) compound is due to dispersive 3D-like $nd_{xz,yz}$ conduction bands with weak electron correlation.

K1.00073 Local antiferromagnetic exchange and collaborative Fermi surface as key ingredients of high temperature superconductors, JIANGPING HU, Purdue University, HONG DING, Institute of Physics, Chinese Academy of Sciences — Cuprates, ferropnictides and ferrochalcogenides are three classes of unconventional high-temperature superconductors, who share similar phase diagrams in which superconductivity develops after a magnetic order is suppressed, suggesting a strong interplay between superconductivity and magnetism, although the exact picture of this interplay remains elusive. Here we show that there is a direct bridge connecting antiferromagnetic exchange interactions determined in the parent compounds of these materials to the superconducting gap functions observed in the corresponding superconducting materials. High superconducting transition temperature is achieved when the Fermi surface topology matches the form factor of the pairing symmetry favored by local magnetic exchange interactions. Our result offers a principle guide to search for new high temperature superconductors. References: Jiangping Hu and Hong Ding, Arxiv:1107.1334 (2011)

K1.00074 Electronic structure of iron-based superconductors from DFT+DMFT: the important role of Hund's coupling and correlations, ZHIPING YIN, KRISTJAN HAULE, GABRIEL KOTLIAR, Department of Physics and Astronomy, Rutgers University — The iron pnictide and chalcogenide compounds are a subject of intensive investigations due to their surprisingly high temperature superconductivity. Density functional theory (DFT) has been widely used in the theoretical study but often suffers from significant discrepancy with experimental observations. The fundamental reason is that the low energy electrons in many iron-based superconductors, while displaying nice Fermi-liquid behavior, form quasiparticles and acquire sizable masses. Thus the actual low energy electronic states are strongly renormalized compared to DFT bands. We show that the combination of DFT and dynamic mean field theory (DFT+DMFT), which incorporates the detail electronic structure and local electronic correlations, overcomes most of DFT limitations and describe well the trends in all the physical properties such as the ordered moments, effective masses, Fermi surfaces, x-ray spectroscopy, optical conductivity, magnetic excitations and so on across all families of iron-based compounds, and find them in good agreement with various different experiments. We stress that Hund's blocking mechanism and electronic correlations are crucial in determining the electronic structures of iron-based superconductors.

K1.00075 Chlorine-doping effects on crystal structure and superconductivity in $\text{FeSe}_{1-x}\text{Cl}_x$ ¹, H.H. SUNG, R.R. HU, S.C. CHEN, W.H. LEE, National Chung Cheng University, W.H. LEE TEAM — According to the assessed Fe-Se phase diagram,² the FeSe compound could crystallize either in tetragonal Pb-O type structure with space group P4/nmm (called β FeSe) or hexagonal Ni-As type structure with space group P6₃/mmc (called δ FeSe) depending on the materials preparation process. In general, different starting composition of FeSe_x results in a mixture of superconducting phase with almost identical T_c and different amounts of magnetic impurity, therefore, it was proposed that the tetragonal β -FeSe superconducting phase ($T_c \sim 8$ K) only exists in a very narrow Se-deficiency range.³ Our experimental data indicated that the single hexagonal δ phase sample could be obtained by carrying out the low-temperature (400 °C) annealing for FeSe_xCl_y after reaction at 680 °C. This result is contrary to what is observed in the FeSe system in which the tetragonal β phase is the predominant stable one at the low annealing temperature 400 °C. As compared with the β -FeSe superconductor reported in the literature, higher T_c values (> 8 K) and larger superconducting volume fraction could be achieved by suitable tuning and heat treatments in the FeSe_xCl_y system.

K1.00076 Effective five band analysis on the lattice structure effect in iron pnictides, HIDETOMO USUI, KAZUHIKO KUROKI, The University of Electro-Communications — The discovery of superconductivity in the iron pnictides[1] and its T_c up to 55K[2] has given great impact to the field of condensed matter physics. From the early stage, much attention has been paid to the correlation between T_c and the lattice structure[3]. In the present study, we focus on the condition for optimizing superconductivity in the iron pnictides, varying hypothetically the lattice structure of LaFeAsO . Studying the band structure of the hypothetical lattice structure of LaFeAsO , the hole Fermi surface multiplicity is found to be maximized around the Fe-As-Fe bond angle regime where the arsenic atoms form a regular tetrahedron. Superconductivity is optimized within this three hole Fermi surface regime, thereby providing a natural explanation as to why T_c is optimized around the regular tetrahedron angle. Combining also the effect of the varying the Fe-As bond length, we provide a guiding principle for obtaining high T_c . [1]Y.Kamihara *et al.*, J. Am. Chem. Soc. **130**, 3296 (2008). [2]Z-A Ren *et al.*, Chinese Phys. Lett. **25**, 2215 (2008). [3]C.H. Lee *et al.*, J. Phys. Soc. Jpn. **77**, 083704 (2008).

K1.00077 The origin of the electron-hole asymmetry of the spin fluctuations and the effect on superconductivity in iron-based superconductors, KATSUHIRO SUZUKI, HIDETOMO USUI, KAZUHIKO KUROKI, University of Electro-Communications — Development of the spin fluctuation has been considered as one of the important features in the iron-based superconductors. One of interesting observation is the electron-hole asymmetry in its incommensurability, which appears in the neutron scattering experiments. In the present study, we study the origin of this electron-hole asymmetry, and its effect on the superconducting gap form. We first obtain a 10 orbital model for 122 iron-based superconductors from first principle calculation and obtain 5 orbital model in the unfolded Brillouin zone, which can only be done approximately in 122 systems. We apply the random phase approximation to these models to obtain the spin susceptibility, and solve the Eliashberg equation for the spin-fluctuation-mediated superconductivity. We find that the origin of the electron-hole asymmetry of the spin fluctuations is the multi-orbital nature of the Fermi surfaces. The multi-orbital nature of the Fermi surface is also found to be important in the appearance of horizontal nodes in the superconducting gap found in the calculation for 122 systems.

K1.00078 Re-entrant Resistance and Transport Anomalies in P-doped Eu Pnictide: $\text{EuFe}_2(\text{As}_{0.7}\text{P}_{0.3})_2$, with coexisting superconducting and ferromagnetic phases¹, NICHOLAS CORNELL, Nanotech Institute, University of Texas at Dallas, TIAN SHENG, HUIQIU YUAN, GUANGHAN CAO, SHENGGAO XU, ZHU'AN XU, Department of Physics, Zhejiang University, AUSTIN HOWARD, NATHANIEL MAYO, MYRON SALAMON, ANVAR ZAKHIDOV, Nanotech Institute, University of Texas at Dallas — The doping of Eu 122 pnictides by Phosphorus has been shown to result in superconductivity which coexists with ferromagnetism of spins ordered in Eu sites. Recently, in the course of exploring Fe-based superconductors, we observed both SC associated with Fe-3d electrons and ferromagnetism due to the long-range ordering of Eu-4f moments in $\text{EuFe}_2(\text{As}_{0.7}\text{P}_{0.3})_2$ and in similar compound with lower P-doping, at 0.27 the $R(T)$ peak appears at $T \sim 19$ K [1]. This $R(T)$ peak is associated with suppression of superconductivity by ferromagnetism and a re-entrance of resistance at low temperature. This presentation further investigates the pnictides at different P doping levels with transport measurements, correlated with magnetic and ESR data. Pnictides were made with a Solid state reaction method including the flux method to grow the single crystals. The dependence of the transition temperature and the behavior of the re-entrant $R(T)$ peak at 18-19 K on magnetic field and amount of dopant are addressed. [1]Amir Ahmed, M. K1.00079 First principles Study on Transparent High-Tc Superconductivity in hole-doped Delafossite CuAlO₂, AKITAKA NAKANISHI, HIROSHI KATAYAMA-YOSHIDA, Graduate School of Engineering Science, Osaka University — The CuAlO₂ is the transparent *p*-type conductor without any intentional doping. Transparent superconductivity and high thermoelectric power are suggested in *p*-type CuAlO₂ [1]. Katayama-Yoshida *et al.* proposed that it may cause a strong electron-phonon interaction and a superconductivity. But, the calculation of superconducting critical temperature T_c is not performed. We performed the first principles calculation about the T_c of hole-doped CuAlO₂ by shifting the Fermi level rigidly. In lightly hole-doped CuAlO₂, the Fermi level is located at Cu and O anti-bonding band. The electrons of this band strongly interact with the A₁L₁ phonon mode because the direction of O-Cu-O dumbbell is parallel to the oscillation direction of the A₁L₁ phonon mode. As a result, T_c of lightly hole-doped CuAlO₂ is about 50 K. We also discuss the materials design to enhance the T_c based on the charge-excitation-induced negative effective U system.

K1.00080 Synthesis of the electron-doped copper superconductors Eu_{2-*x*}Ce_{*x*}CuO_{4-*y*} and their physical property characterization using the X-ray powder diffraction and high pressure¹, GUOQING WU, WILLIAM NELSON, LUIS FLORES, SEAN HEFFERNAN, CHRISTOPHER WECKERLY, Dept. of Physics, University of West Florida, 32514, USA — The electron-doped copper superconductors Eu_{2-*x*}Ce_{*x*}CuO_{4-*y*} ($0 \leq x \leq 0.25$) were synthesized successfully using a solid state reaction method under a series of annealing and reduction procedures. X-ray diffraction and high hydrostatic pressure were used for their structure and electrical property characterization. Preliminary results show that the samples are in a single phase and the T_c drops as the pressure increases with a rate in sign opposite to the hole-doped counterparts and in magnitude apparently smaller than other cuprate superconductors.

K1.00081 Investigation of Un-reacted, Multi-phase, Solution-Derived Targets for Pulse Laser Deposition (PLD) of High T_c Superconducting Y₂Ba₄Cu₈O₁₆ (Y248) In-Situ, Epitaxial Thin Films, GRACE YONG, RODNEY DIXON, STEPHEN MONK, VERA SMOLYANINOVA, RAJESWARI KOLAGANI, Towson University — Y₂Ba₄Cu₈O₁₆ (Y248) is known to be robust in terms of O stability and is characterized by the absence of twin formation, and no structural phase transitions. It is stable in ambient atmosphere, resisting H₂O (and possibly even CO₂ exposure). These characteristics make Y248 more attractive for several applications of thin film superconductors as compared to Y₁Ba₂Cu₃O_{7- δ} (Y123). In addition, Y248 is very likely to have a much lower 1/f electrical noise level than Y123. (Electrical noise in Y123 has been shown to arise from mobile O defects). This would be an important advantage, since it has been established that electrical noise is a performance limiting parameter for Y123 devices. Limited past work on Y248 films has shown that a traditional approach to the growth of thin films by PLD that use stoichiometric, fully reacted, single phase targets has not been successful in achieving in-situ, epitaxial Y248 films. Such studies have also indicated the potential for achieving in-situ, epitaxial, PLD Y248 films using an un-reacted, multi-phase, solution-derived target. We will present results of our work towards obtaining high quality, in-situ, epitaxial thin films of Y248 via PLD employing non-traditional targets.

K1.00082 Superconductivity via Two-Phase Condensation of Localized Electrons, STEVEN KAPLAN, Yorktown Heights, NY, ALAN KADIN, Princeton Junction, NJ — Superconductivity is believed to occur via the formation of bound Cooper pairs of charge $2e$, and Bose condensation of the pairs. Recently, a fundamentally different approach [1] was developed that combines two novel aspects. First, a “distortion lattice” akin to an incommensurate dynamic charge-density wave is induced by the electron-phonon interaction. This localizes individual electrons on the scale of the coherence length by diffraction at the Brillouin zone of this distortion lattice, thus forming an energy gap. Second, these localized electrons are packed together with others of the same energy in two interlocked close-packed sublattices, analogous to ions in an ionic crystal. The electron wavefunctions in each sublattice are coherently in phase with each other, but out of phase with those in the other sublattice. The two sublattices together constitute a stable condensed structure compatible with the Pauli principle, which maintains long-range order of the quantum phase of the localized electrons. This structure can move coherently without pinning or resistance, manifesting itself as a supercurrent. Remarkably, the electron localization gap maps onto the BCS gap equation, and the flux quantum $h/2e$ is reproduced, without the presence of bound electron pairs. Moreover, this picture is easily extended to electron localization mediated by spin waves or other excitations. Experimental approaches to distinguish this new picture from conventional theories will be discussed.

[1] A.M. Kadin, <http://arxiv.org/abs/0909.2901>; <http://arxiv.org/abs/1007.5340>.

K1.00083 Theory of High- T_c Superconductivity: Accurate Predictions of T_c , DALE HARSHMAN, Physikon Research Corporation, Lynden, WA 98264 USA; U. Notre Dame, Notre Dame, IN 46556 USA, ANTHONY FIORY, New Jersey Institute of Technology, Newark, NJ 07102 USA — The superconducting transition temperatures of high- T_c compounds based on copper, iron, ruthenium and certain organic molecules is discovered to be dependent on bond lengths, ionic valences, and Coulomb coupling between electronic bands in adjacent, spatially separated layers [1]. Optimal transition temperature, denoted as T_{C0} , is given by the universal expression $k_B T_{C0} = e^2 \Lambda / \ell \zeta$; ℓ is the spacing between interacting charges within the layers, ζ is the distance between interacting layers and Λ is a universal constant, equal to about twice the reduced electron Compton wavelength (suggesting that Compton scattering plays a role in pairing). Non-optimum compounds in which sample degradation is evident typically exhibit $T_c < T_{C0}$. For the 31+ optimum compounds tested, the theoretical and experimental T_{C0} agree statistically to within ± 1.4 K. The elemental high- T_c building block comprises two adjacent and spatially separated charge layers; the factor e^2/ζ arises from Coulomb forces between them. The theoretical charge structure representing a room-temperature superconductor is also presented.

1. doi:10.1088/0953-8984/23/29/295701

K1.00084 Two-orbital analysis on the material dependence of T_c in the single-layered cuprates, HIROFUMI SAKAKIBARA, HIDETOMO USUI, KAZUHIKO KUROKI, The University of Electro-Communication, RYOTARO ARITA, HIDEO AOKI, The University of Tokyo — The significant material dependence of T_c in the cuprates remains an important puzzle, even within the single-layer family. A recent paper[1] has demonstrated, with a two-orbital model, that, while the usual wisdom is to consider the cuprate as a one-band ($d_{x^2-y^2}$) system, a hybridization with the second (d_{z^2}) one around the Fermi energy significantly affects T_c in the spin-fluctuation mediated pairing. There, the energy offset (ΔE) between the two orbitals has been shown to govern the extent of the d_{z^2} mixture, hence T_c . Here we further extend this line of approach to identify the key factors that determine ΔE in the cuprates, focusing on the structural difference among broader (La, Hg, Bi, and Tl) single-layer cuprates. We have revealed that the apical oxygen height (h_O) above the CuO₂ plane and the separation (d) between the CuO₂ planes are the important parameters that determine ΔE , thereby causing the material dependence of T_c . This picture enables us to capture the T_c variation among the single-layered cuprates in a simple lattice-parameter space. [1]H. Sakakibara *et al.* Phys. Rev. Lett. **105**, 057003 (2010)

K1.00085 Specific heat of cuprate superconductors¹, P. SALAS, Posgrado en Ciencia e Ingeniería de Materiales, UNAM, M. FORTES, F.J. SEVILLA, M.A. SOLIS, Instituto de Física, UNAM — We model cuprate superconductors as a fluid of electrons able to create pairs within an infinite layered structure. The paired electrons (Cooper pairs) coexist with the unpaired electrons in almost two dimensional slabs stacked in their perpendicular direction. Electron pairs are considered as noninteracting zero spin bosons with a linear dispersion relation, and inter-slab penetrable planes are simulated by Kronig-Penney delta potential taken in one dimension, while paired and unpaired electrons are free to move in the other two dimensions. We introduce the slab thickness and the plane “impenetrability”, using real parameters of YBaCuO_{7-x} cuprates. Paired electrons develop a boson condensate with a jump in the specific heat at the superconductor critical temperature. After summing the electronic contributions, paired plus unpaired, we obtain a linear behavior of the electronic specific heat over temperature, C_e/T . By adding the lattice specific heat (phonons) C_l , we are able to qualitatively reproduce the total specific heat. We also obtain a theoretical value for the electronic specific heat constant γ_e , which is in agreement with the experimental values reported.

K1.00086 How to measure the spatial characteristics of the Kosterlitz- Thouless transition in disordered systems?, AMIR EREZ, YIGAL MEIR, Ben Gurion University of the Negev — The effect of disorder on the Kosterlitz-Thouless (KT) transition in two dimensions is unresolved. Here we propose and simulate an experiment to probe the spatial nature of the KT transition in such disordered systems, by studying the effects of cutting individual bonds in the disordered classical two-dimensional XY model. This will allow, similar to experiments carried out on quasi one-dimensional and on quantum Hall systems, to probe the channels through which global phase coherence propagates. We analyze the spatial distribution of these bonds and discuss implications towards a percolation description of the KT transition in superconducting thin films.

K1.00087 ABSTRACT WITHDRAWN —

K1.00088 Determination of superconducting parameters of Gd-123 phase added with Co₂FeO₄ nano ferrite from Excess conductivity and magneto conductivity analysis, ALY ABOU-ALY, NAYERA MOHAMMED, RAMADAN AWAD, Alexandria University, HUSSEIN MOTAWEH, DOAA BAKEER, Damanhur University — Excess conductivity and magneto conductivity data of the Gd-123 added with Co₂FeO₄ nano ferrite were analyzed in terms of Aslamazov-Larkin and Maki-Thompson models for layered superconductors. Co₂FeO₄ nano ferrite was prepared by Co-perceptions method with grain size of about 20 nm. The concentrations of Co₂FeO₄ nano ferrite were varied from 0.0 to 0.1 % wt. of the total sample's weight. The superconducting parameters such as superconducting transition temperature, coherence lengths along *ab*-plane and along *c*-direction at 0K and phase breaking time at 100 K were determined as a function of Co₂FeO₄ nano ferrite concentrations. The superconducting transition temperature decreased from 91.7 K to 79.3 K as Co₂FeO₄ nano ferrite concentrations increased from 0.0 to 0.1 % wt. of the total sample's weight, confirming with the decrease of phase breaking time at 100 K from 2.7×10^{-14} sec to 1.93×10^{-14} sec. The superconducting anisotropy parameter was calculated as a function of Co₂FeO₄ nano ferrite concentrations and its value varied from 6.7 to 8.3.

K1.00089 Magnetothermoelectric effects in Fe_{1+d}Te_{1-x}Se_x¹, MARCIN MATUSIAK, Institute of Low Temperature and Structural Research, PAS, KAZIMIERZ CONDER, Laboratory for Developments and Methods, Paul Scherrer Institute — We report data on resistivity as well as Hall, Seebeck and Nernst coefficients for the Fe_{1+d}Te_{1-x}Se_x single crystals with $x = 0, 0.39$, and 0.40 . The parent compound Fe_{1.04}Te exhibits a Fermi surface reconstruction at $T = 61$ K, which is ascribed to the onset of the antiferromagnetic order. Two very closely doped samples: Fe_{1.01}Se_{0.39}Te_{0.61} (Se39) and Fe_{1.01}Se_{0.4}Te_{0.6} (Se40) are superconductors with $T_c = 13.4$ K and 13.9 K, respectively. Properties of these two single crystals are almost identical at high temperatures, but start to diverge below $T \approx 80$ K. Despite there is no magnetic transition in neither Se39 nor Se40, the observed differences seem to be a consequence of varying with selenium content spin correlations.

K1.00090 Magnetism in EuBCO and YBCO vortex states near and below T_c , R. SCHWARTZ, San Jose State University, M.C. BROWNE, SLAC National Accelerator Laboratory, C. BOEKEMA, San Jose State University — By means of MaxEnt- μ SR [1] analysis, we investigate transverse field μ SR data [2] of EuBa₂Cu₃O_{7- δ} EuBCO; $T_c = 93$ K). Our focus is on a temperature interval near T_c to search for precursor effects, [3] and for predicted [4a] pseudogap loop currents above and below T_c , already observed [4b] above T_c for GdBCO. Further, we continue to study the field-direction dependence of the predicted [5a] and observed [5b] antiferromagnetism (AF) below $0.5T_c$ for the vortex states in *c*-axis-oriented YBCO. This AF in and near the vortex cores is likely three-dimensional. In sum, magnetic roots of cuprate superconductivity are well plausible. Research is supported by LANL-DOE, REU-NSF and AFC.

K1.00091 Confinement induced anisotropy of superconducting films onto porous anodized aluminum oxide, QIONG LUO, ZHILI XIAO, Northern Illinois University, Argonne National Lab, WAI-KWONG KWOK, Argonne National Lab — We investigate the matching effect observed in superconducting Nb films sputtered on anodized aluminum oxide substrates containing regular arrays at various external magnetic field orientations. We find that both the magnetoresistance and the transition temperature exhibits two strong anisotropic effects: Little-Parks oscillations whose period varies with field direction superimposed on a smooth background arising from one dimensional confinement by the finite lateral space between neighboring holes, revealing the anisotropy change due to the confinement effect of artificial holes.

K1.00092 Theoretical Study of Tunneling Conductance in Normal-Metal/Insulator/PrOs₄Sb₁₂ and Ferromagnet/Insulator/PrOs₄Sb₁₂ Junctions¹, SEYYED SAEED BOHLOUL, STEPHANIE CURNÖE, Memorial University of Newfoundland — We theoretically investigate the tunnel conductance in normal-metal/insulator/superconductor and ferromagnet/insulator/superconductor junctions for the unconventional superconductor PrOs₄Sb₁₂. Using several pair potentials provided by group theoretical considerations, the conductance is calculated for singlet as well as triplet pairing. The result shows that the direction of the electric tunneling current and the relative orientation of the superconductor (i.e. position of point nodes) are two main factors that determine the shape of conductance spectrum for a junction. In addition, comparison with experimental results provide useful information regarding the actual symmetry of the pair potential in the superconducting phase of PrOs₄Sb₁₂.

¹This work is supported by NSERC of Canada.

K1.00093 Scattering from incipient stripe order in the high-temperature superconductor $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+x}$ ¹, EDUARDO H. DA SILVA NETO, COLIN PARKER², PEGOR AYNAJIAN, AAKASH PUSHUP³, Princeton University, JIN-SHENG WEN, ZHIJUN XU, GENDA GU, Brookhaven National Laboratory (BNL), ALI YAZDANI, Princeton University — We use spectroscopic mapping with the scanning tunneling microscope to probe modulations of the electronic density of states in single crystals of the high temperature superconductor $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+x}$ as a function of temperature. We show that the Cu-O bond-oriented modulations, with periodicity near four lattice constants ($4a$), that form below the pseudogap temperature have a temperature-dependent energy dispersion displaying different behaviors in the superconducting and pseudogap states. We demonstrate that quasiparticle scattering off impurities does not capture the experimentally observed energy- and temperature-dependence of these modulations. Instead, a model of scattering of quasiparticles from short-range stripe order is necessary to reproduce the experimentally observed energy dispersion of the bond-oriented modulations and its temperature dependence across the superconducting critical temperature, T_c .

K1.00094 STM/STS Study of Li_xCoO_2 Single Crystals, KATSUYA IWAYA, TAKETOSHI MINATO, Tohoku University, KIYOTAKA MIYOSHI, JUN TAKEUCHI, Shimane University, YOUSOO KIM, RIKEN, TARO HITOSUGI, Tohoku University, TOHOKU UNIVERSITY COLLABORATION, RIKEN COLLABORATION, SHIMANE UNIVERSITY COLLABORATION — We have performed low temperature scanning tunneling microscopy/spectroscopy (STM/STS) measurements on Li_xCoO_2 ($x=0.66$) single crystal surfaces. A (1×1) hexagonal lattice was clearly observed and found to be moved by changing bias-voltage polarity, indicating that this could be associated with Li ions on the surface. Under the (1×1) hexagonal lattice, we imaged almost randomly distributed bright dots that were strongly dependent on bias-voltage, with insulating spectroscopic features. Different area on the surface showed a (2×2) hexagonal lattice that could be related to an ordering of Co^{3+} and Co^{4+} ions. These results suggest the electronic structure of Li_xCoO_2 surface is inhomogeneous possibly due to segregation of Li ions.

K1.00095 Scanning tunneling microscopy at 70 mK in the dichalcogenide superconductor TaSe_2 , JOSE GALVIS, HERMANN SUDEROW, SEBASTIAN VIEIRA, Laboratorio de Bajas Temperaturas, Departamento de Física de la Materia Condensada, Facultad de Ciencias, Universidad Autónoma de Madrid, Spain — We present scanning tunneling microscopy and spectroscopy measurements of the layered dichalcogenide 2H-TaSe_2 , performed in a dilution refrigerator cryostat equipped with a three axis superconducting magnet. In this compound superconductivity and charge density wave (CDW) ordering coexist below 200mK . We find CDW order corresponding to hexagonal ($2H$) symmetry, but we also find areas where CDW order corresponding to trigonal ($1T$) symmetry appears. We study the superconducting density of states as a function of position and magnetic field at 70mK and relate the results to the CDW patterns.

K1.00096 Long-Range Superharmonic Josephson Current, LUKA TRIFUNOVIC, University of Basel — We consider a long superconductor-ferromagnet-superconductor junction with one spin-active region. It is shown that an *odd* number of Cooper pairs cannot have a long-range propagation when there is *only one* spin-active region. When temperature is much lower than the Thouless energy, the coherent transport of two Cooper pairs becomes dominant process and the *superharmonic* current-phase relation is obtained ($I \propto \sin 2\phi$).

K1.00097 Ground Capacitance in Josephson Junction Arrays¹, ZLATKO MINEV, IOAN POP, NICHOLAS MASLUK, ARCHANA KAMAL, MICHEL DEVORET, Yale University, QLAB — Josephson junction arrays (JJAs) have gained popularity in modern experiments. They find employment as high impedance “superinductance” elements in fluxonium type qubits [Manucharyan et al. Science 326, 113 (2009)] or in the study of Bloch oscillation. However this high impedance behavior is limited at high frequencies by the junction array capacitance to ground. We investigate the dependence of JJAs impedance on frequency. The JJA behaves as a linear inductance for frequencies sufficiently below the array self resonance. The maximum number of junctions in the array is thus limited by the ground capacitance. We study the dependence of the ground capacitance of JJAs on their geometry, and extract general design principles which will reduce this parasitic coupling and maximize the number of junctions in the superinductance.

K1.00098 Bias current effect on inverse spin-switch behavior in Permalloy/Nb/Permalloy trilayers, DONG HO KIM, TAE-JONG HWANG, Yeungnam University — We investigated the effect of bias current on the inverse spin-switch (ISS) effect in Permalloy(Py)/Nb/Permalloy trilayers. Samples grown by using dc magnetron sputtering methods were patterned in the bar shape of $5\text{ }\mu\text{m}$ wide and $120\text{ }\mu\text{m}$ long, and their magnetoresistance (MR) in the superconducting transition region were measured in sweeping magnetic fields. The MR measured in the transition region of Nb at the antiparallel domain (AD) states of two outer Py layers showed a rapid increase compared to the MR at the parallel (P) states with increasing current density. At high enough bias current densities exceeding 10^5 A/cm^2 , we found a temperature window where the MR at the AD states returned to the normal state resistance whereas the MR at the P state remained superconducting. This ideal ISS effect is assumed to be originated in massive flux flow triggered by the onset of flux motion inside Nb layer due to the large Lorentz force exerting on flux lines where the magnetic flux were induced by the normal component of the stray field from the domain walls in the AD state of Py layers.

K1.00099 Thermal fluctuations and flux-tunable barrier in proximity Josephson junctions, JIAN WEI, Peking University, P.R. China, PAUL CADDEN-ZIMANSKY, Columbia University, VENKAT CHANDRASEKHAR, Northwestern University, PAULI VIRTANEN, University of Wurzburg — The effect of thermal fluctuations in Josephson junctions is usually analysed using the Ambegaokar-Halperin (AH) theory in the context of thermal activation. We report measurements of micron-scale normal metal loops contacted with thin superconducting electrodes, where the unconventional loop geometry enables tuning of the junction barrier with applied flux. We observe stronger “enhanced” fluctuations when the flux threading the normal metal loop is near an odd half-integer flux quantum, and for devices with thinner superconducting electrodes. These findings suggest that the activation barrier, which is the Josephson coupling energy of the proximity junction, is different from that for conventional macroscopic Josephson junctions. Simple one dimensional quasiclassical theory is used to predict the interference effect due to the loop structure, but the exact magnitude of the coupling energy cannot be computed without taking into account the details of the sample dimensions. In this sense, the physics of nanoscale proximity junctions can be related to the thermally activated phase slips (TAPS) model for thin superconducting wires, and indeed our data can be better fitted with TAPS model than AH theory.

K1.00100 Enhancement of shot noise due to the fluctuation of Coulomb interaction, DUO LI, LEI ZHANG, FUMING XU, JIAN WANG, Department of Physics, The University of Hong Kong, DEPARTMENT OF PHYSICS AND THE CENTER OF THEORETICAL AND COMPUTATIONAL PHYSICS TEAM — We have developed a theoretical formalism to investigate the contribution of fluctuation of Coulomb interaction to the shot noise based on Keldysh non-equilibrium Green's function method. We have applied our theory to study the behavior of dc shot noise of atomic junctions using the method of nonequilibrium Green's function combined with the density functional theory (NEGF-DFT). In particular, for atomic carbon wire consisting 4 carbon atoms in contact with two Al(100) electrodes, first principles calculation within NEGF-DFT formalism shows a negative differential resistance (NDR) region in I-V curve at finite bias due to the effective band bottom of the Al lead. We have calculated the shot noise spectrum using the conventional gauge invariant transport theory with Coulomb interaction considered explicitly on the Hartree level along with exchange and correlation effect. Although the Fano factor is enhanced from 0.6 to 0.8 in the NDR region, the expected super-Poissonian behavior in the NDR region is not observed. When the fluctuation of Coulomb interaction is included in the shot noise, our numerical results show that the Fano factor is greater than one in the NDR region indicating a super-Poissonian behavior.

K1.00101 Flux-charge duality and quantum phase fluctuations in one-dimensional superconductors¹, ANDREW KERMAN, MIT Lincoln Laboratory — It has long been thought that superconductivity breaks down in one dimension due to enhanced quantum phase fluctuations. However, the exact mechanism for this is still an active research area. One common feature of existing theories is the idea of “quantum phase-slip” (QPS): quantum tunneling of the superconducting order parameter between states where the relative phase between the wire ends differs by $\pm 2\pi$. Many experiments have been carried out to investigate QPS, and a wide range of phenomena have been observed, including resistive fluctuations well below T_C and an apparent quantum phase transition to an insulating state in the narrowest wires. Although these are all likely connected to QPS, a unified understanding has not yet been possible. I will describe a theory for QPS which is based on the idea that flux-charge duality, a classical symmetry of Maxwell's equations, relates the phase fluctuations associated with QPS to the well-known charge fluctuations associated with Josephson tunneling, at a microscopic level. The predictions of this theory compare favorably with a wide range of experimental observations, and may also provide a conceptual link to 2D phase fluctuation phenomena and insulating transitions in thin films.

K1.00102 Intermediate state of strongly disordered superconductors, IVAN SADOVSKYY, LEV IOFFE, Rutgers University — We study theoretically the superconductor-insulator transition in disordered Josephson junction arrays. Our numerical simulations suggest the existence of the intermediate state between superconducting and insulating states across the SIT that appears in a relatively narrow range of Josephson couplings. In this state the long range order parameter is absent but the excitations have a significant decay rate. We discuss the relation this finding to the experimental data that show the existence of the “bad metal” state characterized by a large temperature-independent resistance (J. Paramanandam, M.T. Bell, L.B. Ioffe, and M.E. Gershenson).

K1.00103 Cooper pair islanding model of insulating nanohoneycomb films, S.M. HOLLEN, E. RUDISAILLE, J. SHAINLINE, Brown University, Department of Physics, J.M. XU, Brown University, Division of Engineering, J.M. VALLES, JR., Brown University, Department of Physics — Nanohoneycomb (NHC) amorphous Bi thin films, made by thermal evaporation onto substrates that contain a nanometer-scale array of holes and regular surface height variations, exhibit an insulating phase of localized Cooper pairs. Recently, we described how thickness variations induced by the substrate height variations can give rise to superconducting island formation.¹ Here, we will present an extension of this analysis to suggest how the island sizes evolve through the magnetic field-driven superconductor-insulator transition. Using this islanding picture, we will discuss the applicability of a granular array model to explain the appearance and behavior of the CPI phase in these films. Finally, we will discuss recent experimental tests of this proposal for thickness-undulation-driven Cooper pair localization.

K1.00104 INSULATORS AND DIELECTRICS —

K1.00105 Large ferroelectric polarization in the new double perovskite NaLaMnWO₆ induced by non-polar instabilities, TETSUYA FUKUSHIMA, Graduate School of Engineering Science, Osaka University, 1-3 Machikaneyama, Toyonaka, Osaka 560-8531, Japan, ALESSANDRO STROPPA, SILVIA PICOZZI, Consiglio Nazionale delle Ricerche-Institute for Superconducting and Innovative Materials and Devices (CNR-SPIN), 67100 L'Aquila, Italy, J. MANUEL PEREZ-MATO, Dept de Física de la Materia Condensada, Facultad de Ciencia y Tecnología, Universidad del País Vasco, Apartado 644, E-48080 Bilbao, Spain — Based on density functional theory and group theoretical analysis, we have studied NaLaMnWO₆ compound. At low temperature, the structure has monoclinic $P2_1$ symmetry, with layered ordering of the Na and La ions and rocksalt ordering of Mn and W ions. By comparing the low symmetry structure with a parent phase of $P4/nmm$ symmetry, two distortion modes are found dominant. They correspond to MnO₆ and WO₆ octahedron tilt modes, often found in many simple perovskites. While in the latter these common tilting instabilities yield non-polar phases, in NaLaMnWO₆ the additional presence of the Na-La cation ordering is sufficient to make these rigid unit modes a source of the ferroelectricity. Through a trilinear coupling with the two unstable tilting modes, a polar distortion is induced, although the system has no intrinsic polar instability. The calculated electric polarization is as large as $16 \mu\text{C}/\text{cm}^2$. Despite its secondary character, this polarization is coupled with the dominant tilting modes and its switching is bound to produce the switching of one of two tilts, enhancing in this way a possible interaction with the magnetic ordering.

K1.00106 InGaZnO₄ based thin film transistors with sputter-deposited PMMA/ BaSrTiO₃ stacked gate dielectrics on flexible substrate, DONG HUN KIM, Massachusetts Institute of Technology, IL-DOO KIM, Korea Advanced Institute of Science and Technology — This study reports the enhanced electrical properties of InGaZnO₄ TFTs with sputter-deposited PMMA/BST stacked gate dielectrics. A noticeable reduction in the leakage current density was achieved by coating a PMMA over-layer. With the introduction of sputter-deposited PMMA film with a high electrical breakdown strength and a smooth surface morphology, the leakage current characteristics were greatly enhanced. The calculated field effect mobility of the InGaZnO₄ TFTs with the PMMA (30 nm)/BST (270 nm) and PMMA (50 nm)/BST (250 nm) gate dielectrics were 10.2 cm²/V-s and 7.4 cm²/V-s, respectively. The noticeable increase of the field effect mobility is thought to have stemmed from an interface improvement that was caused by the addition of the smooth sputter-deposited PMMA layer. The threshold voltages of the InGaZnO₄ TFTs with the PMMA (30 nm)/BST (270 nm) and PMMA (50 nm)/BST (250 nm) gate dielectrics were reduced to 1.1 V and 1.6 V compared to that (1.8 V) of the TFTs with the pure BST gate dielectric. The InGaZnO₄ TFTs using only sputter-deposited PMMA (300 nm) gate insulators exhibited an on/off current ratio of 4.1×10^6 , field effect mobility of 36.1 cm²/V-s at 10 V of VDS, and a relative large threshold voltage of 3.1 V.

K1.00107 Transient absorption and nonlinear refractive index changes in thermally reduced nominally pure LiNbO₃ by sub-100-fs light pulses¹, HOLGER BADORRECK, VOLKER DIECKMANN, MIRCO IMLAU, Department of Physics, University of Osnabrueck, Osnabrueck, Germany — Due to its polaronic features nominally undoped lithium niobate—as grown and thermally reduced—is of great interest for ultrafast optical devices. With formation times in the sub-ps-range short-lived small polarons can be generated in thermally reduced lithium niobate by optical gating of bipolarons due to single photon absorption. Simultaneously, formation of small hole polarons by two-photon-absorption is observed. In this work nonlinear absorption and refractive index changes due to exposure to sub-100-fs light pulses of 488 nm are presented with thermally reduced crystals as an example. It is found that the two-photon absorption coefficient is not affected by the thermal reduction procedure, whereas the nonlinear refractive index change is considerably smaller in the reduced sample. We further present our results on the study of the transient absorption in the blue and NIR spectral range by means of fs-pump-probe technique. The influence of the thermal reduction procedure on lifetime and densities of electron and hole polarons is discussed.

K1.00108 In-situ Characterization of Laser-Induced Crystallization in Glass Using Raman Spectroscopy¹, BRIAN KNORR, PRADYUMNA GUPTA, ADAM STONE, HIMANSHU JAIN, VOLKMAR DIEROLF, Lehigh University — We report crystallization and other structural changes in glasses (such as LaBGeO₅) due to laser-induced localized heating. This heating process is a result of non-radiative decay after a photon absorption process. We explore linear absorption due to both band-to-band excitation or intentionally doped transition metal or rare earth ions using CW lasers as well as nonlinear absorption induced by high-intensity pulsed lasers. The ability to precisely position the laser on the μm length scale makes the crystallization interesting for photonic and optical applications such as waveguides and 3-D active functional devices. To better understand and control the crystallization process we are developing a combined CW laser-writing setup/confocal Raman microscope. This system will allow in-situ monitoring of the Raman emission during the crystallization. The data yielded will help elucidate the relationship between the phase, composition, and structure of the modified glass regions as a function of experimental variables, which include, but are not limited to, writing speed, irradiation time, heating rates, and defect concentration.

K1.00109 Magnetoelastic coupling in doped multiferroic YCrO₃, YOGESH SHARMA, Materials Science Programme, Indian Institute of Technology Kanpur, SOMDUTTA MUKHERJEE, RAJEEV GUPTA, Department of Physics, Indian Institute of Technology Kanpur, ASHISH GARG, Materials Science and Engineering, Indian Institute of Technology Kanpur — Recent years have witnessed a renewed interest in ABO₃ structured perovskites due to possibility of combining ferroelectric and ferromagnetic order parameters in a single phase. Here we show an experimental study on one such material namely YCrO₃ which shows a phase transition from paramagnetic to a canted antiferromagnetic state at $T_N \sim 142\text{K}$ and a ferroelectric transition at $T_C \sim 473\text{K}$. The material has an orthorhombic crystal structure (S.G.Pbnm). In the present work, we prepared polycrystalline samples of $\text{YCr}_{1-x}\text{X}_x\text{O}_3$ (X = V or Ni) by conventional solid-state-reaction method. X-ray diffraction shows the formation of single phase material. DC magnetic measurements exhibit a magnetic transition at $T_N \sim 140\text{K}$ and the presence of magnetic hysteresis below this temperature. Above T_N , the susceptibility follows the Curie-Weiss law with the corresponding effective magnetic moment μ_{eff} of $3.75\mu_B$ close to the theoretically expected value of $3.87\mu_B$. Further, we investigated the magneto-elastic coupling in the material using temperature dependent Raman scattering. We observe 16 phonon modes below T_C . Phonon modes at 145, 403 and 422cm^{-1} showed pronounced deviation from the expected anharmonic behavior below T_N , suggesting a spin-phonon coupling below T_N . Further, we also look at the effect of doping at the Cr site on the magnetoelastic coupling strength in this material.

K1.00110 Magnetodielectric consequences in double perovskite Pr₂CoMnO₆, J.H. ZHANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan, S. MUKHERJEE, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan., H.C. WU, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan, J.Y. LIN, Institutes of Physics, National Chiao Tung University, Hsinchu 30010, Taiwan, A.N. VASILIEV, Department of Low temperature Physics, Moscow State University, Moscow 119991, Russia, H.D. YANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan — We report an intriguing colossal dielectric and magnetodielectric (MD) response on double perovskite Pr₂CoMnO₆(PCMO) system. At the highest applied magnetic field 9T, the giant dielectric constant around $T_m \sim 175\text{K}$ is enhanced almost $\sim 22\%$ (at 10 kHz frequency) compare with that at zero field. The observed positive MD effect is considered to be associated with the direct consequence of negative magnetoresistance changes ($\sim -15\%$ at 175 K). Concomitantly, a pronounced ferromagnetic ordering is observed near $T_C \sim 175\text{K}$ coinciding with T_m of $\epsilon'(T)$. These experimental results suggest that the magnetoresistive MD response is very much conditioned by magnetic property of PCMO.

K1.00111 Enhanced ferromagnetism in co-doped BiFeO₃ ceramics, HARSH TRIVEDI, DEEPA SINGH, Materials Science Programme, Indian Institute of Technology Kanpur, RAJEEV GUPTA, Department of Physics, Indian Institute of Technology Kanpur, ASHISH GARG, Materials Science Engineering, Indian Institute of Technology Kanpur — BiFeO₃ (BFO) is the most studied multiferroic material with high ferroelectric polarization as well as above room temperature transition temperatures. Studies have shown significant improvements in the electrical and magnetic properties of BFO upon atomic substitutions at Bi (A) and Fe (B) sites. While enhanced ferromagnetism upon A-site doping is attributed to the suppression of cycloidal spin ordering of Fe moments, B site substitution reduces leakage current by eliminating oxygen vacancies. This study aims to combine these two aspects by co-doping the material at A- and B- sites using La³⁺ and V³⁺/V⁵⁺ respectively and to investigate the electrical and magnetic characteristics of co-doped BFO. La-doped La_xBi_{1-x}FeO₃ and co-doped La_xBi_{1-x}V_yFe_{1-y}O₃ (x = .05, 0.1, 0.15, 0.2; y = 0.03) samples were prepared solid-state reaction method. While La-doped samples show only reduced leakage without any discernible change in the magnetic characteristics, co-doped samples (La³⁺ & V⁵⁺) show significant enhancements in magnetic properties in addition to reduced leakage attributed to the elimination of oxygen vacancies. Improvement in the magnetic characteristics can be understood as a consequence of enhanced double exchange interaction between adjacent Fe ions. This argument is further strengthened by our observation that co-doped samples made by substitution of Fe with V³⁺ show a magnetic response equivalent to that of only La-doped BFO samples.

K1.00112 Dielectric properties and electrical conduction of high-k LaGdO₃ ceramics¹, SHOJAN PAVUNNY, REJI THOMAS, ASHOK KUMAR, RAM KATYAR, Department of Physics and Institute for Functional Nanomaterials, University of Puerto Rico, San Juan, PR, USA — The temperature and frequency dependent dielectric properties and leakage conduction mechanism in LaGdO₃ (LGO) ceramics have been studied and this material has been identified as a potential high-k candidate for the future complementary metal-oxide-semiconductor (CMOS) and dynamic random access memory (DRAM) technology nodes. The dielectric constant and the loss tangent at 100 kHz were ~ 21.5 and ~ 0.003 respectively at ambient conditions without any significant temperature and voltage dependence. The ac conductivity showed the typical features of universal dynamic response (UDR) and obey the double power law $\sigma_{ac} = \sigma_{dc} + A\omega^{n_1} + B\omega^{n_2}$ with three types of temperature dependent conduction processes involved; i) a dc plateau ($< 3\text{kHz}$) due to long range translational hopping, ii) a mid frequency region due to the short range hopping (3 – 100 kHz), and iii) a high frequency region due to localized or reorientational hopping (100 – 1000kHz). The temperature dependent dc conductivity followed the Arrhenius relation with activation energies of 0.05eV in the 200 – 400 K range and 0.92 eV in the 400 – 600 K range. The leakage current behavior revealed bulk limited Poole-Frenkel (PF) conduction mechanism with very low leakage current density (2 nA / cm² at 5.7 kV/cm).

K1.00113 Electronic, Magnetic and Thermal Properties of Electron Doped YMnO_3 ¹, TIAN YU, PENG GAO, TREVOR A. TYSON, New Jersey Institute of Technology — The thermal, magnetic and electronic properties of the electron doped $\text{Y}_{1-x}\text{Zr}_x\text{MnO}_3$ system were measured at both low and high temperatures. Correlations are made with structural studies on multiple length scales. Raman and IR measurements were performed at room temperature to track the changes in the phonons with doping. The effect of doping on the ferroelectric transition is examined. This work is supported by DOE Grant DE-FG02-07ER46402.

¹DOE Grant DE-FG02-07ER46402

K1.00114 Electrical properties of $\text{NaSr}_2\text{Nb}_5\text{O}_{15}$ ferroelectric ceramic, BANARJI BEHERA, School of Physics, Materials Research Laboratory, Sambalpur University, Jyoti Vihar, Burla - 768 019, Odisha, India, NIHAR PRADHAN, University of Massachusetts, Amherst and Mount Holyoke College, Massachusetts, USA, P. NAYAK, School of Physics, Materials Research Laboratory, Sambalpur University, Jyoti Vihar, Burla - 768 019, Odisha, India — Since the discovery of ferroelectricity, tungsten bronze (TB) ferroelectrics has been a rapid progress in search of new TB-type materials for applications such as capacitors, actuators, transducers, ferroelectric random access memory and display technologies. The materials with TB structure have potential advantages for devices because of their high dielectric constant and low tangent loss. In view of the above importance we have studied the electrical properties of $\text{NaSr}_2\text{Nb}_5\text{O}_{15}$ (NSN) ferroelectric ceramic. The polycrystalline $\text{NaSr}_2\text{Nb}_5\text{O}_{15}$ (NSN) was prepared by mixed oxide method at high temperature. Electrical properties of NSN have been studied using complex impedance spectroscopy (CIS) with wide range of frequency (10^2 - 10^6 Hz) and temperature. The complex impedance plot reveals the main contribution of bulk effect. The bulk resistance has been decreased with rise in temperature. The negative temperature coefficient of resistance (NTCR) manifests a semiconductor like behavior. The ac conductivity spectrum was found to obey Jonscher's universal power law.

K1.00115 Domain walls of ferroelectric BaTiO_3 within the Ginzburg-Landau-Devonshire model¹, P. MARTON, I. RYCHETSKY, J. HLINKA, Institute of Physics, Academy of Sciences of the Czech Republic — Mechanically compatible and electrically neutral domain walls in tetragonal, orthorhombic, and rhombohedral ferroelectric phases of BaTiO_3 are systematically investigated in the framework of the phenomenological Ginzburg-Landau-Devonshire (GLD) model. Domain wall thicknesses, energy densities are derived analytically and evaluated numerically for several temperatures. Apart from simple Ising-type solutions of the model we also discuss more complicated solutions (two-dimensional approximation in polarization - curved polarization path). The calculations indicate that the lowest energy structure of the 109-degree domain wall and few other domain walls in the orthorhombic and rhombohedral phases resemble Bloch-like walls known from magnetism.

¹The authors are grateful to prof. V. Janovec for helpful discussions. The work has been supported by the Czech Science Foundation (Projects Nos. P204/10/0616 and 202/09/0430)

K1.00116 Growth of CaIrO_3 and $\text{Gd}_2\text{Ir}_2\text{O}_7$ by MBE¹, YUEFENG NIE, RAINER HELD, SHOUVIK CHATTERJEE, ERIC MONKMAN, DANIEL SHAI, JOHN HARTEY, BULAT BURGANOVA, CAROLINA ADAMO, Laboratory of Atomic and Solid State Physics, Department of Physics, Cornell University, Ithaca, NY 14853, USA, DARRELL SCHLOM, Department of Materials Science and Engineering, Cornell University, Ithaca, New York 14853, USA, KYLE SHEN, Laboratory of Atomic and Solid State Physics, Department of Physics, Cornell University, Ithaca, NY 14853, USA — Recently, it was pointed out that the 5d transition metal iridium oxides (iridates) are promising candidates to realize topological insulators, which provide a unique platform in studying the interplay of Coulomb interactions, spin-orbit coupling, and the band topology of solids. We successfully grew epitaxial perovskite CaIrO_3 and pyrochlore $\text{Gd}_2\text{Ir}_2\text{O}_7$ films by reactive molecular-beam epitaxy (MBE). A range of biaxial strains for epitaxial CaIrO_3 films was achieved by growing on different substrates. Angle-resolved photoemission spectroscopy (ARPES) will be used to investigate the electronic structure of the epitaxial CaIrO_3 and $\text{Gd}_2\text{Ir}_2\text{O}_7$ films.

¹The work is supported by the Cornell Center for Materials Research through the National Science Foundation.

K1.00117 Epitaxial growth of polar magnetic PbVO_3 thin films on LaAlO_3 substrates, R.H. SHIN, S.H. OH, W. JO¹, Department of Physics, Ewha Womans University, Seoul, 120-750, Korea, Y.-S. SEO, J.S. AHN, Department of Physics, Pusan National University, Pusan 609-735, Korea — Layered perovskite PbVO_3 (PVO) is a curious polar magnetic material, which has a potential of room temperature multiferroics. A sintered PbVO_x ceramic target was prepared for pulsed-laser deposition. To obtain a stoichiometric single-phase PbVO_3 thin-film, it is known that control of oxygen partial pressure during the deposition is critical. With a base pressure of 10^{-6} Torr, the deposition pressure was maintained as low as 10^{-5} Torr, which is a severe reducing condition for most of oxide thin-films. We used $\text{LaAlO}_3(001)$ substrates, of which lattice constant is 0.379 nm. Substrate temperature was changed from 450 to 650°C. X-ray diffraction studies show that all the films show (001) oriented PbVO_3 growth but parasitic peaks are found near 39 and 42°, which are presumably linked with the chervetite $\text{Pb}_2\text{V}_2\text{O}_7$ phase. In addition, the c-axis lattice constant of the PbVO_3 cell is decreasing and the grain size becomes bigger as the growth temperature increases. Microscopic analysis and optical measurements have been performed to investigate their local structures. However, the plume in the low pressure would generate a disperse shape of ablated ions and molecules. We will discuss how to improve the structure of the films via a new set of process parameters and their electrical properties including polarization switching and charge conduction.

¹a corresponding author

K1.00118 Nanoscale Periodic Modulations on Sodium Chloride Induced by Surface Charges¹, KENDAL CLARK, SHENGYONG QIN, XIAO GUANG ZHANG, JOHN WENDELKEN, AN-PING LI, Oak Ridge National Laboratory — The sodium chloride surface is one of the most common platforms for the study of catalysts, thin film growth, and atmospheric aerosols. Here we report a nanoscale periodic modulation pattern on the surface of a cleaved NaCl single crystal, revealed by non-contact atomic force microscopy with a tuning fork sensor. The surface pattern shows two orthogonal domains, extending over the entire cleavage surface. The spatial modulations exhibit a characteristic period of 5.4 nm, commensurate with the atomic rows of the NaCl surface. The modulations are robust in vacuum, not affected by the tip-induced electric field or gentle annealing (<300 °C); however, they are eliminated after exposure to water and an atomically flat surface can be recovered by subsequent thermal annealing after water exposure. A strong electrostatic charging is revealed on the cleavage surface and the modulations appear to reflect a surface structural reconstruction facilitated by surface charges.

¹This research was conducted at the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Office of Basic Energy Sciences, U.S. Department of Energy.

K1.00119 Theoretical study of defects in $c\text{-BC}_2\text{N}$, ONYEKWE LU OKEKE, Harvard University — Periodic supercells with 64 atoms using a zincblende stoichiometry for $c\text{-BC}_2\text{N}$ are generated for various native point defects and random distribution of boron and carbon atoms in B-C-N compound. The atomic structures of these systems were relaxed by first-principles density functional theory. The elastic properties including the bulk modulus, shear modulus, and Young's modulus of the bulk $c\text{-BC}_2\text{N}$ crystals and the defective systems were examined and compared

K1.00120 Charge trapping/de-trapping in nitrided SiO₂ dielectrics and its influence on device reliability, KENNETH KAMBOUR, SAIC, HAROLD HJALMARSON, Sandia National Laboratories, DUC NGUYEN, CAMRON KOUHESTANI, RODERICK DEVINE, AFRL/RVSE — Field effect devices with insulator gate dielectrics are excellent test vehicles to probe the physics of defects and charge trapping in the insulator/ semiconductor structure. p-channel field effect device reliability under negative bias stressing has been identified to originate from at least two terms: a) charged defect generation at the Si substrate/SiO_xNy interface and b) charge trapping at neutral defect pre-cursors in the “bulk” of the SiO_xNy beyond the interface. Measurements of transistor characteristics enable extraction of the two terms. We report the results of such measurements and demonstrate that short time effects are associated primarily with electric field assisted tunneling of holes from the inversion layer to neutral traps. This is confirmed by bias stressing measurements at different frequencies in the range 1 Hz to 2 MHz. First principles modeling of the tunneling/trapping phenomena is presented. K.Kambour worked under contract FA9453-08-C-0245 with the Air Force Research Laboratory/RVSE. Sandia National Labs is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

K1.00121 Structural, electronic, and magnetic properties of cation mixed (Ga,Mn)(As,N) and (In,Mn)(As,N) quaternaries and (Ga,Mn)N, and (In,Mn)N ternaries, AHMAD ALSAAD, ABDULLAH SHUKRI, Jordan University of Science and Technology, DR. I.A.QATTAN, KHALIFA UNIVERSITY OF SCIENCE, TECHNOLOGY AND RESEARCH TEAM — ABINIT simulation package with local density approximation, generalized gradient approximation, and spin local density approximation have been used to investigate the structural, electronic, and magnetic properties of cation mixed (Ga,Mn)(As,N) and (In,Mn)(As,N) quaternaries contain equal and fixed compositions of Ga,In, and Mn atoms. In particular, total energy minimization approach have been used to compute the equilibrium structural parameters of zinc-blende (GaAs, InAs, and MnAs), wurtzite (GaN, InN, and MnN) binary parent compounds, as well as, the corresponding equilibrium parameters of the two (Ga,Mn)(As,N) and (In,Mn)(As,N) quaternary systems. The band structures of zinc-blende GaAs, InAs and MnAs binary parent compounds have been computed and analyzed. Spin polarized band structures of the cation mixed (Ga,Mn)(As,N) and (In,Mn)(As,N) quaternaries contain equal compositions of Ga, In, and Mn cations have been computed and analyzed using spin local density approximation based calculations. Moreover, the magnetic properties of (Ga,Mn)(As,N) and (In,Mn)(As,N) quaternaries for equal concentration of Ga, In, and Mn cations have been investigated. Our simulations indicate that the two quaternary systems are nonmagnetic. This unusual result has been interpreted and explained. In addition, the magnetic properties of (Ga,Mn)N and (In,Mn)N diluted magnetic semiconductors will be presented.

K1.00122 First Principle Ab-initio Study of TiO₂¹, CHINEDU EKUMA, MARK JARRELL, JUANA MORENO, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, USA, DIOLA BAGAYOKO, Southern University and A&M College, Baton Rouge, LA 70803, USA — We report results from first principle computations of electronic properties of rutile TiO₂ within the local density functional approximation (LDA). Our first principle, non-relativistic and ground state calculations employed a local density functional approximation (LDA) potential and the linear combination of atomic orbitals (LCAO) – utilizing a self-consistently obtained, optimized basis set. We solved self-consistently both the Kohn-Sham equation and the equation giving the ground state charge density in terms of the wave functions of the occupied states. Our calculated band structure shows that there is significant O_{2p}-Ti_{3d} hybridization in the valence bands. These bands are well separated from the conduction bands by an indirect band gap of 2.95 eV, from Γ to R. Consequently, this work predicts that rutile TiO₂ is an indirect band gap material, as all other gaps from our calculations are larger than 2.95 eV. A slightly larger, direct band gap of 3.05 eV is found at the Γ point, in excellent agreement with experiment. Our structural optimization led to lattice parameters of 4.65 Å and 2.97 Å for a_o and c_o , respectively, with a u parameter of 0.3051, and a bulk modulus of 215 GPa.

K1.00123 Optically induced transient absorption related to formation of small polarons in Sn₂P₂S₆ in the sub-100-fs time domain¹, VOLKER DIECKMANN, HOLGER BADORRECK, MIRCO IMLAU, Department of Physics, University of Osnabrueck, Osnabrueck, Germany, ALEXANDR SHUMELYUK, Institute of Physics, National Academy of Science, Kyiv, Ukraine — The interaction of sub-100-fs light pulses with single crystals of nominally undoped Sn₂P₂S₆ is studied in the NIR spectral range (590 – 1630 nm). A predominant contribution of two-photon absorption (TPA) is verified. Scans over the photon energy show that the TPA coefficient increases in a superlinear way for photon energies exceeding $E_g/2$; for any photon energy it is nearly independent of propagation direction and polarization of the incident beam. The coefficient saturates at a maximum value of $\beta \approx 8 \text{ cm GW}^{-1}$ at $E_p \approx 1.8 \text{ eV}$. It drops when reaching the bandgap E_g . The TPA coefficients are higher by a factor of two than the values reported for other wide bandgap ferroelectrics, such as LiNbO₃, while being lower in comparison to semiconductor crystals. Using fs-pump-probe measurements at 626 nm, a transient absorption is observed that persists for probe pulse delays much longer than the pump pulse duration, up to 2.5 ns. Such transients are typical for a variety of wide bandgap ferroelectrics, where they are described by optically generated polaronic states. We discuss our results in the frame of the microscopic structure of Sn₂P₂S₆ with emphasis on the optical generation of S⁻ small hole polarons.

K1.00124 Mapping topological order in coordinate space, RAFFAELE RESTA, RAFFAELLO BIANCO, Phys. Dept., Univ. of Trieste — Topological insulators are distinguished from normal ones by the manner in which the electronic ground state is knotted in k-space. But topological order also reflects a peculiar organization of the electrons even when the concept of k-space does not make any sense, for e.g. inhomogeneous systems and finite systems within open boundary conditions. Here we only address Chern vs. normal insulators, within an independent-electron scheme in 2d. We introduce a “topological marker” in the form of a local Chern number, which may vary in different regions of the same sample. Since our marker samples the electron distribution locally, the boundary conditions (either periodic or open) are irrelevant. Actual simulations based on the model Haldane Hamiltonian, all of them adopting open boundary conditions, demonstrate the power of our approach. We provide perspicuous plots of our topological marker for crystalline and disordered samples, either normal or Chern insulators. We also monitor the Chern number switching in two cases: varying the Hamiltonian parameters in homogeneous samples, and addressing heterojunctions where two homogeneous regions (having different order) are joined. In all test cases our marker provides an unmistakable signature of the actual topological order.

K1.00125 ABSTRACT HAS BEEN MOVED TO T24.00016 —

K1.00126 Vacancy-induced bound states in topological insulators, WENYU SHAN, JIE LU, HAIZHOU LU, SHUNQING SHEN, Department of Physics, The University of Hong Kong, Pokfulam Road, Hong Kong — We present an exact solution of a modified Dirac equation for topological insulator in the presence of a hole or vacancy to demonstrate that vacancies may induce bound states in the band gap of topological insulators. They arise due to the Z_2 classification of time-reversal invariant insulators, thus are also topologically-protected like the edge states in the quantum spin Hall effect and the surface states in three-dimensional topological insulators. Coexistence of the in-gap bound states and the edge or surface states in topological insulators suggests that imperfections may affect transport properties of topological insulators via additional bound states near the system boundary.

K1.00127 Electron transmittivity and reflectivity through a barrier in 2D and 3D topological insulators¹, ANDRII IUROV, Hunter College and Graduate Center, City University of New York, GODFREY GUMBS, OLEKSIY ROSLYAK, Hunter College, City University of New York, DANHONG HUANG, USAF Research Lab (AFRL/RVSS) — We investigated theoretically the tunneling through a square potential barrier for both 2D and 3D topological insulators and their relationship to the well-known anomalous tunneling effect in graphene. Additionally, we analyzed the way in which both surface and bulk states are affected by the application of circularly-polarized light in comparison with electron dressed states in graphene where the electron-photon interaction led to the formation of an energy gap and chiral symmetry breaking of the electron eigenstates. We compare our results for topological insulators with recently obtained data for graphene. The difference arising from the presence of the bulk state energy spectrum will be analyzed and discussed in detail.

K1.00128 Electronic structure of $\text{Ti}_2\text{Hg}_3\text{Te}_4$ and related systems - possible topological insulators, ANDREW BACZEWSKI, S.D. MAHANTI, Michigan State University, MERCOURI KANATZIDIS, Northwestern University — Topological insulators (TI) have attracted considerable interest in condensed matter physics in recent years. The origin of TI behavior in 3D systems is band inversion at time reversal invariant points throughout the Brillouin zone, induced by a strong spin-orbit interaction (SOI). Motivated by this physics, we have looked at the electronic structure of $\text{Ti}_2\text{Hg}_3\text{Te}_4$ and related systems focusing on the physics of band gap formation, parentage of near-gap states, and the influence of SOI. Calculations within the GGA give a band gap of 0.48 (0.33) eV in the absence (presence) of SOI, in reasonable agreement with a recent band structure calculation¹. However, there is no SOI-induced band inversion at the Γ point because the lowest conduction band (LCB), which is mainly Hg s, lies below a TI p band, suggesting that $\text{Ti}_2\text{Hg}_3\text{Te}_4$ is probably not a TI. Replacing Hg by other divalent atoms may make the TI p band the LCB, resulting in a system that may be a TI. To this end, we will discuss the electronic structures of several possible candidates. K1.00130 ENERGY RESEARCH AND APPLICATIONS —

K1.00131 The Effect of Secondary Phase on Thermoelectric Properties of Zn_4Sb_3 Compound, GAOHUA ZHU, WEISHU LIU, Boston College, GANG CHEN, MIT, ZHIFENG REN, Boston College, BOSTON COLLEGE TEAM, MIT TEAM — Zn_4Sb_3 is a promising thermoelectric material because of its high thermoelectric performance and the abundance of Zn and Sb in nature. Samples of Zn_4Sb_3 with ZnSb or Zn as the minor phase were prepared to optimize the figure-of-merit (ZT). The effects of ZnSb or Zn secondary phase on the thermoelectric properties of Zn_4Sb_3 were investigated. The highest peak ZT of about 1.3 was achieved at 400 °C in the sample with single Zn_4Sb_3 phase, which has the lowest thermal conductivity. Transmission electron microscopy observations of the nanostructures suggest that the precipitated ZnSb, Zn-rich nanoparticles, and nano voids, caused by volatile Zn diffusion, all contribute to the extraordinarily low thermal conductivity.

K1.00132 Figure of Merit ZT achieved in Nanostructured Half Heusler alloys, DI WU, Department of Physics, University of Virginia, SONG ZHU, WENJIE XIE, Department of Physics and Astronomy, Clemson University, JOSEPH POON, Department of Physics, University of Virginia, TERRY TRITT, Department of Physics and Astronomy, Clemson University, PETER THOMAS, RAMA VENKATASUBRAMANIAN, Center for Solid State Energetics, RTI International, Research Triangle Park, NC — Half-Heusler (HH) phases have recently gained attention due to their high temperature thermoelectric performance, especially in the environment of growing concern over the dependence on the limited fossil fuels for energy production. These materials are investigated from the perspective of thermal and electronic transport properties for enhancing the dimensionless figure of merit (ZT) at 800-1000 K. Refinement on grain sizes and embedment of nanoparticles in HH alloy hosts were employed to produce fine-grained as well as nanocomposites and monolithic nanostructured materials. Present experiments indicated that HH alloys and their nanoparticles-embedded phases can attain $\text{ZT} \sim 1$, or slightly higher near 900-1000K. The observed ZT enhancements could be attributed to multiple origins. HH alloy hosts of nano-sized grains with/without embedment of different nanoparticles are also being investigated to further improve their thermoelectric performance.

K1.00133 Simulation of Photon, Exciton and Charge Transports in Organic Photovoltaics based on the Dynamic Monte Carlo Method coupled with the Maxwell Equation¹, BUYOUNG JUNG, School of Mechanical Engineering, Yonsei University, Korea, JUNGWON KIM COLLABORATION, KANGMIN KIM COLLABORATION, WOCHUL KIM COLLABORATION — Organic photovoltaics (OPVs) have received increasing attention as alternatives to inorganic solar cells. To understand the physics of OPVs, the dynamic Monte Carlo (DMC) method for simulating exciton and charge carrier movements has been regarded as a suitable method. However, simulation of light absorption has been ignored. We presented a simulation of the performance of OPVs by DMC method with solving the Maxwell equation for light absorption. We especially focused on the ordered bulk heterojunction (OBHJ) OPV which is composed of P3HT and PCBM. Our analysis indicated that locations of light absorption are different at different wavelength, which suggests that the simulation of light absorption is essential. In the wavelength of 300 to 400 nm, light absorption occurred dominantly nearby the interface between the P3HT and PCBM. This implies that the generated exciton can be more efficiently dissociated into the free charges. For wavelength longer than 400 nm, most of light are absorbed away from the interface between the P3HT and PCBM. As a result of this, the internal quantum efficiencies gradually decrease from 44.6% to 30.2% as the wavelength increases from 300 to 700 nm.

K1.00134 Fabrication of nanostructured CIGS solar cells¹, HONGWANG ZHANG, Department of Physics, University at Buffalo-SUNY, FANG WANG, Shanxi Normal University & University at Buffalo-SUNY, JAMES PARRY, SAMANTHE PERERA, HAO ZENG, Department of Physics, University at Buffalo-SUNY — We present the work on $\text{Cu}(\text{In,Ga})(\text{Se,S})_2$ based nanostructured solar cells based on nanowire arrays. CIGS as the light absorber for thin-film solar cells has been widely studied recently, due to its high absorption coefficient, long-term stability, and low-cost of fabrication. Recently, solution phase processed CIGS thin film solar cells attracted great attention due to their extremely low fabrication cost. However, the performance is lower than vacuum based thin films possibly due to higher density of defects and lower carrier mobility. On the other hand, one dimensional ordered nanostructures such as nanowires and nanorods can be used to make radial junction solar cells, where the orthogonality between light absorption and charge carrier separation can lead to enhanced PV performance. Since the charge carriers only need to traverse a short distance in the radial direction before they are separated at the heterojunction interface, the radial junction scheme can be more defect tolerant than their planar junction scheme. In this work, a wide band gap nanowire or nanotube array such as TiO_2 is used as a scaffold where CIGS is conformally coated using solution phase to obtain a radial heterojunction solar cell. Their performance is compared that of the planar thin film solar cells fabricated with the same materials.

K1.00135 Electronic properties and mechanism of superionic conductivity in Li_3N , MASARU AOKI, Shizuoka Sangyo University, KAZUO TSUMURAYA, Meiji University — Lithium nitride is a superionic conductor with high Li conductivity. The compound has been studied intensively because of its potential utility as electrolyte in solid-state batteries. Though it is known that the charge carriers responsible for conduction are Li vacancies in the Li_2N plane, the mechanism of the high mobility remains unsolved. To clarify the origin of the mobility we simulate the dynamics in the Li_3N crystal with the first principles molecular dynamics method. We have found the existence of the cooperative dynamics of Li ions in the Li_2N plane.

K1.00136 Light-induced degradation in gallium-doped silicon, JEANETTE LINDROOS¹, MARKO YLI-KOSKI, ANTTI HAARAHILTUNEN, Aalto University, Department of Micro and Nanosciences, MARTIN C. SCHUBERT², Fraunhofer Institute for Solar Energy Systems (ISE), HELE SAVIN, Aalto University, Department of Micro and Nanosciences — Light-induced degradation (LID) is a lifetime-decreasing effect in silicon solar cells attributed to the formation of B-O defect complexes during illumination [1-2]. However, Savin et al. [3] have recently observed degradation similar to LID in B- and P-doped Si contaminated with Cu, suggesting that Cu might be the cause of LID. Since Ga-doped Si is considered a degradation-free option to conventional B-doped Si [2], lifetime stability should also be studied in Cu-contaminated Ga-Si. Hence, in this paper, we intentionally contaminated high-oxygen 0.41 and 10.1 Ωcm Ga-doped Cz-Si with Cu and subjected the material to illumination. No lifetime degradation was measured with μ -PCD in clean Ga-Si or at low Cu levels, which is in agreement with the previously reported LID-free behavior of Ga-Si [2]. However, at higher Cu levels (20 ppb), a clear lifetime degradation was observed in Ga-Si. This lifetime degradation increased with increasing Cu concentration or with increasing wafer resistivity. K1.00137 Simulation of thin nanowires for solar energy conversion: Operation as photoelectrodes and with discrete ohmic-selective contacts, MICHELLE PRICE, JUSTIN FOLEY, STEPHEN MALDONADO, University of Michigan — Nanostructured, high aspect ratio form factors can dramatically improve the performance of solar energy conversion devices made from low cost, earth-abundant materials that are otherwise limited by poor carrier transport properties. This poster presentation identifies and more precisely defines the limiting factors in the operation of thin nanowire photoelectrodes to facilitate their design and synthesis. Results from finite-element simulations used to model the key features of thin nanowire photoelectrodes under low-level injection conditions are shown that illustrate the respective effects of nonuniform doping, tapering along the length, variation in charge carrier mobilities and lifetimes, changes in nanowire radius, and changes in the density of surface defects on the photocurrent-potential responses. Also reported are results from simulations of nanostructures featuring near-intrinsic doping densities and discrete, ohmic-selective contacts operating under high-level injection conditions. The sensitivity of device operation to contact size, carrier mobility, surface recombination velocity, doping density and illumination intensity are reported. The presented work will address the hypothesis that the discrete, ohmic-selective contact photoelectrode design affords large solar energy conversion efficiencies with thin, lightly doped semiconductor nanowires.

K1.00138 Multiple Exciton Generation in Si Nanoparticles under pressure¹, STEFAN WIPPERMANN, Dep. of Chemistry, University of California (UC), Davis, MARTON VOROS, Dep. of Atomic Physics, Budapest University of Technology and Economics (T&E), DARIO ROCCA, Dep. of Chemistry, UC Davis, ADAM GALI, Dep. of Atomic Physics, Budapest University of T&E, GERGELY ZIMANYI, Dep. of Physics, UC Davis, GIULIA GALLI, Dep. of Chemistry, UC Davis — Multiple exciton generation (MEG) in semiconductor nanoparticles (NPs) is a promising path towards surpassing the Shockley-Queisser limit in solar energy conversion efficiency. Recent theoretical and experimental studies demonstrate MEG to be more efficient in semiconductor NPs than in the bulk material [1]. However, the increased efficiency is observed only on a relative energy scale in units of the gap, as the quantum confinement effects believed to be responsible for efficient MEG in NPs also lead to a significant increase of their gap with respect to the bulk. For successful device applications, it is necessary to identify NPs with enhanced MEG rates on an absolute energy scale. We propose that Si nanoparticles with a core structure resembling that of high pressure Si phases may be promising candidates to exhibit enhanced MEG rates on an absolute scale. In the bulk, upon compression the Si gap is reduced and a recent experimental study demonstrated successful fabrication of Si NPs in the BC8 phase. In the present study we investigate the electronic structure and MEG rates of Si NPs made from the beta-tin, R8, BC8 and hexagonal diamond Si phases from first principles.

K1.00139 Crosslinkable P3HT as Hole Transport Layer of Polymer Based Solar Cells, JUNG-KEUN KIM, Department of Polymer Science and Engineering, University of Massachusetts Amherst, MA 01002, JAE WOONG JUNG, Department of Materials Science and Engineering, Seoul National University, Seoul 151-742, Korea, WON HO JO, 2Department of Materials Science and Engineering, Seoul National University, Seoul 151-742, Korea, THOMAS P. RUSSELL, None — A photocrosslinkable bromine-functionalized poly(3-hexylthiophene) (P3HT-Br) copolymer was synthesized and used as the hole transport layer in polymer solar cells based on poly(3-hexylthiophene), and low band gap polymer, poly[2,6-(4,4-bis-(2-ethylhexyl)-4H-cyclopenta[2,1-b;3,4-b']dithiophene)-alt-4,7-(2,1,3-benzothiadiazole)] (PCPDTBT) with [6,6]-phenyl-C61-butyric acid methyl ester. Electrochemical stability of crosslinked P3HT-Br is superior to poly(3,4-ethylenedioxythiophene): poly(styrenesulfonate) (PEDOT:PSS), which has widely been used as the hole transport material in polymer solar cells.

K1.00140 First-principles calculations of covalently-bonded 3D networks of graphitic boron-nitride for hydrogen storage, SANGHOON LEE, Department of Physics, POSTECH, SEUNG-HOON JHI, Department of Physics and Division of Advanced Materials Science, POSTECH — Graphitic nanomaterials such as carbon nanotube (CNT) and covalently-bonded graphene (CBG) have attracted great attention due to their large surface area for high-capacity hydrogen storage. We carried out first-principles calculations based on density functional theory of covalently-bonded 3D networks of hexagonal boron nitride (hBN) layers and investigated the metal dispersion and subsequent hydrogen adsorption inside the networks. We performed a comparative analysis of stability, metal dispersion, and hydrogen sorption between graphene, CNT, hBN single layer, and 3D hBN networks.

K1.00141 Simultaneous description of strong and weak H_2 adsorption sites coexisting in MOFs, MOON-HYUN CHA, KYUNG-SUK KIM, School of Engineering, Brown University, JISOON IHM, Department of Physics and Astronomy, Seoul National University — In designing hydrogen-storage materials, it is a wide-spread practice to introduce transition-metal atoms into the MOF structures in order to increase the binding energy of H_2 . In such systems, it is necessary to understand and describe the H_2 binding behaviors at both strong and weak binding sites. Here, we propose a model that quantitatively characterizes the hydrogen gas adsorption in the presence of different kinds of adsorption sites. Based on equilibrium thermodynamics, this model enables us to figure out the number of H_2 molecules adsorbed to each adsorbing site and the corresponding heat of adsorption. When the present model is applied to real experimental data, different binding sites are identified and the contribution of each term to the storage capacity is obtained. While the virial equation gives the isosteric heat of adsorption averaged over the system, our model gives the heat of adsorption at each adsorbed site. Furthermore, by analyzing the results of fitting, we can estimate the volume occupied by adsorbed H_2 molecules.

K1.00142 Interaction of Cellulose Chains with Ionic Liquids and Water via MD simulations¹, AHMED ISMAIL, BROOKS RABIDEAU, RWTH Aachen University — One promising route for combustible fuel sources which are both renewable and have a low environmental impact is the conversion of waste biomass into tailor-made fuels. An important aspect of this process is the low-energy separation of cellulose from the biomass. Ionic liquids (ILs) have proven to be very good in dissolving cellulose with the added benefit of being essentially non-volatile making them ideal for “green” processing. IL research, however, remains relatively new, with many parts of this dissolution process remaining uncertain. We examine the behavior of cellulose with the ionic liquids [BMIM]Cl, [EMIM]Ac and [DMIM]DMP as well as water via MD simulation. All three ionic liquids have been observed to dissolve cellulose quite well yet have differently sized anions. We explore these differences and the impacts they have on their interactions with cellulose. First we examine the dynamics of a single cellulose strand in these ionic liquids. We determine the radius of gyration and the hydrogen bonds that are formed between the anions and cellulose. Next, we probe the dissolution mechanism of multiple, bound cellulose strands examining of multiple, bound cellulose strands examining interactions at the IL/cellulose interface and the breakup of inter-cellulose hydrogen bonds.

¹This work was performed as part of the Cluster of Excellence “Tailor-Made Fuels from Biomass,” which is funded by the Excellence Initiative by the German federal and state governments to promote science and research at German universities.

K1.00143 Synthesis and Electrochemical Performance of SiOC-Carbon Nanotube Composite Coatings, ROMIL BHANDAVAT, Kansas State University, MARCO COLOGNA, RISHI RAJ, GURPREET SINGH, University of Colorado at Boulder — Rechargeable battery anodes made from crystalline Si-based nanostructures have been shown to possess high experimental first cycle capacities (3000 mAh/g), but face challenges in sustaining these capacities beyond initial cycles mainly due to large volume expansion (400 percent) and chemical degradation (pulverization). Polymer-derived ceramic SiOC due to its high thermodynamic stability and nano domain structure could present a viable alternative. Additionally, functionalization of SiOC with carbon nanotubes could result in increased electronic and ionic conductivities in the ceramic. Here, we demonstrate synthesis and electrochemical characterization of SiOC-CNT composite coatings for use in Li-ion battery anode. Materials characterization performed using electron microscopy, Infrared (FT-IR), and X-ray photoelectron spectroscopy suggests non-covalent functionalization of CNT with oxygen moieties in SiOC. Sustained battery capacities of over 700 mAh/g and first cycle coulombic efficiencies of about 75 percent were achieved. Future work will involve determination of lithium ion intercalation sites characterized by electron microscopy whereas cyclic voltammetry analysis will access the sequential change in anode chemistry.

K1.00144 Polymer-derived Ceramic SiCN-MoS₂ Nanosheet Composite for Lithium Ion Battery Anodes¹, ROMIL BHANDAVAT, GURPREET SINGH, Kansas State University — We demonstrate synthesis of a novel SiCN-MoS₂ nanosheet composite for use as Li-ion battery anode for high power applications. The nanosheet composite was prepared by thermal decomposition of polysilazane (SiCN precursor) on exfoliated MoS₂ surfaces. The morphology and chemical structure was studied using a range of spectroscopy techniques that revealed a sidewall functionalization of exfoliated MoS₂ by the polymeric precursor. The thermodynamic stability of SiCN-MoS₂ nanosheets was also confirmed by thermo-gravimetric analysis (1000 degree C). Batteries assembled using MoS₂-SiCN nanosheets as active anode material showed that lithium can be reversibly intercalated in the voltage range of 0-2.5 V with first cycle discharge capacity of 620 mAh/g at a current density of 100 mA/g.

¹State of Kansas, National Science Foundation

K1.00145 First principles MD simulations of proton diffusion in cubic perovskite BaZrO₃, MARCO FRONZI, YOSHITAKA TATEYAMA, National Institute for Material Science, NICOLA MARZARI, École Polytechnique Fédérale de Lausanne, ENRICO TRAVERSA, National Institute for Material Science — The development of highly proton conductive and chemically stable ceramic materials, including doped barium zirconate, is particularly important for the fabrication of high performance solid oxide fuel cell (SOFCs) operating at intermediate-low temperature (550-900K). In this work, extensive first-principles molecular dynamics simulations have been employed to analyze proton self-diffusion in cubic perovskites BaZrO₃. Simulations have been performed at 1300K, that are typical fuel-cells' working conditions. The runs were carried out for the stoichiometric system in unit cells of 40 atoms, and in the canonical ensemble. We also studied the effect of applied compressive and tensile stresses on the proton motion finding a non linear effect on the proton mobility as a function of the strain. Enhanced diffusion has been found for an isotropic compression of 2% in the lattice parameter. On the other hand, the presence of a tensile strain does not seem to affect the proton diffusion, compared to the equilibrium case. The power spectrum obtained by the velocity-velocity correlation function for the proton shows no significant change in the vibrational frequencies for the strains studied.

K1.00146 Effect of Surfactants on the Physical Properties and Electrochemical Performance of LiFePO₄ Cathode Material for Lithium Ion Batteries, K. BAZZI, Wayne State University, M. NAZRI, Applied Sciences Inc., P. VAISHNAVA, Kettering University, V.M. NAIK, University of Michigan-Dearborn, G.A. NAZRI, R. NAIK, Wayne State University — The lithium iron phosphate chemistry is plagued by the poor electronic conductivity and slow lithium ion diffusion in the solid phase. In order to solve these problems, various research groups have adopted different strategies including decreasing the particle size, covering the particles with carbon, and adding dopants to the cathode material. Here, we report synthesis of C-LiFePO₄ cathode materials using 0.25M lauric, myristic, and oleic acid as surfactants. The phase purity of all three C-LiFePO₄ was confirmed by x-ray diffraction. SEM and TEM investigations reveal that the surfactants coat the LiFePO₄ particles uniformly with carbon and the coating reduces the particle size to 20-30 nm. Due to high electrical conductivity, controlled particle size and suitable microstructure, among the three LiFePO₄ coated samples, the sample with 0.25M lauric acid exhibited superior electrochemical performance in terms of specific capacity, the cycling stability and delivered high discharge capacity of 155, 150 and 123 mAhg⁻¹ at 0.5 C, 1C and 5C, respectively. The correlation between the ratio of the intensities of the D and G bands observed by micro-Raman spectroscopy, conductivity and electrochemical characteristics will be presented.

K1.00147 Block Copolymer Membranes for Biofuel Purification, ALI EVREN OZCAM, NITASH BALSARA, UC Berkeley, EBI TEAM — Purification of biofuels such as ethanol is a matter of considerable concern as they are produced in complex multicomponent fermentation broths. Our objective is to design pervaporation membranes for concentrating ethanol from dilute aqueous mixtures. Polystyrene-*b*-polydimethylsiloxane-*b*-polystyrene block copolymers were synthesized by anionic polymerization. The polydimethylsiloxane domains provide ethanol-transporting pathways, while the polystyrene domains provide structural integrity for the membrane. The morphology of the membranes is governed by the composition of the block copolymer while the size of the domains is governed by the molecular weight of the block copolymer. Pervaporation data as a function of these two parameters will be presented.

K1.00148 Toyota Prius Hybrid Plug-in Conversation and Battery Monitoring system, MICHAEL MCINTYRE, ROBERT KESSINGER, MAEGAN YOUNG, JOSEPH LATHAM, KRISHNANUNNI UNNIKANNAN, Department of Engineering, Western Kentucky University, Bowling Green, KY 42101 — The objective of the project was to analyze the performance of a Toyota Hybrid. We started off with a stock Toyota Prius and taking data by driving it in city and on the highway in a mixed pre-determined route. The batteries can be charged using standard 120V AC outlets. First phase of the project was to increase the performance of the car by installing 20 Lead (Pb) batteries in a plug-in kit. To improve the performance of the kit, a centralized battery monitoring system was installed. The battery monitoring system has two components, a custom data modules and a National Instruments CompactRIO. Each Pb battery has its own data module and all the data module are connected to the CompactRIO. The CompactRIO records differential voltage, current and temperature from all the 20 batteries. The LabVIEW software is dynamic and can be reconfigured to any number of batteries and real time data from the batteries can be monitored on a LabVIEW enabled machine.

K1.00149 Response of High Optical Heterogeneity in Three Dimensional Solar Cells , YUAN LI, Wake Forest University, XIANG WAN, University of Virginia, WENXIAO HUANG, WANYI NIE, Wake Forest University, HUIHUI HUANG, Wuhan University, DAVID CARROLL, Wake Forest University — The incident light throughout the cavity of three dimensional photovoltaic architecture is heterogeneous, and it may influence the cell's outputs, including the open circuit voltage, short current density, and fill factor and corresponding efficiency. In this work, an equivalent circuit for three dimensional solar cells was derived by an infinitesimal method, to model the response at different light distribution. Using this model, an upper bound was given to estimate the difference between two distributions, and this can show heterogeneous light has a similar effect on open circuit voltage (Voc) as well as that from homogeneous light while low heterogeneity. We further provided a method to predict the accurate Voc on very high optical heterogeneity, such that the optimum architecture can be found to design the three dimensional solar cells.

K1.00150 FLUIDS —

K1.00151 Soft, Hydrodynamically Coupled Particles in a Hele-Shaw Channel¹ , WILLIAM USPAL, Physics, Massachusetts Institute of Technology, PATRICK DOYLE, Chemical Engineering, Massachusetts Institute of Technology — Control of flowing suspensions is central to many emerging microfluidic applications. For instance, manipulation of small clusters is important in the synthesis of functional particles. Via theory and simulations, we study small clusters confined in a microchannel with thin cross section and subject to an external flow. We show that many-body hydrodynamic interactions sustain long-lived bound states with complex dynamics. As these interactions are sensitive to confinement, we investigate modulation of channel geometry as a means to perform sequential operations in a continuous process. We also probe the effects of shape and elasticity via a Lattice Boltzmann/Lattice Spring code, finding spontaneous excitation of elastic waves ("flapping"), and enriched behavior through the orientational effects of shape. Our results demonstrate phenomena that could be exploited for assembly of soft colloids in microchannels.

¹Supported by the Institute for Collaborative Biotechnologies through grant W911NF-09-0001 from the U.S. Army Research Office.

K1.00152 Nanoparticle transport and binding dynamics in blood flow , YALING LIU, JIFU TAN, ANTONY THOMAS, Lehigh University — Nanoparticle systems have been widely used in diagnostic imaging and targeted therapeutic applications in recent years. Most current studies on nanoparticle drug delivery considered a Newtonian fluid with suspending spherical nanoparticles. However, blood is a complex biological fluid composed of deformable cells, proteins, platelets, and plasma. For blood flow in capillary, arterioles and venules, the particulate nature of the blood need to be considered in the delivery process. Non-Newtonian effects such as the cell-free-layer and nanoparticle-cell interaction will largely influence both the dispersion and binding rates, thus impact targeted delivery efficacy. A 3D multiscale particle-cell hybrid model is developed to model nanoparticle transport, dispersion, and adhesion dynamics in blood suspension. The motion and deformation of red blood cell is captured through Immersed Finite Element method. The motions and bindings of individual nanoparticles of various shapes are tracked through Brownian adhesion dynamics and molecular ligand-receptor binding kinetics. Nanoparticle dispersion and binding coefficients are derived from the developed model under various rheology conditions. The influences of vascular flow rate, geometry, nanoparticle size on nanoparticle distribution and delivery efficacy are characterized. A non-uniform nanoparticle distribution profile with higher particle concentration near the vessel wall is observed. Such distribution leads to 50% higher particle binding rate compared to the case without RBC considered. The tumbling motion of RBCs in the core region of the capillary is found to enhance nanoparticle dispersion. The modeled binding results are validated through designed experiments in microfluidic devices.

K1.00153 Fabrication of Out-of-Plane Electrodes for ACEO Pumps¹ , YEHYA SENOUSY, CINDY HARNETT, University of Louisville — This abstract reports the fabrication process of a novel AC Electroosmosis (ACEO) pump with out of plane asymmetric interdigitated electrodes. A self-folding technique is used to fabricate the electrodes, that depends on the strain mismatch between the tensile stressed film (metal layer) and the compressive stress film (oxidized silicon layer). The electrodes roll up with a well-defined radius of curvature in the range of 100-200 microns. Two different electrical signals are connected to alternating electrodes using an insulating silicon nitride barrier that allows circuits to cross over each other without shorting. Electroosmotic micropumps are essential for low-cost, power-efficient microfluidic lab-on-chip devices used in diverse application such as analytical probes, drug delivery systems and surgical tools. ACEO pumps have been developed to address the drawbacks of the DCEO pumps such as the faradic reaction and gas bubbles. The original ACEO microfluidic pump was created with planar arrays of asymmetric interdigitated electrodes at the bottom of the channel. This rolled-up tube design improves on the planar design by including the channel walls and ceiling in the active pumping surface area of the device.

¹This project is supported from KY EPSCOR grant: "Engineering Platforms for Exploring Cellular and Molecular Processes."

K1.00154 Design and Simulation of Optically Actuated Bistable MEMS , THOMAS LUCAS, EVGENIYA MOISEEVA, CINDY HARNETT, University of Louisville — In this project, bistable three-dimensional MEMS actuators are designed to be optically switched between stable states for biological research applications. The structure is a strained rectangular frame created with stress-mismatched metal-oxide bilayers. The devices curl into an arc in one of two directions tangent to the substrate, and can switch orientation when regions are selectively heated. The heating is powered by infrared laser, and localized with patterned infrared-resonant gold nanoparticles on critical regions. The enhanced energy absorption on selected areas provides switching control and heightened response to narrow-band infrared light. Coventorware has been used for finite element analysis of the system. The numerical simulations indicate that it has two local minimum states with extremely rapid transition time ($\ll 0.1$ s) when the structure is thermally deformed. Actuation at laser power and thermal limits compatible with physiological applications will enable microfluidic pumping elements and fundamental studies of tissue response to three-dimensional mechanical stimuli, artificial-muscle based pumps and other biomedical devices triggered by tissue-permeant infrared light.

K1.00155 Reactant consumption analysis in microchannel based fuel cells , JOSEPH D'ALESSANDRO, PETRU FODOR, Cleveland State University, Department of Physics — In this work a miniaturized fuel cell design based on microchannels using liquid fuel and oxidizer streams is optimized for improved fuel usage. This particular design exploits the laminar nature of the fluid flow at small Reynolds numbers to keep the fuel and oxidizer confined in the vicinity of the corresponding electrodes without the need of a proton exchange membrane. Thus typical issues associated with the proton exchange membrane, such as reactant crossover, membrane dry-out and fouling are avoided. While the long term functional degradation effects associated with a physical membrane are eliminated, for an arbitrarily chosen geometry the slow thermal diffusion limits the efficiency of the cell due to the formation of depletion layers close to the electrodes. The performance of the cell is sensitive to geometry and rate of fluid flow with high aspect ratio cells operated at high Peclet number regimes being the most efficient.

K1.00156 High-throughput single-cell PCR using microfluidic emulsions¹ , MIRA GUO, LINAS MAZUTIS, JEREMY AGRESTI, MORTEN SOMMER, GAUTAM DANTAS, GEORGE CHURCH, PETER TURNBAUGH, DAVID WEITZ, Harvard University — The human gut and other environmental samples contain large populations of diverse bacteria that are poorly characterized and unculturable, yet have many functions relevant to human health. Our goal is to identify exactly which species carry some gene of interest, such as a carbohydrate metabolism gene. Conventional metagenomic assays sequence DNA extracted in bulk from populations of mixed cell types, and are therefore unable to associate a gene of interest with a species-identifying 16S gene, to determine that the two genes originated from the same cell. We solve this problem by microfluidically encapsulating single bacteria cells in drops, using PCR to amplify the two genes inside any drop whose encapsulated cell contains both genes, and sequencing the DNA from those drops that contain both amplification products.

K1.00157 Competition in the condensation of immiscible vapors on a cold substrate¹, JOSÉ GUADARRAMA-CETINA, WENCESLAO GONZÁLEZ-VIÑAS, University of Navarra — We report experimental results on the breath figures which appear upon condensation of a mixture of vapors on a cold substrate (5° C). Both fluids have similar contact angles on the chosen substrate (72° vs 90°) and are immiscible. After getting the occupation diagram, we focus on the range of experimental conditions where we can see a relevant competition between the two species during the condensation. In the set of experiments, we measure the growth laws and compare them to the case of pure fluids. Also, we study the morphology of the patterns, by paying attention to the relative occupation factors and other related statistical quantities [1].

[1] J. Guadarrama-Cetina & W. González-Viñas, in preparation.

K1.00158 Adsorption kinetics of surfactants at liquid-solid and liquid-vapor interfaces from atomic-scale simulations¹, EUGENIYA K. ISKRENOVA, Propulsion Directorate, Air Force Research Laboratory, Wright Patterson Air Force Base, OH 45433, USA and UES, Inc., Dayton, OH 45432, USA, SOUMYA S. PATNAIK, Propulsion Directorate, Air Force Research Laboratory, Wright Patterson Air Force Base, OH 45433, USA — Nucleate pool boiling of pure liquid is a complex process involving different size- and time-scale phenomena. The appearance of the first nanobubble in the liquid at the bottom of a hot pan, the detachment of the bubble from the solid surface, its subsequent coalescence with other bubbles, all represent complex multiscale phenomena. Surfactants added to water increase the complexity of the process by contributing to the dynamic surface tension at the liquid-vapor and liquid-solid interfaces and thus affecting the heat and mass transfer at those interfaces. We apply molecular dynamics simulations to study the adsorption kinetics of anionic, cationic, and non-ionic surfactants at liquid/solid and liquid/vapor interfaces. The all-atom vs. united-atom approaches for the solid and surfactants are surveyed in view of their applicability at near boiling temperatures and a range of model water potentials is assessed for reproducing the thermal properties of water at boiling conditions.

¹The authors gratefully acknowledge the Air Force Research Laboratory DoD Supercomputing Resource Center for computing time.

K1.00159 Experiment links the afterbounce instability and period doubled emission in single-bubble sonoluminescence, MOGENS LEVINSSEN, Niels Bohr Institute, University of Copenhagen — We report the first direct and long time stable observation for a single sonoluminescing bubble of the afterbounce instability that is believed to be one of the ways for a sonoluminescing bubble to lose stability and eventually break up. Furthermore we show that the instability is directly linked to the curious phenomenon of flash by flash period doubling of the sonoluminescent emission as the afterbounce instability is always period doubled whenever the emission is. This lends credit to a hot core picture coupled with refraction in the surface of the bubble. A theoretical understanding of this peculiar coupling is still missing.

K1.00160 Electrohydrodynamic simulation of an electrospray in a colloid thruster, MANISH JUGROOT, MARTIN FORGET, CECILE MALARDIER-JUGROOT, Royal Military College of Canada — A precise understanding of electrosprays is highly interesting as the complexity of micro-technology (such as nano-material processing, spacecraft propulsion and mass-spectrometers) systems increases. A multi-component CFD-based model coupling fluid dynamics, charged species dynamics and electric field is developed. The simulations describe the charged fluid interface with emphasis on the Taylor cone formation and cone-jet transition under the effect of a electric field. The goal is to recapture this transition from a rounded liquid interface into a Taylor cone from an initial uniform distribution, without making assumptions on the behaviour, geometry or charge distribution of the system. The time evolution of the interface highlights the close interaction among space charge, coulombic forces and the surface tension, which appear as governing and competing processes in the transition. The results from the coupled formalism provide valuable insights on the physical phenomena and will be applied to a colloid thruster for small spacecrafts.

K1.00161 Reaction Force of Micro-scale Liquid Droplets Constrained Between Parallel Plates through CFD, ROBERT FREE, HAIDER HEKIRI, TAKUMI HAWA, School of Aerospace and Mechanical Engineering, The University of Oklahoma — Micro-scale liquid droplets responding to depression between parallel plates are investigated analytically and numerically. The functional dependence of the reaction force accrued in such droplets on droplet size, surface tension, depression amount, and contact angle is explored. For both the 2D and 3D case, an analytical model is developed based on first principles. Computational fluid dynamics is then utilized to evaluate the validity of these models. The reaction force is highly nonlinear, initially increasing very slowly with increasing depression of the droplet, but eventually moving asymptotically to infinity. The force scales linearly with both the droplet free radius and surface tension of the liquid, but has a much more complicated dependence on the contact angle and depression. Explicit expressions for the reaction force have been determined, showing these dependencies. The 3D model has been largely supported by the CFD results. It very accurately predicts the reaction force on the upper plate as the droplet is crushed, accounting for the effect of contact angle, surface tension, and droplet size.

K1.00162 Dynamics control of micro-sized droplets for fluid-based electrothermal management¹, DUSTIN BAKER, TAKUMI HAWA, HAIDER HEKIRI, School of Aerospace and Mechanical Engineering, The University of Oklahoma — Heat transfer rate across a micro-scale liquid droplet constrained in two parallel plates at various contact angles are investigated numerically. Electrowetting is used to change how fluids wet solid surfaces, and two plates are at different temperatures. Computational fluid dynamics (FLUENT) is utilized to understand the heat transfer mechanism between two plates and to evaluate the combinations of design parameters needed to produce effective electrowetting thermal management systems. When the high-thermal conductivity fluid does not wet the plates, it functions as a high thermal resistance layer, allowing limited contact surface area for heat transfer through the high-thermal conductivity fluid between the plates. However, when wettability is altered so the high-thermal conductivity fluid wets the plates, the contact area is increased substantially, leading to heat transfer action between the plates. Understanding the dynamics of fluid rearrangement as long as the heat transfer phenomena associated with the fluid rearrangement is particularly important for this system.

K1.00163 A comparative study of phase separation dynamics of sulfur hexafluoride under fine and coarse temperature quenching in microgravity¹, CATHLEEN WISE, ANA OPRISAN, SORINEL A. OPRISAN, College of Charleston, JOHN J. HEGSETH, University of New Orleans, CAROLE LECOUTRE, YVES GARRABOS, University of Bordeaux, DANIEL BEYSENS, University of Grenoble — Phase separation is determined by thermal quenches that break the symmetry of the homogeneous supercritical phase and leads to the formation of inhomogeneous structures with important implications for the mechanical, thermal, and electrical properties of materials. Sulfur hexafluoride (SF₆) heated about 1 K above its critical temperature then quenched below the critical temperature formed gas and liquid domains in microgravity conditions. Full view and microscopic view images were analyzed to determine the changes in the size distribution of droplets. For the first time, we provided experimental evidences regarding the existence of dimple and nose coalescence mechanisms in pure supercritical fluids under microgravity conditions. We recorded data for two different thermal quenches of 3.6 mK and 0.3mK, respectively. Our results indicate that, during the late stage of phase separation, the number of the liquid clusters decreases due to the coalescence events. We estimated the power law growth of the droplets/clusters and fitted it to a universal curve.

K1.00164 Microfluidic migration of soft particles in shear and Poiseuille flow, YENG-LONG CHEN, Institute of Physics, Academia Sinica, YA-YU HEW, University of Texas-Arlington — We investigate the migration of deformable particles in shear flow and Poiseuille flow due to the competition between shear forces, particle elasticity, particle diffusion, and particle inertia. At low particle Reynolds number ($Re < 1.0$), the soft particles migrate towards the channel center due to the coupling of particle elasticity and wall-induced hydrodynamic interactions. The competition between the shear forces and particle diffusivity, characterized by the Peclet number Pe , is found to affect whether the particles concentrate in the channel center of in an off-center position. As particle Reynolds number increases to moderate values ($Re \geq 1.0$), the particle concentration profile has two maxima at off-center positions. The migration effect is also found to be enhanced for softer particles with longer elastic relaxation time. The variation of particle concentration profiles leads to non-linear variations of the mixture viscosity and the average flow rate.

K1.00165 Surface Design for Efficient Capturing of Rare Cells in Microfluidic Device, YALING LIU, ANTONY THOMAS, Lehigh University, CHI-MON CHEN, SHU YANG, University of Pennsylvania — This work aims to design, fabricate, and characterize a micro-patterned surface that will be integrated into microfluidic devices to enhance particle and rare cell capture efficiency. Capture of ultralow concentration of circulating tumor cells in a blood sample is of vital importance for early diagnostics of cancer diseases. Despite the significant progress achieved in development of cell capture techniques, the enhancement in capture efficiency is still limited and often accompanied with drawbacks such as low throughput, low selectivity, pre-diluting requirement, and cell viability issues. The goal of this work is to design a biomimetic surface that could significantly enhance particle/cell capture efficacy through computational modeling, surface patterning, and microfluidic integration and testing. A PDMS surface with microscale ripples is functionalized with epithelial cell adhesion molecule (EPCAM) to capture prostate cancer PC3 cells. Our microfluid chip with micropatterns has shown significantly higher cell capture efficiency and selectivity compared to the chips with plane surface or classical herringbone-grooves.

K1.00166 A Look at Long Term Trends and Short Term Transition Zones (Fronts) in the Atmosphere using Fourier and Wavelet Analysis, JOSEPH TROUT, Richard Stockton College of New Jersey — An atmospheric front can be defined as sloping zones of pronounce transition of thermal and or wind fields in the atmosphere. This study uses Fourier analysis to look at the long term trends in atmospheric data and uses Wavelet Analysis to analyze the short term transition zones. These transition zones are characterized by a strong horizontal temperature gradient and/or large horizontal wind shear. They also may have large static stability and vertical wind shear. The signature of the front is evident as a large horizontal temperature gradient and moisture gradient. The compact nature of the wavelets make them perfect candidates for analyzing the short term transition zones in the thermal and wind fields that comprise the fronts. The frequency, intensity and shape of these transition zones are analyzed.

K1.00167 Sediment ripple profiles, ABIGAIL KOSS, JUSTIN KAO, TAYLOR PERRON, Massachusetts Institute of Technology — Sand ripples are a commonly observed phenomenon in shallow-water environments with oscillatory flow. Ripple morphology reflects patterns of sediment transport and turbulence across the bottom of the bed, providing easily measurable information about the mathematical form of sediment transport laws. A set of flume experiments has been conducted to record equilibrium ripple profiles produced by a wide range of wave orbital diameters and bed shear stresses. Results indicate that normalized ripple profiles are similar across the experimental range of wave conditions: i.e., that any ripple profile can be predicted from a standard ripple shape scaled by wave orbital diameter and bed shear stress. These experiments have also quantified ripple profile asymmetry and the nonlinear relationship between ripple wavelength and amplitude.

K1.00168 BIOLOGICAL PHYSICS —

K1.00169 Optical properties of large amyloid spherulites, MICHAEL SMITH, JAMES SHARP, University of Nottingham — Amyloid Spherulites, consisting of a central core surrounded by radially oriented birefringent fibres (known as amyloid fibrils), have been found to occur in certain pathologies, such as Alzheimer's disease. Typically ~5 30 m in diameter they can be observed by optical microscopy and easily distinguished by their characteristic maltese cross pattern, seen when viewed under crossed polarisers. Here we report the existence of much larger amyloid spherulites formed from bovine insulin, which grow under a particular set of conditions (10 mg/ml-1 BPI, pH ~2.8, T ~67°C, 25mM NaCl) to diameters of up to ~500 m. These huge spherulites when viewed under crossed polarisers in addition to the maltese cross feature beautiful coloured rings which change with the size and density of the spherulite. Such rings have been observed in other systems such as fish eye lenses and nematic liquid crystal drops and appear to be related to the rather unusual radially oriented birefringence of their internal structure. Using a ray tracing technique we model the optical path of rays through these spherulites. Taking into account refraction and the radially oriented birefringence of the amyloid fibrils, we elucidate the origin of these beautiful patterns.

K1.00170 FTIR and RRS Study of the Archaeorhodopsin-3 Optogenetic Neural Silencer and Transmembrane Voltage Sensor, ERICA SAINT CLAIR, JOHN OGREN, SERGEY MAMAEV, Boston University, Department of Physics, JOEL KRALL, Harvard University, Chemistry and Chemical Biology, KENNETH ROTHSCCHILD, Boston University, Department of Physics — Archaeorhodopsin-3 (AR3) is a light driven proton pump from *H. Sodomense* with a 74% sequence homology to the more extensively studied bacteriorhodopsin (BR) from *H. Salinarum*. Recent studies show that the wild type (WT) AR3 functions as a high-performance, genetically targetable optical silencer of neuronal activity and the mutant D95N functions as a transmembrane fluorescence voltage sensor. In order to understand the molecular similarities and differences between AR3 and BR, we compared light-activated structural changes using resonance Raman spectroscopy (RRS) and Fourier transform infrared (FTIR) difference spectroscopy. RRS pH titration and H/D exchange of WT AR3 showed that the retinylidene chromophore structure and Schiff base hydrogen bond strengths are almost identical to BR. RRS of the mutant D95N revealed a mixture of an N-like and O-like species at a pH greater than 7, unlike WT AR3. Low-temperature and rapid-scan time-resolved FTIR difference spectroscopy of WT AR3 revealed conformational changes during formation of the K, M and N intermediates similar but not identical to BR. Positive/negative bands in the region above 3600 cm⁻¹, which have been assigned to changes in weakly hydrogen bonded internal water molecules, differed substantially between AR3 and BR. These results indicate molecular differences between the AR3 and BR proton pumps which may underlie the ability of AR3 to function as a neurophotonic switch and sensor.

K1.00171 Polymorphic Ab protofilaments exhibit distinct conformational dynamics as calculated by normal mode analysis, MATTHEW ARMBRUSTER, PATRICIA SOTO, Creighton University — This project proposes to test the hypothesis that the physicochemical milieu modulates the conformational dynamics of synthetic Alzheimer's Ab protofilament structures, the main component of Alzheimer's senile plaques. To this end, 3D solid-state NMR structures of Ab protofilaments were used as initial structures for molecular dynamics simulations in explicit water and a water/hexane environment. The initial structures of the simulations and representative structures from the simulation-generated trajectories were taken to perform computational normal mode analysis. We developed a code in python with a graphical user-friendly interface. The program incorporated the ProDy (0.7.1) package. With the application, we examined cross-correlation plots of Ca positions of the 2-fold Ab protofilaments along the most collective mode and the slowest mode. The protofilament structures were highly correlated in the water environment. We hypothesized the protofilament would move as one in water because of the viscosity. The square fluctuation of Ca positions was calculated for the slowest mode for the hexane model and the MD generated ensemble. The two plots match up until midway through the structure. At the midway point a phase shift emerged between the two structures most likely where the surrounding changes. The in-house developed code made it easy to perform analysis and will be used by other students in the research group.

K1.00172 A simple system for the identification of fluorescent dyes capable of reporting differences in secondary structure and hydrophobicity among amyloidogenic protein oligomers, EMMA YATES, University of Cambridge — Thioflavin T and Congo Red are fluorescent dyes that are commonly used to identify the presence of amyloid structures, ordered protein aggregates. Despite the ubiquity of their use, little is known about their mechanism of interaction with amyloid fibrils, or whether other dyes, whose photophysics indicate that they may be more responsive to differences in macromolecular secondary structure and hydrophobicity, would be better suited to the identification of pathologically relevant oligomeric species in amyloid diseases. In order to systematically address this question, we have designed a strategy that discretely introduces differences in secondary structure and hydrophobicity amidst otherwise identical polyamino acids. This strategy will enable us to quantify and compare the affinities of Thioflavin T, Congo Red, and other, incompletely explored, fluorescent dyes for different secondary structural elements and hydrophobic motifs. With this information, we will identify dyes that give the most robust and quantitative information about structural differences among the complex population of oligomeric species present along an aggregation pathway between soluble monomers and amyloid fibrils, and correlate the resulting structural information with differential oligomeric toxicity.

K1.00173 A new multiplexing single molecule technique for measuring restriction enzyme activity, ALLISON HARBOTTLE, JILLIAN CAVANAUGH, Emmanuel College, Boston, MA, WENDY GORDON, JOSEPH LOPARO, Harvard Medical School, Boston, MA, ALLEN PRICE, Emmanuel College, Boston, MA — We present a new multiplexing single molecule method for observing the cleavage of DNAs by restriction enzymes. DNAs are attached to a surface at one end using a biotin-streptavidin link and to a micro bead at the other end via a digoxigenin-antidigoxigenin link. The DNAs are stretched by applying a flow. After introduction of the restriction enzyme, the exact time of cleavage of individual DNAs is recorded with video microscopy. We can image hundreds to thousands of DNAs in a single experiment. We are using our technique to search for the signature of facilitated diffusion in the measured rate dependence on ionic strength.

K1.00174 ABSTRACT WITHDRAWN —

K1.00175 Plasmon-Enhanced Single-Molecule Fluorescence for Sub-Diffraction-Limited Imaging, ESTHER WERTZ, JESSICA DONEHUE, JULIE BITEEN, University of Michigan — Super-resolution microscopy is a powerful tool for noninvasively imaging biological structures below the standard diffraction limit of light. One such technique, single-molecule fluorescence (SMF) imaging, achieves this resolution gain based on localizing isolated fluorophores. The accuracy of such localizations increases as the number of photons collected from each fluorophore increases. The ability to engineer the fluorescence quantum yield, radiative decay rate, and photostability of emitters will therefore greatly enhance the image resolution. In this work, we control SMF by coupling emission to plasmon resonances in metallic nanoparticles. These localized surface plasmons are confined charge density oscillations, and the local enhanced electromagnetic field they generate can be used to reduce the radiative lifetime and improve fluorophore brightness and photostability. We explore the effects of particle plasmons on the fluorescence properties of single dye molecules through wide-field single-molecule microscopy and fluorescence lifetime imaging microscopy experiments. All measurements are made both in the presence and absence of gold plasmonic structures. We observe up to ten-fold enhancements in photostability upon coupling to nanostructured gold, indicating that plasmon-enhanced imaging is a promising means to increase the resolution of single-molecule microscopy. We will extend our current experiments on dyes and quantum dots to fluorescent proteins.

K1.00176 Fluorescence Correlation Spectroscopy of Tryptophan-containing Proteins in Sugar Solutions using Two Photon Excitation¹, YULI WANG, NATHAN HOLMAN, DAVID SIDEBOTTOM, MICHAEL NICHOLS, ERIC HAAS, Creighton University — Sugars are common ingredients for many commercial cryopreserving agents yet their function in this role is poorly understood. Some believe that sugars preferentially bind with a protein surface thereby replacing hazardous, ice-forming water. In an attempt to test idea, we have undertaken studies of the diffusion of proteins and protein-coated nanospheres using fluorescence correlation spectroscopy in an effort to determine if the hydrodynamic size is influenced by the addition of sugars. Some novelty of our approach lies in exploiting the native fluorescence of tryptophan (a common fluorophore found in many proteins) by use of two-photon excitation.

K1.00177 Laser Stimulated Genomic Exchange in Stem Cells. Laser Non-cloning Techniques¹, V.ALEXANDER STEFAN, Institute for Advanced Physics Studies, Stefan University — I propose a novel technique for a pluripotent stem cell generation. Genomic exchange is stimulated by the beat-wave free electron laser, (B-W FEL), frequency matching with the frequencies of the DNA² eigen-oscillations. B-W FEL-1³ scans entire stem cell; B-W FEL-2 probes the chromosomes. The scanning and probing lasers: 300-500nm and 100-300nm, respectively; irradiances: the order-of-10s mW/cm² (above the threshold value for a particular gene structure); repetition rate of few-100s Hz. A variety of genetic-matching conditions can be arranged. Genomic glitches, (the cell nucleus transfer⁴), can be hedged by the use of lasers.

K1.00178 A one-dimensional model of Nucleosome distribution in DNA, BRENDAN OSBERG, University of Munich, WOLFRAM MOEBIUS, University of Munich, Harvard University, KIEN NGUYEN, ULRICH GERLAND, University of Munich, UNIVERSITY OF MUNICH STATISTICAL PHYSICS GROUP TEAM — Nucleosome positioning along DNA is neither random nor precisely regular. Genome-wide maps of nucleosome positions in various eukaryotes have revealed a common pattern around transcription start sites, involving a nucleosome-free region flanked by a periodic pattern in the average nucleosome density. We take a quantitative mathematical description of the nucleosome pattern, and incorporate specifically bound transcription factors. Our model assumes a dense, one-dimensional gas of particles, however, instead of previous work which assumes fixed-size particles interacting only by exclusion, our model explicitly accounts for transient unwrapping of short segments of nucleosomal DNA. Hence, such particles no longer have a fixed size, but interact by an effective repulsive potential. This model has been successfully used, by us, to provide a unified description of 12 *Hemiascomycota* yeast species with a single unified set of model parameters. We incorporate into this model, specifically bound particles, or transcription factors (TF), which serve an important role in gene regulation. Nucleosome distribution patterns have an important influence on TF binding, and can even mediate interactions between transcription factors at a distance. This interaction can account for cooperative or competitive binding between these proteins, and we will discuss the implications this can have on gene regulation.

K1.00179 Unified physical model for statistical nucleosome positioning in different yeast species, WOLFRAM MÖBIUS, Department of Physics, Harvard University, Cambridge, MA, BRENDAN OSBERG, Arnold Sommerfeld Center for Theoretical Physics, LMU Munich, Munich, Germany, ALEXANDER M. TSANKOV, Broad Institute of MIT and Harvard and Department of Electrical Engineering and Computer Science, MIT, Cambridge, MA, OLIVER J. RANDO, Department of Biochemistry and Molecular Pharmacology, University of Massachusetts Medical School, Worcester, MA, ULRICH GERLAND, Arnold Sommerfeld Center for Theoretical Physics, LMU Munich, Munich, Germany — Recent genome-wide maps of nucleosome positions in different eukaryotes have revealed a common pattern around transcription start sites, involving a nucleosome-free region flanked by a pronounced periodic pattern in the average nucleosome density. For the yeast *S. cerevisiae*, a gas of hard rods, known as Tonks gas and equivalent to the statistical positioning mechanism of Kornberg and Stryer, can be used to describe the experimentally observed pattern. Here, we consider 12 *Hemiascomycota* yeast species, each of which displays a distinct nucleosome pattern. Since the mechanisms underlying the formation of the patterns are expected to be related, we undertake a data-driven search for a unified quantitative description. We find that the simple one-dimensional gas model needs to be extended to take into account transient unwrapping of short segments of nucleosomal DNA, such that the particles no longer have a fixed size. Chromatin behavior in all but one species is well described by this generalized gas model, with a single unified set of model parameters where only the average nucleosome density is a species-dependent variable.

K1.00180 Dynamics of Chromatin Silencing at Telomeres: Deterministic and Stochastic Aspects, MANJUL APRATIM, Dept. of Physics and Astronomy, Rutgers University, ADEL DAYARIAN, KITP, University of California, Santa Barbara, EDUARDO SONTAG, Dept. of Mathematics, Rutgers University, ANIRVAN SENGUPTA, BioMaPS Institute and Dept. of Physics and Astronomy, Rutgers University — Epigenetic silencing modifications are often associated with well-defined domains. We study potential mechanisms of formation of boundary of silenced regions. We specially focus on the possibility that some telomeric silencing boundaries are formed in a self-organized manner, as opposed to being defined by specific boundary elements. In particular, we examine systems where a titration-induced feedback can stabilize the boundary of the silenced region. A consequence of having multiple such boundaries is large stochastic cell-to-cell variation of boundary locations. We proceed to make an argument about the nature of the fall-off of the average silencing protein occupancy, coming from such variability, and test the predictions against HA-Sir3 ChIP-seq data from experiments performed on yeast.

K1.00181 Static Magnetic Field Induced Stochastic Resonance in Gene Expression, MEGAN BRADY, Binghamton University, PAUL FRISCH, Memorial Sloan-Kettering, KENNETH MCLEOD, CRAIG LARAMEE, Binghamton University — Biological systems are naturally complex, making singular responses difficult to detect. However, when the emergent behavior is investigated, the collective properties may be observed and characterized. These responses to external stimuli are often evident at the genomic level. When an optimal dose of external noise is used to perturb the system, it may work in synergy with the system's intrinsic noise to produce a change in stable state. This phenomenon, known as stochastic resonance (SR), is responsible for shifts in gene expression. This paper proposes that static magnetic fields (SMFs) elicit a SR genomic response in biological systems under environmentally relevant exposures. Using single reporter biomarkers as well as gene expression microarrays, the responses of three cell model systems (MCF-10A; Rat-1; Caco-2) to SMF exposure were examined. Results show that while responses for a single gene do occur, they are difficult to replicate and are near the detection cutoff limits. However, the system as a whole displays a shift in the pattern of gene expression. The replication of this pattern across different experimental platforms provides evidence that the cells are responding to the noise presented by the SMFs.

K1.00182 Membrane Fusion Mediated by pH-Low-Insertion-Peptide (pHLIP)¹, JENNIFER DANIELS, University of Rhode Island, LAN YAO, Binghamton University, DONALD ENGELMAN, Yale University, OLEG ANDREEV, YANA RESHETNYAK, University of Rhode Island — Liposomes are traditionally used as drug delivery carriers. The major mechanism of liposome entry into cell is endocytotic. First, the endocytotic pathway of cellular entry is non-specific: the delivery of therapeutics occurs to cells in both diseased and healthy tissues. Second, liposomes are usually trapped in endosome/lysosome, which prevents delivery of therapeutics to cytoplasm. We proposed to use pHLIP (pH-Low-Insertion-Peptide) to promote selective delivery of the liposome content to cytoplasm of cancer cells. We showed that liposomes coated with PEG polymer and pHLIP peptide enhance membrane fusion in acidic environments. pHLIP promotes fusion between lipid bilayer of liposome and plasma membrane or membrane of endosome/lysosome, which results in intracellular delivery of payload. Liposomes composed of 5 % pHLIP and 5 % PEG were ideal for the delivery. Since cancer and other pathological states produce an acid extracellular environment, this allows the liposome to target diseased tissue while avoiding healthy tissue (with neutral pH in extracellular space). The work is supported by NIH grants CA133890 to OAA, DME, YRK.

¹Supported by NIH grants CA133890 to OAA, DME, YRK.

K1.00183 Wide-field Time Resolved Microscopy for in-situ Lipid Phase Dynamics¹, NEDA DADASH-VAND, FELIX SCHUPP, CHRISTINA OTHON, Wesleyan University — We have developed a new time-resolved fluorescence platform which enables us to follow the molecular orientation and dynamics of a lipid monolayer at the air – water interface. Confocal microscopy is limited in its ability to characterize dynamic orientation changes within cellular membranes. By implementing an all reflective Cassegrain objective we minimize dispersion while eliminating the restriction of collinear excitation. We investigate the miscibility transition of a ternary lipid mixture, DPPC / DOPC / Cholesterol, using a combination of fluorescence imaging and spectroscopy. The technique affords unprecedented dynamic characterization for lipid orientation as the monolayer is forced from the liquid to the gel phase. We demonstrate the applicability of this device by contrasting the time-resolved fluorescence signal of three different lipid probes (NBD-PC), (BIODIPY), (DiI) which show different orientation and dynamic freedom when bound to the lipid layer for a range of lipid phases. Using this technique we can resolve highly dynamic processes such as the insertion of peptide and proteins into the lipid membrane.

¹Wesleyan grants in support of scholarship

K1.00184 Aggregation of Phosphoinositides at Physiological Calcium Concentrations¹, ADOLPHE KAZADI BADIAMBILE, Physic Department, Syracuse University,, MARTIN B. FORSTNER, Syracuse Biomaterials Institute, Syracuse University — Phosphoinositides play a crucial role in many cellular functions such as calcium signaling, endocytosis, exocytosis and the targeting of proteins to specific membrane sites. To maintain functional specificity, it has been suggested that phosphoinositides are spatially organized in “pools” in the cellular plasma membrane. A possible mechanism that could induce and regulate such organization of phosphoinositides is their interaction with Ca²⁺ ions. Understanding the physicochemical mechanism that can regulate membrane structure is a crucial step in the development of adaptive biomimetic membrane systems. Using Langmuir monolayers, we investigated the effect of bivalent calcium and magnesium cations on the surface pressure-area/lipid isotherm of monolayers of phosphatidylinositol (PI), phosphatidylinositol bisphosphate (PIP2) and dioleoylphosphatidylglycerol (DOPG) and dipalmitoylphosphatidylcholine (DPPC). It is found that the decrease of area per lipid, i.e. the increase in aggregation, is dependent on both the lipid's head group charge, the bivalent cation and temperature. However, electrostatics are not sufficient to account for all experimental observations. Thus additional interactions between ions and phosphoinositides need to be considered.

¹The National Science Foundation (NSF)

K1.00185 ABSTRACT WITHDRAWN —

K1.00186 How evolvable are polarization machines?, LIEDEWIJ LAAN, ANDREW MURRAY, FAS Center for Systems Biology, Harvard University — In many different cell types proper polarization is essential for cell function. Polarization mechanisms however, differ between cell types and even closely related species use a variety of polarization machines. Budding yeast, for example, depends on several parallel mechanisms to establish polarity. One mechanism (i) depends on reaction and diffusion of proteins in the membrane. Another one (ii) depends on reorganization of the actin cytoskeleton. So why does yeast use several mechanisms simultaneously? Can yeast also polarize robustly in the absence of one of them? We addressed these questions by evolving budding yeast in the absence of mechanism (i) or (ii). We deleted a mechanism by deleting one or two genes that are essential for its function. After the deletion of either mechanism the growth rate of cells was highly decreased (2-5 fold) and their cell shape was highly perturbed. Subsequently, we evolved these cells for 10 days. Surprisingly, the evolved cells rapidly overcame most of their polarity defects. They grow at 0.9x wildtype growth rate and their cell shape is significantly less perturbed. Now we will study how these cells rescued polarization. Did they fix the deleted mechanism, strengthen other mechanisms or evolve a completely new one?

K1.00187 Myosins V and VI increase actin filament flexural rigidity through a weak to strong binding transition, BRANNON MCCULLOUGH, WENXIANG CAO, ENRIQUE DE LA CRUZ, Yale University — Myosins are ATPase molecular motors that couple ATP hydrolysis with force generation along actin filaments. Myosin alters the torsional dynamics of actin filaments, which may contribute to aspects of force generation and nucleotide-dependent stability of the actin-myosin complex. We measured how biochemical ATPase-cycle intermediate states of high-duty myosins V and VI affect the flexural rigidity of actin filaments by analyzing the angular correlation of thermally driven shape fluctuations. Both myosins increase the flexural rigidity of actin filaments in a manner that depends on the chemical state of bound adenine nucleotide. High binding affinity states increase the flexural rigidity of actin filaments more than weak binding states. These results indicate that actin filaments may flex during myosin cycling to allow bound motors to coordinate stepping.

K1.00188 Time-temperature-transformation curves in chemical reactions regulated by cytoskeletal activity, BHASWATI BHATTACHARYA, Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore, India, ABHISHEK CHAUDHURI, University of Oxford, UK, KRIPA GOWRISHANKAR, University of California, Davies, SATYAJIT MAYOR, National Centre for Biological Sciences-TIFR, Bangalore, India, MADAN RAO, Raman Research Institute/National Centre for Biological Sciences-TIFR, Bangalore, India — Efficient and reproducible construction of signaling and sorting complexes, both on the surface and within the living cell, is contingent on local regulation of biochemical reactions by the cellular milieu with active components. We have recently proposed that in many cases this spatiotemporal regulation can be mediated by interaction with components of the dynamic cytoskeleton, where the interplay between active contractility and remodeling of the cytoskeleton results in transient focusing of passive molecules to form clusters, leading to a dramatic increase in the reaction efficiency and output levels. In this presentation, we discuss the implications of actin dynamics by introducing an “effective temperature,” which can work as a regulatory parameter for signaling replacing the details of actin dynamics. We show this in time-temperature-transformation plots, with the proposed “effective temperature” as a parameter, which paves way for discussion of active chemical thermodynamics.

K1.00189 Elastic Coupling in Bipedally Crawling Cells¹, ALEX LOOSLEY, JAY TANG, Brown University — Periodic shape changes during cell migration are recorded in fast moving fish epithelial keratocytes where sticking and slipping at opposite sides of the cell's broad trailing edge generate bipedal locomotion and oscillatory lateral displacement of the nucleus. We use a two-dimensional finite element model to study the mechanical coupling, adhesion forces, and cell shapes that recapitulate the dynamics of these crawling cells. The model consists of elastically coupled point-like elements representing regions of the cell: leading edge, opposite sides of the trailing edge, and the nucleus. Based on simple assumptions, such as cell symmetry and localization of each element to a specific cellular region, we determine that there are only four viable permutations of elastic couplings between these four elements. We compare the four configurations and find that centralized elastic coupling to the cell nucleus and wide aspect ratio of the shape is necessary to mechanically generate realistic bipedal shape dynamics and lateral displacement of the nucleus. We suggest one configuration that is most realistic. The dynamics of this configuration are strongly dependent on the elasticity between peripheral elements, but not on the elasticity between these elements and the nucleus.

¹National Science Foundation CMMI 0825873, Natural Sciences and Engineering Research Council of Canada Post Graduate Scholarship D (AJL).

K1.00190 Delivery of imaging and therapeutic agents to tumor using pHILIP, DAYANJALI WIJESINGHE, ANNA MOSHNIKOVA, BETHANY ROSSI, Department of Physics, University of Rhode Island, DONALD ENGELMAN, Department of Molecular Biophysics and Biochemistry, Yale University, OLEG ANDREEV, YANA RESHETNYAK, Department of Physics, University of Rhode Island — We are developing a novel technology for selective delivery of imaging probes and membrane-impermeable molecules to cancer cells. It is based on action of water-soluble membrane peptide, pHILIP® (pH [Low] Insertion Peptide), which has ability to insert and fold in cellular membrane at slightly acidic environment, which is a characteristic for various pathological states including cancer. The insertion of the peptide is unidirectional: C-terminus moves inside the cell across membrane, while N-terminus flags outside. Thus pHILIP possess dual delivery capability. Imaging agents (fluorescent, PET, SPECT or MRI) could be attached to the N-terminus of the peptide to mark tumor mass and tumor margins with high precision. At the same time, therapeutic molecules attached to the C-inserting end, could be moved across membrane to reach cytoplasmic target. Among translocated molecules are synthetic cyclic peptides, gene regulation agent (peptide nucleic acid) and phallo- and amanita toxins with hydrophobicity tuned by attachment of fatty acids for optimum delivery. Currently we have family of pHILIP peptides for various applications. The work is supported by NIH grants CA133890 to OAA, DME, YRK.

K1.00191 The mechanics of cellular compartmentalization as a model for tumor spreading¹, ANATOL FRITSCH, STEVE PAWLIZAK, MAREIKE ZINK, JOSEF A. KAES, University of Leipzig, Division of Soft Matter Physics — Based on a recently developed surgical method of Michael Höckel, which makes use of cellular confinement to compartments in the human body, we study the mechanics of the process of cell segregation. Compartmentalization is a fundamental process of cellular organization and occurs during embryonic development. A simple model system can demonstrate the process of compartmentalization: When two populations of suspended cells are mixed, this mixture will eventually segregate into two phases, whereas mixtures of the same cell type will not. In the 1960s, Malcolm S. Steinberg formulated the so-called differential adhesion hypothesis which explains the segregation in the model system and the process of compartmentalization by differences in surface tension and adhesiveness of the interacting cells. We are interested in to which extent the same physical principles affect tumor growth and spreading between compartments. For our studies, we use healthy and cancerous breast cell lines of different malignancy as well as primary cells from human cervix carcinoma. We apply a set of techniques to study their mechanical properties and interactions. The Optical Stretcher is used for whole cell rheology, while Cell-cell-adhesion forces are directly measured with a modified AFM. In combination with 3D segregation experiments in droplet cultures we try to clarify the role of surface tension in tumor spreading.

K1.00192 Contour instabilities and micro-structures in early tumor growth models, MARTINE BEN AMAR, Ecole Normale Supérieure, PASQUALE CIARLETTA, Université Pierre et Marie Curie, CLÉMENT CHATELAIN, THIBAUT BALOIS, Ecole Normale Supérieure — Clinical diagnosis of skin cancers is based on several morphological criteria, among which growth, color, border instabilities and microstructures (e.g. dots, nests) sparsely distributed within the tumor lesion. We use the multiphase mixture models adapted to the skin to explain various patterning occurring in the avascular phase. Restricting to a simple but realistic version of these models with an elastic cell-to-cell interaction and a growth rate dependent on diffusing nutrients, we prove analytically that the tumor cell concentration at the border acts as a control parameter inducing a bifurcation with loss of circular symmetry which explains the instabilities of the tumor border. The finite wavelength at threshold has the size of the proliferating peritumoral zone. We apply our predictions to melanoma growth since these instabilities are crucial for the early diagnosis. The same model is used to show the existence of micro-structures. Taking into account a reaction-diffusion coupling between nutrient consumption and cellular proliferation, we show that two-phase models may undergo a spinodal decomposition even when considering mass exchanges between the phases. The cell-nutrient interaction defines a typical diffusive length in the problem, which is found to control the saturation of a growing separated domain, thus stabilizing the microstructural pattern. The distribution and the evolution of such emerging cluster morphologies are successfully compared to the clinical observation of microstructural patterns in tumor lesions.

K1.00193 Smart-design of Tunable Nanomaterials for Enhancing Cancer Diagnosis and Radiation Therapy, TABBETHA DOBBINS, CRISTINA IFTODE, Rowan University — Gold nanoparticles (AuNPs) will be studied for both cancer diagnosis and treatment. At present, protocols are being established using benign fibroblast cell phenotype. The diagnosis hypothesis is that approaches may be developed to examine differences in intracellular matrices of healthy and tumor cells (or to examine cell metabolic activity) via understanding the absorption and agglomeration state of intracellular AuNPs. The treatment hypothesis is that the efficacy of irradiation with laser light (and monochromatic x-rays) at killing cells after attachment of AuNPs to the external cell wall has a fundamental mechanism which may not be accounted for solely by particle heating under irradiation. It remains unclear whether quantum effects also play a role. This work will ultimately explore phonon-phonon coupling or electron-phonon coupling at the surface of the AuNP and its contribution to the observed enhanced cell death upon irradiation. Early results will be presented.

K1.00194 Magnetic Hyperthermia in ferrofluid-gel composites¹, HUMESHKAR NEMALA, ANSHU WADEHRA, Wayne State University, MI, AMBESH DIXIT, IIT Rajasthan, India, RAJESH REGMI, Sloan-Kettering Cancer Center, NY, PREM VAISHNAVA, Kettering University, MI, GAVIN LAWES, RATNA NAIK, Wayne State University, MI — Magnetic hyperthermia is the generation of heat by an external magnetic field using superparamagnetic nanoparticles. However, there are still questions concerning magnetic hyperthermia in tissue; in particular the confinement of the nanoparticles at mesoscopic scales. We used Agarose and Alginate gels as models for human tissue and embedded magnetic nanoparticles in them. We report the synthesis and characterization of dextran coated iron oxide (Fe₃O₄) nanoparticles. Characterization of these nanoparticles was done using X-ray diffraction, transmission electron microscopy, magnetometry, and hyperthermia measurements. Temperature dependent susceptibility measurements reveal a sharp anomaly in the ferrofluid sample at the freezing temperature. This is conspicuously absent in the ferrofluid-gel composites. Heat generation studies on these superparamagnetic gel-composites revealed a larger heat production in the ferrofluids (~4W/g) as compared to the gels (~1W/g), which we attribute to a reduction in Brownian relaxation for the nanoparticles embedded in Agarose and Alginate.

K1.00195 Predicting tumor sizes of ductal carcinoma in situ from immunohistochemical images using a novel approach of mathematical pathology: preliminary results, potentials and challenges ahead¹, YAO-LI CHUANG, University of New Mexico, Dept. Pathology, MARY EDGERTON, University of Texas, MDACC, Dept. Pathology, PAUL MACKLIN, University of Southern California, Center for Applied Molecular Medicine, WEI YANG, University of Texas, MDACC, Dept. Radiology, ELAINE BEARER, University of New Mexico, Dept. Pathology, VITTORIO CRISTINI, University of New Mexico, Dept. Pathology and Dept. Chemical Engineering — Differential equation models have recently drawn increasing attentions as a useful tool to help advance the knowledge in cancer research. However, challenges remain for applying such models to clinical practices on a patient-specific basis to assist surgical decisions. Clinical diagnoses essentially at a single time point are often insufficient to fully constrain the time-dependent differential equations. Here we present a novel mathematical pathology approach, identifying robust indicators for time-invariant predictions of the model that can be used for surgical planning. We demonstrate this approach by predicting the sizes of ductal carcinoma in situ by calibrating model parameters from immunohistochemical images. Our preliminary studies of 17 excised tumor cases resulted in a better agreement with the actual measured sizes than the other estimates available to us, showing the potential of our approach for patient-specific cancer diagnosis. Conversely, our studies also revealed challenges to overcome before we can take this approach to the next level.

K1.00196 Preventing biosensor non-specific adsorption: Static to dynamic interfaces, LUCY HARWOOD, NEAL HOPKINS, Dstl — Biosensors are currently being developed for the detection of a wide range of analytes in a variety of scenarios. One such area is that of environmental monitoring for the presence of biological threats, from toxins through to viruses and bacteria. Environmental samples will contain a wide variety of contaminants, dependent on the location and prevalent environmental conditions. The sensing surfaces employed by biosensor instruments must be capable of resisting non-specific adsorption (NSA) of the contaminants whilst specifically capturing targets of interest. The ability to do so reduces the incidence of false positives and negatives increasing confidence in the system. We have assessed a range of biosensor surface chemistries of both two and three dimensional topography using a commercial BIAcore™ platform, for ability to prevent NSA of soluble materials of medical and military significance. This has highlighted that future solutions may benefit from dynamic interfaces as opposed to the conventional static interface often employed.

K1.00197 Vertical nanowire electrode array: a highly scalable platform for intracellular interfacing to neuronal circuits, MARSELA JORGOLLI, Department of Physics, Harvard University, JACOB ROBINSON¹, ALEX SHALEK, Department of Chemistry and Chemical Biology, Harvard University, MYUNG-HAN YOON, Gwangju Institute of Science and Technology, RONA GERTNER, Department of Chemistry and Chemical Biology, Harvard University, HONGKUN PARK, Department of Chemistry and Chemical Biology and Department of Physics, Harvard University — Interrogation of complex neuronal network requires new experimental tools that are sensitive enough to quantify the strengths of synaptic connections, yet scalable enough to couple to a large number of neurons simultaneously. Here, we will present a new, highly scalable intracellular electrode platform based on vertical nanowires that affords parallel interfacing to multiple mammalian neurons. Specifically, we show that our vertical nanowire electrode arrays can intracellularly record and stimulate neuronal activity in dissociated cultures of rat cortical neurons and be used to map multiple individual synaptic connections. This platform's scalability and full compatibility with silicon nanofabrication techniques provide a clear path toward simultaneous high-fidelity interfacing with hundreds of individual neurons, opening up exciting new avenues for neuronal circuit studies and prosthetics.

K1.00198 1/f Noises as a Superposition of First Order Autoregressive Model, TAKAYUKI FUJITA, AKIRA TSUKAMOTO, SHIGERU TADA, National Defense Academy — In various physical and physiological systems, power spectrum densities (PSD) of temporal sequences appear to be inversely proportion to the frequency. Those systems include the fluctuations of resistances in semiconductors, heart beats and membrane currents. Those inverse proportions of PSD to frequency are so called 1/f noises. One of the mechanisms with which 1/f noises are generated is superimposition of Ornstein-Uhlenbeck processes. Although this superimposition of Ornstein-Uhlenbeck processes, sequential temporal sequences, successfully generate 1/f noises, temporal sequences in physical and physiological systems are rarely measured sequentially. Instead, those temporal sequences are usually measured discretely. In this study, 1/f noises were attempted to generate with AR(1) processes, one example of discrete temporal sequences. As a result, PSD of superimposed AR(1) processes was inversely proportion to the frequency under some limitations. Those limitations include uniformly distribution of model parameter for AR(1) processes and white noise of driving noise. Thus, it was suggested that 1/f noises could be generated by superimposing discrete temporal sequences.

K1.00199 Population dynamics on heterogeneous bacterial substrates, WOLFRAM MOBIUS, Department of Physics and FAS Center for Systems Biology, Harvard University, Cambridge, MA, ANDREW W. MURRAY, FAS Center for Systems Biology and Department of Molecular and Cellular Biology, Harvard University, Cambridge, MA, DAVID R. NELSON, Department of Physics and FAS Center for Systems Biology, Harvard University, Cambridge, MA — How species invade new territories and how these range expansions influence the population's genotypes are important questions in the field of population genetics. The majority of work addressing these questions focuses on homogeneous environments. Much less is known about the population dynamics and population genetics when the environmental conditions are heterogeneous in space. To better understand range expansions in two-dimensional heterogeneous environments, we employ a system of bacteria and bacteriophage, the viruses of bacteria. Thereby, the bacteria constitute the environment in which a population of bacteriophages expands. The spread of phage constitutes itself in lysis of bacteria and thus formation of clear regions on bacterial lawns, called plaques. We study the population dynamics and genetics of the expanding phage for various patterns of environments.

K1.00200 Inter- and intracellular signaling induced by magnetomechanical actuation of plasma membrane channels, ELINA A. VITOL, Argonne National Laboratory, Materials Science Division and Center for Nanoscale Materials, ELENA A. ROZHKOVA, Argonne National Laboratory, Center for Nanoscale Materials, VALENTYN NOVOSAD, Argonne National Laboratory, Materials Science Division, SAMUEL D. BADER, Argonne National Laboratory, Materials Science Division and Center for Nanoscale Materials — Magnetic particles allow for non-invasive control over their spatial orientation and motion which makes them ideally suitable for studying real-time processes in living cells. Lithographically defined ferromagnetic disks with spin-vortex ground state have the advantage of zero net magnetization in remanence. This eliminates long-range magnetic forces which otherwise lead to the interaction between particles and their agglomeration. Moreover, magnetically soft permalloy particles have high magnetization of saturation thus requiring very low external field for inducing high magnetomotive force, compared to superparamagnetic particles. Our group has previously demonstrated that micron-sized permalloy disks can be used for destruction of cancer cells (D.-H. Kim, E. A. Rozhkova, I. V. Ulasov, S. D. Bader, T. Rajh, M. S. Lesniak, V. Novosad, Nat. Mater. 9, 165-171 (2010)). In this work, we investigate the effects of magnetomechanical stimulation of human brain cancer cells with these particles. It will be shown that the actuation of ion channels in cell plasma membrane induces, on the one hand side, intracellular signaling triggering cell apoptosis and, on the other hand, it stimulates the energy transfer between the cells which carries the information about apoptotic signal.

K1.00201 Bacterial sensing using phage-functionalized whispering gallery microcavities, HALA GHALI, Department of Engineering Physics, École Polytechnique de Montréal, HICHAM HIBLI, Biomedical Engineering Department, McGill University, PABLO BIANUCCI, Department of Engineering Physics, École Polytechnique de Montréal, JAY NADEAU, Biomedical Engineering Department, McGill University, YVES-ALAIN PETER, Department of Engineering Physics, École Polytechnique de Montréal — Whispering gallery optical microcavities are structures which can efficiently confine light at the micro scale. This confinement is based on total internal reflection of light at the interface between the cavity and the surrounding medium. Devices based on optical microcavities have a wide range of applications, such as microlasers, quantum optical devices and much more. In this work, we describe a biosensing application of these optical microcavities for the label-free detection of bacteria. In order for the sensor to be specific to a particular species of bacteria, we need to properly functionalize its surface so that only that kind of bacteria will produce a signal. The microcavity surface is first functionalized using PEGylated aminosilane. We then introduce phage-derived proteins that are specific to the bacteria we want to detect. The binding between the bacteria and the phage proteins creates a perturbation to the cavity field that leads to a thermo-optic effect. This effect is then observed as a shift in the resonance features of the transmission spectrum. We performed experimental measurements using a tapered fiber to couple the light from red laser (635 nm) into the resonator.

K1.00202 ABSTRACT WITHDRAWN —

K1.00203 Flow-controlled densification in E. Coli suspension¹, GASTÓN MIÑO, PMMH-ESPCI - University Pierre et Marie Curie, France, ERNESTO ALTSHULER, LENIN DEL RIO, CARLOS PEREZ-PENICHET, Dept of Physics, University de la Havana, Cuba, ANKE LINDNER, ANNIE ROUSSELET, ERIC CLEMENT, PMMH-ESPCI - University Pierre et Marie Curie, France — Bacterial suspensions are paradigmatic examples of “active matter.” Each bacterium can be regarded as a self-propelled particle that interact hydrodynamic ally with other bacteria or the suspension boundaries. As we know, in confined environments such as micron size channels or porous systems, solid boundaries act as traps for the bacterial motion and modify drastically the macroscopic transport properties of the suspension [1]. In this presentation, we show a new phenomenon concerning E. Coli suspensions flowing through a funnel-like constrictions between two micro-fluidic channels. The applied flow induces a counter-intuitive symmetry breaking in the bacteria concentration which increases strongly past the funnel. The enhancement persists over large distances. The density dissymmetry increases linearly with the flow rate and disappears at larger flow values. The effect is reversible with the flow. We explain these observations by emerging anomalous dispersion properties due to bacterial swimming trajectories and interactions between the bacteria and the channel boundaries. This experiment opens the possibility to control the bacterial concentration in microfluidic channels by simply tuning the flow of the suspending fluid. [1] Mino et al. Phys.Rev.Lett. 106, 048102(2011).

K1.00204 Small angle scattering study of the structure and organization of RNA and protein in Brome Mosaic Virus (BMV)¹, NARAYAN C. DAS, Center for the Exploration of Energy and Matter, GARFIELD T. WARREN, SI CHENG, Department of Physics, C. CHENG KAO, PENG NI, Department of Molecular and Cellular Biochemistry, BOGDAN DRAGNEA, Department of Chemistry, PAUL E. SOKOL, Center for the Exploration of Energy and Matter & Department of Physics, Indiana University — Brome mosaic virus (BMV) is a small icosahedral of the alpha virus-like superfamily of RNA with a segmented positive-strand RNA genome and a mean diameter $\sim 268\text{\AA}$ that offers high levels of RNA synthesis and virus production in plants. BMV also tightly regulates the packaging of its four RNAs (RNA1 through RNA4) into three separate particles; RNA1 and RNA2 are encapsidated separately while one copy each of RNA3 and RNA4 are normally packaged together. Small angle neutron scattering (SANS) and small angle X-ray scattering (SAXS) were applied to study the size, shape and protein-RNA organization of BMV. D₂O/H₂O mixture was used to enhance contrast in SANS measurement. The radial distribution of BMV from the Fourier transform of scattering spectrum gives a clear indication of RNA packing, and distribution and their structure in the BMV. The result reveals that the virus is about 266 Å in diameter and is composed of RNA inside the virion coated with a protein shell.

K1.00205 Measuring the Rate of Conjugal Plasmid Transfer and Phage Infection in a Bacterial Population Using Quantitative PCR, ZHENMAO WAN, The Graduate Center, CUNY, NOEL GODDARD, Hunter College, CUNY — Horizontal gene transfer between species is an important mechanism for bacterial genome evolution. In *Escherichia coli*, conjugation is the transfer from a donor(F⁺) to a recipient(F⁻) cell through cell-to-cell contact. We demonstrate a novel qPCR method for quantifying the transfer kinetics of the F plasmid in a population by enumerating the relative abundance of genetic loci unique to the plasmid and the chromosome. This approach allows us to query the plasmid transfer rate without the need for selective culturing with unprecedented single locus resolution. It also allows us to investigate the inhibition of conjugation in the presence of filamentous bacteriophages M13. Experimental data is then compared with numerical simulation using a mass action, resource limited model.

K1.00206 Pressure-temperature dependence of growth bottlenecks and phenotypic transitions of *Escherichia coli*, PRADEEP KUMAR, ALBERT J. LIBCHABER, Center for studies in Physics and Biology, Rockefeller University, New York, NY — A vast majority of bacteria and archaea can grow in diverse environmental conditions. The range of those conditions include high pressures, high temperature, low temperature, high salinity, low and high pH etc. We investigate the growth bottlenecks and phenotypic transitions of *Escherichia coli* (*E. coli*), a mesophilic bacterium, as a function of pressure and temperature. We find that *E. coli* can grow and proliferate in a wide range of pressures (1-400 atm) and temperatures (23-40 deg C). Moreover, we find that the division time of *E. coli* increases monotonically upon increasing pressure and exhibits a sharp increase in division time at pressures between 250-400 atm for all the temperatures investigated in our experiments. The sharp change in division time is followed by a sharp change in phenotypic transition of *E. coli* at high pressures where bacterial cells switch to an elongating cell type. We propose that this phenotypic changes in bacteria at high pressures is an irreversible stochastic process whereas the switching probability to elongating cell type increases with increasing pressure. Furthermore, we propose an irreversible stochastic model of cell phenotype switching. We find that model fits well the experimental data. We discuss our experimental results in the light of structural and so the functional changes in proteins and structural changes in membranes at different pressure and temperature.

K1.00207 Quantifying *E. coli* chemotaxis at the population level, with high spatial and temporal resolution, LAURENCE WILSON, RONGJING ZHANG, The Rowland Institute at Harvard — The response of microorganisms to an external chemical stimulus is key to their survival in the wild, and so has obvious connotations for natural selection. Although much is now known about the biochemical signaling pathways that allow bacteria to respond to fluctuating levels of chemoattractant in their environment, the implications for the group behavior of cells are unknown. Previous microscopic studies have focused on single-cell behavior to build up a picture of how cells adapt to changing environmental conditions. Instead of taking this approach, we borrow ideas from light scattering, and apply them to video microscopy data in a manner similar to differential dynamic microscopy (DDM). This approach places emphasis on the local density of bacteria, allowing us to study the collective behavior of around 5000 cells simultaneously with excellent spatial and temporal resolution. We use this new method in conjunction with other techniques developed in the lab to provide a comprehensive and highly automated characterization of bacterial behavior in the presence of a chemical stimulus.

K1.00208 ABSTRACT WITHDRAWN —

K1.00209 Novel Dynamics Observed in a Spiking Neural Network Model of the NTS in the Rat Hind-brain, JINGYI ZHOU¹, J. DAVID SCHAFER², PATRICIA DILORENZO³, CRAIG LARAMEE⁴, Binghamton University — The Nucleus of the Solitary Tract (NTS) is a hind-brain structure in the rat that is the first way-station in taste processing. Its structure and function are poorly understood. Recently our group produced a model, implemented as a spiking neural network (SNN), that successfully replicated experimental data. The model's topology was manually devised and the parameters were set by a genetic algorithm. In order to better understand its information processing capabilities, we probed the model with a variety of input spike patterns and observed a striking winner-take-all decision-making dynamic. We show how the topology and tuned parameters enable this decision to depend on precise spike timing events. It is curious that the experimental data upon which the model was originally evolved did not include winner-take-all examples; this was an emergent capability. It remains for additional experiments on rats to confirm or reject this model prediction.

K1.00210 Criticality in Neuronal Networks, NIR FRIEDMAN, Department of Physics, University of Illinois at Urbana-Champaign, SHINYA ITO, Department of Physics, Indiana University, BRADEN A. W. BRINKMAN, Department of Physics, University of Illinois at Urbana-Champaign, MASANORI SHIMONO, Department of Physics, Indiana University, R.E. LEE DEVILLE, Department of Physics, University of Illinois at Urbana-Champaign, JOHN M. BEGGS, Department of Physics, Indiana University, KARIN A. DAHMEN, Department of Physics, University of Illinois at Urbana-Champaign, TOM C. BUTLER, Department of Physics, Massachusetts Institute of Technology — In recent years, experiments detecting the electrical firing patterns in slices of in vitro brain tissue have been analyzed to suggest the presence of scale invariance and possibly criticality in the brain. Much of the work done however has been limited in two ways: 1) the data collected is from local field potentials that do not represent the firing of individual neurons; 2) the analysis has been primarily limited to histograms. In our work we examine data based on the firing of individual neurons (spike data), and greatly extend the analysis by considering shape collapse and exponents. Our results strongly suggest that the brain operates near a tuned critical point of a highly distinctive universality class.

K1.00211 Multidimensional representations of the phase response curve for both type 1 and type 2 membrane excitability¹ , ROBERT RAIDT, ANDREW J. SMITH, SORINEL A. OPRISAN, Department of Physics and Astronomy, College of Charleston — Neurons are complex excitable cells with a highly nonlinear response to external perturbations, such as presynaptic inputs and biological noise. Single-cell activity is determined by the properties of ionic channels and the ionic makeup of cell's environment and is mathematically described by coupled and nonlinear evolution equations. The phase resetting curve (PRC) reduces the complexity of the biophysical mechanisms involved in generating action potentials to tabulating advances or delays of subsequent spikes of a neuron due to an external perturbation. The PRC is widely used to predict the activity of large neural networks that by replacing the computationally intensive integration of evolution equations with lookup tables. The fundamental assumption of the PRC approach in predicting phase-locked modes in coupled neural networks is that the transient PRC measured for isolated and bursting neurons (open-loop) remains the same under the recurrent inputs of a phase-locked mode (close-loop). The novelties of our approach are: 1) the use of discrete sine transforms (DST's) to store the PRC's as a series of coefficients, and 2) the use of multidimensional stacks to represent multidimensional objects.

K1.00212 Hamiltonian Dynamics of a Forced Two-Degree-of-Freedom Arm with Viscoelastic Muscles Executing Planned Motions¹ , SAYAN PATRA, GREG OJAKANGAS, ANDREW CHASE, ANISH CHAKRABARTI, DALTON SIVILS, EVAN JOHNSON, KIEFER BARRETT, MASON NORTH, PRESTON JULIAN, None — In order to improve our understanding of how the brain controls the human arm both in the presence and absence of gravity, we have developed a two-degree-of-freedom robotic arm which is driven by six servo-actuated viscoelastic muscles. The computer-controlled servos mimic the contractive action of the sarcomeres in actual muscles, sections of elastic tubing represent the elastic behavior of actual muscles, while the behavior of tendons is represented by inelastic strings. The servos receive instructions to move from the visual C++ platform in the computer and the actual motion of the arm is recorded with optical encoders built into each joint axis. This experiment is a purely feed-forward system, and our goal is to determine whether our equations of motion, formulated using Hamiltonian dynamics, when numerically integrated, will predict the observed motion of the arm within experimental uncertainties. Our research was selected as one of 12 teams chosen nationwide as part of NASA Grant Us Space Reduced Gravity Program, to fly and perform experiments aboard NASA's Weightless Wonder aircraft in Summer 2011.

¹This research wouldn't have been possible without funding and support from Drury University Physics Department and Dr. Greg Ojakangas

K1.00213 Modeling the Force Frequency Relation of a Cardiac Cell , DUYN MANH LE, Department of Physics and Graduate Institute of Biophysics, National Central University, Jhongli City 320, Taiwan, ALEXEY V. DVORNIKOV, Nizhny Novgorod State University, Russia, PIK-YIN LAI, Department of Physics and Graduate Institute of Biophysics, National Central University, Jhongli City 320, Taiwan, CHI-KEUNG CHAN, Institute of Physics, Academia Sinica, Nankang, Taipei 115, Taiwan — Recent pacing experiments with hearts of rat have discovered that the contractile response of the hearts can have an unexpected slow non-monotonic response. This later observation cannot be explained by the existing excitation-contraction coupling model. A new discrete map model of the EC coupling is developed to understand these experimental findings. It is found that the biphasic response and the slow time scale can be reproduced when a calcium feedback based on calcium regulation mechanism of the cell is introduced. Furthermore, this model can also reproduce the nonlinear dynamical properties of the system; such as the period doubling in the response of the contractile forces during a step change in the pacing period. The force frequency relation curve generated by the model also compare well with previous published data. Our findings suggest that the feedback is really needed to understand the calcium transient when pacing frequency is changed and the calcium regulation is very important for the calcium handling of cardiac myocytes.

K1.00214 Simulating Growth Dynamics of Neurons on Substrates , SAWYER BERNATH, CRISTIAN STAIL, TIMOTHY ATHERTON, Tufts University — We present computer simulations of neuron growth in which growth cones both create and are guided by growth promoter molecules which move diffusively. Our model predicts several features of the trajectories that are experimentally measurable, including arclength and curvature as functions of time. By comparing these predictions to time-lapse microscopy experiments of axon growth in a controlled environment, we gain new insights into neuronal growth and connectivity.

K1.00215 Controlling growth and electrical connectivity of neuronal cells patterned on surfaces , ROSS BEIGHLEY, ELISE SPEDDEN, Physics and Astronomy, Tufts University, JAMES WHITE, Physics and Astronomy and Biomedical Engineering, Tufts University, CRISTIAN STAIL, Physics and Astronomy, Tufts University — In the developing brain biochemical and geometrical cues are an essential source of information used by neurons when wiring up the nervous system. However, our current understanding of the mechanisms by which various guidance factors control the path that growing axons/dendrites follow to reach their targets and form functional electrical connections remains qualitative. A current limitation for the study of neural network formation is the ability to precisely control the growth and interconnectivity of small numbers of neurons. Here we present a combined Atomic Force Microscopy - Fluorescence Spectroscopy approach for patterning neurons on 2-dimensional substrates and precisely controlling their location, growth and interconnectivity. We demonstrate that this approach allows one to: a) form simple neuronal circuits in well-controlled geometries; b) guide the formation of functional synapses between neurons, and c) measure the electrical activity of small groups of neurons. We also discuss the implications of these results for our current understanding of the fundamental mechanisms that govern the development of electrical connections between neurons.

K1.00216 Are the laws of nature Markovian? , ROBERT JONES, Emporia State University — The present laws of physics are Markovian. The state of the world at the current time step, t , depends only on the state of the world at the previous time step, $t-1$. (If there happen to exist closed timelike curves in our world then general relativity suggests that this may not be true even in physics.) But other sciences may propose laws which are nonMarkovian. Biology (evolution) has the memories stored in DNA, cognitive science has long term and short term memories, economics may exhibit behavior (cooperation) that depends on a memory of past events, etc.

K1.00217 Optical properties of thylakoid stacks , PAVEL SHIBAYEV, Princeton University, PETR SHIBAEV, Fordham University — Optical properties of grana are simulated by means of 4x4 matrix approach (Berreman method). The results of calculations lead to a conclusion that even small degree of chirality, that may be present in a granum structure, results in the dramatic changes of its optical properties. Depending on the birefringence and degree of chirality in granum organization the reflection of left or right handed circularly polarized light can be greatly suppressed. This can explain the light induced difference in the growth of pea and lentil shoots irradiated by left and right handed circularly polarized light [1].

K1.00220 The Use of Magnetite as a Polarisable Anode in the Electrolysis of Water¹, BJORN BERTSON, Imperial College London, J. WOODS HALLEY, ANDY SCHOFIELD, University of Minnesota — We have studied the oxidation of magnetite to Fe_2O_3 in an electrolytic cell in which the cathode is magnetite and the anode is platinum. We report cyclic voltammogram data consistent with the hypothesis that magnetite, without oxygen gas production but with hydrogen gas production at the anode, is occurring. The reaction occurs at a potential at the cathode of about 0.3V vs SCE in 1M NaOH electrolyte, consistent with colloid experiments which also estimated the equilibrium potential of the hypothesized reaction. We find currents on the order of a milliamp per gram of magnetite electrode with the pelletized magnetite powder electrodes which we are using. Electrode characterization results using BET, XDS and macroscopic volume and mass measurements are reported, as well measurements of the amount of hydrogen gas generated per unit current. The quantity of gas generated is also consistent with our hypothesis concerning the electrode chemistry. Some samples exhibit evidence of two oxidation reactions occurring at the cathode and a possible interpretation of these is also discussed.

¹This work was supported by a grant from the Center for Urban and Regional Affairs at the University of Minnesota and by the University of Minnesota Supercomputing Institute.

K1.00221 Interfacial Electron Transfer from a PbSe Ququantum Dot into the TiO_2 Surface¹, RUN LONG, Department of Chemistry, University of Rochester, NY 14627 USA; School of Chemical & Bioprocess Engineering, University College Dublin, Ireland, OLEG PREZHDO, Department of Chemistry, University of Rochester, NY 14627 — We report an *ab initio* nonadiabatic molecular dynamics (NAMD) simulation of ultrafast photoinduced electron transfer (ET) from a PbSe quantum dot (QD) into the rutile TiO_2 (110) surface. The simulation supports the observation that the ET successfully competes with energy losses due to electron-phonon relaxation. The ET proceeds by the adiabatic mechanism due to strong donor-acceptor coupling. High frequency polar vibrations of both QD and TiO_2 promotes the ET, since these modes can rapidly influence the donor-acceptor state energies and coupling. Low frequency vibrations generate a distribution of initial conditions for ET, which shows a broad variety of scenarios at the single-molecule level. The system exhibits diverse scenarios for individual electron injection events, involving a complex interplay of ET mechanisms, time scales, and phonon dynamics.

K1.00222 Semiconducting (Half-Metallic) Ferromagnetism in Mn(Fe) Substituted Pt and Pd Nitrides, SAMIR MATAR, ICMCB-CNRS, Université de Bordeaux, France, VOLKER EYERT, www.materialsdesign.com — Using first principles calculations as based on density functional theory, we propose a class of so far unexplored diluted ferromagnetic semiconductors and half-metals. Here, we study the electronic properties of recently synthesized *4d* and *5d* transition metal dinitrides. In particular, we address Mn- and Fe-substitution in PtN_2 and PdN_2 . Structural relaxation shows that the resulting ordered compounds, $\text{Pt}_{0.75}(\text{Mn,Fe})_{0.25}\text{N}_2$ and $\text{Pd}_{0.75}(\text{Mn,Fe})_{0.25}\text{N}_2$, maintain the cubic crystal symmetry of the parent compounds. On substitution, all compounds exhibit long-range ferromagnetic order. While both $\text{Pt}_{0.75}\text{Mn}_{0.25}\text{N}_2$ and $\text{Pd}_{0.75}\text{Mn}_{0.25}\text{N}_2$ are semiconducting, Fe-substitution causes half-metallic behavior for both parent materials.

K1.00223 Time-dependent Partition Density-functional Theory, MARTIN MOSQUERA, ADAM WASSERMAN, Purdue University — We present an extension of time-dependent density functional theory that allows to partition the time-dependent external potential in terms of localized molecular fragment potentials. As a consequence, localized time-dependent densities arise for each molecular fragment. To enforce the condition that the sum of fragments must add up to the exact total density, a new quantity termed “time-dependent partition potential” is introduced. The Runge-Gross theorem is employed to show that there is a quasi one-to-one correspondence between the partition potential and the electronic density. The corresponding quantum-mechanical actions are derived by using the van Leeuwen’s action and are used to derive a decomposition of the partition potential which allows for practical approximations. Linear response formulas are deduced to obtain the transition energies, and an approximation is suggested to obtain localized excitations in large molecular systems. Finally, numerical illustration of our theory is shown for one-dimensional fermions under the influence of a laser field.

K1.00224 A Density Functional Approach to High Harmonic Generation¹, MICHAEL MACK, DANIEL WHITENACK, Purdue University, ADAM WASSERMAN, Purdue University, THE SUSPENDERS TEAM — The role of the asymptotic behavior of the ground state exchange-correlation (xc) potential is examined for the case of high harmonic generation (HHG) in N_2 via Time-dependent Density Functional Theory (TDDFT) within the adiabatic approximation. High harmonic generation (HHG) is a high-energy phenomenon that has been theoretically investigated using the strong-field approximation (SFA) within the single active electron approximation (SAEA) for small molecules. In the case of N_2 , experimental results for characteristic features of the harmonic emission suggest a breakdown of those approximations. TDDFT bypasses the need for such approximations as it accounts for all the electrons in the system; however, it requires approximations to the xc-potential. We investigate how asymptotic corrections to the Local Density Approximation (LDA) xc-potential influence the HHG spectrum.

