C1.00227 Friction between Brush Layers of Charged and Neutral Bottle-Brush Macromolecules. Molecular Dynamics Simulations¹, DANIEL RUSSANO, Boston University, JAN-MICHAEL CARRILLO, ANDREY DOBRYNIN, University of Connecticut — We used MD simulations to study lubricating properties of neutral and charged bottle-brush coatings as a function of the compression and shear stresses, and brush grafting density. Our simulations have shown that in charged systems under shear there is a layer with excess of counterions found in between brush bearing surfaces. The main deformation mode of the charged layers is associated with the backbone deformation resulting in the backbone deformation ratio, α , and shear viscosity, η , being universal functions of the Weissenberg number, W . In the case of neutral systems in addition to the backbone deformation there is also side chain deformation. The coupling between backbone and side chain deformation violates universality in α dependence on W and results in scaling exponents varying with compression stress and brush grafting density. Existence of different length scales controlling deformation of neutral bottle-brushes manifests itself in shear viscosity, η , dependence on the shear rate, $\dot{\gamma}$. Shear viscosity, η , as a function of the shear rate, $\dot{\gamma}$, has two plateaus and shear thinning regimes. The low shear rate plateau and shear thinning regime correspond to the backbone deformation while the second plateau and shear thinning regime at moderate shear rates is due to side chain deformation. For both systems the value of the friction coefficient increases with increasing the shear rate.

¹NSF # DMR-1004576

C1.00228 Dynamics of Nanoparticle Adhesion¹, ANDREY DOBRYNIN, JAN-MICHAEL CARRILLO, University of Connecticut, ELIE RAPHAEL, ESPCI — We have performed molecular dynamics simulations of peeling of nanoparticles from substrate to understand the dynamics of nanoparticle adhesion. In our simulations we have calculated the potential of mean force characterizing the strength of the nanoparticle interaction with the substrate as a function of the particle-substrate separation. These simulations have shown that the detachment of the nanoparticle from substrate occurs through neck formation. The neck height decreases with increasing nanoparticle shear modulus (crosslinking density). Furthermore our simulations have established that the detachment time t_R scales with the applied force as f^{-5} . This strong force dependence is a result of the fine interplay between nanoparticle surface energy, elastic energy and its adhesion to the substrate that controls the shape of the nanoparticle.

C1.00229 Measuring Adhesion of Freestanding Polymer Nano-fibers, XIN WANG, Northeastern University, JOHNNY NAJEM, SHING-CHUNG WONG, University of Akron, KAI-TAK WAN, Northeastern University — A novel method is used to measure directly adhesion between two freestanding polymer nano-fibers. A single fiber is attached to two microspheres readily glued to an atomic force microscope (AFM) cantilever. Another freestanding fiber is similarly prepared on a mica substrate. The fibers are arranged in orthogonal crossed-cylinder geometry. External load is applied to deform the two fibers into complementary V-shapes, and the force response allows determination of elastic modulus. At a critical tensile load, "pull-off" occurs and the adhering fibers spontaneously detach from each other, yielding the interfacial adhesion energy. Loading-unloading cycles are performed to investigate fiber degradation and repeated adhesion-detachment.

C1.00230 Differential AC chip calorimeter for in situ investigation of vapor deposited thin films, MATHIAS AHRENBURG, CHRISTOPH SCHICK, HEIKO HUTH, EVGENI SCHOIFET, University of Rostock, MARK EDIGER, KATIE WHITAKER, University of Wisconsin - Madison, Wisconsin, USA — Physical vapor deposition (PVD) can be used to produce thin films with particular material properties like extraordinarily stable glasses of organic molecules. We describe an AC chip calorimeter for in-situ heat capacity measurements of as-deposited nanometer thin films of organic glass formers. The calorimetric system is based on a differential AC chip calorimeter which is placed in the vacuum chamber for physical vapor deposition. The sample is directly deposited onto one calorimetric chip sensor while the other sensor is protected against deposition. The device and the temperature calibration procedure are described. The latter makes use of the phase transitions of cyclopentane and the frequency dependence of the dynamic glass transition of toluene and ethylbenzene. Sample thickness determination is based on a finite element modeling (FEM) of the sensor sample arrangement. A layer of toluene was added to the sample sensor and its thickness was varied in an iterative way until the model fits the experimental data.

C1.00231 Effective Temperature: from Red-Blood-Cell Membrane Fluctuations to trapped active particles, EYAL ISAAC BEN ISAAC, NIR GOV, None — Biologically driven nonequilibrium fluctuations are often characterized by their non-Gaussianity or by an “effective temperature”, which is frequency dependent and higher than the ambient temperature. We address these two measures theoretically by examining a randomly kicked particle, with a variable number of kicking motors, and show how these two indicators of nonequilibrium behavior can contradict. Our results are compared with new experiments on shape fluctuations of red-blood cell membranes, and demonstrate how the physical nature of the motors in this system can be revealed using these global measures of nonequilibrium. Furthermore, our concept of The concept of the effective temperature is extended to active particles trapped in a potential well. We calculated the average escape time and find that Kramers’ reaction-rate theory is found to quite hold in this system. Using this calculated escape time, together with the exact calculation of the active diffusion coefficient for the escaped (free) active particle; one can attempt to fully describe the long-time random-walk of the tracer particle in the active gel.

C1.00232 Structural and phase transitions of one and two polymer mushrooms, DELIAN YANG, QIANG (DAVID) WANG, Colorado State University — A polymer mushroom here refers to a group of n homopolymer chains end-grafted at the same point on a flat, impenetrable and homogeneous substrate. Using lattice self-consistent field (LSCF) calculations with the Kronecker δ -function interactions (instead of the commonly used nearest-neighbor interactions), we have studied the structures of one and two polymer mushrooms in an explicit solvent as a function of the polymer volume fraction, the solvent quality characterized by the Flory-Huggins χ parameter, and the distance between the two mushrooms. We have constructed phase diagrams of these systems showing the coil-globule transition (CGT) of one mushroom and how it is coupled with the fused-separated transition (FST) of two mushrooms. Since LSCF results are exact only in the limit of $n \rightarrow \infty$, we also use the newly proposed fast lattice Monte Carlo (FLMC) simulations¹ with the same Hamiltonian as in LSCF theory to examine how this limit is approached with increasing n . Direct comparisons between LSCF and FLMC results without any parameter-fitting quantify the fluctuation/correlation effects neglected in LSCF theory. We also find a second-order symmetric-asymmetric transition (SAT) for one-mushroom system in the globule state, and examine its coupling with CGT and FST. [1] Q. Wang, *Soft Matter*, **5**, 4564 (2009); **6**, 6206 (2010).

C1.00233 Quantification of Complex Topologies in Macromolecular and Nanoscale Structures using Small-Angle Scattering, SIDDHARTH PRADHAN, RAMANTH RAMACHANDRAN, DURGESH RAI, GREGORY BEAUCAGE, University of Cincinnati — Polymers are characterized by molecular weight distribution, tacticity, block copolymer content and branch content and chain topology. The branch structure and particularly the topology of branched chains has remained a difficult characterization problem. Recently we have developed a scaling model that can be coupled with small-angle scattering to measure the average branch length, number of branches and branch-on-branch structure in macromolecules of complex topology. This method has been extended to understand the structure of two dimensional structures and crumpling in these macromolecular systems. We have explored a wide range of materials in this regard. This poster will give an overview of the current uses for the scaling model for macromolecular topology. References pertaining to this poster can be found at <http://www.eng.uc.edu/~gbeaucag/BranchingPapers.html>.

C1.00234 SOFT CONDENSED MATTER —

C1.00235 Microfluidic Insights into Filter Design, SORELL MASSENBURG, DAVID WEITZ, Harvard University — Nearly every application involving fluid relies heavily upon filtration, yet filter design is not well understood. Previous studies show that hard sphere clogging in microfluidic channels is well described by a probabilistic model that also reveals information about the clogging material's proclivity to aggregation. Design features, such as pore size distribution, can be modeled in two dimensions using soft lithographic techniques to fabricate microscale pores. We then test the efficacy of variations in pore design by clogging these pores with polystyrene microparticles. The clogging behavior of these fabricated pores is then compared to the aforementioned probabilistic model to elucidate the function of various features of filter design.

C1.00236 Photoelastic study of sound waves in grain packings, XAVIER NOBLIN, GUILLAUME HUILLARD, JEAN RAJCHENBACH, LPMC, UMR 6622 CNRS-UNS, Parc Valrose, 06108 Nice Cedex 2, France — By means of photoelasticity, we success in visualizing in real time the propagation of acoustic waves in a granular packing of cylinders. Our experimental procedure allows an access to the local state of stress of individual grains as a function of time with a good accuracy. We first present results on 1d chains of cylinders that are constrained by a static confinement force. Both linear and nonlinear regimes are presented. We emphasize the role of the grains roughness on the propagation properties, and also of the solid friction with the walls. Our results concerning the wave velocity as a function of the amplitude, and of the confinement force, are compared to the theory and to the spherical beads case. We then present experimental results on 2d pilings, in particular for the wave speed.

C1.00237 Dense granular flow around a rigid or flexible intruder, EVELYNE KOLB¹, PMMH, ESPCI, MOKHTAR ADDA-BEDIA², LPS, ENS, ANNETTE HOSOI COLLABORATION³, KO OKUMURA COLLABORATION⁴ — We experimentally studied the flow of a dense granular material around an obstacle (rigid cylinder or flexible plate) placed in a 2 dimensional confined cell at a packing fraction near the 2D jamming threshold. In the case of the rigid obstacle, the displacement field of grains as well as the drag force experienced by the obstacle were simultaneously recorded and a parametric study was done by changing the cell size, the intruder diameter or the packing fraction. The drag force experienced by the intruder and the formation of a wake behind the obstacle were very sensitive to the approach to jamming. The same experimental set-up was adapted to a flexible intruder and coupling between the granular flow and fibre deflexion were imaged. The deformation of the fibre could be compared with theoretical predictions from elastica.

C1.00238 Mechanisms of defect motion in hexagonal systems on sinusoidal substrates, NICOLAS GARCIA, LEOPOLDO GOMEZ, DANIEL VEGA, Depto. de Fisica-IFISUR-Univ. Nac. del Sur. ANPCyT y Conicet., Argentina — In this work we have studied through a Landau's free energy functional approach the dynamic and equilibrium configurations of two-dimensional hexagonal systems constrained to lie on a substrate with sinusoidal topography. Similarly to previous studies, we have found a strong coupling between defects and geometry, where the regions with the highest local Gaussian curvature act as sink for disclinations. We have studied the influence of the local curvature of the substrate on the diffusional dynamics of dislocations and disclinations. We have found a novel mechanism of defect diffusion where linearly correlated arrays of dislocations (scars) move according to the gradient of curvature.

C1.00239 Colloidal cluster array formation by weak ac electric fields¹, WENCESLAO GONZÁLEZ-VIÑAS, RAHEEMA ASLAM, MOORTHY PICHUMANI, University of Navarra — We study experimentally the influence of weak alternating electric fields on dilute colloids with a free surface open to the air. When the experimental conditions minimize the evaporation of the solvent, a well-defined one-dimensional cluster array is formed along the straight contact line. The cluster array evolves due to a hydrodynamical instability which can be controlled by the applied field [1]. Once the clusters are formed, if the evaporation is favored, the contact line recedes. Under these conditions, the capillary flows towards the clusters strengthen. As a consequence, elongated columns of particles are deposited on the substrate. The characteristic length between these columns is controlled during the initial stages of the cluster formation [2]. To shed light on the cluster formation mechanisms, further work is currently carried out for identifying similar phenomena without the existence of a free surface.

C1.00240 Melting of Colloidal Crystals¹, YI PENG, ZIREN WANG, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China, AHMED ALSAYED, Complex Assemblies of Soft Matter, CNRS/UPENN/Rhodia UMI 3254, Bristol, Pennsylvania 19007, USA, ARJUN YODH, Department of Physics and Astronomy, University of Pennsylvania, 209 South 33rd Street, Philadelphia, Pennsylvania 19104, USA, YILONG HAN, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China — We experimentally studied the melting and freezing behaviors of colloidal crystals composed of diameter tunable poly-N-isopropylacrylamide (NIPA or pNIPAM) microgel spheres by bright-field and confocal video microscopies. The melting behaviors of three-dimensional (3D), two-dimensional (2D) and multilayer thin films of both single crystals and polycrystals were systematically studied with single-particle dynamics. Thick films (>4 layers) melt heterogeneously, while thin films (<5 layers) melt homogeneously even in polycrystals. A novel heterogeneous melting at dislocation is discovered in 5- to 12-layer films. The equilibrium phase behaviors are different in three thickness regimes: thick films have a liquid-solid coexistence regime which decreases with the film thickness and vanishes at 4 layers, thin films melt into the liquid phase in one step, while monolayers melt in two steps with an intermediate hexatic phase. These results provide new challenges in theory.

C1.00241 Formation of Uniform Hollow Silica microcapsules, HUAN YAN, CHANJOONG KIM, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, Kent, OH44242, USA — Microcapsules are small containers with diameters in the range of 0.1 – 100 μm . Mesoporous microcapsules with hollow morphologies possess unique properties such as low-density and high encapsulation capacity, while allowing controlled release by permeating substances with a specific size and chemistry. Our process is a one-step fabrication of monodisperse hollow silica capsules with a hierarchical pore structure and high size uniformity using double emulsion templates obtained by the glass-capillary microfluidic technique to encapsulate various active ingredients. These hollow silica microcapsules can be used as biomedical applications such as drug delivery and controlled release.

C1.00242 Multiblock Janus particles with tunable patch size, JIE ZHANG, QIAN CHEN, SUNG CHUL BAE, STEVE GRANICK, University of Illinois at Urbana-Champaign — Micro-printing methods are used to systematically tune the size, position and number of functionalized patches on colloidal particles with excellent monodispersity. This study introduces two new members of the Janus particle family: triblock particles with two small poles, and eyeball Janus particles. Without the intervention of any external field, the former form chain, ring, coil and knot structures. In principle, dynamic and reconfigurable colloidal bilayers can be built from eyeball Janus particles.

C1.00243 Effective static and high-frequency viscosities of concentrated suspensions of soft particles, CARLOS I. MENDOZA, Instituto de Investigaciones en Materiales, UNAM — We obtain an analytic expression that allows determining the static and high-frequency viscosities as function of the volume fraction of a concentrated suspension of soft spherical particles. The particles consist of a hard core of radius a covered by a porous layer of thickness d . The proposed expression incorporates the results for the intrinsic viscosity obtained on the basis of a cell model into a recently obtained relation for the effective viscosity of concentrated colloidal suspensions [J. Chem. Phys. 130, 044904 (2009)]. In this model, the correlations between the particles due to crowding effects are introduced through an effective volume fraction which is then used as integration variable in a differential effective medium procedure. The final expression is simple, accurate, and allows collapsing all the data in a universal master curve. The only difference between the static and high-frequency cases is that in the last case the effective volume fraction also incorporates hydrodynamic interactions arising from the so-called relaxation term. We have tested the accuracy of our model with experiments and simulations. In all cases the agreement with the data is extremely good.