K1.00225 Measuring the Performance of Generalized Gradient Approximations in Solids, ZACHARY NAULT, A.C. CANCIO, Ball State University — There recently have been a number of generalized gradient approximations (GGA’s) developed to address a major limitation of the approach—the inability to model both energies and structural constants at the same time. We examine the performance for bulk systems of four different GGA exchange-correlation (XC) functionals: the PBE functional, best for energy calculations in molecules, the PBEsol functional developed to improve calculations of solid structures, the SOGGA functional developed to improve lattice constant calculations, and the VMT1 functional developed to improve atomization energy calculations without a loss in lattice constant accuracy. These XC functionals are tested on a set of 12 solids composed of metals, semiconductors, ionic metals, and transition metals. The plane-wave DFT code ABINIT was used to calculate the cohesive energy for each solid using each XC approximation. The bulk moduli and lattice constants were determined by fitting to the Murnaghan equation of state. We look particularly into how the use of a pseudopotential will effect the predictions of each model in comparison to experiment.

K1.00226 Investigating optical properties of Atmospheric gases using multi-color collocated Laser system: an application of elastic and inelastic backscattering, WATHEQ AL-BASHEER, KEVIN STRAWBRIDGE, Science and Technology Branch, Environment Canada, Center for Atmospheric Research Experiments, 6248 eight line, Egbert, ON, Canada L0L 1N0, SCIENCE AND TECHNOLOGY BRANCH, ENVIRONMENT CANADA, CENTER FOR ATMOSPHERIC RESEARCH EXPERIMENTS TEAM — The application of nanosecond pulsed lasers to probe optical properties of atmospheric gases by the application of elastic and inelastic backscattering mechanisms, is one of the most effective tools to investigate atmospheric gases effect on short and long term climate changes. Capabilities, properties, and limitations of newly built multi-color lidar (light detection and ranging) system at the CARE facility, Ontario, Canada, will be presented and thoroughly discussed. CARE’s setup utilizes elastic and inelastic backscattered signals of the second (532 nm), third (355 nm), and forth (266 nm) harmonic outputs of simultaneously employed YAG lasers, which are manipulated to investigate optical properties of ozone, water vapor, and nitrogen molecules up to 25 km geometrical altitude. In particular, by employing inelastic backscattering lidar signals of Raman nitrogen channel (386.7 nm) and Raman water vapor channel (407.5 nm), vertical profiles of water vapor mixing ratio (WVMR) from the near ground up to 12 km geometrical altitude are deduced, calibrated, and compared against WVMR profiles obtained from collocated radiosonde launches. Furthermore, a detailed theoretical treatment to the lidar technique will be presented and related to recent experimental findings.

K1.00227 Nonspherical structure of aqueous organic nanodroplets¹, BARBARA E. WYSLOUZIL, HARSHAD PATHAK, Ohio State University, FAWAZ HRAHSEH, GERALD WILEMSKI, Missouri University of Science and Technology — The structure of nanodroplets plays a critical role in many natural phenomena involving atmospheric nucleation and aerosol formation. Here, we review our experimental and theoretical work on the structure of nonane/water nanodroplets. The experiments involve small angle x-ray scattering (SAXS) of nanodroplets formed in supersonic nozzles. Classical density functional theory (DFT) calculations of species density profiles are made in cylindrical coordinates, which allows for the possibility of non-spherical droplets under appropriate conditions. One key theoretical result is the occurrence of a nonspherical Russian-Doll (RD) structure at low temperatures that is confirmed by molecular dynamics (MD) simulations. Some, but not all, of the measured SAXS spectra can be well-fit by a simple RD model, but the poor x-ray contrast between nonane and deuterated water generally makes it difficult to distinguish among well-mixed, core-shell, and RD structural models.

K1.00228 Investigation of Forces Exerted During the Expansion of Nanomechanically Tensioned Organosilica Materials, THERESA ALBON, PAUL EDMISTON, SUSAN LEHMAN, The College of Wooster, Wooster, OH — Osorb® is a sol-gel derived organosilica that instantaneously swells up to four times in volume with organic liquids. The nanoporous glass-like material is hydrophobic and does not swell in water but absorbs non-polar organic solutes from aqueous solution. Swelling due to absorption of organic solutes, liquids, or gases leads to the generation of substantial mechanical force, presumably derived from the relaxation of the interconnected network of organosilica nanoparticles that comprise the material. We have investigated the force exerted by placing a powdered sample in a cylinder with a freely movable piston. As solvent percolates into the cylinder from below, the exerted force is measured by a load cell. The piston is then gradually moved upward to allow the material to expand. As the sample just begins to swell, we have routinely observed forces in excess of 500 N per gram; the exerted force then decreases as the volume is allowed to increase. The relationship between the exerted force and sample volume is shown to be exponential, and we define the exponential decay constant as the characteristic volume V_C . We also determine the absorption capacity and fractional change in volume of the organosilica samples, and correlate these with changes in V_C .

K1.00229 2D IR Spectroscopy of Nucleic Acid Bases and the Folding of DNA Aptamers, CHUNTE SAM PENG, KEVIN C. JONES, CARLOS BAIZ, MICHAEL E. REPPERT, HELENA DE PUIG GUIXE, KIMBERLY HAMAD-SCHIFFERLI, ANDREI TOKMAKOFF, MIT, TOKMAKOFF COLLABORATION, HAMAD-SCHIFFERLI COLLABORATION — DNA can adopt a wide variety of conformations that have important roles in their biological functions, such as DNA packaging, replication, and protein recognition. Vibrational spectroscopy is known to reflect DNA conformation, and basic assignments of resonances in the IR and Raman spectra of nucleic acids have existed for decades. However, traditional spectral assignments are based on simple local vibrational mode basis such as C=O and C=N double bond stretches, although computational studies describe highly delocalized vibrations. We acquired polarization dependent 2D IR spectra of the base vibrations of five nucleotide monophosphates (NMPs) as the building blocks for developing a model of DNA and RNA vibrational spectroscopy. The distinctive cross-peaks between the vibrational modes of NMPs, such as ring vibrations and C=O stretches, indicate that these vibrational modes are strongly coupled anharmonic oscillators. We have characterized the eigenstate energies, vibrational anharmonicities, transition dipole strengths, and their relative orientations through the analysis and modeling of the experimental 2D IR spectra. We are currently applying this knowledge to study the folding of some G-rich DNA aptamers.

K1.00230 Intense-field ionization of heterocyclic organic molecules: fragmentation and metastable states¹, DAVID FOOTE, TIM SCARBOROUGH, CORNELIS UITERWAAL, University of Nebraska, Lincoln — Pyridine and the diazine molecules (pyridazine, pyrimidine, and pyrazine) are ionized by intense-field, ultrafast (50 fs), 800 nm laser pulses, and the resulting ion mass spectra are recorded as a function of laser intensity (ranging from $\sim 10^{13}$ W/cm² to $\sim 10^{15}$ W/cm²). Log-log plots of ion yield vs. intensity suggest resonance-enhanced multiphoton ionization (REMPI) mechanisms. These measurements are made possible by a unique tuning of the time of flight mass spectrometer that eliminates the focal volume effect in the ion yields. We also report on the fragmentation of the molecular ions under these same conditions. Fragment ion yields vary greatly when measured from different molecular parents, even those coming from the same mass. Furthermore, we observe evidence of metastable decays in the ion mass spectrometer, and measure the decay product mass by deliberately detuning the potentials on the time of flight mass spectrometer. This result is presented as a method of determining the nature of the metastable fragments—their masses and kinetic energy distributions.

K1.00231 Photoionization cross sections of atomic impurities in spherical quantum dots¹, CHIH-YUAN LIN, Y.K. HO, Institute of Atomic and Molecular Sciences — Quantum dots with atomic impurities have attracted considerable attention due to not only its theoretical but also practical significance. The confinement potentials associated with the structure of quantum dots are often described by the rectangular potential well or harmonic oscillator potential. However, the non-parabolic shape at the center for the rectangular well and the infinite depth for the harmonic oscillator potential make the models unrealistic in practical applications. Recently, the finite oscillator and Gaussian potentials are proposed to mimic the spherical quantum dots, which are defined respectively as $V_{FO}(r) = -A(1 + Br/\sqrt{A}) \exp(-Br/\sqrt{A})$ and $V_G(r) = -C \exp(-r^2/D^2)$ with the confining strengths A and C, and the radii of quantum dots 1/B and D. In this work, the method of complex-coordinate rotation in the finite-element discrete variable representation is implemented to study the photoionization of atomic impurities in spherical quantum dots. We explore the energy spectra and photoionization of atomic impurities influenced by the quantum confinement. The shifting of Cooper minima caused by the quantum confinement is observed.

K1.00232 A DFT Study of Palladium Clusters and their Reactions with H₂ and O₂: Application to catalyzed H₂O₂ synthesis¹, ADAM PELZER, Central Michigan University/Argonne National Lab, KOBLAR JACKSON, Central Michigan University, JULIUS JELLINEK, Argonne National Lab — Adsorption of oxygen and hydrogen in both atomic and molecular forms on small Pd_n clusters (n=2-13 and 19) is investigated using density functional theory. An extensive search for the energetically preferred structural forms and spin states of the clusters is performed. The geometries and energetics of the cluster-adsorbate systems and their transition states are mapped out as well. Cases of both single and multiple adsorptions are considered, and trends in the saturation coverage of the clusters versus cluster size are examined. Edge sites are found to be energetically preferred for O₂ adsorption, whereas the atop sites favor binding of H₂. Atomic adsorption of hydrogen is examined as well and limits to the number of H atoms that can be dissociated on each size cluster are found. In order to understand how trends in the results extend to larger cluster sizes, limited calculations have also been performed for Pd₅₅. The role of Pd_n clusters as catalysts for production of H₂O₂ from H₂ and O₂ is discussed as well.

K1.00233 Morphologies of an anisotropic diffusion limited growth model to study electroless deposition¹, STEPHEN M. KUEBLER, Department of Chemistry and The College of Optics and Photonics, University of Central Florida, CHRISTOPHER J. CLUKAY, Department of Chemistry, University of Central Florida, ANIRUDDHA DUTTA, Department of Physics, University of Central Florida, CHRISTOPHER N. GRABILL, Department of Chemistry, University of Central Florida, HELGE HEINRICH, Department of Physics and The Advanced Materials Processing and Analysis Center, University of Central Florida, ANIKET BHATTACHARYA, Department of Physics, University of Central Florida — We report results of Monte Carlo simulation of a model which mimics certain aspects of electroless deposition of metals on polymeric surfaces. In the proposed model growth germinates from certain “active” particles residing on a flat surface. Further growth occurs via sticking of a diffusing particle while it is within the range of one of these active particles. Once within the attractive range of an “active” particle, the motion of the approaching particle is considered ballistic. This newly adsorbed particle then acts as an “active” site for further growth and the process continues. We monitor the layer by layer density variation, the pair correlation function and the structure factor as a function of the initial density of the particles and the range of the reaction, and comment on the fractal aspect of the morphology.

K1.00236 Magneto-optical contrast in liquid-state optically-detected NMR spectroscopy, DANIELA PAGLIERO, CARLOS MERILES, Physics Department. City College of New York. CUNY — We use optical Faraday rotation (OFR) to probe nuclear spins in real time at high-magnetic field in a range of diamagnetic sample fluids [1]. This technique is shown to spectiate functional groups with the same chemical shifts as is seen in conventional NMR, however, the intensities of the OFR-NMR peaks are influenced by optical detuning and hyperfine couplings. We investigate protons at chemically-distinct sites and other lower-gyromagnetic-ratio nuclei including carbon, fluorine and phosphorous [2]. Binary mixtures for protonated systems were also tested and the results suggest that the present approach is sensitive to the solvent-solute dynamics in ways complementary to those known in inductive NMR.

[2] D. Pagliero and C. A. Meriles. *Proc. Natl. Aca. Sci. USA* (2011) in press.

K1.00237 Hypo/hyperchromy in orthorhombic molecular crystals: Fluorene, and Dibenzofuran¹, ZAHRA NASROLLAHI, Department of Physics, University of Florida, Gainesville, Florida 32611, USA, LENINA NAKHIMOVSKY, Chemistry Department, Stony Brook University, Stony Brook, NY 11794, USA, JOHN TRUNK, Biology Department, Brookhaven National Laboratory, Upton, NY 11973, USA, D.B. TANNER, Department of Physics, University of Florida, Gainesville, Florida 32611, USA — The transmission of Fluorene and Dibenzofuran molecular crystals was measured over the near ultraviolet to vacuum ultraviolet (4-10 eV) range at the National Synchrotron Light Source. Polarized spectra were measured for both *a* and *b* crystallographic axes, and the spectrum in the *c* direction was found using the spectrum of a 40° rotated sample. Oscillator strengths were calculated by fitting the data to the Drude-Lorentz model. Comparison of the oscillator strength in the gas phase and in crystal show significant differences. These differences are attributed to the effect of intermolecular interaction in these molecular crystals.

K1.00238 Superradiant light source for atmospheric remote sensing, DMITRI VORONINE, ANDREW TRAVERSO, RODRIGO SANCHEZ-GONZALEZ, LUQI YUAN, MICHAEL GRUBB, KAI WANG, ALEXEI ZHELTIKOV, Texas A&M University, College Station, TX 77843, ARTHUR DOGARIU, JAMES MICHAEL, RICHARD MILES, Princeton University, Princeton, NJ 08544, YURI ROSTOVTSSEV, University of North Texas, Denton, TX 76203, VLADIMIR SAUTENKOV, ALEXEI SOKOLOV, SIMON NORTH, MARLAN SCULLY, Texas A&M University, College Station, TX 77843 — We have studied coherent emission from ambient air and demonstrated efficient generation of laser-like beams directed both forward and backward with respect to a nanosecond ultraviolet pumping laser beam. The generated optical gain is a result of two-photon photolysis of atmospheric O₂, followed by two-photon excitation of atomic oxygen. We have analyzed the temporal shapes of the emitted pulses and have thereby shown that a large atomic coherence may well be responsible for the observed temporal structures. Our results suggest that the emission process is coherence brightened in its nature, and is to be compared with ordinary lasing where atomic coherence remains small on the one hand and cooperative Dicke superradiance where atomic coherence is maximized on the other. The collective coherence in this process adds insight as to the optical emission physics. The present superradiant source holds promise for remote sensing techniques employing nonlinear spectroscopy.

K1.00239 Estimating the contributions to the Low Energy Tail in Cu and Ag (100) using Positron Annihilation Auger Electron Spectroscopy¹, K. SHASTRY, P.V. JOGLEKAR, S. SATYAL, A.H. WEISS, Univ of Texas at Arlington — Low energy Auger lineshapes are difficult to measure because they sit on a large background due to secondary electrons arising from loss processes unrelated to the Auger mechanism. In this poster we discuss the implications of our Positron Annihilation Auger electron Spectroscopy (PAES) measurements of the ratio of the integrated Auger Peak and integrated low energy tail (LET) intensities for comparisons between theoretical and measured values of the Auger intensities. The experiments were carried out at university of Texas at Arlington on Ag (100) crystal. The various contributions to the low energy tail are highlighted in terms of processes intrinsic and extrinsic to the Auger mechanism. Our conclusions regarding the importance of the LET in determining the ratio of electrons in the Auger peak to the number of initial core holes are discussed in light of the electron stimulated Auger results obtained by Seah et al. using monte carlo simulations on various elements.

K1.00240 Peroxynitrous Acid Dimer: Ab Initio Density Functional Study, RAJEEV PATHAK, Department of Physics, University of Pune, Pune 411007, MH, India — Peroxynitrous acid (PNA) HOONO, isomeric to nitric acid, is a very strong oxidant. A novel *dimeric* hydrogen-bonded cluster of peroxynitrous acid (PNA-D) is proposed herein; *ab initio* quantum chemical investigations performed whereupon lead to several stable structures that have a direct bearing on the reactivity of the participating monomers, quantified in terms of the molecular electrostatic potential. The electron-correlation lending stability to PNA and its dimers is gauged through several density functionals namely B3LYP, B3PW91, M06-2X, M06-L, and ω -B97X, etc.; as well as from popular wave-function based second order Møller-Plesset (MP2) perturbation theory, using the basis sets 6-311++G(d,p) and 6-311++G(2d,2p). The infra-red vibrational spectra reveal spectral shifts and intensity redistribution after dimerization. While the lowest energy PNA-D has a perfect inversion symmetry; the other stable dimers emerge as combinations of monomers in different orientation.

K1.00241 High resolution infrared spectra of protonated benzene isolated in solid parahydrogen, YU-JONG WU, National Synchrotron Radiation Research Center, MOMO BAHOU, YUAN-PERN LEE, Department of Applied Chemistry, National Chiao Tung University, NSRRC COLLABORATION, NCTU COLLABORATION — Identification of infrared (IR) spectra of protonated polyaromatic hydrocarbons (PAH) is important in understanding the unidentified IR bands of interstellar media. We demonstrate a new method that is superior to the Ar-tagging IR photodissociation or the IR-multiphoton-dissociation (IRMPD) methods currently used. The protonated benzene ($C_6H_7^+$) was produced on electron bombardment of a mixture of benzene (C_6H_6) and *para*-hydrogen ($p\text{-}H_2$) during deposition. IR features of $C_6H_7^+$ and C_6H_7 were identified by observing the change in intensity upon photolysis and comparison with theoretical calculations. Lines of $C_6H_7^+$ decreased in intensity when the matrix was irradiated with light at 365 nm, those of C_6H_7 increased in intensity. Similar experiments were performed for a sample of $C_6D_6/p\text{-}H_2$ and the production of $C_6D_6H^+$ was confirmed. Observed wavenumbers, relative IR intensities and deuterium isotopic shifts agree with those predicted for $C_6H_7^+$ and C_6H_7 . Compared with previous methods, this method provides a wider spectral coverage with much narrower lines and more accurate relative IR intensities, and may be readily applied to larger protonated and neutral PAH.

K1.00242 Pressure-temperature surface phase diagrams of $LaMnO_3$ surfaces in oxidative environments from first principles based kinetic Monte Carlo simulations¹, GHANSHYAM PILANIA, R. RAMPRASAD, University of Connecticut — Perovskite oxide surfaces catalyze many important oxidation reactions. They are also promising for oxygen ion conducting cathode materials in solid oxide fuel cells and efficient catalytic components for removal of NO_x gases in auto exhausts. Oxygen interaction with perovskite surfaces is of central importance in all such above mentioned technologically relevant examples. Here, we have employed first-principles based kinetic Monte Carlo (kMC) simulations to investigate the relative stability of the clean as well as molecular and atomic oxygen covered $LaMnO_3$ surfaces over a vast range of temperatures and oxygen partial pressures. The energetics as well as the activation energies of various surface reactions (adsorption, desorption, surface dissociation, and the surface diffusion of molecular and atomic oxygen) were computed and used in large-scale kMC simulations to predict the surface oxygen content and configuration at various combinations of temperature and pressure, thereby yielding a surface phase diagram. Owing to the state-of-the-art theory, algorithms and computations employed, these results are believed to represent the real situation with high fidelity. The phase boundaries as predicted by our kMC simulations are identified to be the catalytically active regions.

K1.00243 A New Technique for the Direct Determination of the Quasi-free Electron Energy in Dense Fluids, YEVGENIY LUSHTAK, CHERICE EVANS, Queens College – CUNY and the Graduate Center – CUNY, New York, NY, GARY FINDLEY, University of Louisiana at Monroe, Monroe, LA — Previous experimental studies of the quasi-free electron energy $V_0(\rho)$ in fluids of density ρ either directly measured $V_0(\rho)$, using photoemission from an electrode immersed in the fluid, or extracted $V_0(\rho)$ from field ionization of a dopant dissolved in the fluid. We present a new method to determine $V_0(\rho)$ directly, namely field enhanced photoemission. We show that this new method yields data of comparable quality to those obtained from dopant field ionization, thereby greatly improving on prior direct photoemission studies. Moreover, unlike dopant field ionization, field enhanced photoemission is not limited by the solubility of a dopant in the fluid of interest.

The experimental measurements reported here were performed at the University of Wisconsin Synchrotron Radiation Center (NSF DMR-0537588). This work was supported by grants from the Petroleum Research Fund (45728-B6) and from the National Science Foundation (NSF CHE-0956719).

K1.00244 Nonequilibrium Phase Transitions in Supercooled Water, DAVID LIMMER, DAVID CHANDLER, University of California, Berkeley — We present results of a simulation study of water driven out of equilibrium. Using transition path sampling, we can probe stationary path distributions parameterize by order parameters that are extensive in space and time. We find that by coupling external fields to these parameters, we can drive water through a first order dynamical phase transition into amorphous ice. By varying the initial equilibrium distributions we can probe pathways for the creation of amorphous ices of low and high densities.

K1.00245 Investigating the Glass Transition Temperature of Water using a Variety of Models and Methods via Molecular Dynamics Simulation, JOHN MURYN, Baldwin-Wallace College, GARY LEUTY, MESFIN TSIGE, Department of Polymer Science, The University of Akron — In everyday life, we think of solid water existing as crystalline ice. The majority of water in the universe, however, exists as an amorphous solid or “glassy” form. This glassy form has garnered significant interest and sparked sizable debate in recent years over the nature and conditions surrounding the transition from liquid to amorphous solid, not the least of which centers on the determination of the glass transition temperature. Previous experimental studies have suggested a glass transition temperature below the temperature at which water undergoes homogeneous nucleation, thus making experimental determination of the glass transition temperature difficult because of the need to avoid ice formation. In this study, we have used molecular dynamics simulation to study the structure, order and dynamics of water molecules at small timescales and under rapid cooling conditions to elucidate the formation of the amorphous solid and better understand the glass transition. Constant-pressure and constant-volume simulations have been performed in order to examine convergence or divergence of water dynamics under differing conditions. In addition, the van der Waals energy of simulation systems has been examined in an attempt to identify the glass transition temperature in a way that, to our knowledge, has not previously been used. Results suggest a glass transition temperature higher than previous widely accepted values but comparable to more recent results.

K1.00246 Ion size effects on the electrokinetics of spherical particles in salt-free concentrated suspensions¹, RAFAEL ROA, FELIX CARRIQUE, Fisica Aplicada I, Universidad de Malaga, EMILIO RUIZ-REINA, Fisica Aplicada II, Universidad de Malaga — In this work we study the influence of the counterion size on the electrophoretic mobility and on the dynamic mobility of a suspended spherical particle in a salt-free concentrated colloidal suspension. Salt-free suspensions contain charged particles and the added counterions that counterbalance their surface charge. A spherical cell model approach is used to take into account particle-particle electro-hydrodynamic interactions in concentrated suspensions. The finite size of the counterions is considered including an entropic contribution, related with the excluded volume of the ions, in the free energy of the suspension, giving rise to a modified counterion concentration profile. We are interested in studying the linear response of the system to an electric field, thus we solve the different electrokinetic equations by using a linear perturbation scheme. We find that the ionic size effect is quite important for moderate to high particles charges at a given particle volume fraction. In addition for such particle surface charges, both the electrophoretic mobility and the dynamic mobility suffer more important changes the larger the particle volume fraction for each ion size. The latter effects are more relevant the larger the ionic size.

K1.00247 Modeling the transport of binary fluid/nanoparticle mixtures through microchannels with ciliated walls, YONGTING MA, AMITABH BHATTACHARYA, OLGA KUKSENOK, University of Pittsburgh, Pittsburgh, PA 15261, DENNIS PERCHAK, Kodak Research Laboratories, Rochester, NY 14650, ANNA C. BALAZS, University of Pittsburgh, Pittsburgh, PA 15261 — We study the dynamic behavior of nanoparticle-filled binary fluids that are driven through a microchannel with ciliated walls. To carry out these studies, we use a hybrid computational approach that combines the lattice Boltzmann model for binary fluids and a Brownian dynamics model for the nanoparticles. The ciliated walls of the microchannels are composed of flexible filaments that are modeled as beads connected by elastic springs. This hybrid model allows us to capture the interactions between the binary fluids, nanoparticles, and the hairy walls. We show that the process of capillary filling of such microchannels strongly depends on the rigidity of the hairs, their grafting density, and their affinity to the fluid components and nanoparticles. We demonstrate that by tailoring the properties of the nanoparticles, one can effectively control not only the velocities of the capillary filling, but also the deposition of nanoparticles on the hairy walls, and hence dynamically alter the properties of these ciliated surfaces. Our findings provide fundamental insights into the dynamics of this complex system, as well as potential guidelines for technological processes involving capillary filling with nanoparticles in a structured flexible porous medium.

K1.00248 Roles of Low Molecular Weight Amide on Crystallization Behavior of Poly (L-lactic acid)¹, XIA DONG, QIAN XING, XIUQIN ZHANG, DUJIN WANG, Institute of Chemistry Chinese Academy of Sciences — Organic nucleating agents play an important role in enhancing the crystallization rate of polymers. The aim of this study is to investigate the effect of low molecular weight aliphatic amides on the crystallization behavior and mechanism of poly (L-lactic acid) (PLLA). The crystallization rate of PLLA during non-isothermal crystallization and isothermal crystallization has been significantly improved with the addition of N, N'-ethylenebis (12-hydroxystearamide) (EBH) and/or N, N'-ethylenebisstearamide (EBSA), and EBH exhibits stronger nucleating ability. Time-resolved FTIR spectra illustrate the chain conformational changes and the crystallization kinetics during isothermal crystallization of PLLA mixtures and pure PLLA, especially in the early stages. The formation of interchain conformational-ordered structure and intrachain 103 helix structure for amide-doped PLLA precedes that of pure PLLA, suggesting a stimulatory nucleating effect of EBH and EBSA. In the case of PLLA/EBH, the interchain interactions of -(COC+CH3) and -CH3 groups are faster than the -(CH3+CC) intrachain interactions, while the interchain interactions and the intrachain 103 helix formation are nearly synchronous for PLLA/EBSA, indicating that EBH has an improved effect on the nucleating ability and crystallization kinetics of PLLA, compared to EBSA. The possible mechanism has been discussed, which may be attributed to the hydrogen bond interaction between hydroxyl groups in EBH and the carbonyl groups in PLLA.

K1.00249 Ion Energy Distribution Studies of Ions and Radicals in an Ar/H₂ Radio Frequency Magnetron Discharge During a-Si:H Deposition Using Energy-Resolved Mass Spectrometry, SAMUEL MENSAH, University of Arkansas, HUSAM ABU-SAFE, Labanese American University, Byblos, HAMEED NASEEM, University of Arkansas, MATT GORDON, Denver University — Ion energy distributions of sputtered Si particles have been measured by an energy-resolved mass spectrometer, and we correlate the results with measured thin film properties. The plasmas have been generated in a conventional magnetron chamber powered at 150W, 13.56MHz at hydrogen flow rates ranging from 0-25sccm. Various H_n⁺, SiH_n⁺, SiH_n fragments (with n = 1, 2, 3) together with Ar⁺ and ArH⁺ species were detected in the discharge. The most important species for the film deposition is SiH_n with n = 0,1,2, and H fragments affect the hydrogen content in the material. The flux of Ar⁺ decreases and that of ArH⁺ increases when the hydrogen flow rate was increased. However both fluxes saturate at hydrogen flow rates above 15sccm. Plasma parameters, such as plasma potential V_p, electron density n_e and electron energy T_e, are measured with the Langmuir probe. The ion energy distribution (IED) of all prominent species in the plasma is measured with an energy resolved mass analyzer. The plasma parameters decreased with increasing hydrogen flow rate; V_p, n_e and T_e decreased from 36.5V, 7.2x10¹⁵ m⁻³, 5.6eV to 32.8, 2.2x10¹⁵ m⁻³ and 3.8eV respectively. The ion energy of the heavy species, Ar, Ar⁺, ArH, ArH⁺, SiH and SiH_n⁺ radicals have ion energies comparable to the plasma potential. Analysis of the IEDs shows an inter-dependence of the species and their contribution to the thin film growth and properties.

K1.00250 Calculation of exciton binding energy and electron-hole recombination probability in quantum dots using explicitly correlated electron-hole wavefunction based method, ARINDAM CHAKRABORTY, Syracuse University — Accurate description of electron-hole correlation plays a central role in describing optical properties of quantum dots. This talk will focus on development of explicitly correlated wavefunction based methods for accurate treatment of electron-hole correlation. In this method, the wavefunction depends explicitly on the electron-hole inter-particle distance (R12) term and electron-hole wavefunction is obtained using variational procedure by minimizing the total energy. In inclusion of R12 term allows for a better description of wavefunction at small electron-hole distances and is found to be crucial for calculation of accurate electron-hole recombination probability and binding energy. The 2-particle electron-hole reduced density matrix (2-RDM) is obtained from the optimized wavefunction and the electron-hole recombination probability is computed from the diagonal elements of the 2-RDM. The developed method is applied to InGaAs/GaAs, CdSe/ZnS, and InP/InGaP quantum dots and exciton binding energy and electron-hole recombination probability are computed for a range of dot sizes. The computed results are compared with experimental results and path-integral Monte Carlo and configuration interaction calculations.

K1.00251 The Use of Confocal Raman Spectroscopy to Quantitatively Study the Interactions Between Immersive Water and Graphene/Graphene Oxide Surfaces, HANNAH NARCROSS, BYUNG HO JEON, JONG-WON LEE, CHANG YEOL RYU, Rensselaer Polytechnic Institute — The unique mechanical, chemical, optical, and electrical properties of graphene allow for many potential applications in biomaterials. Understanding and quantifying the surface interactions between graphene/graphene oxide and aqueous liquid is essential for the design of such graphene-based nanocomposites. Graphene sheets were produced by the mechanical exfoliation of graphite. We have used depth Confocal Raman Spectroscopy (CRM) profiles to measure graphene wettability using a water immersive objective lens, and demonstrated how surface energy between graphene/graphene oxide and immersive aqueous liquid can be affected to simultaneously measure the depth image profiles. Contact angles were also measured to further investigate the compatibility between graphene/graphene oxide and its environment.

K1.00252 Preparation and anisotropy of large-scale lyotropically aligned functionalized multilayer graphene, QIZHEN LIANG, XUXIA YAO, WEI WANG, C.P. WONG, Georgia Institute of Technology — Comparing with ballistic electron and phonon transport along graphene sheets, phonon and electron transferring traversing stacked graphene layers are conducted by weak Van der Waals forces and hopping conduction so that inevitably debate mechanical, electrical and thermal properties in "out-of-plane" direction. Alignment of graphene sheets can orient covalent chemical bonds in these parallel planes, resulting in a strong anisotropy of the large-scale materials from various graphitic forms with optimized mechanical, electrical and thermal properties. Moreover, systematic characterizations of the anisotropy of the ordered structures are rarely available due to their low profile in thickness directions. Here, conductors with highly ordered lamellar structure in large scale are prepared at room temperature from functionalized multilayer graphene (fMGs) by a lyotropical alignment methodology. Distinct difference in mechanical, electronic and thermal properties between lateral (in-plane) and thickness (out-of-plane) directions of the aligned fMGs indicates a strong anisotropy. Benefiting from the anisotropy, ultrahigh electrical and thermal conductivities in lateral direction are obtained, without aid of any chemical or thermal reduction. The finding facilitates the potential large-scale preparation and application of multilayer graphenes in photonic and electronic components, electrodes for energy collectors, conductive polymeric adhesives and composites.

K1.00253 Using computational chemistry to understand proton transfer in Green Fluorescent Protein¹, CHRISTA HOSKIN, PAUL CHAMPION, TIMOTHY SAGE, ABDELKRIM BENABBAS, ALEXANDER DEMIDOV, BRIDGET SALNA, Northeastern University, JASPER VAN THOR COLLABORATION², LEE THOMPSON COLLABORATION³ — Green Fluorescent Protein has been studied experimentally by the scientific community for years yet frustratingly little is known about the underlying proton transfer process that produces the green fluorescence. We are trying to elucidate more about this process using Density Functional Theory to prepare and run various calculations on GFP that we compare with kinetics data, Raman and vibrational coherence spectra. I am building a model of wild type GFP that is realistically sized for our computational power, yet still contains key residues that might affect the proton transport process. I will compare my results to those of the E222D GFP mutant. This comparison will allow us to see any differences in energy and normal modes that give insights regarding the proton transfer process. For example, how does it depend on a variety of factors such as temperature, buffer, pH, mutations, etc.? We also plan to examine if the proton transfer propagates through the three donor-acceptor pairs of the “proton wire” consecutively versus the three protons on the wire transferring simultaneously. Finally, we will consider how quantum tunneling may be involved in the proton transfer.

K1.00254 ABSTRACT WITHDRAWN —

K1.00255 ATOMIC, MOLECULAR AND OPTICAL PHYSICS —

K1.00256 MEST-The quantum space-time explain some questions of quantum mechanics, DAYONG CAO, Beijing Natural Providence Science & Technology Development Co., Ltd — The probability of displacement and period of wave are the quantum space-time. The paper explain of the two-slit interference and the uncertainty relation. (1) $S = P(r) = P(\lambda) = f^2$. According to the Benford's law, (2) $T = P(t) = \ln(1 + \frac{1}{t}) = \nu$. Among it, S: the quantum space, f: the amplitude, r: the displacement, T: the quantum time, t: the period, ν : the frequency, λ : the wavelength, P(x): the probability function. (3) $E'\psi = i\hbar \frac{\partial \psi}{\partial t}$. (4) $m'\psi = i\hbar \frac{\partial \psi \partial t}{(\partial x)^2}$, equation (3) over equation (4), substituting equation (1) and (2) into it, (5) $E'\psi = m'\psi c'^2 = m'\psi \frac{(\partial f^2)^2}{(\partial \nu)^2}$, getting the energy-wave and mass-wave equation, (6) $E' = i\hbar \frac{\partial f^2}{\partial \nu}$. (7) $m' = i\hbar \frac{\partial \nu}{\partial f^2}$. (8) $\Delta E' \Delta \nu = \Delta E' \Delta t = i\hbar \Delta f^2$, ($\Delta f^2 \geq \frac{1}{2}$). (9) $\Delta p' \Delta f^2 = \Delta p' \Delta \lambda = i\hbar \Delta f^2$, ($\Delta f^2 \geq \frac{1}{2}$). Among it, E' : the energy of wave, m' : the mass of wave, c' : the velocity of light, ψ : the Wave Functions, f^2 : the probability. Here, the equation (8) and (9) are new uncertainty relation. In the two-slit interference, because (10) $c' = \frac{\lambda}{t} = \frac{f^2}{t}$, so (11) $f^2 = \lambda(\text{the wavelength})$, so (12) $\lambda \geq d$ (the width of the slits). Measuring the time of light at one slit(1) and its energy at other slit(2) together. And the measuring probability, if (13) $f_1^2 \geq \frac{1}{2}, f_2^2 \geq \frac{1}{2}, f_1^2 = f_2^2, (f_1^2 + f_2^2) \leq 1$, then (14) $f_1^2 = f_2^2 = \frac{1}{2}$.

K1.00257 Initial-state dependence of the quench dynamics in integrable quantum systems¹, MATTIAS FITZPATRICK, Middlebury College, MARCOS RIGOL, Georgetown University — We identify and study classes of initial states in integrable quantum systems that, after the relaxation dynamics following a sudden quench, lead to near-thermal expectation values of few-body observables. In the systems considered here, those states are found to be insulating ground states of lattice hard-core boson Hamiltonians. We show that, as a suitable parameter in the initial Hamiltonian is changed, those states become closer to Fock states (products of single site states) as the outcome of the relaxation dynamics becomes closer to the thermal prediction. At the same time, the energy density approaches a Gaussian. Furthermore, the entropy associated with the generalized canonical and generalized grand-canonical ensembles, introduced to describe observables in integrable systems after relaxation, approaches that of the conventional canonical and grand-canonical ensembles. We argue that those classes of initial states are special because a control parameter allows one to tune the distribution of conserved quantities to approach the one in thermal equilibrium. This helps in understanding the approach of all the quantities studied to their thermal expectation values.

K1.00258 Many-body physics of optically excited, frozen Rydberg gases¹, DOMINIK MUTH, ACHIM LAUER, Fachbereich Physik und Forschungszentrum OPTIMAS, TU Kaiserslautern, Germany, JOHANNES OTTERBACH, Department of Physics, Harvard University, Cambridge, MA, USA, MICHAEL FLEISCHHAUER, Fachbereich Physik und Forschungszentrum OPTIMAS, TU Kaiserslautern, Germany — We discuss the many-body physics of an ensemble of optically excited Rydberg atoms with van der Waals dipole-dipole interactions [1]. Starting from a fully quantized model of the optical excitation we show that Rydberg excitations always possess a finite kinetic energy mediated by photon exchange even if the motion of the atoms can be disregarded. The kinetic energy competes with the repulsive vdW interactions. Using discretization and DMRG, we calculate the many-body ground state in the one-dimensional case. It is correlated much more strongly than possible for any local interaction, i.e., with a Luttinger parameter $K \ll 1$. In the presence of an additional lattice, a fractal phase diagram [2] emerges with Mott-insulating phases at any rational filling fraction. [1] see e.g. H. Weimer, R. Löw, T. Pfau, and H. P. Büchler; Phys. Rev. Lett. 101, 250601 (2008) [2] F. J. Burnell, M. M. Parish, N. R. Cooper, and S. L. Sondhi; Phys. Rev. B 80, 174519 (2009)

K1.00259 Topological insulators in cold-atom gases with non- Abelian gauge fields: the role of interactions, PETER P. ORTH, Karlsruhe Institute of Technology (KIT), DANIEL COCKS, MICHAEL BUCHHOLD, Institut fuer Theoretische Physik, Goethe Universitaet, 60438 Frankfurt/Main, Germany, STEPHAN RACHEL, Yale University, KARYN LE HUR, 1 Center for Theoretical Physics, Ecole Polytechnique, 91128 Palaiseau Cedex, France, 2 Yale University, WALTER HOFSTETTER, Institut fuer Theoretische Physik, Goethe Universitaet, 60438 Frankfurt/Main, Germany — With the recent technological advance of creating (non)- Abelian gauge fields for ultracold atoms in optical lattices, it becomes possible to study the interplay of topological phases and interactions in these systems. Specifically, we consider a spinful and time-reversal invariant version of the Hofstadter problem. In addition, we allow for a hopping term which does not preserve S_z spin symmetry and a staggered sublattice potential. Without interactions, the parameters can be tuned such that the system is a topological insulator. Using a combination of analytical techniques and the powerful real-space dynamical mean-field (R-DMFT) method, we discuss the effect of interactions and determine the interacting phase diagram.

K1.00260 Composite-pulse magnetometry in the solid-state , CLARICE AIELLO, MASASHI HIROSE, PAOLA CAPPELLARO, Department of Nuclear Science and Engineering, Massachusetts Institute of Technology — The sensitivity yielded by magnetometry schemes at the quantum level is limited by experimental imperfections in the interrogation pulses and, especially in the solid-state, by relatively short dephasing times. We investigate the use of composite-pulse magnetometry sequences as a means of addressing both limitations. We perform proof-of-principle experiments on magnetometry and noise characterization through a continuous sequence of rotary echoes applied to a single qubit in the nitrogen-vacancy center in diamond. The rotary echo is the simplest unit of a composite pulse sequence, consisting of two consecutive pulses of identical nominal rotation angle applied with opposite excitation phases. Unlike other composite sequences, the rotary echo corrects for excitation field, but not for static field, inhomogeneities. The presented scheme is flexible in that a suitable choice of rotation angle compensates for different scenarios of noise strength and origin (dephasing or fluctuations in excitation intensity). Obtained sensitivities are in the range between those obtained with the widely used Ramsey spectroscopy sequence and the recently implemented method relying on frequency beats in Rabi oscillations.

K1.00261 Atoms talking to SQUIDS¹ , J.E. HOFFMAN, J.A. GROVER, S. RAVETS, K.D. VOIGT, J. LEE, Z. KIM, A.K. WOOD, I. SCHOCH, J.R. ANDERSON, A.J. DRAGT, M. HAFEZI, C.J. LOBB, L.A. OROZCO, S.L. ROLSTON, J.M. TAYLOR, F.C. WELLSTOOD, Joint Quantum Institute, Department of Physics and National Institute of Standards and Technology, University of Maryland, College Park, MD 20742 — We present our advances towards a hybrid quantum system of ⁸⁷Rb atoms coupled to a superconducting flux qubit through the magnetic dipole transition. We plan to trap atoms in the evanescent field outside a 500 nm nanofiber. This will allow us to bring the atoms less than 5 μ m above the surface of the superconductor without producing excessive heating or changing magnetic fields. As an intermediate step, we plan on coupling the atoms to a superconducting LC resonator. Current progress includes production of nanofibers with >98% transmission, and a tunable high-Q superconducting resonator. Additionally, we show how to use our system as a unified interface for microwave and optical photons, in which the atoms act both as a quantum memory and transduce excitations between the two frequency domains. Using coherent control techniques, we examine conversion and storage of quantum information between microwave photons in superconducting resonators, ensembles of ultracold atoms, and optical photons as well as a method for transferring information between two resonators.

¹Work supported by the NSF through the PFC at JQI , and the ARO Atomtronics MURI.

K1.00262 Nonequilibrium steady state for strongly-correlated many-body systems: a variational cluster approach¹ , MICHAEL KNAP, WOLFGANG VON DER LINDEN, ENRICO ARRIGONI, Graz University of Technology — The understanding of the nonequilibrium behavior of strongly correlated quantum many-body systems is a long standing challenge, both in theory as well as in experiments. Here, we present a new numerical approach that allows to calculate nonequilibrium steady state properties of strongly correlated quantum many-body systems. The approach is formulated in the framework of Keldysh Green's functions and is based on the ideas of the variational cluster approach (VCA), which has been successfully applied to a variety of strongly correlated many-body systems in equilibrium. As in equilibrium VCA, one crucial aspect appears to be the variational procedure, consisting in a self-consistent adjustment of the equilibrium reference system to the nonequilibrium target state. We apply the presented approach to non-linear transport across a strongly correlated quantum wire described by the fermionic Hubbard model.

K1.00263 Two dimensional analysis of a free oscillation atom interferometer , RUDRA KAFLE, ALEX ZOZULYA, Worcester Polytechnic Institute, Worcester, MA 01609 — In a free oscillation atom Michelson interferometer, a Bose Einstein condensate in the ground state of a harmonic oscillator potential is split by a sequence of laser pulses and then the split wave packets are allowed to undergo a free oscillation. The wave packets are recombined at the splitting location after they make one or more full cycle oscillations. The motion of the wave packets becomes two dimensional if they are misaligned from the axis of the wave guide at the time of splitting. The dynamics of the split condensates becomes more complicated in this situation than a purely one dimensional oscillation. We develop a simple two dimensional model to analyze the effects of a slightly misaligned atomic wave packets on interferometry.

K1.00264 Exciton-polariton Vortex-Antivortex lattices in two-dimensional hexagonal potential geometries , NA YOUNG KIM, Stanford University, KENICHIRO KUSUDO, National Institute of Informatics, SVEN HOEFLING, ALFRED FORCHEL, University of Wuerzburg, YOSHIHISA YAMAMOTO, Stanford University — Microcavity exciton-polaritons possess the duality nature of wave and particle associated with the constituent particles, cavity photons and quantum well excitons. They are quantum bosons in the dilute density limit at low temperatures, exhibiting Bose-Einstein condensation (BEC) as a testbed to explore fundamental nature of physics. In particular, they are confined in two-dimensional plane, where exotic physical phenomena appear. Here, we discuss how to form vortex-antivortex lattices formed by exciton-polariton condensates trapped in two-dimensional hexagonal potential landscapes: triangular-, honeycomb- and Kagome- geometries. This will provide insights to investigate the BEC to Berenskii-Kosterlitz-Thouless transition.

K1.00265 Tunable Spin-orbit Coupling and Quantum Phase Transition in a Trapped Bose-Einstein Condensate , YONGPING ZHANG, GANG CHEN, CHUANWEI ZHANG, Department of Physics and Astronomy, Washington State University, Pullman, WA, 99164 USA — Spin-orbit coupling (SOC), the intrinsic interaction between a particle spin and its motion, is responsible for various important phenomena, ranging from atomic fine structure to topological condensed matter phenomena. While the SOC strength in typical solid state materials is much smaller than the Fermi velocity of electrons, it can reach the same order or even beyond the Fermi velocity of atoms in a recent breakthrough experiment that realizes SOC for ultra-cold atoms. However, the SOC strength in the experiment, determined by the applied laser wavelengths, is not tunable. Here we propose a scheme for tuning the SOC strength through a fast modulation of the laser intensities. We find that tuning SOC strength can drive a quantum phase transition (QPT) from a spin-balanced to a spin-polarized state in a harmonic trapped Bose-Einstein condensate (BEC). The QPT is similar as that in the long-sought Dicke model in quantum optics, which has important applications in quantum information. We characterize the QPT using the periods of collective oscillations (center of mass motion and scissors mode) of the BEC, which show pronounced peaks and damping around the quantum critical point.

K1.00266 Non-equilibrium spin dynamics in an ultra-cold gas , JEFFREY MCGUIRK, DORNA NIROOMAND, LYDIA ZAJICZEK, Simon Fraser University — We study spin dynamics in an out-of-equilibrium quantum gas. Using an optical technique, we imprint arbitrary one-dimensional spin structures in a trapped gas of Rb-87 atoms near quantum degeneracy. These spin structures can exhibit instabilities or lead to spin wave oscillations. The spin system has a highly nonlinear nature, and these spin waves can lead to collapse and revival of coherence. In particular, we measure spin currents in the ultra-cold gas, observe spatially localized collapse and revival of Ramsey fringe contrast, and show how the pattern of coherence depends on the strength of the spin-wave excitation. Lastly, we explore instabilities in the non-equilibrium spin system that can lead to spontaneous amplification of coherence.

K1.00267 Calculation of BEC transition using the Mathieu equation¹, QINQIN LU, Louisiana State University, KELLY PATTON, Seoul National University, DANIEL SHEEHY, Louisiana State University — While most calculations of the properties of bosons in optical lattices focus on the tight-binding Hubbard model regime, generally the single-particle states of bosons in an optical lattice satisfy the Mathieu equation. We have developed a formalism for studying bosons in an optical lattice using the Mathieu equation. The Mathieu equation formalism provides a natural way to explore physics in regimes where the Hubbard model description breaks down. We use this formalism to compute the momentum distribution of bosons in an optical lattice as probed in time-of-flight expansion, as well as finite size effects and signatures of the phase transition.

¹This work has been supported by the Louisiana Board of Regents, under grant LEQSF (2008-11)-RD-A-10.

K1.00268 A Theory of BCS-BEC Crossover, YASEMIN GURCAN, CUNY Graduate Center, J.L. BIRMAN, Distinguished Prof., CCNY, CUNY Graduate Center — In ultracold atomic fermions, the sign and the magnitude of pairing interactions can be controlled by using the magnetically-tuned Feshbach resonances to achieve a continuous transition between Cooper pairs of dilute fermi gas to BEC of diatomic molecules, which is known as the “BCS-BEC crossover.” At present, although several models have been proposed, there is still no exact analytical solution of the many-body problem of BCS-BEC crossover region. The standard BCS mean-field theory of superconductivity was used to describe the whole crossover resulting a useful approximation. In our studies, we introduced solvable models for an exact analytical solutions of BCS-BEC crossover region at $T = 0$ using the generalized $SU(2) \times SU(1,1)$ coherent states.

K1.00269 Boson gas in a periodic array of tubes¹, P. SALAS, Posgrado en Ciencia e Ingenieria de Materiales, UNAM, F.J. SEVILLA, M.A. SOLIS, Instituto de Fisica, UNAM — We report the thermodynamic properties of an ideal boson gas confined in an infinite periodic array of channels modeled by two, mutually perpendicular, Kronig-Penney delta-potentials. The particle's motion is hindered in the x - y directions, allowing tunneling of particles through the walls, while no confinement along the z direction is considered. It is shown that there exists a finite Bose-Einstein condensation (BEC) critical temperature T_c that decreases monotonically from the 3D ideal boson gas (IBG) value T_0 as the strength of confinement P_0 is increased while keeping the channel's cross section, $a_x a_y$ constant. In contrast, T_c is a non-monotonic function of the cross-section area for fixed P_0 . In addition to the BEC cusp, the specific heat exhibits a set of maxima and minima. The minimum located at the highest temperature is a clear signal of the confinement effect which occurs when the boson wavelength is twice the cross-section side size. This confinement is amplified when the wall strength is increased until a dimensional crossover from 3D to 1D is produced.

¹We thank support from grant PAPIIT IN105011, IN117010, IN106908, CONACyT 104917

K1.00270 Dynamics and evaporation of defects in Mott-insulating clusters of boson pairs¹, DOMINIK MUTH, FB Physik und Forschungszentrum OPTIMAS, TU Kaiserslautern, Germany, DAVID PETROSYAN, Institute of Electronic Structure and Laser, FORTH, Heraklion, Crete, Greece, MICHAEL FLEISCHHAUER, FB Physik und Forschungszentrum OPTIMAS, TU Kaiserslautern, Germany — Repulsively bound pairs of particles in a lattice governed by the Bose-Hubbard model can form stable clusters corresponding to finite-size Mott insulators. Here we study the dynamics of hole defects in such clusters corresponding to unpaired particles which can resonantly tunnel out of the cluster into the lattice vacuum. Because of bosonic statistics, the unpaired particles have different effective mass inside and outside the cluster, and “evaporation” from the cluster boundaries is allowed only when their quasi-momenta are within a certain range of transparency. We show that quasi-thermalization of hole defects occurs in the presence of catalyzing defects of triple occupied sites which thereby purify the Mott insulating clusters. We study the dynamics of 1D systems, verifying the analytical reasoning by numerically exact t-DMRG simulations. We derive an effective strong-interaction model that enables simulations of the system dynamics for longer times and allows checking with a higher number of defects. We also discuss a more general case of two bosonic species which for equal tunneling rates reduces to the special case of the fermionic Hubbard model in the strong interaction limit, where dynamical purification has been discussed before [2].

¹We gratefully acknowledge financial support by the DFG through the SFB TR 49 project and by the Humboldt Foundation.

K1.00271 Experimental witnessing of the initial correlation between an open quantum system and its environment¹, CHUAN-FENG LI, JIAN-SHUN TANG, YU-LONG LI, GUANG-CAN GUO, Key Laboratory of Quantum Information, University of Science and Technology of China, Chinese Academy of Sciences, Hefei 230026, P. R. C. — System-environment correlations, which determine the (non-)Markovian character of a dynamical process, is an area of intense interest in the study of open quantum systems. We send photons emitted from a quantum dot sample into a 15-m polarization-maintaining optical fiber to generate different system-environment correlated states and then witness the correlations by observing the growth of trace distances. This experimental scheme of correlation witnessing based on system-environment information flow can also be used for other similar systems.

¹We thank J. Piilo, H. P. Breuer, and E. M. Laine for their helpful discussions. This work is supported by the National Fundamental Research Program, National Natural Science Foundation of China (Grants No. 60921091, No. 10874162, and No. 10734060).

K1.00272 Time-dependent Hamiltonian identification, ALEXEI GOUN, Postdoctoral researcher — It is demonstrated that the time dependence of the Hamiltonian operator can be extracted by measurement of the evolution operator of the quantum system for a set of control parameters. For the case where the time dependence is weak and can be treated as a perturbation it is possible to express the inversion procedure in an analytic form. In the case of general time dependence, the iterative procedure is developed and its stability is analyzed.

K1.00273 Open Optomechanical Whispering Gallery Mode Resonators, DAVID AVELINE, LUKAS BAUM-GARTEL, NAN YU, Jet Propulsion Laboratory, California Institute of Technology — We have investigated open cavity Whispering Gallery Mode Resonators (WGMR) suitable for optomechanical coupling, and we present our initial demonstrations of structurally modified WGMR using microfabrication techniques. There has been strong interest in WGMR technology due to its extremely high optical quality and its compact robust nature. These monolithic optical resonators offer many advantages over mirror-based Fabry-Perot cavities that typically require special optical coatings. Standard WGMR, however, are constrained because only a tiny portion of the mode volume is externally accessible, limited to the perimeter of the disk where the evanescent field exists slightly outside the resonator. We have applied focused ion beam milling to augment WGMR discs with open structure, which allows direct access to the internal optical fields. By incorporating a mechanical cantilever inside the cavity, the coupled optomechanical system can yield extremely high sensitivity to displacement and acceleration, which would be well suited for miniature accelerometers and gyroscopes. This novel open cavity WGMR scheme could lead to many innovative applications that are unviable within the closed structure of conventional WGMR, including inertial sensors, trace gas detection, and laser sources.

K1.00274 Local Structural Study of Prussian Blue Analog $Fe_3(Co(CN)_6)_2 \cdot nD_2O$, JOE PETERSON, SOURAV ADAK, HEINZ NAKOTTE, New Mexico State University, LUKE DAEMEN COLLABORATION, KATHERINE PAGE COLLABORATION — The family of Prussian Blue analogs (PBA) is of interest, in part, because a number of them have been shown to exhibit negative thermal expansion. $Fe_3(Co(CN)_6)_2 \cdot nH_2O$ is particularly interesting because, when fully hydrated, it has been shown to have both positive and negative thermal expansion in the region from 80-298K while its partially dehydrated form demonstrates a linear-like negative thermal expansion over the same temperature region. To investigate the role local structural properties play in these systems we conducted temperature varying neutron pair distribution function (PDF) analysis on both the fully hydrated and partially dehydrated $Fe_3(Co(CN)_6)_2 \cdot nD_2O$.

K1.00275 Reduced-Density-Matrix Description for Multi-Photon Processes in Quantized Electronic Systems¹ , VERNE JACOBS, ALEX KUTANA, Naval Research Laboratory — A reduced-density-matrix description is developed for multi-photon processes in quantized many-electron systems, taking into account environmental electron-photon and electron-phonon interactions. Using a perturbation expansion of the frequency-domain Liouville-space self-energy operator, the spectral-line widths and shifts are evaluated in the isolated-line and short-memory-time (Markov) approximations. Applications of interest include spectral simulations for single-photon and two-photon absorption processes in atomic, molecular, and solid-state systems.

¹Work supported by the Office of Naval Research.

K1.00276 Ab Initio Calculations for Electronic Relaxations in Molecules and Solids Due to Scattering by Phonons¹ , ALEX KUTANA, VERNE JACOBS, Naval Research Laboratory, CENTER FOR COMPUTATIONAL MATERIALS SCIENCE TEAM — We carry out first-principles calculations for relaxations of excited electrons in molecules and solids due to scattering by phonons. Density matrix theory (DMT) is employed, which allows for a rigorous evaluation of electronic lifetimes, line widths and shifts, entirely from first principles. The three main ingredients in these calculations – electronic energy levels, dipole-transition matrix elements, and electron-phonon coupling matrix elements – are obtained from configuration interaction (CI) and density functional theory (DFT). Combining DMT, CI, and DFT allows one to avoid the use of the empirical line widths, as commonly employed in most previous investigations, and instead calculate their values from first principles. The calculated line widths and shifts are used to construct theoretical linear absorption spectra, which are then compared with experimental results.

K1.00277 Creation of superposition states in many-body systems by scattering , JAMES DOUGLAS, KEITH BURNETT, University of Sheffield — When quantum systems interact with the environment the interaction typically leads to decoherence of the system's quantum state. Here we show that one mechanism of interacting with the environment—uncontrolled scattering of probe particles by a many-body system—can instead lead to coherent superpositions of the system particles. For a system of two particles scattering leads to relative localization of the particle positions, while for more than two particles the system particles localize relative to one another in a pairwise fashion allowing superpositions in position space. We simulate scattering and the creation of these superposition states for many-body systems in free space and trapped in optical lattices. The different superpositions created are signaled in the scattering distributions and could be detected by allowing the particle wavefunctions to expand and interfere.

K1.00278 Analysis of Low-Z EUV Spectra from “Sparky” Laboratory Plasma Experiments , PENKA WILCOX, ALLA SAFRONOVA, VICTOR KANTSIREV, University of Nevada Reno — This study provides an analysis of recent experimental EUV and soft X-ray laser plasma spectra from the compact laser facility “Sparky”, generated under various plasma conditions. The developed non-LTE kinetic models of low-atomic number elements, such as C, O, F, etc., based on the Flexible Atomic Code data, are utilized. By matching the features of experimental spectra to the predictions of our atomic and plasma models, whose parameters are studied and precisely specified, the conditions of source plasmas can be inferred. The emitted EUV radiation we examine generally falls in the 90 Å to 260 Å wavelength range. In addition, the most intense lines from He-like ions of C and O in the soft X-ray region (20 Å - 40 Å) are observed. The most diagnostically significant temperature and density sensitive spectral lines are identified and proposed to use in plasma diagnostics for various applications including fusion research. This work is supported by DOE under grant DE-FG02-08ER54951.

K1.00279 Smart Combinatorial Research Equipment (SmartCoRE) for Sample Environmental Control and Automated Analysis with Optical Methods¹ , MATTHEW CHURCH, XIAODONG DING, NORMAN NANTEL, Jema Science Inc., SMARTCORE TEAM — Combinatorial research (CR) has revolutionized the way research is done in every major chemistry, physics and material science laboratory. We propose to bring the same success of automation and capabilities of CR to a widely used technique, small- and wide- angle x-ray scattering (SAXS/WAXS) through our development of a small, modular sample environmental chamber with embedded control electronics that can easily be used in large arrays. The device however is not restricted to a SAXS/WAXS techniques as it can easily be adapted to almost any kind of small volume sample prep or optical analysis technique requiring control of basic sample environmental parameters such as temperature, atmosphere, light and electromagnetic fields. The prototype has the following capabilities: 1. Automated switching of external electronic instrumentation between modules. 2. Thermoelectric temperature control from -50 to 200 C. 3. Ports for gas flow through or evacuation of sample environment. 4. Sealed sample environment using minimally scattering window material. 5. 90 degree field of view of both sides of sample. 6. Optional fiber-optic connections for UV-Vis spectroscopy. 7. Optional GISAXS mounting geometry. 8. Optional liquid sample flow cell.

¹SmartCoRE is supported by a DOE SBIR grant.

K1.00280 QUANTUM INFORMATION, CONCEPTS AND COMPUTATION —

K1.00281 Non-Perturbative and Moments Methods Applied to the Morse Potential , NATHAN WALSH, Fordham University, ERIC ASHENDORF, Kingsborough College of CUNY, JOHN TOLAND, Stevens Institute of Technology, VASSILIOS FESSATIDIS, Fordham University, JAY D. MANCINI, Kingsborough College of CUNY, SAMUEL P. BOWEN, Chicago State University — The well-known Morse potential has been well known to both physicists and quantum chemists for a number of years and has been used to model the behavior of diatomic molecules. Explicitly it may be written as

$$V(r) = D_e \left(e^{-2a(r-r_e)} - 2e^{-a(r-r_e)} \right) + D_e$$

where r is the inter-atomic separation, r_e is the (equilibrium) bond length and D_e is the depth of the potential well. The width of the well is given by $a^2 = k_e/2D_e$ with k_e the effective spring constant. Here we wish to study both the ground state energy (using both the Connected Moments Expansion and the Generalized Moments expansion) as well as the entire spectrum using a Lanczos scheme. Our results will be compared with other well-established results.

K1.00282 Low Frequency Perturbations, Adiabatic Ground States and Wave Function Collapse, SAMUEL P. BOWEN, Chicago State University, JAY D. MANCINI, Kingsborough College of CUNY, VASSILIOS FESSATIDIS, Fordham University — It is a well known and established fact that Time Dependent Perturbation Theory (TDPT) predicts that non- resonant time dependent perturbations will provoke no change in the excited state probability amplitudes of quantum systems. In this work we study a number of quantum systems wherein, at low frequencies, a response is indeed generated (by non-resonant perturbations) causing the system to respond adiabatically and hence resulting in the creation of instantaneous (time-dependent) ground states. These instantaneous time-dependent ground states are a linear combination of both the ground state and the excited states. The wave-function collapse of these adiabatic ground states calls into question the common wisdom that off-resonant perturbations can have no effect on quantum systems.

K1.00283 Topologically Protected Quantum State Transfer in a Chiral Spin Liquid, NORMAN YAO, CHRIS LAUMANN, Harvard University, ALEXEY GORSHKOV, California Institute of Technology, HENDRIK WEIMER, Harvard University, LIANG JIANG, California Institute of Technology, J. IGNACIO CIRAC, Max Planck Institute for Quantum Optics, PETER ZOLLER, University of Innsbruck, MIKHAIL LUKIN, Harvard University — Topology plays a central role in ensuring the robustness of a variety of physical phenomena. Notable examples range from the robust current carrying edge states associated with the quantum Hall and the quantum spin Hall effects to proposals involving topologically protected quantum memory and quantum logic operations. In this talk, I will describe a topologically protected channel for the transfer of quantum states between remote spin-based quantum registers. In our approach, state transfer is mediated by the edge-mode of a chiral spin liquid. I will demonstrate that the proposed method is intrinsically robust to realistic imperfections associated with disorder and decoherence. Possible experimental implementations and applications to the detection and characterization of spin liquid phases will be discussed.

K1.00284 Landau-Zener-Stückelberg Interference of Microwave Dressed States in a Superconducting Phase Qubit, GUOZHU SUN, RISE, Nanjing University, China, XUEDA WEN, School of Physics, Nanjing University, China, BO MAO, University of Kansas, YANG YU, School of Physics, Nanjing University, China, JIAN CHEN, WEIWEI XU, LIN KANG, PEIHENG WU, RISE, Nanjing University, China, SIYUAN HAN, University of Kansas — Landau-Zener-Stückelberg (LZS) interference is a well-known quantum phenomenon in a variety of physical systems, including atoms and solid-state systems. However, all the previous works were performed in simple systems having avoided level crossings in their energy diagrams. From both theoretical curiosity and practical significance it is important to know whether LZS interference can be observed in the dressed states, usually generated from the interaction between photons and atoms. We present the observation of LZS interference of the dressed states arising from a macroscopic quantum object, a superconducting phase qubit, interacting with a microwave field. The dependence of LZS interference fringes on the microwave power, microwave frequency, and the initial state of the qubit agrees quantitatively very well with the theoretical prediction. Such LZS interferometry involving the dressed states enables us to control the quantum states of multipartite systems with ease. In fact, this method is applicable to ANY quantum systems, which have avoided level crossings resulting from interaction between the individual constituents and photons.

K1.00285 Switching Phenomena in Bifurcation Amplifiers, WILLIAM SOO, ANDREW DOHERTY, School of Physics, University of Sydney, NSW 2006 — Recent experiments have seen high fidelity single shot measurement of superconducting qubits using the latching readout of a bifurcation amplifier. In these measurements, the coupling of the qubit to a nonlinear resonator correlates the qubit state with bistable states of the resonator. So qubit state discrimination, and hence readout quality, is ultimately governed by the dynamics of switching between the resonator states. In order to investigate how the quality of the measurement depends on system parameters, we study the physical mechanism of this probabilistic switching between the bistable resonator states. Recent simulations have shown that the switching rate can be very accurately obtained from a quantum trajectory model of the dynamics. We study Arrhenius formulae to model the switching rate and look to a Gaussian variational solution to the trajectory equations in order to gain an improved qualitative picture of the dynamics of these switching events.

K1.00286 Towards Realization of a Tunable Josephson Superinductor, MATTHEW BELL, IVAN SADOVSKYY, LEV IOFFE, MICHAEL GERSHENSON, Department of Physics and Astronomy, Rutgers, the State University of New Jersey, ALEXEI KITAEV, Institute for Quantum Information, Caltech — Many Josephson circuits intended for quantum computing would benefit from the realization of the Josephson “superinductor”: a phase-slip-free element whose inductive impedance at the plasma frequency exceeds the quantum of resistance, $h/(2e)^2$. With this aim, we have fabricated a chain of cells whose Josephson coupling can be frustrated by the magnetic field. These asymmetric dc-SQUID-like cells have several large Josephson junctions (JJs) in one arm shunted by a single small JJ in the other arm. The phase slips in this chain are suppressed by the phase rigidity across larger JJs, which remains strong even when the cell is frustrated by the magnetic field (while its Josephson inductance increases). Numerical simulations which explicitly take into account quantum fluctuations were used to optimize the JJ parameters. The inductance and phase rigidity of the device was probed by measuring the microwave response of the array coupled to a lumped-element microwave resonator. The resonance frequency of this circuit, f_r , and its quality factor Q were measured as functions of the magnetic field B. The observed dependences $f_r(B)$ and $Q(B)$ which reflects the variations of the Josephson inductance and phase rigidity of the array, will be compared with numerical simulations.

K1.00287 Collective Phenomena in a Capacitively-Coupled Transmon Array, ARTHUR SAFIRA, DEVIN UNDERWOOD, WILLIAM SHANKS, JAMES RAFTERY, ANDREW HOUCK, Princeton University — The manifestation of condensed matter physics phenomena in interacting photon systems has been of recent theoretical interest. Under the circuit quantum electrodynamics (cQED) architecture, light-matter interactions can be engineered into a strong coupling regime and many-body interacting photon systems can be fabricated. In this experiment, we create a triangular array of 100 niobium transmon qubits on a sapphire substrate. Photon-mediated interactions are facilitated through capacitive coupling among the transmons, each with a charging energy of approximately 200MHz. Collective quantum behavior of the Josephson-junction array is explored by measuring transmission across the array through input-output ports on the device itself as well as through a 3D cavity. This experiment is an important step towards realizing many-body, interacting quantum phenomena with photons.

K1.00288 Compact superconducting coplanar microwave beam splitters¹, A. BAUST, N. KALB, M. HAE-BERLEIN, J. GOETZ, E. HOFFMANN, E.P. MENZEL, M. SCHWARZ, F. WULSCHNER, L. ZHONG, F. DEPPE, A. MARX, R. GROSS, Walther-Meißner-Institute and TU Muenchen, Garching, Germany, SUPERCONDUCTING QUANTUM CIRCUITS AND NANOMECHANICS TEAM — The recent evolution of circuit quantum electrodynamics with standing-wave microwave modes towards setups for propagating quantum microwaves has triggered the need for low-loss superconducting microwave beam splitters. Such a device should have ports obeying the coplanar geometry relevant for circuit QED and, at the same time, be compact for the sake of scalability. This combination presents a serious challenge. In this work, we present an experimental characterization of various compact superconducting coplanar microwave beam splitters. In addition, we briefly discuss efforts towards a tunable beam splitter.

¹This work is supported by the DFG via SFB 631 and by the German Excellence Initiative via NIM.

K1.00289 Design and measurement of a silicon double quantum dot qubit with dispersive microwave readout¹, EDWARD HENRY, ANDREW SCHMIDT, UC Berkeley, QNL, MATHEW HOUSE, UCLA, YAO-TSENG WANG, CHEUK LO, UC Berkeley, HONG PAN, XIN XIAO, UCLA, HANHAN LI, LOREN GREENMAN, BIRGITTA WHALEY, UC Berkeley, HONGWEN JIANG, UCLA, ELI YABLONOVITCH, JEFFREY BOKOR, UC Berkeley, I. SIDDIQI, UC Berkeley, QNL — The electronic states of a semiconductor quantum dot are a promising candidate for quantum information processing. We describe a circuit QED qubit architecture in which a semiconductor qubit in silicon is capacitively coupled to a 6 GHz superconducting resonator. Silicon is an attractive material on account of the long electron spin lifetime. We discuss the design and operation of both the laterally defined double quantum dot qubit as well as the balanced coplanar stripline resonator. We focus in particular on the chip design and the specifics of the measurement setup, including both low and high frequency filtering. We also discuss the possibility of operating this device as a spin qubit by way of applying an inhomogeneous magnetic field.

¹This work is supported by the DARPA-QuEST program.

K1.00290 Improved rf-SSET Performance using On-Chip Superconducting LC Matching Networks on Si/Ge¹, ZHEN YANG, MINGYUN YUAN, CHUNYANG TANG, A.J. RIMBERG, Dartmouth College, M.A. ERIKSSON, D.E. SAVAGE, University of Wisconsin-Madison, RIMBERG TEAM, ERIKSSON COLLABORATION — The radio-frequency superconducting single electron transistor (rf-SSET) has been demonstrated to be a nearly quantum-limited charge sensor [1]. Building upon previous successful coupling of an aluminum SSET in the vicinity of quantum dots (QDs) on Si/SiGe using an off-chip inductor [2], we now developed on-chip matching networks to improve the charge sensing of Si/SiGe double quantum dots. Here, we report measurements in superconducting rf-SSETs, where the SET is directly fabricated with an on-chip inductor, giving enhanced sensitivity at our operating temperature of 0.3K. Recent experimental results including the investigation of the range of in-plane magnetic field compatible with RF-SET operation will also be discussed.

K1.00291 Observable measure of quantum correlations, GERARDO ADESSO, DAVIDE GIROLAMI, University of Nottingham, School of Mathematical Sciences — The correlations of multipartite quantum states have nonclassical features that go beyond entanglement. A full theoretical and experimental characterization of these features is necessary to understand their foundational role in quantum theory, and to explore the usefulness of such nonclassical resources for quantum computation and communication. We introduce a measure of general bipartite quantum correlations for arbitrary two-qubit states, expressed as a state-independent polynomial function of the density matrix elements. The amount of quantum correlations can be quantified experimentally by measuring the expectation value of a small set of observables on up to four copies of the state, without the need for a full tomography. We extend the measure to $2 \times d$ systems, providing its explicit form in terms of observables for the relevant class of multiqubit states employed in the DQC1 model for quantum computation. Finally, we study the evolution of quantum correlations between two qubits embedded in a bosonic bath, showing that our measure can reliably identify the transition between weak and strong system-environment coupling regimes. This leads us to propose an experimentally friendly signature of non-Markovianity based on quantum correlations dynamics.

K1.00292 New Families of Coherent States for the Supersymmetric Oscillator¹, MORDECHAI KORNBLUTH, FREDY ZYPMAN, Yeshiva University, New York; Department of Physics — Supersymmetry is a viable theoretical framework to provide a unified picture of fermionic and bosonic fields. The subjacent supersymmetric algebra intrinsically transforms bosonic degrees of freedom into fermionic ones and vice-versa. Aside from physical realizations, the mathematical objects of supersymmetry (e.g. superspace, supertransformations) have proved fruitful for solving quantum problems based on the concept of partner Hamiltonians. The harmonic oscillator has been extensively studied in this context; a result of particular interest is the vanishing zero-point energy. The supercoherent states were first introduced 25 years ago [1], defined as eigenstates of a generalized annihilation operator that mixes fermionic and bosonic degrees of freedom. Here we extend that original annihilation operator to a family of complex 3-parameter annihilation operators. Our presentation shows the properties of those new operators as well as the properties of the corresponding eigenstates. In particular, after explicitly calculating the eigenstates in parameter space, we present a subspace with bounded uncertainty, for both the Heisenberg and entropic formulations of uncertainty. K1.00293 Room-temperature solid-state quantum memory using pairs of nuclear spins in diamond, NIR BAR-GILL, STEPHEN DEVIENCE, DAVID LE SAGE, CHINMAY BELTHANGADY, LINH PHAM, RONALD WALSWORTH, Harvard University — We propose a robust, room-temperature solid-state quantum memory scheme using a pair of nuclear spin impurities in diamond. The memory qubit is encoded in a decoherence-free subspace of this nuclear spin pair, which protects it from noise originating from the surrounding environment. In addition, nuclear spins close to a Nitrogen-Vacancy (NV) color center experience a significant electron-mediated coupling, which further suppresses decoherence of the qubit. We obtain coherence times on the order of a second, along with fast manipulation and readout through the coupling of the nuclear spins to the NV electronic spin. We show that through engineering of the diamond sample this scheme could offer scalability to a many-qubit memory, and could be used as a basic building block for hybrid quantum networks and quantum computing architectures.

K1.00294 Novel quantum behavior generated by traveling across a quantum phase transition¹, O.L. ACEVEDO, F.J. RODRIGUEZ, L. QUIROGA, Universidad de los Andes, N.F. JOHNSON, University of Miami — We report novel dynamical behavior in a multi-qubit-light system described by the Dicke model, which is being driven across its thermodynamic quantum-phase boundary. Analyzing the system's quantum fidelity, we find that the near-adiabatic regime exhibits the richest phenomena, with a strong asymmetry in the internal collective dynamics depending on which phase is the starting point. Depending on the quenching regime a highly non-trivial behavior emerges in both the qubit and radiation subsystems. For the former, we find that for some paths in parameter space the final fidelity of the near-adiabatic process does not depend on the direction of the trajectory, but depends only on the *speed* at which the path is traveled. This behavior is contrasted with Landau-Zener tunneling and the Kibble-Zurek mechanism. Furthermore, for some qubit subsystems, we identify purification and screening effects which could be used for quantum control. By contrast, the evolution of the Wigner function shows the radiation subsystem exhibits the emergence of complexity and non-classicality. These findings could be experimentally tested in several condensed matter scenarios – for example, diamond-NV centers and superconductor qubits in confined radiation environments.

K1.00295 Exploring the Nitrogen-Vacancy center as a high resolution magnetometer¹, ABDELGHANI LARAOUI, CARLOS MERILES, Department of Physics, City College of New York - CUNY — New schemes that exploit the unique properties of NV centers in diamond are presently being explored as a platform to high resolution magnetic sensing [1, 2]. First we focus on the ability of a NV center to monitor a set of adjacent nuclear spins. For this purpose, we conduct comparative experiments where the NV spin evolves under the influence of surrounding ¹³C nuclei or, alternatively, in the presence of asynchronous AC fields engineered to emulate bath fluctuations [3]. Our study reveals substantial differences that underscore the limitations of the semi-classical picture when interpreting and predicting the outcome of experiments designed to probe small nuclear spin ensembles. In particular, our study sheds light on the role of bath fluctuations in the response of NV centers to common pulse sequences, and explores a detection protocol designed to probe time correlations within the random nuclear spin dynamics. Further, we show that the presence of macroscopic nuclear spin order is key to the emergence of traditional spin magnetometry. [1] J. R. Maze, et al., Nature 455, 644 (2008). [2] A. Laraoui, J.S. Hodges, C.A. Meriles, Appl. Phys. Lett. 97, 143104 (2010). [3] A. Laraoui, J. S. Hodges, C. A. Ryan, and C. A. Meriles, Phys. Rev.B 84, 104301 (2011).

K1.00296 High dynamic range diamond magnetometry for time dependent magnetic fields¹, M. UMMAL MOMEEN, N.M. NUSRAN, M.V. GURUDEV DUTT, Department of Physics and Astronomy, University of Pittsburgh — Nitrogen-Vacancy (NV) centers in diamond have become a topic of great interest in recent years due to their promising applications in high resolution nanoscale magnetometry and quantum information processing devices at ambient conditions. We will present our recent progress on implementing novel phase estimation algorithms with a single electron spin qubit associated with the NV center, in combination with dynamical decoupling techniques, to improve the dynamic range and sensitivity of magnetometry with time-varying magnetic fields.

¹This work is supported by NSF, DOE and the Alfred P. Sloan Research Fellowship.

K1.00297 Optical Control of Nuclear Spin Ensembles in Diamond, JONATHAN KING, JEFFREY REIMER, University of California, Berkeley — We present new results on the hyperpolarization of ¹³C nuclear spins in diamond through optically-oriented nitrogen vacancy (NV-) defects. Optical illumination of high NV- concentration diamonds at cryogenic temperatures and 9.4 Tesla results in a negative nuclear spin temperature with measured bulk-average polarization over 5%, although local polarization may be higher. The negative spin-temperature is attributed to a population inversion within the dipolar energy levels of the NV- spin ensemble. In our quantitative model, nuclei near defects equilibrate with the NV- dipolar energy reservoir and polarization is transported to the bulk material via spin diffusion. This model is tested by investigating a series of samples with varied defect density. We also investigate the nuclear hyperpolarization of NV- containing diamond nanocrystals. Such materials may be useful for surface transfer of polarization to target molecules for enhanced NMR sensitivity. Additionally, we investigate the dynamics and decoherence of the hyperpolarized nuclear spin ensemble and its interaction with electronic defect spins. Such phenomena are of fundamental interest to the use of diamond for quantum information applications.

K1.00298 Thwarting the Photon Number Splitting Attack with Entanglement Enhanced BB84 Quantum Key Distribution, CHRIS RICHARDSON, CARL SABOTTKE, Louisiana State University, ULVI YURTSEVER, MathSense Analytics, ANTIA LAMAS, National University of Singapore, JONATHAN DOWLING, Louisiana State University, PETR ANISIMOV, Stony Brook University — We develop an improvement to the weak laser pulse BB84 scheme for quantum key distribution, which utilizes entanglement to improve the security of the scheme and enhance its resilience to the photon number splitting attack. This protocol relies on the non-commutation of photon phase and number to detect an eavesdropper performing quantum non-demolition measurement on number. The potential advantages and disadvantages of this scheme are compared to the coherent decoy state solution. Most entanglement based quantum key distribution schemes rely on violations of Bell's inequalities to ensure security. However, this is not the strategy that our entanglement enhanced (EE) BB84 employs here. Instead, we detect Eve by introducing an entangled quantum state into the system that is sensitive to Eve's QND measurements. This allows for a recovery of an approximately linear dependence on transmittivity for the key rate. EE BB84 shares this advantage with coherent decoy state protocols as well as schemes that utilize strong phase reference pulses to eliminate Eve's ability to send Bob vacuum signals.

K1.00299 Efficient quantum communication under collective noise¹, MICHAEL SKOTINIOTIS, University of Calgary, BARBARA KRAUS, WOLFGANG DÜR, University of Innsbruck — We propose a novel communication protocol for the transmission of quantum information via quantum channels subject to collective noise. Our protocol makes use of decoherence-free subspaces in such a way that an optimal asymptotic rate of transmission is achieved, while at the same time encoding and decoding operations can be implemented efficiently. In particular, for a quantum channel whose collective noise is associated with a discrete group, G , i.e. with a discrete number, $|G|$, of possible noise operators, our protocol achieves perfect transmission at a rate of $m/(m+r)$, where r is a finite number of auxiliary systems that depends solely on the channel in question. In the case where the collective noise of the channel is associated with a continuous group, such as a collective phase noise channel, our protocol leads to efficient, approximate transmission of quantum data with arbitrarily high fidelity and optimal transmission rate. The coding and decoding circuit of our protocol requires a number of elementary gates that scale linearly with the number of transmitted qudits, m , in contrast to the best known protocols utilizing a decoherence-free subspace.

K1.00300 Continuous-Variable Quantum Key Distribution using Thermal States, CHRISTIAN WEED-BROOK, University of Toronto, STEFANO PIRANDOLA, University of York, TIM RALPH, University of Queensland — We consider the security of continuous-variable quantum key distribution using thermal (or noisy) Gaussian resource states. Specifically, we analyze this against collective Gaussian attacks using direct and reverse reconciliation where both protocols use either homodyne or heterodyne detection. We show that in the case of direct reconciliation with heterodyne detection, an improved robustness to channel noise is achieved when large amounts of preparation noise is added, as compared to the case when no preparation noise is added. We also consider the theoretical limit of infinite preparation noise and show a secure key can still be achieved in this limit provided the channel noise is less than the preparation noise. Finally, we consider the security of quantum key distribution at various electromagnetic wavelengths and derive an upper bound related to an entanglement-breaking eavesdropping attack and discuss the feasibility of microwave quantum key distribution.

K1.00301 Interaction Free Measurement of Quantum Systems, ONOFRIO RUSSO, Department of Physics, New Jersey Institute of Technology, LIANG JIANG, Institute for Quantum Information, Caltech — A measurement of the state of a physical system always causes some degree of disturbance in the system. When the scaling consists of nano or smaller quantities, measurements can cause severe changes in the information contained in the system. Noteworthy are the quantum computing elements, or qubits, used operationally and as memory. The main and foremost concern for the quantum computing elements is decoherence which is exacerbated by the measuring process. We propose to overcome these obstacles using an intriguing quantum mechanical interaction free measurement (IFM) method. High-efficiency IFM has been demonstrated by combining quantum interference and the quantum Zeno effect [P. G. Kwiat, et al., Phys. Rev. Lett. 83, 4725 (1999)]. In addition, IFM can be useful for quantum information processing, because it eliminates photon absorbing/scattering processes, which often are responsible for undesired information loss and decoherence in neighboring atoms. This is manifested in optical lattices, dephasing of proximal nuclear spins of nitrogen-vacancy centers in diamond, etc. We further propose and investigate using IFM to replace conventional optical readouts for specific quantum systems with the advantage of elimination of undesired decoherence.

K1.00302 Spatial entanglement in two-electron atomic systems¹, YEW KAM HO, Y.-C. LIN, Institute of Atomic and Molecular Sciences — Recently, there have been considerable interests to investigate quantum entanglement in two-electron model atoms [1, 2]. Here we investigate quantum entanglement for the ground and excited states of two-electron atomic systems using correlated wave functions, concentrating on the particle-particle entanglement coming from the continuous spatial degrees of freedom. We use the two-electron wave functions constructed by employing B -spline basis to calculate the linear entropy of the reduced density matrix $L = 1 - \text{Tr}_A(\rho_A^2)$ as a measure of the spatial entanglement. Here $\rho_A = \text{Tr}_B(|\varphi\rangle_{AB} \langle \varphi|)$ is the one-electron reduced density matrix obtained after tracing the two-electron density matrix over the degrees of freedom of the other electron. Here, we investigate spatial entanglement for two-electron systems with $Z=1$ to $Z=10$. When Z is decreased from $Z=1.0$ to about $Z \leq 0.911$, the H^- ion becomes unbound. This would lead in a situation of one electron bound by the nucleus with the other electron being free. Such a wave function would be expected to have a spatial entanglement of $L=1/2$. Numerical results will be presented at the meeting.

K1.00303 Delayed Choice with Haunted Quantum Entanglement for Choosing at a Distance an Overall Distribution Exhibiting Either Which-Way Information or Interference, DOUGLAS SNYDER, None — Particles 1 and 2 are entangled at one of two possible locations (providing which-way info). The entangled particles physically separate from each other where one particle [P1] preserves the ww information that accompanied entanglement and the other particle's motion [P2] supports interference in P2's overall distribution due to the device setup. With this step, P1 now supplies which-way info to P2 due to their entanglement. Next, there is a delayed choice at a distance. Choice A: P1 and the ww info it carries are essentially lost by releasing many other particles of similar character to P1 into the container with P1 before P2 is detected and before ww info for P1 becomes available to the environment or an irreversible ww measurement is made on P1. (The entanglement is then lost and so is the ww info supplied by P1 to P2.) Choice B: P1 that carries ww info is not lost. (The entanglement is not lost and neither is the ww info P1 has supplied to P2.) Repeat runs of method with choice A 100 times consecutively to develop an overall interference distribution pattern for P2, or instead repeat runs of method with choice B 100 times consecutively to develop an overall ww distribution pattern for P2.

K1.00304 Full counting statistics and entanglement in a disordered free fermion system¹, MICHAEL BANTEGUI, JOSEPH BURG, GREGORY LEVINE, Hofstra University — The Full Counting Statistics (FCS) is studied for a one-dimensional system of non-interacting fermions with and without disorder. For two L site translationally invariant lattices connected at time $t = 0$, the charge variance increases logarithmically in t , following the universal expression $\langle \delta N^2 \rangle \approx \frac{1}{\pi^2} \log t$, for t much shorter than the ballistic time to encounter the boundary, $t_b \sim L$. Since the static charge variance for a length L region is given by $\langle \delta N^2 \rangle \approx \frac{1}{\pi^2} \log L$, this result reflects the underlying relativistic or conformal invariance and dynamical exponent $z = 1$. With disorder and strongly localized fermions, the variance is also found to increase logarithmically in time, but saturates at times $t \approx t_d \propto L^2$, a diffusive time scale. Despite the fact that 1-d fermions are fully localized for any disorder strength, the entanglement responsible for charge fluctuations appears to propagate with dynamical exponent $z = 2$.

K1.00305 Excitation and entanglement dynamics of light harvesting complex II B850 ring, SHU-HAO YEH, JING ZHU, SABRE KAIS, Department of Chemistry, Purdue University, West Lafayette, IN 47907 — The electronic excitation and the entanglement dynamics between the chromophores of photosynthetic harvesting complex II (LHCII) B850 ring have been studied and analyzed theoretically. Since the coupling energy between the adjacent chromophore electronic excitation is comparable to the bath organization energy, the modified scaled hierarchical equation of motion (HEOM) approach is implemented to treat the whole system in an intermediate coupling regime. Comparing our results to the well-studied Fenna-Matthews-Olson (FMO) protein, we found that quantum coherence of electronic excitation between chromophores also exist in this system at the same temperature level (77K), which also suggests that the excitation energy transfer coherently through the B850 ring instead of incoherent hopping. The calculation of bipartite entanglement between chromophore electronic excitation shows the existence of a long-lived entanglement in this system, illustrates that this kind of quantum effect could survive even in such a noisy environment.

K1.00306 Tuning the entanglement for a two-dimensional magnetic system with anisotropic coupling and impurities, QING XU, SABRE KAIS, Purdue University — We study a set of localized spins coupled through exchange interaction and subject to an external magnetic field. For such a class of two-dimensional magnetic systems, we introduce two impurities, and treat as the source, while the rest as the environment bath. It is demonstrated that entanglement can be controlled and tuned by varying the anisotropy parameter γ , the ratio of magnetic field h and exchange interaction J in the Hamiltonian and three different exchange interaction strengths: J (between environment spins), J' (impurity - impurity) and JJ' (between impurities and environment), respectively.

K1.00307 Decoherence and Quantum Walks under the regime of weak measurements and weak values, DEBABRATA GHOSHAL, George Mason University, MARCO LANZAGORTA, ITT Corporation, SALVADOR VENEGAS-ANDRACA, Tecnológico de Monterrey Campus Estado de México — Our research on Quantum Walks under the regime of quantum weak measurements and weak values (QWWM) is being continued from the perspective of quantum algorithms. Previously we investigated several statistical measures of a QWWM on an infinite line, and did some comparative study of such results with corresponding classical and quantum walks position probability distributions and statistical measures. Now we are interested to show the entanglement and decoherence effects of QWWM. We show preliminary results with respect to how the performance of Grover's algorithm is affected by entangled qubits when decoherence happens due to temperature difference. Furthermore, we provide a physical interpretation of such decoherence of the QWWM so that our results could have some useful applications in the area of quantum information.

K1.00308 Perfect mixed state quantum transport in correlated spin networks, ASHOK AJOY, PAOLA CAPPELLARO, Massachusetts Institute of Technology — Spin-based quantum networks form an attractive physical setting for quantum information processing and simulation. We consider the transport of quantum states in arbitrarily large and complex spin networks, with applications to distributed quantum computing. Specifically, we consider transport through spin networks in the mixed-state, since they are the least experimentally demanding to produce in high-temperature laboratory settings. We analyze conditions on the interaction and propagators that allow perfect state transfer in such networks. We show that when there is more than one possible transport path through the network, it is necessary to phase correlate the transport processes occurring along each path. We provide a modified isotropic XY-Hamiltonian that achieves this correlation, and use it to derive engineered couplings for perfect transport in complicated network topologies. Finally, we show that this Hamiltonian can perfectly transfer mixed states, even in arbitrary networks, as long as the spins between which the transport occurs are weakly coupled to the remaining spins.

K1.00309 APL simulation of Grover's algorithm , SAMIR LIPOVACA, None — Grover's algorithm is a fast quantum search algorithm. Classically, to solve the search problem for a search space of size N we need approximately N operations. Grover's algorithm offers a quadratic speedup. Since present quantum computers are not robust enough for code writing and execution, to experiment with Grover's algorithm, we will simulate it using the APL programming language. The APL programming language is especially suited for this task. For example, to compute Walsh-Hadamard transformation matrix for N quantum states via a tensor product of N Hadamard matrices we need to iterate $N-1$ times only one line of the code. Initial study indicates the quantum mechanical amplitude of the solution is almost independent of the search space size and rapidly reaches 0.999 values with slight variations at higher decimal places.

K1.00310 Non-Markovian finite-temperature two-time correlation functions of system operators of a quantum Brownian motion model , PO-WEN CHEN, YU-AN TASI, HSI-SHENG GOAN, Department of Physics, National Taiwan University, NTU TEAM — We evaluate the non-Markovian two-time correlations (CF's) of system operators of a quantum Brownian motion (QBM) model in two different ways, one by the exactly solvable Heisenberg equation of motion through fluctuation-dissipation theorem and the other by the projection operator technique through the perturbative time-convolutionless non-Markovian effective master equation. In Markovian case, a famous procedure to compute two-time CF's of system operators in open quantum systems is the quantum regression theorem (QRT). However, the QRT is not valid or needs corrections in the non-Markovian domain even in the weak system-bath coupling regime. The calculated non-Markovian two-time CF's up to fourth order in system-environment coupling strength agree well with those obtained from exact evaluation in the weak and mediate coupling regime, which demonstrates the validity of our derived non-Markovian evolution equations. But, the exact analytical two-time CF's for an Ohmic bath presented in the literature are only for the initial time t_2 being in the steady state ($t_2 \rightarrow \infty$), i.e. at equilibrium. Our evolution equations of the non-Markovian two-time CF's are, however, valid for any initial time t_2 . For a finite initial time t_2 , considerable difference in the non-Markovian CF's between the fourth-order system-bath coupling case and its second order counterparts can be observed. These results obtained using our derived non-Markovian evolution equations differ significantly from the Markovian case obtained using the QRT and from the non-Markovian case obtained directly using the QRT.

K1.00311 Combatting decoherence in OAM states due to turbulence , JOSE RAUL GONZALEZ ALONSO, TODD BRUN, University of Southern California — Photons have always been the information carriers of choice in quantum information, with many protocols taking advantage of the polarization degrees of freedom to encode quantum information. Exploiting the photon's orbital angular momentum (OAM) can provide distinctive advantages. The main one is an increased alphabet size for information transmission. Since the Hilbert space of OAM states is infinite dimensional, it can be used to encode more than one bit (or qubit) per photon. However, this potential can only be realized if suitable quantum information can be encoded in the OAM photon states, and if it can be protected from the decohering effect of atmospheric turbulence. In this work, we will numerically simulate the effects of turbulence (using the Kolmogorov model) on photons with a certain value of OAM and how to protect them from the decoherence caused by the atmospheric turbulence.

K1.00312 Average quantum tunneling times for asymmetric potentials , LUIZ MANZONI, BRYCE FRENTZ, Concordia College, Moorhead, MN, JOSE LUNARDI, Universidade Estadual de Ponta Grossa, Brazil — We generalize a recent definition of average quantum tunneling times, using the Salecker-Wigner-Peres (SWP) clock, to be applicable to the tunneling of a localized wave packet through asymmetric potentials. We investigate the properties of the average transmission and reflection times, including their interpretation in the framework of the weak measurement theory, and compare them with other standard average times. Finally, we discuss the advantages of the definition of average tunneling times as prescribed by the SWP clock (such as the non-saturation of the transmission time for opaque barriers).

K1.00313 A Modified Special Relativity Theory in the Light of Breaking the Speed of Light , AZZAM ALMOSALLAMI, Malaya University — In the OPERA experiment the neutrino broke the speed of light. It moved with speed greater than the highest speed in the universe (the speed of light in vacuum) according to the special relativity [32]. This experiment if it is confirmed will contradict the main basis that the special relativity built on which is the constancy of speed of light, and no particle or electromagnetic wave can exceed this speed [37]. Quantum tunneling experiments have shown that the signal moving superluminal [1-9]. In this work (the modified special relativity theory), we will unify the special relativity theory and quantum theory (Copenhagen school) in concepts, principles and laws. While this new theory is in agreement with the concepts, principles and laws of the quantum theory (Copenhagen school), and it introduces some changes in the concepts, principles and laws of quantum to be descriptive, and imaginative. Quantum theory was applied to the micro world, while the macro world was controlled by the laws of classical physics. In my paper I believe that the theory that controls the micro and macro worlds are the same.

K1.00314 Relativistic tunneling times for Gaussian wave packets , BRENT PERREAULT, LUIZ MANZONI, Concordia College, Moorhead, MN, JOSE LUNARDI, Universidade Estadual de Ponta Grossa, Brazil — We investigated an average tunneling time, as suggested by the Salecker-Wigner-Peres clock, for a localized particle described by the Dirac equation. Then we evaluate this average transmission time for a Gaussian wave packet incident on a square barrier. It was found that the time does not saturate for large barriers, that is, the average time doesn't suffer from the Hartmann effect. We also consider the contribution of the negative energy components of the localized wave packet for the average time.

K1.00315 Wheeler thought experiment with delayed choice , JEFFREY BOYD, Retired — This is an alternative interpretation of Jacques, et. al. (2007), Wheeler's thought experiment with delayed choice. The researchers find that the choice of observables changes the previous behavior of the photon inside the interferometer. Stepping outside the QM box, we propose that elementary waves from the detectors travel backwards through the interferometer, and the photon is following such a ray in the reverse direction. Thus a change in observables changes the behavior of the photon for the simple reason that the observable is transmitting information to the photon and the photon is able to change its polarization mid-stream in response to a change in that information. According to this explanation there is no delayed choice. It is an illusion.

K1.00316 PHYSICS OF BEAMS —

K1.00317 Measurement of the Depression of the Velocity of Focused Beams of Light with a Gouy-Phase Interferometer , ANDREW MADEY¹, University of Oregon — An apparatus is demonstrated that was constructed to show the depression in group velocity v_g of a focused Gaussian (HeNe laser) beam, and arguments presented for the effects of this demonstration on the theoretical basis of Special Relativity. An exploration is conducted of Einstein's theoretical underpinnings for Special Relativity, that light pulses travel at a fixed group velocity $v_g = c$. This is accompanied by theoretical proof that v_g for a focused Gaussian beam is depressed upon focusing, if the beam has a frequency-independent radius, related to the Gouy phase shift. An account of the operation of the apparatus is presented, and data from the operations related, verifying the change in v_g . This contradiction of Einstein's assumption, without effect on the experimental validity of Special Relativity, is reconciled by referring to Poincaré's derivation of Special Relativity's equations, which assumes simply that Maxwell's equations retain their form across inertial reference frames.

¹Andrew Madey is an Undergraduate Physics student at the University of Oregon

K1.00318 POLYMERS AND SOFT MATTER PHYSICS —

K1.00319 Amphiphilic Peptide-Polymer Conjugates with Side-Conjugation, NIKHIL DUBE, University of California, Berkeley, ANDREW PRESLEY, JESSICA SHU, TING XU, Department of Materials Science and Engineering, University of California, Berkeley — As an emerging family of soft matter, peptide-polymer conjugates are highly promising for the design of functional materials. The fundamental understanding of the effect of the interaction between peptides and polymers on the structural and functional properties of these materials is crucial for their development into technologically relevant materials. We have designed a family of amphiphilic materials based on polymer conjugates of coiled-coil helix bundle and characterized their self assembly in surfactant containing aqueous solution. Conjugation of two hydrophobic polymers, PS and PMMA to the exterior of bundle led to unfolding of helix and the extent of structural retention was dependant on polymer hydrophobicity. However, the deleterious effects of hydrophobic polymers on the peptide structures can be eliminated on adding organic solvent to solubilize the hydrophobic polymers. To understand the importance of polymer hydrophobicity, conjugates of the peptide with PNIPAM, which exhibits temperature controlled hydrophobicity, have been studied and the results underscore the significance of the hydrophobic interaction between the polymer and the peptide on the structural retention of peptide. These fundamental studies signify the importance of maintaining the balance between different competitive intermolecular interactions on the peptide structure in these hybrid materials.

K1.00320 POST-DEADLINE ABSTRACTS —

K1.00321 Carbon nanotubes synthesized by pulsed laser deposition for light harvesting devices, JIN CHU, University of Puerto Rico, BOQIAN YANG, University of Massachusetts Amherst, PETER FENG, University of Puerto Rico — A large-area vertically aligned carbon nanotubes (CNTs) have been fabricated by catalyst-assisted pulsed laser deposition techniques on indium tin oxide (ITO) glass substrates. The CNTs have a uniform shape and length, aligned vertically on the surface of the ITO substrates and the average diameter is about 8 nm. The long-term field emission current stability of the CNTs has also been investigated. No obvious current density decay was observed after 15 days continuous experiments, indicating the super stability of the sample. A highly stable, cheap and nontoxic material which can be used as electrodes in dye-sensitized solar cells was obtained.

K1.00322 Thermodynamic curvature measures interactions, GEORGE RUPPEINER, New College of Florida — Thermodynamic fluctuation theory originated with Einstein who inverted the relation $S = k_B \ln \Omega$ to express the number of states in terms of entropy: $\Omega = \exp(S/k_B)$. The theory's Gaussian approximation is discussed in most statistical mechanics texts. I review work showing how to go beyond the Gaussian approximation by adding covariance, conservation, and consistency. This generalization leads to a fundamentally new object: the thermodynamic Riemannian curvature scalar R , a thermodynamic invariant. I argue that $|R|$ is a thermodynamic measure of the correlation length and suggest that the sign of R corresponds to whether the interparticle interactions are effectively attractive or repulsive. These ideas have been tested in a number of model systems. They are also significant in real fluids near the critical point, along the coexistence curve, and near the triple point. Also interesting are results for black hole thermodynamics, for which a foundation in terms of an underlying microscopic system is so far absent.

K1.00323 Numerical method of the quasiclassical theory for mesoscopic superconductors, YUKI NAGAI, CCSE, Japan Atomic Energy Agency, K. TANAKA, Department of Physics and Engineering Physics, University of Saskatchewan, NOBUHIKO HAYASHI, N2RC, Osaka Prefecture University — We propose a numerical method for describing mesoscopic superconductors in terms of the quasiclassical theory of superconductivity. Our method releases us from the problems as to how to determine initial values in a system that does not have a bulk solution. To examine the efficiency of our method, we calculate the local density of states of a circular d -wave island sustaining a single vortex. We find that the vortex shadow effect strongly depends on the quasiparticle energy in the circular mesoscopic island.

K1.00324 Discontinuous percolation transition with full step order parameter jump, HYUN KEUN LEE, University of Seoul, HYUNGGYU PARK, Korea Institute for Advanced Study, JAE DONG NOH, University of Seoul, PARK COLLABORATION, NOH COLLABORATION — We demonstrate that there is a class of discontinuous percolation that is characterized by full step jump in order parameter at threshold $p_c = 1$. Such a percolation takes place in the infinite dimension if the critical exponent τ , the decay exponent of the cluster number density distribution in critical regime, holds $1 < \tau \leq 2$. The scaling relations of $\sigma = 2 - \tau$ and $\gamma = 1/\sigma$ are derived for the critical exponents σ and γ associated with the characteristic cluster size and with the susceptibility, respectively. We also show that the cluster number density distribution is compact and can be widened up to $\sim \sqrt{N}$ for system size N .

K1.00325 Three Dimensional Morphology of Lamellae-forming Block Copolymer Thin Films between Two Chemically Nanopatterned Surfaces, GUOLIANG LIU, ABELARDO RAMIREZ-HERNANDEZ, PAUL F. NEALEY, JUAN J. DE PABLO, Department of Chemical and Biological Engineering, University of Wisconsin-Madison, Madison, Wisconsin 53706, USA — Previous work has demonstrated the directed assembly of block copolymers on one chemically patterned surface into desired two dimensional and three dimensional structures. Here, we report on the structures formed by block copolymer thin film equilibrated between two chemically patterned surfaces with orthogonal stripes. The patterned stripes have a width of $L_0/2$ and a period of L_0 , where L_0 is the natural period of the block copolymer. Our experiments and simulations reveal that the block copolymer domains are continuous through the film and the interface between domains resembles the Scherk's first minimal surface. Different from that in the bulk, the interface between the domains is at equilibrium in the presence of the defined boundary conditions, and has a remarkable level of perfection over the patterned areas in centimeter scale. The impact of chemical patterns on block copolymer morphologies and the underlying physics gives insight into the nanofabrication of complex nanostructures with directed self-assembly using two engineered boundary conditions, as opposed to only one.

K1.00326 Initial condition dependence of the probability density function of the injected power in the Langevin equation, JAE SUNG LEE, Korea Institute for Advanced Study, CHULAN KWON, Department of Physics, Myongji University, HYUNGGYU PARK, School of Physics, Korea Institute for Advanced Study — We study the diffusive dynamics of a Brownian particle described by the Langevin's equation with time varying heat bath temperature. Initially (when time $t < 0$) the heat bath temperature is T_{init} and the particle equilibrates with the heat bath. At time $t = 0$, the temperature abruptly changes from T_{init} to T , where their ratio is denoted by $\alpha = T/T_{\text{init}}$. Then the particle follows the Langevin dynamics with the temperature T for $t > 0$. Using the path integral method, we compute the probability density function (PDF) of the injection power (injected energy per unit time into the Brownian particle by the random noise, see J. Stat. Phys. 107, 314 (2002)). We find that the PDF or the corresponding large deviation function depends on the initial temperature T_{init} even in the $t \rightarrow \infty$ limit. In addition, we show that “phase transition” of the large deviation function occurs at $\alpha = 1/4$.

K1.00327 Mechanical detection of flux quanta as a candidate for small force standard, JAE-HYUK CHOI, HEON-HWA CHOI, YUN WON KIM, Korea Research Institute of Standards and Science, SOON-GUL LEE, Dep. of Display and Semiconductor Physics, Korea University, MAHN-SOO CHOI, Dep. of Physics, Korea University — Ultra-small force measurement with a micro-cantilever is a novel and powerful tool to probe micro- and nano-scale physical quantities, such as persistent current in mesoscopic metal rings, with unprecedented sensitivity. However, the precision of such small force is often limited by uncertainty of cantilevers spring constant, partly because of absence of small force standard. In this talk, I will introduce our metrological project for developing a small force standard based on superconducting flux quantum, from its concept to experimental progress. Our experimental results will cover the device fabrication, optical cooling effect, and mechanical detection of magnetic flux quantization and relaxation in a well-defined Nb micro-annulus at a temperature of 4 K.

K1.00328 Exploring Photocarrier Generation and Recombination in a Smectic Semiconductor *via* Transport Simulations, SANJOY PAUL, Department of Physics, Kent State University, JARROD WILLIAMS, ROBERT TWIEG, Department of Chemistry, Kent State University, BRETT ELLMAN, Department of Physics, Kent State University — Photocarrier generation and charge transport in the smectic B phase of the liquid crystalline semiconductor 2-(4'-octylphenyl)-6-dodecyloxynaphthalene (8PNPO12) have been investigated by using the time of flight (TOF) technique as a function of light intensity, electric field, and wavelength. The results probe both the low-intensity and space-charge perturbed regimes. The sharply different hole and electron TOF transients are quantitatively analyzed using comprehensive transport simulations to explore exciton dynamics, exciton decay, and bimolecular recombination.

K1.00329 Charge density waves and superconductivity in a minimal tight-binding model¹, JASON W. SADOWSKI², K. TANAKA, Department of Physics and Engineering Physics, University of Saskatchewan, YUKI NAGAI, CCSE, Japan Atomic Energy Agency — Charge density waves (CDW) and superconductivity (SC) are observed in a variety of materials such as layered transition-metal dichalcogenides, high-temperature cuprates, organic compounds, and other novel superconductors. The question as to whether CDW cooperate or compete with SC in those materials is under hot debate. In this work, we study possible mechanisms of CDW and its interplay with SC within an extended Hubbard model. In particular, CDW states caused by van Hove singularities as due to the mechanism proposed by Rice and Scott [1] are examined in detail.

K1.00330 Evidence of anisotropic Kondo coupling in nanostructured devices¹, LUIZ N. OLIVEIRA, KRISSIA ZAWADZKI, Instituto Fisica Sao Carlos, University of Sao Paulo — In spite of recent advances, the theory of electrical conductance through semiconducting nanodevices has fallen short of quantitative agreement with experiment. Consider, in particular, the single-electron transistor, a quantum dot bridging two otherwise independent two-dimensional electron gases. One would expect the universal function $G_u(T/T_K)$ describing the zero-bias conductance for the symmetric spin-degenerate Anderson model as a function of the temperature scaled by the Kondo temperature T_K to match experimental data. In practice, however, attempts to fit measurements with G_u have had to rely on *ad hoc* offset adjustments and, even then, obtained only fair agreement. Here, we extend a freshly-derived mapping between the function $G_u(T/T_K)$ and the conductance for the (generally asymmetric) Anderson model to allow for partial screening of the dot moment at high temperatures and show the mapping to fit the zero-bias conductances reported by Grobis et al., Phys. Rev. Lett. **100**, 246601 (2008) within experimental error. While other sources of partial screening cannot be ruled out, our results suggest the Kondo coupling between the dot moment and the electron spins in the adjacent gases to be anisotropic.

K1.00331 Interactive Learning Solid State with Quantum Mechanical programs, SABINA RUIZ-CHAVARRIA, PABLO DE LA MORA, Fac. de Ciencias, Universidad Nacional Autonoma de Mexico — Nowadays Solid State can be learnt interactively with Quantum Mechanical programs. Here we present four systems Na, graphite, diamond and MgB₂. With these programs their properties, charge density, band structure, density of states can be obtained and with the help of plotting programs their particular characteristics can be studied; type of bond (covalent, ionic, metallic, van der Waals), electrical properties (conductivity, anisotropy). In this form the student can interactively learn to ask questions and obtain answers about the properties of crystalline solids.

K1.00332 Observation of All-Optical Berezinskii-Kosterlitz-Thouless Transition¹, GUOHAI SITU, JASON W. FLEISCHER, Princeton University — The Berezinskii-Kosterlitz-Thouless (BKT) transition is a two-dimensional dynamic phase transition in which vortex creation competes with entropy production. Each factor is logarithmic in energy, with attempts at long-range order restricted by both geometry and thermal fluctuations. The BKT transition has been observed in a variety of quantum systems, including superfluid films, superconductors, and trapped atomic gases, but it is at root a classical process. Here, we demonstrate a classical BKT transition by observing the 2+1D propagation of an optical beam in a photonic lattice. In this system, there is a one-to-one mapping between the discrete nonlinear Schrödinger equation for paraxial propagation and the traditional XY model of condensed matter physics, with thermodynamic averaging replaced by ensemble averaging over initial random phases. We show experimentally that both the number of vortices produced and the universal jump in correlations agree with predictions from mean-field theory. The results give new confirmation of BKT theory, in a purely classical context, and reinforce the use of photonic systems as an experimental testbed for statistical physics.

K1.00333 Study of the ionic conductivity in Ce_{1/3}NbO₃, JOSE FRANCISCO GOMEZ GARCIA, GUSTAVO TAVIZON, Fac. de Quimica, PABLO DE LA MORA, Fac. de Ciencias, Universidad Nacional Autonoma de Mexico — Ce_{1/3}NbO₃ was synthesized using stoichiometric quantities of CeO₂ and Nb₂O₅ and heated for 48h at 1350°C in air. The electric conductivity was measured in the 25°C-1000°C interval. A small gap of 0.25-0.78eV was found. To study the origin of the transport DFT calculations were carried out; the results show a 0.4eV gap, but since the gaps are not correctly predicted with DFT, a further calculation with a modified Becke-Johnson (mBJ) potential was carried out obtaining a gap of 2eV, but a Ce 4f peak was found at the Fermi energy (E_F). When an intra-atomic repulsion term was added (LDA+U) the Ce 4f peak moved down and a 2.4eV gap was found. The calculations show that the conductivity does not have electronic origin but ionic. Atomistic calculations rule out that the transport is due to the Ce ions; on the other hand, these calculations agree very well with oxygen ions as charge carriers in this material.

K1.00334 Sensitive imaging of electromagnetic fields with cold polar molecules, SERGEY ALYABYSHEV, University of British Columbia, MIKHAIL LEMESHKO, Institute for Theoretical Atomic, Molecular, and Optical Physics Harvard-Smithsonian Center for Astrophysics, ROMAN KREMS, University of British Columbia — Detection of electromagnetic fields from rf to infrared frequency range is required for numerous applications ranging from test of fundamental symmetries to bioimaging. We propose to use polar paramagnetic molecules, such as SrF, CaH and NH, for sensitive parallel detection of electromagnetic fields. We discuss several methods of detection of both electric and magnetic field components in a wide range of detectable frequencies up to a few THz with high sensitivity and μm spatial resolution. Our calculations show that, using a gas of SrF molecules, it is possible to achieve sensitivity to ac fields that is two orders of magnitude higher than with ultracold Rb atoms [1]. Various applications are discussed.

K1.00335 Resistively Detected NMR and phonon-assisted dynamical nuclear polarization, GERSON J. FERREIRA, J. CARLOS EGUES, IFSC, USP, Brazil, W.A. COISH, McGill University, Canada — The resistively detected NMR (RDNMR) is used to detect the nuclear spin polarization and relaxation rates via magnetotransport in the quantum Hall regime. The diagonal term of the hyperfine coupling act on the electrons as an effective magnetic field B_n (Overhauser effect) proportional to the nuclear spin polarization. An oscillatory magnetic field with RF frequency in resonance with the nuclear spin splitting destroys the nuclear spin polarization, and thus the effective magnetic B_n . This induces a measurable change in the longitudinal resistance. Here we show that a finite current dynamically enhances the nuclear spin polarization via two processes: (i) near Landau level crossings a first order hyperfine spin-flip dominates, while (ii) away from crossings a second order phonon-assisted hyperfine spin-flip dominates. Our model show quantitative agreement with recent experiments [Zhang et al., PRL 98, 246802 (2007); Dean et. al., PRB, 80, 153301 (2009); Guo et al., PRB 81, 041306 (2010)]. See also [Ferreira et al., PRL 104, 066803 (2010)].

K1.00336 Crystal structure and electronic properties of the oxygen deficient $\text{Sr}_3\text{Ru}_2\text{O}_{7-y}$ ($0 \leq y \leq 0.5$) ruthenate, OLIVER MARTINEZ-ANAYA, GUSTAVO TAVIZON, Facultad de Química, PABLO DE LA MORA, Facultad de Ciencias, ROBERTO ESCUDERO, Instituto de Investigación en Materiales, Universidad Nacional Autónoma de México — In this work a study of the structural properties of the new non-stoichiometric Ruddlesden-Popper type $\text{Sr}_3\text{Ru}_2\text{O}_{7-y}$ compounds is presented. $\text{Sr}_3\text{Ru}_2\text{O}_{7-y}$ ($y = 0.17, 0.23, 0.28, 0.40$ and 0.47) were synthesized by hydrogen reduction of the parent $\text{Sr}_3\text{Ru}_2\text{O}_7$ ruthenate. Rietveld structure refinements were performed to determine the crystal structure of the reduced compounds. Oxygen content of the samples was studied by redox chemical titration and ESR spectra confirmed the presence of Ru^{3+} . Removal of oxygen atoms from the parent compound results in shrinkage of the c and growing of the a lattice parameters, which we related to the Ru^{4+} to Ru^{3+} partial reduction in $\text{Sr}_3\text{Ru}_2\text{O}_7$. On basis of DFT calculations, with WIEN2k code, we compared the electronic properties of reduced and stoichiometric compounds.

K1.00337 Dielectrophoretic Tweezers as a Platform for Single Molecular Force Spectroscopy in a Highly Parallel Format, PENG CHENG, MICHAEL BARRETT, PIERCEN OLIVER, DMITRI VEZENOV, Chemistry Department, Lehigh University — Miniaturization has driven down the cost of tools used in bioanalysis and diagnostics, with single molecules becoming the ultimate detection limit. I will describe how one can exploit mechanical properties of individual biomolecules to determine changes in their state or structure. Our aim is to build a force-spectroscopy-on-a-chip device that can detect and manipulate many (millions) single molecules in parallel. A critical element of this approach is the design of materials properties of molecular handles or probes. By tuning interactions of these probes with electric fields which generate by a simple electrode geometry, we are able to apply piconewton forces to individual DNA molecules and record their response with a single base sensitivity. I will present how we determined the approximate crossover frequency between negative and positive DEP using plain electrodes instead of conventional micro-structures. The technique is attractive not only for conducting single molecule force spectroscopy but also for label-free single cell detection. I will discuss potential applications of this approach to high throughput analyses such as genome sequencing and HIV detection.

K1.00338 New structural phase transitions in PbMBO_4 complex oxides: Raman spectroscopy and x-ray diffraction studies¹, PATRICIA KALITA, ANDREW CORNELIUS, Dept. of Physics and Astronomy, University of Nevada Las Vegas, Las Vegas, NV, USA, KRISTINA LIPINSKA, OLIVER HEMMERS, Harry Reid Center for Environmental Studies, University of Nevada Las Vegas, NV, USA, STANISLAV SINOGEIKIN, Geophysical Lab., Carnegie Institution of Washington, Washington, DC, USA, M. MANGIR MURSHED, THORSTEN GESING, Chemische Kristallographie fester Stoffe, Universität Bremen, Bremen, Germany, HARTMUT SCHNEIDER, Inst. of Crystallography, University of Köln, Köln, Germany — Complex oxides with the mullite crystal structure belong to the most important phase in both traditional and advanced ceramics. Mullites are built of infinite chains of edge-sharing MO_6 octahedra, bridged by various oxide groups. Interest in metal borates stems from their useful nonlinear optical properties. New complex oxides in the mullite family PbMBO_4 ($M = \text{Fe}, \text{Mn}, \text{Al}$) were synthesized and characterized. Using Raman spectroscopy and synchrotron x-ray diffraction at elevated pressure we demonstrate new structural phase transitions.

K1.00339 Spin-orbit coupling in GaN/AlGaN wurtzite quantum wells¹, POLIANA H. PENTEADO, J.Y. FU, ESIMERINDO BERNARDES, J. CARLOS EGUES, University of São Paulo — We investigate the spin-orbit coupling for electrons in wurtzite quantum wells with two subbands [1]. By folding down the 8×8 Kane model, accounting for the s-pz orbital mixing [2, 3] absent in zincblende structures, we derive an effective 2×2 Hamiltonian for the conduction electrons. In this derivation we consider the renormalization of the spinor component of the conduction band wave function, which is crucial to properly obtain the corresponding spin-orbit couplings. In addition to the Rashba-type term arising from the bulk inversion asymmetry of the wurtzite lattice, we obtain the usual linear in momentum Rashba term induced by the structural inversion asymmetry of the well and; interestingly, we also find a new Rashba-like contribution. The spin-orbit coupling parameters are obtained via a self-consistent calculation. For completeness, the Dresselhaus term is also included in our calculation.

K1.00340 Decoherence Times of Rabi Oscillations in Micro-Plasmas¹, DMITRI ROMANOV, GEORGE HECK, ALEX FILIN, ROBERT LEVIS, Center for Advanced Photonics Research, Temple University — We study the broadband Rabi oscillations supported by excited states of oxygen atoms in a microplasma. The contrast of characteristic fringe patterns of spectral interference in dynamic Rabi sidebands is determined by decoherence phenomena in a nonequilibrium underdense microplasma channel formed in atmospheric-pressure oxygen gas via interaction with a femtosecond pump pulse. We have established the decoherence rate as a function of the pump pulse intensity, and we have traced the evolution of the decoherence rate as the microplasma evolved toward equilibrium. The rate increases with the pump laser intensity and decreases with the delay with corresponding decoherence times in the range of 750 fs to 3 ps, in good agreement with theory revealing that electron scattering dominates the dynamics for the subnanosecond relaxation processes. The results provide insight into both the behavior of the transient effective two-state systems and the evolution of the characteristics of the laser-generated microplasma.

K1.00341 Formation of Alkaline Earth Template Layers for Oxide Epitaxy on Semiconductors: Surface Alloying and Self-Organization, BORIS LUKANOV, KEVIN GARRITY, JAMES REINER, FRED WALKER, SOHRAB ISMAIL-BEIGI, ERIC ALTMAN, Yale University — The finding that Sr and Ba titanates can be grown epitaxially on Si and Ge (100) surfaces without oxidizing the semiconductor and with atomically abrupt interfaces, has spurred research into exploiting these materials for high-k gate dielectrics and for integrating new functionality into traditional semiconductor devices. To date, all successful oxide epitaxy on Si and Ge (100) surfaces has required the initial formation of a sub-monolayer of an alkaline earth metal. To understand how this layer promotes oxide epitaxy, we have been using scanning tunneling microscopy complemented by electron diffraction and density functional theory to characterize the formation of the template layer on the atomic scale. The results reveal a complex series of phase transitions as Sr is deposited onto Ge(100). Interestingly, each phase transition is accompanied by drastic changes in the surface morphology that can only be explained by formation of an alloy surface. Through comparison of atomic-resolution STM images with DFT predictions, structural models of two of the surface alloy phases have been deduced. Incorporation of the larger alkaline earth atoms into the surface creates strain that is ultimately relieved by the formation of remarkably well-ordered arrays of stripes and trenches. The alloy formation leads to double-height steps on the surface, resulting in unidirectional trenches and nanowires extending for thousands of Angstroms.

K1.00342 Photothermal Therapy of Cancer Cells mediated by Blue Hydrogel Nanoparticles, TAEYJUANA CURRY, Department of Physics, University of Michigan, Ann Arbor, MI, USA 48109, TAMIR EPSTEIN, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, USA 33612, RAOUL KOPELMAN, Department of Chemistry, University of Michigan, Ann Arbor, MI, USA 48109 — Coomassie Blue dye has been covalently linked into a polyacrylamide nanoparticle matrix, so as to form nontoxic, biologically compatible, biodegradable and cell-specific targetable nanoparticles for photothermal therapy (PTT) of cancer. The nanoparticles were found to be approximately 80-95 nm in diameter, with an absorbance value of 0.52. Using an inexpensive, low intensity LED array light source (590nm, 25mW/cm²), with 20 minute excitation times, at 37°, PTT induced hyperthermia/thermolysis in HeLa cells, in vitro, resulting in virtually complete cell death when observed 3 hours after exposure. These multifunctional particles have been previously used in cancer delineation, for surgery, and in photoacoustic imaging studies; the addition of the PTT function now enables a multi-pronged medical approach to cancer.

K1.00343 Entangled Photon Fluorescence with Organic Conjugated Dendrimers, LESLIE UPTON, THEODORE GOODSON, University of Michigan — The use of entangled photons for spectroscopy is a novel technique with several potential applications in entangled two-photon excited fluorescence microscopy, quantum imaging and remote sensing. Classical TPA depends quadratically on the input photon flux, whereas, non-classical entangled two-photon absorption (ETPA) has a linear dependence on input flux rate. The total TPA rate measured using an entangled photon source is given by the summation of the ETPA rate and the random TPA rate. This work focuses on the entangled two-photon absorption cross-section and the entangled two-photon fluorescence efficiency of a G1 Dendrimer. From these results, it is shown that the entangled two-photon excited fluorescence of the G1 Dendrimer has a linear dependence at low input photon fluxes. This result has great impact on spectroscopy where the need for small numbers of photons is great, such as microscopy and sensing.

Tuesday, February 28, 2012 2:30PM - 5:30PM –

Session L1 DMP GIMS: Focus Session: Imaging and Modifying Materials at the Limits of Space and Time Resolution 203

2:30PM L1.00001 In-Situ Transmission Electron Microscopy with Nanosecond Temporal Resolution¹, NIGEL BROWNING, Pacific Northwest National Laboratory — The dynamic transmission electron microscope (DTEM) can obtain both high spatial (~1nm or better) and high temporal (~1μs or faster) resolution. The high temporal resolution is achieved by using a short pulse laser to create the pulse of electrons through photo-emission. This pulse of electrons is propagated down the microscope column in the same way as in a conventional high-resolution TEM. The only difference is that the spatial resolution is limited by the electron-electron interactions in the pulse (a typical 10ns pulse contains ~10⁹ electrons). To synchronize this pulse of electrons with a particular dynamic event, a second laser is used to “drive” the sample a defined time interval prior to the arrival of the laser pulse. The important aspect of the DTEM is that one pulse of electrons is used to form the whole image, allowing irreversible transitions and cumulative phenomena such as nucleation and growth, to be studied directly in the microscope. The use of the drive laser for fast heating of the specimen presents differences and several advantages over conventional resistive heating *in-situ* TEM – such as the ability to drive the sample into non-equilibrium states. So far, the drive laser has been used for *in-situ* processing of nanoscale materials, rapid and high temperature phase transformations, and controlled thermal activation of materials. In this presentation, a summary of the development of the DTEM and *in-situ* stages to control the environment around the specimen will be described. Particular attention will be paid to the potential for gas stages to study catalytic processes and liquid stages to study biological specimens in their live hydrated states. The future potential improvements in spatial and temporal resolution that can be expected through the implementation of upgrades to the lasers, electron optics and detectors will also be discussed.

¹Pacific Northwest National Laboratory is operated by Battelle Memorial Institute for the U.S. Department of Energy under Contract No. DE-AC05-76RL01830.

3:06PM L1.00002 Design and performance of a Near Ultra High Vacuum Helium Ion Microscope, BENE POELSEMA, RAOUL VAN GASTEL, GREGOR HLAWACEK, HAROLD J.W. ZANDVLIET, Physics of Interfaces and Nanomaterials, MESA+ Institute for Nanotechnology, University of Twente, P.O.Box 217, 7500 AE Enschede — The advent of He Ion Microscopy (HIM) as a new nanoscopic technique to image materials has enabled a new look at materials that is based on the interaction of swift light ions with matter. Initial HIM instruments have demonstrated high-resolution imaging, combined with great surface sensitivity, the ability to neutralize charge very efficiently, and with enhanced materials contrast when ion induced secondary electrons are used for imaging. To achieve ultimate performance, the chamber vacuum of the existing platform may be improved. For instance, carbon deposits due to beam interaction are readily seen due to the surface sensitivity of the technique. At high current densities the sharply focused beam may very efficiently decompose residual hydrocarbons. Not only can this obscure a clear view of the sample, thereby negating the benefits of the small spot size, it also limits the available acquisition time. This has proven extremely useful for nanopatterning for sensors, and other device fabrication applications at the sub-10nm level. However, it is undesirable when the instrument is used for materials characterization. We will discuss the basic considerations that went into the design of a Near-UHV He Ion Microscope [1]. First applications that the instrument was used for will be highlighted and its impact in surface physics and other research areas that require increased imaging sensitivity will be discussed.

3:18PM L1.00003 Instrumentation Development for Dynamic Atom Probe Tomography¹, BRIAN GORMAN, DAVID DIERCKS, Colorado School of Mines — Atom probe tomography (APT) is a materials characterization technique widely recognized as having the highest combined spatial (sub-nm) and chemical (less than 10^{17} atoms / cm^3) resolution. This imaging time of flight mass spectrometry technique typically utilizes laser pulsed field emission in semiconductors and dielectrics. Laser pulsed field emission is widely considered to be a thermal effect, with specimen temperatures from 100 K to greater than 1500 K observed. Following the thermal spike, specimens typically cool to their base temperature in less than 5 ns, depending upon their thermal transport and geometry. Combining the laser pulsed atom probe experiment with pulsed transmission electron diffraction will enable thermal annealing and quenching experiments at atomic resolution with nanosecond temporal resolution. The combined instrument, titled a Dynamic Atom Probe, will be used to monitor solid state processes including solute drag effects on grain boundary motion, atomic scale kinetics of crystallization in amorphous semiconductors and oxides, atomic scale nucleation and spinodal decomposition kinetics in oxides, and phase transformations in metallic alloys. This discussion will include the specifics of the instrumentation currently under development as well as proof of principle first experiments.

3:30PM L1.00004 Simulation of ultrashort photoelectron pulses as a guide for developing reliable ultrafast electron diffraction systems¹, JENNI PORTMAN, HE ZHANG, ZHENSHENG TAO, CHONG-YU RUAN, MARTIN BERZ, PHILLIP DUXBURY, Michigan State University — The development of a reliable experimental ultrafast electron diffraction and imaging system requires a theoretical understanding of the underlying physical phenomena and an accurate modeling of the optical elements present in the beam column. To achieve this goal, we have developed two types of computer simulations: a mean-field Gaussian approximation, in which the linear effects of realistic optical elements are incorporated. Due to the limitations inherent in the theory, it fails to capture the intricate behavior of a real system but it is computationally very inexpensive and offers valuable information on the relevant parameter ranges. The second type of simulation considered is an explicit N particle model which uses a O(N) method for calculating the space charge effects, enabling simulations of over one million electrons in a pulse. While being computationally very expensive, it offers the advantage of incorporating realistic descriptions for the electromagnetic fields of the optical elements, along with their linear and non-linear contributions. The results of this work show the limits of the validity of the mean-field approach and offer a detailed and highly accurate physical description of the beam dynamics under different operational regimes.

3:42PM L1.00005 Charged nanoparticle dynamics in water induced by scanning transmission electron microscopy¹, E.R. WHITE, MATTHEW MECKLENBURG, BRIAN SHEVITSKI, S.B. SINGER, B.C. REGAN, UCLA Department of Physics and Astronomy & CNSI — Using scanning transmission electron microscopy we image ~ 4 nm platinum nanoparticles deposited on an insulating membrane, where the membrane is one of two electron-transparent windows separating an aqueous environment from the microscope's high vacuum. Upon receiving a relatively moderate dose of $\sim 10^4 e^-/\text{nm}^2$, initially immobile nanoparticles begin to move along trajectories that are directed radially outward from the center of the field of view. As the dose rate is increased the particle motion becomes increasingly dramatic. These observations demonstrate that even under mild imaging conditions, the *in situ* electron microscopy of aqueous environments can produce charging effects that dominate the dynamics of nanoparticles under observation. Such effects provide a new tool for modifying *in vitro* environments such as those used for TEM studies of wet biological systems.

3:54PM L1.00006 Coherent X-ray microscopy of real materials at 10nm resolution, ANDREAS MENZEL, Paul Scherrer Institut — Coherent X-ray microscopy replaces image-forming optics by mathematical algorithms to “reconstruct” the micrograph from the distribution of scattered light. In case of X-rays, its popularity is largely based on its ability to alleviate limitations of resolution and efficiency of available optics. Various methodologies have been developed, and high resolving power could be demonstrated. Yet, stringent constraints on sample preparation and data quality had to be addressed before the technique could advance from proof of principle studies to application. About a decade after the first demonstration using X-rays [J.W. Miao et al., Nature 400 (1999) 342] coherent diffractive imaging (CDI) seems to have matured into a microscopy technique that proves useful in real-life scientific investigations. The major coherent diffractive imaging methods will be reviewed, i.e., its original implementation using plane waves, the so-called Fresnel CDI that exploits curvature in the illuminating wavefront, and ptychographic CDI, which is a scanning microscopy method using multiple exposures. Being fully compatible with spectroscopic contrast channels makes quantitative structural, chemical, and magnetic information accessible, and the penetration power of X-rays can be exploited by tomographic or ab initio reconstruction methods in order to yield three-dimensional reconstructions with high resolution, high specificity, and high dose efficiency. These recent advances have turned coherent X-ray microscopy into a reliable and robust method that is attractive for scientists independent on how (un-)familiar they are with X-ray microscopy. Applications from the materials and life sciences will be discussed.

4:30PM L1.00007 Time-Resolved Near-Edge Coherent Diffractive Imaging, FABIAN WEISE, DANIEL NEUMARK¹, STEPHEN R. LEONE², OLIVER GESSNER, Ultrafast X-ray Science Laboratory, Chemical Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, California 94720, USA — Coherent diffractive imaging (CDI) with x-rays is a well-established technique that provides structural information beyond the limitations of optical microscopy. Free electron lasers provide ultrashort x-ray pulses with sufficiently high peak brightness to facilitate single-shot imaging and the extension of CDI into the time-domain. Recent progress in the generation of spatially coherent ultrashort x-ray pulses by high harmonic generation (HHG) using tabletop lasers lead to the emergence of a new field of laboratory-based CDI. While a relatively low photon flux and limited photon energies result in lower imaging resolution compared to x-ray studies at large-scale facilities, the significantly greater availability makes laboratory-based experiments well suited for developing new CDI techniques. We present a new apparatus for CDI, which provides ultrashort XUV pulses with tunable photon energies. By implementing a monochromator in a HHG-based CDI setup, the photon energy can be tuned to the inner-shell absorption edges of different elements in the sample. The wavelength-dependence of the x-ray optical constants close to the resonances facilitates to exploit the element selectivity and chemical sensitivity of x-ray transitions in time-domain CDI experiments.

4:42PM L1.00008 In-situ proton radiography of solidification in Sn-Bi, Al-Cu, Al-In and Bi-Ga melts¹, JASON COOLEY, AMY CLARKE, CHRISTOPHER MORRIS, BRIAN HOLLANDER, TIM TUCKER, Los Alamos National Laboratory, THOMAS OTT, Florida State University, ROBERT FIELD, DAVID KORZEKWA, DUNCAN HAMMON, KESTER CLARKE, PATRICK KENNEDY, FRANK MERILL, FESSAHA MARIAM, Los Alamos National Laboratory, MARTHA BARKER, New Mexico Institute of Mining and Technology, JAMES FOLEY, ROBERT AIKIN, JOSHUA HILL, DAN THOMA, Los Alamos National Laboratory, FINIAN O'NEILL, Boston College, MEGAN EMIGH, New Mexico Institute of Mining and Technology, BO FOLKS, Los Alamos National Laboratory — In-situ observation of the solidification phenomena in metals can lead to better understanding and control of microstructure evolution. Proton radiography offers the ability to image thick samples of high z material. Recently, in-situ proton radiography was used to directly observe dynamic processes during melting and solidification in bulk binary alloy systems. The spatial resolution was ~65 microns for a 44 x 44 mm² field of view. The time scale of each experiment was 2 to 6 hours. The data collected allowed for the determination of solidification front velocities, captured the changes in solid/liquid densities and showed evidence of convective fluid flow in the melt. Microstructural features larger than approximately 100 microns in the solid phase were observed.

¹Work at Los Alamos supported by NNSA and the Department of Energy

4:54PM L1.00009 True Attosecond Imaging of Inhomogeneous Systems with Standing-Wave Inelastic X-Ray Scattering¹, YU GAN, PETER ABBAMONTE, University of Illinois at Urbana-Champaign — Inelastic X-ray scattering (IXS) has recently been used to image electron dynamics at the attosecond scale, but it has been shown that these images are spatially averaged. The problem is that the existing technique can only access the “diagonal” ($k_1 = -k_2$) elements of the electron density response $\chi(k_1, k_2, \omega)$. It has been shown, however, that inelastic X-ray scattering at the Bragg position is sensitive to the entire response $\chi(k_1, k_2, \omega)$. With this method, a standing wave field is established in the sample by exciting a Bragg condition, allowing access to all the off-diagonal ($k_1 \neq -k_2$) elements of χ . In this talk I will present a simple model demonstrating that, in principle, this approach can be used to map the entire density response. In particular, I show that a one-dimensional system is experimentally impossible to probe, a two-dimensional system is experimentally accessible but typically difficult to measure in practice, and a three-dimensional system is experimentally both plausible and practicable. Finally, I propose possible experimental realizations of this technique.

5:06PM L1.00010 Sub-Picosecond Dynamics of Displacement Cascades¹, BENNETT LARSON, JON TISCHLER, ROGER STOLLER, YURI OSETSKIY, Oak Ridge National Laboratory, CHRISTIAN DAVID, Paul Scherrer Institute — Sub-picosecond x-ray pulses produced by the Linac Coherent Light Source (LCLS) now enable real time experimental measurements of atomic displacement cascade structure and dynamics on sub-picosecond time scales. Such measurements will make possible the first direct experimental test of molecular dynamics (MD) displacement cascade simulations. Here we will discuss the potential to use single, seeded, 100-fs LCLS hard x-ray pulses focused to ~100 nm diameter by diamond-based Fresnel zone plate optics to make real-time diffuse scattering measurements on 50 keV Ar-ion-induced cascades in thin single-crystal samples. We will present x-ray Bragg diffuse scattering calculations based on ~4M atom, 25 keV primary knock-on energy MD cascade simulations demonstrating that temporally-random, 100 fs LCLS x-ray pulse measurements of diffuse scattering near low index Bragg reflections can be time-ordered from sub-picoseconds to a few picoseconds. Time ordering is made possible in this regime by the distinct nature of diffuse scattering profiles as a function of time that are produced by shock-induced pressure waves according to MD cascade simulations in Fe. The expected results and the experimental challenges anticipated to perform such measurements will be discussed.

5:18PM L1.00011 Nanostructure Formation on Sb₂Te₃ Thin Films Induced by Femtosecond Laser Irradiation¹, YUWEI LI, VLADIMIR A. STOICA, LYNN ENDICOTT, GUOYU WANG, Dept. of Physics, Univ. of Michigan, HUARUI SUN, KEVIN. P. PIPE, Dept. of Mechanical Engineering, Univ. of Michigan, CTIRAD UHER, ROY CLARKE, Dept. of Physics, Univ. of Michigan — Sb₂Te₃ has applications in thermoelectrics, phase-change memory devices and topological insulators. In the case of thermoelectricity, nanostructure formation in this type of material has been predicted to enhance its figure of merit for thermal energy conversion. Here, we present our results on modification of the surface morphology of Sb₂Te₃ thin films after femtosecond laser irradiation. Under a narrow range of laser fluence and irradiation time, long and highly-aligned nanotracks were formed in the plane of the film, having a periodicity 10 times smaller than the irradiation laser wavelength. The laser fluence and irradiation time can result in different surface nanostructure morphologies with varying degrees of order. Finally, using an optical pump-probe technique, we find that the laser-irradiated nanostructured areas of the film have a lower thermal conductivity compared to that of the reference smooth areas not irradiated by the laser. Such Sb₂Te₃ nanostructures can be important for thermoelectric applications as well as for further studies of femtosecond laser interaction with opaque materials.

¹This work is supported as part of the Center for Solar and Thermal Energy Conversion, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award No. De-SC00000957

Tuesday, February 28, 2012 2:30PM - 5:30PM – Session L2 DPB FIP: Invited Session: Andrei Sakharov Prize Session 204AB

2:30PM L2.00001 A. Sakharov and Fusion Research¹, BRUNO COPPI, MIT — In the landmark paper by Tamm and Sakharov [1], a controlled nuclear fusion reactor based on an axisymmetric magnetic confinement configuration whose principles remain valid to this day, was proposed. In the light of present understanding of plasma physics the virtues (e.g. that of considering the D-D reaction) and the shortcomings of this paper are pointed out. In fact, relatively recent results of theoretical plasma physics (e.g. discovery of the so called second stability region) and advances in high field magnet technology have made it possible to identify the parameters of meaningful experiments capable of exploring D-D and D-³He burn conditions. At the same time an experimental program (IGNIR) has been undertaken through a (funded) collaboration between Italy and Russia to investigate D-T plasmas close to ignition conditions based on an advanced high field toroidal confinement configuration. A. Sakharov envisioned a bolder approach to fusion research than that advocated by some of his contemporaries. The time taken to design and decide to fabricate the first experiment capable of reaching ignition conditions is due in part to the problem of gaining an adequate understanding the expected physics of fusion burning plasmas. However, most of the relevant financial effort has gone in the pursuit of slow and indirect enterprises complying with the “playing it safe” tendencies of large organizations or motivated by the purpose to develop technologies or maintain a high level of expertise in plasma physics to the expected benefit of other kinds of endeavors. The creativity demonstrated by A. Sakharov in dealing with civil rights and disarmament issues is needed, while maintaining our concerns for energy and the environment on a global scale, to orient the funding for fusion research toward a direct and well based scientific effort on concepts for which a variety of developments can be envisioned. These can span from uncovering new physics relevant, for instance, to high energy astrophysics to the feasibility of new neutron sources.

3:06PM L2.00002 CP Violation and the Matter Anti-Matter Asymmetry of the Universe¹

ROBERT CAHN, Lawrence Berkeley National Laboratory — There is no scientific question more fundamental than “Why are we here?” or as we physicists might phrase it “Why is there more matter than anti-matter?” Because, as Andrei Sakharov first showed, CP violation is necessary to any explanation of the matter anti-matter asymmetry, CP violation is the focus of much of the international experimental program in particle physics. CP conservation was what could be salvaged after parity was overthrown in 1956, but it survived only until 1964 when K mesons were found not to respect it. While parity violation was a large effect in weak interactions, CP violation seemed small and confined to the kaons. When the Standard Model of particle physics emerged in early 1970's, Kobayashi and Maskawa observed that if there were three families of quarks, CP violation would arise quite naturally. The Standard Model suggested that CP violation could be large in decays of B mesons. Nonetheless, no matter what parameters are used in the Standard Model, CP violation among quarks cannot be large enough to explain the matter anti-matter asymmetry. Major experiments in the U.S. and Japan were undertaken to explore CP violation in B mesons to search for signs of CP violation outside the Standard Model, which might explain the dominance of matter over anti-matter. Neither experiment found such a discrepancy, but new programs will continue this search with much higher statistics. While the three families of leptons are in many ways analogous to the three families of quarks, the neutrinos have a unique character. As neutral particles, it is possible that they are their own antiparticles. If this is so, there may be additional, very heavy, neutrinos beyond those we know already. If they violate CP they may be the source of the matter anti-matter asymmetry. But do neutrinos experience CP violation? Experiments around the world are just now setting out to answer this question.

2:30PM L3.00001 Hidden Fermi Liquid: Self-Consistent Theory for the Normal State of High-Tc Superconductors , PHILIP ANDERSON, Princeton Univ — No abstract available.

3:06PM L3.00002 Quantum oscillations and nodal pockets from Fermi surface reconstruction in the underdoped cuprates , NEIL HARRISON¹, Los Alamos National Laboratory — Fermiology in the underdoped high T_c cuprates presents us with unique challenges, requiring experimentalists to look deeper into the data than is normally required for clues. Recent measurements of an oscillatory chemical potential affecting the oscillations at high magnetic fields provide a strong indication of a single type of carrier pocket. When considered in conjunction with photoemission and specific heat measurements, a Fermi surface comprised almost entirely of nodal pockets is suggested. The mystery of the Fermi surface is deepened, however, by a near doping-independent Fermi surface cross-sectional area and negative Hall and Seebeck coefficients. We explore ways in which these findings can be reconciled, taking an important hint from the diverging effective mass yielded by quantum oscillations at low dopings. The author wishes to thank Suchitra Sebastian, Moaz Atarawneh, Doug Bonn, Walter Hardy, Ruixing Liang, Charles Mielke and Gilbert Lonzarich who have contributed to this work. The work is supported by the NSF through the NHMFL and by the DOE project “Science at 100 tesla.”

¹NHMFL

3:42PM L3.00003 Phase competition in trisected superconducting dome , INNA VISHIK, Stanford University — The momentum-resolved nature of angle-resolved photoemission spectroscopy (ARPES) has made it a key probe of emergent phases in the cuprates, such as superconductivity and the pseudogap, which have anisotropic momentum-space structure. ARPES can be used to infer the origin of spectral gaps from their distinct phenomenology—temperature, doping, and momentum dependence, and this principle has been used to argue that the pseudogap is a distinct phase from superconductivity, rather than a precursor [1]. We have studied $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ (Bi-2212) using laser-ARPES, and our data give evidence for three distinct quantum phases comprising the superconducting ground state, accompanied by abrupt changes at $p \sim 0.076$ and $p \sim 0.19$ in the doping-and-temperature dependence of the gaps near the bond-diagonal (nodal) direction [2]. The latter doping likely marks the quantum critical point of the pseudogap, while the former represents a distinct competing phase at the edge of the superconducting dome. Additionally, we find that the pseudogap advances closer towards the node when superconductivity is weak, just below T_c or at low doping, and retreats towards the antinode well below T_c and at higher doping. This phase competition picture together with the two critical doping are synthesized into our proposed phase diagram, which also reconciles conflicting phase diagrams commonly used in the field. Our results underscore the importance of quantum critical phenomena to cuprate superconductivity, provide a microscopic picture of phase competition in momentum space, and predict the existence of phase boundaries inside the superconducting dome which are different from simple extrapolations from outside the dome.

4:18PM L3.00004 Novel Magnetism in the Pseudogap Phase of the Cuprates¹, MARTIN GREVEN, University of Minnesota — Magnetic correlations might cause the superconductivity in the cuprates and are generally believed to be antiferromagnetic. Following our success in growing sizable crystals of the tetragonal compound $\text{HgBa}_2\text{CuO}_{4+\delta}$ [1], we used polarized neutron diffraction to demonstrate that the unusual magnetic order previously observed in $\text{YBa}_2\text{Cu}_3\text{O}_{6+\delta}$ [2] is a universal property of the pseudogap phase [3]. Subsequent inelastic neutron scattering experiments revealed several accompanying, weakly-dispersive magnetic excitation branches in $\text{HgBa}_2\text{CuO}_{4+\delta}$ [4]. Unlike antiferromagnetism, the novel magnetic order does not break the lattice translational symmetry. Nevertheless, the excitations mix with conventional antiferromagnetic fluctuations. Our results point toward the need for a multi-band description of the cuprates, and they are consistent with the notion that the phase diagram is controlled by an underlying quantum critical point [5]. The neutron scattering results will be discussed together with new dc resistivity data for the pseudogap phase of $\text{HgBa}_2\text{CuO}_{4+\delta}$ [6].

4:54PM L3.00005 From Spin Liquid to High T_c Superconductors, PATRICK A. LEE, MIT — The discovery of high T_c superconductors has revived interest in Anderson's resonating valence bond theory (RVB) of a quantum spin liquid, first proposed in 1973. In the past few years, several examples of quantum spin liquids have been discovered experimentally. The organic spin liquid has been studied most thoroughly and shows strong evidence for emergent fermionic spinons. I shall review some of the data and argue that theories based on slave particles and gauge fields have been successful in accounting for these remarkable data. The question remains as to whether a similar formulation of fermionic spinon and bosonic holes can form the basis for a theory of high T_c superconductors. I shall show that a recent modification¹ of the mean field RVB phase diagram can explain a lot of the phenomenology. I shall also attempt to put this theory in the context of recent discoveries concerning symmetry breaking in the pseudogap phase.

Session L4 DAMOP: Focus Session: Numerical Methods for Studying Nonequilibrium Many-Body Dynamics; DMRG, DMFT, Truncated Wigner Approximation, Exact Diagonalization 205C

2:30PM L4.00001 Finite temperature DMRG and the Drude weight of spin 1/2 Heisenberg chains, CHRISTOPH KARRASCH, JENS BARDARSON, JOEL MOORE, University of California at Berkeley — We propose an easy-to-implement approach to study time-dependent correlation functions of one dimensional systems at finite temperature T using the density matrix renormalization group (DMRG). If the auxiliary degrees of freedom which purify the statistical operator are time-evolved with the physical Hamiltonian but reversed time, the entanglement blow-up inherent to any time-dependent DMRG calculation is dramatically reduced. The numerical effort of finite temperature DMRG becomes comparable to that at $T = 0$, and thus significantly longer timescales can be reached. We exploit this to investigate current correlation functions of the XXZ spin 1/2 Heisenberg chain. At intermediate to large T , we can explicitly extract the Drude weight D from the long-time asymptotics. For the isotropic chain, D is finite. At low temperatures, we establish an upper bound for the Drude weight.

2:42PM L4.00002 Universal non-equilibrium quantum dynamics in imaginary time, CLAUDIA DE GRANDI, Yale University, ANATOLI POLKOVNIKOV, ANDERS SANDVIK, Boston University — We propose a method to study the dynamical response of a quantum system by evolving it with an imaginary-time dependent Hamiltonian. The leading non-adiabatic response of the system driven to a quantum-critical point is universal and characterized by the same exponents in real and imaginary time. For a linear quench protocol, the fidelity susceptibility and the geometric tensor naturally emerge in the response functions. Beyond linear response we extend the finite-size scaling theory of quantum phase transitions to non-equilibrium setups. Imaginary-time dynamics is also amenable to quantum Monte Carlo simulations, which we apply here to quenches of the transverse-field Ising model to quantum critical points in one and two dimensions.

2:54PM L4.00003 The Approach To Typicality in Many-Body Quantum Systems, SAI VINJANAMPATHY, SHAWN DUBEY, LUCIANO SILVESTRI, KURT JACOBS, University of Massachusetts, Boston — The recent discovery that for large Hilbert spaces, almost all (that is, typical) Hamiltonians have eigenstates that place small subsystems in thermal equilibrium, has shed much light on the origins of irreversibility and thermalization. Here we present numerical evidence that many-body lattice systems generically approach typicality as the number of subsystems is increased, and thus provide further support for the eigenstate thermalization hypothesis. We will present our results that indicate that the deviation of many-body systems from typicality scales as an inverse power of the number of systems, and we compare this with the equivalent scaling for random Hamiltonians.

3:06PM L4.00004 Quantum Dynamics of Population-Imbalanced Fermi Mixture in One-dimensional Optical Lattices¹, BIN WANG, Department of Physics and Astronomy, University of Pittsburgh, ERHAI ZHAO, Department of Physics and Astronomy, George Mason University, W. VINCENT LIU, Department of Physics and Astronomy, University of Pittsburgh — We study the (pseudo-)spin dynamics of two-component Fermi mixture with population imbalance in one-dimensional (1D) optical lattices within the framework of 1D Hubbard model, utilizing the time-evolving block decimation (TEBD) algorithm. We consider the situation in which the center region of the system is initially fully occupied and the left-over fully polarized fermions are initially localized on the wings. It is found that for strong interaction the (pseudo-)spin polarization diffuses throughout the system qualitatively in the same way as the diffusion of non-interacting particles in 1D optical lattices. We further look into the time evolution of correlation functions such as pairing correlation and single particle green functions. According to our simulations, the partially polarized inhomogeneous Fermi gas appears to show no tendency of dynamically developing into a FFLO-type of state, contrary to what might have been expected.

¹We acknowledge the support from DARPA OLE.

3:18PM L4.00005 Non-equilibrium dynamics of the driven Hubbard model , ADRIANO AMARICCI, CNR-IOM, uos SISSA Trieste, Via Bonomea 265, 34125 Italy, CEDRIC WEBER, Cavendish Laboratory, Cambridge University, J.J. Thomson Ave. , Cambridge, UK, MASSIMO CAPONE, CNR-IOM, uos SISSA Trieste, Via Bonomea 265, 34125 Italy/Physics Department, University “Sapienza”, Piazzale A. Moro 2, 00185 Rome, Italy, GABRIEL KOTLIAR, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — We investigate the dynamics of a two-dimensional Hubbard model in a static electric field in order to identify the conditions to reach a non-equilibrium stationary state. For a generic electric field, the convergence to a stationary state requires the coupling to a thermostating bath absorbing the work done by the external force. Following the real-time dynamics of the system, we show that a non-equilibrium stationary state is reached for essentially any value of the coupling to the bath. We map out a phase diagram in terms of dissipation and electric field strengths and identify the dissipation values in which steady current is largest, and correspondingly a suitable entropy function is smallest, for a given field.

3:30PM L4.00006 Probing Phases and Quantum Criticality using Deviations from the Local Fluctuation-Dissipation Theorem¹ , ERIC DUCHON, The Ohio State University, YASUYUKI KATO, Los Alamos National Laboratory, NAOKI KAWASHIMA, University of Tokyo, NANDINI TRIVEDI, The Ohio State University — One of the major open questions in the study of ultracold atom systems is how to obtain the finite temperature phase diagram of a given Hamiltonian directly from experiments.² Previous work in this direction required quantum Monte Carlo simulations to directly model the experimental situation in order to extract quantitative information, clearly defeating the purpose of an optical lattice emulator. We propose a new method that utilizes deviations from a local fluctuation dissipation theorem to construct a finite temperature phase diagram, for the first time, from local observables accessible by *in situ* experimental observations. Our approach extends the utility of the fluctuation-dissipation theorem from thermometry to the identification of quantum phases, associated energy scales and the quantum critical region. We test our ideas using large-scale quantum Monte Carlo simulations of the two-dimensional Bose Hubbard model.³

3:42PM L4.00007 A new theoretical method to describe nonequilibrium cold atoms in optical lattices , KARLIS MIKELSONS, JIM FREERICKS, Georgetown University, H. R. KRISHNAMURTHY, Indian Institute of Science, Bangalore — We use perturbation theory in the hopping (strong-coupling expansion) to describe the nonequilibrium dynamics of strongly correlated fermions. Our expansion is a self-consistent expansion for the self-energy which goes beyond the RPA and allows for damping and relaxation effects. We apply this method to solve the homogeneous Fermi - Hubbard model driven by an external field. We investigate the damping of Bloch oscillations (for a uniform dc field) and show results for the current, the nonequilibrium density of states and the momentum distribution. We carefully benchmark the technique using the exact sum rules to determine its accuracy and we discuss regions of parameter space where the method no longer converges. This technique is quite competitive with other methods (such as DMFT) in the regions where it converges.

3:54PM L4.00008 A Slave Spin Impurity Solver for Non Equilibrium Dynamical Mean Field Theory , MARCO SCHIRO, Princeton Center for Theoretical Science and Department of Physics, Joseph Henry Laboratories, Princeton University, Princeton, NJ 08544 — The non equilibrium dynamics of strongly correlated electronic systems represents a challenging theoretical problem in condensed matter physics with applications ranging from pump probe experiments in correlated materials to dynamics in ultracold atomic gases. Dynamical Mean Field Theory (DMFT) has emerged in recent years as a powerful theoretical framework to deal with strong correlations in a non perturbative way. Its extension to the out of equilibrium case requires the solution of an auxiliary quantum impurity model in a non equilibrium bath. Here we present an impurity solver for Non Equilibrium DMFT based on a slave spin representation of the fermionic degrees of freedom. We apply this method to study the quench dynamics in the single band fermionic Hubbard model and compare the results with the time dependent Gutzwiller method.

4:06PM L4.00009 A multi-site mean-field theory for cold bosonic atoms in optical lattices¹ , PAWEL PISARSKI, THOMAS MCINTOSH, ROBERT GOODING, EUGENE ZAREMBA, Queen's University — Mean-field theory is one of the most commonly used approximate methods in condensed matter physics. As applied to the Bose-Hubbard model it provides a simple, qualitative explanation of the Mott insulator – superfluid transition. In its usual form, one invokes a superfluid order parameter to decouple the Bose-Hubbard Hamiltonian into a sum of independent site Hamiltonians. Within this single-site mean-field theory (SSMFT) the equilibrium state is determined by minimizing the grand potential with respect to the order parameter. To improve on this procedure we have developed a multi-site mean-field theory (MSMFT), whereby the lattice is partitioned into small clusters which are decoupled by means of the usual mean-field method. The most general decoupling procedure necessitates the assignment of site-dependent order parameters to the sites bounding the cluster. This leads to a non-trivial topology of the grand potential and one finds, in general, that the equilibrium state is a saddle point. As a result, one cannot use a variational principle to locate the equilibrium states of interest. In this talk, we outline the MSMFT we have developed and give an example of its application.

4:18PM L4.00010 Feynman diagrams versus Feynman quantum emulator , KRIS VAN HOUCKE, Ghent University, FÉLIX WERNER, Laboratoire Kastler Brossel, Ecole Normale Supérieure, EVGENY KOZIK, ETH, Zürich, NIKOLAY PROKOF'EV, BORIS SVISTUNOV, University of Massachusetts, Amherst, MARK KU, ARIEL SOMMER, LAWRENCE CHEUK, Massachusetts Institute of Technology, ANDRÉ SCHIROTZEK, Advanced Light Source, Lawrence Berkeley National Laboratory, MARTIN ZWIERLEIN, Massachusetts Institute of Technology — Precise understanding of strongly interacting fermions, from electrons in modern materials to nuclear matter, presents a major goal in modern physics. However, the theoretical description of interacting Fermi systems is usually plagued by the intricate quantum statistics at play. Here we present a cross-validation between a new theoretical approach, Bold Diagrammatic Monte Carlo (BDMC), and precision experiments on ultra-cold atoms. Specifically, we compute and measure with unprecedented accuracy the normal-state equation of state of the unitary gas, a prototypical example of a strongly correlated fermionic system. Excellent agreement demonstrates that a series of Feynman diagrams can be controllably resummed in a non-perturbative regime using BDMC. This opens the door to the solution of some of the most challenging problems across many areas of physics.

4:30PM L4.00011 Non-equilibrium dynamics, heating, and thermalization of cold atoms in optical lattices, ANDREW DALEY, University of Pittsburgh — In recent years, out of equilibrium many-body dynamics have become accessible in a controlled way in experiments with ultracold quantum gases. Time-dependent processes in these systems are not only intrinsically interesting, but also extremely important for understanding many-body state preparation, heating, and thermalization as they arise in experiments. They also offer new connections to phenomena studied in solid-state systems. This interest has been complemented by the development of a range of numerical methods, including time-dependent density matrix renormalization group (t-DMRG) methods and matrix product state approaches, which have been applied to study dynamics in 1D lattice systems and spin chains. We have extended and applied these methods to study the non-equilibrium dynamics of cold atoms in optical lattices arising from different heating mechanisms, especially due to spontaneous emissions from incoherent scattering of the lattice light, or via classical noise on the optical potential. Understanding how these heating mechanisms affect the properties of different many-body states is crucial in addressing current experimental challenges in the preparation of interesting quantum phases at low temperatures. The resulting non-equilibrium dynamics typically depend strongly on the properties of the many-body state, with different states being more or less sensitive to different heating mechanisms. Moreover, there is often a separation of timescales between some excitations that thermalize rapidly, and some that do not properly thermalize in the duration of an experimental run, which can strongly modify, and even reduce the overall effects of the heating processes. Part of this work involves the treatment of open many-body quantum systems, where we derive many-body master equations to describe the dynamics and solve these numerically by combining t-DMRG methods with quantum trajectory techniques from quantum optics.

5:06PM L4.00012 Pattern formation in time-of-flight images of heavy-light mixtures of atoms undergoing Bloch oscillations¹, JAMES FREERICKS, Department of Physics, Georgetown University — Nonequilibrium dynamical mean-field theory is employed to solve for the response of a light-heavy Fermi-Fermi mixture of atoms to the presence of a uniform electric field (via “pulling” the lattice through the cloud of atoms). When we express the (momentum-dependent) light atom distribution functions as functions of the band energy and the projection of the velocity along the direction of the artificial electric field, the system develops characteristic spiral patterns that become more complex as the system evolves, but remain stable for a long period of time. These patterns typically show a contrast of about 10-20% fluctuations about the mean density, so they are challenging but possible to observe in a time-of-flight measurement. We also show a characteristic change of character of the system between small fields and large fields. The best candidate system for examining these patterns is a $\text{Li}^6\text{-K}^{40}$ mixture on a two-dimensional optical lattice. We expect similar results should occur for light Fermi-heavy Bose mixtures as well, but it is likely this behavior will not be seen in Bose-Bose mixtures.

Tuesday, February 28, 2012 2:30PM - 5:30PM – Session L5 DMP: Focus Session: Interfaces in Complex Oxides - Nickelates 206A

2:30PM L5.00001 Exchange Bias in LaNiO_3 -based heterostructures, MARTA GIBERT, RAOUL SCHERWITZL, PAVLO ZUBKO, DPMC, University of Geneva, JORGE IÑIGUEZ, ICMAB-CSIC, JEAN-MARC TRISCONE, DPMC, University of Geneva — The wide spectrum of exotic properties exhibited by transition-metal based oxides is triggered by the interplay between the spin, charge, orbital and lattice degrees of freedom. In this context, interface engineering in complex oxide heterostructures enables not only further tuning of the exceptional properties of these materials, but also gives access to hidden phases and emergent physical phenomena. Here, we show how interface engineering can induce a complex magnetic structure in a non-magnetic material. We specifically show that exchange bias phenomenon can unexpectedly emerge in (111)-oriented heterostructures involving materials a priori non-candidates for the development of such behavior, namely paramagnetic LaNiO_3 (LNO) and ferromagnetic LaMnO_3 (LMO). The observation of the exchange bias in LNO/LMO superlattices not only implies the development of interface-induced magnetism in the paramagnetic LNO layers, but also provides us with a very subtle tool for probing the interfacial coupling between the LNO and the LMO layers. First-principles calculations indicate that this interfacial interaction may give rise to an unusual spin order resembling a spin density wave within the LNO layers. Other possible magnetic orders are also discussed.

2:42PM L5.00002 Resonant x-ray reflectivity study of interface reconstructions in LaCoO_3 and other transition-metal-oxide heterostructures, VLADIMIR HINKOV, Max-Planck-UBC Centre for Quantum Materials and University of British Columbia, Canada, WOO-SEOK CHOI, Oakridge National Laboratory, U.S.A., JORGE HAMANN-BORRERO, IFW Dresden, Germany and University of British Columbia, Canada, GEORGE A. SAWATZKY, Department of Physics and Astronomy, University of British Columbia, Canada, HO-NYUNG LEE, Oakridge National Laboratory, U.S.A., SEBASTIAN MACKE, Max-Planck-Institut, FKF, Germany and Max-Planck-UBC Centre for Quantum Materials, ABDULLAH RAD, Department of Chemistry, University of British Columbia, Canada — Transition-metal-oxide (TMO) heterostructures offer the opportunity to combine the study of unconventional physical properties with the design of novel functionalities, which are not observed in simple semiconductor or metal heterostructures. In my talk I will concentrate on electronic and chemical reconstructions observed at the interfaces of heterostructures based on LaCoO_3 and other correlated oxides. After briefly summarizing the properties of the novel resonant x-ray technique of orbital reflectometry which we recently used to study the orbital reconstruction in LaNiO_3 heterostructures (Benckiser et al., Nature Materials 10, 189, (2010)), I will discuss the application of this technique, and of usual resonant x-ray reflectometry, to study the electronic and orbital properties at the interfaces and at the surface of LaCoO_3 / LaAlO_3 heterostructures. Finally, I will offer an outlook to the application of orbital reflectometry to other systems.