C1.00244 Nanoparticle adsorption from a crowded solution at a solid/liquid interface, INDERMEET KOHLI, SHARMINE ALAM, ASHIS MUKHOPADHYAY, Wayne State University — Adsorption of nanoparticles at solid-liquid interface is of great importance in the field of colloidal science and biophysics. Protein adsorption is one of the most significant processes and can be mimicked by colloidal systems. We will present results of our studies of the kinetics of adsorption of gold nanoparticles from a crowded polyvinyl alcohol (PVA) polymer solution on a solid/liquid interface using phase-modulated ellipsometry. The experimental system mimics many biological processes, where the adsorption of particles or proteins takes place in the presence of many other components.

C1.00245 Responsive Poly (ϵ -carbobenzyloxy-L-lysine)-based Colloidal Particles: Exploring and Characterizing the Inverse α -Helix to Random Coil Transition in m-Cresol¹, CORNELIA ROSU, Louisiana State University, SIBEL TURKSEN-SELÇUK, ERIC SOTO-CANTU, None, PAUL S. RUSSO, Louisiana State University — Like other synthetic polypeptides, poly (ϵ -carbobenzyloxy-L-lysine), PCBL, exhibits unique properties that make it a good candidate for a broad range of applications and fundamental investigations. This work explores one particular feature found in PCBL in the single solvent, m-cresol: a sharp, reversible coil-to-helix transition at 27°C. In nature, such polypeptides undergo similar transitions while attached to living cells. Tethering PCBL polymers to spherical silica particles enables the study of effects such as polypeptide chain length, grafting density and core particle curvature in a fundamental way. This can be accomplished in a single, organic solvent without interference from strong pH and salt effects. This presentation will concern steps taken to make such studies a reality. Methods to characterize grafting density have been established, good control has been exerted over the core size and, by some synthetic routes, also the molecular weight of the PCBL chains in the shell. The coil-to-helix transition is observed for some particles but not all.

C1.00246 Evidence for localized surface plasmon polaritons in a liquid crystal containing gold nanoparticles¹, KUNAL TIWARI, ANKIT SINGH, SURESH SHARMA, University of Texas at Arlington — We report an observation of the localized surface plasmon polaritons (SPPs) in a nematic liquid crystal containing 14 nm diameter gold nanoparticles (Au NPs). We observe attenuated total reflection (ATR) of p-polarized laser beam incident upon a high-index prism/liquid-crystal-Au-NPs/glass structure used in the Kretschmann configuration.¹ Unlike the ubiquitous ATR configuration, in which the prism base is coated with a noble metal thin film, our experimental set up does not utilize any such coating. The ATR observed at a specific incident angle and only for p-polarized laser reflects the excitation of localized SPPs at NP/liquid-crystal interface. We discuss possible SPPs related effects, which can significantly change the electro-optical properties of polymer-dispersed liquid crystals.²

C1.00247 Novel Ordering of Soft Matter Using Chromonic Lyotropic Liquid Crystals¹, MATTHEW LOHR, DANIEL BELLER, MARCELLO CAVALLARO, University of Pennsylvania, SEVDE ARPACI, Bogazici University, JOHN NAPP, California Institute of Technology, KATHLEEN STEBE, RANDALL KAMIEN, University of Pennsylvania, PETER COLLINGS, Swarthmore College, ARJUN YODH, University of Pennsylvania — Chromonic lyotropic liquid crystals (CLLCs) are a unique and powerful system for governing self-organization in soft materials due to their temperature- and concentration-dependent ability to form nematics in (bio-compatible) aqueous suspensions. We present preliminary observations on several novel soft matter phases governed by the ordering of CLLCs. We first examine the phase behavior of low-concentration chromonic aggregates in surfactant-based lyotropic lamellar, hexagonal and nematic phases, and observe phase separation and mutual ordering. We also discuss the placement of colloidal particles at the interface of a thermotropic nematic liquid crystal and a chromonic nematic liquid crystal, and present initial results on defect coupling across the interface and colloidal self-organization from elastic interactions. We also present additional preliminary work examining the structure of CLLCs in confinement and their interactions with biologically inspired materials.

C1.00248 Segregation by Complementarity of nanoDNA based on Liquid Crystal Ordering and Centrifugation¹, GREGORY SMITH, ETHAN TSAI, T. ROBINS, ARMOND KHODAGHLYAN, Liquid Crystal Materials Research Center, University of Colorado, Boulder (CO) U.S.A., GIULIANO ZANCHETTA, TOMMASO FRACCIA, TOMMASO BELLINI, Dipartimento di Chimica, Biochimica e Biotecnologie per la Medicina, Università degli Studi di Milano, Italy, DAVID WALBA, NOEL CLARK, Liquid Crystal Materials Research Center, University of Colorado, Boulder (CO) U.S.A., LIQUID CRYSTAL MATERIALS RESEARCH CENTER, UNIVERSITY OF COLORADO, BOULDER (CO) U.S.A. COLLABORATION, DIPARTIMENTO DI CHIMICA, BIOCHIMICA E BIOTECNOLOGIE PER LA MEDICINA, UNIVERSITÀ DEGLI STUDI DI MILANO COLLABORATION — Nanometer length DNA segments (<20 base pair long) that are complementary can duplex and condense to make liquid crystal phases at concentrations >~500 mg/mL. This nanoDNA duplexing combined with order-disorder phase separation offers a means of sequestering molecules in mixtures of different DNA sequences based on their degree of complementarity. Here we show that isotropic and liquid crystalline phases, comprising respectively single strands and duplexes in multi-component nanoDNA solutions, can be physically separated by liquid crystal condensation followed by centrifugation.

¹This work was supported by NSF MRSEC Grant DMR-0820579.

C1.00249 Ferromagnetic viscoelastic liquid crystalline materials, CRISTINA SCHLESIER, PETR SHIBAEV, SCOTT MCDONALD, Fordham University, Dept of Physics — Novel ferromagnetic liquid crystalline materials were designed by mixing ferromagnetic nanoparticles with glass forming oligomers and low molar mass liquid crystals. The matrix in which nanoparticles are embedded is highly viscous that reduces aggregation of nanoparticles and stabilizes the whole composition. Mechanical and optical properties of the composite material are studied in the broad range of nanoparticle concentrations. The mechanical properties of the viscoelastic composite material resemble those of chemically crosslinked elastomers (elasticity and reversibility of deformations). The optical properties of ferromagnetic cholesteric materials are discussed in detail. It is shown that application of magnetic field leads to the shift of the selective reflection band of the cholesteric material and dramatically change its color. Theoretical model is suggested to account for the observed effects; physical properties of the novel materials and liquid crystalline elastomers are compared and discussed. [1] P.V. Shibaev, C. Schlesier, R. Uhrlass, S. Woodward, E. Hanelt, Liquid Crystals, 37, 1601 (2010) [2] P.V. Shibaev, R. Uhrlass, S. Woodward, C. Schlesier, Md R. Ali, E. Hanelt, Liquid Crystals, 37, 587 (2010)

C1.00250 Modeling Mechanotunable Transmembrane Transport in Lipid Vesicles, ISAAC G. SALIB, OLGA KUKSENOK, ANNA C. BALAZS, University of Pittsburgh, Pittsburgh, PA 15261, USA — Using Dissipative Particle Dynamics approach, we study the effects of applied stress on transmembrane transport in lipid vesicles. The lipids comprising the vesicle are composed of a hydrophilic head group and two hydrophobic tails. The vesicle is immersed into the hydrophilic solution and initially contains a number of amphiphilic species inside its cavity. We show that such enclosed species can be released “on demand” by vesicle’s stretching. We find that the magnitude of the external force required to release the vesicle’s content depends on the chemical nature and volume fraction of the enclosed species. Furthermore, we isolate the scenarios where the stretching of the lipid vesicle depleted of the enclosed species results in its “refilling” with the fresh species from the outer solution. Our results illustrate that applied mechanical stress provides an effective means to fine tune the transmembrane transport in lipid vesicles.

C1.00251 ABSTRACT WITHDRAWN —

C1.00252 Simulations of buckling of gel-phase lipid bilayers , JAMES KINDT, Emory University, Department of Chemistry — The structure of lipid bilayer vesicles below the main chain transition temperature is believed to be approximately polygonal, based on evidence of faceting from electron microscopy. The structure and mechanics of the interfaces between facets, (ridges) are issues that may be pertinent to the rate of trans-bilayer permeability as well as vesicle melting. Here we present evidence from atomistic molecular dynamics simulations that the preferred angle between facets is strongly dependent on the tilt orientation of lipid tails with respect to the ridge vector.

C1.00253 Investigation of the Physics of Flocculation in Algal Systems¹ , FLINT PIERCE, JEREMY LECHMAN, JOHN HEWSON, Sandia National Laboratories — Algae biofuel production has gained a great deal of interest in recent years due to the high photosynthetic efficiency of various algae strains and the ability of stressed algae populations to produce large quantities of lipids within their cells. Separation of the algae from the background aqueous medium engenders large energetic costs for standard separation techniques including filtration, centrifugation, and dissolved air flotation since algae cells are small (microns to 10s of microns), have densities similar to the surrounding fluid, and normally occur at low volume fractions ($1E-4$ -> $1E-3$). Flocculation is one possible route to reducing the cost of collecting the algae biomass, since large algae flocs can easily be removed from the aqueous environment through either differential settling or standard filtration. To this end, We model flocculating systems of algae cells using discrete particle dynamics techniques which incorporate a recently developed adhesive granular potential to govern the cell interactions. This potential is shown to reproduce morphological characteristics, kinetics, and size distributions that agree well with known results for flocculation in the diffusive regime (DLCA). We further investigate flocculation under steady shear and compare our results to both experiment and predictions from various orthokinetic models.

C1.00254 Nonlinear Dynamic Heat Capacity of a Simple Chain Polymer , JONATHAN BROWN, JOHN MCCOY, New Mexico Tech — Molecular dynamics simulations were run on a simple bead-spring polymer system, known to be a glass former, with varying amplitude sinusoidal temperature oscillations. Small amplitude sinusoidal temperature produces a small amplitude sinusoidal energy, and dynamic heat capacity is the complex-valued transfer function between the two. For large amplitude temperature oscillations, the energy is no longer sinusoidal, and linear response theory breaks down. Instead, the resulting energy is can be written as a Fourier series. From the Fourier coefficients, we derived the entropy generated per cycle, which is related to the imaginary part of the dynamic heat capacity in the linear limit. Using this, we formulated a nonlinear extension of the dynamic heat capacity.

C1.00255 High-Pressure Dynamic Light Scattering Implemented in a Diamond Anvil Cell¹ , KEVIN LYON, WILLIAM OLIVER, University of Arkansas — In recent years full-spectrum analysis in light-scattering has been utilized to explore the liquid-glass transition at variable temperatures and ambient pressure. Our lab is currently working on developing dynamic light scattering in a diamond anvil cell to extend this characterization method to high pressures. There are many inherent complications in the implementation of dynamic light scattering in a diamond anvil cell such as distinguishing between self-beating and homodyne contributions to the signal. However, if successful, it would give rise to a several decade window for analysis of glass-forming dynamics not attainable through Brillouin or Raman alone. Progress toward an effective method for obtaining DLS in a diamond anvil cell for the purposes of such analyses will be presented.

¹We gratefully acknowledge support from NSF under grant NO.: DMR-0552944

C1.00256 Wet granular walkers and climbers , ZEINA S. KHAN, Chemical Engineering Department, Texas Tech University, AUDREY STEINBERGER, Laboratoire de Physique, Ecole Normale Supérieure de Lyon, RALF SEEMANN, Experimental Physics, Saarland University, STEPHAN HERMINGHAUS, Max Planck Institute for Dynamics and Self-Organization — We have observed that when a bidisperse mixture of glass beads is moistened by a fluid and shaken sinusoidally in a vertical container, small clusters of beads take off from the surface of the pile and rapidly climb up the container walls against gravity. These self-organized clusters are held together and against the wall by liquid capillary bridges, and are led by one large grain with one or more small grains trailing behind. When similar clusters are placed on a horizontally vibrating substrate they self-align and travel horizontally along the axis of vibration with a ratchet-like motion. We report a detailed experimental study performed for the simplest walker system consisting of one large and one small bead, and present a simple model that accounts for the observed behavior. Reference: Z.S. Khan *et al.*, *New J. Phys* **13**, 053041 (2011).

C1.00257 Surface melting of wet granular matter in two dimensions , CHRISTOPHER MAY, KAI HUANG, INGO REHBERG, Experimentalphysik V, Universität Bayreuth, 95440 Bayreuth, Germany — The transition from the solidlike to the liquidlike state of a monolayer of wet glass beads under horizontally swirling motion is investigated experimentally. Due to the cohesion arising from the formation of capillary bridges, the wet particles initially form a crystal like structure at moderate driving. As the driving frequency increases, this structure is found to melt with two steps: A rearrangement into a hexagonal packing sheltered by a premelted layer, followed by a melting from the surface. This process is characterized by means of Voronoi tessellation and bond orientational order parameters, and discussed within the scenario of KTHNY theory that accounts for crystal melting in two dimensions.

C1.00258 Coefficient of restitution for wet impacts , FRANK GOLLWITZER, KAI HUANG, Experimentalphysik V, Universität Bayreuth, 95440 Bayreuth, Germany, CHRISTOF A. KRÜLLE, Maschinenbau und Mechatronik, Hochschule Karlsruhe - Technik und Wirtschaft, D-76133 Karlsruhe, Germany, INGO REHBERG, Experimentalphysik V, Universität Bayreuth, 95440 Bayreuth, Germany — As the experience of playing football in the rain may tell, wetting could influence the coefficient of restitution (COR) dramatically. This is due to the extra energy dissipation from the wetting liquid, for instance viscous damping. To unveil the underlying mechanisms accounting for the influence, we study experimentally the COR by tracing free falling particles bouncing on a wet surface. The dependence of the COR on the impact velocity, various particle and liquid properties will be presented and discussed in terms of dimensionless Stokes' and capillary numbers.

C1.00259 Characterizing the movement of grains in a 2D rotating drum with imposed vibrations , NORA SWISHER, BRIAN UTTER, James Madison University — We study particle trajectories and surface behavior of photoelastic grains in a 2D circular rotating drum subjected to imposed vertical vibrations. Granular materials are ubiquitous, from industrial processing and pharmaceutical powder mixing to avalanches and sinkholes, yet general equations of flow are not known for these materials. For granular materials, flow is characterized by sudden avalanches, large shear gradients, and history dependence and these characteristics make it difficult to form general equations of flow. This jamming transition is general, occurring in foams, emulsions, and traffic, and can vary significantly with vibration (the "granular temperature"). To quantitatively measure the flow, jamming, and mixing properties of the grains, we analyze images to determine each particle's position and velocity for each frame. External vibration leads to increased compaction of the grains, larger rearrangements, and a narrower shear band. Particle tracking allows us to closely analyze the velocity profiles, trajectories of individual grains, and separation and diffusion of originally neighboring grains. We will present results on the stability of the pile as well as the effects on mixing as external vibration is varied.

C1.00260 Simulating Topological Defects in Twisted Fiber Bundles¹, ISAAC R. BRUSS, GREGORY M. GRASON, Department of Polymer Science and Engineering, University of Massachusetts, Amherst — Twisted bundles are a common motif found in naturally occurring structures of self-assembled fibers, such as collagen and fibrin. By understanding the general principles governing such organizations, new synthetic materials—from the nano to the macroscale—may also be realized. Recently, continuum elasticity theory has been applied to describe generic twisted fiber bundles. This has revealed a relation between a bundle's twist and the presence of topological defects in the cross-sectional packing of the fibers. Here we employ numerical simulations to examine this interdependence. We model a bundle's cross-section as beads confined to a plane. The interactions between beads is governed by a modified Lennard-Jones potential that accounts for the effects of twist. We observe configurations that range from perfect hexagonal packing for cases of no twist, to defect populated structures above a critical amount of twist. For small bundles of less than ~ 100 beads, there exists a discrete spectrum of energy ground states corresponding to integer numbers of five-fold disclinations. For larger bundles, we hope to uncover what types of defect arrangements effectively screen the stresses caused by twist, and compare these to current predictions of the internal organization of collagen fibrils.

¹Center for Hierarchical Manufacturing (CMMI-1025020)

C1.00261 Molecular Adhesion of Curved Filaments: Self-Assembly of Bacterial Flagellar Bundles¹, LUIS CAJAMARCA, University of Massachusetts Amherst, Physics Department, GREGORY GRASON, University of Massachusetts Amherst, PSE Department — The self-assembly of chiral filaments, such as filamentous proteins, introduces an unavoidable frustration between inter-filament and intra-filament geometries. We study the self-assembly of bacterial flagella with a model that focuses on three geometric features: a preferred distance of closest approach; a preferred relatively-parallel orientation; and a mechanical cost for changes of helical shape. As a result, intrinsically curved filaments cannot simultaneously minimize all three driving forces, even in the limiting case of 2-filament contacts. Using a model of depletion-driven and electrostatically-stabilized interactions we present a phase diagram for two filament bundles depicting the complex thermodynamic behavior of adhesive contact using three ratios: one describes the shape of the filaments, and the other two capture the competition of the modulus associated with mechanical deformations and with the cost of having a non-zero twist vs the modulus associated to changes in inter-filament spacing. Finally, we describe the dependence of these ratios on experimentally-adjustable variables and predict critical concentrations of depletant molecules for known polymorphic configurations which may favor the filaments to undergo a transition from non-adhesive to adhesive state.

¹NSF CMMI 10-68852

C1.00262 Self-assembly of Janus Ellipsoids¹, YA LIU, University of Pittsburgh, WEI LI, Lehigh University, TONI PEREZ, Newcastle University, GENEVIEVE BRETT, Skidmore University, JAMES GUNTON, Lehigh University — The self-assembly of particles into a desired mesoscopic structure and function are considered as a bottom-up strategy to obtain new bulk materials that have potential applications in broad fields including drug delivery, photonic crystals, biomaterials and electronics. We propose a primitive model of Janus ellipsoids that represent particles with an ellipsoidal core and two semi-surfaces coded with dissimilar properties, for example, hydrophobicity and hydrophilicity, respectively. We investigate the effects of the aspect ratio on the self-assembly morphology and dynamical aggregation processes using Monte Carlo simulations. We find that the size and structure of the aggregates can be controlled by the aspect ratio, which should be an interesting result from a design viewpoint.

¹We thank the support from Mathers Foundation, NSF, NSF REU grant and NSF Teragrid resources.

C1.00263 Electron Shock Waves with a Significant Current behind the Shock Front¹, MOSTAFA HEMMATI, Arkansas Tech University — Electrical breakdown of a gas in a strong electric field is carried out by a wave with a strong discontinuity at the wave front, traveling with speed comparable to speed of light. For theoretical investigation of electrical breakdown of a gas, we apply a one-dimensional, steady profile, constant velocity, three component fluid model. For current bearing breakdown waves, in addition to the set of electron fluid dynamical equations, the shock conditions on electron velocity and temperature need to be modified as well. For breakdown waves, considering a significant current behind the shock front, we will derive the boundary conditions on electron velocity and temperature at the shock front. The modified set of boundary conditions has made the integration of the set of electron fluid dynamical equations through the dynamical transition region of the wave possible. The wave profile for electric field and electron velocity, temperature and number density will be presented.

¹The author would like to acknowledge the Arkansas Space Grant Consortium's financial support of this research project.

C1.00264 X-ray Studies of Rapidly Evolving Interfacial Nanostructures, YELING DAI, Department of Physics, UC San Diego, BINHUA LIN, MATI MERON, KYUNGIL KIM, BRIAN LEAHY, Center for Advanced Radiation Sources(CARS), University of Chicago, OLEG SHPYRKO, Department of Physics, UC San Diego — Interfacial nanostructures represent a class of systems that is of great interest for studies of quasi-2D systems, chemical self-assembly, surfactant behavior and biologically relevant membranes. During the compression process, the self-assembled nanoparticle films at the air-liquid interface exhibit rich mechanical behavior, undergoing a rapid structural evolution which is marked by the transition from monolayer to multilayer and/or the formation of periodic wrinkles and folds. Due to the compression rate of the barrier, the timescale of this evolution is typically several minutes, which is much shorter than the time the conventional X-ray Reflectivity (XR) takes for a liquid surface measurement. Therefore we explore the ability of Grazing Incidence X-ray Off-Specular (GIXOS) scattering to capture the elastic properties, structures and surface fluctuating modes of Au nanoparticle films during the rapid structural evolution. We present here the detailed analysis of GIXOS data from the self-assembled Au nanoparticle films and show how we obtain quantitative, Angstrom-resolution details of electron density profile normal to the surface with a temporal resolution that allows us to study in-situ the rapid evolution of Au nanoparticle films structure in response to the compression.

C1.00265 STATISTICAL AND NONLINEAR PHYSICS —

C1.00266 Frequency Enhancement in Coupled Noisy Excitable Elements: The effect of excitability, system size and topology¹, WEI-YIN CHIANG, PIK-YIN LAI, Dept. of Physics and Center for Complex Systems, National Central University, Chungli, Taiwan 320, R.O.C., C.K. CHAN, Institute of Physics, Academia Sinica, Nankang, Taipei, Taiwan 115, R.O.C. — The oscillatory dynamics of coupled noisy excitable FitzHugh-Nagumo elements is investigated as a function of the coupling strength g . For a system consists of coupled noisy excitable elements, the synchronize frequency will be higher than the uncoupled frequencies of each element. As g increases, there is an unexpected peak in the mean of frequency distribution before reaching synchronization at the optimal coupling strength. This enhancement level is investigated systematically on depending on hypercubic lattices in different dimensions, Erdos-Renyi random graphs and random networks with fixed coordination numbers. It is found that the maximal enhancement coupling and enhancement level depend on the connection topology and spatial dimensions, the enhancement level and the frequency distribution widths follow scaling laws as verified by different lattices(honeycomb, square, and hexagonal) in two-dimensions, suggesting some sort of universality in frequency enhancement.

¹National Science Council of Taiwan under grant nos. 98-2112-M-008-023-MY3, 97-2112-M-001-003

C1.00267 Phase Diagram of the mixed spin-2 and spin-5/2 Ising system with two different single-ion anisotropies¹ , JOSÉ CRUZ FILHO, MAURICIO GODOY, ALBERTO ARRUDA, Instituto de Física, Universidade Federal de Mato Grosso, 78060-900, Cuiabá, MT, Brazil — In the last five decades the Ising model has been one of the most largely used to describe critical behavior of several systems in the nature. In particular, in the physics of the condensed matter it is important to describe critical behavior and other thermodynamics properties of a variety of physic systems (disordered system, spins glass, random field Ising model, etc.). Recently, several extensions have been made in the spin-1/2 Ising model to describe a wide variety of physic systems. For example, the models consisting of mixed spins of different magnitudes are interesting extensions, which are so-called mixed-spin Ising models. In this work we present a study of the effects of two single-ion anisotropies in the phase diagram and in the compensation temperatures of the mixed spin-2 and spin-5/2 Ising ferrimagnetic system. We employ the mean-field theory based on the Bogoliubov inequality for the Gibbs free energy, and the Landau expansion of the free energy in the order parameter to describe the phase diagrams. In the plane critical temperature versus single-ion anisotropie the phase diagram display behavior tricritical (second-order transition separated of the first-order transition lines by a tricritical point).

¹Financial support from the Brazilian Agencies FAPEMAT, CAPES, and CNPq is gratefully acknowledged

C1.00268 Monte Carlo Study of a Mixed Spin-1 and Spin-3/2 Ising Ferrimagnet with Random Anisotropies¹ , JOAO PEREIRA, ALBERTO ARRUDA, MAURICIO GODOY, Instituto de Física, Universidade Federal de Mato Grosso, 78060-900, Cuiaba, Mato Grosso, Brazil — The interest in studying magnetic properties of systems of mixed spin Ising has been grown in last years. This is due to such systems have less translational symmetry than their single-spin counterparts. This property is very important to study some type of ferrimagnetism, which are of current interest. One of the most interesting features of the ferrimagnetism is that they can exhibit compensation temperature. Spin systems mixed with spins in the two sublattices and with random anisotropies are not commonly studied. Monte Carlo method have been proven to be reliable and relatively simple technique to analyze mixed Ising model. In this work, we performed Monte Carlo simulations to study a mixed system ferrimagnetism on a square lattice. The model system consists of two interpenetrating sublattices with spins spin-1 and spin-3/2 in the presence of random anisotropies. The magnetic properties such as magnetization, susceptibility and Binder cumulant, were determined to obtain the critical temperature of the system in various situations. We also determined the phase diagram in the plane temperature versus anisotropy strength for several values of the randomness anisotropy probability.

¹Financial support from the Brazilian Agencies FAPEMAT, CAPES and CNPq is gratefully acknowledged.

C1.00269 Measurement of organization in complex and co-evolving networks¹ , GEORGI GEORGIEV, Assumption College and Tufts University — We apply a new method for measurement of organization of complex and co-evolving networks using the quantity of physical action. We consider simple arrangements of elements in a network and constraints to their motion along paths and calculate the amount of organization in each system using the following measure: organization is the inverse of the average sum of physical actions of all elements in a system per unit motion multiplied by the Planck's constant. The meaning of quantity of organization here is the number of quanta of action per one unit motion along a path of an element. A unit motion along a path for a network, such as internet, is the transmission of one bit of information. The calculation can be expanded to systems consisting of many elements and constraints and also can be followed as a function of time with improvement of the organization of a system or connected systems and networks. Thus, the principle of least action becomes the driving force, and the least action state of the system, the attractor for all of the paths of its elements and states of its constraints. We consider also the rate of constraint minimization, or decrease of action per element and motion, as a function of the number of elements i.e. quality as a function of quantity. Increase of quantity, within specified limits, leads to increase of level of organization and vice versa.

¹The author thanks Assumption College for research support.

C1.00270 Direct Method in Determining the Direction of Action in the Coupling Map Ring , WANG-CHUANG KUO, DI LUO, Department of Physics, Natl. Sun Yat-Sen University, Kaohsiung, Taiwan, ROC — Recently, Hung and Hu provided a genuine way to carry binary data on a coupling map ring (CMR) for the chaotic communication (Phys. Rev. Lett., 101, 244102 (2008)). They use the temporal transfer entropy (TTE) to determine the direction of action, which tells bit 1 or 0, between two neighboring chaotic maps of the CMR. A direct method based on the correlation between the changes of two chaotic data is not only capable to resolve the carried bits but more efficient than the scheme of TTE.

C1.00271 Jamming in complex networks with degree correlation , ANA PASTORE Y PIONTTI, IFIMAR Universidad Nacional de Mar del Plata- CONICET, Funes 3350 (7600) Mar del Plata, Argentina, LIDIA BRAUNSTEIN, IFIMAR Universidad Nacional de Mar del Plata- CONICET and Center for polymer studies, Boston University, Boston, MA 02215, USA, PABLO MACRI, IFIMAR Universidad Nacional de Mar del Plata- CONICET, Funes 3350 (7600) Mar del Plata, Argentina — We study the effects of the degree-degree correlations on the pressure congestion J for a diffusive transport process on scale free complex networks. Using the gradient network approach we find that the pressure congestion for disassortative (assortative) networks is lower (bigger) than the one for uncorrelated networks which allow us to affirm that disassortative networks enhance transport through them. This result agrees with the fact that many real world transportation networks naturally evolve to this kind of correlation. We explain our results showing that for the disassortative case the clusters in the gradient network turn out to be as much elongated as possible, reducing the pressure congestion J and observing the opposite behavior for the assortative case. Finally, we apply our transportation process to real world networks, and the results agree with our findings for model networks.

C1.00272 Stretch-induced stress patterns and wrinkles in hyperelastic thin sheets , RUI HUANG, VISHAL NAYYAR, K RAVI-CHANDAR, University of Texas at Austin — Wrinkles are commonly observed in stretched thin sheets and membranes. This paper presents a numerical/experimental study on stretch-induced wrinkling of hyperelastic thin sheets. The model problem is set up for uniaxial stretching of a rectangular sheet with two clamped ends and two free edges. A two-dimensional stress analysis is performed first under the plane-stress condition to determine stretch-induced stress distribution patterns in the elastic sheets, assuming no wrinkles. As a prerequisite for wrinkling, development of compressive stresses in the transverse direction is found to depend on both the length-to-width aspect ratio of the sheet and the applied tensile strain. Next, an eigenvalue analysis is performed to find the potential buckling modes of the elastic sheet under the prescribed boundary conditions. A nonlinear post-buckling analysis is performed to show evolution of stretch-induced wrinkles. The wrinkle wavelength decreases with increasing strain, in good agreement with the prediction by a scaling analysis. However, as the tensile strain increases, the wrinkle amplitude first increases and then decreases, eventually flattened beyond a moderately large strain, in contrast to the scaling analysis. Finally, experimental measurements with polyethylene sheets will be presented in comparison with the numerical results.