2:54PM L5.00003 Quantum confinement of correlated e_g^1 electrons in rare earth nickelate heterostructures, JIAN LIU¹, Department of Physics, University of Arkansas, M. VAN VEENENDAAL, Argonne National Lab, S. OKAMOTO, Oak Ridge National Lab, M. KAREEV, B. GRAY, Department of Physics, University of Arkansas, P. RYAN, J.W. FREELAND, Argonne National Lab, J. CHAKHALIAN, Department of Physics, University of Arkansas — Complex oxide heterostructures have emerged as a new playground for controlling the mutually coupled charge, spin, orbital and lattice degrees of freedom, and a promising route to stabilize unusual phases not existing in the bulk. In particular, quantum well structures have recently attracted attention due to the potential in creating novel two-dimensional systems with confined correlated electrons. To this end, we have studied the e_g^1 system based on the $3d^7$ low-spin state in perovskite rare earth nickelates which are artificially confined by wide-gap dielectrics LaAlO_3 . The combination of transport measurements and dynamical-mean-field calculations indicate that, a Mott-type metal-insulator transition can be induced by confinement via dimensionality-control. X-ray absorption spectroscopy reveals that the electronic modification in proximity to the confining interfaces is caused by modulated covalency, which is in good agreement with cluster calculations. 3:06PM L5.00004 Epitaxial Stabilization of Ultrathin Rare-Earth Nickelates¹, D.J. MEYERS, E.J. MOON, M. KAREEV, University of Arkansas, I.C. TUNG, Northwestern University, B.A. GRAY, JIAN LIU, University of Arkansas, M.J. BEDZYK, Northwestern University, J.W. FREELAND, Advanced Photon Source, Argonne National Laboratory, J. CHAKHALIAN, University of Arkansas — The nickelate family of perovskite materials has attracted great attention in recent years due to the interesting range of properties they exhibit. In this talk we report on the successful synthesis of EuNiO_3 , YNiO_3 , and PrNiO_3 films grown by interrupted pulse laser epitaxy on various substrates. Investigation of the phase space of nickelate thin film epitaxy revealed a linear trend between the optimized growth temperature and the Goldschmidt tolerance factor. This correlation is explained through epitaxial stabilization and the increase of the lattice energy via distortion of the ideal perovskite cell. This explanation offers the additional benefit of not being restricted only to the nickelate perovskite family, giving it possible applicability for a wide range of perovskite-structured materials.

3:18PM L5.00005 Unipolar Field-Effect Diode Based on a Complex Oxide¹, WENG LEE LIM, SERGEI URAZHIN, Department of Physics, Emory University, Atlanta, EUN JU MOON, MICHAEL KAREEV, DEREK MEYERS, JAK CHAKHALIAN, Department of Physics, University of Arkansas, Fayetteville, JOHN FREELAND, Argonne National Laboratory, Argonne — We demonstrate rectifying behavior in a field-effect device structure fabricated from thin NdNiO_3 films grown on SrTiO_3 substrates by the pulsed laser deposition technique. In contrast to the conventional three-terminal field effect devices, the device has only two terminals with the field gate electrode connected to one of the terminal electrodes. The active device area is a $10\mu\text{m} \times 10\mu\text{m}$ square with a $\text{Au}/\text{Al}_2\text{O}_3/\text{NdNiO}_3/\text{SrTiO}_3$ structure, where Au and Al_2O_3 are the gate and the gate insulator, respectively. At small bias voltages, the device exhibits a metal-insulator transition near $T=150\text{K}$, similar to extended NdNiO_3 films. I-V measurements reveal a strong dependence of device characteristics on temperature, applied bias, and both thermal and applied bias histories. We analyze the IV characteristics by using a modified charge-control model based on accumulation of charges in the channel near the gate oxide interface. We deduce the temperature dependence of the effective zero-field charge carrier mobility for the channel by including a field-dependence mobility. The observed hysteretic effects can be utilized in complex oxide devices that combine together both the diode and the memory functionalities.

¹This work is supported by ONR grant 10-001-SA1002031.

3:30PM L5.00006 Asymmetric Orbital-Lattice Interactions in Ultrathin Correlated Oxide Films¹, JAK CHAKHALIAN, Physics Department, University of Arkansas — Epitaxial control of strongly correlated electrons offers opportunities to push beyond the bulk phase diagram and access new ground states. Using resonant x-ray spectroscopies combined with density functional calculations, we report the discovery of an asymmetric biaxial strain-induced 3d-orbital response in ultrathin films of the correlated metal LaNiO_3 that are not accessible in the bulk [J. Chakhalian et al., PRL, 107, 116805 (2011)]. Compressive strain results in an orbital polarization due to structural induced changes in the crystal field, but tensile strain shows no orbital response. This is accompanied by a strong change in the oxygen hole states due a systematic change of the charge transfer energy as a function of strain. We suggest that knowledge of this asymmetric orbital-lattice interaction is fundamental to the rational design of quantum materials with exotic correlated phases and enhanced critical temperatures.

3:42PM L5.00007 ABSTRACT WITHDRAWN —

3:54PM L5.00008 *in situ* studied correlated oxide LaNiO_3 ultra thin film by angle resolved photoemission spectroscopy, H.K. YOO, Seoul National University, Y.J. CHANG, Advanced Light Source (ALS), LBNL & Fritz-Haber-Institut, K.S. KIM, L. MORESCHINI, Advanced Light Source (ALS), LBNL, D.W. JEONG, Y.S. KIM, Seoul National University, A. BOSTWICK, E. ROTENBERG, Advanced Light Source (ALS), LBNL, T.W. NOH, Seoul National University — Recently, RNiO_3 (R : rare earth) attracted increasing attention due to the possible realization of the electronic band structure similar to the high-temperature superconductor cuprates. Among them, LaNiO_3 based heterostructures have shown various fascinating physical properties such as dimensionality controlled electronic phase transitions. Theoretical works on confined LaNiO_3 through heterostructuring predicted cuprate-like band structure and magnetic properties. Here, we reports *in-situ* angle resolved photoemission spectroscopy results on the LaNiO_3 films grown by pulsed laser deposition method. We carefully controlled the thickness of LaNiO_3 films from one to 30 unit cells and measured the thickness dependent band dispersions. First, we will discuss the strong electronic correlation effect in bulk-like band structure of thick LaNiO_3 films comparing to the previously reported LDA+DMFT calculation. Moreover, we will discuss the thickness dependent band structure. As decreasing the film thickness, we observed the charge redistribution of two $\text{Ni } e_g$ orbitals at the Fermi surface. The origins of thickness dependent electronic structure will be discussed.

4:06PM L5.00009 Influence of Symmetry on the Octahedral Rotations of Epitaxial RNiO_3 Thin Films, I.C. TUNG, Department of Materials Science and Engineering, Northwestern University; Advanced Photon Source, Argonne National Laboratory, JIAN LIU, B. GRAY, J. CHAKHALIAN, Department of Physics, University of Arkansas, J.M. RONDINELLI, E.A. KARAPETROVA, J.H. LEE, Advanced Photon Source, Argonne National Laboratory, M.J. BEDZYK, Department of Materials Science and Engineering, Northwestern University, J.W. FREELAND, Advanced Photon Source, Argonne National Laboratory — Understanding the structural and electronic behavior of ABO_3 thin films subjected to confinement, lattice misfit and broken symmetry at the interface in the ultra-thin limit is fundamentally important for the rational design of new materials [1]. However, the epitaxial strain will not only due to a change the in-plane lattice constants but also the octahedral rotations connected to bond angles and crystallographic symmetry. Here we present a study of the effect of the bulk lattice symmetry on octahedral rotations under epitaxial strain in thin films of RNiO_3 ($R=\text{La, Pr, Nd}$) grown on various substrates by pulsed laser deposition. A combination of high-resolution x-ray diffraction, polarization-dependent soft x-ray absorption spectroscopy, and first-principles density functional calculations has been applied to elucidate structural and electronic properties of the samples. Work at the Advanced Photon Source, Argonne is supported by the U.S. Department of Energy, Office of Science under Contract No. DE-AC02-06CH11357.

4:18PM L5.00010 Probing the Nickelate Ground State in NdNiO_3 Superlattices, ANKIT DISA, DIVINE KUMAR, JOSEPH NGAI, FRED WALKER, CHARLES AHN, Center for Research on Interface Structures and Phenomena and Department of Applied Physics, Yale University — The rare-earth nickelates of the type RNiO_3 exhibit tunable, sharp metal-insulator transitions as a function of R size, film thickness, and external fields. The nature of these transitions has been the subject of much study, including examination of the insulating ground state. NdNiO_3 has garnered particular interest due to a concomitant magnetic crossover to an antiferromagnetic state occurring at the metal-insulator transition temperature. Several previous studies have focused on thin films; in this work, we examine NdNiO_3 layers confined in heterostructures. The metal-insulator transition temperature can be manipulated based on the thickness of the NdNiO_3 layers within the heterostructure, and a suppression of the high-temperature metallic phase leads to a crossover to localization related to a change in dimensionality. The electronic structure of these phases probed using x-ray absorption spectroscopy enables us to elucidate the link between potential charge ordering and dimensionality in the ground state of this system.

4:30PM L5.00011 Electrostatic control of the metal-insulator transition of ultrathin NdNiO₃ films, JUNWOO SON, BHARAT JALAN, ADAM P. KAJDOS, Materials, UCSB, LEON BALENTS, S. JAMES ALLEN, Physics, UCSB, SUSANNE STEMMER, Materials, UCSB — Rare earth nickelates (RNiO₃) exhibit a first order metal insulator transition upon cooling. Bulk studies on chemical doping indicated that both divalent and quaternary ions were effective in shifting T_{MIT} to lower temperatures by ~ 50 to 25 K for 1 % hole and electron doping, respectively. However, separating the influence of structural distortions from band filling is particularly important for the nickelates. Here we present a new approach to control the band-filling in nanoscale NdNiO₃ thin films by modulation doping. NdNiO₃ is remotely doped by interfacing it with a degenerately doped conventional band insulator, La-doped SrTiO₃. We show that the remote doping approach allows for purely electronic modulation of a carrier density in the absence of other structural changes. The proposed approach is experimentally tested using ultrathin (2.5 nm) NdNiO₃ films grown on La-doped SrTiO₃ films with different carrier concentrations. We show that remote doping systematically changes the charge carrier density in the NdNiO₃ film and causes a moderate shift (~ 20 K) in the metal-insulator transition temperature. These results will be discussed in the context of theoretical models of the materials exhibiting a metal-insulator transition.

4:42PM L5.00012 Tuning Electronic Conductivity in Nickelate Heterostructures, DIVINE KUMAR, JOSEPH NGAI, HANGHUI CHEN, ANKIT DISA, Center for Research on Interface Structure and Phenomena and Department of Applied Physics, Yale University, KARYN LEHUR, Department of Physics Yale University, SOHRAB ISMAIL-BEIGI, CHARLES AHN, FREDRICK WALKER, Center for Research on Interface Structure and Phenomena and Department of Applied Physics, Yale University — Bulk LaNiO₃ (LNO) is a metallic material, but for thin films below a critical thickness of about 5-6 unit cells of LNO, a transition occurs from metallic to insulating transport behavior. This transition is suppressed in superlattice structures with LaAlO₃ (LAO) spacers which are found to be metallic down to 3 unit cell thick LNO. To understand the differences between thin film and superlattices, we have identified structural differences in thin films and superlattice structures of LNO and LAO using a combination of first principles theory and synchrotron x-ray diffraction. Distortions are observed in the Ni-O-Ni bond angle in LNO epilayers grown on LAO resulting from relaxations at the vacuum-LNO interface. These distortions are suppressed in superlattice structures. Based on our observations, we propose that the electronic properties of nickelate superlattices can be designed by carefully selecting spacer layers that result in specific structural distortions in the LNO conducting layers. By tuning the observed distortions in this fashion, we identify a new pathway for controlling the electronic properties of rare earth nickelate compounds.

4:54PM L5.00013 Composition spread studies of (RE)NiO₃-LaNiO₃ thin films¹, RICHARD SUCHOSKI, ICHIRO TAKEUCHI, University of Maryland, College Park - MSE, CNAM, KUI JIN, RICHARD GREENE, University of Maryland, College Park - Physics, CNAM — Epitaxial thin films of La_xNd_{1-x}NiO₃ and La_xPr_{1-x}NiO₃ were grown via pulsed laser deposition on SrTiO₃ (001) with an automated moving shutter system to create 100 nm thick composition spreads. These films have the advantage of providing a continuous spectrum of doping compositions at the same deposition conditions, such as temperature and oxygen pressure, without the need to prepare different stoichiometric targets or perform different depositions for desired compositions. Composition evolution is verified via wavelength dispersive spectroscopy, and x-ray diffraction mapping shows that the lattice constant of the film varies continuously from LaNiO₃ to NdNiO₃. Simultaneous measurements of resistance versus temperature down to 4.2 K across the spreads show evolution in transport behavior. The details will be discussed.

¹Funding provided by AFO SR MURI Grant #FA95500910603 and NSF MRSEC @ UMD (DMR 0520471).

5:06PM L5.00014 Conduction mechanisms in epitaxial and polycrystalline SmNiO₃ thin films, SIEU D. HA, SHRIRAM RAMANATHAN, Harvard University, School of Engineering and Applied Sciences — Correlated oxides that exhibit metal-insulator phase transitions are emerging as potential candidates for switching devices and their fundamental physical properties are of interest. One such material is SmNiO₃, which has a transition temperature above room temperature (~ 400 K in bulk crystals). We present temperature- and bias-dependent conduction mechanisms in epitaxial and polycrystalline SmNiO₃ thin films. In both cases, at low electric field we observe thermally assisted hopping conduction through defect states. At high electric field the conduction transitions to a space-charge limited regime controlled by an exponential trap distribution. The trap decay parameter in epitaxial films does not have the expected $1/T$ temperature dependence, which may be a signature of band gap narrowing at high temperature due to the insulator to metal transition. The role of defects in affecting charge transport parameters will be discussed.

5:18PM L5.00015 Many-body effects in the capacitance of multilayers composed of Mott insulators, SIMON HALE, JIM FREERICKS, Georgetown University — Inhomogeneous dynamical mean-field theory is employed to investigate the non-linearity of the capacitance of multilayer nanostructures. The multilayer nanostructures are constructed with semi-infinite metallic leads coupled via a strongly correlated (Mott insulating) dielectric barrier. Results on the effects of varying barrier thickness, temperature, potential difference, screening length, and chemical potential will be presented. In addition, we also intend to examine phase separation effects which have been experimentally measured to enhance the many-body capacitance over the geometric capacitance.

Tuesday, February 28, 2012 2:30PM - 5:18PM —

Session L6 DMP: Focus Session: van der Waals Bonding in Advanced Materials - Metal Oxide Frameworks & Active Materials 206B

2:30PM L6.00001 Trends in CO₂-MOF Binding from First Principles: Implications for Gas Separations¹, JOSHUA HOWE, Department of Chemical and Biomolecular Engineering, UC Berkeley; The Molecular Foundry, LBNL, BEREND SMIT, Department of Chemical and Biomolecular Engineering, UC Berkeley, JEFFREY NEATON, Molecular Foundry, LBNL — Metal-organic frameworks (MOFs) are a class of highly ordered, highly customizable nanoporous materials that are attractive for use in energy-relevant gas separations. MOF-253 Al(OH)(bpydc) can be post-synthetically modified by introduction of metal cations and charge-stabilizing anions [1]. These post-synthetically modified MOF-253 samples have been shown to exhibit enhanced CO₂-N₂ selectivity over the unmodified framework [1]. Here we use van der Waals-corrected density functional theory (DFT) to study CO₂ binding energy trends in this series of modified frameworks. Particular focus is paid to examining the predictive power of our calculations on modified bipyridine fragments as a proxy for the full framework, as well as the suitability of binding energy trends to predict measured gas selectivity trends [1]. We focus on the following series of 10 post-synthetic modifications: CoCl₂, CuCl₂, FeCl₂, NiCl₂, PdCl₂, Co(BF₄)₂, Cu(BF₄)₂, Fe(BF₄)₂, Ni(BF₄)₂, Pd(BF₄)₂. [1] E. Bloch, et. al, J. Am. Chem. Soc., 132, 14382-14384, 2010.

¹We acknowledge support from DOE and computational resources from NERSC.

2:42PM L6.00002 Ligand-Assisted Enhancement of CO₂ Capture in Tunable MOFs: Balancing Electrostatic and van der Waals Interactions¹, ROBERTA POLONI, Molecular Foundry, LBNL and UC Berkeley, BEREND SMIT, UC Berkeley, JEFFREY B. NEATON, Molecular Foundry, LBNL — Metal-organic frameworks (MOFs) are promising nanoporous materials for CO₂ separation technologies. Here, we use first-principles van der Waals (vdW)-corrected calculations to identify and understand how CO₂ binds to a novel “BTT-type” MOF [1] featuring open metal centers. Our study indicates that CO₂ binds to the open metal cation sites, but with an adsorption energy that can be enhanced by more than a factor of two depending on the choice of the bridging ligand. Judicious choices for metal cations and bridging ligands are shown to lead to a maximum binding energy of 0.67 eV for MgBTT. In all cases, the binding can be attributed to a combination of electrostatics and dispersion, both critically sensitive to the local environment, and contributing nearly equally to the overall binding strength. The possibility to independently tailor these energetics in a manner optimal for CO₂ capture is discussed in the context of recent experiments.

¹We acknowledge DOE-BES for support, and NERSC for computational resources

2:54PM L6.00003 Simulations of physical adsorption of gases in IRMOFs, OSARO HARRIOTT, SILVINA GATICA, Howard University — We performed grand canonical Monte Carlo simulations to study the adsorption of noble gases, H₂ and CO₂ in IRMOF-1. The IRMOF is modeled as a simple structure where a cubic lattice is composed of adsorption centers that reproduce the strength of the metallic corners and organic linkers in the real structure. From the adsorption isotherms obtained in our simulations we calculated the isosteric heat of adsorption and compare with available experimental results. Research supported by NSF and ACS, PRF.

3:06PM L6.00004 Graphene Oxide Derived Carbons (GODC); High-Surface Area NanoPorous Materials for Hydrogen Storage and Carbon Capture¹, TANER YILDIRIM, NIST, Gaithersburg, MD 20899 and UPENN/Philadelphia, PA 19104 — Even though there has been extensive research on gas adsorption properties of various carbon materials based on activated carbon and nanotubes, there has been little work done on the gas adsorption properties of graphite oxide (GO). In this study [1], we show that one-and-a-half-century-old graphite oxide can be easily turned into a potentially useful gas storage material. In order to create high-surface nanoporous materials from GO, we used two different approaches. In the first approach, we have successfully synthesized graphene-oxide framework materials (GOFs) by interlinking GO layers by diboric acids. The resulting GOF materials have well defined pore size and BET surface area up to 500 m²/g with twice larger heat of adsorption of H₂ and CO₂ than those found in other physisorption materials such as MOF5. In the second approach, we synthesized a range of high surface area GO derived carbons (GODC) and studied their applications toward H₂, CO₂ and CH₄ gas storage. The GODCs, with wide range of pore structure, have been prepared by chemical activation with potassium hydroxide (KOH). We obtain largely increased surface areas up to nearly 1900 m²/g for GODC samples from 10 m²/g for initial GO. A detailed experimental study of high pressure excess sorption isotherms on GODCs reveal an increase in both CO₂ and CH₄ storage capacities compared to other high surface area activated carbons. Finally, we compared the gas sorption properties of our GO-based materials with other systems such as MOFs, ZIFs, and COFs.

¹The work was done in close collaboration with G. Srinivas, J. Bures, J. Ford, J. Simmons, and W. Zhou. The work is supported by DOE BES DE-FG02-08ER46522.

3:42PM L6.00005 Isosteric heat of adsorption of CO₂ in bundles of carbon nanotubes., MAMADOU MBAYE, SIDI MAIGA, SILVINA GATICA, Howard University — Using the grand canonical Monte Carlo method, we have evaluated the adsorption isotherms of CO₂ on the exterior of a bundle of carbon nanotubes. The isosteric heat is a property of the adsorbate that can be calculated from experimental or simulation data, and gives hints of the energy of adsorption and the structure of the adsorbate. From the simulated adsorption isotherms we calculated the isosteric heat of CO₂, Ar and CH₄ and compare with existing experimental data. Research supported by NSF and ACS, PRF.

3:54PM L6.00006 Gas Adsorption and Selectivity in Zeolitic Imidazolate Frameworks from First Principles Calculations, KEITH RAY, UC Berkeley Department of Physics, DAVID OLMSTED, UC Berkeley Department of Materials Science and Engineering, NING HE, University of Kansas Department of Chemistry, YAO HOUNDONOUGBO, Eastern Washington University Department of Chemistry and Biochemistry, BRIAN LAIRD, University of Kansas Department of Chemistry, MARK ASTA, UC Berkeley Department of Materials Science and Engineering — Zeolitic Imidazolate Framework (ZIFs) are excellent candidate materials for carbon capture and gas separation. Here we employ the van der Waals density functional (vdW-DF) [1] in an analysis of the binding energetics for CO₂, CH₄ and N₂ molecules in a set of ZIFs featuring different chemical functionalizations. We investigate multiple low-energy binding sites, which differ in their positions relative to functional groups on the imidazole linkers. In all cases an accurate treatment of van der Waals forces appears essential to provide reasonable binding energy magnitudes. We report results obtained from different parameterizations of the vdW-DF, providing comparisons between calculations and experimental values of the heat of adsorption [2]. This research is supported by the Energy Frontier Research Center “Molecularly Engineered Energy Materials,” funded by the US Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DE-SC0001342. Asta, B. B. Laird, O. M. Yaghi, J. AM. CHEM. SOC. 2010, 132, 11006-11008

4:06PM L6.00007 A theoretical study of the hydrogen-storage potential of (H₂)₄CH₄ in nanotubes and MOFs, TIMO THONHAUSER, QI LI, Wake Forest University — The material (H₂)₄CH₄, also called H4M, has exceptional hydrogen-storage potential of up to 33.3 mass%, not including the hydrogen in CH₄.¹ But, unfortunately, H4M is not stable under ambient conditions. For hydrogen storage near ambient pressure, it needs to be cooled to 65 K, and ambient temperature requires a pressure of 5–6 GPa.² In this study we use *ab initio* methods based on van der Waals DFT^{3,4} to investigate the possibility of creating such pressures through external agents such as metal organic framework (MOF) materials and carbon nanotubes. We find that MOFs can create considerable pressure for H4M in their cavities, but not the required 5–6 GPa, and therefore moderate cooling is still necessary. On the other hand, carbon nanotubes can create these high pressures for H4M, but the fact that this pressure exists only inside the nanotubes—and not in-between tubes in e.g. a bundle—lowers the volumetric storage density and makes this option less favorable for practical applications.

4:18PM L6.00008 The Role of Many-Body Dispersion Interactions in Molecular Crystal Polymorphism, LESLIE LEISEROWITZ, Weizmann Institute of Science, Rehovoth, Israel, NOA MAROM, Institute for Computational Engineering and Sciences, The University of Texas at Austin, ROBERT A. DISTASIO, JR., Department of Chemistry, Princeton University, NJ, VIKTOR ATALLA, SERGEY LEVCHENKO, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, SERGEY KAPISHNIKOV, Weizmann Institute of Science, Rehovoth, Israel, JAMES R. CHELIKOWSKY, Institute for Computational Engineering and Sciences, The University of Texas at Austin, ALEXANDRE TKATCHENKO, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin — Molecular crystals often have several polymorphs that are close in energy (few meV per molecule), but possess very different physical and chemical properties. Treating polymorphism from first principles has been a long standing problem because conventional density-functional theory (DFT) lacks a proper description of long-range dispersion interactions that govern the structure and energetics of molecular crystals. Here we assess the effect of the many-body dispersion (MBD) energy on the structure and relative energies of the polymorphs of benchmark molecular crystals: glycine, alanine, and para-diiodobenzene. This is accomplished by using the recently developed first-principles DFT+MBD method [A. Tkatchenko, R.A. DiStasio Jr., R. Car, M. Scheffler, submitted], based on the earlier Tkatchenko-Scheffler (TS) dispersion correction [PRL 102, 073005 (2009)]. We show that the non-additive MBD energy plays a crucial role in making qualitatively and quantitatively accurate predictions for the structure and relative energies of polymorphs.

4:30PM L6.00009 Interaction of endohedral molecular hydrogen with C₆₀: infrared study¹, TOOMAS RÖÖM, MIN GE, D. HÜVONEN, U. NAGEL, NICPB, Tallinn, Estonia, S. MAMONE, M.H. LEVITT, M. CARRAVETTA, Southampton Uni., UK, Y. MURATA, K. KOMATSU, Kyoto Uni., Japan, XUEGONG LEI, N.J. TURRO, Columbia Uni., New York — We report on the dynamics of isotopically different hydrogen molecules, H₂, D₂ and HD, trapped in the molecular cages of a fullerene C₆₀ [Min Ge et al., J. Chem. Phys. **134**, 054507 (2011), **135**, 114511 (2011)]. The infrared spectra were measured at temperatures from 5K to 300K and analyzed using a model of a vibrating rotor trapped in a spherical potential. The interaction potential was determined in the ground and in the first excited vibrational state of a hydrogen molecule. The isotropic part of the potential is similar for all three molecules studied. In HD@C₆₀ we observe the mixing of rotational states and an interference effect of the dipole moment terms due to the displacement of the HD rotation center from the fullerene cage center. A three-site Lennard-Jones potential in the pairwise additive five-dimensional potential energy surface reproduces the hydrogen IR spectrum with great accuracy [M. Xu et al., J. Chem. Phys. **130**, 224306 (2009)].

4:42PM L6.00010 ABSTRACT HAS BEEN MOVED TO D28.00007 —

4:54PM L6.00011 The role of dispersion interactions in the formation of near-surface oxygen defects in CeO₂(111): Comparing DFT+*U* with HF/DFT hybrid functionals using plane-waves as a basis set¹, JOACHIM PAIER, CHRISTOPHER PENSCHKE, JOACHIM SAUER, Humboldt-University, Unter den Linden 6, 10099 Berlin, Germany — Cerium oxide is of paramount importance in the field of heterogeneous catalysis and in solid oxide fuel cells. Its ability to easily release and store oxygen goes together with the distinct facility to form and heal oxygen vacancies. Upon its formation, the electrons left need to localize, but conventional semilocal density functionals (LDA, GGA) are known to fail here. Viable solutions to this problem are the DFT+*U* approach and hybrid Hartree-Fock/DFT functionals being computationally more demanding [1]. However, common implementations of aforementioned approaches do not incorporate long-range dispersion interactions. Given that relaxation effects upon defect formation lead to more open structures and given the relatively high polarizability of Ce-atoms, dispersion interactions are supposed to be non-negligible. We apply Grimme's dispersion correction [2] and carefully cross-check results. Furthermore, we will give thorough estimates on dynamic effects and try to shed some light on the effects induced by the defect concentration. [1] M. V. Ganduglia-Pirovano, J. L. F. Da Silva, and J. Sauer, Phys. Rev. Lett. **102**, 026101 (2009). [2] S. Grimme, J. Comput. Chem. **27**, 1787 (2006).

5:06PM L6.00012 Interaction of W(CO)₆ with SiO₂ Surfaces, JUAN SHEN, KALIAPPAN MUTHUKUMAR, HARALD O. JESCHKE, ROSER VALENTI, Institut fuer Theoretische Physik, Goethe Universitaet Frankfurt, 60438 Frankfurt Germany — The interaction of tungsten hexacarbonyl W(CO)₆ precursor molecules with SiO₂ substrates is investigated by means of density functional theory calculations with and without inclusion of long range van der Waals interactions. We consider two different surface models, a fully hydroxylated and a partially hydroxylated SiO₂ surface, corresponding to substrates under different experimental conditions. For the fully hydroxylated surface we observe only a weak interaction between the precursor molecule and the substrate with physisorption of W(CO)₆. Inclusion of van der Waals corrections results in a stabilization of the molecules on this surface. In contrast, we find a spontaneous dissociation of the precursor molecule on the partially hydroxylated SiO₂ surface where chemisorption of a W(CO)₅ fragment is observed upon removal of one of the CO ligands from the precursor molecule. Irrespective of the hydroxylation, the precursor molecule prefers binding of more than one of its CO ligands. In the light of these results, implications for the initial growth stage of tungsten nano-deposits on SiO₂ in an electron beam induced deposition process are discussed. [1] K. Muthukumar et al. Phys. Rev. B (in press) (2011)

Session L7 DMP: Carbon Nanotube Hybrid Structures - Properties, Synthesis, Characterization

207

2:30PM L7.00001 Self-assembly and electrostatic interactions of carbon nanotubes in nonpolar dielectric liquids, LUCIANA OLIVEIRA, RAMAKRISHNA PODILA, Clemson University, JAY GAILLARD, STEVEN SERKIZ, Savannah River National Laboratory, APPARAO RAO, Clemson University, SAVANNAH RIVER NATIONAL LABORATORY COLLABORATION — We report on the self-assembly of carbon nanotubes (CNTs) in nonpolar dielectric liquids under the influence of DC-generated electric fields. This process gives rise to electrostatic and hydrodynamic interactions of the CNTs in insulating nonpolar solvents. While some studies of the self-assembly of carbon nanotubes in response to a DC-field have been carried out in conductive solvents, the analysis of the self-assembly process is complicated by the current flow temporally affecting the particle charge and an assembly timescale of tenths to hundredths of seconds. In contrast, experiments in insulating liquids allow for the investigation of self-assembly processes where: the particle charge is not expected to change as a function of time and at a timescale of seconds this allows for an investigation of the transient states of the assembly process. In the presence of an electric-field, CNTs present in the solution experience an electrophoretic force due to their surface charges. When a DC field is applied across the electrodes, CNT bundles move according to their electrophoretic mobility. We find that the threshold voltage, above which the insulator-to-conductor transition occurs, varies sensitively as a function of zeta potential and hydrodynamic particle size. In addition, a percolation power law supports the observed threshold voltage as a function of CNT concentration and zeta potential.

2:42PM L7.00002 A Group Theoretic Approach to Nonlinear and Gradient Elastic Terms for Graphene and Carbon Nanotubes, ALEXANDER ALEMI, JAMES SETHNA, Cornell — Nonlinear and gradient corrections to the elastic theory of graphene and carbon nanotubes are important for determining the thermal conductivity, mechanical properties under large deformations, dissipation in nanotube oscillators and other mechanical properties. By applying group theory, we can systematically and efficiently work out all nonlinear elastic terms that can appear in a Ginzburg-Landau formulation of the elastic free energy in terms of the material displacement gradient tensor. Graphene serves as a perfect example material, having an interesting hexagonal symmetry and being a material in which nonlinear elastic terms are important. This approach allows us to demonstrate the usual cubic corrections. Additionally, we find higher order strain corrections which correspond to bending and rolling the graphene sheet, as well as gradient terms which are important for describing the long wavelength phonon dispersion. We will enumerate the most important contributions to the free energy, and measure the corresponding elastic constants with simulation.

2:54PM L7.00003 A Signature of Spatial Correlations between rare earth ions and single-wall nanotubes wrapped with DNA in their mixed solution, TETYANA IGNATOVA, SLAVA V. ROTKIN, Lehigh University, Physics Department — We propose that the fluorescence resonance energy transfer (FRET) between the rare earth ions (REI) and single-wall nanotubes (SWNT) can be used to measure their Coulomb correlation in solution. As a calibration experiment the FRET between two different REIs, being the energy donor and the acceptor, in their mixed solution has been used. From the photoluminescence decay time we were able to extract the characteristic distance between unlike REIs. Our study revealed negative correlation (the repulsion) for Tb-Eu solution. In the case of the solution containing the REI and the SWNTs wrapped with DNA we observed a significant positive correlation (the attraction and the complex formation). The data is in a good agreement with the theoretical estimates and allows to propose REIs and their FRET as a sensitive tool for detecting kinetics of interaction of SWNTs in aqueous solutions.

3:06PM L7.00004 Computational Modeling of Cancer Treatment Using Carbon Nanotubes, FENG GONG, HONGYAN ZHANG, JIN WEN TAN, National University of Singapore, DIMITRIOS V. PAPAVALASSILIOU, University of Oklahoma, USA, VINCENT B.C. TAN, SWEE HIN TEOH, HAI MINH DUONG, National University of Singapore — Laser thermal therapy selectively kills cancer cells without harming surrounding cells due to the high-energy absorbance of the functionalized carbon nanotubes (CNTs). However, the technique application is still very limited due to lack of experimental and computational works to understand how to kill cancer cells effectively and how the CNTs are heated by the external laser. The goal of this work is to present integrated computer models to capture changes in CNT heat transfer characteristics due to variations in the properties of CNTs and tissues during laser surgery. Numerical results show that the models are able to characterize variations of tissue properties for laser surgical procedures (by three dimensional finite element models) and predict anisotropic temperature fields within the CNTs (by finite different models). The current model is made more realistic and accurate than previous models by taking into account the anisotropic properties of CNTs and the energy loss from the CNT surface. The effects of the CNT concentration, morphology, orientations, and the power and heating duration of the laser are also investigated. The developed models help experimentalists to understand cancer treatment mechanisms and optimize operating conditions of the laser thermal therapy.

3:18PM L7.00005 Synthesis and Electronic Properties of Silicon-Nitrogen Hetero-doped Single Walled Carbon Nanotubes, MARTHA AUDIFFRED, Universidad de Guanajuato, Mexico, ANA LAURA ELIAS, HUMBERTO R. GUTIERREZ, PSU, FLORENTINO LOPEZ-URIAS, IPICYT, HUMBERTO TERRONES, PSU, MAURICIO TERRONES, PSU, Shinshu University, GABRIEL MERINO, Universidad de Guanajuato, Mexico — We investigated the stability and electronic properties of hetero-doped carbon nanotubes using first-principles density functional theory. Silicon, silicon-nitrogen, and silicon-oxygen were incorporated within the lattice of different types of single-walled carbon nanotubes. The structural stability, electronic density of states, doping energy, band structure, HOMO and LUMO were analyzed. When silicon and nitrogen are bonded and inserted in the nanotube lattice, non-dispersive bands appear around the Fermi level. The Nitrogen arranged in a pyridine-like fashion together with a silicon atom placed inside the vacancy was also studied. The latter configuration becomes more stable than the substitutional nitrogen embedded in the (9,0) and (5,5) nanotubes. We have also succeeded in the synthesis of Si and SiN-doped single-walled carbon nanotubes (CSixNy-SWNTs) by chemical vapor deposition. We carried out Raman spectroscopy, high-resolution electron microscopy, electron energy loss spectroscopy, energy-dispersive X-Ray spectroscopy, Auger spectroscopy and X-Ray photoelectron spectroscopy, in order to identify the presence of both dopants within the nanotube lattice.

3:30PM L7.00006 Magneto-photoluminescence in lanthanide-bearing endohedral metallofullerenes with various cage symmetries¹, TRAVIS MERRITT, HARRY DORN, GITI A. KHODAPARAST, Virginia Tech, STEVE MCGILL, National High Magnetic Field Laboratory — Taken as a family, endohedral metallofullerenes (EMF) nanomaterials provide opportunities for exquisite functional tunability at the nanoscale, enabling a wide range of synthetic nanoparticles with diverse sizes, symmetries, electronic, optical and, especially, magnetic properties. In particular, metallofullerenes incarcerating lanthanide ions will permit endohedral luminescence due to the 4f optically-active electrons being uninvolved in the stabilizing charge transfer between the endohedral guest and cage. In addition, if those lanthanide ions possess optical transitions beyond the absorption onset of the cage, a well-defined optical spectrum may be observed for the metallofullerene system. In this talk, several magneto-optical and time-resolved studies at high magnetic fields on lanthanide-based EMFs with different cage symmetries will be presented, where the residual magnetic degeneracies in the lanthanide ion energy levels are lifted and observed in the optical spectrum with magnetic field strengths in excess of 10 T.

¹Supported by: NSF-Career Award DMR-0846834

3:42PM L7.00007 Exploring the Fundamental Properties of Carbon Nanotubes using Electro-mechanical Resonators, MEHMET AYKOL, WILLIAM BRANHAM, SHUN-WEN CHANG, ROHAN DHALL, STEPHEN B. CRONIN, University of Southern California — By monitoring the nanoelectromechanical (NEM) response of suspended individual carbon nanotubes (CNT), we measure the expansion coefficient of individual suspended single-walled CNTs. Here, the temperature dependence of the mechanical resonance frequency of NEM CNT resonator is used to determine the change in tension on the device caused by the expansion on the nanotube. We also measured the effects of gas adsorption on the CNT surface, by measuring change in conductivity and its response to gate doping. By monitoring the mass loading on the surface of the resonator we calculate the adsorption energy of the specific gasses on the surface of the nanotube.

3:54PM L7.00008 Fano Resonances in Mid-Infrared Spectra of Single-Walled Carbon Nanotubes, FRANÇOIS LAPOINTE, ÉTIENNE GAUFRÈS, ISABELLE TREMBLAY, NATHALIE TANG, Université de Montreal, PATRICK DESJARDINS, Ecole Polytechnique de Montreal, RICHARD MARTEL, Université de Montreal, REGROUPEMENT QUÉBÉCOIS SUR LES MATÉRIAUX DE POINTE (RQMP) TEAM — We show that optical phonon modes in single-walled carbon nanotubes (SWNTs) become observable in mid-infrared (MIR) spectroscopy by the means of Fano resonances. The scattering of a low energy electronic continuum over phonon discrete states yields anti-resonances that are recognizable in the spectra by their characteristic asymmetric line shape. Experimentally, we control the charge carrier density in SWNTs by p doping with different molecular oxidizers at saturation and compare the spectra of doped and intrinsic samples. The only measurable feature in the intrinsic state is a kink at $\sim 865 \text{ cm}^{-1}$. Kinks at ~ 1600 and $\sim 1250 \text{ cm}^{-1}$ appear upon doping. We find no significant differences between the dopants; hence the bands belong to the SWNTs. Fitting of the band at $\sim 1600 \text{ cm}^{-1}$ yields good agreement with a phenomenological Fano resonance model. Finally, SWNTs mats are functionalized with bromophenyls, which are known to increase the number of defects. We find that upon p doping, the Fano resonances' cross sections of damaged SWNTs increase compared to that of p doped pristine SWNTs. Hence, we conclude that defects lower the symmetry of the lattice and activate optical phonon modes in MIR spectroscopy.

4:06PM L7.00009 Computational modeling of electron transfer in hydrogenase and carbon material complexes, KWISEON KIM, HAI LONG, National Renewable Energy Laboratory — In biohybrid and biomimetic devices for energy conversion, the electron transfer between the enzyme and the electrode plays a central role. We use hydrogenase and carbon material as model systems and investigate the binding and electron transfer configurations between hydrogenase and carbon materials, including single-wall carbon nanotubes and graphene surfaces. We use Brownian dynamics simulations to sample the hydrogenase/carbon material phase-space. The results provide an atomistic picture of how enzyme interacts with the electrode materials. We find that the optimal enzyme/electrode binding configurations are not optimal for electronic transfer.

4:18PM L7.00010 ABSTRACT WITHDRAWN —

4:30PM L7.00011 Theory of coherent phonons in carbon nanoribbons¹, GARY SANDERS, CHRIS STANTON, University of Florida — We have developed a microscopic theory for the generation and detection of coherent phonons in armchair and zigzag carbon nanoribbons using an extended tight-binding model for electrons and a valence force field model for the phonons. Coherent phonons are generated through the electron-phonon deformation potential interaction and we use Heisenberg's equation to obtain a driven oscillator equation for the coherent phonon amplitudes. We find that the driving function depends explicitly on the time-dependent photoexcited carrier distribution functions. We simulate the generation and detection of coherent phonons in coherent phonon spectroscopy experiments. We consider coherent phonon oscillations of the lowest lying radial breathing like mode (RBLM) in zigzag and armchair nanoribbons as a function of ribbon width and pump/probe polarization angle.

¹Supported by NSF through grants OISE-0968405 and DMR-1105437.

4:42PM L7.00012 Biomimetic Carbon Nanotube for Catalytic Hydrolysis of CO₂: First Principles Investigation of Role of Oxidation State and Metal Substitution, DONGHWA LEE, Lawrence Livermore National Laboratory, YOSUKE KANAI, University of North Carolina — Reducing the amount of carbon dioxide (CO₂) in the atmosphere is one of the most important challenges we face in this century. Metallo-enzyme, carbonic anhydrase (CA), is known for its catalytic activity of CO₂ hydrolysis, and a number of research groups have been experimentally working to mimic this activity in small molecules for the CO₂ collection processes. Using accurate first principles electronic structure calculations, we investigate how the catalytic hydrolysis reaction of CA can be mimicked in a metal-porphyrin carbon nanotube system. Our work shows that the two-step catalytic process can be improved remarkably by controlling the oxidation state and also through the metal substitution in the porphyrin unit. Our work shows the feasibility of CO₂ hydrolysis in the metal-porphyrin carbon nanotube and also how the catalytic activity could be improved. This work is Prepared by LLNL under Contract DE-AC52-07NA27344.

4:54PM L7.00013 Coupling of carbon nanotubes and graphene nanoribbons by the titanium and vanadium nanowires: First-principles study¹, CHI-HSUAN LEE, CHIH-KAI YANG, Graduate Institute of Applied Physics, National Chengchi University — We investigate the combined structure of a carbon nanotube (CNT) and graphene nanoribbon (GNR) through the adsorption of a titanium or vanadium nanowire (NW), using first-principles calculations. The binding energy depends upon the stacked configuration and is much larger than that between the two subsystems without the nanowire. The band structure reveals strong hybridization between d orbitals of the transition metal and p orbitals of the carbon atoms. Furthermore, if the CNT is deposited near the border of GNR, structural stability is enhanced and magnetic moments of the edge atoms are reduced. The result points to possible application for synthesizing nanowires in nanoelectronic devices.

¹This work was supported in part by the National Center for High-performance Computing, the National Center for Theoretical Sciences, and the National Science Council of Taiwan, the Republic of China under Grant number NSC 98-2112-M-004-003-MY3

5:06PM L7.00014 Synthesis and phase behavior of AgI atomicwires in carbon nanotubes, SHIN-ICHI ITO, RYO KITAUURA, YASUMITSU MIYATA, HISANORI SHINOHARA, Nagoya University, HIROSHI KITAGAWA COLLABORATION, KUNIO AWAGA COLLABORATION — α -phase silver iodide (α -AgI) has been well-known as a solid state ionic conductor due to its superionic conductivity and is one of the promising candidates for solid-state electrolytes for various electrochemical devices. Below 420 K, α -AgI undergoes a phase transition into the poorly conducting β - and γ -polymorphs, thereby limiting their applications. Recently, we have found that AgI nanowires with a diameter of 10 nm can retain α -phase even at 313 K where size and morphology of AgI presumably plays a great role in this α -AgI stabilization [1]. To investigate the effect further, we have focused on low dimensional nanostructure of AgI with a diameter of 5 - 10 nm. For this purpose, one-dimensional (1D) nanospace of carbon nanotubes (CNTs) has been utilized. CNTs have unique 1D nanospace ranging in diameter from 0.4 to 50 nm, which can stabilize otherwise unstable nanomaterials. We have synthesized AgI@CNTs by the sublimation method already reported [2]. In the presentation, we will discuss detailed characterization of structure and properties based on electron beam diffraction and HR-TEM.

Tuesday, February 28, 2012 2:30PM - 5:30PM —
Session L8 DMP GMAG: Focus Session: Frustrated Magnetism - 1D 208

2:30PM L8.00001 Magnon pairing in Quantum Spin Nematic, MIKE ZHITOMIRSKY, SPSMS, CEA-Grenoble — The phenomenon of the Bose-Einstein condensation is inherent not only to superfluid He-4 and cold atomic gases but also describes in a unified way a variety of field-induced transitions in quantum magnets. In this talk we discuss a novel example of the Bose-Einstein condensation of bound magnon pairs. The binding mechanism is based on a competition between ferro- and antiferromagnetic exchange bonds in a frustrated quantum spin system. As a result bound magnon pairs are formed in the fully polarized magnetic state at high fields. Upon decreasing field magnon pairs undergo a condensation into a state which is bosonic analog of a BCS superconductor [1]. The magnon-pair condensate lacks a conventional transverse magnetic order and is described instead by a quadrupolar or spin-nematic order parameter. We consider in detail magnon-pairing mechanism for two spin models: frustrated chains weakly coupled by interchain interactions and frustrated square-lattice antiferromagnet, which exhibit high-field spin-nematic states. Our theory predicts existence of the long-range spin-nematic phase in the frustrated chain material LiCuVO₄. We also review recent experimental evidences, which support presence of a new phase in this material. Work done in collaboration with H. Tsunetsugu (ISSP, University of Tokyo)

3:06PM L8.00002 Competition between Spin Nematic and Spin Density Wave Orders in Spatially Anisotropic Frustrated Magnets in Magnetic Fields, MASAHIRO SATO, Department of Physics and Mathematics, Aoyama Gakuin University, Japan, TOSHIYA HIKIHARA, Faculty of Engineering, Gunma University, Japan, TSUTOMU MOMOI, Condensed Matter Theory Laboratory, RIKEN, Japan — Magnetic multipolar order including spin nematic order is one of the current topics in frustrated magnetism. Recently, frustrated spin chains with ferromagnetic nearest-neighbor coupling J_1 and antiferromagnetic next-nearest-neighbor one J_2 have been theoretically shown to exhibit multipolar quasi long-range orders in the wide region of J_1/J_2 as an external magnetic field is applied. In addition, it is known that several kinds of quasi one-dimensional cuprates can be described by this J_1 - J_2 spin chain. Particularly, a recent experiment shows that LiCuVO_4 , one of the cuprates, possesses a new phase near saturation and it is expected to be a spin nematic ordered phase. Motivated by these results, we have completed the field-temperature phase diagram for spatially anisotropic magnets consisting of weakly coupled J_1 - J_2 spin chains, by making use of accurate results of the single J_1 - J_2 spin chain. The phase diagram contains spin nematic and spin-density-wave ordered phases, and these two orders compete with each other. We will discuss some universal features of the phase diagram and the relevance of our result to LiCuVO_4 .

3:18PM L8.00003 Unusual interchain coupling effects in frustrated edge-shared chain cuprates with ferromagnetic NN in-chain coupling, STEFAN-LUDWIG DRECHSLER, SATOSHI NISHIMOTO, JEROEN VAN DEN BRINK, JIRI MALEK, IFW-Dresden, Institute of Theoretical Solid State Physics, Dresden, Germany, ROMAN KUZIAN, Institute of Material Sciences NASU, Ukraine, Kiev, JOHANNES RICHTER, University of Magdeburg, Germany, MIRIAM SCHMITT, HELGE ROSNER, MPI-CPFS, Dresden, Germany, KUZIAN COLLABORATION, RICHTER COLLABORATION, ROSNER COLLABORATION — We consider the effect of weak antiferromagnetic interchain coupling (AFM IC) on the saturation field, the magnetization curve, the phase diagram of multipolar phases at high magnetic fields, the dynamical magnetic structure factor, as well as the pitch angle at ambient fields applying the DMRG-technique to clusters of coupled long chains and the hard-core boson method to quasi-1D spin nematics at $T=0$. The critical AFM IC couplings for various multipolar phases and types of IC are determined. The results are applied to Li_2CuO_2 , LiVCuO_4 , $\text{Ca}_2\text{Y}_2\text{Cu}_5\text{O}_{10}$, as well as to linarite. The multipolar phases can be stabilized by easy-axis spin anisotropy. Linarite and LiVCuO_4 , are found to be good candidates for the detection of multipolar phases. Microscopic considerations based on the extended five-band Hubbard model and $L(S)\text{DA}+U$ calculations provide exchange integrals which support the empirically found values for the main exchange integrals. We discuss the applicability of spin-wave theory and the role of quantum fluctuations for a correct description of magnetic excitations. Cases when a weak IC coupling dominates solely or predominantly the saturation field and/or the pitch angle are emphasized.

3:30PM L8.00004 Frustrated 1D Spin-S chain Below Saturation Magnetization¹, TEIMURAZ VEKUA², Leibniz University of Hannover, ALEXEI KOLEZHUK, University of Kiev, FABIAN HEIDRICH-MEISNER, University of Muenchen, SEBASTIAN GRESCHNER, Leibniz University of Hannover, MARCELO ARLEGO, GERARDO ROSSINI, University of La Plata, ANDREAS HONECKER, University of Goettingen — Ground states of frustrated spin-S chains in strong magnetic field in the immediate vicinity of saturation are mapped out. For ferromagnetic nearest-neighbor and frustrating antiferromagnetic next-nearest-neighbor exchange interactions generic feature is metamagnetic behavior under the influence of an external magnetic field for small S, in the form of a first-order transition to the fully polarized state. The magnetization jump increases gradually starting from an S-dependent critical value of exchange couplings and takes a maximum in the vicinity of a ferromagnetic Lifshitz point. The metamagnetism results from resonances in the dilute magnon gas caused by an interplay between quantum fluctuations and frustration. For antiferromagnetic nearest neighbour interactions generic feature is emergence of two-component Luttinger liquid phase and series of phase transitions between that phase and chiral phase.

3:42PM L8.00005 Quasi-one-dimensional antiferromagnetism and multiferroicity in CuCrO_4 ¹, REINHARD K. KREMER, J.M. LAW, P. REUVEKAMP, MPI for Solid State Research, Stuttgart, Germany, R. GLAUM, Institut fuer Anorganische Chemie, Universitaet Bonn, Bonn, Germany, C. LEE, J. KANG, M.-H. WHANGBO, Department of Chemistry, North Carolina State University, Raleigh, North Carolina 27695-8204, U.S.A — The bulk magnetic properties of the new quasi-one-dimensional Heisenberg antiferromagnet, CuCrO_4 , were characterized by magnetic susceptibility, heat capacity, optical spectroscopy, EPR and dielectric capacitance measurements and density functional evaluations of the intra- and interchain spin exchange interactions. We found type-II multiferroicity below the Néel temperature of 8.2(5) K, arising from competing antiferromagnetic nearest-neighbor (J_{nn}) and next-nearest-neighbor (J_{nnn}) intra-chain spin exchange interactions. Experimental and theoretical results indicate that the ratio J_{nn}/J_{nnn} is close to 2, putting CuCrO_4 in the vicinity of the Majumdar-Ghosh point. First low-temperature neutron powder diffraction data are consistent with a canted magnetic structure below ~ 8 K.

3:54PM L8.00006 Magnetic field induced ferroelectric transition of quantum spin chain system $\text{Rb}_2\text{Cu}_2\text{Mo}_3\text{O}_{12}$, YUKIO YASUI, YUDAI YANAGISAWA, RYUJI OKAZAKI, ICHIRO TERASAKI, Department of Physics, Nagoya University, YASUHIRO YAMAGUCHI, TSUYOSHI KIMURA, Graduate School of Engineering Science, Osaka University — Dielectric and magnetic properties have been studied for $\text{Rb}_2\text{Cu}_2\text{Mo}_3\text{O}_{12}$, which includes quasi one-dimensional spin 1/2 chains formed of edge-sharing CuO_4 square planes called CuO_2 ribbon chains. The system does not exhibit a magnetic transition above temperature $T > 2\text{K}$ owing to quantum fluctuation and low dimensionality. We have observed anomalous increase of dielectric constant ϵ with decreasing T below ~ 50 K, which is originated from growing a short range ordering of a helical magnetic structure. For an external magnetic field $H > 0.5\text{T}$, a peak structure is observed in the $\epsilon - T$ curves at $T_c \sim 8\text{K}$ and the ferroelectric polarization has been observed below T_c . However, the magnetic susceptibility and specific heat do not have anomaly at T_c for $H > 0.5\text{T}$. The anomalous increase of ϵ and field-induced ferroelectric transition are found to be suppressed by impurity doping such as Zn and Ni atoms to the Cu sites. These results indicate that the ferroelectric transition is found to be induced by applying field without magnetic transition which strongly suggests a new type of ferroelectric transition triggered by the magnetism of frustrated quantum spin systems.

4:06PM L8.00007 On the onset of incommensurate behavior in the J_1 - J_2 -chain with an odd number of sites, ANDREAS DESCHNER, ERIK S. SORENSEN, McMaster University — The anti-ferromagnetic spin-1/2- J_1 - J_2 -chain is one of the most researched spin-systems. For a chain with an even number of sites the ground-state is analytically known at $J_2/J_1 = 0.5$ and at $J_2/J_1 > 0.5$ spin-spin-correlations become incommensurate. Very little is known about how this incommensurability is manifested in chains with an odd number of sites. In this presentation we show results of variational calculations for J_1 - J_2 -chains with an odd number of sites and open boundary conditions in this incommensurate regime. The results indicate that the system becomes gapless at $J_2/J_1 \approx 0.53$. We show results for the on-site magnetization, the entanglement as well as correlation functions and discuss how the incommensurability dramatically affects them. In particular we show how the usual well defined single soliton excitation breaks up at $J_2/J_1 \approx 0.53$.

4:18PM L8.00008 Broken vector spin chirality in biatomic Fe chains on Ir(001)¹, S. BLUGEL, Y. MOKROUSOV, Peter Grunberg Institut and Institute for Advanced Simulation, Forschungszentrum Juelich and JARA, 52425 Juelich, Germany, M. MENZEL, R. WIESER, K. VON BERGMANN, E. VEDMEDENKO, A. KUBETZKA, R. WIESENDANGER, Institut für Angewandte Physik, Universität Hamburg, 20355 Hamburg, Germany, S. HEINZE, Institut für Theoretische Physik und Astrophysik, Christian-Albrecht-Universität zu Kiel, 24098 Kiel, Germany — We investigate from *ab initio* the magnetism of biatomic Fe chains, which form due to self-organization on the (5×1)-reconstructed Ir(001) surface [1,2]. Using the FLEUR code [3], we calculate the magnetic properties and exchange interactions in this system, finding a very small Heisenberg exchange along the chain of the order of 10 meV/Fe-atom. Upon including spin-orbit coupling we obtain the contribution from the Dzyaloshinskii-Moriya interaction and find that it leads to a 120° spin-spiral ground state of the Fe chains with a unique rotational sense. The results of the Monte-Carlo simulations based on the parameters from *ab initio* are in a very good agreement to STM experiments on the system. Moreover, simulations indicate a robustness of the spin chiral order parameter, which decays with temperature much slower than the scalar spin correlation, in analogy to a vector spin chiral liquid state. We discuss possible applications of the magnetism in these chains with respect to the transfer of information on the nanoscale.

4:30PM L8.00009 Highly frustrated quantum magnetism in the mineral azurite: multi-step approach from first-principles computations to experimental data, HARALD O. JESCHKE, INGO OPAHLE, ROSER VALENTI, Institut für Theoretische Physik, Goethe-Universität Frankfurt, Max-von-Laue-Str. 1, 60438 Frankfurt, Germany, HENA DAS, TANUSRI SAHA-DASGUPTA, Satyandranath Bose National Centre for Basic Sciences, Kolkata 700098, India, MICHAEL LANG, Physikalisches Institut, Goethe-Universität Frankfurt am Main, 60438 Frankfurt, Germany, SHIJIE HU, XIAOQUN WANG, Department of Physics, Renmin University of China, Beijing 100872, China, ROBERT PETERS, Department of Physics, Graduate School of Science, Kyoto University, Kyoto 606-8502, Japan, ANDREAS HONECKER, Institut für Theoretische Physik, Georg-August-Universität Göttingen, 37077 Göttingen, Germany — The natural mineral azurite $\text{Cu}_3(\text{CO}_3)_2(\text{OH})_2$ is a frustrated magnet displaying unusual and controversially discussed magnetic behavior. We perform a theoretical study based on density functional theory as well as state-of-the-art numerical many-body calculations [1]. We propose an effective generalized spin-1/2 diamond chain model which provides a consistent description of experiments: low-temperature magnetization, inelastic neutron scattering, nuclear magnetic resonance measurements, magnetic susceptibility as well as new specific heat measurements. With this study we demonstrate that the balanced combination of first principles with powerful many-body methods successfully describes the behavior of this frustrated material.

4:42PM L8.00010 Magnetic anisotropy in the frustrated spin-ladder system BiCu_2PO_6 from magnetostriction in pulsed fields, ATSUKO UCHIDA, YOSHIMITSU KOHAMA, MPA-CMMS, Los Alamos National Laboratory, USA, SHUANG WANG, Laboratory for Quantum Magnetism, Ecole Polytechnique Fédérale de Lausanne, CH-1015 Lausanne, Switzerland Laboratory for Developments and Methods, Pau, MARCELO JAIME, MPA-CMMS, Los Alamos National Laboratory, USA, CHRISTIAN RÜEGG, Laboratory for Neutron Scattering, Paul Scherrer Institute, CH-5232 Villigen, Switzerland — The spin interactions in BiCu_2PO_6 have been studied by inelastic neutron scattering, magnetic susceptibility, and numerical calculation. There is strong frustration between magnetic interactions along the ladder leg, J_{leg} and J_{NNN} , and it has been pointed out that a spin gap persists in this frustrated system. Both J_{leg} and J_{NNN} are intra-ladder and two-leg ladder is always gapped. Longitudinal magnetostriction (MS) measurements were performed using a fiber optic strain gauge in a 60 T pulsed magnet [1]. Specific heat (C_p) and magnetocaloric effect (MCE) measurements were performed in a 35 T DC magnet. C_p vs T was obtained using both a thermal relaxation time and dual slope techniques. We have in this way determined the (H,T) phase diagram of BiCu_2PO_6 up to 45 T. The 3D character of phase transitions is suggested by the observation of sharp anomalies in CM and $\Delta L/L$. Our MCE and MS data provides direct evidence of first-order phase transitions for H//c, while phase transitions for H//a and H//b are characterized as second-order phase transitions. The anisotropic and complex phase boundaries will be discussed.

4:54PM L8.00011 Magnetism of a Frustrated Four-Spin-Tube¹, WOLFRAM BRENIG, Technical University Braunschweig, Germany, MARCELO ARLEGO, Universidad Nacional de La Plata, Argentina — We report on the magnetism of a frustrated four-leg spin-1/2 tube (FFST) [1]. Using a combination of series expansion, based on the continuous unitary transformation method and density-matrix renormalization group we analyze the ground-state correlations, and the one-, and the two-particle excitations in the regime of strong rung-coupling. We find that frustration destabilizes the spin-gapped quadrumer singlet-phase of the FFST, leading to first order quantum phase transitions. Apart from the well-know triplon branch of two-leg spin-ladders, the FFST is shown to sustain additional elementary excitations, including a singlon, and additional triplons. Finally, in the two-particle sector the FFST exhibits several collective (anti)bound states. Frustration has significant impact on the FFST leading to a flattening of the ground-state energy landscape, a mass-enhancement of the excitations, and a relative enhancement of the (anti)binding strength.

5:06PM L8.00012 Pursuit of a spin Bose-metal phase in Hubbard-type models on the two-leg triangular strip, RYAN V. MISHMASH, UCSB, IVAN GONZALEZ, CESGA, ROGER MELKO, University of Waterloo, OLEXEI I. MOTRUNICH, Caltech, MATTHEW P.A. FISHER, UCSB — Motivated by recent experiments on the organic materials $\kappa\text{-(ET)}_2\text{Cu}_2(\text{CN})_3$ and $\text{EtMe}_3\text{Sb}[\text{Pd}(\text{dmit})_2]_2$, we numerically investigate the Mott metal-insulator transition in a system of interacting, itinerant electrons at half-filling on the two-leg triangular strip (i.e., zigzag chain). Previous work [1] has revealed that an exotic “spin Bose-metal” (SBM) phase with three gapless modes is stabilized on the zigzag strip in a pure spin model of Heisenberg exchange supplemented with four-site cyclic ring exchange, a model appropriate for describing weak Mott insulators near the Mott transition. Indeed, a physically appealing picture of the realized SBM phase is to view it as a particular Mott insulating instability out of a two-band metal of interacting electrons. Guided by this idea, we perform large-scale DMRG calculations across the Mott transition in various Hubbard-type models (e.g., with on-site repulsion, longer-ranged repulsion, and/or explicit spin exchange terms). We focus on the successes and failures of describing the insulating phase near the transition within the SBM framework. Finally, the implications of our findings to the full 2D triangular lattice will be discussed.

5:18PM L8.00013 Symmetry protected topological phases for 1-dimensional spin-1 antiferromagnets, ZHENG-XIN LIU, Tsinghua university, XIE CHEN, XIAO-GANG WEN, Massachusetts Institute of Technology — Symmetry protected topological phases for 1-dimensional $S=1$ antiferromagnets respecting D_2+T symmetry (D_2 is a point group and T is the time reversal symmetry) are studied. There are 15 different nontrivial topological phases, all of them are non-symmetry-breaking. One of these phases is the usual Haldane phase, and the others are new. We find that four of the nontrivial SPT phases can be realized in spin-1 chains and the rest can be realized in spin-1 ladders. We propose experimental methods to distinguish all of these phases.

2:30PM L9.00001 Thermodynamics of Ferrotoroidic Materials, AVADH SAXENA, Los Alamos National Lab., TERESA CASTAN, ANTONI PLANES, University of Barcelona — The three primary ferroics, namely ferromagnets, ferroelectrics and ferroelastics exhibit corresponding large (or even giant) magnetocaloric, electrocaloric and elastocaloric effects when a phase transition is induced by the application of an appropriate external field (E , H and stress). Recently the suite of primary ferroics has been extended to include ferrotoroidic materials in which there is an ordering of toroidic moments in the form of magnetic vortex-like structures, examples being $\text{LiCo(PO}_4)_3$ and $\text{Ba}_2\text{CoGe}_2\text{O}_7$. We formulate the thermodynamics of ferrotoroidic materials. Within a Landau free energy framework we calculate the toroidocaloric effect by quantifying isothermal entropy change (or adiabatic temperature change) in the presence of an applied toroidic field ($G = E \times H$) when usual magnetization and polarization may also be present simultaneously.

2:42PM L9.00002 Theory of K-edge Resonant Inelastic X-ray Scattering for Perovskite Manganites¹, TSEZAR F. SEMAN, New Jersey Institute of Technology, XUERONG LIU², JOHN P. HILL³, Brookhaven National Laboratory, MICHEL VAN VEENENDAAL, Argonne National Laboratory and Northern Illinois University, KEUN HYUK AHN, New Jersey Institute of Technology — We present calculations of K-edge resonant inelastic x-ray scattering (RIXS) spectrum for layered and three dimensional perovskite manganites with charge, orbital, and spin orderings. We extend the approach in Ref. [1] to the tight binding model for the manganites, calculate RIXS intensity in momentum and energy space, and compare with experiment data. The results show strong dependence of the RIXS intensity on momentum, which agrees well with experimental observation. We discuss its implications on the material properties and the RIXS process.

2:54PM L9.00003 Nonreciprocal Directional Dichroism and Toroidalmagnons in Helical Magnets, SHIN MIYAHARA, ERATO-MF, JST, NOUBO FURUKAWA, Aoyama Gakuin Univ. — We investigate a dynamical magnetoelectric effect owing to a magnetic resonance in helical spin structures through a coupling between magnetization and electric polarization via a spin current mechanism [1]. We show that the magnon has a dynamical magnetic moment dM and an electric moment dP which is perpendicular to dM , simultaneously, i.e., a dynamical toroidal moment $T^d = dM \times dP$ under the external magnetic fields, and thus named it as a toroidalmagnon. The toroidalmagnon exists in most conical spin structures due to generality of the spin current mechanism. In absorption of electromagnetic wave, the toroidalmagnon excitation process generally induces nonreciprocal directional dichroism as a consequence of the interference of the magnetic and the electric responses. The nonreciprocal directional dichroism should be experimentally observed in various cycloidal multiferroic materials, e.g. RMnO_3 . [1] H. Katsura, A.V. Balatsky, and N. Nagaosa: Phys. Rev. Lett. **98** 027203 (2007)

3:06PM L9.00004 First-principles Wannier function based methods for disordered materials and applications to studies of oxides and Fe-superconductors¹, WEI KU, CMPMSD, Brookhaven National Laboratory — This talk will discuss recently developed first-principles methods for materials with disordered impurities, and their applications to case studies of correlated oxides and Fe-based superconductors containing vacancies, substitutions and intercallants. Simplified via the use of Wannier functions, the first method [1] is to unfold the one-particle spectral function from the reduced Brillouin zone of a broken symmetry state back to the regular Brillouin zone of the normal state. This unfolding not only allows a clearer visualization of the physical effects of the broken translational symmetry, but also connects directly to the experimental spectral weight of angular resolved photo emission spectroscopy. The second method [2] is to reduce the computational expense of configuration-averaged spectral function of disordered materials by orders of magnitude, to allow inclusion of large length scale required for weakly localized states and short-range orders. This Wannier function based method is systematically improvable, beyond-mean-field, and not perturbation limited. Case studies to be discussed include dilute magnetic semiconductors [3], transition metal oxides[1,2], and Fe-based superconductors [4,5].

3:42PM L9.00005 Incommensurate spin excitations stabilized multiferroic phase in CuO, LIXIN HE, University of Science and Technology of China — Cupric oxide is a unique magnetoferroelectrics with transition temperature way above the boiling point of liquid nitrogen. However, the mechanism of high T_c multiferroicity in CuO is still puzzling. In this paper, we clarify the mechanism of high T_c multiferroicity in CuO using combined first-principles calculations and an effective Hamiltonian model. We find that CuO contains two magnetic sublattices, with strong intra-sublattice interactions and weakly frustrated inter-sublattice interactions, which might be one of the main reasons that the compound has a high ordering temperature. The weak spin frustration leads to incommensurate spin excitations that dramatically enhances the entropy of the multiferroic phase, and eventually stabilize the multiferroic phase in CuO.

3:54PM L9.00006 Pressure-driven high-spin to low-spin and orbital-selective insulator to metal transition in cubic CoO, LI HUANG, XI DAI, YILIN WANG, The Institute of Physics, Chinese Academy of Sciences — We studied the magnetic and spectral properties for cubic para-magnetic phases of CoO under high pressures by using *ab initio* many-body method which combining local density approximation with dynamical mean-field theory. Experimentally observed metal-insulator transition at high pressure is successfully reproduced in calculations. Our calculation predicts CoO as a Mott insulator at ambient pressure and metal at extreme high pressure. In the intermediate pressure regime, our results indicate that there is an orbital selective Mott phase with t_{2g} orbitals being metallic and e_g orbitals being insulating. In contrast with MnO and Fe_2O_3 (d^5 configuration) where metal-insulator transition is accompanied by a high-spin to low-spin transition, we found that the local moment of CoO (d^7 configuration) decreases gradually from 2.8 ($S = 3$ states) to 1.4 ($S = 1$ states) with increasing pressure, which is in agreement with experimental data.

4:06PM L9.00007 Mott physics in multi-band Hubbard model with strong spin-orbit interaction, LIANG DU, LI HUANG, XI DAI, Institute of Physics, The Chinese Academy of Sciences — Spin-orbit coupling and electron correlation both play very crucial roles in the Mott physics of $4d$ and $5d$ transition-metal oxides. By studying three band Hubbard model with full Hund's rule coupling and spin-orbit coupling, we show that spin-orbit coupling intends to strongly enhance the Mott transition. By means of generalized Gutzwiller variational method and dynamical mean field (DMFT) with continuous time quantum Monte Carlo (CTQMC) as impurity solver, we obtain the complete phase diagram for this problem, which can be divided into metal, Mott insulator and band insulator phases. At mean while, we have also studied the effect of the Coulomb interaction on the strength of the spin-orbital coupling in the metallic phase. Our conclusion is that the correlation effect on the spin-orbital coupling is far beyond the mean field treatment even in the intermediate coupling regime.

4:18PM L9.00008 Covalency, Excitons, Double Counting and the Metal-Insulator Transition in Transition Metal Oxides, XIN WANG, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park — We present single-site dynamical mean-field studies of realistic models of transition metal oxides, including the cuprate superconductors and rare earth nickelates (in bulk and superlattice form). We include orbital multiplet effects and hybridization to ligands. We explicitly calculate the d-d exciton spectra for cuprates, finding sharp exciton lines in both metallic and insulating phases, which should be visible in experiments. We also find that the additional $d_{3z^2-r^2}$ orbital does not contribute to an additional Fermi surface at any reasonable doping, in contradiction to previous slave-boson studies. The hybridization to ligands is shown to have crucial effects, for example suppressing the ferro-orbital order previously found in Hubbard model studies of nickelates. Hybridization to ligands is shown to be most naturally parametrized by the d-orbital occupancy. For cuprates and nickelates, insulating behavior is found to be present only for a very narrow range of d-occupancy, irrespective of the Coulomb repulsion. The d-occupancy predicted by standard band calculations is found to be very far from the values required to obtain an insulating phase, calling into question the interpretation of these materials as charge transfer insulators.

5:06PM L9.00010 Exact results on magnon-mediated pairing of spin-polarons¹, MIRKO MOELLER, MONA BERCIU, University of British Columbia — The motion of a charged particle in a magnetically ordered background determines the electronic behavior of weakly doped, magnetically ordered insulators and semiconductors. This problem can be solved exactly for a single charge carrier in a ferromagnetic background at zero-temperature. The solution is a spin-polaron, i.e. a dressed quasiparticle consisting of a charge carrier and a bound magnon which is dynamically emitted and reabsorbed by the charge carrier. If the exchange interaction between the charged particle and the ferromagnetic background is antiferromagnetic, then the spin polaron describes the low-energy states. We generalized the exact solution to the case of two charge carriers. This allows us to characterize the conditions (what ranges of parameters and for what types of lattices) under which magnon-mediated pairing occurs, so that spin-bipolarons describe the low-energy states.

5:18PM L9.00011 Understanding the interplay between crystal structures and magnetic states of RCO_2 (R = heavy rare earths)¹, DURGA PAUDYAL, Y. MUDRYK, The Ames Laboratory, U. S. Department of Energy, V.K. PECHARSKY, K.A. GSCHNEIDNER, JR., The Ames Laboratory, U. S. Department of Energy and Department of Materials Science and Engineering, Iowa State University, Ames, IA — The RCO_2 compounds with R = heavy lanthanides are well known model systems for both experimentalists and theorists because of the complex nature of the magnetism of these materials. Better understanding of the magnetism can be achieved from parameter-free first principles calculations as well as carefully executed experiments. From first principles calculations we show that the indirect $4f$ - $4f$ exchange polarizes the $5d$ spins and the spin up $5d$ and spin down $3d$ hybridization gives rise to ferrimagnetism, i.e. antiparallel $5d$ and $3d$ itinerant magnetic moments at low temperature. The itinerant electron metamagnetism is known to support first order phase transformations in some of the RCO_2 compounds. However the clear understanding of this mechanism is lacking and, therefore, we clarify this mechanism from first principles calculations and experimentally confirm the nature of phase transformation of TbCo_2 . The interrelation between the crystal structure and the magnetic states has also been investigated considering TbCo_2 as an example.

Session L10 DLS: Invited Session: Quantum Optics in Condensed Matter 210A

2:30PM L10.00001 Two-photon interference from quantum dot and parametric-down conversion single photons, GLENN SOLOMON, Joint Quantum Institute, NIST & Univ. Maryland — No abstract available.

3:06PM L10.00002 Quantum spectroscopy of semiconductors with Schrödinger's cat states, MACKILLO KIRA, Department of Physics, Philipps-University Marburg, Germany — Quantum investigations on simple systems — such as atoms or quantized light modes — have reached a level where one can read and write information directly onto the density matrix itself. Currently, the same level of quantum-information control seems inconceivable in condensed-matter systems simply because the many-body states involved are unimaginably complicated. In this talk, I will present the first steps in realizing targeted access of many-body states within condensed-matter systems by combining quantum-optics and many-body theory [1] with classical high-precision laser spectroscopy. The light-matter interaction has an inherent capability to directly excite targeted many-body states through the light source's quantum fluctuations [2]. The related quantum-optical responses can be projected from the classical data set by applying the cluster-expansion transformation [3] (CET). As a proof of principle, we CET project the measured nonlinear absorption of semiconductor quantum wells [4] into the quantum absorption generated by Schrödinger's cat-state sources. The results expose a completely new level of many-body physics that remains otherwise hidden. Especially, the investigations reveal an anomalous reduction of Coulomb scattering of excitons, the excitation-induced narrowing of the exciton-molecule resonance, and the formation of electron-hole complexes (multi-exciton clusters) [5].

3:42PM L10.00003 Quantum optics with solid-state atom-like systems, MIKHAIL LUKIN, Harvard Univ — No abstract available.

4:18PM L10.00004 Quantum Dot Spins and Photons, METE ATATUR, University of Cambridge — Self-assembled semiconductor quantum dots are interesting and rich physical systems. Their inherently mesoscopic nature leads to a multitude of interesting interaction mechanisms of confined spins with the solid state environment of spins, charges and phonons. In parallel, the relatively clean spin-dependent optical transitions make quantum dots strong candidates for stationary and flying qubits within the context of spin-based quantum information science. The recently observed quantum dot resonance fluorescence has become a key enabler for further progress in this context. I will first discuss the real-time optical detection (or single-shot readout) of quantum dot spins, and then I will discuss how resonance fluorescence allows coherent generation of single photons suitable (and tailored) for linear-optics quantum computation and for establishing a high-efficiency spin-photon quantum interface within a distributed quantum network.

4:54PM L10.00005 Dynamics of vortices in polariton quantum fluids : From full vortices, to half vortices and vortex pairs¹, BENOIT DEVEAUD-PLÉDRAN, EPFL, Lausanne, Switzerland — Polariton quantum fluids may be created both spontaneously through a standard phase transition towards a Bose Einstein condensate, or may be resonantly driven with a well-defined speed. Thanks to the photonic component of polaritons, the properties of the quantum fluid may be accessed rather directly with in particular the possibility of detained interferometric studies. Here, I will detail the dynamics of vortices, obtained with a picosecond time resolution, in different configurations, with in particular their phase dynamics. I will show in particular the dynamics of spontaneous creation of a vortex, the dissociation of a full vortex into two half vortices as well as the dynamics of the dissociation of a dark soliton line into a street of pairs of vortices. Work done at EPFL by a dream team of Postdocs PhD students and collaborators: K. Lagoudakis, G. Nardin, T. Paraiso, G. Grosso, F. Manni, Y Léger, M. Portella Oberli, F. Morier-Genoud and the help of our friend theorists V. Savona, M. Vouters and T. Liew.

Session L11 DMP: Focus Session: Graphene Structure, Stacking, Interactions: Magnetism and Interactions 210B

2:30PM L11.00001 Kondo Effect in Bilayer Graphene¹, DIEGO MASTROGIUSEPPE, SERGIO ULLOA, NANCY SANDLER, Ohio University — Because of the linear dependence of the density of states (near Dirac points), the physics of localized magnetic moments on graphene exhibits unique characteristics [1]. From the experiments by Mattos *et al* [2], where a possible observation of the 2-channel Kondo effect was reported, to recent studies on vacancies [3], the role of local moments on graphene remains poorly understood. The technical difficulties to determine the nature of the origin of the local moment add to the complexity of the problem. To gain insight into this problem, we have undertaken a study of a bilayer graphene system with Bernal stacking and an intercalated magnetic impurity. We model the system with a multiband Anderson impurity model and obtain the effective Kondo Hamiltonian via a Schrieffer-Wolff transformation. Although several conducting channels couple to the impurity, the standard 1-channel Kondo regime is recovered at low temperatures. The effective Kondo exchange couplings depend on the interlayer hopping giving rise to tunable Kondo temperatures.

2:42PM L11.00002 Mid-gap states and Kondo effect in disordered graphene, CAIO LEWENKOPF, VLADIMIR MIRANDA, Universidade Federal Fluminense, LUIS DIAS DA SILVA, Universidade de São Paulo — Recent experiments on graphene flakes with short range scattering defects have strengthen the interest on Kondo physics in graphene systems. The experimental data show a temperature dependence of the resistivity consistent with the low-temperature Kondo screening of local magnetic moments. While the linear dispersion in the density of states in graphene justify a pseudogap Kondo model showing a rich variety of quantum critical behavior as a function of the gate-controlled chemical potential, the presence of disorder can alter this effect in favor of the "standard" Kondo model, with a Fermi-liquid ground state. We study these effects with different numerical methods. Tight-binding calculations for diluted scattering defects show the appearance of quasi-localized midgap states in the local density of states at the vicinity of the charge neutrality point. This leads to the formulation a Anderson-like model of localized states within the graphene matrix, which may lead to a Kondo screening consistent with the experiments. To verify this hypothesis, we perform numerical renormalization group (NRG) calculations to study the gate-dependence of the Kondo temperature and the transport properties of this model.

2:54PM L11.00003 Dynamic RKKY interaction in graphene, MAURO FERREIRA, STEPHEN POWER, School of Physics, Trinity College Dublin, Ireland, FILIPE GUIMARAES, Department of Physics and Astronomy, University of California, Irvine, ANTONIO COSTA, ROBERTO MUNIZ, Instituto de Física, Universidade Federal Fluminense, Brazil — The growing interest in carbon-based spintronics has stimulated a number of recent theoretical studies on the RKKY interaction in graphene, based on which the energetically favourable alignment between magnetic moments embedded in this material can be calculated. The general consensus is that the strength of the RKKY interaction in graphene decays as $1/D^3$ or faster, where D is the separation between magnetic moments. Such an unusually fast decay for a 2-dimensional system suggests that the RKKY interaction may be too short ranged to be experimentally observed in graphene. Here we show in a mathematically transparent form that a far more long ranged interaction arises when the magnetic moments are taken out of their equilibrium positions and set in motion. We not only show that this dynamic version of the RKKY interaction in graphene decays far more slowly but also propose how it can be observed with currently available experimental methods.

3:06PM L11.00004 Formation of Localized Magnetic States on Adatoms in Uniaxially Strained Graphene, ANAND SHARMA, VALERI KOTOV, University of Vermont, Burlington — We investigate the effect of applied uniaxial strain on the formation of localized magnetic states on adatoms in graphene. In the framework of the single impurity Anderson model, we systematically analyze the interplay between the anisotropic (strain-induced) nature of the Dirac fermions and the on-site Hubbard interaction. We numerically calculate the polarization of the electrons in the localized orbital within the mean-field self-consistent scheme. A phase diagram is obtained, containing non-magnetic as well as large magnetic regions, which can find prospective applications in the field of carbon-based spintronics.

3:18PM L11.00005 Spin and band ferromagnetism in trilayer graphene, RALPH VAN GELDEREN, Utrecht University, LIH-KING LIM, LPS Orsay, Université Paris-Sud, CRISTIANE MORAIS SMITH, Utrecht University — We study the ground state properties of an ABA-stacked trilayer graphene. The low energy band structure can be described by a combination of both a linear and a quadratic particle-hole symmetric dispersion, reminiscent of monolayer- and bilayer-graphene, respectively. The multi-band structure offers more channels for instability towards ferromagnetism when the Coulomb interaction is taken into account. Indeed, if one associates a subband-index degree of freedom to the bands (parabolic/linear), it is possible to realize also a band-ferromagnetic state, where there is a shift in the energy bands, since they fill up differently. By using a variational procedure, we compute the exchange energies for all possible variational ground states and identify the parameter space for the occurrence of spin- and band-ferromagnetic instabilities as a function of doping and interaction strength.

3:30PM L11.00006 Magnetic order in graphene with broken inversion symmetry, J. FERNANDEZ-ROSSIER, International Iberian Nanotechnology Laboratory, Braga, Portugal, D. SORIANO, Institut Català de Nanotecnologia (ICN), Barcelona, Spain — We study the effect of sublattice symmetry breaking on the magnetic and transport properties of two dimensional graphene as well as zigzag terminated one dimensional graphene nanostructures. The systems are described with the Hubbard model within the collinear mean field approximation. In the case of 2D and zigzag ribbons we compute the phase diagram, at half-filling, defined by the normalized interaction strength U/t and the sublattice potential V/t , where t is the first neighbor hopping. In the case of 2D graphene we find that the system is always insulating, except at the transition between the antiferromagnetic (AF) and the non-magnetic (NM) phase where the system is half-metallic. In the case of zigzag ribbons, at finite V we find that the system undergoes a phase transition from non-magnetic insulator for $U < U_c(V)$ to a phase with ferromagnetic order in the edges and antiferromagnetic inter-edge coupling. The conduction properties of the magnetic phase depend on V and can be insulating, conducting and even half-metallic, yet the total magnetic moment in the system is zero. In the latter case, we find a strong spin filter effect.

3:42PM L11.00007 Magnetic Properties of Rhombohedral Graphene Thin Films¹, THANH CUONG NGUYEN, MINORU OTANI, NRI-AIST, Tsukuba, Japan, SUSUMU OKADA, University of Tsukuba, Tsukuba, Japan — Ever since the fabrication of single and few layers graphene, the graphene thin films have been attracting so much attention in the field not only of low-dimensional sciences but also of nano-scale technologies due to their perfect two-dimensional network. One of fascinating issues in this carbon allotrope is the intrinsic magnetism that is inherent in their topological properties. We have demonstrated that the (0001) surfaces of graphene thin film with rhombohedral-stacked arrangement exhibit ferrimagnetic spin ordering induced by flat dispersion band associated with the peculiar surface localized electron states classified as the “edge state” [1]. In this work, we systematically investigate how the electronic and magnetic properties of the rhombohedral-stacked graphene thin films depend on the number of graphene layers, BN substrate, and uniaxial pressure using first-principles total-energy calculations in the framework of density functional theory [2].

3:54PM L11.00008 Emergence of atypical magnetic and electronic properties in graphitic nanowiggles, VINCENT MEUNIER, Rensselaer Polytechnic Institute, EDUARDO COSTA-GIRAO, Universidade Federal do Ceará, LIANGBO LIANG, Rensselaer Polytechnic Institute, EDUARDO CRUZ-SILVA, University of Massachusetts, Amherst, ANTONIO GOMES SOUZA FILHO, Universidade Federal do Ceará — Graphitic nanowiggles (GNWs) are periodic repetitions of non-aligned finite-sized graphitic nanoribbon domains seamlessly stitched together without structural defects. These complex nanostructures have been recently fabricated using the self-assembly and subsequent fusion of small aromatic compound (Nature 466, 470 (2010)). The structures are predicted to possess unusual properties, such as tunable bandgaps and versatile magnetic behaviors (Phys. Rev. Lett. 107, 135501 (2011)). First-principles theory was used to highlight the microscopic origin of the emerging electronic and magnetic properties of the main subclasses of GNWs, thereby establishing a road-map for guiding the design and synthesis of specific GNWs with targeted nanoelectronic, optoelectronic, and spintronic properties. We will show the unusual versatility of GNWs' magnetic properties, we will highlight the variation of electronic properties with the details of the structures and how these structures can be used to transport electrons.

4:06PM L11.00009 Chiral superconductivity from repulsive interactions in doped graphene, RAHUL NANDKISHORE, LEONID LEVITOV, Massachusetts Institute of Technology, ANDREY CHUBUKOV, University of Wisconsin-Madison — We present a model wherein repulsive interactions unambiguously lead to superconductivity with enhanced T_c . The superconducting state is the chiral $d + id$ superconducting state, which has no known experimental realizations. Intriguingly, our model has a natural realization in graphene that is doped to the M point of the Brillouin zone. At this doping level, the Fermi surface nesting and the divergent density of states can produce interaction driven instabilities to exotic phases with high energy scales. Analyzing the competition between various ordering tendencies within a renormalisation group framework, we find that the leading instability is to d-wave superconductivity, for any choice of weak repulsive interactions. The instability develops simultaneously in two distinct d-wave channels, which are degenerate by lattice symmetries. Analysis of the pairing below T_c reveals that both orders co-exist to produce $d + id$ superconductivity, with the phase of the order parameter winding by 4π as we go around the Fermi surface.

4:18PM L11.00010 Competing many-body instabilities and unconventional superconductivity in graphene, CHRISTIAN PLATT, MAXIMILIAN KIESEL, WERNER HANKE, Institute for Theoretical Physics, University of Würzburg, DMITRY A. ABANIN, Department of Physics, Harvard University, RONNY THOMALE, Department of Physics, Stanford University — The band structure of graphene exhibits van Hove singularities (VHS) at doping $x = \pm 1/8$ away from the Dirac point. Near the VHS, interactions effects, enhanced due to the large density of states, can give rise to various many-body phases at experimentally accessible temperatures. We study the competition between different many-body instabilities in graphene using functional renormalization group (FRG). We predict a rich phase diagram, which, depending on long range hopping as well as screening strength and absolute scale of the Coulomb interaction, contains a $d + id$ -wave superconducting (SC) phase, or a spin density wave phase at the VHS. The $d + id$ state is expected to exhibit quantized charge and spin Hall response, as well as Majorana modes bound to vortices. In the vicinity of the VHS, we find singlet $d + id$ -wave as well as triplet f -wave SC phases.

[1] arXiv:1109.2953v1

4:30PM L11.00011 Power law Kohn anomaly in graphene induced by Coulomb interactions, FERNANDO DE JUAN, HERBERT A. FERTIG, Indiana University, Bloomington — Phonon dispersions generically display non-analytic points, known as Kohn anomalies, due to electron-phonon interactions. We analyze this phenomenon for a zone boundary phonon in graphene. When electron-electron interactions with coupling constant β are taken into account, one observes behavior demonstrating that the electrons are in a critical phase: the phonon dispersion and lifetime develop power law behavior with β dependent exponents. The observation of this signature would allow experimental access to the critical properties of the electron state, and would provide a measure of its proximity to an excitonic insulating phase.

4:42PM L11.00012 Effect of electron-phonon coupling on energy and density of states renormalizations of dynamically screened graphene, J.P.F. LEBLANC, University of Guelph, J.P. CARBOTTE, McMaster University, E.J. NICOL, University of Guelph — Motivated by recent tunneling and angle-resolved photoemission (ARPES) work [1,2], we explore the combined effect of electron-electron and electron-phonon couplings on the renormalized energy dispersion, the spectral function, and the density of states of doped graphene. We find that the plasmarons seen in ARPES are also observable in the density of states and appear as structures with quadratic dependence on energy about the minima. Further, we illustrate how knowledge of the slopes of both the density of states and the renormalized dispersion near the Fermi level can allow for the separation of momentum and frequency dependent renormalizations to the Fermi velocity. This analysis should allow for the isolation of the renormalization due to the electron-phonon interaction from that of the electron-electron interaction.

4:54PM L11.00013 Screening and electrostatic doping in multilayer graphene systems, MARCELO KURODA, J. TERSOFF, RAZVAN NISTOR, GLENN MARTYNA, IBM TJ Watson Research Center — We study the electrostatic screening in multilayer graphene systems using ab initio calculations and analytical models. First principles calculations reveal that oriented (Bernal) and turbostratic graphene multilayers in contact with a metal slab show only small differences in their charge distribution despite their dissimilar electronic structure. In the turbostratic systems the layer decoupling enables the identification of the Dirac point for each individual layer. We then measure the shift of each Dirac point relative to the Fermi level of the system and compute the charge transfer to each layer. Results are compared with an analytical model considering discrete layers. The model shows that at $T = 0$ charge screening is highly nonlinear due to the vanishing density of states at the Fermi level. More importantly a strong dependence on charge and temperature results in a change of the screening length by more than an order of magnitude depending on the experimental conditions, reconciling the large range of screening lengths previously reported in experiments.

5:06PM L11.00014 Screening in Chiral Multilayer Graphene¹, HONGKI MIN, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea, EUYHEON HWANG, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742, USA — We calculate the static polarization function of multilayer graphene and study the effects of stacking arrangement, carrier density and onsite energy difference. At low densities, the energy spectrum of multilayer graphene is described by a set of chiral two-dimensional electron systems and the associated chiral nature determines the screening properties of multilayer graphene showing very different behavior depending on whether chirality indices are even or odd. As the density increases, the energy spectrum follows that of monolayer graphene thus the polarization function approaches that of monolayer graphene.

¹The work is supported by ONR-MURI and NRI-SWAN.

5:18PM L11.00015 Unusual electron self-energy in graphene, CHOONGYU HWANG, Lawrence Berkeley National Laboratory, DAVID SIEGEL, University of California, Berkeley, SUNG-KWAN MO, Lawrence Berkeley National Laboratory, WILLIAM REGAN, University of California, Berkeley, ARIEL ISMACH, YUEGANG ZHANG, Lawrence Berkeley National Laboratory, ALEX ZETTL, ALESSANDRA LANZARA, University of California, Berkeley — Electron-Electron interactions bear important information on fundamental electronic properties such as electron effective mass, conductivity, and charge mobility. By using angle-resolved photoemission spectroscopy, we study unusual electron self-energy in graphene induced by the electron-electron interactions, which are distinguished from those of an ordinary Fermi liquid. Our findings provide a new route for two-dimensional electron systems toward device applications.

Tuesday, February 28, 2012 2:30PM - 5:30PM –
Session L12 DMP: Focus Session: Graphene: Growth, Mechanical Exfoliation, and Properties
- Growth on Single Crystals 210C

2:30PM L12.00001 Graphene growth on coinage-metal substrates¹, KEVIN MCCARTY, Sandia National Laboratories, Livermore, CA USA — The low solubility of carbon in Cu and Au gives these coinage metals advantages as substrates for graphene growth. Namely, growth occurs exclusively by surface processes, avoiding the complications of C segregating from the bulk of the metal substrate. However, the relatively weak interactions of Cu and Au with graphene can lead to mosaic films having large ranges of in-plane orientations. This talk will emphasize understanding the relationship between the microstructure of graphene sheets and the mechanisms of island nucleation and growth. We use low-energy electron microscopy (LEEM) to observe growth. We find that bunches of substrate steps on Cu(111) can generate misorientation boundaries in a graphene sheet as it overgrows the steps [1]. Thus, growth on rough Cu(111) leads to large rotational disorder. Optimized growth on smooth Cu(111) and Au(111), however, produces islands all in close registry to a single in-plane orientation. On Cu(100), the most abundant grain orientation of commercial Cu foils, graphene islands align around two equivalent in-plane Cu directions [2]. This inherent source of disorder from symmetry mismatch is further compounded by large spreads of orientation around the equivalent directions. The substrate choice also affects the microscopic growth mechanism. The rate that C diffuses to the graphene islands limits growth on Cu(111) [and likely on Au(111)]. The sheet edges are then morphologically unstable, with dendritic islands at low temperature and six-fold loped islands at higher temperature. In contrast, growth on Cu(100) is limited by the rate of C attaching to the graphene edge. This mechanism, combined with the symmetry mismatch, produces two-fold islands. Finally, the coinage metals will be compared to other transition metal substrates.

[1] Phys. Rev. B 84, p. 155425 (2011).

[2] Nano Lett. 10, p. 4890 (2010).

¹Work joint with S. Nie, E. Starodub, K. Thuermer, N. C. Bartelt (Sandia), J. M. Wofford and O. D. Dubon (U.C. Berkeley/LBL) and was supported by the Office of Basic Energy Sciences, Division of Materials and Engineering Sciences of the US DOE.

3:06PM L12.00002 Growth and Characterization of Graphene on Single Crystal Cu Substrates¹, Z.R. ROBINSON, P. TYAGI, H. GEISLER, C.A. VENTRICE, JR., University at Albany, A.A. BOL, J.B. HANNON, IBM T. J. Watson Research Center — One of the key issues for the use of CVD graphene in device applications is the influence of defects on the transport properties of the graphene. Therefore, it is important to understand the influence of the substrate on the orientation of the graphene. Growth of graphene films on Cu(111) has the potential for producing films with a low defect density because of the hexagonal symmetry of the substrate and relatively small lattice mismatch, whereas growth on Cu(100) is expected to result in multi-domain growth because of its square symmetry. In this study, graphene films were grown on Cu single crystal substrates, and characterized with LEEM, LEED, SEM, AFM, and Raman spectroscopy. The clean Cu substrates were prepared by sputtering and annealing in UHV. For the initial growth studies, the samples were transferred to a tube furnace for graphene growth using a technique optimized for Cu foils. The UHV system has recently been modified with a button heater compatible with the conditions needed for graphene growth to enable in-situ growth and characterization.

¹Support from the NSF (1006350/1006411) is appreciated.

3:18PM L12.00003 Suppression of Grain Boundaries in Graphene Growth on Superstructured Mn-Cu(111) Surface¹, WEI CHEN, Univ. of Tennessee, Univ. of Sci. & Tech. of China, HUA CHEN, Univ. of Tennessee, Univ. of Texas at Austin, HAIPING LAN, PING CUI, Univ. of Sci. & Tech. of China, TIM SCHULZE, Univ. of Tennessee, WENGUANG ZHU, Univ. of Tennessee, Oak Ridge National Lab, ZHENYU ZHANG, Univ. of Sci. & Tech. of China, Harvard University — A standing obstacle in epitaxial graphene growth on metal substrates is the prevalence of undesirable grain boundaries (GB) that severely degrade the electronic, transport and mechanical properties of graphene. Employing density functional theory calculations, we demonstrate that the inherent multi-orientational degeneracy of the graphene islands on Cu(111) is the underlying reason for the prevalence of GB. We propose a possible solution, by invoking a functionalized Cu(111) surface to lift the orientational degeneracy of graphene islands and consequently suppress the creation of GB. We have identified the candidate substrate—a superstructured Mn-Cu(111) alloyed surface, which is experimentally achievable and ensures a single orientation for the graphene islands. The proposed approach promises to drastically improve the quality of epitaxial graphene without compromising on efficiency and yield.

¹Supported by USNSF, DMSE/BES of USDOE, and NNSF of China.

3:30PM L12.00004 Rotational homogeneity in graphene grown on Au(111)¹, JOSEPH WOFFORD, UC Berkeley, Lawrence Berkeley National Lab, ELENA STARODUB, Sandia National Laboratories, ANDREW WALTER, Advanced Light Source, LBNL, and Fritz-Haber-Institut der Max-Planck-Gesellschaft, SHU NIE, Sandia National Laboratories, AARON BOSTWICK, Advanced Light Source, LBNL, NORMAN BARTELT, KONRAD THÜRMER, Sandia National Laboratories, ELI ROTENBERG, Advanced Light Source, LBNL, KEVIN MCCARTY, Sandia National Laboratories, OSCAR DUBON, UC Berkeley, Lawrence Berkeley National Lab — The set of properties offered by the (111) surface of gold makes it intriguing as a platform on which to study the fundamental processes that underpin graphene growth on metals. Among these are the low carbon solubility and an interaction strength with graphene that is predicted to be smaller than most transition metals. We have investigated this synthesis process using low-energy electron microscopy and diffraction to monitor the sample surface in real time, and found that the resulting graphene film possesses a remarkable degree of rotational homogeneity. The dominant orientation of the graphene is aligned with the Au lattice, with a small minority rotated by 30 degrees. The origins of this in-plane structuring are puzzling because angularly resolved photo-emission spectroscopy and scanning tunneling microscopy experiments both suggest only a relatively small interaction between the two materials. Finally, the implications of these findings for the growth of high structural-quality graphene films are discussed.

¹DOE Contracts DE-AC04-94AL85000 and DE-AC02-05CH11231.

3:42PM L12.00005 Fundamental growth mechanisms of graphene on nickel surfaces¹, MATTHIAS BATZILL, University of South Florida — CVD growth of graphene over transition metal surfaces has become a main approach for synthesizing large area graphene wafers. The low carbon solubility in copper makes a good material for monolayer graphene synthesis, while carbon dissolution and re-segregation from the bulk of other transition metals, namely nickel, make these materials more demanding for controlling graphene growth. However, lower growth temperatures and defined graphene orientation relative to the substrate are some benefits for graphene synthesis on nickel compared to copper. Here we thoroughly characterize the fundamental growth processes of graphene on nickel substrate with the aim to find growth procedures that enable controlled graphene synthesis. We also identify defect structures in graphene that are formed as a consequence of the nickel substrate.

¹Funding by Office of Naval Research

4:18PM L12.00006 DFT studies of Graphene on Ni(111) and Surface Nickel Carbide Ni₂C ,

ANDREAS GARHOFER, Vienna University of Vienna, PETER JACOBSEN, Vienna University of Vienna, Tulane University, BERNHARD STÖGER, GARETH S. PARKINSON, MICHAEL SCHMID, Vienna University of Vienna, ROMAN CAUDILLO, Intel Corporation, FLORIAN MITTENDORFER, JOSEF REDINGER, Vienna University of Vienna, ULRIKE DIEBOLD, Vienna University of Vienna, Tulane University — Graphene with its unique transport properties supported on ferromagnetic materials is a promising candidate for the fabrication of spin-filtering devices. In order to study the growth of graphene on metal surfaces, graphene on Ni(111) is a perfect system from a structural point of view. The CVD growth of graphene on Ni(111) was studied with STM. The experiments showed not only perfectly aligned (1x1) structures, but also several moiré patterns are observed. They are due to grain rotations of graphene on both Ni(111) and also surface nickel carbide Ni₂C. During CVD growth carbon atoms segregate into the Ni bulk. With an increasing carbon concentration first the surface carbide and then a graphene layer on top is built. We studied the systems using the DFT program package VASP with the DFT-D2 method of Grimme to include van der Waals interactions. In our theoretical analysis we tried to understand the formation of the graphene and Ni₂C on Ni(111). We calculated the stability of the surface carbide phase and the binding energies of rotated and unrotated graphene on Ni(111) as well as on Ni₂C in order to understand the experimental findings. Graphene and Ni₂C have no epitaxial relationship due to their incommensurate lattices, leading to a spread in grain rotations.

4:30PM L12.00007 Graphene nucleation and growth on the transition metal surfaces: the role of pentagon, metal step and magic carbon clusters , JUNFENG GAO, JIJUN ZHAO, Dalian University of Technology, FENG DING, Hong Kong Polytechnic University — The nucleation behavior of graphene on transition metal surfaces, either on a terrace or near a step edge, is systematically explored using density functional theory calculations. The supported carbon clusters, CN (N=1~24), on the Ni(111) surface are carefully optimized [1,2]. A structural transformation from a C chain to a sp² C network at C₁₂ and the most stable structures of sp² graphene islands contain one to three pentagons. In agreement with experimental observations, our calculations show that graphene nucleation near a metal step edge is superior to that on a terrace. Besides, ground state structures of supported CN (N = 16~26), clusters on four selected transition metal surfaces: (Rh(111), Ru(0001), Ni(111) and Cu(111)) are explored [3]. A core-shell structured of C₂₁ stands out as a magic cluster, which is one of the dominating carbon precursors in graphene CVD growth and has been observed in experimental STM images. The energy barrier of two C₂₁ clusters' coalescence is computed to illustrate their influence on the kinetics of graphene CVD growth at different temperatures.

4:42PM L12.00008 Optimizing Epitaxial Cu and Ni Films on Al₂O₃(0001) for Uniform Graphene Growth ,

DAVID L. MILLER, MARK W. KELLER, ROBERT R. KELLER, JUSTIN M. SHAW, ANN N. CHIARAMONTI, National Institute of Standards and Technology, Boulder, CO — Copper and nickel are the most commonly used substrates for the growth of graphene by chemical vapor deposition. While cold-rolled polycrystalline foils are most often selected for their commercial availability and ability to withstand the high temperatures required for graphene growth, (111) crystal faces have been shown to offer better growth characteristics on both materials. We deposited Cu and Ni films onto single crystal Al₂O₃(0001) using magnetron sputtering at temperatures between 250°C and 700°C. This gave films with pure (111) texture but with two epitaxial in-plane orientations as measured by x-ray diffraction and electron backscatter diffraction. Upon heating to graphene CVD temperatures (900°C to 1000°C), the grain boundaries widen and deepen into trenches that prevent the growth of uniform graphene over large areas. Reactive sputtering of a thin layer of Al₂O₃ before depositing the metal results in a single in-plane orientation over > 90% of the film for Ni. In addition, gradually increasing the temperature during metal deposition suppresses the formation of deep trenches under graphene CVD conditions. We compare CVD graphene grown on the optimized films with that grown on commercial foils.

4:54PM L12.00009 Kinetic Pathways towards Fabrication of Narrow Graphene Nanoribbons on Stepped Metal Surfaces¹ ,

PING CUI, JIN-HO CHOI, Univ. of Sci. and Tech. of China, HUA CHEN, Univ. of Tennessee, Univ. of Texas at Austin, WEI CHEN, Univ. of Tennessee, WENGUANG ZHU, Univ. of Tennessee, Oak Ridge National Lab, CHANGGAN ZENG, Univ. of Sci. and Tech. of China, ZHENYU ZHANG, Univ. of Sci. and Tech. of China, Harvard University — Graphene nanoribbons (GNRs) are predicted to exhibit intriguing electronic transport properties that strongly depend on their widths. To this end, one standing challenge is controlled fabrication of narrow GNRs with sizeable band gaps. In this study, we use first-principles approaches to explore the possibility of growing narrow GNRs along the step edges of catalytic metal surfaces. By minimizing the lattice mismatches of the growing graphene islands, optimizing their adsorption geometries, and exploiting the diffusion anisotropy of selective precursor monomers on the stepped surfaces, we identify the growth conditions under which the precursor monomers can be nucleated at the steps and then grow along the steps. Our studies point to kinetic pathways towards controlled fabrication of some of the narrowest GNRs with zigzag or armchair edges, and are expected to stimulate experimental efforts to realize these predictions.

5:06PM L12.00010 Molecular Beam Epitaxy of graphene nanocrystals¹ ,

JORGE M GARCIA², ULRICH WURSTBAUER, THEANNE SCHIROS, Columbia University, NY, NY, ANNETTE S. PLAUT, University of Exeter, UK, LOREN N. PFEIFFER, Princeton University, NJ, ANTONIO LEVY, Columbia University, NY, NY, CHERNO JAYE , DANIEL FISHER , National Institute of Standards and Technology, Gaithersburg, USA, ABHAY PASUPATHY, Columbia University, NY, N, ARON PINCZUK, Columbia University, NY, NY — The ability to produce large-area graphene films on commonly used dielectric substrates can lead to many technological applications. We demonstrate the fabrication of large area conducting graphene nanocrystalline films on arbitrary dielectric substrates by MBE (molecular beam epitaxy) using a solid carbon source that can offer the integration of capable graphene production with high flexibility and variety in ultra-high vacuum environment together with state of the art thin film technology. Synchrotron x-ray and Raman spectroscopies show that the films consist on graphene nanocrystals oriented parallel to the sample surface. The growth rate is a key parameter that determines the bonding environment. Careful control of the growth conditions results in the production of predominantly sp²-bonded carbon thin films on arbitrary substrates, with the potential of growing large graphene grains on epitaxial substrates.

5:18PM L12.00011 ABSTRACT WITHDRAWN —

Tuesday, February 28, 2012 2:30PM - 5:30PM —

Session L13 DMP GMAG: Focus Session: Low-Dimensional and Molecular Magnetism - 1D Magnetism/Single-Chain Magnets - Experiment 211

2:30PM L13.00001 Magnetic Order in the Spin Chain Antiferromagnet $\text{Ca}_3\text{Co}_2\text{O}_6$, MARTIN LEES, Department of Physics, University of Warwick, Coventry CV4 7AL, United Kingdom, O.A. PETRENKO, C.L. FLECK, Department of Physics, University of Warwick, Coventry, United Kingdom, S. AGRESTINI, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, C. MAZZOLI, Dip.to di Fisica, Politecnico di Milano, Milano, Italy, A. BOMBARDI, Diamond Ltd, Chilton, Oxford, United Kingdom, L.C. CHAPON¹, Institut Laue-Langevin, Grenoble, France — We have used powder neutron diffraction to investigate the magnetic structure of the Ising spin chain compound $\text{Ca}_3\text{Co}_2\text{O}_6$. Our investigation focuses on the low-temperature regime ($T < 14 \text{ K} \ll T_N = 25 \text{ K}$) where previous neutron diffraction studies have shown that there is an increasing instability in the spin density wave (SDW) order within this material. The results of this work reveal that there is an order-order transition from the SDW structure to a new commensurate antiferromagnetic phase. The extraordinary time dependence of the magnetic reflections demonstrates that this transition occurs via a very slow transformation process. As the temperature is reduced the characteristic time of the transition process increases rapidly and at low temperatures the magnetic states become frozen. We have also investigated the stability of the low-temperature commensurate phase in an applied magnetic field.

2:42PM L13.00002 Density functional calculation of the electronic and magnetic properties of $\alpha\text{-CoV}_2\text{O}_6$, ANDRES SAUL, CINaM/CNRS, GUILLAUME RADTKE, IM2NP — In this work, the magnetic properties of the low dimensional $\alpha\text{-CoV}_2\text{O}_6$ system have been investigated using density-functional calculations. This system is constituted of CoO_6 octahedra connected by the edges and forming one dimensional linear chains. The experimental magnetization curves recorded at very low temperature show a surprising magnetization plateau at one-third of the saturation magnetization and a strong anisotropy. The estimated Co magnetic moment is large reaching a value of $4.5 \mu_B$ suggesting a large orbital contribution. Our calculations show that three different magnetic configurations for the Co are possible, the lowest energy one being a high spin configuration in agreement with the $S=3/2$ character of the Co^{2+} ion observed in this compound. Spin-orbit interactions have been included in order to calculate the magnetic anisotropy and the orbital contribution to the magnetic moment. The results are discussed in terms of crystal field splitting of the $3d$ orbital and a tight-binding Hamiltonian. Using a broken-symmetry formalism we have evaluated the effective exchange interactions of the Heisenberg Hamiltonian. They allow us to propose the magnetic structures corresponding to the ground state and to the observed magnetization plateaus.

2:54PM L13.00003 Heat capacity and magnetization of CoNb_2O_6 near quantum critical point¹, TIAN LIANG, Department of Physics, Princeton University, SEYED KOOHPAYEH, Institute for Quantum Matter, Johns Hopkins University, JASON KRIZAN, SIAN DUTTON, Department of Chemistry, Princeton University, TYREL MCQUEEN, Department of Physics and Astronomy, Johns Hopkins University, ROBERT CAVA, Department of Chemistry, Princeton University, N. PHUAN ONG, Department of Physics, Princeton University — CoNb_2O_6 is a quasi-1D quantum magnet in which magnetic Co^{2+} ions are ferromagnetically arranged into nearly isolated chains along the c axis with the magnetic moment confined in the ac -plane. By applying transverse magnetic field along b -axis, quantum phase transition from magnetically ordered phase to paramagnetic phase occurs. Evidence for emergent E_8 symmetry was recently obtained by neutron scattering near the quantum critical point (QCP) in an applied transverse magnetic field of 5.5 T. We will report on experiments to investigate the behavior of the heat capacity and torque magnetization in the vicinity of the QCP and discuss their implications.

3:06PM L13.00004 Terahertz excitations in the 1D Ising chain quantum magnet CoNb_2O_6 ¹, CHRISTOPHER M. MORRIS, R. VALDÉS AGUILAR, S. KOOPAYEH, C. BROHOLM, N.P. ARMITAGE, The Institute for Quantum Matter, Department of Physics & Astronomy, The Johns Hopkins University — The one-dimensional magnet CoNb_2O_6 was recently demonstrated to be an excellent realization of a one-dimensional quantum Ising spin chain. It has been shown to undergo a quantum phase transition in a magnetic field oriented transverse to its ferromagnetically aligned spin chains. Low energy spin-flip excitations in the chains were recently observed via inelastic neutron scattering.² The energy spectrum of these excitations was shown to have an interesting energy scaling governed by symmetries of the E_8 exceptional Lie group. Here, time-domain terahertz spectroscopy (TDTS) is used to investigate optically active low energy excitations in CoNb_2O_6 . We take advantage of the polarization sensitivity of this technique to characterize both electric and magnetic dipole active excitations in this compound. A connection is made from the $q = 0$ response observed here to the excitations observed by neutron scattering. In addition, we will show preliminary data on the terahertz spectra of this material as it undergoes the magnetic field-tuned quantum phase transition.

3:18PM L13.00005 Thermal Transport in CuSb_2O_6 single crystals¹, NARAYAN PRASAI, JOSHUA L. COHN, University of Miami, MICHAEL G. SMITH, ALWYN REBELLO, JOHN J. NEUMEIER, Montana State University — CuSb_2O_6 behaves as a uniform, one-dimensional (1D) $S = 1/2$ Heisenberg spin chain with long-range, antiferromagnetic ordering below $T_N \simeq 8.5 \text{ K}$.² Unusual for cuprates, the Cu^{2+} ions lie within quite regular CuO_6 octahedra and 1D magnetism appears to arise from orbital ordering driven by correlation effects.³ We will report the results of thermal conductivity measurements on single crystals over the temperature range $5 \text{ K} \leq T \leq 330 \text{ K}$.

3:30PM L13.00006 Static and dynamic properties of Single-Chain Magnets with broad domain walls, ALESSANDRO VINDIGNI, THOMAS MICHAELS, Laboratory for Solid State Physics, ETH Zurich, Switzerland, ORLANDO BILLONI, Universidad Nacional de Cordoba, Argentina, DANILO PESCIA, Laboratory for Solid State Physics, ETH Zurich, Switzerland — It is well-known that long-range order cannot occur in 1d magnetic systems with short-range interactions. Remanent magnetization may, however, be observed in anisotropic spin chains due to slow dynamics. The physics of such systems – called Single-Chain Magnets (SCMs) – is mainly dictated by the temperature dependence of the relaxation time (τ) and the correlation length (ξ). The behavior of τ and ξ is, in turn, determined by domain-wall (DW) excitations. Both statics and dynamics are dependent on whether DWs extend over more than one lattice distance (*broad*) or not (*sharp*). The transition from one regime to the other is controlled by the strength of the magnetic anisotropy energy with respect to the exchange interaction. For broad domain walls, we found that the interplay between localized excitations and spin waves turns crucial at finite temperatures. Moreover, all the relevant quantities display universal behaviour, provided that temperature is measured in units of DW energy and distance in units of DW widths. These facts allowed us to explain the experimental behavior of a class of Mn-based SCMs with broad DWs and may also be relevant to the study of metallic nanowires.

3:42PM L13.00007 Light induced kickoff of magnetic domain walls in Ising chains¹, LAPO BOGANI,

1. Physikalisches Institut, Universität Stuttgart — Controlling the speed at which systems evolve is a challenge shared by all disciplines, and otherwise unrelated areas use common theoretical frameworks towards this goal. A particularly widespread model is Glauber dynamics, which describes the time evolution of the Ising model and can be applied to any binary system. Here we show, using molecular nanowires under irradiation, that Glauber dynamics can be controlled by a novel domain-wall kickoff mechanism. Contrary to known processes, the kickoff has unambiguous fingerprints, slowing down the spin-flip attempt rate by several orders of magnitude, and following a scaling law. The required irradiation power is very low, a substantial improvement over present methods of magneto-optical switching: in our experimental demonstration we switched molecular nanowires with light, using powers thousands of times lower than in previous optical switching methods. This manipulation of stochastic dynamic processes is extremely clean, leading to fingerprint signatures and scaling laws. These observations can be used, in material science, to better study domain-wall displacements and solitons in discrete lattices. These results provide a new way to control and study stochastic dynamic processes. Being general for Glauber dynamics, they can be extended to different kinds of magnetic nanowires and to a myriad of fields, ranging from social evolution to neural networks and chemical reactivity. For nanoelectronics and molecular spintronics the kickoff affords external control of molecular spin-valves and a magnetic fingerprint in single molecule measurements. It can also be applied to the dynamics of mechanical switches and the related study of phasons and order-disorder transitions.

4:18PM L13.00008 On-Surface Design and Characterization of Magnetic Macromolecules, SHIH-

HSIN CHANG, Research Center for Applied Sciences, Academia Sinica, Taipei, Taiwan, ANDREW DILULLO, KENDAL CLARK, Department of Physics and Astronomy, Ohio University, Athens OH 45701, USA, JAN-PETER KLOECKNER, MARC-HEINRICH PROSENC, Institute of Inorganic Chemistry, University of Hamburg, Germany, ROLAND WIESENDANGER, GERMAR HOFFMANN, Institute of Applied Physics, University of Hamburg, Germany, SAW-WAI HLA, Department of Physics and Astronomy, Ohio University, Athens OH 45701, USA — The formation of molecular chains from basic magnetic molecular building blocks is addressed on various surfaces. Via a surface catalyzed reaction multi-spin macromolecules are synthesized in ultra-high vacuum and then investigated by scanning tunneling microscopy (STM) at low temperatures. In my presentation, I will discuss the impact of the surface on the catalytic step and present a systematic comparison between Cu(111), Cu(100), NaCl/Cu(111), Co/Cu(111), and Au(111) surfaces. Depending on the substrate system, either unwanted sideproducts or spin-active macromolecules are created. In the latter case, scanning tunneling spectroscopy measurements are performed revealing an intermolecular spin-spin interaction through the analysis of the Kondo resonance. Our approach sheds new light on molecular magnetism where magnetically coupled complexes will be synthesized from basic units on surfaces for future spintronic applications.

4:30PM L13.00009 NMR Study of the Spin-Peierls transition in TiPO_4 ¹, RAIVO STERN, IVO HEINMAA,

ENNO JOON, NICPB, Tallinn, JOSEPH LAW, REINHARD KREMER, Max Planck Institut für Festkörperforschung, Stuttgart, ROBERT GLAUM, Institut für Anorganische Chemie, Universität Bonn — We investigated the magnetic and structural properties of the quasi-one dimensional $3d^1$ -quantum chain system TiPO_4 ($J \sim 965$ K) by NMR measurements. TiPO_4 undergoes two magnetostructural phase transitions, one at 111 K and the other at 74 K. Below 74 K, NMR detects two different ^{31}P signals and the magnetic susceptibility vanishes, while DFT calculations evidence a bond alternation of the $\text{Ti} \dots \text{Ti}$ distances within each chain. Thus, the 74 K phase transition is a spin-Peierls transition which evolves from an incommensurate phase existing between 111 K and 74 K.

4:42PM L13.00010 Magnetic exchange studies of one-dimensional Co(II) molecular chains

, ASMA AMJAD, University of Central Florida, Orlando, G.M. ESPALLARGAS, J.M. CLEMENTE-JUAN, Instituto de Ciencia Molecular, Universidad de Valencia, Spain, R. KLEMM, E. DEL BARCO, University of Central Florida, Orlando, E. CORANADO, Instituto de Ciencia Molecular, Universidad de Valencia, Spain, M. EVANGELISTI, ICMA, Universidad de Zaragoza, Spain — We present a detailed experimental and theoretical study of a 1D spin $1/2$ Co-based molecular chain, $\text{trans}[\text{CoCl}_2(3,5\text{-Br}_2\text{py})_2]$. Our results show distinct features that are associated to both intra-molecular interactions (along the chain) and inter-molecular interactions (perpendicular to the direction of chains). The hysteresis observed at low temperature (230mK), indicate presence of 3D ordering attributed to the exchange interactions between the chains. Measurements done at different angles from the chains axial direction (c-axis), restricted within the a-c and b-c planes, reveal uniaxial anisotropy along the c-axis. The experimental data are explained using the mean field approximation, focusing on the behavior of inter-chain interactions and g-tensor anisotropy at the Co sites in the presence of a static magnetic field. A transition between two different relaxation regimes encountered for variable sweep rates will also be discussed.

4:54PM L13.00011 Magnetic structure and stability of 1D Co/Fe wires, JESSICA BICKEL, MATTHIAS

MENZEL, KIRSTEN VON BERGMANN, ANDRE KUBETZKA, ROLAND WIESENDANGER, Institute of Applied Physics, University of Hamburg — As device scales continue to decrease low dimensional structures are needed to take the place of wires and thick films. Particularly in the field of spintronics, it is important to develop 1D structures that can transmit information via the spin. This work realizes one method of spin transport via mixed Co/Fe 1D chains on Ir(001). Pure chains and mixed chains were examined by spin-polarized scanning tunneling microscopy (SPSTM) and spectroscopy. Both Fe and Co self-assemble into bi-atomic chains on the Ir(001)-(5x1) surface reconstruction. The Fe deposits as a single stacking chain while the Co exhibits two different stackings. When co-deposited, the materials can be differentiated from one another by spectroscopy due to differences in the local density of states. Spin-resolved measurements of pure Fe chains show a periodic spin-spiral along the entire length of the chain which is stabilized in an applied field but fluctuates at a speed greater than the time resolution of the STM in zero applied field. The Co, however, exhibits a ferromagnetic ground state that is stable at 8K. When the materials are co-deposited on the surface, the Co stabilizes the Fe spin-spiral and information about the magnetic state of the Co can be transmitted via the Fe spin-spiral.

5:06PM L13.00012 Magnetic diamond chains of Cu_3O_4 ¹, BRIGITTE LERIDON, WILLEM RISCHAU, PHILIPPE MONOD,

LPHEM-CNRS/ESPCI ParisTech - 10 rue Vauquelin - 75005 Paris - France, DOROTHÉE COLSON, SPEC - DSM/DRECAM - CEA Saclay - 91191 Gif-Sur-Yvette Cedex - France — We present magnetization measurements on a satellite phase of $\text{YBa}_2\text{Cu}_3\text{O}_x$ namely BaCu_3O_4 . This two-dimensional material is composed of alternate layers of Ba and Cu_3O_4 . In the latter, the Cu and O atoms are one-dimensionally ordered in diamond-shaped chains of formula unit Cu_3O_4 . We will show that this material encounters a magnetic phase transition at around 336 K which is due to intra-ordering through superexchange coupling of the spins born by the Cu atoms in these diamond chains. We will discuss the possibility of either ferrimagnetic or antiferromagnetic inter-ordering of these weakly coupled one-dimensional objects and the possible role of Dzyaloshinskii-Moriya interactions.

¹This work was supported through SESAME grants from Région Ile-de-France.

5:18PM L13.00013 Competing ^1H Spin Relaxation Mechanisms in Low-Dimensional $\text{Per}_2\text{Pt}[\text{mnt}]_2$, ELIZABETH GREEN, J.S. BROOKS, P.L. KUHN, A.P. REYES, NHMFL, J.A. WRIGHT, S.E. BROWN, UCLA, M. ALMEIDA, ITN, M.J. MATOS, R.T. HENRIQUES, Lisboa, NHMFL TEAM¹, UCLA TEAM², ITN TEAM³, LISBOA TEAM⁴ — $\text{Per}_2[\text{Pt}(\text{mnt})_2]$ is a low-dimensional organic conductor consisting of parallel conducting (*perylene*) and magnetic chains ($\text{Pt}[\text{mnt}]_2$) which undergo a charge density wave (CDW) and spin-Peierls (SP)-transition, respectively. The conducting chain has been studied extensively, however fundamental questions about the spin-dynamics of the magnetic chain in the SP-state remained. By using ^1H NMR, we discovered the low temperature nuclear relaxation rates (T_1^{-1}) display an anomalous upturn at the SP-transition which differs from classical SP-systems. This “bump” is suppressed by magnetic field and coincides with the Curie tail, seen in susceptibility measurements. The field-dependent activation energies, extracted from NMR and susceptibility, reveal two distinct behaviors evidencing coexisting spin systems. At low fields, the spin relaxation mechanism derived from a paramagnetic contribution, possibly unpaired Pt spins, is dominant, but is suppressed above 10T. Hence, the intrinsic SP behavior is recovered for high fields. Furthermore, spectra in the field induced (FICDW) state, up to 33T, reveal an increase in the electronic spin polarization. *DMR-NSF-1005293*

2:30PM L14.00001 The intra-gap electromagnetic response of gated GaMnAs in an electric double-layer field effect, BRIAN CHAPLER, T.W. ELSON, University of California San Diego, S. MACK, D.D. AWSCHALOM, University of California Santa Barbara, E. NAMMAS, University of Queensland, J. YUEN, A.J. HEEGER, University of California Santa Barbara, L. JU, F. WANG, University of California Berkeley, D.N. BASOV, University of California San Diego — We have fabricated field effect transistors (FETs) utilizing an electrolyte oxide gate insulator for monitoring electrostatic doping in GaMnAs via infrared (IR) spectroscopy. Previous studies of gated GaMnAs have been confined primarily to transport measurements. IR experiments are able to probe the electric field induced changes to the optical conductivity spectrum, providing direct insight into the electronic structure of GaMnAs. The IR spectra show an enhancement of the Drude response and mid-IR resonance of GaMnAs upon hole accumulation, with symmetric decrease in these features in the depletion mode. A sum rule analysis of the IR spectra, combined with charge accumulation/depletion information from transport measurements for the same gated structures, enables accurate evaluation of the effective masses of mobile holes without any underlying assumptions about the level of compensation and/or disorder in the films. The low bound for the effective mass is several m_e , where m_e is the free electron mass. We therefore conclude that electronic states in the vicinity of the Fermi energy retain significant impurity band character.

2:42PM L14.00002 Effect of As vacancies on the binding energy and exchange splitting of Mn impurities on a GaAs surface, M.R. K. MAHANI, C.M. CANALI, Linnaeus University, Kalmar, Sweden, A.H. MACDONALD, University of Texas at Austin — State-of-the-art STM spectroscopy is nowadays able to manipulate and probe the magnetic properties of individual magnetic impurities located near the surface of a semiconductor. A recent advance of these techniques employs the electric field generated by a As vacancy in GaAs to affect the environment surrounding substitutional Mn impurities in the host material [1]. Here we calculate the binding energy of a single Mn dopant in the presence of nearby As vacancies, by using a recently-introduced tight-binding method [2] that is able to capture the salient features of Mn impurities near the (110) GaAs surface. The As vacancies, modeled by the repulsive potential they produce, are expected to decrease the acceptor binding energy in agreement with experiment [1]. Within this theoretical model, we investigate the possible enhancement of the exchange splitting for a pair of ferromagnetically ordered Mn impurities, observed experimentally when As vacancies are present [3]. We also calculate the response of the Mn-impurity—As-vacancy complex to an external magnetic field.

2:54PM L14.00003 Observation of a Sharp Band Edge Response in GaMnAs Using Nonlinear Spectroscopy¹, TRISTAN DE BOER, ANGELA GAMOURAS, SAM MARCH, Dalhousie University, VIT NOVAK, Institute of Physics AS CR, Czech Republic, KIMBERLEY HALL, Dalhousie University — Diluted magnetic semiconductors (DMS) have gained considerable interest over the last decade owing to their potential use in magneto-sensitive electrical and optical devices, in which the carrier-mediated nature of the ferromagnetism allows the magnetic properties to be controlled using optical or electrical gating techniques. The position of the Fermi level, which may lie within the valence band or within an impurity band, plays a critical role in current theories of ferromagnetism in DMS and has been the subject of intense controversy in recent years. Linear spectroscopy techniques are unable to address this issue due to strong band tailing in the vicinity of the fundamental band gap. Here we present results of time- and spectrally-resolved differential reflection measurements on GaMnAs, as well as low-temperature-grown GaAs and semi-insulating GaAs. Our results indicate a sharp band edge response due to the diminished contributions of band tail states in the nonlinear optical regime. We observe a blue shift of the band gap in GaMnAs, supporting a valence band model of ferromagnetism in DMS. Numerical simulations of the measured nonlinear response using an effective mass model support our conclusions.

3:06PM L14.00004 Tuning the magnetic interaction between Mn dopants in GaAs, DAVID GOHLKE, JAY GUPTA, Ohio State University, Department of Physics — Manganese can be used as a dopant in gallium arsenide to create a ferromagnetic semiconductor. We use low-temperature scanning tunneling microscopy to study these magnetic properties. The magnetic coupling between Mn dopants in GaAs(110) changes between ferromagnetic and antiferromagnetic depending on the orientation of the acceptors due to the zincblende crystal structure of the surface [Kitchen et al, *Nature*, 2006]. We have recently reported tuning of the resonance energy for a single Mn acceptor by moving charged atomic point defects [Lee and Gupta, *Science*, 2010]. Here, we tune the magnetic interaction between surface-layer Mn atoms in the same way. Funding for this research was provided by the Center for Emergent Materials at the Ohio State University, an NSF MRSEC (Award Number DMR-0820414). <http://www.physics.ohio-state.edu/~jgupta/>

3:18PM L14.00005 Spin-Seebeck Effect in III-V Based Semiconductors, CHRISTOPHER M. JAWORSKI, ROBERTO C. MYERS, JOSEPH P. HEREMANS, The Ohio State University — The spin-Seebeck effect has now been observed in metals¹ (NiFe), semiconductors² (GaMnAs), and insulators³ (YIG). It consists of a thermally generated spin distribution that is phonon driven. Here we extend our measurements of the spin-Seebeck effect to other group III-V based magnetic semiconductors and present measurements of conventional thermomagnetic and galvanomagnetic properties as well as the spin-Seebeck effect. 3:30PM L14.00006 High Resolution Magneto-Optic Measurements in GaAs using a Sagnac Interferometer, ALEXANDER FRIED, AHARON KAPITULNIK, Stanford University — The Sagnac Interferometer is a tool which measures the Polar Kerr effect—a direct indicator of magnetism. Using 820 nm light from a superluminescent diode, we probe GaAs structures and measure the Kerr angle with sub-microradian resolution. By utilizing diffraction limited optics and a piezoelectric scanner, we also achieve high spatial resolution. Our measurements are performed at cryogenic temperatures and offer a way to measure the Spin Hall Effect in the DC regime along with other forms of magnetic order.

3:42PM L14.00007 All-optical four-state magnetization reversal in (Ga,Mn)As ferromagnetic semiconductors, MYRON KAPETANAKIS¹, ILIAS PERAKIS, Physics Department, University of Crete, Greece, JINGANG WANG, Department of Physics and Astronomy, Iowa State University, and Ames Laboratory US-DOE, CARLO PIERMAROCCHI, Department of Physics and Astronomy, Michigan State University — The emerging field of femtomagnetism has revealed the central role of non-equilibrium interactions and transient optical coherence in determining photoinduced spin dynamics. However the many-body theory of such effects remains controversial. A microscopic theory that engages the elements of coherence, correlation and nonlinearity on an equal footing is needed. We propose here such a theory, based on density matrix equations of motion and a tight-binding band calculation. We prepare the system within 100fs, via coherent nonlinear photoexcitation close to the strong peak of the density of states for interband transitions along the eight equivalent directions {111} of the GaAs BZ in the vicinity of 3eV. It then selectively relaxes to one of the four local minima of the magnetic free energy with biaxial anisotropy. We thus propose a non-thermal mechanism for all-optical switching between four metastable magnetic states, initiated non-thermally within 100fs and completed within 100ps. Our predicted switching comes from magnetic nonlinearities triggered by a femtosecond magnetization tilt that is sensitive to un-adiabatic light-induced spin interactions and controlled via the optical and the external magnetic field.

3:54PM L14.00008 First-Principle Calculation of The Effective Hamiltonian for (Ga,Mn)As and (Ga,Mn)N, RYKY NELSON, ANH NGO, Louisiana State University, WEI KU, Brookhaven National Laboratory, JUANA MORENO, MARK JARRELL, Louisiana State University — Most of the models used to study (Ga,Mn)As have failed to explain the experimental results of (Ga,Mn)N especially its ferromagnetic critical temperature T_C . The need for a consistent and comprehensive model for the dilute magnetic semiconductors (DMS) motivates our study. We obtain the effective Hamiltonian for (Ga,Mn)As and (Ga,Mn)N using a Wannier function based first-principles method. We use density functional theory to calculate the band structure of a range of disordered supercell configurations of (Ga,Mn)As and (Ga,Mn)N and Wannier functions to obtain downfolded Hamiltonians. Those are then disorder averaged to get an effective Hamiltonian. We solved this effective model using the dynamical mean field approximation.

4:06PM L14.00009 Polaronic trapping in magnetic semiconductors¹, HANNES RAEBIGER, Yokohama National University, Yokohama, Japan — GaN doped with iron is an interesting candidate material for magnetic semiconductors, as p-d coupling between the localized Fe-d and extended N-p hole states is expected to facilitate long-range ferromagnetic alignment of the Fe spins [1]. This picture of extended states in GaN:Fe, however, falls apart due to a polaronic localization of the hole carriers nearby the Fe impurities. To elucidate the carrier localization in GaN:Fe and related iron doped III-V semiconductors, I present a systematic study using self-interaction corrected density-functional calculations [2]. These calculations predict three distinct scenarios. (i) Some systems do sustain extended host-like hole states, (ii) some exhibit polaronic trapping, (iii) and some exhibit carrier trapping at Fe-d orbitals. These behaviors are described in detail to give an insight as to how to distinguish them experimentally. I thank T. Fujita, C. Echeverria-Arrondo, and A. Ayuela for their collaboration.

4:18PM L14.00010 Magnetoresistance in antiferromagnet-based spin tunnel junctions, TOMAS JUNGWIRTH, Institute of Physics ASCR, Prague and University of Nottingham — To date spintronics research and applications of magnetically ordered systems have focused on ferromagnets (FMs). There are, however, fundamental physical limitations for FM materials which may make them impractical to realize the full potential of spintronics. Metal FMs offer high temperature operation but the large magnetic stray fields make them unfavorable for high-density integration and metals are unsuitable for transistor and information processing applications. FM semiconductors on the other hand do not allow for high-temperature operation. We present a concept in which these limitations are circumvented in spintronics based on antiferromagnets. The concept is based on relativistic magnetic and magneto-transport anisotropy effects in nanodevices whose common characteristics is that they are an even function of the microscopic magnetic moment vector, i.e., can be equally strong in AFMs as in FMs. As a demonstration we present our experimental observation of >100% tunneling anisotropic magnetoresistance in a device with an IrMn AFM tunnel electrode [1]. We will also discuss candidate materials for high-temperature AFM semiconductor spintronics [2].

4:54PM L14.00011 Numerical studies of non-Drude ac-conductivity and infrared magneto-optics in $(\text{Ga}_{1-x}\text{Mn}_x)\text{As}$, HUAWEI GAO, JAIRO SINOVA, Texas A&M University — Optical absorption experiments on (III,Mn)V diluted magnetic semiconductors (DMS's) show that the ac-conductivity has non-Drude behavior at low frequency. The numerical simulation of this problem has been done previously using the effective Hamiltonian model with various treatments of the disorder effects. We are re-examining the previous works with a similar numerical method to establish the nature of the transitions in the low to the high doped regime. We use the effective Hamiltonian k.p model to describe the holes introduced by Mn impurities and treat the Mn impurities exactly using the envelope function approximation. With this technique we are able in principle to analyze spectrally the origin of the mid-infrared absorption peak, its trends, and the nature of the states near the Fermi energy as well as the excitation states. We will also report on numerical results of the magneto-optical response with this more accurate treatment of the effect of disorder.

5:06PM L14.00012 Electric field manipulation of room temperature ferromagnetism in anatase $\text{Ti}_{1-x}\text{Co}_x\text{O}_{2-\delta}$, YOSHINORI YAMADA, Tohoku University, KAZUNORI UENO, TOMOTERU FUKUMURA, HONGTAO YUAN, University of Tokyo, HIDEKAZU SHIMOTANI, Tohoku University, YOSHIHIRO IWASA, University of Tokyo, LIN GU, SUSUMU TSUKIMOTO, Tohoku University, YUICHI IKUHARA, MASASHI KAWASAKI, University of Tokyo — Ferromagnetic semiconductor is one of the most attractive materials for semiconductor spintronics because of the controllability of both charge and spin degrees of freedom. Electric field effect of magnetism in the ferromagnetic semiconductors such as (Ga,Mn)As has been demonstrated only at low temperature due to their low Curie temperatures. In this study, we report the electric field manipulation of ferromagnetism in a ferromagnetic semiconductor $\text{Ti}_{1-x}\text{Co}_x\text{O}_{2-\delta}$ at room temperature [1]. Anatase $\text{Ti}_{1-x}\text{Co}_x\text{O}_{2-\delta}$ (001) epitaxial film was deposited on TiO_2 buffer 5 nm / LaAlO_3 (100) substrate in various oxygen pressures in order to vary an electron density by pulsed laser deposition method. An electric double layer transistor was fabricated on a paramagnetic film with an electron density of $1 \times 10^{19} \text{ cm}^{-3}$. With increasing gate voltage, the electron density was increased to $7 \times 10^{19} \text{ cm}^{-3}$. Ferromagnetic hysteresis loop was observed for V_G above 3.0 V in an anomalous Hall resistivity, which is proportional to a magnetization of the film. This result represents that the ferromagnetism was induced at room temperature by an electrostatic charge accumulation, indicating that the ferromagnetism in this compound is mediated by the electron carriers.

[1] Y. Yamada et al., Science **332**, 1065 (2011).

5:18PM L14.00013 BaMn_2Sb_2 : A New Semiconducting Ferromagnet¹, JIANNENG LI, S. STADLER, A. KARKI, Y. XIONG, R. JIN, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803 — We have grown high-quality single crystals of BaMn_2Sb_2 , which possesses the ThCr_2Si_2 structure as determined by X-ray powder diffraction technique. Magnetization measurements indicate that BaMn_2Fe_2 is ferromagnetic below $T_C = 580\text{K}$. On the other hand, the temperature dependence of electrical resistivity shows semiconducting behavior, which can be described by thermally-activated resistivity formula with thermal activation energy about 0.25 eV. While the Hall coefficient has positive sign between 2 and 300 K, the Seebeck Coefficient undergoes sign change from positive at high temperatures to negative at low temperatures, reaching $-260 \mu\text{V/K}$ at 70 K. The implication will be discussed.

Session L15 DMP FIAP GMAG: Focus Session: Spins in Metals - Resonance Phenomena I, Spin Wave Excitation and Spin Torque Oscillators 213

2:30PM L15.00001 Spin-torque excited spin waves revealed by micro-focused Brillouin light scattering¹, MARCO MADAMI, CNISM, Unità di Perugia and Dipartimento di Fisica, Università di Perugia — Since the discovery of the spin transfer torque (STT) effect [1,2] a great effort has been devoted to the realization and study of spin torque oscillators (STOs) because of their potential applications as spin waves injectors in magnonic devices or current-tunable broad-band microwave sources. More recently the possibility to synchronize multiple STOs [3,4] via the emitted spin waves, propagating in the magnetic “free” layer, envisioned a way to overcome their main limitation in the output power. For these reasons it’s now crucial to obtain a detailed knowledge and understanding of the emitted spin waves properties like: their spatial distribution, their propagating or localized character, their decay length, wavelength and group velocity. In the last two years micro-focused Brillouin light scattering (μ -BLS) revealed to be a powerful tool in order to investigate several of these properties [5,6]. In this presentation we discuss the potentialities of μ -BLS to the study of emitted spin waves in STOs systems with particular focus on the results of our latest work [6]. Here we took advantage of our μ -BLS setup in order to study spin waves emitted by an out-of-plane magnetized nano-contact STO. Performing a “wave-vector resolved” μ -BLS experiment we provided the first direct experimental evidence of the *propagating* nature of SWs emitted from an out-of-plane magnetized STO. The decay of the propagating SW intensity up to several microns away from the nano-contact position showed great potential for STT based magnonic devices. We also investigated the STO tunability measuring the emitted SW frequency as a function of both the applied direct current and external field intensities. Micromagnetic simulations provided the theoretical support to quantitatively reproduce the results.

3:06PM L15.00002 Probing spin wave excitations using magnetic tunnel junction structures¹, XIN FAN, CHONG BI, JOHN XIAO, Department of Physics, University of Delaware, CENTER FOR SPINTRONICS AND BIODETECTION TEAM — We propose a quantitative method based on the use of high tunneling magnetoresistance and small lateral dimension of magnetic tunnel junction (MTJ) to detect spin excitations in magnetic films with promising high spatial resolution and sensitivity. One ferromagnetic (FM) layer of the MTJ is pinned by an antiferromagnetic layer and the other one is free to rotate in response to an external magnetic field. In the presence of microwave magnetic fields, the free layer will precess, leading to the average resistance of MTJ change. By applying a constant dc current bias to the MTJ, a time dependent voltage can be introduced and measured which is related to the time dependent magnetization along the external static field direction. We have demonstrated the usefulness of this method by studying the spin wave excitations in a single elliptical Permalloy thin film ($50 \mu\text{m} \times 30 \mu\text{m} \times 40 \text{nm}$). At low microwave power, a uniform linear ferromagnetic resonance behavior has been observed. Surprisingly, above the spin wave instability threshold, the experimental results show a linear response of the microwave field over a large range, which is followed by a phase limiting behavior. The linear behavior can be described by the theoretical model describing subsidiary resonance.

3:18PM L15.00003 Generating Damon-Eshbach Spin Waves in Py using a Conducting Diffraction Grating , J. SKLENAR, Northwestern University, V.S. BHAT, L. DELONG, University of Kentucky, Lexington, J.B. KETTERSON, Northwestern University — We have patterned silver hole arrays directly on top of uniform permalloy (Py) films. Typical Py and Ag film thicknesses are 25nm and 40 nm respectively; the holes in the Ag have a 500nm diameter and are patterned on a 1 micron lattice constant. We have measured resonant modes arising from a quasi-uniform microwave excitation field, applied in the plane of the sample, as a function of the in-plane external field and the in-plane field orientation relative to the principal axes of the array. Measurements were done using our broadband meanderline-based ferromagnetic resonance (FMR) spectrometer.¹ In addition to a uniform FMR mode we observe satellite modes that correspond to the Damon-Eshbach spin waves² with wave vectors having Fourier components of the reciprocal lattice of the silver array. Hence, in an otherwise uniform magnetic film the silver array acts as a *diffraction grating* which excites spin waves with $k \neq 0$ from the dynamic $k \approx 0$ microwave magnetic field. The observed spin wave angular dispersion is in excellent agreement with a magnon dispersion relation for spin waves in a uniform film given by Kriesel et al.³

3:30PM L15.00004 Time-dependent spin-wave theory¹ , ANDREAS KREISEL, ANDREAS RÜCKRIEGEL, PETER KOPIETZ, Institute for Theoretical Physics, University of Frankfurt, Germany — We generalize the spin-wave expansion in powers of the inverse spin to time-dependent quantum spin models describing rotating magnets or magnets in time-dependent external fields. We show that in these cases the spin operators should be projected onto properly defined rotating reference frames before the spin components are bosonized using the Holstein-Primakoff transformation. As a first application of our approach, we calculate the re-organization of the magnetic state due to Bose-Einstein condensation of magnons in the magnetic insulator yttrium-iron garnet; we predict a characteristic dip in the magnetization which should be measurable in experiments.

¹With special thanks to DFG for funding within "Transregio 49".

3:42PM L15.00005 Autonomous and driven dynamics of spin torque nano-oscillators¹ , SERGEI URAZHIDIN, Emory University — Understanding the dynamical properties of autonomous spin torque nano-oscillators (STNO) and their response to external perturbations is important for their applications as nanoscale microwave sources. We used spectroscopic measurements to study the dynamical characteristics of nanopillar- and point contact-based STNOs incorporating a microstrip in close proximity to the active magnetic layer. By applying microwave current at frequency f_{ext} to the microstrip, we were able to generate large microwave fields of more than 30 Oe rms at the location of STNO. We demonstrate that for a wide range of f_{ext} , STNO exhibits multiple synchronization regimes with integer and non-integer rational ratios between f_{ext} and the oscillation frequency f . We show that the synchronization ranges are determined by the symmetry of the oscillation orbit and the orientation of the driving field relative to the symmetry axis of the orbit. We observe synchronization hysteresis, i.e. a dependence of the synchronization limits on the dynamical history caused by the nonlinearity of STNO. We also show that the oscillation can be parametrically excited in the subcritical regime of STNO by a microwave field at twice the frequency of the oscillation. By measuring the threshold and the frequency range of parametric excitation, we determine damping, spin-polarization efficiency, and coupling to the microwave signal. In addition, by measuring the frequency range of parametric synchronization in the auto-oscillation regime, we determine the dynamic nonlinearity of the nanomagnet. Thus, analysis of the driven oscillations provides complete information about the dynamical characteristics of STNO. Finally, we discuss several unusual dynamical behaviors of STNO caused by their strong nonlinearity.

4:18PM L15.00006 Improved coherence of a quasi-linear spin-torque nano-oscillator , OUKJAE LEE, VLAD PRIBIAG, DAN RALPH, ROBERT BUHRMAN, Cornell University, CORNELL UNIVERSITY TEAM — We have fabricated tapered nanopillar spin-valve devices, $\sim 50 \times 145$ nm², from a Py(5)/Cu(12)/Py(20) multilayer (thickness in nm) for spin torque nano-oscillator (STNO) studies. When biased with electron flow from the thick layer to the thin layer multiple, high power, but broad ($\Delta f > 50$ MHz), spin torque excitation modes are obtained at hard-axis fields $H_y < 500$ Oe. For $H_y \sim 700$ Oe we obtain much more coherent ST oscillations, $\Delta f < 10$ MHz, close to that predicted for a linear STNO at 300 K. A macrospin model successfully explains the optimum field bias as being where the amplitude-dependent red shift effect due to the demagnetization field is closely balanced by the blue shift effect due to the in-plane anisotropy field. We have also modeled the internal field within the free layer as a function of H_y and conclude that the multiple modes at lower fields originate from the relatively broad spatial distribution of the internal field, or equivalently from the broad natural frequency distribution of the individual magnetic elements. Our results suggest pathways for further enhancements in STNO performance.

4:30PM L15.00007 Time-Domain Measurements of Real-Space Magnetization Trajectories in Spin Torque Oscillators , GRAHAM E. ROWLANDS, JIAN ZHU, Department of Physics and Astronomy, University of California, Irvine, JORDAN A. KATINE, Hitachi Global Storage Technologies, San Jose, CA, JUERGEN LANGER, Singulus Technologies, 63796 Kahl am Main, Germany, PEDRAM KHALILI AMIRI, KANG L. WANG, Department of Electrical Engineering, University of California, Los Angeles, ILYA N. KRIVOROTOV, Department of Physics and Astronomy, University of California, Irvine — We make time-domain measurements of the microwave signal emitted by spin torque nano-oscillators (STNOs) based on magnetic tunnel junctions with Fe-rich free layers. The perpendicular magnetic anisotropy of the free layer nearly cancels its easy-plane shape anisotropy, allowing the magnetization to undergo large amplitude precession. The microwave power emitted by such STNOs reaches values approaching 0.4 μ W. We employ a high-gain low-noise amplifier to further amplify the emitted signal, thereby bringing it to a level (~ 0.5 V rms) far exceeding the noise floor (5mV rms) of a 12 GHz, 40 Gs/s storage oscilloscope used for time-domain measurements. Relying on the assumption that extrema of the measured voltage versus time trace correspond to the magnetization crossing the sample plane, we use these time-domain traces to reconstruct the statistical distributions of the azimuthal angles at which the magnetization vector of the free layer crosses the plane of the sample. We measure the evolution of these crossing angle distributions as a function of current density and compare to theoretical predictions.

4:42PM L15.00008 Network Analyzer Measurements of Spin-Torque Dynamics , LIN XUE, CHEN WANG, YONGTAO CUI, R.A. BUHRMAN, D.C. RALPH, Cornell University — A microwave current flowing through a magnetic tunnel junction (MTJ) produces an oscillating spin torque. This oscillating spin torque is able to excite resonant magnetic dynamics and produce an oscillating resistance. The oscillating resistance combined with an applied DC current can generate a microwave voltage signal at the same frequency as the input microwave signal. We show that a network analyzer measurement of the amplitude and phase of this signal provides a simple way to make a quantitative measurement of the strength and direction of the spin transfer torque vector in MTJs at non-zero biases, the regime of primary interest for applications. Compared with a previous time-domain technique for measuring the spin torque vector, this technique requires no specialized equipment and provides roughly similar sensitivity. Compared to dc-detected spin-torque ferromagnetic resonance, the network-analyzer method is free of artifacts at high bias.

4:54PM L15.00009 Spin-transfer-driven parametric resonance in magnetic nanodomains¹, C. WANG, H. SEINIGE, T. STAUDACHER, M. TSOI, Physics Department, University of Texas at Austin — We study experimentally the parametric excitation of a magnetic nanodomain by spin-transfer-torque (STT). In our experiments, we use a nanoscale point contact to inject high-density ac (microwave frequency) and dc currents into an exchange-biased IrMn/NiFe/Cu/NiFe spin valve (EBSV) and to produce STT [1] on NiFe moments in a small contact region. Here a time-dependent STT associated with the microwave current produces a time-dependent modulation of the effective damping parameter which, in turn, drives the magnetic moments into parametric resonance [2]. The resonance was detected electrically by measuring a small rectified dc voltage which appears across the contact at resonance [3]. We study this resonance signal as a function of frequency and power of the applied microwaves. As expected for parametric excitation, this resonance has an ac threshold and occurs at double the natural frequency of magnetic precession (FMR frequency). We found that both the excitation threshold and the width of the resonance depend on the applied dc bias. Detailed dc bias dependent measurements of the resonance signal provide a means to characterize instability regions in parameter space known as Arnold tongues. The parametric excitation can be potentially used in magnetic memory technology for reducing power and increasing speed of logic and memory devices. [1] J. C. Slonczewski (1996); L. Berger (1996); M. Tsoi et al. (1998). [2] M. Faraday (1831). [3] T. Staudacher and M. Tsoi (2011).

5:06PM L15.00010 Spin-orbit coupling and spin excitations in nanoscopic structures, ANTONIO COSTA, Universidade Federal Fluminense, SAMIR LOUNIS, Forschungszentrum Jülich, ROBERTO MUNIZ, Universidade Federal Fluminense, DOUGLAS MILLS, University of California Irvine — We have developed a formalism to calculate the spectra of spin excitations of structures of nanoscopic dimensions that takes into account spin-orbit coupling. We study structures composed by magnetic units (adatoms, clusters, ultrathin films) deposited on metallic substrates. The reduced symmetry of the magnetic units enhance the effects of spin-orbit coupling and activate mechanisms such as the Dzyaloshinskii-Moriya anti-symmetric exchange coupling. We are also able to predict anisotropic g-factors. In the case of ultrathin films, our formalism can span the entire Brillouin zone, being able to describe within the same framework FMR results and spectra obtained with SPEELS. We can also calculate the spectra that would be obtained by local probes such as inelastic scanning tunneling spectroscopy. We will present results for Fe ultrathin films on W(110) and for several transition metal adatoms on metallic substrates.

5:18PM L15.00011 Spin orbit driven ferromagnetic resonance and torques in single ferromagnetic layers¹, FERRAN MACIÀ, CHARLES PÉPIN, A.D. KENT, New York University, KENT'S GROUP TEAM — The coupling of spin and charge may convert electrical currents into spin currents in non-magnetic metals. In non-magnetic metals with strong spin orbit (SO) interaction in combination with magnetic metals one can also use the effect to excite magnetization dynamics; electrical currents in the non-magnetic metal transform to spin currents and the spin currents diffuse to the magnetic metal interacting with the magnetic moments. The combination of non-magnetic metals and magnetic metals has been recently used to determine spin hall angles. Here we demonstrate that spin currents in a ferromagnetic layer associated with SO interactions can excite ferromagnetic precession in the same layer. We have studied Co—Ni multilayers with both in-plane anisotropy and weak out-of-plane anisotropy. Results show that the samples have strong SO interactions. We have injected microwaves into patterned samples with several geometries and measured the mixed voltage in the same leads. Oscillatory currents drive FMR in the thin-film layer. We show that SO torques are primarily responsible for the magnetic excitations in samples with strong SO interactions, whereas samples with a weaker SO barely respond to the injected microwaves and show asymmetric components from charge current induced Oersted fields.

Tuesday, February 28, 2012 2:30PM - 5:30PM — Session L16 DCMP: Heavy Fermions - Theory and Experiment 251

2:30PM L16.00001 $\beta - YbAlB_4$: a critical vortex metal¹, ALINE RAMIRES, PIERS COLEMAN, Rutgers University, ALEXEI TSVELIK, Brookhaven National Laboratory — $\beta - YbAlB_4$ is the first Yb based heavy fermion superconductor and has a non Fermi Liquid behavior in the normal state that develops without external tuning by pressure or doping, making it intrinsically quantum critical [1]. Application of a magnetic field is found to drive the development of a Fermi Liquid in which the Fermi temperature is determined by the Zeeman energy [2]. Here we present a theory for the intrinsic quantum criticality in which the main ingredient is an anisotropic hybridization matrix with line nodes in momentum space that carry a vorticity and resemble topological defects. Our theory predicts that the application of a field induces a novel Lifshitz transition, in which a quasi-two dimensional Fermi Liquid with density of states $N^*(B) \propto 1/\sqrt{B}$ nucleates around the line node in momentum space. We also discuss how the vortex metal picture can account for the ESR anomalies observed in this system [3].

2:42PM L16.00002 Correlated disorder in Kondo lattice¹, MAXIM DZERO, XINYI HUANG, Kent State University — Motivated by recent experiments on Yb-doped CeCoIn₅, we study the effect of correlated disorder in Kondo lattice. Correlations between the impurities are considered at the two-particle level. We use mean-field theory approximation for the Anderson lattice model to calculate how the emergence of coherence in the Kondo lattice is impacted by correlations between impurities. We show that the rate at which disorder suppresses coherence temperature depends on the length of impurity correlations. As impurity concentration increases, we generally find that the suppression of coherence temperature is significantly reduced. The results are discussed in the context of available experimental data.

2:54PM L16.00003 High-energy dispersion anomalies in actinide compounds, T. DAS, T. DURAKIEWICZ, J.-X. ZHU, J.J. JOYCE, MATTHIAS J. GRAF, Los Alamos National Lab. — The observation of a prominent peak-dip-hump feature in the spectral weight in number of actinide compounds including Pu-115 superconductors and non-superconducting U-115 remains an unsolved problem. We have developed a first-principles intermediate coupling model to show that most aspects of these strong correlation features can be understood from the spin-fluctuation interaction.[1] The results show that a strong peak in the spin-fluctuation dressed self-energy is present around 0.5 eV in all these materials, which is mostly created by spin-orbit split 5f bands. These fluctuations couple to the single-particle spectrum and give rise to a peak-dip-hump feature, characteristic of the coexistence of itinerant and localized electronic states. Results are in quantitative agreement with photoemission spectra. Finally, we show that the studied actinides can be understood within the rigid-band filling approach, in which the spin-fluctuation coupling constant follows the same materials dependence as the superconducting transition temperature T_c . Work is supported by US DOE.

3:06PM L16.00004 The Electronic Correlation Strength of Pu¹, R.C. ALBERS, JIAN-XIN ZHU, Los Alamos National Laboratory, A. SVANE, N.E. CHRISTENSEN, Aarhus University, MARK VAN SCHILFGAARDE, Arizona State University — Many materials have strong electron-electron correlation effects that can cause large deviations in electronic structure and materials properties from those predicted by conventional band-structure theory based on the local density approximation. We present a new method or scale to quantify electronic correlations in strongly correlated electron systems and apply it to the different phases of elemental Pu. Using the GW approximation, we show that the f-electron band-width reduction due to correlation effects scales as a function of the initial LDA bandwidth. This relationship is a universal relationship in that it is independent of crystal structure and atomic volume.

3:18PM L16.00005 The Role of the Kondo and Phonon Correlations in the Cerium Volume Collapse¹, PETER REIS, PENG ZHANG, KA MING TAM, JUANA MORENO, MARK JARRELL, Louisiana State University, FAKHER ASSAAD, University of Wuerzburg, ANDY MCMAHAN, Lawrence Livermore National Lab, KONDO VOLUME COLLAPSE COLLABORATION — We review the most recent experimental and theoretical progress of the $\alpha \leftrightarrow \gamma$ volume collapse occurring in the element cerium. We discuss the experimental results which have been important in differentiating the various electronic and phononic properties of the volume collapse of cerium, these experiments illustrate that drastically different electronic and phononic properties exist between the small volume phase α and large volume phase γ of cerium. After interpreting the physical data and realizing that the volume collapse in cerium is primarily the result of different electronic and vibronic correlations in the α and γ phases we set up a Hamiltonian which encompasses the physical properties of the collapse. To model the electronic and phononic properties of the $\alpha \leftrightarrow \gamma$ transition of cerium we use the Periodic Anderson Model (PAM) + Holstein Model, with the aim that the Kondo like electronic correlations of the α phase is encoded in the PAM where the large vibronic physics of the γ phase is encompassed in the Holstein Model which incorporates a conduction electron-phonon mediated interaction.

3:30PM L16.00006 Numerical Study of the Electron-Phonon coupling in the Cerium Volume Collapse, PENG ZHANG, PETE REIS, KA-MING TAM, Department of Physics, Louisiana State University, LA, FAKHER ASSAAD, Department of Physics, University of Wuerzburg, Germany, JUANA MORENO, Department of Physics, Louisiana State University, LA, ANDY MCMAHAN, Lawrence Livermore National Laboratory, CA, MARK JARRELL, Department of Physics, Louisiana State University, LA — Rare earth elements, for example Cerium, will experience a volume collapse with increasing pressure. Researchers have struggled for six decades to discover the mechanism behind this unusual first order phase transition. Although different models have been proposed that provide some qualitatively correct results, there is no theory that completely captures the volume collapse. Notably, some recent experiments show that lattice oscillations play an important role, contrary to the previous consensus that this phase transition is mainly driven by the contributions from spins and electrons. In this talk, we will discuss our study which employs the DMFA method to explore the role of electron-phonon coupling in the Periodic Anderson Model.

3:42PM L16.00007 Lifshitz transition with interactions in high magnetic fields: Application to CeIn₃¹, PEDRO SCHLOTTMANN, Florida State University — The Néel ordered state of CeIn₃ is suppressed by a magnetic field of 61 T at ambient pressure. There is a second transition at ~ 45 T, which has been associated with a Lifshitz transition [1,2]. Skin depth measurements [2] indicate that the transition is discontinuous as $T \rightarrow 0$. Motivated by this transition we study the effects of Landau quantization and interaction among carriers on a Lifshitz transition. The Landau quantization leads to quasi-one-dimensional behavior for the direction parallel to the field. Repulsive Coulomb interactions give rise to a gas of strongly coupled carriers [3]. The density correlation function is calculated for a special long-ranged potential [4]. It is concluded that in CeIn₃ a pocket is being emptied as a function of field in a discontinuous fashion in the ground state. This discontinuity is gradually smeared by the temperature [4] in agreement with the skin depth experiments [2].

3:54PM L16.00008 Coexistence of antiferromagnetism and superconductivity induced by Pauli-paramagnetic pair breaking, KAZUSHI AOYAMA, Young Researcher Development Center, Kyoto University, RYUSUKE IKEDA, Department of Physics, Kyoto University — The heavy-fermion material CeCoIn₅ is a spin singlet d -wave superconductor with a strong Pauli-paramagnetic pair-breaking (PPB) effect. In the case with a magnetic field parallel to the basal plane of this material, there exists a distinct high field and low temperature (HFLT) superconducting (SC) phase in which a Fulde-Ferrell-Larkin-Ovchinnikov vortex lattice may be realized as a result of the strong PPB. Recently, it has been clarified that an antiferromagnetic (AFM) order exists inside the HFLT SC phase in spite of the absence of AFM order in the nonsuperconducting state [1]. Considering that AFM and SC orders are competing with each other in zero field, it is surprising that the AFM ordering is enhanced in the SC state. We theoretically study the stability of an AFM order in a d -wave and paramagnetic superconductor. We show that the PPB enhanced strongly by increasing the magnetic field induces an AFM order inside the SC phase and that, in contrast to the competitive nature of AFM and SC orders, the induced AFM order is not localized in vortex cores but coexistent with the SC order [2]. [1] M. Kenzelmann *et al.*, Science **321**, 1652 (2008). [2] K. Aoyama and R. Ikeda, arXiv:1107.5577.

4:06PM L16.00009 Current-Carrying States in Fulde-Ferrell-Larkin-Ovchinnikov superconductors, JIN AN, CHIN-SEN TING, Texas Center for Superconductivity, University of Houston, CHIA-REN HU, Department of Physics, Texas A&M University — Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) superconducting state is believed to be favorable in Pauli-limited heavy-fermion superconductors such as CeCoIn₅. Based on Bogliubov de-Gennes equations, we present a theoretical study of current-carrying FFLO states, including the stability and characterization of a superconducting order parameter for a current-carrying FFLO state. Inhomogeneous and anisotropic current density distribution and quasi-particle current contribution related to the order parameter modulation and sign change are found in FFLO state, which are expected to provide an easy way to detect the existence of an FFLO state.

4:18PM L16.00010 CeRu₂Al₂B: A new local moment 4f magnet with a complex T-H phase diagram, RYAN E. BAUMBACH, X. LU, K. GOFRYK, F. RONNING, J.D. THOMPSON, Los Alamos National Laboratory, H. CHUDO, HIROSHI YASUOKA, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, Advanced Science Research Center, Japan Atomic Energy Agency, Tokai, Ibaraki, JAPAN, C.H. WANG, V.O. GARLEA, A.D. CHRISTIANSON, Oak Ridge National Laboratory, E.D. BAUER, Los Alamos National Laboratory — There is ongoing interest in the study of Ce-based compounds that are derivatives of certain structure types (e.g., ThCr₂Si₂ and PbClF), as they are often associated with correlated electron phenomena. We will report results for a new system that falls into this category, CeRu₂Al₂B. This compound crystallizes in a filled variant of the layered/tetragonal CeMg₂Si₂ structure. Contrary to what is often observed for Ce-based compounds, we find pronounced local moment behavior of the Ce ions, resulting in complicated magnetic ordering at strikingly high temperatures: i.e., antiferromagnetism (AFM) at $T_N = 14.1$ K followed by ferromagnetism (FM) at $T_C = 12.8$ K, which is first order in character. We also find a temperature-magnetic field phase diagram that consists of three distinct ordered phases: (1) AFM, (2) spin reoriented, and (3) FM. Since this type of behavior is unusual for Ce-based compounds, we will discuss prospects for suppressing the ordered state toward $T = 0$ in order to produce a Doniach-like phase diagram, which may provide a route towards a FM quantum critical point.