C1.00273 Random fields at an absorbing state transition , HATEM BARGHATHI, THOMAS VOJTA, Department of Physics, Missouri University of Science and Technology, Rolla, MO 65409 — We investigate a nonequilibrium phase transition in the presence of disorder that locally breaks the symmetry between two equivalent absorbing states. Such "random-field" disorder is known to have dramatic effects on equilibrium phase transitions; in low dimensions it can completely destroy the phase transition. In contrast, we demonstrate that the absorbing state transition of the one-dimensional generalized contact process persists in the presence of random fields. However, the dynamics in the inactive phase becomes ultraslow. We illustrate our theory by means of large-scale Monte-Carlo simulations.

C1.00274 Fluctuation-driven Turing patterns in predator-prey dynamics, THOMAS BUTLER, Massachusetts Institute of Technology, NIGEL GOLDENFELD, University of Illinois at Urbana-Champaign — Models of diffusion-driven pattern formation that rely on the Turing mechanism are utilized in many areas of science. However, many such models suffer from the defect of requiring fine tuning of parameters or an unrealistic separation of scales in the diffusivities of the constituents of the system in order to predict the formation of spatial patterns. In the context of a generic model of predator-prey population dynamics, we show that the inclusion of intrinsic noise in Turing models leads to the formation of “quasipatterns” that form in generic regions of parameter space and are experimentally distinguishable from standard Turing patterns. The existence of quasipatterns removes the need for unphysical fine tuning or separation of scales in the application of Turing models to real systems. We also exhibit numerical simulations of the formation of quasi-patterns deep in the quasi-pattern phase.

C1.00275 The Explanation of the Photon’s Electric and Magnetic Fields; and its Particle and Wave Characteristics, RUSSELL MOON, Dr, VICTOR VASILIEV, Pr — Using the principles of the Vortex Theory, the creation of the photon’s electric and magnetic components are explained: the condensed region of space is responsible for creating the photon’s electric component and its particle effect; its expansion and contraction is responsible for its frequency; its motion through three dimensional space creates a wave in the surrounding space. This wave is responsible for the photon’s magnetic component and wave characteristics. The simultaneous expansion and contraction of both the dense region of space that is the photon and the surrounding space it passes through explains why the electric and magnetic effects are at right angles to each other. Also the photon’s particle and wave characteristics are explained.

C1.00276 Pure Quantum Gravity Simulation in 1+1 Dimensions using Causal Dynamical Triangulation, NORMAN ISRAEL, JOHN LINDNER, The College of Wooster — Causal Dynamical Triangulation (CDT) is a conservative approach to quantizing gravity. It involves decomposing spacetime into “triangular” building blocks. In computer simulations, we implement CDT in 1+1 dimensions without matter. We compute the ratio of the corresponding universe’s mean size to its spread and compare with analytical results.

C1.00277 Contesting the paradigm of chirality, EFI EFRATI, University of Chicago — In 1893 Lord Kelvin coined the term chirality, and stated what is to become the elementary paradigm of chirality: ‘I call any geometrical figure, or any group of points, chiral, and say it has chirality, if its image in a plane mirror, ideally realized cannot be brought to coincide with itself’. While the notion of chirality has greatly advanced our understanding of the structures of molecules and crystals, it has been shown to be inconsistent with every pseudo-scalar quantification. In this talk I will present a tabletop demonstration of a chiral structure which is constructed through the achiral summation of identical elementary units which are symmetric under reflection. The seeming contradiction to the definition of chirality is reconciled by proposing an alternative definition, relying on the physicist interpretation of the right hand rule.

C1.00278 Phase-Space Networks of Frustrated Spin Models, YILONG HAN, Hong Kong University of Science and Technology — We propose a complex-network approach to study phase-space structures of frustrated spin models and lattice gas models. Their highly degenerated ground states are mapped as discrete networks such that the quantitative network analysis can be applied to phase-space studies. The resulting phase spaces share some common features and establish a class of complex networks with unique Gaussian spectral densities. A one-to-one correspondence is discovered between the six-vertex model (jigsaw puzzle) and sphere stack.

C1.00279 Common features in phase-space networks of frustrated spin models and lattice-gas models, FENG WANG, YI PENG, YILONG HAN, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China, SOFT MATTER AND VIDEO MICROSCOPY LAB TEAM — We mapped the phase spaces of the following four models into networks: (1a) the Ising antiferromagnet on triangular lattice at the ground state and (1b) above the ground state, (2) the six-vertex model (i.e. square ice or spin ice), (3) 1D lattice gas and (4) 2D lattice gas. Their phase-space networks share some common features including the Gaussian degree distribution, the Gaussian spectral density, and the small-world properties. Models 1a, 2 and 3 with long-range correlations in real space exhibit fractal phase spaces, while models 1b and 4 with short-range correlations in real space exhibit non-fractal phase spaces. This result supports one of the untested assumptions in Tsallis’s non-extensive statistics.

C1.00280 Simple Design Rules for Spike Neural Network Based General Purpose Networks, ARNAB ROY, J. DAVID SCHAFFER, CRAIG LARAMEE, Binghamton University — It has been much lamented over the past decade that, although spiking neural networks (SNNs) have exciting proven computational properties, there are no design rules for assembling networks for specific purposes. Here we offer design approaches for creating three general purpose networks namely, a temporal pattern (serial channel) detector, sequence detector (parallel channel), and any specific mapping of input to output spike patterns on a serial channel. Central pattern generators are instances of this last design. These design rules are based on synchrony detection which SNNs do so well. Here we also introduce a modification to the basic SRM0 model which not only reduces the computational cost, but also enables us to develop these design rules. We discuss how these designs may be combined into fairly general spatio-temporal pattern detectors. Finally, by adding a capability for feature discovery/extraction, we envision an approach to learning spatio-temporal pattern classifiers.

C1.00281 Vulnerability and Vaccination Strategies on realistic complex network, THIERRY PLATINI, Virginia Bioinformatics Institute, ANDREA APOLLONI, Laboratoire de Physique ENS-Lyon — The general understanding of non-equilibrium stochastic processes evolving on complex networks become an important challenge. In the framework of epidemiology, one of the key challenges is the identification and the understanding of the role of critical and vulnerable nodes in the diffusion process. Considering the SIER model evolving on a large realistic complex networks, we present a study of the vulnerability for different viral strength. Our result are used to evaluate the possible vaccination strategies.

C1.00282 Transitions in Physiologic Coupling: Sleep Stage and Age Dependence of Cardio-respiratory Phase Synchronization¹, RONNY P. BARTSCH, PLAMEN CH. IVANOV, Harvard Medical School and Division of Sleep Medicine, Brigham and Womens Hospital, Boston, MA 02115, USA — Recent studies have focused on various features of cardiac and respiratory dynamics with the aim to better understand key aspects of the underlying neural control of these systems. We investigate how sleep influences cardio-respiratory coupling, and how the degree of this coupling changes with transitions across sleep stages in healthy young and elderly subjects. We analyze full night polysomnographic recordings of 189 healthy subjects (age range: 20 to 90 years). To probe cardio-respiratory coupling, we apply a novel phase synchronization analysis method to quantify the adjustment of rhythms between heartbeat and breathing signals. We investigate how cardio-respiratory synchronization changes with sleep-stage transitions and under healthy aging. We find a statistically significant difference in the degree of cardio-respiratory synchronization during different sleep stages for both young and elderly subjects and a significant decline of synchronization with age. This is a first evidence of how sleep regulation and aging influence a key nonlinear mechanism of physiologic coupling as quantified by the degree of phase synchronization between the cardiac and respiratory systems, which is of importance to develop adequate modeling approaches.

C1.00283 Levels of complexity in scale-invariant neural signals¹, PLAMEN CH. IVANOV, Harvard Medical School and Division of Sleep Medicine, Brigham and Womens Hospital, Boston, MA 02115, USA, QIANLI D.Y. MA, Nanjing University of Posts and Telecommunications, Nanjing 210003, China, RONNY P. BARTSCH, Harvard Medical School and Division of Sleep Medicine, Brigham and Womens Hospital, Boston, MA 02115, USA — Many physiological systems exhibit complex scale-invariant and nonlinear features characterized long-range power-law correlations, indicating a possibly common control mechanism. It has been suggested that dynamical processes, influenced by inputs and feedback on multiple time scales, may be sufficient to give rise to this complexity. Two examples of physiologic signals that are the output of hierarchical multiscale physiologic systems under neural control are the human heartbeat and human gait. We show that while both cardiac interbeat interval and gait interstride interval time series under healthy conditions have comparable scale-invariant behavior, they still belong to different complexity classes. We compare results from empirical findings and stochastic feedback modeling approaches to cardiac and locomotor dynamics, which provide new insights into the multicomponent neural mechanisms regulating these complex systems.

¹Supported by: NIH Grant 1R01HL098437-01A1, Office of Naval Research Grant 000141010078, Brigham and Womens Hospital BRI Fund and the German Academic Exchange Service (DAAD).

C1.00284 Characteristics of group networks in the KOSPI and the KOSDAQ, KYUNGSIK KIM, JEUNG-SU KO, Department of Physics, Pukyong National University, Busan 608-737, Korea, MYUNGGI YI, Department of Biomedical Engineering, Pukyong National University, Busan 608-737, Korea — We investigate the main feature of group networks in the KOSPI and KOSDAQ of Korean financial markets and analyze daily cross-correlations between price fluctuations for the 5-year time period from 2006 to 2010. We discuss the stabilities by undressing the market-wide effect using the Markowitz multi-factor model and the network-based approach. In particular we ascertain the explicit list of significant firms in the few largest eigenvectors from the undressed correlation matrix. Finally, we show the structure of group correlation by applying a network-based approach. In addition, the relation between market capitalizations and businesses is examined.

C1.00285 Multifractal Analysis of Asian Foreign Exchange Markets and Financial Crisis, GABJIN OH, Chosun University, OKYU KWON, National Institute for Mathematical Sciences, WOO-SUNG JUNG, POSTECH — We analyze the multifractal spectra of daily foreign exchange rates for Japan, Hong-Kong, Korea, and Thailand with respect to the United States Dollar from 1991 to 2005. We find that the return time series show multifractal spectrum features for all four cases. To observe the effect of the Asian currency crisis, we also estimate the multifractal spectra of limited series before and after the crisis. We find that the Korean and Thai foreign exchange markets experienced a significant increase in multifractality compared to Hong-Kong and Japan. We also show that the multifractality is strongly related to the presence of high values of returns in the series.

C1.00286 Rural-urban migration including formal and informal workers in the urban sector: an agent-based numerical simulation study, NILTON BRANCO, THARNIER OLIVEIRA, Departamento de Física, Universidade Federal de Santa Catarina, Florianopolis SC, Brazil, JAYLSON SILVEIRA, Departamento de Economia, Universidade Federal de Santa Catarina, Florianopolis SC, Brazil — The goal of this work is to study rural-urban migration in the early stages of industrialization. We use an agent-based model and take into account the existence of informal and formal workers on the urban sector and possible migration movements, dependent on the agents' social and private utilities. Our agents are placed on vertices of a square lattice, such that each vertex has only one agent. Rural, urban informal and urban formal workers are represented by different states of a three-state Ising model. At every step, a fraction a of the agents may change sectors or migrate. The total utility of a given agent is then calculated and compared to a random utility, in order to check if this agent turns into an actual migrant or changes sector. The dynamics is carried out until an equilibrium state is reached and equilibrium variables are then calculated and compared to available data. We find that a generalized Harris-Todaro condition is satisfied [1] on these equilibrium regimes, i.e, the ratio between expected wages between any pair of sectors reach a constant value.

C1.00287 Non-equilibrium vortex relaxation in disordered type-II superconductors¹, ULRICH DOBRAMYSL, MICHEL PLEIMLING, UWE C. TAUBER, Department of Physics, Virginia Tech — We study the non-equilibrium steady states and relaxation properties of driven vortex lines in the presence of both randomly distributed point and columnar pinning centers. We model the vortices as interacting elastic lines and employ a Langevin molecular dynamics algorithm to extract steady-state and non-stationary time-dependent behavior. In order to characterize the relaxation properties towards thermal equilibrium, we investigate transient two-time correlation functions. In particular we compare results obtained for systems with randomly distributed point pins and parallel columnar defects.

¹Research supported by DOE-BES, Grant No. DE-FG02-09ER46613.

C1.00288 Dynamics of Sheared Polydisperse Emulsions, XIN DU, KENNETH DESMOND, DANDAN CHEN, KAZEM EDMOND, ERIC WEEKS, Physics Dept., Emory University, WEEKS' LAB TEAM — Polydispersity is an important parameter in the jamming transition of soft materials which has not been well understood yet. In our work, we study the elastic response of a high volume fraction polydisperse emulsion to a periodic shear stress. The droplets' dynamics is imaged by confocal microscopy. Our results reveal that most of the droplets in the emulsion exhibit an elastic and periodic motion under the shear stress. However, the smaller droplets often move with anomalously large or small amplitudes compared to the mean motion. Some droplets also move nearly perpendicular to the mean flow field. The broad distribution of the amplitudes and phases of the smaller droplets' motions can be attributed to the motion of the larger droplets and the distribution of the droplet sizes.

C1.00289 The rigidity (unjamming) transition of disordered solids is caused by non-affinity, ALESSIO ZACCONE, Cavendish Laboratory, University of Cambridge — I will present a theoretical framework which allows one to account for the non-affinity of particle displacements due to disorder within a statistical mechanical description of the elasticity of disordered solids (1). A few important results can be derived analytically from first principles for disordered harmonic packings/lattices. First of all, the theory successfully recovers the unjamming or rigidity transition $G(z-2d)$, where G is the shear modulus and z the coordination number, in excellent quantitative agreement with the numerical simulations of Ref. (2). Secondly, the theory explains this scaling law, which was hitherto enigmatic, in terms of the competition between the elastic (bonding) energy of the solid and the non-affine relaxations which are a consequence of structural disorder and contribute a dissipative term to the free energy of the solid. Potential applications to unsolved issues related to transport and vibrational properties of disordered solids will be briefly discussed. References (1) A. Zaccane and E. Scossa-Romano, *Phys. Rev. B* **83**, 184205 (2011) (2) C.S. O'Hern, et al. *Phys. Rev. E* **68**, 011306 (2003).

C1.00290 Amended tunneling model to explain the anisotropy of the glassy properties of crystals and quasicrystals¹, DRAGOS-VICTOR ANGHEL, Horia Hulubei National Institute of Physics and Nuclear Engineering, DMITRY CHUROCHKIN, University of Chile — The low temperature acoustic and thermal properties of amorphous, glassy materials are remarkably similar and they can be explained to a large extent by assuming that the material contains a large number of dynamic defects. These dynamic defects are tunneling systems and are modeled by an ensemble of two-level systems (TLS). Crystals with defects—with a large enough amount of disorder—exhibit also glass-like properties, but these properties are not so universal and, even more, they are not isotropic. In Phys. Rev. B **75**, 064202 (2007) we proposed an amended model for the description of the interaction of two-level systems with arbitrary strain fields. Here we show how this model explains the anisotropy of the glass-like properties of disordered crystals and quasicrystals.