4:30PM L16.00011 T-P phase diagram for the new local moment 4f ferromagnet CeRu₂Ga₂B, ERIC D. BAUER, R.E. BAUMBACH, X. LU, T. SHANG, F. RONNING, J.D. THOMPSON, Los Alamos National Laboratory, C.H. WANG, V.O. GARLEA, A.D. CHRISTIANSON, Oak Ridge National Laboratory — We will report results for single crystals of a new Ce-based local moment ferromagnet, CeRu₂Ga₂B. Electrical resistivity, magnetization, and magnetic susceptibility measurements reveal ferromagnetism and hysteresis around $T_C = 16.1$ K, while specific heat measurements uncover a huge anomaly at the phase transition, which results in a large discontinuity in the magnetic entropy ($\Delta S_{mag} = 1.7$ J/mol-K). Taken together, these data show that CeRu₂Ga₂B undergoes a first order ferromagnetic phase transition at a surprisingly high temperature. Since this type of behavior is unusual for Ce-based compounds, we additionally undertook an effort to tune the magnetic state using pressure. We will present electrical resistivity measurements under applied pressures and the resulting temperature-pressure phase diagram, with an emphasis on implications for possible nearness to a ferromagnetic quantum critical point.

4:42PM L16.00012 Superconductivity and Magnetic Ordering in RE₂Pt₃Ge₅ (RE = La and Pr) Single Crystals, NAKHEON SUNG, C.J. ROH, B.K. CHO¹, School of Materials Science and Engineering, Gwangju Institute of Science and Technology (GIST), Gwangju 500-712, Korea — Superconductivity and magnetic properties of rare-earth ternary germanide intermetallic compounds, RE₂Pt₃Ge₅ (RE = La and Pr), are investigated. La₂Pt₃Ge₅ and Pr₂Pt₃Ge₅ single crystals were synthesized by high temperature metal flux method with Ge self flux. These two compounds were formed in U₂Co₃Si₅-type orthorhombic structure (space group *Ibam*) and the lattice parameters were determined using XRD of pulverized single crystals. La₂Pt₃Ge₅ exhibits an onset of superconducting phase transition at $T_c = 8.1$ K, which, to the best of our knowledge, is the highest T_c in U₂Co₃Si₅-type superconductors. Pr₂Pt₃Ge₅ shows both superconducting phase transition at $T_c = 7.9$ K and antiferromagnetic transition at $T_N = 4.4$ K. In addition, Pr₂Pt₃Ge₅ reveals strong magnetic anisotropy with an easy magnetic axis perpendicular to the *c*-axis, due to crystalline electric field effect. Including these results, we will discuss the nature of RE₂Pt₃Ge₅ single crystals in detail.

4:54PM L16.00013 Multi-orbital Kondo physics of Co in Cu hosts, ALEXANDER LICHTENSTEIN, TIM OLIVER WEHLING, ALJOSCHA WILHELM, 1st Institute for Theoretical Physics, University of Hamburg, Germany, BRIGITTE SURER, MATTHIAS TROYER, PHILIPP WERNER, Theoretische Physik, ETH Zurich, Switzerland, ANDREAS LÄUCHLI, MPI fuer Physik komplexer Systeme, Dresden, Germany — We investigate the electronic structure of cobalt atoms on a copper surface and in a copper host by combining density functional calculations with a numerically exact continuous-time quantum Monte Carlo treatment of the five-orbital impurity problem. In both cases we find low energy resonances in the density of states of all five Co *d*-orbitals. The corresponding self-energies indicate the formation of a Fermi liquid state at low temperatures. Our calculations yield the characteristic energy scale – the Kondo temperature – for both systems in good agreement with experiments. We quantify the charge fluctuations in both geometries and suggest that Co in Cu must be described by an Anderson impurity model rather than by a model assuming frozen impurity valency at low energies. We show that fluctuations of the orbital degrees of freedom are crucial for explaining the Kondo temperatures obtained in our calculations and measured in experiments.

5:06PM L16.00014 Origin of the Heavy-Fermion behavior in Ca_{2-x}Sr_xRuO₄, NAOYA ARAKAWA, MASAO OGATA, Department of Physics, The University of Tokyo — We investigate the electronic states in Ca_{2-x}Sr_xRuO₄ for $0.5 \leq x \leq 2.0$ on the basis of the three-orbital Hubbard model in the Gutzwiller approximation. We take the dominant effects of the Ca-substitution into account as the changes of the hybridizations, whose squares are proportional to the nearest-neighbor hopping integrals of the Ru-*t_{2g}*-orbitals, between the Ru-4*d*- and O-2*p*-orbitals. In this presentation, we show the renormalization factors for the Ru *t_{2g}*-orbitals as a function of the intraorbital Coulomb interaction or an angle of the rotation of RuO₆-octahedra and discuss the origin of the heavy-fermion behavior around $x = 0.5$. Our calculation suggests that moderately strong Coulomb interaction and the orbital-dependent modifications of the electronic structures for the Ru-*t_{2g}*-orbitals due to the Ca-substitution cause the heavy-fermion behavior in Ca_{2-x}Sr_xRuO₄.

5:18PM L16.00015 Far-infrared optical properties of pyrochlore heavy fermion superconductor Cd₂Re₂O₇ in the normal and superconducting states¹, M. REEDYK, M. HAJIALAMDARI², D.A. CRANDLES, F.S. RAZAVI, Dept. Physics, Brock University, R.K. KREMER, Max Planck Institute for Solid State Research — Cd₂Re₂O₇ is a pyrochlore oxide which exhibits superconductivity with a transition temperature T_C near 1 K. The far-infrared optical properties of Cd₂Re₂O₇ will be presented at temperatures above and below T_C . Superconductivity induced changes in the phonon structure are observed. Thermal reflectance spectra show two absorption features, near 9.6 and 19.3 cm⁻¹ which arise in the superconducting state. Optical conductivity spectra reveal a softening (~ 1 cm⁻¹) of the phonon mode at 35 cm⁻¹ in the superconducting state. Analysis of the frequency dependent optical effective mass and scattering rate support the classification of this material as a modest heavy electron system at low temperatures.

Session L17 DMP GERA FIAP: Focus Session: Thermoelectrics - Electronic Structure and Transport 252A

2:30PM L17.00001 Potassium is a resonant level in $\text{Bi}_{1-x}\text{Sb}_x$ alloys¹, JOSEPH P. HEREMANS, The Ohio State University, Department of Mechanical and Aerospace Engineering, and Department of Physics, HYUNGYU JIN, The Ohio State University, Department of Mechanical and Aerospace Engineering, BARTLOMIEJ WIENDLOCHA, AGH University of Science and Technology, Faculty of Physics and Applied Computer Science, Krakow, Poland — $\text{Bi}_{1-x}\text{Sb}_x$ alloys are the most promising thermoelectric materials for cryogenic Peltier cooling. Resonant impurity levels are known to increase the thermoelectric power and figure of merit of semiconductors and known examples are Ti:PbTe [1] and $\text{Sn:Bi}_2\text{Te}_3$ [2]. Here we add $\text{K:Bi}_{1-x}\text{Sb}_x$ to that list. Band structure calculations show that substitutional potassium in bismuth can form sharp density of states peaks, suggesting the presence of a resonant level. Single crystal samples were synthesized by a modified horizontal Bridgman-Hor method. Cryogenic thermoelectric transport data will be presented as a function of K and Sb concentrations. At certain concentrations, the addition of potassium has a large effect on the thermopower, and increases the figure of merit to reach $zT = 0.7$ at 100K with $zT > 0.5$ at all temperatures from 50K up to room temperature, numbers are valid along the trigonal axis of single crystals. [1] J. P. Heremans & al. Energy Environ. Sci. DOI:10.1039/C1EE02612G; Science **321**, 554 (2008); [2] C.M. Jaworski & al., Phys. Rev. B **80**, 233201, (2009)

2:42PM L17.00002 Fermi level pinning in Ti doped PbTe ¹, YI-BIN GAO, Dept of Mechanical and Aeronautical Engineering (MAE), Ohio State University (OSU), JAN KOENIG, Fraunhofer Institute for Physical Measurement Techniques, Germany, MICHELE D. NIELSEN, MAE OSU, BARTLOMIEJ WIENDLOCHA, AGH University of Science and Technology, Poland, HARALD BOETTNER, Fraunhofer Institute for Physical Measurement Techniques, Germany, JOSEPH P. HEREMANS, MAE, Dept of Physics, OSU — The doping of PbTe attracts much interest due to the possible improvement of the thermoelectric properties by forming resonant levels. Here we report on doping of PbTe with Ti by molecular beam epitaxy, and back up the results with band structure calculations that show that Ti is a resonant level in the conduction band of PbTe . Ti is found to be a donor, leading to electron concentrations up to $1 \times 10^{19} \text{cm}^{-3}$, above which it pins the Fermi level at about 52 meV above the conduction band edge, and further increase of Ti shows no effect. At higher Ti contents the concentration of free electrons starts to rise again. However, Ti doping does not enhance the thermopower above that of similarly-doped PbTe , suggesting that the electrons on Ti are localized. We propose a model for Fermi level pinning due to different ionization states of the donor impurity which is similar to a chemical buffer. Further electronic structure calculations for Ti:PbTe confirm existence of the quasi-localized Ti states in the conduction band of PbTe and predict a local magnetic moment on Ti atom of 1.8 Bohr magnetons.

2:54PM L17.00003 Enhancement of Thermoelectric Figure-of-Merit by Resonant States of Aluminum Doping in Lead Selenide, QINYONG ZHANG, Xihua University, HUI WANG, WEISHU LIU, HENGZHI WANG, BO YU, QIAN ZHANG, Boston College, ZHITING TIAN, GEORGE NI, SANGYEOP LEE, KEIVAN ESFAJANI, GANG CHEN, MIT, ZHIFENG REN, Boston College, XIHUA UNIVERSITY COLLABORATION, BOSTON COLLEGE TEAM, MIT TEAM — By adding aluminium (Al) into lead selenide (PbSe), we successfully prepared n-type PbSe thermoelectric materials with a figure-of-merit (ZT) of 1.3 at 850 K. Such high ZT is achieved by a combination of high Seebeck coefficient caused by very possibly the resonant states in the conduction band created by Al dopant and low thermal conductivity from nanosized phonon scattering centers.

3:06PM L17.00004 Thermoelectric properties of indium-doped PbSe ¹, ERIC EVOLA, The Ohio State University, MICHELE NIELSEN, PhD Student Mentor (OSU), JOSEPH HEREMANS, Advisor (OSU) — P-type [1,2] and n-type [3] PbSe have recently exhibited good thermoelectric properties without using the relatively uncommon element Tellurium. Here we report thermal conductivity, galvanomagnetic and thermomagnetic properties of bulk samples of n-type PbSe doped with indium at varying concentrations within the solid solution solubility range. A figure of merit zT value well in excess of 1 has been achieved. Resonant level effect and changes in the dimensionless figure of merit will be discussed although data indicate that the thermoelectric properties do not lie above the Pisarenko relation.

3:18PM L17.00005 Study on thermoelectric properties of n-type PbSe doped with B, Ga, and In, QIAN ZHANG, Boston College, QINYONG ZHANG, Xihua University, BO YU, DEZHI WANG, Boston College, GEORGE NI, GANG CHEN, Massachusetts Institute of Technology, ZHIFENG REN, Boston College, BOSTON COLLEGE TEAM, XIHUA UNIVERSITY COLLABORATION, MASSACHUSETTS INSTITUTE OF TECHNOLOGY COLLABORATION — We report here systematic study of the thermoelectric properties of n-type PbSe with B, Ga, and In doping. The comparison of the electrical resistivity, Seebeck coefficient, and thermal conductivity is conducted. Room temperature Hall measurements show the effective increase of carrier concentration by both Ga and In doping to $\sim 10^{20} \text{cm}^{-3}$. The high power factor $\sim 2.4 \times 10^{-3} \text{Wm}^{-1} \text{K}^{-2}$ is obtained when B is doped, however, it is decreased with increasing temperature, which is inverted with the other dopants. No resonant state is found in all these three materials. A figure of merit, $ZT > 1.2$ at 873 K is achieved in 0.5% In doped PbSe .

3:30PM L17.00006 Electronic structure of ferroelectrically distorted PbTe¹, MAL-SOON LEE, Michigan State University, MERCOURI G. KANATZIDIS, Northwestern University, S.D. MAHANTI, Michigan State University — PbTe is one of the most promising thermoelectric materials. The electronic transport properties of the p-doped system are generally explained based on the nearly degenerate pockets near L and along Σ at high temperatures, where the energy at the L point decreases with increasing temperature and approaches the Σ point maxima. Recently, Bozin et al. showed that structure of PbTe is ferroelectrically distorted at high temperatures.² Following this experiment, a lattice dynamics study using first-principle molecular dynamics simulations have shown an increase of the band gap with increased temperature as seen experimentally.³ Motivated from these studies, we have performed electronic structure calculations to investigate the effect of structural distortion and expansion on the band structure. We observe that the ordering of energy levels changes dramatically with distortion. In addition to these results we will also discuss how this can affect the electronic transport properties at high temperatures.

3:42PM L17.00007 Potential thermoelectric performance from optimization of hole-doped Bi₂Se₃¹, DAVID PARKER, DAVID SINGH, Oak Ridge National Laboratory — We present an analysis of the potential thermoelectric performance of hole-doped Bi₂Se₃, which is commonly considered to show inferior room temperature performance when compared to Bi₂Te₃. We find that if the lattice thermal conductivity can be reduced by nanostructuring techniques (as have been applied to Bi₂Te₃) the material may show optimized ZT values of unity or more in the 300 - 500 K temperature range and thus be suitable for cooling and moderate temperature waste heat recovery and thermoelectric solar cell applications. Central to this conclusion are the larger band gap and the relatively heavier valence bands of Bi₂Se₃.

¹This research was supported by the U.S. DoE, EERE, Vehicle Technologies, Propulsion Materials Program (DP) and the “Solid State Solar-Thermal Energy Conversion Center (S3 TEC),” an Energy Frontier Research Center funded by the US DOE(DJS)

3:54PM L17.00008 Electronic and Thermoelectric properties of RuIn_{3-x}A_x (A=Sn, Zn) from first principles¹, DEEPA KASINATHAN, MPI CPfS - Dresden, KLAUS KOEPERNIK, IFW Dresden, HELGE ROSNER, MPI CPfS - Dresden — Recently, substitution derivatives of the intermetallic compound RuIn_{3-x}A_x (A = Sn, Zn) have been shown to exhibit relatively high Seebeck coefficients. Substitution by Sn results in n-type behavior while p-type is the norm for substitution of In by Zn. We discuss in detail the electronic structure of the parent compound and the substitution derivatives obtained from density functional theory (DFT) based calculations using the Full Potential Local Orbital (FPLO) code. The substitution effects have been studied using three different approximations: the simple virtual crystal approximation (VCA), the ordered supercell approach and the disordered coherent potential approximation (CPA). Both Sn and Zn prefer different site symmetry positions in the unit cell. While the parent compound RuIn₃ is a semiconductor, the substitution derivatives are not. For small doping concentrations, we observe a rather rigid-band-like behavior due to the parabolic nature of the bands forming the valence band maximum and the conduction band minimum. Transport properties calculated using the semi-classical Boltzmann transport equations (BoltzTraP) based on the constant scattering approximation are consistent with the experiments.

4:06PM L17.00009 Electronic structure and thermopower of Cu₃SbSe₄¹, DAT DO, Michigan State University, VIDVUDS OZOLINS, University of California, Los Angeles, S.D. MAHANTI, MAL-SOON LEE, Michigan State University, YONGSHENG ZHANG, CHRIS WOLVERTON, Northwestern University — Cu₃SbSe₄ (Se₄), a ternary derivative of the II-VI zincblende semiconductors, is a narrow band gap semiconductor (band gap $\sim 0.1 - 0.4$ eV) and a promising thermoelectric. Recently, Skoug et al. [1] have measured transport properties of pure and doped Se₄ (Ge and Sn substituting for Sb). They find that p-doping by 2% Sn results in optimized value of $ZT=0.72$ at 630 K. To understand the electronic structure and transport properties of Se₄ we have carried out ab initio density functional electronic structure calculations. LDA/GGA/GGA+U approximations do not show that Se₄ is a standard semiconductor. They give a resonance-like peak near the top of the valence band of width ~ 0.5 eV. The Fermi energy for the undoped system lies below the peak, making it a pseudo-gap system, in disagreement with experiment. Non-local exchange with relaxation of Sb-Se bonds lead to the opening of a gap (0.26 eV), its origin being intimately related to the valency of Sb. Transport calculations show that Se₄ is an excellent p-type thermoelectric, in agreement with experiment.

4:18PM L17.00010 Thermoelectric Properties of CoSb₃-xSn_x¹, MICHELE D. NIELSEN, Department of Mechanical Engineering, The Ohio State University, SI HUI, Department of Mechanical Engineering, University of Michigan, CTIRAD UHER, Department of Physics, University of Michigan, JANUSZ TOBOLA, Department of Condensed Matter Physics, AGH University of Science and Technology, Krakow, Poland, JOSEPH P. HEREMANS, Department of Physics, Department of Mechanical Engineering, The Ohio State University — We substitute Sn for Sb in CoSb₃. Band structure calculations predict that Sn should be a resonant level with an energy near the top of the heavy (Co-3d) valence band. This is confirmed experimentally. Indeed, heavily Sn-doped samples show a low-temperature anomaly in their thermopower consistent with this prediction. The hole concentration, however, is too high for this materials to have a high thermopower and figure of merit.

¹This material is based upon work supported by the Department of Energy Award Number DE-PI0000012.

4:30PM L17.00011 Is the high frequency thermopower useful for predicting properties of strongly correlated materials?¹, JESUS CRUZ, JAMES FREERICKS, Georgetown University — Shastry has proposed that the high-frequency thermopower can be used for meaningful predictions of the dc thermopower in many strongly correlated materials. If true, this will make it much easier to screen strongly correlated materials for useful thermoelectric properties because it is much easier to calculate the high-frequency limit. By solving this problem exactly for the Falicov-Kimball model using dynamical mean-field theory, we find that this approach often does not work. We also compare with usual approximations for the thermopower, we find that the Heikes formula gives a good description of the high frequency thermopower while the Kelvin formula is equivalent at high temperature. Unfortunately, the only accurate way to find the dc thermopower is with the conventional Kubo formula.

4:42PM L17.00012 Electrical and thermal transport properties of the substituted defect manganese silicides $\text{Mn}_{1-x-y}\text{Cr}_x\text{Ru}_y\text{Si}_{\delta\sim 1.74}$ ¹, VIJAYABARATHI PONNAMBALAM, DONALD T. MORELLI, Department of Chemical Engineering and Materials Science, Michigan State University, East Lansing, MI- 48824 — Crystallizing in the TiSi_2 structure with considerable amount of random vacancies at the Si site, defect manganese silicides MnSi_{δ} ($\delta \sim 1.72\text{--}1.74$) are unusual in many respects. One of them is their structural stability which is determined by the electron concentration. In addition, MnSi_{δ} is known for unusually low thermal conductivity $\sim 3\text{--}3.5\text{ W/m K}$ at 300 K. We have substituted MnSi_{δ} with Cr and Ru simultaneously and studied the electrical and thermal transport properties of the resulting alloys. Both resistivity and Seebeck coefficient are less sensitive to substitutions and maintain robust values as high as that of $\text{MnSi}_{\sim 1.74}$. Hall measurements indicate that the carrier concentration remains high around $10^{21}/\text{cm}^3$ and more or less same for all compositions. Thermal conductivity is decreased further and interestingly increases with T reaching values $\sim 2.5\text{ W/m K}$ at 300 K. These results will be presented and discussed.

¹This work was supported as part of the Center for Revolutionary Materials for Solid State Energy Conversion, an Energy Frontier Research Center funded by the U.S. DoE, Office of Science, Office of Basic Energy Sciences under Award Number DE-SC0001054.

4:54PM L17.00013 Transport in Old and New Thermoelectric Materials¹, DAVID SINGH, Oak Ridge National Laboratory — There is increasing interest in thermoelectric materials motivated in part by recent progress and in part by the potential of these materials in various energy technologies. Thermoelectric performance is a multiply contra-indicated property of matter. For example, it requires (1) high thermopower and high electrical conductivity, (2) high electrical conductivity and low thermal conductivity and (3) low thermal conductivity and high melting point. The key is finding an optimal balance. In this talk, I discuss some of the issues involved in the context of recent results. These include the surprising doping dependence of the thermopower in PbTe and PbSe , and the interplay between acoustic and optical phonons in PbTe . The potential of some new materials is discussed. This work was done in collaboration with David Parker, Olivier Delaire and Mao-Hua Du.

2:30PM L18.00001 The Role of Surface Ligands in Electronic Charge Transport in Semiconductor Nanocrystal Arrays, CHERIE KAGAN, University of Pennsylvania — The long, insulating ligands commonly used in the synthesis of colloidal semiconductor nanocrystals (NCs) inhibit strong interparticle coupling and charge transport once NCs are assembled in the solid state into NC arrays. We introduce ammonium thiocyanate (NH_4SCN) and its derivatives, ammonium selenocyanate and selenourea to exchange the long, insulating ligands commonly used in the synthesis of colloidal semiconductor NCs. NCs may be exchanged with the new ligand in solution to form dispersions from which NC arrays are deposited or NC arrays with the long, insulating ligands may be exchanged in the solid state with the new ligands. The new compact ligands enhance interparticle coupling and charge transport in thin film, NC arrays as seen by red-shifts in the optical absorption and concomitant increases in carrier mobilities. Thiocyanate-capped CdSe thin film, NC arrays form sensitive photodetectors and n-type field-effect transistors with electron mobilities of $\sim 10\text{ cm}^2/\text{Vs}$ and current modulation of $>10^6$, while preserving NC quantum confinement. Temperature-dependent transport measurements reveal band-like transport in NC arrays, overcoming carrier hopping that has typified transport in NC arrays until recently. The non-caustic, chemically benign nature of the ammonium thiocyanate treatment enables the fabrication of NC thin film devices and circuits on flexible plastics.

3:06PM L18.00002 n and p Type HgTe Colloidal Quantum Dot Film¹, HENG LIU, SEAN KEULEYAN, PHILIPPE GUYOT-SIONNEST, James Franck Institute, The University of Chicago — HgTe colloidal quantum dots (CQDs) are a new system that can be stably charged n- and p-type by electrochemistry and it exhibits carrier-dependent photoresponse and magneto-resistance. For both electron or hole injection, interband bleach and intraband absorption confirm that the charges can be injected in the delocalized quantum states. Both carrier types lead to conductivity and show similar mobilities ($\sim 0.1\text{ cm}^2/\text{Vs}$). However p-type films show good photoresponse and long photocurrent lifetime of hundreds of microseconds, while n-type films show 100 times shorter lifetimes and little or no photoresponse. With these samples, p-type will therefore be better for photovoltaic response. The magneto-resistance of n-type films is also found to be large while that of p-type films is negligible. This is consistent with the heavier hole mass compared to electrons in HgTe . The HgTe CQDs share similar features with the II-VI CdSe but with the advantage of allowing both n- and p-type charging. While this property is shared with the narrow gap IV-VI PbSe , HgTe has a simpler electronic structure and better stability in ambient conditions. The stability of the HgTe CQDs for n- and p-type charging opens many further investigations.

3:18PM L18.00003 Tailoring Quantum Dot Assemblies to Extend Exciton Coherence Times and Improve Exciton Transport¹, KENTON SEWARD, ZHIBIN LIN, MARK LUSK, Department of Physics, Colorado School of Mines — The motion of excitons through nanostructured assemblies plays a central role in a wide range of physical phenomena including quantum computing, molecular electronics, photosynthetic processes, excitonic transistors and light emitting diodes. All of these technologies are severely handicapped, though, by quasi-particle lifetimes on the order of a nanosecond. The movement of excitons must therefore be as efficient as possible in order to move excitons meaningful distances. This is problematic for assemblies of small Si quantum dots (QDs), where excitons quickly localize and entangle with dot phonon modes. Ensuing exciton transport is then characterized by a classical random walk reduced to very short distances because of efficient recombination. We use a combination of master equation (Haken-Strobl) formalism and density functional theory to estimate the rate of decoherence in Si QD assemblies and its impact on exciton mobility. Exciton-phonon coupling and Coulomb interactions are calculated as a function of dot size, spacing and termination to minimize the rate of intra-dot phonon entanglement. This extends the time over which more efficient exciton transport, characterized by partial coherence, can be maintained.

¹Renewable Energy Materials Research Science and Engineering Center (NSF Grant No. DMR-0820518) at the Colorado School of Mines and the National Renewable Energy Laboratory

3:30PM L18.00004 Efficient Exciton Transport Between Strongly Quantum-Confined Silicon Quantum Dots¹, MARK LUSK, ZHIBIN LIN, Department of Physics, Colorado School of Mines, ALBERTO FRANCESCHETTI, National Renewable Energy Laboratory — First-order perturbation theory and many-body Green function analysis are used to quantify the influence of size, surface reconstruction and surface treatment on exciton transport between small silicon quantum dots. Competing radiative processes are also considered in order to determine how exciton transport efficiency is influenced. The analysis shows that quantum confinement causes small (~ 1 nm) Si quantum dots to exhibit exciton transport efficiencies far exceeding that of their larger counterparts. We also find that surface reconstruction significantly influences the absorption cross-section and leads to a large reduction in both transport rate and efficiency. Exciton transport efficiency is higher for hydrogen-passivated dots as compared with those terminated with more electronegative ligands. This is because such ligands delocalize electron wave functions towards the surface and result in a lower dipole moment. This work [1] is a first step in the development of a framework for the design of quantum dot assemblies with improved exciton transfer efficiency.

3:42PM L18.00005 Finite Element Modeling of Current-Induced Filaments in Nanocrystalline Silicon, SEAN FISCHER, CHRISTIAN OSORIO, NICHOLAS WILLIAMS, HELENA SILVA, ALI GOKIRMAK, University of Connecticut — Rapid, heat induced phase transitions in a mixed phase semiconductor may lead to current percolation along a highly conductive preferred path, or filament. In this study, we use 2-D, finite element simulations to model the time dependent evolution of current-induced filaments in nanocrystalline silicon (nc-Si) wires. nc-Si wires are modeled as isolated crystalline silicon (c-Si) circles randomly distributed in an amorphous silicon (a-Si) wire 500 nm in length and 75 nm in width. Simulations include temperature dependent material parameters for electrical conductivity, thermal conductivity, heat capacity, and account for latent heat of fusion during phase transition from solid to liquid silicon. Field dependent material parameters are neglected to improve simulation convergence. Voltage pulses of amplitude 300 V and rise time less than 1 ns produce molten filaments ~ 5 nm in width extending the length of the wire. The resistance of each wire decreases by four orders of magnitude during formation and filament current density exceeds 500 MA/cm².

3:54PM L18.00006 Ultrashort channel length quantum-dot photodetectors, FERRY PRINS, Kavli Institute of Nanoscience, Delft University of Technology — We present an efficient photodetector based on a one-dimensional array of parallel contacted PbSe quantum dots. In this device-architecture, the electrodes act as optical nano-antennae which concentrate incident light into the nanoparticle junction where they are converted into electron-hole pairs. The excitons are extracted with high efficiency due to the fact that the quantum dots are in direct contact with both source and drain electrodes, in contrast to previous studies which employed assemblies of quantum dots.

4:06PM L18.00007 The Influence of Phonons and Surface Termination on Optical Transitions in Small Silicon Quantum Dots and Implications for Exciton Transport¹, ZHIBIN LIN, Department of Physics, Colorado School of Mines, ALBERTO FRANCESCHETTI, National Renewable Energy Laboratory, MARK LUSK, Department of Physics, Colorado School of Mines — Bulk silicon is an indirect-gap semiconductor, and radiative recombination can proceed only through phonon assistance. Recent experiments suggest, though, that fast, zero-phonon, pseudo-direct transitions occur in silicon quantum dots (Si QDs) as a result of quantum confinement. On the other hand, previous theoretical studies based on tight-binding and effective mass methodologies yield contradictory conclusions on the degree to which phonons play a role in radiative recombination within Si QDs. The resolution of this issue has important repercussions for ways in which Si QDs can be incorporated into future photovoltaic designs. This also has implications as to how QD size, phonons, and surface ligands collectively influence exciton transport. Density functional theory, in concert with a phonon-corrected version of Fermi's Golden Rule, is used to investigate the degree to which phonons influence the rate of optical transitions in Si QDs and to elucidate how the role of phonons changes with dot size and surface termination (H, CH₃, and OH). The results are compared with available experimental data and those of previous calculations. In addition, the implications for phonon-assisted exciton transport dynamics within Si QD assemblies will be discussed.

4:18PM L18.00008 Dual MOSFET Charge Sensing in PbS Nanocrystal Quantum Dots, NIRAT RAY, TAMAR MENTZEL, KENNETH MACLEAN, DARCY WANGER, MOUNGI BAWENDI, MARC KASTNER, Massachusetts Institute of Technology — We use nanoscale metal-oxide-semiconductor field-effect transistors (MOSFETs) as charge sensors for measuring transport in a nearby nanocrystal array. While our technique enables a high resistance measurement, and enables us to probe a wide range of conductance, the main limitations of using single MOSFET charge sensors is the step-like switching of the current caused by electrons tunneling into and out of traps, presumably in the oxide. This makes it difficult to distinguish events that originate in the film from those that originate in the MOSFETs. We use two MOSFETs as simultaneous charge sensors to perform a correlation analysis and distinguish these events. We pattern a 80 nm wide ordered array of PbS nanocrystals, approximately 50 nm away from each sensor, to maximize the signal in the MOSFETs from charge fluctuations in the nanocrystal film. This configuration then enables us to probe electron transport in the nanocrystal array.

4:30PM L18.00009 Measuring electron transport in nano-patterned films of PbS nanocrystals using a charge sensor, TAMAR MENTZEL, Massachusetts Institute of Technology, Department of Physics, DARCY WANGER, Massachusetts Institute of Technology, Department of Chemistry, NIRAT RAY, Massachusetts Institute of Technology, Department of Physics, BRIAN WALKER, MOUNGI BAWENDI, Massachusetts Institute of Technology, Department of Chemistry, MARC KASTNER, Massachusetts Institute of Technology, Department of Physics — The ability to form nanoscale patterns of semiconductor nanocrystal films and to align those patterns to a substrate with nanoscale precision opens the possibility of novel electronic measurements and optoelectronic devices. We demonstrate a novel method for patterning nanoscopic films of semiconductor nanocrystals with electron-beam lithography. The resulting films are ordered and do not suffer from the cracking that arises when annealing or exchanging the capping ligand of the film. The patterning method is effective for a wide range of nanocrystal materials and capping ligands. We pattern a film of PbS nanocrystals approximately 80 nm wide, and position it within 100 nm of charge sensors made from nanoscale metal-oxide-semiconductor field-effect transistors (MOSFETs). The charge sensors, which can measure the fluctuations of individual electrons in the nearby electrostatic environment, are used to measure electron transport in the films as a function of temperature and applied field.

4:42PM L18.00010 Photoinduced modification of surface states in nanoporous InP observed by terahertz spectroscopy, JAMES LLOYD-HUGHES, University of Oxford, Department of Physics, SUSANNE MUELLER, GIACOMO SCALARI, ETH Zurich, Institute for Quantum Electronics, HUGH BISHOP, ALISON CROSSLEY, University of Oxford, Department of Materials, MIHAI ENACHI, LILIAN SIRBU, ION TIGINYANU, Technical University of Moldova — A precise control of the surface properties of semiconductor nanomaterials is vital for their functionality and use in many opto-electronic applications. Terahertz time-domain spectroscopy allows the non-contact investigation of electron transport in semiconductor nanomaterials, without the complication of contact fabrication. The technique allows the photoconductivity to be determined on picosecond timescales, under the assumption that the material's properties are not permanently altered by photoexcitation. Here we demonstrate that this assumption is not always valid. We report an investigation of nanoporous honeycombs of n-type InP using terahertz time-domain and X-ray photoemission spectroscopies. After photoexcitation the dark conductivity was found to increase quasi-irreversibly, recovering only after several hours in air. The calculated electron density for different surface pinning energies suggests that photoexcitation may reduce the density of surface states. The photoinduced modification of porous semiconductors may be useful in material processing as it is a clean, dry, and area-selective method to increase the conductivity.

4:54PM L18.00011 Delayed photoluminescence in three-dimensional silicon/silicon germanium nanostructures, LEONID TSYBESKOV, NIKHIL MODI, SELINA MALA, New Jersey Institute of Technology, J.-M BARIBEAU, X WU, D. J. LOCKWOOD, Institute for Microstructural Sciences, National Research Council of Canada — In three-dimensional (3D), SiGe nano-island multi-layers separated by nanometer-thick Si layers with the enhanced local strain field visualized by transmission electron microscopy (TEM), we find unusual low temperature photoluminescence (PL) dynamics. The PL detected at 1350 nm rises practically instantly and decays with a lifetime faster than 20 nanoseconds. In contrast, the PL detected at 1550 nm has a rise time of longer than 3-4 microseconds, and it decays with a characteristic lifetime which changes from 10 microseconds to milliseconds. The proposed model considers recombination of excitons bound to SiGe/Si interface as a mechanism responsible for the fast PL at 1350 nm. The observed slow rising PL with a peak near 1550 nm is associated with Auger ionization of SiGe clusters and separation of electrons and holes followed by carrier/exciton diffusion within Si layers toward a longer wavelength luminescence sites. These sites are associated with SiGe cluster areas containing a higher Ge concentration, and they are detected by analytical TEM.

5:06PM L18.00012 Transport of exciton-polariton condensation in semiconductor microcavity at BEC-BCS crossover, JUNG-JUNG SU, YOSHIHISA YAMAMOTO, National Institute of Informatics, Japan; E. Ginzton Laboratory, Stanford University — We study the transport properties of exciton-polariton condensation in the microcavity at the BEC-BCS crossover. Exciton-polariton (EP) is the quasiparticle of exciton and photon that can condense at a temperature as high as room temperature due to its extreme lightness. So far intense studies of this intriguing condensation have been limited to the photoluminescence (PL) measurement, mostly at the lower density BEC regime. When increasing density, the condensate enters the EP BCS regime in which the fermionic nature of electron and hole inside of exciton becomes important. This electron-hole nature is more prominent in the transport than in the PL measurements. We propose a transport measurement scheme of creating indirect-excitons in semiconductor bilayer which is embedded in the planar microcavity filled with photons. Leads are attached to the two sides of the bilayers to perform transport measurements. We present the different features of tunneling conductance signature for EP condensation in the BCS and in the BEC regime.

Tuesday, February 28, 2012 2:30PM - 5:30PM – Session L19 DCMP GMAG: Invited Session: Spin Liquids with Disorder 253AB

2:30PM L19.00001 The spin liquid ground state of the $S = 1/2$ Heisenberg model on the kagome lattice, STEVEN WHITE, UC Irvine — Condensed matter physicists have long sought a realistic two-dimensional (2D) magnetic system whose ground state is a *spin liquid*—a zero temperature state in which quantum fluctuations have melted away any form of magnetic order. The nearest-neighbor $S = 1/2$ Heisenberg model on the kagome lattice has seemed an ideal candidate, but in recent years some approximate numerical approaches to it have yielded instead a valence bond crystal. We have used the density matrix renormalization group to perform very accurate simulations on numerous cylinders with circumferences up to 12 lattice spacings, finding instead of the valence bond crystal a spin liquid, gapped in both the singlet and triplet sectors, with substantially lower energy. [Simeng Yan, David A. Huse, and Steven R. White, *Science* 332, 1173 (2011). *Cover article*] Our results, through a combination of very low energy, short correlation lengths and corresponding small finite size effects, a new rigorous energy bound, and consistent behavior on many cylinders, provide strong evidence that the 2D ground state of this model is a gapped spin liquid. One key feature of this spin liquid is that the predominant valence bond resonances occur on eight site loops rather than the shortest six site loops. The eight site loops allow a greater fraction of the bonds in the lattice to resonate. Our recent studies including a next nearest neighbor interaction J_2 reveal that the $J_2 = 0$ point is near the edge of a substantial spin liquid phase centered near $J_2 = 0.05 - 0.1$.

3:06PM L19.00002 Structure, disorder, and magnetism in Herbertsmithite, a kagomé Heisenberg antiferromagnet, TYREL MCQUEEN, Johns Hopkins University — Geometric frustration of magnetic ordering on triangle-based lattices is thought to be one avenue to inducing macroscopic quantum states in electron systems. Due to the triangular arrangement of ions, it is impossible to satisfy all nearest-neighbor interactions simultaneously. This “frustration” suppresses classical magnetic long-range order and is thought to be capable of resulting in novel quantum states such as various resonating-valence-bond or “spin-liquid” ground states for a two-dimensional (2D) $S = 1/2$ antiferromagnet. However, “structurally perfect” frustrated materials are rare; frequently, materials undergo a structural distortion at low temperature, relieving the magnetic frustration and giving rise to a classical ground state. In this talk, I will present recent structural and property studies of the 2D candidate spin-liquid material “ $\text{ZnCu}_3(\text{OH})_6\text{Cl}_2$.” Using X-ray scattering differences at elemental absorption edges and an improved analysis technique, I will show that there is no Zn occupation of the intralayer Cu sites within the kagomé layer, as previously reported; however there is Cu present on the Zn intersite, leading to a real structural formula of $(\text{Zn}_{0.85}\text{Cu}_{0.15})\text{Cu}_3(\text{OH})_6\text{Cl}_2$. Combined with recent pulsed high field magnetic measurements, the lack of Zn mixing onto the kagomé lattice sites lends support to the idea that the electronic ground state in “ $\text{ZnCu}_3(\text{OH})_6\text{Cl}_2$ ” and its relatives is non-trivial.

3:42PM L19.00003 Disorder in a quantum spin liquid: the Kitaev honeycomb model with vacancies, RODERICH MOESSNER¹, MPI-PKS Dresden — We address the effects of disorder in the Kitaev honeycomb model, focussing on the interplay of disorder and strong interactions in a quantum spin liquid. It is shown that nonmagnetic impurities bind a quantum of the emergent gauge flux. We find the formation of a local moment, which leads to a local magnetic response near the impurity which is parametrically larger than in the bulk. The magnetic response of a pair of impurities can be parametrically larger than that of an isolated one, and can in particular dominate the magnetic response of the system. The role of such impurities as diagnostic of the spin liquid state are emphasized – most remarkably, they provide a direct signature of the emergent gauge field.

¹In collaboration with Adam Willans and John Chalker (Oxford University): Phys. Rev. Lett. 104, 237203 (2010); Phys. Rev. B 84, 115146 (2011).

4:18PM L19.00004 Hole doping in frustrated spinels, ZnCr_2O_4 and MgCr_2O_4 , and their two dimensional analogue SCGO, $\text{SrCr}_8\text{Ga}_4\text{O}_{19}$ ¹, SIAN DUTTON, Princeton University — Recent experiments on the complex geometrically frustrated magnet, $\beta\text{-CaCr}_2\text{O}_4$, clearly illustrate the divergent effect of hole and static doping on the magnetic properties [1]. Given the complex parent state of $\beta\text{-CaCr}_2\text{O}_4$ this is not an ideal system for studying perturbations to the magnetic interactions. However, the onset of ferromagnetic fluctuations and ferrimagnetic ordering in $\beta\text{-Ca}_{1-y}\text{Cr}_2\text{O}_4$ suggests that other hole doped $\text{Cr}^{3+/4+}$ systems may be of interest. The extreme sensitivity in the balance of competing magnetic interactions in geometrically frustrated magnets is illustrated clearly in Cr^{3+} spinels, ACr_2O_4 . Antiferromagnetic (AFM) ordering in ACr_2O_4 occurs at a spin-Peierls transition. Both the low temperature magnetic and structural regimes are found to be highly sensitive to the A cation. In the case of ZnCr_2O_4 we find that very fine control of the reaction conditions is necessary to make stoichiometric ZnCr_2O_4 , rather than hole doped $\text{Zn}_{1+x}\text{Cr}_{2-x}\text{O}_4$ ($x \leq 0.04$). From analysis of magnetic measurements, specific heat and neutron diffraction we have probed the nature of the transitions at T_N [2]. How hole doping effects the low temperature properties and the role of the $d^2 \text{Cr}^{4+}$ cations on the isotropic $d^3 \text{Cr}^{3+}$ magnetic lattice will be discussed. Our results on the more robust MgCr_2O_4 spinel will also be presented. A 2D analogue of the 3D pyrochlore magnetic lattice in the ACr_2O_4 spinels is found in SCGO, $\text{SrCr}_8\text{Ga}_4\text{O}_{19}$. In hole doped SCGO, $\text{SrCr}_8\text{M}_x\text{Ga}_{4-x}\text{O}_{19}$ ($\text{M} = \text{Zn, Mg, Cu}$), a larger fraction of the Cr^{3+} can be oxidized. Hole doping is found to have a significant effect on the magnetic fluctuations, how this depends on the nature of the dopant cation will be addressed [3].

4:54PM L19.00005 Impurity Effects in Highly Frustrated Diamond-Lattice Antiferromagnets, LUCILE SAVARY, University of California, Santa Barbara — We consider the effects of local impurities in highly frustrated diamond lattice antiferromagnets, which exhibit large but non-extensive ground state degeneracies. Such models are appropriate to many A-site magnetic spinels. We argue very generally that sufficiently dilute impurities induce an *ordered* magnetic ground state, and provide a mechanism of degeneracy breaking. The states which are selected can be determined by a “swiss cheese model” analysis, which we demonstrate numerically for a particular impurity model in this case. Moreover, we present criteria for estimating the stability of the resulting ordered phase to a competing frozen (spin glass) one. The results may explain the contrasting finding of frozen and ordered ground states in CoAl_2O_4 and MnSc_2S_4 , respectively.

Tuesday, February 28, 2012 2:30PM - 5:30PM –

Session L20 CSWP COM: Invited Session: STEM Outreach to Underrepresented Communities

253C

2:30PM L20.00001 LIGO: Impacting science education through gravity-wave research in the local community and beyond¹, STEPHEN MCGUIRE, Southern University and A&M College — We describe our integration of the science teacher pre-service and in-service education programs at Southern University (SUBR) with the Laser Interferometer Gravitational-wave Observatory (LIGO) Science Education Center (SEC). Inquiry-based interactive exhibits are employed wherein we emphasize classical physics concepts of oscillations, waves, wave propagation, interference, resonance, lasers, light and Newtonian gravity. An aggressive museum docent training program is providing a means for undergraduates to learn how to effectively communicate science concepts within informal learning environments. This local educational partnership will ultimately create a science education continuum of engagement, working at multiple levels and multiple audiences to strengthen science literacy within the targeted STEM African-American community. Following a brief overview of our program of LIGO-related optical materials research, we give a detailed presentation of our K-12 science teacher preparation program with results.

3:06PM L20.00002 STEM Outreach to the African Canadian Community - The Imhotep Legacy Academy¹, KEVIN HEWITT, Dalhousie University — Like the African American community in the US, the African Canadian community is underrepresented in the Science Technology Engineering and Mathematics (STEM) fields. To serve these communities two outreach organizations emerged in Canadian cities where there is a critical mass of learners of African Descent - Toronto and Halifax. I will describe the Imhotep's Legacy Academy, which began in the Physics labs of Dalhousie University in Halifax, Nova Scotia and has grown to a province-wide program serving three-quarters of the school boards in the province with an annual budget that has grown to \$400,000 in 2011-12. It follows the learner from the time they enter grade 7 to the time they graduate from university, through three programs: (a) Weekly After-School science enrichment for junior high learners, (b) Virtual High school tutoring program and (c) Summer student internships and research scholarships for post-secondary students. This year, the program was the beneficiary of funding from TD Bank to establish scholarships for program participants to enter Dalhousie university. Modeled on the Meyerhoff scholarships the program participants are identified at an early stage and are promised a subset of funding as they meet selected criteria during participation in the program. The program enjoys support from the Department of Education and the highest levels of government. A tri-mentoring system exists where faculty of African descent train mentors, who are science students of African descent at associated universities, to deliver hands-on enrichment activities to learners of African Descent. Evidence supporting the success of the program will be highlighted. Project outcomes measured include (i) recruitment; (ii) attendance; (iii) stakeholder relationships; (iv) programming; (v) staff training; (vi) perception of ILASP's value; (vii) academic performance. The end results are new lessons and best practices that are incorporated into a strategic plan for the new project year. Teachers perceived that ILASP had a positive ripple effect on the entire academic and non-academic educational experience of the learners, crediting the project with (i) encouraging self-learning; (ii) assisting in honing learners' science and math skills; (iii) developing core skills that were applicable in learners' schoolwork; (iv) boosting learners' self-esteem; (v) improving school attendance; (vi) boosting learners' motivation to be engaged participants in all other classes.

¹We acknowledge financial support from the Nova Scotia Department of Education - African Canadian Services Division, NSERC, EnCana Corporation, TD Bank, Dalhousie University, CACE, OANSA, NS Labour and Advanced Education and SuperNova.

3:42PM L20.00003 Knowing your Hispanic community to improve outreach effectiveness, CRISTINA TORRES, LIGO Livingston Observatory — “Know your audience,” wise words for properly conveying information. For outreach, this can make the difference between successful connection or failure to connect to the community around us. When the target audience is the Hispanic community knowing your audience can potentially take on unexpected complexity. Like some other minority communities, the Hispanic community's culture is complex dual culture system. I will discuss my own personal observations about how this community interacts with the academic world. I also will discuss how the Hispanic community perceives itself as a member of the broader community we all live in and how non-homogeneous, our broadly defined Hispanic community really is. Discussing the Hispanic community's hidden nuances will bring to light the difficulty in getting to “know your audience,” when it comes to effective outreach in the rapidly growing Hispanic community.

4:18PM L20.00004 Outreach to the Native American community through the Navajo-Hopi program, KEVIN SCHINDLER, Lowell Observatory — No abstract available.

4:54PM L20.00005 Intersections of Gender and Power: Improving the Status of Women in Physics, SAEQA VRTILEK, Harvard-Smithsonian Center for Astrophysics — Numerous problems bedevil the twin goals of increasing the numerical participation in science, technology, engineering, and mathematics (STEM) fields by women and increasing the quality of that participation. The nature of the difficulties is everywhere slightly different, but there are underlying commonalities. A wide portfolio of lessons learned that can be applied to the confluence of cultures, backgrounds, and experiences that shape any given institution have been developed and will be presented. Among these, common and dominant themes are the need for mentoring, management training, and the increased visibility of successful women scientists. These have been identified (Nelson and Rogers 2004; Sonnert and Holton 1995a; Vetter 1996) as some of the key factors in securing the encouragement and increased stability needed for more senior women scientists to thrive to their full potential and provide the example and mentoring needed for a larger and more productive new generation.

Tuesday, February 28, 2012 2:30PM - 5:18PM —
Session L21 DCMP: Superconductivity: Mostly Mesoscopics & Low-d 254A

2:30PM L21.00001 Superconducting and Critical Current Properties of NiBi₃ Microfibers and Thin Films¹, NEEL HALDOLAARACHCHIGE, YIMIN XIONG, PHIL ADAMS, DAVID YOUNG, Louisiana State University — We report the superconducting and critical current properties of thin films of NiBi₃ formed on the surface of carbon microfibers and on sapphire substrates. The NiBi₃ coated C-fibers were prepared by reacting 7- μ m diameter Ni-coated carbon fibers with Bi shot, and the thin films on sapphire were formed by exposing electron-beam deposited Ni films to Bi vapor. The fibers and films show $T_c = 4.25$ K and $T_c = 4.35$ K, respectively, which was slightly higher than that of bulk polycrystalline NiBi₃. The extrapolated upper critical fields of the fibers [$H_{c2}(0) = 12$ T] and films [$H_{c2}(0) = 9$ T] are higher than the reported data on polycrystalline samples. The temperature dependence of the critical current density (J_c) is well described by Ginzburg-Landau theory and gives an extrapolated value of 5.26×10^5 A/cm².

¹NSF DMR Grant #1005764

2:42PM L21.00002 Proximity effect in superconductor exchange spring-superconductor junction, JIYEONG GU, CHRISTOPHER SAFRANSKI, HANMING YUAN, California State University, Long Beach — It is known that in ferromagnet/superconductor hybrid system when the magnetizations of the ferromagnetic layer are inhomogeneous superconductivity is not necessarily suppressed by the ferromagnet due to the presence of the triplet superconducting pairing. In our current work we used exchange spring magnet to produce inhomogeneous noncollinear magnetic configuration in the ferromagnet. Exchange spring trilayer structure, soft/hard/soft, was fabricated between two superconducting Nb layers; Nb/Py/SmFe(SmCo)/Py/Nb. Magnetic property of the structure was characterized using Vibrating Sample Magnetometer and Magneto Optical Kerr Effect (MOKE). MOKE was used to measure the magnetizations of the top Py and the bottom Py separately. Transition temperature of the system was measured as a function of magnitude and direction of the external magnetic field.

2:54PM L21.00003 Results of Resonant Activation and Macroscopic Quantum Tunneling Experiments in Magnesium Diboride Thin Film Josephson Junctions¹, ROBERTO RAMOS, Indiana Wesleyan University, STEVE CARABELLO, JOSEPH LAMBERT, JEROME MLACK, Drexel University, WENQING DAI, YI. SHEN, QI LI, The Pennsylvania State University, DANIEL CUNNANE, C.G. ZHUANG, KE CHEN, X.X. XI, Temple University — The Josephson junction is an experimental testbed widely used to study resonant activation and macroscopic quantum tunneling. These phenomena have been observed in junctions based on conventional low-temperature superconductors such as Nb and Al, and even in high- T_c , intrinsic superconductors. We report results of superconducting-to normal state switching experiments below 1 K using MgB₂-based Josephson heterojunctions with Pb and Nb counter-electrodes. Measurements were made with and without RF excitation. With microwaves, we see evidence of a resonant peak, in addition to the primary escape (from ground state) peak – consistent with resonant activation. We also observe features suggestive of macroscopic quantum tunneling including peaks in the escape rate enhancements and an “elbow” in the graph of calculated escape temperatures T_{esc} versus sample temperature.

¹This research has been supported by a grant-in-aid from Sigma Xi.

3:06PM L21.00004 Carrier Transport in Heterojunction Nanocrystals Under Strain, MARK SWEENEY, JOEL EAVES, Department of Chemistry and Biochemistry, University of Colorado, Boulder — We present a theory for carrier transport in semiconducting nanoscale heterostructures that emphasizes the effects of strain at the interface between two different crystal structures. An exactly solvable model shows that the interface region, or junction, acts as a scattering potential that facilitates charge separation. As a case study, we model a Type-II CdS/ZnSe heterostructure. After advancing a theory similar to that employed in model molecular conductance calculations, we calculate the electron and hole photocurrents and conductances, including non-linear effects, through the junction at steady-state.

3:18PM L21.00005 Progress towards measuring electron-electron interactions in persistent currents, MANUEL A. CASTELLANOS-BELTRAN, DUSTIN Q. NGO, Department of Physics, Yale University, JACK G.E. HARRIS, Department of Physics and Department of Applied Physics, Yale University — The equilibrium persistent current (PC) in normal metal rings have been a challenge for both experimentalists and theorists. Specifically, the magnitude of the average PC's in normal metals has been a long-standing puzzle. Previous measurements of the average current ($\langle I_{h/2e} \rangle$) were larger than theoretical predictions and indicated a diamagnetic sign. A possible explanation for these results is that they arise from the interplay of attractive electron-electron interactions within the metal (leading to the enhanced average PC) and trace magnetic impurities (which suppress the BCS superconductivity that would otherwise result from the attractive interactions). In this talk, I will discuss our progress towards measurements that intend to clarify the role that electron-electron interactions and magnetic impurities play in the persistent current.

3:30PM L21.00006 Tuning effective pairing potential through atomic scale control of super-conductor heterostructures¹, CHENDONG ZHANG, Department of Physics, the University of Texas at Austin; Institute of Physics, Chinese Academy of Sciences, JISUN KIM, JUNGDAE KIM, HYOUNGDO NAM, QIAN NIU, Department of Physics, the University of Texas at Austin, HONGJUN GAO, Institute of Physics, Chinese Academy of Sciences, CHIH-KANG SHIH, Department of Physics, the University of Texas at Austin — Previous experiments showed that superconductivity persists in ultrathin films of conventional superconductors, even in films that are only 1-2 atomic layers thick. However, it has also been implied that the interface and substrate can strongly influence the electronic properties in the quasi two-dimensional regime. In this work, we fabricated a heterostructure with a normal metal layer (Ag here) placed in between a superconducting film (Pb here) and an insulating substrate, and measured its superconductivity with scanning tunneling spectroscopy subsequently. The most striking observation is the requirement of an overlayer (L_{Pb}) to recover the superconductivity, while the recovery thickness is linearly dependent on the underlayer thickness. Considering the renormalization of pairing interaction strength for Cooper pair in the hybrid structure, the “effective attractive potential” model was developed in this work. It could serve as a model with predictive power to describe the general behavior of superconductor heterostructures. Moreover, the physical origin of some discrepancies in the reported transition temperature as a function of film thickness is partly elucidated by this work as well.

3:42PM L21.00007 Area-dependence of spin-triplet supercurrent in ferromagnetic Josephson junctions¹, YIXING WANG, WILLIAM P. PRATT, JR., NORMAN O. BIRGE, Department of Physics and Astronomy, Michigan State University, East Lansing, MI 48824 — Spin-triplet supercurrents in strong ferromagnetic Josephson junctions were reported by several groups in 2010. At the same time, the 0- π current-phase relationship of the spin-triplet supercurrent was predicted to be controllable by the magnetization orientations of different ferromagnetic layers. Our junctions contain a series of ferromagnetic layers consisting of a synthetic antiferromagnet Co/Ru/Co sandwiched between two thin magnetic layers such as PdNi or Ni [1]. When looking along the direction of current flow, one should obtain 0 junctions if the rotation direction of magnetizations is the same from one to the next, and π junctions when the opposite rotation direction is the case. Since our magnetic layers have multiple domains in the virgin state, we should expect 0 and π phases to alternate randomly in different locations in the junctions. The critical current in the virgin state should scale with the square-root of the junction area. After aligning the outer ferromagnetic layers in the same direction with an external field, the current-phase relation should be uniform across the whole junction area and the critical current should be proportional to the junction area. We will present data confirming this expectation for the magnetized state, whereas the situation for the virgin state is presently unclear.

3:54PM L21.00008 Magnetic-field dependence of energy levels of superconducting nano-scale metallic grains with strong spin-orbit scattering¹, KONSTANTIN NESTEROV, YORAM ALHASSID, Center for Theoretical Physics, Sloane Physics Laboratory, Yale University, New Haven, CT 06520, USA — We study the Zeeman splitting of discrete energy levels of superconducting nano-scale metallic grains whose single-electron dynamics is chaotic [1]. In the absence of spin-orbit scattering the Zeeman splitting of a single-electron level is trivial; it is the same for all levels and linear in magnetic field. Spin-orbit coupling suppresses this splitting, induces level-to-level fluctuations and non-linear corrections to the energies. We investigate the combined effect of pairing correlations, which lead to superconductivity in the bulk limit, and spin-orbit scattering on the many-electron energy levels in a weak magnetic field. In particular, we focus our studies on the linear (g-factor) and quadratic (zero-field level curvature) corrections and their mesoscopic fluctuations. The single-electron part of the Hamiltonian follows the statistics of the Gaussian symplectic ensemble of random matrix theory, which is applicable in the limit of strong spin-orbit scattering and a large dimensionless Thouless conductance. The interaction is given by a BCS-like pairing term and the magnetic field coupling is described by a Zeeman term. [1] K. Nesterov and Y. Alhassid, to be published.

4:06PM L21.00009 Temperature induced epitaxial strain and superconductivity in (Cu,C)Ba₂CuO_{4+ δ} thin films, F.N.U. SHIPRA, University of Cincinnati, Jawaharlal Nehru Centre for Advanced Scientific Research, A. SUNDARESAN, Jawaharlal Nehru Centre for Advanced Scientific Research, SUPERCONDUCTIVITY AND MAGNETISM LAB TEAM — We have studied the effects of substrate temperature in establishing superconductivity in carbon incorporated thin films of Infinite Layered (IL) BaCuO_{2+ δ} . Carbon in the form of CO₃²⁻ group modulates the IL structure into a superstructure with doubled out of plane lattice parameter, ‘c’. The superstructure, (Cu,C)Ba₂CuO_{4+ δ} (Cu-1201) shows superconductivity within a narrow window of ‘c’ lattice parameter varying between 8.28 Å and 8.33 Å. The structural analysis of these thin films using reciprocal space maps (RSMs) shows a pseudomorphic growth with an in-plane lattice parameter, ‘a’, of 3.90 Å, similar to that of the SrTiO₃ substrate. Growth of these films under compressive strain is obtained at substrate temperatures varying between 530 °C and 560 °C. At deposition temperatures less than 500 °C, films with a relaxed in-plane lattice parameter of 4.00 Å were obtained which were non-superconducting. Deviations in the substrate temperature led to the coexistence of strained and relaxed phases. Thus the elongation along c – axis is compensated by the compression along a– axis with increasing substrate temperature. Flexibility of tuning the in-plane mismatch between substrate and film also rule out the use of buffer layers. Such structural changes result in the change of bond lengths and subsequently rearrange the number of charge carriers in the CuO₂ planes. Optimum number of charge carriers lead to superconductivity.

4:18PM L21.00010 Coexistence of a Triplet Nodal Order Parameter and a Singlet Order Parameter at Co / CoO / In contacts, SHAY HACOEN-GOURGY, BOAZ ALMOG, GUY DEUTSCHER, Tel-Aviv University — We present differential conductance measurements of Cobalt / Cobalt-Oxide / Indium planar junctions, 500nm x 500nm in size. The junctions span a wide range of barriers, from very low to a tunnel barrier. The characteristic conductance of all the junctions show a V-shape structure at low bias instead of the U-shape characteristic of a s-wave order parameter. The bias of the conductance peaks is, for all junctions, larger than the gap of indium. Both properties exclude pure s-wave pairing. The data is well fitted by a model that assumes the coexistence of s-wave singlet and equal spin p-wave triplet fluids. We find that the values of the s-wave and p-wave gaps follow the BCS temperature dependence and that the amplitude of the s-wave fluid increases with the barrier strength.

4:30PM L21.00011 Exploring triplet superconductivity by controlling the magnetic non-collinearity, L.Y. ZHU, YAOHUA LIU, MSD, Argonne National Laboratory, F.S. BERGERET, Centro de Física de Materiales, Centro Mixto CSIC-UPV/EHU, Donostia International Physics Center, J.E. PEARSON, S.G.E. TE VELTHUIS, S.D. BADER, J.S. JIANG, MSD, ANL — Recent theories predict spin-triplet superconductivity at the interface between a singlet superconductor (SC) and a ferromagnet (FM) with *inhomogeneous* magnetization [1]. Magnetic non-collinearity is a crucial but not quantitatively controlled parameter in most experiments inferring triplet superconductivity [2]. In this work, we use Nb as the SC, and an epitaxial exchange spring Py/Sm-Co bilayer with in-plane uniaxial anisotropy in Sm-Co layer as the FM. Due to the interfacial exchange coupling, a *tunable* noncollinear spin spiral can be achieved by controlling the external field. At a fixed temperature within the superconducting transition, starting from a collinear magnetic configuration, as the spin spiral winding angle ϕ increases, the superconducting critical current (I_c) first increases. There is an optimized winding angle ϕ_o , which maximizes I_c , after which I_c decreases with increasing ϕ . This *non-monotonic* $I_c(\phi)$ dependence cannot be explained by the short range proximity effect alone and suggests triplet pairing. More importantly, combining micromagnetic simulations with magnetoresistance measurements, we have determined the magnetic non-collinearity and correlated it *quantitatively* with the superconducting transport results. Our findings demonstrate the superconducting proximity effect can be tuned by manipulating the magnetic non-collinearity in a *single* sample.

4:42PM L21.00012 The Images of vortex penetration into superconducting MoGe plates observed by scanning SQUID microscope¹, HO THANH HUY, Osaka Prefecture University, MASAHICO HAYASHI, Akita University, TSUTOMU YOTSUYA, TAKEKAZU ISHIDA, Osaka Prefecture University — The amorphous superconducting film is very preferential as a good model in studying nanostructured superconductors because it has weakened pinning centers compared to other superconductors. The MoGe films have been deposited by a DC sputtering apparatus using a Mo₈₀Ge₂₀ target and a number of small MoGe plates were fabricated with the aid of photolithography. The vortex distribution in a MoGe circle has been investigated by means of a scanning SQUID microscope. We found that vortices form different configurations including shell structures, which evolves with the increase in applied magnetic field. Observed results are compared to theoretical studies for vortices in mesoscopic circles.

¹This work was partly supported by a Grant-in-Aid for Scientific Research from the Ministry of Education, Culture, Sports, Science and Technology of Japan (Grant Nos. 19206104, 23246173, 23226019).

4:54PM L21.00013 Image processing of scanning SQUID microscope for observing superconducting nanostructures, MASAHICO HAYASHI, Akita University, HO THANH HUY, TAKEKAZU ISHIDA, Osaka Prefecture University — A newly developed image processing technique for the scanning superconducting quantum interference device (SQUID) microscope is presented and its application to several measurements on superconducting nanostructures, including networks and dots, is discussed. This method is based on the detailed analysis of the structures characteristic to the measurement apparatus, such as the shape and position of the pickup coil. We take account of the Meissner effect in the coil body and its influences on the obtained image are carefully removed. The separation between the coil and the sample is also considered. Actually applying this method, we present images of the superconducting networks and dots, which show clear improvement from the raw images. The results are also discussed from physical point of view.

5:06PM L21.00014 Fluctuating pancake vortices revealed by dissipation of Josephson vortex lattice¹, ITSUHIRO KAKEYA, Kyoto University, Japan, ALEXEI KOSHELEV, Materials Science Division, Argonne National Laboratory, IL, ALEXANDER BUZDIN, Institut Universite de France and Universite de Bordeaux, France, TAKASHI YAMAMOTO, KAZUO KADOWAKI, University of Tsukuba, Japan — In strongly anisotropic layered superconductors in tilted magnetic fields the Josephson vortex lattice coexists with the lattice of pancake vortices. Due to the interaction between them, the dissipation of the Josephson-vortex lattice occurs to be very sensitive to the presence of the pancake vortices. If the c-axis magnetic field is smaller than the corresponding lower critical field the pancake stacks are not formed but the individual pancakes may exist in the fluctuational regime either near surface in large-size samples or in the central region for small-size mesas. We calculate the contribution of such fluctuating pancake vortices to the c-axis conductivity of the Josephson vortex lattice and compare the theoretical result with measurements on small mesas fabricated out of Bi₂Sr₂CaCu₂O_{8+δ} crystals. A fingerprint of fluctuating pancakes is characteristic exponential dependence of the c-axis conductivity observed experimentally. Our results provide strong evidence of the existence of the fluctuating pancakes and their influence on the Josephson-vortex-lattice dissipation.

Session L22 DMP DCOMP: Focus Session: Fe-based Superconductors: – Inelastic Neutron Scattering and Magnetic Excitations 254B

2:30PM L22.00001 Interstitial Iron Effects on Magnetic Excitations in Parent Phases Fe_{1+x}Te from Polarized and Inelastic Neutron Scattering, EFRAIN RODRIGUEZ, NIST Center for Neutron Research — One of the simplest systems of the iron-based superconducting family, Fe_{1+x}Ch (where Ch = S, Se, or Te) presents ample opportunity to study the relationship between antiferromagnetism and superconductivity. Several studies have demonstrated how the makeup of the Ch anions changes the electronic properties drastically, but the effect of excess interstitial iron, the x in Fe_{1+x}Ch, is not as well understood. Our previous diffraction experiments on samples varying x from 4 % to 16 % demonstrated how the magnetic ordering changes from collinear antiferromagnetic to helical incommensurate via a spin-density wave state at the special composition of x ≈ 12%. We present inelastic neutron scattering measurements of the phases Fe_{1+x}Te for two amounts of interstitial iron in the lattice, 5% and 14 %. We have combined data from cold neutron triple-axis, thermal neutron triple-axis, and spallation source time-of-flight to provide a full picture of the magnetic excitations in Fe_{1+x}Te for x = 14% from 0.5 meV to 150 meV. In addition, we present polarized inelastic studies on this particular composition to investigate the nature of the spin waves, *i.e.* longitudinal *vs.* transverse. The results are compared with those found in the phase with low amounts of interstitial iron (≈ 5 %), in order to understand the nature of the exchange interactions in this important parent compound.

3:06PM L22.00002 Temperature-enhanced nearly critical magnetic scattering in nearly superconducting $\text{FeTe}_{0.87}\text{S}_{0.13}$ ¹, IGOR ZALIZNYAK, CEDOMIR PETROVIC, RONGWEI HU, Brookhaven National Laboratory, ANDREI SAVICI, KAROL MARTY, MARK LUMSDEN, Oak Ridge National Laboratory — Recent neutron scattering measurements [1] have revealed an unusual temperature-induced enhancement of dynamical magnetism in iron telluride, FeTe , the parent material of the chalcogenide family of iron-based superconductors. Here we report a study of magnetic excitations in the sulfur-doped $\text{FeTe}_{0.87}\text{S}_{0.13}$, where bulk measurements show presence of the filamentary superconductivity [2]. Our neutron measurements probe the bulk of the material, which is nearly critical (filamentary superconductivity emerges in a small volume fraction of the sample, which is supercritical). We observe a peculiar pattern of low-energy magnetic scattering, characteristic of critical magnetic fluctuations, and find that it is also anomalously enhanced with the increasing temperature up to ~ 100 K.

3:18PM L22.00003 Friedel-like Oscillations from Interstitial Iron in Superconducting $\text{Fe}_{1+y}\text{Te}_{0.62}\text{Se}_{0.38}$ ¹, VIVEK THAMPY, Johns Hopkins University, J. KANG, Institute for Quantum Matter, Johns Hopkins University, J.A. RODRIGUEZ-RIVERA, NIST Center for Neutron Research, W. BAO, Department of Physics, Renmin University of China, A.T. SAVICI, NSSD, Oak Ridge National Laboratory, J. HU, T. J. LIU, B. QIAN, D. FOBES, Z.Q. MAO, Department of Physics, Tulane University, C.B. FU, Department of Physics, Indiana University, W.C. CHEN, Department of Materials Science and Engineering, University of Maryland, Q. YE, NSSD, Oak Ridge National Laboratory, R.W. ERWIN, NIST Center for Neutron Research, T.R. GENTILE, National Institute of Standards and Technology, Z. TESANOVIC, C. BROHOLM, Institute for Quantum Matter, Johns Hopkins University — Using polarized and unpolarized neutron scattering we show that interstitial Fe in superconducting $\text{Fe}_{1+y}\text{Te}_{1-x}\text{Se}_x$ induces a magnetic Friedel-like oscillation that diffracts at $\mathbf{Q}_{\perp} = (\frac{1}{2}, 0)$ and involves >50 neighboring Fe sites. The interstitial $> 2 \mu_B$ moment is surrounded by compensating ferromagnetic four spin clusters that may seed double stripe ordering in Fe_{1+y}Te . A semi-metallic 5-band model with $(\frac{1}{2}, \frac{1}{2})$ Fermi surface nesting and four fold symmetric super-exchange between interstitial Fe and two in-plane nearest neighbors largely accounts for the observed diffraction.

3:30PM L22.00004 Copper-tuned magnetic order and excitations in iron-based superconductors $\text{Fe}_{1+y}\text{Te}_{1-x}\text{Se}_x$ ¹, JINSHENG WEN, University of California at Berkeley, ZHIJUN XU, GUANGYONG XU, Brookhaven Natl Lab, MARK LUMSDEN, MASAAKI MATSUDA, Oak Ridge Natl Lab, PATRICK VALDIVIA, UC Berkeley, EDITH BOURRET, Lawrence Berkeley Lab, DUNGHAI LEE, UC Berkeley, GENDA GU, JOHN TRANQUADA, Brookhaven Natl Lab, ROBERT BIRGENEAU, UC Berkeley — We report neutron scattering results on the Cu-substitution effects in the iron-based superconductors, $\text{Fe}_{1+y}\text{Te}_{1-x}\text{Se}_x$. In the parent compound, it is found that Cu drives the low-temperature magnetic ground state from long-range commensurate antiferromagnetic order in $\text{Fe}_{1.06}\text{TeCu}_{0.04}$ to short-range incommensurate order in $\text{FeTeCu}_{0.1}$. In the former sample, the structural and magnetic ordering temperature is 40 K; in $\text{FeTeCu}_{0.1}$, the structural phase transition is not obvious and a transition to the spin-glass state is found at 22 K. Cu suppresses superconductivity in $\text{FeTe}_{0.5}\text{Se}_{0.5}$ — T_c is reduced to 7 K with a 2% Cu doping, and no superconductivity is found in the 10% Cu-doped sample. In the meantime, the intensity and energy of the resonance mode are suppressed in the 2% Cu-doped sample, while there is no resonance in the non-superconducting sample. Besides, the low-temperature magnetic excitation spectra are distinct for these two samples, with the superconducting one having an “hour-glass” shape and the other one having a “waterfall” shape. Our results provide further insights on the interplay between magnetism and superconductivity in the iron-based superconductors.

¹The work is supported by the U.S. Department of Energy.

3:42PM L22.00005 Neutron Scattering Study of Magnetic Excitation Spectrum on $\text{Fe}_{1-x}(\text{Ni/Cu})_x\text{Te}_{0.5}\text{Se}_{0.5}$, ZHIJUN XU, JINSHENG WEN, GUANGYONG XU, GENDA GU, JOHN TRANQUADA, Brookhaven National Laboratory — We have performed a series of neutron scattering and magnetization measurements on $\text{Fe}_{1-x}(\text{Ni/Cu})_x\text{Te}_{0.5}\text{Se}_{0.5}$ with different Ni/Cu compositions to study the interplay between magnetism and superconductivity. Substituting 2% and 4% of Ni for Fe reduces T_c from 15 K to 12 K and 8 K, while 10% of Cu results in loss of superconductivity. Spin resonance with lower energy are found in all superconducting samples. The overall shape of the low energy magnetic dispersion changes from two incommensurate vertical columns at $T \gg T_c$ to a distinctly different U-shaped dispersion at low temperature in superconducting samples. This spectral reconstruction is apparent for temperature up to $3T_c$. On the other hand, no static order around $(0.5, 0, 0.5)$ was found in any of these samples.

3:54PM L22.00006 Magnetic excitations in $\text{Fe}_{1.01}\text{Te}_{0.7}\text{Se}_{0.3}$, JOOSEOP LEE, University of Virginia, IGOR ZALIZNYAK, Brookhaven National Laboratory, NAOYUKI KATAYAMA, Nagoya University, RYOICHI KAJIMOTO, Japan Proton Accelerator Research Complex, SEUNGHUN LEE, University of Virginia — Recently, there have been intense studies on the magnetism in $\text{FeTe}_{1-x}\text{Se}_x$, which resulted in contradicting observations making the nature of its magnetism controversial. While the Fermi surface nesting picture can well predict the position of magnetic resonance in superconducting region, it clearly fails to predict the magnetic ordering wave vector in the parent compound. To investigate the magnetism in this iron chalcogenide series, we synthesized $\text{Fe}_{1.01}\text{Te}_{0.7}\text{Se}_{0.3}$. At this doping, it resides very close to the superconducting doping region, but is in spin glass phase. By using the Time-of-Flight neutron scattering, we obtained magnetic dispersions in this material at energies up to 257 meV. We find characteristic lines of diffuse scattering in Q-space, which provide the evidence for highly frustrated interactions. These lines of degeneracy persist up to about 10 meV, and start to disperse above it. Based on the shape of this quasi-degenerate manifold in Q-space, we propose a description of spin excitations using the J1-J2-J3 Heisenberg model on square lattice model near the limit of maximum frustration with weak extrinsic perturbation.

4:06PM L22.00007 Temperature Dependence of Magnetic Correlations in Fe-based Parents, LELAND HARRIGER, University of Tennessee at Knoxville, HUIQIAN LUO, Beijing National Laboratory for Condensed Matter Physics, MENGSHU LIU, University of Tennessee at Knoxville, CHRISTOPHER FROST, ISIS Facility, Rutherford Appleton Laboratory, PENGCHENG DAI, University of Tennessee at Knoxville — Key results from time of flight (TOF) neutron scattering measurements of BaFe_2As_2 and Fe_2Te_2 will be reviewed. These measurements were carried out over temperatures directly above and below T_N as well as base temperature measurements deep inside the order state and intermediate temperatures between T_N and room temperature where loosely correlated spin fluctuations persist. The large (TOF) data sets provide enough coverage of $(\mathbf{Q}, \omega)$ space to integrate out the correlated fluctuating moment, dispersion softening, and correlation length of the excitations as a function of temperature. Taken together, these results provide a systematic accounting of how the magnetic excitations in these parents evolve as they transition from long range ordered magnets to paramagnets.

4:18PM L22.00008 Effect of the in-plane magnetic field on the neutron spin resonance in optimally doped FeSe_{0.4}Te_{0.6} and BaFe_{1.9}Ni_{0.1}As₂ superconductors¹, XINGYE LU, SHILIANG LI, MENG WANG, HUIQIAN LUO, Institute of Physics, Chinese Academy of Sciences, Beijing, 100190, China, PENGCHENG DAI², Department of Physics and Astronomy, The University of Tennessee, Knoxville, Tennessee 37996-1200, USA, PANDA, FRM II COLLABORATION³, IN22, ILL COLLABORATION⁴, NIST COLLABORATION⁵ — We use inelastic neutron scattering to study the effect of an in-plane magnetic field on the magnetic resonance in optimally doped superconductors FeSe_{0.4}Te_{0.6} (T_c = 14 K) and BaFe_{1.9}Ni_{0.1}As₂ (T_c = 20 K). While the magnetic field up to 14.5 T does not change the energy of the resonance, it partially suppresses T_c and the corresponding superconductivity-induced intensity gain of the mode. However, we find no direct evidence for the field-induced spin-1 Zeeman splitting of the resonance. Therefore it is still unclear if the resonance is the long-sought singlet-triplet excitation directly coupled to the superconducting electron Cooper pairs.

4:30PM L22.00009 Itinerant Spin Excitations in SrFe₂As₂ Measured by Inelastic Neutron Scattering, RUSSELL EWINGS, TOBY PERRING, ISIS Pulsed Neutron and Muon Source, JACK GILLET, SITIKANTHA DAS, SUCHITRA SEBASTIAN, University of Cambridge, ALICE TAYLOR, University of Oxford, TATIANA GUIDI, ISIS Pulsed Neutron and Muon Source, ANDREW BOOTHROYD, University of Oxford — We have performed inelastic neutron scattering (INS) measurements of the magnetic excitations in SrFe₂As₂, an iron pnictide parent compound [1]. The data extend up to energies of ~ 260 meV. We find that the spectrum calculated from a local-moment J₁-J₂ model fails to describe our data in several key respects. In particular, the data can only be fitted by using different exchange parameters at high and low energies, for which there is no obvious physical justification. In both cases the nearest-neighbor exchange parameters, J_{1a} and J_{1b}, are very different. Also, on warming above the magnetic/structural ordering transition, one would expect J_{1a} → J_{1b} and hence a soft mode at **Q** = (0.5, 0.5), due to frustration in the local-moment model. However we find that the spectrum is largely unaltered. We find that the qualitative features of the INS spectra that cannot be described by the J₁-J₂ model are readily explained by calculations from a 5-band itinerant mean-field model. This also implies that it is not necessary to invoke additional broken symmetry, such as electronic nematic or orbital order, to explain the lack of a soft mode. [1] R. A. Ewings et al, Phys. Rev. B **83**, 214519 (2011)

4:42PM L22.00010 Magnetic resonance from the interplay of frustration and superconductivity, ILYA EREMIN, Institute for Theoretical Physics III, Ruhr-University Bochum, JOHANNES KNOLLE, Max Planck Institute for the Physics of Complex Systems, JOERG SCHMALIAN, Karlsruhe Institute of Technology, Institute for Theory of Condensed Matter, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems — Motivated by iron-based superconductors, we develop a self-consistent electronic theory for the itinerant spin excitations in the regime of coexistence of the antiferromagnetic stripe order with wave vector **Q**₁ = (π, 0) and s[±] superconductivity. The onset of superconductivity leads to the appearance of a magnetic resonance near the wave vector **Q**₂ = (0, π), where magnetic order is absent. This resonance is isotropic in spin space, unlike the excitations near **Q**₁, where the magnetic Goldstone mode resides. We discuss several features which can be observed experimentally.

4:54PM L22.00011 Spin excitations in isovalently doped Ba(Fe_{1-x}Ru_x)₂As₂¹, JUN ZHAO, UC Berkeley, Y. ZHAO, NIST NCR, K. MARTY, ORNL, C. ROTUNDU, LBNL, M. MATSUDA, ORNL, E. BOURRET-COURCHESNE, LBNL, H. YAO, J. WEN, P.N. VALDIVIA, T.R. FORREST, UC Berkeley, J.P. HU, Purdue University, DUNG-HAI LEE, R.J. BIRGENEAU, UC Berkeley — Iron based superconductors exhibit remarkably rich phase diagrams: superconductivity can be obtained through carrier doping, application of external pressure, or isovalent doping. Here we present the elastic and inelastic neutron scattering measurements on the magnetic correlations in isovalently doped Ba(Fe_{1-x}Ru_x)₂As₂. For the underdoped sample the static order moment are partially suppressed and the low energy spin correlation length increases upon entering the superconducting state. The spin excitation intensity is reduced with increasing Ru doping toward the over doped regime. We also studied the transfer of the magnetic spectral weight across T_c in this system.

¹J.Z. is supported by a fellowship from the Miller Institute for Basic Research in Science

5:06PM L22.00012 Polarized Neutron Scattering Study of Over-doped BaFe_{2-x}Ni_xAs₂, MENGSHU LIU, University of Tennessee, CHRIS LESTER, University of Bristol, JIRI KULDA, ILL, France, XINGYE LU, HUIQIAN LUO, Institute of Physics, Beijing, STEPHEN HAYDEN, University of Bristol, PENGCHENG DAI, University of Tennessee — Spin excitations in over-doped superconducting BaFe_{2-x}Ni_xAs₂ (x=0.15) were investigated using polarized neutron scattering. In a previous experiment on the optimally (x=0.1) doped sample, polarization analysis reveals that the magnetic response is highly anisotropic, at energies as high as 10 meV. Since this optimally doped sample is close to the boundary where antiferromagnetism disappears, there are still relatively strong antiferromagnetic correlations presented in the normal state. We will report our results on the over-doped sample, where the correlation is considerably weakened but still superconducting.

5:18PM L22.00013 Neutron scattering studies on LiFeAs and BaFe₂As₂, M. BRADEN, N. QURESHI, J. BRAND, P. STEFFENS, Univ. of Cologne, Germany, A. STUNAU, ILL, Grenoble, France, Y. SIDIS, D. LAMAGO, LLB, Saclay, France, L. HARNAGEA, S. WURMEHL, B. BÜCHNER, IFW, Dresden, Germany — The anisotropy of the magnetic excitations in BaFe₂As₂ was studied by polarization analysis. We find the in-plane polarized transverse magnon to lie at higher energy than the out-of-plane polarized one indicating very strong in-plane single-ion anisotropy. Superconducting LiFeAs exhibits the suppression of local susceptibility expected for spin-singlet pairing. Inelastic correlations appear in LiFeAs at the incommensurate wave vectors, they respond to the opening of the superconducting gap by a transfer of spectral weight.

Tuesday, February 28, 2012 2:30PM - 5:06PM —

Session L23 DMP DCOMP: Focus Session: Fe-based Superconductors - First Principles, Models, and Spectroscopy 255

2:30PM L23.00001 Fe Based Superconductors from first Principles, FRANK ESSENBERGER, PAWEŁ BUCZEK, ARTHUR ERNST, ANTONIO SANNA, LEONID SANDRATSKII, EBERHARD K.U. GROSS, Max-Planck-Institut für Mikrostrukturphysik — Density functional theory (DFT) for superconductors (SCs) is, in principle, exact and contains no adjustable parameters.¹ However, for real calculations an approximation to the pairing potential Δ_{xc} is needed. Many-body perturbation theory can be used to derive approximations to Δ_{xc} . The perturbation series is developed in orders of the screened Coulomb and phonon interactions and truncated at the first order. Unfortunately, this approach fails to predict superconductivity in unconventional SCs, like Fe based compounds.² Hence, an alternative pairing mechanism has to be present in these materials, the leading contender for which is spin fluctuations.³ We present a scheme to extend the current approximation Δ_{xc} to include spin fluctuations, which involves two steps: (1) the fluctuations are calculated with time dependent DFT,⁴ (2) an effective electron interaction mediated by the spin fluctuations is constructed.⁵ We present results for FeSe.

2:42PM L23.00002 First-principles study on electronic structure of Ca-Fe-Pt-As-type iron-based superconductors, HIROKI NAKAMURA, MASHIKO MACHIDA, Japan Atomic Energy Agency — Since the discovery of the iron-based superconductor, LaFeAsO_{1-x}F_x whose T_c reached 26K, various types of iron-based superconductors have been fabricated to attain higher T_c. Recently, new Ca-Fe-Pt-As system of iron-based superconductors was discovered, and the highest T_c in this class becomes 38K. In this system, the crystal structure is different from those of well-known iron-based superconductors. In particular, the blocking layers of some materials in this system are expected to be metallic unlike the other types of iron-based superconductors. We perform first-principles calculations for Ca-Fe-Pt-As system and evaluate their electronic structure.

2:54PM L23.00003 First-principles study of cobalt pnictides: Example compound SrCo₂N₂, ANDREW O'HARA, ALEXANDER DEMKOV, The University of Texas at Austin — Although it has been known for several decades that many materials with chemical form AT₂X₂ (A = alkaline earth element or lanthanide, T = transition metal, X = an element of groups IIIB-VIB) crystallize with the same structure, it was only recently that interest was renewed in these materials with the discovery that BaFe₂As₂ can be made to superconductor at temperatures as high as 38 K. Although the precise mechanism of superconductivity has yet to be determined, there is a growing interest in the study of materials that have similar electronic properties to BaFe₂As₂. In our work, we employ density functional theory in the local density approximation in order to study the isochemically substituted variant, SrCo₂N₂. In this work, we determine both the stability of SrCo₂N₂ as well as how the substitution changes the electronic properties in comparison to BaFe₂As₂.

3:06PM L23.00004 Density functional study on d-orbital characters of the Fe magnetic moment in BaFe₂As₂, HYUNGJU OH, HYOUNG JOON CHOI, Department of Physics and IPAP, Yonsei University — There have been many published papers related on the orbital characters of band structures in the iron-based superconductors. However, the orbital characters of the Fe magnetic moment still remain unrevealed. By performing first-principles calculations of the electronic and magnetic properties with constraint on the real space shape of Fe magnetic moments, we study the d-orbital characters of the Fe magnetic moment in BaFe₂As₂. We compare obtained band structures with published angle-resolved photoemission spectroscopy (ARPES) result, and propose that the Fe magnetic moment in BaFe₂As₂ has in-plane d_{xy} character. This work was supported by the NRF of Korea (Grant Nos. 2009-0081204 and 2011-0018306). Computational resources have been provided by KISTI Supercomputing Center (Project No. KSC-2011-C3-05)

3:18PM L23.00005 Theoretical insight on layered Mn-compounds under pressure, MARIA PEZZOLI, Department of Physics and Astronomy, Stony Brook University, Stony Brook, NY 11794, USA, ZHIPING YIN, Serin Physics Laboratory, Rutgers University, Piscataway, NJ 08854, USA., JACK SIMONSON, Department of Physics and Astronomy, Stony Brook University, Stony Brook, NY 11794, USA, MEIGAN ARONSON, Department of Physics and Astronomy, Stony Brook University, Stony Brook, NY 11794, USA and Brookhaven National Laboratory, Upton, NY, 11973, USA., GABRIEL KOTLIAR, Serin Physics Laboratory, Rutgers University, Piscataway, NJ 08854, USA. — Since the unexpected discovery of Fe-based superconductors, the search for new materials with a higher superconducting T_c has been reinvigorated. Mn based compounds in the ThCr₂Si₂ structure contain square lattice layers of the transition metal atom, like the cuprates and the iron arsenides, but the strong antiferromagnetic correlations typical of these compounds suggest that superconductivity in the manganites is impossible. However new experiments carried under pressure show that some of these layered Mn-compounds go through an electron delocalization transition. Here we study these compounds from a theoretical point of view. Looking at the magnetic properties and the Fermi surfaces close to the electron delocalization transition, we discuss the possibility of superconductivity for these compounds.

3:30PM L23.00006 Renormalization group study up to two-loop order of an effective two-band model for iron-based superconductors¹, HERMANN FREIRE, VANILDO DE CARVALHO, Federal University of Goias — We perform a renormalization group (RG) study up to two-loop order of an effective low-energy two-band model to describe some of the recently discovered iron-based superconductors. Our starting point is the itinerant electronic model proposed by Chubukov *et al.* [*Phys. Rev. B* **78**, 134512 (2008)], which displays two small, almost nested Fermi pockets with one hole pocket centered at (0,0) and one electron pocket centered at **Q** = (π, π) in the folded Brillouin zone. We then proceed to implement a two-loop RG calculation for this model of four-point vertex corrections, quasiparticle weight and several order-parameter susceptibilities in order to evaluate the robustness of one-loop RG results available in the literature with respect to including self-energy effects and higher-order quantum fluctuations.

¹ We acknowledge support from the Brazilian agency CNPq through grant No. 474109/2010-0 for this project.

3:42PM L23.00007 Microscopic derivation of GL theory for magnetism and superconductivity in multiband electronic systems¹, VLADIMIR CVETKOVIC, OSKAR VAJEK, National High Magnetic Field Laboratory, Florida State University — The superconductivity in pnictides arises due to interband scattering between Cooper pairs belonging to hole and particle Fermi surfaces. The amplitude of the scattering, while weak at bare level, is enhanced under RG flow, and competes with the SDW to become the leading instability when the hole and particle FS's are nearly, but not perfectly, nested. This motivates us to construct a GL theory with multiple order parameters from the microscopic action. It allows us to study the two competing orders and their interplay including a possible coexistence. The presence of both attractive and repulsive pairing terms requires a novel approach to the derivation with imaginary terms in the action as one consequence. The construction of the GL theory is a two-step process, with RG flow to an intermediate cut-off scale, determined by the deviations from the nesting, as the first step.

¹ This work was supported in part by the NSF CAREER Award under Grant no. DMR-0955561.

3:54PM L23.00008 Impurity Dimer Scattering as Reflection of Band Reconstruction in Iron Pnictides¹, JIAN KANG, ZLATKO TESANOVIC, Institute for Quantum Matter, Johns Hopkins University — While the impurity induced nanoscale electronic disorder has been extensively reported in the underdoped iron pnictides its microscopic origin remains a theoretical challenge. Recent STM measurements reveal a resonance in the impurity dimer scattering in cobalt-doped iron arsenides. These resonant dimers are randomly distributed but aligned with antiferromagnetic a-axis. We present a theoretical study of the impurity induced quasiparticle interference patterns in these materials, based on the five orbital model. The local density of states oscillates with the “imperfect nesting” wavevector encoded in the reconstructed Fermi pockets, provided one assumes the ordered pocket density wave (PDW) state along the b-axis. This anisotropic oscillation pattern breaks C_4 symmetry and is in agreement with the electronic dimer resonance found in the STM experiments, hinting at the existence of “hidden” PDW order in iron-based superconductors [1]. [1] J. Kang and Z. Tesanovic, Phys. Rev. B 83, 020505(R) (2011).

4:06PM L23.00009 Jump in specific heat at the superconducting transition in iron pnictides¹, MAXIM G. VAVILOV, ANDREY V. CHUBUKOV, University of Wisconsin, ANTON B. VORONTSOV, Montana State University — Experiments reveal that in iron-based superconductors the jump ΔC of the specific heat at the superconducting transition is not proportional to the transition temperature T_c , as expected in the BCS theory. Rather, the ratio $\Delta C/T_c$ varies with T_c , and has a peak near optimal doping and decreases at smaller and larger dopings. We show that this behavior can be naturally explained by the interplay between superconductivity and antiferromagnetism in the underdoped regime. We demonstrate that $\Delta C/T_c$ is indeed peaked at the doping where the coexistence phase with antiferromagnetism develops, and decreases at deviations from this doping in both directions.

¹NSF-DMR 0955500, 0906953, 0954342

4:18PM L23.00010 Beyond anharmonicity: signature of spin-phonon coupling at the surface of BaFe₂As₂¹, CHEN CHEN, JING TENG, YIMIN XIONG, JIANDI ZHANG, RONGYING JIN, E.W. PLUMMER, Louisiana State University — High Resolution Electron Energy Loss Spectroscopy (HREELS) has been used to investigate the temperature dependence of the lattice dynamics of cleaved single crystals of BaFe₂As₂, one of the parent compounds of Fe-based superconductors. Both the phonon frequency as well as phonon linewidth of the intense 32 meV out-of-plane Fe/As mode (A_{2u}) and the 24 meV out-of-plane As vibration mode (A_{1g}) show a dramatic temperature dependence and anomalous behavior below ~ 150 K. The anomalous behavior is associated with the coupled elasto-magnetic transition in the bulk but occurs appreciably higher at the surface than in the bulk (~ 138 K). The anharmonicity at the surface is considerably larger than that in the bulk for the orthorhombic phase, but is significantly less in the tetragonal phase. A detailed discussion is given in terms of the interplay between the spin and lattice in this novel system.

¹Supported by NSF DMR-1002622

4:30PM L23.00011 Low magnetic field microwave absorption and ESR studies of coexisting superconductivity and ferromagnetism in Eu-based pnictides¹, AUSTIN HOWARD, Nanotech Institute, University of Texas at Dallas, TIAN SHANG, JIAOWEN HE, GUANGHAN CAO, HUIQUI YUAN, Zhejiang University, MYRON SALAMON, ANVAR ZAKHIDOV, Nanotech Institute, University of Texas at Dallas — We have studied the coexistence of FM ordering and SC in the doped pnictide EuFe₂(As_{1-x}P_x)₂ system, with doping levels of $x = 0.3$ and 0.27 , by combined ESR and non-resonant low field microwave absorption (LFMA) methods, and magnetization in SQUID. LFMA uses an external magnetic field to create vortices in the material, which are non-resonantly excited by MW radiation. The resulting spectrum's hysteresis shape and form changes with T , revealing transitions around 9 and 20 K, and showing the FM onset and SC T_c . Two types of coexisting LFMA signals have been observed: a) a superconducting hysteretic LFMA loop, appearing below T_c and changing its shape, phase and intensity with T , and b) the non-hysteretic, reversed phase LFMA, above SC T_c , which is assigned to the magnetically ordered ferromagnetic phase, since it does not depend on T . Additionally, in the $x = 0.27$ sample, a reemergence of hysteresis is seen near 18K, corresponding with the reentrant superconductivity observed in transport measurements. LFMA has also been used to determine the position of the irreversibility line and to estimate the critical current density for the two samples.

¹AFOSR grant FA 9550-09-10384

4:42PM L23.00012 ab Plane Point Contact Spectroscopy of Co-doped Iron Pnictide Superconductors, JOHN TIMMERWILKE, J.S. KIM, G.R. STEWART, AMLAN BISWAS, Dept. of Physics, University of Florida — Point contact measurements on iron-based superconductors provide valuable information about these new superconductors, including gap sizes, number of gaps, and gap symmetries. We use a point contact apparatus capable of taking measurements in the abplane using a tungsten wire lowered mechanically onto a superconducting sample. Using this method allows us to measure the variation of superconducting gap(s) with Z, a dimensionless barrier strength parameter. Previous point contact measurements have shown Co-doped iron pnictide superconductors to be a two gapped material. Our measurements confirm the presence of two gaps in single crystal Ba(Fe_{0.926}Co_{0.074})₂As₂ and the Z variation of the measurements imply the gaps are isotropic. Acknowledgments: NSF DMR-0804452, DOE contract # DE-FG02-86ER45268

4:54PM L23.00013 Highly anisotropic Dirac fermions in a Bi square net of SrMnBi₂, JUN SUNG KIM, JOONBUM PARK, Department of Physics, Pohang University of Science and Technology, GEUNSIK LEE, Department of Chemistry, Pohang University of Science and Technology, FREDERIK WOLFF-FABRIS, Dresden High Magnetic Field Laboratory, Helmholtz-Zentrum Dresden-Rossendorf, YOON YOUNG KOH, Institute of Physics and Applied Physics, Yonsei University, MAN JIN EOM, Department of Physics, Pohang University of Science and Technology, YEONGKWAN KIM, Institute of Physics and Applied Physics, Yonsei University, M.A. FARHAN, Department of Chemistry, Pohang University of Science and Technology, YOUNJUNG JO, Department of Physics, Kyungpook National University, CHANGYOUNG KIM, Institute of Physics and Applied Physics, Yonsei University, Seoul 120-749, Korea, JI HOON SHIM, Department of Chemistry, Pohang University of Science and Technology, Pohang 790-784, Korea — We report the highly anisotropic Dirac fermions in a Bi square net of SrMnBi₂, based on a first principle calculation, angle resolved photoemission spectroscopy, and quantum oscillations for high-quality single crystals. We found that the Dirac dispersion is generally induced in the (SrBi)⁺ layer containing a double-sized Bi square net. In contrast to the commonly observed isotropic Dirac cone, the Dirac cone in SrMnBi₂ is highly anisotropic with a large momentum-dependent disparity of Fermi velocities of ~ 8 . These findings demonstrate that a Bi square net, a common building block of various layered pnictides, provide a new platform that hosts highly anisotropic Dirac fermions.

Session L24 DMP: Focus Session: Dopants and Defects in Semiconductors - Chalcogenides, Oxides, and Ternaries 256

2:30PM L24.00001 AX centers in II-VI semiconductors: Hybrid functional calculations¹, KOUSHIK BISWAS, MAO-HUA DU, Materials Science and Technology Division, Center for Radiation Detection Materials and Systems, Oak Ridge National Laboratory — Group-V acceptors should be efficient hole producers in II-VI compounds as in ZnTe. However, good *p*-type conductivity remains elusive, for example in ZnO and ZnS. With regard to this low doping efficiency, we will discuss the dopant self-compensation in II-VI semiconductors through the formation of the AX center. These are acceptor-induced defect that acts as a donor to compensate the acceptor itself. We show that the artificially high valence band maximum in Local density approximation and Generalized gradient approximation calculations can lead to incorrect prediction on the stability of the AX center in these semiconductors. The hybrid functional calculations that correct the band gap, significantly stabilize the AX centers for selected group-V acceptor dopants in ZnO, ZnS, and ZnSe. The results on AX centers obtained by hybrid functional calculations agree well with the experimentally observed doping phenomena in ZnS and ZnSe.[1] [1] Koushik Biswas and Mao-Hua Du, Applied Physics Letters 98, 181913 (2011).

2:42PM L24.00002 Magnetic Main Group Impurities in CdS, PEDRO BEDOLLA-VELAZQUEZ, CHRISTOPH GRUBER, PETER MOHN, Vienna University of Technology — With the development of magnetic semiconductors, the role of the magnetism of impurities came again into the focus of research. For *d*- and *f*-electron impurities, the situation seems to be rather clear. A new field appears when one starts to study magnetism produced by vacancies or by atoms, which usually do not carry any magnetic moments in a bulk solid. Starting from the magnetism of carbon vacancies in graphene we will present a study of CdS where S is replaced by main group elements. On the basis of abinitio supercell calculations employing density functional theory (DFT) we investigate the behaviour of impurities (B, N, C, O, F, Al, Si, P, Ga, Ge) in wurtzite (w) and zincblende (zb) CdS lattices. It is found that the impurities prefer the sulfur position and most of them, depending on the concentration exhibit magnetic order. We find that for small concentrations (64zb/72w and 32zb atom supercells) a half metallic ferromagnetic behaviour is found. For a 16 atom supercell for both zb and wstructure partly also unsaturated magnetic moments occur. A field dependence of the magnetic moments in these materials may lead to new technological applications in these magnetic semiconductors as tunable spin injection materials.

2:54PM L24.00003 Mechanisms and Kinetics of Tellurium Precipitation in CdTe-based Materials, VINCENZO LORDI, Lawrence Livermore National Lab — CdTe and related alloys are important materials for solar photovoltaic application as well as for high-resolution room-temperature gamma radiation detectors. However, the performance of devices, particularly in high-energy applications, is limited by various material defects. Among the most important defects are Te precipitates of various sizes caused by non-stoichiometric growth conditions. In this work, we study the kinetics of Te aggregation and precipitation at the atomic scale. Density functional theory is used to compute the energetics, migration rates, and binding energies of point defects involved in Te aggregation, which include various interstitials, vacancies, and anti-site defects. Kinetic Monte Carlo is then used to simulate the aggregation process leading to precipitation nuclei. The mechanisms and kinetics of formation of these Te-rich regions are analyzed for various conditions. Prepared by LLNL under Contract DE-AC52-07NA27344.

3:06PM L24.00004 Luminescence-Based Characterization of Copper Vacancies in Optical Float Zone Refined Cuprous Oxide, N. LASZLO FRAZER, KELVIN CHANG, KENNETH POEPELMEIER, JOHN KETTERSON, Northwestern University — Cuprous oxide (Cu₂O) is ideal for studying Wannier-Mott excitons which have anomalously long lifetimes in this material. However copper vacancies have a deleterious effect on the exciton lifetimes. We have measured the associated luminescence spectra in optically excited single crystals. These crystals were prepared in a radiantly-heated float-zone refiner from thermally oxidized copper rod of purity 0.999. The behavior of the vacancy luminescence can be related to exciton propagation.

3:18PM L24.00005 Ab initio calculations of intrinsic defects in ZnSb, LASSE BJERG, Aarhus University & Massachusetts Institute of Technology, GEORG K.H. MADSEN, Ruhr-Universität Bochum, JEFFREY C. GROSSMAN, Massachusetts Institute of Technology, BO B. IVERSEN, Aarhus University — Thermoelectric materials are capable of interconverting heat and electricity. The most efficient thermoelectric materials are heavily doped semiconductors, and hence they can be either *n*- or *p*-type. ZnSb has recently been predicted by theoretical calculations to be a good *n*-type thermoelectric material. However, synthesis produces *p*-type materials. Intrinsic point defects have been investigated as a possible origin using ab initio calculations. Negatively charged Zn vacancies are found to have a low formation energy, and an intrinsic *p*-type behavior is predicted.

3:30PM L24.00006 First-principles study of defect properties of zinc blende MgTe, JI-HUI YANG, Key Laboratory for Computational Physical Sciences (MOST) and Surface Physics Laboratory, Fudan University, SHIYOU CHEN, HONGJUN XIANG, XINGAO GONG, Key Laboratory for Computational Physical Sciences (MOST) and Surface Physics Laboratory, Fudan University, SU-HUAI WEI, National Renewable Energy Laboratory, Golden, Colorado 80401, USA — We studied the general chemical trends of defect formation in MgTe using first-principles band structure methods. The formation energies and transition energy levels of intrinsic defects and extrinsic impurities and some defect complexes in zinc blende MgTe were calculated systematically using a new hybrid scheme. The limiting factors for *p*- and *n*-type doping in MgTe were investigated. Possible solutions to overcome the doping limitation of MgTe are proposed. The best *p*-type dopant is suggested to be N with nonequilibrium growth process and the best *n*-type dopant is suggested to be I with its doping complex $V_{Mg} + 4I_{Te}$.

3:42PM L24.00007 Charged excitons and biexcitons bound to isoelectronic centers, GABRIEL ETHIER-MAJCHER, STEPHANE MARCET, CLAUDERIC OUELLET-PLAMONDON, PHILIPPE ST-JEAN, Ecole Polytechnique de Montreal, REGIS ANDRE, Institut Neel, CEA/CNRS/Universite Joseph Fourier, Grenoble, France, JOHN F. KLEM, Sandia National Laboratory, Albuquerque, New Mexico, SEBASTIEN FRANCOEUR, Ecole Polytechnique de Montreal — We demonstrate that isoelectronic centers formed from two isoelectronic traps can bind, in addition to the well-studied excitons, various number of positive and negative charges. Two different systems are studied by microphotoluminescence: 1) tellurium dyads in ZnSe forming hole traps and 2) nitrogen dyads in GaAs forming electron traps. By analyzing their emission fine structure, polarization and diamagnetic shifts, we establish that Te and N dyads can bind, respectively, positively and negatively charged excitons. Using the power dependence of the emission intensity, we clearly demonstrate that both systems can also bind biexcitons. This ability to bind various charge configurations, in addition to their very low inhomogeneous broadenings and perfectly defined symmetries, further establishes isoelectronic centers as an interesting alternative to epitaxial quantum dots for a number of applications.

3:54PM L24.00008 New perspective on formation energies and energy levels of point defects in non-metals, HONG ZHU, University of Connecticut, PATRICK RINKE, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, RAMPI RAMPRASAD, University of Connecticut — We propose a powerful scheme to accurately determine the formation energy and thermodynamic charge transition levels of point defects in non-metals. Previously unknown correlations between defect properties and the valence-band width of the defect-free host material are identified allowing for a determination of the former via an accurate knowledge of the latter. These correlations are identified through a series of hybrid density functional theory computations and an unbiased exploration of the parameter space that defines the Hyde-Scuseria-Ernzerhof family of hybrid-functionals. The applicability of this paradigm is demonstrated for point defects in several insulators, including Si, Ge, ZrO₂ and ZnO

4:06PM L24.00009 Hydrogen-related defects in SnO_2 ¹, W. BEALL FOWLER, FIGEN BEKISLI, MICHAEL STAVOLA, Lehigh University — Symmetry arguments along with a mass-and spring analysis of infrared absorption experiments made with polarized light on OH defects in SnO_2 yield significant insights into the possible structures of one- and two-OH defects that have been observed recently [1]. Namely, a two-OH defect must involve symmetry-equivalent OH sites, and the axes of both one- and two-OH defects are only slightly displaced from the perpendicular to the c-axis of the rutile structure. Such results cannot be explained by models involving one or two H trapped at a Sn vacancy. Rather, they are consistent with OH defects associated with either a metal atom substituting for Sn, or an interstitial metal atom (such as Sn). Results of detailed quantum-mechanical calculations [2] using CRYSTAL06 are consistent with OH structures involving a Sn interstitial.

¹Supported in part by NSF grant DMR 0802278.

4:18PM L24.00010 Polarization effect in the Ionic conductor TlBr ¹, CEDRIC ROCHA LEO, VINCENZO LORDI, Lawrence Livermore National Laboratory — TlBr is an ionic crystal that in recent years has been standing out as one of the most promising materials for effective room temperature radiation detection. However, its exceptional performance invariably degrades after operation times that vary from hours to several weeks. This phenomenon, known as polarization, is assigned to the undesirable ionic current that sets in the crystal under an applied bias, leading to the accumulation of oppositely charged Tl^+ and Br^- ions at the electric contacts of the device. This charge build up induces a field that opposes the applied bias, impairing the collection of the photo-induced carriers. In this presentation, we use parameter free quantum mechanical simulations to discuss the possible origins of the polarization effect in TlBr , showing that ionic mobility in the intrinsic material is not enough to account for effects reported by several groups. We then discuss other possible causes for the degradation of biased TlBr and propose ways to prevent its occurrence, via careful co-doping as well as a judicious choice of the metal contacts to be employed.

¹Prepared by LLNL under Contract DE-AC52-07NA27344.

4:30PM L24.00011 Structural diversity and electronic properties of Cu_2SnX_3 (X=S, Se): A first-principles investigation, YINGTENG ZHAI, Key Laboratory for Computational Physical Sciences (MOE) and Surface Physics, Fudan University, Shanghai 200433, China, SHIYOU CHEN, Key Laboratory of Polar Materials and Devices (MOE), East China Normal University, Shanghai 200241, China, JIHUI YANG, HONGJUN XIANG, XINGAO GONG, Key Laboratory for Computational Physical Sciences (MOE) and Surface Physics, Fudan University, Shanghai 200433, China, ARON WALSH, Centre for Sustainable Chemical Technologies and Department of Chemistry, University of Bath, Claverton Down, Bath BA2 7AY, United Kingdom, JOONGOO KANG, SUHUAI WEI, National Renewable Energy Laboratory, Golden, Colorado 80401, USA — The ternary semiconductors Cu_2SnX_3 (X=S, Se) are found frequently as secondary phases in synthesized $\text{Cu}_2\text{ZnSnS}_4$ and $\text{Cu}_2\text{ZnSnSe}_4$ samples, but previous reports on their crystal structures and electronic band gaps are conflicting. Here we report their properties as calculated using a first-principles approach. We find that: (i) the diverse range of crystal structures can all be derived from the zinc-blende structure. (ii) The energy stability of different structures is determined primarily by the local cation coordination around anions, which makes Cu and Sn partially disordered in the cation sublattice. (iii) The direct band gaps of the low energy compounds Cu_2SnS_3 and Cu_2SnSe_3 should be in the range of 0.8-0.9 eV and 0.4 eV respectively.

4:42PM L24.00012 Fe_2MCh_4 (M=Si,Ge, Ch=S,Se): optical, electrical properties and defects, ROBERT KOKENYESI¹, Department of Chemistry, Oregon State University, Corvallis, OR, LIPING YU, STEPHAN LANY, National Renewable Energy Lab, Golden, CO, ALEX ZUNGER, University of Colorado at Boulder, Boulder, CO, DOUGLAS KESZLER, Department of Chemistry, Oregon State University, Corvallis, OR, CENTER FOR INVERSE DESIGN, EFRC COLLABORATION — Fe_2MCh_4 (M=Si,Ge, Ch=S,Se) are proposed as solar absorber materials, as a single phase, stable alternative to FeS_2 pyrite. Native defects have high formation energy in the band gap and no Fermi level pinning is predicted by DFT. External defect calculations, including B,Al,Ga,In, N, P, As, Sb, Bi, O, Se, predict substantial effect on the bulk electronic properties.

¹formerly Robert Kykyneshi

4:54PM L24.00013 Structure, stability, and defect analysis of potential solar absorber Cu_3PSe_4 , DAVID H. FOSTER, JASON M. VIELMA, GUENTER SCHNEIDER, Oregon State University — The semiconductor Cu_3PSe_4 has recently been established to have a direct band gap of 1.4 eV and exhibit p-type conductivity [Applied Physics Letters, 99, 181903 (2011)]. Here we present density functional theory (DFT) and post-DFT results regarding the structure, stability, and dopability of Cu_3PSe_4 . We find a strong coupling between the electronic band gap and the atomic structure, clearly caused by the strong P-Se antibonding character of the conduction band. Using the Heyd-Scuseria-Enzerhof hybrid functional and *GW* approximation methods, we find that structural relaxation using standard DFT is not sufficiently accurate to be used as input to static, post-DFT electronic structure calculations. We use the generalized gradient approximation (GGA) and the GGA+*U* method to show a thermodynamically stable low temperature region. We calculate the formation enthalpies of intrinsic and extrinsic defects in order to understand the observed p-type behavior and to examine n-type doping mechanisms.

5:06PM L24.00014 Effect of Cation Disorder on Electronic Structures and Optical Properties of Magnetoelectric Gallium Ferrite: A First-principles Study, AMRITENDU ROY, IIT Kanpur, SUSHIL AULUCK, NPL Delhi, RAJENDRA PRASAD, ASHISH GARG, IIT Kanpur — Discovery of photovoltaic effects in oxide materials, especially in magnetoelectrics and multiferroics has lead to renewed interests in the optical properties of these materials. Magnetoelectrics with their transition temperature close to room temperature are of particular interest from the perspective of practical applications. Magnetoelectric gallium ferrite (GFO), a material of current interest, exhibits good optical activity and a transition temperature tunable to room temperature and above upon tailoring of cation stoichiometry. Here, we show a detailed first principle study on the electronic structure and optical properties of GFO. We have performed first-principles density functional calculations using GGA+*U* method to compute the electronic band structure and density of states of the ground state structure of GFO having orthorhombic $Pc2_1n$ symmetry and A-type antiferromagnetic spin configuration. The calculations show that GFO possesses a direct band gap of ~ 2.3 eV, making it a rather low band gap oxide. Subsequent calculations of real and imaginary parts of dielectric constants, refractive index (*n*), extinction coefficient (*k*), reflectivity (*R*), etc demonstrate good agreement with experimental spectra which is further improved upon introduction of cationic site disorder into the ground state structure substantiating the presence of cation site disorder in the material. We also show that major optical transitions in GFO involve transitions from valence band O 2p to conduction band Fe 3d states.

5:18PM L24.00015 Radiative defects in thallium chalcogenide semiconductors¹, J.A. PETERS, N.K. CHO, ZHIFU LIU, B.W. WESSELS, Dept. of Materials Science and Engineering, Northwestern University, S. JOHNSEN, S. NGUYEN, M. SEBASTIAN, M.G. KANATZIDIS, Dept. of Chemistry, Northwestern University, Evanston, IL 60208 — Thallium chalcogenides constitute a promising new class of semiconductor compounds for radiation detectors. Due to their wide energy bandgap, high atomic number, and high resistivity, they are being considered as potential replacement for conventional II-VI semiconductor x-ray and γ -ray detectors for room temperature operation. For these applications resistivities of $\sim 10^{10}$ ohm-cm are required. Although defects play a major role in detector response, little is known about their nature and origin in these compounds. We have investigated $\text{Ti}_6\text{I}_4\text{Se}$ and $\text{Ti}_6\text{I}_4\text{S}$ compounds which have bandgaps of 1.86 and 2.03 eV, respectively. Photoluminescence (PL) spectra of single crystals were investigated in the 650-885 nm wavelength region and over a temperature range of 20-100 K. For $\text{Ti}_6\text{I}_4\text{Se}$ we observed PL bands centered at 1.61 eV. A detailed study of the peak, as function of temperature and excitation intensity, indicates that it is due to radiative transitions from donor-acceptor pairs (DAP). The ionization energies of the donor and acceptor levels in $\text{Ti}_6\text{I}_4\text{Se}$ were estimated at 52 and 290 meV, respectively. Similarly DAP emission in $\text{Ti}_6\text{I}_4\text{S}$ with a peak at 1.66 eV was observed. The role of crystalline stoichiometry in DAP formation is currently under study.

Session L25 DCOMP GSCCM DMP: Focus Session: Simulation of Matter at Extreme Conditions - Warm Dense Matter 257A

2:30PM L25.00001 Simulation of the Correlated Electron Plasma in the Warm Dense Matter Regime by Restricted Path-Integral Molecular Dynamics¹, VIVEK KAPILA, University of Florida, PIERRE DEYMIER, University of Arizona, KEITH RUNGE, University of Florida — Warm dense matter (WDM) can be characterized by electron temperatures of a few eV and densities an order of magnitude or more beyond ambient. This regime currently lacks any adequate highly developed class of simulation methods. Recent developments in orbital-free Density Functional Theory (ofDFT) aim to provide such a simulation method, however, little benchmark information is available on temperature and pressure dependence of simple but realistic models in WDM regime. The present work aims to fill this critical gap using the restricted path-integral molecular dynamics (rPIMD) method. Within the discrete path integral representation, electrons are described as harmonic necklaces, while, quantum exchange takes the form of cross linking between electron necklaces. The fermion sign problem is addressed by restricting the density matrix to positive values and a molecular dynamics algorithm is employed to sample phase space. Here, we focus on the behavior of strongly correlated electron plasmas under WDM conditions. We compute the kinetic and potential energies and compare them to those obtained with the ofDFT method.

¹Work supported under US DoE Grant DE-SC0002139

2:42PM L25.00002 Comparison of Finite Temperature Hartree-Fock and Density Functional Theory for Confined Systems¹, TRAVIS SJOSTROM, S.B. TRICKEY, Quantum Theory Project, University of Florida, FRANK E. HARRIS, Quantum Theory Project, University of Florida and Physics Dept. University of Utah — Warm dense matter (WDM) at elevated temperatures (*e.g.*, $T \approx 1$ to several eV) and densities (*e.g.* one or more orders of magnitude denser than equilibrium) is of growing importance. So far, the most detailed studies of WDM use Born-Oppenheimer molecular dynamics with ground-state density functional theory (DFT) approximations. Little, however, is known about the behavior of the free energy over the temperature and density ranges of interest. In the case of DFT, this deficiency is a barrier to assessing the validity of proposed approximate free-energy functionals. For insight into this problem, we have undertaken systematic numerical study of the thermal Hartree-Fock (THF) approximation. We report progress on application of THF to the problem of eight one-electron atoms at arbitrary positions in a hard-walled box. We discuss the physics which emerges for both high- and low-symmetry ionic arrays, including molecular binding transitions. In addition, we compare the THF results directly with approximate DFT results, including approximate finite-temperature orbital-free kinetic and exchange functionals.

¹Supported in part under US DoE Grant DE-SC0002139.

2:54PM L25.00003 The Korrington-Kohn-Rostoker Method Applied to Warm Dense Matter¹, DANIEL FINKENSTADT, U.S. Naval Academy, Physics Dept., Annapolis, MD, CHARLES E. NEWNAM, U.S. Naval Academy, Aerospace Dept., Annapolis, MD, BRIAN G. WILSON, Lawrence Livermore National Laboratory, Livermore, CA — The electronic structure, EOS and transport properties of warm electrons in an amorphous or disordered configuration of ions is not well described by either solid-state or plasma models. Such warm, dense systems share the characteristic of the solid state that multi-center scattering effects are of paramount importance in forming bands of valence states. Theoretical treatment of the EOS of warm, dense matter therefore requires a way to include significant occupation of higher energy and angular momentum channel continuum states. We are extending the Green's function Kohn-Korrington-Rostoker code *MECCA* as an all-electron (non-pseudo potential) method that treats arbitrary mixtures of atoms on an ab-initio basis over a broad range of conditions, from cold, solid matter up to hot plasmas at extreme (ICF) compression. Specific examples of Aluminum and Boron-Nitride will be discussed.

¹Supported by the Military Academy Research Associates program, LLNL/USNA.

3:06PM L25.00004 Density Functional versus Thermal Hartree-Fock Approximations in Warm Dense Lithium¹, VALENTIN V. KARASIEV, TRAVIS SJOSTROM, S.B. TRICKEY, Quantum Theory Project, Physics Dept. U. Florida — We compare the behaviors of the thermal Hartree-Fock (tHF) model and thermal Density Functional Theory (tDFT) using both ground-state and temperature-dependent approximate functionals. The test system is bcc Li in the temperature-density regime of warm dense matter. In the exchange-only case, we find significant qualitative differences between the exact tHF and the DFT calculations with zero-temperature local density approximation (LDA) exchange. A temperature-dependent LDA functional provides much better agreement with the tHF exchange. An underlying need is for well-characterized, reliable pseudopotentials over demanding temperature and density ranges. Thus we compare pseudopotential and all-electron results for small Li clusters of local bcc symmetry and bond-lengths appropriate to high density bulk Li. We determine the density range over which both standard projector-augmented wave (PAW) and norm-conserving pseudopotentials are reliable. Then we construct small-cutoff-radius PAW data sets (for both the local density and the generalized gradient exchange-correlation approximations) which are valid for lithium densities up to at least 80 g/cm³.

¹Supported in part under US DoE Grant DE-SC0002139.

3:18PM L25.00005 A Different Time-Dependent Variational Principle Approach: Going Beyond Wave Packet Molecular Dynamics, PAUL GRABOWSKI, Los Alamos National Laboratory, ANDREAS MARKMANN, Yale University, MIKE SURH, Lawrence Livermore National Laboratory, MICHAEL MURILLO, Los Alamos National Laboratory, FRANK GRAZIANI, Lawrence Livermore National Laboratory, CIMARRON COLLABORATION — During inertial confinement fusion, matter evolves from a solid condensed matter phase through the warm dense matter (WDM) regime to a hot dense matter. In WDM, quantum mechanical effects are important because of both Fermi-Dirac statistics and the rate of electrons transitioning in and out of bound states is large. The time-dependent temperature and quickly changing local environment require a time-dependent quantum method. A converged dynamical quantum simulation is intractable for more than a few particles. Instead, we take as a feasible goal to match the statistical properties of a warm dense plasma. The time-dependent variational principle gives a framework for producing equations of motion. A commonly used variational form is a Hartree product of isotropic Gaussian wave packets (wave packet molecular dynamics). The resulting dynamics do not produce the right statistics. We therefore introduce a plane wave basis and discuss its advantages and test its ability to reproduce radial distribution functions produced by hyper-netted chain calculations.

3:30PM L25.00006 All-Electron Path Integral Simulations of Warm, Dense Matter: Application to Water and Carbon¹, KEVIN DRIVER, Department of Earth and Planetary Science, University of California, Berkeley, CA 94720, USA, BURKHARD MILITZER, Department of Earth and Planetary Science and Department of Astronomy, University of California, Berkeley, CA 94720, USA — We develop an all-electron path integral Monte Carlo (PIMC) method for warm dense matter and apply it to study water and carbon. PIMC pressures, internal energies, and pair-correlation functions compare well with density functional theory molecular dynamics (DFT-MD) at lower temperatures and enable the construction of a coherent equation of state over a density-temperature range of 3–12 g/cm³ and 10²–10⁹ K. PIMC results converge to the Debye-Huckel limiting law at high-temperatures and illuminate the breakdown of DFT pseudopotentials due to core excitations.

3:42PM L25.00007 ABSTRACT WITHDRAWN —

3:54PM L25.00008 Non-equilibrium Warm Dense Matter: Electron-Ion Dynamics of Pumped Nanofoils¹, YUAN PING, TADASHI OGITSU, ALFREDO CORREA, ERIC SCHWEGLER, GILBERT COLLINS, LLNL, JUN ZHOU, JIANMING CAO, Florida State University, BYOUNG-ICK CHO, KYLE ENGELHORN, PHILIP HEIMANN, ROGER FALCONE, LBNL/UC Berkeley — In 2006, it was reported that the dielectric function of laser-excited gold nanofoils exhibits a peculiar behavior; the interband transition peak of gold is enhanced and undergoes a clear red shift [PRL **96**, 255003 (2006)]. In 2009, based on ultrafast electron diffraction measurements on pumped gold nanofoils, it was reported that the time evolution of the Debye-Waller factor is too slow to be explained by a two-temperature model that included temperature dependent el-ph coupling. This anomaly has been attributed to a phonon hardening process caused by high electron temperatures (a few eV) [Science **323**, 1033 (2009)]. Later, it was pointed out that at such a high electron temperatures the dielectric function of gold calculated by first-principles DFT simulations does not reproduce the enhanced and red-shifted interband transition peak and an alternative explanation was proposed to reconcile the discrepancies where the effect of ejected electrons was addressed [HEDP **6**, 246 (2010)]. In this talk, we will discuss recent experimental/theoretical efforts to further examine the issues relevant to this problem, el-ph coupling, dynamics of ejected electrons, and ballistic transport of electrons [submitted to HEDP; PRL **106**, 167601(2011)].

4:06PM L25.00009 High field terahertz response of materials, DAN DARANCIANG, Department of Chemistry, Stanford University, JOHN GOODFELLOW, Department of Materials Science, Stanford University, ALAN FISHER, Linac Coherent Light Source, SLAC National Accelerator Laboratory, AARON LINDENBERG, Department of Materials Science, Stanford University — We report on studies of the response of materials to intense ultrashort electromagnetic fields at terahertz frequencies. These are generated through coherent transition radiation using femtosecond electron bunches at the Linac Coherent Light Source and correspond to single-cycle pulses with electric field amplitudes $\gtrsim 20$ MV/cm with a frequency centered at 10 THz. Large amplitude nonlinear responses are observed in a range of semiconductor materials associated with field-induced ionization processes, and we show how these processes can be used to carry out nonlinear autocorrelation measurements of the pulse shape. We also discuss recent results probing the response of ferroelectric materials at high fields coupled with ultrafast x-ray probes enabling measurement of their atomic-scale response on sub-picosecond time-scales.

4:18PM L25.00010 An Analytic Screening Potential for Dense, Strongly-Coupled Plasmas¹, LIAM STANTON, LLNL, MICHAEL MURILLO, LANL, FRANK GRAZIANI, LLNL — Characterizing warm dense matter (WDM) has gained renewed interest due to advances in powerful lasers and next generation light sources. Because WDM is strongly coupled and moderately degenerate, we must often rely on simulations of WDM, which are necessarily based on molecular dynamics of ions interacting through a screened potential. Almost always, a Debye- (Yukawa-) like interaction is assumed; however, it is well known that such long wavelength models over-screen. Here, we present a new effective ion-ion interaction, which recovers the exact fermionic linear response in the long-wave limit while retaining a pair-potential functionally similar to that of the Yukawa form. This new potential not only improves the accuracy of screening effects without contributing to the computational complexity of the model, but it also adds physics entirely missing from Yukawa models (such as the onset of Friedel oscillations). Simulations of the ion structure factor are compared to XRTS data for Be and C in the WDM regime.

4:30PM L25.00011 Large-Scale Reactive Simulations of Materials in Extreme Conditions, ANDRES JARAMILLO-BOTERO, WILLIAM GODDARD, California Institute of Technology, MSC TEAM — First-principles quantum mechanics methods are inadequate for accurately describing the effects of thermal, mechanical, chemical or radiation excitations that may occur in materials operating under extreme conditions, or impractical to use due to the prohibitive scaling cost of propagating the total Schrodinger equation for a large set of atoms. In the regime of a high number of electronic excitations, the electronic portion of the wave function contains contributions from many stationary states, and the Born-Oppenheimer approximation breaks down. We have been developing a mixed quantum-classical dynamics approach, called the Electron Force Field (eFF), to simulate the non-adiabatic dynamics of materials in extreme conditions. We have demonstrated its application to describe the: thermodynamics of dense hydrogen over 0-100,000 Kelvin; real-time dynamics of Auger fragmentation of diamond nano particles; transient electronic effects in high-strain rate silicon fracture; Coulomb explosion of carbon clusters; dynamics of cascaded valence ionizations in shocked hydrocarbons; and the dynamics of hypervelocity impact of materials. Here, we summarize our recent progress in the theory and application of eFF for modeling and simulation of materials in extreme conditions.

4:42PM L25.00012 ABSTRACT WITHDRAWN —

4:54PM L25.00013 First-principle Calculations of Equation of State for Metals at High Energy Density, DMITRY MINAKOV, PAVEL LEVASHOV, KONSTANTIN KHISHCHENKO, Joint Institute for High Temperatures RAS — In this work, we present quantum molecular dynamics calculations of the shock Hugoniot of solid and porous samples as well as release isentropes and isentropic sound velocity behind the shock front for aluminum. Also we perform similar calculations for nickel and iron. We use the VASP code with ultrasoft and PAW pseudopotentials and GGA exchange-correlation functional. Up to 512 particles have been used in calculations. To calculate Hugoniot we solve the Hugoniot equation numerically. To obtain release isentropes, we use Zel'dovich's approach and integrate an ordinary differential equation for the temperature thus restoring all thermodynamic parameters. Isentropic sound velocity is calculated by differentiation of pressure along isentropes. The results of our calculations are in good agreement with experimental data at densities both higher and lower than the normal one. Thus, quantum molecular dynamics results can be effectively used for verification or calibration of semiempirical equations of state under conditions of lack of experimental information at high energy densities.

5:06PM L25.00014 Color quantum simulations of strongly coupled quark-gluon plasma, VLADIMIR FILINOV¹, VLADIMIR FORTOV, Joint Institute for High Temperatures RAS, Moscow, Russia, MISHAEL BONITZ, Institute for Theoretical Physics and Astrophysics, Kiel, Germany, YURI IVANOV, GSI Helmholtzzentrum für Schwerionenforschung GmbH, Darmstadt, Germany, PAVEL LEVASHOV, Joint Institute for High Temperatures RAS, Moscow, Russia — We propose stochastic simulation of thermodynamics and kinetic properties for quark-gluon plasma (QGP) in semi-classical approximation in the wide region of temperature, density and quasi-particles masses. In grand canonical ensemble for finite and zero baryon chemical potential we use the direct quantum path integral Monte Carlo method (PIMC) developed for finite temperature within Feynman formulation of quantum mechanics to do calculations of internal energy, pressure and pair correlation functions. The QGP quasi-particles representing dressed quarks, antiquarks and gluons interact via color quantum Kelbg pseudopotential rigorously derived for Coulomb particles. This method has been successfully applied to strongly coupled electrodynamic plasmas (EMP). A strongly correlated behavior of the QGP is expected to show up in long-ranged spatial correlations of quarks and gluons which, in fact, may give rise to liquid-like and, possibly, solid-like structures. We have done already the first calculation of the QGP equation of state, spatial and color pair distribution functions, diffusion coefficients and shear viscosity.

5:18PM L25.00015 Proton crystallization and quantum melting of proton crystals in a dense hydrogen plasma, PAVEL LEVASHOV, VLADIMIR FORTOV, VLADIMIR FILINOV, Joint Institute for High Temperatures RAS, Moscow, Russia, HOLGER FEHSKE, Institut für Physik, EMAU Greifswald, Germany, MICHAEL BONITZ, Institute for Theoretical Physics and Astrophysics, Kiel University, — We present extensive new simulation results which allow to predict the temperature and density range for proton crystallization. We simulate a macroscopic spatially homogeneous fully ionized two-component electron-proton plasma in thermodynamic equilibrium from first principles using direct fermionic path integral Monte Carlo simulations. Our results for the phase diagram differ substantially from the previous predictions based on the one-component plasma (OCP) model: In the classical part of the phase diagram the crystal appears to be stabilized compared to the OCP prediction. In contrast, in the quantum part of the phase diagram the crystal appears to be de-stabilized and vanishes at lower densities compared to the OCP prediction. Finally, the maximum temperature for the proton crystal is found to be around 40 000K, slightly below the previous prediction. Our results indicate that the OCP treatment of the liquid-solid transition in a two-component plasma has to be questioned. The OCP-assumption of a homogeneous rigid neutralizing background gives rise to substantial deviations of the critical parameters.

Session L26 DCOMP GSNP: Focus Session: Friction, Fracture and Deformation Across Length Scales - Dislocations and Fracture 257B

2:30PM L26.00001 How dislocations and grain boundaries control wear at the nanoscale, IZABELA SZLUFARSKA, University of Wisconsin — Ceramics show outstanding mechanical properties such as high strength and high hardness over a wide range of temperatures and are stable in harsh environments. However, the low fracture toughness of ceramics limits their practical utility for instance as wear-resistance coatings. There have been several reports of improving wear resistance of ceramics by reducing the grain sizes and/or the dimension of the cutting tools to the nanometer regime. Using SiC as a model covalent ceramic, we performed molecular dynamics (MD) simulations of wear for both single crystal and nanocrystalline material. We determined the role of dislocations and grain boundary sliding in improving wear resistance of SiC and we have quantified contributions from these mechanisms to friction and wear. We have discovered instabilities that control sliding of the amorphous-like highly disordered grain boundaries in SiC, in analogy to instabilities and deformation mechanisms that occur in bulk amorphous materials. In this talk we will also present our newly developed analytical model for plowing friction in nanoscale contacts, which model has been validated for both ceramics and metals. In order to isolate the contribution from grain boundary sliding to deformation of nanocrystalline materials, we have performed MD simulations of nanoindentation and uniaxial testing on ultrananocrystalline diamond (UNCD). We have shown that in the absence of dislocation plasticity, hardness and yield strength of nanocrystalline materials scale linearly with the grain boundary shear strength, where the latter property can be controlled by grain boundary doping. Our findings explain the experimental observations that hardness and elastic properties of UNCD decrease with an increasing H content.

3:06PM L26.00002 Plastic flow and failure in metallic glass/nanocrystal composites¹, MICHAEL FALK, PENGFEI GUAN, Johns Hopkins University — The exploitation of metallic glasses' high strength in structural applications is limited by their lack of any hardening subsequent to yield. This lack of hardening leads to plastic localization as evidenced by the spontaneous formation of shear bands. One proposed method of forestalling such instabilities is to introduce nanocrystal inclusions to disrupt shear band nucleation and propagation. We have undertaken a series of molecular dynamics simulations of glasses with different morphologies of nanocrystallites. We report the resulting plastic response, and we use various simulations of these types to test the applicability of the shear transformation zone (STZ) constitutive relation for modeling such complex nano-composite materials.

¹Funded by NSF under grant DMR0808704

3:18PM L26.00003 Atomic Origins of Friction Reduction in Metal Alloys, MICHAEL CHANDROSS, SHENGFENG CHENG, Sandia National Laboratories — Gold is a desirable material for use in high performance electrical contacts because it offers low contact resistance, does not corrode or oxidize, and can be easily made into thin sheets. However, gold contacts generally suffer from high adhesion and friction. The tribological issues are mitigated in nanocrystalline gold alloys (with, for example, Ni or Co), which can exhibit both low friction and low contact resistance. The atomic scale mechanisms responsible for the change in frictional response are poorly understood. We will present the results of large scale molecular dynamics simulations which study the tribological response of nanocrystalline films of pure gold and alloys under a variety of sliding conditions. Our results indicate that in pure metals, cold welding and microstructural reorientation lead to the formation of a commensurate sliding interface and high friction resulting from dislocation controlled plasticity. In alloys, however, differing lattice constants suppress the reorientation of grains at the contact point, which leads to grain boundary sliding and lower friction.

3:30PM L26.00004 Deformation Initiation by Non-planar {10-12} Twinning Nucleation in Magnesium Crystal, SUNGHO KIM, HAITHAM KADIRI, MARK HORSTEMEYER, Mississippi State University — The nucleation mechanism of experimentally most commonly observed twinning in Mg crystal initiating deformation process are studied using molecular dynamic simulation. We observed nucleation of radially growing {10-12} twinning under tensile loading in Mg rectangular wire system without artificial creation of an twinning. The twinning nucleation mechanism is very different from the conventional twinning mechanism in that the twin nucleates from a point source rather than the fault plane following the partial dislocation line in FCC crystal. The wire axis is normal to basal plane of Mg crystal. The tensile deformation in c-axis nucleates {10-12} twinning starting at the corner of square of cross section of the wire. The twin boundary is spherical at the beginning and become linear boundaries in {10-12} planes as time goes by.

3:42PM L26.00005 Softening of nanocrystalline materials at small grain size, GEORGIOS KOPIDAKIS, NIKOS GALANIS, IOANNIS REMEDIKIS, Dept. of Materials Science and Technology, University of Crete — We examine the dependence of the mechanical properties of nanocrystalline materials on grain size. Our extensive atomistic simulations for several nanocrystalline solids show a universal softening at grain sizes of less than a few nanometers. The elastic constants decrease as the average grain size becomes smaller, in analogy with the reverse Hall-Petch effect for nanocrystalline metals. This behavior is explained by the increase of the fraction of grain boundary atoms as grain size decreases. We derive simple scaling laws for various mechanical properties as a function of the grain size by decomposing the energy into contributions from atoms in the bulk of grains and from atoms at the interfaces. Our theoretical predictions fit very well our results from atomistic simulations of different nanocrystalline materials, from nanocrystalline metals to ultrananocrystalline diamond. It is therefore argued, and quantitatively explained, that softening at small grain size is a general nanoscale effect.

3:54PM L26.00006 Large scale NEMD simulations of polycrystalline Al sliding interfaces¹, JACQUELINE MILHANS, J.E. HAMMERBERG, R. RAVELO, T.C. GERMANN, B.L. HOLIAN, Los Alamos National Laboratory — We present the results of NonEquilibrium Molecular Dynamics (NEMD) simulations for the frictional force between polycrystalline Al samples. Polycrystalline Al samples of order 26M atoms with grain sizes from 10 - 20 nm at compressions of 15 GPa are considered as a function of sliding velocity. Typical sample dimensions are 58nm in the sliding and transverse directions and 116nm in the direction normal to the sliding interface. A constant temperature (300K) and constant tangential velocity boundary condition is imposed at the boundaries in the direction normal to the sliding plane. We discuss the modes of plastic deformation and polycrystalline deformation which determine the steady state frictional force and compare these results with results for defect free Al single crystals and highly defective Al single crystal samples.

¹This work was performed under the auspices of the U.S. Dept. of Energy under contract DE-AC52-06NA25396.

4:06PM L26.00007 Fracture In Disordered Media: Nucleated, Critical or Percolative?¹, ASHVINI SHEKHAWAT, Cornell University, STEFANO ZAPPERI, CNR - Consiglio Nazionale delle Ricerche, JAMES SETHNA, Cornell University — Fracture is often considered to be an abrupt transition and is modeled by nucleation theory. However, the precursor events leading to macroscopic failure display scaling behavior and are understood in terms of critical phenomena. Further, the universal roughness properties of fracture surfaces have been explained by modeling fracture as a percolative process. We attempt to unify these disparate descriptions of fracture in one comprehensive theory. We study the random fuse network as a typical model of disordered brittle media. We show that in this model fracture can be nucleated, critical or percolative depending on the behavior of the tail of the distribution of fuse strengths. We explore the phase diagram by using numerical simulations as well as theoretical arguments.

¹This research was supported by DOE-BES DE-FG02-07ER-46393

4:18PM L26.00008 Homogeneous Dislocation Nucleation, ASAD HASAN, CRAIG MALONEY, Carnegie Mellon University — We perform atomistic computer simulations to study the mechanism of homogeneous dislocation nucleation (HDN) in a 2D hexagonal crystalline film under circular indentation. The nucleation process is governed by vanishing of energy associated with a single normal mode. For fixed film thickness, L , the spatial extent, ξ , of the critical mode grows with indenter radius, R . For fixed R/L , ξ scales roughly as $\xi \sim L^{0.4}$. We perform a *mesoscale* analysis to determine the lowest energy normal mode for regions of varying radius, r_{meso} , centered on the critical mode's core. The energy of the lowest normal mode $\lambda_{\text{meso}} \rightarrow 0$ rapidly as $r_{\text{meso}} \rightarrow \xi$. The lowest mode shows a spatial extent, ξ_{meso} , which increases sublinearly for $r_{\text{meso}} \leq \xi$ and saturates at $r_{\text{meso}} \approx 1.5 \xi$. We demonstrate that the ξ_{meso}/ξ versus r_{meso}/ξ curve is *universal* (independent of L or R). Hence small regions, $r_{\text{meso}} \leq \xi$, can reveal the presence of incipient instability but give excellent estimates for the critical mode's energy and spatial extent *only* for $r_{\text{meso}} \geq 1.5 \xi$. Thus HDN is a *quasi-local* phenomenon.

4:30PM L26.00009 Fracture Energy Issues of Brittle, Microcrack Brittle, and Dislocation Ductile Materials¹, RAY B. STOUT, RhoBetaSigma Aff, 954 Venus Way, Livermore CA 94550-6346, RHOBETASIGMA AFF COLLABORATION — Somigliana elasticity models(1915) for dislocation-microcrack defect discontinuities in a material form an analog basis to relate dislocation density evolution to microcrack density evolution near an existing idealized crack-tip. Thus, a recent idealized field solution derived for stochastic dislocation density evolution near a crack-tip in a ductile material is also an analog applicable field solution for stochastic microcrack density evolution in a brittle material near a crack-tip. A non-equilibrium thermodynamic functional is derived and integrated to evaluate rates of dislocation and microcrack internal energy evolution due to the singularity terms of these crack-tip solutions in an arbitrary spatial crack-tip neighborhood and during an arbitrary fracture toughness load-up time interval of $[0, t^*]$. At some time greater than t^* , the available inter-atomic lattice(analog recoverable elastic) internal energy at a crack-tip becomes probabilistically sufficient, in an energy transfer-stability sense of Gibbs[1906], Griffith[1920], and Eshelby[Phil Trans Roy Soc, 1951], to be configurationally transported from locally recoverable internal energy at a crack-tip to non-recoverable crack-tip surface energy as a crack-tip propagates.

¹N/A

4:42PM L26.00010 Role of interactions and damage in a cohesive fracture model, JOSEPH GRAN, JOHN RUNDLE, DONALD TURCOTTE, University of California, Davis, WILLIAM KLEIN, Boston University — We study the influences of local and long range interactions in a numerical model of tensile fracture. Our model simulates fracture events on a 2D square lattice plane with a Metropolis algorithm. We chose a Hamiltonian that is written as a function of the crack separation (offset field) and includes contributions from an external field, interactions, as well as a cohesive energy across the crack surfaces. Included in our study is both a ferromagnetic-type (attractive) and antiferromagnetic-type (repulsive) interactions. We test both of these interactions individually as well as a hybrid interaction in which over a short range the interaction is antiferromagnetic and in the long range the interaction becomes ferromagnetic. This dual interaction approximates a Lennard-Jones potential. We also propose a characterization of damage and investigate the increase of damage in time for fractures occurring by a static-load as well as a time-dependent load. Damaged sites do not interact with neighboring sites and cannot hold any load. We compare our damage model to previous studies of fiber-bundle models.

4:54PM L26.00011 Indentation of Graphene Membranes: Non-Linear Response, Nano-Fracture, and Crack Propagation, ROMAIN PERRIOT, YOU LIN, VASILY ZHAKHOVSKY, Department of Physics, University of South Florida, XIANG GU, Department of Applied Physics, Aalto University, IVAN OLEYNIK, Department of Physics, University of South Florida — Recent indentation experiments on graphene have revealed its exceptional strength, making it an excellent candidate for the design of nano- and micro- electromechanical systems. Therefore, it is critical to understand the mechanical properties of graphene, and its response to a wide range of loading pressures beyond the elastic regime. In this work molecular dynamics (MD) simulations of indentation of circular graphene membranes were performed with a newly developed interatomic potential, specifically designed to study graphene under extreme tensile stress. The indentation curves confirmed the experimental observation of a non-linear response at large loads, as well as the brittle failure of the membranes via the generation of nano-cracks. Our MD simulations showed that the fracture process consists of two consecutive stages: an initial bond-breaking event followed by the formation and propagation of cracks. The kinetic theory of bond breaking was applied to determine the breaking strength of graphene and its dependence on the indenter radius, as well as the waiting time for failure. MD simulations were used to provide an atomic-scale description of fracture dynamics.

5:06PM L26.00012 Investigation of Nonlinear Elastic Behavior of Two-Dimensional Molybdenum Disulfide¹, RYAN COOPER, Columbia University, CHANGGU LEE, Sung Kyun Kwan University, CHRISTOPHER MARIANETTI, JAMES HONE, JEFFREY KYSSAR, Columbia University — The present study investigates the nonlinear elastic properties of a single-layer molybdenum disulfide crystal through experiment, finite element modeling, and density functional theory. Suspended single-layer molybdenum disulfide crystals are suspended over circular holes that were etched on a silicon oxide surface. Crystals are loaded at the center with an atomic force microscope until fracture occurs. The load-displacement curve is used to determine the pretension and linear-elastic response of the crystal. The force at which fracture occurs gives insight into the intrinsic strength and higher order elastic constants of the crystal. These experiments provide a platform to validate first-principles derivation of fifth-order elastic constants for in-plane stiffness using density functional theory. The derived higher order elastic constants are used in a finite element model to predict the breaking strength of two-dimensional molybdenum disulfide. The study bridges the gap between density functional theory and finite element analysis with experimental evidence.

Session L27 DCMP FIAP: Invited Session: Quantum Design of Low-Dimensional Materials Structures for Enhanced Solar Energy Conversion 258AB

2:30PM L27.00001 Use of First-Principles Theory to Identify materials and nano structures for next-generation solar cells¹, ALEX ZUNGER, University of Colorado, Boulder, Colorado 80309 — Three genomic-like material design approaches are explored for finding energy relevant semiconductors: (i) *Search of nanostructure combinations leading to intermediate band solar cells*: Within the ideology of intermediate band solar cells (IBSC) based on quantum dots, it is presently unknown which combination of dot material + matrix material + substrate satisfies the energetic criteria enabling IBSC. Using the modern theory of nano structures (based on atomistic pseudo potentials in plane waves), we examine various combinations, finding that some of the “usual suspect” long believed to be ideal, are, in fact inappropriate. (ii) *Finding new inorganic absorbers with first-principles*: Standard compilations of inorganic compounds reveal thousands of candidate materials that were unexplored for their potential as PV absorbers, among others, because of the absence of a quantifiable “Design Principle” that sorts out various materials. The common Schockley - Queisser criteria gives a universal, gap vs efficiency curve which does not distinguish different types of gaps (direct-allowed vs direct-forbidden vs-indirect) nor does it account for non radiative recombination. A simple treatment, called “Spectroscopically Limited Maximum efficiency” (SLME) accounts for such factors and can be calculated for hundreds of compounds (using the GW approach), providing insight into previously unrecognized candidates, as well as to the mechanisms at work causing absorption enhancement. (iii) *Inverse Band structure search for direct gap Si-Ge nano structures*: Using a genomic approach to pseudo potential configurational search we identify a Si-Ge nano structures that have direct band gaps, solving the long-standing dilemma of crystalline Column IV absorbers. In collaboration with L. Yu, V. Popescu, J.W. Luo and M. Davezac.

3:06PM L27.00002 Photovoltaic effect for narrow-gap Mott insulators, EFSTRATIOS MANOUSAKIS, Department of Physics, Florida State University, Tallahassee, Florida, 32306 — Solar cells, based on conventional band-semiconductors, have low efficiency for conversion of solar into electrical energy. The main reason is that the excess energy of the photon absorbed by an electron/hole pair beyond the band-gap becomes heat through electron-phonon scattering and phonon emission; through these processes electrons and holes relax to their band edges within a characteristic time scale of the order of $10^{-12} - 10^{-13}$ secs. We will discuss that a narrow-gap Mott insulator can produce a significant photovoltaic effect and, more importantly, if appropriately chosen it can lead to solar cells of high efficiency. In this case, a single solar photon can produce multiple electron/hole (doublon/hole) pairs, an effect known as impact ionization, faster than other relaxation processes such as relaxation through phonons. It has been proposed previously that this process could lead to an efficient solar cell using band-gap semiconductors; however, the characteristic time-scale for impact ionization is comparable to that for electron-phonon relaxation in band-gap semiconductors. The reason that a Mott insulator can behave differently is that the large Coulomb repulsion present in a Mott insulator leads to a large enhancement of the impact ionization rate. Provided that this enhancement does occur in an appropriately chosen Mott insulator, it can be demonstrated that the efficiency can improve significantly over conventional band-insulators. At present, we are doing calculations on specific transition-metal-oxide based materials believed to be Mott-insulators using extensions of the density functional theory (hybrid functionals) in combination with many-body perturbation theory. Our goal is to determine a promising candidate with suitable band structure and transition matrix elements leading to fast transition rates for impact ionization to occur in a time-scale faster than other relaxation processes.

3:42PM L27.00003 Quantum Dot Solar Cells, VLADIMIR BULOVIC, Massachusetts Institute of Technology —

4:18PM L27.00004 Shaping anomalous molecular electroluminescence by resonant nanocavity plasmons¹, ZHENCHAO DONG, University of Science and Technology of China — Exciton formation and decay of molecules near metallic nanostructures is important for the control of energy conversion at the nanoscale and plasmonic devices. While extensive research has been carried out to such end using photon-excited techniques, complementary insights into the optical transitions and plasmon-exciton coupling can be obtained through electron excitations by a scanning tunneling microscope [1]. In this talk, we shall describe such reversed process of light-to-electricity conversion through single-molecule electroluminescence that demonstrates the critical role of nanocavity plasmons in the generation and decay of molecular excitons. By tuning the resonant interplay between molecular excitons and plasmons in nearby metallic nanostructures, we demonstrate that plasmons can do much more beyond intensity enhancement [2]: the emission band of molecular fluorescence can be effectively tuned by resonant nanocavity plasmons. New optoelectronic effects including resonant hot-electroluminescence and upconversion electroluminescence from higher vibronic levels of singlet excited states have been realized for porphyrin molecules near metals, which breaks the Kasha's rule and conventional Franck-Condon distribution. The highly confined nanocavity plasmons can behave like a strong coherent optical source with tunable frequency, and can be used to actively control the radiative channels of molecular emitters near metals over a wide spectral range. We shall also discuss critical factors that are responsible for the realization of single-molecule electroluminescence [3].

4:54PM L27.00005 Quantum Photocell: Using Quantum Coherence to Reduce Radiative Recombination and Increase Efficiency, MARLAN SCULLY, Texas A&M and Princeton Universities — Laser and photocell quantum heat engines (QHEs) are powered by thermal light and governed by the laws of quantum thermodynamics. We here show how to use quantum coherence (PRL, 104, 207701 (2010)) induced by quantum noise (PNAS, 108, 15097 (2011)) to improve the efficiency of a laser or photocell QHE. Surprisingly, this coherence can be induced by the same noisy (thermal) emission and absorption processes that drive the QHE. Furthermore, this noise-induced coherence can be robust against environmental decoherence. Application of the ideas to photosynthesis (Nature, 446, 782-786 (2007)) will also be discussed.

Tuesday, February 28, 2012 2:30PM - 5:30PM –
Session L28 FIAP GERA DMP: Electricity-to-Light Conversion: Solid State Lighting 258C

2:30PM L28.00001 Auger recombination in gallium arsenide from first principles¹, DANIEL STEIAUF, Materials Department, University of California, Santa Barbara, EMMANOUIL KIOUPAKIS, Materials Department, UC Santa Barbara; Materials Science and Engineering, University of Michigan, Ann Arbor, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara — GaAs and its alloys are technologically important materials for solid-state optoelectronic devices such as LEDs and lasers. The internal quantum efficiency of these devices, defined as the fraction of electron-hole pairs converted to photons, is limited by loss mechanisms. Of particular importance at high carrier densities is Auger recombination, a non-radiative process where the energy and momentum of the recombining electron-hole pair is transferred to a third carrier. Here we use density functional theory to study Auger recombination in GaAs from first principles. When considering Auger recombination due to Coulomb interaction only, the calculated rate is too small and cannot account for the experimental observations. However, once additional electron-phonon interactions are included, the theoretical recombination rate increases towards the experimental value. Our work provides insight into the microscopic origins of the loss in III-V LEDs at high injected-carrier densities, and in the mechanisms governing Auger recombination rates in general.

¹This work was supported by DOE.

2:42PM L28.00002 Surface Energies and Cracking in GaN¹, CYRUS E. DREYER, CHRISTIAN CARBOGNO, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara — Cracking is one of the biggest limitations to growing thick GaN single crystals and films, caused by the buildup and release of strain energy. Cracking occurs along preferential crystallographic planes in the GaN wurtzite structure, and depends on the tensile stress on the given plane and the energetic balance between the strain energy released from the crack formation versus the cleaved surface area created. It is also well known that the equilibrium shape of a crystal is largely determined by its surface free energy. Therefore, to correctly predict the stresses under which certain planes will crack and aid in understanding crystal growth, knowledge of the absolute surface energy is required. We use first-principles calculations based on density functional theory and a hybrid functional to determine the surface energy for the nonpolar {11-20} *a*- and {10-10} *m*-planes, as well as to explore approximations to the surface energies of the polar {0001}/{000-1} *c*-planes in GaN. The effects of structure relaxations and reconstructions are fully taken into account, and the results are discussed in the light of available experimental observations.

2:54PM L28.00003 Crystalline Fe films grown on non-polar GaN: theory and experiment, STEVEN ERWIN, Naval Research Laboratory, CUNXU GAO, CLAUDIA RÖDER, JONAS LAEHNEMANN, OLIVER BRANDT, Paul Drude Institute, Berlin — We report an unexpected mechanism by which single crystals of Fe grow epitaxially on *M*-plane GaN substrates despite having a different crystal structure and strongly mismatched lattice constant. A simple model is proposed in which one material tilts out of the interface plane to create a coincidence-site lattice that balances two competing geometrical criteria—low residual strain and short coincidence-lattice period. We apply this model, along with complementary first-principles total energy calculations, to the interface formed by molecular-beam epitaxy of cubic Fe on hexagonal GaN and find excellent agreement between theory and experiment. The success of this model also suggests a strategy for growing non-polar GaN films on a substrate material with a suitably chosen Miller index. One very promising material is Si, which is already in widespread use as a flat substrate for GaN/Si epitaxy despite high dislocation densities. The next talk will present our predictions of the most promising Si(*hkk*) substrates for growing non-polar GaN with high crystalline quality.

3:06PM L28.00004 Crystalline non-polar GaN films grown on vicinal Si: theoretical predictions¹, ALEX KUTANA, STEVEN ERWIN, Naval Research Laboratory, CENTER FOR COMPUTATIONAL MATERIALS SCIENCE TEAM — The ability to grow highly crystalline non-polar GaN films on silicon substrates would be an important advance in optoelectronic device fabrication. We propose a simple strategy to achieve this goal: tilting the Si substrate out of interface plane to provide a good lattice match between the film and substrate. We consider epitaxial interfaces between *M*-plane GaN and arbitrary Si(*hkk*) substrates. Using the model introduced in the previous talk, we downselect these substrates using two geometric criteria—low residual strain and short coincidence-lattice period. We then use density-functional theory to compute the interface formation energies of these selected candidates, which include Si(001), (112), (113), (114), and (223). We find that *M*-plane GaN films have the lowest interface formation energy when grown on the (113) and (112) surfaces. The formation energies are significantly lower than on Si(001) or (111), the substrates most often used for growing GaN. On this basis we predict that Si(113) and (112) substrates will enable growth of non-polar GaN films of higher crystalline quality than can be attained on Si(001) or (111).

¹Part of this work was performed under the ASEE program at NRL.

3:18PM L28.00005 Hybrid functional studies of stability and diffusion of hydrogen in Mg-doped GaN, JI-SANG PARK, K.J. CHANG, Department of Physics, Korea Advanced Institute of Science and Technology — Nitride semiconductors are known to suffer from low p-type doping efficiency due to the high activation energy of Mg acceptors and the compensation of hole carriers. To enhance hole carrier concentration, the hydrogen co-doping method is widely used, in which hydrogen is intentionally doped with Mg dopants and removed by subsequent thermal annealing. In this work, we perform first-principles density functional calculations to study the stability and diffusion of hydrogen in Mg-doped GaN. For the exchange-correlation potential, we employ both the generalized gradient approximation (GGA) proposed by Perdew, Burke, and Ernzerhof and the hybrid density functional of Heyd, Scuseria, and Ernzerhof. We examine the diffusion pathways and dissociation barriers of H from the Mg-H complex using the nudged elastic band and dimer methods. We compare the results of the GGA and hybrid density functional calculations for the stability of various H interstitial configurations and the migration barriers for H diffusion. Finally, using the calculated migration barriers as inputs, we perform kinetic Monte Carlo simulations for the dissociation of the Mg-H complex and find that the Mg acceptors are activated by thermal annealing up to 700-800 °C, in good agreement with experiments.

3:30PM L28.00006 Electroluminescent Schottky Diodes Fabricated Using Plasma Ion Implantation¹, SARAH PURDY, University of Saskatchewan, MARCEL RISCH, Massachusetts Institute of Technology, PHILLIP DESAUTELS, SED Systems, MICHAEL BRADLEY, University of Saskatchewan — Carbon-implanted silicon light-emitting Schottky diodes were produced by Plasma Ion Implantation (PII) in an RF ICP plasma chamber using methane feedstock gas. The electroluminescence spectrum of the devices was fitted with a set of Gaussian peaks corresponding to known emission centers including disordered silicon (broad white background), buried porous silicon and hydrogenated carbon-rich silicon. Some of the emission peaks exhibit a peak intensity at a drive current density of several A/cm², followed by a drop in emission intensity at higher drive current densities. In this presentation we discuss a possible model for this observed drop in electroluminescent intensity.

3:42PM L28.00007 Sub-250nm room-temperature optical gain from AlGaIn/AlN multiple quantum dot structures, EMANUELE FRANCESCO PECORA, WEI ZHANG, Department of Electrical and Computer Engineering and Photonics Center, Boston University, LIN ZHOU, DAVID J. SMITH, Department of Physics, Arizona State University, JIAN YIN, ROBERTO PAIELLA, LUCA DAL NEGRO, THEODORE D. MOUSTAKAS, Department of Electrical and Computer Engineering and Photonics Center, Boston University — There are many pressing but yet unrealized applications for optoelectronic materials and devices that can function well into the deep-UV. Group-III nitrides, in particular AlGaIn, are particularly suited to cover UV spectral ranges. An intense research effort is targeting the investigation and demonstration of deep-UV lasing from these materials. We developed AlGaIn/AlN MQWs by Molecular Beam Epitaxy under a novel growth mode that introduces band structure potential fluctuations and high-density of nanocluster-like features within the AlGaIn wells. A characterization of this material will be presented. The Variable-Stripe Length technique, a well-established methodology for measuring optical gain coefficient, is applied for a detailed quantification of the gain properties and polarization. We demonstrate optical gain in AlGaIn nanostructures down to 230 nm at room temperature with a maximum net modal gain value of 118 ± 9 cm⁻¹ at the highest excitation fluence of 15 μ J/cm². The optical gain threshold was measured to be 5 ± 1 μ J/cm² from which we estimate the density of optically excited carriers at the threshold to be 1.4×10^{17} cm⁻³, which is two orders of magnitude lower than what currently achieved by quantum well structures. Moreover, we demonstrate that gain is TE-polarized.

3:54PM L28.00008 Room temperature low threshold stimulated emission of electron beam-pumped AlGaIn-based deep UV laser structures emitting below 250 nm, A. NIKIFOROV, W. ZHANG, Boston University, J. WOODWARD, Boston, J. YIN, E. PECORA, Boston University, L. ZHOU, Arizona State University, L. DAL NEGRO, R. PAIELLA, Boston University, D. SMITH, Arizona State University, T. MOUSTAKAS, A. MOLDAWER, Boston University — The development of semiconductor lasers, operating in the deep UV, will find a number of applications such as identification of biological and chemical agents, non-line-of-sight free space communications and point of site medical diagnostics. In this paper we report the growth of QW laser structures in the configuration 6H-SiC / AlN / AlGaIn - AlN MQWs / AlN by PAMBE. A novel growth mode was developed in which arriving active nitrogen species and aluminum atoms dissolve in the excess liquid Ga covering the surface of the growing film and incorporate into the AlGaIn film from the liquid phase. This liquid phase epitaxy (LPE) growth was found to introduce band structure potential fluctuations and high-density of nanocluster-like features within the AlGaIn wells. The structure and microstructure of these devices were investigated by AFM, XRD and TEM and their emission properties were investigated by electron beam pumping at room temperature. The investigated laser structures were found to emit in the 235-250 nm range and stimulated emission was observed at a threshold power of 20-40 KW / cm². This low threshold value is attributed to nanoclusters-like features in the wells.

4:06PM L28.00009 Electronic transport through InGaIn heterojunctions¹, MATHIEU CÉSAR, DONPING LIU, HONG GUO, McGill University — InGaIn nanowires have recently sparked great interest for their high tunability and potential in applications like solid-state lighting (LEDs) and concentrated photovoltaics. Determination of device characteristics from first principles modeling is of great importance. In order to treat quantum transport properties of nanoelectronic devices with atomistic disorder, a non-equilibrium vertex correction (NVC) theory was recently developed and implemented into the Keldysh non-equilibrium Green's function (NEGF) -based density functional theory (DFT). NEGF-DFT-NVC enables the representation of disordered structures such as the InGaIn heterojunction under non-equilibrium conditions. Electronic and transport properties of a InGaIn heterojunction are investigated using this accurate ab initio method.

4:18PM L28.00010 Effects of Internal Fields on the Optical Emission in Nanostructured III-N LEDs, KRISHNA YALAVARTHI, SASI SUNDARESAN, KY MERRILL, SHAIKH AHMED, Southern Illinois University — Nanostructured optical emitters can accommodate a broader range of lattice mismatch, be used in full-solar-spectrum light emitting diodes, and provide higher temperature stability of the threshold current and the luminescence. However, strong quantum confinement and certain symmetry-lowering mechanisms (caused by various internal fields) lead to pronounced optical polarization anisotropy and strong suppression of interband transitions in these structures. The objective of this work is to study the competing effects of various internal fields on the electronic structure and optical properties of nanostructured III-N LEDs. A multiscale approach has been employed where: 1) the NEMO 3-D tool is used to calculate the atomistic strain distribution and one-particle electronic states within a $sp^3s^*d^5$ tight-binding framework, and 2) the outputs from NEMO 3-D are then coupled to the Synopsys TCAD tool to determine the terminal electrical and optical properties of the device.

4:30PM L28.00011 Accurate first-principles calculation of the rare earth crystal field, FEI ZHOU, VIDVUDS OZOLINS, UCLA — Rare earth (RE) doped wide band-gap semiconductors play an important role in solid state lighting. Many aspects of the performance of these materials are characterized and determined by the f -electron crystal field (CF). However, CF effects are usually rather small for f electron: the CF splitting is at the order of 0.1 eV, compared to several eV for d -electrons. Therefore accurate theoretical description of RE crystal field is challenging. We present a first-principles method of CF calculation based on an improved LDA+U method. By careful cancellation of errors, the method can reach relatively high accuracy for the CF parameters. As a demonstration we calculate the experimentally well-characterized RE:LaF₃ system, which has low point-group symmetry and a large number of CF parameters, representing a stringent test of theory. The predicted CF excitation energies of Ce:LaF₃ agree within about 10 meV with experiment, and within several meV if the errors in the free-ion parameters are excluded. Work is underway to apply the method to other materials for solid-state lighting and laser applications.

4:42PM L28.00012 The role of extended defects in Nitride Semiconductors on the performance of optoelectronic devices, T. MOUSTAKAS, Boston University — The question is why nitride semiconductors, which are plagued by high concentration of extended defects, produce efficient minority carrier optoelectronic devices. The equilibrium phase of these materials is the wurtzite and the metastable phase is the zinc blende. However, since the enthalpy of formation of these two structures differ by only a few meV, the conversion from one to the other can occur easily by the creation of stacking faults on the close packed planes. Thus, stacking faults are one of the most abundant defects in these materials even when they are grown homoepitaxially. Since the basal plane stacking fault is the equivalent of a monolayer of a cubic domain and since the energy band gaps of the wurtzite and their cubic counterparts differ by about 0.2 eV, one expects that stacking faults introduce band structure potential fluctuations. Such fluctuations are beneficial to the performance of lasers and LEDs since they lead to exciton localization and efficient radiative recombination. Other types of abundant defects in heteroepitaxially grown materials are threading dislocations. The insensitivity of the performance of LEDs and lasers to such defects is due to the strong ionicity of these materials as well as to the deep band structure potential fluctuations in the InGaN and AlGaN alloys. Due to the strong ionicity the surface states at free surfaces and dangling bonds in edge dislocations have moved towards the band edges and act as traps rather non-radiative recombination centers.

4:54PM L28.00013 Surface scattering from ceramic phosphors, ALAN LENEFF, JOHN KELSO, CHRISTOPHER PETERS, OSRAM SYLVANIA Inc — Scattering from phosphor converters and epitaxial surfaces is critical for solid state lighting device performance. Volume and surface scattering in solid state lighting devices can play a critical role in efficiency/efficacy, color points, and color angular consistency. Surface scattering in particular has not been well characterized in solid state lighting devices and can be complex to model. Because large angle scattering is important in lighting applications, surface scattering models generally require vector electromagnetic theory to avoid ambiguities often associated with scalar theory at these angles. Furthermore, surface features are often on the order of a few wavelengths, bringing ray tracing approaches into question. In this work, experimental angular scattering measurements are made on ceramic phosphor components where surface scattering dominates. The surface ceramic grain structure is responsible for the scattering. The results are compared to approximate statistical vector theory predictions that use the height autocorrelation functions as input. The autocorrelation measurements were derived from atomic-force microscopy topography measurements. Resulting predictions are in fairly good agreement with measurements.

5:06PM L28.00014 Light emission from electrically stressed ZnO nanorods, LUCA LUCERA, LHACENE ADNANE, KADIR CIL, VENKATA MANTHINA, ALEXANDER AGRIOS, HELENA SILVA, ALI GOKIRMAK, University of Connecticut — Zinc oxide (ZnO) nanorods were grown on various substrates by a chemical growth process based on a ZnO seed solution, and starting from Zinc acetate (ZnAc) material. The nanorods were grown on insulating silicon (low doped) and oxidized silicon substrates, and also over patterned conducting (highly-doped) nanocrystalline silicon microwires. When high voltage is applied directly to the ZnO film using tungsten needles (~ 50 -60 V across ~ 5 -10 μm), high intensity blue and white light emission is observed, both in air and under high vacuum (10^{-4} - 10^{-5} Torr). Blue light appears as broad bright flashes covering a large area whereas white light is more localized and appears to come from individual nanostructures. The results suggest a combination of electroluminescence and photoluminescence processes that take place after an electrical breakdown (possibly across individual ZnO nanorods) that is observed as an exponential increase in current. Percolative conduction and light paths are also observed during the measurements. Measurements of the ZnO films of rods on conducting silicon substrate give more repeatable results, likely due to the higher probability of conducting paths between the two probes. The electrical stress results in significant self-heating and modification of the ZnO nanostructures and the contacts.

5:18PM L28.00015 A First-Principles Analysis of the Crystal Structure, Band Gap Energy, Polarization, and Piezoelectric Properties of ZnO-BeO Solid Solutions, LIANG DONG, S. PAMIR ALPAY, University of Connecticut — The electrical properties, the spontaneous polarization, and the piezoelectric response of ZnO can be tailored by alloying ZnO with BeO for various optoelectronics applications. We present here the results of a study that employs density functional theory to analyze the crystal structure, the band structure, elastic constants, spontaneous polarization, and piezoelectric properties of $\text{Zn}_{1-x}\text{Be}_x\text{O}$ solid solutions. Our findings indicate that $\text{Zn}_{1-x}\text{Be}_x\text{O}$ alloys may have a different crystal structure than the end components ZnO and BeO that crystallize in the prototypical wurtzite structure (P6₃mc). It is shown that orthorhombic lattices with Pmn2₁, Pna2₁, or P2₁ structures may have lower formation energies than the wurtzite lattice at a given Be composition. The band gap energies of $\text{Zn}_{1-x}\text{Be}_x\text{O}$ in the wurtzite and the orthorhombic structures are nearly identical and the bowing of the band gap energy increases with increasing Be concentration. The spontaneous polarization of $\text{Zn}_{1-x}\text{Be}_x\text{O}$ in the orthorhombic lattice is markedly larger compared to the wurtzite structure while the piezoelectric polarization in the wurtzite and orthorhombic structures varies linearly with the Be concentration.

Session L29 GQI: Focus Session: Semiconductor Qubits - Single and Multi-Qubit Demonstrations 259A

2:30PM L29.00001 Coherent control and detection of spin qubits in semiconductor with magnetic field engineering¹

YASUHIRO TOKURA, NTT Basic Research Laboratories — Electrical control and detection of the spin qubits in semiconductor quantum dots (QDs) are among the major rapidly progressing fields for possible implementation of scalable quantum information processing. Coherent control of one-[1-3] and two-[4,5] spin qubits by electrical means had been demonstrated with various approaches. We have used an engineered magnetic field structure realized with proximal micro-magnets to transduce the spin and charge degrees of freedom and to selectively address one of the two spins [3]. We have demonstrated an all-electrical two-qubit gate consisting of single-spin rotations and interdot spin exchange in double QDs. A partially entangled output state is obtained by the application of the two-qubit gate to an initial, uncorrelated state. Our calculations taking into account of the nuclear spin fluctuation show the degree of entanglement. Non-uniform magnetic field also enables spin selective photon-assisted tunneling in double QDs, which then constitutes non-demolition spin read-out system in combination with a near-by charge detector [6].

3:06PM L29.00002 Coherent Singlet-Triplet Oscillations in a Silicon-based Double Quantum

Dot, BRETT MAUNE, MATTHEW BORSELLI, BIQIN HUANG, THADDEUS LADD, PETER DEELMAN, KEVIN HOLABIRD, ANDREY KISELEV, IVAN ALVARADO-RODRIGUEZ, RICHARD ROSS, ADELE SCHMITZ, MARKO SOKOLICH, CHRISTOPHER WATSON, MARK GYURE, ANDREW HUNTER, HRL Laboratories LLC — We have performed coherent spin manipulation of a singlet-triplet qubit in a Si/SiGe double quantum-dot device fabricated in an undoped heterostructure. A charge stability diagram showed that the (0,0) charge state was reached and Pauli spin blockade was detected at the (1,1)-(0,2) anticrossing. A singlet-triplet splitting of $\sim 140 \mu\text{eV}$ in the (0,2) charge state provided a read-out window sufficiently wide for singlet-triplet discrimination. We used the S/T₋ spin funnel, Rabi oscillation, and T_2^* pulsing experiments to measure (1,1) exchange energies spanning $\sim 0.6\text{--}700 \text{ neV}$ over a large detuning range and measured a T_2^* of 360 ns, consistent with theoretical expectations for our device. Sponsored by the United States Department of Defense. Approved for Public Release, Distribution Unlimited. 3:18PM L29.00003 Tunable singlet-triplet splitting in a few-electron Si/SiGe quantum dot

ZHAN SHI, University of Wisconsin-Madison, CHRISTIE SIMMONS, Massachusetts Institute of Technology, JONATHAN PRANCE, JOHN GAMBLE, MARK FRIESEN, DONALD SAVAGE, MAX LAGALLY, SUSAN COPPERSMITH, MARK ERIKSSON, University of Wisconsin-Madison — The singlet-triplet energy splitting in a double quantum dot is an important parameter for singlet-triplet qubits, because it determines the energy gap for both initialization and readout. This splitting can also be used to perform gate operations in a newly proposed hybrid qubit [1]. We describe measurements in which we tune the singlet-triplet energy splitting by changing gate voltages on a Si/SiGe double quantum dot [2]. We argue that the energy is changed largely by lateral translation of the dot, which changes the local atomic structure that the electrons experience in the quantum dot, leading to variations in the valley-orbit coupling. We present calculations indicating the experimental results are consistent with the first excited state of the dot having non-zero valley-orbit coupling. [1] Z. Shi, et al., e-print: <http://lanl.arxiv.org/abs/1110.6622>. [2] Z. Shi, et al., e-print: <http://lanl.arxiv.org/abs/1109.0511>.

3:30PM L29.00004 Electric dipole spin resonance measurement of spin-orbit anisotropy in InSb nanowire quantum dots

SERGEY FROLOV, STEVAN NADJ-PERGE, VLAD PRIBIAG, JOHAN VAN DEN BERG, TU Delft, SEBASTIEN PLISSARD, TU Eindhoven, ERIK BAKKERS, LEO KOUWENHOVEN, TU Delft — Indium antimonide nanowires are considered a leading platform for the generation of Majorana fermion bound states, and as hosts of spin-orbit quantum bits based on single electrons. Both efforts are motivated by the strong spin-orbit interaction in the bulk InSb. Here we present measurements of the strength and orientation of the effective spin-orbit magnetic field in InSb nanowire double quantum dots. Spin-orbit interaction induces avoided level crossings between triplet (1,1) and singlet (0,2) double dot states. These avoided crossings are observed in the spectrum of the electric dipole spin resonance performed on strongly-coupled double dots. We find that the spin-orbit field is oriented perpendicular to the nanowire axis, and parallel to the substrate plane. This orientation is consistent with Rashba spin-orbit interaction and is favorable for Majorana experiments. The strength of spin-orbit interaction is characterized by the spin-orbit length which we estimate to be 200 nm. This translates into a temperature scale of 3K for the observation of Majorana states.

3:42PM L29.00005 Coherent manipulation of spin-orbit quantum bits in InSb nanowires

STEVAN NADJ-PERGE, JOHAN VAN DEN BERG, SERGEY FROLOV, VLAD PRIBIAG, TU Delft, SEBASTIEN PLISSARD, TU Eindhoven, ERIK BAKKERS, LEO KOUWENHOVEN, TU Delft — Semiconductor nanowires with strong spin-orbit coupling are becoming an attractive platform for spin-based quantum computation. Here we demonstrate coherent transitions between spin-orbit doublet states of individual electrons in indium antimonide (InSb) nanowire quantum dots induced by gigahertz-frequency electric fields. The spin-orbit doublet states form a qubit which initialization and detection relies on Pauli blockade in the double quantum dot (1,1) configuration. The maximum Rabi frequency exceeds 100 MHz and more than 10 periods of coherent oscillations are observed. We estimate fidelities of single qubit rotations and analyze qubit decoherence times by performing spin echo sequence. The two qubits in a double quantum dot are individually addressable due to different g-factors. The coupling between the qubits can be mediated by exchange interaction. The fidelities of single qubit rotations are sufficiently high to permit the implementation of two-qubit quantum gates such as controlled-not (C-NOT) or controlled-phase (C-Phase).

3:54PM L29.00006 Spin Relaxation and Manipulation in Spin-orbit Qubits¹

MASSOUD BORHANI, Laboratory for Physical Sciences, XUEDONG HU, SUNY at Buffalo — We derive a generalized form of the Electric Dipole Spin Resonance (EDSR) Hamiltonian in the presence of the spin-orbit interaction for single spins in an elliptic quantum dot (QD) subject to an arbitrary (in both direction and magnitude) applied magnetic field. We predict a nonlinear behavior of the Rabi frequency as a function of the magnetic field for sufficiently large Zeeman energies, and present a microscopic expression for the anisotropic electron g-tensor. Similarly, an EDSR Hamiltonian is devised for two spins confined in a double quantum dot (DQD). Finally, we calculate two-electron-spin relaxation rates due to phonon emission, for both in-plane and perpendicular magnetic fields. Our results have immediate applications to current EDSR experiments on nanowire QDs, g-factor optimization of confined carriers, and spin decay measurements in DQD spin-orbit qubits.

4:06PM L29.00007 Spin coherence in Multi-electron GaAs double dots¹, ANDREW P. HIGGINBOTHAM, FERDINAND KUEMMETH, CHRISTIAN BARTHEL, CHARLES M. MARCUS, Department of Physics, Harvard University, MICAH P. HANSON, ARTHUR C. GOSSARD, Materials Department, University of California, Santa Barbara — Experimental investigation of spin manipulation and readout in multi-electron double quantum dots is reported. For occupations of order 10 electrons, spin blockade in both transport and pulsed-gate measurements is identified. Exchange rotations, dynamical decoupling, S/T+ beamsplitter experiments, and single-shot readout can all be implemented similar to the single-electron case. These demonstrations are relevant for the practical operation and scaling of GaAs spin qubits.

¹Support from IARPA/MQCO, DARPA/QuEST, DOE SCGF, NSF-MWN, and Harvard University is acknowledged.

4:18PM L29.00008 Fast Exchange Oscillations in Quantum Dot Spin Qubits, SHANNON HARVEY, MICHAEL SHULMAN, OLIVER DIAL, Harvard University, HENDRIK BLUHM, RWTH Aachen University, VLADIMIR UMANSKY, Weizmann Institute of Science, AMIR YACOBY, Harvard University — The exchange splitting, J , is an important tool in semiconductor spin qubits, as it can drive both single qubit rotations and two qubit entangling operations. However, qubits operating under exchange can be dephased by electrical noise, as J is a function of the local electrostatic environment. We investigate the exchange interaction in a singlet-triplet qubit created in double quantum dot by measuring exchange oscillations ranging in frequency over three orders of magnitude. In particular, we resolve exchange oscillations at frequencies up to 30GHz, where both electrons occupy the same quantum dot. Here, J saturates to approximately the singlet-triplet splitting, and no longer depends on the electrostatic environment. In this regime exchange oscillations are insensitive to electrical noise. Since semiconductor spin qubits are usually limited by dephasing, these potentially dephasing-free exchange oscillations offer a new regime for studying quantum control in spin qubits.

4:30PM L29.00009 Coherent electrical manipulation of a quantum dot qubit, MATTHEW POOLEY, RAJ PATEL, ANTOINE BOYER DE LA GIRODAY, IAN FARRER, CHRISTINE NICOLL, DAVID RITCHIE, Cavendish Laboratory, Cambridge University, J. J. Thomson Avenue, Cambridge, CB3 0HE, UK, ANTHONY BENNETT, MARK STEVENSON, MARTIN WARD, NIKLAS SKOLD, ANDREW SHIELDS, Toshiba Research Europe Limited, Cambridge Research Laboratory, 208 Science Park, Milton Road, Cambridge, CB4 0GZ, UK — We demonstrate the initialization and coherent manipulation of a spin-based qubit in a InAs quantum dot (QD), implementing a spin-flip gate with a fidelity of 97%. We will discuss new measurements on the effect of fluctuating nuclear magnetic field which have implications on state initialisation, operation fidelity, and qubit storage time. An exciton spin-state is initialised by absorption of an incident polarised photon. The exciton state of QDs has two spin-eigenstates separated by fine-structure splitting (s), which can be manipulated using applied electric field. Superposition spin-states precess around the Bloch-sphere with an angular frequency $|s|/\hbar$. An electric field is used to vary the rate and axis of the spin-state precession, and thus control the time-evolution of the stored qubit. Nuclear magnetic field fluctuations induce additional random variations in s , the effects of which we investigate to understand the ideal initialisation and storage regime. Subsequent radiative decay maps the spin of the exciton onto the polarisation of the emitted photon. These results demonstrate a photon-spin interface, which has potential applications in scalable optical quantum computing schemes.

4:42PM L29.00010 Fabrication and Characterization of Si MOS-Based Triple Quantum Dot Devices, HONG PAN, HONGWEN JIANG, University of California, Los Angeles, RUSKO RUSKOV, CHARLES TAHAN, Laboratory for Physical Sciences, UNIVERSITY OF CALIFORNIA, LOS ANGELES COLLABORATION, LABORATORY FOR PHYSICAL SCIENCES COLLABORATION — We have fabricated electrostatically defined, few electron triple quantum dot (TQD) devices in a silicon metal-oxide-semiconductor structure. The devices show good electrical stability and gate controllability. We have obtained charge stability diagrams for identifying the charging states of the TQD. In this talk, we will describe the technical challenges in the TQD fabrication and present the experimental results of tuning three dots into a resonance. We will also discuss the prospect of these devices to encode a spin qubit that uses exchange interaction alone and possible ways to perform coherent manipulations within the tunable range of inter-dot tunneling of these devices. The work is supported by ARO.

4:54PM L29.00011 Pairwise control of exchange interaction between individual spins in a triple quantum dot, G. GRANGER, SERGEI STUDENIKIN¹, G. AERS, A. KAM, P. ZAWADZKI, L. GAUDREAU, R. WASILEWSKI, National Research Council of Canada, M. PIORO-LADRIERE, University of Sherbrooke, A. SACHRAJDA, National Research Council of Canada — The original spin qubit proposal [1] suggested a linear array of spins for quantum computations and the exchange interaction for 2 qubit operations. An essential component of the proposal was the ability to control pairwise the exchange interaction between neighbouring pairs of spins. In this work we experimentally demonstrate such a pairwise control of the exchange interaction between three spins localized in a triple quantum dot (TQD) device. The TQD potential was formed using electrostatic lateral split-gate technology on a GaAs/GaAlAs heterostructure with a high-mobility two-dimensional electron gas [2]. We employ fast pulsing technique based on the Landau-Zener-Stueckelberg (LZS) approach for creating and manipulating coherent superpositions of three spin quantum states [3]. We show that we are able to maintain coherence when increasing the exchange coupling of one spin with another while simultaneously decreasing its coupling with the third.

¹Presenting this work

5:06PM L29.00012 Entanglement of Two Singlet-Triplet Qubits¹, MICHAEL SHULMAN, OLIVER DIAL, SHANNON HARVEY, Harvard University, HENDRIK BLUHM, RWTH Aachen University, VLADIMIR UMANSKY, Weizmann Institute of Science, AMIR YACOBY, Harvard University — Semiconductor spin qubits are promising candidates for quantum computation because of their potential for scalability. However, their weak interaction with the environment, which leads to long coherence times, makes two-qubit operations challenging. We perform the first two-qubit operation between singlet-triplet qubits. The two qubit operation relies on the capacitive coupling between two adjacent qubits to generate a CPHASE gate. In order to combat low frequency noise we use a dynamically decoupled gate that maintains the two-qubit coupling while decoupling each qubit from its fluctuating environment. Using state tomography we measure the two-qubit density matrix and show that the operation produces the expected state. We extract a concurrence of 0.44 and a Bell state fidelity of 0.72, each providing definitive proof of entanglement.

¹This work is supported by IARPA, the NSA, and HRL.

5:18PM L29.00013 Two-axis Control and Readout of an Exchange-Only Spin Qubit in a GaAs Triple Quantum Dot¹, J. MEDFORD, Harvard University, J.M. TAYLOR, Joint Quantum Institute, NIST, B.D. ARMSTRONG, Harvard University, D.P. DIVINCENZO, RWTH Aachen, C.M. MARCUS, Harvard University, Niels Bohr Institute, University of Copenhagen, H. LU, A.C. GOSSARD, Materials Department, University of California, Santa Barbara — The initialization, full control, and readout of a GaAs triple quantum dot exchange qubit is demonstrated. Appropriate depletion gate design has enabled control and single-shot readout along multiple Bloch sphere axes in a three electron device. Rotations around both non-orthogonal control axes are projected along three separate Bloch sphere axes, and quality factors ($Q \equiv \omega/T_2^*$) of 500 are observed. Finally, we analyze decoherence and dynamical decoupling schemes unique to this system.

¹Support from IARPA MQCO, DARPA QuEST, and NSF Materials World Network.

Tuesday, February 28, 2012 2:30PM - 5:42PM – Session L30 GQI: Focus Session: Topologically Protected Qubits I 259B

2:30PM L30.00001 Non-Abelian Braiding of Lattice Bosons, ELIOT KAPIT, PAUL GINSPARG, ERICH MUELLER, Cornell University — We report on a numerical experiment in which we use time-dependent potentials to braid non-abelian quasiparticles. We consider lattice bosons in a uniform magnetic field within the fractional quantum Hall regime, where ν , the ratio of particles to flux quanta, is near $1/2$, 1 or $3/2$. We introduce time-dependent potentials which move quasiparticle excitations around one another, explicitly simulating a braiding operation which could implement part of a gate in a quantum computation. We find that different braids do not commute for ν near 1 and $3/2$, with Berry matrices respectively consistent with Ising and Fibonacci anyons. Near $\nu = 1/2$, the braids commute.

2:42PM L30.00002 Parafermion braid statistics in quasi-one-dimensional networks, DAVID CLARKE, JASON ALICEA, UC Irvine, KIRILL SHTENGEL, UC Riverside — One dimensional systems with Majorana zero modes at phase boundaries may be thought of as physical realizations of a discrete quantum wire model first put forth by Kitaev [1]. Proposed methods for braiding such Majorana fermions in one-dimensional wire networks [2] have greatly expanded the set of plausible avenues toward topological quantum computation. Recently, a generalization of the Kitaev model to parafermion modes has been developed.[3] Here, we describe the transport of such parafermion modes along the chain by the adiabatic transformation of the Hamiltonian, analogous to the transport of Majorana fermion modes. We determine the (braid) transformations of the ground state sector allowed by the adiabatic exchange of the parafermion modes in wire networks. We show that, as with Majorana fermions, none of the parafermion braid sets are universal for quantum computation. Certain parafermion chain models, unlike Majorana fermion systems, become universal with the addition of measurement operations. We discuss possible physical realizations of the parafermion models.

2:54PM L30.00003 Ettingshausen effect due to Majorana modes, CHANG-YU HOU, UC Riverside and Caltech, KIRILL SHTENGEL, University of California, Riverside, GIL REFAEL, California Institute of Technology, PAUL GOLDBART, Georgia Institute of Technology — Due to the presence of Majorana fermions (zero mode) at the vortex core of topological superconductor, each vortex carries an extra entropy $s_0 = k_B \ln[2]/2$ that is independent of temperature. Utilizing this special property of Majorana fermions, one can show that the edge states appearing at the edge of a topological superconductor can be cooled (heated) due to the motion of the vortices. We will also discuss possible experimental setups to observe this cooling thermoelectric mechanism tied with the extra entropy carried by the vortex.

3:06PM L30.00004 Quantum information transfer between topological and spin qubit systems, MARTIN LEIJNSE, KARSTEN FLENSBERG, Niels Bohr Institute and Nano-Science Center, University of Copenhagen — In this talk I will introduce a method to coherently transfer quantum information, and to create entanglement, between topological qubits and conventional spin qubits. The transfer method uses gated control to transfer an electron (spin qubit) between a quantum dot and edge Majorana modes in adjacent topological superconductors. Because of the spin polarization of the Majorana modes, the electron transfer translates spin superposition states into superposition states of the Majorana system, and vice versa. Furthermore, I will discuss how a topological superconductor can be used to facilitate long-distance quantum information transfer and entanglement between spatially separated spin qubits.

3:18PM L30.00005 Braiding anyons and communication between topological and non-topological systems¹, HAITAN XU, JACOB TAYLOR, JQI, University of Maryland-College Park and NIST — Quasi-particles with non-Abelian statistics are intriguing in both fundamental and applied physics. Here we propose a “proof of principle” experimental setup for braiding anyons and observing non-Abelian statistics using nearest-neighbor spin interactions inspired by the Kitaev honeycomb model. We also show an explicit method for teleportation between the topological and non-topological systems.

¹This work is supported by the NSF through the JQI Physics Frontier Center.

3:30PM L30.00006 Electrical manipulation of Majorana Fermions in an interdigitated superconductor-ferromagnet device¹, SHU-PING LEE, California Institute of Technology, JASON ALICEA, University of California, Irvine, GIL REFAEL, California Institute of Technology — We show that a topological phase supporting Majorana fermions can form in a 2DEG adjacent to an interdigitated superconductor-ferromagnet structure. An advantage of this setup is that the 2DEG can inherit the required Zeeman splitting and superconductivity from a single interface, allowing one to utilize a wide class of 2DEG's including the surface states of bulk InAs. We demonstrate that the interdigitated device supports a robust topological phase when the finger spacing λ is smaller than the Fermi wavelength λ_F . In this regime the electrons effectively see a “smeared” Zeeman splitting and pairing field despite the interdigitation. The topological phase survives even in the opposite limit $\lambda < \lambda_F$, though with a reduced bulk gap. We also describe how to electrically generate a vortex in this setup to trap a Majorana mode, which can be detected through edge tunneling spectroscopy.

3:42PM L30.00007 Interacting topological phases in multiband nanowires¹, ROMAN LUTCHYN, Microsoft Research, Station Q, University of California, Santa Barbara, CA 93106, MATTHEW P.A. FISHER, Department of Physics, University of California, Santa Barbara, California 93106 — We show that semiconductor nanowires coupled to an s-wave superconductor provide a playground to study effects of interactions between different topological superconducting phases supporting Majorana zero-energy modes. We consider quasi-one dimensional system where the topological phases emerge from different transverse subbands in the nanowire. In a certain parameter space, we show that there is a multi-critical point in the phase diagram where the low-energy theory is equivalent to the one describing two coupled Majorana chains. We study effect of interactions as well as symmetry-breaking perturbations on the topological phase diagram in the vicinity of this multi-critical point. Our results shed light on the stability of the topological phase around the multi-critical point and have important implications for the experiments on Majorana nanowires.

3:54PM L30.00008 Magnetic Control of Majorana Edge Modes in Topological Insulator-Ferromagnet-Superconductor Heterostructures, XIAOTING ZHOU, CHEN FANG, Purdue University, WEI-FENG TSAI, National Sun Yat-sen University, JIANGPING HU, Purdue University — A surface of a strong 3D topological insulator (TI) doped with ferromagnetic atoms can be spin-polarized and similar to a 2D quantum anomalous Hall state. If an s-wave superconductivity can be induced by proximity effect on such a surface, a 2D topological superconducting phase is obtained. If we consider a TI-ferromagnet(FM)-superconductor(SC) heterostructure, a 2D time-reversal symmetry breaking topological superconducting (TSC) phases with Majorana edge mode(s) will be realized. We demonstrate that the existence of the edge modes critically depend on the combination of the directions and magnitudes of spin polarization on all surfaces, and that a model describing the states on only one surface is insufficient. We find that the number, the positions and the chirality of these edge modes corresponding to various TSC phases can be engineered by controlling the ferromagnetism on different surfaces. Our results are obtained by self-consistently solving for the edge modes in a 3D lattice model for topological insulator in contact with an s-wave BCS superconductor. We also offer an analysis to illustrate the underlying physics, using an effective 2D theory for the surface states.

4:06PM L30.00009 Self-consistent Study of Majorana Fermions on a Topological Insulator Surface π Junction, MAHMOUD LABABIDI, ERHAI ZHAO, George Mason University — It has been proposed that a Josephson π junction that resides on the 2D surface of a 3D topological insulator (TI) is host to the Majorana fermion. We present a microscopic study of the π junction TI surface through self-consistent calculations with the Bogoliubov-de Gennes equation. We calculate the order parameter, the singlet correlation function along with the energy spectrum, local density of states, and the spectral function. We also show the evolution of the energy dispersion of Majorana fermion as a function of the TI chemical potential.

4:18PM L30.00010 Unpaired Majorana fermions in a layered topological superconductor¹, BABAK SERADJEH, Indiana University, Bloomington, EYTAN GROSFELD, Ben Gurion University — We study the conditions for the existence of unpaired Majorana modes at the ends of vortex lines or the side edges of a layered topological superconductor. We show that the problem is mapped to that of a general Majorana chain and extend Kitaev's condition for the existence of its nontrivial phase by providing an additional condition when a supercurrent flows in the chain. Unpaired Majorana bound states may exist in a vortex line that threads the layers if the spin-orbit coupling has certain in-layer components but, interestingly, only if a nonzero supercurrent is maintained along the vortex. We discuss the exchange statistics of vortices in the presence of unpaired Majorana modes and comment on their experimental detection.

¹Work supported by and performed at ICMT of UIUC, and published in Phys. Rev. B 83, 174521 (2011).

4:30PM L30.00011 Quantum point contact as a probe of a topological superconductor, MICHAEL WIMMER, ANTON AKHMEROV, JAN DAHLHAUS, CARLO BEENAKKER, Instituut-Lorentz, Universiteit Leiden, The Netherlands — We calculate the conductance of a ballistic point contact to a superconducting wire, produced by the s-wave proximity effect in a semiconductor with spin-orbit coupling in a parallel magnetic field. The conductance G as a function of contact width or Fermi energy shows plateaus at half-integer multiples of $4e^2/h$ if the superconductor is in a topologically nontrivial phase, supporting Majorana fermions. In contrast, the plateaus are at the usual integer multiples in the topologically trivial phase without Majorana fermions. Disorder destroys all plateaus except the first, which remains precisely quantized in the case of a topological superconductor, consistent with previous results for a tunnel contact. The advantage of a ballistic contact over a tunnel contact as a probe of the topological phase is the strongly reduced sensitivity to finite voltage or temperature.

4:42PM L30.00012 Genetic braid optimization for topological quantum computation, R.B. McDONALD, Department of Physics & Astronomy, Texas A&M University, H.G. KATZGRABER, Department of Physics & Astronomy, Texas A&M University, Department of Physics, ETH Zurich — In topologically-protected quantum computation quantum gates can be carried out by adiabatically braiding quasiparticles in two space dimensions, reminiscent of entangled world lines. Bonesteel *et al.* [Phys. Rev. Lett. 95, 140503 (2005)] showed recently how to find braids that yield a universal set of quantum gates. Mathematically, the problem of executing a gate becomes that of finding a product of the matrices in that set that approximates the gate, up to an error. To date efficient methods to compute these gates only strive to optimize for accuracy. We explore the possibility of using evolutionary (genetic) algorithms to efficiently find optimal braids while allowing the user to optimize for the relative utilities of accuracy and length. Furthermore, when optimizing for error only, the method can efficiently produce braids of error $\sim 10^{-6}$ outperforming brute force approaches.

4:54PM L30.00013 Quantum memory on topological spin glass, JEONGWAN HAAH, Institute for Quantum Information and Matter, Caltech, SERGEY BRAVYI, IBM Watson Research Center — We show that any topologically ordered local stabilizer model of spins in three dimensional lattices that lacks string logical operators can be used as a reliable quantum memory against thermal noise. It is shown that any local process creating a topologically charged particle separated from other particles by a distance R must cross an energy barrier of height $c \log R$. This property makes the model glassy. We devise an efficient decoding algorithm that should be used at the final read-out, and prove a lower bound on the memory time until which the fidelity between the outcome of the decoder and the initial state is close to 1. The memory time increases as $L^{c\beta}$ where L is the system size and β the inverse temperature, as long as $L < L^* \sim e^{\beta}$. Hence, the optimal memory time scales as $e^{c\beta^2}$. Our bound applies when the system interacts with thermal bath via a Markovian master equation. We give an example of a strictly local stabilizer code that satisfies all of our assumptions. We numerically verify for this example that our bound is tight up to constants.

5:06PM L30.00014 3D local qubit quantum code without string logical operator, ISAAC KIM, Institute of Quantum Information and Matter — Recently Haah introduced a new class of local quantum error correcting code embedded on a cubic lattice without any string logical operator. We present new codes with similar properties by relaxing the condition on the local particle dimension. The resulting code is well-defined when the local Hilbert space dimension is prime. These codes can be divided into two different classes: the local stabilizer generators are either symmetric or antisymmetric with respect to the inversion operation. We lower bound the number of encoded qudits by computing the commutation relation between the logical operators confined on a plane.

5:18PM L30.00015 Topological Decoding through Artificial Confinement¹, GUILLAUME DUCLOS-CIANCI, DAVID POULIN, Université de Sherbrooke — 2D topological stabilizer codes have attracted a lot of attention in recent years for two main reasons. First, they provide exactly solvable models which exhibit topological order and anyonic excitations. Second, they naturally lead to quantum stabilizer error-correcting codes having macroscopic minimum distance. Although these codes are robust at zero temperature, quasi-particles appear and freely diffuse in the system at any finite temperature. If this diffusion is unchecked, errors will occur. Consequently, active error-correction is needed. We want to propose a cellular automaton that would perform this correction. It would "manually" confine the quasi-particles by simulating artificial attraction between them and moving them accordingly. We obtained encouraging preliminary results for error-correction and hope to generalize them to fault-tolerance.

5:30PM L30.00016 Andreev Bound states in One Dimensional Topological Superconductor with Broken Spatial Inversion Symmetry¹, XIONG-JUN LIU, KAI SUN, SANKAR DAS SARMA², Joint Quantum Institute and Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742 — We study the Andreev bound states (ABSs) at the Josephson junction of one dimensional topological superconductors (SC) when the spatial inversion symmetry (SIS) is broken. While in the absence of inversion symmetry, we show a hidden symmetry for the Bogoliubov de Gennes equations in the case of SC gap much smaller than Fermi energy in addition to the particle-hole symmetry, due to which the ABSs are predicted to carry irrational charge, with the charge value solely depending on the SIS breaking term, regardless of the details of the superconductor order parameter and whether the disorder scattering is present or not. We demonstrate that in the tunneling transport spectroscopy the irrationally charged ABSs are measured by the resonant differential tunneling conductance.

2:30PM L31.00001 Thin films of magnetically doped topological insulators, CUI-ZU CHANG, Dept. of Physics, Tsinghua University, China — The interplay between the Dirac surface state and ferromagnetic order in topological insulators can lead to a number of very exotic quantum phenomena. To observe the quantum phenomena such as quantized anomalous Hall (QAH) effect in magnetically doped topological insulators, the materials are required to be in the form of thin film with tunable chemical potential and carrier-independent ferromagnetism. In this talk, I will report our recent progress in molecular beam epitaxy growth, chemical potential tuning and electronic properties of the magnetically doped topological insulator thin films. By Cr doping, we have realized both n-type and p-type conductivity in $(\text{Bi}_x\text{Sb}_{1-x})_2\text{Te}_3$ thin films. Remarkably their ferromagnetism was found independent of the type and concentration of carriers. Moreover, the anomalous Hall effect is significantly enhanced at low carrier concentration regime, with the anomalous Hall angle reaching an unusually large value of 0.2 and the zero field Hall resistance reaching one quarter of the quantum resistance (h/e^2). These findings pave the way to ultimately observing the QAH effect and other quantum effects in magnetic topological insulators.

3:06PM L31.00002 Proximity induced ferromagnetism at the interface between a topological insulator (TI) Bi_2Se_3 and a ferromagnetic insulator (FI)¹, PENG WEI, FERHAT KATMIS, Francis Bitter Magnet Lab, MIT, Cambridge, MA, BADIH ASSAF, DON HEIMAN, Physics Department, Northeastern University, Boston, MA, PABLO JARILLO-HERRERO, Physics Department, MIT, Cambridge, MA, JAGADEESH MOODERA, Francis Bitter Magnet Lab and Physics Department, MIT, Cambridge, MA — The ferromagnetic phase of the surface states of a TI is predicted to carry many exotic properties, for example quantum anomalous Hall effect, magnetic monopole, and magneto-electric effects etc. In our study, we explore this novel phase utilizing the proximity induced exchange splitting to introduce ferromagnetism close to the surface of the Bi_2Se_3 film. High quality Bi_2Se_3 thin films were grown using molecular-beam-epitaxy, and in-situ deposited the ferromagnetic insulator (FI) EuS over this film. Magnetization measurements demonstrated a magnetic moment of more than $7\mu_B$ per Eu^{2+} ion (bulk value), and reaching up to $11\mu_B$ per Eu^{2+} ion for 1nm thick EuS film, showing the unambiguous existence of excess ferromagnetism. The transport studies of these TI/FI bilayers unveiled a clear switching behavior of the magnetoresistance in the Bi_2Se_3 film. There was significant temperature dependence seen in both MR and the coercivity. Due to the near range nature of the exchange interactions, these extra magnetic moments and the MR results are attributed to come from the induced ferromagnetism at the Bi_2Se_3 surface.

3:18PM L31.00003 Possible transport evidence for a surface state gap in a magnetically doped topological insulator, D.M. ZHANG, A. RICHARDELLA, D.W. RENCH, A. KANDALA, T.C. FLANAGAN, P. SCHIFFER, N. SAMARTH, Dept. of Physics, Penn State University, University Park 16802, S.-Y. XU, H. BEIDENKOPF, A. YAZDANI, M.Z. HASAN, Dept. of Physics, Princeton University, Princeton, NJ 08544, A.L. YEATS, B.B. BUCKLEY, P. KLIMOV, D.D. AWSCHALOM, Dept. of Physics, University of California, Santa Barbara CA 93016 — We report magnetoresistance measurements in thin films of a magnetically doped topological insulator $\text{Bi}_{2-x}\text{Mn}_x\text{Se}_3$ synthesized by molecular beam epitaxy. We observe a crossover from positive magnetoresistance to negative magnetoresistance at low temperature ($T \lesssim 15$ K), accompanied by onset of ferromagnetic signatures (hysteresis and anisotropic magnetoresistance). The observations are consistent with the prediction of a transition of diffusive quantum transport from the symplectic to the unitary class due to a magnetically induced surface state gap. This interpretation is supported by the observation of strongly suppressed surface states at the Dirac point in angle-resolved photoemission spectroscopy. We use the magneto-optical Kerr effect, anomalous Hall effect, SQUID magnetometry, electron microscopy and scanning tunneling microscopy to clarify the source of the ferromagnetism in these samples. Supported by DARPA, ONR and NSF-MRSEC.

3:30PM L31.00004 Magnetoconductance crossover and non-linear Hall effect in MBE-grown Cr-doped $\text{Bi}_2\text{Te}_2\text{Se}$ ¹, BADIH A. ASSAF, Physics Dept. Northeastern University, PENG WEI, FERHAT KATMIS, JAGADEESH S. MOODERA, MIT, Francis Bitter Magnet Lab, DON HEIMAN, Physics Dept. Northeastern University — Recent predictions have shown that the magnetoconductance (MC) of a topological insulator should show a crossover from negative MC to positive MC when time-reversal symmetry is broken [1]. Observations of this crossover have been reported in 3 QL thick Cr- Bi_2Se_3 [2] in the quasi-2D regime where surface hybridization is not negligible. We report magneto-transport results on 15 QL thick Cr-doped and undoped $\text{Bi}_2\text{Te}_2\text{Se}$ films grown on Si (111) substrates by MBE. The undoped film exhibits weak anti-localization at low temperatures. In the Cr-doped film, a crossover from negative to positive MC is observed versus temperature at $T=12$ K. SQUID measurements show that the sample is ferromagnetic in this temperature range. In addition, a non-linear Hall voltage is observed despite the large bulk carrier concentration. This paves the way for further experiments on $(\text{Bi,Cr})_2\text{Te}_2\text{Se}$ in our search for the quantum anomalous Hall effect. [1] H.Z. Lu et al. Phys. Rev. Lett. **107**, 076801(2011). 3:42PM L31.00005 Ferromagnetism in chromium doped topological insulator thin films and nanoplate crystals¹, ZHIYI CHEN, LUKAS ZHAO, INNA KORZHOVSKA, HAIMING DENG, LIMIN HUANG, City College of New York - CUNY, SIMONE RAOUX, JEAN JORDAN-SWEET, STEPHEN O'BRIEN, IBM Research - Yorktown, LIA KRUSIN-ELBAUM, City College of New York - CUNY — The surface states of topological insulators are protected by time-reversal symmetry. Introducing magnetic impurities should break this symmetry and open a gap in the otherwise gapless surface states. Recent first-principle calculations predict that when topological insulators are doped with transition metal elements, such as Cr or Fe, a *magnetically ordered* insulating state will form – a state that in thin (quasi-2D) samples may support a quantized Hall conductance. Here we report on electrical and magnetic characterization of thin Cr doped topological insulators: Sb₂Te₃ nanoplate crystals and ~ 50 nm thin films of Bi₂Te₃. Electrical contacts to samples were lithographically defined, with *rf* sputtered films grown on pre-patterned substrates. Low-temperature in-plane resistivity, Hall, and magnetization measurements were performed in up to 5 T magnetic fields. For 5 at% Cr content, a distinct ferromagnetic hysteretic response is observed at temperatures below 10 K. Hysteretic loops, also observed in Hall resistivity, indicate low-*T* coercive fields of the order of 0.5 T. Correlation of transport and magnetic measurements indicating anomalous Hall effect, and strong dependence on dopant concentration and sample thickness will be presented.

¹Supported in part by NSF-DMR-1122594.

3:54PM L31.00006 Ferromagnetism in vanadium doped thin films of a topological insulator Bi₂Te₃¹, LUKAS ZHAO, ZHIYI CHEN, INNA KORZHOVSKA, HAIMING DENG, City College of New York - CUNY, SIMONE RAOUX, JEAN JORDAN-SWEET, IBM Research - Yorktown, MYRIAM SARACHIK, LIA KRUSIN-ELBAUM, City College of New York - CUNY — Recent first-principle calculations predict a new class of ferromagnetic systems that are distinctly different from the conventional dilute magnetic semiconductors. A novel ferromagnetic topological insulator (ferro-TI) state can be obtained when topological insulator are doped with certain transition metal elements. In the the quasi-2D limit these ferro-TIs are expected to support a quantized anomalous Hall effect. Here we report on electrical and magnetic characterization of vanadium doped thin (~ 50 nm) films of a topological insulator Bi₂Te₃. Films were grown by *rf* sputtering on S₃N₄/Si substrates with lithographically pre-patterned contact pads. Low-temperature in-plane and Hall resistivity measurements were performed in magnetic fields up to 5 T fields. We find that below 100 K, V-doped films display *negative linear magnetoresistance*, which at lower temperatures becomes hysteretic. Hall resistivity is also hysteretic, suggesting an unusual ferromagnetic ordering below 10 K. Moreover, V-doping turns the *p*-type conduction in as-grown films into *n*-type. The doping and thickness dependence of these effects will be discussed.

¹Supported in part by NSF-DMR-1122594

4:06PM L31.00007 Controllable ferromagnetism of iron doped topological insulator, SHAN QIAO, ZHEN LIU, FUHAO JI, BIN LI, FUCHUN XI, fudan university, K. KURODA, MAO YE, K. MIYAMOTO, A. KIMURA, Hiroshima University — The higher than room temperature ferromagnetism was found in iron doped Bi₂Se₃. Samples generated by different processes have different magnetic characters. The Curie temperature is independent on iron concentration which against all discovered dilute magnetic systems. EXAFS observations show that the local structure of iron in samples with paramagnetic character is complex. On the contrary, that with ferromagnetic character is very simple that the iron atoms make up small single atom, dimer or trimer structures and these structures randomly distributed in Bi₂Se₃ crystal. The ferromagnetism can be enhanced or suppressed by the shift of Fermi edge by co-doping of Mg and Fe to Bi₂Se₃ crystal. The less than 3 atoms small structure cannot have room temperature ferromagnetism, so we believe that the higher than room temperature controllable ferromagnetism is intrinsic character of iron doped topological insulator.

4:18PM L31.00008 In-plane anisotropy of Fe atoms on Bi₂Se₃(111), T. WEHLING, A. LICHTENSTEIN, 1. Institut für Theoretische Physik I, Universität Hamburg, Germany, J. HONOLKA, S. STEPANOW, K. KERN, Max-Planck-Institut für Festkörperforschung, Stuttgart, Germany, V. SESSI, N. BROOKES, ESRF, Grenoble, France, J. MI, B.B. IVERSEN, P. HOFMANN, iNANO, Aarhus University, Denmark, A.A. KHAJETOORIAN, J. WIEBE, T. SCHLENK, R. WIESENDANGER, Institute for Applied Physics, Universität Hamburg, Germany — Topological insulators exhibit a linearly dispersing gapless topological surface state where both the spin and momentum degrees of freedom are locked. The topological nature of this state results in interesting effects such as suppression of back-scattering. Recently, the robustness of these surface states against magnetic order has come under heavy investigation. Here, we explore the magnetic properties of single Fe adatoms on the Bi₂Se₃ surface, in the coverage range < 1%, with combined non-local x-ray magnetic circular dichroism techniques and local low temperature scanning tunneling spectroscopy. We reveal that the adatoms heavily relax into the surface and exhibit a magnetic easy axis within the surface-plane, contrary to recent reports. Furthermore, we demonstrate, using *ab-initio* approaches, how the easy axis can reorient from out-of-plane to in-plane when considering the interplay of Coulomb interactions, spin-orbit coupling, and dynamic hybridization effects.

4:30PM L31.00009 Topological insulators with magnetic impurities in the bulk, GILAD ROSENBERG, MARCEL FRANZ, University of British Columbia — We show that a three dimensional topological insulator with magnetic impurities could have a regime where the surface is magnetically ordered but the bulk is not. This is in contrast to conventional materials where bulk ordered phases are typically more robust than surface ordered phases. This difference originates from the topologically protected gapless surface states characteristic of topological insulators. We study the problem using a mean field approach, using two concrete models that give the same qualitative result, with some interesting differences. This work could help explain recent experimental results showing the emergence of a spectral gap in the surface state of Bi₂Se₃ doped with Mn or Fe atoms, but with no measurable bulk magnetism.

[1] Massive Dirac Fermion on the Surface of a Magnetically Doped Topological Insulator, Y. L. Chen *et al.*, Science **329**, 659-662 (2010).

4:42PM L31.00010 Interface-driven magnetism in topological insulators Bi₂Te₃ and Bi₂Se₃¹, KYUNGWHA PARK, Virginia Tech, Blacksburg, VA 24061 — Topological insulators (TIs) draw great attention due to their unique quantum properties and applications. TIs possess metallic surface states within band gaps induced by spin-orbit coupling (SOC), and they allow only an odd number of Dirac cones in dispersion of the surface states at a given surface. Novel physical phenomena and applications proposed including TIs, critically rely on stability and topological nature of the surface states when TIs are interfaced with other types of materials. Despite many studies on TIs, it still remains unclear how the surface states of TIs behave in contact with other materials. In this talk, we present our study of an effect of interfaces on the surface states of TIs Bi₂Te₃ and Bi₂Se₃, using density-functional theory including SOC self-consistently. We simulate interfaces using adsorption layers on TI films in an asymmetric fashion. We discuss unexpected results on stability and topological nature of the surface states, as well as changes in their spin structure and energy gaps at zero momentum. Our findings reveal importance of interfaces and a possibility of engineering new hybrid TI structures using adsorption layers.

4:54PM L31.00011 Magnetic structure of magnetic semiconductor NdBiPt studied by elastic neutron diffraction, ROGER MUELLER, ALEXANDRE DESILETS-BENOIT, ANDREA BIANCHI, LUC LAPOINTE, University of Montreal, ZAHRA YAMANI, Canadian Neutron Beam Centre National Research Council, MICHEL KENZELMANN, Paul Scherrer Institut — We report a study of the magnetic structure of the antiferromagnetic (AFM) half-Heusler NdBiPt via neutron scattering. NdBiPt exhibits an AFM transition at $T_N = 2.2\text{K}$ with an ordered moment of $3.6\mu_B$ per Nd atom, as determined from magnetization measurement. The insulating state of NdBiPt has been proposed to be a new class of a three dimensional topological insulator, which possesses surface states at step edges on facets, with properties that are analogous to those observed in quantum Hall states. However, this would require an orientation of the magnetic moments in the ordered state along the crystallographic direction [001]. Triple-axis neutron diffraction on a single crystal was used to study the magnetic order. We found that in the ordered state consists of a conventional two sublattice antiferromagnet with the spins oriented along [001] with very little fluctuations present close to T_N .

5:06PM L31.00012 Iron impurities on Sb (111) surface and their effects on topological surface state, JINHEE HAN, HYUNJUN LEE, HYOUNG JOON CHOI, Department of Physics and IPAP, Yonsei University — We study iron impurities on Sb (111) surface and their effects on topological surface state by using an *ab-initio* pseudopotential density-functional method. We implemented the spin-orbit interaction into the SIESTA in a form of additional fully non-local projectors. To calculate electronic structure of topological surface states, we consider a slab of Sb using a supercell containing 20 atomic layers with experimental bulk Sb lattice parameters. We determine atomic positions of Fe impurities on Sb (111) surface by minimizing the total energy, and calculate surface band structures near the Fermi level. To find effects of the impurity on the surface states of Sb (111) surface, we simulate ARPES spectra as a function of impurity density on the surface. From the results, we find that Fe impurity states are present near Fermi level and they strongly interact with the surface states. This work was supported by the NRF of Korea (Grant Nos. 2009-0081204 and 2011-0018306) and KISTI Supercomputing Center (Project No. KSC-2011-C2-04).

5:18PM L31.00013 Impurities in Bi₂Se₃ topological insulator: *ab initio* calculation, TOME M. SCHMIDT, ROBERTO H. MIWA, Universidade Federal de Uberlândia, ADALBERTO FAZZIO, Universidade de São Paulo — Topological insulators are materials that have a bulk as an ordinary insulator but have protected conducting states on their surface. The surface states with an odd number of Dirac cones are robust against time-reversal invariant perturbation. However the interaction of magnetic impurities with the Dirac fermions can break time reversal symmetry open up a surface band gap. In this work we investigate the magnetic anisotropy and spin-texture of Co impurities embedded at the interlayer vdW spacings and onto the topmost Se network of the topological insulator Bi₂Se₃. The interaction of the magnetic impurity with the surface spin texture break time reversal symmetry, opening up a surface band gap. For Co atom adsorbed onto the surface, the net magnetic moment is aligned perpendicular to the surface plane, with anisotropy energy of $6\sim\text{meV}$. On the other hand for the Co impurity at the vdW interlayers, the net magnetic moment is aligned in-plane. While pristine Bi₂Se₃ presents helical spin-texture in the massless surface Dirac cone and states resonant within the valence band, the presence of Co impurity reduces the planar spin helicity of now massive Dirac fermions. On the other hand O impurities do not break the protected surface Dirac cones, but they move the position of the Dirac crossing upwards. Also we observe that there is an energy barrier for the O₂ molecule when it approximates to the Bi₂Se₃ surface, but atomic O inside the Bi₂Se₃ is more stable than the formation of O₂ molecules.

- Mechanisms of Ferroelectricity 261

2:30PM L32.00001 General Theory for the Ferroelectric Polarization Induced by Spin-Spiral Order, HONGJUN XIANG, Fudan University, ERJUN KAN, Nanjing University of Science and Technology, YUEMEI ZHANG, M.-H. WHANGBO, North Carolina State University, XINGAO GONG, Fudan University — Multiferroics display magnetic, polar and elastic order parameters simultaneously and hence present fascinating fundamental physics and potentially promising applications. The multiferroic phenomenon has been explained by several different models. However, none of them can correctly describe the ferroelectric polarization of triangular-lattice antiferromagnets induced by helical spin-spiral order. To resolve this problem, we develop a general theory for the ferroelectric polarization induced by spin-spiral order on the basis of symmetry considerations and then evaluate the coefficients needed to specify the general theory on the basis of density functional calculations. Our theory not only explains the ferroelectricity of triangular-lattice antiferromagnets driven by helical spin-spiral order, but also incorporates all known models of magnetic-order-driven ferroelectricity as special cases.

2:42PM L32.00002 Modeling functional piezoelectricity in perovskite superlattices with competing instabilities, CHARLES SWARTZ, XIFAN WU, Temple University — Multi-component Perovskite Superlattices (SLs) of the form ABO₃, provide a very promising avenue for the design of materials with multifunctional properties. Furthermore the interfaces of such multi-component SLs are home to competing anti-ferrodistortive and ferroelectric instabilities which can produce unexpected functionalities. However, at present first principles calculations exceeding more than 10 units cells, are particularly costly as they scale with the valence electrons as N^3 . We present a first-principles modeling technique that allows us to accurately model the piezoelectric strains of paraelectric/ferroelectric SLs, BaTiO₃/CaTiO₃ and PbTiO₃/SrTiO₃, under a fixed displacement field. The model is based on a maximally localized Wannier center layer polarization technique, as well as a truncated cluster expansion, that makes use of the fact that such PE/FE SLs have been shown to have highly localized ionic and electronic interface effects. The prediction of the piezoelectricity for a SL of an arbitrary stacking sequence will be demonstrated. We also use our model to conduct a systemic study of the interface effects on piezoelectric response in the above SLs paying special attention to a strong non-linear effect observed in Bulk SrTiO₃.

2:54PM L32.00003 Competing (anti-)ferrodistortive and ferroelectric instabilities in SrTiO₃ and layered La₂Ti₂O₇, ULRICH ASCHAUER, NICOLA SPALDIN, Materials Theory, ETH Zürich — We present first-principles calculations on the competition between antiferrodistortive (AFD) and ferroelectric instabilities in oxides. High temperature cubic SrTiO₃ is well known to undergo an AFD transformation at around 105 K. Further reducing the temperature shows a softening of the ferroelectric polar phonons, however the material remains incipient-ferroelectric with an overall paraelectric behavior. This behavior is believed to be linked to a suppression of the polar instability by the AFD one, the mechanism still being debated. Our calculations show that freezing in the AFD indeed reduces the polar instability. At the theoretical equilibrium angle, the material however still retains a polar instability with a double-well depth of $\sim 0.2\text{ meV}$ per SrTiO₃ unit, inline with the material being incipient-ferroelectric. A change in polar eigenvectors with increasing AFD rotation together with a decomposition of forces into long- and short-range components allows us to propose an underlying mechanism. We will further discuss a similar suppression mechanism observed in layered La₂Ti₂O₇, where conventional ferroelectricity is suppressed by ferrodistortive modes, these modes however still leading to improper ferroelectricity due to the layered structure.

3:06PM L32.00004 First Principles Study of Piezoelectricity in Improper Ferroelectrics, KEVIN GARRITY, KARIN RABE, Rutgers University — Piezoelectric materials are key components of many important technologies, and discovering materials with improved piezoelectric responses is a major goal of materials science. In particular, finding new mechanisms for piezoelectricity which allow for high piezoelectric coefficients, especially in lead-free materials, could have great technological impact. Recently, there has been a renewed interest in improper ferroelectrics, which are materials where a non-zero polarization is induced indirectly by the coupling of the polar distortion to non-polar unstable modes, frequently oxygen octahedral rotations. This mechanism for creating a polarization may also offer the possibility of increased coupling to strain, leading to high piezoelectric coefficients. Here, we use first principles density functional theory to investigate the mechanism of the piezoelectric response of $\text{Ca}_3\text{Ti}_2\text{O}_7$, an improper ferroelectric which we find to have large piezoelectric coefficients.

3:18PM L32.00005 Engineering polar perovskites from centric polyhedra building blocks, JAMES RONDINELLI, Drexel University, CRAIG FENNIE, Cornell University — Increasing demands for electric field-tunable electromagnetic (EM) materials has renewed interests in ferroelectricity and its coupling to EM properties in perovskite oxides. Using density functional computations combined with group theoretical methods, we detail the crystal-chemistry criteria that enable the rational design of new perovskite oxides displaying octahedral rotation-induced ferroelectricity—electric polarizations (P) without second-order Jahn-Teller cations from BO_6 building blocks. We show that interleaving two bulk perovskites to form an ordered and layered arrangement of A-site cations [chemical composition $(A, A')\text{B}_2\text{O}_6$] produces a new trilinear free energy term coupling BO_6 rotations to P . This symmetry rule combined with an energetic condition, describing the lattice dynamical properties of the bulk materials, enables the routine design of synthetic ferroelectric perovskites. We illustrate these guidelines and achieve sizeable electric polarizations in layered gallate and aluminate perovskites, i.e. bulk materials with no tendencies to ferroelectricity. Finally, we argue that this strategy could be exploited for the design of ferroelectricity in a variety of crystal classes exhibiting flexible cation–anion polyhedral frameworks.

3:30PM L32.00006 Crossover between hybrid improper ferroelectricity and proper ferroelectricity in layered perovskites, ANDREW MULDER, NICOLE BENEDEK, CRAIG FENNIE, School of Applied and Engineering Physics, Cornell University — Recent progress in designing materials with unconventional mechanisms of ferroelectricity has shown that nominally non-polar octahedral rotations can induce an electrical polarization in certain layered perovskites, e.g., the $n=2$ Ruddlesden-Popper $\text{Ca}_3\text{Mn}_2\text{O}_7$, and certain A-site ordered $\text{AA}'\text{B}_2\text{O}_6$ double perovskites. In these (what have recently been termed) hybrid improper ferroelectrics, two unstable octahedral rotations of different symmetries couple trilinearly with the polarization. A key question that is still unclear is what the consequences of this coupling are in determining whether these materials exhibit conventional proper ferroelectricity, as in $\text{SrBi}_2\text{Ta}_2\text{O}_9$, or something resembling improper ferroelectricity. In this talk we discuss this question of proper vs improper in $\text{A}_3\text{B}_2\text{O}_7$ layered perovskites. First we develop simple criteria for realizing this novel form of ferroelectricity based solely on the properties of the ABO_3 parent perovskites. Then we explore how composition and epitaxial strain lead to different ferroelectric behaviors arising from the same rotation-polarization coupling. Finally we show how strain can tune a single material between rotation-driven hybrid improper ferroelectricity and conventional proper ferroelectricity.

3:42PM L32.00007 Competition and cooperation between octahedral rotations and ferroelectricity in simple and layered ABX_3 perovskites, NICOLE BENEDEK, School of Applied and Engineering Physics, Cornell University — Researchers have been studying octahedral rotations in perovskites for over half a century. It is now known that such lattice distortions are generally driven by the coordination preferences of the A-site cation. The role of octahedral rotations in modulating the magnetic, electronic and orbital properties of perovskites has been elucidated and a set of empirical rules for rationalizing the structures of known materials and for predicting the structures of as yet unsynthesized materials has been established. Despite this progress, there remains a long-standing problem concerning octahedral rotations and ferroelectricity: there are very few ferroelectric ABX_3 perovskites with octahedral rotations. This has led to the widespread assumption that octahedral rotations compete with and suppress ferroelectricity. In this talk, I will describe our recent work on the interaction between ferroelectricity and octahedral rotations in simple and layered perovskites. Using a combination of Density Functional Theory and simple crystal chemical models, we have shown that in contrast to the common assumption, ferroelectricity and octahedral rotations do not always compete. In particular, I will discuss the manner in which rotations can actually induce ferroelectricity in ABX_3 perovskites and present strategies for designing new functional materials based on this mechanism. In a related direction, I will also discuss the role of layering in inducing hybrid improper ferroelectricity in some Ruddlesden-Popper phases and double perovskites. Our approach provides a chemically intuitive picture – one that combines first-principles lattice dynamics with a local description of bonding – to explain why particular materials adopt particular structures. Such knowledge is at the foundation of the current materials-by-design effort.

4:18PM L32.00008 ABSTRACT WITHDRAWN —

4:30PM L32.00009 A Unified Formalism toward Polarization, Magnetization and the θ -term in a Periodic Insulator, KUANG-TING CHEN, PATRICK LEE, MIT — The traditional perturbative calculation expands in powers of the gauge potential. This procedure proves problematic when a uniform electric or magnetic field is present. Here we provide a perturbative expansion of the electronic Green's functions directly in powers of the fields. On the other hand, the first order correction to the free energy to an insulator with periodic boundary conditions in the presence of the electric field is actually a Berry's phase. To express the Berry's phase in terms of the Green's functions, one is required to extend the Green's function to one extra dimension. With the trick, one can then calculate the effective action to arbitrary order of the electric and magnetic field. One new result we have obtained is that the θ -term is given by the combination of the Green's functions in the extended momentum space, similar to the Wess-Zumino-Witten term, even without time reversal symmetry.

4:42PM L32.00010 Observation and Theory of Intrinsic Ferromagnetism in Ferroelectric Materials, J. LASHLEY, K. GOFRYK, D.J. SAFARIK, J.L. SMITH, Los Alamos National Laboratory, I.E. DZYLASHINSKII, University of California, Irvine — Quantized waves obeying Bose-Einstein statistics will contribute a $T^{3/2}$ term to the specific heat if the dispersion relation goes as q^2 . We measure the magnetic and electric field dependence of the specific heat on the ferroelectric material tri-glycine sulphate (TGS) over the temperature range $0.05 \text{ K} < T < 350 \text{ K}$. We detect a $T^{3/2}$ term in the specific heat in the low-temperature limit, which is taken to be the dielectric analog to magnetic spin wave. Near the Curie temperature ($T_C = 320 \text{ K}$), the shape of the specific-heat anomaly is thermally broadened. However, the anomaly changes to the characteristic sharp lambda-shape expected for a continuous transition with the application of either a magnetic field or electric field, giving the expected entropy change at T_C of $R \ln 2$. These results are explained on the basis that the frequencies of optical dipole oscillations are split by the magnetic field, and the resulting gas of excitations are paramagnetic. Consequently they contribute to the specific heat near T_C , which increases with magnetic field.

4:54PM L32.00011 Dramatic effect of the near-electrode layer configurations on the phase transition characteristics of ferroelectric-paraelectric superstructures¹, BURC MISIRLIOGLU, Asst. Prof., ARKADI LEVANYUK, Professor (Retired) — Ferroelectric-paraelectric superstructures have attracted great interest. A few experimental reports have emphasized the effect of individual layer thickness on the transition temperature of these systems. Here, we theoretically show that the phase transition characteristics of these systems are very sensitive to the structural configuration near the electrodes. The phase transition is homogeneous in the system only if the layers contacting the electrodes are paraelectric layers of 1/2 thickness of other individual layers. If the ferroelectric layer contacts the electrode (and the other electrode is contacted by a paraelectric layer) the phase transition temperature is higher than in the previous structure and the spatial distribution of the polarization at the phase transition is inhomogeneous being maximal near the electrode and disappearing far from it. A striking result is that the transition temperature in one unit bilayer is the same as a system consisting of any number of bilayers. Moreover, the profile of the polarization is unchanged upon addition of new bilayer units to the system. We also discuss general features of the domain structures below the phase transition temperature and transition anomalies.

5:06PM L32.00012 The phase diagram of $\text{Sr}_{1-x}\text{Eu}_x\text{TiO}_3$: Crossover from displacive to order-disorder dynamics, ZURAB GUGUCHIA¹, HUGO KELLER², Physik Institut der Universität Zürich, ALEXANDER SHENGELAYA³, Department of Physics, Tbilisi State University, JÜRGEN KÖHLER⁴, ANNETTE BUSSMANN-HOLDER⁵, Max-Planck-Institut für Festkörperforschung — The phase diagram of $\text{Sr}_{1-x}\text{Eu}_x\text{TiO}_3$ is determined experimentally by EPR and resistivity measurements and analyzed theoretically in terms of the self-consistent phonon approximation (SPA) as a function of x ($0.0 \leq x \leq 1.0$). It is observed that the oxygen octahedral tilting instability temperature T_S increases nonlinearly with x . The theoretical analysis demonstrates that a crossover from displacive to order-disorder dynamics takes place for $x \geq 0.25$, signaled by a change in the local double-well potential and the soft mode temperature dependence.

5:18PM L32.00013 Electrocaloric effect in ferroelectric alloys from atomistic simulations¹, SERGEY LISENKOV, INNA PONOMAREVA, University of South Florida — Caloric effects, such as magnetocaloric and electrocaloric effects, have attracted a lot of attention recently in the context of increasing interest in energy conversion and renewable energy materials and devices. Here we develop and use accurate first-principles-based simulations to study electrocaloric effect (ECE) from an atomistic point of view. In particular, we develop a computational technique that allows both direct and indirect simulations of ECE within the *same* atomistic framework. We then use such a tool to provide first systematic comparison between ECE estimates obtained from direct and indirect approach which will allow us to bridge the macroscopic and atomistic description of ECE. The results of our direct atomistic simulations are then used to explore the intrinsic features of ECE in ferroelectrics with multiple transitions.

Tuesday, February 28, 2012 2:30PM - 5:30PM – Session L33 GSNP DFD: Invited Session: Frontiers of Granular Physics 106

2:30PM L33.00001 Packing Nonspherical Particles: All Shapes Are Not Created Equal¹, SALVATORE TORQUATO, Departments of Chemistry and Physics, and Princeton Center for Theoretical Science, Princeton University, Princeton, NJ 08544 — Over the past decade there has been increasing interest in the effects of particle shape on the characteristics of dense particle packings, since deviations from sphericity can lead to more realistic models of granular media, nanostructured materials, and tissue architecture. It is clear that the broken rotational symmetry of a nonspherical particle is a crucial aspect in determining its resulting packing characteristics, but given the infinite variety of possible shapes (ellipsoids, superballs, regular and irregular polyhedra, etc.) it is desirable to formulate packing organizing principles based the particle shape. Such principles are beginning to be elucidated; see Refs. 1 and 2 and references therein. Depending upon whether the particle has central symmetry, inequivalent principle axes, and smooth or flat surfaces, we can describe the nature of its densest packing (which is typically periodic) as well as its disordered jammed states (which may or may not be isotropic). Changing the shape of a particle can dramatically alter its packing attributes. This tunability capability via particle shape could be used to tailor many-particle systems (e.g., colloids and granular media) to have designed crystal, liquid and glassy states.

3:06PM L33.00002 Network Analysis of Granular Flows, MICHELLE GIRVAN, University of Maryland — The flow of granular materials is important to many natural and industrial processes, yet connecting microscale materials properties of grains to bulk flow behavior has remained a challenging task. Our work leverages tools from complex network theory to study granular flow at multiple scales. By characterizing the statistical properties of time-evolving contact networks using metrics like average path length, giant component size, and modularity, we are able to identify how macroscale system features like the loss of reversibility are connected to micro- and meso- scale rearrangements in the contact network. In addition, we employ a network-based approach to explore the role of rotations in facilitating cooperative rearrangements. For both the reversibility and rotation studies, we apply network analysis to time-dependent contact network data obtained from both experiments and simulations and show that this approach can provide new insights on how bulk system properties are connected to particle-scale motion.

3:42PM L33.00003 Swimming in a granular frictional fluid¹, DANIEL GOLDMAN, School of Physics, Georgia Institute of Technology — X-ray imaging reveals that the sandfish lizard swims within granular media (sand) using axial body undulations to propel itself without the use of limbs. To model the locomotion of the sandfish, we previously developed an empirical resistive force theory (RFT), a numerical sandfish model coupled to an experimentally validated Discrete Element Method (DEM) model of the granular medium, and a physical robot model. The models reveal that only grains close to the swimmer are fluidized, and that the thrust and drag forces are dominated by frictional interactions among grains and the intruder. In this talk I will use these models to discuss principles of swimming within these granular “frictional fluids”. The empirical drag force laws are measured as the steady-state forces on a small cylinder oriented at different angles relative to the displacement direction. Unlike in Newtonian fluids, resistive forces are independent of speed. Drag forces resemble those in viscous fluids while the ratio of thrust to drag forces is always larger in the granular media than in viscous fluids. Using the force laws as inputs, the RFT overestimates swimming speed by approximately 20%. The simulation reveals that this is related to the non-instantaneous increase in force during reversals of body segments. Despite the inaccuracy of the steady-state assumption, we use the force laws and a recently developed geometric mechanics theory to predict optimal gaits for a model system that has been well-studied in Newtonian fluids, the three-link swimmer. The combination of the geometric theory and the force laws allows us to generate a kinematic relationship between the swimmer’s shape and position velocities and to construct connection vector field and constraint curvature function visualizations of the system dynamics. From these we predict optimal gaits for forward, lateral and rotational motion. Experiment and simulation are in accord with the theoretical prediction, and demonstrate that swimming in sand can be viewed as movement in a localized frictional fluid.

4:18PM L33.00004 Geometrically Cohesive Granular Materials¹, SCOTT FRANKLIN, Rochester Institute of Technology — Geometrically cohesive granular materials (GCGM) are collections of particles whose individual shape leads to entanglements that resist extension forces, resulting in a non-zero Young’s modulus. Examples include long, thin (anisometric) rods, arcs of varying length, and U-shaped staples. I will report on experimental and computational work that investigates the peculiar rigidity of GCGM. These include canonical stress-strain and vibration-induced melting experiments on U-shaped staples that have revealed a non-monotonic dependence of collective rigidity on particle shape. For concave particles, rigidity appears proportional to an “entanglement number” — the number of neighbors that pass through the area partially bounded by the particle. Computational and analytic work on arcs and staples confirm the non-monotonic behavior of the entanglement number, and simulations that match the experimental conditions are underway to confirm entanglement as the basic mechanism of GCGM’s rigidity.

¹This work funded in part by the National Science Foundation and Donors from the Petroleum Research Fund.

4:54PM L33.00005 Strain-stiffening in random packings of entangled granular chains¹, ERIC BROWN, University of California, Merced — Random packings of granular chains are presented as a model polymer system to investigate the consequences of entanglements in the absence of Brownian motion. The packings are compressed uniaxially and the structure is characterized by x-ray tomography. For short chain lengths, these packings yield when the shear stress exceeds the scale of the confining pressure, similar to packings of spherical particles. In contrast, packings of chains which are long enough to bend into closed loops exhibit strain-stiffening, in which the effective stiffness of the material increases with strain, similar to many polymer materials. The latter packings can sustain stresses orders-of-magnitude greater than the confining pressure, and do not yield until the chain links break. These strain-stiffening packings are found to contain system-spanning clusters of entangled chains.

Tuesday, February 28, 2012 2:30PM - 4:54PM – Session L34 DCP: Focus Session: Impact of Ultrafast Lasers IV: Applications I 107A

2:30PM L34.00001 Adding a dimension to the infrared spectra of interfaces: 2D SFG spectroscopy via mid-IR pulse shaping, MARTIN ZANNI, University of Wisconsin-Madison — Sum-frequency generation spectroscopy provides an infrared spectrum of interfaces and thus has widespread use in the materials and chemical sciences. In this presentation, I will present our recent work in developing a 2D pulse sequence to generate 2D SFG spectra of interfaces, in analogy to 2D infrared spectra used to measure bulk species. To develop this spectroscopy, we have utilized many of the tricks-of-the-trade developed in the 2D IR and 2D Vis communities in the last decade, including mid-IR pulse shaping. With mid-IR pulse shaping, the 2D pulse sequence is manipulated by computer programming in the desired frequency resolution, rotating frame, and signal pathway. We believe that 2D SFG will become an important tool in the interfacial sciences in an analogous way that 2D IR is now being used in many disciplines.

3:06PM L34.00002 Ultrafast Broadband Infrared Source for Nonlinear Infrared Spectroscopy¹, KRUPA RAMASESHA, ARITRA MANDAL, LUIGI DE MARCO, ANDREI TOKMAKOFF², Massachusetts Institute of Technology — Existing optical parametric amplifiers can generate 200cm⁻¹ to 400 cm⁻¹ of bandwidth at mid-infrared frequencies, which limit the use of these pulses for studying vibrational dynamics. We have developed a new broadband infrared source that can generate pulses with 1000 cm⁻¹ of bandwidth, spanning most of the mid-infrared region of the spectrum. These pulses can allow us to simultaneously probe higher frequency vibrations like the OH stretch and the fingerprint region at lower frequencies. By focusing the first, second and third harmonics of a 25 fs 800 nm pulse in air to create a plasma, we have been able to generate infrared pulses with a broad spectrum ranging from 3 microns to 9 microns and a sub-100 fs pulse duration. This source can thus allow us to study dynamics that involve distinct vibrational transitions on ultrafast timescales. This presentation will discuss our efforts in characterizing the broadband infrared source and the progress we are making towards setting up a pump-probe 2D IR experiment using these broadband infrared pulses.

3:18PM L34.00003 Development of a Tunable Ultra-Broadband Mid IR Pulsed Source for Nonlinear Spectroscopy¹, MARK CHENG, ANTHONY REYNOLDS, HEATHER WIDGREN, MUNIRA KHALIL, Department of Chemistry, University of Washington, Seattle, WA 98195 — We generate ultra- broadband mid-IR pulses tunable from 2.5 – 8 μm by focusing 800 nm/400 nm pulses into various gas media. The input 800 nm light is doubled to 400 nm in a type I BBO crystal. The two orthogonally polarized $\omega/2\omega$ pulses encounter a birefringent calcite crystal for time delay compensation and are subsequently focused in various gas media (air, argon, neon and nitrogen) contained within a 1.2 m gas cell using a 1 m focal length silver mirror. The tunability of the broadband mid-IR pulses arises from different gases, pressure of gases and the amount of incident 800 nm/400 nm light focused into the gas cell at a given pressure. We measure IR energies as high as 0.5 μJ /pulse for an input 800 nm energy of 3 mJ/pulse in 900 Torr of Argon. The mid IR pulses exhibit $\sim 2\%$ long term stability. The ultrabroadband IR pulses have a spectral bandwidth of $\sim 2000\text{ cm}^{-1}$ corresponding to a sub-cycle pulse centered at 4.5 μm . We will present our preliminary efforts on using the ultrabroadband IR pulses in nonlinear experiments. The broad spectral content of this novel source affords the possibility of probing multiple vibrations in a coherent manner.

3:30PM L34.00004 Transient IR Probes of Spinning Molecules in an Optical Centrifuge¹, AMY MULLIN, University of Maryland — A high-power optical centrifuge based on ultrafast laser pulses is used to drive molecules into very high rotational states. The optical centrifuge consists of reversed-chirped laser pulses that generate a linearly polarized electric field that angularly accelerates over the time of the pulse. Molecules trapped in the optical field are spun into high rotor states through sequential Raman transitions. The properties of the spinning molecules and their spatial distribution are interrogated with high-resolution state-resolved IR transient absorption probing.

¹Supported by the University of Maryland and NSF

4:06PM L34.00005 Ultrafast Nonlinear Opto-Electronic Spectroscopy, SHAWN M. PERDUE, JOONHEE LEE, ALEJANDRO RODRIGUEZ PEREZ, V. ARA APKARIAN, Department of Chemistry, University of California, Irvine — Using a single color of light and rf beam tagging, parametric nonlinear optical mixing processes can be read not just in photons, but also in electrons. The scheme allows ultrafast time-resolved opto-electronics, which we demonstrate at a tunneling junction. Acousto-optic modulators are used to frequency tag ultrashort laser pulse trains, whereby carrier beats generated in nonlinear mixing processes are down shifted by sampling at the repetition rate of the laser (80 MHz). The method down converts optical carrier frequencies (PHz) to baseband (kHz), where direct current readout is possible with single electron sensitivity. Various parametric processes can be identified through their one-to-one map in baseband. Illustrative implementations that will be presented include the determination of the temporal profile of field-emitted ultrashort electron packets and characterization of the highly nonlinear dynamics involved in light-induced tunneling emission.

4:18PM L34.00006 Coherence-Modulated Third Harmonic Generation for Second Hyper-Raman Spectroscopy of Molecules at an Interface, KEVIN DILLMAN, Colorado State University, JESSE WILSON, Duke University, RANDY BARTELS, NANCY LEVINGER, Colorado State University — We have developed a method of probing the low-frequency (sub-1000 cm^{-1}) vibrational modes of molecules at interfaces using third-harmonic generation (THG). The THG process is enhanced at an interface due to the differences in the third-order nonlinear susceptibilities of the materials. We have used this method to collect low-frequency second hyper-Raman spectra from BGO, BaF_2 and CdWO_4 crystals. In addition, we have observed coherent second hyper-Raman scattering arising from CCl_4 molecules at the liquid-glass interface. We are presently extending these techniques to observe resonant second hyper-Raman scattering from dye molecules adsorbed on gold nanoparticles in order to gain surface enhancement effects. We aim to use this method to characterize the environment at interfaces of reverse micelle systems. The development of this method is significant because we can sensitively probe the low-frequency vibrational modes of only those molecules at an interface.

4:30PM L34.00007 New generation ultrafast fiber-lasers with automated pulse compression for biomedical imaging, BAI NIE, Michigan State University, DMITRY PESTOV, Biophotonic Solutions Inc, ILYAS SAYTASHEV, SERGEY ARKHIPOV, Michigan State University, ANDY CHONG, HUI LIU, FRANK WISE, Cornell University, MARCOS DNATUS, Michigan State University — A double-clad Yb-doped all-normal-dispersion fiber laser is demonstrated to produce 22 nJ pulses at 42.5 MHz repetition rate. With a 3 nm intracavity spectral filter, self-similar evolution is formed in the gain segment. The formation of self-similar evolution allows the achievement of both short pulse duration and high pulse energy from a fiber laser oscillator. These pulses are characterized and compressed via multiphoton intrapulse interference phase scan to as short as 42 fs and 10 nJ/pulse. Adaptive compression underlies the achievement of 250-kW peak power, which enables efficient second and third harmonic generation with spectra spanning 30 nm and 20 nm, respectively. Using the newly developed fiber laser, multiphoton imaging on live tissues is demonstrated.

4:42PM L34.00008 Ionization and Coulomb explosion of small hydrocarbons exposed to short intense laser pulses¹, SERGIY BUBIN, KALMAN VARGA, Vanderbilt University — We have performed first principles numerical simulation of high field ionization in small hydrocarbons followed by a Coulomb explosion. The process was driven by 790 nm 27 fs laser pulses of high intensity (of the order of 10^{15} W/cm^2), for which case there exists recent experimental data [S. Roither et al., Phys. Rev. Lett. 106, 163001 (2011)]. We have analyzed the spectra of ejected protons and investigated the ionization-fragmentation mechanism that takes place when molecules are subjected to short intense laser pulses. The results of our simulations support the all-at-once (concerted) fragmentation scenario proposed by Roither et al. At the same time we also observed some quantitative differences between the theoretical and experimental spectra.

Tuesday, February 28, 2012 2:30PM - 5:30PM —

Session L35 DCP: Focus Session: DFT IV: Ground-State DFT: New Directions 107B

2:30PM L35.00001 Progress in fractional perspectives of density functional theory, WEITAO YANG, Duke University — Density functional theory of electronic structure is widely and successfully applied in simulations throughout engineering and sciences. However, there are major failures for many predicted properties. These errors can be characterized and understood through the perspective of fractional charges and fractional spins introduced recently. The fractional perspectives offer a possible pathway forward. I will report progress in excited states, spin state splitting, open-shell singlet states, Fukui functions and band gaps.

3:06PM L35.00002 Generalized-gradient approximations with non-vanishing exchange-correlation magnetic torque, GIOVANNI SCALMANI, Gaussian, Inc., STEFANO PITTALIS, Department of Physics and Astronomy, University of Missouri-Columbia, MICHAEL J. FRISCH, Gaussian, Inc., GIOVANNI VIGNALE, Department of Physics and Astronomy, University of Missouri-Columbia — The description of systems of interacting electrons in the presence of magnetic fields, within spin-density functional theory (SDFT), requires the non-collinear magnetization density vector $\mathbf{m}(\mathbf{r})$ to be used as basic variable, along with the particle density $n(\mathbf{r})$. Furthermore, for a meaningful description of spin-dynamics, the magnetization density and its conjugate exchange-correlation (xc) field $\mathbf{B}_{xc}(\mathbf{r})$ must not be constrained to be locally parallel at every point in space. It is well known that the local density approximation (LDA) cannot, by construction, provide such a non-collinear configuration of the two vector fields. Here we show how popular generalized gradient approximations (GGAs), developed assuming collinear spin-density, can be used to describe non-collinear magnetization states, including the presence of non-vanishing local torque between $\mathbf{m}(\mathbf{r})$ and $\mathbf{B}_{xc}(\mathbf{r})$. Unlike previous attempts to extend the use of collinear GGAs to the domain of non-collinear magnetization densities, the approach we introduce is invariant with respect of spin-rotations, globally satisfies the *zero-torque theorem*, reduces to the proper collinear limit and is numerically stable.

3:18PM L35.00003 New gradient functional for SDFT derived from spin spirals in the uniform electron gas, F.G. EICH, E.K.U. GROSS, Max Planck Institute of Microstructure Physics, Halle, Germany — The development of functionals in SDFT depending on gradients of the spin magnetization is a long standing challenge. We present a new functional based on the spin-spiral state of the uniform electron gas. Comparing the principal idea of the new functional to the LSDA and GGAs, we highlight the intrinsic way non-collinearity is built into the proposed approximation. As key feature the functional yields exchange-correlation magnetic fields that are non-collinear w.r.t. the spin magnetization, while obeying the zero-torque theorem by construction. This means that an adiabatic application of the functional within TD-SDFT accounts for the local torque exerted by the exchange-correlation field and retains the numerical simplicity of explicit density functionals. An implementation of the functional based on the RPA-treatment of spin spirals in the electron gas is shown.

3:30PM L35.00004 Tuning the correlation energy in second-order Møller-Plesset perturbation theory with an effective electron-electron interaction potential, TIM KOWALCZYK, TROY VAN VOORHIS, Massachusetts Institute of Technology — For practical electronic structure calculations on large molecules, wave function theories (WFT) remain less popular than density functional theory (DFT) despite the systematic improvability of WFT. The greater computational cost of WFT is largely to blame and is two-fold in nature: WFT generally presents unfavorable scaling with system size relative to DFT, and WFT results converge more slowly than those of DFT with respect to basis set size. We propose that each of these issues can be partially mitigated by the introduction of an effective electron-electron interaction potential, in lieu of the true $1/r$ potential, for evaluating the correlation energy in WFT. We discuss the design and optimization of such an effective interaction, in the context of second-order Møller-Plesset perturbation theory (MP2), for two distinct purposes: to accelerate basis set convergence of MP2 correlation energies, and to re-scale the MP2 correlation to improve agreement with experiment and/or higher-level methods.

3:42PM L35.00005 Toward Improved Semilocal and Nonlocal Density Functionals for Atoms, Molecules, and Solids¹, JOHN P. PERDEW, Tulane University — Semilocal density functionals construct the exchange-correlation energy density at a point from the electron density and orbitals in the neighborhood of that point. They can be constructed nonempirically, and work best for sp-bonded systems near equilibrium. They increase in sophistication from the local spin density approximation to the generalized gradient approximation to the meta-GGA. For a molecule like CO on a transition metal surface, it appears that only a meta-GGA can give a good simultaneous description of the lattice constant and surface energy of the metal, on the one hand, and the adsorption energy of the molecule on the other [1]. I will discuss two remaining deficiencies of the revised TPSS meta-GGA [2]: its artificial order-of-limits problem, and its need for more information about non-bonded interaction. When electrons are shared over stretched bonds, full nonlocality is needed, and typically empirical parameters are also needed. This suggests that we don't yet know enough about the full nonlocality of the density functional for the exchange-correlation energy.

4:18PM L35.00006 Energy expressions for model exchange potentials: Beyond the Levy-Perdew virial relation, ALEX P. GAIDUK, VIKTOR N. STAROVEROV, University of Western Ontario — The common way to assign energies to Kohn-Sham exchange potentials is by using the Levy-Perdew virial relation. However, for model potentials that are not functional derivatives, this approach leads to energy expressions that lack translational invariance. We point out that there is a more general procedure for constructing density functionals from model potentials, of which the Levy-Perdew relation is just a special case. Using this generalization we propose a method for converting model potentials into density functionals that ensures translational invariance of the energy. To illustrate our approach we construct a competitively accurate exchange functional from the model potential of van Leeuwen and Baerends.

4:30PM L35.00007 Laplacian-based models for the exchange energy¹, ANTONIO C. CANCIO, Ball State University, CHRISTOPHER E. WAGNER, University of Florida, SHAUN WOOD, Ball State University — Recent Quantum Monte Carlo data for the exchange-correlation energy density of pseudopotential systems strongly suggest the value of using the Laplacian of the density as a variable for constructing first order corrections to the local density approximation of density functional theory. We report on an exchange functional built upon these observations and extended to the all-electron case. The model keeps the typical properties of constraint-based generalized gradient approximations (GGA) and also has a finite-valued potential at the nucleus, unlike the GGA. Problems with oscillatory behavior in the potential due to higher order derivatives are controlled by a curvature minimization constraint. The results are tested against exact potentials for the He and Ne atom. A combination of gradient and Laplacian as suggested by a gradient expansion of the exchange hole gives the best overall results.

¹Work support by National Science Foundation grant DMR-0812195.

4:42PM L35.00008 A non-empirical improvement of PBE and its hybrid PBE0¹ , ALBERTO VELA,

Departamento de Química, Cinvestav, JORGE M. DEL CAMPO, Departamento de Física y Química Teórica, UNAM, JOSÉ L. GÁZQUEZ, Departamento de Química, UAM-Iztapalapa, S.B. TRICKEY, Quantum Theory Project, Physics & Chemistry, U. Florida — We present a non-empirical re-parameterization of the Perdew-Burke-Ernzerhof (PBE) generalized gradient approximation (GGA) exchange-correlation functional and of the related PBE hybrid (PBE0) obtained by imposing the constraint that, for the hydrogen atom, the exchange energy cancels the Coulomb repulsion energy. The new parameterization is validated with well-known test sets. The results for the re-parameterized PBE GGA, called PBE_{mol}, show a substantial improvement over the original PBE in predicted heats of formation, while retaining the quality of the original PBE functional for description of all the other properties considered. The results for the hybrids indicate that, although the PBE0 functional provides a rather good description of those properties, the predictions of the re-parameterized functional are, except in the case of the ionization potentials, modestly better. Also, the results are better than B3LYP, except for the case of the ionization potentials and the harmonic frequencies.

¹AV and JLG were partially supported by the Conacyt project grant 128369, and SBT was supported in part by US DOE SC-0002139.

4:54PM L35.00009 Effect of the orbital-overlap dependence on Meta Generalized Gradient Approximation , JIANWEI SUN, JOHN PERDEW, BING XIAO, ADRIENN RUZSINSZKY, Department of Physics and Engineering Physics, Tulane University — The dimensionless inhomogeneity parameter, α , characterizing the extent of orbital overlap, is disentangled from the other dimensionless inhomogeneity parameter, s , the reduced density gradient, in terms of constructing a meta generalized gradient approximation (MGGA) for the exchange functional. We show that the formation of the intershell region inside an atom is associated with increase of α , which suggests MGGA should expect a monotonically decreasing α dependence for a wide range of density. This leads to a simple nonempirical MGGA exchange functional, which interpolates between the single-orbital regime for confinement systems, where $\alpha=0$, and the slowly varying density regime, where $\alpha \approx 1$, and then extrapolates to $\alpha \rightarrow \infty$. The new MGGA exchange functional, combined with the variant of the Perdew-Burke-Ernzerhof (PBE) GGA correlation as used in the revised Tao-Perdew-Staroverov-Scuseria (revTPSS) MGGA [1], performs equally well for atoms, molecules, surfaces, and solids, with an implication of a tight Lieb-Oxford bound.

[1] J.P. Perdew, A. Ruzsinszky, G.I. Csonka, L.A. Constantin, and J. Sun, Phys. Rev. Lett. 103, 026403 (2009).

5:06PM L35.00010 The derivative discontinuity in density functional theory from an electrostatic description of the exchange and correlation potential , XAVIER ANDRADE, ALAN ASPURU-GUZI, Department of Chemistry and Chemical Biology, Harvard University, 12 Oxford Street, Cambridge, Massachusetts 02138, USA — We present an approach that we have recently proposed [Phys. Rev. Lett. 107, 183002 (2011)] to approximate the exchange and correlation (XC) term in density functional theory. In our approach the XC potential is considered as an electrostatic potential, generated by a fictitious XC density, which is in turn a functional of the electronic density. In this picture, the exact asymptotic limit for low density regions, wrongly predicted by many XC functionals, can be imposed as a local condition. Based on this XC density representation we develop a correction scheme that fixes the asymptotic behavior of any approximated XC potential for finite systems. The procedure is simple, computationally inexpensive, and does not depend on adjusted parameters. Additionally, from the correction procedure it is possible to extract an approximation to the derivative discontinuity of XC energy. This value can be used to directly obtain the gap of the system as a ground-state property. Results are presented for the application of the method to atoms and small molecules. The correction results in a significant improvement in the value of the ionization energy and the gap, with errors that are comparable to the results given by orbital dependent functionals.

5:18PM L35.00011 Multi-Scale Approach to Simulations of Kelvin Probe Force Microscopy¹ , ALI SADEGHI, ALIREZA GHASEMI, STEFAN GOEDECKER, ALEXIS BARATOFF, THILO GLATZEL, ERNST MEYER, University of Basel — The distance dependence and atomic-scale contrast recently observed in nominal contact potential difference (CPD) signals simultaneously recorded during non-contact atomic force microscopy on surfaces of insulating and semiconducting samples have stimulated theoretical attempts to explain how the applied bias voltage affects electrostatic forces acting on the atomic scale. We attack the problem in two steps. First, the electrostatics of the macroscopic tip-cantilever-sample system is treated by a finite-difference method on an adjustable nonuniform mesh. It has the advantages of getting a systematically increasable accuracy as well as the ability of considering the cantilever which turns out to be important for insulating samples. The resulting electric field near the tip apex is then inserted into a series of wavelet-based density functional theory calculations. Results are obtained for a reactive disordered neutral silicon nano-scale tip interacting with a NaCl(001) sample. Bias-dependent forces and resulting atomic displacements are computed to an accuracy of 1 pN. Theoretical expressions for Kelvin signals and local contact potential difference (LCPD) are obtained combining both contributions to the electrostatic force and evaluated for several tip oscillation amplitudes.

Tuesday, February 28, 2012 2:30PM - 5:42PM — Session L36 DCP: Focus Session: New Energy IV 107C

2:30PM L36.00001 Molecular photovoltaics: Tricks from theory, from fission to gaps to traps , MARK RATNER, Northwestern University — No abstract available.

3:06PM L36.00002 Study of excitonic energy transport in thin-film J-aggregates , STEPHANIE VALLEAU, SEMION SAIKIN, MAN-HONG YUNG, ALAN ASPURU-GUZI, Department of Chemistry and Chemical Biology, Harvard University — The concentration and transfer of light through materials is one of the main current scientific goals in the ongoing quest for a new clean energy source. Molecular structures with optimal exciton transfer properties find widespread applications, ranging from solar cells and photonic devices to photographic and lithographic systems. J-aggregates of organic dye molecules are a good example of such structures where a strong interaction between molecular electronic transitions results in a partial exciton delocalization and a large exciton diffusion length. In this presentation I will discuss theoretical aspects of exciton dynamics in two dimensional films of J-aggregates with an emphasis on macroscopic transport properties that could be used for device modeling. As specific illustrations I will use results of our recent studies of exciton dynamics in aggregates of cyanine dyes.

3:18PM L36.00003 Control of exciton delocalization pathways using ZnTPP functionalization, ROBERT BARTYNSKI, SYLVIE RANGAN, SENIA COH, JONATHAN ROCHFORD, ELENA GALOPPINI, Rutgers University — Zn(II)-Tetraphenylporphyrin (ZnTPP) derivatives are attractive candidates for photoinduced electron-transfer mediators in dye sensitized solar cells. We have investigated the influence on solar cells efficiency, of the energy alignment and of the molecular adsorption geometry at the ZnTPP/metal-oxides interface. In this work, using x-ray, UV and inverse photoemission spectroscopies in conjunction with density functional theory (DFT) calculations, we have determined the energy alignment of molecular levels with respect to the substrate band edges for several ZnTPP derivatives adsorbed on ZnO(11-20) and TiO₂(110) surfaces. The ZnTPP derivatives were functionalized with COOH anchoring groups, to allow upright or flat adsorption on the surfaces. While the energy alignment is found similar for all of these systems, large differences in devices efficiencies are observed. We have thus explored the adsorption geometry of the same ZnTPPs at the surface of ZnO and TiO₂ using UV-visible absorption and NEXAFS spectroscopies and scanning tunnel microscopy. It is found that for ZnTPPs, upright adsorption opens deleterious exciton delocalization pathways, due to dipole/dipole interactions competing with electron transfer to the substrate. Choosing the adsorption geometry is thus critical for the electronic pathway control.

3:30PM L36.00004 Coupled polaronic and ion transport in nanocrystalline metal oxide electrodes, KEVIN ROSSO, Pacific Northwest National Laboratory — We report new computational methods and fundamental understanding in the dynamics of coupled charge and ion transport in nanoscale metal oxides. The methods attack the multi-scale problem of simulating the collective diffusivities of ions and charge compensating e⁻/h⁺ carriers in single crystal particles, across particle-particle grain boundaries, and through networks of grains for select systems. Methods include embedded quantum mechanical clusters at the DFT and MP2 levels of theory for atomic-scale polaronic and ion transport kinetics, classical DFT-based free energy calculations for grain-scale conductivity in the framework of the Poisson-Nernst-Planck formalism, and phase field simulation of charged particle diffusivity for conductivity at the grain network scale. This combination of approaches is one of a kind in terms of its multi-scale range, scaling, and computational efficiency. We are presently focused on coupled electron and Li⁺ ion transport in polymorphs of TiO₂, and also in mixed valence spinel oxides, for electrode conductivity optimization and improving energy storage materials performance for Li⁺ batteries.

4:06PM L36.00005 Electrochemical properties of Pt-Co-Zr thin films on high surface area NSTF supports, CHARLES HAYS, POYAN BAHRAMI, MICHAEL ERRICO, JAMES KULLECK, DANIEL KONOPKA, ADAM KISOR, STUART COOLEY, HAROLD GREER, California Institute of Technology, Jet Propulsion Laboratory — Nanostructured thin film supports (NSTF) are a promising fuel cell (FC) technology demonstrated by 3M [1]. We have examined the electrochemical performance of Pt-Co-Zr films deposited onto NSTF supports by dc-magnetron sputtering. In this presentation, we will present results of microstructural, composition, and electrochemical properties, for NSTF supported (Pt₃Co)_{100-x}Zr_x thin films, with 10 < x < 40 (At. %). Electrochemical measurements show that the films are electrochemically stable, and active for the oxygen-reduction-reaction (ORR), with ORR kinetic current densities at 0.9 V (vs. NHE), up to 57X greater than those of Pt(111) films measured in the same cell. The composition dependence of the ORR, and relevant physical properties will be discussed.

4:18PM L36.00006 Enhanced Surfactant Adsorption on Activated Carbon through Manipulation of Surface Oxygen Groups¹, JOHN COLLINS, DEYANG QU, MICHELLE FOSTER, University of Massachusetts, Boston — Passive energy storage is a necessary component for balancing the lifecycle budget with new forms of green energy. The work presented describes how surface oxygen groups (SOG) on granulated activated carbon have been manipulated using Nitric Acid in a controlled, stepwise fashion. The structure and surface functionality of the activated carbon samples were characterized using DRIFTS, Raman Spectroscopy and Porosimetry. Total surface area was found to increase proportionally with the removal of heteroatom material, exposing previously insulated active sites responsible for SOG attachment. Broad oxide peaks were deconvoluted and analyzed, allowing for absolute identification of evolving functionality at each oxidation stage. SOGs were maximized on the third oxidation cycle with the presence of conjugated aromatic, phenol, lactone, and carboxylic acid groups. FSN Zonyl nonionic was applied to all oxidized samples at various concentrations. Total adsorbed surfactant was quantified for each concentration / oxidation scheme using attenuated total reflection. The relative quantity and polarity of chemisorbed surfactant were qualitatively assessed for each equilibrium concentration.

4:30PM L36.00007 Coarse-grained potential models for structural prediction of carbon dioxide in confined environments, TARUN SANGHI, NARAYANA ALURU, University of Illinois at Urbana-Champaign — Geological storage of carbon dioxide is a promising option to reduce the level of carbon dioxide in the atmosphere and mitigate its effect on climate change. In geological storage, high-pressure carbon dioxide is injected into the underground porous rock formations, where it gets trapped inside the tiny nanometer size pores of the rocks. Thus, a good understanding of the microstructure of carbon dioxide inside nanoscale confinements is of great practical importance in developing an efficient technology for carbon dioxide storage. In this work, we discuss the systematic development of coarse-grained single-site (CGSS) potential models to study the structure of carbon dioxide in confined environments. These single-site potentials allow computationally efficient simulations, which are several orders of magnitude faster than all-atom MD (AAMD) simulations. The potential models are used in our earlier proposed multi-scale quasi-continuum theory, called EQT, and in coarse-grained MD (CGMD) to predict the equilibrium structure of carbon dioxide confined inside graphite slit pores. The results obtained from both EQT and CGMD are found to be in good agreement with those obtained from computationally expensive AAMD simulations.

4:42PM L36.00008 Multiscale Simulation of Electrochemical Phenomena: Fuel Cells and Batteries, RYAN JORN, Argonne National Laboratory — Results will be presented from multiscale simulations of two important systems from renewable energy technology, fuel cell proton membranes and electrochemical cells. In the first case, the solvation and transport of hydrated protons in proton exchange membranes (PEMs) such as NafionTM will be described using a novel multi-state reactive molecular dynamics (MD) approach. The multi-state MD methodology allows for the treatment of explicit (Grotthuss) proton shuttling and charge defect delocalization which, in turn, can strongly influence the properties of the hydrated protons in various aqueous and complex environments. The role of PEM hydration level and morphology on these properties will be further described. A new multiscale computational methodology for describing the mesoscopic features of the proton transport will also be described, which can be coupled to the results from the molecular-scale simulations. On the second topic, a computationally efficient method will be presented for the treatment of electrostatic interactions between polarizable metallic electrodes held at a constant potential and separated by an electrolyte. The method combines a fluctuating uniform electrode charge with explicit image charges to account for the polarization of the electrode by the electrolyte, and a constant uniform charge added to the fluctuating uniform electrode charge to account for the constant potential condition. The method is used to calculate electron transport rates using electron transfer theory; these rates are incorporated in a multiscale approach to model oxidation/reduction reactions in an electrochemical cell efficiently.

5:18PM L36.00009 Collective Behavior of Water on Platinum, DAVID LIMMER, University of California, Berkeley, ADAM WILLARD, University of Texas, Austin, DAVID CHANDLER, University of California, Berkeley — We present the results of molecular dynamics simulations of a interface between water and a platinum electrode. Using importance sampling techniques we probe a variety of collective phenomenon that emerge at the interface. We consider platinum electrodes with two different geometries and discuss how different behaviors result from a competition between geometrical frustration and favorable local interactions.

5:30PM L36.00010 Superstructured tungsten oxide photoanodes, ROBERT CORIDAN, Division of Chemistry and Chemical Engineering, California Institute of Technology, KEVIN ARPIN, PAUL BRAUN, Department of Materials Science and Engineering, University of Illinois, Urbana-Champaign, NATHAN LEWIS, Division of Chemistry and Chemical Engineering, California Institute of Technology — Tungsten oxide is a robust and stable semiconductor for photoanodic applications in aqueous solutions. Typical deposition techniques like electroplating or sputtering produce granular films which increase interfacial recombination of minority carriers. This has a deleterious effect on the photovoltaic performance of these materials. Using a variety of templating methods, we explore multiscale structuring strategies for increasing the surface area of the photoanode while maintaining significant light absorption. We describe photoelectrochemical and reflectivity measurements on structured and templated tungsten oxide photoanodes and consider how these results guide future photosynthetic electrochemical device design.

Tuesday, February 28, 2012 2:30PM - 3:54PM – Session L37 FEd: Informal Education and Public Outreach - Policy Questions 108

2:30PM L37.00001 Selectively Bringing Down the Curtain on OPERA Superluminal Neutrino Papers, ROBERT GARISTO, American Physical Society (Physical Review Letters) — Picture this: instead of watching from afar the daily flow of superluminal proposals trying to explain OPERA's preliminary data, you are the PRL Editor charged with deciding what to do with each paper. How do you address the validity of a manuscript whose starting point involves circumventing Einstein? I'll discuss the general issues of controversial claims and data-driven floods of theory papers through the unusual lens of the OPERA-motivated papers. Along our ten minute journey, I'll show some interesting correspondence.

2:42PM L37.00002 Superluminal Neutrinos: The Good Kind of Science Controversy, MICHAEL LUCIBELLA, American Physical Society — After OPERA released results indicating neutrinos were traveling faster than the speed of light, a number of scientists said that the team shouldn't have prematurely engaged in "science by press release." However, controversial claims like this, if handled properly, can actually be a boon to science. Getting the public interested in cutting edge physics is notoriously difficult, but the public is always interested in hearing about a controversy. The press conference and following debate becomes a great "teaching moment" which offers the public a unique opportunity to get an inside and in-depth look at how science works. Scientists willing to publicly engage in this kind of civil controversy are important because when other scientific controversies arise, ones with major public policy implications, the public starts out with a better understanding of how science works, and scientists have better practice managing questions from the public.

2:54PM L37.00003 Controversial Science and the Media, JAMES RIORDON, American Physical Society — The possibility that the OPERA collaboration has detected superluminal neutrinos was among the most controversial topics in physics news in decades, and one of the most widely covered stories in all of science in 2011. Word of the research initially reached journalists and the public prior to publication in peer-reviewed journals. Understandably, many physicists are concerned that the significance of controversial science may be exaggerated or distorted when news organizations report on science at such an early stage. I will offer an overview of the ways the story was promoted by the media relations personnel, and outline the rationales that motivate media relations efforts along with the associated benefits and drawbacks that can result. Finally, I will examine the accuracy and completeness of the superluminal neutrino news stories that ultimately were made available to the general public.

3:06PM L37.00004 Controversial Physics: Perfect Public Outreach Opportunity, REBECCA THOMPSON, American Physical Society — The goal of public outreach is to excite and engage the public in physics. What can be more exciting than controversy? When OPERA announced their discover of superluminal neutrinos, controversy within the physics community quickly followed. This result could overturn a century of established physics. From a public outreach perspective there was no better way to bring people usually unaware of current research into the discussion of this result. If handled well this could be used as a gateway to interest in other physics research. The public drive to learn more about this particular result can be harnessed to create interest in other cutting edge physics research and drive the public to continue their informal physics learning. If the results of OPERA and eventually proven incorrect as many physicists believe they will, that will not erase the public's new-found interest in physics but hopefully continue to fuel it.

3:18PM L37.00005 Informal Physics Education: Outreach from a National Laboratory, JOSE SANCHEZ, PATRICIA DIXON, ROXANNE HUGHES, National High Magnetic Field Laboratory — This presentation highlights strategies for K-20 teaching and learning about materials research in informal settings. The National High Magnetic Field Laboratory's Center for Integrating Research & Learning is in a unique position to conduct programs that reach K-20 students and teachers. As part of a national laboratory the Center provides the infrastructure around which informal education programs are implemented, including the nationally-recognized programming as well as facilitating scientists' educational outreach in the community. Research Experiences for Undergraduates, focuses on encouraging women and other underrepresented groups to pursue STEM careers reaching approximately 200 students many of whom have pursued careers in research as well as academia. The Research Experiences for Teachers program has provided internships for over 150 teachers; the Center also reaches over 10,000 students each year through school and community outreach. Success of informal education programs relies heavily on establishing strong mentoring relationships between scientists and K-20 students and teachers. The Center's success at maintaining diverse programming that transforms how materials education is presented beyond the traditional classroom is the focus for this presentation.

3:30PM L37.00006 ABSTRACT WITHDRAWN –

3:42PM L37.00007 Houston, we have a problem: What the Voting Public Believes about Science Funding, JODI LIEBERMAN, Senior Government Relations Specialist, APS Physics — In an election year with a tight Federal budget outlook, the views of the voting public are critical to forecasting what may be in store for the National Science Foundation, Department of Energy Office of Science and National Institute for Standards and Technology. It is these people who weigh in with their legislators to identify what is important and what should be cut. The results of some recent polling commissioned by the APS and other scientific societies reveal that the general public may not be as supportive of Federal science funding as has been previously believed. Jodi Lieberman will present the results of that polling data and how it is likely to impact the next Federal science budget.

Tuesday, February 28, 2012 2:30PM - 5:18PM – Session L39 GQI: Focus Session: Superconducting Qubits: 3D Cavities 109B

2:30PM L39.00001 How coherent are Josephson junctions?¹, HANHEE PAIK, Yale University — Superconducting quantum circuits based on Josephson junctions are a promising technology to realize a electronically controlled, solid-state based large-scale quantum information processor but their future prospects rely on the intrinsic coherence of Josephson junctions and the engineering of the isolated environment for the quantum circuits. We introduce a new architecture for superconducting quantum circuits employing a single-Josephson junction in a three dimensional waveguide cavity where we carefully engineer the environment of the qubit to effectively reduce the coupling of the qubit to the environment while maintaining sufficient coupling to the control signal. With this architecture we demonstrate that Josephson junction qubits are at least an order of magnitude more coherent with $T_2^{Ramsey} \sim 10$ to $20 \mu s$ without the use of spin echo than previously reported and highly stable, enabling us to observe the physics in a Josephson junction with a unprecedented level of precision. These results suggest that the overall quality of Josephson junctions will allow error rates of a few 10^{-4} , approaching the error correction threshold. We will also discuss how to scale this architecture and perform two-qubit gates.

¹This work was performed in collaboration with D. I. Schuster, Lev S. Bishop, G. Kirchmair, G. Catelani, A. P. Sears, B. R. Johnson, M. J. Reagor, L. Frunzio, L. I. Glazman, S. M. Girvin, M. H. Devoret and R. J. Schoelkopf

3:06PM L39.00002 Bottom-up construction of artificial molecules for superconducting quantum processors, STEFANO POLETTI, CHAD RIGETTI, JAY M. GAMBETTA, SETH MERKEL, JERRY M. CHOW, ANTONIO D. CORCOLES, JOHN A. SMOLIN, JIM R. ROZEN, GEORGE A. KEEFE, MARY B. ROTHWELL, MARK B. KETCHEN, MATTHIAS STEFFEN, IBM T.J. Watson Research Center — Recent experiments on transmon qubits capacitively coupled to superconducting 3-dimensional cavities have shown coherence times much longer than transmons coupled to more traditional planar resonators. For the implementation of a quantum processor this approach has clear advantages over traditional techniques but it poses the challenge of scalability. We are currently implementing multi-qubits experiments based on a bottom-up scaling approach. First, transmon qubits are fabricated on individual chips and are independently characterized. Second, an artificial molecule is assembled by selecting a particular set of previously characterized single-transmon chips. We present recent data on a two-qubit artificial molecule constructed in this way. The two qubits are chosen to generate a strong Z-Z interaction by matching the 0-1 transition energy of one qubit with the 1-2 transition of the other. Single qubit manipulations and state tomography cannot be done with “traditional” single tone microwave pulses but instead specifically shaped pulses have to be simultaneously applied on both qubits. Coherence times, coupling strength, and optimal pulses for decoupling the two qubits and perform state tomography are presented

3:18PM L39.00003 Quasiparticle tunneling in a single-junction transmon qubit¹, DIEGO RISTÉ, JOSEPHINE VAN LEEUWEN, LEONARDO DICARLO, Kavli Institute of Nanoscience, Delft University of Technology — The recent increase in transmon qubit quality factor into the million range [1] makes non-equilibrium quasiparticle tunneling a potentially limiting mechanism for qubit coherence. We investigate the dynamics of quasiparticle tunneling in a single-junction transmon qubit with relaxation time $T_1 = 85 \mu s$ ($Q = 2.6$ million). The qubit operates at moderate ratio of Josephson to charging energy, $E_J/E_C \sim 30$, where charge parity in the qubit islands is encoded in the qubit transition frequency. Using Ramsey-type and stimulated echo experiments, we investigate quasiparticle tunneling across the qubit junction on time scales short and long compared to T_1 . We observe that the quasiparticle tunneling time for the single-junction qubit is at least as long as T_1 , but shorter than the 1 ms repetition rate. This result is consistent with recent theory and qualitatively different from the two-junction transmon. The dephasing time $T_2^* = 10 \mu s$ is limited by slow background charge fluctuations and extended to $T_2 = 95 \mu s$ using dynamical decoupling.

3:30PM L39.00004 Varying Cavity Quality Factor in situ for a Transmon in Circuit QED, ANDREI PETRENKO, ADAM SEARS, GERHARD KIRCHMAIR, HANHEE PAIK, LUYAN SUN, GIANLUIGI CATELANI, LEONID GLAZMAN, ROBERT SCHOELKOPF, Yale University — Superconducting transmon qubits have recently been studied within 3D cavities. In addition to increasing the coherence times of the qubits this has enabled a simple scheme for varying the quality factor Q (or decay rate κ) of a cavity in situ. This decay rate plays an important role in our understanding of a number of effects in circuit quantum electrodynamics, many of which have direct bearing on qubit decoherence processes. Here we study how adjusting the cavity Q affects the coherence times of a single qubit within the 3D architecture. We demonstrate that varying the coupling enables us to not only examine the limitations of qubit T_1 due to the Purcell Effect, but also probe new decoherence mechanisms such as the dephasing due to photon shot noise. By understanding and minimizing these effects, we obtain record coherences times T_2 and T_2^{Echo} of $\sim 27 \mu s$ and $\sim 47 \mu s$ respectively.

3:42PM L39.00005 Dephasing Due to Shot Noise in the Strong Dispersive Limit of Circuit QED, ADAM SEARS, ANDREI PETRENKO, GERHARD KIRCHMAIR, HANHEE PAIK, LUYAN SUN, GIANLUIGI CATELANI, LEONID GLAZMAN, ROBERT SCHOELKOPF, Yale University — The design parameters of superconducting qubits inside resonant cavities have evolved over time to minimize decoherence, allow fast pulses and enable high fidelity readout. The two are often coupled so strongly that the dispersive shift of the qubit due to a single photon in the cavity (or AC Stark shift) is much larger than a linewidth. In this strong dispersive regime, the passage of any photons can lead to an unintended and complete measurement of the qubit state. We study photon shot noise dephasing in this limit for a transmon and derive a simple relation between the dephasing rate and the product $\bar{n}\kappa$, where $\bar{n}$ is the average cavity occupancy and κ is the cavity decay rate. We find good experimental agreement for a large range of κ , varied *in situ* using a simple mechanism, and note several ways this can influence qubit experiments.

3:54PM L39.00006 Effective model of nonlinear circuit quantum electrodynamics¹, SIMON NIGG, Physics Department, Yale University, MICHEL DEVORET, Department of Applied Physics, Yale University, STEVEN GIRVIN, Physics Department, Yale University — Superconducting electronic circuits containing nonlinear elements such as Josephson junctions are of interest for quantum information processing. The low-energy spectrum of such circuits can now be measured to a precision of better than one part per million. A precise knowledge of their Hamiltonian that goes beyond current models is thus desirable. In this talk I will show how to quantize a superconducting, weakly nonlinear circuit from the knowledge of its classical linear admittance matrix. This approach represents a change of paradigm in circuit quantum electrodynamics and may potentially become a useful alternative to the standard models based on the language of atomic physics and quantum optics.

¹I acknowledge financial support from the Swiss National Science Foundation.

4:06PM L39.00007 Designing a three mode circuit QED experiment, BRIAN VLASTAKIS, GERHARD KIRCHMAIR, HANHEE PAIK, SIMON NIGG, LUIGI FRUNZIO, STEVEN GIRVIN, MICHEL DEVORET, ROBERT SCHOELKOPF, Yale University — Circuit QED employs the coupling of nonlinear elements to resonant modes of an electronic circuit. We demonstrate that all resonant modes will attain some degree of nonlinearity from even a single nonlinear element. This can result in individually addressable transitions for each mode and allow direct control of each quantum state. Furthermore, we show that the transition frequency of any one mode will depend on the state of all other modes. These state dependent shifts can be used to directly readout the quantum state of one mode probing another. We illustrate this behavior by coupling two three-dimensional resonators to a superconducting transmon qubit and present a method to determine the Hamiltonian for this system using a nonlinear circuit QED model.

4:18PM L39.00008 Experiments on a three mode circuit QED system, GERHARD KIRCHMAIR, BRIAN VLASTAKIS, HANHEE PAIK, Applied Physics Department Yale University, SIMON NIGG, Physics Department Yale University, LUIGI FRUNZIO, Applied Physics Department Yale University, STEVEN GIRVIN, Physics Department Yale University, MICHEL DEVORET, ROBERT SCHOELKOPF, Applied Physics Department Yale University — Current research in superconducting circuit QED is working towards combining an increasing number of cavities and qubits to investigate larger scale quantum systems. Here we will discuss measurements on a system consisting of two three-dimensional microwave resonators coupled to a single transmon qubit. We demonstrate that each mode of the system has sufficient anharmonicity to coherently manipulate the state of the lowest two energy levels. This allows us to measure the coherence of a single excitation in a mode and detect the frequency shift due to excitations of the other modes. These effects are important to consider when using a resonator as a quantum memory to decouple the quantum state from the rest of the system. Furthermore we show that we can use the state dependent shifts to detect the quantum state of one mode with another. The full characterization of the system allows us to determine the Hamiltonian and compare it to the theoretical predictions obtained with a nonlinear circuit QED model.

4:30PM L39.00009 Material and Geometric Effects in 3D Transmon Qubits, MATTHEW WARE, M.P. DEFEQ, J.D. STRAND, B. XIAO, B.L.T. PLOURDE, Syracuse University, STEFANO POLETTI, CHAD RIGETTI, IBM Research, SYRACUSE UNIVERSITY COLLABORATION, IBM RESEARCH COLLABORATION — Optimization of coherent behavior is a key ingredient for any scalable architecture using qubits. Recent breakthroughs in novel qubit designs have resulted in significant improvements in coherence by coupling superconducting qubits to 3-dimensional microwave cavities. We are investigating material and geometric factors affecting the coherence of these 3D transmon qubits. Various loss mechanisms limiting the qubit coherence will be discussed. The role played by device geometry and size in determining the effective qubit-cavity coupling will also be explored.

4:42PM L39.00010 3D Microwave Cavity for Qubit Measurement, SERGEY NOVIKOV, V. ZARETSKEY, B. SURJ, Z. KIM, Dept. of Physics, Univ. of Maryland, B. S. PALMER, Lab. for Physical Sciences, F. C. WELLSTOOD, JQI, CNAM, Dept. of Physics, Univ. of Maryland — We have investigated the loss mechanisms of the TE_{101} mode (resonant frequency $f_0 = 8$ GHz) of a superconducting Al microwave cavity. The internal quality factor Q_{int} of the cavity has been measured for a range of temperatures from 23 mK to 360 mK in a low photon number regime and from 360 mK to $T_c \sim 1.1$ K in a high photon number regime, both with and without a sapphire chip in the cavity. With sapphire present, $Q_{int} \sim 10^6$ was strongly reduced by an applied magnetic field. Without sapphire, $Q_{int} \sim 4 \times 10^6$ was only weakly dependent on the applied field. The frequency stability of the cavity and the use of the cavity for qubit readout (following recent experiments by H. Paik *et al.*¹) will be discussed.

¹arXiv:1105.4652v4

4:54PM L39.00011 Characterization of superconducting accelerator cavity at millikelvin temperature for use in quantum computation, BING LI, YANG GE, University of Chicago, ALEX ROMANENKO, LANCE COOLEY, Fermi National Laboratory, DAVID SCHUSTER, University of Chicago — Quantum computation using 2D superconducting circuits has been advancing rapidly but has been limited to coherence times of a few microseconds. On the other hand, 3d superconducting cavities for accelerators routinely achieve quality factors exceeding ten billion, corresponding to coherence times exceeding one second. With the recent demonstration of coupling a superconducting qubit to a 3d resonator [1], it should be possible to take advantage of this advanced accelerator technology. However, accelerator cavities are typically used above 2 K and at 1 W input powers. The ultimate residual resistance of accelerator cavities is not yet well understood and it is unclear if they will maintain their exceptional properties at millikelvin temperatures and ultra-low powers. We present measurements of a 3.9 GHz accelerator cavity from 2K-20mK and at powers less than one attowatt. [1] Paik, *et. al.* arXiv:1105.4652

5:06PM L39.00012 Improving the Coherence Time of Microwave Cavities, MATTHEW REAGOR, HANHEE PAIK, LUYAN SUN, ERIC HOLLAND, LUIGI FRUNZIO, ROBERT SCHOELKOPF, Department of Physics and Applied Physics, Yale University — A superconducting cavity resonator is able to store quantum states of light, protect qubits from decoherence and place bounds on material losses. The resonator's utility in all three goals is inherently tied to its quality factor. We report recent progress in improving the quality factors of aluminum waveguide cavities in the quantum regime. We will also report on the use of these cavities to measure the dielectric properties of low-loss substrates and the surface impedance of bulk superconductors and thin films.

Session L40 DBIO GSNP: Focus Session: Systems Biology and Biochemical Networks II 156A

2:30PM L40.00001 Microbial interaction networks in soil and in silico, KALIN VETSIGIAN, University of Wisconsin-Madison — Soil harbors a huge number of microbial species interacting through secretion of antibiotics and other chemicals. What patterns of species interactions allow for this astonishing biodiversity to be sustained, and how do these interactions evolve? I used a combined experimental-theoretical approach to tackle these questions. Focusing on bacteria from the genus *Streptomyces*, known for their diverse secondary metabolism, I isolated 64 natural strains from several individual grains of soil and systematically measured all pairwise interactions among them. Quantitative measurements on such scale were enabled by a novel experimental platform based on robotic handling, a custom scanner array and automatic image analysis. This unique platform allowed the simultaneous capturing of ~15,000 time-lapse movies of growing colonies of each isolate on media conditioned by each of the other isolates. The data revealed a rich network of strong negative (inhibitory) and positive (stimulating) interactions. Analysis of this network and the phylogeny of the isolates, together with mathematical modeling of microbial communities, revealed that: 1) The network of interactions has three special properties: “balance”, “bi-modality” and “reciprocity”; 2) The interaction network is fast evolving; 3) Mathematical modeling explains how rapid evolution can give rise to the three special properties through an interplay between ecology and evolution. These properties are not a result of stable co-existence, but rather of continuous evolutionary turnover of strains with different production and resistance capabilities.

3:06PM L40.00002 ABSTRACT WITHDRAWN –

3:18PM L40.00003 Regulatory schemes to achieve optimal flux partitioning in bacterial metabolism¹, LEI-HAN TANG, Department of Physics, Hong Kong Baptist University and Beijing Computational Science Research Center, ZHU YANG, Department of Physics, Hong Kong Baptist University, SHENG HUI, Department of Physics, UCSD, PAN-JUN KIM, APCTP, Korea, XUE-FEI LI, Department of Physics, Hong Kong Baptist University, TERENCE HWA, Department of Physics, UCSD — The flux balance analysis (FBA) offers a way to compute the optimal performance of a given metabolic network when the maximum incoming flux of nutrient molecules and other essential ingredients for biosynthesis are specified. Here we report a theoretical and computational analysis of the network structure and regulatory interactions in an *E. coli* cell. An automated scheme is devised to simplify the network topology and to enumerate the independent flux degrees of freedom. The network organization revealed by the scheme enables a detailed interpretation of the three layers of metabolic regulation known in the literature: i) independent transcriptional regulation of biosynthesis and salvage pathways to render the network tree-like under a given nutrient condition; ii) allosteric end-product inhibition of enzyme activity at entry points of synthesis pathways for metabolic flux partitioning according to consumption; iii) homeostasis of currency and carrier compounds to maintain sufficient supply of global commodities. Using the amino-acid synthesis pathways as an example, we show that the FBA result can be reproduced with suitable implementation of the three classes of regulatory interactions with literature evidence.

¹Work supported in part by the RGC of the HKSAR under grant 201910.

3:30PM L40.00004 A Realtime Active Feedback Control System For Coupled Nonlinear Chemical Oscillators, NATHAN TOMPKINS, SETH FRADEN, Brandeis University — We study the manipulation and control of oscillatory networks. As a model system we use an emulsion of Belousov-Zhabotinsky (BZ) oscillators packed on a hexagonal lattice. Each drop is observed and perturbed by a Programmable Illumination Microscope (PIM). The PIM allows us to track individual BZ oscillators, calculate the phase and order parameters of every drop, and selectively perturb specific drops with photo illumination, all in realtime. To date we have determined the native attractor patterns for drops in 1D arrays and 2D hexagonal packing as a function of coupling strength as well as determined methods to move the system from one attractor basin to another. Current work involves implementing these attractor control methods with our experimental system and future work will likely include implementing a model neural network for use with photo controllable BZ emulsions.

3:42PM L40.00005 Stochastic gene expression with bursting and positive feedback, THIERRY PLATINI, Virginia Bioinformatics Institute, HODJAT PENDAR, RAHUL KULKARNI, Department of Physics, Virginia Tech — Stochasticity (or noise) in the process of gene expression can play a critical role in cellular circuits that control switching between probabilistic cell-fate decisions in diverse organisms. Such circuits often include positive feedback loops as critical elements. In some cases (e.g. HIV-1 viral infections), switching between different cell fates occurs even in the absence of bistability in the underlying deterministic model. To characterize the role of noise in such systems, we analyze a simple gene expression circuit that includes contributions from both transcriptional and translational bursting and positive feedback effects. Using a combination of analytical approaches and stochastic simulations, we explore how the underlying parameters control the corresponding mean and variance in protein distributions.

3:54PM L40.00006 mRNA Noise Reveals that Activators Induce a Biphasic Response in the Promoter Kinetics of Highly Regulated Genes, KATIE QUINN, Massachusetts Institute of Technology, TSZ-LEUNG TO, University of California, San Francisco, NARENDRA MAHESHRI, Massachusetts Institute of Technology — A dominant source of fluctuations in gene expression is thought to be the process of transcription. The statistics of these fluctuations arise from the kinetics of transcription. Multiple studies suggest the bulk of fluctuations can be understood by a simple process where genes are inactive for exponentially distributed times punctuated by geometric bursts of mRNA. Yet it's largely unknown how cis and trans factors affect the two lumped kinetic parameters, burst size and burst frequency, that describe this process. Importantly, how these parameters are regulated in a single gene can qualitatively affect the dynamical behavior of the network it is embedded within. Here, we ask whether transcriptional activators increase gene expression by increasing the burst size or burst frequency. We do so by deducing these parameters from steady-state mRNA distributions measured in individual yeast cells using single molecule mRNA FISH. We find that for both a synthetic and natural promoter, activators appear to first increase burst size, then burst frequency. We suggest this biphasic response may be common to all highly regulated genes and was previously unappreciated because of measurement techniques. Furthermore, its origins appear to relate to cis events at the promoter, and may arise from combinations of basal and activator-dependent bursts. Our measurements shed new light on transcriptional mechanisms and should assist in building synthetic promoters with tunable statistics.

4:06PM L40.00007 Determining the stability of genetic switches: Explicitly accounting for mRNA noise, MICHAEL ASSAF, ELIJAH ROBERTS, ZAN LUTHEY-SCHULTEN, University of Illinois at Urbana-Champaign — Cells use genetic switches to shift between alternate gene expression states, e.g. to adapt to new environments or to follow a developmental pathway. Here, we study the dynamics of switching in a generic-feedback on/off switch. Unlike protein-only models, we explicitly account for stochastic fluctuations of mRNA, which have a dramatic impact on the genetic switch dynamics. Employing a semi-classical theory to treat the underlying chemical master equations, we obtain accurate results for the quasi-stationary distributions of mRNA and protein copy numbers and for the mean switching time, starting from either state. Our analytical results agree well with extensive Monte Carlo simulations. Importantly, one can use the approach to study the effect of varying biological parameters, and of extrinsic noise, on the switch stability.

4:18PM L40.00008 Quantitative Model of microRNA-mRNA interaction, JAVAD NOORBAKHS, ALEX LANG, PANKAJ MEHTA, Boston University — MicroRNAs are short RNA sequences that regulate gene expression and protein translation by binding to mRNA. Experimental data reveals the existence of a threshold linear output of protein based on the expression level of microRNA. To understand this behavior, we propose a mathematical model of the chemical kinetics of the interaction between mRNA and microRNA. Using this model we have been able to quantify the threshold linear behavior. Furthermore, we have studied the effect of internal noise, showing the existence of an intermediary regime where the expression level of mRNA and microRNA has the same order of magnitude. In this crossover regime the mRNA translation becomes sensitive to small changes in the level of microRNA, resulting in large fluctuations in protein levels. Our work shows that chemical kinetics parameters can be quantified by studying protein fluctuations. In the future, studying protein levels and their fluctuations can provide a powerful tool to study the competing endogenous RNA hypothesis (ceRNA), in which mRNA crosstalk occurs due to competition over a limited pool of microRNAs.

4:30PM L40.00009 On the control of gene expression in small RNA post-transcriptional regulation pathway: role of conserved weak targets¹, DANIEL JOST, ANDRZEJ NOWOJEWSKI, EREL LEVINE, Department of Physics and FAS Center for Systems Biology - Harvard University — Small RNA molecules play critical regulatory roles in organisms across all kingdoms of life. Many small RNA families achieve target-specificity via base-pairing of a very short (6-8 nucleotides) "seed" region with the targeted mRNA, and consequently many genes carry a matching seed in their sequence. Evidence in bacteria and animals suggest that a single small RNA may regulate the gene expression of many different targets, although most of them very weakly. On the other hand, in all cases we are aware of where the functionality of a small RNA has been carefully studied, only a small number of target genes were identified as being phenotypically relevant. Here, we present a Langevin formalism which describes the dynamics of the different interacting entities (small RNA and targets), including the stochasticity of the underlying biochemical reactions and the effect of transport. Using analytical or numerical computations, we study the influence of (many) weak targets on the mean and noise properties of (few) principal targets. In particular, we argue that the role of these weak targets is to confer robustness to the regulation of the principal targets without significantly affecting their temporal responses to changing environments.

¹This work was supported by the National Science Foundation under Grant No. MCB1121057.

4:42PM L40.00010 Approaches to Chemical and Biochemical Information and Signal Processing, VLADIMIR PRIVMAN, Clarkson University — We outline models and approaches for error control required to prevent buildup of noise when "gates" and other "network elements" based on (bio)chemical reaction processes are utilized to realize stable, scalable networks for information and signal processing. We also survey challenges and possible future research.

4:54PM L40.00011 Organizing biochemical reactions: Lessons from cyanobacteria¹, NIAL MANGAN, Harvard University Systems Biology PhD Program, MICHAEL BRENNER, Harvard School of Engineering and Applied Sciences — Cyanobacteria are model organisms for photosynthesis and are of interest for bio-fuel production and carbon dioxide sequestration. I present a mathematical model of the carbon concentrating mechanism (CCM) in cyanobacteria. The CCM is a combination of transporters and enzymes distinctively organized in the cell, which increase the internal concentration of carbon dioxide, and improve the efficiency of converting carbon dioxide to sugar. I find that the internal carbon concentration can be completely described by solutions in two parameter regimes of the model. These solutions correspond to varying transporter and enzymatic activity, which can be directly connected to experimental measurements. I also find a dependence of the carbon concentration on the spatial organization of the reactions within the cell. Understanding the CCM in cyanobacteria gives us insight into design principles for the cellular organization of biological reactions.

2:30PM L41.00001 A Thermodynamic Model for Behavioral Intelligence, ALEXANDER WISSNER-GROSS, CAMERON FREER, Massachusetts Institute of Technology — Recent advances in cosmology and computer science have hinted at a potentially deep connection between intelligence and thermodynamics. Here we attempt to elucidate that connection by showing that a generalization of entropic forces can induce archetypically intelligent behaviors in a variety of classical mechanical systems. These results suggest a simple, but general, thermodynamic model for behavioral intelligence.

2:42PM L41.00002 Data collapse and critical dynamics in neuronal avalanche data, THOMAS BUTLER, Massachusetts Institute of Technology, NIR FRIEDMAN, KARIN DAHMEN, University of Illinois at Urbana-Champaign, JOHN BEGGS, Indiana University, LEE DEVILLE, University of Illinois at Urbana-Champaign, SHINYA ITO, Indiana University — The tasks of information processing, computation, and response to stimuli require neural computation to be remarkably flexible and diverse. To optimally satisfy the demands of neural computation, neuronal networks have been hypothesized to operate near a non-equilibrium critical point. In spite of their importance for neural dynamics, experimental evidence for critical dynamics has been primarily limited to power law statistics that can also emerge from non-critical mechanisms. By tracking the firing of large numbers of synaptically connected cortical neurons and comparing the resulting data to the predictions of critical phenomena, we show that cortical tissues in vitro can function near criticality. Among the most striking predictions of critical dynamics is that the mean temporal profiles of avalanches of widely varying durations are quantitatively described by a single universal scaling function (data collapse). We show for the first time that this prediction is confirmed in neuronal networks. We also show that the data have three additional features predicted by critical phenomena: approximate power law distributions of avalanche sizes and durations, samples in subcritical and supercritical phases, and scaling laws between anomalous exponents.

2:54PM L41.00003 Self Organized Criticality as a new paradigm of sleep regulation¹, PLAMEN CH. IVANOV, RONNY P. BARTSCH, Harvard Medical School and Division of Sleep Medicine, Brigham and Womens Hospital, Boston, MA 02115, USA — Humans and animals often exhibit brief awakenings from sleep (arousals), which are traditionally viewed as random disruptions of sleep caused by external stimuli or pathologic perturbations. However, our recent findings show that arousals exhibit complex temporal organization and scale-invariant behavior, characterized by a power-law probability distribution for their durations, while sleep stage durations exhibit exponential behavior. The co-existence of both scale-invariant and exponential processes generated by a single regulatory mechanism has not been observed in physiological systems until now. Such co-existence resembles the dynamical features of non-equilibrium systems exhibiting self-organized criticality (SOC). Our empirical analysis and modeling approaches based on modern concepts from statistical physics indicate that arousals are an integral part of sleep regulation and may be necessary to maintain and regulate healthy sleep by releasing accumulated excitations in the regulatory neuronal networks, following a SOC-type temporal organization.

3:06PM L41.00004 Frost nucleation, growth and propagation on a hydrophobic surface¹, JOSÉ GUADARRAMA-CETINA, University of Navarra, ANNE MONGRUEL, PMMH, UMR 7636 CNRS-ESPCI-University Paris 6-University Paris 7, WENCESLAO GONZÁLEZ-VIÑAS, University of Navarra, DANIEL BEYSENS, PMMH, UMR 7636 CNRS-ESPCI-University Paris 6-University Paris 7 and CEA-Grenoble — We report experimental results on the condensation of water vapor on a substrate (-9°C) at supercooled conditions. The resulting breath figure grows until the liquid to solid phase transition takes place. The frost seeds start to grow by deposition at the expense of neighboring supercooled water drops that evaporate. Sometimes the propagation (due to the growth of the ice) is faster than the evaporation of the drops, hence they transit to the solid state via a percolation mechanism. In this work [1], we analyze the growth of supercooled condensed drops (first stage), the growth of the ice crystals and the evolution of the supercooled water drops (intermediate and late stages). We also consider the liquid - solid front propagation (growth of the frost figure).

3:18PM L41.00005 Pattern formation in oscillatory fluid flows, DAPHNE KLOTSAS, University of Michigan, MICHAEL SWIFT, University of Nottingham — Rigid spherical particles in oscillating fluid flows form interesting structures as a result of fluid mediated interactions. Here we show that two spheres under horizontal vibration align themselves at right angles to the oscillation and sit with a gap between them, which scales in a non-classical way with the boundary layer thickness. The details of this behavior have been investigated through experiments and simulations. We then look at a collection of spherical particles, which form chains perpendicular to the direction of oscillation. Comparing experiments and simulations we study the stages of evolution from a dispersed initial configuration to an ordered chain structure. We investigate the details of the interactions and find that the nonlinear hydrodynamic effect of steady streaming is the driving force.

3:30PM L41.00006 Dynamic effects induced by renormalization in anisotropic pattern forming systems, MATTEO NICOLI, Physique de la Matière Condensée, École Polytechnique, CNRS, Palaiseau, France, ADRIAN KELLER, STEFAN FACKSO, Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany, RODOLFO CUERNO, Departamento de Matemáticas and Grupo Interdisciplinar de Sistemas Complejos, Universidad Carlos III de Madrid, Leganés, Spain — The dynamics of patterns in large two-dimensional domains remains a challenge in nonequilibrium phenomena. Often it is addressed through mild extensions of one-dimensional equations. We show that full two-dimensional generalizations of the latter can lead to unexpected dynamic behavior. As an example we consider the anisotropic Kuramoto-Sivashinsky equation, which is a generic model of anisotropic pattern forming systems and has been derived in different instances of thin film dynamics. A rotation of a ripple pattern by 90° occurs in the system evolution when nonlinearities are strongly suppressed along one direction. This effect originates in nonlinear parameter renormalization at different rates in the two system dimensions, showing a dynamic interplay between scale invariance and wavelength selection. Potential experimental realizations of this phenomenon are identified. A. Keller, M. Nicoli, S. Fackso, and R. Cuerno, Phys. Rev. E 84, 015202(R) (2011).

3:42PM L41.00007 Self-Sustained Front Propagation in Disordered Flow, SEVERINE ATIS, HAROLD AURADOU, CNRS, DOMINIQUE SALIN, UPMC, LAURENT TALON, CNRS — We generate propagative fronts resulting from a balance between molecular diffusion and non-linear chemical reaction. These fronts behave as solitary waves with a constant velocity and a stationary concentration profile. The interaction between this self-sustained system and a disordered flow leads to complex structures formation. We have performed experiments of the front propagation over a wide range of stochastic flow rates, in porous media. We have determined the structure and the velocity distribution measured along the front. The concentration profile displays salient spatial features such as scaling laws and pattern formation.

3:54PM L41.00008 Sidebranching in the Dendritic Crystal Growth of Ammonium Chloride, ANDREW DOUGHERTY, Lafayette College — We report measurements of the dendritic crystal growth of NH_4Cl from supersaturated aqueous solution at small supersaturations. Sidebranch growth in this regime is challenging to model well, and the origin of the sidebranches is not fully understood. The early detection of sidebranches requires measurements of small deviations from the smooth steady state shape, but that shape is not well known at the intermediate distances relevant for sidebranch measurements. One model is that sidebranches result from the selective amplification of microscopic noise. We compare measurements of the sidebranch envelope with predictions of the noise-induced sidebranching model of González-Cinca, Ramírez-Piscina, Casademunt, and Hernández-Machado [Phys. Rev. E, 63, 051602 (2001)]. We find that the measured amplitude is somewhat larger than predicted, and the shape of the sidebranch envelope is also different. A second model is that sidebranches result from small oscillations of the tip. We have observed no such oscillations, but very small ones can not be ruled out. No measurement of the tip region can be completely free of contamination from early sidebranches, so it can be challenging to distinguish between an oscillating tip and a smooth tip with sidebranches starting nearby.

4:06PM L41.00009 Burning invariant manifolds in spatially disordered advection-reaction-diffusion¹, DYLAN BARGTEIL, Bucknell University/University of Maryland, TOM SOLOMON, Bucknell University, JOHN MAHONEY, KEVIN MITCHELL, University of California, Merced — We introduce burning invariant manifolds (BIMs) which act as barriers to front propagation, similar to the role played by invariant manifolds as barriers to passive transport in two-dimensional flows. We present experimental studies of BIMs in a spatially disordered, time-independent flow. We generate the flow with a magnetohydrodynamic technique that uses a DC current and a disordered pattern of permanent magnets. The velocity field is determined from this flow using particle tracking velocimetry, and reaction fronts are produced using the Ferriin-catalyzed Belousov-Zhabotinsky (BZ) chemical reaction. We use the experimental velocity field and a three-dimensional set of ODEs to predict from theory the location and orientation of BIMs. These predicted BIMs are found to match up well with the propagation barriers observed experimentally in the same flow using the BZ reaction. We explore the nature of BIMs as one-sided barriers, in contrast to invariant manifolds that act as barriers for passive transport in all directions. We also explore the role of projection singularities in the theory and how these singularities affect front behavior.

¹NSF Grants DMR-0071771, PHY-0552790

4:18PM L41.00010 Chaotic advection of immiscible fluids¹, BENJAMIN VOLLMAYR-LEE, Bucknell University, DANIEL BELLER, University of Pennsylvania, SOHEI YASUDA, Purdue University — We consider a system of two immiscible fluids advected by a chaotic flow field. A nonequilibrium steady state arises from the competition between the coarsening of the immiscible fluids and the domain bursting caused by the chaotic flow. It has been established that the average domain size in this steady state scales as an inverse power of the Lyapunov exponent. We examine the issue of local structure and look for correlations between the local domain size and the finite-time Lyapunov exponent (FTLE) field. For a variety of chaotic flows, we consistently find the domains to be smallest in regions where the FTLE field is maximal. This raises the possibility of making universal predictions of steady-state characteristics based on Lyapunov analysis of the flow field.

4:30PM L41.00011 Hamiltonian traffic dynamics in microfluidic-loop networks, RAPHAEL JEANNERET, DENIS BARTOLO, PMMH-ESPCI, Université Paris Diderot, BARTOLO TEAM — Recent microfluidic experiments revealed that large particles advected in a fluidic loop display long-range hydrodynamic interactions. However, the consequences of such couplings on the traffic dynamics in more complex networks remain poorly understood. In this letter, we focus on the transport of a finite number of particles in one-dimensional loop networks. By combining numerical, theoretical, and experimental efforts, we evidence that this collective process offers a unique example of Hamiltonian dynamics for hydrodynamically interacting particles. In addition, we show that the asymptotic trajectories are necessarily reciprocal despite the microscopic traffic rules explicitly break the time reversal symmetry. We exploit these two remarkable properties to account for the salient features of the effective three-particle interaction induced by the exploration of fluidic loops.

4:42PM L41.00012 Intensity statistics of branched flow, JAKOB METZGER, RAGNAR FLEISCHMANN, THEO GEISEL, Max-Planck-Institute for Dynamics and Self-Organization, Goettingen, Germany — Branched flow is a universal phenomenon of particle and wave flows which are subjected to weak, correlated disorder. It has been observed on length scales ranging from a few micrometres, affecting the transport properties of semiconductor devices [1], up to several thousand kilometres, influencing sound propagation through the ocean [2]. It is also responsible for the appearance of large and hazardous freak waves and tsunamis [3]. While the statistics of the number of such branches has recently been calculated [4], the influence on the statistics of the intensity of the waves remains an open question [5]. Here, we show how the classical ray intensity impacts on the wave intensity statistics, and illuminate the role played by the decoherence of the wavefunction.

4:54PM L41.00013 Flow past a circular cylinder with momentum injection: Optimal control cylinder design, SUBHASH REDDY, PRASAD PATNAIK, Indian Institute of Technology, Madras — The primary aim of this work is to suppress vortex shedding behind a circular cylinder by placing two small rotating control cylinders very close to it and hence injecting momentum into the boundary layer. The position and circulation strengths of the control cylinders are the important aspects of our study. Solving the complete Navier-Stokes (NS) equations can be time consuming while identifying the position and circulation strength of the control cylinders. Instead, reduced order models (ROM) can be used to save the computational expenditure associated with solving the complete NS model. Physics-based approaches to reduced order modeling include many of the techniques for modeling and simplification commonly used in fluid dynamics analysis such as potential flow analysis, vortex methods etc. Each of these are approximations to the full NS equations and each can serve as effective ROMs under appropriate conditions. In the present study, we try to achieve potential flow behavior by optimum positioning of the control cylinders and hence potential flow analysis is carried out with different analytical methods like Föppl vortex model and conformal mapping techniques. For these optimum values, the analytical solution obtained is compared with the numerical viscous flow simulations.

5:06PM L41.00014 ABSTRACT WITHDRAWN —

5:18PM L41.00015 Simulating Tablet Dissolution in Complex Hydrodynamic Environment with Lattice-Boltzmann Method, ARPON RAKSIT, Harvard University, NING SUN, VADIM POZIN, DILIP GERSAPPE, Department of Materials Science and Engineering, Stony Brook University — Using the Lattice-Boltzmann method, we developed a 3D mesoscopic model to study the drug-dissolution process in a complex hydrodynamic environment involving spatially varying velocity and shear forces. The results showed turbulent flow in region above tablet, which was also obtained by visualization experiments. The dissolution profiles obtained by incorporating detailed kinetics showed good agreement with case studies from literature. The influence of the paddle speed and the size of the system were studied, and a multicomponent approach was also incorporated. Our results show how that the hydrodynamic environment would affect the dissolution process by changing the local concentration of components near the tablet and by the particle erosion under high fluid velocity. The code was also successfully parallelized so that the simulation of comparatively large system is now possible.

Session L42 DBIO: Focus Session: Physics of Cancer II – Physical Aspects 156C

2:30PM L42.00001 A Condensed Matter Physicist Looks at Cancer and the Tumor Microenvironment¹, CLARE YU, University of California, Irvine — We will discuss what physics can bring to cancer biology, and give an example by taking a closer look at the tumor microenvironment. Cancer cells do not act alone. They get their cues from the their environment which consists of the extracellular matrix and the cells (fibroblasts) that form it. These cues can be both chemical and mechanical in nature.

¹Work supported by the Princeton Physical Sciences Oncology Center

3:06PM L42.00002 Senescent cells in growing tumors, STEFANO ZAPPERI, National Research Council of Italy, IENI-CNR, Milano, Italy, CATERINA A.M. LA PORTA, Department of Biomolecular Science and Biotechnology, University of Milano, Italy, JAMES P. SETHNA, LASSP, Department of Physics, Cornell University, Ithaca NY — Tumors are defined by their intense proliferation, but sometimes cancer cells turn senescent and stop replicating. In the stochastic cancer model in which all cells are tumorigenic, senescence is seen as the result of random mutations, suggesting that it could represent a barrier to tumor growth. In the hierarchical cancer model a subset of the cells, the cancer stem cells, divide indefinitely while other cells eventually turn senescent. Here we formulate cancer growth in mathematical terms and obtain distinct predictions for the evolution of senescence in the two models. We perform experiments in human melanoma cells which confirm the predictions of the hierarchical model and show that senescence is a reversible process controlled by survivin. We conclude that enhancing senescence is unlikely to provide a useful therapeutic strategy to fight cancer, unless the cancer stem cells are specifically targeted.

3:18PM L42.00003 Clustering of brain tumor cells: a first step for understanding tumor recurrence, EVGENIY KHAİN, Department of Physics, Oakland University, M.O. NOWICKI, E.A. CHIOCCA, S.E. LAWLER, Department of Neurological Surgery, The Ohio State University Medical Center, C.M. SCHNEIDER-MIZELL, L.M. SANDER, Department of Physics, University of Michigan — Glioblastoma tumors are highly invasive; therefore the overall prognosis of patients remains poor, despite major improvements in treatment techniques. Cancer cells detach from the inner tumor core and actively migrate away [1]; eventually these invasive cells might form clusters, which can develop to recurrent tumors. In vitro experiments in collagen gel [1] followed the clustering dynamics of different glioma cell lines. Based on the experimental data, we formulated a stochastic model for cell dynamics, which identified two mechanisms of clustering. First, there is a critical value of the strength of adhesion; above the threshold, large clusters grow from a homogeneous suspension of cells; below it, the system remains homogeneous, similarly to the ordinary phase separation. Second, when cells form a cluster, there is evidence that their proliferation rate increases. We confirmed the theoretical predictions in a separate cell migration experiment on a substrate and found that both mechanisms are crucial for cluster formation and growth [2]. In addition to their medical importance, these phenomena present exciting examples of pattern formation and collective cell behavior in intrinsically non-equilibrium systems [3].

3:30PM L42.00004 Targeting tumor acidity, YANA K. RESHETNYAK, Physics, University of Rhode Island, DONALD M. ENGELMAN, Mol. Biophys & Biochem., Yale, OLEG A. ANDREEV, University of Rhode Island, URI TEAM, YALE TEAM — One of the main features of solid tumors is extracellular acidity, which correlates with tumor aggressiveness and metastatic potential. We introduced novel approach in targeting of acidic tumors, and translocation of cell-impermeable cargo molecules across cellular membrane. Our approach is based on main principle of insertion and folding of a polypeptide in lipid bilayer of membrane. We have identified family of pH Low Insertion Peptides (pHLIPs), which are capable spontaneous insertion and folding in membrane at mild acidic conditions. The affinity of peptides of pHLIP family to membrane at low pH is several times higher than at neutral pH. The process of peptides folding occurs within milliseconds. The energy released in a result of folding (about 2 kcal/mol) could be used to move polar cargo across a membrane, which is a novel concept in drug delivery. pHLIP peptides could be considered as a pH-sensitive single peptide molecular transporters and conjugated with imaging probes for fluorescence, MR, PET and SPECT imaging, they represent a novel in vivo marker of acidity. The work is supported by NIH grants CA133890 and GM073857 to OAA, DME, YRK.

3:42PM L42.00005 Stress Modulus of Cancer Cells¹, KEITH BONIN, MARTIN GUTHOLD, XINYI GUO, JUSTIN SIGLEY, Wake Forest University — Our main goal is to study the different physical and mechanical properties of cells as they advance through different stages of neoplastic transformation from normal to the metastatic state. Since recent reports indicate there is significant ambiguity about how these properties change for different cancer cells, we plan to measure these properties for a single line of cells, and to determine whether the changes vary for different cellular components: i.e. whether the change in physical properties is due to a change in the cytoskeleton, the cell membrane, the cytoplasm, or a combination of these elements. Here we expect to present data on the stress modulus of cancer cells at different stages: normal, mortal cancerous, immortal cancerous, and tumorigenic. The cells are Weinberg cell line Human Mammary Epithelial (HME) cells. Atomic force microscope (AFM) probes with different diameters are used to push on the cell membrane to measure the local, regional and global cell stress modulus. Preliminary results on normal HME cells suggests a stress modulus of 1.5 ± 0.8 kPa when pushing with $7 \mu\text{m}$ spherical probes. We anticipate reporting an improved value for the modulus as well as results for some of the Weinberg cancer cells.

¹This work is supported by NSF Materials and Surface Engineering grant CMMI-1152781.

3:54PM L42.00006 Cancer-stroma evolutionary dynamics in stress-gradient microenvironment, AMY WU, Princeton University, GUILLAUME LAMBERT, New York University, ROBERT AUSTIN, JAMES STURM, Princeton University, ZAYAR KHIN, ARIOSTO SILVA, Moffitt Cancer Center, PRINCETON PHYSICAL SCIENCES-ONCOLOGY CENTER TEAM, PRINCETON INSTITUTE FOR THE SCIENCE AND TECHNOLOGY OF MATERIALS TEAM — In order to study the evolution of drug resistance in cancer, it is important to mimic the tumor microenvironment, in which cells are exposed to not uniform concentrations but rather gradients of drugs, nutrients, and other factors Compared to traditional in-vitro methods, microfluidic structure enables better control of the temporal and spatial profile of gradients. Here we demonstrate a microfluidic Doxorubicin gradient environment with heterogeneous landscape, and culture multiple myeloma (8226-S, expressing RFP) and bone marrow stroma (HS-5, expressing GFP) cell lines together. The myeloma cells are not directly motile, but they are able to migrate via the adhesion to motile stroma cells. The indirect motility mechanism of the myeloma cells is crucial for the adaptation to stress environment. Finally, we will report the co-culture dynamics under the stress of doxorubicin gradients, observing for cellular migrations and growth

4:06PM L42.00007 Dynamic density functional theory of solid tumor growth: Preliminary models, JOHN LOWENGRUB¹, UC Irvine — Cancer is a complex system whose dynamics and growth result from nonlinear processes coupled across wide ranges of spatio-temporal scales. The current mathematical modeling literature addresses issues at various scales but the development of theoretical methodologies capable of bridging gaps across scales needs further study. We present a new theoretical framework based on Dynamic Density Functional Theory (DDFT) extended, for the first time, to the dynamics of living tissues by accounting for cell density correlations, different cell types, phenotypes and cell birth/death processes, in order to provide a biophysically consistent description of processes across the scales. We present an application of this approach to tumor growth.

¹This is joint work with Arnaud Chauviere, Haralampos Hatzikirou, and Vittorio Cristini.

4:18PM L42.00008 The physics of Eukaryotic cell crawling through elastic media, ELNAZ ALIPOUR, BAUM-SNOW, CHARLES WOLGEMUTH, University of CT Health Center — Understanding the motion of cells through deformable media, such as the extra-cellular matrix (ECM), is important for understanding many biological processes, such as cancer metastasis, wound healing, and organismal development. Crawling eukaryotic cells exert dipole-distributed traction stresses on the external environment. These stress distributions pull backwards at the front of the cell and forward at the rear of the cell. Recent experiments have shown the magnitude of the deformations induced in a collagen matrix by migrating cancer cells. We propose a model to understand cell movements through the ECM, by considering a dipole-crawler moving through an isotropic, linear elastic medium. This model captures the major features of the deformations that are induced by motile cancer cells in collagen. In addition, the model suggests that the deformations that are induced in the matrix can provide a mechanism by which distal cells can interact with one another through matrix-mediated interactions. We, therefore, study the forces, torques, and trajectories of two cells migrating through the ECM. Our analysis suggests a mechanism that may be relevant for the collective migration of cells during cancer metastasis and other processes where numerous cells move through the ECM.

4:30PM L42.00009 Monte Carlo Simulations for Radiobiology, NICOLE ACKERMAN, Stanford University, Dept of Physics, MAGDALENA BAZALOVA, Stanford University, Dept of Radiation Oncology, KEVIN CHANG, Stanford University, Dept of Bioengineering, EDWARD GRAVES, Stanford University, Dept of Radiation Oncology — The relationship between tumor response and radiation is currently modeled as dose, quantified on the mm or cm scale through measurement or simulation. This does not take into account modern knowledge of cancer, including tissue heterogeneities and repair mechanisms. We perform Monte Carlo simulations utilizing Geant4 to model radiation treatment on a cellular scale. Biological measurements are correlated to simulated results, primarily the energy deposit in nuclear volumes. One application is modeling dose enhancement through the use of high-Z materials, such gold nanoparticles. The model matches in vitro data and predicts dose enhancement ratios for a variety of in vivo scenarios. This model shows promise for both treatment design and furthering our understanding of radiobiology.

4:42PM L42.00010 A two-phase mixture model of avascular tumor growth, DENIZ OZTURK, M. BURCIN UNLU, SIRIN YONUCU, UGUR CETINER, Bogazici University, Bebek, 34342 Istanbul / Turkey, MEDICAL & BIOLOGICAL PHYSICS RESEARCH GROUP TEAM — Interactions with biological environment surrounding a growing tumor have major influence on tumor invasion. By recognizing that mechanical behavior of tumor cells could be described by biophysical laws, the research on physical oncology aims to investigate the inner workings of cancer invasion. In this study, we introduce a mathematical model of avascular tumor growth using the continuum theory of mixtures. Mechanical behavior of the tumor and physical interactions between the tumor and host tissue are represented by biophysically founded relationships. In this model, a solid tumor is embedded in inviscid interstitial fluid. The tumor has viscous mechanical properties. Interstitial fluid exhibits properties of flow through porous medium. Associated with the mixture saturation constraint, we introduce a Lagrange multiplier which represents hydrostatic pressure of the interstitial fluid. We solved the equations using Finite Element Method in two-dimensions. As a result, we have introduced a two-phase mixture model of avascular tumor growth that provided a flexible mathematical framework to include cells' response to mechanical aspects of the tumor microenvironment. The model could be extended to capture tumor-ECM interactions which would have profound influence on tumor invasion.

Session L43 DBIO DPOLY: Invited Session: Precursors to the Folding and Aggregation of Biological Molecules 157AB

2:30PM L43.00001 Postranslational modifications significantly alter the binding-folding pathways of proteins associating with DNA, GAREGIN PAPOIAN, The University of Maryland — Many important regulators of gene activity are natively disordered, but fully or partially order when they bind to their targets on DNA. Interestingly, the ensembles of disordered states for such free proteins are not structurally featureless, but can qualitatively differ from protein to protein. In particular, in random coil like states the chains are swollen, making relatively few contacts, while in molten globule like states a significant collapse occurs, with ensuing high density of intra-protein interactions. Furthermore, since many DNA binding proteins are positively charged polyelectrolytes, the electrostatic self-repulsion also influences the degree of collapse of the chain and its conformational preferences in the free state and upon binding to DNA. In our work, we have found that the nature of the natively disordered ensemble significantly affects the way the protein folds upon binding to DNA. In particular, we showed that posttranslational modifications of amino acid residues, such as lysine acetylation, can alter the degree of collapse and conformational preferences for a free protein, and also profoundly impact the binding affinity and pathways for the protein DNA association. These trends will be discussed in the context of DNA interacting with various histone tails and the p53 protein.

3:06PM L43.00002 Mesoscopic Aggregation in Protein Solutions¹, VASSILIY LUBCHENKO, University of Houston — Long-lived mesoscopic clusters of a dense protein liquid are observed in concentrated solutions of numerous proteins. These clusters are a necessary kinetic intermediate for the formation of solid aggregates of native and misfolded protein molecules. We propose a novel physicochemical mechanism, by which the clusters consist of an off-equilibrium mixture of single protein molecules and long-lived protein-containing complexes. The puzzling mesoscopic size of the clusters is determined by the lifetime of the complexes and their diffusivity. We have predicted and observed a number of interesting kinetic and thermodynamic behaviors that are associated with the mesoscopic clusters. These behaviors include: (a) Ostwald-like ripening of the clusters (b) a crossover to long-range density fluctuations at high concentrations; (c) a universal, diffusion-like scaling of the autocorrelation function of light scattered off the protein solution; (d) non-trivial dependencies of the cluster size and volume fraction on the protein concentration in the solution. Our analysis of the anisotropic Coulomb interactions suggests for mesoscopic clusters to form in lysozyme solutions, protein molecules must undergo conformational changes.

3:42PM L43.00003 Protein misfolding and aggregation, DAVE THIRUMALAI, University of Maryland — No abstract available.

4:18PM L43.00004 The impact of conformational transformations on the pathways and kinetics of protein self-assembly into extended matrices¹, JIM DE YOREO, Lawrence Berkeley Nat'l Lab — The concept of a folding funnel with kinetic traps is used to describe folding of individual proteins. Using in situ AFM to investigate both collagen fibril and S-layer membrane assembly on mica, we show this concept is equally valid during self-assembly of proteins into extended matrices. Moreover, considering the conformational changes required to achieve the ordered structure is critical to understanding the pathway to the final state and the kinetics of assembly. In the collagen system, both the pathway and the final conformational state can be finely tuned by varying the ionic strength. This alters the relative strengths of the collagen-collagen and collagen-mica binding free energy, which we quantify using dynamic force spectroscopy. Moreover, when conditions result in the ordered D-band structure of collagen, the emergence of order catalyzes the further transformation leading to non-linear attachment kinetics. In the S-layer system, there is a kinetic trap associated with conformational differences between a long-lived transient state and the final stable state. Both ordered tetrameric states emerge from clusters of an amorphous precursor phase, however, they then track along two different pathways. One leads directly to the final low-energy state and the other to the kinetic trap. Over time, the trapped state transforms into the stable state. By analyzing the time and temperature dependencies of formation and transformation we find the energy barriers to formation of either state to be nearly identical, but once the high-energy state forms, the barrier to transformation to the low-energy state is large. Thus the transient state exhibits the characteristics of a kinetic trap in a folding funnel.

¹This work was performed at the Molecular Foundry, Lawrence Berkeley National Laboratory, with support from the Office of Science, Office of Basic Energy Sciences, of the U.S. DoE under Contracts No. DE-AC52-07NA27344 and DE-AC02-05CH11231.

4:54PM L43.00005 The role of proteins and peptides in shaping the structure and microstructure of biogenic and biomimetic crystals, BOAZ POKROY, Department of Materials Engineering and the Russell Berrie Nanotechnology Institute, Technion Israel Institute of Technology, Haifa, Israel — In the course of biomineralization organisms form crystals which demonstrate superior characteristics as compared to their non-biogenic counterparts. One of the main reasons for this is that these crystals are actually hybrid nano-composites. In fact, each biogenic single crystal is not only encapsulated by an intercrystalline organic phase but in addition there are intracrystalline proteins within each individual single crystal. These proteins are the key players in the formation of biominerals and are vital in the precursor phase of their formation. I will show that both in biogenic and biomimetic crystals, these proteins have a major effect on their atomic structure and microstructure. This effect is in the form of lattice distortions which relax upon mild annealing. The distortions can be detected by means of high-resolution synchrotron diffraction. The activation energy of the relaxation of the lattice distortions is rather low and is comparable to the energy needed for protein unfolding. Furthermore, it will be shown that these intracrystalline proteins can stabilize metastable phases of calcium carbonate and even stabilize a previously unidentified twin law in calcite.