¹Financial support from the ANCS grant 114/05.10.2011 and JINR-IFIN grants N4063 and Titeica-Markov are gratefully acknowledged

C1.00291 Dynamical Mechanism of Superdiffusive Processes and Multifractals, KYUNGSIK KIM, Department of Physics, Pukyong National University, Busan 608-737, Korea, JAE-WON JUNG, National Institute of Meteorological Research, KMA, Seoul 156-720, Korea, SEUNG-KYU SEO, Department of Physics, Pukyong National University, Busan 608-737, Korea — The diffusive process and the multifractal property are investigated in the Baduk. We ascertain that the difference of position between black and white stones undergoes the superdiffusion. In our study, we mainly estimate and analyze the generalized Hurst exponent, singularity spectrum, and multifractal strength in the tipping points of the Baduk. We also discuss the multifractal property of three segments, after analyzing the multifractality. In multifractal structures, it is found that segment 5 has shown a stronger multifractal behavior than the other segments for the tipping points of the Baduk.

C1.00292 On the metal-insulator-transition in vanadium dioxide, AZITA JOVAINI, SHIGEJI FUJITA, University at Buffalo, SALVADOR GODOY, UNAM, AKIRA SUZUKI, Tokyo University of Science — Vanadium dioxide (VO₂) undergoes a metal-insulator transition (MIT) at 340 K with the structural change from tetragonal to monoclinic crystal. The conductivity σ drops at MIT by four orders of magnitude. The low temperature monoclinic phase is known to have a lower ground-state energy. The existence of the k -vector $\mathbf{k}$ is prerequisite for the conduction since the $\mathbf{k}$ appears in the semiclassical equation of motion for the conduction electron (wave packet). The tetragonal (VO₂)₃ unit is periodic along the crystal's x -, y -, and z -axes, and hence there is a three-dimensional k -vector. There is a one-dimensional $\mathbf{k}$ for a monoclinic crystal. We believe this difference in the dimensionality of the k -vector is the cause of the conductivity drop.

C1.00293 On Van Hove Singularities in Pure Cubic Crystals, AZITA JOVAINI, JAMES PIENKA, SHIGEJI FUJITA, University at Buffalo, SALVADOR GODOY, UNAM, AKIRA SUZUKI, Tokyo University of Science — Pure elements form crystals of various lattices, cubic, tetragonal and others. At very low temperatures the lattice heat capacities in three dimensional crystals obey Debye's T^3 -law, where T is the absolute temperature. X-ray scattering experiments and lattice dynamics calculations reveal van Hove singularities when the density of states is plotted as a function of the phonon frequency. A physical origin of the singularities, jumps in the derivative of the density of states, is clarified. The singularities occur in three and two dimensions when the constant-frequency plane touches the Brillouin zone boundary *and* undergoes a curvature inversion. The face-centered cubic lattice is composed of two simple cubic sublattices and one tetragonal sublattice. The first (second) major peaks in the observed density of states in aluminum (Al) are shown to arise from the transverse phonons associated with the cubic (tetragonal) sublattices. We predict that the density of states has one major peak with a shoulder (two peaks with shoulders) for a body-centered cubic (face-centered cubic) crystal.

C1.00294 Aging processes in reversible reaction-diffusion systems¹, NASRIN AFZAL, Virginia Tech, JUSTIN WAUGH, University of Colorado Boulder, MICHEL PLEIMLING, Virginia Tech — Reaction-diffusion systems with reversible reactions generically display power-law relaxation toward chemical equilibrium. In this work we investigate, through numerical simulations, aging processes that characterize the non-equilibrium relaxation. Studying a model which excludes multiple occupancy of a site, we find that the scaling behaviors of the two-time correlation and response functions are similar to that discovered previously in an exactly solvable version with no restrictions on the occupation numbers. In particular, we find that the scaling of the response depends on whether the perturbation conserves a certain quantity or not. Our results point to a high degree of universality in relaxation processes taking place in diffusion-limited systems with reversible reactions.

C1.00295 Numerical master equation approach for complex transport processes¹, JANNE KAUTTONEN, JUHA MERIKOSKI, University of Jyväskylä — Applicability of the numerical master equation analysis in studies of complex non-equilibrium systems is discussed. For small systems (up to $\sim 10^6$ states), solving of master equations directly is found very useful especially when studying parameter sensitive and elusive properties, such as drifts caused by the ratchet effect. Also various types of optimization methods can be applied. Efficient numerical methods for solving large master equation systems are discussed. Properties that can be readily computed include mean values and fluctuations of trajectory and state dependent observables, such as velocity, diffusion coefficient and shape deformations of the object. To further study the microscopic mechanisms of complex transport processes, we apply a graph optimization method to master equation sets. This allows one to identify the dominating processes that are responsible for the transport. We present detailed case studies for reptating polymers and metal-on-metal atomic islands in non-homogeneous potentials. These models represent complex many-particle systems with rich nonlinear behavior, such as inversions and increasing of velocity and large shape deformations in external potentials.

C1.00296 String Theory (Knot Really), KARL SMITH, JOHN LINDNER, The College of Wooster — Knots can make one string out of two, without adhesive, simply by entanglement. We present a computer simulation of knots untying. A series of spherical masses connected by spring forces and excluded by normal forces approximate the strings. We tie the simulated strings into knots and tug on their ends with constant forces. Plotting time to untie versus a static coefficient of friction reveals critical frictions above which the knots hold. The critical frictions depend on the knot type (including square, thief, and surgeon's thief knots) and might be used to classify practical knots.

C1.00297 Metal Insulator transition in Vanadium Dioxide, AZITA JOVAINI, SHIGEJI FUJITA, AKIRA SUZUKI, SALVADOR GODOY, None, FUJITA AND ALL COLLABORATION, SUZUKI AND ALL COLLABORATION — MAR12-2011-000262 Abstract Submitted for the MAR12 Meeting of The American Physical Society Sorting Category: 03.9 (T) On the metal-insulator-transition in vanadium dioxide AZITA JOVAINI, SHIGEJI FUJITA, University at Buffalo, SALVADOR GODOY, UNAM, AKIRA SUZUKI, Tokyo University of Science — Vanadium dioxide (VO₂) undergoes a metal-insulator transition (MIT) at 340 K with the structural change from tetragonal to monoclinic crystal. The conductivity σ drops at MIT by four orders of magnitude. The low temperature monoclinic phase is known to have a lower ground-state energy. The existence of the k -vector $\mathbf{k}$ is prerequisite for the conduction since the $\mathbf{k}$ appears in the semiclassical equation of motion for the conduction electron (wave packet). The tetragonal (VO₂)₃ unit is periodic along the crystal's x -, y -, and z -axes, and hence there is a three-dimensional k -vector. There is a one-dimensional $\mathbf{k}$ for a monoclinic crystal. We believe this difference in the dimensionality of the k -vector is the cause of the conductivity drop. Prefer Oral Session X Prefer .

C1.00298 GENERAL PHYSICS —

C1.00299 Neutrosophic Physics as a new field of research

FLORENTIN SMARANDACHE, University of New Mexico — Neutrosophic Physics describes collections of objects or states that are individually characterized by opposite properties, or are characterized neither by a property nor by the opposite of that property. Neutrosophic Physics means a mixture of physical concepts/ideas/spaces/laws/theories $\langle A \rangle$ with their opposite $\langle \text{anti}A \rangle$ or with their neutral $\langle \text{neut}A \rangle$ {where $\langle \text{neut}A \rangle$ means neither $\langle A \rangle$ nor $\langle \text{anti}A \rangle$, but in between, i.e. the neutral part}, and it is a combination of heterogeneous contradictory things which hold together. There are many cases in scientific fields (and in humanistic fields) that an item $\langle A \rangle$ and its opposite $\langle \text{anti}A \rangle$ or their neutral $\langle \text{neut}A \rangle$ are simultaneously valid. - Several examples of neutrosophic physics: (1) unmatter, which is formed by matter and antimatter that bind together (Smarandache, 2004); (2) neutral Kaon, which is a pion & anti-pion composite (Santilli, 1978) and therefore a form of unmatter; (3) neutrosophic cosmological model (Rabounski-Borissova, 2011); (4) among possible Dark Matter candidates there may be exotic particles that are neither Dirac nor Majorana fermions; (5) mercury (Hg) is a state that is neither liquid nor solid under normal conditions at room temperature; (6) non-magnetic materials are neither ferromagnetic nor anti-ferromagnetic; (7) quark gluon plasma (QGP) is a phase formed by quasi-free quarks and gluons that behaves neither like a conventional plasma nor as an ordinary liquid; (8) neutrosophic methods in General Relativity (Rabounski-Smarandache-Borissova, 2005); (9) neutrosophic cosmological model (Rabounski-Borissova, 2011); etc.

C1.00300 Superconductors (*History & Advanced Research*)

MONA KHORRAMI, Sanofi-Aventis Group Co. — *Superconductors* are materials that have no resistance to electricity's flow; they are one of the last great frontiers of scientific discovery. In 1911 superconductivity was first observed in mercury by Dutch physicist Heike Kamerlingh Onnes When he cooled it to the temperature of liquid helium, 4 degrees Kelvin (-452F, -269C), its resistance suddenly disappeared. It was necessary for Onnes to come within 4 degrees of the coldest temperature that is theoretically attainable to witness the phenomenon of superconductivity. The next great milestone in understanding how matter behaves at extreme cold temperatures occurred in 1933. German researchers Walther Meissner and Robert Ochsenfeld discovered that a superconducting material will repel a magnetic field. A magnet moving by a conductor induces currents in the conductor. This is the principle on which the electric generator operates. But, in a superconductor the induced currents exactly mirror the field that would have otherwise penetrated the superconducting material - causing the magnet to be repulsed. This phenomenon is known as strong diamagnetism and is today often referred to as the "Meissner effect" (an eponym). In 1941 niobium-nitride was found to superconduct at 16 K. In 1953 vanadium-silicon displayed superconductive properties at 17.5 K. And, in 1962 scientists at Westinghouse developed the first commercial superconducting wire, an alloy of niobium and titanium (NbTi).

C1.00301 Teaching: the Wave Mechanics of McLeods' Stringy Electron, Explicit Nucleons, and Through-the-Earth Projections of Constellations' Stick Figures

ROGER DAVID MCLEOD, Univ. Massachusetts Lowell. Naturoptics for Safe Recovery of Vision., DAVID MATTHEW MCLEOD¹, Naturoptics for Safe Recovery of Vision. Bastyr Univ — This shows how Hooke's law, for electron, proton and neutron, 2D and 3D, strings, builds electromagnetic string-waves, extending, and pleasing, Schrödinger. These are composed of spirally linked, parallel, north-pole oriented, neutrino and antineutrino strings, stable by magnetic repulsions. Their Dumbo Proton is antineutrino-scissor cut, and compressed in the vicinity of a neutron star, where electrostatic marriage occurs with a neutrino-scissor cut, and compressed, electron, so a Mickey Neutron emerges. Strings predict: electron charge is $-1/3 e$, Dumbo P is 25 % longer than Mickey N, and Hooke says relaxing springs fuel three, separate, non-eternal, inflations, after Big Bangs. Gravity is strings, longitudinally linked. Einstein says Herman Grid's black diagonals prove human vision reads its information from algebraically-signed electromagnetic field distributions, (diffraction) patterns, easily known by ray-tracing, not requiring difficult Spatial Fourier Transformation. High-schoolers understand its application to Wave Mechanics, agreeing that positive-numbered probabilities do not enter, to possibly displease God. Detected stick-figure forms of constellations: like Phoenix, Leo, Canis Major, and especially Orion, fool some observers into false beliefs in things like UFHumanoids, or Kokopelli, Pele and Pamola!

C1.00302 Properties of Neutrinos and Leptonic Processes

SAMINA MASOOD, University of Houston Clear Lake — We study the effect of the modifications in the properties of neutrinos to the scattering crosssections of purely leptonic processes. Neutrinos change their behavior in the hot and dense media and the properties like mass, induced magnetic moment, number density and the refractive energy are also modified as a result. We investigate that how these properties affect the leptonic decays and scattering processes. Some of the important applications of these results are also indicated in this study.

C1.00303 POST-DEADLINE ABSTRACTS —

C1.00304 Measurement Setup for Characterizing Thermoelectric Materials at High Pressure¹

MATTHEW JACOBSEN, WEI LIU, BAOSHENG LI, Mineral Physics Institute, Stony Brook University — Several investigations have recently resulted in the development of methods for studying thermoelectric materials at high pressure. However, these investigations have focused primarily on probing the electrical resistivity and Seebeck coefficient. While these are important to the effective operation of thermoelectric materials, they are only part of the whole picture. In an effort to address this on a bulk materials scale, facilities have been developed in the High Pressure Laboratory of the Mineral Physics Institute to investigate these properties, along with investigations of the thermal conductivity and ultrasonic sound velocity. With these facilities, it is likely that further studies of these materials will help advance the theoretical understanding of thermoelectrics and further the development of new, more effective thermoelectric materials.

C1.00305 X-ray imaging of electrospinning polymer solutions¹

ISRAEL GREENFELD, ARKADII ARINSTEIN, Technion, KAMEL FEZZAA, Argonne National Laboratory, MIRIAM H. RAFILOVICH, State University of New York, Stony Brook, EYAL ZUSSMAN, Technion — The study of electrospinning polymer solution jets, and the evolution of the polymer entangled network during electrospinning, is of interest in clarifying nanofibers microstructure. We used fast X-ray phase-contrast imaging to investigate the flow of electrospinning PEO and PMMA semidilute solutions. The jet profile, velocity and absorbance were measured at high resolution ($< 1 \mu\text{m}/\text{pixel}$) for the first 10 mm of jet length, at various electrospinning conditions. Jet radius measurements demonstrate a viscosity-dominated flow, with common power-dependence on the distance from the orifice. The flow field was analyzed by imaging solutions with micron-size silica particles, revealing axial velocities of 0.5-1 m/s and strain rates of 200-300 1/s, as well as radial and rotational velocity components. The measured axial velocity provides a direct indication for rapid solvent evaporation as early as 2-3 mm from the jet start. X-ray absorption measurements reveal substantial polymer concentration rise along the jet and at the jet boundaries, evidence for rapid evaporation. Additionally, at high stretching conditions, the polymer concentration rises at the jet center, implying polymer network lateral contraction as predicted by theory.

C1.00306 Nano-indentation experiments: from viruses to cells, WOUTER ROOS, DAAN VORSELEN, Department of Physics and Astronomy, VU University, Amsterdam, The Netherlands, JACK VAN LOON, DESC, Department of Oral Cell Biology, ACTA-VU University, Amsterdam, The Netherlands, GJJS WUITE, Department of Physics and Astronomy, VU University, Amsterdam, The Netherlands — Over the last years AFM imaging and nanoindentation have become an indispensable tool for biophysical studies in liquid at the nano- and micro-scale. We look at both these length scales, at the cellular as well as the sub-cellular level. In particular, we perform combined imaging and force spectroscopy experiments on viral particles to elucidate their structure and mechanics [1]. These studies revealed that Noro virus has found an intriguing way to increase its mechanical strength. These self-assembling, natural nanoparticles incorporate a pre-stress during assembly, consolidating the structure of its protein shell that protects the genome [2]. Next, we studied whole cells. Mechanical loading is increasingly recognized as an important stimulus to cells. Establishing the local viscoelastic properties within a cell is vital to the understanding of the underlying mechanisms of cytoskeletal changes in response to these stimuli. We study the mechanical response of mammalian bone forming (osteoblast-like) cells on a substrate of physiological stiffness using spherical, μm -sized probes and we compare these results to the properties of bone forming cells originating from fish (teleosts).

C1.00307 Study of the interactions of magnetosomes inside magnetotactic bacteria (MTB) through modeling and experimentation¹, JIAJIA DONG, Hamline University, ANDRÉ KÖRNIG, Max Planck Institute of Colloids and Interfaces, Department of Biomaterials, STEFAN KLUMPP, Max Planck Institute of Colloids and Interfaces, Department of Theory & Biosystems, DAMIEN FAIVRE, Max Planck Institute of Colloids and Interfaces, Department of Biomaterials — Since the discovery in 1970s, magnetotactic bacteria (MTB) have enjoyed great interest to biomimetic and biophysical research, due to their fine-tuned synthesis of magnetosomes (magnetic nanocrystals enclosed in organelles) and challenges in understanding the precise mechanism of magnetotaxis via aligning the magnetosomes. We investigate magnetosomes inside an MTB cell as a chain of magnetic crystals and explore their internal interactions as well as the influence from an external magnetic field. Applying both analytical and simulation approaches, we are able to identify the threshold external magnetic field for effective magnetosome alignment depending on crystal configurations. The results agree well with high resolution X-ray diffraction data. They also provide a simple and quantitative model for elucidating the mechanical stability of the magnetosome chain, thus the energetically favorable states of MTB in the presence of an external magnetic field.

¹Study of the interactions of magnetosomes inside magnetotactic bacteria (MTB) through modeling and experimentation

C1.00308 Tailoring the localelectronic and structural properties of colloidal nanocrystals, MARIA LONGOBARDI, University of California, Berkeley, LBNL and University of Salerno, Italia, MATT SHELDON, TOMOYA ARAI, University of California, Berkeley and LBNL, ALESSANDRO SCARFATO, University of Salerno, Italia, A. PAUL ALIVISATOS, MICHAEL F. CROMMIE, University of California, Berkeley and LBNL — Recent advances in wet-chemical synthesis techniques allow unprecedented control of the composition, size, shape, and surface chemistry of colloidal nanocrystals. The structural, opto-electronic and magnetic properties of these materials can be tailored to enable new quantum phenomena with applications in biology, energy harvesting, and fundamental physical studies. Moreover, sophisticated understanding of colloidal nanocrystals requires local probes of individual particles, such as scanning tunneling microscopy (STM) and spectroscopy (STS), that can measure the local density of states (LDOS) and particle wave-functions in real space with atomic resolution. Here, we present our STM/STS studies of the structural and electronic properties of individual CdS, Cu₂S and binary CdS/Cu₂S heterostructure nanocrystals. Detailed local study of electronic properties of the nanocrystals could bridge the existing knowledge gap between bulk and nanoscale. Such understanding is crucial for the design of novel materials based on colloidal nanocrystals.

C1.00309 Non-uniform forcing of a magnetic soap film, RANDY BACK, REGAN BECKHAM, The University of Texas at Tyler — The effects of a non-uniform magnetic field on a suspension of magnetic nanoparticles in a soap film are investigated. Experiments show that a strong non-uniform field will form a two-dimensional structure of magnetic nanoparticles within the soap film. A model is developed to compare with experimental results for several different magnetic field configurations. The system is modeled with a two-dimensional thin film equation with no-flux boundary conditions. We show qualitative agreement between the model and experiments.

C1.00310 The cryogenics magnetocaloric effect in the blocking state superparamagnetic nanocapsules¹, SONG MA, XIANGUO LIU, TENG YANG, ZHIDONG ZHANG, Institute of Metal Research, Chinese Academy of Sciences — The large cryogenics magnetocaloric effect was obtained in superparamagnetic nanocapsules when they are in blocking state. Interestingly, the entropy change of superparamagnetic nanocapsules (Lanthanide-transition metal intermetallic compound), including GdAl₂/Al₂O₃, TbAl₂/Al₂O₃, DyAl₂/Al₂O₃ nanocapsules, shows an unusual sharp increase, when the nanocapsules go into their blocking state. Combining the structural and magnetic analysis, we find the high moment density and low anisotropy energy play crucial role in exciting and hindering the rotation of the moment process, which finally decide the magnitude of the entropy change. The entropy change dependence of the temperature change and applied magnetic field was obtained according to the Langevin theory.

C1.00311 ABSTRACT WITHDRAWN —

C1.00312 ABSTRACT WITHDRAWN —

C1.00313 Following the Dynamics of DNA in Living Cells, JOSHUA MILSTEIN, Department of Physics, University of Toronto, KRISHNAN RAGHUNATHAN, MIKE CHU, JENS-CHRISTIAN MEINERS, Department of Biophysics, University of Michigan — Cells are brimming with molecular activity, but the cellular interior is much more than a test tube for biochemical reactions. The intracellular environment imposes a variety of mechanical constraints and engenders interactions from molecular crowding to a range of motor-driven activity responsible for transcription, replication, cargo transport, cytoskeletal rearrangement, chromosomal remodeling, and so on. We have developed a two-color correlational microscopy technique to follow the dynamics of DNA interacting with the *in vivo* cellular environment. Substantial differences between live cells and dead, yet structurally intact, cells point to a strong coupling of active, motor-driven fluctuations in the cell. This suggests that the motion of native, cellular DNA may similarly be driven by active processes, instead of relying on purely thermal, passive fluctuations. We also note that the correlations provide a sensitive measure for the effective length of the DNA probe on a length scale around one persistence length (~ 50 nm). This paves the way for experiments with more complex DNA probes that can bind transcription factors to form protein-mediated DNA loops, the dynamics of which could be observed through this method.

C1.00314 Enhanced resonant magnetoelectric coupling in frequency-tunable composite multiferroic bimorph structures, PETER FINKEL, NUWC, SAM LOFLAND, Rowan University, DWIGHT VIEHLAND, Virginia Tech — We report on the enhanced resonant magnetoelectric (ME) coupling in composite multiferroic magnetostrictive/piezoelectric composites bimorph structures. The approach was shown to provide more than ten-fold gain in ME coefficient and broad-band range magnetic and electric field assisted stress-configurable resonance frequency tuning up to 100% in these ME structures. The ME structures were investigated using optical spectroscopy. It was shown that this principle of continuously tuned resonance could be used to improve selectivity, signal to noise ratio and universality and sensitivity of ME magnetic sensors.

C1.00315 Strongly interacting lattice bosons in disorder potential: a strong coupling approach¹, CHIEN-HUNG LIN, RAJDEEP SENSARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742, USA, KRISHNENDU SENGUPTA, Theoretical Physics Department, Indian Association for the Cultivation of Science, Kolkata-700032, India, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742, USA — We use a strong coupling canonical transformation to study the phase diagram of strongly interacting bosons in an optical lattice in the presence of one-body disorder potential. Our strong coupling approach treats the disorder potential non-perturbatively and can be applied to moderately high disorder potentials as long as the on site repulsion energy scale for the bosons (U) is larger than the scale of the disorder potential (V). Within the strong coupling approach, we systematically derive the low energy effective Hamiltonian, and, using variational Gutzwiller type wavefunctions, study the phase diagram of the disordered Hubbard model, identifying the Mott insulator, superfluid and Bose glass phases.

¹This work is supported by ARO-DARPA-OLE and UMD-CNAM.

C1.00316 Imaging of nearby NV centers beyond diffraction limit, FANG-WEN SUN, JIN-MING CUI, GUANG-CAN GUO, Key Lab of Quantum Information, University of Science and Technology of China, MICRO-CAVITY TEAM — Nitrogen-Vacancy (NV) centers in diamond have been widely applied in physical and biological study. Single NV center has shown its good quality as a single-photon source. More importantly, when two NV centers are close to each other within tens of nanometers, the strong dipole-dipole interaction can be applied in quantum information techniques. Diamond nanocrystal with NV center has been applied for imaging biological processes. Therefore, to image and distinguish two nearby NV centers is becoming more and more important. In experiment, NV centers are usually detected with scanning confocal optical fluorescence microscopy where the single-photon counts of spontaneous emission are measured to describe their optical imaging. Also, the method of stimulated emission depletion fluorescence microscopy was used to distinguish two nearby NV centers. Here, we proposed a new technique based on our home-built confocal scanning microscopy to image two nearby single NV centers. With the new imaging technique, we have experimentally imaged and distinguished two NV centers with the distance about 40nm, which is well beyond the diffraction limit. This imaging technique can, in principle, distinguish particles with any overlapping.

C1.00317 Phase transition kinetics and critical phenomena of the site dilute Ising model with long range interactions¹, KANG LIU, CHRISTOPHER SERINO, WILLIAM KLEIN, Boston University, HARVEY GOULD, Clark University — We consider the effect of quenched site dilution on the phase transition kinetics and critical phenomena of the Ising model with long range interactions. First, we generalize the Harris criterion to mean-field and near mean-field systems with long range interactions and show that the critical exponents of both the critical point and spinodal do not change regardless of the dimensionality. This is supported by measurements of the isothermal susceptibility near the spinodal line from Monte-Carlo simulations. We also generalize the Coniglio-Klein method by mapping the dilute Ising critical point onto an equivalent site-bond percolation problem. In addition, using the Hubbard-Stratanovich transformation, we are able to write down a coarse-grained field theory for a specific dilution realization and use it to interpret simulations of the defect density dependent local growth of the stable phase after an instantaneous quench.

¹The authors wish to thank the DOE for support.

C1.00318 Computation of Shock Waves in Binary Inert Gas Mixtures of Diatomic Gases Using the Generalized Boltzmann Equation, RAMESH AGARWAL, GENG QIAN, Washington University in St. Louis — This paper describes the methodology for computing non-equilibrium shock waves in a binary inert mixture of monoatomic and diatomic gases using the Generalized Boltzmann Equation (GBE). For solving the classical Boltzmann equation for a mixture of monoatomic gases or the Generalized Boltzmann equation for a mixture of diatomic gases, these equations are formulated in impulse space, instead of velocity space. A binary mixture of two inert gases results in four coupled GBEs. The computational framework available for the classical Boltzmann equation is extended by including the rotational and vibrational degrees of freedom in the GBE for a mixture of diatomic gases in impulse space. The problem including both rotational - translational (RT) and vibrational - translational (VT) energy transfers is solved by applying a two-stage splitting procedure to the four coupled GBEs. The two stages consist of free molecular transport and RT -VT relaxations. Computations are presented for the shock structure in a binary mixture of N_2 and Ar, and N_2 and O_2 with 1:1 density ratio at Mach 5. This is the first time, such complex computations are being reported in the literature. The methodology can be easily applied to an inert mixture containing an arbitrary number of species.

C1.00319 Optomechanically Induced Transparency and Slow Microwaves in Circuit Nano-electromechanics, XIAOQING ZHOU, École Polytechnique Fédérale de Lausanne, Switzerland/Max-Planck-Institut für Quantenoptik, Germany, FREDRIK HOCKE, Walther-Meißner-Institut, Germany, ALBERT SCHLIESSER, École Polytechnique Fédérale de Lausanne, Switzerland, ACHIM MARX, HANS HUEBL, Walther-Meißner-Institut, Germany, RUDOLF GROSS, Walther-Meißner-Institut, Germany/Technische Universität München, Germany, TOBIAS J. KIPPENBERG, École Polytechnique Fédérale de Lausanne, Switzerland/Max-Planck-Institut für Quantenoptik, Germany — Using a low-mass (~ 15 pg), high-Q ($> 100\,000$) nanomechanical oscillator coupled to a Nb superconducting quarter wave cavity, we realize a circuit nano-electromechanical system coupling microwaves to mechanical motion oscillating at 1.45 MHz. By exciting the system on the lower motional sideband with a strong drive tone, a transparency window for a probe field is created originating from the effect of optomechanically induced transparency (OMIT). This phenomenon, analogous to electromagnetically induced transparency in Atomic Physics, arises from the interference of different excitation pathways for an intracavity probe field. We utilize the transparency window to demonstrate slow microwave propagation. A tunable delay up to 4 ms is demonstrated experimentally for a microwave pulse on resonance with the cavity. Furthermore, we systematically investigate the temporal dynamics of this transparency window when the drive tone is modulated, and the effect of the oscillator's Duffing nonlinearity on the OMIT window.

C1.00320 Performance of Multi Walled Carbon Nanotubes Grown on Conductive Substrates as Supercapacitors Electrodes using Organic and Ionic liquid electrolytes, ANDREW WINCHESTER, SUJOY GHOSH, BEN TURNER, Southern Illinois University Carbondale Department of Physics, X.F. ZHANG, Northeastern University Boston, SAIKAT TALAPATRA, Southern Illinois University Carbondale Department of Physics — In this work we will present the use of Multi Walled Carbon Nanotubes (MWNT) directly grown on inconel substrates via chemical vapor deposition, as electrode materials for electrochemical double layer capacitors (EDLC). The performance of the MWNT EDLC electrodes were investigated using two electrolytes, an organic electrolyte, tetraethylammonium tetrafluoroborate in propylene carbonate (Et_4NBF_4 in PC), and a room temperature ionic liquid, 1-butyl-3-methylimidazolium hexafluorophosphate (BMIM- PF_6). Cyclic voltammetry, galvanostatic charge-discharge, and electrochemical impedance spectroscopy measurements to obtain values for the capacitance and internal resistance of these devices will be presented and compared.

C1.00321 Measure of nonclassical correlation in coherence vector representation, TAO ZHOU, JINXIN CUI, GUI LU LONG¹, Department of Physics, Tsinghua University, Beijing 100084 — We consider the coherence vector representation (CVR) of a bipartite state and obtain a necessary and sufficient condition for a zero-discord state. Based on this, a measure of quantum, classical and total amount of correlations in bipartite states is proposed in this representation. Analytical expressions for this measure are available for any bipartite states. Our measure of nonclassical correlation coincides with the geometric measure of quantum discord for some particular states. References: T Zhou, J. Cui and G L Long, PRA A84, 062105 (2011)

C1.00322 Law of Universal Repulsion, YONGQUAN HAN, None — All objects in the universe repel each other. Repulsion between two objects is directly proportional to the external energy (mv^2) of their relative motion and indirectly proportional to their relative motion radius (one object is in relative rest, while the other one is in relative motion). **Application examples** Suppose a man whose mass is 100 kg, runs on the earth at a speed of 10 meters per second. The radius of the earth is 637100 meters. The repulsion between the earth and the man is: $F=mv^2/r=0.00157N$; if his speed reaches the first cosmic speed (7.9 km per second), then calculate: $F=mv^2/r=980N$, just overcome the gravity of the earth. A car with a certain velocity running in a straight highway (actually with some slight curves) can't fly up. However, if it encounters an arched bridge, it is possible for the car to fly. That is the consequence of the arch bridge has changed its movement radius, and the repulsion is increased. A aircraft's taking off and flying are not only because of the fluid - air, but also because of the change of its motion radius (forming virtual arched bridge in the air), which increases the repulsion.