3:06PM L44.00002 Nano to Meso-scale Structure in Liquid Crystals: the Cybotactic Nematic Phase of Bent-core Mesogens

, ORIANO FRANCESCANGELI, Polytechnic University of Marche, SIMAU Department, Via Brecce Bianche, 60131 Ancona, Italy — The extent of molecular order and the resulting broken symmetry determine the properties and mesophase type of liquid crystals (LCs). Thermotropic bent-core mesogens (BCMs) represent a new class of LCs exhibiting substantially different physical properties than traditional linear (calamitic) materials. In recent years BCMs have become the focus of intense experimental and theoretical investigation, with several exciting new developments. These include chiral mesophases composed of achiral BCMs, giant flexoelectricity, biaxial nematic (N) order, a ferroelectric response in the N phase, and a large flow birefringence. A key issue that is currently widely debated concerns the actual nature of the N phase of BCMs which gives rise to some of the above mentioned effects and is unambiguously identified by a peculiar low-angle X-ray diffraction pattern (the “four-spot pattern”). The consensus emerging is that this N phase of BCMs constitutes a new type of mesophase, namely, a cybotactic nematic (N_{cyb}) phase unrelated to pretransition cybotaxis, in agreement with experimental [1-3] and theoretical findings [4]. This N_{cyb} phase is composed of nanometer-size clusters of BCMs exhibiting a relatively high degree of internal order—orientational as well as translational order (strata) imposed by close packing the BCM nonlinear shape. This peculiar supramolecular structure of the N_{cyb} mesophase of BCMs—evanescent, biaxial clusters of tilted and stratified nonlinear mesogens percolating the nematic fluid—accounts for their unusual properties, e.g., biaxial order [4], ferroelectric response [1], and extraordinary field-induced effects [5]. In this talk I will give an overview of the most recent developments and the current state of research on this subject.

3:42PM L44.00003 Nanoscale Positional Order Correlations: Swarms, Cybotactic Groups, Clusters, and Pretransitional Fluctuations in Liquid Crystals¹

, SATYENDRA KUMAR, DENA AGRA-KOOIJMAN, Kent State University, BHARAT ACHARYA, Platypus Technologies, LLC — Short-range molecular associations in organic liquids were first described as “cybotactic” groups [1] followed by the development of the swarm theory [2] to explain the structure, strong light scattering, and flow behavior of the nematic (N) liquid crystal phase. However, these ideas became inconsequential with the advent of the Oseen-Frank’s continuum theory [3]. In 1970, de Vries reinvented cybotactic groups for the N phase of bis-(4'-n-octyloxybenzal)-2-chloro-1,4-phenylenediamine. These were eventually understood to be SmC pretransitional fluctuations, i.e., small correlated regions of the lower symmetry phase near the transition. Thermotropic biaxial mesophases have resurrected the faith in cybotacticity in the guise of a new word - “clusters”. Previous x-ray studies of normal organic fluids, and calamitic, lyotropic, and bent-core mesogens show that these clusters fall into three groups depending on the relative contributions of normal liquid structure and pretransitional fluctuations. A comparison with other organic and inorganic fluids will also be made.

3:54PM L44.00004 Randomized Grain Boundary Liquid Crystal Phase

, D. CHEN, University of Colorado at Boulder, H. WANG, M. LI, Jilin University, M. GLASER, J. MACLENNAN, N. CLARK, University of Colorado at Boulder, UNIVERSITY OF COLORADO AT BOULDER TEAM, JILIN UNIVERSITY TEAM — The formation of macroscopic, chiral domains, in the B4 and dark conglomerate phases, for example, is a feature of bent-core liquid crystals resulting from the interplay of chirality, molecular bend and molecular tilt. We report a new, chiral phase observed in a hockey stick-like liquid crystal molecule. This phase appears below a smectic A phase and cools to a crystal phase. TEM images of the free surface of the chiral phase show hundreds of randomly oriented smectic blocks several hundred nanometers in size, similar to those seen in the twist grain boundary (TGB) phase. However, in contrast to the TGB phase, these blocks are randomly oriented. The characteristic defects in this phase are revealed by freeze-fracture TEM images. We will show how these defects mediate the randomized orientation and discuss the intrinsic mechanism driving the formation of this phase. This work is supported by NSF MRSEC Grant DMR0820579 and NSF Grant DMR0606528.

4:06PM L44.00005 Resonant X-ray Scattering Studies of Smectic and Columnar Bent-Core Liquid Crystal Phases¹

, RONALD PINDAK, Brookhaven National Laboratory, PHILIPPE BAROIS, VIRGINIE PONSINET, Universite Bordeaux, CESAR FOLCIA, JOSU ORTEGA, Universidad del País Vasco, LIDONG PAN², SHUN WANG, University of Minnesota, SUNTAO WANG³, Brookhaven National Laboratory, CHENG-CHER HUANG, University of Minnesota — Resonant X-ray scattering provides a direct probe of orientational structures in liquid crystals with periodicities that range from molecular dimensions (0.1 nm) to dimensions that can be observed with visible light (1.0 micron). We have recently applied this technique to study the orientational ordering of bent-core molecules in the smectic B₂ phase and the columnar B₁ phase. Using resonant scattering “forbidden” reflections due to glide or screw symmetry elements can be measured and an analysis of their polarization state enabled us to identify a chiral anticlinic antiferroelectric B₂ phase (Smectic C_{AP}A) coexisting with an achiral synclinic antiferroelectric B₂ phase (Smectic C_{SP}A) [1]. We were also able to determine the structure of a columnar B₁ phase and study the transition mechanism between the B₁ and B₂ phases [2].

4:18PM L44.00006 Polyhedral Liquid Crystalline Vesicles¹

, MARK BOWICK, Syracuse University — Vesicles with internal liquid-crystalline order can assume a variety of shapes depending on the ratio of the Frank moduli to the bending rigidity. Using both analytic and numerical tools one can show that the possible low free energy morphologies include nano-fibers, faceted tetrahedral vesicles, ellipsoidal vesicles and cylindrical vesicles. The tetrahedral vesicle is a particularly fascinating example of a faceted liquid-crystalline membrane. Faceted liquid vesicles may lead to the design of supra-molecular structures with tetrahedral symmetry and new classes of nano-carriers.

¹NSF DMR-0808812

4:30PM L44.00007 Packing Cheerios: Simulation studies of torus-shaped hard particles¹, AN-DREW KONYA, ROBIN SELINGER, Kent State University — We perform simulation studies of hard torus-shaped particles under compression or in granular flow. A major challenge in performing simulations of non-spherical hard particles is determination of possible overlap between particle pairs. To simplify this calculation, we model a torus particle as an assembly of overlapping hard spheres arranged in a ring, and implement GPU acceleration to create an efficient Monte Carlo algorithm. For particles shaped approximately like Cheerios, with major radius $R=1$ and minor radius $r=0.6$, the hexagonal columnar crystal structure has packing fraction of about 2/3, but—as easy to observe in your cereal box—the system is easily trapped in a glassy disordered state. Preliminary simulation studies of the disordered state formed via rapid compression show short-range orientational correlations in which neighboring particles are either parallel or at right angles. We also examine structures that form when particles rain down onto a flat surface. Results are compared with the known liquid crystal phases of oblate ellipsoids and experiments on discotic colloidal phases.

¹Supported by NSF DMR-1106014.

4:42PM L44.00008 Effect of CNTs and Induced Chirality on Smectic- Smectic Liquid Crystal Phase Transitions, P. KALAKONDA, G.S. IANNACCHIONE, WPI, R. BASU, C. ROSENBLATT, CWRU, R.P. LEMIEUX, Queens U., CA — High-resolution calorimetry results are presented of carbon nanotubes (CNTs) and the liquid crystal (LC) 9004 nano-colloidal dispersions as a function of temperature, scan rate, and CNT concentration (0, 0.025, 0.05, 0.20 wt%). The CNT used have an enantiomeric excess that has been shown to induce chirality into this LC. The pure LC exhibits the phase sequence $I-N-SmA-SmC-SmB-Cr$ on cooling with the expected heat capacity C_p signatures, except for the $SmA-SmC$ transition, manifesting a double- C_p peak ~ 2 K apart at low effective scan rates (< 0.5 K min⁻¹). The introduction of CNTs results in the $I-N$, $N-SmA$, and $SmA-SmC$ double C_p features shifting to higher temperatures by ~ 1 K and remain sharp. However, the $SmC-SmB$ and $SmB-Cr$ transitions shift to lower temperatures by $\sim 3-4$ K and broaden dramatically with increasing CNT content. We interpret these observations as a consequence of the $\pi-\pi$ interactions between the phenyl rings of 9004 and the graphene surfaces that induces bulk chirality, and the pinning of the director parallel to the CNT long-axis far from the surface. The balance of these two mechanisms may stabilize phases that lack any in-smectic-plane ordering.

4:54PM L44.00009 ABSTRACT WITHDRAWN —

5:06PM L44.00010 Mesophase behavior and effect of polydispersity in assemblies of polyhedral particles¹, FERNANDO ESCOBEDO, UMANG AGARWAL, Cornell University — Mesophase behavior of polyhedral particles is uniquely linked to the inherent interactions embedded in their geometrical shape. A two-parameter model based on particle shape anisotropy and order of symmetry has been proposed for predicting phase behavior of polyhedral particles. The focus of the current work is to explore the phase behavior of a distinct class of polyhedral shapes, which emerge at different growth stages of PbSe nanocrystal formation. The body of knowledge that is emerging from these studies may prove useful in designing optimal self-assembly strategies for many desired nanostructures; e.g., as in our ongoing efforts in understanding the nanocrystal superlattice formation for solar cell applications. Moreover the effect of particle size polydispersity is explored by simulating the assembly of two representative shapes exhibiting totally different mesophase behavior. It is found that while mesophases are quite resilient to particle size anisotropy, the ordered structures are a complex function of the polydispersity and geometric attributes.

¹Support from Department of Energy grant no. ER46517

5:18PM L44.00011 Submolecular organization of de Vries smectics with tuned frustration between SmA- and SmC- promoting elements¹, DENA MAE AGRA-KOOIJMAN, S DEY, Kent State University, Q. SONG, Queens University, Canada, D. NONNENMACHER, F. GIESSELMANN, Universität Stuttgart, Germany, R. LEMIEUX, Queens University, Canada, SATYENDRA KUMAR, Kent State University — Structure-property relationships and the $SmA-SmC$ (AC) transition were investigated with x-ray diffraction in de Vries smectics compounds with tuned frustration between SmA and SmC promoting elements in the molecules. These are isometric analogues of a compound with a 2-phenylpyrimidine core that combines a trisiloxane-terminated alkoxy side-chain with a chloro-terminated alkoxy side-chain. The results reveal the local molecular structure in which, both siloxane and hydrocarbon segments are segregated and oriented parallel to the director in the SmA phase. But the siloxane segments oriented at an angle ($\sim 14^\circ$) different from the remaining hydrocarbon part of the molecule. This provides the first direct evidence of a kinked molecular conformation and nano-segregation of the molecule in the SmC phase. The two parts of the molecule possess different orientational order, siloxane part being more disordered, in both phases. The rate of change of the tilt angle with temperature appears to be different in the three compounds investigated.

Session L45 DPOLY: Friction and Brushes 159

2:30PM L45.00001 DILLON MEDAL BREAK —

3:06PM L45.00002 Velcro[®] as a Mesoscopic Model System for Stick-Slip Motion¹, LISA MARIANI, CARA ESPOSITO, PIOTR HABDAS, PAUL ANGIOLILLO, Saint Joseph's University — The Amontons-Coulomb (AC) laws of friction, established during the 18th Century, serve to explain many of the phenomenological observations of friction in the macroscopic world. The AC laws for friction do not adequately explain certain systems, which undergo stick-slip motion, however. The hook-and-loop system (Velcro), in particular, exhibits easily observed stick-slip motion. Velcro evinces clear evidence of stick-slip dynamics that is independent of sliding velocity in accordance with Coulomb but, the maximum static friction force $F_s^{\max}$ and kinetic friction F_k are keenly dependent on "area of contact" (hook number) in contrast to accepted law, but consistent with recent studies of frictional dynamics in nanoscopic systems. Both the $F_s^{\max}$ and F_k as a function of area follow power law dependences with an exponent of approximately 2/3. Moreover, the fluctuations of the kinetic friction F_k also follow a power law dependence with an exponent of approximately 1/2 in accordance with random walk theory. On the other hand, the $F_s^{\max}$ and F_k both follow a linear dependence with applied load in accordance with the classical theory of AC.

3:18PM L45.00003 The Use of Microscale Geometry to Tailor Stimulus-Responsive Surface Friction, LIN HAN, JIE YIN, LIFENG WANG, KHEK-KHIANG CHIA, ROBERT COHEN, MICHAEL RUBNER, MARY BOYCE, CHRISTINE ORTIZ, Massachusetts Institute of Technology — The capability to tailor stimulus-responsive surface friction, including sensitivity profile, range, temporal response and deformation mechanisms, holds great potential for an array of engineering and biomedical applications. In this study, the pH-dependent friction of layer-by-layer assemblies of poly(allylamine hydrochloride) and poly(acrylic acid) (PAH/PAA) were quantified for structures of a continuous planar film and anisotropic microtube forests via lateral force microscopy. By comparing experiments to microstructure-specific finite element modeling, a mechanistic change from surface adhesion-dominated friction ($\mu=0.11$) to viscoelasticity-governed shear ($\mu=0.017$) was predicted upon ionic crosslink density reduction of PAH/PAA from pH 5.5 to 2.0 for the film ($6.5\times$ decrease). The responsiveness of μ was further tuned by the tube forest geometry to be $3.5\times$. At pH 5.5, μ ($=0.094$) was lower than the film due to discrete tube bending/buckling and smaller tip-sample interface stress. At pH 2.0, μ ($=0.027$) was higher because of inter-tube contact and weaker substrate effect. This study provides an excellent platform to quantitatively access and design dynamic substrates with tailorable stimulus-responsive surface friction.

3:30PM L45.00004 Viscous friction of hydrogen-bonded matter, AYKUT ERBAS, North Carolina State University, DOMINIK HORINEK, University of Regensburg, ROLAND R. NETZ, Free University of Berlin — Amontons' law successfully describes friction between macroscopic solid bodies for a wide range of velocities and normal forces. For the diffusion and forced sliding of adhering or entangled macromolecules, proteins and biological complexes, temperature effects are invariably important and a similarly successful friction law at biological length and velocity scales is missing. Hydrogen bonds are key to the specific binding of bio-matter. Here we show that friction between hydrogen-bonded matter obeys in the biologically relevant low-velocity viscous regime a simple equation: the friction force is proportional to the number of hydrogen bonds, the sliding velocity, and a friction coefficient γ_{HB} . This law is deduced from atomistic molecular dynamics simulations for short peptide chains that are laterally pulled over hydroxylated substrates in the presence of water and holds for widely different peptides, surface polarities and applied normal forces. The value of γ_{HB} is extrapolated from simulations at sliding velocities in the range from $v = 10^{-2}$ m/s to 100 m/s by mapping on a simple stochastic model and turns out to be of the order of $\gamma_{HB} \simeq 10^{-8}$ kg/s. 3 hydrogen bonds act collectively.

3:42PM L45.00005 Molecular mechanisms of friction at soft polymer interfaces¹, FREDERIC RESTAGNO, CELINE COHEN, CHRISTOPHE POULARD, LILIANE LEGER, Laboratoire de physique des solides - CNRS/Univers. Paris-Sud — Polymer molecules strongly anchored to a solid substrate and interdigitated into bulk crosslinked elastomer have been shown recently to efficiently promote adhesion and friction between substrate and elastomer. Concerning friction, the regime of low surface coverage in surface anchored chains has been fully and quantitatively accounted for by the pull off mechanisms, where individual chains are dynamically extracted from the elastomer. Then, the stretching energy of these chains dominates the friction losses. We focus here on the dense surface coverage regime. We present systematic experiments performed on the polydimethylsiloxane (PDMS) - silica system, and determine molecular weight and sliding velocity dependences of the friction stress. We show that the friction is dominated by the shear thinning of the grafted layer confined between the elastomer and the substrate, and responding to the shear sollicitation like a melt, but with very long relaxation times. We also show that the friction stress appears highly sensitive to the molecular organization inside the surface anchored polymer layer, comparing end grafted and strongly adsorbed layers having otherwise the same molecular characteristics (molecular weight of the chains, and thickness of the surface anchored layer).

¹We thank the RTRA "Triangle de la physique" for financial support.

3:54PM L45.00006 Frictional properties of the end-grafted polymer layer in presence of salt solution, MARYAM RAFTARI, ZHENYU ZHANG, Department of Physics and Astronomy, University of Sheffield, Sheffield S3 7RH, UK, GRAHAM J. LEGGETT, Department of Chemistry, University of Sheffield, Sheffield S3 7HF, UK, MARK GEOGHEGAN, Department of Physics and Astronomy, University of Sheffield, Sheffield S3 7RH, UK — We have studied the frictional behaviour of grafted poly[2-(dimethylamino)ethyl methacrylate] (PDMAEMA) films using friction force microscopy (FFM). The films were prepared on native oxide-terminated silicon substrates using the technique of atom transfer radical polymerization (ATRP). These brushes had constant grafting density (1.18 nm^2), and of a thickness of $\sim 66 \text{ nm}$, as measured by ellipsometry. We show that single asperity contact mechanics (Johnson-Kendall-Roberts (JKR) and Derjaguin-Müller-Toporov (DMT) models) as well as a linear (Amontons) relation between applied load and frictional load all apply to these systems depending on the concentration of salt and the nature of the FFM probe. Measurements were made using gold-coating and polymer functionalized silicon nitride triangular probes. Polymer functionalized probe included growth the PDMAEMA with same method on tips. The frictional behaviour are investigated between PDMAEMA and gold coated and PDMAEMA tips immersed in different concentrations of KCl, KBr and KI.

4:06PM L45.00007 Nanofluidity of Polymer Melt: Two velocity hydrodynamics, SERGEI OBUKHOV, University of Florida, ALBERT JOHNER, CNRS Institut Charles Sadron, Strasbourg, France — According to the traditional macroscopic theory, the flow of the entangled polymer melt is associated with the relaxation processes in the network of entanglements. Each entanglement is formed by polymer chains, and these chains are moving randomly along their reptation tubes. Because of this random motion of polymers each entanglement has a finite lifetime. The lifetime is equal to the time needed for a polymer to leave its original tube. We should point out, that the motion of individual polymer chain in a tube is assumed to be completely random (diffusive). It means, that according to traditional theory, in average there is no systematic displacement of polymers with respect to the network of entanglements. The local polymer flow velocity in this theory is just the instant local velocity of individual entanglements forming this network. But the drift of individual polymers provides additional mechanism of a flow of a polymer melt, which becomes dominant at small scale. We suggest two velocity hydrodynamic equations which describe combined contribution of these two mechanisms. For illustration of this method we solve the problem of mobility of a small particle in a polymer melt.

4:18PM L45.00008 Poly(ethylene oxide) Chains Are Not "Hydrophilic" When They Exist As Polymer Brush Chains, HOYOUNG LEE, DAE HWAN KIM, KEVIN N. WITTE, KIMBERLY OHN, JE CHOI, School of Chemical Engineering, Purdue University, KYUNGIL KIM, MATI MERON, BINHUA LIN, CARS, The University of Chicago, BULENT AKGUN, SUSHIL SATIJA, NIST Center for Neutron Research, NIST, YOU-YEON WON, School of Chemical Engineering, Purdue University — By using a combined experimental and theoretical approach, a model poly(ethylene oxide) (PEO) brush system, prepared by spreading a poly(ethylene oxide)-poly(*n*-butyl acrylate) (PEO-PnBA) amphiphilic diblock copolymer onto an air-water interface, was investigated. The polymer segment density profiles of the PEO brush in the direction normal to the air-water interface under various grafting density conditions were determined from combined X-ray and neutron reflectivity data. In order to achieve a theoretically sound analysis of the reflectivity data, we developed a new data analysis method that uses the self-consistent field theoretical modeling as a tool for predicting expected reflectivity results for comparison with the experimental data. Using this new data analysis method, we discovered that the effective Flory-Huggins interaction parameter of the PEO brush chains is significantly greater than that corresponding to the theta condition, suggesting that contrary to what is more commonly observed for PEO in normal situations, the PEO chains are actually not "hydrophilic" when they exist as polymer brush chains, because of the many body interactions forced to be effective in the brush situation.

4:30PM L45.00009 ABSTRACT WITHDRAWN —

4:42PM L45.00010 Tunable Surface Properties from Bioinspired Polymers, WENDY VAN ZOELLEN, ADRIANNE M. ROSALES, University of California, Berkeley, RONALD N. ZUCKERMANN, The Molecular Foundry, Lawrence Berkeley National Laboratory, RACHEL A. SEGALMAN, University of California, Berkeley — Tunability of surface properties is of importance for a variety of coating applications, including antifouling coatings. We have investigated the surface properties of polypeptoids, a class of non-natural biomimetic polymers based on an N-substituted glycine backbone, that combine many of the advantageous properties of bulk polymers with those of synthetically produced proteins, including controllable chain shape, sequence, and self-assembled structure. We demonstrate the influence of the amount and sequence of hydrophobic monomers in a predominantly hydrophilic peptoid chain on surface properties. Especially the surface reconstruction behavior of block copolymers of these amphiphilic polypeptoids with polystyrene upon contact with water will be addressed. It has been found that surface reconstruction of peptoid chains that contain a sequence of only three fluorinated monomers and up to forty-two hydrophilic monomers occurs within seconds, whereas reorganization of surfaces containing five fluorinated monomers was an order of magnitude slower. Surfaces with higher fluorine content also showed lower settlement of spores of the green algae *Ulva*.

4:54PM L45.00011 Concentration Fluctuations of a Semidilute Polymer Solution in Good Solvent Near a Repulsive Surface, CATHERINE YEH, PHILIP PINCUS, Department of Physics, University of California, Santa Barbara, ALEXANDRA ZIDOVSKA, Dept. of Systems Biology, Harvard Medical School and School of Engineering and Applied Sciences/Dept. of Physics, Harvard University — The concentration profile of a semidilute polymer solution in good solvent near a repulsive surface has been previously calculated.¹ In this work we consider fluctuation corrections to the mean field concentration profile in the presence of a repulsive surface using the Cahn-Hilliard square-gradient approach extended to polymer interfaces. Our results predict that at strongly repulsive surfaces, a polymer in good solvent exhibits concentration fluctuations associated with the surface in addition to fluctuations of the bulk polymer solution. We compare our predictions with current experiments which have measured fluctuations in the concentration of interphase chromatin (DNA with its associated proteins) inside the nucleus of mammalian cells *in vivo* using ultrafast high space resolution spinning disc confocal microscopy.

5:06PM L45.00012 Kinetics of Polymer Interfacial Reaction, SHUO ZHANG, JEFFREY KOBERSTEIN, Columbia University — Germanium crystals modified with high quality azide functional monolayers are used to directly monitor in situ the kinetics of interfacial “click” reactions with complementary alkyne end-functional poly(n-butyl acrylate) (PnBA) and polystyrene (PS) by attenuated total reflectance infrared spectroscopy (ATR-IR). In the presence of copper (I), the azide-modified Ge substrates react quantitatively with PnBA and PS via a 1,3-dipolar cycloaddition reaction. Time-resolved ATR-IR measurements show two regimes of kinetic behavior, as predicted by theory. In the first regime the rate is rapid and is controlled by diffusion of the polymer through the solvent, scaling with the square root of time. The rate slows considerably in the second regime, limited by penetration of the reacting polymer through the covalently bound polymer brush layer, scaling with the natural logarithm of time. The influence of polymer size and solvent quality are reported.

5:18PM L45.00013 Influence of Substrate Surface Energy on the Morphological Evolution of PS/PMMA Blend Thin Films, YIFU DING, DAE-UP AHN, ZHEN WANG, IAN CAMPBELL, MARK STOYKOVICH, University of Colorado at Boulder — In this study, the morphological evolutions of PS/PMMA blend thin films are systematically characterized during thermal annealing on both preferential and non-preferential surfaces. The evolution of phases on preferential surfaces was dictated by the preferential wetting of the components, and the coarsening process of the PMMA domains. PS droplets with high spatial correlation were formed in a moderately asymmetric PS/PMMA blend because of PS dewetting via a controlled nucleation mechanism. In contrast, a more asymmetric blend evolved into PS droplets via a random nucleation process, such that the PS droplets did not exhibit spatial correlation and had a broad size distribution. The morphological evolution of the blends on relatively non-preferential surfaces was also dictated by domain coarsening, but proceeds without the formation of PMMA wetting layer. As a result, a diverse set of non-equilibrium, micro- and nanoscale morphologies were observed.

Tuesday, February 28, 2012 2:30PM - 5:30PM –
Session L46 DPOLY: Dillon Medal Symposium 160ABC

2:30PM L46.00001 John H. Dillon Medal Lecture: Self-assembly of rod-coil block polymers, RACHEL SEGALMAN, University of California, Berkeley — While the self-assembly of coil-like block copolymers into morphologies with well-defined nanometer-sized periodicities is now classic, the translation of this strategy to functional polymers with non-Gaussian chain shapes is significantly more complicated. Control and predictive understanding of nanoscale structure in rod-coil block copolymer systems are of particular importance in both conjugated polymers (for optoelectronic devices) and biomimetic polymers. Our work is targeted at gaining a fundamental understanding of the thermodynamics and kinetics of self-assembling functional rod-coil block copolymer systems, and then applying this to conjugated polymers to understand structure-property relationships in plastic electronics. We demonstrate that phase space for weakly segregated model systems is described by the Flory-Huggins block interaction parameter (χN), the Maier-Saupé parameter (μN) (which parameterizes rod-rod interactions and also scales with temperature), the coil volume fraction (φ_{coil}), and a geometrical asymmetry term (ν) to account for aspect ratio differences in the rod and coil. Further, we also find that careful molecular design to moderate molecular interactions is essential in creating controllable systems. In particular, both sidechain substitution and sequence control can be used to control melting temperatures and liquid crystalline interactions in order to create a processing window in which self-assembly can occur.

3:06PM L46.00002 Wrinkles and Folds as Photonic Structures in Polymer Photovoltaics, YUEH-LIN LOO, JONG BOK KIM, Chemical and Biological Engineering, PILNAM KIM, HOWARD STONE, Mechanical and Aerospace Engineering, NICOLAS PEGARD, JASON FLEISCHER, Electrical Engineering, Princeton University, SOONG JU OH, CHERIE KAGAN, Materials Science and Engineering, University of Pennsylvania — We exploit the elastic instabilities of polymer surfaces under compressive mechanical stress to generate wrinkles and deep folds with prescribed dimensions and at pre-specified coverage over large areas. These wrinkles and deep folds act as photonic structures; they increase light coupling into and trapping within polymer photovoltaics. Devices on these surfaces show a 79% increase in the external quantum efficiency (EQE) in the visible compared to analogous devices on flat surfaces. More significantly, we observe an exponential increase in near-infrared light absorption in these devices. In both experiments and numerical simulations, we find that these structures extend the useful range of energy conversion by >200 nm, corresponding to a 600% increase in the EQE in the near-infrared where light is otherwise minimally absorbed. While we demonstrate this concept with polymer photovoltaics, the controlled introduction of compressive stress provides a straightforward and economical route to large-scale patterning of photonic structures for flexible opto-electronics.

3:18PM L46.00003 Molecular Exchange Dynamics in Block Copolymer Micelles¹ , FRANK BATES, JIE LU, SOOHYUNG CHOI, TIMOTHY LODGE, University of Minnesota — Poly(styrene-*b*-ethylene propylene) (PS-PEP) diblock copolymers were mixed with squalane (C₃₀H₆₂) at 1% by weight resulting in the formation of spherical micelles. The structure and dynamics of molecular exchange were characterized by synchrotron small-angle x-ray scattering (SAXS) and time resolved small-angle neutron scattering (TR-SANS), respectively, between 100 °C and 160 °C. TR-SANS measurements were performed with solutions initially containing deuterium labeled micelle cores and normal cores dispersed in a contrast matched squalane. Monitoring the reduction in scattering intensity as a function of time at various temperatures revealed molecular exchange dynamics highly sensitive to the core molecular weight and molecular weight distribution. Time-temperature superposition of data acquired at different temperatures produced a single master curve for all the mixtures. Experiments conducted with isotopically labeled micelle cores, each formed from two different but relatively monodisperse PS blocks, confirmed a simple dynamical model based on first order kinetics and core Rouse single chain relaxation. These findings demonstrate a dramatic transition to nonergodicity with increasing micelle core molecular weight and confirm the origins of the logarithmic exchange kinetics in such systems.

¹Support for this work was provided by Infinium

3:30PM L46.00004 Direct Imaging of Nanoscale Ionic Clusters in a Polymer Electrolyte Membrane , NITASH BALSARA, University of California, Berkeley, KENNETH DOWNING, SERGEY YAKOVLEV, Lawrence Berkeley National Laboratory — One of the factors hindering development of technologies such as fuel cells that rely on polyelectrolyte membranes (PEMs) is the lack of quantitative morphological characterization. While it has been recognized that clustering of ionic groups, can impede proton transport rates, model-free methods to quantify clustering in PEMs have not been developed. We present the first electron micrographs of sulfonic acid clusters in a polymer electrolyte membranes (PEM). The clusters are spherical with an average diameter of 1.4 nm and a standard deviation of 0.25 nm. Obtaining images of densely packed clusters of this size in a soft material is non-trivial due to their overlap in projection. Imaging of the sulfur-rich clusters by dark field microscopy was facilitated by the spontaneous formation of thin, cluster-containing layers on the top and bottom surfaces of free-standing films.

3:42PM L46.00005 Mechanisms underlying conductivity of lamellar block copolymer electrolytes , VENKAT GANESAN, VICTOR PRYAMITSYN, The University of Texas at Austin — Recent experiments have reported intriguing trends for the molecular weight (MW) dependence of the conductivity of block copolymer lamellae which are opposite that exhibited by homopolymer matrices. Using coarse-grained simulations of the transport of penetrant ions, we probe the possible mechanisms underlying such behavior. Our results indicate that the MW dependence of the conductivity of homopolymeric and block copolymeric matrices owe their origins to different mechanisms. On the one hand, the solubility of penetrants in block copolymer matrices themselves exhibit a MW dependence which arises from the MW dependence of the thickness of the conducting phase relative to the interfacial zones. Moreover, distinct mechanisms are shown to be responsible for the mobilities of ions in homopolymer and block copolymers. In the former, the mobility effects associated with the free ends of the polymers play an important role. In contrast, in block copolymer lamellae, the interfacial zone between the blocks presents a zone of hindered mobility for ions and manifests as a molecular weight dependence of the ionic mobility. Together, the preceding mechanisms are shown to provide a plausible explanation for the experimentally observed trends for the conductivity of block copolymer matrices.

3:54PM L46.00006 Physical Aspects of Photodynamic Corneal Collagen Crosslinking , JULIA KORNFIELD, California Institute of Technology — Healthy vision depends on the stability of the shape of the cornea, which provides most of the lens power of the optical system of the eye. Diseases in which the cornea progressively undergoes irregular deformation over time (e.g., keratoconus) can be treated clinically by inducing additional protein-protein crosslinks using a photosensitizing drug and a tailored dose of light. Unfortunately, the treatment moving through clinical trials is toxic to cells in and on the cornea. A path to a safer treatment is offered by the nanostructure of the corneal stroma—reminiscent of a HEX phase in block copolymers with 30nm diameter collagen cylinders spaced 60nm center-to-center in a hydrogel matrix of proteoglycans and water. We show that using a photosensitizing drug that sequesters itself in the collagen fibrils can minimize the toxicity of therapeutic protein-protein cross-linking. Photorheology and transport measurements are used to quantify the parameters of a simple physical model that is useful for optimizing clinical protocols.

4:06PM L46.00007 Directed Assembly of Block Copolymer Cylinders: Fundamental Physical Limits to Cylinder Spacing¹ , VINDHYA MISHRA, GLENN H. FREDRICKSON, Department of Chemical Engineering, UCSB, EDWARD J. KRAMER, Departments of Materials and Chemical Engineering, UCSB — Understanding the fundamental 2D physics of disordering and defect generation in block copolymer films is important in setting the limits for directed assembly based block copolymer lithography. Our experiments on monolayer films of cylindrical morphology block copolymer show that the monolayer structure disorders at a lower temperature compared to the bulk order-disorder transition temperature by thermal generation of a critical density of dislocations (point defects in the monolayer). We demonstrate experimentally and theoretically how this process sets lower limits on the monolayer cylinder spacing and thus pattern spacing that can be achieved by directed assembly of a given block copolymer using graphoepitaxy. Self-consistent field theoretic simulations are used to predict the compressional elastic constant B of the cylinder monolayer and cylinder spacing a as a function of χN and f , the minor block volume fraction. In turn these are used to estimate the formation energies E_d ($\sim Ba^3$) of dislocations in cylinder monolayers of various block copolymers.

¹We acknowledge funding from NSF DMR-07-04539 and DMR-09-04499

4:18PM L46.00008 Measurement of Diffusion in Entangled Rod-Coil Triblock Copolymers , B.D. OLSEN, M. WANG, Massachusetts Institute of Technology — Although rod-coil block copolymers have attracted increasing attention for functional nanomaterials, their dynamics relevant to self-assembly and processing have not been widely investigated. Because the rod and coil blocks have different reptation behavior and persistence lengths, the mechanism by which block copolymers will diffuse is unclear. In order to understand the effect of the rigid block on reptation, tracer diffusion of a coil-rod-coil block copolymer through an entangled coil polymer matrix was experimentally measured. A monodisperse, high molecular weight coil-rod-coil triblock was synthesized using artificial protein engineering to prepare the helical rod and bioconjugation of poly(ethylene glycol) coils to produce the final triblock. Diffusion measurements were performed using Forced Rayleigh scattering (FRS), at varying ratios of the rod length to entanglement length, where genetic engineering is used to control the protein rod length and the polymer matrix concentration controls the entanglement length. As compared to PEO homopolymer tracers, the coil-rod-coil triblocks show markedly slower diffusion, suggesting that the mismatch between rod and coil reptation mechanisms results in hindered diffusion of these molecules in the entangled state.

4:30PM L46.00009 Taking a Hard Look at Soft X-ray Scattering , ALEXANDER HEXEMER, CHENG WANG, LBNL — For many years neutron and X-ray scattering has been a trusted tool for polymer scientist. In the hard X-ray regime contrast for scattering has been limited to the difference in electron density between different components. At the Advanced Light Source we have been developing a techniques that combines the advantages of traditional scattering with chemical sensitive spectroscopy. Using soft X-rays at selected photon energies we can tune the contrast between different polymers based on there chemical makeup. We have applied this to a variety of polymer systems.

4:42PM L46.00010 Neither crystalline nor amorphous: measuring disorder in polymers and assessing its effect on charge transport, ALBERTO SALLEO, JONATHAN RIVNAY, RODRIGO NORIEGA, Stanford University, MICHAEL TONEY, Stanford Synchrotron Radiation Lightsource — Conjugated polymers displaying high mobility are semicrystalline. Thin films of these materials are comprised of ordered regions (crystallites) and disordered regions. Because of the inherent anisotropy of polymers, the crystallites exhibit varying degrees of disorder in different directions. I will show a quantitative measurement of disorder as applied to these materials, which allows us to quantify a paracrystalline parameter g . This parameter can be used to rank polymers. I will show how g is related to the electronic structure of the polymer and with the presence of electronic traps in particular. By studying the dependence of g on molecular weight we can get to a definition of polymer behavior in an electronic transport sense.

4:54PM L46.00011 Shear Alignment of Perpendicular Lamellae in Block Copolymer Thin Films¹, RICHARD REGISTER, SASWATI PUJARI, Princeton University, PAUL CHAIKIN, New York University — Thin supported block copolymer films, containing a single layer of cylindrical microdomains lying parallel to the substrate, can be effectively aligned by applying a shear stress to the molten, ordered film. Such films have been used effectively as contact masks for pattern transfer via reactive ion etching, permitting the fabrication of in-plane nanowire arrays, where the nanowires are aligned over macroscopic (cm) distances. Such a nanowire array could also be formed from a film which contains lamellae whose interdomain interfaces lie perpendicular to the substrate; such a template film would in principle allow for the formation of nanostructures of high aspect ratio, provided that the lamellae can be aligned along a single in-plane direction while retaining their perpendicular orientation. We have generated such films of perpendicular lamellae in a polystyrene-poly(methylmethacrylate) diblock, PS-PMMA, by neutralizing the substrate with a random terpolymer brush. Shearing the film, using a moving polydimethylsiloxane (PDMS) pad in contact with the film surface, can indeed produce alignment over cm-scale distances; however, the orientational order is poorer and the defect density higher than in typical cylinder-forming systems, and a significantly higher stress is required. After peeling off the PDMS pad, both PS and PMMA blocks are exposed at the surface in thinner films, but for films thicker than one domain spacing, the lower-energy PS block tends to cap the film surface, overlaying aligned perpendicular lamellae.

¹support from PCCM (NSF-MRSEC, DMR-0819860)

5:06PM L46.00012 Role of nanoscale morphology on the nano and macro-scale performance of polythiophene based polymer solar cells, PETER GREEN, JOJO AMONOO, EMMANOUIL GLYNOS, CHELSEA CHEN, Materials Science and Engineering, University of Michigan, Ann Arbor — Maximization of the short circuit current, J_{SC} , the open circuit voltage, V_{OC} , and the fill factor (FF) to achieve highest power conversion efficiencies (PCEs) in donor/acceptor, polymer/polymer, solar cells is dependent on optimization of variables associated with the active material's chemical and morphological structure. Control of the nanoscale structure of polythiophene (P3HT)/phenyl-C61-butyric acid methyl ether (PC₆₁BM) active materials was achieved through use of a novel low temperature processing strategy. With the use of energy filtered transmission electron microscopy (EF-TEM), electron and X-ray diffraction, together phase contrast, deflection and photocurrent measurements at the nanoscale, we were able to tailor nanoscale morphologies to achieve increases in the J_{SC} by a factor of 1.2 and the PCE by 30%, beyond that using conventional heat treatments for processing.

5:18PM L46.00013 Semiconducting block copolymers as nano-structuring agents for high-efficiency and annealing-free bulk hetero-junction organic solar cells, GEORGES HADZIOANNOU, SÉBASTIEN-JUN MOUGNIER, CEDRIC RENAUD, CYRIL BROCHON, GUILLAUME FLEURY, DARGIE DERIBEW, ERIC CLOUTET, University of Bordeaux, LAURENCE VIGNAU, ENSCBP, LCPO UMR 5629 CNRS TEAM, IMS UMR 5218 CNRS TEAM — Three main requirements for the industrial development of the polymer solar cells have to be addressed in order to obtain a competitive technology: a fabrication process compatible with common polymer printing technologies, an enhanced life time stability and an improved power conversion efficiency (PCE). The active layer nano-structure in bulk heterojunction organic solar cells plays a key role on the properties of charge transfer, transport and consequently on the PCE. Ideally a bi-continuous network of donor-acceptor domains with a length scale comparable to the exciton diffusion length is required. To obtain an optimized nano-structured active layer, an annealing process (thermal and/or solvent) is commonly performed leading to an increase of the photovoltaic performance. Currently, the implementation of common printing technologies for the fabrication of polymer solar cells on a mechanically flexible polymer substrate is impeded by this annealing step. In order to overcome the limitations above a novel approach based on an annealing-free fabrication process will be presented making use of a block copolymer as a nano-structuring agent for the polymer/fullerene derivative blend.

Tuesday, February 28, 2012 2:30PM - 5:30PM —
Session L48 DPOLY DBIO: Polymers and DNA Coated Colloid Particles 161

2:30PM L48.00001 DILLON MEDAL BREAK —

3:06PM L48.00002 Structure and Assembly of Polymeric Dots Formed by Conjugated Polymers, NARESH OSTI, DILRU RATNAWEERA, THUSITHA ETEMPAWALA, UMESH SHRESTHA, DVORA PERAHIA, Clemson University — Rigid conjugated polymers assume extended conformation in dilute solution and often behave as colloidal suspensions. When forced into a collapsed configuration, they form highly fluorescing particles, or poly-dots, which have demonstrated potential as intracellular imaging markers, as well as building blocks for light harvesting devices. The current work investigates the structure and stability of poly-dots of *di-alkyl para polyphenyleneethynylene* (PPE) conjugated polymers in solution and follows their assembly at interfaces. Small angle neutron scattering measurements of the poly-dots in water have shown that at low concentrations, stable unimolecular spherical poly-dots are formed with a polydispersity that corresponds to that of the polymer itself. With increasing concentration, yet, below the critical micelle concentration of these rod-like polymers in good solvents, the size and density of the NPs increases, however the spherical symmetry is retained. The nature and length of the substituents affect the internal density and the degree of swelling of the poly dots. Atomic Force Microscopy results show that these PPE poly-dots assemble into arrays with different symmetries, depending on molecular parameters and assembly conditions.

3:18PM L48.00003 Molecular dynamics study of polymer-silica nanoparticle hybrids: Building blocks for directed assembly, SABINA MASKEY, Clemson University, FLINT PIERCE, GARY GREEST, Sandia National Laboratories, DVORA PERAHIA, Clemson University — Molecular dynamic simulations have been used to study the conformation and interactions of a polymer nanoparticle hybrid that consists of *para* dialkyl phenyleneethynylenes (PPEs) grafted to a silica nanoparticle, with the goal of deriving the factors that control their assembly. PPEs are electro-optically active polymers whose conformation determines their degree of conjugation and their assembly mode which in turn affects the electro-optical properties of the nanoparticle-polymer complexes. When confined to a nanoparticle surface, the PPE chains are fully extended in good solvents but cluster as the quality of the solvents is decreased. Tuning the degree of clustering by tuning the solvent-polymer interaction is expected to direct the assembly of the particles. Results for the conformation of grafted PPE molecules on a single nanoparticle and the forces between two nanoparticles as a function of solvent quality will be presented.

3:30PM L48.00004 Structural and Dynamical Characteristics of Polyelectrolyte Dendrimer Solutions Revealed by Neutron Scattering and Atomistic Simulation, BIN WU, Oak Ridge National Laboratory, YUN LIU, National Institute of Standards and Technology, LIONEL PORCAR, PETER FALUS, Institut Laue-Langevin, CHANGWOO DO, Oak Ridge National Laboratory, MICHAELA ZAMPONI, Forschungszentrum Julich, KUNLUN HONG, GREGORY SMITH, WEI-REN CHEN, Oak Ridge National Laboratory — Solutions of polyelectrolyte dendrimers were investigated using small angle neutron scattering (SANS) and dynamical measurements including quasi-elastic neutron scattering, neutron spin-echo and high resolution NMR. The goal of the experiments was to understand the structural and dynamical responsiveness polymer toward the variation of molecular charge. Experimental spatial correlation functions and temporal correlation functions such as intermediate scattering functions and the dynamic structure factor were evaluated quantitatively. Complementary atomistic simulations were developed for providing the microscopic interpretation of the scattering measurements and for investigating the material characteristics that are not accessible experimentally. Based on this synergistic approach, we attempt to provide a detailed understanding of the microscopic mechanisms underlying the observed electrostatic responsive properties in these very important classes of materials.

3:42PM L48.00005 A theoretical study of the phase behavior of spherical colloids decorated with adhesive domains, HOMIN SHIN, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — We propose a nonlinear self-consistent phonon theory for the self-assembly of spherical particles with patterned adhesive surfaces, such as Janus colloids. The approach is first tested against the known crystallization behavior of hard spheres, and also homogeneous particles that interact via short range attractions. Janus colloid pair interactions are described by an anisotropic extension of the Baxter adhesive sphere potential where particles attract only if their hydrophobic domains are in contact. Given various crystalline symmetries, the effective harmonic potential experienced by a colloid confined to its Wigner-Seitz cell is self-consistently computed. The characteristic vibrational displacements or localization lengths are determined by the lattice symmetry as well as the strength and surface pattern of adhesive interactions. The crystal free energy is then computed, and thermodynamic stability evaluated, including pressure-driven solid-solid transitions, and the fluid-solid coexistence boundary based on the Baxter solution of the Percus-Yevick integral equation for adhesive hard sphere liquids. A primary goal is to evaluate the influence of patch size, attraction strength, and geometric patterning on the formation of heterogeneous crystalline phases.

3:54PM L48.00006 In situ electrochemical small-angle neutron scattering (eSANS) for quantitative structure and redox properties of polymer-coated nanoparticles¹, VIVEK PRABHU, Polymers Division, NIST, VYTAS REIPA, Biochemical Sciences Division, NIST, PETER BÖNNESEN, ADAM RONDINONE, ERIC FORMO, Center for Nanophase Materials Sciences, ORNL — Rapid growth in nanomaterial applications (energy, cosmetics and healthcare products) highlights limitations of available physicochemical characterization methods. An in situ electrochemical small-angle neutron scattering (eSANS) methodology was devised that enables direct measurements of nano and colloid material dispersion structure while undergoing reduction-oxidation (redox) reactions. By combining the electrochemical signal with contrast variant SANS, the structure of the polymer-nanoparticle complexes can be examined under electrochemical conditions. Specially-synthesized poly(ethyleneglycol)-stabilized zinc oxide nanoparticles were examined by eSANS showing an irreversible change in nanoparticle-complex structure during the potential cycle. We will report on the kinetics of the nanoparticle transformation as measured at BL-6 EQSANS, Spallation Neutron Source, Oak Ridge National Laboratory.

4:06PM L48.00007 Topological Interaction by Entanglement of DNA, LANG FENG, Center for Soft Matter Research, New York University, RUOJIE SHA, NADRIAN SEEMAN, Chemistry department, New York University, PAUL CHAIKIN, Center for Soft Matter Research, New York University — We find and study a new type of interaction between colloids, Topological Interaction by Entanglement of DNA (TIED), due to concatenation of loops formed by palindromic DNA. Consider a particle coated with palindromic DNA of sequence “P1.” Below the DNA hybridization temperature (T_m), loops of the self-complementary DNA form on the particle surface. Direct hybridization with similar particle covered with a different sequence P2 do not occur. However when particles are held together at $T > T_m$, then cooled to $T < T_m$, some of the loops entangle and link, similar to a Olympic Gel. We quantitatively observe and measure this topological interaction between colloids in a $\sim 5^\circ\text{C}$ temperature window, $\sim 6^\circ\text{C}$ lower than direct binding of complementary DNA with similar strength and introduce the concept of entanglement binding free energy. To prove our interaction to be topological, we unknot the purely entangled binding sites between colloids by adding Topoisomerase I which unconcatenates our loops. This research suggests novel history dependent ways of binding particles and serves as a new design tool in colloidal self-assembly.

4:18PM L48.00008 Measuring in situ primary and competitive hybridization events on microspheres, VALERIA MILAM, JAMES HARDIN, Georgia Institute of Technology — Understanding hybridization events at surfaces is crucial for optimizing nucleic acid detection platforms as well as DNA-mediated colloidal assembly. We used flow cytometry to measure time-dependent primary and competitive hybridization events of perfectly matched and mismatched targets on microsphere surfaces. In addition to more conventional sample preparation involving multiple wash and resuspension steps prior to measurement, we sampled the reaction volume directly for in situ measurements to minimize potential dissociation events between weaker partner strands during wash steps. Similar to prior reports for oligonucleotide solutions, the nearly identical rates for primary hybridization events on microsphere surfaces were independent of target sequence and reached an equilibrium value within 30 min. The extent of in situ primary hybridization events for immobilized probes, however, deviated from solution model predictions. In situ competitive hybridization events were at least 100-fold slower than primary hybridization events and did not appear to reach equilibrium. The kinetics of competitive hybridization events on microspheres are consistent with predicted effects stemming from toehold effects or base length differences between primary and secondary targets.

4:30PM L48.00009 You can always get what you want, ZORANA ZERAVCIC, School of Engineering and Applied Sciences, Harvard University, SAHAND HORMOZ, Kavli Institute for Theoretical Physics, University of California, JESSE COLLINS, VINOTHAN MANOHARAN, MICHAEL BRENNER, School of Engineering and Applied Sciences, Harvard University — Colloidal particles coated with DNA strands can self assemble into complex structures. Which structures are formed and with what yield depends on the specifics of the design rules. We numerically study the directed self assembly of DNA coated colloidal particles. By testing different design rules for self-assembly with short-range interactions and studying the stability of equilibrium structures, we uncover the principles for always getting a desired assembled structure.

4:42PM L48.00010 Rigid and Soft Minima of DNA-colloid Clusters, JESSE COLLINS, ZORANA ZERAVCIC, Harvard SEAS, VINOTHAN MANOHARAN, Harvard SEAS and Physics, MICHAEL BRENNER, Harvard SEAS — What are the limits of self-assembly via short-ranged, isotropic potentials? We investigate how carefully tuning the interaction matrix—breaking the permutation symmetry—of a small number of particles leads to unique ground states and novel energy landscape features, including soft local and global minima. We coat microspheres with highly specific and thermodynamically optimized DNA-sequences, and observe a few of these at a time organize in wells and droplets. DIC and other imaging techniques reveal 3D cluster structure, and fluorescence reveals the identity of each bead in the cluster. Although our experiments equilibrate timely over only a small temperature window, they elucidate how discrete sphere packing geometry governs both the statistical equilibrium and theoretical “zero T” cluster probabilities. Finally, I'll describe how relaxing some constraints can shift equilibria and flatten maxima on the energy landscapes of these specific spheres.

4:54PM L48.00011 Uniform colloidal clusters from random aggregation of bidisperse spheres¹, NICHOLAS B. SCHADE, MIRANDA C. HOLMES-CERFON, Harvard University, ELIZABETH R. CHEN, None, DINA ARONZON, JESSE W. COLLINS, JONATHAN A. FAN, VINOTHAN N. MANOHARAN, Harvard University — Using a combination of experiment and simulation, we investigate the structures that form when colloidal spheres cluster around smaller spheres. We use either oppositely charged particles or particles coated with complementary DNA sequences to form the clusters, and we observe them under optical microscopy. We find that random sphere parking serves as a useful model for cluster self-assembly in these systems and that the sphere diameter ratio controls the distribution of cluster sizes. In particular, near a critical diameter ratio, random parking produces tetrahedral clusters in theoretically unlimited yield. Experimentally we observed 90% tetramer yield near this geometrical singularity. We investigate how this method can be used to assemble tetrahedral plasmonic resonators from metallo-dielectric nanospheres in order to create a bulk, isotropic, optical metamaterial.

5:06PM L48.00012 The Internal Structure of Nanoparticle Dimers Linked by DNA, FERNANDO VARGAS LARA, Physics Department, Wesleyan University, Middletown, CT, CHING-JUNG CHENG, OLEG GANG, Center for Functional Nanomaterials, Brookhaven National Laboratory, Upton, NY, FRANCIS W. STARR, Physics Department, Wesleyan University, Middletown, CT — The self-assembly of inorganic units controlled by the interactions of biological molecules, like DNA, has received attention for the possibility to specify higher-order structure, with potential biological, optical and electronic applications. In biology, self-assembly of complex materials (eg. bone, spider silk) frequently occurs in a stepwise, hierarchical fashion. Here, we consider a first step towards a hierarchical approach for synthetic nanostructures of nanoparticles (NPs) linked by DNA. The most basic unit in this multiscale approach is a dimer of NPs linked by DNA. We use a coarse-grained molecular model to explain experimental measurements of the separation of two DNA-coated NPs connected by linking single-stranded DNA (ssDNA). We show that the dimer separation is primarily controlled by the number of DNA links between NPs. If these links are not constrained to lie along the axis between NPs, the separation is limited by off-axis connections that force the NPs to be closer. We also determine how the number of connections alters the effective persistence length of the ssDNA that connects the dimer. We discuss how these dimers might be used for subsequent assembly at larger scales.

5:18PM L48.00013 Specific interactions in complex mixtures: effects on the thermodynamic stability of multicomponent protein solutions, WILLIAM JACOBS, DAAN FRENKEL, University of Cambridge — Multicomponent protein solutions, such as the cytosol, comprise complex networks of specific interactions in a crowded environment of molecules with nonspecific interactions, with dissociation constants spanning many orders of magnitude. We investigate the phase behavior of a multicomponent lattice model with both specific and non-specific interactions. We use bit strings to encode the binding strength between interacting patches on particles at neighboring lattice sites. The boundary of the well-mixed dilute phase is calculated for a statistical ensemble of mixtures using semi-grand Monte Carlo simulations and multicanonical histogram reweighting techniques. We examine the sensitivity of this phase boundary to the distribution of component interactions and demonstrate that the phase behavior is extremely sensitive to the high-end tail of the distribution of interaction strengths.

Session L49 DPOLY: Focus Session: Fluctuation-Induced Forces in Soft Matter and Polymeric Systems - Charge, Shape and Nucleation 162A

2:30PM L49.00001 DILLON MEDAL BREAK —

3:06PM L49.00002 Ion-induced interactions between charged macroions and dielectric inhomogeneities, JOS ZWANIKKEN, MONICA OLVERA DE LA CRUZ, Northwestern University — We present a theoretical study of the interactions between macroions in ionic solutions, that are induced by the surrounding electrolyte. In a first scenario, we consider responsive nanoparticles with positively and negatively charged surface groups, and predict that thermal fluctuations of the net surface charge are responsible for an effective attraction, as a chemical analogue of the atomic London-forces. In a second scenario, we consider nanoparticles in solvents with a low dielectric permittivity, where the Coulomb interactions between ions easily exceed the thermal energy. We predict an ionic condensation in the confinement between two nearby nanoparticles, where the suppression of fluctuations leads to a locally dense state of ions, and a consequent strong effective attraction between the nanoparticles. The induced potential between the nanoparticles is also related to the ion-nanoparticle interactions, by e.g. Van der Waals, surface charge, or image charge attractions. Recently developed theoretical methods are discussed, based on earlier work [1,2].

[1] J. W. Zwanikken, and M. Olvera de la Cruz, Phys. Rev. E 82, 050401(R) (2010).

[2] J. W. Zwanikken, P. K. Jha, and M. Olvera de la Cruz, J. Chem. Phys. 135, 064106 (2011);

3:18PM L49.00003 Dielectric many-body effects in arrays of charged cylindrical macromolecules, DANIEL W SINKOVITS, University of Illinois at Urbana-Champaign, KIPTON BARROS, Los Alamos National Laboratory, JURE DOBNIKAR, University of Cambridge and Jožef Stefan Institute (IJS), MATEJ KANDUČ, Technische Universität München and IJS, ALI NAJI, Institute for Research in Fundamental Sciences (IPM), RUDOLF PODGORNIK, IJS and University of Ljubljana, ERIK LUIJTEN, Northwestern University — Nonuniform dielectric constants are a ubiquitous aspect of condensed-matter systems, but nevertheless widely ignored in simulations. Analytical work suggests that the polarization effects resulting from these inhomogeneities can produce many-body interactions that qualitatively alter the behavior of systems driven by electrostatic interactions, but such work relies on approximations. Recently, we have developed an algorithm that computes the fluctuating polarization charge at the interface between dielectric materials during a molecular dynamics simulation, without approximation. Here, we apply this approach to investigate arrays of charged cylindrical macromolecules in the presence of explicit counterions. We study the dielectric many-body effects as a function of separation, dielectric constant variation, and counterion valency. Our findings have implications for the aggregation of polyelectrolytes such as F-actin or DNA.

3:30PM L49.00004 ABSTRACT WITHDRAWN —

3:42PM L49.00005 Influence of probe shape on polymer configurations and entropic forces, YACOV KANTOR, Tel Aviv University — The free energy of long polymers is frequently dominated by entropy with the interaction energy playing a minor role. In the absence of an energy scale, the corresponding forces are then governed by the thermal energy scale $k_B T$ and by the length scales associated with the experimental set-up. Recent advances in single molecule manipulation techniques have brought the accuracy of position and force determination into the range where the measurement of relatively small deformations becomes possible. In these situations the detailed shape of probes to which the molecule is attached must be taken into account. The behavior of a polymer of size R_0 attached to the rounded tip of a probe (sphere, paraboloid, spherocylinder) with radius of curvature R , differs qualitatively for large and small values of the ratio $s = R_0/R$. The scaled compliance (inverse force constant) S/R_0^2 , is anisotropic and quite large in the direction parallel to the surface when $s \sim 1$ [1]. When a cone with a polymer attached to its sharp tip approaches a plate, then for cone-plate separation $h \ll R_0$ the polymer-mediated force between them [2] is given by $F = Ak_B T/h$. The coefficient A can be related to geometry-dependent correlation exponents of long polymers. We computed A for phantom polymers, and for self-avoiding polymers by ϵ -expansion, as well as by numerical simulations in 3 dimensions.

4:18PM L49.00006 Topological obstacles and the forces on them in systems of strongly interacting directed polymers, DAVID ZEB ROCKLIN, University of Illinois at Urbana-Champaign, PAUL M. GOLDBART, SHINA TAN, Georgia Institute of Technology — Owing to their extended structure and impenetrability, polymers are strongly influenced by topological obstacles. To shed light on this issue we consider a model system of noncrossing directed polymers in two dimensions. As first exploited by de Gennes [1], the configurations of this system can be mapped onto the worldlines of noninteracting fermions—an analogy that enables the application to the polymer system of techniques initially developed for one-dimensional quantum systems. Via this approach, we discuss how an obstacle that forces a fixed number of polymers to pass to one side of a single topological constraint is associated with a large fluctuation of the quantum system. In addition, via the use of techniques from quantum hydrodynamics, we find that such a constraint on a system of noncrossing polymers generates an effective, long-ranged repulsion between the polymers. This repulsion causes a void to appear in the polymer fluid and generates a super-Hookean force opposing the constraint. [1] P.-G. de Gennes, J. Chem Phys. **48**, 2257-2259 (1968).

4:30PM L49.00007 Critical exponents in the presence of a tip, MOHAMMAD F. MAGHREBI, MIT, YACOV KANTOR, Tel Aviv University, MEHRAN KARDAR, MIT — The behavior of Landau-Ginzburg model of a critical system, appropriate to describe SAW polymers, in the presence of a conical boundary is studied within mean field and by epsilon expansion in $d=4-\epsilon$ dimensions. New exponents emerge for correlation functions near the boundaries, in this case the tip of the cone. In the limit of a sharp cone we find a new exponent which we interpret for a SAW polymer by using its fractal dimension.

4:42PM L49.00008 Trapping fluctuations in confined carbon dioxide near the supercritical ridge, MANFRED HEUBERGER, ERICH SCHURTENBERGER, EMPA, Materials Science and Technology, CH-9014 St. Gallen — We investigate the properties of a confined supercritical carbon dioxide film. Density fluctuations are theoretically predicted near the critical point and along the supercritical extension of the liquid-gas coexistence line (ridge). We have confined carbon dioxide between two atomically smooth surfaces in a new generation of surface forces apparatus. The nanometers to micrometer films are found to be laterally divided into nano domains of two distinct refractive indices. The two-refractive index structure is apparent, yet different on behavior, above or below the supercritical ridge. This non-equilibrium phase separated film exhibits long-range attractive forces (up to 500 nm), which results from an interfacial energy between the different domains. High refractive nano domains can be trapped and stretched to lengths of several micrometers, until we observe coalescence of the domains. Our observations suggest that density fluctuations can be trapped and pinned between surfaces in the form of nano strings of significantly different molecular order.

4:54PM L49.00009 Homogeneous crystal nucleation from the melts of flexible n -alkanes by molecular simulation, PENG YI, GREGORY C. RUTLEDGE, Massachusetts Institute of Technology — Homogeneous crystal nucleation from a dense melt is particularly interesting for chain molecules due to their anisotropy and conformational flexibility. We report our molecular simulation study of the homogeneous crystal nucleation from n -alkane melts. For short n -alkane (C20) (J.Chem.Phys. **135**, 024903), the nucleation trajectory was sampled using brute force molecular dynamics (MD) simulations at about 20% supercooling and the nucleation free energy was sampled using the Monte Carlo (MC) umbrella sampling method for temperatures ranging from 10% to 20% supercooling. In the MD simulation, we identified the induction period unambiguously and calculated the nucleation rate through a mean-first-passage time analysis. A typical critical nucleus consists of a bundle of stretched segments organized into a cylindrical shape. The remaining CH₂ groups form a disordered interfacial layer. By fitting the free energy curve sampled by MC to the cylindrical nucleus model, the crystal-melt interfacial free energies are calculated. We have found good agreement between the melting temperature and the interfacial free energies obtained in our simulation and those from experiment. For a long n -alkane above the entanglement length (C150), MD simulation of nucleation was performed at super-cooling as small as 15%. Chain folding was observed during the nucleation stage, and thickening of crystallites was observed during the subsequent crystal growth. The resulting crystal-amorphous interface is characterized in terms of loops, bridges and tails.

Session L50 DMP DPOLY: Focus Session: Organic Electronics and Photonics - Morphology

162B

2:30PM L50.00001 DILLON MEDAL BREAK —

3:06PM L50.00002 Real-time observation of optoelectronic properties during poly(3-alkylthiophene) crystallization, VICTOR HO, BRYAN BOUDOURIS, University of California, Berkeley, LESLIE JIMISON, Stanford University, MICHAEL TONEY, Stanford Synchrotron Radiation Lightsource, ALBERTO SALLEO, Stanford University, RACHEL A. SEGALMAN, University of California, Berkeley — Poly(3-alkylthiophenes) (P3ATs) are commonly used semiconducting polymers in organic electronic applications where the nanoscale morphology of the active layer largely dictates device performance. However, during solution processing, a large driving force for crystallization results in thin film morphologies that are kinetically trapped and cannot be easily controlled. We show that rational side chain design, particularly the use of branched alkyl chains, can reduce the melting transition increasing thermal control relative to P3HT. Importantly, the lower crystallization transition temperature provides the opportunity to monitor crystallization in real-time using grazing-incidence x-ray diffraction and UV-vis absorption spectroscopy, and the relative degree of crystallinity is observed to increase gradually over the course of crystallization. In contrast to the gradual increase in crystallinity and optical properties, the field-effect mobility monitored during crystallization exhibits a sharp increase of approximately two orders of magnitude. We propose that the difference in time scales may be due to the formation of a percolated network between electrodes, and that increases in the degree of crystallinity beyond this point are not probed by the transistor geometry.

3:18PM L50.00003 In Situ Annealing Study of Organic Photovoltaic Morphology via Non-invasive Polarized Neutron Reflectivity, BRETT GURALNICK, MICHAEL MACKAY, University of Delaware, BRIAN KIRBY, CHARLES MAJKRZAK, NIST Center for Neutron Science — Polarized neutron reflectivity, a non-invasive technique, allows the unambiguous density distribution within a thin film to be determined. By utilizing this technique with organic photovoltaics it is possible to study the same device pre- and post-annealing. We studied a bulk heterojunction cell consisting of an organic semiconductor (P3HT) and a nanoparticle electron acceptor (PCBM). We found a shift in the location of PCBM within the organic film which migrates toward the anode and cathode following annealing. However, while some PCBM can reach the substrate interface it never fully blooms to the air interface and pure P3HT resides at the surface for the thick (200 nm) films used in this study. These results differ from previous research in that the same device was characterized allowing a true study on the effect of annealing to be performed.

3:30PM L50.00004 Solvent Studies for Solution Processing of Polymer-Fullerene Bulk Heterojunctions, MARGARET J. SOBKOWICZ, University of Massachusetts Lowell Plastics Engineering Department, RONALD L. JONES, R. JOSEPH KLINE, DEAN M. DELONGCHAMP, National Institute of Standards and Technology Polymers Division — A major advantage of polymer solar cells over higher-efficiency photovoltaic alternatives is the low cost of printing technologies. Solution-based film preparation relies on the self-assembly of the polymer and fullerene phases as the layer dries from the casting ink into a bulk heterojunction morphology. The nanoscale morphology must facilitate optimal charge separation and transport; thus solution processing parameters heavily influence the device performance. Current technology uses chlorinated aromatic solvents and small processing windows with stringent requirements on ink properties. In this study, the stability of various ink formulations is investigated to develop more reliable, sustainable alternatives. Model solutions of poly(3-hexylthiophene) (P3HT) and phenyl-C61-butyric acid methyl ester (PCBM) are prepared using a range of solvents and solvent mixtures. P3HT solution crystallization behavior is investigated using differential scanning calorimetry, UV-visible absorbance measurements and neutron and light scattering. The behavior of the solutions under shear is investigated in order to predict the success of disparate printing and coating techniques.

3:42PM L50.00005 Morphology in Hybrid Oxide/Polymer Core-Shell Nanowire Photovoltaics, JIE JIANG, SOHRAB ISMAIL-BEIGI, Yale University — We use first principles theory (DFT) to gain insight into the Poly(3-hexylthiophene) (P3HT)-ZnO nanowire binding morphology where the P3HT is bound to ZnO via SiO_3 linkers [1]: understanding the experimentally realized morphology is the first step in trying to predict and enhance electronic energy alignments conducive to photovoltaic operation. For large diameter ZnO nanowires, the morphology is that of P3HT bound to the $(10\bar{1}0)$ surface of ZnO. The existence of a lattice mismatch of the ZnO surface and the polymer backbone creates a competition between linker binding and strain energy. We solve this realization of the classic Frenkel-Kontorova model based on ab initio parameters to obtain the lowest energy binding morphology on the surface. For small ZnO nanowire diameters, curvature effects become important: the P3HT polymer must bend around the nanowire, and the reduction of linker spacing due to curvature enlarges the lattice mismatch for helical wrappings. We use DFT to estimate these curvature energies, and we predict a morphology change from helical wrapping to linear alignment with the nanowire axis at a diameter close to 25 nm. [1] S. Zhang, Adv. Mater. (in press, 2011).

3:54PM L50.00006 An Improved Forcefield for Molecular Modeling of Crystalline Poly(3-Hexyl Thiophene)¹, RAM BHATTA, Department of Chemistry, University of Akron, YENENEH YIMER, Department of Polymer Science, University of Akron, DAVID PERRY, Department of Chemistry, University of Akron, MESFIN TSIGE, Department of Polymer Science, University of Akron — A fundamental understanding of molecular structure and dynamics of poly(3-hexyl thiophene) (P3HT), one of the most promising organic solar cell materials, is crucial for improving the efficiency of organic solar cells containing P3HT as the donor. Molecular dynamics (MD) simulations can produce the correct structures and dynamics of P3HT provided that robust forcefields are employed for this system. The forcefields that are currently used for MD simulations of P3HT are mostly taken from the analogous thiophene molecule, bi-thiophene. However, such forcefields may lack to produce the correct morphology and stacking properties of P3HT. We present the results of MD simulations using an improved forcefield for P3HT. In the improved forcefield the torsional and partial atomic charge parameters for both the alkyl side chains and backbone were derived from ab initio calculations. Our results from MD simulations are compared with available experimental and theoretical data and the range of accessible structures is explored.

¹This work is supported by the NSF (DMR0847580).

4:06PM L50.00007 Device simulation of morphologies that are consistent with small angle scattering and reflectometry, DANIEL OLDS, PHILLIP DUXBURY, Michigan State University — Through the use of a dynamic Monte Carlo simulation, we are able to evaluate the efficiency of bulk heterojunction morphologies of P3HT/PCBM based photovoltaic devices that are consistent with neutron reflectometry and SANS data. We have developed a method to efficiently generate simulated small angle scattering data from hypothetical nanoscale systems such as polymer-fullerene bulk heterojunctions found in organic photovoltaic devices. We will show how this method can be used to accurately calculate the scattering information of well known systems such as a polydisperse collection of hard and soft spheres. We will then demonstrate this method on the calculated device morphologies, and show how the simulated scattering can grant insight into the validity of assumptions based on traditional fitting methods.

4:18PM L50.00008 Three dimensional device simulations to model conducting probe AFM measurements of organic semiconductors with fibrous morphologies, KANOKKORN PIMCHAROEN, DANIAL OLDS, JIEBING SUN, PENG PENG ZHANG, PHILLIP DUXBURY, Michigan State University — Organic semiconductors offer a promising material for many optoelectronic devices, with device performance depending significantly on the nanoscale morphology. Atomic force microscopy (AFM) is one of the major instruments for investigating the dependence of current-voltage response on nanoscale structures. We are developing computational methods for fundamental study of charge transport probed by these measurements, using continuum device models and Kinetic Monte Carlo simulations. The simulations are performed on complex three dimensional model morphologies that are consistent with the topology observed in AFM measurements. The calculated IV response of these models is compared with CP-AFM measurements.

4:30PM L50.00009 Self-Limiting Crystal Microstructure in Poly(3-hexylthiophene), CHAD SNYDER, RYAN NIEUWENDAAL, DEAN DELONGCHAMP, JESSICA HENRY, Polymers Division, National Institute of Standards and Technology — Polymeric semiconductors, such as poly(3-hexylthiophene-2,5-diyl) (P3HT), hold great potential for a variety of technologies. These solution processable materials are promising as active layers for low cost or large area flexible electronic or optoelectronic devices that can be prepared through high-throughput deposition processes, such as inkjet or roll-to-roll printing. Of the myriad of materials currently under examination, P3HT is one of the most widely studied materials because of its electronic properties and commercial availability. However, most, if not all, commercially available P3HT is produced with some non-negligible level of regiodefects that has a predefined impact on its crystalline fraction. We examine the effect of regiodefects in P3HT on the semicrystalline microstructure, i.e., lamellar thickness and distribution, and overall crystallinity, and discuss the impact of these effects on potential device performance and bulk heterojunction morphology.

4:42PM L50.00010 X-ray and neutron reflectivity and electronic properties of PCBM-poly(bromo)styrene blends and bilayers with poly(3-hexylthiophene)¹, STUART KIRSCHNER, NATHANIEL SMITH, KEVIN WEPASNICK, HOWARD KATZ, Johns Hopkins University, BRIAN KIRBY, JULIE BORCHERS, NIST Center for Neutron Research, DANIEL REICH, Johns Hopkins University — We used neutron reflectivity to complement x-ray reflectivity characterization of PCBM-based layers formed on poly(3-hexylthiophene) (P3HT). Single-layer analyses were used to provide reliable scattering length density values for bilayer fitting. Atomic force microscopy analyses showed trends similar to the reflectivity experiments when observing upper surfaces. Styrene polymers added to PCBM in small concentrations (ca. 10 percent) led to processing advantages while retaining substantial electron mobility, about 0.001 cm²/V s. The further introduction of a relatively heavy bromo atom substituent on the styrene rings greatly increased the film smoothness, as revealed by increases of the oscillation amplitudes in the reflectivity. In addition, the bromine heavy atom increased x-ray reflectivity scattering length density of the upper layer. Finally, we confirm that P3HT is capable of extracting PCBM from a subsequently deposited overlying layer, consistent with predictions based on published phase diagrams of the P3HT-PCBM system.

¹This research was supported in part by NSF grant ECCS-0823947.

4:54PM L50.00011 Controlled phase separation in conjugated polymer blends using quadruple hydrogen bonding interactions¹, YEN-HAO LIN, RAFAEL VERDUZCO, Rice University — All-polymer photovoltaic blends have significant promise for low-cost, solution processed photovoltaics, but large-scale phase separation can lead to non-optimal active layer structures for charge-separation and transport. We propose a novel strategy for controlling phase separation in conjugated polymer blends using quadrupole hydrogen bonding interactions. We investigate a series of end-modified conjugated and coil-like polymers in blends, including poly(3-hexyl thiophene) (P3HT), poly(styrene), poly(ethylene glycol), poly(9,9-dioctyl fluorene). Polymers are end-terminated with the multiple hydrogen bonding group 2-ureido-4(1H)-pyrimidinone (UPy) using isocyanate chemistry. Atomic force microscopy and grazing incidence x-ray scattering show phase separation is suppressed and, in some cases, P3HT crystallite orientation is improved in films for blends of UPy functionalized polymers. These results show the quadruple hydrogen bonding groups can prevent large-scale phase separation and direct the orientation of polymer chains.

¹This work was supported by the Welch Foundation for Chemical Research (Grant No. C-1750)

5:06PM L50.00012 Synthesis and Characterization of All-Conjugated Block Copolymers Prepared via Click Chemistry¹, RAFAEL VERDUZCO, KENDALL SMITH, Rice University — All-conjugated block copolymers with both hole-conducting and electron-conducting polymer blocks can be used to address fundamental questions regarding the structure, optoelectronic properties, and photovoltaic performance of organic photovoltaic blends, but synthetic challenges have precluded comprehensive studies on such systems. Here, we present a novel synthetic approach for preparing all-conjugated block copolymers and detailed studies of their nanoscale structure and optical properties. Our synthetic approach is based on copper-catalyzed azide-alkyne “click” chemistry and enables us to prepare block copolymers with a poly(3-alkylthiophene) block covalently linked to a conjugated polymer prepared by Suzuki polycondensation polymerization, including poly(9,9-dioctyl fluorene), poly(9,9-dioctyl fluorene-alt-benzothiadiazole) and poly((9,9-dioctylfluorene)-2,7-diyl-alt-[4,7-bis(thiophen-5-yl)-2,1,3-benzothiadiazole]-2',2"-diyl) (PFOTBT). A combination of x-ray diffraction, grazing-incidence x-ray scattering, atomic force microscopy, and fluorescence quenching measurements give insight into their microstructure and potential for use in high-performance all-polymer photovoltaics.

¹This work was supported by the Welch Foundation for Chemical Research (Grant No. C-1750)

5:18PM L50.00013 Undulation instability in drop-cast poly(3-hexylthiophene) film originated from self-assembly, MIN SANG PARK, School of Materials Science and Engineering, Georgia Institute of Technology, AVISHEK AIYAR, School of Chemical and Biomolecular Engineering, Georgia Institute of Technology, JUNG OK PARK, School of Materials Science and Engineering, Georgia Institute of Technology, ELSA REICHMANIS, School of Chemical and Biomolecular Engineering, Georgia Institute of Technology, MOHAN SRINIVASARAO, School of Materials Science and Engineering, Georgia Institute of Technology — In this study, we characterize the undulated structures which appear at the edge of drop-cast regio-regular poly(3-hexylthiophene) (rr-P3HT, head-to-tail > 95%) film using optical microscopy and atomic force microscopy. We propose that these periodic structures originate from the undulations of the layered structure of liquid crystal-air interface. Evidence of rr-P3HT solution forming liquid crystalline phases at higher concentrations was obtained by the observation of distinct birefringence and characteristic textures under crossed polarizers using an optical microscope. Synchrotron x-ray diffraction pattern provides additional structural information at the undulated area compared with those at the area without undulated pattern. Based on these experimental results, we propose rr-P3HT solution can form a lyotropic liquid crystal at specific concentrations. This work was partially supported by NSF funding (DMR-0706235).

Tuesday, February 28, 2012 2:30PM - 5:42PM —

Session L51 DCMP DFD: Self Assembly: Mostly Colloids, Lipids and Surfactants Boston Convention Center 154

2:30PM L51.00001 Basic parameters affecting nanoparticle self-assembly: An experimental approach, CHAKRA JOSHI, The University of Toledo, Department of Chemistry, YEVGEN KRYUKOV, JACQUES AMAR, University of Toledo, Department of Physics and the Wright Center for Photovoltaics Innovation and Commercialization, TERRY BIGIONI, The University of Toledo, Department of Chemistry and the Wright Center for Photovoltaics Innovation and Commercialization — Understanding the basic parameters that govern the nanoparticle self-assembly process is important for high-quality monolayer formation and technological advances. A complete theory that explains nanoparticle self assembly, in the bulk and at the liquid-air interface, is lacking. In this paper, dodecanethiolated gold nanoparticles were used as a model system for studying the forces that govern self assembly. These nanoparticles are known to make compact and highly-ordered monolayers at the liquid-air interface via a mechanism that is analogous to epitaxial growth of atomic layers. Epitaxial theory was used as a starting point to study the nanoparticle self-assembly at the liquid-air interface. Experimental measurements were successfully interpreted using an epitaxy-based analysis, including flux of nanoparticles onto the liquid air-interface, decay rate of the island density, and the dependence of critical nucleus size on nanoparticle diameter. Furthermore, anomalous diffusion was observed as was a remarkable ordering of islands at the liquid-air interface. This ordering was determined to be due to a long-range repulsive force between islands.

2:42PM L51.00002 Self-assembly of gold nanoparticles at water/vapor interface, GARY S. GRETT, J. MATTHEW D. LANE, Sandia National Laboratories — The self-assembly of coated gold nanoparticles at the water/vapor interfaces are studied using explicit-atom molecular dynamic simulations. While it is often assumed that uniformly coating spherical nanoparticles with short organic ligands lead to symmetric nanoparticles, we find that the high curvature of small nanoparticle and the relatively short dimensions of the coatings can produce highly asymmetric coatings. At an interface this asymmetry of the ligands tends to orient the nanoparticles with the surface to minimize free energy. First results for individual gold nanoparticles of diameter 2-8 nm coated with alkanethiol ligands of various lengths and different end group will be presented. Results for the self-assembly of the multiple nanoparticles at the water/vapor interfaces will then be presented for the diameter 2 and 4 nm nanoparticles which show how these asymmetric and oriented coatings affect the interactions between nanoparticles and the structure of the resulting aggregate. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

2:54PM L51.00003 Electric Field Driven Self-Assembly of Colloidal Rods, JAIME JUAREZ, KUNDAN CHAUDHARY, QIAN CHEN, STEVE GRANICK, JENNIFER LEWIS, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign — The ability to assemble anisotropic colloidal building blocks into ordered configurations is of both scientific and technological importance. We are studying how electric field-induced interactions guide the self-assembly of these blocks into well aligned microstructures. Specifically, we present observations of the assembly of colloidal silica rods ($L/D \sim 4$) within planar electrode cells as a function of different electric field parameters. Results from video microscopy and image analysis demonstrate that aligned microstructures form due to the competition between equilibrium interactions of induced dipoles and non-equilibrium processes (i.e., electro-osmosis). Under the appropriate electric field conditions ($\sim$ kHz AC fields), aligned colloidal rod fluids form over large areas on the electrode surface. The superposition of a DC electric field to this aligned colloidal rod fluid initiates their condensation into a vertically oriented crystalline phase. Ongoing work is now focused on exploring how temporal changes to electric fields influence colloidal rod dynamics and, hence, the assembly kinetics of aligned colloidal monolayers.

3:06PM L51.00004 Electron-induced Three Dimensional Self-assembly and Disassembly of Molecules on a Gold Surface, QING LI, Oak Ridge National Laboratory, CHENGBO HAN, North Carolina State University, MIGUEL FUENTES-CABRERA, HUMBERTO TERRONES, BOBBY SUMPTER, Oak Ridge National Laboratory, JERRY BERNHOLC, North Carolina State University, JIEYU YI, ZHENG GAI, ART BADDORF, PETRO MAKSYMOWYCH, MINGHU PAN, Oak Ridge National Laboratory — The immensely successful methodology of molecular self-assembly on surfaces has produced thousands of new applications and paved ways to new research areas, such as molecular electronics and the dip-pen nanolithography. Here we demonstrate a seminal example of non-thermal control over molecular self-assembly, where hot-electrons transform a largely disordered layer of hydrocarbon molecules, into a highly ordered, densely packed and three-dimensional monolayer on a gold surface. Subsequently, hot-electron/hot-hole injection can heal the defects within the self-assembled layer, and even entirely and reversibly disassemble it. From a theoretical analysis we have identified that electron-induced processes allow the formation of a very strongly-bonded molecule, and yet it is inaccessible by thermally-activated reactions due to a large number of competing processes. This work thus demonstrates the feasibility of accessing and controlling non-thermal reaction pathways that may lead to unique and controllable order-disorder transitions in supported molecular layers.

3:18PM L51.00005 Self assembly of anisotropic colloidal particles, DANIEL FLOREA, HANS WYSS, Eindhoven Technical University — Colloidal particles have been successfully used as "model atoms", as their behavior can be more directly studied than that of atoms or molecules by direct imaging in a confocal microscope. Most studies have focussed on spherical particles with isotropic interactions. However, a range of interesting materials such as many supramolecular polymers or biopolymers exhibit highly directional interactions. To capture their behavior in colloidal model systems, particles with anisotropic interactions are clearly required. Here we use a colloidal system of nonspherical colloids, where highly directional interactions can be induced via depletion. By biaxially stretching spherical PMMA particles we create oblate spheroidal particles. We induce attractive interactions between these particles by adding a non-adsorbing polymer to the background liquid. The resulting depletion interaction is stronger along the minor axis of the oblate spheroids. We study the phase behavior of these materials as a function of the ellipsoid aspect ratio, the strength of the depletion interactions, and the particle concentration. The resulting morphologies are qualitatively different from those observed with spherical particles. This can be exploited for creating new materials with tailored structures.

3:30PM L51.00006 Adsorption of Core-Shell Nanoparticles at Liquid-Liquid Interfaces, EMANUELA DEL GADO, LUCIO ISA, ETH Zurich, ESTHER AMSTAD, Harvard, KONRAD SCHWENKE, PATRICK ILG, MARTIN KROEGER, ETH Zurich, ERIK REIMHULT, BOKU Wien, SURFACE TECHNOLOGY, ETH ZURICH TEAM, MICROSTRUCTURE AND RHEOLOGY, ETH ZURICH TEAM, POLYMER PHYSICS, ETH ZURICH TEAM, NANOBIO TECHNOLOGY, BOKU TEAM — The use of nanoparticles as building blocks for the self-assembly of functional materials has been rapidly increasing in recent years. In particular, two-dimensional materials can be effectively self-assembled at liquid interfaces thanks to particle localization and mobility at the interface in combination with tailoring of specific interactions. Many recent advances have been made in the understanding of the adsorption and assembly at liquid interfaces of small hydrophobic nanoparticles, stabilized by short-chain rigid dispersants, but the corresponding studies on core-shell nanoparticles sterically stabilized by extended hydrophilic polymer brushes are presently missing. Such particles offer significant advantages in terms of fabrication of functional, responsive and bio-compatible materials. We present here a combination of experimental and numerical data together with an intuitive and simple model aimed at elucidating the mechanisms governing the adsorption of iron oxide nanoparticles (5-10nm) stabilized by low molecular weight poly(ethylene glycol) (1.5-10 kDa). We show that the adsorption dynamics and the structure of the final assembly depend on the free energy of the particles at the interface and discuss the thermodynamics of the adsorption.

3:42PM L51.00007 ABSTRACT WITHDRAWN —

3:54PM L51.00008 Encapsulation by Janus Oblate Spheroids¹, WEI LI, YA LIU, Lehigh University, GENEVIEVE BRETT, Skidmore College, JAMES GUNTON, Lehigh University — The micro/nano encapsulation technology has acquired considerable attention in the fields of drug delivery, biomaterial engineering, and material science. Based on recent advances in chemical particle synthesis, we propose a preliminary model of encapsulation system induced by self-assembly of Janus oblate ellipsoids, the particles with oblate ellipsoidal cores and two semi-surfaces coded with dissimilar chemical properties. Using Monte Carlo simulation, we investigate the encapsulation system with spherical particles as encapsulated guests in different densities. We study the anisotropic effect brought by encapsulating agent's geometric shape and chemical composition on encapsulation morphology and efficiency. In the relative high encapsulation efficiency we observe from the simulation, we believe this method of encapsulation is of potential value in practical use.

4:06PM L51.00009 Particle Deposition in Drying Drops of Colloidal Suspensions Containing Different Surfactants¹, TIM STILL, PETER J. YUNKER, A.G. YODH, University of Pennsylvania — When a drop of water containing small solid particles dries, most of the solid material is deposited in a ring-shape stain after evaporation (the so-called coffee ring), driven by initial contact line pinning and a subsequent outward-flow. The fluid dynamics and, hence, the deposition mechanism in such suspensions can be dramatically changed when surfactants are introduced into the system. In a colloidal model-system, the ionic sodium dodecyl sulfate (SDS) produces a concentration-driven Marangoni flow counteracting the outward-flow of the coffee ring effect. SDS locally concentrates at the air/water interface next to the contact line, leading to a reduced local surface tension. Thus, a circulating flow ('Marangoni eddy') is introduced that prevents particles from deposition. This flow is visualized by the movements of the dragged particles using video microscopy. Other surfactants can influence this highly non-equilibrium systems in completely other ways. E.g., the non-ionic Poloxamer block-copolymer surfactants lead to a uniform particle deposition, which we explain by hydrophilization of the colloidal particles. Controlling the solid deposition in drying drops is of major importance for many technical applications.

¹We acknowledge financial support from MRSEC DMR11-20901 and DAAD.

4:18PM L51.00010 Formation of Lipid-Based Nanodiscs and Their Dependence of Temperature and Chemical Composition¹, YING LIU, YONGKUN YANG, MU-PING NIEH, UNIVERSITY OF CONNECTICUT — Phospholipid mixtures composed of 1,2-dipalmitoyl-sn-glycero-3-phosphocholine (DPPC), 1,2-dihexanoyl-sn-glycero-3-phosphocholine (DHPC) and 1,2-dipalmitoyl-sn-glycero-3-phospho-(1'-rac-glycerol) (sodium salt)(DPPG) and 1,2-distearoyl-sn-glycero-3-phosphoethanolamine-N-[methoxy(polyethylene glycol)-2000] (ammonium salt) (PEGylated DSPE) and cholesterol were found to form nanodiscs (bicelles) in both non-ionic and phosphate buffer solutions. The structure of the aggregates is resolved using dynamic light scattering, transmission electron microscopy and small angle neutron scattering. The effects of temperature and chemical composition (e.g., PEGylated DSPE and cholesterol) on the structural variation and polydispersity will be discussed in this presentation. These nanodiscs have the potential of serving as a model delivery carrier for hydrophobic molecules for their biological compatibility and capability of incorporating with targeting molecules.

¹Thanks NSF - CMMI 1131589

4:30PM L51.00011 How to control GUV shape transformations, KEJIA CHEN, ADAM SZMELTER, SUNG CHUL BAE, STEVE GRANICK, University of Illinois at Urbana-Champaign — Using a microfluidic platform, we expose giant unilamellar vesicles (GUVs) to programmed time-varying profiles of osmotic pressure. In response to these conditions that intentionally do not approach equilibrium, water flows in and out, and the excess area changes in response. Shape transformations are observed that were not previously reported, nor predicted theoretically.

4:42PM L51.00012 Aqueous Gemini Surfactant Self-Assembly into Complex Lyotropic Phases, MAHESH MAHANTHAPPA, GREGORY SORENSON, Department of Chemistry, University of Wisconsin-Madison, 1101 University Ave., Madison, WI 53703 — In spite of the potentially wide-ranging applications of aqueous bicontinuous lyotropic liquid crystals (LLCs), the discovery of amphiphiles that reliably form these non-constant mean curvature morphologies over large phase windows remains largely serendipitous. Recent work has established that cationic gemini surfactants exhibit a pronounced tendency to form bicontinuous cubic (e.g. gyroid) phases as compared to their parent single-tail amphiphiles. The universality of this phenomenon in other surfactant systems remains untested. In this paper, we will report the aqueous LLC phase behavior of a new class of anionic gemini surfactants derived from long chain carboxylic acids. Our studies show that these new surfactants favor the formation of non-constant mean curvature gyroid and primitive ("Plumber's Nightmare") structures over amphiphile concentration windows up to 20 wt% wide. Based on these observations, we will discuss insights gained into the delicate force balance governing the self-assembly of these surfactants into aqueous bicontinuous LLCs.

4:54PM L51.00013 Shear-Driven Circulation Patterns in Lipid Membrane Vesicles, FRANCIS WOODHOUSE, AURELIA HONERKAMP-SMITH, RAYMOND GOLDSTEIN, DAMTP, University of Cambridge — Recent experiments [C. Vézy, G. Massiera, and A. Viallat, *Soft Matter* 3, 844 (2007)] have shown that when a near-hemispherical lipid vesicle attached to a solid surface is subjected to a simple shear flow it exhibits a pattern of membrane circulation much like a dipole vortex. This is in marked contrast to the toroidal circulation that would occur in the related problem of a drop of immiscible fluid attached to a surface and subjected to shear. This profound difference in flow patterns arises from the lateral incompressibility of the membrane, which restricts the observable flows to those in which the velocity field in the membrane is two-dimensionally divergence free. We theoretically study these circulation patterns within the simplest model of membrane fluid dynamics. A systematic expansion of the flow field is developed for differing bulk fluid viscosities incorporating a non-zero membrane shear viscosity and curvature effects. It is shown how such studies can allow measurements of the membrane viscosity from flow field data. New experimental results utilising this method are discussed.

5:06PM L51.00014 Self standing nanoparticulate networks by self assembly surfactant H₁ mesophase, GURUSWAMY KUMARASWAMY, NCL, Pune, India, KAMENDRA SHARMA, SAYAM SEN GUPTA, NCL — We show that nanoparticles (size > 10 nm) that are dispersed in nonionic surfactant/water system, assemble into networks on cooling into the H₁ phase, independent of particle surface chemistry. Coating the particles with a crosslinkable polymer, and covalent coupling of the coated particle assemblies in the H₁ phase allows us to form free standing particulate networks that are stable after surfactant removal. Thus, dynamic templating of surfactant H₁ domains is a facile technique that involves near ambient temperatures, and a benign water wash for template removal. The network mesh size can be varied from the sub-micron to tens of microns by controlling the cooling rate. Particle networks can be flow-oriented prior to crosslinking, and interpenetrating networks can also be formed. We will show examples of macroporous nanoparticulate networks formed using nanoparticles of inorganic oxides, polymer latices, as well as bionanoparticles such as proteins.

5:18PM L51.00015 SAXS on ice crystals reveals fractal structure on nanometer length scales, JESSE HOPKINS, RYAN BADEAU, MATTHEW WARKENTIN, ROBERT THORNE, Cornell University — We have used small angle x-ray scattering (SAXS) to probe ice formation in supercooled aqueous solutions and water. The SAXS shows that the ice formed in supercooled aqueous solutions and water has power law behavior that is invariant across a wide range of solute type, concentration, and temperature. We interpret this power law as scatter from fractal structures in the ice. The consistency of this power law across four different solutes and in pure water, and at temperatures between 150 K and 220 K suggests an underlying similarity between macroscopically/visually different forms of ice on length scales of 10-100 nm. Time dependent SAXS curves reveal two scattering regimes, one occurring at early times and one dominating at later times, which we interpret within the context of fractal scatterers. Finally, we use scaling collapses on the data to extract information about the time and temperature dependence of the ice growth. We interpret this within the established framework of the ice nucleation and growth community.

5:30PM L51.00016 Molecular Dynamics simulations of flow-structure interactions in fluids containing cylindrical micelles and micelle-nanoparticle complexes¹, RADHAKRISHNA SURESHKUMAR, Syracuse University, Syracuse, NY, ASHISH SANGWAI, Intel Corporation, Hillboro, OR, ABHINANDEN SAMBASIVAM, Syracuse University, Syracuse, NY, SYRACUSE UNIVERSITY TEAM — Coarse-grained (CG) force fields, benchmarked against fully atomistic ones, are used in Molecular Dynamics simulations to predict shape transitions and binary interactions in cationic surfactant micelles as well as to understand the molecular mechanisms of self-assembly of micelles with noble metal nanoparticles germane to plasmonics. Non-equilibrium MD simulations are conducted to probe the effect of flow shear on cylindrical micelle dynamics and estimate properties such as tumbling frequency, relaxation time and scission energy. Simulations are also performed to understand flow-mediated alignment and merger of two cylindrical micelles which is hypothesized to be the mechanism underlying the formation of shear-induced structures in micellar fluids.

Tuesday, February 28, 2012 2:30PM - 5:30PM –
Session L52 GSNP DFD: Focus Session: Extreme Mechanics - Origami, Creasing, and Folding
153C

2:30PM L52.00001 Extreme Folding, ERIK DEMAINE, Massachusetts Institute of Technology — Our understanding of the mathematics and algorithms behind paper folding, and geometric folding in general, has increased dramatically over the past several years. These developments have found a surprisingly broad range of applications. In the art of origami, it has helped spur the technical origami revolution. In engineering and science, it has helped solve problems in areas such as manufacturing, robotics, graphics, and protein folding. On the recreational side, it has led to new kinds of folding puzzles and magic. I will give an overview of the mathematics and algorithms of folding, with a focus on new mathematics and sculpture.

3:06PM L52.00002 Geometry in the mechanics of origami, MARCELO A. DIAS, CHRISTIAN D. SANTANGELO, University of Massachusetts Amherst — We present a mechanical model for curved fold origami in which the bending energies of developable regions are balanced with a phenomenological energy for the crease. The latter energy comes into play as a source of geometric frustration, allowing us to study shape formation by prescribing crease patterns. For a single fold annular configuration, we show how geometry forces a symmetry breaking of the ground state by increasing the width of the ribbon. We extend our model to study multiple fold structures, where we derive geometrical constraints that can be written as recursive relations to build the surface from valley to mountain, and so on. We also suggest a mechanical model for single vertex folds, mapping this problem to an elastica on the sphere.

3:18PM L52.00003 Photo-Origami – Using Light to Bend, Fold, and Buckle¹, JENNIE RYU, University of Colorado, MATTEO D'AMATO, University of Trento, KEVIN LONG, Sandia National Laboratories, XIAODONG CUI, H. JERRY QI, MARTIN DUNN, University of Colorado — We describe photo-origami, a method to program spatially- and temporally-variable mechanical, chemical, and optical fields into a polymer that enable controllable, sequenced, macroscopic bending and folding to create three-dimensional structures. We combine mechanical and optical stimuli to locally rearrange the polymer's network topology which allows us to program a residual stress state into the film; upon release of mechanical constraints, we realize a wide variety of desired shapes. We demonstrate, through a combination of theory, simulation-based design, synthesis, and experiment, the operative phenomena and capabilities of photo-origami. We demonstrate architectures that rely on bending, folding, instabilities, and post-buckling behavior to achieve their three-dimensional form, starting from a flat sheet. We also describe a theory that couples the hereditary nature of photophysics, chemistry, and large-deformation mechanics and enables simulations of the fabricated structures that are in good agreement with the experiments.

3:30PM L52.00004 Pleated and Creased Structures¹, LEVI DUDTE, ZHIYAN WEI, L. MAHADEVAN, Harvard University — The strategic placement of curved folds on a paper annulus produces saddle-shaped origami. These exotic geometries resulting from simple design processes motivate our development of a computational tool to simulate the stretching, bending and folding of thin sheets of material. We seek to understand the shape of the curved origami figure by applying the computational tool to simulate a thin annulus with single or multiple folds. We aim to quantify the static geometry of this simplified model in order to delineate methods for actuation and control of similar developable structures with curved folds. Miura-ori pattern is a periodic pleated structure defined in terms of 2 angles and 2 lengths. The unit cell embodies the basic element in all non-trivial pleated structures - the mountain or valley folds, wherein four folds come together at a single vertex. The ability of this structure to pack and unpack with a few degrees of freedom leads to their use in deployable structures such as solar sails and maps, just as this feature is useful in insect wings, plant leaves and flowers. We probe the qualitative and quantitative aspects of the mechanical behavior of these structures with a view to optimizing material performance.

3:42PM L52.00005 Hierarchical Stress Focusing in Elastic Ridge, LEE WALSH, BENNY DAVIDOVITCH, University of Massachusetts — A crumpled or confined elastic sheet contains many stress-focusing structures and singularities, primarily ridges and vertices, which may contain much of the strain. We seek to determine the degree and quality of stress focusing within the geometry of a single ridge. Previous work on the ridge assumes the asymptotic limit of infinitely sharp vertices. However, in a physically realistic sheet any vertex or intersection of ridges will naturally have a finite radius of curvature greater than the sheet's thickness. We simulate these more physically realistic boundary conditions in a ridge using Surface Evolver.

3:54PM L52.00006 Stress focusing and collapse of a thin film under constant pressure¹, EUGENIO HAMM, NICOLAS CABEZAS, Universidad de Santiago de Chile — Thin elastic sheets and shells are prone to focus stress when forced, due to their near inextensibility. Singular structures such as ridges, vertices, and folds arising from wrinkles, are characteristic of the deformation of such systems. Usually the forcing is exerted at the boundaries or at specific points of the surface, in displacement controlled experiments. On the other hand, much of the phenomenology of stress focusing can be found at micro and nanoscales, in physics and biology, making it universal. We will consider the post-buckling regime of a thin elastic sheet that is subjected to a constant normal distributed force. Specifically, we will present experiments made on thin elastoplastic sheets that collapse under atmospheric pressure. For instance, in vacuum-sealing technology, when a flat plastic bag is forced to wrap a solid volume, a series of self-contacts and folds develop. The unfolded bag shows a pattern of scars whose structure is determined by the geometry of the volume and by the exact way it stuck to its surface, by friction. Inspired by this everyday example we study the geometry of folds that result from collapsing a hermetic bag on regular rigid bodies.

4:06PM L52.00007 Creasy modeling of a compressed elastic surface, TUOMAS TALLINEN, L. MAHADEVAN, Harvard University — Compression of an elastic layer attached to a rigid substrate leads to nucleation and growth of creases. We explore crease formation by a numerical model allowing control of compressive strain, anisotropy and bulk modulus. We address questions on arrangement and geometry of creases and model also the stabilizing effect of surface tension at small scales.

4:18PM L52.00008 Creasing instability of elastomers under uniaxial compression, DAYONG CHEN, RYAN HAYWARD, Polymer Science and Engineering Department at UMass-Amherst — Soft polymers placed under compressive stress can undergo an elastic creasing instability in which sharp folds spontaneously form on the free surfaces. This process may play an important role in contexts as diverse as brain morphogenesis, failure of tires, and electrical breakdown of soft polymer actuators, but our understanding of this instability is still quite limited. We describe a simple experimental system to study creasing of thin elastomer films under uniaxial compression. The equilibrium depths, spacings and shapes of creases are characterized and found to show excellent agreements with numerical results. Further, we use this system to explore the important roles played by surface energy and adhesion in the onset and hysteretic behavior of creases.

4:30PM L52.00009 Sulcus formation in a compressed elastic half space, JOHN BIGGINS, L. MAHADEVAN, Harvard University — When a block of rubber, biological tissue or other soft material is subject to substantial compression, its surfaces undergo a folding instability. Rather than having a smooth profile, these folds contain cusps and hence have been called creases or sulci rather than wrinkles. The stability of a compressed surface was first investigated by Biot (1965), assuming the strains associated with the instability were small. However, the compression threshold predicted with this approach is substantially too high. I will introduce a family of analytic area preserving maps that contain cusps (and hence points of infinite strain) that save energy before the linear stability threshold even at vanishing amplitude. This establishes that there is a region before the linear stability threshold is reached where the system is unstable to infinitesimal perturbations, but that this instability is quintessentially non-linear and cannot be found with linear strain elasticity.

4:42PM L52.00010 Compression induced folding of a sheet: An integrable system, HAIM DIAMANT, Tel Aviv University, THOMAS A. WITTEN, University of Chicago — The apparently intractable shape of a fold in a compressed elastic film lying on a fluid substrate is found to have an exact solution. Such systems buckle at a nonzero wave vector set by the bending stiffness of the film and the weight of the substrate fluid. Our solution describes the entire progression from a weakly displaced sinusoidal buckling to a single large fold that contacts itself. The pressure decrease is exactly quadratic in the lateral displacement. We demonstrate a subtle connection to the sine-Gordon problem, which reveals a new symmetry in the folding phenomenon.

4:54PM L52.00011 Wrinkles or creases in a bi-layer structure, LIHUA JIN, School of Engineering and Applied Sciences, Kavli Institute, Harvard University, ANESIA BURNS, RYAN HAYWARD, Department of Polymer Science & Engineering, University of Massachusetts, ZHIGANG SUO, School of Engineering and Applied Sciences, Kavli Institute, Harvard University — Wrinkles and creases are different modes of instability. In this work, we try to answer for a bi-layer structure with different modulus ratios and thickness ratios of the film and substrate whether wrinkles or creases form first when the bi-layer is under uniform compression. The onset of wrinkles corresponds to a bifurcation point, and we use the linear perturbation method to analyze the critical strain for the onset of wrinkles. Since the initiation of creases is autonomous, we directly apply the critical condition for crease initiation in a half space calculated by the finite element method in the literature to the situation of a bi-layer structure with finite thickness. By comparing the critical strains for the formation of wrinkles and creases under different modulus and thickness ratios, a phase diagram of the formation of wrinkles or creases is obtain. Although the critical strains for both wrinkle and crease initiation depend on the state of strain, remarkably the phase diagram is independent of the state of strain. As a result, creases tend to set in for more compliant and thicker films, while wrinkles tend to set in for stiffer and thinner films. Especially, when the modulus ratio of the film and substrate is smaller than 1.67, creases always form earlier than wrinkles, no matter what the thickness ratio is. We further verify the result experimentally by compressing a bi-layer of polymers with different modulus and thickness ratios.

5:06PM L52.00012 Wrinkles and Folds in Ultra-Thin Polymer Films¹, YURI EBATA, University of Massachusetts, Amherst, ANDREW B. CROLL, North Dakota State University, ALFRED J. CROSBY, University of Massachusetts, Amherst — Wrinkles and folds are observed in many biological systems during morphogenesis processes. However, the mechanics of how these wrinkles and folds form are not completely understood. Studying the mechanics of wrinkles and folds will not only provide us with fundamental insights of nonlinear deformation processes but also allow for the fabrication of unique patterned surfaces that can be controlled reversibly. In this study, we examine wrinkles and folds of polystyrene films of thickness ranging from 5 nm to 180 nm attached to uniaxially-strained polydimethylsiloxane substrates. The strain is released incrementally to apply increasing compressive strain to the attached film. The wavelength and the amplitude of local out-of-plane deformation are measured as global compression is increased to distinguish between different buckling modes. The transition from wrinkling to folding is observed by tracking the statistics of amplitude distribution sampled across a large lateral area, and a critical strain map is constructed to observe how film thickness affect the resulting buckling modes.

5:18PM L52.00013 Relaxation mechanisms in the unfolding of thin sheets, BENJAMN THIRIA, PMMH-ESPCI, MOKHTAR ADDA-BEDIA, LPS-ENS — When a thin sheet is crumpled, creases form in which plastic deformations are localized. Here we study experimentally the relaxation process of a single fold in a thin sheet subjected to an external strain. The unfolding process is described by a quick opening at first, and then a logarithmic slow relaxation of the crease. In the latter regime, the necessary force needed to open the folded sheet at a given displacement is found to decrease logarithmically in time, allowing its description through an Arrhenius activation process. We accurately determine the parameters of this law and show its general character by performing experiments on both Mylar and paper sheets.

Tuesday, February 28, 2012 2:30PM - 5:30PM – Session L53 GSNP DCMP: Frontiers of Statistical Physics 153B

2:30PM L53.00001 Lars Onsager Prize Lecture: A Random Walk Through Theoretical Physics, IAN AFFLECK, University of British Columbia — A historical account will be given of my efforts to apply conformal field theory techniques to experimentally relevant models of condensed matter. This began with a so far unsuccessful attempt to find the exact critical exponents for the localization transition in the integer quantum Hall effect, using techniques developed by field/string theorists. It was followed by a program to classify critical behavior of Heisenberg antiferromagnetic spin chains of arbitrary spin magnitude. It eventually led to a general theory of the low energy behavior of quantum impurity models including exact solutions for non-Fermi liquid critical points.

3:06PM L53.00002 Dannie Heineman Prize for Mathematical Physics Lecture: Understanding Nonequilibrium via Rare Fluctuations, GIOVANNI JONA-LASINIO, Dipartimento di Fisica, Università di Roma “La Sapienza” and INFN, Roma, Italy — Irreversible processes are a hot subject in statistical mechanics. During the last decade through the effort of several people, including the recipient of the prize and his collaborators, a progress in understanding stationary nonequilibrium states has been achieved. The key has been the study of rare fluctuations. The talk will review some basic ideas, results and perspectives.

3:42PM L53.00003 Experimental confirmation of Landauer's principle¹ , JOHN BECHHOEFER, YONGGUN JUN², Simon Fraser University — Landauer's principle, formulated in 1961, postulates that irreversible logical or computational operation such as memory erasure must dissipate heat, no matter how slowly they are performed. For example, to "reset to one" a memory that can be in state 0 or 1 requires at least $kT \ln 2$ of work, which is dissipated as heat. In 1982, Bennett pointed out a link to Maxwell's Demon: Were Landauer's principle to fail, it would be possible to repeatedly extract work from a heat bath. We report the first confirmation of Landauer's principle in an experimental system, where a virtual double-well potential is created via a feedback loop. We observe the position of a charged, fluorescent, colloidal particle in water and calculate and then apply a force $= -\text{grad } U(x,t)$ via an electric field. In a first experiment, the probability of "erasure" (resetting to one) is unity, and at long cycle times, we observe that the work is compatible with $kT \ln 2$. In a second, the probability of erasure is zero; the system may end up in two states; and, at long cycle times, the measured work tends to zero.

3:54PM L53.00004 The Basis of the Second Law of Thermodynamics in Quantum Field Theory¹ , DAVID SNOKE, GANGQIANG LIU, Department of Physics and Astronomy, University of Pittsburgh, STEVEN GIRVIN, Department of Physics, Yale University — We derive the quantum Boltzmann equation for a closed system with a two-particle collision process on the basis of quantum field theory. In the thermodynamic limit, the system evolves deterministically and irreversibly towards equilibrium, on the time scale of the scattering time of the particles. This irreversibility is related to the loss of information which comes from the vanishing off-diagonal phase coherence in the system. By calculating the time evolution of the off-diagonal elements of the generalized density matrix, we show that these terms decay rapidly due to the interaction. In the case of Bose-Einstein condensates, all phase coherence is not lost. We deduce the onset of phase coherence in a Bose-Einstein condensate, which gives rise to macroscopic wavelike behaviors of Bose systems. We also derive the H-theorem by combining our results with standard definitions of entropy.

¹We thank A. Duncan, D. Boyanovsky, and K. Sengupta for helpful discussions. This work has been partly supported by the National Science Foundation through grant DMR-0706331.

4:06PM L53.00005 The Stochastic Geometry of non-Gaussian Fields , THOMAS BEUMAN, Institute Lorentz, Leiden University, ARI TURNER, University of Amsterdam, VINCENZO VITELLI, Institute Lorentz, Leiden University — Gaussian random fields pervade various areas of physics and have distinctive and well understood stochastic properties. Here we study the stochastic geometry of a random surface, whose height is given by a nonlinear function of a Gaussian field. We find that, as a result of the non-Gaussianity, the density of maxima and minima no longer match and calculate the relative imbalance between the two. We perform similar calculations for the density of umbilical points, which are topological defects of the lines of curvature. Our results apply to the analysis of speckle patterns generated by nonlinear random waves and more generally to detect and quantify non-Gaussianities present in any scalar field that can be represented as a smooth two-dimensional surface.

4:18PM L53.00006 Differential geometry of the space of Ising models , BENJAMIN MACHTA, RICKY CHACHRA, Department of Physics, Cornell University, MARK TRANSTRUM, Department of Bioinformatics and Computational Biology at the MD Anderson Cancer Center, JAMES SETHNA, Department of Physics, Cornell University — We use information geometry to understand the emergence of simple effective theories, using an Ising model perturbed with terms coupling non-nearest-neighbor spins as an example. The Fisher information is a natural metric of distinguishability for a parameterized space of probability distributions, applicable to models in statistical physics. Near critical points both the metric components (four-point susceptibilities) and the scalar curvature diverge with corresponding critical exponents. However, connections to Renormalization Group (RG) ideas have remained elusive. Here, rather than looking at RG flows of parameters, we consider the reparameterization-invariant flow of the manifold itself. To do this we numerically calculate the metric in the original parameters, taking care to use only information available after coarse-graining. We show that under coarse-graining the metric contracts very anisotropically, leading to a "sloppy" spectrum with the metric's Eigenvalues spanning many orders of magnitude. Our results give a qualitative explanation for the success of simple models: most directions in parameter space become fundamentally indistinguishable after coarse-graining.

4:30PM L53.00007 Growth Inside a Corner: Limiting Interface Shape , JASON OLEJARZ, PAUL KRAPIVSKY, SIDNEY REDNER, Boston University, KIRONE MALLICK, CEA Saclay, France — We investigate a simple model for crystal growth in which elemental cubes are stochastically deposited onto the inside of a three-dimensional corner. The interface of this crystal evolves into a deterministic limiting shape in the long-time limit. We incorporate known results from the corresponding two-dimensional system and use geometrical symmetries of the three-dimensional problem to conjecture an equation of motion for the interface profile which we solve analytically. The agreement between the result of the calculation and simulations of the growth process is excellent. We also present a generalization of our equation of interface motion to arbitrary spatial dimension.

4:42PM L53.00008 The magnetisation distribution of the Ising model for $d \geq 5$, PER LUNDOW, ANDERS ROSENGREN, KTH - Royal Institute of Technology — The magnetisation distribution of the Ising model for $d > 4$ is excellently fitted by a generalised binomial distribution. We have computed exactly an ansatz expression which can be fitted to the distribution near T_c . Though the ansatz is long and complicated it only has three parameters, besides the number of vertices, which then provides us with details about the distribution. This method also provided us with an estimate of T_c for $d = 6$. For extremely dense regular graphs, such as a complete bipartite graph, we can show what the parameter values are and that these values give asymptotically correct behaviour of eg the susceptibility and the free energy. Also a possible approach for $d \leq 4$ will be briefly discussed as well as boundary effects for $d = 5$.

4:54PM L53.00009 A Topological Phase Transition in Models of River Networks , JACOB OPPENHEIM, MARCELO MAGNASCO, Rockefeller University — The classical Scheidegger model of river network formation and evolution is investigated on non-Euclidean geometries, which model the effects of regions of convergent and divergent flows - as seen around lakes and drainage off mountains, respectively. These new models may be differentiated by the number of basins formed. Using the divergence as an order parameter, we see a phase transition in the number of distinct basins at the point of a flat landscape. This is a surprising property of the statistics of river networks and suggests significantly different properties for riverine networks in uneven topography and vascular networks of arteries versus those of veins among others.

5:06PM L53.00010 Finite size scaling of the dynamical free-energy in the interfacial regime of a kinetically constrained model, VIVIEN LECOMTE, Laboratoire Probabilités et Modèles Aléatoires (LPMA), CNRS UMR 7599, Universités Paris 6 et Paris 7, France, THIERRY BODINEAU, DMA, Ecole Normale Supérieure (UMR 8553), 45 rue d'Ulm, Paris, France, CRISTINA TONINELLI, Laboratoire Probabilités et Modèles Aléatoires (LPMA), CNRS UMR 7599, Universités Paris 6 et Paris 7, France — Glassy phenomena have proven difficult to understand: they present a variety of features – slow dynamics, ageing, dynamical heterogeneity, frustration – which make their study arduous from a theoretical point of view. Kinetically Constrained Models (KCMs) are a simple class of lattice gas whose dynamics present features similar to those of glassy phenomena, with the advantage that no disorder is present in the model – making them easier to study. A dynamical approach has been recently proposed: it consists in determining the large deviation function associated to the probability distribution function of time-integrated observables quantifying the “activity” of histories followed by the system. We determine the finite size corrections to the large deviation function of the activity in a KCM (the Fredrickson-Anderson model in one dimension), in the regime of dynamical phase coexistence. Numerical results agree with an effective model where the boundary between active and inactive regions is described by a Brownian interface. We show that the scalings of this physical picture are reflected in the finite size scaling of the dynamical free energy of the model. We expect the same picture to hold in other kinetically constrained models where the particle number is not conserved.

5:18PM L53.00011 Effective Temperature Dynamics of Radiation Induced Amorphization, IDO REGEV, Center for non linear studies and Theoretical division, Los Alamos National Laboratory, XIANGDONG DING, TURAB LOOKMAN, Theoretical division, Los Alamos National Laboratory 61097340 — Materials exposed to radiation suffer structural changes over time. Typically, after exposure to radiation, a crystal will gradually lose its periodic structure and become amorphous. A theory of radiation amorphization should provide a description of the structural evolution. We study radiation amorphization in a simple molecular dynamics model and show that one can describe the amorphous steady-state using a structural effective temperature (different from the thermal bath temperature). We derive a theory that predicts the value of the steady-state effective-temperature as a function of the thermal bath temperature for a constant intensity of radiation. The theory agrees well with simulations results.

Tuesday, February 28, 2012 2:30PM - 5:30PM – Session L54 DCMP: Superconductivity: Mostly Devices and Applications 152

2:30PM L54.00001 Proximity Induced Superconductivity in Ferromagnetic Nanowires: Magnetoresistance Oscillations and Steps in I-V Characteristics¹, MEENAKSHI SINGH, Pennsylvania State University, MINGLIANG TIAN, University of Science and Technology of China, Hefei, JIAN WANG, Pennsylvania State University, HE LIN, Beijing Normal University, Beijing, MOSES CHAN, Pennsylvania State University — Ferromagnetic order requires electronic spins to be aligned parallel whereas singlet superconducting order requires spins to be aligned antiparallel. This spin incompatibility limits the superconducting proximity effect to ~ 1 nm in bulk ferromagnets. In ferromagnetic nanowires contacted with superconducting W electrodes however, the proximity effect is seen to extend to ~ 400 nm [Wang et al., Nat. Phys. 6, 389 (2010)]. The mechanism behind the long range proximity in these systems is not certain. We have studied single crystalline Co nanowires contacted with normal electrodes with a single superconducting W strip patterned on the nanowire. The long range proximity effect is found to persist in this geometry. Robust magnetoresistance oscillations were found when an external field parallel to the axis of the wire was applied. In addition, regularly spaced peaks were seen in the dI/dV vs. V characteristics of the sample. The origin of the oscillations and the peaks is not understood.

¹This work was supported by NSF under grant no. DMR-0820404.

2:42PM L54.00002 Imaging point-like defects in two dimensional superconductors: theory and experiment, HILARY NOAD, JULIE BERT, KATJA NOWACK, BEENA KALISKY, ILYA SOCHNIKOV, THOMAS LIPPMAN, Stanford Institute for Materials and Energy Science, Stanford University, Stanford CA 94305, JOHN KIRTLEY, Department of Applied Physics, Stanford University, Stanford CA 94305, KATHRYN MOLER, Stanford Institute for Materials and Energy Science, Stanford University, Stanford CA 94305 — Point defects in two-dimensional superconductors produce significant local variations in the superconducting properties. A model [1] of point defects in a weak, two-dimensional superconductor, based on London's equations, shows that defects appear as haloes of decreased diamagnetic susceptibility as seen by the imaging kernel of a scanning SQUID susceptometer. We report theoretical limits on the defect strength and superconducting Pearl length Λ required for defects to be visible. We compare these models to our experimental data showing similar haloes in the superconducting state of several types of superconducting films as a function of magnetic field, gate voltage, temperature, and height. Our ability to image these defects offers new possibilities for studying the interplay between materials properties and superconducting phenomena in thin film systems.

[1] V.G. Kogan and J.R. Kirtley, Phys. Rev. B **83**, 214521 (2011).

2:54PM L54.00003 Half-quantum vortices in superconducting networks¹, ILYA SOCHNIKOV, KATHRYN MOLER, Department of Physics and Department of Applied Physics, Stanford University, Stanford, California 94305, USA, VICTOR VAKARYUK, Argonne National Laboratory, Argonne, Illinois 60439, USA — We study numerically the magnetic field and temperature dependence of vortex occupation in superconducting wire networks assuming that the underlying material allows for the presence of half-quantum vortices. We focus on thermodynamic stability of half-quantum vortices, which are believed to be present in large size networks even when a stability of a single isolated half-quantum vortex is not expected. The spatial arrangements of half- and full vortices in networks are studied as well.

3:06PM L54.00004 DNA templating for *in situ* growth and measurement of 1D superconducting wires, LIUQI YU, JINGJIAO GUAN, PENG XIONG, Florida State University — Controllable and reproducible fabrication of sub-10 nm metal wires is of broad scientific and technological interest. One notable example is nanowires of disordered superconductors; such a small width is generally required to place them in the 1D regime where questions remain on the nature of superconductivity and superconducting fluctuations. Molecular templating based on macromolecules, such as carbon nanotubes and DNA strands, offers a relatively straightforward and reliable method of producing nm-wide wires. Here, we report the fabrication of nanowire templates using a unique procedure of DNA stretching.¹ DNA wires are assembled onto Si/SiO₂/Si₃N₄ substrates across trenches with an overhang, fabricated via e-beam lithography and combination of dry and wet etching. The location and orientation of the DNA wires can be well controlled. The template will be used as the substrate for *in situ* growth and electrical measurement of 1D superconductor nanowires in a custom dilution refrigerator. The experiments are expected to enable a close examination of the emergence and evolution of superconductivity in true 1D limit as the wire cross-section is varied in situ on one and the same sample.

¹J.J. Guan *et al*, Adv. Mater. 19, 1212 (2007).

3:18PM L54.00005 The role of dissipation in quantum phase slip production in superconducting nanowires, DIMA MOZYRSKY, Los Alamos National Laboratory — We study dynamics of quantum phase slips (QPS) in ultrathin superconducting wires. At sufficiently low temperatures momentum conservation is known to pose a constraint on QPS creation, which can be lifted due to inhomogeneous external potential or due to production of quasiparticles. We argue that while the former mechanism is weak in nanowires with diameters significantly exceeding the Fermi wavelength (which is the case for most up-to-date QPS experiments), the dissipation caused by quasiparticles is likely to be the major source for the QPS generation. We argue that dissipation can be enhanced in superconductors with broken time reversal symmetry, and therefore such systems are likely to exhibit phase slips at ultralow temperatures. Our studies may clarify recent experiments (Nature Physics 5, 503 (2009)) showing the evidence of QPS at sufficiently high values of bias-current.

3:30PM L54.00006 Quantum oscillations in superconducting mesoscopic rings of Sr_2RuO_4 ¹, XINXIN CAI, YIQUN YING, NEAL STALEY, Pennsylvania State University, YAN XIN, NHMFL, Florida State University, DAVID FOBES, TIJIANG LIU, ZHIQIANG MAO, Tulane University, YING LIU, Pennsylvania State University — Sr_2RuO_4 has attracted considerable amount of attention recently because of its potential application in topological quantum computing as a $p_x \pm ip_y$ superconductor. Cantilever magnetometry measurements carried out on doubly connected Sr_2RuO_4 samples of a micron size were found to exhibit jumps in magnetization suggesting the presence of both integer and half-integer flux quanta. To search for quantum oscillations with periods corresponding to integer and half-integer flux, we prepared micron size rings of Sr_2RuO_4 from thin flakes of Sr_2RuO_4 obtained by mechanical exfoliation and carried out transport measurements at low temperatures. Photolithography technique was applied to make contact probes on the flake and focused ion beam (FIB) was used in the fabrication. Disorder introduced by the FIB process employing high-energy beams of Ga ions was characterized by transmission electron microscopy. We succeeded in the preparation of superconducting rings of roughly 1 μm in diameter with 200~400nm line width. Strong oscillations of ring resistance with a conventional period of full flux quantum have been observed. In some samples a different period of oscillations was also found at high field range. The nature of these oscillations will be discussed.

3:42PM L54.00007 Superconductivity of a Sn film controlled by an array of Co nanowires, ZHIYUAN WEI, ZUXIN YE, DAYA RATHNAYAKA, IGOR LYUKSYUTOV, WENHAO WU, DONALD NAUGLE, Texas A&M University, DEPARTMENT OF PHYSICS TEAM — Superconducting properties of a hybrid structure composed of ferromagnetic Co nanowire arrays and a superconducting Sn film have been investigated. Ordered Co nanowires arrays with 60 nm, 150 nm and 200 nm diameter were electroplated into the pores of self organized anodic aluminum oxide (AAO) membranes. Hysteretic dependence of the Sn film superconducting properties on applied magnetic field and critical current enhancement at moderate fields has been observed. This behavior strongly depends on the ratio of the Sn film thickness to the Co nanowire diameter.

3:54PM L54.00008 Measurements on Superconducting Nanorings Smaller than the Coherence Length¹, STEPHEN SNYDER, MICHAEL J. ERICKSON, JOSEPH KINNEY, YEONBAE LEE, J.J. NELSON, ALLEN GOLDMAN, University of Minnesota — The Little-Parks experiment on superconducting cylinders is an important demonstration of fluxoid quantization in superconductors. The transition temperature oscillations in magnetic field have a period of $h/2e$ for the micro cylinders in their studies, which was further evidence for Cooper pairing at the time [W. A. Little, R. D. Parks, *PRL* **9**, 9 (1964)]. However recent theoretical works have suggested that in superconducting loops smaller than the coherence length this period changes from $h/2e$ to h/e , for details see [F. Loder, et al. *PRB* **78**, 174526 (2008)] and references therein. The destructive regime has also been observed experimentally in cylinders whose diameter is small compared to the coherence length [Y. Liu, et al. *Science* **294**, 2332 (2001)]. We present experimental work in an effort to achieve this limit in Al nanorings prepared by electron beam lithography. These measurements achieve a regime hitherto unexplored in nanorings with interesting consequences.

4:06PM L54.00009 Flux noise in SQUIDS: calculations of geometrical dependence¹, SEAN O'KELLEY, KEENAN PEPPER, STEVEN ANTON, JEFFREY BIRENBAUM, JOHN CLARKE, UC Berkeley — Low frequency ($1/f$) magnetic flux noise in SQUIDS is understood to arise from the random reversal of electron spins localized at the surface of the superconducting film. Analytical results¹ that assume independent electron spins predict that the spectral density at 1 Hz scales with the washer geometry approximately as R/W in the limit $R/W \gg 1$. Here, R is the outer radius and W is the linewidth. We present numerical calculations that reproduce the analytical result in the appropriate limit and extend these results to arbitrary values of R/W . In addition, a logarithmic dependence on W , evident when R/W is fixed and W is varied, is reproduced and discussed. The contribution of spins at the edge of the film is also computed. We compare the predicted geometrical scaling to our recent measurements of several SQUIDS with varying geometries. Our calculation that is valid for all values of R/W enables us to investigate a possible breakdown of the independent spin model in our experimental data. ¹R. C. Bialczak et al., Phys. Rev. Lett. **99**, 187006 (2007).

4:18PM L54.00010 Geometry and temperature dependence of low frequency flux noise in dc SQUIDS¹, JEFFREY BIRENBAUM, S.M. ANTON, S.R. O'KELLEY, UC Berkeley, V. BOLKHOVSKY, D.A. BRAJE, G. FITCH, M. NEELEY, W.D. OLIVER, MIT Lincoln Laboratory, F.C. WELLSTOOD, Univ of Maryland, JOHN CLARKE, UC Berkeley — Measurements of low frequency magnetic flux noise in dc SQUIDS demonstrate a spectral density $S_\Phi(f) = A^2/f^\alpha$ in which the magnitude A scales only weakly with the washer geometry and typically $0.5 < \alpha < 1$. An analytical model assuming non-interacting spins localized to the surface of the SQUID loop predicts that $A^2 \propto R/W$ for $R/W \gg 1$. Here, R and W are the outer radius and linewidth, respectively. Our numerical calculations extend the analytical results to arbitrary washer geometries. We compare both models to flux noise measurements on several dc SQUIDS fabricated simultaneously on a single chip using a Nb trilayer process. Multiple SQUIDS were measured within a single cool-down. The SQUID geometries were divided into two categories: fixed $W=500$ nm with $3 < R/W < 24$ and fixed $R/W = 3$ with $1.5 \mu\text{m} < R < 24 \mu\text{m}$. Our measurements are in approximate agreement with the theoretical predictions for temperatures between 100 mK and 4 K, despite the fact that the slope α —for which we have no theoretical model—varies with temperature. We present measured values of α as functions of both geometry and temperature. Finally, we interpret our results within the framework of the non-interacting spin model.

4:30PM L54.00011 Investigation of $1/f$ flux noise in superconducting circuits, STEVEN SENDELBAACH, ANTONIO PUGLIELLI, Department of Physics, University of Wisconsin-Madison, CHANG-BEOM EOM, JACOB PODKAMINER, KWANG HWAN CHO, Department of Materials Science and Engineering, University of Wisconsin-Madison, ROBERT MCDERMOTT, Department of Physics, University of Wisconsin-Madison — Low-frequency $1/f$ flux noise is a dominant source of dephasing in the Josephson phase and flux qubits. Recent work has revealed the presence of a high density of unpaired spins at the surfaces of superconducting thin films; it is now believed that these spins are the source of the noise, although the microscopic noise mechanism is not understood. Here we describe experiments on SQUIDS and Josephson phase qubits designed to shed light on the underlying noise mechanism, and we describe efforts to develop novel materials with reduced levels of noise.

4:42PM L54.00012 Critical Exponents and Cluster Analysis on STM Studies of a Cuprate Superconductor, BENJAMIN PHILLABAUM, ERICA CARLSON, Purdue University, KARIN DAHMEN, University of Illinois at Urbana-Champaign — In this presentation we will show results from a new kind of analysis for surface probes allowing us to gather some information about the bulk behavior of the sample that is studied. This presentation will introduce the analysis in as general a way as practical and use a particular example to concretely demonstrate how it can be applied. The particular example is the case of a local nematic order observed in a Scanning Tunneling Microscopy (STM) experiment on a BSCCO sample from which we determine which model best describes the behavior of nematic orientation using critical exponents derived from the properties of clusters and correlations of these orientations. These results would highlight key physical contributions to the nematic's orientation and guide further studies into the underlying physics. We fully expect similar impact on the study of other systems for which this analysis can be performed.

4:54PM L54.00013 Extracting the Bosonic Spectra of Pb Using Superconducting-Tip STS and Comparing it with the Cuprates, F.C. NIESTEMSKI, Stanford University, S. JOHNSTON, IFW Dresden, A.W. CONTRYMAN, C.D. CAMP, T.P. DEVEREAUX, H.C. MANOHARAN, Stanford University — In high-temperature superconductors the meaning of the common feature labeled "peak-dip-hump" is still a point of great debate. In terms of scanning tunneling spectroscopy (STS) this refers to the shape of satellite features that occur outside the coherence peaks in the dI/dV spectra. There are many conflicting interpretations and labeling schemes for this feature in both the hole- and electron-doped cuprates. The path to resolving this confusion is to study a well-understood BCS superconductor to better observe the way that the STM measures bosonic information. Utilizing the ultra-low electronic noise of our home-built low-temperature STM, and utilizing a superconducting tip for increased spectral resolution, we recreate the original McMillan and Rowell S-I-S junction¹ with the STM equivalent (S-Vacuum-S). This method provides very high energy resolution for both the filled and empty electronic states in both the superconducting and normal state. We compare this data to first-principle Eliashberg calculations and relate this data to "peak-dip-hump" in the high T_c case.

5:06PM L54.00014 Comparison between Simmons's Equations and Quantum Tunneling Experimental Results in A Thin Film, LIANXI MA, Blinn College, TEXAS A&M UNIVERSITY COLLABORATION — The theoretical predictions of J.G. Simmons's equations are compared with quantum tunneling experimental results and a discrepancy is found at bias voltage $V_b = U/e$, where U is the barrier's potential height and e is the electron charge. Specifically, he divided the bias voltage into 2 regions: $V_b < U/e$ and $V_b > U/e$, and the $I - V$ characteristics are different in these two regions. The derived equations show a kink on differential conductance dI/dV vs. V_b at $V_b = U/e$, because starts at this bias the thickness of the insulation film decreases with V_b in addition to the lowering of the barrier's average height. Therefore, the differential conductance decreases more rapidly in the region $V_b > U/e$ than in the region $V_b < U/e$. However, in tunneling experiment in which Pt is used as conductor and solid neon as insulator, we have not observed such kink even the bias was increased to 4 volts. Our speculation is either 1) there should not be a kink on conductance at $V_b = U/e$ so Simmons's equations need to be modified; 2) the kink should exist but bias voltage is not high enough to observe it in the experiments.

5:18PM L54.00015 Size effect on supercurrent screening in large array superconducting anti-dot thin films¹, HSIANG-HSI KUNG, TING-HUI CHEN, CHIA-TSO HSIEH, CHI-CHIH HO, Institute of Physics, Academia Sinica, Nankang, Taipei, Taiwan R.O.C., KEN-HUI LIN, Institute of Physics and Research Center of Applied Science, Academia Sinica, Nankang, Taipei, Taiwan R.O.C., WEN-TAU JUAN, WEI-LI LEE, Institute of Physics, Academia Sinica, Nankang, Taipei, Taiwan R.O.C. — We fabricated well-ordered and large array niobium (Nb) anti-dot thin films using a monolayer of polymer/nanosphere hybrid as a template. The hole diameter and center-to-center distance can be tuned independently. By applying a perpendicular magnetic field, we observed pronounced oscillations with field in both magnetization and resistivity due to the criteria of the flux quantization, which is reminiscent of the well-known Little-Parks experiment in a thin-walled superconducting cylinder. By varying the hole diameter, the detailed size effect on supercurrent screening can be explored and will be discussed.

Wednesday, February 29, 2012 8:00AM - 11:00AM – Session P2 GSNP: Invited Session: Large Fluctuations Far From Equilibrium 204AB

8:00AM P2.00001 Characterizing Order in Glassy Systems, DOV LEVINE, Technion - IIT — Crystals and quasicrystals can be characterized by an order that is a purely geometric property of an instantaneous configuration, independent of particle dynamics or interactions. Glasses, on the other hand, are ostensibly amorphous arrangements of particles. A natural and long-standing question has been whether they too have, albeit in a hidden way, some form of geometric order. I will examine a recent proposal for a coherence length that applies to systems which are typically characterized as amorphous, as well as to those that are conventionally ordered. The question of whether exotic order can arise in physical systems will be addressed.

8:36AM P2.00002 Drift, diffusion and barrier crossing of small objects on a surface assisted by an external noise: roles of non-linear friction, MANOJ CHAUDHURY, Lehigh University — We study experimentally the behaviors of several driven diffusive systems that involve the sliding and rolling of small solid objects or liquid drops on a surface with an external noise and an external field. The displacement statistics here are non-Gaussian at short observation time, but they tend towards a Gaussian behavior at long time scale. Furthermore, in each of these cases, the drift velocity increases sub-linearly, but the diffusivity increases super-linearly with the strength of the noise. These observations reflect the underlying non-linear friction control of their stochastic dynamics. Specific experiments have also been designed to study the hopping of a small object over a physical barrier assisted by an external noise. These results mimic the classical Arrhenius behavior from which an effective temperature may be deduced. However, the regimes controlled by a Coulombic like friction and a linear kinematic friction need to be treated somewhat differently. All the drifted diffusive systems studied here exhibit substantial negative fluctuations of displacement at a short observation time that diminishes at longer time scale. Using the integrated fluctuation theorem, we characterize the persistence time of negative fluctuations in terms of the diffusivity and the drift velocity that can be measured experimentally.

9:12AM P2.00003 Noise induced stabilization in population dynamics¹, ALEX KAMENEV, University of Minnesota — We investigate a model where strong noise in a sub-population creates a metastable state in an otherwise unstable two-population system. The induced metastable state is vortex-like, and its persistence time grows exponentially with the noise strength. A variety of distinct scaling relations are observed depending on the relative strength of the sub-population noises.

¹supported by NSF grant DMR-0804266

9:48AM P2.00004 Speeding up spontaneous disease extinction, MICHAEL KHASIN¹, University of Michigan — The dynamics of epidemic in a susceptible population is affected both by the random character of interactions between the individuals and by environmental variations. As a consequence, the sizes of the population groups (infected, susceptible, etc.) fluctuate in the course of evolution of the epidemic. In a small community a rare large fluctuation in the number of infected can result in extinction of the disease. We suggest a novel paradigm of controlling the epidemic, where the control field, such as vaccination, is designed to maximize the rate of spontaneous disease extinction. We show that, for a limited-scope vaccination, the optimal vaccination protocol and its impact on the epidemics have universal features: (i) the vaccine must be applied in pulses, (ii) the spontaneous disease extinction is synchronized with the vaccination. We trace this universality to general properties of the response of large fluctuations to external perturbations.

¹in collaboration with Mark Dykman, Michigan State University, and Baruch Meerson, Hebrew University of Jerusalem

10:24AM P2.00005 Cooperativity-Driven Singularities in Cooperative Asymmetric Exclusion¹, SIDNEY REDNER, Boston University — We investigate the effect of cooperative interactions on the asymmetric exclusion process. In the simplest case a particle can hop to its vacant right neighbor only if its left neighbor is occupied. We show that an initial density downstep develops into a rarefaction wave that can have a jump discontinuity at the leading edge, while an upstep results in a shock wave. We also investigate a more general model in which the particle velocity can be an increasing function of the density. Within a hydrodynamic theory, initial density upsteps and downsteps can evolve into: (a) shock waves, (b) continuous compression or rarefaction waves, or (c) a mixture of shocks and continuous waves. These unusual phenomena arise because the current versus density relation has an inflection point, so that the group velocity can either be an increasing or a decreasing function of the density on either side of the inflection point.

Wednesday, February 29, 2012 8:00AM - 11:00AM – Session P3 DCMP: Invited Session: Alkaline Iron Selenides vs Iron Pnictides: Properties and Their Implications 205AB

8:00AM P3.00001 Neutron Scattering Study on the New 245 Iron Selenide Superconductors¹, WEI BAO, Renmin University of China, Beijing 100872, China — We determine using neutron and x-ray diffraction method the sample composition, crystalline structure and magnetic order of the recently discovered $A_2Fe_4Se_5$ superconductors ($A=K, Rb, Cs, Tl/K$ or Tl/Rb). Contrary to initial belief that these materials are heavily electron-doped variety of the $BaFe_2As_2$ family of Fe-based superconductors, they are almost charge balanced with the Fe valence close to $2+$ as in the 11 iron selenide superconductors, and crystalize in an Fe vacancy-ordered lattice structure [1,2]. Coexisting with superconductivity is a novel block antiferromagnetic order which conforms to the tetragonal crystalline symmetry and possesses a very large ordered magnetic moment $3.3\mu_B$ per Fe and a very high ordering temperature above 500 K [1]. Such Fe vacancy ordered crystal structure and coexisting antiferromagnetism and superconductivity occur in all 5 types of new iron selenide superconductors discovered so far. With Fe vacancy number departs from the chemical formulas $A_2Fe_4Se_5$, an imperfect version of the Fe vacancy order results at base temperature while phase separation into two vacancy-ordered phases exists at the intermediate temperature range [4]. The Fe site disorder renders the materials insulating and destroys the superconductivity as spin-glass disorder does in previous 11 iron selenide superconductors [5].

8:36AM P3.00002 Distinct Fermi Surface Topology and nearly Isotropic Superconducting Gap in $A_x\text{Fe}_{2-y}\text{Se}_2$ ($A=\text{K, Tl, Rb}$) Superconductors¹, XINGJIANG ZHOU, Institute of Physics, Chinese Academy of Sciences, Beijing 100190 — High resolution angle-resolved photoemission measurements have been carried out to study the electronic structure and superconducting gap of the newly discovered $A_x\text{Fe}_{2-y}\text{Se}_2$ [$A=\text{K, (Tl,K)}$ and (Tl,Rb)] superconductors[1,2,3] 1. Distinct Fermi surface topology, consisting of two electron-like Fermi surface sheets around the $\Gamma(0,0)$ point and an electron-like Fermi surface sheet near the $M(\pi,\pi)$ point, was revealed in all these samples. This is in strong contrast to the Fermi surface topology of other Fe-based superconductors where hole-like Fermi surface sheets are present near the $\Gamma(0,0)$ point. 2. Both the electron-like Fermi surface sheet near M point and the large electron-like Fermi surface sheet near Γ point show nearly isotropic superconducting gap without nodes 3. The doping evolution of the electronic structure from insulating samples to the superconducting samples is consistent with a phase separation picture. The information on the Fermi surface topology and superconducting gap of this new $A_x\text{Fe}_{2-y}\text{Se}_2$ superconductor will provide key insights and constraints to understand the superconductivity mechanism in iron-based superconductors.

9:12AM P3.00003 Pairing strength and symmetries of 122 iron selenides in comparison with iron pnictides¹, PALLAB GOSWAMI, National High Magnetic Field Laboratory and Florida State University — High temperature superconductivity with comparable transition temperatures has been observed in the vicinity of an antiferromagnetic phase, in both 122-alkaline iron selenides and 122-iron pnictides. In contrast to iron pnictides, where the parent state is an antiferromagnetic semimetal, the parent state of 122-iron selenides is a large moment, antiferromagnetic insulator. This provides a clear indication of strong electronic correlations. The 122-selenides possess only electron pockets, while the pnictides have both hole and electron pockets. In addition, the observed block spin magnetic order in 122-selenides can not be explained by Fermi surface nesting. At the same time, the comparable T_c suggests a commonality in the underlying mechanism for superconductivity in the two classes of materials. Motivated by these observations and considerations, we present a comparative strong coupling analysis of the pairing strength and symmetries in these two classes of materials [1,2]. The analysis of appropriate five orbital $t - J_1 - J_2$ models, reveals a similar pairing phase diagram for both materials, with $A_{1g} s(x^2y^2)$ and $B_{1g} d(x^2 - y^2)$ as two dominant pairing channels. The pairing amplitudes in both materials are of comparable strength, making it natural for a comparable maximum T_c . In contrast to the pnictides case, an $A_{1g} s(x^2 + y^2)$ state is not competitive, making the dominant pairing channels fully gapped. We also discuss the magnetism of the vacancy-ordered insulating 122 iron selenides [3], showing that the observed block-spin state occurs over a wide parameter range. The predicted magnetic excitation spectrum has been verified by inelastic neutron scattering experiments. Our study also reveals some commonality with the magnetism of the parent iron pnictides [4].

Wednesday, February 29, 2012 8:00AM - 11:00AM – Session P4 DAMOP: Multi-Component BECs and Mixtures 205C

8:00AM P4.00001 Analytical solutions to the spin-1 Bose-Einstein condensates, SHI-JIE YANG, ZHI-HAI ZHANG, Department of Physics, Beijing Normal University — We present classes of exact stationary solutions for the one-dimensional coupled nonlinear Gross-Pitaevskii equations which describe the $F = 1$ spinor Bose-Einstein condensates, both with and without the Zeeman splitting. The spin magnetization configurations and the spin currents are investigated. The soliton or the soliton train complexes are naturally produced.

8:12AM P4.00002 Geometry of Spinor Condensates with Large Spins, OMNARAYANI NAYAK, University of California, Berkeley, ARI TURNER, University of Amsterdam — Laser cooled atoms with spin can become magnetically ordered in a variety of ways, like electrons in a frustrated lattice, but the phases are more geometrical in this setting. For spin one, two and three atoms, states have been predicted with a nematic symmetry (the symmetry of a toothpick), a hexagon, and an octahedron, as well as other possibilities. As the spin becomes larger, the phase diagrams become more and more complicated. I will present a geometrical way of predicting regularities in the phases as the spin increases. For a certain form of interaction, we find a phase diagram for arbitrarily large spin. (In particular, a nematic phase does not occur beyond spin 2.) We have used a mapping to a classical problem of interacting particles arranging themselves on a sphere.

8:24AM P4.00003 Pomeranchuk cooling of $SU(N)$ ultracold fermions in optical lattice¹, ZI CAI, HSIANG-HSUAN HUNG, Department of physics, UCSD, DONG ZHENG, Department of physics, Tsinghua University, CONGJUN WU, Department of physics, UCSD — We investigate thermodynamic properties of a half-filled $SU(2N)$ Fermi-Hubbard model in two-dimensional square lattice using the determinantal Quantum Monte Carlo simulation. We address the question how the large number of hyperfine-spin components makes thermodynamic properties of $SU(N)$ ultracold fermions different from the conventional Hubbard model with $N=2$. Various thermodynamic quantities such as entropy, charge fluctuations, and spin correlations have been calculated. We devote special attention to the interaction-induced adiabatic cooling: an analogue of the Pomeranchuk effect in Helium-3.

¹This work was supported by the NSF DMR-1105945 and the AFOSR-YIP program

8:36AM P4.00004 Determinant Quantum Monte Carlo simulations on quantum magnetism of the $SU(2N)$ ultra-cold fermions¹, DONG ZHENG, Department of Physics, Tsinghua University, HSIANG-HSUAN HUNG, Department of electrical and computer engineering, University of Illinois at Urbana-Champaign, ZI CAI, CONGJUN WU, Department of Physics, University of California, San Diego — We investigate the quantum magnetism of the repulsive $SU(2N)$ -Hubbard model on a two-dimensional square lattice at half-filling. At $2N = 4$, our numerical results suggest that there exists a long-range Neel ordering at large U . In this regime, both of the antiferromagnetic structure factor per site and the farthest two-point spin-spin correlation functions are saturated to finite values in the thermodynamic limit. The single-particle excitations are finite and the spin gaps vanish. All of above evidences support the presence of the Neel ordering in the $SU(4)$ -Hubbard model. For $2N > 4$, such features are not explicitly observed.

¹NSF DMR-1105945

8:48AM P4.00005 Multi-component integrable models in cold atoms, YUZHU JIANG, Beijing Computational Science Research Center, Beijing 100084, China, JUNPENG CAO, YUPENG WANG, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, PR China, HAIQING LIN, Beijing Computational Science Research Center, Beijing 100084, China — The quantum gases are intensively studied for the inspiring advances in ultra-cold atomic physics. Various kinds of lattice and gas systems are created in different dimensions. The multi-component cold atomic systems have rich phase diagrams. Our works focus on the one-dimensional integrable quantum systems. We find a series of integrable models of $Sp(2s+1)$ fermions and $SO(2s+1)$ bosons and solve them via Bethe ansatz techniques, where s the hyperfine spin of the atoms. We find the paired bosons exist in both repulsive and attractive $SO(3)$ integrable bosonic gases with hyperfine spin-1. For the $Sp(2s+1)$ repulsive fermions, there are no bound states in the ground state, while 2-string bound solutions appear in the spin sector. We also calculate the spin-wave velocities and low temperature specific heat of the repulsive fermions. These systems have spin-charge separation property of Luttinger liquid. Different from the $SU(2s+1)$ repulsive models, the spin-wave velocities of the $Sp(2s+1)$ models are no longer the same. The holes of 1-strings (real rapidities) of different branches in the spin sector have a same spin-wave velocity v_1 and the ones of 2-strings share a same spin-wave velocity v_2 . The two velocities are different.

9:00AM P4.00006 Haldane Phase of Ultra Cold Atom Gas Loaded on Pseudo-One-Dimensional Optical Lattice, KEITA KOBAYASHI, MASAHIKO OKUMURA, Center for Computational Science & e-System Japan Atomic Energy Agency, YUKIHIRO OTA, REKIN, SUSUMU YAMADA, MASAHIKO MACHIDA, Center for Computational Science & e-System Japan Atomic Energy Agency — Ultracold Fermi gas loaded on optical lattice (FGOL) has attracted considerable attention since its temperature, interaction, and filling factor are flexibly controllable and various quantum phases are accessible. In this study, we examine properties of pseudo-one-dimensional (P1D) FGOL obtained by including effects of the transverse excitations. At first, we prove that the P1D system at half-filling can be theoretically mapped on spin-1 Heisenberg chain. Secondly, we reveal by using DMRG scheme that Haldane phase emerges in the P1D FGOL. Finally, we clarify effects of trap potential and spin imbalance on not only the central Haldane phase but also various different magnetic structures around the Haldane phase.

9:12AM P4.00007 Half-quantum vortex state and its excitations in a spin-orbit coupled spinor Bose-Einstein condensate¹, B. RAMACHANDHRAN, Department of Physics and Astronomy, and Rice Quantum Institute, Rice University, Houston, TX 77005, USA, BOGDAN OPANCHUK, XIA-JI LIU, ACQAO and Centre for Atom Optics and Ultrafast Spectroscopy, Swinburne University of Technology, Melbourne 3122, Australia, HAN PU, Department of Physics and Astronomy, and Rice Quantum Institute, Rice University, Houston, TX 77005, USA, HUI HU, ACQAO and Centre for Atom Optics and Ultrafast Spectroscopy, Swinburne University of Technology, Melbourne 3122, Australia — We investigate theoretically the condensate state and collective excitations of a spin-orbit coupled spinor Bose gas in two-dimensional harmonic traps. In the weakly interacting regime, when the inter-species interaction is larger than the intra-species interaction ($g_{\uparrow\downarrow} > g$), we find that the condensate state has a half-quantum-angular-momentum vortex configuration (half-vortex state) with spatial rotational symmetry and skyrmion-type spin texture. We investigate the stability of half-vortex state in the regime when g is greater than a threshold g_c , and in the regime when $g_{\uparrow\downarrow} < g$, by solving the Bogoliubov equations for collective density oscillations. In addition, we also investigate the dynamical properties of the half-vortex state. We present the phase diagram as a function of interatomic interaction and spin-orbit coupling.

9:24AM P4.00008 Searching for Non-abelian Phases in Bose-Einstein Condensate of Dy, BIAO LIAN, HUI ZHAI, Institute for Advanced Study, Tsinghua University — Recently Bose-Einstein condensate of a spin 8 element, Dysprosium, has been realized. We compute the mean-field ground state and Bogoliubov excitation of Dy condensate for different scattering lengths and in presence of a magnetic field, and find various non-abelian phases in the parameter space. We suggest an experimental scheme for detecting the remaining discrete point group symmetry of these phases simply by looking at population of each spin components and the degeneracy of Goldstone modes. A BEC whose remaining symmetry is a non-abelian group can support exotic non-abelian vortices.

9:36AM P4.00009 Quasiparticles in a Bose-Fermi mixture in optical lattice, KAZUTO NODA, ROBERT PETERS, NORIO KAWAKAMI, Kyoto University, THOMAS PRUSCHKE, University of Goettingen — We investigate a mixture of interacting bosons and fermions using a generalized dynamical mean-field theory combined with the numerical renormalization group. We focus on many-body effects in the presence of the superfluidity. It is elucidated that fermionic particles are strongly renormalized by low-energy bosonic excitations via the boson-fermion interaction, giving rise to an anomalous peak structure in the density of states for fermions. We also address how the renormalization effects appear in the phases with long-range order such as a supersolid phase.

9:48AM P4.00010 Ultracold bosons in the presence of a second species in the Tonks-Girardeau regime: dynamics and quantum features¹, MIGUEL ANGEL GARCIA-MARCH, THOMAS FOGARTY, THOMAS BUSCH, Department of Physics, University College Cork — We develop a framework to study the interaction between two ultracold bosonic species in different regimes. One species is in the low correlation limit forming a Bose-Einstein condensate (BEC), while the other is in the strongly correlated Tonks-Girardeau regime. We use a Bose-Hubbard-like model where, due to the momentum distribution of the Tonks gas, many single particle states are considered and study the dynamics of the system by numerical simulation of the equations obtained. The atoms in the Tonks gas act as impurities submerged in the BEC, and the excitations created by their interactions with the BEC gas can be understood in terms of polarons. We focus on the fundamental quantum properties of the system and investigate the effects the condensed environment has on the Tonks-Girardeau gas as a function of the interspecies scattering strength.

10:00AM P4.00011 The Many-Body Correlation of Bose-Fermi Mixture in the Ring Trap, RYOSUKE SHIBATO, Department of Physics, Tokyo Metropolitan University, TAKUSHI NISHIMURA, Division of Advanced Sciences, Ochanai Academic Production, Ochanomizu University — Since the realization of Bose-Einstein Condensation in alkali atoms in 1995, studies on cold atomic gases have greatly advanced. The cold atoms are precisely controlled by electromagnetism and optics, and flexible to design quantum systems. In 2001, A. Görlitz's group has realized the Bose-Einstein condensates in the quasi-one-dimensional system [1]. One have now obtained the ideal system to study the one-dimensional many-body physics experimentally. The purpose of our study is to clarify the effect of quantum many-body correlation beyond the mean-field approximation. To accomplish this purpose, we first prepare the bosons and fermions in the ring trap [2]. We prepare the initial state in the trap with the small distortion and obtained that both kinds of particles tend to be localized. After taking off this distortion, we solved the time-dependent Schrödinger equation. We derived the energy spectrum, density profile, and studied pair-correlation effect. Our results predict that the many-body correlation emerges, which has never been observed experimentally up to now.

10:12AM P4.00012 Cooling by corralling: a route to antiferromagnetism in optical lattices¹, YEN LEE LOH, University of North Dakota — Cold atoms in optical lattices have emerged as a promising tool for emulating condensed matter Hamiltonians. Current experiments have observed “Mott insulating” behavior in the Fermi-Hubbard model at an average entropy $S/N \approx 1k_B/\text{atom}$. Our quantum Monte Carlo simulations [1], in agreement with other methods, show that $S/N \approx 0.65k_B/\text{atom}$ is low enough to produce antiferromagnetism (AF) at the center of a harmonic trap. However, further progress in the field requires even lower entropies that are beyond the reach of traditional cooling techniques. I have proposed a way to attain very low temperatures and entropies ($S/N < 0.03k_B/\text{atom}$) by trapping fermions in a corral formed from another species of atoms [2]. This Fermi system can then be evolved into an antiferromagnet by morphing the lattice into a set of double wells, quasi-adiabatically. Quantum dynamics simulations have, so far, given promising results.

10:24AM P4.00013 Magnetic order in the doped Hubbard model and the crossover from two- to three-dimensions: a Hartree-Fock study¹, JIE XU, ERIC J. WALTER, SHIWEI ZHANG, College of William and Mary — We report unrestricted Hartree-Fock (UHF) results for the ground state of the single-band Hubbard model in three-dimensions (3D), with repulsive onsite interactions and nearest-neighbor hopping. Magnetic and charge properties are determined by full numerical solutions of the self-consistent UHF equation in large supercells, and quantified as a function of hole doping h . We focus on weak to intermediate interaction strengths, where UHF has been shown to capture the main characteristics of the magnetic correlations in two-dimensions (2D). ² We find linear spin-density wave (SDW) states with AFM order and a long wavelength modulation whose wavelength is inversely proportional to h . We also study the dimensional crossover from 2D to 3D as the inter-plane distance is increased.

10:36AM P4.00014 Continuous measurement quantum state tomography of atomic spins, CARLOS RIOFRIO, IVAN DEUTSCH, Department of Physics and Astronomy, Center for Quantum Information and Control, University of New Mexico, AARON SMITH, BRIAN ANDERSON, HECTOR SOSA, POUL JESSEN, College of Optical Sciences, Center for Quantum Information and Control, University of Arizona — Quantum state tomography is a fundamental tool in quantum information science and technology. It requires estimates of the expectation values of an “informationally complete” set of observables. This is, in general, a very time-consuming process that requires a large number of measurements to gather sufficient statistics. There are, however, systems in which the data acquisition can be done more efficiently. An ensemble of quantum systems can be prepared and driven by external fields while being continuously and collectively probed, producing enough information in the time evolving measurement record to estimate the initial state. Such protocol has the advantage of being fast and robust. In this talk, we present a study of a continuous-measurement quantum-state tomography protocol and its application to controlling large spin ensembles. We perform reconstruction of quantum states prepared in the 16 dimensional ground-electronic hyperfine manifolds of an ensemble of 133Cs atoms, controlled by microwaves and radio-frequency magnetic fields and probed via polarization spectroscopy. We present theoretical and experimental results of its implementation and discuss two estimation methods: constrained maximum likelihood and compressed sensing.

10:48AM P4.00015 Measuring spin correlations in optical lattices, K.G.L. PEDERSEN, B.M. ANDERSEN, Niels Bohr Institute, University of Copenhagen, Denmark, G.M. BRUUN, Department of Physics and Astronomy, Aarhus University, Denmark, O.F. SYLJUÅSEN, Department of Physics, University of Oslo, Norway, A.S. SØRENSEN, Niels Bohr Institute, University of Copenhagen, Denmark — The study of ultracold atoms in optical lattices has produced several groundbreaking results. A major, but presently unrealized goal, is to study quantum magnetism using atoms in optical lattices. We suggest three different experimental methods for probing both short- and long-range spin correlations of atoms in optical lattices. The first method involves an adiabatic doubling of the periodicity of the underlying lattice to probe neighboring singlet (triplet) correlations for fermions (bosons) by the occupation of the resulting vibrational ground state. The second method utilizes a time-dependent superlattice potential to generate spin-dependent transport by any number of prescribed lattice sites, and probes correlations by the resulting number of doubly occupied sites. The third method relies on the difference in tunneling times for the vibrational ground state and the first excited state. Correct timing then allows for the spin correlations to be fingerprinted. For experimentally relevant parameters, we demonstrate how all three methods yield large signatures of antiferromagnetic correlations of strongly repulsive fermionic atoms in a single shot of the experiment.

Session P5 DCMP: Surfaces, Interfaces, and Thin Films: Kinetics, Dynamics, and Reactions

206A

8:00AM P5.00001 Direct versus hydrogen assisted CO dissociation on metal surfaces, DOMINIC ALFONSO, National Energy Technology Laboratory - Department of Energy — We present investigations of the formation of precursor hydrocarbon species relevant to production of liquid hydrocarbons on low index surfaces of various important noble and transition metals. The formation could occur via the so-called carbide mechanism where direct CO dissociation takes place, followed by stepwise hydrogenation of C yielding CH_x species. Formation of precursor CH_x species could also potentially take place through hydrogenated CO intermediates. First-principles calculations of energetics and barriers of CO conversion to hydrocarbons species were performed using plane-wave periodic density functional theory. Our calculations indicate that the two pathways are generally competitive on transition metals. A microkinetic model, with input thermodynamics and kinetic parameters estimated from electronic structure calculations, has been developed. The two pathways will be further examined using microkinetic approach to determine whether the aforementioned finding holds at realistic conditions.

8:12AM P5.00002 Multi-lattice approach to first-principles kinetic Monte Carlo simulations: Application to catalytic CO oxidation at Pd(100), MAX HOFFMANN, TU München, MATTHIAS SCHEFFLER, Fritz-Haber-Institut, Berlin, Germany, KARSTEN REUTER, TU München — First-principles kinetic Monte Carlo (1p-kMC) simulations enable a quantitative microkinetic modeling of heterogeneous chemical reactions while accounting for the full spatial distributions at the surface. Application to reaction-induced surface morphological transitions is hitherto prevented by the inability to describe the system within prevalent fixed-lattice 1p-kMC and the excessive cost of off-lattice 1p-kMC variants. To this end we develop a novel multi-lattice 1p-kMC approach and apply it as a case in point to the CO oxidation at Pd(100). In the catalytically active state this system is suspected to undergo transitions from the pristine metal surface to a PdO surface-oxide film. As a first step towards a comprehensive simulation we focus on the initial oxide destruction step induced by clustering of oxygen vacancies. First simulations confirm the stability of the oxide film at stoichiometric feed as predicted by preceding fixed-lattice 1p-kMC simulations [1].

8:24AM P5.00003 The role of non-conventional supports for single-atom Platinum-based catalysts in fuel cell technology: A theoretical surface science approach, ALOYSIUS SOON, RENQIN ZHANG, Yonsei University, Seoul, Korea — Platinum-based heterogeneous catalysts are known to play a key role in the fuel cell technology, such as their use in the low-temperature proton exchange membrane (PEM) fuel cells. However, the high cost and low lifecycle of these PEM fuel cells are the major hindrances to its large-scale commercial production. To elevate the high-cost and to optimize its catalytic activity, it was recently proposed that catalysts with single-Pt atom dispersions and a more durable, corrosion-resistant TiN support could play an important role in the next generation of Pt-based PEM fuel cells [1]. As a first step towards a microscopic understanding of single-Pt atom-dispersed catalysts on these new supports, we present density-functional theory (DFT) calculations to investigate the adsorption properties of Pt atoms on pristine TiN(001). Optimized atomic geometries, energetics, and analysis of the electronic structure of the Pt/TiN system are reported for various surface coverages of Pt. We find that atomic Pt does not bind preferably to the clean TiN surface, but under operational conditions, TiN surface vacancies play a crucial role in anchoring the Pt atom for its catalytic function. [1] B. Qiao, *et al.* Nat. Chem. 3 (2011) 634; B. Avsarala and P. Haldar, Int. J. Hydrog. Energy 36 (2011) 3965

8:36AM P5.00004 Water-Pd Interface in Catalytic Biomass Conversion: Atomic-Scale Structure and Properties, YAKE WANG, SHUXIA YIN, XIN LIU, DARWIN SHIELDS, SANWU WANG, Department of Physics and Engineering Physics, The University of Tulsa — Biomass pyrolysis and other relevant catalytic reactions often occur at the liquid-solid interface. It is therefore of great importance to investigate the interfacial structure and other properties in order to achieve a deep understanding about the catalytic reactions for biomass conversion. We used *ab initio* molecular dynamics simulations to study the interfaces formed by liquid water and the palladium surfaces. Such interfaces are involved in many catalytic reactions for biomass conversion. We report results about the structural properties of the water/Pd(100) and water/Pd(111) interfaces, the interaction between liquid water and the metal surfaces, and how the interaction affects the structure. We found that while the interaction between water and the metal surface is weak, it could still cause considerable effects. In particular, the interaction promotes the formation of close-packed local clusters of liquid water.

8:48AM P5.00005 Multilayer epitaxial graphene oxide: structural and chemical properties from a combined theoretical and experimental XPS study, SI ZHOU, SUENNE KIM, ELISA RIEDO, ANGELO BONGIORNO, Georgia Inst of Tech — Multilayer graphene oxide (GO) is a material holding great promise in future energy storage and nano-electronic technologies. This material remains qualitatively known to date. In this work, we present a combined density functional theory (DFT) and experimental X-ray photo-emission spectroscopy (XPS) study of the structural, chemical, and thermal stability of multilayer GO grown epitaxially on silicon carbide. This investigation shows that at room temperature multilayer GO is a metastable material. GO films undergo spontaneous modifications and chemical reduction with a relaxation time of about one month. These processes lead multilayer GO toward a longer-living quasi-equilibrium state, consisting a structure deprived of epoxide groups, rich of hydroxyl groups, and with a O/C ratio of 0.38. Our study suggests that the presence of excess H chemisorbed on the graphitic sheets is the origin of the metastable character of multilayer GO. These H species favor the reduction of epoxide groups and the consequent transformation of hydroxyls into water molecules intercalated between the graphitic layers. Our DFT calculations show that these molecular transformations are controlled by diffusion processes.