C1.00323 Supersymmetry approach to delocalization transition in the network model of weak field quantum Hall effect and related models, VAGHARSH MKHITARYAN, Department of Physics and Astronomy, University of Utah, Salt Lake City, UT 84112, USA, SHANTHANU BHARDWAJ, ILYA GRUZBERG, James Franck Institute, University of Chicago, Chicago IL 60637, USA — Recently, a two-channel random network model was proposed for quantum Hall effect in a weak (non-quantizing) magnetic field. For the anisotropic variant of this network, we analytically average over the randomness using the supersymmetry method, and map the network onto a model of interacting $u(1,1|2)$ superspins. We analyze the resulting superspin model by relating it to a nonlinear sigma-model. We argue that the phase diagram of the superspin model does not change qualitatively if we identify $u(1,1|2)$ superspins with ordinary $su(2)$ spin-1/2's. This allows us to develop a deeper insight and extend the phase diagram into the regions inaccessible to a sigma-model approach. We further extend our approach to a related two-channel network models and discuss their physical implications.

C1.00324 Giant Electro-Mechanical Energy Conversion in [011] cut Relaxor Ferroelectric Single Crystals, PETER FINKEL, NUWC, WEN DONG, CHRIS LYNCH, UCLA, AHMED AMIN, NUWC — Giant electro-mechanical energy conversion is demonstrated under a ferroelectric/ferroelectric phase transformation in [011] cut and poled lead titanate-based relaxor perovskite morphotropic single crystals. It is found that under mechanical pre-stress, a relatively small oscillatory stress drives the material reversibly between rhombohedral and orthorhombic phases with a remarkably high polarization and strain jumps induced at zero bias electric field and room temperature. The measured electrical output per cycle is more than an order of magnitude larger than that reported for linear piezoelectric materials. Ideal thermodynamic cycles are presented for this electro-mechanical energy conversion followed by a presentation and discussion of the experimental data.

C1.00325 Direct and Indirect Two-color Coherent Control in Bulk Silicon, JINLUO CHENG, JULIEN RIOUX¹, JOHN SIPE, Department of Physics, University of Toronto, 60 St. George Street, Toronto, Ontario, Canada M5S 1A7 — Using an empirical pseudopotential model for electron states and an adiabatic bond charge model for phonon states, we investigate the two-color direct and indirect coherent current injection with an incident optical field composed of a fundamental frequency and its second harmonic, and calculate the response tensors of the electron (hole) charge and spin currents. We show the current control for three different polarization scenarios: For co-circularly polarized beams, the direction of the charge current and the polarization direction of the spin current can be controlled by a relative-phase parameter; for the co-linearly and cross-linearly polarized beams, the current amplitude can be controlled by that parameter. For the indirect gap injection, the spectral dependence of the maximum swarm velocity shows that the direction of charge current reverses under an increase in photon energy.

¹Currently at Department of Physics, University of Konstanz, D-78457 Konstanz, Germany.

C1.00326 C-Axis Properties of DyNi₂B₂C System, W.C. LEE, Dept. of Physics, Sookmyung Women's Univ. Seoul 140-742, Korea — We have measured the electrical resistivity along c-axis $\rho_c(T, H)$ of the DyNi₂B₂C single crystal with the magnetic fields perpendicular to the c-axis and the magnetization isotherms $M(H)$ of the DyNi₂B₂C single crystal with magnetic fields perpendicular and parallel to the c-axis. We confirmed that Neel temperature T_N is 10.3K from the $\rho_c(T)$ result which is consistent with that from previous $\rho_{ab}(T)$ result. In addition, the constructed critical fields $H_{c2}(T)$ curve and magnetic transitions diagram of DyNi₂B₂C from $\rho_c(T)$ magnetic fields perpendicular to c-axis is similar to that of $\rho_{ab}(T)$ result, which is thought to arise that 3 D magnetic structure of DyNi₂B₂C.

C1.00327 Topological insulators on a Mobius Strip¹, LANG-TAO HUANG, Department of Physics, Tsinghua University, Beijing 100084, China, DUNG-HAI LEE², Department of Physics, University of California at Berkeley, Berkeley, CA 94720, USA — We study the two dimensional Chern insulator and spin Hall insulator on a non-orientable Riemann surface, the Mobius strip, where the usual bandstructure topological invariant is not defined. We show that while the flow pattern of edge currents can detect the twist of the Mobius strip in the case of Chern insulator, it can not do so in spin Hall insulator [1].

C1.00328 Extension of the Non-Hermitian Quantum Walk Model into a 2D Hexagonal Lattice¹

, LANG-TAO HUANG, Department of Physics, Tsinghua University, Beijing 100084, China — We generalize the 1D non-Hermitian quantum walk model of M. S. Rudner, and L. S. Levitov [1] to three different cases: 1D model with next nearest hopping, 2D model with and without next nearest hopping on hexagonal lattice respectively. We find that the quantization of the average decay length is always robust to next nearest hopping with real hopping parameter in 1D, but in the case of 2D, this quantization is only present in some special circumstances. We also find the 2D model is compatible to the 1D one by setting one of the hopping terms to zero. As to the Haldane model, quantization of this type exists only in 0 or π magnetic flux phases.

C1.00329 The Pirouette effect in turbulent flows

, ALAIN PUMIR, Ecole Normale Supérieure de Lyon and CNRS, HAITAO XU, EBERHARD BODENSCHATZ, Max-Planck Institute for Dynamics and Self Organisation, Goettingen, Germany — The dynamics of the velocity gradient tensor plays a crucial role for our understanding of turbulent flows. I will discuss recent numerical and experimental results concerning the “perceived velocity gradient tensor,” constructed with the help of 4 points (a tetrad). This tensor depends on the overall size of the tetrad, thus permitting to study the properties of the flow as a function of scale. I will in particular consider the statistical properties, as well as the dynamical properties of the velocity gradient tensor, in relation to the dynamics of the shape of the tetrad. These properties shed some new light on the intriguing preferential alignment between vorticity and the eigenvector, corresponding to the intermediate eigenvalue of the strain.

C1.00330 Spintronic Oscillator based on feed-back mechanism

, ASHWIN TULAPURKAR, Department of Electrical Engineering, Indian Institute of Technology-Bombay, Mumbai, India, DINESH DIXIT, Department of Physics, Indian Institute of Technology-Bombay, Mumbai, India, KATSUNORI KONISHI, Graduate School of Engineering Science, Osaka University, Osaka, Japan, C. TOMY, Department of Physics, Indian Institute of Technology-Bombay, Mumbai, India, YOSHISHIGE SUZUKI, Graduate School of Engineering Science, Osaka University, Osaka, Japan — Nano-scale rf oscillators based on the magnetic tunnel junctions is an active area of research. These oscillators are based on the spin-transfer torque effect, in which a dc current drives the magnetization into precessional motion. Here we present a novel design of a spintronic oscillator which is not based on spin-transfer torque effect. This new oscillator is comprised of a magnetic tunnel junction whose top and bottom contacts are connected to a bias-T. A dc current is passed through the low frequency port of the bias-T and the high frequency port is connected to a “feed-back” wire which runs below the MTJ. Any fluctuation in the magnetization direction of the free layer of MTJ, drives ac current through the feed-back wire, which in turn exerts ac magnetic field on the free layer. The feedback wire is oriented such that the ac magnetic field amplifies the magnetization fluctuations for positive value of dc current. For negative value of dc current, the feedback loop suppresses the fluctuations. We find that if the positive dc current passing through the MTJ is more than a critical value, continuous precessing states of the magnetization are possible. Oscillators with better quality factors are possible using the feedback scheme.

C1.00331 Stability and collapse of a dipolar condensate in a 1D optical lattice¹

, MATTIA JONASINIO, LUIS SANTOS, Leibniz University of Hannover, STEFAN MÜLLER, JULIETTE BILLY, EMANUEL HENN, HOLGER KADAU, AXEL GRIESMAIER, TILMAN PFAU, 5 Institute of Physics, University of Stuttgart — The stability properties of a dipolar condensate are strongly affected by the external confining potential, as a consequence of the long range and anisotropic character of the dipole-dipole interaction. In contrast to a contact interacting gas, the presence of a 1D lattice induces a crossover from a dipolar destabilized to a dipolar stabilized regime for increasing lattice depth. In the deep lattice regime, a dipolar condensate can be stabilized at large negative scattering length in the interaction-dominated regime. As a consequence of the dipolar potential shape, the condensate collapse in the deep lattice regime features a *local* character (as opposed to the global character of the usual contact interacting gas): the condensate develops a surface density modulation resulting in several isolated local collapses. Finally, the stabilizing effect of the external potential plays an important role during the time-of-flight expansion. A dipolar condensate can be stable as long as it is trapped but can immediately collapse as soon as the external potential is removed. This makes the mapping of the time of flight expansion onto the momentum distribution highly non trivial.

C1.00332 Spin wave excitation by spin-transfer torque in a magnetic insulator

, JIANG XIAO, Department of Physics, Fudan University, GERRIT BAUER, IMR, Tohoku University — We study the excitation of spin waves in magnetic insulators by the current-induced spin-transfer torque. We predict preferential excitation of surface spin waves induced by an easy-axis surface anisotropy. The critical excitation current for the surface spin wave is inversely proportional to the penetration depth and surface anisotropy. Compared to the bulk modes, the critical current and excitation power of such surface spin wave are greatly reduced and enhanced, respectively.

C1.00333 Calculating the density of states in disordered systems using free probability¹

, JIAHAO CHEN, ERIC HONTZ, MATTHEW WELBORN, JEREMY MOIX, TROY VAN VOORHIS, Department of Chemistry, Massachusetts Institute of Technology, ALBERTO SUÁREZ, Departamento de Ingeniería Informática, Escuela Politécnica Superior, Universidad Autónoma de Madrid, Ciudad Universitaria de Cantoblanco, RAMIS MOVASSAGH, ALAN EDELMAN, Department of Mathematics, Massachusetts Institute of Technology — We approximate the density of states in disordered systems by decomposing the Hamiltonian into two random matrices and constructing their free convolution. The error in this approximation is determined using asymptotic moment expansions. Each moment can be decomposed into contributions from specific joint moments of the random matrices; each of which has a combinatorial interpretation as the weighted sum of returning trajectories. We show how the error, like the free convolution itself, can be calculated without explicit diagonalization of the Hamiltonian. We apply our theory to Hamiltonians for one-dimensional tight binding models with Gaussian and semicircular site disorder. We find that the particular choice of decomposition crucially determines the accuracy of the resultant density of states. From a partitioning of the Hamiltonian into diagonal and off-diagonal components, free convolution produces an approximate density of states which is correct to the eighth moment. This allows us to explain the accuracy of mean field theories such as the coherent potential approximation, as well as the results of isotropic entanglement theory.

C1.00334 Transport Coefficients of a Normal Fermi Gas at Unitarity

, HUA LI, KEVIN BEDELL, Boston College, JASON JACKIEWICZ, New Mexico State University — We studied the transport properties of a two component Fermi gas in the unitary limit. Transport coefficients of the Fermi gas are calculated in the extreme low-temperature limit. To calculate the transport coefficients we need the scattering amplitudes. The scattering amplitudes are calculated from the Landau parameters. These parameters are obtained from the local version of the induced interaction model for computing Landau parameters [1]. The leading order finite temperature corrections to the transport coefficients are also calculated [2]. The calculated temperature dependent spin diffusivity is compared with the experimental measurement. A minimum of the spin diffusivity with a value of order $\hbar/m$ is observed at some finite temperature below the Fermi temperature.

C1.00335 Thermally-induced resonance in folding-unfolding transition of a stretched RNA, WON KYU KIM, Department of Physics and PCTP, Pohang University of Science and Technology, Pohang 790-784, South Korea, CHANGBONG HYEON, School of Computational Sciences, Korea Institute for Advanced Study, Seoul 130-722, South Korea, WOKYUNG SUNG, Department of Physics and PCTP, Pohang University of Science and Technology, Pohang 790-784, South Korea — The biopolymers are often situated in constrained, thermally fluctuating environment in the cell. To understand how they respond to a minute but temporally varying signal, we study folding-unfolding dynamics of a stretched RNA under a small oscillatory force. We find via numerical simulations that the small oscillation enhances the folding (unfolding) dynamics, even at a high (low) stretching condition where the folding (unfolding) is improbable, leading to a minimum mean transition time at an optimal frequency, a phenomenon dubbed as Resonant Activation (RA). In addition, the folding-unfolding transition can be maximally synchronous to the oscillation at another optimal frequency, characteristics of the Stochastic Resonance (SR). These noise-assisted resonance phenomena, RA and SR, which can also be largely modulated by the polymer parameters, provide a glimpse of how a biopolymer self-organizes in response to the environmental fluctuation in the cell.

C1.00336 Effect of inter-layer single-electron hopping and pair-hopping on superconductivity in multi-layered cuprates, KAZUTAKA NISHIGUCHI, Department of Physics, The University of Tokyo, KAZUHIKO KUROKI, Department of Applied Physics and Chemistry, The University of Electro-Communications, RYOTARO ARITA, Department of Applied Physics, The University of Tokyo, TAKASHI OKA, HIDEO AOKI, Department of Physics, The University of Tokyo — The multi-layered cuprates, which remain the highest- T_c material to date, still harbor unsolved problems. Specifically, the reason why T_c increases as we go from the single-layer system to trilayer has not been microscopically understood. Here we have studied the superconductivity in the n -layered Hg-series cuprate $\text{HgBa}_2\text{Ca}_{n-1}\text{Cu}_n\text{O}_{2+2n+\delta}$ by solving the Eliashberg equation for a multi-orbital Hubbard model with the random phase approximation (RPA) as well as with the fluctuation exchange approximation (FLEX). The hopping parameters are obtained by downfolding from first principles calculations based on the density functional theory (DFT) for the Hg-series cuprates with $n=1, 2, 3$. The result indicates that the enhancement of T_c with n is not explained in terms of the band structure alone. We then consider the possible ingredients in multi-layered cuprates that may affect T_c for different numbers of CuO_2 planes, specifically, the inter-layer single-electron hopping and inter-layer Cooper-pair hopping originating from the inter-layer Coulomb interaction, which we vary to probe the superconducting nature.