9:00AM P5.00006 Switching of molecules at metal surfaces¹, PETRA TEGEDER, Freie Universitaet Berlin, Fachbereich Physik, Arnimallee 14, 14195 Berlin, Germany — Understanding the switching ability of molecules on surfaces upon excitation with external stimuli is a prerequisite for the development of functional molecular devices with possible applications to information processing, storage, or switching. While the switching mechanisms in many classes of molecular switches are thoroughly studied and understood in solution, their counterparts on surfaces still remain largely unresolved. In particular, many switching processes are suppressed or irreversible when the molecules are anchored to a metallic substrate. The adsorption configuration and steric hindrance are only one factor influencing the switching capability. More important is the electronic coupling strength between adsorbate and substrate and accordingly the lifetime of molecular excited states which is significantly reduced at metal surfaces. I will discuss several examples of optically and thermally induced conformational changes in molecular switches at noble metal surfaces.

9:12AM P5.00007 Competing Atomic and Molecular Mechanisms of Thermal Oxidation of Si versus SiC, XIAO SHEN, Vanderbilt University, BLAIR R. TUTTLE, Penn State Behrend College, SOKRATES T. PANTELIDES, Vanderbilt University — Thermal oxidation is a universal process in solids and is of practical importance in semiconductor technology. The oxidation of Si and SiC provide a unique opportunity for studying the oxidation mechanism because the products are the same oxide SiO₂. The oxidation of Si follows a linear-parabolic law with molecular oxygen identified as the oxidant. The oxidation of SiC obeys the same linear-parabolic law as Si but with different rates and temperature dependences. Using results from first-principle calculations, we first show that an atomic oxygen mechanism can account for the oxidation of Si-face SiC. We then discuss implications of the results and identify the determining factors in the competition between atomic and molecular mechanism. This work is supported by NSF GOALI grant DMR-0907385.

9:24AM P5.00008 Scanning tunneling microscopy uncovers the mechanism of silicon oxidation in aqueous solutions, MELISSA HINES, MARC FAGGIN, KUN BAO, ANKUSH GUPTA, BRANDON ALDINGER, Cornell University — Because of their immense technological importance, silicon oxidation reactions have been studied intensely for decades under a variety of conditions. However, the disordered nature of the reaction product, silicon oxide, makes these reactions notoriously difficult to understand. In this work, silicon oxidation is coupled with a subsequent etching reaction, allowing the oxidation reactions to literally write an atomic-scale record of their reactivity into the etched surface – a record that can be decoded into site-specific reaction rates, and thus chemical understanding, with the aid of simulations and infrared spectroscopy. This record overturns the long-standing and much-applied mechanism for the (low-temperature) oxidation of the technologically important face of silicon, Si(100), and shows that the unusually high reactivity of a previously unrecognized surface species leads to a self-propagating etching reaction that produces near-atomically-flat surfaces terminated by a single monolayer of hydrogen atoms. This finding shows that, contrary to expectation, the low-temperature oxidation of Si(100) is a highly site-specific reaction and suggests strategies for the uniform functionalization of the technologically relevant face of silicon by low-temperature reactions.

9:36AM P5.00009 Metal pulled-off effect: A unique explanation of different oxidation process on Cu and Al surfaces, JUNYI ZHU, JOONGOO KANG, SU-HUAI WEI, National renewable Energy Lab — One interesting oxidation phenomenon is the difference of the oxidation of Cu and Al. Cu forms disordered domains, large surface reconstructions and oxide islands on the surface with some O atoms diffuse into inner layers to further oxidize inner Cu atoms. Al forms a dense oxide layer which protects the inner Al atoms from oxidation. In this talk, we demonstrate a possible electronic origin of this oxidation difference by using the first-principles method to calculate the initial oxidation of different metal surfaces and nanoclusters. On Cu 55 Icosahedron surface, we found that 2 O atoms at neighboring sites form a structure with a Cu atom in the middle pulled off from the surface. We also found the similar pull-offs on Cu, Pd, Zn surfaces, but not on Al surface, which is not a transition metal. This pulled off effect is explained by the strong metal d and O p coupling. We also checked different O concentration on Cu (111) surface and on Cu cluster surface and found that O atoms form chain or ring like structures. Our first principle molecular dynamic calculation confirms that these structures are stable. With this pull-off effect, additional O atoms can further oxidize inner Cu atoms and make Cu relative easy to oxidize. This finding enhances the scientific understanding of the initial oxidation of metallic nano-particles and surfaces, which may have important applications in catalysis, thermal storage and other surface science fields.

9:48AM P5.00010 Electrical and Structural Properties of Thin Films Fabricated by E-Beam Lithography from Gold Nanoparticle Resists¹, STEFAN DICKERT, MYOUNG-HWAN PARK, COLIN JERMAIN, VINCENT ROTELLO, MARK TUOMINEN, University of Massachusetts Amherst — Drop- and spin-coated solutions of ligand-coated nanoparticles act as novel “direct write” e-beam resist, which can be prepared with metallic, magnetic and semiconducting nanoparticles. We prepared thin films from gold nanoparticles, in which we varied the film thickness. Small angle X-Ray scattering experiments as well as SEM imaging of the samples were performed to determine structural properties of the nanoparticles films at various stages of the fabrication process, after drop coating, ebeam exposure and annealing. We further performed DC charge transport measurements in the 2-350K temperature range and report different conductivity mechanisms based on the film thickness, ranging from insulating to Mott hopping conduction to metallic.

¹This research is supported by NSF grant CMMI-1025020.

10:00AM P5.00011 Self-Diffusion of small Ag and Ni islands on Ag(111) and Ni(111) using the self-learning kinetic Monte Carlo method¹, SYED ISLAMUDDIN SHAH, GIRIDHAR NANDIPATI, ABDELKADER KARA, TALAT S. RAHMAN, University of Central Florida — We have applied a modified Self-Learning Kinetic Monte Carlo (SLKMC) method [1] to examine the self-diffusion of small Ag and Ni islands, containing up to 10 atom, on the (111) surface of the respective metal. The pattern recognition scheme in this new SLKMC method allows occupancy of the fcc, hcp and top sites on the fcc(111) surface and employs them to identify the local neighborhood around a central atom. Molecular static calculations with semi empirical interatomic potential and reliable techniques for saddle point search revealed several new diffusion mechanisms that contribute to the diffusion of small islands. For comparison we have also evaluated the diffusion characteristics of Cu clusters on Cu(111) and compared results with previous findings [2]. Our results show a linear increase in effective energy barriers scaling almost as 0.043, 0.051 and 0.064 eV/atom for the Cu/Cu(111), Ag/Ag(111), and Ni/Ni(111) systems, respectively. For all three systems, diffusion of small islands proceeds mainly through concerted motion, although several multiple and single atom processes also contribute. [1] Oleg Trushin et al. Phys. Rev. B 72, 115401 (2005) [2] Altaf Karim et al. Phys. Rev. B 73, 165411 (2006)

10:12AM P5.00012 Collective Excitations in Ultrathin Magnesium Films on Silicon¹, XIAO GUANG LI, Fudan University, Shanghai, China, U of Tennessee, U of Sci. & Tech. of China, DI XIAO, Oak Ridge National Laboratory, JIAN SHEN, Fudan University, Shanghai, China, HANNO WEITERING, U of Tennessee, Oak Ridge National Laboratory, ZHENYU ZHANG, U of Sci. & Tech. of China, Harvard U — We present a systematic study of plasmon excitation in ultrathin Mg overlayer on Si(111) substrate. Our numerical results qualitatively reproduce the experimentally observed plasmon spectra of the Mg/Si systems [1]. The underlying physics of the formation of various absorption peaks can be understood using the simple hybridization concept. Based on this concept, the coexistence of surface and bulk plasmons in the experimental observation turns out to be a clear evidence for the existence of multiple surface plasmons due to the quantum confinement in Mg thin films [2]. In addition, we clearly see the plasmon enhanced substrate absorption, which comes from the screening of the substrate to the oscillatory charges.

¹Supported by NNSF of China, USNSF, DMSE/BES of USDOE.

10:24AM P5.00013 Scaling Properties of Exciton Binding Energies in Two-Dimensional Insulating Films¹, HAIPING LAN, PING CUI, Univ. of Sci. and Tech. of China, ZHENYU ZHANG, Univ. of Sci. and Tech. of China, Harvard University — Using the GW and Bethe-Salpter Equation (BSE) methods with inclusion of many-electron effects, we carry out a systematic study of the quasiparticle energy and optical absorption spectra of various two-dimensional (2D) thin-film insulators, including boron nitride, graphane, fluorographene, fluorosilicene, etc. All the calculated band gaps of these systems are increased by the GW corrections, and their optical responses are dominated by the strongly bound excitons, which can be attributed to the enhanced Coulomb attraction in 2D. Most strikingly, we find a well-defined linear scaling dependence between the exciton binding energy and band gap, and this scaling relationship is in stark contrast with the established ones in 3D and 1D insulating systems. The likely underlying physical mechanism for the linear scaling relationship will also be discussed.

¹Supported by NNSF of China, USNSF, and DMSE/BES of USDOE.

10:36AM P5.00014 Spatially and Temperature Resolved Photoluminescence (PL) Of Excitons in Highly Oriented Phthalocyanine Films, NAVEEN RAWAT, ZHENWEN PAN, LANE MANNING, Physics Dept and the Material Science Program, UVM, Burlington, VT, ANTHONY WETHERBY, RORY WATERMAN, Chemistry Dept, UVM, Burlington, VT, RANDY HEADRICK, MADALINA FURIS, Physics Dept and the Material Science Program, UVM, Burlington, VT — Phthalocyanines and their derivatives are interesting alternative to polymer materials for the development of electronic devices such as organic thin field effect transistors, organic Light Emitting Diodes and photovoltaic cells. The present study focuses on spatially resolved, temperature-dependent PL of highly-oriented metal free and Zn -Octa-butoxy phthalocyanine (OBPc) polycrystalline thin films. Samples were fabricated using an in-house solution processing method¹ that results in mm-sized grains which can be individually probed using a focused laser beam. The experiments indicate the lowest optically active excitonic state which dominates the PL spectrum at 5K is optically-forbidden at room temperature. Linear Dichroism microscopy experiments indicate a reorientation of molecular planes below T~200K which may favor a mixing of Frenkel and intermolecular excitons, changing the nature of excitonic ground state.

¹R. L. Headrick et al, APL, 92, 063302 (2008)

10:48AM P5.00015 Grain Boundary Exploration of Excitonic States in Organic Crystalline Thin Films, LANE MANNING, NAVEEN RAWAT, ZHENWEN PAN, CODY LAMARCHE, ISHVIENE COUR, RANDY HEADRICK, MADALINA FURIS, University of Vermont — The electronic states of Metal-Phthalocyanine (MPc) crystalline thin films are investigated. These samples are fabricated by solution processed pen-writing deposition technique.¹ Specifically, a linear dichroism mapping is performed, and excitonic emission is studied both close to and far from the large grain boundaries found in these phthalocyanine thin films. Multiple M-Pc samples are examined, including nickel, zinc and cobalt. In phthalocyanine crystalline films, it is believed that a monomer-like emission feature exclusively associated with a grain boundary is observed. The presence of this feature and its intensity are correlated with the relative orientation of neighboring grains at the boundary. The experiments are performed using a combined Linear Dichroism/Photoluminescence Microscopy experiment developed at the University of Vermont.

¹R. Headrick et al, APL, 92, 063302 (2008)

Wednesday, February 29, 2012 8:00AM - 11:12AM – Session P6 DMP: Graphene Optical Phenomena 206B

8:00AM P6.00001 Graphene-based photonic crystals¹, ROMAN YA. KEZERASHVILI, OLEG L. BERMAN, VLADIMIR S. BOYKO, Physics Department, New York City College of Technology, City University of New York — A novel type of photonic crystals formed by embedding a periodic array graphene and dielectric material into a background dielectric medium is discussed. One-dimensional (1D) photonic crystal formed by an array of periodically located stacks of alternating graphene and dielectric stripes, while the two-dimensional (2D) one is formed by constituent stacks of alternating graphene and dielectric discs. The electromagnetic wave propagation in 1D crystal analyzed in the framework of the Kronig-Penney model. The frequency band structure of 1D graphene-based photonic crystal is obtained analytically as a function of the filling factor and the thickness of the dielectric between graphene stripes. The photonic frequency corresponding to the electromagnetic wave localized by a defect that breaks the symmetry of the system is obtained. For 2D crystal the photonic band structure and transmittance are calculated. The graphene-based photonic crystals can be used effectively as the frequency filters and waveguides for the far infrared region of electromagnetic spectrum. Due to substantial suppression of absorption of low-frequency radiation in doped graphene the damping and skin effect in the photonic crystal are also suppressed. The advantages of the graphene-based photonic crystal are discussed.

8:12AM P6.00002 Graphene Plasmonic Terahertz Filters and Polarizers, FENGNIAN XIA, HUGEN YAN, XUESONG LI, BHUPESH CHANDRA, GEORGE TULEVSKI, YANQING WU, MARCUS FREITAG, WENJUAN ZHU, PHAEDON AVOURIS, IBM T. J. Watson Research Center — Graphene has remarkably strong interaction with light, especially in the terahertz frequency range. Free carriers in graphene exhibit Drude behavior and the Drude weight can be tuned by electrostatic or chemical doping. Graphene can support surface plasmons. In this paper, we'll show that with multiple stacked CVD graphene layers, terahertz filters and polarizers can be realized by patterning them into micro-disks and ribbons. The influence of dipole-dipole interaction on the extinction spectra will be discussed.

8:24AM P6.00003 ABSTRACT WITHDRAWN –

8:36AM P6.00004 Surface-plasmon polaritons on graphene-metal surface, COSKUN KOCABAS, OMER SALIHOGLU, SINAN BALCI, Bilkent University, Department of Physics, ADVANCED RESEARCH LABORATORY TEAM — In this presentation we present a new application of graphene in the field of plasmonics. We studied excitation of surface-plasmon polaritons on graphene-metal surface. The metal surface is functionalized by transfer printing of a graphene layer grown by chemical vapor deposition on copper foils. Surface plasmon resonance (SPR) characteristics of monolayer and multilayer graphene on the metal surface are presented. The results reveal the essential features predicted by the calculations based on transfer matrix method. As an application, we fabricated a surface plasmon resonance sensor integrated with a microfluidic device to study nonspecific physical interaction between graphene layer and proteins. We obtained association and dissociation coefficient of BSA adsorbed on graphene layer. We believe that graphene functionalized SPR sensors could provide a new platform to study interactions between graphene and molecules.

8:48AM P6.00005 New Aspects of Photocurrent Generation at Graphene pn Junctions Revealed by Ultrafast Optical Measurements¹, GRANT AIVAZIAN, DONG SUN, AARON JONES, JASON ROSS, University of Washington, WANG YAO, University of Hong Kong, DAVID COBDEN, XIAODONG XU, University of Washington — The remarkable electrical and optical properties of graphene make it a promising material for new optoelectronic applications. However, one important, but so far unexplored, property is the role of hot carriers in charge and energy transport at graphene interfaces. Here we investigate the photocurrent (PC) dynamics at a tunable graphene pn junction using ultrafast scanning PC microscopy. Pump-probe measurements show a temperature dependent relaxation time of photogenerated carriers that increases from 1.5ps at 290K to 4ps at 20K; while the amplitude of the PC is independent of the lattice temperature. These observations imply that it is hot carriers, not phonons, which dominate ultrafast energy transport. Gate dependent measurements show many interesting features such as pump induced saturation, enhancement, and sign reversal of probe generated PC. These observations reveal that the underlying PC mechanism is a combination of the thermoelectric and built-in electric field effects. Our results enhance the understanding of non-equilibrium electron dynamics, electron-electron interactions, and electron-phonon interactions in graphene. They also determine fundamental limits on ultrafast device operation speeds (~500 GHz) for graphene-based photodetectors.

¹We acknowledge DARPA YFA.

9:00AM P6.00006 Relaxation dynamics of photoexcited carriers in graphene probed by optical pump-THz probe spectroscopy, LIANG ZHAO, Case Western Reserve University, KIN FAI MAK, NICK PETRONE, JIM HONE, TONY HEINZ, Columbia University, JIE SHAN, Case Western Reserve University — The relaxation of hot carriers in graphene is a subject of much current interest. The role of electronic and phonon relaxation channels is a topic of particular focus, with phenomena such as carrier multiplication, in which multiple charge carriers are generated from absorption of a single photon, having been predicted.¹ In this work, we apply the optical pump-THz probe spectroscopy to investigate the relaxation dynamics of photoexcited carriers in large-area single-layer graphene samples grown by chemical vapor deposition (CVD). The complex optical conductivity induced by optical excitation is determined over a broad range of THz frequencies as a function of the pump-probe delay time. To probe carrier relaxation dynamics, we compare the transient optical conductivity to a single-particle model for the intraband response. The effect of pump fluence and the static doping density on the carrier dynamics will be discussed.

9:12AM P6.00007 Excitonic Effects and Optical Absorption Spectrum of Doped Graphene, FELIPE JORNADA, University of California at Berkeley, JACK DESLIPPE, STEVEN LOUIE, University of California at Berkeley and Lawrence Berkeley National Laboratory — First-principles calculations based on the GW-Bethe-Salpeter Equation (GW-BSE) approach and subsequent experiments have shown large excitonic effects in the optical absorbance of graphene. Here we employ the GW-BSE formalism to probe the effects of charge carrier doping and of having an external electric field on the absorption spectrum of graphene. We show that the absorbance peak due to the resonant exciton exhibits systematic changes in both its position and profile when graphene is gate doped by carriers, in excellent agreement to very recent measurements¹. We analyze the various contributions to these changes in the absorption spectrum, such as the effects of screening by carriers to the quasiparticle energies and electron-hole interactions. This work was supported by National Science Foundation Grant No. DMR10-1006184, the U.S. Department of Energy under Contract No. DE-AC02-05CH11231, and the U.S. DOD - Office of Naval Research under RTC Grant No. N00014-09-1-1066. Computer time was provided by NERSC.

9:24AM P6.00008 Magneto-phonon resonance in graphene, YOUNGHEE KIM, J.-M. POUMIROL, National High Magnetic Field Laboratory, Tallahassee, FL 32310, USA, A. LOMBARDO, Engineering Department, Cambridge University, Cambridge, CB3 0FA, UK, N.G. KALUGIN, Department of Materials and Metallurgical Engineering, New Mexico Tech, Socorro, NM 87801, USA, J. KONO, Department of Electrical & Computer Engineering, Rice University, Houston, TX 77005, USA, T. GEORGIOU, A.K. GEIM, K.S. NOVOSELOV, School of Physics & Astronomy, University of Manchester, Oxford Road, Manchester M13 9PL, UK, A.C. FERRARI, Engineering Department, Cambridge University, Cambridge, CB3 0FA, UK, D. SMIRNOV, National High Magnetic Field Laboratory, Tallahassee, FL 32310, USA — Recently, much attention has been paid to electron-phonon coupling in graphene. In particular, significant re-normalization and broadening of long-wavelength optical phonons are predicted to occur through resonant interaction with Landau-quantized Dirac fermions. We report a high-field magneto-Raman spectroscopy study of single-layer graphene in magnetic fields up to 45 T. The Raman G peak exhibits clear splitting at approximately 30 T, which we attribute to the fundamental magneto-phonon resonance associated with (0,1) inter Landau level transitions. The coupled electron-phonon modes exhibit characteristic anti-crossing behavior allowing for an accurate determination of the electron-phonon coupling strength in graphene.

9:36AM P6.00009 Coherent photocurrent control in a graphene bilayer in a magnetic field, KIRAN RAO, JOHN SIPE, University of Toronto — We consider theoretically the coherent control of a Bernal-stacked graphene bilayer in a perpendicular magnetic field. When the system is exposed to a two-color optical pulse, photocurrents of electrons and holes are induced through interference between one- and two-photon excitation processes. The generated photocurrents are time-dependent as a result of the two processes placing electrons or holes in different Landau levels. The direction and phase of the terahertz current oscillation can be tuned through the polarization and relative phase parameter of the optical pulses. We compare the results to those obtained in the absence of a magnetic field [1] and also to the results for monolayer graphene.

9:48AM P6.00010 Giant optical nonlinearity of graphene in a strong magnetic field¹, XIANGHAN YAO, ALEXEY BELYANIN, Texas A&M University — We demonstrate theoretically that graphene placed in a strong magnetic field possesses by far the highest third-order optical nonlinearity among all known materials. The giant nonlinearity originates from unique electronic properties and selection rules near the Dirac points, which gives rise to resonantly enhanced nonlinear response. We present rigorous and intuitive quantum-mechanical density-matrix formalism for calculating linear and nonlinear optical properties of graphene, valid for arbitrarily strong magnetic and optical field [1]. The calculated magnitude of the third-order nonlinearity is of the order of 0.01 esu for the field of several Tesla in the mid/far-infrared spectral range. Due to this giant nonlinearity, even one monolayer of graphene gives rise to appreciable nonlinear frequency conversion efficiency for incident mid/far-infrared radiation.

10:00AM P6.00011 Mid-Infrared Magneto-Optical Kerr and Faraday Studies in Gated Monolayer and Rotated Bilayer CVD Graphene, C.T. ELLIS, N. TESAROVA, ALOK MUKHERJEE, A. STABILE, SUNY Buffalo, Dept. of Physics, YUFENG HAO, R.S. RUOFF, The University of Texas at Austin, Dept. of Mechanical Engineering and the Materials Science and Engineering Program, G. SAMBANDAMURTHY, J. CERNE, SUNY Buffalo, Dept. of Physics — Previous studies of multi-layer graphene grown on C-face SiC have proven that mid-IR (111-135 meV) Polar Magneto-Optical Kerr Effect (PMOKE) measurements provide a unique and sensitive way to probe the Landau Level (LL) structure of graphene. Graphene PMOKE measurements, which are proportional to the Hall conductivity (σ_{xy}), have revealed large changes in the Kerr angle due to the chiral nature of LL transitions in mono- and multi-layer graphene, as well as the dependence of these Kerr features on the position of the Fermi level. In this work we present new results that extend these measurements to more ideal samples consisting of large area (5x5mm), epitaxial single layer CVD grown graphene that has been deposited onto a Si/SiO₂ substrate. Unlike epitaxial SiC graphene these new samples can be back-gated and also allow magneto-optical measurements to be made in transmission (Faraday geometry). The ability to tune parameters such as the Fermi energy, probing photon energy, magnetic field strength, and temperature allows us to better understand graphene through its mid-IR Hall conductivity and to test for theoretical predictions of an infrared quantum Hall effect in graphene (Morimoto, PRL, 2009). This work is supported by NSF-DMR1006078 and by the Office of Naval Research.

10:12AM P6.00012 Substrate effects and photon energy dependence of ultrafast carrier relaxation in graphene¹, ADAM ROBERTS, DANIEL CORMODE, University of Arizona, JOHN FOREMAN, US Army Aviation and Missile RD&E Center, HENRY EVERITT, Duke University, US Army Aviation and Missile RD&E Center, BRIAN LEROY, ARVINDER SANDHU, University of Arizona — Ultrafast photo-excitation in graphene creates non-equilibrium carrier distributions and provides an avenue for the measurement of couplings between electronic and lattice degrees of freedom. Previous studies have explored the carrier relaxation dynamics in graphene on various substrates albeit primarily in the linear dispersion regime. We investigate the ultrafast carrier dynamics of graphene both in the linear band regime and near the saddle point. We perform femtosecond-resolved degenerate pump-probe differential transmission experiments to extract the timescales for electronic relaxation from different starting points on the band structure. The use of degenerate pump-probe allows us to obtain exact relaxation timescales corresponding to the local band structure without contributions from other carriers. We use multiple transparent substrates, such as fused silica, quartz, sapphire etc. to probe the substrate-graphene interactions at various points along the local electronic band structure. We find that in the UV regime, the relaxation dynamics in graphene shows remarkable dependence on the substrate, with relaxation timescales ranging from a few to hundreds of picoseconds. We will also compare our measurements with those obtained in freestanding graphene samples.

10:24AM P6.00013 Excitonic Effects on Optical Absorption Spectra of Doped Graphene, LI YANG, Washington University in St. Louis — We have performed first-principles calculations to study optical absorption spectra of doped graphene with many-electron effects included. Both self-energy corrections and electron-hole interactions are reduced due to the enhanced screening in doped graphene. However, self-energy corrections and excitonic effects nearly cancel each other, making the prominent optical absorption peak fixed around 4.5 eV under different doping conditions. On the other hand, an unexpected increase of the optical absorbance is observed within the infrared and visible-light frequency regime (1 ~ 3 eV). Our analysis shows that a combining effect from the band filling and electron-hole interactions results in such an enhanced excitonic effect on the optical absorption. These unique variations of the optical absorption of doped graphene are of importance to understand relevant experiments and design optoelectronic applications.

10:36AM P6.00014 Dirac Plasmas in Graphene, HUGEN YAN, FENGNIAN XIA, XUESONG LI, BHUPESH CHANDRA, GEORGE TULEVSKI, YANQING WU, MARCUS FREITAG, WENJUAN ZHU, PHAEDON AVOURIS, IBM T. J. Watson Research Center — Collective excitation of Dirac Fermions in graphene has many similarities to that of conventional semiconductor two dimensional electron gas (2DEG). For instance, the resonance frequency is proportional to $q^{1/2}$, where q is the wave-vector. However, there are some fundamental differences. In this paper, we'll present our far-infrared spectroscopy studies of Dirac plasma in graphene. Localized plasmons in graphene disks and micro-ribbons are excited by far-infrared photons. The resonance frequency scales as $n^{1/4}$, where n is the sheet carrier density. This is distinctively different from conventional semiconductor. In addition, plasmons in graphene superlattice are compared to their counterparts in semiconductor superlattice.

10:48AM P6.00015 Experimental and theoretical investigations on SERS enhancement mechanism of graphene, QINGZHEN HAO, Physics Department, SETH MORTON, Chemistry Department, BEI WANG, Physics Department, YANHUI ZHAO, Engineering Science and Mechanics Department, LASSE JENSEN, Chemistry Department, TONY JUN HUANG, Engineering Science and Mechanics Department, The Pennsylvania State University — Graphene has recently been shown to improve the Surface-enhanced Raman Scattering (SERS) performance of traditional nanostructured metallic substrates. Here we present an experimental and theoretical study on its SERS enhancement mechanism. We observed that SERS enhancement of graphene can be tuned by changing its Fermi level via doping. Both molecular doping and gate doping experiments show that hole-doped graphene yields a larger SERS enhancement in methylene blue (MB) than electron-doped one. The MB-graphene system is then modeled using both a fully quantum mechanical (QM) description as well as a QM-polarizable force field model wherein the graphene is modeled using a Drude-Lorentz function. In the first model, charge transfer (CT) excitations between MB and a graphene cluster can be accounted for, while in the second model we can account for the "infinite" size of the graphene sheet. Both of the models confirm the role of graphene Fermi level on its SERS enhancement. Our preliminary results suggest that graphene SERS enhancement would likely be coming from a ground-state chemical enhancement.

11:00AM P6.00016 Exciting and probing plasmons in graphene by local defects, ANATOLY EFIMOV, KIRILL VELIZHANIN, Los Alamos National Laboratory — The short wavelength of collective excitations, i.e., plasmons, in doped graphene (~10-20 nm) is very attractive for multiple applications. However, the same short wavelength makes photoexcitation of plasmons in graphene a very challenging task. In this work, we discuss various types of local defects including semiconductor quantum dots, metallic nanoclusters, edges and holes in graphene as means to "squeeze" the large wavelength of optical excitation down to the nanometer scale, thus, providing an effective coupling between free photons and plasmons in graphene. In the case of semiconductor quantum dots, we show how plasmons in graphene can be excited and probed by Förster resonance energy transfer from the optically excited quantum dot to the graphene sheet. Specifically, we demonstrate how the calculated dispersion relation of plasmons in graphene as well as of other electronic excitations can be accurately extracted by controlling the backgate voltage and the distance between the quantum dot and graphene [1].

Wednesday, February 29, 2012 8:00AM - 10:48AM —
 Session P7 DMP DCOMP: Focus Session: Computational Design of Materials: Graphene - Electronic Structure and Transport 207

8:00AM P7.00001 Electronic transport properties of a graphene monolayer covered by another layer with infinite or finite width, DANIEL VALENCIA, JI LUO, JUN-QIANG LU, University of Puerto Rico Mayaguez — Intrinsic graphene, a zero-gap semiconductor, is one of the most promising materials for nanodevices. In this work, the electronic transport properties of a graphene monolayer covered by another infinite or finite layer were studied. The results of the transmission spectrum and the local density of states (LDOS) showed a weak interaction between the two layers when the top layer is infinite or semi-infinite. Thus the transport properties of the monolayer do not change much. However, when the monolayer is covered by a finite-width nanoribbon, the change in its transmission spectrum is dependent on the width of the ribbon. In order to understand the origin of this phenomenon we calculated the transmission spectrum of one individual channel, and observed that the changes are due to antiresonance in the electronic transmission, which is caused by interlayer interference between the wavefunctions.

8:12AM P7.00002 Electronic transport proprieties of graphene few-layers¹, JUNQIANG LU, CARLOS SIERRA, DANIEL VALENCIA, University of Puerto Rico at Mayaguez — We study electronic transmission spectrums of graphane few-layers (up to 6 layers) with AA or AB stacking by using of first-principle transport calculations. The results demonstrate flat transmission spectrum for even layers while linear transmission for odd layers, which can be understood by different band structures of graphene few-layers due to the interlayer interaction.

¹JQL acknowledges the support from the Institute for Functional Nanomaterials, University of Puerto Rico.

8:24AM P7.00003 Quantum Transport Properties of Modified Graphene Nanoribbons with Boron Nitride Domains at the Mesoscopic Scale, ALEJANDRO LOPEZ-BEZANILLA, ORNL — Graphene nanoribbons are seen as promising building blocks for engineering graphene based field effect transistor (GNR-FET). The quest for fabricating efficient GNR-FETs requires a trade-off between a sufficiently wide energy gap and a reasonably large charge mobility. The solution might be the chemical codoping of one-atom thick layers of C with B and N atoms. These hybrid systems are attracting much attention as they can provide an efficient way to create new materials with complementary properties to those of graphene and h-BN. I will present a study of charge transport in graphene nanoribbons with BN domains randomly distributed along the ribbon surface. My results describe how the conductance of the hybrid systems is altered as a function of the incident electron energy and the BN domain density which leads to transport band gap opening. We explore the transport regimes comparing different degrees of BN codoping and BN domain size for ribbons of various widths and lengths on the order of the micrometer. A comparison with other types of defects such as oxygen atoms in epoxy configuration and functional groups covalently attached to the ribbon surface will be discussed as well.

8:36AM P7.00004 First-principles study of charge transfer doping and electronic transport in single-walled carbon nanotubes¹, XIANGGUO LI, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida, Gainesville, Florida 32611, USA — It is well known that charge transfer doping can greatly enhance the conductivity in single-walled carbon nanotube thin films. Recent experiments showed that the tube-tube contact resistance dominates the impedance in the films. To understand effects of doping on the tube-tube contact, we studied the tube-tube distance changes and electron transport properties upon doping (K and Br) using first-principles calculations. Our results suggest that the effect of doping on the tube-tube distance depends not only on the type of dopants but also on the electronic properties of the carbon nanotubes.

8:48AM P7.00005 Computational Study of the Thermal and Electronic Transport Properties of Rigidly-Interconnected Carbon Nano Foam, SORA PARK, YOUNG-KYUN KWON, Department of Physics and Research Institute for Basic Sciences, Kyung Hee University, DAVID TOMÁNEK, Physics and Astronomy Department, Michigan State University — We study the thermal and electronic transport properties of rigidly-interconnected structures having sp^2 carbon minimal surface called schwarzites. The system consists of core parts composed of schwarzite and interconnection parts with (4,4) carbon nanotube segments [1]. Using direct molecular dynamics simulations with the Tersoff potential, we compute the thermal conductivity of various configurations to explore the dependence on the number of core parts and on the length of interconnection parts. Our calculations show that each core part plays as a scattering center, which reduces the phonon mean free path and thus the thermal conductivity. We also investigate the electronic transport properties of the system by applying the non-equilibrium Green function approach in combination with density functional theory. We explore the effects of different core connectivity and structural defects introduced near the core parts on the electrical conductance. These thermal and electronic properties may be connected to the thermoelectric properties of the schwarzite system.[1] S. Park, K. Kittimanapun, J. S. Ahn, Y.-K. Kwon and D. Tománek, J. Phys.: Condens. Matter **22**, 334220 (2010).

9:00AM P7.00006 Klein, anti-Klein tunneling and pseudo-spintronics in graphene heterojunctions¹, REDWAN SAJJAD, AVIK GHOSH, University of Virginia — Electrons in monolayer graphene act like massless spin-1/2 Dirac fermions. Backscattering is suppressed due to the pseudospin orthogonality of the forward and reverse scattering modes. The resulting Klein tunneling provides unit transmission for normally incident electrons at a pn junction, regardless of barrier height. By combining voltage gating with a tunnel barrier, we can realize a gate tunable metal insulator transition that promotes subthermal switching [1] and also makes the conduction unipolar. In contrast, bilayer graphene electrons act like parabolic spin-1 systems with perfect reflection for normal incidence (anti-Klein tunneling). For n^+n or p^+p junction, the transmission maximizes for normal incidence like single layer, but unlike monolayer graphene, it's barrier-dependent. We also perform atomistic numerical calculation of graphene sheets with experimentally relevant size (hundreds of nanometer) using non-equilibrium Green's function formalism and we show that the conductance can be varied substantially with gate voltage for multiple sequenced pn junctions with smoothly varying potential.

9:12AM P7.00007 Curvature-induced spin-orbit coupling and spin relaxation in a chemically-clean single-layer graphene¹, JAE-SEUNG JEONG, School of Physics, Korea Institute for Advanced Study, Seoul 130-722, Korea, JEONGKYU SHIN, HYUN-WOO LEE, Department of Physics and PCTP, Pohang University of Science and Technology, Pohang 790-784, Korea — Based on the second-order perturbation theory, we show that curvature induced by corrugations or periodic ripples in single-layer graphenes generates two types of effective spin-orbit coupling. In addition to the spin-orbit coupling reported previously that couples with sublattice pseudospin and corresponds to the Rashba-type spin-orbit coupling, there is an additional spin-orbit coupling that does not couple with the pseudospin. The additional spin-orbit coupling depends on the direction of principal curvature, which is similar with the curvature-induced spin-orbit coupling of carbon nanotubes that depends on the chiral angle. However, the spin-orbit coupling of single-layer graphenes can not be obtained from the trivial extension of the spin-orbit coupling of carbon nanotubes owing to their distinct topological structure. Via the numerical calculation, we show that both types of the curvature-induced spin-orbit coupling make the same order of contribution to spin relaxation in chemically-clean single-layer graphene with nanoscale corrugation. The spin relaxation dependence on the corrugation roughness is also investigated.

9:24AM P7.00008 Fractional topological phases, triplet superconductivity and spontaneous time reversal symmetry breaking in strained graphene, POUYAN GHAEMI, Department of Physics, University of Illinois, Urbana, IL 61801, USA, JEROME CAYSSOL, LOMA (UMR-5798), CNRS and University Bordeaux, F-33045 Talence, France, DONNA SHENG, Department of Physics and Astronomy, California State University, Northridge, California 91330, USA, ASHVIN VISHWANATH, Department of Physics, University of California, Berkeley, CA 94720, USA — Despite wide interests to realize fractional time-reversal symmetric phases, an experimentally realizable system with these exotic topological orders is still lacking. Recent experiment has confirmed that strain can be used to control the electronic states of graphene and create flat pseudo-Landau levels in the absence of external magnetic field. In this talk, I show that graphene under strain is a natural playground for the observation of exotic phases such as fractional valley Hall insulator as well as flat band superconductivity. For neutral graphene, we find a competition between the Ising valley ferromagnet and the spin ferromagnet ruled by the value of short range Hubbard and long range Coulomb interactions. At fractional filling with different intervalley and intravalley interactions, a spin triplet superconductor, a valley-polarized Laughlin state or a time-reversal symmetric fractional valley-Hall state could be realized.

9:36AM P7.00009 Satellite Structures in Spectral Functions of Silicon and Graphene from *ab initio* GW and Cumulant Expansion Calculations¹, DEREK VIGIL CURREY, JOHANNES LISCHNER, STEVEN LOUIE, University of California at Berkeley and Lawrence Berkeley National Lab — The GW approximation is a well-established method for obtaining accurate quasiparticle properties in a wide range of materials. Its suitability for satellite structures (e.g., those measured in photoemission spectroscopies), however, has rarely been addressed in detail for real materials and the fact that GW overestimates the position of the plasmon satellite peaks in the spectral function of silicon indicates the need for an improved method for satellites. One such method is the cumulant expansion. The cumulant expansion is a method that includes, approximately, higher-order processes beyond GW that are important for satellite properties. We present here full-frequency results for the satellite and quasiparticle properties of silicon and doped graphene using the GW and the cumulant expansion methods, and discuss the improvements in satellite properties given by the cumulant expansion. We also compare our results to earlier model calculations on doped graphene.

¹This work was supported by NSF Grant No. DMR10-1006184 and U.S. DOE Contract No. DE-AC02-05CH11231. Computational resources have been provided by the NERSC and NICS. Derek Vigil Currey acknowledges funding from the DOD's NDSEG fellowship.

9:48AM P7.00010 Static and dynamical response of graphene, TOBIAS STAUBER, GUILLERMO GOMEZ SANTOS, Universidad Autonoma de Madrid — We discuss the static and dynamical response of graphene. First, we show that including the full hexagonal lattice leads to anisotropic Friedel oscillations and paramagnetic orbital susceptibility around the neutrality point [1]. We then apply the dynamical current-current correlation function to discuss graphene's fluorescence quenching including also transverse decay channels and full retardation [2]. We finally discuss the optical properties of double layer graphene.

[1] G. Gómez-Santos and T. Stauber, Phys. Rev. Lett. 106, 045504 (2011).

[2] G. Gómez-Santos and T. Stauber, Phys. Rev. B 84, 165438 (2011).

10:00AM P7.00011 First-principles study of graphene - carbon nanotube contacts, BRANDON COOK, KALMAN VARGA, Vanderbilt University — The electron transport properties of carbon nanotube – graphene junctions are investigated with first-principles total energy and electron transport calculations. By combining the advantageous material properties of graphene and nanotubes one can create all carbon hybrid architectures with properties that are particularly well suited to applications. The p-type Schottky barrier height is calculated in model junctions with (8,0) and (10,0) nanotubes in a top-contact configuration. Results indicate a lower barrier in carbon nanotube – graphene junctions than in other carbon nanotube – metal systems.

10:12AM P7.00012 Electronic Band Structures of Graphene Nanomeshes, WILLIAM OSWALD, ZHIGANG WU, Department of Physics, Colorado School of Mines — Owing to its many remarkable properties, graphene is very promising for electronic and opto-electronic applications for size miniaturization and improving performance; however, bulk graphene is a semi-metal with zero band gap, and many methods have been proposed to open up a sizable band gap. In this work, we carry out first-principles calculations based on the density functional theory (DFT) to investigate electronic band structures of graphene nanomeshes (GNMs), the defected graphene containing a high-density array of nanoholes, studying the bandgap opening mechanism and evaluating band gap as functions of structural parameters, including hole size, hole shape, hole-hole distance, and hole arrangement. Our results suggest that while the band gap opening is a result of quantum confinement at nanomesh necks, the size of band gap depends strongly on the detailed GNM structures. For the simplest hexagonal holes, two thirds of GNMs remain semi-metallic and the rest one third are semiconductors.

10:24AM P7.00013 Quantum Mechanics on a Möbius Strip: Energy Levels, Symmetries, and Level Splitting in a Magnetic Field, ZHAO LI, RAMDAS RAM-MOHAN, Physics Department, Worcester Polytechnic Institute — We investigate the energy levels of an electron on a Möbius strip. Schrödinger's equation on this curved surface is shown to have terms that do not have invariance under parity transformation in parameter space for the strip. The double degeneracy of energy levels that exists for flat cylindrical rings is shown to be removed for the pairs of energies in the Möbius strip due to parity symmetry breaking. The orbital angular momentum is found to have approximately not only integer but also half-integer values of $\hbar$. The splitting of the energy levels in an external magnetic field is displayed. The effects of multiple twists are investigated to further clarify that the parity symmetry breaking is the effect of the curved geometry, while the appearance of half-integer angular momentum states is a topological effect. The implications for twisted rings composed of graphene will be discussed, and carrier transport through the Möbius strip will be considered. This work was supported by AFRL/DARPA under grant FA8650-10-1-7046.

10:36AM P7.00014 QED Kapitza conductance of nano-carbon thermal interconnects¹, SLAVA V. ROTKIN, Physics Department, Lehigh University, ALEXEY G. PETROV, Ioffe Institute — The theory for the near-field Kapitza conductance across the interface of a nano-carbon material and the quartz is thoroughly investigated. The near-field photon tunneling is shown to contribute to the total heat flux between the hot and cold sides of the interface on the order of or even larger than the normal thermal conductance. Quartz is chosen as the most common example of non-conductive and strongly polar substrate material with the well known polarization properties, though the theory is not restricted to quartz only. Our approach allowed us to derive a unified expression for QED Kapitza conductance of the nanocarbon thermal interconnect material, such as graphene, a nanotube, or a nanotube forest and predict thermal phenomena, such as the heat rectification, as a function of the materials properties of the interface.

Wednesday, February 29, 2012 8:00AM - 11:00AM – Session P8 DMP GMAG: Focus Session: Spin Liquids I 208

8:00AM P8.00001 Quantum Ice : Experimental Signatures, NIC SHANNON, Clarendon Laboratory, University of Oxford, Oxford OX1 3PU, UK; Okinawa Institute of Science and Technology, Okinawa, Japan 904-0495, OWEN BENTON, H H Wills Physics, University of Bristol, Bristol BS8 1TL, UK, OLGA SIKORA, H H Wills Physics, University of Bristol, Bristol BS8 1TL, UK; Okinawa Institute of Science and Technology, Okinawa, Japan 904-0495, KARLO PENC, Research Institute for Solid State Physics and Optics, H-1525, Budapest, Hungary, PAUL MCCLARTY, FRANK POLLMANN, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany, PETER FULDE, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany; Asia Pacific Center for Theoretical Physics, Pohang, Korea — “Quantum Spin Ice” materials have attracted considerable attention as three-dimensional examples of quantum spin liquids. Recently, we have used zero-temperature Quantum Monte Carlo simulation to explore one possible scenario for these materials, confirming the possibility of a “quantum ice” state driven by quantum tunnelling between an extensive number of different spin-ice configurations [1]. Here we address the simple question : what would such a quantum ice look like in experiment ? We focus in particular on the fate of “pinch point” singularities seen in neutron scattering experiments on spin ice materials, showing how these are suppressed and ultimately eliminated as the system is cooled to its ground state [1,2].

8:12AM P8.00002 Quantum Ice : A Quantum Monte Carlo Study, OLGA SIKORA, HH Wills Physics, University of Bristol, Tyndall Avenue, Bristol BS8 1TL, UK, Okinawa Institute of Science and Technology, Japan, OWEN BENTON, HH Wills Physics, University of Bristol, Tyndall Avenue, Bristol BS8 1TL, UK, NIC SHANNON, HH Wills Physics, University of Bristol, Tyndall Avenue, Bristol BS8 1TL, University of Oxford, UK; Okinawa Institute of Science and Technology, Japan, KARLO PENC, Research Institute for Solid State Physics and Optics, H-1525 Budapest, P.O.B. 49, Hungary, PAUL MCCLARTY, FRANK POLLMANN, RODERICH MOESSNER, MPI PKS, Dresden, Germany, PETER FULDE, MPI PKS, Dresden, Germany, Asia Pacific Center for Theoretical Physics, Pohang, Korea — The magnetic “ice” state found in spin ice materials has recently generated great excitement for its magnetic monopole excitations. However the deconfined nature of these monopoles depends crucially on the macroscopic degeneracy of the classical ice ground state. And at very low temperatures we might expect this degeneracy to be lifted by quantum tunneling between different ice configurations. Here we present the results of large-scale Green's function Monte Carlo simulation of ice-type models which include quantum tunneling. We find compelling evidence of an extended quantum U(1)-liquid ground state with deconfined monopole excitations in both the quantum dimer model [1,2] and the quantum ice model on the diamond lattice [3]. This quantum U(1) liquid proves to be remarkably robust against the inclusion of long range dipolar interactions.

8:24AM P8.00003 Three-dimensional generalized Kitaev models¹, ZHOUSHEN HUANG, DANIEL AROVAS, University of California, San Diego — We generalize Kitaev's honeycomb lattice spin model to a gamma matrix model on three-dimensional cubic octahedron and pyrochlore lattices. We find the ground state Z_2 flux configuration, reducing the problem to free Majorana fermion hopping. For the cubic octahedron lattice, which has reflection planes, the ground states must obey Lieb's theorem, i.e. the Z_2 fluxes are reflection symmetric. By adding flux-flux interaction terms, a variety of interesting phases can be stabilized, including metallic, semimetallic, and both trivial and topological insulating phases.

8:36AM P8.00004 High pressure sequence of Ba₃NiSb₂O₉ structural phases: new $S=1$ quantum spin-liquids based on Ni²⁺, LUIS BALICAS, National High Magnetic Field Laboratory — A quantum spin-liquid (QSL) is a ground-state where strong quantum-mechanical fluctuations prevent a phase-transition towards conventional magnetic order and makes the spin ensemble to remain in a liquid-like state. Most QSL candidates studied to date are two-dimensional frustrated magnets with either a triangular or a kagome lattice composed of $S=1/2$ spins. Here, we report the use of a high pressure, high temperature technique to transform the antiferromagnetically ordered ($T_N=13.5$ K) 6H-A phase of Ba₃NiSb₂O₉ into two new QSL candidates with larger $S=1$ (Ni²⁺) moments: the 6H-B phase of Ba₃NiSb₂O₉ which crystallizes in a triangular lattice and the 3C-phase of Ba₃NiSb₂O₉ which forms a three-dimensional edge-shared tetrahedral lattice. Both compounds show no evidence for magnetic order down to $T=0.35$ K despite Curie-Weiss temperatures θ_{CW} of -75.5 K (6H-B) and -182.5 K (3C), respectively. Below ~ 25 K the magnetic susceptibility of the 6H-B phase is found to saturate at a constant value $\chi=0.013$ emu/mol which is followed below 7 K, by a linear in temperature dependence for the magnetic contribution to the specific heat (C_M) which displays a giant coefficient $\gamma=168$ mJ/mol-K² comparable to values observed in heavy-fermion metallic systems. Taken together, both observations indicate the development of a Fermi-liquid like ground-state characterized by a Wilson ratio of 5.6 in this otherwise insulating material. It also points to the formation at finite temperatures of a well defined Fermi surface of $S=1$ spin-excitations which behave as charged quasiparticles. For the 3C phase one observes $C_M \propto T^2$ indicating a unique $S=1$ three-dimensional QSL ground-state as previously reported for Na₃Ir₄O₈ although this later compound is composed of Ir⁴⁺ ions having $S=1/2$.

9:12AM P8.00005 Generalizations of the Kitaev-Heisenberg model and connections to experiment, ITAMAR KIMCHI, University of California, Berkeley, YI-ZHUANG YOU, Institute for Advanced Study, Tsinghua University, Beijing, China, ASHVIN VISHWANATH, University of California, Berkeley — Generalizations of Kitaev-Heisenberg spin models are both interesting on their own right and potentially relevant for the Mott insulating layered Iridates $A_2\text{IrO}_3$ ($A=\text{Na},\text{Li}$) and other complex oxides of 5d transition metal compounds. To describe Na_2IrO_3 and Li_2IrO_3 we propose the Kitaev-Heisenberg- J_2 - J_3 model, a combination of the Kitaev honeycomb model and the Heisenberg model with all three nearest neighbor couplings J_1 , J_2 and J_3 . A rich phase diagram is obtained at the classical level, including the experimentally suggested *zigzag* ordered phase; as well as the *stripy* phase, which extends from the Kitaev-Heisenberg limit to the J_1 - J_2 - J_3 one. Combining the experimentally observed spin order with the optimal fitting to the uniform magnetic susceptibility data gives an estimate of possible parameter values, which in turn reaffirms the necessity of including both the Kitaev and farther neighbor couplings in describing the materials. Generalizations for other spin-orbit coupled Mott insulating 5d transition metal oxides with Kitaev-Heisenberg type models exhibit related magnetically ordered phases as well as different spin liquid phases.

9:24AM P8.00006 Topological phases of the 2D AKLT like model via study of degenerate singular value spectra, CHING-YU HUANG, FENG-LI LIN, Department of Physics, National Taiwan Normal University, Taipei, 116, Taiwan — We study the two-dimensional quantum spin-3/2 systems on the honeycomb lattice, which include the 2D AKLT model. We use the infinite time-evolving block decimation (iTEBD) method to numerically solve the ground state wave function by adopting the tensor product states (TPS) ansatz. We then evaluate the singular value spectra, entanglement entropy, and the Neel order by the method of tensor renormalization group (TRG). With all these results we determine the phase diagram of the spin-3/2 model. Our result shows the singular value spectra become doubly degenerate in a belt region including the AKLT point, and indicates the existence of possible topological phases. The double degeneracy of singular value spectra is related to the recent observation in [C.-Y. Huang and F.-L. Lin, Phys. Rev. B 84, 125110 (2011)] of using it to characterize the topological phase. We also cross check this statement by calculating the topological Renyi entropy. The 2D AKLT state has been shown to be a universal resource for measurement-based quantum computation. Our results indicate this state is topological in nature and should be robust against local perturbations.

9:36AM P8.00007 Finite temperature phase diagram of the classical Heisenberg-Kitaev model., NATALIA PERKINS, CRAIG PRICE, Physics Department, UW Madison — We study finite-temperature properties of classical version of the Heisenberg-Kitaev model on the honeycomb lattice. This model is a prominent example of anisotropic spin-orbital models, which can possibly describe the low-energy physics of Na_2IrO_3 and Li_2IrO_3 . In these compounds, Ir^{4+} ions are in a low spin $5d^5$ configuration and form weakly coupled hexagonal layers. Our main result is a finite-temperature phase diagram obtained by classical Monte Carlo simulations. Because of highly anisotropic Kitaev interaction, the spin symmetry of the model is reduced to the discrete symmetry, which may be regarded as $Z_3 \times Z_2$. As the discrete symmetry can be broken at finite temperature even at 2D, the model undergoes phase transitions as a function of temperature. At low temperature phase, thermal fluctuations induce order-by-disorder, just as the quantum fluctuations do at zero temperature. As a result, magnetically ordered ground states of the Heisenberg-Kitaev model persist up to a certain critical temperature. Finally, we discuss the relevance of obtained results for experimental findings in real compounds.

9:48AM P8.00008 Dynamical Jahn-Teller effect in spin-orbital coupled system, JOJI NASU, SUMIO ISHIHARA, Department of Physics, Tohoku University — Orbital degree of freedom is one of the most attractive themes in strongly correlated electron system. A coupling between the orbital and the lattice vibration is known as a Jahn-Teller effect (JTE). The dynamical aspect of the Jahn-Teller interaction is often neglected in solid, because it is strongly suppressed by the cooperative JTE. Recently, $\text{Ba}_3\text{CuSb}_2\text{O}_9$ has been reported as a candidate of the spin liquid. A Cu^{2+} has the e_g orbital degree of freedom and is surrounded by the O^{2-} octahedron. The octahedra on the neighboring sites do not have the common O ions. This fact implies that the cooperative JTE is weak, and the dynamical JTE is expected to play some key roles on orbital and magnetic properties. The purpose of this research is to study the dynamical JTE in a spin-orbital coupled system. In particular, we focus on the competitive or cooperative phenomena between the superexchange interaction and the dynamical JTE. The superexchange interactions are derived from the $d-p$ model on a honeycomb lattice. We have confirmed this interaction stabilizes the antiferro-spin and ferro-orbital configurations for the realistic parameters. The dynamical JTE described as the orbital-lattice coupling is obtained by extracting the low energy states of the vibronic Hamiltonian. We analyze the model including the two kinds of interactions by using the Bethe approximation. We find that the magnetic order is unstable in wide parameter region and the spin-dimer state with the orbital order is realized. Furthermore the orbital order is strongly suppressed by the dynamical JTE.

10:00AM P8.00009 Quantum spin liquid in frustrated one dimensional LiCuSbO_4 ¹, MARTIN MOURIGAL, Johns Hopkins University, SIAN E. DUTTON, MANORANJAN KUMAR, ZOLTAN G. ZOOS, Princeton University, JIAJIA WEN, COLLIN L. BROHOLM, Johns Hopkins University, NIELS H. ANDERSEN, Risø-DTU, QING HUANG, NIST Center for Neutron Research, MOHAMED ZBIRI, Institut Laue Langevin, RASMUS TOFT-PETERSEN, Risø-DTU, ROBERT J. CAVA, Princeton University — A quantum magnet, LiCuSbO_4 , with chains of edge-sharing $S=1/2$ CuO_6 octahedra is reported. Short-range ordering is observed while no phase transition or spin freezing occurs down to 100 mK in zero magnetic field. Specific heat indicates a distinct low-temperature high-field phase near the 12 T saturation field. Neutron scattering shows incommensurate spin correlations with $q=0.47 \pm 0.01 \pi/a$ and places an upper limit of 70 μeV on a potential spin gap. Exact diagonalization of easy plane $S=1/2$ chains with competing nearest neighbor ferro- and next-nearest neighbor antiferromagnetic interactions ($J_1=-75$ K, $J_2=34$ K) accounts for the $T>2$ K bulk and neutron data. Close to a quantum critical point, free from long-range order and with an achievable saturation field, LiCuSbO_4 is a promising candidate material to test long-standing predictions for chiral and nematic states in quantum spin chains

10:12AM P8.00010 Exotic $S=1$ spin liquid state with fermionic excitations on triangular lattice, MAKSYM SERBYN, SENTHIL TODADRI, PATRICK A. LEE, Massachusetts Institute of Technology — Motivated by recent experiments on the material $\text{Ba}_3\text{NiSb}_2\text{O}_9$ we consider a spin-one quantum antiferromagnet on a triangular lattice with the Heisenberg bilinear and biquadratic exchange interactions and a single-ion anisotropy. Using a fermionic “triplon” representation for spins, we study the phase diagram within mean-field theory. In addition to a fully gapped spin-liquid ground state, we find a state where one gapless triplon mode with Fermi surface coexists with $d+id$ topological pairing of the other triplons. Despite the existence of a Fermi surface, this ground state has fully gapped bulk spin excitations. Such a state has linear in-temperature specific heat and constant in-plane spin susceptibility, with an unusually high Wilson ratio.

10:24AM P8.00011 Spin Liquid Phases for Spin-1 systems on the Triangular lattice, CENKE XU, University of California Santa Barbara, FA WANG, Massachusetts Institute of Technology, YANG QI, Tsinghua University, LEON BALENTS, Kavli Institute for Theoretical Physics, University of California Santa Barbara, MATTHEW FISHER, University of California Santa Barbara — Motivated by recent experiments on material $\text{Ba}_3\text{NiSb}_2\text{O}_9$, we propose two novel spin liquid phases (A and B) for spin-1 systems on a triangular lattice. At the mean field level, both spin liquid phases have gapless fermionic spinon excitations with quadratic band touching, thus in both phases the spin susceptibility and C_v/T saturate to a constant at zero temperature, which are consistent with the experimental results on $\text{Ba}_3\text{NiSb}_2\text{O}_9$. On the lattice scale, these spin liquid phases have $\text{Sp}(4) \sim \text{SO}(5)$ gauge fluctuation; while in the long wavelength limit this $\text{Sp}(4)$ gauge symmetry is broken down to $\text{U}(1) \times \text{Z}_2$ in type A spin liquid phase, and broken down to Z_4 in type B phase. We also demonstrate that the A phase is the parent state of the ferro-quadrupole state, nematic state, and the noncollinear spin density wave state.

10:36AM P8.00012 Stability of the U(1) Dirac spin liquid state on the kagome lattice ,

MICHAEL LAWLER, Binghamton University, BRYAN CLARK, Princeton University, JESSE KINDER, Case Western Reserve University, Cornell University, ERIC NEUSCAMMAN, UC Berkeley, Cornell University, GARNET CHAN, Cornell University — The ground state of the spin 1/2 nearest neighbor Heisenberg antiferromagnet on the kagome lattice is still unknown. Recent DMRG calculations[1] have challenged the proposal[2] that this ground state is an algebraic spin liquid with Dirac fermions and photons as elementary excitations. We numerically study all time reversal invariant Gutzwiller projected variational wave functions for this system and find a state with mild symmetry breaking as the lowest energy state. To avoid getting stuck in a local minimum, we begin our Monte-Carlo calculation from all Z2 spin liquid states cataloged in Ref. [3]. Analyzing the resulting wave function, we find it lies very close to the U(1) Dirac state proposed in Ref. [2] in terms of its gauge fluxes, but with lower energy. We believe these results strongly emphasize the dominance and stability of the U(1) Dirac spin liquid state among Gutzwiller projected wave functions. However, our state has higher energy than the DMRG matrix product state, so correlations beyond those captured by it must play a fundamental role in the characterization of the ground state. [1]S. Yan, D.A. Huse, and S.R. White, Science 332, 1173 (2011) [2]Y. Ran, M. Hermele, P.A. Lee, and X.-G. Wen, PRL, 98, 117205 (2007) [3]Y.-m. Lu, Y. Ran, and P. Lee, PRB, 83, 12 (2011)

10:48AM P8.00013 Theory of spin liquids in integer spin pyrochlores , SUNGBIN LEE, University of California,

Santa Barbara, SHIGEKI ONODA, Condensed Matter Theory Laboratory, RIKEN, LEON BALENTS, Kavli Institute for Theoretical Physics, University of California, Santa Barbara — Rare earth pyrochlores, with a chemical formula $A_2B_2O_7$, exhibit many interesting features in A site spin system. Depending on A site rare earth elements, spin ice and magnetically ordered phases are shown in several experiments. Moreover, they have been also focused as possible candidates of U(1) spin liquid. In order to explore such versatile phases, we study the pseudospin-1/2 model, which is quite generic to describe rare earth pyrochlores with integer spins, in the presence of spin-orbit coupling and crystalline electric field. Using a new "gauge mean field theory," we show the possible ground states, corresponding to several phases listed above. We also briefly discuss the experimental suggestions based on our theory.

Session P9 GMAG DMP: Focus Session: Magnetic Oxide Thin Films And Heterostructures: Manganite Thin Films 209

8:00AM P9.00001 Magnetic non-uniformity in $(La_{0.4}Pr_{0.6})_{0.67}Ca_{0.33}MnO_3$ films and measurement of the strain-magnetization coupling coefficient¹ , S. SINGH, M.R. FITZSIMMONS, T. LOOKMAN, Los Alamos National Laboratory, H. JEEN, Oak Ridge National Laboratory, M.A. ROLDAN, Complutense University, Madrid 28040, Spain, M. VARELA, Oak Ridge National Laboratory, A. BISWAS, University of Florida — We have characterized the non-uniformity of chemical and magnetic properties of $(La_{0.4}Pr_{0.6})_{0.67}Ca_{0.33}MnO_3$ (LPCMO) films grown on $NdGaO_3$ using polarized neutron reflectometry (PNR). Our data indicate that the films exhibit coexistence of different magnetic phases as a function of depth. The variation of magnetism with depth is correlated with a variation of chemical composition with depth. Using PNR we also measured the magnetization depth profile of the LPCMO film as a function of applied bending stress. From these measurements we were able to obtain values for the coupling coefficients relating strain to the variation of the magnetization depth profile. Our results suggest that application of compressive (tensile) bending stress increases (suppresses) magnetization. We will discuss the implications of our results on the prevailing theories of the role of strain on phase separation in manganites.

8:12AM P9.00002 The dead layer in $La_{0.67}Sr_{0.33}MnO_3$ thin films , HANS BOSCHKER, JAAP KAUTZ, MARK HUIJBEN, Mesa+ Institute for Nanotechnology, JO VERBEECK, RICARDO EGOAVIL, SARA BALS, STAF VAN TENDELOO, EMAT Antwerp, GERTJAN KOSTER, DAVE BLANK, GUUS RIJNDERS, Mesa+ Institute for Nanotechnology, MESA+ TEAM, EMAT TEAM — $La_{0.67}Sr_{0.33}MnO_3$ (LSMO) films have an interfacial dead layer that is attributed to either changes in the Mn valence state at the interface, a change in the Mn orbital ordering at the interface or a change in the magnetic exchange interaction due to a structural reconstruction at the interface. We studied the dead layer in LSMO films grown on $SrTiO_3$ (STO) substrates. To directly compare the effect of the polar discontinuity on the dead layer, we removed the polar discontinuity by compositional interface engineering. We also studied films in the (110) direction. We found the presence of the dead layer in all types of films and interface configurations. The LSMO (001) samples with compositional interface engineering have the thinnest dead layer (2 nm). Using electron energy loss spectroscopy, we found no deviations in the Mn valence state at the interface. Using linear dichroism in x-ray absorption spectroscopy, we also found no deviations in the orbital ordering. Therefore, we suggest that the dead layer is caused by the structural reconstruction at the interface. An outlook towards preventing the structural reconstruction and further improving the interfacial properties of the LSMO thin films will be given.

8:24AM P9.00003 Angular dependence of the anomalous Hall effect in $La_{0.8}Sr_{0.2}MnO_3$ films , NETANEL NAFTALIS, NOAM HAHAM, Department of Physics, Nano-magnetism Research Center, Institute of Nanotechnology and Advanced Materials, Bar-Ilan University, JASON HOFFMAN, MATTHEW MARSHALL, CHARLES AHN, Department of Applied Physics, Yale University, LIOR KLEIN, Department of Physics, Nano-magnetism Research Center, Institute of Nanotechnology and Advanced Materials, Bar-Ilan University — The anomalous Hall effect (AHE) is an intriguing magnetotransport phenomenon linked to various intrinsic and extrinsic mechanisms. While for some conductors quantitative understanding of this phenomenon has been achieved, the understanding of the AHE in the manganites is far from comprehensive. We measured the transverse resistivity (ρ_{xy}) of thin films of $La_{0.8}Sr_{0.2}MnO_3$ at temperatures between 5 to 200 K and magnetic fields up to 9 T as a function of the angle θ between the film normal and the magnetic field. We find that for fields above 4 T, for which the magnetization (M) is practically parallel to the magnetic field, $\rho_{xy} = A \cos \theta + B \cos(3\theta)$. The first term is attributed to the ordinary and anomalous Hall effect, and the unexpected $\cos(3\theta)$ term is attributed only to the anomalous Hall effect. We show that the angular dependence of the longitudinal resistivity, ρ_{xx} , and of the magnitude of M cannot explain the existence of a $\cos(3\theta)$ term. We discuss the implication of this term on the possible mechanisms of the anomalous Hall effect in this compound.

8:36AM P9.00004 Effect of electronic reconstruction on the superconducting properties in high T_C superconducting spin valve structures¹, YAOHUA LIU, L.Y. ZHU, A. HOFFMANN, S.G.E. TE VELTHUIS, Argonne National Laboratory, USA, N.M. NEMES, C. VISANI, J. TORNOS, C. LEON, J. SANTAMARIA, Universidad Complutense de Madrid, Spain, M.R. FITZSIMMONS, M. ZHERNENKOV, Los Alamos National Laboratory, USA — We have studied the angular dependence of the magnetoresistance (MR) and magnetization alignment in $\text{La}_{0.7}\text{Ca}_{0.3}\text{MnO}_3$ (LCMO)/ $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$ (YBCO)/LCMO trilayers in the superconducting transition region. The top and bottom LCMOs have different easy-axis coercivities (H_C 's) so that the mutual alignment between the two LCMO's magnetizations is tunable with in-plane rotation of the magnetic field. When the amplitude of the applied field is between the two H_C 's, the MR shows a quasi-four-fold symmetry, an angular hysteresis between clockwise and anticlockwise rotations, and a unidirectional offset along the initial saturation direction. We find that the MR is not correlated with the LCMO's magnetization alignment. More interestingly, the angular dependence of the MR is understandable by the alignment between the applied magnetic field and the (exponential tail of the) induced exchange fields in YBCO, the latter of which originate from the electronic reconstruction at the LCMO/YBCO interfaces. Our results support the scenario recently proposed by Salafranca and Okamoto [Phys. Rev. Lett. **105**, 256804 (2010)], which explains the inverse superconducting spin switch effect in this system.

8:48AM P9.00005 STEM-EELS and theoretical analysis of the electronic structure in cuprate-manganite heterostructures¹, J. SALAFRANCA, J. TORNOS, C. LEÓN, J. SANTAMARIA, Universidad Complutense de Madrid, Spain, M. VARELA, S.J. PENNYCOOK, Oak Ridge National Laboratory, TN, E. DAGOTTO, University of Tennessee, TN; Oak Ridge National Laboratory, TN — Scanning transmission electron microscopy in combination with electron energy loss spectroscopy allows sub-nanometer scale resolution mapping of the formal oxidation state of the transition metal ions in $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}/\text{La}_{0.7}\text{Ca}_{0.3}\text{MnO}_3$ superlattices. The experiments show an unexpected excess of valence electrons near the interface. We compare these results with tight binding model calculations where Coulomb interactions are included within Hartree approximation. Neither the polar catastrophe mechanism nor the mismatch of chemical potentials between the two materials are sufficient to account for the observed profile. We study the effect of oxygen vacancies near the interface and find that they can explain the measured electronic structure.

9:12AM P9.00007 Domain Structures in Perovskite Oxide Superlattices¹, YAYOI TAKAMURA, Dept. Chemical Engineering and Materials Science, University of California, Davis — Perovskite oxides possess a wide range of technologically relevant functional properties including ferromagnetism, ferroelectricity, and superconductivity. Furthermore, the interfaces of perovskite oxides have been shown to exhibit unexpected functional properties not found in the constituent materials. These functional properties arise due to various structural and chemical changes as well as electronic and/or magnetic interactions occurring over nanometer length scales at the interfaces. In order to understand how these interfacial effects impact the ferromagnetic (FM) properties of the half metal $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ (LSMO), we have examined superlattices composed of LSMO sublayers alternating with either the antiferromagnetic (AFM) insulator $\text{La}_{0.7}\text{Sr}_{0.3}\text{FeO}_3$ (LSFO) or the non-magnetic metal $\text{La}_{0.5}\text{Sr}_{0.5}\text{TiO}_3$ (LSTO). A comprehensive approach consisting of bulk magnetization, magneto-transport measurements, and scanning transmission electron microscopy as well as soft x-ray magnetic spectroscopy and microscopy has been used to fully characterize the properties of the interfaces. We find that the nature of the charge transfer across the interfaces affects the FM properties of LSMO, such that at a given sublayer thickness, the LSMO/LSTO system displays a similar Curie temperature but a higher saturation magnetization than the LSMO/LSFO system. For a specific range of sublayer thicknesses, the LSMO/LSFO system displays a unique spin-flop coupling where the FM moments and the AFM spin axis maintain a perpendicular orientation relative to one another. Through this coupling mechanism, the direction of the AFM spin axis can be reoriented with an applied magnetic field. In this talk, I will discuss how these interfacial phenomena contribute to the types of FM and AFM domain patterns observed in the individual layers in the superlattices.

9:48AM P9.00008 Temperature dependent optical properties of thin films of the doped manganite $\text{La}_{0.67}\text{Ca}_{0.33}\text{MnO}_3$ ¹, NAWREEN ANAND, NAVEEN MARGANKUNTE, DAVID TANNER, Department of Physics, University of Florida, HYOONGJEEN JEEN, Oak Ridge National Laboratory, Tennessee, AMLAN BISWAS, Department of Physics, University of Florida — Reflectivity as a function of temperature has been measured for thin film samples of the manganite $\text{La}_{0.67}\text{Ca}_{0.33}\text{MnO}_3$ across the metal-insulator transition. The optical properties in the infrared and visible range were determined by fits to a Drude-Lorentz model, using exact formulas for the thin film optics and the measured properties of the substrate. The phonon modes were identified and verified with lattice dynamical calculations for distorted orthorhombic crystal structure of the material. The reflectance has a strong temperature dependence in the far infrared and in the region of the phonons, rising as the temperature is lowered and the film becomes metallic. In the near-infrared and visible range, there are conductivity peaks due to electronic band transition shifts to the lower frequencies with decreasing temperature. We also observe the spectral weight shift with temperature.

10:00AM P9.00009 Induced ferromagnetism in $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{LaFeO}_3$ interfaces and its role on magnetic tunnel junctions¹, FLAVIO Y. BRUNO, C. VISANI, CNRS, France, A. RIVERA-CALZADA, J. TORNOS, N.M. NEMES, Universidad Complutense de Madrid, Spain, S. VALENCIA, R. ABRUDAN, Helmholtz-Zentrum-Berlin für Materialien und Energie, Germany, Y. LIU, J.W. FREELAND, S.G.E. TE VELTHUIS, Argonne National Laboratory, USA, M. GARCIA-HERNANDEZ, ICMN, Spain, M. VARELA, S.J. PENNYCOOK, Oak Ridge National Laboratory, USA, J. SANTAMARIA, Universidad Complutense de Madrid, Spain, J.E. VILLEGAS, M. BIBES, A. BARTHELEMY, CNRS, France — Magnetic tunnel junctions with antiferromagnetic barriers have so far been poorly studied. We have investigated $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ (LSMO)/ LaFeO_3 (LFO)/LSMO magnetic tunnel junctions (MTJ) where LFO is an antiferromagnetic tunnel barrier. We examined the tunneling magnetoresistance (TMR) behavior of junctions as a function of temperature finding a 30% maximum at 100K. If the top ferromagnetic electrode is replaced by a non-ferromagnetic metal (Au) we still observe a TMR effect, which we attribute to spin filtering. We will show that this effect is connected to the presence of an induced (ferro)magnetic moment in the nominally antiferromagnetic LFO barrier at the interface with LSMO, which was detected by XMCD measurements. Finally, we will conclude discussing the new opportunities offered by such type of interfaces to obtain large spin filtering effects.

¹Research at ORNL sponsored Department of Energy, Office of Basic Energy Sciences, Materials Sciences and Engineering Division (MV, SJP)

10:12AM P9.00010 Magnetic studies on thin films of $\text{La}_{0.65}\text{Pb}_{0.35}\text{MnO}_3$ ¹, STEVEN TIDROW, THOMAS MION, MAGDALENA DORINA CHIPARA, The University of Texas Pan American, ANDREI SOKOLOV, LIU SY-HWANG, RALPH SKOMSKI, PETER DOWBEN, SHIREEN ADENWALLA, University of Nebraska-Lincoln, MIRCEA CHIPARA, The University of Texas Pan American, DAVID J SELLMYER, University of Nebraska-Lincoln, THE UNIVERSITY OF TEXAS PAN AMERICAN TEAM, UNIVERSITY OF NEBRASKA-LINCOLN TEAM — Magnetic and structural investigations on thin films of $\text{La}_{0.65}\text{Pb}_{0.35}\text{MnO}_3$ deposited on a LaAlO_3 substrate are reported. Transmission electron microscopy showed an almost epitaxial growth of the perovskite film, indicating fourfold symmetry for both substrate and thin film. Low Energy Electron Diffraction and Wide Angle X-Ray Scattering support transmission electron microscopy and scanning tunneling microscopy results. Magneto-optical Kerr effect data are consistent with the fourfold symmetry. Ferromagnetic Resonance experiments performed in the X band revealed a more complex structure. The angular dependence of the resonance line width, resonance line intensity, and double integral of the resonance line support a slightly distorted four-fold symmetry whereas the angular dependence of the resonance line position has a two-fold symmetry. This discrepancy was ascribed to the mismatch between the film and the substrate and it is considered as a proof of the sensitivity of ferromagnetic resonance.

¹The research was funded by: NSF-MRSEC grant to the University of Nebraska-Lincoln and U.S. Army Research Office grant #W911NF-08-1-0353 awarded to the University of Texas Pan-American.

10:24AM P9.00011 Using ultrafast optical pump-probe spectroscopy to reveal coexisting magnetic orders in epitaxial RMnO_3 films, JINGBO QI, LI YAN, STUART TRUGMAN, JIAN-XIN ZHU, QUANXI JIA, ANTOINETTE TAYLOR, ROHIT PRASANKUMAR, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, CENTER FOR INTEGRATED NANOTECHNOLOGIES, LOS ALAMOS NATIONAL LABORATORY TEAM — Recent discoveries of spin-driven ferroelectricity in perovskite manganites, RMnO_3 (R =rare-earth ions), have attracted enormous interest in the research of multiferroics. Although extensive experimental and theoretical studies have already been done on single crystal RMnO_3 , there are only a few reports describing the properties of RMnO_3 thin films. Here, we choose two typical materials in RMnO_3 manganites as examples: SmMnO_3 and TbMnO_3 . Previously, ultrafast optical pump-probe spectroscopy has proven to be an ideal technique for unraveling the interplay between different orders in the time domain. In this work, we used this technique to study ultrafast dynamics in epitaxial SmMnO_3 and TbMnO_3 films grown on SrTiO_3 substrates. At low temperatures, we observed an extraordinarily slow rising process, with a timescale of tens of picoseconds, followed by another decay process with a relaxation time of hundreds of picoseconds. Analysis of the time constants associated with these two processes as a function of temperature reveals that antiferromagnetic, ferromagnetic, and ferroelectric orders can coexist in these materials.

10:36AM P9.00012 Influence of growth mode & substrate doping on the reversed remanent magnetic configuration in $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ films, D.A. ARENA, C.S. NELSON, National Synchrotron Light Source, Brookhaven Nat. Lab, J.-S. LEE, C.-C. KAO, SSRL, SLAC Nat. Accelerator Lab, E. NEGUSSE, Physics Dept, Montana State Univ., T.S. SANTOS, Center for Nanoscale Materials, Argonne Nat. Lab — Charge transfer effects which can occur at oxide interfaces can modify the properties of oxide thin films. In such a system, an unusual reversed orientation of the remanent magnetic state was observed recently for $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ on Nb-doped SrTiO_3 (001) deposited via pulsed laser deposition¹. We observe a similar effect for $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ grown via molecular beam epitaxy, a deposition method with different growth kinetics, onto both Nb-doped and undoped SrTiO_3 (STO) substrates. The reversed magnetic state occurs in both samples, and a region of slightly increased charge density was revealed with x-ray reflectivity. Intriguingly, the onset of the reversed remanent state occurred at different temperatures: $\sim 125\text{K}$ for the Nb:STO substrate and $\sim 240\text{K}$ for the undoped STO substrate. High resolution x-ray diffraction reveals a subtle relationship with the cubic-to-tetragonal structural transition of the STO substrate at $\sim 105\text{K}$. Our results point to an additional mechanism for controlling the magnetism in mixed-valence oxide films².

10:48AM P9.00013 Magnetic Exchange Between Superconducting and Ferromagnetic Oxide Layers, SEAN GIBLIN, JON TAYLOR, ISIS Facility, UK, JON DUFFY, University of Warwick, UK, STEPHEN DUGDALE, University of Bristol, UK, T. NAKAMURA, SPring-8 Japan, Japan, JACOBO SANTAMARIA, Universidad de Complutense de Madrid, Spain — The origins of high temperature superconductivity and the rich phase diagrams in complex oxides are still a matter of contention that have stimulated many novel experimental studies and observations. Recently the improvement of layer by layer growth techniques of thin films has enabled investigations of both bulk and surface properties. For most common superconductors the order parameter is thought to be antagonistic to that of the exchange mechanism in ferromagnets. Accurately grown thin films have enabled these competing interactions to be probed experimentally. In particular, the growth of epitaxial oxide layers, with well-characterized atomically flat interfaces, consisting of superconducting layers of $\text{YBa}_2\text{Cu}_3\text{O}_7$ (YBCO) and lattice-matched ferromagnetic $\text{La}_{2/3}\text{Ca}_{1/3}\text{MnO}_3$ (LCMO) has flourished. Using XMCD we demonstrate that the known superexchange between Mn and Cu across the YBCO/LCMO is modified when an apparent critical thickness of the superconducting layer is reduced. All samples show an apparent exchange below the superconducting transition but above it is dependent on the YBCO thickness. Possible origins of this behaviour will be discussed.

Wednesday, February 29, 2012 8:00AM - 11:00AM —
Session P10 DAMOP GQI: Invited Session: Quantum Simulations 210A

8:00AM P10.00001 Quantum simulations and artificial gauge fields with ultracold atoms , IAN SPIELMAN, NIST — Here I present our experimental work synthesizing gauge fields for Bose-Einstein condensates (BECs). I will first summarize our earlier work creating a scalar (abelian) gauge field (akin to the electromagnetic vector potential) and then focus in detail our current work creating a matrix valued (although still abelian) gauge field. I will discuss this gauge field in the language of spin-orbit coupling where it consists of an equal sum of Rashba and Dresselhaus couplings. Specifically, we couple two internal states of rubidium 87 with a pair of “Raman” lasers and load our BEC into the resulting adiabatic eigenstates. In agreement with theory, we observe that below a critical coupling strength our BEC has well defined spin degrees of freedom and acts like a spin-orbit-coupled spin-1/2 Bose gas. As a function of the Raman laser strength, a new exchange-driven interaction between the two dressed spins develops, which drives a (quantum) phase transition from a state where the two dressed spin states spatially mix, to one where they phase separate. Our 3D mean field theory accurately locates the critical laser strength for this transition.

8:36AM P10.00002 Quantum simulations with trapped Ca^+ ions , RAINER BLATT, Innsbruck University — No abstract available.

9:12AM P10.00003 Circuit QED Simulation of Interacting Bosons with Microwave Polaritons¹ , STEVEN GIRVIN, Yale University — A polariton is a coherent superposition of a photon and an electronic excitation such as an exciton. Polaritons can have very low mass (associated with the photon component) and repulsive interactions (associated with the exciton component). Recent experimental progress has observed Bose-Einstein condensation and superfluidity in polaritons in semiconductor quantum wells. In this talk I will discuss the possibility that many-body physics and quantum phase transitions of interacting polaritons [1-3] can be observed in arrays of microwave resonators containing superconducting qubits [4-6]. If the qubits are not far-detuned from the cavities, the natural excitations are coherent superpositions of cavity and qubit excitations and they have interactions acquired from the anharmonicity of the qubits. These interactions can lead to quantum phase transitions in the limit of weak dissipation. It may even be possible to simulate the fractional quantum Hall effect for bosons by coupling the polaritons between sites using superconducting structures which act as ‘circulators’ that break time-reversal and charge-conjugation symmetry. In light of recent progress in achieving very long-coherence times for superconducting qubits and strong qubit coupling to microwave photons, experimental prospects for observing quantum phase transitions in microwave resonator lattices will be described.

9:48AM P10.00004 Quantum Hall physics with photons and its application¹ , MOHAMMAD HAFEZI, Joint Quantum Institute — Phenomena associated with the topological properties of physical systems can be naturally robust against perturbations. This robustness is exemplified by quantized conductance and edge state transport in the quantum Hall and quantum spin Hall effects. Here we demonstrate how quantum spin Hall Hamiltonians can be simulated with linear optical elements using a network of coupled resonator optical waveguides (CROW) in two dimensions. Key features of quantum Hall systems, including the characteristic Hofstadter butterfly and robust edge state transport, can be obtained in such systems. As a specific application, we show that topological protection can be used to improve the performance of optical delay lines and to overcome some limitations related to disorder in photonic technologies. Furthermore, the addition of an optical non-linearity to our proposed system leads to the possibility of implementing a fractional quantum Hall state of photons, where phenomenon such as fractional statistics may be observable.

¹This work was partially supported by the US Army Research Office MURI award W911NF0910406

10:24AM P10.00005 Mixed Bose-Fermi Mott Phases and Phase Transitions¹ , EHUD ALTMAN, Weizmann Institute of Science — A recent experiment with an ultra-cold mixture of ^{174}Yb and ^{173}Yb atoms in an optical lattice [S. Sugawa et al. *Nature Physics* **7**, 642 (2011)] found a remarkable quantum phase that can be described as a mixed Mott insulator. Such a an incompressible state established at integer combined filling of the two species, must have residual low energy Fermionic degrees of freedom associated with relative motion of the two species. I will discuss the novel quantum states formed by the composite Fermions in the mixed Mott insulator as well as the unconventional phase transitions separating these states from the compressible Bose-Fermi mixture established at weak interactions. Finally I will propose to utilize the mixed Mott insulator as a quantum simulator for models of the doped Mott insulator relevant to high T_c superconductivity. The new approach, where the bosonic atoms play the role of doped holes offers significant advantages over direct simulation of the Hubbard model. In particular the mixed Mott plateau naturally provides a flat trap potential to the doped holes, while the hole doping is easily tuned by varying the relative fraction of the bosons.

¹Support from the Israel Science Foundation and from DIP is gratefully acknowledged

Wednesday, February 29, 2012 8:00AM - 11:00AM —
Session P11 DMP: Focus Session: Graphene Structure, Stacking, Interactions: Strain and Stacking 210B

8:00AM P11.00001 Non-Abelian gauge potentials in graphene bilayers , JOSE GONZALEZ, PABLO SAN-JOSE, Instituto de Estructura de la Materia, CSIC, Madrid, FRANCISCO GUINEA, Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid — We discuss the effect of spatial modulations in the interlayer hopping of graphene bilayers, such as those that arise upon shearing or twisting. We show that their single-particle physics, characterized by charge localization and recurrent formation of zero-energy bands as the pattern period L increases, is governed by a non-Abelian gauge potential arising in the low-energy electronic theory due to the coupling between layers. We find that such gauge-type couplings give rise to a confining potential that, for certain discrete values of L , localizes states at zero energy in particular regions of the Moire patterns. We also draw the connection between the recurrence of the flat zero-energy bands and the non-Abelian character of the potential.

8:12AM P11.00002 Electronic Topological Transition in Sliding Bilayer Graphene, YOUNG-WOO SON, SEON-MYUNG CHOI, YOON PYO HONG, SUNGJONG WOO, Korea Institute for Advanced Study, Seoul, Korea, SEUNG-HOON JHI, POSTECH, Pohang, Korea — We demonstrate theoretically that the topology of energy bands and Fermi surface in bilayer graphene undergoes a very sensitive transition when an extremely tiny lateral interlayer shift occurs in arbitrary directions. The phenomenon originates from a generation of an effective non-Abelian vector potential in the Dirac Hamiltonian by the sliding motions. The characteristics of the transition such as pair annihilations of massless Dirac fermions are dictated by the sliding direction owing to a unique interplay between the effective non-Abelian gauge fields and Berry's phases associated with massless electrons. The transition manifests itself in various measurable quantities such as anomalous density of states, minimal conductivity, and distinct Landau level spectrum.

8:24AM P11.00003 Fictitious gauge fields in bilayer graphene, EROS MARIANI¹, ALEX PEARCE, University of Exeter (UK), FELIX VON OPPEN, Freie Universitaet Berlin (Germany) — We discuss the effect of elastic deformations on the electronic properties of bilayer graphene membranes. Distortions of the lattice translate into fictitious gauge fields in the electronic Dirac Hamiltonian which are explicitly derived for arbitrary elastic deformations. We include gauge fields associated to intra- as well as inter-layer hopping terms and discuss their effects on the strain-induced Lifshitz transition and on the electron-phonon resistivity. Of special interest is the appearance of a linear coupling for flexural modes which is shown to dominate the temperature-dependent resistivity in suspended samples with low tension.

¹College of Engineering, Mathematics and Physical Sciences, Stocker Road EX4 4QL, Exeter (UK)

8:36AM P11.00004 Effective theory of rotationally faulted multilayer graphene, MARKUS KINDERMANN, Georgia Institute of Technology — The crystal structure of graphene multilayers with an interlayer twist is characterized by Moiré patterns with various commensurabilities. Also the electronic structure of the material, which grows for instance epitaxially on SiC, is remarkably rich. In this talk an effective low-energy description of such multilayers will be discussed. In certain limits the theory reduces to a (single-layer) Dirac model with space-dependent potentials and mass term. The consequences of this theory will be explored and comparison with experiment will be made. The discussion of experimental consequences will focus on the Landau quantization in a magnetic field, where much experimental data is available. For instance, a spatially modulated splitting of the zeroth Landau level in the material has been observed through scanning tunneling spectroscopy [1]. That splitting finds a natural explanation in the space-dependent mass term of the presented theory [2]. Also a large low-field splitting of higher Landau levels recently observed in graphene multilayers [3] will be shown to follow from that theory. Finally, a theoretically expected [4] amplitude modulation of the Landau level wavefunctions on the top layer of the material will be discussed.

9:12AM P11.00005 High-temperature topological insulator states in strained graphene, DMITRY ABANIN, Harvard University, DMITRO PESIN, University of Texas, Austin — Recently, it was realized that the electronic properties of graphene can be manipulated via mechanical deformations, which opens prospects for both studying the Dirac fermions in new regimes and for device applications. More specifically, non-uniform strains give rise to pseudomagnetic fields that are opposite in the two valleys of Dirac fermions. Certain natural configurations of strain generate large nearly uniform pseudo-magnetic field, leading to flat spin- and valley-degenerate Landau levels (LL). Here we consider the effect of the Coulomb interactions in strained graphene with nearly uniform pseudo-magnetic field. We show that the spin/valley degeneracies of the LL get lifted, giving rise to topological insulator-like states. We find that both anomalous quantized Hall states and quantum spin Hall states can be realized. These many-body states are characterized by quantized conductance and persist to high temperature scale set by the Coulomb interactions. This work provides a new route to designing robust topological insulator states in mesoscopic graphene and other 2D Dirac materials.

9:24AM P11.00006 Theory of topological phases in multilayer Graphene, XIAO LI, ZHENHUA QIAO, QIAN NIU, Department of Physics, The University of Texas at Austin — We present microscopic theories of possible topological phases (i.e. quantum anomalous Hall effect, quantum valley Hall effect, and two-dimensional topological insulators) in bilayer graphene systems. We show the phase diagrams as well as the resulting nontrivial edge states in these systems. We further generalize our findings to trilayer graphene systems, where similar topological states may exist. Finally, we give low energy effective models to reveal the underlying physics of these topological states.

9:36AM P11.00007 The correct solution for strain-induced pseudo vector potentials in graphene, ALEXANDER L. KITT, Boston University, Boston, MA, VITOR M. PEREIRA, National University of Singapore, Singapore, ANNA K. SWAN, BENNETT B GOLDBERG, Boston University, Boston, MA — Prior calculations of the strain-induced pseudo vector potential considered only the change in the nearest neighbor hopping energy in their derivations [1,2]. Here we show that including lattice deformations introduces new terms of the same order in strain. These terms are different at each K point, causing each population of electrons to feel different strain induced pseudo magnetic fields. We use isotropic strain, a situation where lattice deformations solely determine the pseudo vector potential, to illustrate the conceptual importance of these new terms. Finally, we exhibit how the additional terms force us to rethink the strain geometries that were previously thought to generate particular pseudo magnetic fields.

9:48AM P11.00008 Two-Dimensional Topological Insulator State and Topological Phase Transition in Bilayer Graphene, ZHENHUA QIAO, WANG-KONG TSE, Department of Physics, The University of Texas at Austin, Austin, Texas 78712 USA, HUA JIANG, International Center for Quantum Materials, Peking University, Beijing 100871, China, YUGUI YAO, School of Physics, Beijing Institute of Technology, Beijing 100081, China, QIAN NIU, Department of Physics, The University of Texas at Austin, Austin, Texas 78712 USA — In this talk, we show that gated AB-stacking bilayer graphene can host a quantum phase transition from a quantum valley Hall (QVH) insulator to a two-dimensional strong topological insulator (TI) as a function of Rashba spin-orbit (SO) coupling. Different from a conventional TI phase, the edge modes of our strong TI phase exhibit both spin and valley filtering, and thus share the properties of both TI and QVH insulators. The strong TI phase remains robust in the presence of weak intrinsic SO coupling.

10:00AM P11.00009 Disorder-induced inhomogeneity in bilayer graphene¹, DAVID ABERGEL, University of Maryland — We describe the effect of charge density inhomogeneity (electron and hole puddles) and a spatially fluctuating band gap caused by charged impurity disorder in bilayer graphene. We derive a phenomenological averaging technique to calculate $\frac{d\mu}{dn}$ in the presence of this disorder and apply it recent experimental measurements in suspended bilayer graphene. This work was done in collaboration with S. Das Sarma, E. Hwang, and H. Min.

¹Support from US-ONR, NRI-SWAN, and UMD-CNAM

10:12AM P11.00010 Raman spectra of strained bilayer graphene, DUHEE YOON, SUNYOUNG JEGAL, YUJIN CHO, Department of Physics, Sogang University, Seoul 121-742, Korea, YOUNG-WOO SON, Korea Institute for Advanced Study, Seoul 130-722, Korea, HYEONSIK CHEONG, Department of Physics, Sogang University, Seoul 121-742, Korea — In the Raman spectra of strained single layer graphene, modified electron and phonon dispersions result in the splitting of the double resonance 2D Raman band. It originates from significant changes in the resonant conditions owing to both the distorted Dirac cones and anisotropic modifications of the phonon dispersion under uniaxial strains [D. Yoon et al., Phys. Rev. Lett. **106**, 155502 (2011)]. In unstrained bilayer graphene, the Raman 2D band consists of 4 Lorentzian peaks corresponding to the double resonance Raman scattering processes between the two conduction bands and the two valence bands. Under uniaxial strain, each of the four peaks in the Raman 2D band. We examined the polarization behaviors of the split 2D band and analyzed using a model similar to the one used for single layer graphene.

10:24AM P11.00011 Field Effects on the Optical Vibrations in Bilayer Graphene, JIA-AN YAN, Department of Physics, Astronomy and Geosciences, Towson University, Towson, MD 21252 USA — A first-principles study of the optical phonon modes in bilayer graphene (BLG) under a perpendicular electric field is presented. It is found that the electric field breaks the inversion symmetry of BLG and mixes the eigenvectors of the in-phase and out-of-phase optical modes. Detailed analysis shows that the mixing effect is more evident on the out-of-plane optical modes than on the in-plane modes. The field effects on the electron-phonon coupling in BLG will also be discussed.

10:36AM P11.00012 Six-band nearest-neighbor tight-binding model for the π -bands of bulk graphene and graphene nanoribbons¹, TIMOTHY BOYKIN, The University of Alabama in Huntsville, MATHIEU LUISIER, Integrated Systems Laboratory, GERHARD KLIMECK, Purdue University, XUEPING JIANG, NEERAV KHARCHE, YU ZHOU, SAROJ NAYAK, Rensselaer Polytechnic Institute (RPI), RPI COLLABORATION — The commonly used single- p_z orbital first nearest-neighbor tight-binding model faces two main problems: (i) it fails to reproduce asymmetries in the bulk graphene bands; (ii) it cannot provide a realistic model for hydrogen passivation of the edge atoms. As a result, some armchair graphene nanoribbons (AGNRs) are incorrectly predicted as metallic. A new nearest-neighbor, three orbital per atom p/d tight-binding model [1] is built to address these issues. The parameters of the model are fit to bandstructures obtained from first-principles density-functional theory and many-body perturbation theory within the GW approximation, giving excellent agreement with the ab initio AGNR bands. This model is employed to calculate the current-voltage characteristics of an AGNR MOSFET and the conductance of rough-edge AGNRs, finding significant differences versus the single- p_z model. Taken together these results demonstrate the importance of an accurate and computational efficient band structure model for predicting the performance of graphene-based nanodevices. [1] T. B. Boykin, M. Luisier, G. Klimeck, X. Jiang, N. Kharche, Y. Zhou and S. Nayak, J. Appl. Phys. 109, 104304 (2011)

¹NSF, NSF PetaApps, NRI MIND, NICS, IFC, CCNI

10:48AM P11.00013 Electronic structures of geometrically restricted nanocarbons, ARTEM BASKIN, PETR KRAL, University of Illinois at Chicago — We use large scale ab-initio calculations to explore the electronic structures of graphene, graphene nanoribbons, and carbon nanotubes periodically perforated with nanopores. We disclose common features in electronic structures of these porous nanocarbons (PNCs) with nanopores of different size, shapes, and localization. We develop a unified picture that permits to analytically predict and systematically characterize metal-semiconductor transitions in PNCs, allowing mapping of their electronic structures on those in pristine nanocarbons [1]. In contrast to other studies, we show that porous graphene can be metallic for certain arrangements of the pores. When we replace pores by defects (such as SW 55-77), we observe similar features in the electronic structures of the formed nanocarbons. We also study magnetic ordering in these nanocarbons and show that the position of pores/defects can influence the ordering of localized electronic spin states. These periodically modified nanocarbons with highly tunable band structures have great potential applications in electronics and optics. [1] A.I. Baskin and P. Kral, Sci. Rep.1, 36 (2011).

Wednesday, February 29, 2012 8:00AM - 9:30AM –

Session P12 Tutorial for Authors and Referees 210C

8:00AM P12.00001 Tutorial for Authors and Referees — Editors from Physical Review Letters and Physical Review will provide information and tips for our less experienced referees and authors. This session is aimed at anyone looking to submit to or review for any of the APS journals, as well as anyone who would like to learn more about the authoring and refereeing processes. Topics for discussion will include advice on how to write good manuscripts, similarities and differences in writing referee reports for PRL and PR, and other ways in which authors, referees, and editors can work together productively. Following a short presentation from the editors, there will be a moderated discussion. Refreshments will be served.

Wednesday, February 29, 2012 8:00AM - 11:00AM –

Session P13 DMP GMAG: Focus Session: Low-Dimensional and Molecular Magnetism - Single-Molecule Magnets - Dynamics, structure and interactions 211

8:00AM P13.00001 Quantum Tunneling of Magnetization in Trigonal Single-Molecule Magnets, JUNJIE LIU, Department of Physics, University of Florida, ENRIQUE DEL BARCO, Department of Physics, University of Central Florida, STEPHEN HILL, NHMFL and Department of Physics, Florida State University — We perform a numerical analysis of the quantum tunneling of magnetization (QTM) that occurs in a spin $S = 6$ single-molecule magnet (SMM) with idealized C_3 symmetry. The deconstructive points in the QTM are located by following the Berry-phase interference (BPI) oscillations. We find that the $\hat{O}_4^3 (= \frac{1}{2}[\hat{S}_z, \hat{S}_+^3 + \hat{S}_-^3])$ operator unfreezes odd- k QTM resonances and generates three-fold patterns of BPI minima in all resonances, including $k = 0$! This behavior cannot be reproduced with operators that possess even rotational symmetry about the quantization axis. We find also that the $k = 0$ BPI minima shift away from zero longitudinal field. The wider implications of these results will be discussed in terms of the QTM behavior observed in other SMMs.

8:12AM P13.00002 Exploration of the Berry phase interference in a single-molecule magnets of trigonal symmetry, H.M. QUDDUSI, Department of Physics, University of Central Florida, J. LIU, Department of Physics, University of Florida, P.L. FENG, Department of Chemistry and Biochemistry, University of California at San Diego, E. DEL BARCO, Department of Physics, University of Central Florida, S. HILL, National High Magnetic Field Laboratory and Department of Physics, Florida State University, D.N. HENDRICKSON, Department of Chemistry and Biochemistry, University of California at San Diego — The quantum behavior of single-molecule magnets (SMM) is mainly governed by their molecular composition and crystallographic symmetries, thus playing an essential role in the tunneling dynamics. We present low temperature magnetometry measurements on a trigonal symmetric, low nuclearity Mn₃ SMM. The experiments are designed to explore the behavior of the tunnel splittings within the transverse field magnitude/direction phase space, by applying a transverse field (0-1 T) along different directions within the hard anisotropy plane of the molecules. The expected quantum interference pattern can be understood as an outcome of a competition between different intramolecular magnetic interactions. A multi-spin description using non-collinear zero-field splitting tensors and intra molecular dipolar interactions between the manganese ions is employed to explain the symmetry patterns.

8:24AM P13.00003 Investigation of the Barriers of Blocking of Magnetization In Strongly Anisotropic SMM By Ab Initio Methods, LIVIU CHIBOTARU, LIVIU UNGUR, University of Leuven — A large amount of data concerning the blocking barriers of reversal of magnetization in various complexes with strongly anisotropic metal ions (Ln^{III} , Co^{II}) became recently available. Understanding the mechanisms of formation of these barriers is of primary importance for an efficient design of Ln-based single-molecule magnet (SMM) and represents a challenging task for the theory. Here an ab initio based approach for the investigation of blocking barriers will be presented. The methodology will be applied for the construction of the blocking barriers and the understanding of the variation of SMM properties in the series of mixed 3d-4f trinuclear complexes Co-Ln-Co, Ln=Gd, Tb, Dy. In particular, the reasons for a more pronounced SMM behavior manifested by the gadolinium complex will be elucidated. Another example is a recently synthesized Dy_3 complex, for which the origin of magnetization steps in the hysteresis loops will be explained.

8:36AM P13.00004 Decoherence: Intrinsic, Extrinsic, and Environmental¹, PHILIP STAMP, University of British Columbia — Environmental decoherence times have been difficult to predict in solid-state systems. In spin systems, environmental decoherence is predicted to arise from nuclear spins, spin-phonon interactions, and long-range dipolar interactions [1]. Recent experiments have confirmed these predictions quantitatively in crystals of Fe_8 molecules [2]. Coherent spin dynamics was observed over macroscopic volumes, with a decoherence Q -factor $Q_\phi = 1.5 \times 10^6$ (the upper predicted limit in this system being $Q_\phi = 6 \times 10^7$). Decoherence from dipolar interactions is particularly complex, and depends on the shape and the quantum state of the system. No extrinsic “noise” decoherence was observed. The generalization to quantum dot and superconducting qubit systems is also discussed. We then discuss searches for “intrinsic” decoherence [3,4], coming from non-linear corrections to quantum mechanics. Particular attention is paid to condensed matter tests of such intrinsic decoherence, in hybrid spin/optomechanical systems, and to ways of distinguishing intrinsic decoherence from environmental and extrinsic decoherence sources.

9:12AM P13.00005 The Effect of Uniaxial Pressure on the Spin Hamiltonian of Mn12-Ac Single-Molecule Magnet¹, JAMES ATKINSON², JONATHAN FRIEDMAN, Department of Physics, Amherst College, Amherst, Massachusetts 01002, C. BEEDLE, D. HENDRICKSON, Department of Chemistry & Biochemistry, UCSD, La Jolla, California 92093, Y. MYASOEDOV, E. ZELDOV, Department of Condensed Matter Physics, Weizmann Institute of Science, Rehovot 76100, Israel, K. PARK, Department of Physics, Virginia Tech, Blacksburg, Virginia 24061 — We study the effect of uniaxial pressure on the magnetic hysteresis loops of the single-molecule magnet Mn12-Ac. We find that the application of pressure along the easy axis increases the fields at which quantum tunneling of magnetization occurs. Density functional theory (DFT) calculations yield the pressure dependence of the energy barrier for spin reversal that is consistent with the experimental results. The observations, when constrained by the DFT calculations, indicate that the pressure induces changes in both the second-order anisotropy constant D and the fourth-order anisotropy constant A .

9:24AM P13.00006 Mitigation of decoherence in crystals of a $\text{Ho}_x\text{Y}_{1-x}\text{W}_{10}$ ($x = 0.001$ to 0.25) single-molecule magnet, SANHITA GHOSH, SAITI DATTA, STEPHEN HILL, National High Magnetic Field Laboratory and Deptt. of Physics, Florida State University, Tallahassee, FL 32310, ENRIQUE DEL BARCO, Deptt. of Physics, University of Central Florida, Orlando, FL 32816, SALVADOR CARDONA-SERRA, EUGENIO CORONADO, Instituto de Ciencia Molecular, Universidad de Valencia, Polígono la Coma s/n, 46980 Paterna, Spain — Mononuclear lanthanide-based single-molecule magnets (SMMs) have attracted considerable recent attention due to their potential application in quantum information processing devices [Nat. Nanotechnol. **2**, 312 (2007)]. In these systems, the magnetization is associated with a single rare-earth ion, which facilitates mitigation of spin decoherence due to nuclear hyperfine and electron dipolar interactions via isotope purification and dilution. Their large magnetic moments enable coherent manipulation at low driving fields. We report multi-frequency electron paramagnetic resonance (EPR) studies on a Ho polyoxometalate (POM). Simulations indicate appreciable transverse spin-orbit anisotropy, resulting in a gap in the spectrum of several GHz between pairs of levels having the same nuclear projection (effectively a tunneling gap between excited electron-nuclear spin states). Measurements at 9 GHz reveal electron-spin-echoes at low temperatures. Remarkably, a T_2 time of several hundred nanoseconds is found for concentrated samples, with much longer values found in diluted samples containing deuterated solvent. We show that these long coherence times are related to the tunneling gap, which results in an insensitivity of the spin dynamics to dipolar field fluctuations.

9:36AM P13.00007 Single-molecule magnets “without” intermolecular interactions, W. WERNSDORFER, Institut Neel, CNRS, Grenoble, France, L. VERGNANI, M.J. RODRIGUEZ-DOUTON, A. CORNIA, INSTM, Uni-Modena e Reggio Emilia, Italy, P. NEUGEBAUER, A.L. BARRA, LNCMI, CNRS, Grenoble, France, L. SORACE, R. SESSOLI, INSTM, Uni-Firenze, Italy — Intermolecular magnetic interactions (dipole-dipole and exchange) affect strongly the magnetic relaxation of crystals of single-molecule magnets (SMMs), especially at low temperature, where quantum tunneling of the magnetization (QTM) dominates. This leads to complex many-body problems [1]. Measurements on magnetically diluted samples are desirable to clearly sort out the behaviour of magnetically-isolated SMMs and to reveal, by comparison, the effect of intermolecular interactions. Here, we diluted a Fe_4 SMM into a diamagnetic crystal lattice, affording arrays of independent and iso-oriented magnetic units. We found that the resonant tunnel transitions are much sharper, the tunneling efficiency changes significantly, and two-body QTM transitions disappear. These changes have been rationalized on the basis of a dipolar shuffling mechanism and of transverse dipolar fields, whose effect has been analyzed using a multispin model. Our findings directly prove the impact of intermolecular magnetic couplings on the SMM behaviour and disclose the magnetic response of truly-isolated giant spins in a diamagnetic crystalline environment.

9:48AM P13.00008 How Weak Dipole Interactions Can Enhance of the Collective Coupling of an Ensemble of Single-molecule Magnets to a Microwave Cavity¹, JONATHAN FRIEDMAN, Amherst College Department of Physics, Amherst, MA 01002 — When N identical spins are on resonance with a resonant mode of an electromagnetic cavity, the coupling strength (Vacuum Rabi splitting) is enhanced by $\sqrt{N}$ [1]. Add some inhomogeneity so that the spins' resonant frequencies are distributed around the cavity frequency with width σ_ω , and this enhancement will remain as long as $\sigma_\omega < \sqrt{N}g_1$, where g_1 is the coupling strength of a single, isolated spin to the cavity [2]. Recent experiments have shown that $\sim 10^{16}$ spins in a crystal of the single-molecule magnet Fe_8 nevertheless exhibit the enhanced collective coupling to a cavity, despite substantial inhomogeneous broadening. I present numerical calculations that show that weak dipole interactions between the spins can enhance the coupling of the spins to the cavity, allowing collective coupling even when the inhomogeneous broadening is large (i.e. when $\sigma_\omega > \sqrt{N}g_1$).

10:00AM P13.00009 Quantum deflagration in Mn_{12} -acetate in the presence of a transverse field, PRADEEP SUBEDI, New York University, SAUL VELEZ, University of Barcelona, SHIQI LI, MYRIAM SARACHIK, CCNY, CUNY, JAVIER TEJADA, University of Barcelona, ANDREW KENT, New York University, SHREYA MUKHERJEE, GEORGE CHRISTOU, UF-Gainesville — Mn_{12} -acetate single crystal have been shown to exhibit abrupt reversal of the magnetic moment through propagation of a narrow front at subsonic velocities, termed magnetic deflagration [1]. Experiments where avalanches in Mn_{12} -acetate are triggered at a fixed applied field have shown that the velocity of the front has maxima at resonant fields (kH_o , $\text{H}_o = 0.45 \text{ T}$, $k > 1$), due to thermally assisted tunneling of magnetization [2]. Application of a transverse field increases the tunnel splitting, which increases the magnetic relaxation and allows us to explore the deflagration for the first time at small longitudinal fields ($k=0$ and 1). Using time resolved measurements of local magnetization by an array of micron sized Hall sensors at temperature of 350 mK , we present the measurements on both spontaneously ignited and triggered deflagration for a large transverse field ($> 3 \text{ T}$) allowing us to explore directly the effect of a significant tunneling splitting on both the ignition and the velocity of the front. [1] Y. Suzuki, et. al PRL **95**, 147201 (2005)
 [2] A. Hernandez-Minguez, et. al, PRL **95**, 217205 (2005)

10:12AM P13.00010 Demagnetizing effect in local magnetic measurements¹, BO WEN, CUNY-CCNY/GC, PRADEEP SUBEDI, NYU, YOSI YESHURUN, Bar-Ilan Univ., MYRIAM SARACHIK, CUNY-CCNY, ANDREW KENT, NYU, ANDREW MILLIS, Columbia Univ., ENRIC PARDO, Slovak Academy of Sciences, SHREYA MUKHERJEE, GEORGE CHRISTOU, Univ. of Florida — It is well-known that magnetic measurements need to be corrected for the presence of demagnetizing fields that depend on both χ and the sample shape. Calculated demagnetization factors are generally available in tabular form for standard shapes, such as ellipsoids, spheres, and parallelepipeds, thereby providing corrections for measurements of the magnetization of the entire sample. However, appropriate corrections are not available for measurements obtained by local probes, such as micron-size Hall sensors. In this talk we present calculations of the local demagnetizing field profile and show how these results can be applied to interpret local magnetization measurements in Mn_{12} -ac.

10:24AM P13.00011 Simulation of AC Susceptibility and Electronic Structure of Mn-containing Molecular Magnets¹, MARK PALENIK, JORGE H. RODRIGUEZ, Department of Physics, Purdue University — The family of Mn_{12} -Acetate molecular magnets has been recently enhanced by the synthesis of new members with $S = 20/2$ and $S = 19/2$ ground states. These closely related systems display similar but not identical AC susceptibility patterns which we have modelled in terms of their real (χ') and imaginary (χ'') components. The fits of AC data, as a function of frequency, show subtle differences between the parameters that control the spin dynamics in the $S = 20/2$ and $S = 19/2$ systems. To further understand the dynamic parameters we have performed electronic structure calculations based on spin density functional theory (SDFT) on both systems. Results from SDFT calculations, which describe the ground state and magnetic structures, have been correlated to the AC data to gain insight about the subtle differences in their magnetization dynamics.

10:36AM P13.00012 Exact and quasi exact numerical methods for giant magnetic molecules, JÜRGEN SCHNACK, University of Bielefeld, Germany — The determination of the energy spectra of large magnetic molecules is a demanding numerical problem. In this contribution we demonstrate that theory has advanced very much in recent years. We first show that it is possible to diagonalize the Heisenberg Hamiltonian by employing the spin-rotational symmetry $\text{SU}(2)$ in combination with arbitrary point-group symmetries [1]. This goes far beyond earlier approaches and enables us to evaluate thermodynamic observables such as the magnetization and spectroscopic data for molecules as large as the famous ferric wheel Fe_{10} with a Hilbert space dimension of more than 60 Millions. Then we explain how the finite-temperature Lanczos method can be applied to magnetic molecules in order to determine thermodynamic functions for Hilbert spaces as large as up to 1 Billion [2]. The new method enables us to discuss the magnetic properties of the highly frustrated Keplerate molecule $\{\text{W}_{72}\text{V}_{30}\}$ which behaves like a finite size Kagome lattice antiferromagnet.

10:48AM P13.00013 Low temperature magnetic properties of antiferromagnetic rings V6 and V7 studied by NMR¹, YUJI FURUKAWA, Iowa State University, HIROKI OSHIO, TAKUTO MATSUMOTO, University of Tsukuba, Japan — The recent progress in synthesizing odd-member antiferromagnetic (AF) ring molecules gives us the opportunity to investigate spin frustration effects on magnetic properties in systems with small number of magnetic ions. $\text{Na}_7[(\text{VO})_7\text{Na}_7(\text{H}_2\text{O})_7(\beta\text{-CD})_{14}]_2]59\text{D}_2\text{O}$ (in short, V7) is known to be one of the odd-member AF rings, in which seven V^{4+} ($S=1/2$) ions make an almost coplanar ring shape. Magnetic susceptibility measured at $T=1.8\text{--}300\text{K}$ follows a Curie-Weiss law with a Weiss temperature of -0.5K . This indicates an AF interaction between V^{4+} spins is of order of 0.5K . In order to investigate ground state magnetic properties of the spin frustrated V7 ring, we have carried out proton NMR measurements at low temperatures down to 0.05K using a dilution refrigerator. We also carried out proton NMR in another non-frustrated ring system (V6) which is comprised by six V^{4+} ions for a comparison. NMR spectrum line width in V7 increases with decreasing temperature down to 0.05K . On the other hand, for V6, line width shows a peak around 0.2K and decreases below the temperature. These results clearly indicate that these systems have a different magnetic ground state and the ground state of V6 is a spin singlet state but V7 has a magnetic ground state.

Wednesday, February 29, 2012 8:00AM - 11:00AM – Session P14 GMAG DMP FIAP: Focus Session: Spins in Semiconductors - Quantum Dots and Qubits 212

8:00AM P14.00001 Magnetic Polarons and Bipolarons in Quantum Dots¹, RAFAL OSZWALDOWSKI, University at Buffalo — Magnetically doped (typically by Mn) semiconductor quantum dots (QDs) allow a control of magnetic ordering in ways not available in the bulk. For example, onset of magnetism can be realized by adding a single carrier or changing symmetry of the quantum confinement, even at a fixed carrier number [1]. Recent experiments revisit the concept of magnetic polaron [2], formed when a single carrier added to a QD aligns the Mn spins through exchange interaction. The experiments [3,4] show that the induced magnetization persists at relatively high temperatures. First, we discuss a QD system, in which the experimental magnetic polaron energy, in addition to its relatively high value, shows a surprisingly weak temperature dependence [4]. We explain this effect by magnetic anisotropy of the QD. Next, we turn to the case where a magnetic QD contains two carriers. We find theoretically that Mn spins align, forming a magnetic 'bipolaron', even when the ground state has zero carrier-spin [5]. The corresponding state breaks spatial symmetry, unlike in the case of a single magnetic polaron. We propose experimental tests of our prediction. We also explore the stability of the broken-symmetry state with zero net magnetization versus other patterns of magnetization [6]. Finally, we show some interesting consequences of diffusive coupling of a magnetic QD to a reservoir of carriers [7]. This work was done in collaboration with P. Stano, J. Pientka, A. Petukhov, and I. Zutic.

8:36AM P14.00002 Reentrant Magnetic Polaron Formation in Quantum Dots¹, JAMES PIENKA, RAFAL OSZWALDOWSKI, JONG HAN, IGOR ZUTIC, SUNY at Buffalo, ANDRE PETUKHOV, South Dakota School of Mines and Technology — Recently, there have been several theoretical studies that show multiple ways of manipulating magnetic ordering in Quantum Dots (QD) [1,2]. Experiments [3,4] display the formation of Magnetic Polarons in both colloidal and self-assembled QDs. We focus on a type-II QD band profile, where the electrons reside in the barrier, while the holes are localized in the QD interior, which contains the magnetic impurities. In our model, photo-excitation of carriers induces a quasi equilibrium. We consider various QD states to describe the carrier-mediated magnetic ordering in QDs. Allowing for different QD states changes the magnetic properties due to different carrier spin density [5], which affects the alignment of the magnetic impurities. [1] R. M. Abolfath, A. G. Petukhov, and I. Zutic, Phys. Rev. Lett. 101, 207202 (2008); [2] I. Zutic and A. G. Petukhov, Nature Mater. 4, 623 (2009). [3] R. Beaulac et al., Science 325, 973 (2009). [4] I. R. Sellers, R. 8:48AM P14.00003 Magnetic anisotropies of quantum dots¹, KAREL VYBORNÝ, University at Buffalo, SUNY, NY and Academy of Sciences of the Czech Republic, J.E. HAN, RAFAL OSZWALDOWSKI, IGOR ZUTIC, University at Buffalo, SUNY, NY, A.G. PETUKHOV, South Dakota School of Mines and Technology, Rapid City, SD — Magnetic anisotropies in quantum dots (QDs) doped by magnetic ions are discussed in terms of two frameworks: anisotropic g-factors and magnetocrystalline anisotropy energy [1]. Two examples, related to zinc-blende *p*-doped materials, are given of how these frameworks are utilized: four-level Hamiltonian of a flat QD and a cuboid infinite-well QD containing a single hole. The latter model, despite being an idealization of a real QD, displays a rich phenomenology of anisotropies. We quantify the anisotropy constants for ZnSe and CdTe QDs, confirming that the Ising-like effective Hamiltonians apply to magnetic QDs [2]. Compared to bulk systems, confinement tuning offers a new way to control easy axes in magnetic QDs. [1] K. Vyborný et al., preprint (2011). [2] C. Le Gall et al., Phys. Rev. Lett. 107, 057401 (2011).

¹The work is supported by DOE-BES, NSF-DMR, AFOSR-DCT, U.S. ONR, and NSF-ECCS.

9:00AM P14.00004 The Interplay of Electronic Properties and Magnetic Anisotropy in Quantum Dots, IGOR ZUTIC, JEONGSU LEE, SUNY at Buffalo, KAREL VYBORNÝ, SUNY at Buffalo / Institute of Physics, ASCR, JONG HAN, SUNY at Buffalo, ANDRE PETUKHOV, South Dakota School of Mines & Technology — Tunability of magnetic anisotropy (MA) in nanostructures is a fascinating topic, for both fundamental understanding of nanomagnetism and possible spintronic applications. While there have been preceding efforts to systematically study the MA in bulk [1], we still lack a fundamental understanding of that in magnetic quantum dots (QDs). We first explore electronic properties of nonmagnetic QDs that can be significantly altered from the bulk-state depending upon the material and geometry. Focusing on II-VI materials forming both cubic and non-cubic QDs, we confirm qualitatively different energy spectra between different materials [2]. These findings can guide the control of MA in magnetic QDs. Supported by DOE-BES, NSF-DMR, AFOSR-DCT, U.S. ONR, and NSF-ECCS.

9:12AM P14.00005 Theory of collective quantum effects of the nuclear spin bath in a Ge/Si core/shell nanowire quantum dot, WILLIAM A. COISH, STEFANO CHESI, McGill University — We study a quantum-dot spin-valve setup with a uniform hyperfine coupling of the electron spin to the nuclear bath. We propose Ge/Si core/shell nanowire quantum dots as a promising platform in which, through engineering of the nuclear spin positions and of the radial and longitudinal electron confinement, a nearly uniform hyperfine interaction can be realized. The dynamics of this coupled system are exactly soluble in terms of collective nuclear states with fixed total angular momentum. We theoretically show that the quantum-mechanical properties of such collective states of the nuclear spins can be probed through electron transport in this spin-valve setup. The associated transport current shows an enhancement due to coupling to collective modes in the nuclear-spin system directly analogous to the problem of superradiance in quantum optics. This effect is robust to dephasing of the nuclear spins and would provide a demonstration of large-scale collective quantum effects in a nuclear-spin system.

9:24AM P14.00006 Magnetotransport in Ge/Si Quantum Dot Molecules Fabricated by Directed Self-Assembly¹, DONGYUE YANG, Department of Physics and Astronomy, University of Pittsburgh, CHRIS PETZ, Department of Materials Science and Engineering, University of Virginia, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh, JERROLD FLORO, Department of Materials Science and Engineering, University of Virginia — The electronic states of strained self-assembled Ge quantum dots embedded in silicon provide an attractive system for controlling electron spin interactions via direct exchange². Directed self-assembly of sub-10 nm Ge islands are fabricated to produce laterally coupled quantum dot molecules with geometrically-defined spin exchange couplings. Ge islands are coupled to the Si capping layer, and geometries can be defined that are suitable for either vertical or lateral transport. We describe low-temperature vertical magneto-transport measurements on individual and small arrays of Ge islands grown on SOI substrate. Characteristic features in the magnetotransport are observed that correspond to specific geometrical arrangements of the quantum dots.

9:36AM P14.00007 Singlet-triplet splitting in double dots due to spin orbit and hyperfine interactions, DIMITRIJE STEPANENKO, University of Basel, MARK RUDNER, BERTRAND I. HALPERIN, Harvard University, DANIEL LOSS, University of Basel — We analyze the low-energy spectrum of a detuned double quantum dot in the presence of magnetic fields, spin orbit interaction, and nuclear spins, and focus on the regime of spin blockade. Starting from a realistic model for two interacting electrons in a double dot, we derive perturbatively an effective two-level Hamiltonian in the vicinity of an avoided crossing between singlet and triplet levels, which are coupled by the spin-orbit and hyperfine interactions. We evaluate the level splitting at the anticrossing in various parameter regimes, and show that it depends on two controllable parameters: the angle between the external magnetic field and the internal spin orbit field, and on the detuning, as well as on the difference between nuclear fields in the two dots. We identify a parameter regime where spin orbit and hyperfine terms can become of equal strength and propose a protocol for tuning their relative sizes.

9:48AM P14.00008 Single-shot correlations and two-qubit gate of solid-state spins¹, LIEVEN VANDERSYPEN, Kavli Institute of Nanoscience, TU Delft — Recent advances in nanotechnology and quantum engineering have made it possible to probe single spins in the solid-state. Here we report independent single-shot read-out of two electron spins in a double quantum dot. The read-out method is all-electrical, cross-talk between the two measurements is negligible, and read-out fidelities are $\sim 86\%$ on average. This allows us to directly probe the anti-correlations between two spins prepared in a singlet state and to demonstrate the operation of the two-qubit exchange gate on a complete set of basis states. Ongoing work focuses on integration with single-spin rotations, scaling and extending coherence times.

10:24AM P14.00009 Spin-orbit effects on the full dynamics of double quantum dot qubit states¹, ERNESTO COTA, Centro de Nanociencias y Nanotecnología - UNAM, Ensenada, Mexico, JUAN E. ROLON, Department of Physics and Astronomy, Ohio University, Athens, OH 45701-2979 USA, GLORIA PLATERO, Instituto de Ciencia de Materiales de Madrid - CSIC, Cantoblanco 28049, Madrid, Spain, SERGIO E. ULLOA, Department of Physics and Astronomy, Ohio University, Athens, OH 45701-2979 USA — We study spin-orbit interaction (SOI) and relaxation effects on the measurement of the extended singlet state return probability $P(S)$ in a double quantum dot (DQD) system with two electrons, in the presence of hyperfine interaction (HFI) and weak external magnetic fields. Using appropriate pulse cycles to change the detuning between the two quantum dots, we describe the full dynamical behavior of the system taking into account the complete set of states. We find that the mixing of the $m_s = 1$ (T_+) triplet with the (0,2) local singlet, induced by SOI via non-spin-conserving tunneling transitions, has an important effect on the measurement of $P(S)$, and a clear experimental signature. The numerical results are also analyzed in terms of a Feshbach projection to the effective low-energy dynamics, which explain the role of SOI on the relaxation and overall dynamics relevant in experiments. We also explore the case of the Landau-Zener-Stückelberg interferometry realized via voltage sweeps through the $S - T_+$ anticrossing generated by HFI in the DQD energy spectrum [1]. We focus on studying the effects of SOI and relaxation on the interferometric properties of the system in this regime. [1] J.R. Petta, H. Lu and A.C. Gossard, Science 327, 669 (2010).

10:36AM P14.00010 Spin blockade in a triple silicon quantum dot in CMOS technology¹, E. PRATI, G. PETRETTO, M. BELL, Laboratorio MDM, CNR-IMM, G. MAZZEO, Laboratorio MDM, CNR-IMM and Università Milano Bicocca, S. COCCO, M. DE MICHELIS, Laboratorio MDM, CNR-IMM, M. FANCIULLI, Laboratorio MDM, CNR-IMM and Università Milano Bicocca, F. GUAGLIARDO, Politecnico di Milano, M. VINET, LETI-Minatec, CEA, R. WACQUEZ, CEA Grenoble and Université Joseph Fourier — We study the spin blockade (SB) phenomenon by quantum transport in a triple quantum dot made of two single electron transistors (SET) on a CMOS platform separated by an implanted multiple donor quantum dot [1]. Spin blockade condition [2] has been used in the past to realize single spin localization and manipulation in GaAs quantum dots [3]. Here, we reproduce the same physics in a CMOS preindustrial silicon quantum device. Single electron quantum dots are connected via an implanted quantum dot and exhibit SB in one current direction. We break the spin blockade by applying a magnetic field of few tesla. Our experimental results are explained by a theoretical microscopic scheme supported by simulations in which only some of the possible processes through the triple quantum dot are spin blocked, according to the asymmetry of the coupling capacitances with the control gates and the central dot. Depending on the spin state, the SB may be both lifted and induced. Spin control in CMOS quantum dots is a necessary condition to realize large fabrication of spin qubits in some solid state silicon quantum device architectures. [1] Pierre et al., Appl. Phys. Lett., 95, 24, 242107 (2009); [2] Liu et al., Phys. Rev. B 77, 073310 (2008); [3] Koppens et al., Nature 442, 766-771 (2006)

10:48AM P14.00011 Spin-orbit effects in triple dot quantum shuttles, JORGE VILLAVICENCIO, Facultad de Ciencias-UABC, IRENE MALDONADO, Centro de Investigación Científica y de Educación Superior de Ensenada (CICESE), ERNESTO COTA, Centro de Nanociencias y Nanotecnología-UNAM, GLORIA PLATERO, Instituto de Ciencia de Materiales de Madrid (CSIC) — Within the framework of a fully quantum mechanical approach we use a generalized density matrix formalism to study the spin-orbit coupling effects in a triple dot quantum shuttle. An interesting feature of this type of nanoelectromechanical systems is that the interplay between the electronic, spin, and mechanical degrees of freedom give rise to novel transport phenomena that has attracted a great deal of interest in both the applied and basic research. In this work, the effect of spin-orbit coupling is incorporated into the system by introducing non spin-conserving tunneling elements between the quantum dots. We explore the features of spin-polarized current by changing the Zeeman-split levels of the dots, and the frequency of the oscillating central dot. We show that the spin-orbit effect manifests itself as sidebands in the spin-polarized current, and that the tunneling channels can be controlled by adequately tuning the relative energies of the Zeeman-split levels, and by manipulating the current contribution from the vibrational modes.

Wednesday, February 29, 2012 8:00AM - 11:00AM –
Session P15 DMP FIAP GMAG: Focus Session: Spins in Metals - Spin Current Generation and Spin Motive Force 213

8:00AM P15.00001 Slonczewski-like torque due to Rashba spin-orbit coupling in thin magnetic layers, HYUN-WOO LEE, KYOUNG-WHAN KIM, Department of Physics, POSTECH, SOO-MAN SEO, Department of Material Science and Engineering, Korea University, JISU RYU, Department of Physics, POSTECH, KYUNG-JIN LEE, Department of Material Science and Engineering, Korea University — Recent experiments report that large Rashba spin-orbit coupling (RSOC) can exist for ferromagnetic nanostructure with structural asymmetry. Previous theories of spin-transfer torque (STT) induced by RSOC addressed this problem by introducing an effective field due to RSOC. However, the Rashba field is not sufficient, and another STT perpendicular to the Rashba STT is required to explain experimental results. In this work, we propose the mechanism of such STT based on nonadiabaticity and examine the effect of the torque. By studying the domain wall (DW) motion, we demonstrate that the DW motion is significantly affected by our result. We show that the effect of the RSOC-induced torque on the DW velocity can be so large that the DW can move along the current direction without assuming negative nonadiabaticity or spin polarization. Our result is discussed in comparison with experimental results.

8:12AM P15.00002 Spin-orbit coupling of Pt studied by circular dichroism in soft x-ray ARPES¹, JUN MIYAWAKI, ASHISH CHAINANI, YASUTAKA TAKATA, MASAKI OURA, RIKEN SPring-8 Center, YASUNORI SENBA, HARUIHIKO OHASHI, JASRI/SPring-8, SHIK SHIN, RIKEN SPring-8 Center, ISSP Univ. Tokyo, GUANG-YU GUO, Taiwan Univ., SADAMICHI MAEKAWA, JAEA, NAOTO NAGAOSA, Univ. Tokyo — Pt has a large spin-orbit coupling (SOC) and is reported to exhibit the largest spin Hall conductivity among all materials studied to date [1,2]. To establish the role of SOC in the electronic structure, we investigate the bulk electronic structure of Pt(111) using circular dichroism (spin-orbit dichroism) in soft x-ray (SX)-ARPES. We have measured band dispersions along Γ -K-X, L-W and Γ -L and the complete set of Fermi surfaces of Pt. Calculated band dispersions including SOC gives a very good match with the experimental results [2,3], thus demonstrating the role of SOC. Our results also show a k -dependent suppression of spin-orbit dichroism, implying a k -dependent quenching of the spin polarization [3]. [1] T. Kimura *et al.*, Phys. Rev. Lett. **98**, 156601 (2007). [2] G. Y. Guo *et al.*, Phys. Rev. Lett. **100**, 096401 (2008). [3] M. Gradhand *et al.*, Phys. Rev. B **80**, 224413 (2009).

8:24AM P15.00003 Spin pumping with coherent elastic waves¹, M. WEILER, H. HUEBL, F.S. GOERG, F.D. CZESCHKA, R. GROSS, S.T.B. GOENNENWEIN, Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — The generation and detection of pure spin currents is an important topic for spintronic applications. Spin currents may be generated, e.g., via spin pumping. In this approach, a precessing magnetization relaxes via the emission of a spin current. Conventionally, electromagnetic waves, i.e. microwave photons, are used to drive the magnetization precession. We here show that a spin current can also be pumped by means of an acoustic wave, i.e. microwave phonons. In the experiments, coherent surface acoustic wave (SAW) phonons with a frequency of 1.55 GHz traverse a ferromagnetic thin film/normal metal (Co/Pt) bilayer. The SAW phonons drive the resonant magnetization precession via magnetoelastic coupling [1]. We use the inverse spin Hall voltage in the Pt film as a measure for the generated spin current and record its evolution as a function of time and external magnetic field magnitude and orientation. Our experiments show that a spin current is generated in the exclusive presence of a resonant elastic excitation. This establishes acoustic spin pumping as a resonant analogue to the spin Seebeck effect and opens intriguing perspectives for applications in, e.g., micromechanical resonators.

8:36AM P15.00004 Giant spin accumulation and long-distance spin precession in metallic lateral spin valves, YASUHIRO FUKUMA, RIKEN — The non-local spin injection technique in lateral spin valves (LSVs) has provided not only scientific interests to study spin transport and relaxation in a nanowire but also potential spintronic device applications. The non-local method involves no charge-current flow but spin accumulation in the nonmagnetic wire. In order to increase the output signal, related to the spin accumulation splitting for electrochemical potential, efficient spin injection into nonmagnet from ferromagnet as well as high applied current are indispensable. The spin resistance mismatch between the ferromagnet and the nonmagnet needs to be overcome by using high interface resistance such as tunnel barrier for the efficient spin injection, while a low junction resistance is preferred for applying high current. In this talk, I will discuss a guideline to design metallic LSVs with high output signal. The interface resistance of around $0.1 \Omega \mu\text{m}^2$, several orders of magnitude smaller than that of a typical tunnel junction, could effectively overcome the spin resistance mismatch in the metallic system [1] and leads to the giant spin accumulation signal over $200 \mu\text{V}$ in LSVs with NiFe/MgO/Ag junctions [2,3]. The Hanle effect measurements demonstrate a long-distance collective 2π spin precession along the $10 \mu\text{m}$ long Ag wire. This result will accelerate the development of novel spintronic devices utilizing the pure spin current and the spin accumulation.

9:12AM P15.00005 Temperature and temporal evolution of nonlocal spin signals¹, HAN ZOU, YI JI, University of Delaware — An unusual non-monotonic temperature dependence of spin signals was previously observed for nanoscale metallic nonlocal spin valves (NLSV): The spin signal increases as the temperature decreases from room temperature, reaches a maximum value around 50 K, and then decreases as the temperature approaches 4 K. This has been interpreted as due to a high rate of surface spin-flip scattering in the nonmagnetic channel, but the origins of the high surface spin-flip rate are yet to be understood. In this work, we show that for an as fabricated Py-Cu NLSV device this temperature dependence is clearly observed. The device was then stored in the ambient environment for a period of 5 months. Afterwards, an increase of the spin signals was found, and more interestingly the temperature dependence became monotonic. From room temperature to 50 K the spin signal increases, but from 50 K to 4 K the spin signal levels off instead of decreasing further. We conclude that the surface spin-flip scattering originates from the magnetic impurities embedded in the Cu channel near the side surfaces. The impurities are introduced into the Cu during the fabrication procedure. Upon oxidizing the Cu in the ambient environment, the surface impurities are buried in copper oxide and become less accessible to the conduction electrons. Therefore the surface spin-flip rate is reduced over time, resulting in a larger spin signal and monotonic temperature dependence.

9:24AM P15.00006 Continuous dc Spinmotive Force in a Patterned Ferromagnetic Film, YUTA YAMANE, Advanced Science Research Center, Japan Atomic Energy Agency and Institute for Materials Research, Tohoku University, KOHEI SASAGE, TOSHU AN, KAZUYA HARIU, Institute for Materials Research, Tohoku University and CREST, Japan Science and Technology Agency, Japan, JUN-ICHIRO OHE, CREST, Japan Science and Technology Agency and Dept of Physics, Toho University, JUN'ICHI IEDA, Advanced Science Research Center, JAEA, and CREST, Japan Science and Technology Agency, STEWART BARNES, Physics Department, University of Miami, EIJI SAITOH, Advanced Science Research Center, JAEA; Institute for Materials Research, Tohoku University; and CREST, Japan Science and Technology Agency, SADAMICHI MAEKAWA, Advanced Science Research Center, Japan Atomic Energy Agency and CREST, Japan Science and Technology Agency — Recently, a motive force of spin origin, i.e., a “spinmotive force”, has been theoretically predicted[1] and experimentally observed[2,3]. A spinmotive force reflects the spin of electrons in an essential manner and is a new concept relevant to electronic devices. However, problems remain, one of which is the continuous generation of such a spinmotive force. In this study, we present experiment and theory that demonstrate the continuous generation of a dc spinmotive force by exciting a ferromagnetic resonance of a single comb-shaped ferromagnetic thin film[4]. Experimental results are well reproduced by theoretical calculations, offering a quantitative and microscopic understanding of this spinmotive force.

9:36AM P15.00007 Theory of anomalous Hall and spin Hall effects in ferromagnetic metals, BO GU, Advanced Science Research Center, Japan Atomic Energy Agency, TIMOTHY ZIMAN, CNRS and Institut Laue Langevin, SADAMICHI MAEKAWA, Advanced Science Research Center, Japan Atomic Energy Agency — We give a unified theory of the anomalous Hall effect (AHE) and the spin Hall effect (SHE) in ferromagnetic metals (FM). We do this by extending Kondo's theory of the AHE in FM and including the short range spin-spin correlations. We find a novel relation between the SHE and the second order nonlinear spin fluctuation in FM near Curie temperature T_c , which has been hidden for about 50 years, since Kondo gave a relation between the AHE and the first order nonlinear spin fluctuation in pure FM near T_c in 1962. Our results show an essential difference between the AHE and SHE in terms of the symmetry. Our theory can be applied to the recent SHE experiment in FM near T_c by Y. Otani et al.

9:48AM P15.00008 Spin motive force in a Rashba system, KYOUNG-WHAN KIM, Department of Physics, POSTECH, JUNG-HWAN MOON, KYUNG-JIN LEE, Department of Material Science and Engineering, Korea University, HYUN-WOO LEE, Department of Physics, POSTECH — Spin motive force (SMF) is the nonconservative spin force induced by magnetization dynamics. In addition to spin-transfer torque (STT), SMF is considered as one of the representative interactions between magnetization and conduction electrons. It has been reported that large Rashba-type spin-orbit coupling (RSOC) can show up in magnetic nanostructures containing thin ferromagnetic layers with structural asymmetry. In this work, we investigate the effect of RSOC on SMF. The additional SMF induced by RSOC is proportional only to time variation of magnetization while the conventional SMF is proportional to both time and space variation of magnetization. This result indicates that SMF can be induced from even homogeneous magnetic structure. The resulting RSOC SMF has so large magnitude that the feedback effect on the magnetization dynamics can be significant. Combining RSOC SMF and the previously known Rashba STT effect, we derived that Gilbert damping is one or two orders of magnitude enhanced by RSOC. Lastly, we show that the symmetry breaking nature of RSOC and the induced SMF greatly help the electrical distinction of magnetization structure. It is expected that RSOC will play a key role in extending applicable area of SMF.

10:00AM P15.00009 Light-induced pure spin current¹, JINGZHE CHEN, YIBIN HU, HONG GUO, Physics department of McGill University, HONG GUO'S GROUP TEAM — We propose theoretically that a pure spin current without an accompanying charge current can be generated by light in magnetic tunneling junctions. The principle is based on a photovoltaic effect combined with the spin selectivity of the magnetic electrodes of the junction. We demonstrate this effect in graphene nanostructures by atomic first principles calculation. The results show that appreciable pure spin-currents and open circuit spin bias are generated in pure graphene nanostructures, and it can reach significant values if half metal with high spin polarization is used as the electrodes.

10:12AM P15.00010 Perpendicular switching of a single ferromagnetic layer induced by in-plane current injection, KEVIN GARELLO, Catalan Institute of Nanotechnology (ICN-CIN2), E-08193 Barcelona, Spain, I.M. MIRON, G. GAUDIN, P.J. ZERMATTEN, SPINTEC, UMR-8191, CEA/CNRS/UJF/GINP, INAC, F-38054 Grenoble, France, M. COSTACHE, Catalan Institute of Nanotechnology (ICN-CIN2), E-08193 Barcelona, Spain, S. AUFFRET, SEBASTIEN BANDERA, B. RODMACQ, A. SCHUHL, SPINTEC, UMR-8191, CEA/CNRS/UJF/GINP, INAC, F-38054 Grenoble, France, P. GAMBARDELLA, Catalan Institute of Nanotechnology (ICN-CIN2); Universitat Autònoma de Barcelona; Institució Catalana de Recerca i Estudis Avançats (ICREA) — We demonstrate switching of a ferromagnetic Pt/Co/AIOx layer with perpendicular anisotropy through lateral current-injection. Magnetization reversal occurs as an unpolarized electric current is injected parallel to an in-plane magnetic field of moderate magnitude. The switching direction depends on the sign of the current with respect to that of the in-plane field. The critical switching current scales with the lateral dimensions of the layer and duration of the current pulse. Our measurements also indicate that the switching efficiency increases with the magnetic anisotropy of the Co layer and oxidation of the top Al layer. The symmetry of this effect corresponds to an in-plane torque perpendicular to the current. We will discuss possible contributions to this torque, including Rashba-induced spin accumulation and the spin Hall effect [1].

10:24AM P15.00011 Current induced magnetization dynamics in spin-orbit coupled thin film ferromagnets¹, DMYTRO PESIN, ALLAN MACDONALD, The University of Texas at Austin, Austin, TX — We consider the effect of an in-plane current on the magnetization dynamics of a two-dimensional spin-orbit coupled nanoscale itinerant ferromagnet. By solving the appropriate kinetic equation for an itinerant electron ferromagnet, we show that Rashba spin-orbit interaction provides transport currents with a switching action, as observed in a recent experiment (I. M. Miron *et al.*, Nature 476, 189 (2011)). The dependence of the effective switching field on the magnitude and direction of an external magnetic field in our theory agrees well with experiment. We comment on the possibility of finding materials in which this spin-orbit switching effect can be achieved at moderate current densities

10:36AM P15.00012 Spin-flipping at Sputtered Co/Ag Interfaces¹, HOANG NGUYEN, REZA LOLOEE, WILLIAM PRATT, JACK BASS, Department of Physics and Astronomy, Michigan State University — We measured at 4.2K the Current-Perpendicular-to-Plane Magnetoresistances (CPP-MRs) of sputtered ferromagnetically coupled $[\text{Co}(3\text{ nm})/\text{Ag}(1.8\text{ or }2.0\text{ nm})]_n\text{Co}(3\text{ nm})$ multilayers with $n = 0$ to 8 that were imbedded in the middle of symmetric, Py-based, double exchange-biased spin-valves. The measurements yielded the parameter for spin-flipping at the Co/Ag interface, $\delta_{\text{Co/Ag}} = 0.30^{+0.05}_{-0.1}$. δ is related to the probability P of spin-flipping at the Co/Ag interface by $P = [(1-\exp(-\delta))]$. Despite the expected larger lattice-mismatch-induced disorder at the Co/Ag interface, this value is similar to that reported earlier for the Co/Cu interface [1], suggesting that such disorder does not play a major role in $\delta_{F/N}$ at ferromagnetic/non-magnetic (F/N) interfaces.

10:48AM P15.00013 Large non-inverted and inverted spin signals in break-junction-based nonlocal spin valves¹, SHUHAN CHEN, HAN ZOU, SIU-TAT CHUI, YI JI, University of Delaware — A nonlocal spin valve (NLSV) is a lateral structure with a ferromagnetic (F) spin injector, an F spin detector and a nonmagnetic (N) channel. A pure spin current can be generated in the N channel by electrical injection through the injector, and can be detected as a spin signal between the spin detector and the N channel. For a typical metallic NLSV, one expects a regular spin signal meaning that the nonlocal resistance is high for the parallel (P) states of the injector and the detector and low for the antiparallel (AP) states. We investigate spin signals of NLSV's with a break junction formed between the detector and the copper N channel by electrostatic discharge. We observed both non-inverted and inverted spin signals with large magnitudes. An inverted spin signal has low nonlocal resistance values for the P states and high values for the AP states. The magnitude is up to 90 milliohms at 4 K and up to 30 milliohms at 300 K, larger than the typical metallic NLSV with similar dimensions. The large magnitude can be explained by the spin-charge coupling across the highly resistive break-junction. The signs of the spin signals (non-inverted vs. inverted) are determined by the local spin-dependent density of states near the break-junction.

Wednesday, February 29, 2012 8:00AM - 11:00AM – Session P16 DCMP: Heavy Fermions- Mostly URu₂Si₂ 251

8:00AM P16.00001 Fano resonance and hybridization gap in the Kondo lattice URu₂Si₂^{*1}, WAN KYU PARK, University of Illinois at Urbana-Champaign, P.H. TOBASH, F. RONNING, E.D. BAUER, J.L. SARRAO, J.D. THOMPSON, Los Alamos National Laboratory, L.H. GREENE, University of Illinois at Urbana-Champaign — The nature of the 'hidden' order transition in URu₂Si₂ remains puzzling despite intensive research over the past two and half decades. A key question under debate is whether a hybridization gap between the renormalized bands can be identified as the long-sought hidden order parameter. We report on the measurement of a hybridization gap in URu₂Si₂ employing a spectroscopic technique based on quasiparticle scattering across a ballistic metallic junction [1]. The differential conductance data exhibit an asymmetric double-peak structure, a signature for a Fano resonance in a Kondo lattice [2]. The extracted hybridization gap opens well above the hidden order transition temperature, indicating that it is not the order parameter for the hidden order phase. Our results place constraints on the origin of the hidden order transition in URu₂Si₂.

8:12AM P16.00002 Tuning soft point-contact spectroscopy of URu₂Si₂ from hidden order to antiferromagnetic state through pressure¹, XIN LU, F. RONNING, P.H. TOBASH, K. GOFTRY, E.D. BAUER, J.D. THOMPSON, Los Alamos National Laboratory — We have extended the soft point-contact spectroscopy technique under nearly hydrostatic pressure to make charge-spectroscopy measurements of URu₂Si₂ in both hidden order (HO) and large-moment antiferromagnetic (LMAF) states. In the HO state at ambient pressure, the spectroscopy shows two asymmetric peaks around the Fermi energy that emerge below the hidden order temperature $T_{HO} \sim 17.5\text{ K}$. In the LMAF state at higher pressures, the spectra are remarkably similar to those in the HO state, indicating a similar Fermi surface gapping in the HO and LMAF states. The energy scale of this gap is, within experimental uncertainty, consistent with that of the incommensurate spin resonance at $Q_1 = (1 \pm 0.4, 0, 0)$, which also is present in both HO and LMAF states. Our results provide a new clue to unraveling the puzzling HO state.

¹Work at Los Alamos was performed under the auspices of the U. S. Department of Energy, Division of Materials Science and Engineering and supported in part by the Los Alamos LDRD program.

8:24AM P16.00003 Temperature-dependent phonon dispersions in URu₂Si₂, NICHOLAS BUTCH¹, JASON JEFFRIES, MICHAEL MANLEY, Lawrence Livermore National Laboratory, JEFFREY LYNN, NIST Center for Neutron Research, MARC JANOSCHEK², BRIAN MAPLE, University of California, San Diego — The acoustic and low-energy optical phonon modes of a single crystal of URu₂Si₂ were studied via inelastic neutron scattering. The temperature dependence of the phonon dispersions will be compared with results of prior studies of phonons in this material. Our measurements were also sensitive to the temperature evolution of magnetic excitations in the hidden order phase. We will reflect on implications for the nature of the hidden order parameter.

8:36AM P16.00004 Hidden Order Transition in URu₂Si₂: Evidence for the Emergence of a Coherent Anderson Lattice from Scanning Tunneling Spectroscopy, JEREMY FIGGINS, TING YUAN, DIRK MORR, University of Illinois at Chicago — The heavy-fermion compound URu₂Si₂ exhibits an onset of Kondo screening around $T \approx 55\text{K}$ and undergoes a second order phase transition at $T_0 = 17.5\text{K}$ into a state with a still unknown hidden order parameter. Recent scanning tunneling spectroscopy experiments have provided insight into the temperature evolution of the electronic structure. Above the hidden order transition, the differential conductance, dI/dV , exhibits a characteristic Fano lineshape. In contrast, below T_0 , a soft gap opens up in dI/dV and a quasi-particle interference (QPI) analysis reveals a band structure similar to that expected in a screened Kondo lattice. We demonstrate that the experimental dI/dV and QPI results below T_0 are consistent with the formation of a coherent Anderson lattice (CAL). In particular, dI/dV exhibits characteristic signatures of the Anderson lattice band structure, such as an asymmetric gap and a peak inside the gap which arises from the van Hove singularity of the heavy f-electron band. We identify several branches of the QPI pattern arising from intra- and interband scattering. Finally, the temperature evolution of dI/dV suggests that the formation of the CAL below the HOT is primarily driven by a strong increase of the lifetime of the heavy quasi-particles.

8:48AM P16.00005 Nuclear Magnetic Resonance Study of the Paramagnetic State of URu₂Si₂, KENT SHIRER, ADAM DIOGUARDI, JOHN CROCKER, ABIGAIL SHOCKLEY, NICHOLAS APROBERTS-WARREN, PETER KLAVINS, NICHOLAS CURRO, UC Davis — URu₂Si₂ is a heavy fermion system that has challenged researchers for many years due to its transition into a hidden order (HO) state at 17.5K. We present new nuclear magnetic resonance (NMR) data in the paramagnetic phase near the HO phase transition. An analysis of the spin-lattice relaxation rate indicates a suppression of the spin fluctuations above the HO phase transition extending up to approximately 30 K. We analyze this data in the context of several different models for the spin lattice relaxation.

9:00AM P16.00006 Evidence of New Features in the c-axis Optical Conductivity of URu₂Si₂, JESSE HALL, McMaster University, TOOMAS RÕÕM, TAANIEL ULEKSIN, URMAS NAGEL, Estonian National Institute for Chemical Physics and Biophysics, TRAVIS WILLIAMS, GRAEME LUKE, TOM TIMUSK, McMaster University — The hidden order state of URu₂Si₂ remains mysterious despite many years of investigation. High quality, low noise optical data on both cleaved and cut-and-polished faces with in-plane c-axis of the tetragonal structure offer new insight into the electronic behavior at the ordering temperature. As the gap opens in the density of states, a new mode appears in the gap region that is visible in the conductivity only when reflectance is measured with light polarized along the crystal c-direction. A marked anisotropy in the gap energy seen in the optical conductivity between a-axis and c-axis provides further insight into the structure and magnitude of the energy gap and the behavior of the electrons near the greatly-reduced Fermi surface.

9:12AM P16.00007 Linear and Nonlinear Susceptibility Measurements in URu₂Si₂ and UPt₃¹, BELLAVE SHIVARAM, University of Virginia, PRADEEP KUMAR, University of Florida, DAVID HINKS, Argonne National Labs — We will discuss both DC and AC susceptibility measurements in single crystals of URu₂Si₂ and UPt₃. In URu₂Si₂ we detect a ferromagnetic signature separated only by $\sim 1\text{ K}$ from the well established antiferromagnetic signature due to the hidden order at 17.5 K. This ferromagnetic signature appears to be well pronounced only in those samples where a strong ferromagnetic anomaly (also observed by others previously) appears at 35 K. This new ferromagnetic signature is further apparent in AC measurements, with its fingerprint appearing in a pronounced manner in first order, third order and fifth order susceptibility measurements. In contrast at the hidden order transition signatures are seen only in the first order and the fifth order susceptibility with no apparent change in the third order susceptibility. In UPt₃, the DC third order susceptibility measurements reveal a broad peak at $\sim 10\text{ K}$ which is at half the temperature where a peak in the linear susceptibility is observed. This proportionality appears thus far to be universal across the f-electron based strongly correlated metals.

¹Supported by NSF DMR

9:24AM P16.00008 Small Angle Neutron Scattering Studies of the Vortex Lattice of UPt₃¹, W.J. GANNON, W.P. HALPERIN, Northwestern University, IL, USA, M.R. ESKILDSEN, University of Notre Dame, IN, USA, J. GAVILANO, Paul Scherrer Institute, Switzerland — Although a paradigm for unconventional superconductivity, the true nature of the superconducting order parameter in UPt₃ is still an open question. We present results from small angle neutron scattering (SANS) studies on the vortex lattice (VL) of UPt₃, for fields both perpendicular and parallel to the crystal c-axis, that have implications for the superconducting order parameter. For perpendicular fields, an unconventional temperature dependence of the VL form factor – and thus penetration depth – is seen, with different dependences in the A and B-phases. This bulk measurement of the penetration depth indicates the presence of nodes in the superconducting gap. For parallel fields, we report the first measurement of a rocking curve from the VL. This is an encouraging result for the viability of using SANS to detect signatures of time reversal symmetry breaking, as the c-axis is taken as the chiral axis in these order parameter theories.

¹Support from DOE/BES awards DE-FG02-10ER46783 and DE-FG02-05ER46248.

9:36AM P16.00009 Hidden order and unconventional superconductivity in URu₂Si₂, JEFFREY RAU, HAE-YOUNG KEE, University of Toronto — The nature of the so-called hidden order in URu₂Si₂ and the subsequent superconducting phase have remained a puzzle for over two decades. Motivated by evidence for rotational symmetry breaking seen in recent magnetic torque measurements [Okazaki et al. Science **331**, 439 (2011)], we derive a simple tight-binding model consistent with experimental Fermi surface probes and ab-initio calculations. From this model we use mean-field theory to examine the variety of hidden orders allowed by existing experimental results, including the torque measurements. We then construct a phase diagram in temperature and pressure and discuss relevant experimental consequences.

9:48AM P16.00010 Hastatic Order in URu₂Si₂, PREMALA CHANDRA, PIERS COLEMAN, Center for Materials Theory, Department of Physics and Astronomy, Rutgers University, REBECCA FLINT, Department of Physics, Massachusetts Institute of Technology — The hidden order that develops below 17.5K in URu₂Si₂ has eluded identification for twenty-five years. Here we show that the recent observation of Ising quasiparticles in URu₂Si₂ suggests a novel “hastatic order” (Latin: *spear*), with a two-component order parameter describing hybridization between electrons and the Ising $5f^2$ states of the uranium atoms. Hastatic order breaks time-reversal symmetry by mixing states of different Kramers parity; this accounts for the magnetic anomalies observed in torque magnetometry and the pseudo-Goldstone mode observed in neutron scattering. Hastatic order is predicted to induce a basal-plane magnetic moment of order $0.01\mu_B$, a gap to longitudinal spin fluctuations that vanishes continuously at the first-order antiferromagnetic transition and a narrow resonant nematic feature in the scanning tunneling spectra.

10:00AM P16.00011 Staggered spin-orbit coupling induced hidden order state in heavy-fermion metal URu₂Si₂, TANMOY DAS, LANL — The order parameter responsible for a second-order phase transition in the heavy fermion metal URu₂Si₂ at T = 17.5 K has remained a long-standing mystery. Here we show via ab-initio calculations that an incommensurate Fermi surface “nesting” in the partially-filled f-states causes a staggered spin-orbit coupling in the hidden-order state. In this cause neither the spin (S) nor the orbital (L) alone causes ordered state, rather a modulated spin-momentum locked density wave propagates along the unidirectional nesting direction with a polarized total angular momentum $m_J = \pm 2$, in excellent agreement with experiments. It breaks spontaneous rotational symmetry, but not the time-reversal symmetry and thus gives rise to the recently observed “nematic order” in this state. The hidden order state will be immune to any time-reversal invariant perturbation such as pressure, whereas magnetic field will destroy it. Remarkably, these are the hallmark properties of the hidden order state. We also compute the topological quantum number to show that the hidden-order gap opening can cause a trivial to non-trivial topological phase transition, and hence defines a novel “topological quantum critical point.” Work is supported by US DOE.

10:12AM P16.00012 Emergent Rank-5 “Nematic” Order in URu₂Si₂, HIROAKI IKEDA, Department of Physics, Kyoto University, MICHITO SUZUKI, CCSE, Japan Atomic Energy Agency, RYOTARO ARITA, Department of Applied Physics, University of Tokyo, TETSUYA TAKIMOTO, Asia Pacific Center for Theoretical Physics, POSTECH, TAKASADA SHIBAUCHI, YUJI MATSUDA, Department of Physics, Kyoto University — In the strongly correlated f-electron systems, novel electronic states often appear due to the interplay between electron correlations and entangled spin and orbital degrees of freedom. A spectacular example is the so-called “hidden-order” phase in the heavy-electron metal URu₂Si₂. The phase transition is characterized by the large amount of entropy loss observed at $T_{HO} = 17.5\text{K}$, however no evidence of magnetic/structural phase transition below T_{HO} have been reported so far. Despite efforts over a quarter century, the order parameter has remained unidentified. We show here that the hidden order is a rank-5 multipole (dotriacontapole) state with E^- symmetry, based on the first-principles theoretical approach. This novel electronic state provides natural explanations of the key features including anisotropic magnetic excitations, nearly degenerate antiferromagnetic state, and spontaneous fourfold symmetry breaking.

10:24AM P16.00013 Electronic Structure and Correlation Effects in PuCoIn₅ as Compared to PuCoGa₅¹, JIAN-XIN ZHU, P.H. TOBASH, E.D. BAUER, F. RONNING, B.L. SCOTT, Los Alamos National Laboratory, K. HAULE, G. KOTLIAR, Rutgers University, R.C. ALBERS, J.M. WILLS, Los Alamos National Laboratory — Since their discovery nearly a decade ago, plutonium-based superconductors have attracted considerable interest, which is now heightened by the latest discovery of superconductivity in PuCoIn₅. In the framework of density functional theory (DFT) within the generalized gradient approximation (GGA) together with dynamical mean-field theory (DMFT), we present a comparative study of the electronic structure of superconducting PuCoIn₅ with an expanded unit cell volume relative to its PuCoGa₅ cousin. Overall, a similar GGA-based electronic structure, including the density of states, energy dispersion, and Fermi surface topology, was found for both compounds. The GGA Pu 5f band was narrower in PuCoIn₅ than in PuCoGa₅ due to the expanded lattice, resulting in an effective reduction of Kondo screening in the former system, as also shown by our DMFT calculations.

10:36AM P16.00014 Upper critical field of p-wave superconductors with orthorhombic symmetry, CHRISTOPHER LÖRSCHER, RICHARD KLEMM, University of Central Florida — Recent experiments on exotic ferromagnetic superconducting materials such as UCoGe and topological superconductors such as Cu_xBi₂Se₃, have spawned renewed interest in p-wave superconductivity. We present an extension of the Scharnberg-Klemm theory of H_{c2} in p-wave superconductors to cases of partially broken symmetry in an orthorhombic crystal. Using a uniaxial anisotropic pairing interaction as is appropriate for the low-field regime of UCoGe, we have shown that a field induced crossover from one p-wave state to another can lead to kinks in $H_{c2}(T)$, which can mimic upward curvature in all three crystal axis directions. Reasonably good fits to the low-field UCoGe data are obtained. We have also investigated the angular dependence of the axial p-wave state, which might prove useful in identifying the p-wave state present in certain materials, and possibly suggest new experiments on well known p-wave superconductors.

10:48AM P16.00015 Time-resolved quasiparticle dynamics of the itinerant antiferromagnet UPtGa₅¹, ELBERT CHIA, Nanyang Technological University, JIAN-XIN ZHU, Los Alamos National Laboratory, DIYAR TALBAYEV, Tulane University, H.J. LEE, University of California at Berkeley, NAMJUNG HUR, Inha University, N.O. MORENO, Federal University of Sergipe, R.D. AVERITT, Boston University, J.L. SARRAO, A.J. TAYLOR, Los Alamos National Laboratory — Time-resolved photoinduced reflectivity is measured in the spin-density-wave phase of the itinerant antiferromagnet UPtGa₅. Two relaxation components were seen: (a) a slow component whose amplitude appears below T_N , and relaxation time τ_{slow} exhibits an upturn near T_N ; (b) the fast component persists at all temperatures, with the relaxation time τ_{fast} also exhibiting an upturn near T_N . Comparing with pump-probe data on UNiGa₅, the differences are explained in the context of UPtGa₅ having A-type, (rather than G-type) antiferromagnetism, resulting in partial Fermi surface nesting, partial gapping and consequently finite density of states, at the Fermi surface.

Session P17 DMP GERA FIAP: Focus Session: Thermoelectrics - TE and Thermal Conductivity

252A

8:00AM P17.00001 Skutterudite Thermoelectric Generator for Electrical Power Generation from Automotive Waste Heat¹, GREGORY MEISNER, GM Global Research and Development — Filled skutterudites are state-of-the-art thermoelectric (TE) materials for electrical power generation from waste heat. They have suitable intrinsic transport properties as measured by the thermoelectric figure of merit $ZT = S^2\sigma T/\kappa$ (S = Seebeck coefficient, σ = electrical conductivity, T = temperature, and κ = thermal conductivity) and good mechanical strength for operation at vehicle exhaust gas temperatures of $>550^\circ\text{C}$. We have demonstrated TE electrical power generation on a production test vehicle equipped with a fully functional prototype TE generator (TEG). It was assembled with TE modules fabricated from filled skutterudites synthesized at GM. Our results and analysis show that improvement in total power generated can be achieved by enhanced thermal and electrical interfaces and contacts. A substantial T decrease along the exhaust gas flow results in a large variation of voltage, current, and power output for each TE module depending on its position in the module array. Total TEG output power depends directly on the position-dependent T profile via the temperature dependence of both ZT and Carnot efficiency. Total TEG power output also depends on how the modules are connected in parallel or series combinations because mismatch in output voltage and/or internal resistance among the modules degrades the performance of the entire array. Uniform T profiles and consistent TE module internal resistances improve overall TEG performance.

¹Supported by the US DOE Vehicle Technologies Program

8:12AM P17.00002 Theoretical Study of the Properties of the Type II Clathrates $A_x\text{Si}_{136}$ and $A_x\text{Ge}_{136}$ ($A = \text{Na}, \text{K}$), CRAIG HIGGINS, Texas Tech University, CHARLEY MYLES, Professor, Texas Tech University, TEXAS TECH TEAM — Type II clathrate semiconductors have cage-like lattices where atoms are tetrahedrally coordinated and sp^3 bonded. An observed property of these materials is the variation of unit cell volume as different types of alkali metal atoms are placed in the clathrate cages. Experiments¹ on $\text{Na}_x\text{Si}_{136}$ reveal that, starting with Si_{136} , as x increases ($0 < x < 8$), the cell volume contracts; where ($8 < x < 24$), the cell volume expands. This variation with x has been explained² as due to preferential incorporation of Na into the Si_{28} cages for $x < 8$, followed by incorporation into the Si_{20} cages for $8 < x$ (when all Si_{28} cages are full). With this motivation, we have used density functional theory to explore the possibility Type II Si and Ge clathrates with alkali atom guests other than Na may exhibit a similar variation in cell volume with guest inclusion. We present results for the electronic and vibrational properties of the $\text{Na}_x\text{Si}_{136}$, $\text{Na}_x\text{Ge}_{136}$, $\text{K}_x\text{Si}_{136}$, and $\text{K}_x\text{Ge}_{136}$ clathrates. These results are compared with experiment and the properties of the materials are compared and contrasted.

8:24AM P17.00003 Enhanced Thermoelectric Property of Single Phase $\text{MnSi}_{1.75}$ through Non-equilibrium Synthesis Method, XIAOYA SHI, Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory, Upton, New York, 11973, IVO DIMITROV, Brookhaven National Lab, SU JUNG HAN, QIANG LI, Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory, Upton, New York, 11973, BROOKHAVEN NATIONAL LAB TEAM — We report thermoelectric properties of the single phase $\text{MnSi}_{1.75}$ using a one-step non-equilibrium synthesis method. Extremely high quenching speed of melt spinning prevents the formation of the second phase MnSi, which is usually found in this class of materials made by using the conventional solid state reaction methods. We found that the phase-pure $\text{MnSi}_{1.75}$ samples exhibit much higher electrical conductivity, as compared with the conventionally prepared samples. Thermal conductivity is measured and analyzed by introducing the Debye model. It is found that the reduced grain sizes after melt spinning play an important role on decreasing lattice thermal conductivity. The combination of enhanced electrical conductivity and reduced lattice thermal conductivity results in large increase of the thermoelectric figure of merit zT at room temperature.

8:36AM P17.00004 Investigation of phonon mass-difference scattering model by molecular dynamics, TAKUMA SHIGA, TAKUMA HORI, SHIGEO MARUYAMA, JUNICHIRO SHIOMI, Department of Mechanical Engineering, The University of Tokyo — While nanostructuring has been shown to be a promising approach to effectively reduce lattice thermal conductivity and enhance efficiency of thermoelectrics, alloying still remains to be a key process that determines the base material performance. Therefore, understanding lattice thermal conductivity of alloyed crystals, particularly from the viewpoint of mode-dependent phonon transport, holds importance. In this work, we have investigated phonon scattering rates in alloy crystals by focusing on the mass-difference scattering. The phonon mass-difference scattering rates were obtained through spectral analysis of phase-space molecular trajectories computed by molecular dynamics simulations. Obtained results for simple Lennard-Jones crystals show that the mass-difference scattering rates of long-wavelength phonons follow the frequency dependence of Rayleigh scattering regardless of isotope mass and concentration. Meanwhile we obtained the large deviation from scattering models based on the mass perturbation theory. We will report and discuss details of frequency-dependence of mass-difference scattering rates to clarify validity and limit of the models. Furthermore, the analysis will be extended to thermoelectric materials, such as lead telluride. This work is supported by Global COE Program, Global Center of Excellence for Mechanical System Innovation.

8:48AM P17.00005 Stronger phonon scattering by larger differences in atomic mass and size in p-type half-Heuslers $\text{Hf}_{1-x}\text{Ti}_x\text{CoSb}_{0.8}\text{Sn}_{0.2}$, XIAO YAN, WEISHU LIU, HUI WANG, SHUO CHEN, Boston College, JUNICHIRO SHIOMI, The University of Tokyo, HENGZHI WANG, DEZHI WANG, Boston College, GANG CHEN, MIT, ZHIFENG REN, Boston College, BOSTON COLLEGE TEAM, MIT COLLABORATION, THE UNIVERSITY OF TOKYO COLLABORATION — High lattice thermal conductivity has been the bottleneck for further improvement of thermoelectric figure-of-merit (ZT) of half-Heuslers (HHs) $\text{Hf}_{1-x}\text{Zr}_x\text{CoSb}_{0.8}\text{Sn}_{0.2}$. Theoretically the high lattice thermal conductivity can be reduced by exploring larger differences in atomic mass and size in the crystal structure. In this paper, we experimentally demonstrated that lower than ever reported thermal conductivity in p-type HHs can indeed be achieved when Ti is used to replace Zr, i.e., $\text{Hf}_{1-x}\text{Ti}_x\text{CoSb}_{0.8}\text{Sn}_{0.2}$, due to larger differences in atomic mass and size between Hf and Ti than Hf and Zr. The highest peak ZT of about 1.1 in the system $\text{Hf}_{1-x}\text{Ti}_x\text{CoSb}_{0.8}\text{Sn}_{0.2}$ ($x=0.1, 0.2, 0.3$, and 0.5) was achieved with $x=0.2$ at 800°C .

9:00AM P17.00006 Neutron Scattering Study of the Temperature-Dependent Phonon Spectra of AgSbTe_2 ¹, JIE MA, OLIVIER DELAIRE, ANDREW MAY, MICHAEL MCGUIRE, BRIAN SALES, OLIVIER GOURDON, ASHFIA HUQ, DOUGLAS ABERNATHY, MATTHEW STONE, Oak Ridge National Laboratory, PO Box 2008, Oak Ridge, TN 37831, USA, OAK RIDGE NATIONAL LABORATORY, PO BOX 2008, OAK RIDGE, TN 37831, USA COLLABORATION — The thermoelectric material AgSbTe_2 has attracted much attention due to its simple rocksalt structure, high thermoelectric figure-of-merit, and its extremely low thermal conductivity in bulk samples. Previous theoretical studies have suggested that phonons can be scattered by anharmonicity (phonon-phonon coupling) and nano-defects in AgSbTe_2 . However, systematic measurements of phonons in this compound have not been available. We report our results of detailed time-of-flight neutron scattering measurements, as a function of temperature, and departure from stoichiometry. The temperature dependence of the phonon density-of-states is discussed, and compared with the reported thermal conductivity in this system.

9:12AM P17.00007 Inelastic Neutron Study of Phonon Lifetime Effects in Thermoelectric $\text{Bi}_2(\text{Se},\text{Te})_3$ Alloys¹, DILLON GARDNER, Massachusetts Institute of Technology, OLIVIER DELAIRE, MARK LUMSDEN, TAO HONG, Oak Ridge National Laboratory, DOYLE TEMPLE, Norfolk State University, YOUNG LEE, Massachusetts Institute of Technology — One important avenue of optimizing the thermoelectric figure of merit, ZT , is to reduce the thermal conductivity of phonons while preserving the electrical conductivity. Mass disorder caused by alloying provides an avenue of enhancing phonon scattering. In this work, the phonon spectra of different alloys of $\text{Bi}_2(\text{Se},\text{Te})_3$ are measured using inelastic neutron measurements. The temperature and composition dependence provide information on phonon softening and enhanced phonon scattering of acoustic phonon modes. Measurements on single crystals also reveal the dependence on the polarization of the modes. An additional low energy dispersing mode has been observed.

¹This work was supported by the US DOE, Office of Basic Energy Sciences as part of the S3TEC Energy Frontier Research Center, DOE DE-SC0001299

9:24AM P17.00008 Anomalous Lattice Dynamics in PbTe and Its Implications to Low Intrinsic Lattice Thermal Conductivity, YI ZHANG, Department of Physics and HiPSEC, University of Nevada, Las Vegas, XUEZHI KE, Department of Physics, East China Normal University, Shanghai, China, PAUL KENT, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, CHANGFENG CHEN, Department of Physics and HiPSEC, University of Nevada, Las Vegas, JIHUI YANG, Materials Science and Engineering Department, University of Washington — Recent experiments on PbTe-based high performance thermoelectric materials raise fundamental questions about the nature of low intrinsic lattice thermal conductivity and underlying lattice dynamics. We show by first-principles calculations that the reported results can be attributed to abnormally large-amplitude thermal vibrations that stem from a delicate competition of dual ionicity and covalency, which puts PbTe near ferroelectric instability. It produces anomalous properties such as partially localized low-frequency phonon modes, a soft transverse optical phonon mode, and a positive temperature coefficient for the band gap. These results account for experimental findings and resolve the underlying atomistic mechanisms. The relation between these anomalies and the low intrinsic lattice thermal conductivity will be discussed.

9:36AM P17.00009 Phonon Anharmonicity in PbTe Thermoelectrics¹, OLIVIER DELAIRE, JIE MA, KAROL MARTY, ANDREW MAY, MICHAEL MCGUIRE, MAO-HUA DU, DAVID SINGH, ANDREY PODLESNYAK, GEORG EHLERS, MARK LUMSDEN, BRIAN SALES, Oak Ridge National Laboratory — Achieving high thermoelectric conversion efficiency requires limiting the thermal conductivity, through the disruption of phonon propagation. A detailed understanding of phonon dispersions and linewidths is thus critical to develop accurate microscopic theories of thermal conductivity, and design efficient thermoelectric materials. We investigate the phonon dispersions and linewidths in the thermoelectric material PbTe with inelastic neutron scattering experiments. Our measurements indicate that the soft transverse optic mode in PbTe is strongly anharmonic, which could cause a lowering of thermal conductivity by scattering the heat-conducting acoustic modes [1]. We also present results on the effect of alloying.

9:48AM P17.00010 Anharmonic vibrational effects of thermoelectric Cu-Sb-Se ternary semiconductors: Density-functional theory studies, YONGSHENG ZHANG, Materials Science and Engineering, Northwestern University, ERIC SKOUG, JEFFREY CAIN, DONALD MORELLI, Chemical Engineering and Materials Science, Michigan State University, VIDVUDS OZOLINS, Materials Science and Engineering, University of California, Los Angeles, CHRISTOPHER WOLVERTON, Materials Science and Engineering, Northwestern University — Strong anharmonicity can lead to intrinsically minimal thermal conductivity even in defect-free single crystals. In an effort to understand this behavior, we have investigated two Cu-Sb-Se ternary semiconductors, Cu_3SbSe_4 and Cu_3SbSe_3 , by both experimental measurements and density functional theory (DFT) calculations. The experimental lattice thermal conductivity measurements show that while Cu_3SbSe_4 exhibits classical behavior, the lattice thermal conductivity in Cu_3SbSe_3 is anomalously low and nearly temperature independent. The vibrational properties of these two semiconductors are calculated by DFT phonon calculations within the quasi-harmonic approximation. The average of the Grüneisen parameters of the acoustic mode in Cu_3SbSe_3 is larger than that of Cu_3SbSe_4 , which theoretically confirms that Cu_3SbSe_3 has a stronger lattice anharmonicity than Cu_3SbSe_4 . Using our DFT-determined longitudinal and transverse Grüneisen parameters, Debye temperatures, and phonon velocities, we calculate the lattice thermal conductivity using the Debye-Callaway model (without the use of any adjustable parameters). The calculated thermal conductivity is in good agreement with the experimental measurements.

10:00AM P17.00011 First-principles calculation of anharmonicity induced phonon lifetimes in FeSi¹, MOSES NTAM, JIANJUN DONG, Auburn University, OLIVIER DELAIRE, PAUL R. KENT, Oak Ridge National Laboratory — FeSi has attracted a lot of interest as a promising thermoelectric material for refrigeration applications. We present a first principle calculation of phonon lifetimes of FeSi based on our newly developed computational technique which combines first-principles density functional theory (DFT) and quantum scattering theory. Phonon lifetimes are calculated within the Fermi's golden rule using third order lattice anharmonicity tensors and vibrational phonon frequencies as inputs. Second order force constant matrices and third order lattice anharmonicity tensors are extracted using a real space supercell technique within the local density approximation (LDA). We compare our calculated phonon spectrum and lifetimes with recent neutron scattering measurements of phonon dispersions and linewidths. Finally we use the calculated phonon lifetimes to estimate the thermal conductivity of FeSi using kinetic transport theory.

¹NSF (EAR-0757847)

10:12AM P17.00012 Resistivity and Specific Heat under Localized Anharmonic Motion in Type-I $\text{Ba}_8\text{Ga}_{16}\text{Sn}_{30}$ Clathrate, XIANG ZHENG, SERGIO Y. RODRIGUEZ, LAZIZ SARIBAEV, JOSEPH H. ROSS, JR, Department of Physics and Astronomy, Texas A&M University, College Station, TX, 77843, USA — Anharmonic guest atom oscillation has direct connection to the thermal transport and thermoelectric behavior of type-I $\text{Ba}_8\text{Ga}_{16}\text{Sn}_{30}$ clathrate. This behavior can be observed through several physical properties, with for example the heat capacity providing a measure of the overall excitation level structure. In addition the nuclear magnetic resonance (NMR) relaxation behavior provides a sensitive probe for the oscillator dynamics, as we have recently reported. Localized anharmonic excitations also influence the low-temperature resistivity, as we show in this paper. By combining heat capacity and transport measurements we address the distribution of local-oscillators in this material, as well as the shape of the confining potential for Ba ions in the cages. Analyzed along with NMR relaxation measurements for the same sample, a two phonon Raman process is used to extract information about the excitation energies, which along with a quantum computational solver we have used to address the potential structure. We also compare to the soft-potential model and other models used for this system. The results indicate that a single confining potential cannot describe the system properly, whereas a distribution of local oscillators provides a more reasonable fit to the data.

10:24AM P17.00013 The Debye-Waller factor and its application to anharmonic vibrations, DOUGLAS SAFARIK, ANNA LLOBET, JASON LASHLEY, Los Alamos National Laboratory — The Debye-Waller factor relates the intensities of the Bragg peaks to the mean square displacements of the atoms. In the structural refinement of diffraction data it is standard practice to use the harmonic expression for Debye-Waller factor. For most materials and conditions the phonons are only mildly anharmonic, thus the harmonic assumption is a good one. For some materials and conditions, however, the phonons can be strongly anharmonic, and thus the harmonic assumption is physically unrealistic. As examples we cite the rattling atoms in clathrates and skutterudites, and atoms participating in displacive phase transitions. In the present study we investigate the error associated with using the harmonic Debye-Waller factor to analyze anharmonic vibrations. We find that even for strongly anharmonic potentials, such as a double well, the mean square displacements deduced using the harmonic approximation are at most 15% larger than those deduced using a full anharmonic analysis. Furthermore, the quasi-harmonic and anharmonic values have nearly the same temperature dependences. We conclude that the error introduced by using the harmonic approximation is comparable to or smaller than the usual errors associated with measurement and refinement of diffraction patterns.

10:36AM P17.00014 Minimum thermal conductivity in superlattices: A first-principles formalism¹, JIVTESH GARG, GANG CHEN, Massachusetts Institute of Technology — In certain superlattice systems such as silicon-germanium superlattices a minimum in thermal conductivity with increase in period thickness has been observed. This minimum has been reported at a relatively short superlattice period of a few nanometers and cannot be explained by existing formalisms. An accurate prediction of this minimum thermal conductivity holds importance for thermoelectrics where low thermal conductivity is desired. We develop a first-principles formalism based on use of harmonic and anharmonic force-constants derived from density-functional perturbation theory and single-mode relaxation time approximation to predict the thermal conductivity of superlattices. The phonon relaxation times are computed based on scattering due to both anharmonicity and interface roughness. We show that the formalism leads to an excellent agreement between predicted and measured values and also explains the observed minimum in thermal conductivity.

¹This material is based upon work supported as part of the S3TEC, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DE-FG02-09ER46577

10:48AM P17.00015 Thermal transport across perovskite superlattices¹, JAYAKANTH RAVICHANDRAN, AJAY YADAV, University of California, Berkeley, RAMEZ CHEAITO, University of Virginia, Charlottesville, PIM ROSSEN, University of California, Berkeley, SIRIYARA SURESHA, Lawrence Berkeley National Lab, Berkeley, PATRICK HOPKINS, University of Virginia, Charlottesville, ARUN MAJUMDAR, Department of Energy, RAMAMOORTHY RAMESH, University of California, Berkeley — Understanding thermal transport across interfaces is useful for designing materials for thermal management, thermoelectricity etc. Despite years of investigation, there are several open questions on the nature of thermal transport across solid-solid interfaces. The ability to control materials synthesis down to a monolayer has enabled study of interface phonon scattering in systems such as superlattices, heterostructures etc. We chose perovskite oxides, which are excellent thermoelectric materials, as model systems to study interfacial thermal transport. Superlattices of SrTiO₃, CaTiO₃ and CaMnO₃, with period thicknesses ranging from 1-176 monolayers were grown using pulsed laser deposition, monitored by in-situ RHEED. We measured temperature dependent (100 - 400 K) cross plane thermal conductivity of these superlattices using the time domain thermoreflectance (TDTR). The lowest thermal conductivity measured is below the alloy limit at room temperature. The period thickness dependent thermal conductivity shows signs of zone folding for short period superlattices.

Wednesday, February 29, 2012 8:00AM - 11:00AM –
Session P18 DMP: Focus Session: Electron, Ion, and Exciton Transport in Nanostructures - Quantum Transport I 252B

8:00AM P18.00001 Electrostatic tuning between 1-dimensional and 2-dimensional electron gases, DIGBIJOY NATH, PIL SUNG PARK, MICHELE ESPOSTO, The Ohio State University, DAVID BROWN, STACIA KELLER, UMESH MISHRA, University of California, Santa Barbara, SIDDHARTH RAJAN, The Ohio State University, THE OHIO STATE UNIVERSITY TEAM, UNIVERSITY OF CALIFORNIA, SANTA BARBARA TEAM — Although low dimensional systems such as 1-D and 2-D electron gases have been separately studied in details, a system enabling co-existence of both dimensions is still challenging to achieve. Such a system where the dimensionality can be tuned between 1-D and 2-D electrons can be an extremely promising platform to explore new phenomena. Here we investigate a novel system based on vicinal GaN-based heterostructure where we exploit its polarization charges to demonstrate for the first time, direct electrostatic tuning of the dimensionality of electrons between 1-D and 2-D. This tuning is achieved by adjusting the Fermi level with applied gate bias. A capacitance-voltage profiling to probe the Fermi occupation function of electron gas was used to demonstrate distinct signatures of the density of states for both the dimensions at room temperature. We developed a 2-sub-band model consisting of 1-D and 2-D sub-bands to describe the behavior of the electron gas, which is in excellent agreement with our experimental data, confirming the co-existence of electrons of both dimensions. This demonstration of co-existence of 1-D and 2-D electrons and the ability to tune between their dimensions at room temperature could open new research paths for low-dimensional physics besides enabling devices with added functionalities.

8:12AM P18.00002 Quantum coherence phenomena in bismuth thin film nanostructures, MARTIN RUDOLPH, J. J. HEREMANS, Virginia Tech — We present low temperature quantum magnetotransport measurements on bismuth nanostructures. The large spin-orbit interaction and prominent surface states in Bi films are expected to produce non trivial mesoscopic quantum transport. Bi thin films are grown by thermal evaporation onto SiO₂ with a two-step process to optimize the film mobility and ensure oriented growth along the [111] direction. The optimization leads to a minimum thickness of 25 nm for continuous films. Structures as small as 100 nm are subsequently patterned into the film via lithographic techniques. Phase and spin coherence lengths are obtained by analyzing electron interference phenomena in mesoscopic wires and rings. We show that the phase coherence shows a decreasing trend with decreasing channel width. The decrease in phase coherence in Bi wires ranging in width from 1200 nm to 100 nm cannot readily be accounted for by increased boundary scattering. A width dependence of the spin coherence is also detected. The observed confinement dependence of the phase and spin coherence in Bi nanostructures will be discussed (DOE DE-FG02-08ER46532).

8:24AM P18.00003 Resistance oscillations and dephasing in ring patterns on InGaAs/InAlAs two-dimensional electron systems, SHAOLA REN, J.J. HEREMANS, Virginia Tech, C.K. GASPE, S. VIJAYARAGUNATHAN, T.D. MISHIMA, M.B. SANTOS, University of Oklahoma — In InGaAs/InAlAs heterostructures with spin-orbit interaction, patterned into mesoscopic rings, we experimentally investigate low-temperature Aharonov-Bohm resistance oscillations. The oscillation amplitude was studied as function of applied current and temperature, to obtain the dependence of these parameters on dephasing. Previous results on mesoscopic quantum interferometers have shown a lobe structure in the dependence of the oscillation amplitude on measurement bias, in some models ascribed to Coulomb interaction, and have surmised a universal behavior with an energy scale dependent on interferometer size. The ring interferometers studied here were of typical radius of 700 nm, and lithographic arm width of 300 nm, similar-sized but of higher carrier density than in the previous studies, and used for similar bias- and temperature-induced dephasing studies. The measurements so far show the expected temperature dependence, but have not revealed the lobe structure in the bias dependence. We discuss the results in the light of dephasing phenomena expected in mesoscopic quantum interferometers (DOE DE-FG02-08ER46532, NSF DMR-0520550).

8:36AM P18.00004 Transport through double quantum dot with electron-LO-phonon interaction, AKIHIRO YAMADA, RIN OKUYAMA, MIKIO ETO, Keio University — We theoretically study the transport through a serial double quantum dot (DQD) in the presence of electron-LO-phonon interaction. In contrast to the case of acoustic phonon,¹ the coherent coupling between an electron and an optical phonon, so-called polaron formation, has a small dissipation, which influences the transport properties markedly. We calculate the current through the DQD using the Keldysh Green function, as a function of the tuning of energy levels between the quantum dots, when the bias voltage is sufficiently large. The electron-phonon interaction is considered by the perturbation expansion. We find a subpeak structure of the current due to the polaron formation and evaluate elastic and inelastic components of the current.

8:48AM P18.00005 Imaging Spatial Current Eigenmodes in Nanoscopic Quantum Networks¹

, TANKUT CAN, University of Chicago, DIRK MORR, University of Illinois-Chicago — Using the Keldysh Green's function formalism, we study the non-equilibrium charge transport in nanoscopic quantum networks [1]. Due to quantum confinement, charge transport takes place via current eigenmodes that possess characteristic spatial patterns of current paths. In the ballistic limit, these patterns exhibit unexpected features such as current backflow and closed loops of circulating currents. These current eigenmodes are the non-equilibrium analogue of eigenmodes in the local density of states of confined systems [2]. Moreover, we demonstrate that dephasing leads to a smooth evolution of the current patterns, and ultimately reproduces the charge transport in a classical resistor network. Finally, we propose a new method using scanning tunneling spectroscopy to image the spatial current patterns associated with individual current eigenmodes in nanoscopic quantum networks.

9:00AM P18.00006 Microscopic Theory for the 0.7 Anomaly in Quantum Point Contacts - the Role of Geometry- and Interaction-Enhanced Spin-Fluctuations

, JAN HEYDER, FLORIAN BAUER, ENRICO SCHUBERT, DAVID BOROWSKY, DANIELA TAUBERT, Ludwig-Maximilians University, DIETER SCHUH, University Regensburg, WERNER WEGSCHEIDER, ETH Zurich, JAN VON DELFT, STEFAN LUDWIG, Ludwig-Maximilians University — We present a detailed microscopic analysis of some local observables of a quantum point contact (QPC) to gain better understanding of the origin of the 0.7 conductance anomaly. We model the system by a one-dimensional tight binding model with local interactions, a smooth potential barrier and a homogeneous magnetic field. We calculate conductance G , local density n and local magnetization m as a function of magnetic field at zero temperature, using the functional Renormalization Group (fRG). Our potential can be tuned to describe the smooth crossover from a single barrier, representing a QPC, to a double barrier, modelling a quantum dot (QD) exhibiting the Kondo effect. We find that both geometries show interaction-enhanced spin-fluctuations, manifested via an enhanced local spin susceptibility, for gate voltages that lead to an anomalously large negative magnetoconductance, characterized by an anomalously small low-energy scale B_* . This finding explains why both the Kondo effect and the 0.7-anomaly exhibit a very similar conductance behavior at sufficiently low magnetic fields and temperatures ($T, B \ll T_*$), amenable to a similar Fermi-liquid description. We also show that at high fields ($B \gg B_*$) the analogy between Kondo effect and 0.7-anomaly breaks down.

9:12AM P18.00007 Towards a Fermi-Liquid description of the 0.7 Anomaly in Quantum Point Contacts

, FLORIAN BAUER, JAN HEYDER, ENRICO SUBERT, Ludwig-Maximilians-Universitaet Muenchen, DAVID BOROWSKI, None, DANIELA TAUBERT, Ludwig-Maximilians-Universitaet Muenchen, DIETER SCHUH, Universitaet Regensburg, WERNER WEGSCHEIDER, ETH Zuerich, JAN VON DELFT, STEFAN LUDWIG, Ludwig-Maximilians-Universitaet Muenchen — In addition to plateaus in integer values of $G_0 = \frac{2e^2}{h}$, the linear conductance of a quantum point contact (QPC) shows an anomalous shoulder at around $0.7G_0$ that evolves in a characteristic fashion with rising magnetic field and temperature. We present a microscopic theory for the 0.7 conductance anomaly, based on a one-dimensional tight binding model with a local interaction, a smooth potential barrier and a homogeneous magnetic Zeeman field. We calculate the conductance as a function of magnetic field and temperature using standard second order perturbation theory. Furthermore we use a more sophisticated method, the functional Renormalisation Group (fRG), to obtain a more reliable description at zero temperature and finite magnetic field. We analyze the leading temperature T and magnetic field B dependence of the conductance, which define, respectively, low-energy scales T_* and B_* and find that both T_* and B_* depend exponentially on gate voltage, whereas the ratio $\frac{B_*}{T_*}$ is almost independent of gate voltage. This result indicates that the low-energy behavior of the 0.7 anomaly displays Fermi-liquid behavior. We present new experimental data that corroborate this conclusion.

9:24AM P18.00008 Quantum Wires with Electrons and Cold Atoms

, LINEY HALLA KRISTINSDDOTTIR, JONAS C. CREMON, ANDREAS WACKER, STEPHANIE M. REIMANN, Lund University — Advances in atom trapping and atom chip techniques allow the controlled preparation and manipulation of clouds of cold, neutral atoms, in optical lattices as well as on lithographically patterned gate structures. This opens up many new possibilities to study quantum transport in systems other than semiconductor quantum dots or nanowires, with the exciting perspective of future "atomtronic" systems. Inspired by these developments, we study transport through two different interacting systems as a function of externally controllable parameters: Electrons in a nanowire, and cold atoms in a one-dimensional finite well. For a nanowire system we can demonstrate that Wigner crystallization occurs, when the length of the wire is changed in the experiment [1]. Distinct diamond patterns appear, when conductance is plotted against source-drain bias and the gate voltage, as common for quantum dot systems. The same holds for more general types of "interaction blockade," and we demonstrate that such phenomena can also be studied by cold atom systems.

9:36AM P18.00009 Functional dependence of the exact time-dependent Kohn-Sham potential for quantum transport

, JAMES RAMSDEN, REX GODBY, University of York — We present methods for determining exact steady-state and time-dependent Kohn-Sham potentials from known charge and current densities. Applying these methods to cases of a single electron added to the conduction band of a model semiconductor, we calculate the exact Kohn-Sham potentials and discuss their meaning in the context of describing quantum transport. We show that the inclusion of a longitudinal Kohn-Sham vector potential is quite unavoidable in describing steady-state current-carrying systems, whereas the addition of an electron in a wavepacket state necessitates, inter alia, the appearance of an exchange-correlation electric field. We also present our findings on the functional dependence of the exact Kohn-Sham scalar and vector potentials on the charge and current density.

9:48AM P18.00010 Waiting time distributions of mesoscopic conductors

, GERALDINE HAACK, University of Geneva, Switzerland, MATHIAS ALBERT, University of Paris Sud, Orsay, France, CHRISTIAN FLINDT, MARKUS BUETTIKER, University of Geneva, Switzerland — Electronic transport through mesoscopic structures is stochastic due to the quantum nature of the charge carriers. In full counting statistics the interest is in the number of particles that are detected in a given time interval. Another important and fundamental question concerns the waiting time between consecutive carriers. Recently, waiting time distributions (WTD) have been calculated for periodically driven systems described by master equations and shown to clearly distinguish random charge emissions from charge transfer processes which are frequency-locked to the period of the external drive [1]. In this work we investigate the WTD of a biased quantum point contact (QPC) with one channel [2]. The WTD clearly reflects the fermionic statistics of the elementary charges: with increasing transmission probability of the QPC, the WTD changes from that of a Poisson process for a nearly closed QPC to a Wigner-Dyson distribution, known from the analogous problem of free fermions described by random matrix theory. [1] M. Albert, C. Flindt and M. Buettiker, *Phys. Rev. Lett.* **107**, 086805 (2011). [2] M. Albert, G. Haack, C. Flindt and M. Buettiker, *in preparation*.

10:00AM P18.00011 Magnetic field induced mixed level Kondo effect in two-level quantum dots, ARTURO WONG, U of Florida, ANH NGO, SERGIO ULLOA, Ohio U — Semiconductor quantum dots provide an easily tunable environment in which to investigate the Kondo effect. As it is known, Kondo correlations are suppressed by magnetic fields, showing e.g. a drop in the conductance of a quantum dot device. However, certain systems may exhibit an increasing conductance as a function of an applied magnetic field [1]. In this work we use the numerical renormalization group method to study a two-level quantum dot system with on-level and interlevel Coulomb repulsion, coupled to a single channel. When there is a finite detuning between levels, and a local singlet develops in one of them, the linear conductance of the device shows a maximum structure as a function of an in-plane magnetic field, which depends on the temperature of the system. This maximum occurs at a magnetic field strength such that the spin up state of one of the levels and spin down of the other are degenerate, allowing a “mixed level” Kondo effect. The respective spectral functions feature a resonance at the Fermi energy, commensurate with the Kondo physics. We discuss the properties of this mixed level Kondo state in terms of the detuning and the other parameters of the system.

10:12AM P18.00012 Time dependent quantum transport in a vibrating quantum dot in Kondo regime¹, ALI IHSAN GOKER, Department of Physics, Bilecik University — We employ the time dependent non-crossing approximation to investigate the effect of strong electron-phonon coupling on the instantaneous conductance and thermopower of a single electron transistor which is abruptly shifted into the Kondo regime via a gate voltage. We find that the instantaneous conductance exhibits decaying sinusoidal oscillations on the long timescale for infinitesimal bias [1]. The ambient temperature and electron-phonon coupling strength influence the amplitude of these oscillations and the frequency of oscillations is equal to the phonon frequency. We discuss the origin of these oscillations and the effect of finite bias on them. On the other hand, we argue that measurement of the decay time of thermopower to its steady state value in linear response might be an alternative tool in determination of the Kondo temperature and the actual value of the electron-phonon coupling strength in an experiment.

10:24AM P18.00013 Dynamic response of a single-electron transistor in the ac Kondo regime, THANH NGUYEN, CARLOS BOLECH, NAYANA SHAH, Department of Physics, University of Cincinnati — A single-electron transistor (SET) consisting of a small conducting island contacted by macroscopic conductors can be used to study strongly correlated electrons in artificial systems. SETs also provide possibilities of exploring non-equilibrium Kondo phenomena by applying source-drain voltage. In the context of recent measurements, we will discuss the non-trivial dynamics that emerges when externally imposed energy scales compete with the Kondo correlations. The response of the system to a simultaneous application of a magnetic field and a high-frequency modulation of the SET voltages will also be reported.

10:36AM P18.00014 Double Quantum Dot Kondo Effect in a Magnetic Field, SAMI AMASHA, ANDREW J. KELLER, ILEANA G. RAU, Stanford University, JORDAN A. KATINE, Hitachi Global Storage Technologies, HADAS SHTRIKMAN, Weizmann Institute, DAVID GOLDBERGER-GORDON, Stanford University — Conventionally the Kondo effect is thought of as describing how conduction electrons screen a localized spin. More generally, it describes how itinerant electrons screen a degenerate degree of freedom of a localized site. A double quantum dot (with negligible inter-dot tunneling) can have both spin degeneracy, as well as a degeneracy associated with an electron being on dot 1 or dot 2. The latter degeneracy corresponds to a pseudo-spin degree of freedom that can also be screened by the Kondo effect [A. Hübel, et al. PRL 101, 186804 (2008)]. Applying a finite magnetic field can split the spin degeneracy of the dots, which should allow the realization of a purely pseudo-spin Kondo effect. We present conductance measurements of this double dot Kondo effect in a magnetic field. We compare our measurements to theoretical predictions for SU(2) Kondo to check whether we have realized a purely pseudo-spin Kondo effect in a double dot.

10:48AM P18.00015 Theory of anomalous magnetotransport in triple quantum dots¹, BENJAMIN D'ANJOU, WILLIAM A. COISH, McGill University — Magneto-transport measurements on a triple quantum dot ring have recently shown anomalous quantum oscillations with dominant frequencies separated by a factor of three in magnetic flux [1]. Such oscillations, suggestive of a one-third periodicity in the flux quantum, are usually not observed in larger mesoscopic rings in which only larger periods are observed. We develop a microscopic transport model for the triple dot and show that the anomalous oscillations can dominate the transport behavior under certain conditions. Furthermore, we discuss the range of validity of our model by studying dephasing due to broadening and electric dipole interactions.

Wednesday, February 29, 2012 8:00AM - 11:00AM –
Session P19 DCMP GIMS: Invited Session: Dynamics of Strongly Correlated Systems: Control and Ultrafast X-Ray Probes 253AB

8:00AM P19.00001 Controlling Quantum Condensed Matter With Light, ANDREA CAVALLERI, Max Planck Department for the Structure and Dynamics of Matter, Hamburg; Department of Physics - University of Oxford — In this talk I will discuss some of our recent work aimed at controlling the properties of quantum condensed matter with light, for instance in High-Tc cuprates or in Mott Insulators. The focus is on the use of high-field THz radiation rather than near-visible excitations, thus using photon energies that do not destroy the broken symmetry state of the solid, for example by breaking Cooper pairs. Rather we study the non-linear electrodynamics of the solid, for example by manipulating low-lying lattice vibrations coherently or by driving the phase excitations in superconducting condensates. A straightforward conceptual analogy can be found with experiments that that study driven dynamics of strongly correlated atomic gases in optical lattices. Due to the short lengthscales and the fast timescales involved in condensed matter, femtosecond x-ray scattering and spectroscopy experiments with the LCLS Free Electron Laser are necessary to interrogate the microscopic non-equilibrium paths explored by the stimulated solid.

8:36AM P19.00002 Light induced meltdown of quasiparticles in high temperature superconductors, ALESSANDRA LANZARA, University California, Berkeley and Material Sciences Division, Lawrence Berkeley National Laboratory — Ultrafast time- and angle- resolved photoemission spectroscopy (tr-ARPES) is emerging as a powerful tool to access the non-equilibrium quasiparticles dynamics and Cooper pairs formation in unconventional superconductors. In a tr-ARPES experiment a non-equilibrium transient state is created by pumping with an infrared pulse and is then measured via photoemission with an ultraviolet probe pulse. By varying the time delay between pump and probe we can directly access the recovery of the superconducting gap and the non-equilibrium quasiparticles population decay. Here we present a detailed momentum, temperature, doping and density dependent study of the response of a high temperature Bi2212 superconductor to a femtosecond pump-probe. In particular, through systematic pump fluence dependence we have induced the meltdown of quasiparticles and have driven the system normal by inducing a collapse of the superconducting gap. Interestingly we observed that only quasiparticles beyond a particular boson mode respond to the pump laser excitations, while the others remain untouched and that both quasiparticles recombination and gap dynamics are a density, momentum and doping dependent process, showing a crossover from a weakly perturbed to a strongly perturbed regime. These results point to a new dichotomy between the ultrafast gap and quasiparticles response within and beyond the Fermi arc and reveal a new window into the nature of the pairing interaction in high T_c superconductors.

9:12AM P19.00003 Shooting the electronic structure movie: Femtosecond time-resolved photoemission of layered charge-density-wave systems, KAI ROSSNAGEL, University of Kiel — Charge-density waves (CDWs) are broken-symmetry states of low-dimensional materials that are brought about by strong electron-phonon interaction. Yet surprisingly, a universal microscopic understanding beyond this statement has not really evolved for this classical paradigm of condensed matter physics. In quasi-two-dimensional systems, for example, the common approaches based on ARPES band structure results—looking for nested sections of the Fermi surface or for a peak in the electronic susceptibility—have almost no predictive power. Apparently, more successful explanations have to take into account the delicate balance between several factors including not only electronic and phononic structure, but also electron-electron and electron-phonon interactions. Here, we will show that femtosecond time-resolved XPS and ARPES using pulsed extreme ultraviolet radiation generated by the free-electron laser FLASH [1] as well as by a table-top high-harmonic-generation source [2] can provide novel insights into the relative roles that the various factors play in CDW formation. We will focus on three conspicuous CDWs in prominent members of the family of layered transition-metal dichalcogenides: the $(\sqrt{13} \times \sqrt{13})$ CDW in the Mott insulator 1T-TaS₂, the $c(2\sqrt{3} \times 4)rect.$ CDW in the Peierls insulator Rb_xTaS₂, and the $(2 \times 2 \times 2)$ CDW in the possible excitonic insulator 1T'-TiSe₂. The specific program is to reveal the relative importance of electronic and phononic contributions to the various CDW transitions by relating measured melting and relaxation times of CDW-induced spectral features to typical elementary time scales in layered materials.

9:48AM P19.00004 Theoretical description of photo-doping in Mott and charge-transfer insulators, MARTIN ECKSTEIN, Max Planck Research Department for Structural Dynamics, University of Hamburg, Centre for Free Electron Laser Science, Hamburg, Germany — Many aspects of photo-excited insulator-to-metal transitions in Mott and charge-transfer systems are theoretically not well understood: How is the photo-doped state related to a chemically doped state? On what timescale do we expect the formation of quasiparticles? To describe the electronic dynamics of Mott insulators, we have used nonequilibrium dynamical mean-field theory (DMFT) in combination with Quantum Monte Carlo and various weak and strong-coupling [1] techniques. In the talk, I will briefly present the current status of this approach and of related cluster approaches for nonequilibrium. I will then discuss results for the photo-doping in the Hubbard model, and in a p-d model for charge-transfer insulators. When the onsite Coulomb repulsion U is much larger than the hopping, rapid thermalization of the pump-excited Mott insulator is inhibited by the energetic stabilization of doublon-hole pairs [2], and various types of non-thermal states can arise. Immediately after the excitation process, the system of doublons and holes is too hot to form quasiparticle states, but coupling to a heat-bath of phonons can drive the system into a metallic state with well developed doublon and hole bands. Close to the metal-insulator transition, on the other hand, when U is of the order as the hopping, doublons and holes rapidly thermalize due to the electron-electron interaction, which makes the system a bad metal rather than a Fermi liquid.

10:24AM P19.00005 High frequency properties of individual metallic carbon nanotubes¹, DANIEL SANTAVICCA, Department of Applied Physics, Yale University — We study the electrical and electrothermal dynamics of individual metallic single-walled carbon nanotubes (SWNT). Using Johnson noise thermometry, we characterize the dependence of the electron temperature on the dc bias current. This allows us to determine the thermal conductance associated with cooling of the nanotube electron system as a function of both temperature and nanotube length [1]. This thermal conductance can be used to predict the measured radio frequency (rf) bolometric response. At low temperatures and low bias current, an additional rf response is observed from the (non-thermal) electrical nonlinearity of the contacts [2]. Finally, we compare these rf measurements with measurements of terahertz (THz) detection. The THz measurements are used as a probe of plasmon standing wave resonances on the SWNT.

Wednesday, February 29, 2012 8:00AM - 11:00AM – Session P20 FEd: Invited Session: Scientific Reasoning in a Physics Course 253C

8:00AM P20.00001 Empowering the crowd: faculty discourse strategies for facilitating student reasoning in large lecture, DEDRA DEMAREE, Oregon State University — Oregon State University (OSU) has restructured its introductory calculus-based sequence including reformed curriculum modeled after the Interactive Science Learning Environment (ISLE). ISLE is driven by an experimental cycle roughly summarized as: observe phenomena, find patterns and devise explanations, test explanations, develop a model, apply the model to new observations. In implementing ISLE at OSU we have chosen to focus on student scientific reasoning, specifically student ability to develop and test models, make explicit judgments on how to approach open-ended tasks, and take an authoritative role in knowledge development. In order to achieve these goals, the lecture course heavily utilizes social engagement. During large-lecture group work, emphasis is placed on facilitating student discourse about issues such as what systems to choose or how to define an open-ended problem. Instructional strategies are aimed at building off the group discourse to create a full-class community where knowledge is developed through collaboration with peers. We are achieving these goals along with an increase in measured student conceptual knowledge and traditional problem solving abilities, and no loss of content coverage. It is an ongoing effort to understand “best” instructional strategies and to facilitate new faculty when they teach the curriculum. Our research has focused on understanding how to facilitate activities that promote this form of discourse. We have quantitative analysis of engagement based on video data, qualitative analysis of dialogue from audio data, classroom observations by an external researcher, and survey data. In this session we share a subset of what we have learned about how to engage students in scientific reasoning discourse during large lecture, both at the group-work and full-class level.

8:36AM P20.00002 Designing and using multiple-possibility physics problems in physics courses, VAZGEN SHEKOYAN, Queensborough Community College, CUNY — One important aspect of physics instruction is helping students develop better problem solving expertise. Besides enhancing the content knowledge, problems help students develop different cognitive abilities and skills. This presentation focuses on multiple-possibility problems (alternatively called ill-structured problems). These problems are different from traditional “end of chapter” single-possibility problems. They do not have one right answer and thus the student has to examine different possibilities, assumptions and evaluate the outcomes. To solve such problems one has to engage in a cognitive monitoring called epistemic cognition. It is an important part of thinking in real life. Physicists routinely use epistemic cognition when they solve problems. I have explored the instructional value of using such problems in introductory physics courses.

9:12AM P20.00003 Assessing high-level scientific reasoning in a physics exam: Pipe-dream or reality?, DAVID BROOKES, Florida International University — What do we want students to be able to do when they have finished their introductory physics course? In addition to learning the physics content, we want students to learn to think like physicists. We want students to develop specific scientific reasoning abilities that are the hall-mark of scientific thinking. These include, analyzing and interpreting experimental data, designing an experiment to test different hypotheses, identifying assumptions in a physical model amongst many others. Physics courses such as the Investigative Science Learning Environment (ISLE) have been developed to focus specifically on developing students' scientific reasoning abilities. Research has shown that ISLE is successful in achieving its goal. We would like our assessments to directly reflect our learning goals for our students. In order to measure higher-level scientific reasoning, we can, for example, require students to participate in a laboratory practical exam in which they have to engage in experimental design and analysis. However, this assessment method could become very difficult to administer and grade in a large-enrollment class. Is it possible to assess scientific thinking abilities of students using traditional formats such as paper and pencil exams? In this talk I will present some of our latest ideas about how to re-design traditional exam questions to measure a range of scientific reasoning abilities.

9:48AM P20.00004 Using mathematics to make sense in undergraduate physics, SUZANNE BRAHMIA, Rutgers University — Physics courses involve the study of physical quantities constructed to facilitate the characterization of nature, and the study of the connections between these quantities. These connections are often ratios or products of more familiar quantities. Learning to use the predictive power these relationships provide is an important part of learning to make sense of the physical world. Mathematically inspired reasoning is foundational to the way physicists make sense of the natural world and math is often referred to as the language of physics. Students rarely understand the relationships between the physical quantities in the way their instructors hope they will. There is often a disconnect between the specialized way we use mathematics in physics and the broad spectrum of processes that students learn to master as they progress through the pre-college mathematics curriculum. We are often surprised by how little math our students are able to use in physics, despite successful performance in their previous math classes. Much of the reasoning used in introductory physics is borrowed from mathematics that is taught in middle school and early high school (facility and practice with integers, fractions and ratios, multiplication and division using symbolic representations, manipulation of linear equations, analyzing right triangles.) But physics is a very different context, with confounding factors that often render the mathematics opaque to the learner. In this talk, I will discuss the specific ways in which physicists' use of mathematics differs from what many students acquired in their math classes. I will discuss how a weak mastery of conceptualizing fundamental mathematical operations interferes with students' ability to make sense in physics, and can carry over into difficulties with subsequently more abstract reasoning at higher levels. I will also offer suggestions for ways in which instructors can be more cognizant of (and transparent about) their specialized use of mathematics, thereby helping their students to effectively use mathematics for making sense of the physics they are learning.

10:24AM P20.00005 Student reasoning about ratio and proportion in introductory physics¹, ANDREW BOUDREAUX, Western Washington University — To many students, introductory physics must seem a fast-moving parade of abstract and somewhat mysterious quantities. Most such quantities are rooted in proportional reasoning. Using ratio, physicists construct the force experienced by a unit charge, and attach the name electric field, or characterize a motion with the velocity change that occurs in a unit time. While physicists reason about these ratios without conscious effort, students tend to resort to memorized algorithms, and at times struggle to match the appropriate algorithm to the situation encountered. Although the term “proportional reasoning” is prevalent, skill in reasoning with these ratio quantities is neither acquired nor applied as a single cognitive entity. Expert ability seems to be characterized by the intentional use of a variety of components, or elements of proportional reasoning, by a fluency in shifting from one component to another, and by a skill in selecting from among these components. Based on this perspective, it is natural to expect students to develop proportional reasoning ability in fits and starts as various facets are acquired and integrated into existing understandings. In an ongoing collaboration between Western Washington University, New Mexico State University, and Rutgers, we are attempting to map the rich cognitive terrain of proportional reasoning, and to use our findings to guide the design of instruction that develops fluency. This talk will present a provisional set of proportional reasoning components, along with research tasks that have been developed to measure student ability along these components. Student responses will be presented as evidence of specific modes of thinking. The talk will conclude with a brief outline of our approach to improving student understanding.

Wednesday, February 29, 2012 8:00AM - 11:00AM — Session P21 DCMP: Superconductivity: Electronic Structure of Cuprates 254A

8:00AM P21.00001 Co-existence of spin fluctuation and superconductivity in electron doped cuprate $\text{Pr}_{1-x}\text{LaCe}_x\text{CuO}_4$, DONGJOON SONG, S.R. PARK, CHUL KIM, S.K. CHOI, W.S. JUNG, Y.Y. KOH, Y.K. KIM, Yonsei University, Rep. of Korea, H. EISAKI, Y. YOSHIDA, AIST, Japan, C. KIM, Yonsei University, Rep. of Korea — Even though spin fluctuation has been proposed to be as the pairing glue in the cuprate high temperature superconductivity, there is lack of a clear evidence for its coupling to electron. One of the reasons is that, for hole doped cuprates, both anti-ferromagnetism (AFM) and recently proposed charge ordering effects due to Fermi surface nesting occur in the same region of the momentum space (anti-nodal region). On the other hand, electron doped cuprates are known to have the pseudo gap effect at hot spots from AFM band renormalization. This fact makes it advantageous to investigate electron doped cuprates for the spin fluctuation issue. We performed ARPES studies on superconducting electron doped cuprates PLCCO ($x=0.1, 0.15, 0.18$) to investigate the relation between the spin fluctuation and superconductivity. We observe pseudo gap for all the dopings, which indicates that the short range AFM ordering survives far away from the AFM phase boundary. This coincidence of the short range AFM and superconductivity even in the over doped state may support the spin fluctuation scenarios at least in the electron doped side.

8:12AM P21.00002 Evidence for the coexistence of antiferromagnetism and superconductivity in the electron-doped infinite-layer cuprate $\text{Sr}_{1-x}\text{La}_x\text{CuO}_2$ from ARPES, JOHN HARTE, DANIEL SHAI, ERIC MONKMAN, YUEFENG NIE, DARRELL SCHLOM, Cornell University, LUIGI MARITATO, University of Salerno, KYLE SHEN, Cornell University — The asymmetry between hole doping and electron doping of cuprates has major implications for theories of high- T_c superconductivity, yet the vast majority of our knowledge of electron-doped cuprates originates from the $\text{Re}_{2-x}\text{Ce}_x\text{CuO}_4$ (RCCO) materials. One salient feature of electron doping is the robustness of antiferromagnetism, but at present it has not been established whether this is intrinsic to the electron-doped CuO_2 plane or idiosyncratic to the RCCO family. Here we report high-resolution *in situ* angle-resolved photoemission spectroscopy measurements of superconducting $\text{Sr}_{1-x}\text{La}_x\text{CuO}_2$ (SLCO) thin films grown by molecular beam epitaxy. The observed electronic structure exhibits many features consistent with (π, π) scattering, and the clear observation of such scattering in this material demonstrates that strong antiferromagnetism is generic to the electron-doped CuO_2 plane. Furthermore, the (π, π) order in SLCO is sufficiently strong to fully gap the nodal portion of the Fermi surface, leaving only electron pockets at $(\pi, 0)$; these pockets are gapped by the coexisting (presumably d-wave) superconductivity. This offers a simple explanation for the many reports of s-wave superconductivity in this material.

8:24AM P21.00003 Electronic structure modulations in the stripe phase of $\text{La}_{1.475}\text{Nd}_{0.4}\text{Sr}_{0.125}\text{CuO}_4$, ANDREW ACHKAR, University of Waterloo, FEIZHOU HE, Canadian Light Source, RONNY SUTARTO, University of British Columbia, JOCHEN GECK, Leibniz Institute for Solid State and Materials Research IFW Dresden, HARRY ZHANG, YOUNG-JUNE KIM, University of Toronto, DAVID HAWTHORN, University of Waterloo — A prevailing description of the stripe phase in underdoped cuprate superconductors is that the charge carriers (holes) phase segregate into hole rich regions that form anti-phase boundaries between regions of anti-ferromagnetic order. I will present resonant elastic x-ray scattering measurements of stripe-ordered $\text{La}_{1.475}\text{Nd}_{0.4}\text{Sr}_{0.125}\text{CuO}_4$ at the Cu $L_{3,2}$ and O K absorption edges that point to an alternate interpretation of the stripe phase. Analysis of the energy dependence of the scattering intensity reveals that the dominant feature of the charge density wave state is a spatial modulation in the energies of Cu $3d$ and O $2p$ states rather than the large modulation of the valence (charge density) envisioned in the common stripe paradigm. These energy shifts are interpreted as a spatial modulation of the electronic structure, possibly involving a modulation of the Cu $3d$ – O $2p$ hopping, t_{pd} , the onsite Coulomb repulsion, U_{dd} , and other local electronic structure parameters. This result may point towards a valence-bond-solid interpretation of the stripe phase, where translational symmetry can be broken with minimal modulation of the charge density.

8:36AM P21.00004 Quantum Oscillations in a π -Striped Superconductor, MIRSAEED ZELLI, CATHERINE KALLIN, McMaster University, JOHN BERLINSKY, McMaster University and Perimeter Institute for Theoretical Physics — Within Bogoliubov-de Gennes theory, a semiclassical approximation is used to calculate the Fermi surface area associated with quantum oscillations in a model of a π -striped superconductor, where the d-wave superconducting order parameter oscillates spatially with zero average value. This system has a non-zero density of particle-hole states at the Fermi energy, which form Landau-like levels in the presence of a magnetic field. The oscillation frequency found for large pairing interaction, for π -stripes with period 8, is close to that reported for experimental measurements in the cuprates. A comparison is made of this theory to data for quantum oscillations in the specific heat measured by Riggs et al.

8:48AM P21.00005 Density-functional theory calculation of Fermi surface in stripe ordered $\text{YBa}_2\text{Cu}_3\text{O}_{6.5}$, SIMON BLACKBURN, MICHEL COTE, University of Montreal — High temperature superconductors (HTSC) attract a lot of interests since their discovery in 1986. More recently, observations of quantum oscillations in underdoped $\text{YBa}_2\text{Cu}_3\text{O}_{6.5}$ (YBCO6.5) at a low frequency suggested a small pocket constitute the Fermi surface (Doiron-Leyraud et al. Nature 447, 565 (2007)). In this work, we present results of density-functional theory (DFT) calculations of YBCO electronic structure. In order to better represent the electron-electron interaction, we add an on-site repulsion term (Hubbard term) on the copper d-orbitals (DFT+U). This method is known to improve DFT calculations for Mott insulators like La_2CuO_4 and $\text{YBCO}_{6.0}$ since the Hubbard term favors an anti-ferromagnetic ground state. Using this method, we compare various magnetic states calculated with different values of the Hubbard term U. Our results suggest that an atom-centered stripe, similar to the one found in $\text{La}_{1.875}\text{Sr}_{0.125}\text{CuO}_4$ (Tranquada et al. Nature 375 561 (1995)), is consistent with the presence of a Fermi pocket of the size reported in the experiments. We further show that the size of the pocket and the nature of the carriers (electrons or holes) can be varied with pressure suggesting a way to test this hypothesis.

9:00AM P21.00006 Kinetics-Driven Superconducting Gap in Underdoped Cuprate Superconductors Within the Strong-Coupling Limit¹, WEI KU, YUCEL YILDIRIM, CMPMSD, Brookhaven National Laboratory — A generic theory [1] of the quasiparticle superconducting gap in underdoped cuprates is derived in the strong-coupling limit, and found to describe the experimental “second gap” in absolute scale. In drastic contrast to the standard pairing gap associated with Bogoliubov quasiparticle excitations, the quasiparticle gap is shown to originate from anomalous kinetic (scattering) processes, with a size unrelated to the pairing strength. Consequently, the k dependence of the gap deviates significantly from the pure $d_{x^2-y^2}$ wave of the order parameter. Our study reveals a new paradigm for the nature of the superconducting gap, and is expected to reconcile numerous apparent contradictions among existing experiments and point toward a more coherent understanding of high-temperature superconductivity.

¹Work supported by DOE DE-AC02-98CH10886

9:12AM P21.00007 Recent ARPES study on extremely underdoped LSCO system, YU HE, Department of Applied Physics, Stanford University, MAKOTO HASHIMOTO, SLAC National Accelerator Laboratory, SUNG-KWAN MO, RUIHUA HE, Advanced Light Source, LBNL, YOICHI ANDO, Department of Quantum Functional Materials, Institute of Scientific and Industrial Research, SEIKI KOMIYA, Central Research Institute of Electric Power Industry, ZHI-XUN SHEN, Department of Applied Physics, Stanford University — It has been widely accepted that Mott physics plays an important role in how superconductivity develops in high T_c cuprates. However, only a few in the family can reach to deeply underdoped region where Mott physics truly dominates, where the “pseudogap” is entirely disentangled from superconducting gap. Being an important compound to tackle this issue, extremely underdoped $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$ samples were systematically investigated through ARPES experiments. The doping dependence of Gaussian envelope at higher binding energy suggests strong polaronic contribution to the near Fermi level coherent feature. In complementary to previous observation of nodal gap in semiconducting LSCO, we found the Fermi surface to be fully gapped over wide range in the phase diagram in accordance with transport measurements. By comparing the marginal Fermi liquid model with momentum/temperature dependent MDC width analysis, we will extend our discussion on the intriguing connections between the nodal gap, polaronic excitation and “pseudogap” in this system.

9:24AM P21.00008 One gap, two gaps, and universality in high temperature superconductors, JUNJING ZHAO, University of Illinois at Chicago, UTPAL CHATTERJEE, MIKE NORMAN, Argonne National Lab, MOHIT RANDERIA, Ohio State University, JUAN CARLOS CAMPUZANO, University of Illinois at Chicago — A dramatic change in energy gap anisotropy upon reducing carrier concentration has often been observed in the cuprate high temperature superconductors (HTSC). A simple d-wave gap in materials with the optimal T_c evolves with underdoping into a ?two-gap? structure, with different dependences in different regions of momentum space. It is tempting to associate the large antinodal gap with a second order parameter distinct from d-wave superconductivity. We use angle-resolved photoemission spectroscopy (ARPES) to show that this two-gap behavior, and the concomitant destruction of well defined electronic excitations, are not universal features of HTSC, and depend sensitively on how the underdoped materials are prepared. Depending on cation substitution, underdoped crystals either show two-gap behavior or not. In contrast, many characteristics of HTSC like the superconducting dome (T_c versus doping), nodal quasiparticles, antinodal gap that decreases monotonically with doping, and the pseudogap, are present in all samples, irrespective of whether they exhibit two-gap behavior or not. Our results imply that universal aspects of high T_c superconductivity are insensitive to differences in the electronic states in the antinodal region of the Brillouin zone.

9:36AM P21.00009 Imaging Doped Holes in a Cuprate Superconductor with High-Resolution Compton Scattering, B. BARBIELLINI, Northeastern U. (NU), Y. SAKURAI, M. ITOU, JASRI, SPring-8, P.E. MIJNAREND, NU and Delft University of Technology, R.S. MARKIEWICZ, NU, S. KAPRZYK, NU and AGH Krakow, J.-M. GILLET, Ecole Centrale Paris, S. WAKIMOTO, Quantum Beam Science Directorate, Japan Atomic Energy Agency, M. FUJITA, Tohoku University, S. BASAK, Y.J. WANG, W. AL-SAWAI, H. LIN, A. BANSIL, NU, K. YAMADA, Tohoku University — The high-temperature superconducting cuprate $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$ (LSCO) shows several phases ranging from antiferromagnetic insulator to metal with increasing hole doping. To understand how the nature of the hole state evolves with doping, we have carried out high-resolution Compton scattering measurements at room temperature together with first-principles electronic structure computations on a series of LSCO single crystals in which the hole doping level varies from the underdoped (UD) to the overdoped (OD) regime [1]. Holes in the UD system are found to primarily populate the O 2p_x/p_y orbitals. In contrast, the character of holes in the OD system is very different in that these holes mostly enter Cu d orbitals. High-resolution Compton scattering provides a bulk-sensitive method for imaging the orbital character of dopants in complex materials.

9:48AM P21.00010 Anisotropic quasiparticle scattering in overdoped La-based cuprate superconductors: An angle resolved photoemission study, JOHAN CHANG, EPFL Lausanne and Paul Scherrer Institut, Switzerland, MARTIN MAANSSON, YASMINE SASSA, CHRISTIAN MATT, ETH Zurich, Switzerland, OLOF GOTBERG, OSCAR TJERNBERG, KTH, Sweden, STEFAN PAILHES, University of Lyon, France, OLIVER LIPSCOMPE, STEPHEN HAYDEN, Bristol University, UK, MING SHI, LUC PATTHEY, Swiss light source, Paul Scherrer Institut, Switzerland, JOEL MESOT, EPFL Lausanne and Paul Scherrer Institut, Switzerland — High-temperature superconductivity remains one of the outstanding unresolved problems of condensed matter physics. In the cuprate superconductors, a central part of the problem is to understand the unusual normal state properties. Here we present a new angle resolved photoemission spectroscopy (ARPES) study on the normal state of overdoped La-based cuprates. The pseudogap phase is found to vanish in a quantum critical point x_c inside the superconducting dome. Momentum dependent quasiparticle scattering has been studied for doping concentrations larger than x_c . Comparison to angle-integrated bulk probes such as electrical transport measurements will be made.

10:00AM P21.00011 ARPES evidence for a unidirectional bond-direction order in La-based cuprates, RUI-HUA HE, ALS-Stanford, M. HASHIMOTO, Stanford, K. TANAKA, S.-K. MO, ALS, T. SASAGAWA, TIT, M. FUJITA, T. ADACHI, K. YAMADA, Y. KOIKE, Tohoku, Z. HUSSAIN, ALS, Z.-X. SHEN, Stanford — Lattice translational symmetry breaking has wide implications with a variety of emergent quantum phases of condensed matters. In cuprate superconductors, various types of shadow bands have been observed in ARPES as band replicas that are displaced from the main bands by specific wave vectors in momentum space, suggestive of the breaking of lattice translational symmetry in different forms. Shadow bands associated with a wave vector along the Cu-O bond direction, were recently observed in a Y-based cuprate, which are ascribed to the unique occurrence of oxygen ordering in the CuO chains of the material. In contrast, the shadow bands reported so far in other cuprates without CuO chains in their crystal structures are associated with some wave vectors all along the bond-diagonal direction and it remains controversial, in most cases, whether they are due to some orderings of primarily structural or electronic origins. Here we report the first clear observation of shadow bands in ARPES associated with a bond-direction wave vector in the La-based cuprates (without CuO chains). These shadow bands were observed under various polarization conditions over a wide doping range in $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$ and are associated with a unidirectional order. We will present a doping and temperature dependence study of this order and discuss the results in relation to the complementary bulk-sensitive scattering experiments on the same system.

10:12AM P21.00012 Synchrotron X-ray study reveals oxygen chains in $\text{HgBa}_2\text{CuO}_{4+\delta}$ ¹, WOJCIECH TABIS, University of Minnesota — X-ray scattering work shows that the double-layer high- T_c superconductors $\text{YBa}_2\text{Cu}_3\text{O}_{8+\delta}$ and $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{6+\delta}$ are intrinsically inhomogeneous [1-3], with short-range lattice modulations driven by oxygen dopants. $\text{HgBa}_2\text{CuO}_{4+\delta}$ (Hg1201) has a simpler (tetragonal) structure and the highest T_c (at optimal doping) among all single-layer cuprates. It is thus a very good candidate system to address the issue of charge modulations. Using synchrotron X-ray scattering and high-quality single crystals, we have observed a short-range lattice modulations in Hg1201. Careful analysis of the diffuse intensity pattern, and a study of the doping and temperature dependence, point toward the formation of local one-dimensional order in the form of uncorrelated oxygen chains in the charge-reservoir layer. The chains exist at intermediate and high doping, form along [100], and have typical lengths of 15-30 lattice constants [4].

10:24AM P21.00013 Doping dependent intrinsic line width of the Cu-O bond-stretching phonon with $\mathbf{q}=(0.25\ 0\ 0)$ in $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$, S.R. PARK, University of Colorado at Boulder, A. HAMANN, L. PINTSCHOVUS, KIT, D. LAMAGO, KIT; Laboratoire Leon Brillouin, CEA-Saclay, G. KHALIULLIN, MPI, M. FUJITA, K. YAMADA, Tohoku University, G.D. GU, J.M. TRAN-QUADA, Brookhaven National Laboratory, D. REZNIK, University of Colorado at Boulder — We have recently found that the charge inhomogeneities provide significant broadening in the Cu-O bond stretching phonon of $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$, and the line shape of the phonon at zone boundary is well reproduced by the simple model which takes charge inhomogeneous effect into account [1]. The question is, now, how large intrinsic line width of the phonon at $\mathbf{q}=(0.25\ 0\ 0)$, where the giant phonon softening and broadening exist [2], is apart from the charge inhomogeneous effect on the line width. In this talk, we will show the doping dependence of the intrinsic line width of the phonon from $x=0.05$ to $x=0.30$. Interestingly, the intrinsic line width as a function of doping follows the superconducting transition temperature. We will discuss relationship between the phonon and the superconductivity in $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$.

10:36AM P21.00014 Investigation of Fermi & Luttinger surfaces in $\text{Ca}_{2-x}\text{Na}_x\text{CuO}_2\text{Cl}_2$ using ARPES, SIMON BELL, San Jose State University, GEY-HONG GWEON, JIANQIAO MENG, UC Santa Cruz, K.H. KIM, H G LEE, Pohang University of Science & Technology, S.I. LEE, Seogang University — The electronic structure & occupancy of doped cuprate superconductors $\text{Ca}_{2-x}\text{Na}_x\text{CuO}_2\text{Cl}_2$ of various doping levels is probed using angle-resolved photoemission spectroscopy (ARPES). The Fermi surface investigated shows that the Luttinger sum rule involving only the Fermi surface fails to account for the particle sum rule. Instead, the Luttinger sum rule that involves both the Fermi surface and the Luttinger surface seems necessary. We argue that such a generalized sum rule indicates the importance of very strong electron correlations.

10:48AM P21.00015 The electronic structure of tetragonal CuO, SIMON MOSER, Ecole Polytechnique Federale de Lausanne, Advanced Light Source, LUCA MORESCHINI, Advanced Light Source, DAVIDE INNOCENTI, University of Rome Tor Vergata, YOUNG JUN CHANG, AARON BOSTWICK, ELI ROTENBERG, Advanced Light Source, MARCO GRIONI, Ecole Polytechnique Federale de Lausanne — The cupric oxide CuO exhibits an insulating ground state with a correlation-induced charge-transfer gap and antiferromagnetism. It is, in principle, the most straightforward parent compound of the doped cuprates, and therefore has been theoretically studied as a model material for high temperature superconductivity. Bulk CuO crystallizes in a low-symmetry monoclinic form, in contrast to the rocksalt structure typical of late 3d transition metal monoxides. It was recently synthesized by epitaxial growth on SrTiO_3 substrates in a higher symmetry tetragonal structure with elongated c-axis (Siemons et al. PRB 79, 2009). Extrapolating the behavior of other 3d transition metal monoxides, this phase of CuO is predicted to have a much higher Neel temperature than its bulk counterpart. At beamline 7 of the Advanced Light Source, we have grown tetragonal CuO thin films by pulsed laser deposition and investigated their electronic structure by angle-resolved photoelectron spectroscopy (ARPES). These measurements represent the first mapping of the band structure of this new material, not available in bulk phase, and will serve as a reference point for future doping experiments.

Wednesday, February 29, 2012 8:00AM - 10:48AM – Session P22 DMP DCOMP: Focus Session: Fe-based Superconductivity - Fe(Te,Se) 254B

8:00AM P22.00001 Electronic disorder and magnetic-field-induced superconductivity enhancement in $\text{Fe}_{1+y}(\text{Te}_{1-x}\text{Se}_x)$, JIN HU, TIJIANG LIU, BIN QIAN, ZHIQIANG MAO, Department of Physics and Engineering Physics, Tulane University — The iron chalcogenide $\text{Fe}_{1+y}(\text{Te}_{1-x}\text{Se}_x)$ superconductor system exhibits a unique electronic and magnetic phase diagram distinct from those seen in iron pnictides: bulk superconductivity does not appear immediately following the suppression of long-range $(\pi,0)$ AFM order. Instead, an intermediate phase with weak charge carrier localization appears between AFM order and bulk superconductivity (Liu et al., Nat. Mater. 9, 719 (2010)). In this talk, we report our recent studies on the relationship between the normal state and superconducting properties in $\text{Fe}_{1+y}(\text{Te}_{1-x}\text{Se}_x)$. We show that the superconducting volume fraction V_{SC} and normal state metallicity significantly increase while the normal state Sommerfeld coefficient γ and Hall coefficient R_H drop drastically with increasing Se content in the underdoped superconducting region. Additionally, V_{SC} is surprisingly enhanced by magnetic field in heavily underdoped superconducting samples. The implications of these results will be discussed. Our analyses suggest that the suppression of superconductivity in the underdoped region is associated with electronic disorder caused by incoherent magnetic scattering arising from $(\pi,0)$ magnetic fluctuations.

8:12AM P22.00002 The structure of the oxygen-annealed $\text{Fe}_{1.08}\text{Te}_{0.55}\text{Se}_{0.45}\text{O}_x$ superconductor, HEFEI HU, JIAN-MIN ZUO, MAO ZHENG, JAMES N. ECKSTEIN, WAN KYU PARK, LAURA H. GREENE, University of Illinois at Urbana-Champaign, JINSHENG WEN, ZHIJUN XU, ZHIWEI LIN, QIANG LI, GENDA GU, Brookhaven National Laboratory — Effect of oxygen annealing on the iron chalcogenide superconductor with excess Fe is studied and structure change is investigated by using electron microscopy. The as-grown single crystal $\text{Fe}_{1.08}\text{Te}_{0.55}\text{Se}_{0.45}$ with the tetragonal PbO-type structure is non-superconducting owing to the excess Fe. Superconductivity is induced after oxygen annealing with an onset and zero resistance transition temperature around 14.5 K and 11.5 K, respectively. The oxygen doping is evidenced by electron energy loss spectroscopy, and accompanied by improved homogeneity in the remaining PbO-type phase as well as an increase in the $L_{3/2}$ intensity ratio of the Fe- $L_{2,3}$ edge, indicating an increase in Fe valence. Local phase transformation from the tetragonal PbO-type phase to the hexagonal NiAs-type phase is also observed after oxygen annealing.

8:24AM P22.00003 Unusual Persistence of Superconductivity Against High Magnetic Fields in the Strongly-Correlated Iron-Chalcogenide Film FeTe:O_x , IVO DIMITROV, WEIDONG SI, WEI KU, SU-JUNG HAN, QIANG LI, Brookhaven National Laboratory — We report an unusual persistence of superconductivity against high magnetic fields in the iron chalcogenide film FeTe:O_x below 2.52 K. Instead of saturating like a mean-field behavior with a single order parameter, the measured low-temperature upper critical field increases progressively, suggesting a large supply of superconducting states accessible via magnetic field or low-energy thermal fluctuations. We demonstrate that superconducting states of finite momenta can be realized within the conventional theory, despite its questionable applicability. Our findings reveal a fundamental characteristic of superconductivity and electronic structure in the iron-based superconductors.

8:36AM P22.00004 Growth conditions for pulsed laser deposited FeTeO_y superconducting thin films and observation of a low temperature structural transition¹, LAHIRU NARANGAMMANA, University of Connecticut, Storrs, CT, YUEFENG NIE, Cornell University, Ithaca, NY, JOSEPH BUDNICK, University of Connecticut, Storrs, CT, XUERONG LIU, JOHN HILL, GENDA GU, Brookhaven National Laboratory, Upton, NY, CHRISTOF NIEDERMAYER, Paul Scherrer Institut Villigen, PSI, Switzerland, BARRETT WELLS, University of Connecticut, Storrs, CT — FeTe thin films were grown by pulsed laser deposition and oxygen was incorporated to make superconducting FeTeO_y . The Te concentration of the films was highly dependent on growth temperature, due to the evaporation of Te at higher temperatures. Films grown using a porous, unreacted Fe/Te target showed islanding, an open structure, and a strong c axis texture. Oxygen could be easily added or removed by low temperature anneals. Films grown using a dense, polycrystalline conglomerate for a target and a short target-substrate distance had better epitaxy, and were dense, continuous and smooth. Post processing of oxygen on these films was difficult, but we were able to control oxygen concentration during growth using a small oxygen partial pressure. Initial low temperature diffraction studies of these films using both x-rays and neutrons indicate a sudden change in c axis lattice parameter at the superconducting T_C , but continued exposure of the beam drives out oxygen. Dense epitaxial films should allow for studying this phase change.

¹Supported by DOE through contact # DE-FG02-00ER45801(Uconn).

8:48AM P22.00005 Growth and oxygen doping of thin film FeTe by Molecular Beam Epitaxy¹, MAO ZHENG, CAN ZHANG, HEFEI HU, JIAN-MIN ZUO, JAMES ECKSTEIN, University of Illinois Urbana-Champaign — FeTe is isomorphic to FeSe , a representative of the 11 family of iron based superconductors. While not a superconductor itself, FeTe , particularly in thin film form, undergoes a superconducting transition when doped with oxygen. In this presentation, we will discuss the growth of FeTe by MBE and various schemes we used to dope the samples. Evidence from our investigation suggests that FeTe films are doped via an oxygen diffusion process which is strongly activated by temperature.

¹This material is based upon work supported as part of the Center of Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DE-AC0298CH10

9:00AM P22.00006 Suppression of superconductivity in Fe chalcogenides by annealing: A reverse effect to pressure, PENG TONG, DESPINA LOUCA, Department of Physics, University of Virginia, ANNA LLOBET, Lujan Neutron Scattering Center, Los Alamos National Laboratory, JIAQIANG YAN, Department of Materials Science and Engineering, University of Tennessee, RYOTARO ARITA, Department of Applied Physics, University of Tokyo, and JST TRIP — Superconductivity in $\text{FeTe}_{1-x}\text{Se}_x$ can be controlled by annealing, in the absence of extrinsic influences. Using neutron diffraction, we show that T_C sensitively depends on the atomic configurations of the Te and Se ions. Low temperature annealing not only homogenizes the Te and Se ion distribution as previously observed, it suppresses T_C because of changes in the chalcogen ions' z-parameter. In particular, the height of Te from the Fe basal plane is much reduced while that for Se shows a modest increase. These trends are reverse of the effects induced by pressure.

9:12AM P22.00007 Phase diagram and oxygen annealing effect of $\text{FeTe}_{1-x}\text{Se}_x$ iron-based superconductor, YASUNA KAWASAKI, KEITA DEGUCHI, SATOSHI DEMURA, HIROYUKI OKAZAKI, TOSHINORI OZAKI, TAKAHIDE YAMAGUCHI, HIROYUKI TAKEYA, YOSHIHIKO TAKANO, National Institute for Materials Science — Phase diagrams of as-grown and O_2 -annealed $\text{FeTe}_{1-x}\text{Se}_x$ decided by magnetic susceptibility measurement were obtained. For as-grown samples, the antiferromagnetic order was fully suppressed in the region of $x \geq 0.15$ and superconductivity appeared at $x \geq 0.1$. However, bulk superconductivity emerged at only $x = 0.5$. Interestingly, for O_2 -annealed samples, complete suppression of the magnetic order and bulk superconductivity was observed at $x \geq 0.1$. We found that O_2 annealing induces the bulk superconductivity for $\text{FeTe}_{1-x}\text{Se}_x$. The O_2 probably play a key role of a suppression of the magnetic order and appearance of bulk superconductivity.

9:24AM P22.00008 Magnetism and superconductivity in $\text{Pd}_{1-x}\text{Fe}_x\text{Te}$, AMAR KARKI, SHANE STADLER, DANA BROWNE, JIANNENG LI, RONGYING JIN, Louisiana State University — PdTe is a long-known superconductor but its physical properties are almost unknown. We have recently studied its basic physical properties in both normal and superconducting states. While FeTe forms different crystallographic structure and is known to form spin density wave below $T_N = 70$ K, we have successfully synthesized $\text{Pd}_{1-x}\text{Fe}_x\text{Te}$ with x from 0 to 1. By measuring its electrical and magnetic properties, we establish the phase diagram of $\text{Pd}_{1-x}\text{Fe}_x\text{Te}$ for the first time. With increasing x, we found that T_C is quickly suppressed. Ferromagnetism appears for the samples with $x \geq 0.02$. For $0.25 \leq x \leq 1.0$, the system exhibits antiferromagnetic ordering with T_N increasing with x. This is a prototype system for studying the interplay between superconductivity and magnetism.

9:36AM P22.00009 $\text{FeSe}_{0.5}\text{Te}_{0.5}$ thin films with critical current density above $1\text{MA}/\text{cm}^2$, WEIDONG SI, SU JUNG HAN, IVO DIMITROV, QIANG LI, Brookhaven National Laboratory — High quality $\text{FeSe}_{0.5}\text{Te}_{0.5}$ thin films have been prepared on various substrates, such as SrTiO_3 , LaAlO_3 and YSZ, some with buffer layers. T_C 's as high as 20K with superconducting transition widths of about 1K were obtained. These T_C 's are much higher than those of bulk $\text{FeSe}_{0.5}\text{Te}_{0.5}$ ($\sim 15\text{K}$). Our films carry high critical current densities J_c 's (above $1\text{MA}/\text{cm}^2$) at liquid helium temperature. These films hold J_c 's above $1 \times 10^5 \text{A}/\text{cm}^2$ and very low J_c anisotropies (< 3) under magnetic fields as high as 30T at 4.2K. We have also prepared textured $\text{FeSe}_{0.5}\text{Te}_{0.5}$ thin films on a buffered metal template with results similar to the ones mentioned above. This shows that iron chalcogenides have a very promising future for high-field applications at liquid helium temperatures. Pinning force analysis indicates the presence of a point defect flux-pinning mechanism, suggesting a straightforward approach to conductor optimization.

9:48AM P22.00010 London penetration depth measurements of $\text{Fe}_{1+y}(\text{Te}_{1-x}\text{Se}_x)$ single-crystals at ultra-low temperatures¹, ANDREI DIACONU, Department of Physics, AMRI, University of New Orleans, New Orleans, Louisiana 70148, USA, JIN HU, TIJIANG LIU, BIN QIAN, ZHIQIANG MAO, Department of Physics and Engineering Physics, Tulane University, New Orleans, Louisiana 70118, USA, LEONARD SPINU, Department of Physics, AMRI, University of New Orleans, New Orleans, Louisiana 70148, USA — The evolution of the superconducting properties as derived from the in-plane penetration depth measurements as a function of temperature in single crystals of $\text{Fe}_{1.02}(\text{Te}_{1-x}\text{Se}_x)$, with Se concentration spanning from 25% to 45%, was studied using a tunnel diode oscillator technique in a dilution refrigerator down to a temperature of 30mK. By using a set of two mutually coupled planar inductors parallel to the ab plane of the samples, the probing ac field is uniform across the sample along the c axis making the variation in susceptibility solely due to in-plane currents while significantly increasing the signal to noise ratio compared to usual inductors used in similar experiments. The evolution of the topology of the superconducting gap from underdoped to optimally doped samples, as derived from exponential and power law behavior of λ_{ab} at low temperatures, is presented.

¹Work supported by the DOD ARO under Grant No. W911NF0910530

10:00AM P22.00011 Electron-phonon coupling in layered FeSe compounds¹, TIMUR BAZHIROV, MARVIN L. COHEN, University of California, Berkeley — Iron-chalcogenide superconductors, showing many characteristic physical properties, can serve as a model materials to study the electron-pairing mechanism for all iron-based superconductivity. Layered iron-chalcogenide systems including single layer FeSe, bulk FeSe, K-intercalated FeSe, were studied using first principle pseudopotential density functional based approach. Electronic structure, vibrational properties and electron-phonon coupling strength were studied for the cases with and without iron magnetic moment ordering. The latter is incorporated using local spin density approximation. Our results show significant changes to electronic structure resulting in much higher electron-phonon coupling for spin-resolved configurations. Electron-phonon matrix elements for particular phonon mode of A_{1g} symmetry are showing dramatic increase. Superconducting transition temperature estimates based on McMillan's equation are showing values significantly higher than previously reported, but still not high enough to account for the experimental results.

¹This work was supported by National Science Foundation Grant No. DMR10-1006184, the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by the Lawrence Berkeley National Laboratory

10:12AM P22.00012 Magnetism and superconductivity in modulated FeTe systems., KALUM PALANDAGE, Trinity College, Hartford, CT, GAYANATH FERNANDO, University of Connecticut, Storrs, CT, ARMEN KOCHARIAN, California State University, Los Angeles, CA — We examined the interplay between magnetism and superconductivity by monitoring the non-superconducting chalcogenide FeTe. We studied its transitions under insertion of oxygen, iron and vacancies of iron using spin-polarized band structure methods (LSDA with GGA) starting from the collinear and bicollinear magnetic arrangements. A supercell with 8-Fe and 8-Te atoms was used so that it can capture local changes in magnetic moments. The calculated values of magnetic moments agree well with available experimental data while some of the modulations lead to significant changes in the bicollinear or collinear magnetic moments/arrangements. The total energies of these systems indicate that the collinear-derived structure is more favorable prior to a possible superconducting transition.

10:24AM P22.00013 Revealing the dual nature of magnetism in iron pnictides and iron chalcogenides using x-ray emission spectroscopy, HLYNUR GRETTARSSON, ANDREEA LUPASCU, YOUNG-JUNE KIM, WENLONG WU, STEPHEN R. JULIAN, University of Toronto, JUNGHO KIM, DIEGO CASA, THOMAS GOG, Argonne National Laboratory, ZHI JUN XU, JIN SHENG WEN, GENDA GU, Brookhaven National Laboratory, R.H. YUAN, Z.G. CHEN, NAN-LIN WANG, Chinese Academy of Sciences, SEUNGHYUN KHIM, KEE HOON KIM, Seoul National University, IGNACE JARRIGE, SHINICHI SHAMOTO, M. ISHIKADO, Japan Atomic Energy Agency, JIUN-HAW CHU, IAN RANDAL FISHER, Stanford University — We present a Fe $K\beta$ x-ray emission spectroscopy study of local magnetic moments in various iron-based superconductors in their paramagnetic phases. Our findings show that a local magnetic moments exists in all samples studied: PrFeAsO , $\text{Ba}(\text{Fe}, \text{Co})_2\text{As}_2$, LiFeAs , $\text{Fe}_{1+x}(\text{Te}, \text{Se})$, and $\text{A}_2\text{Fe}_4\text{Se}_5$ (where $\text{A} = \text{K}, \text{Rb}, \text{and Cs}$). The moment size is independent of temperature or carrier concentration, but varies significantly across different families. Specifically, all iron pnictides samples have local moments of about $1\mu_B/\text{Fe}$, while FeTe and $\text{K}_2\text{Fe}_4\text{Se}_5$ families have much larger local moments of $\sim 2\mu_B/\text{Fe}$ and $\sim 3.3\mu_B/\text{Fe}$, respectively. Our results illustrate the importance of multi-orbital physics in describing magnetism of these compounds.

10:36AM P22.00014 Electronic Structure of $\text{A}_y\text{Fe}_{2-x}\text{Se}_2$ from First Principles¹, CHAO CAO, JIANHUI DAI, Hangzhou Normal University — The newly discovered $\text{A}_y\text{Fe}_{2-x}\text{Se}_2$ iron-selenide material family was studied in a series of first-principles simulations. The electronic structure and magnetic properties of possible vacancy-superstructure phases $\text{A}_2\text{Fe}_3\text{Se}_4$ and $\text{A}_2\text{Fe}_4\text{Se}_5$, as well as the possible parental phase of superconductivity AFe_2Se_2 were examined. It was discovered that AFe_2Se_2 ground state is a SDW-AFM metal without hole Fermi-surface, thus FS-nesting is absent and its magnetism is very likely to be local moment; $\text{A}_2\text{Fe}_3\text{Se}_4$ is a Mott insulator with SDW-AFM magnetism; $\text{A}_2\text{Fe}_4\text{Se}_5$ shows block-spin AFM ground state with $400\sim 600$ meV band gap. Under high pressure, the $\text{A}_2\text{Fe}_4\text{Se}_5$ phase exhibits rich and exotic physical properties.

Wednesday, February 29, 2012 8:00AM - 11:00AM – Session P23 DCMP: Superconductivity Theory II: p-wave, chiral, and topological 255

8:00AM P23.00001 Spin-orbit induced mixed-parity pairing in Sr_2RuO_4 : a self-consistent quantum many-body analysis, JOHN DEISZ, TIM KIDD, University of Northern Iowa — The unusual superconducting state in Sr_2RuO_4 has long been viewed as being analogous to a superfluid state in liquid ^3He . Nevertheless, calculations based on a pure odd-parity state are presently unable to completely reconcile the properties of Sr_2RuO_4 . Using a self-consistent quantum many-body scheme that employs realistic parameters, we are able to model several signature properties of the normal and superconducting states of Sr_2RuO_4 such as the weak temperature dependence of the spin susceptibility below T_c . However, we find that the dominant component of the model superconducting state is of even parity and closely related to superconducting state for the high- T_c cuprates although a smaller odd-parity component is induced by spin-orbit coupling. This mixed parity pairing state provides an alternative scenario for understanding the complex phenomena measured in Sr_2RuO_4 .

8:12AM P23.00002 Spin and charge collective excitations in the multiband superconductivity of Sr_2RuO_4 , SUK BUM CHUNG, SRINIVAS RAGHU, STEVE KIVELSON, Stanford University — Multiband superconductors with weak interband pair scattering can support soft collective modes. In the case of spin-singlet superconductivity, interband pair scattering leads to fluctuations of the relative phase of the order parameter on the different bands. However, when the superconductivity is spin-triplet, the interband pair scattering gives rise to fluctuations of both the relative phase and the relative spin on the different bands. One possible example of a multiband triplet superconductor is a recently proposed model [1] of the superconductivity in Sr_2RuO_4 in which the pairing occurs primarily on the two quasi-1D bands. We show that the collective excitations arising from relative spin fluctuations can lead to a double resonance peak in the presence of an oscillating magnetic field. We discuss how the presence or absence of such collective modes can yield clear information concerning the precise microscopic structure of the order parameter.

8:24AM P23.00003 Dynamics of domain walls in chiral p-wave superconductors¹, KIRILL SAMOKHIN, Brock University — Two-fold degeneracy of the ground state of chiral p-wave superconductors or superfluids with $k_x \pm ik_y$ order parameter makes it possible for domain walls separating regions of opposite chirality to exist. In addition to affecting the scattering spectrum in the bulk, the domain walls also carry localized low-energy fermionic quasiparticles, whose energy essentially depends on the Josephson phase difference between the domains. Dynamical properties of the domain walls are determined by the transitions between different quasiparticle states induced by the domain wall motion. We present a microscopic calculation of the viscous friction coefficient and the effective mass of the domain walls.

8:36AM P23.00004 Stability of topological defects in chiral superconductors: London theory¹, VICTOR VAKARYUK, Argonne National Lab — We examine thermodynamic stability of chiral domain walls and vortices – topological defects which can exist in chiral superconductors. Using London theory it is demonstrated that at sufficiently small applied and chiral fields the existence of domain walls and vortices in the sample is not favored and the sample's configuration is a single domain. The particular chirality of the single-domain configuration is neither favored nor disfavored by the applied field. Increasing the field leads to an entry of a domain wall loop or a vortex into the sample. Formation of a straight domain wall is never preferred in equilibrium. Values of the entry (critical) fields for both types of defects, as well as the equilibrium size of the domain wall loop, are calculated. The applicability of these results to Sr_2RuO_4 – a tentative chiral superconductor – is discussed.

8:48AM P23.00005 Intrinsic Hall effect in a multiband chiral superconductor¹, EDWARD TAYLOR, CATHERINE KALLIN, McMaster University — We identify an intrinsic, dissipationless Hall effect in multiband chiral superconductors in the absence of a magnetic field (i.e., an *anomalous* quantum Hall effect). Similarly to its analog in ferromagnets, this effect arises from inter-band transitions when time-reversal symmetry is spontaneously broken. We discuss the implications of this effect for the putative chiral p-wave superconductor, Sr_2RuO_4 , and show that it can be of the right order of magnitude to contribute significantly to the polar Kerr rotation observed in experiments, depending on the structure of the order parameter across the bands.

9:00AM P23.00006 Topologically protected surface Majorana arcs and bulk Weyl fermions in ferromagnetic superconductors¹, SUMANTA TEWARI, Department of Physics and Astronomy, Clemson University, Clemson, SC 29634, JAY SAU, Department of Physics, Harvard University, Cambridge, MA 02138 — A number of ferromagnetic superconductors have been recently discovered which are believed to be in the so-called “equal spin pairing” (ESP) state. In the ESP state the Cooper pairs condense forming order parameters $\Delta_{\uparrow\uparrow}, \Delta_{\downarrow\downarrow}$, which are decoupled in the spin-sector. We show that these 3D systems generically support topologically protected surface Majorana arcs and bulk Weyl fermions as gapless excitations. Similar protected low-energy exotic quasiparticles should also appear in the recently discovered non-centrosymmetric superconductors in the presence of a Zeeman field. The protected surface arcs can be probed by angle-resolved photoemission (ARPES) as well as fourier transform scanning tunneling spectroscopy (FT-STs) experiments.

9:12AM P23.00007 Thermodynamic signatures of half-quantum vortices in $p + ip$ Josephson junction arrays¹, GRAHAM KRAHN, UC Riverside, KIRILL SHTENGEL, Associate Professor of Physics, UC Riverside — A very interesting type of excitation in a chiral p-wave superconductor is a half-quantum vortex. As the name suggests, they carry half of a superconducting flux quantum, and are only possible in superconductors with spin-triplet pairing. An astonishing feature of these excitations is the presence of topologically protected Majorana zero modes. Single half-quantum vortices were recently discovered (J. Jang et al, Science **331**(6014): 186-188) in superconducting mesoscopic rings made of Sr_2RuO_4 , yet to this date they have not been observed in macroscopic samples. We propose a method for detecting half-quantum vortices in Josephson junction arrays, which could host a large number of these vortices. Contrary to a 3D setting, we argue that half-quantum vortices can be energetically preferable in quasi-2D chiral spin-triplet superconductors. As a result, half-quantum vortices rather than full vortices could drive a Berezinskii-Kosterlitz-Thouless transition (which manifests itself as a resistive transition). We propose to look for their signatures by comparing transition temperatures in $p + ip$ Josephson junction arrays in a transverse magnetic field in both unfrustrated and frustrated cases.

¹NSF DMR-0748925

9:24AM P23.00008 Scattering theory of chiral Majorana fermion interferometry¹, JIAN LI, Department of Theoretical Physics, University of Geneva, Switzerland, GENEVIÈVE FLEURY, CEA-Saclay, France, MARKUS BUTTIKER, Department of Theoretical Physics, University of Geneva, Switzerland — Using scattering theory, we investigate interferometers composed of chiral Majorana fermion modes coupled to normal metal leads. We advance an approach in which also the basis states in the normal leads are written in terms of Majorana modes. As a consequence the scattering at the junctions of the lead to the Majorana mode couples modes effectively only pair-wise irrespective of the number of normal scattering modes. We demonstrate that the charge current can also be expressed in terms of interference between pairs of Majorana modes. These two basic facts permit a treatment and understanding of current and noise signatures of chiral Majorana fermion interferometry in an especially elegant way. As a particular example of applications, in Fabry-Perot-type interferometers where chiral Majorana modes form loops, resonances (anti-resonances) upon such loops always lead to peaked (suppressed) Andreev differential conductances and negative (positive) cross-correlations originate purely from two-Majorana-fermion exchange. These investigations are intimately related to current and noise signatures of Majorana bound states.

¹Swiss NSF and the NCCR Quantum Science and Technology

9:36AM P23.00009 Probing Majorana fermions in one-dimensional topological superconductors using non-equilibrium transport: an open-quantum-system study, DIBYENDU ROY, CARLOS J. BOLECH, NAYANA SHAH, Department of Physics, University of Cincinnati, Cincinnati, Ohio 45221 — We study one-dimensional topological superconductors using an open-quantum-system approach based on Langevin equations. We go beyond a low-energy effective model of Majorana fermions, to derive different non-equilibrium transport properties exactly in these systems. The role of the coupling between the superconducting wire and metallic leads in physical experiments to detect Majorana bound states is also examined.

9:48AM P23.00010 Majorana End States of Au Wires in Proximity to $d_{x^2-y^2}$ -wave Superconductors, KAM TUEN LAW, LOK MAN WONG, Hong Kong University of Science & Technology — We propose a one dimensional DIII class Hamiltonian which respects time-reversal symmetry and supports zero-energy double Majorana end states. Single Majorana end states can appear if time-reversal symmetry is broken. Majorana fermions survive in the quasi-1D regime when multiple transverse sub-bands of the wire are occupied. More importantly, this model can be realized by inducing $d_{x^2-y^2}$ -wave superconductivity on a quantum wire with strong spin-orbit coupling. We suggest Au wires deposited on doped LSCO realize this topological superconducting phase. The energy scales of this set-up, an induced proximity gap of 10meV and the Rashba energy of 60meV, are two orders of magnitude larger than the corresponding energy scales in semiconductor-based proposals.

10:00AM P23.00011 Topological Josephson effect for arbitrary values of the tunnel coupling in the Kitaev model¹, FLAVIO NOGUEIRA, ILYA EREMIN, Institut für Theoretische Physik III, Ruhr-Universität Bochum, Universitätsstraße 150, 44801 Bochum, Germany — We investigate the Josephson effect for a setup with two lattice quantum wires featuring fused Majorana boundary modes at the tunnel junction. We show exactly that additional degeneracies occur when the size of the Josephson coupling attains a certain critical value, thus introducing additional energy level crossings. The physical consequences of these additional level crossings are discussed. It is shown that for this critical coupling the Andreev levels can be cast in the form $E_{m\sigma} = 2\sigma\sqrt{2}w \cos(\phi/6 - \pi m/3)$, where $m = -1, 0, 1$ and $\sigma = \pm 1$. The exact Josephson current exhibits the characteristic 4π periodicity along with additional features related to the extra crossings of Andreev levels at the critical value of the tunnel coupling.

10:12AM P23.00012 ABSTRACT WITHDRAWN —

10:24AM P23.00013 Single-particle off-diagonal long range order in $|Pf\rangle$ wave function for topological superconductors, OLEXEI MOTRUNICH, California Institute of Technology — We ask what can be glimpsed about a fermion system from a boson wave function obtained as the absolute value of the fermion wave function in the particle number basis. We consider examples of spinless p -wave superconductors in one and two dimensions and find that thus constructed wave function shows single-boson off-diagonal long range order when the fermion system is in the weak-coupling topological phase, but only pair-boson order in the strong-coupling non-topological phase. We discuss implications when such fermion states are used as factors in trial wave functions e.g. from slave-fermion construction.

10:36AM P23.00014 Topological Superconductivity in Spin-Orbit Coupled Bands, AARON FARRELL, TAMI PEREG-BARNEA, McGill University — Topological superconductors have nontrivial winding of their order parameter phase and are expected to support Majorana Fermions in their vortex cores. For this reason they have been sought after in the past couple of decades. Over the past few years, a new and promising route for realizing topological superconductors has opened due to recent advances in the field of topological insulators. The current proposals are based on semiconductor heterostructures. In the proposed devices, spin-orbit coupled bands are Zeeman split by a magnetic field and superconductivity is induced by proximity to a conventional superconductor. This leads to heterostructures of two or three layers. This talk will focus on the prospect of realizing a topological superconductor in materials with inherent spin-orbital coupling and an intrinsic tendency for superconductivity. The proposed device will allow simplification of recently suggested devices as the need for a superconducting layer will be eliminated.

10:48AM P23.00015 Theory of Superconductivity in Mesoscopic Systems¹, JIAWEI HUO, WEIQIANG CHEN, Department of Physics, The University of Hong Kong, Hong Kong, China, SRINIVAS RAGHU, Department of Physics, Stanford University, Stanford, CA, 94305, FUCHUN ZHANG, Department of Physics, The University of Hong Kong, Hong Kong, China — By using Bogoliubov-de Gennes (BdG) equations, we study superconducting (SC) states in a quasi 2-dimensional system of radius R . It is shown that no vortices exist in s -wave SC samples with $R < R_c \sim \xi(0)$, the $T = 0$ coherence length. We predict that chiral p -wave states exhibit superconductivity for $R < R_c$ only in the presence of a vortex with opposite chirality. This *reentrant* SC phase is a consequence of non-zero chirality of the pairing order parameter and implies the presence of chiral edge currents. Our study may be applied to sharply probing the pairing symmetry of unconventional superconductors.

Wednesday, February 29, 2012 8:00AM - 11:00AM – Session P24 FIAP: Fractional Quantum Hall Effect I 256

8:00AM P24.00001 Exploring the possibility of Universal Edge Physics in the Fractional Quantum Hall States¹, ZI-XIANG HU, RAVIN BHATT, XIN WAN, Princeton University, KUN YANG, Florida State University — The edge of a fractional quantum Hall (FQH) droplet is described by the chiral Luttinger liquid theory which predicts a universal power-law behavior in the current-voltage (I - V) characteristics when electrons tunneling into the FQH edge through a barrier, e.g., from a three-dimensional Fermi liquid. However, this universality has not been unambiguously observed in transport experiments in two-dimensional electron gases based on GaAs/GaAlAs heterostructures or quantum wells. One plausible cause is reconstruction of the fractional quantum Hall edge, which introduces non-chiral edge modes. The coupling between counterpropagating edge modes can modify the exponent of the I - V characteristics. By comparing the fractional quantum Hall states at the filling factor $\nu = 1/3$ in modulation-doped semiconductor devices and in graphene devices, we show that the GaAs-based FQH experiments are always in the edge reconstruction regime, whereas graphene-based systems have an experimental accessible parameter region where edge reconstruction can be avoided. This regime offers the possibility of the exploration of the universal edge tunneling exponent predicted by the chiral Luttinger liquid theory.

8:12AM P24.00002 Exploration of the Limits to Mobility in Two-Dimensional Hole Systems in C-Doped (001) GaAs/AlGaAs Quantum Wells¹, JOHN WATSON, Dept. of Physics and Birck Nano Center, Purdue University, W. Lafayette, IN, SUMIT MONDAL, Dept. of Physics, Purdue University, GEOFF GARDNER, Birck Nano Center and School of Materials Engineering, Purdue University, MICHAEL MANFRA, Dept. of Physics, Birck Nano Center, and Schools of Materials Engineering and Electrical and Computer Engineering, Purdue University — We report on the growth of a series of high mobility two-dimensional hole systems (2DHSs) in 20 nm (001) oriented GaAs/AlGaAs quantum wells and the analysis of possible scattering mechanisms. The hole density was controlled by changing the delta-doping setback and Al mole fraction and was measured at low temperature ($T = 300$ mK) after illumination with a red LED. We varied the density over a range from $2.0 \times 10^{10} \text{ cm}^{-2}$ to $1.9 \times 10^{11} \text{ cm}^{-2}$, and the mobility was observed to peak at an intermediate density of $6.5 \times 10^{10} \text{ cm}^{-2}$ where we report a new record $T = 300$ mK mobility of $2.3 \times 10^6 \text{ cm}^2/\text{Vs}$. We find that even when the density dependent effective mass is taken into account, remote and background impurity scattering cannot qualitatively explain the behavior of the mobility, in contrast with comparable 2DEGs. We discuss possible mechanisms leading to the observed non-monotonic density dependence of the mobility and the factors leading to our new record mobility.

8:24AM P24.00003 Effective Field Theory of Fractional Quantized Hall Nematics, MICHAEL MULLIGAN, Massachusetts Institute of Technology, CHETAN NAYAK, University of California at Santa Barbara and Station Q, SHAMIT KACHRU, Stanford University — We present a Landau-Ginzburg theory for a fractional quantized Hall nematic state and the transition to it from an isotropic fractional quantum Hall state. This justifies Lifshitz-Chern-Simons theory – which is shown to be its dual – on a more microscopic basis and enables us to compute a ground state wave function in the symmetry-broken phase. In such a state of matter, the Hall resistance remains quantized while the longitudinal DC resistivity due to thermally-excited quasiparticles is anisotropic. We interpret recent experiments by Xia et al. (cond-mat/1109.3219) at Landau level filling factor $\nu = 7/3$ in terms of our theory.

8:36AM P24.00004 Dipolar Bogolons: From Superfluids to Pfaffians, SIDDHARTH PARAMESWARAN, UC Berkeley, STEVEN KIVELSON, Stanford University, R. SHANKAR, Yale University, SHIVAJI SONDHI, Princeton University, BORIS SPIVAK, University of Washington — We study neutral fermionic ‘Bogolons’ which are quasiparticle excitations of gapped phases that arise due to fermion (BCS) pairing, such as superfluids, superconductors, and paired quantum Hall states. As we demonstrate, a naïve construction of a quasiparticle wavepacket by solving the mean-field BCS equations leads to a contradiction: there is a net electrical current *even when the group velocity vanishes*. Resolution of this paradox requires the computation of supercurrents in the wavepacket state, typically a complicated exercise in self-consistency. In this Letter we demonstrate that these corrections may be approximately calculated from correlations in the mean-field ground state, and lead to a divergence-free, dipolar current pattern associated with the quasiparticle. When Maxwell electrodynamics is included, as appropriate to a superconductor, this pattern is confined over a penetration depth. For paired quantum Hall states of composite fermions, the Maxwell term is replaced by a Chern-Simons term, which leads to a dipolar *charge* distribution, paralleling Read’s observation that composite fermions are neutral dipoles.

8:48AM P24.00005 Coulomb Oscillations in Antidots in the Integer and Fractional Quantum Hall Regimes¹, A. KOU, C.M. MARCUS, Harvard University, L.N. PFEIFFER, K.W. WEST, Princeton University — We present measurements of Coulomb oscillations as a function of both top gate and magnetic field in gate-defined, micron-scale antidots in the integer and fractional quantum Hall regimes. We find resistance oscillations at filling factors $\nu = 2, \nu = 1, \nu = 2/3$, and $\nu = 1/3$. At $\nu = 1$, we find the tunneling charge to be e and the presence of one edge. At $\nu = 2$, we also find the tunneling charge to be e and the presence of two edges. A generalized picture of Coulomb oscillations in the fractional quantum Hall regime suggests the presence of one charged edge at both $\nu = 1/3$ and $\nu = 2/3$. We find the tunneling charge at $\nu = 1/3$ to be $e/3$ but unexpectedly find the tunneling charge at $\nu = 2/3$ to be $(2/3)e$.

9:00AM P24.00006 Lande's g values and the quantum Hall effect, KESHAV SHRIVASTAVA, University of Hyderabad — It is reported that the Lande's formula for the g values of the electron as a function of L, S and J does not have the particle-hole symmetry needed for the understanding of high magnetic field data of quantum Hall effect. Hence it is modified to yield the particle-hole symmetry by means of the two signs before S in $J = L \pm S$. The correct g value is then given by $g = (2J+1)/(2L+1)$. Since the Bohr magneton involves the charge of the particles, the corrected g value formula explains the data of quantum Hall effect. The value $L/2L+1$ gives $1/3$ and $(L+1)/(2L+1)$ gives $2/3$. The consideration of Landau levels gives many values in agreement with the data. In electron clusters the spin need not be $1/2$. Hence a lot of data is explained by means of spin greater than $1/2$. Some of the clusters show the formation of spin waves so that there is a finite spin deviation which is characteristic of electron lattices. It is found that Laughlin's wave function is the ground state of $\nabla^2 \delta(r_i - r_j)$ type Hamiltonian which is not equivalent to Coulomb's Hamiltonian. K. N. Shrivastava, Intl. J. Mod. Phys. B 25, 1301-1357(2011).

9:12AM P24.00007 Numerical Study of Realistic Models of the $\nu = 5/2, 7/3, 8/3$ Hamiltonians: Effects of Landau-level mixing and Finite Well-width¹, MICHAEL PETERSON, California State University Long Beach, University of California Santa Barbara, CHETAN NAYAK, Microsoft Research, University of California Santa Barbara — We construct a realistic effective Hamiltonian for electrons in the first excited Landau level, taking into account the effects of both Landau-level mixing and the finite width of the GaAs quantum well. The latter includes both short-distance softening of the Coulomb interaction as well as sub-band mixing. Through exact diagonalization, we find a rich phase diagram as a function of the Landau level mixing parameter κ and quantum well width d . In particular, small changes in either parameter can drive phase transitions between states in the universality classes of the Moore-Read Pfaffian, anti-Pfaffian, and exotic compressible metallic states.

9:24AM P24.00008 Thermopower and the Fractional Quantized Hall Effect in the N=1 Landau Level¹, W.E. CHICKERING, J.P. EISENSTEIN, Caltech, L.N. PFEIFFER, K.W. WEST, Princeton — Having recently eliminated an issue involving long thermal time constants [1], we are now able to resolve diffusion thermopower deep into the fractional quantized Hall effect (FQHE) regime. In this talk we report measurements of thermopower in the first excited (N=1) Landau level as a continuous function of magnetic field down to temperatures as low as 30mK. Above 50mK we can clearly resolve the $\nu = 5/2$ as well as $\nu = 7/3, 8/3$, and $14/5$ FQHEs in both the electrical and thermoelectrical transport. Below 50mK a prominent feature of the electrical transport in the first excited Landau level is the Re-entrant Integer Quantized Hall Effect (RIQHE) which is associated with insulating collective phases [2]. In this temperature regime the thermopower exhibits a series of intriguing sign reversals that are as yet not fully understood. We will conclude with a brief discussion of the connection between thermopower and the entropy of the 2D electron system. This connection is invoked by a recent prediction [3] of the thermopower at $\nu = 5/2$, which assumes the ground state is the non-Abelian Moore-Read paired composite fermion state.

9:36AM P24.00009 Tilt Magnetic Field Dependence of the 12/5 Fractional Quantum Hall State, CHI ZHANG, Princeton University, Sandia National Labs, CHAO HUAN, JIAN-SHENG XIA, NEIL S. SULLIVAN, University of Florida and NHMFL, WEI PAN, Sandia National Labs, K.W. BALDWIN, K.W. WEST, L.N. PFEIFFER, D.C. TSUI, Princeton University — The 12/5 state has attracted growing interest due to its superior potential in performing universal topological quantum computation. Up to date, except for the observation of a well developed quantum Hall plateau at this filling, much less experimental work has been carried out and there is no experimental evidence to support this state being a parafermionic or non-Abelian state. Here, we present our tilt magnetic field dependence results in examining its spin-polarization. It was observed that the diagonal resistance R_{xx} at $\nu=12/5$ shows a non-monotonic dependence on tilt angle (θ). It first increases sharply with increasing θ , reaches a maximal value of $\sim 60 \Omega$ around $\theta \sim 14^\circ$, and then decreases with θ further increased. Correlated with this R_{xx} dependence, the 12/5 activation energy gap ($\Delta_{12/5}$) also shows a non-monotonic θ dependence. $\Delta_{12/5}$ first decreases. Around 14° , R_{xx} becomes non-activated and a true activation energy gap is not obtainable. With further increasing θ , R_{xx} becomes activated again and $\Delta_{12/5}$ increases with θ . This tilt dependence in R_{xx} and $\Delta_{12/5}$ is similar to the composite fermion states at $\nu=2/5$ and $8/5$ in the lowest Landau level, which was interpreted as a spin transition. Our results thus call for more investigations on the nature of the 12/5 ground state.

9:48AM P24.00010 The temperature-dependences of the dissipative conductance in quantum Hall states, N. D'AMBRUMENIL, University of Warwick, Coventry, CV4 7AL, UK, B.I. HALPERIN, Harvard University, Cambridge, Massachusetts 02138, USA, RUDOLF H. MORF, Paul Scherrer Institute, CH-5232 Villigen, Switzerland — We discuss how to estimate the saddle point gap of quantized Hall states from the temperature dependence of the longitudinal response, $\log \sigma_{xx}$. The dissipative response is assumed to be the result of thermally activated quantum tunneling through saddle points in the long-range impurity potential set up by the ionized donors (see Phys. Rev. Lett. 106, 126804 (2011)). We apply the method to published data on states at $\nu = 5/2$, as well data at other integer and fractional filling fractions, and compare the gap estimates and the typical parameters of the saddle points with expectation from microscopic calculations. Even in the case of very weak quantum Hall states, we find that the analysis suggests saddle point gaps which are consistently around 50% of the gap predicted for the homogeneous system.

10:00AM P24.00011 Fractionalization in spontaneous integer quantum Hall systems¹ , ARMIN RAHMANI, RODRIGO MUNIZ, IVAR MARTIN, Los Alamos National Laboratory — We show that electron fractionalization can occur in quantum Hall liquids even in the absence of strong correlations. Focusing on a Kondo lattice model that exhibits spontaneous integer Hall effect due to non-coplanar magnetic ordering, we find that Z_2 vortices in the magnetic order parameter can bind fractional quantum numbers. The vortices have anyonic exchange statistics.

¹LANL DE-AC52-06NA25396

10:12AM P24.00012 Exact soliton solutions in a many-body system in non-trivial background¹ , ANDREY GROMOV, ALEXANDER ABANOV, Stony Brook University, MANAS KULKARNI, University of Toronto — Soliton solutions are usually described as lumps of density propagating without changing their shape. They usually occur in integrable systems. We consider the classical Calogero model in an external harmonic potential. Due to the presence of the external potential, momentum in the system is not conserved and the aforementioned description of solitons is inapplicable, nevertheless the system remains integrable. Naturally, the question about the existence and the form of soliton solutions arises. I will explain what a soliton solution of this model is and I will show how to find these solutions in the case of finite number of particles and in the hydrodynamic limit. In the latter limit the model is described by hydrodynamic equations on continuous density and velocity fields. Soliton solutions in this case are finite dimensional reductions of the hydrodynamic model and describe the propagation of lumps of density and velocity in the nontrivial background. These solutions of Calogero model were previously qualitatively described by A. Polychronakos in the context of the quantum Hall effect.

¹The work was supported by the NSF under grant no DMR-0906866

10:24AM P24.00013 On the hydrodynamic description of FQHE fluid¹ , ALEXANDER ABANOV, Stony Brook University — A simple classical two-dimensional hydrodynamic model for FQHE fluid has been constructed. Hydrodynamics of this model is Hamiltonian, nonlinear and has many features of fractional quantum Hall states. The effective classical fluid is incompressible and has a correct static structure factor. The model incorporates FQHE relation between the density and the vorticity of the fluid, gives the correct value for the Hall viscosity and for the Hall conductivity at finite wavevectors. The model can serve as a starting point in deriving the boundary theory of FQHE states beyond chiral Luttinger liquid. Indeed, in the leading approximation the model is reduced to chiral waves with nonlinearities defined by a curvature of the confining potential.

¹The work was supported by the NSF under grant no DMR-0906866

10:36AM P24.00014 Anomalous resistance across a quantum point contact in the integer and fraction quantum Hall regimes , COLIN DILLARD, XI LIN, MARC KASTNER, MIT, LOREN PFEIFFER, KEN WEST, Princeton University — A ~ 600 nm quantum point contact (QPC) is studied in various integer and fractional quantum Hall states. An anomalous increase of the differential resistance across the QPC from the expected quantized value is observed at nonzero DC bias. The onset of this increased differential resistance occurs sharply at DC bias values which vary continuously with magnetic field and gate voltage. Dependence of the increased resistance on filling factor, magnetic field, gate voltage, and temperature is presented. Of particular interest is the observation that the onset DC bias shows opposite gate voltage dependence for integer and fractional quantum Hall states.

10:48AM P24.00015 Improved Measurements of Quasi-Particle Tunneling in the $\nu = 5/2$ Fractional Quantum Hall State¹ , XI LIN, COLIN DILLARD, MARC KASTNER, MIT, LOREN PFEIFFER, KEN WEST, Princeton University — It is predicted that the $\nu = 5/2$ fractional quantum Hall state may potentially exhibit novel non-abelian quasi-particle statistics, which would make it a candidate for implementation of topological quantum computation. We present measurements of quasi-particle tunneling between edge channels, which provide information about the wave function of the $\nu = 5/2$ state. Weak tunneling is investigated as a function of temperature and DC bias and fit to the theoretical tunneling conductance. We improve on previous quasi-particle tunneling measurements by reducing measurement noise and studying two different quantum point contact (QPC) geometries. For both QPCs the best fits give e^* , the quasi-particle effective charge, close to the expected value of $e/4$ and g , the strength of the interaction between quasi-particles, close to $3/8$. Here we show that fits corresponding to the various proposed wave functions, along with qualitative features of the data, strongly favor the abelian 331 state.

8:00AM P25.00001 A new metastable phase of silicon in the *Ibam* structure , BRAD D. MALONE, MARVIN L. COHEN, Department of Physics, University of California, Berkeley, and Materials Science Division, Lawrence Berkeley National Laboratory — In a study aimed at finding new useful forms of silicon, we use an *ab initio* random structure searching (AIRSS) method to identify a new phase of silicon in the *Ibam* structure. The *Ibam* phase is found to be semimetallic within density functional theory with a small band overlap, and it is expected that quasiparticle corrections using the GW approximation would yield a semiconducting state with a small band gap. Calculation of the lattice dynamics reveals that the structure is locally stable. Enthalpy-pressure relations are calculated for the *Ibam* structure as well as all other known Si structures, including the previously predicted phases *st12* and *bct*. These results indicate that *Ibam* silicon is metastable over the pressure range considered. Calculated coexistence pressures of the other known phase transitions are in good agreement with experimental observation.

8:12AM P25.00002 Ultra-incompressible Three Dimensional Long-range Ordered Amorphous Carbon Clusters¹ , LIN WANG, Carnegie Institution of Washington, 1HPSYNC, GEOPHYSICAL LABORATORY, CARNEGIE INSTITUTION OF WASHINGTON, ARGONNE, IL 60439, USA TEAM — Here we report the synthesis of a long range ordered material constructed from units of amorphous carbon clusters and solvent molecular. This material has super-incompressibility which can make indents on diamonds. It was synthesized by crushing the fullerenes cages at high pressure. Using high pressure x-ray diffraction and Raman spectroscopy, we observed that the fullerenes cages collapse as the pressure higher but the sample remains in crystalline phase even at 60 GPa. The high pressure phase is ultraincompressible, quenchable and much denser than the starting material. The discovery of the existence of such a unique phase should lead to a great deal of interest for design and synthesis of materials with this characteristic.

8:24AM P25.00003 Anharmonicity and bonding electrons in silicon under high pressures, GUOYIN SHEN, DAIJO IKUTA, HPCAT, Carnegie Institution of Washington — Electron density distributions have been measured for silicon at high pressures by single crystal diffraction using a diamond anvil cell. An abrupt change in charge density distribution is observed at 10.1 GPa, a pressure close to a phase transition from diamond structure to beta-tin structure at 12.5 GPa. Our results show a strong anharmonicity effect in silicon in a pressure range of 2.5 GPa before the phase transition to beta-tin.

8:36AM P25.00004 Formation of superconducting platinum hydride under pressure: an *ab initio* approach, DUCK YOUNG KIM, Geophysical laboratory, Carnegie institution of Washington, RALPH SCHEICHER, Uppsala University, Uppsala, Sweden, CHRIS PICKARD, University College London, London, UK, RICHARD NEEDS, University of Cambridge, Cambridge, UK, RAJEEV AHUJA, Uppsala University, Uppsala, Sweden — Noble metals such as Pt, Au, or Re are commonly used for electrodes and gaskets in diamond anvil cells for high-pressure research because they are expected to rarely undergo structural transformation and possess simple equation of states. Specifically Pt has been used widely for high-pressure experiments and has been considered to resist hydride formation under pressure. Pressure-induced reactions of metals with hydrogen are in fact quite likely because hydrogen atoms can occupy interstitial positions in the metal lattice, which can lead to unexpected effects in experiments. In our study, PRL 107 117002 (2011), we investigated crystal structures using *ab initio* random structure searching (AIRSS) and predicted the formation of platinum mono-hydride above 22 GPa and superconductivity T_c was estimated to be 10 – 25 K above around 80 GPa. Furthermore, we showed that the formation of fcc noble metal hydrides under pressure is common and examined the possibility of superconductivity in these materials.

8:48AM P25.00005 New ultrahigh pressure phases of H₂O ice predicted using an adaptive genetic algorithm¹, MIN JI, CAI-ZHUANG WANG, Iowa State University, KOICHIRO UMEMOTO, University of Minnesota, KAI-MING HO, Iowa State University, RENATA WENTZCOVITCH, University of Minnesota — We propose three new phases of H₂O under ultrahigh pressure. Our structural search was performed using an adaptive genetic algorithm which allows an extensive exploration of crystal structure at density functional theory(DFT) accuracy. The new sequence of pressure-induced transitions beyond ice X at 0 K should be ice X → Pbcm → Pbca → Pmc2₁ → P2₁ → P2₁/c phases. Across the Pmc2₁-P2₁ transition, the coordination number of oxygen increases from 4 to 5 with a significant increase of density. All stable crystalline phases have nonmetallic band structures up to 7 TPa.

9:00AM P25.00006 Quantum Monte Carlo applied to Solids under Pressure, LUKE SHULENBURGER, T.R. MATTSSON, Sandia National Laboratories — Diffusion quantum Monte Carlo (DMC) has been applied to solids under pressure in several different contexts a high degree of success.¹ All of these calculations must address three errors present in DMC calculations of solids: the fixed node approximation, the pseudopotential approximation and the finite size approximation. Due to the varying approximations to address these errors, these calculations suffer from an uncertainty that is almost comparable to that introduced by the choice of functional in density functional theory (DFT). In this presentation, we present lattice constants and bulk moduli of more than fifteen solids under compression performed with a consistent approach to these three approximations. These results help establish the general accuracy that may be expected from DMC calculations of solids under pressure and also provide a reference from which improvements to DMC methods may be judged.

Sandia National Laboratories is a multiprogram laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

9:12AM P25.00007 First-principles simulations on bonding pathways of chemical transformations under hydrostatic compression, ANGUANG HU, FAN ZHANG, DRDC Suffield — High pressure as a thermodynamic parameter provides a strong structural constraint to lead chemical transformations with selective ways. Thus, chemical transformations under pressure can create novel materials which may not be accessible by covalent synthesis. However, bonding evolution toward high pressure chemical transformations can be a complex process and may happen over widely different pressures. To understand bonding evolution pathways of high pressure chemical transformations, first-principles simulations were performed following hydrostatic compression enthalpy minimization paths to obtain experimentally and theoretically established phase transitions of carbon. The results showed that the chemical transformations from hydrostatic compression carbon to single-bonded phases were characterized by a sudden decrease in principal stress components, indicating the onset of chemical transformation. On this basis, a number of hydrostatic compression chemical transformations from molecular precursors to novel materials were predicted, such as hydrocarbon graphane, a hydrogenated carbon nitride sheet, and carbon nitrides. All predicted hydrostatic compression transformations are featured as a sudden change in principal stress components, representing chemical bonding destruction and formation reactions with a cell volume collapse.

9:24AM P25.00008 Dielectric constant of water under deep Earth pressures and temperature conditions¹, DING PAN, LEONARDO SPANU, Department of Chemistry, University of California, Davis, FRANCOIS GYGI, Department of Computer Science, University of California, Davis, GIULIA GALLI, Department of Chemistry, University of California, Davis; Department of Physics, University of California, Davis — The knowledge of the dielectric constant of water as a function of pressure (P) and temperature (T) plays a critical role in understanding the chemistry of aqueous systems, and in particular of fluids in the Earth mantle, where water is stored in hydrous minerals. By using first-principles molecular dynamics, we have computed the dielectric constant of water at T = 1000 K, between 1 and 10 GPa, under conditions of the Earth upper mantle. We present a detailed comparison of our results with available experimental data and empirical models, and we discuss how the liquid dielectric constant is affected by the changes in the hydrogen-bond network and molecular dipole moment observed upon compression.

¹DOE/SciDAC-e: DE-FC02-06ER25777

9:36AM P25.00009 Hydrogen-Helium Mixtures at High Pressures, MIGUEL A. MORALES, SEBASTIEN HAMEL, KYLE CASPERSEN, ERIC SCHWEGLER, LLNL — We extend our previous work on hydrogen-helium mixtures (Morales, M. A., et. al. PNAS 106, 1324 (2009).) to lower pressures and lower temperatures, across the molecular dissociation regime in hydrogen, to the low pressure molecular liquid. Using density functional theory-based molecular dynamics together with thermodynamic integration techniques, we calculate the Gibbs free energy of the dense liquid as a function of pressure, temperature, and composition. Our work focuses on the mixing properties of the liquid, the optical properties including conductivity and reflectivity, and the creation of accurate mixing models for thermodynamic properties, including pressure and entropy. The resulting models will provide the basis for accurate first-principles equations of state for planetary modeling. Prepared by LLNL under Contract DE-AC52-07NA27344.

9:48AM P25.00010 Pressure makes mercury a transition metal: a first-principles study of HgF₄ solid phases, XIAOLI WANG, HAIQING LIN, Beijing Computational Science Research Center, YANMING MA, State Key Lab of Superhard Materials, Jilin University, MAOSHENG MIAO, Materials Research Lab, University of California Santa Barbara — Mercury is considered as a post-transition metal, because its d shell is filled and does not involve in forming chemical bonds. Yet, because the large relativistic effect pushes up the outmost d level, there is a high expectation that Hg can be stabilized in a higher oxidation state. The HgF₄ molecule has been predicted by calculations, and an evidence of such molecule is shown by IR absorption recently. However, there is neither computation nor experiment report on possible high oxidation state of Hg in solid. By using first-principles density functional theory and a structure-searching method, we studied the structural change of a solid system of Hg and F under pressures from 0 to 300 GPa. We found that at lower pressure, the stable structure consists of HgF₂ and F₂ molecules. At about 25 GPa, the system undergoes a structural change and forms HgF₄ planar molecules featuring d₈ configuration. The calculations show that the d orbitals of Hg involve in chemical bonding, which is the signature of a transition metal.

10:00AM P25.00011 Ab-initio parametrization of a fully polarizable and dissociable force field for water¹, C. PINILLA, A. IRANI, N. SERIANI, S. SCANDOLO, The Abdus Salam International Centre for Theoretical Physics Trieste, 34151, Italy — A novel all-atom, dissociative, and polarizable force field for water is presented. The force field is parameterized based on forces, stresses and energies obtained from ab-initio calculations of liquid water at ambient conditions. The accuracy of the force field is tested by calculating structural and dynamical properties of liquid water and the energetics of small water clusters. The transferability of the force field to dissociated states is studied by considering the solvation a proton and the ionization of water at extreme conditions of pressure and temperature. In the case of the solvated proton the force field properly describes the presence of both Eigen and Zundel configurations. In the case of the pressure-induced ice VIII / ice X transition and the temperature-induced transition to a superionic phase, the force field is found to describe accurately the proton symmetrization and the melting of the proton sublattice,

10:12AM P25.00012 ABSTRACT WITHDRAWN —

10:24AM P25.00013 Spin states and hyperfine interactions of iron incorporated in MgSiO₃ post-perovskite¹, YONGGANG YU, HAN HSU, MATTEO COCCIONI, RENATA WENTZCOVITCH, University of Minnesota — Using density functional theory + Hubbard *U* (DFT+*U*) calculations, we investigate the spin states and nuclear hyperfine interactions of iron incorporated in magnesium silicate (MgSiO₃) post-perovskite (Ppv), a major mineral phase in the Earth's D'' layer, where the pressure ranges from about 120 to 135 GPa. In this pressure range, ferrous iron (Fe²⁺) substituting for magnesium at the dodecahedral (A) site remains in the high-spin (HS) state; intermediate-spin (IS) and low-spin (LS) states are highly unfavorable. As to ferric iron (Fe³⁺), which substitutes magnesium at the A site and silicon at the octahedral (B) site to form (Mg,Fe)(Si,Fe)O₃ Ppv, we find the combination of HS Fe³⁺ at the A site and LS Fe³⁺ at the B site the most favorable. Neither A-site nor B-site Fe³⁺ undergoes a spin-state crossover in the D'' pressure range. The computed iron quadrupole splittings are consistent with those observed in Mössbauer spectra. The effects of Fe²⁺ and Fe³⁺ on the equation of state of Ppv are found nearly identical, expanding the unit cell volume while barely affecting the bulk modulus.

¹This work was supported by EAR-081272, EAR-1047629, and by the MRSEC Program of NSF grants DMR 0212302 and DMR-0819885. Calculations were performed at the Minnesota Supercomputing Institute (MSI).

10:36AM P25.00014 Effects of aluminum on spin-state crossover of iron in the Earth's lower mantle¹, RENATA WENTZCOVITCH, HAN HSU, YONGGANG YU, University of Minnesota — Using density functional theory + Hubbard *U* (DFT+*U*) calculations, we investigate how aluminum affects the spin-state crossover of iron in MgSiO₃ perovskite and post-perovskite, the major mineral phases in and at the bottom of the Earth's lower mantle. We find that aluminum does not change the response of iron spin state to the increasing pressure, namely, only the ferric iron (Fe³⁺) residing the octahedral (B) site undergoes a crossover from high-spin to low-spin state, same as aluminum-free iron-bearing MgSiO₃. The presence of aluminum, however, does affect the population of B-site ferric iron significantly — the majority of Fe³⁺ reside the dodecahedral (A) site at lower pressures, and the population of B-site Fe³⁺ increases with pressure at higher pressure range. Therefore, in the Earth's lower mantle, the amount of B-site Fe³⁺ and the degree of elastic anomalies (and thus the possible seismic anomalies) associated with spin-state crossover is directly affected by the concentration and configuration of aluminum.

¹This work was supported by the MRSEC Program of NSF grants DMR 0212302, DMR-0819885, EAR-081272, and EAR-1047629. Calculations were performed at the Minnesota Supercomputing Institute (MSI).

10:48AM P25.00015 Phase stability of mixtures at extreme conditions: implications for the interior structure of the Outer Planets, SEBASTIEN HAMEL, Lawrence Livermore National Lab — The unusual magnetic fields of the planets Uranus and Neptune represent important observables for constraining and developing deep interior models. Models suggests that the non-dipolar and non-axial magnetic fields of these planets originate from a thin convective and conducting shell of material around a stratified fluid core. We present a computational study of the physical properties of a fluid compositionally similar to what is expected in the interior of Uranus and Neptune. Our diffusivity and conductivity results suggest that the core cannot be well mixed if it is to generate non-axisymmetric magnetic fields. The simulations highlight the importance of chemistry on the properties of this complex mixture, including the possible formation of carbon and nitrogen clusters. We present results concerning the overall phase stability of the mixture under conditions relevant to the planetary interiors.

Session P26 DCOMP GSNP: Focus Session: Friction, Fracture and Deformation Across Length Scales - Friction and Geometric Effects 257B

8:00AM P26.00001 Effect of Atomic Scale Geometry on Contact and Friction Between Rough Solids¹, TRISTAN A. SHARP, MARK O. ROBBINS, Johns Hopkins University — Microscopic roughness on real surfaces is known to have a profound influence on macroscopic contact mechanics. It has previously been reported that surfaces that differ only at the atomic level can show different relationships between load, stiffness, and friction. Here we use molecular dynamics simulations to study contact properties of self-affine rough surfaces that are identical at continuum scales, but differ at the atomic scale. We compare surfaces that have atomic positions displaced to a self affine surface to "stepped" surfaces that have been cut from a lattice. The stepped surfaces exhibit more plasticity, contributing to a larger contacting area at a given load. A unified framework captures the relation between roughness, system size, surface separation, stiffness, and contact area.

¹ AFOSR FA9550-0910232

8:12AM P26.00002 Breakdown of Amontons' Law of Friction in Sheared-Elastomer with Local Amontons' Friction, HIROSHI MATSUKAWA, Department of Physics and Mathematics, Aoyama Gakuin University, 5-10-1 Fuchinobe, Sagamihara 252-5258, MICHIO OTSUKI, Retired — It is well known that Amontons' law of friction i.e. the frictional force against the sliding motion of solid object is proportional to the loading force and not dependent on the contact area, holds well for various systems. Here we show, however, the breakdown of the Amontons' law for the elastic object which have local friction obeying Amontons' law and is under uniform pressure by FEM calculation. The external shearing force applied to the trailing edge of the sample induces local slip. The range of the slip increases with the increasing external force adiabatically at first. When the range reaches the critical magnitude, the slips moves rapidly and reaches the leading edge of the sample then the whole system slides. These behaviors are consistent with the experiment by Rubinstein et.al. (Phys. Rev. Lett. 98, 226103). The static frictional coefficient, the ratio between the static frictional force for the whole system and the loading force, decreases with the increasing pressure. This means the breakdown of Amontons' law. The pressure dependence of the frictional coefficient is caused by the change of the critical length of the local slip. The behaviors of the local slip and the frictional coefficient are well explained by the 1 dimensional model analytically.

8:24AM P26.00003 Geometry and elasticity for detachment fronts in friction, ALESSANDRO TALONI, ANDREA BENASSI, STEFANO ZAPPERI, CNR-IENI istituto per l'energetica e le interfaci — Mesoscale friction bridges nanoscale contact mechanics to the macroscopic Amontons laws and is relevant for several mechanical problems including seismology. Recent experiments on polymeric blocks show that the onset of friction occurs by nucleation of detachment fronts and that frictional properties vary along the sample surface. The earthquake-like dynamics found at the millimeter scale is in contrast with the usual assumption of uniform detachment without a coherent pattern in the front formation. Simulating the quasi-equilibrium dynamics of an elastic sample sliding on a rough surface under a shear force, we show that the dynamics of detachment fronts depends on the sample geometry. In particular, we study the effect of the sample aspect ratio by computing the elastic Green function for a finite three-dimensional slider. Our model allows to study the onset of friction in different geometries, from the thin slabs used in the aforementioned experiments to more general samples shapes.

8:36AM P26.00004 Local friction at a rubber/glass multicontact interface, ANTOINE CHATEAUMINOIS, DANH TOAN NGUYEN, CHRISTIAN FRETIGNY, ESPCI - PPMD Laboratory, YOHAN LE CHENADEC, MAUDE PORTIGLIATTI, Manufacture Francaise des Pneumatiques Michelin — When rubber is squeezed against a hard, rough surface contact only occurs at localized spots between surface asperities. Friction thus involves the shearing of a myriad of micro-contacts which are distributed over length scales ranging from micrometers down to nanometers. In order to get more insights into this widely debated problem, spatially resolved measurements of frictional stresses are much needed. We recently proposed a method to measure local friction of rubbers by means of a contact imaging approach. Silicon rubber substrates marked on their surface are prepared in order to measure the displacement field induced by the steady state friction of a glass lens. Then, the deconvolution of this displacement field provides a spatially resolved measurement of the actual shear stress and contact pressure distributions within the contact interface. As a result, the local friction law, i.e. the relationship between the actual shear stress and normal pressure, is obtained. The effect of roughness are analyzed from experiments using statistically rough surfaces differing in their roughness power density spectrum. Experimental results are discussed in the light of theoretical contact models for the friction of multi-contact interfaces.

8:48AM P26.00005 Adhesive contact of randomly rough surfaces, LARS PASTEWKA, MARK ROBBINS, Johns Hopkins University — The contact area, stiffness and adhesion between rigid, randomly rough surfaces and elastic substrates is studied using molecular statics and continuum simulations. The surfaces are self-affine with Hurst exponent 0.3 to 0.8 and different short λ_s and long λ_L wavelength cutoffs. The rms surface slope and the range and strength of the adhesive potential are also varied. For parameters typical of most solids, the effect of adhesion decreases as the ratio λ_L/λ_s increases. In particular, the pull-off force decreases to zero and the area of contact A_c becomes linear in the applied load L . A simple scaling argument is developed that describes the increase in the ratio A_c/L with increasing adhesion and a corresponding increase in the contact stiffness [1]. The argument also predicts a crossover to finite contact area at zero load when surfaces are exceptionally smooth or the ratio of surface tension to bulk modulus is unusually large, as for elastomers. Results that test this prediction will be presented and related to the Maugis-Dugdale [2] theories for individual asperities and the more recent scaling theory of Persson [3]. [1] Akarapu, Sharp, Robbins, Phys. Rev. Lett. 106, 204301 (2011) [2] Maugis, J. Colloid Interface Sci. 150, 243 (1992) [3] Persson, Phys. Rev. Lett. 74, 75420 (2006)

9:00AM P26.00006 The Effect of Surface Topography on Interface Stresses During Peeling, YE XU, ERIC DUFRESNE, Yale University — Surface topography can have a large impact on the adhesive strength of soft interfaces. While previous experiments have revealed some of the underlying mechanisms, there has been no direct measurement of interface stresses during adhesive failure. We use traction force microscopy to measure the microscopic distribution of interface stresses during peeling. We focus on the relationship between local stresses and topography near the peeling front.

9:12AM P26.00007 Direction dependence of static friction for commensurate and moderately incommensurate surfaces, MICHAEL WOLLOCH, Vienna University of Technology / Austrian Center of Competence for Tribology, PETER MOHN, JOSEF REDINGER, Vienna University of Technology, ANDRAS VERNES, Austrian Center of Competence for Tribology — We present results from our calculations of quasi-static sliding of two atomically flat surfaces in dry, wearless contact using the Density Functional Theory package VASP. The main focus of our work was to determine to which extent commensurability of the surfaces and the sliding direction effects the friction force. The examined systems include commensurate fcc (111) Aluminium slabs and moderately incommensurate surfaces like bcc (110) Titanium on hcp (001) Titanium. A model consistent with stick-slip friction was devised to calculate the friction forces along sliding paths of up to $1\ \mu\text{m}$ on a quantum mechanical basis. To map all forces and energies for rigid and relaxed atomic positions the top slab was scanned over the bottom one on a properly fine grid, which covers the entire unit cell. In this manner, it is shown that the mean friction force depends on the sliding direction and that due to relaxations incommensurate paths may result, counter-intuitively, in higher friction than commensurate ones.

9:24AM P26.00008 Laser induced projectile impact test (LIPIT): A micron-scale ballistic test for high-strain rate mechanical study of nano-structures, JAE-HWANG LEE, Department of Mechanical Engineering and Materials Science, Rice University, DAVID VEYSSET, KEITH NELSON, Department of Chemistry, MIT, EDWIN THOMAS, Department of Mechanical Engineering and Materials Science, Rice University — We present a method to apply a highly localized deformation at a high-strain-rate for the study of mechanical characteristics of micro- and nano-structures. In the technique, Laser Induced Projectile Impact Test (LIPIT), micro-projectiles (solid silica spheres of $3.7\ \mu\text{m}$ diameter) are accelerated to a supersonic speed (up to 4 km/s) in air by a micro-explosion created by laser ablation of polystyrene and impact a sample target. The velocity information of the micro-projectiles is explicitly determined by two consecutive high-speed images during the flight of the projectiles. For demonstration, a glassy-rubbery nanocomposite consisting of a periodic self-assembled stack of 20 nm thick layers of polystyrene and polydimethylsiloxane blocks (PS-b-PDMS) is tested by LIPIT at the extremely high-strain rate of $10^8\ \text{s}^{-1}$. The polymer nanocomposite demonstrates new orientation dependent deformation and failure mechanisms including a surprising order to disorder transition fluidization, and the energy absorbing ability of a layered nanocomposite through plastic deformation leading to a melting of the layered structure.

9:36AM P26.00009 Probing the sliding interactions between bundled actin filaments, ANDY WARD, ZVONIMIR DOGIC, Brandeis University — Assemblies of filamentous biopolymers are hierarchical materials in which the properties of the overall assemblage are determined by structure and interactions between constituent particles at all hierarchical levels. For example, the overall bending rigidity of a two bundled filaments greatly depends on the bending rigidity of, and the adhesion strength between individual filaments. However, another property of importance is the ability for the filaments to slide freely against one another. Everyday experience indicates that it is much easier to bend a stack of papers in which individual sheets freely slide past each other than the same stack of papers in which all the sheets are irreversibly glued together. Similarly, in filamentous structures the ability for local re-arrangement is of the utmost importance in determining the properties of the structures observed. We have developed a method to directly measure the frictional interactions between a pair of aligned filaments in a well-defined and controllable configuration. This enables us to systematically investigate the role of adhesion strength, filament orientation, length, and surface structure.

9:48AM P26.00010 Harnessing polymer gels to regulate friction between sliding surfaces¹, HASSAN MASOUD, ALEXANDER ALEXEEV, Georgia Institute of Technology, George W. Woodruff School of Mechanical Engineering — We examine the microscale tribological behavior of a pair of gel coated surfaces separated by a thin layer of lubricant. The soft, elastic gel is modeled using a bond-bending lattice spring model that captures the micromechanics of a random network of interconnected filaments. We couple this model with the dissipative particle dynamics that explicitly models the hydrodynamics of a viscous fluid. We probe how elasticity and internal structure of compliant gels affect the tribological behavior and examine how gel elasticity can be harnessed to regulate friction between sliding surfaces. We also study the effect of lubricant composition and the inclusion of nanoscopic particles of different shapes on the friction forces between wet compliant surfaces. Our findings could be useful for developing new methods for regulating friction and reducing wear of lubricated surfaces and also for understanding the micro-mechanics of friction in biological systems.

¹Financial support from the Donors of the Petroleum Research Fund, administered by the ACS, is gratefully acknowledged.

10:00AM P26.00011 On the Equilibrium of an Heavy Elastic Cylinder on Horizontal Nondeformable Plane, LAVRENT SHEKYAN, SERGEY VERLINSKI, Dr. — The plane static contact problem of the equilibrium of a homogeneous heavy elastic cylinder on fixed non-deformable horizontal plane is discussed. In the vicinity of the initial contact between these bodies, there is some contact area, which covers the central angle and which are unknown contact stresses. The elastic equilibrium of a cylinder under the influence of its gravity and some unknown contact stress is discussed. To determine the distribution of contact stress, the size of the contact area of the cylinder and immersion in the horizontal plane is required.

10:12AM P26.00012 Internal friction peak in silicon revealed by moderate temperature annealing¹, THOMAS METCALF, XIAO LIU, JEREMY ROBINSON, Naval Research Laboratory — In order to maximize of the quality factor of a mechanical resonator, one must minimize energy loss mechanisms. We have identified a new internal friction (IF) peak that is present in as-fabricated ultra-high Q silicon resonators known as Double Paddle Oscillators. The IF peak can be removed (and thus its presence revealed) by annealing at moderate (300 °C) temperatures in both inert (Argon) and reactive (H₂) atmospheres, and does not re-appear after aging for 10⁷ s. The success of a relatively low temperature operation in eliminating this mechanism indicates that the phenomenon is surface-, as opposed to bulk- related. We compare this loss mechanism to other known loss mechanisms in silicon.

10:24AM P26.00013 ABSTRACT WITHDRAWN —

10:36AM P26.00014 Investigation of stability for an electrostatically actuated flexible electrode, CORY HINTON, MATTHEW MCFARLAND, THOMAS WARD, North Carolina State University — An argument for employing dimensional analysis to explore stability in an electrostatically actuated flexible electrode is presented theoretically and experimentally. The electrode is configured as a cantilever beam, as many applications in MEMs, medical devices, and sensing devices have been studied for years. This study investigates a macro scale beam (length = 100mm - 150mm), for applications in cooling fan and flapping micro air vehicle devices. The influence of scale is validated, voltage potential and frequency contributions are quantitatively measured, and a comparison of input signal (analog versus digital) is discussed using dynamical systems analysis. Based on experimental data and numerical models, characteristics of stability are presented that could influence design considerations for various micro- and macro-scale devices.

Wednesday, February 29, 2012 8:00AM - 11:00AM —
Session P27 DCMP: Invited Session: Transport Studies of Topological Insulators 258AB

8:00AM P27.00001 Towards the quantum anomalous Hall effect in HgMnTe, HARTMUT BUHMANN, Physikalisches Institut, Universität Würzburg — Although there are plenty of theoretical and experimental studies of the anomalous Hall effect in the ferromagnetic materials, the quantum version, namely “quantum anomalous Hall effect”, has never been observed in the realistic materials. In this work, we report the experimental evidence of the quantum anomalous Hall effect in the Mn doped HgTe quantum wells. We observe a long quantized Hall plateau from 0.2 T to > 25 T with the Hall conductance e^2/h in the p-doped regime. By carefully analyzing the gate voltage and temperature dependence of the experimental data, we find the long plateau originates from the fact that the two zero Landau levels in HgMnTe doped system have the same slope, which is exactly the required condition for the quantum anomalous Hall effect. Theoretical $\mathbf{k}\cdot\mathbf{p}$ calculation is carefully compared with the experimental data to identify the influence from the magnetic impurities. A HgMnTe-ferromagnet hybrid structure is proposed for the possible future device applications.

8:36AM P27.00002 Quantum Spin Hall Insulator Made of InAs/GaSb, IVAN KNEZ, Rice University — Quantum Spin Hall Insulator (QSHI) is a two-dimensional variant of a novel class of materials characterized by topological order, whose unique properties have recently triggered much interest and excitement in the condensed matter community. Most notably, topological properties of these systems hold a great promise in mitigating the difficult problem of decoherence in implementations of quantum computers. Although QSHI has been theoretically predicted in a few different materials, so far only the semiconductor systems of HgTe/CdTe and, more recently, inverted InAs/GaSb, have shown direct evidence for the existence of this phase. Ideally insulating in the bulk, QSHI is characterized by one-dimensional channels at the sample perimeter, which have helical property, with carrier spin tied to the carrier direction of motion, and protected from back-scattering by time-reversal symmetry. Here we present low temperature transport measurements of inverted InAs/GaSb quantum wells, showing strong evidence for the existence of proposed helical edge channels. Edge modes persist in spite of conductive bulk, which is of non-trivial origin but highly tunable via electrostatic gates, and show only a weak magnetic field dependence. This is a direct consequence of a gap opening away from the zone center leading to effective decoupling of edge to bulk states due to the Fermi velocity mismatch. Low Schottky barrier of this material system and good interface to superconductors allows us to further probe topological properties of helical channels in Andreev reflection measurements and opens a promising route in realization of exotic Majorana modes.

9:12AM P27.00003 Transport Studies of Topological Insulators and Superconductors¹, YOICHI ANDO, Institute of Scientific and Industrial Research, Osaka University — A topological state of matter is characterized by a topological feature of the quantum-mechanical wavefunction in the Hilbert space. In 3D topological insulators (TIs), a non-trivial Z_2 topology of the bulk valence band leads to the emergence of Dirac fermions on the surface. Similarly, in 3D topological superconductors (TSCs), a non-trivial winding number of the superconducting wavefunction leads to the appearance of Majorana fermions on the surface. The Dirac or Majorana fermions in those topological states of matter are of fundamental interest, but there have been significant materials problems that hindered their experimental studies so far: In the case of TIs, most of the materials identified as such are poor insulators in the bulk, making it difficult to probe the peculiar surface transport properties; in the case of TSCs, no concrete example has yet been discovered. In this talk, I will present our recent contributions to address these issues. For TIs, we discovered that the chalcogen-ordered tetradymite TI material $\text{Bi}_2\text{Te}_2\text{Se}$ presents a high bulk resistivity, allowing one to observe clear surface quantum oscillations [Z. Ren *et al.*, PRB **82**, 241306(R) (2010)]; more recently, we discovered that the bulk-insulating nature can be further improved in the solid-solution system $\text{Bi}_{2-x}\text{Sb}_x\text{Te}_{3-y}\text{Se}_y$, making it possible to achieve the surface-dominated transport in a bulk crystal and observe both Dirac holes and electrons via Shubnikov-de Haas oscillations [A. A. Taskin *et al.*, PRL **107**, 016801 (2011)]. For TSCs, we developed a new synthesis technique for a candidate TSC, $\text{Cu}_x\text{Bi}_2\text{Se}_3$, to obtain single-crystal samples with a high shielding fraction [M. Kriener *et al.*, PRL **106**, 127004 (2011); PRB **84**, 054513 (2011)]. Using these crystals, we have recently succeeded in observing the surface Andreev bound state which gives evidence for an unconventional superconductivity; since the unconventional superconductivity in $\text{Cu}_x\text{Bi}_2\text{Se}_3$ can only be topological (thanks to the simple and peculiar band structure), one can conclude with confidence that this material is the first concrete example of a TSC [S. Sasaki *et al.*, PRL **107** (2011)]. Work in collaboration with A. A. Taskin, Z. Ren, S. Sasaki, and K. Segawa.

9:48AM P27.00004 Quantum anomalous Hall effect in the thin film of magnetic topological insulators and semimetals¹, XI DAI, Institute of Physics, Chinese Academy of Sciences — The great interests on Hall effects come with their quantization under certain conditions. By now all five types of the Hall effects have been discovered, and the only remaining one is the quantized anomalous Hall effect, which is the quantized Hall effect without external magnetic field and the formation of Landau levels. In the present talk, I will summarize two possible ways proposed by our group to reach such an effect, which are thin films of magnetically doped topological insulators and topological semimetals. I will mainly focus on the latter proposal, which is important in the following sense. First the proposal is based on the stoichiometric material, which is very good for obtaining large mobility. Second, the exchange coupling energy between the magnetization and the valence electrons is of the order of eV, which makes QAHE more easy to be realized.

8:00AM P28.00001 An optical antenna for high-count-rate single-photon-sensitive superconducting transition edge sensors¹, FAUSTIN CARTER, DANIEL SANTAVICCA, DANIEL PROBER, Yale University — There are number of promising applications for a GHz count-rate, energy-resolving single-photon detector in the near-infrared. However, such a detector has not yet been perfected. For thermal detectors, this is partly due to the difficulty of coupling relatively large (~ 1 micron) photons into the necessarily small (~ 100 nm) thermal sensor element. We report on the simulation, fabrication, and preliminary measurements of an antenna-coupled superconducting transition edge sensor. The optical antenna is designed to directly couple incident near-infrared photons into much shorter wavelength surface plasmons, which are then delivered to a nanoscale superconducting niobium detector element at the antenna feed. This detector is inherently energy resolving, unlike the superconducting nanowire single-photon detector (SNSPD) or the single-photon avalanche photodiode (SPAD), and it operates at the relatively convenient temperature of 4 K.

8:12AM P28.00002 Nanocrystal-based Optoelectronic Devices¹, KENNETH EVANS, Applied Physics Ph.D. Program, Rice University, JOSEPH HERZOG, DANIEL WARD, DOUGLAS NATELSON, Department of Physics & Astronomy, Rice University — Optoelectronic devices capable of detecting and emitting light on a scale well below its wavelength could have a profound impact on basic and applied experimental research in light-based electronics, on-demand photon generation, and for studying poorly understood quantum phenomena such as blinking and spectral wandering. We present a fabrication procedure for ultrasmall, nanocrystal optoelectronic devices based on self-assembled layers of quantum dots in plasmonically-active gold nanogaps. We provide preliminary experimental results which examine the possibility for surfaced-enhanced fluorescence, subwavelength detection and emission of light as well as plasmon-based optical trapping in these systems.

8:24AM P28.00003 Frequency and Intensity Stabilization of Planar Waveguide-External Cavity Lasers, GREGORIO TELLEZ, STEVEN SHOEN, VOLKER QUETSCHKE, University of Texas at Brownsville — Planar Waveguide External Cavity Lasers (PW-ECL) show an immense potential for use in precision measurement tasks and space missions because of its compactness and simple design. We show the techniques used to frequency and intensity stabilize a PW-ECL 1550nm laser system with the goal of achieving a frequency stability of 30 Hz/sqrt(Hz) and a RIN of less than 10^{-6} . These PW-ECL systems are a potential replacement for Non-Planar Ring Oscillator (NPRO) laser systems, which have become a standard for low-noise interferometric applications, if the PW-ECL can meet the required stability. We present the initial experimental results of the intensity and frequency stabilization setup and we show a comparison between PW-ECL lasers and NPRO lasers with respect to measurements and applications requiring a high frequency and intensity stability.

8:36AM P28.00004 Experimental setup to demonstrate low-frequency high-precision frequency stabilization of 1550 nm ECL Lasers, STEVEN SHOEN, GREGORIO TÉLLEZ, VOLKER QUETSCHKE, University of Texas at Brownsville — Advances in fiber and waveguide technologies have brought about a new type of laser: the Planar Waveguide External Cavity Laser (PW-ECL) that shows a great potential for precision interferometric measurements. We show an experimental setup based on a 1550nm PW-ECL which was designed to achieve a frequency stabilization of $30 \text{ Hz}/\sqrt{\text{Hz}}$ or less at 10 mHz. The presented design makes use of thermal shielding to suppress temperature fluctuations at low frequencies as well as a vacuum system, high finesse cavity and low-noise electronics to reduce the frequency noise. A description of the components used in the design is given and initial results are presented.

8:48AM P28.00005 Experimental demonstration waveguide with arbitrary bending angles in hyperuniform disordered photonics materials, WEINING MAN, San Francisco State University, MARIAN FLORESCU, University of Surrey, SEYED HASHEMIZAD, ERIC WILLIAMSON, DEVIN LINER, YINGQUAN HE, BRIAN LEUNG, San Francisco State University, PAUL CHAIKIN, New York University — Contradicting to the long standing intuition that long-range translational order is required in photonic band gap formation, recently a new class of disordered hyperuniform materials was predicted to possess sizeable photonic band gaps. We report the first experimental demonstration of complete and isotropic photonic band gap for all polarizations in such disordered hyperuniform structures made of alumina with a dielectric constant of 8.7. In periodic structures there are only a limited number of allowed rotational symmetries; hence bending angles of waveguiding channels are greatly limited. In isotropic hyperuniform disordered structures there are no preferential symmetry directions and waveguiding channels can be constructed with arbitrary bending angles. In our study, near 100 percent transmission of electromagnetic waves around sharp corners of arbitrary angles with bending radii smaller than one wavelength are observed experimentally. The hyperuniform disordered structures also enable the realization of isotropic confinement of radiation in cavities and can be used as flexible optical insulator platforms.

9:00AM P28.00006 Kerr Nonlinear Modes in Photonic Crystal Waveguide with Off-channel Features¹, BUDDHI RAI, Western Michigan University, GULAY BIRKOK, Gebze Institute of Technology, ARTHUR MCGURN, Western Michigan University — A theoretical method using nonlinear difference equation approach has been developed for investigating guided modes of photonic crystal waveguide for cases in which the guided modes interact with multiple bound electromagnetic modes localized on off-channel impurity features of Kerr nonlinear media. The interest is on the properties of resonant scattering of the modes exhibited by the system formed of both linear and nonlinear media sites in the photonic crystal lattice. The scattering is treated and compared with results of the scattering of the modes in the linear limit of the Kerr media, i.e. in the absence of intensity $|E|^2$ term in the Kerr dielectrics derived in recursive difference equation formulation. The equations of the system are simple and can be quickly solved to demonstrate the wide and interesting varieties of behavior present in the system, including among others, optical bistability and induced transparency. Additionally, the method is applied for a case in which the field dependence of Kerr dielectric properties allows two different frequency waveguide modes to interact with one another by a modulation of the off-channel site dielectric properties. In this interaction, the one mode is used to model numerically the transmission characteristics of the other.

9:12AM P28.00007 The Phase Effect in perturbative nonlinear optics, CI-LING PAN, National Tsing Hua University, RUEI-YIN LIN, National Chiao Tung University, WEI-JAN CHANG, National Tsing Hua University, CHAO-KUEI LEE, National Sun yat-sen University — Waveform control is essential for ultrafast nonlinear optical processes such as high-order harmonic generation (HHG). For example, a sawtooth-like waveform can enhance the kinetic energies of the electrons such that the cutoff of HHG is extended. In this work, we show that relative phase of the two-color driving laser can affect the outcome of perturbative nonlinear optical processes such as lower-order harmonic generation. Consider the third-harmonic signal generated in argon by the fundamental and second-harmonics of a pump laser with frequencies of ω_1 , and ω_2 . A cross-term emerges due to interference of four-wave mixing signals of $(\omega_1 + \omega_1 + \omega_1)$ and $(\omega_2 + \omega_2 - \omega_1)$. When the intensities of two-color pump at ω_1 and ω_2 are equal, the modulation in the third-harmonic signal by the cross-term is about 30% of the DC term. As the relative phase between ω_1 and ω_2 varies, a sinusoidal modulation in output intensity at $3\omega_1$ is expected. We have also calculated the phase effects for fifth, seventh and ninth harmonic generation, which show more complicated behavior.

9:24AM P28.00008 Micro-Photoluminescence for Optoelectronic Material Characterization, EMIR MAGDEN, VICTOR MINDEN, COREY SHEMELYA, THOMAS VANDERVELDE, Tufts University — A hardware environment and software bundle have been developed for measuring the absolute value of and the variance in photoluminescence (PL) intensity across samples of optoelectrical materials. The fully automated assembly uses a dual-axis translation stage to allow for “micro-PL” measurements of the sample surface with a resolution of 10 microns on either axis. The user is given the option to digitally adjust the boundaries of the area being mapped, and set the measurement resolution to produce coarse or fine detailed PL maps of the sample surface. By using a monochromator, the system can perform preliminary measurements of PL at wavelengths ranging from 400nm to 1.7um, and determine the optimal spectral operation settings for detailed mapping. Since the system is a modular design, components can be switched to operate in other spectra ranges as well. As all components are digitally controlled by a PC, a universal user interface and integration module has been created to allow for simultaneous operation of all components with minimal user interaction, and intuitive representations of final data for material quality assessment. Various materials are characterized and discussed to demonstrate the utility.

9:36AM P28.00009 Rapid adiabatic passage in nonlinear optics for complete power transfer between ultrabroadband optical pulses, JEFFREY MOSES, Massachusetts Institute of Technology, FRANZ KÄRTNER, Massachusetts Institute of Technology and DESY-Center for Free-Electron Laser Science, Hamburg, Germany, HAIM SUCHOWSKI, Weizmann Institute of Science and UC Berkeley — Rapid adiabatic passage is a central tool for full transfer of level populations in an atomic system. Recent work showed the equation of motions describing three-optical-wave mixing in a dielectric medium through a nonlinear electric susceptibility are isomorphic to the optical Bloch equations for a two-level atom (neglecting radiative losses) when the middle frequency wave is strong. We have exploited this analogy for the first time to prove the principle of complete Landau-Zener adiabatic transfer in nonlinear wave mixing. Using intense laser pulses and a specially designed poled potassium titanyl phosphate nonlinear crystal with an adiabatic longitudinal variation of the poling period, we demonstrate complete energy transfer of a near-IR pulse to the mid-IR. Moreover, we find the principle is upheld for huge laser bandwidths. In our experiment the power transfer covers two-thirds of an octave of bandwidth with preservation of the power spectral density profile. Control of optical power transfer through rapid adiabatic passage thus can serve to optimize sources for coherent control and strong-field physics.

9:48AM P28.00010 Nano-Gap Embedded Plasmonic Gratings for Surface Plasmon Enhanced Fluorescence, KUNAL BHATNAGAR, SANGHO BOK, VENUMADHAV KORAMPALLY, SHUBHRA GANGOPADHYAY, University of Missouri - Columbia, CENTER FOR NANO/MICRO SYSTEMS AND NANOTECHNOLOGY TEAM — Plasmonic nanostructures have been extensively used in the past few decades for applications in sub-wavelength optics, data storage, optoelectronic circuits, microscopy and bio-photonics. The enhanced electromagnetic field produced at the metal/dielectric interface by the excitation of surface plasmons via incident radiation can be used for signal enhancement in fluorescence and surface enhanced Raman scattering studies. Novel plasmonic structures on the sub wavelength scale have been shown to provide very efficient and extreme light concentration at the nano-scale. The enhanced electric field produced within a few hundred nanometers of these structures can be used to excite fluorophores in the surrounding environment. Fluorescence based bio-detection and bio-imaging are two of the most important tools in the life sciences. Improving the qualities and capabilities of fluorescence based detectors and imaging equipment has been a big challenge to the industry manufacturers. We report the novel fabrication of nano-gap embedded periodic grating substrates on the nanoscale using micro-contact printing and polymethylsilsequioxane (PMSSQ) polymer. Fluorescence enhancement of up to 118 times was observed with these silver nanostructures in conjugation with Rhodamine-590 fluorescent dye. These substrates are ideal candidates for low-level fluorescence detection and single molecule imaging.

10:00AM P28.00011 Micro-manufacturing with Three-dimensional Intensity Patterns: Practical Limits and Considerations¹, DANIEL MCADAMS, DANIEL COLE, University of Pittsburgh — It is possible to generate 3D intensity patterns for micro-manufacturing using a phase hologram displayed on a liquid-crystal spatial light modulator (SLM). Knowledge of the phase and amplitude of a field in a single plane (the SLM plane) allows for calculation of the phase and amplitude in any set of subsequent planes. Iterative phase retrieval algorithms can take a 3D target intensity pattern and generate a hologram for display on the SLM; however, arbitrary 3D intensity patterns are not necessarily achievable because the light field must obey the wave equation. Furthermore, these algorithms have not been discussed from the point of view of lithographic micro-manufacturing. This paper presents one method for making a 3D intensity pattern that can be used to cure resist in a single-shot, and discusses the limits to patterning due to power, resolution, and SLM-related issues. The relationship between the resolution in the patterning volume and physical specifications of the SLM is more restrictive than if the patterning were being done in a single plane, but with sufficient laser power, this algorithm could be used in high-throughput 3D micro-manufacturing.

10:12AM P28.00012 High Finesse Microcavity for Gas Sensing, BENJAMIN PETRAK, KUMARASIRI KONTHAS-INGHE, ANDREAS MULLER, University of South Florida — We report our progress in using optical Fabry-Perot microcavities for multiatomic gas sensing. The microcavities consist of one micromirror at a fiber tip and another micromirror on a planar silica substrate, each with a diameter near 50 microns. The micromirrors were fabricated by an improved CO₂ laser ablation process that uses feedback from the light emitted during ablation to control the mirror dimensions. A cavity finesse in excess of 50 000 was obtained in the near-infrared. Our goal is to make use of the Purcell effect of cavity quantum electrodynamics to obtain an enhancement of Raman scattering when a double resonance condition is achieved.

10:24AM P28.00013 Control of transverse optical patterns in semiconductor quantum well microcavities¹, M.H. LUK, Y.C. TSE, Physics Department, Chinese University of Hong Kong, N.H. KWONG, College of Optical Sciences, University of Arizona, P.T. LEUNG, Physics Department, Chinese University of Hong Kong, S. SCHUMACHER, Physics Department, University of Paderborn, R. BINDER, College of Optical Sciences and Department of Physics, University of Arizona — Recently, a low intensity all optical switching scheme exploiting directional optical instabilities in a semiconductor quantum well microcavity was proposed. It was demonstrated numerically that a sufficiently strong laser (pump) beam normally incident on the microcavity can suffer directional instabilities, generating new beams in oblique directions. These off-axis beams form a pattern when projected onto a plane in the far field placed transverse to the pump. Furthermore, the numerical results showed that the azimuthal orientation of the transverse optical pattern can be reversibly switched by applying a control beam much weaker than the pattern intensity. These phenomena are mediated by the nonlinear interactions among elementary excitations of the microcavity — polaritons formed from strong coupling between the quantum well excitons and photons in a cavity mode. In this Contribution, we provide an overview of the rich parametric dependencies of pattern selection, the time scale of pattern formation, and the switching process. We also present an analysis of system's dynamics based on the contributing polariton wave-mixing processes.

10:36AM P28.00014 MEMS Fabricated MM-Wave Slow Wave Structure¹, MARK FIELD, ROBERT BORWICK, Teledyne Scientific & Imaging LLC, 1049 Camino Dos Rios, Thousand Oaks CA 91360, YOUNG-MIN SHIN, Department of Physics, Northern Illinois University, DeKalb, IL 60115 & Fermi National Accelerator Laboratory, Batavia, IL 60510, LARRY BARNETT, NEVILLE LUHMANN, Department of Electrical Engineering, University of California Davis, Davis, CA 95616, TAKUJI KIMURA, JOHN ATKINSON, Communications and Power Industries, 811 Hansen Way, Palo Alto, CA 94304 — We report on the fabrication and test of a MEMS slow wave structure designed for a > 40 GHz bandwidth centered on 220 GHz operation, that slows radiation down to group velocity of $8.16 \times 10^7 \text{ ms}^{-1}$ where the velocity matches the speed of electrons from a 20 keV source. The slow wave device uses a 40 mm long staggered interdigitated vane structure within a waveguide [1]. Ultimately, such a device will be integrated with an electron beam to become part of a sheet beam travelling wave tube (SBTWT) amplifier. A gold coated deep reactive ion etched (DRIE) silicon test structure was fabricated to test the RF properties of the design. This MEMS structure was coupled to WR-4 waveguide in a metal fixture and the S-parameters measured using a vector network analyzer, allowing extraction of the insertion loss and signal delay as a function of frequency. A further MEMS structure with just 10 cells of the vane structure within a cavity were fabricated which allows points on the dispersion curve to be directly measured as resonances of the structure. Extraction of the dispersion curve verifies the group velocity measurement of the device.