C1.00337 Superfluid correlations of ladder-type Hubbard model with trapping potential, SUSUMU YAMADA, MASAHIKO OKUMURA, RYO IGARASHI, ATSUSHI YAMAMOTO, MASAHIKO MACHIDA, Japan Atomic Energy Agency — In this study, we investigate possibility of superfluidity derived from repulsive interactions in optical lattice systems using the DMRG method. We calculate superfluid correlations in 2-leg ladder-type Hubbard models with varying the repulsive parameter U and the trapping one V , and then clarify dependences of the superfluid correlations on the parameters. The calculation results show that there are two hotspots, whose superfluid correlations are remarkably high, in the space spanned by U and V for suitable fillings. In this presentation, we present the results, compare them with those in more than 2-leg Hubbard models, and reveal the best situation in which the superfluidity correlation develops.

C1.00338 Critical Lamellar Thickness of Polymer Crystal Growth Studied by Dynamic Monte Carlo Simulations¹, XIAOMING JIANG, WENBING HU, State Key Laboratory of Coordination Chemistry, School of Chemistry and Chemical Engineering, Nanjing University, China — We set up a parallel-oriented slit to block lamellar crystal growth of chain molecules, and found a critical spacing of the slit gate, which reflected the critical lamellar thickness (L_{min}) for crystal growth. The values of L_{min} measured at various temperatures provided useful information about the role of lamellar crystal thickness in the kinetics of polymer crystal growth. More interesting, we found that the excess lamellar thicknesses decreased with the increase of temperatures, in contradictory to the prediction of Lauritzen-Hoffman theory.

¹This work is supported by National Natural Science Foundation of China (Grant No. 20825415) and National Key Basic Research Program of China (Grant No. 2011CB606100).

C1.00339 Strain-induced transition from intramolecular to intermolecular crystal nucleation¹, YIJING NIE, WENBING HU, State Key Laboratory of Coordination Chemistry, School of Chemistry and Chemical Engineering, Nanjing University, China — We performed dynamic Monte Carlo simulations of strain-induced crystallization of bulk polymer chains. We observed that for small crystallites grown at relatively high temperatures, the probabilities of adjacent chain-folding jump down at a critical strain. The result implies that polymer chains prefer to choose intramolecular crystal nucleation at small strains, and the intermolecular crystal nucleation becomes dominant only when the strain is higher than the critical value. In addition, the critical strains appear as almost constant to temperatures.

¹This work is supported by National Natural Science Foundation of China (Grant No. 20825415) and National Key Basic Research Program of China (Grant No. 2011CB606100).

C1.00340 Single Crystalline TiO_2 Nanorod grown on Transparent Conducting Substrates for Dye-Sensitized Solar Cells, XIAOYAN PENG, University of Puerto Rico, BOQIAN YANG, University of Massachusetts Amherst, PETER FENG, University of Puerto Rico — Single crystalline TiO_2 nanorods have been synthesized by pulse laser deposition technique on indium tin oxide glass substrates. During the deposition, oxygen pressures were kept under 100, 200 and 500 mTorr, respectively. Scanning Electron Microscopy images show vertical nanorod arrays with the same diameters of 200-300 nm were obtained under different oxygen pressures, but with various density of the arrays. The TiO_2 nanorods growth under 200 mTorr oxygen pressures were pure highly crystalline anatase according to X-ray diffraction measurement. The highly crystalline and vertical TiO_2 nanorod arrays contributed to the achievement of the high conversion efficiency of light-to-electricity. High conversion efficiency was obtained with the vertically aligned TiO_2 single crystalline nanorod cell.

C1.00341 Transitions between multiple attractors in a granular mixing experiment, RALF STANNARIUS, FRANK RIETZ, University of Magdeburg — We report on a granular experiment that produces multiple quasi-periodic patterns in a rotating flat container filled with a bidisperse mixture (0.3 mm and 0.9 mm diameter) of spherical grains. The cell depth is fixed to 0.5 cm (of the order of 10 bead layers), the height is 8 cm. Cell widths are either 17 cm or 50 cm. After an initial transient period, the system develops a lateral band texture of size-segregated grains. These bands show a pronounced spatio-temporally periodic drift in axial direction, sometimes with reflection at the cell ends. In the course of long durations of the experiment, the system switches between different states that appear to be marginally stable oscillatory solutions over many periods. Ageing of the particles as well as external influences on the experiment can be excluded as explanations. In the long term limit, the system does not tend towards a stationary state, neither to a complete segregation, nor to stable bands or uniformly mixed states. The results complement and extend previous observations in cylindrical geometries, and represent a challenge for modeling and theoretical description.

C1.00342 Ultra high resolution neutron scattering: Neutron Resonance Spin-Echo and Larmor Diffraction, ANDREW WALTERS, THOMAS KELLER, BERNHARD KEIMER, Max Planck Institute for Solid State Research — The TRISP spectrometer at the FRM II neutron source near Munich, Germany, is a unique world-leading neutron scattering instrument which employs the Neutron Resonance Spin-Echo technique (NRSE). Linewidths of dispersive excitations with energy transfers up to 50 meV can be measured with an energy resolution in the μeV range without the restrictive flux limitations that normally apply to high resolution neutron triple-axis spectrometers. Pioneering studies on the electron-phonon interaction in elemental superconductors¹ and the lifetimes of magnetic excitations in archetypal magnetic systems will be reviewed.² The instrument can also be used as a Larmor diffractometer, enabling d-spacings to be measured with a resolution of $\frac{\Delta d}{d} \sim 10^{-6}$, i.e. more than one order of magnitude more sensitive than conventional diffraction techniques.³ Ongoing and future NRSE and Larmor diffraction projects will be outlined, especially in regard to prospective studies which will take full advantage of the new low temperature and high pressure sample environment capabilities now available at TRISP.

C1.00343 ABSTRACT WITHDRAWN —

C1.00344 Quantum Diffraction Without de Broglie Waves, A.M. KADIN, Princeton Junction, NJ, S.B. KAPLAN, Yorktown Heights, NY — It is well established that composite particles, from neutrons to atoms to large molecules, sometimes behave as de Broglie waves, with wavelength $\lambda = h/p$, where p is the total momentum of the given composite particle. The primary evidence of these de Broglie waves is the observation of diffraction patterns from diffracting objects such as crystal lattices or one or more orifices. Indeed, it is generally believed that such de Broglie waves are universal quantum aspects of all matter. It is argued here (see also [1]) that only primary quantum fields such as electrons are truly de Broglie waves. In contrast, composite particles are small confined quantum waves that follow essentially classical particle trajectories, without extended wavelike behavior given by the de Broglie relation. For example, a neutron is properly a particle on the fm scale, not an extended wave on the nm scale. The momentum change of such a quasiclassical particle during a collision is constrained by quantum transition rules of the crystal lattice or other extended object. In particular, for elastic scattering from a crystal lattice with reciprocal lattice vectors $\mathbf{G}_i$, the allowable momentum changes are $\Delta\mathbf{p} = \hbar\mathbf{G}_i/2\pi$, which reproduces the standard crystal diffraction pattern. This corresponds to emission of a degenerate phonon with zero energy. This provides a logically consistent picture of the microworld, avoiding most of the paradoxes associated with the orthodox interpretation of quantum mechanics. [1] A.M. Kadin, "Waves, Particles, and Quantized Transitions: A New Realistic Model of the Microworld", <http://arxiv.org/abs/1107.5794> (2011).

2:30PM D1.00001 Novel magnetic textures in $\text{SrCu}_2(\text{BO}_3)_2$ from magnetostriction up to 97.4 tesla¹, MARCELO JAIME, Marcelo Jaime, National High Magnetic Field Laboratory (NHMFL), Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — Quantum magnets are model systems wherein strongly frustrated spin interactions generate a variety of exotic magnetic phases of current interest, including quantum spin ices, spin liquids, spin supersolids and complex magnetic superstructures. $\text{SrCu}_2(\text{BO}_3)_2$, the only classic realization of the spin-1/2 Heisenberg antiferromagnet in the Shastry-Sutherland (orthogonal spin dimer) lattice is known to exhibit numerous magnetization plateaus due formation of stripe-like magnetic textures in high fields. However, the fine structure of these plateaus remains controversial on both experimental and theoretical fronts due to the existing limits for achievable magnetic fields in the laboratory, the sensitivity of current magnetization techniques, and the uncontrolled nature of available theoretical approaches for highly frustrated magnetic lattices. This talk will describe how we probe magnetic textures in $\text{SrCu}_2(\text{BO}_3)_2$ via a recently-developed *magnetostriction* technique based on optical fiber Bragg gratings [1]. We achieve microstrain (nm-resolution) sensitivity in ultrahigh pulsed fields to 97.4 T using the NHMFL 100 tesla multi-pulse magnet system [2]. The magnetostriction data reveal fine structure corresponding to all magnetization plateaus, and a significant lattice response to the long-predicted 1/2-saturation plateau at 82 T, as well as a new feature at 73.6 T that we attribute to a never before observed structure corresponding to 2/5 of magnetization saturation [3]. These data are complemented by simultaneous magnetocaloric-effect measurements, and are supported by numerical results obtained using a controlled density matrix renormalization group method.

3:06PM D1.00002 Superconducting critical current measurements in pulsed magnets, FEDOR F. BALAKIREV, Los Alamos National Laboratory, Los Alamos, NM, USA, PHILIP J.W. MOLL, NIKOLAI D. ZHIGADLO, JANUSZ KARPINSKI, BERTRAM BATLOGG, Laboratory for Solid State Physics, ETH Zurich, Switzerland — Measurements of critical current in single crystals of high temperature superconductor using pulsed magnetic fields are tricky due to short time scale, fast field sweep rate and sheer absolute current values in restricted sample space. We will present a measurement system design that addresses the challenges via a combination of Field Programmable Gate Array (FPGA) fast-response signal generation and detection architecture and Focused Ion Beam crystal shaping.

3:18PM D1.00003 Development of a high-field electron paramagnetic resonance spectrometer, EKATERINA E. ROMANOVA, FRANKLIN H. CHO, VIKTOR STEPANOV, SUSUMU TAKAHASHI, University of Southern California — Electron paramagnetic resonance (EPR) spectroscopy is a powerful and versatile technique to study structure and dynamics of biomolecules. Structural investigations of biological molecules begin with site-directed spin labeling (SDSL). Using SDSL, a nitroxide spin label containing a stable unpaired electron is covalently attached at a specific site within a bio-macromolecule. The time resolution and the sensitivity of EPR spectrometer become higher when the system is operated at higher frequencies and magnetic fields. In addition, a fine spectral resolution obtained with a high-field EPR (HFEP) enables us to study details of the conformation in biological molecule by determining the orientation of a spin-label or the relative orientation of two spin-labels embedded in the molecule. In this presentation, we will report the development of a 115/230 GHz continuous wave (cw) and pulsed EPR spectrometer at USC. The spectrometer is based on a 700/100 mW solid-state source at 115/230 GHz respectively, a 12-Tesla magnet and a superheterodyne detection system. The system also has the 2nd synthesizer for double electron-electron resonance (DEER) spectroscopy. HFEP measurements with spin-labeled CS DNA will be discussed.

3:30PM D1.00004 Sensitivity of charge transport measurements to local inhomogeneities, DANIEL KOON, St. Lawrence University, FEI WANG, DIRCH HJORTH PETERSEN, OLE HANSEN, Department of Micro- and Nanotechnology, Technical University of Denmark — We derive analytic expressions for the sensitivity of resistive and Hall measurements to local variations in a specimen's material properties in the combined linear limit of both small magnetic fields and small perturbations, presenting exact, algebraic expressions both for four-point probe measurements on an infinite plane and for symmetric, circular van der Pauw discs. We then generalize the results to obtain corrections to the sensitivities both for finite magnetic fields and for finite perturbations. Calculated functions match published results and computer simulations, and provide an intuitive, visual explanation for experimental misassignment of carrier type in n-type ZnO and agree with published experimental results for holes in a uniform material. These results simplify calculation and plotting of the sensitivities on an $N \times N$ grid from a problem of order N^5 to one of order N^3 in the arbitrary case and of order N^2 in the handful of cases that can be solved exactly, putting a powerful tool for inhomogeneity analysis in the hands of the researcher: calculation of the sensitivities requires little more than the solution of Laplace's equation on the specimen geometry.

3:42PM D1.00005 Polarization Modulation THz TDS of Topological Insulators¹, DEEPU GEORGE, CHASE ELLIS, Dept of Physics, SUNY Buffalo, TOBIAS KIESSLING, Universitat Wurzburg, JOHN CERNE, ANDREA MARKELZ, Dept of Physics, SUNY Buffalo, MARKELZ GROUP COLLABORATION, CERNE GROUP COLLABORATION — Optical hall conductivity measurements are powerful alternatives to DC transport measurements in samples in which the latter are challenging. They provide a deeper understanding of interactions in correlated systems and also serve as a measure of disorder in such systems. Aoki et al[1] has studied Quantum Hall Effect in graphene theoretically and has predicted that Optical Hall Conductivity should be measurable with an accurate detection of the Hall angle in the THz regime. Shimano et al [2] has reported evidence for Quantum Hall Plateau in the longitudinal conductivity σ_{xx} in the THz region in a 2DEG system. In this work, we have developed a new broadband technique which rapidly measures complex Faraday and Kerr angles. Our technique is capable of measuring the entire complex conductivity tensor with a single scan, with an accuracy of 5mRad in the frequency range 0.2 to 2.5THz. We have employed this to study topological insulators and have observed a magnetic field dependent absorption around 0.5THz. 1. Morimoto, T., Jour. of Phys: Conference Series, 2009. 150(2). 2. Ikebe, Y., et al., PRL, 2010. 104(25): p. 256802.

3:54PM D1.00006 Analysis of complex mixtures using a new, high resolution Trapped Ion Mobility Spectrometer – Mass Spectrometer¹, FRANCISCO FERNANDEZ-LIMA, Texas A&M University, CHRISTOPHER THOMPSON, DESMOND KAPLAN, MELVIN PARK, Bruker Daltonics — Over the last decade, a variety of new types of Ion Mobility Spectrometry (IMS) analyzers have been developed (e.g., periodic focusing DC ion guide, segmented quadrupole drift cell, multistage IMS, field asymmetric IMS and transient wave ion guide). High resolution IMS ($R > 50$) has been mainly restricted to long IMS cells (1-2 m), where ions are separated based on size-to-charge ratio as they are pushed by an electric field through a stationary bath gas. In the present work we describe a Trapped Ion Mobility Spectrometer (TIMS) and its applications. In as much as TIMS uses an electric field to hold ions stationary in a moving bath gas, it represents a paradigm shift in mobility analysis. This results in an analyzer capable of high resolution mobility separations ($R > 80$) in a compact (< 10 cm), low voltage (< 300 V) design. Hybridization with a mass analyser (TIMS-MS) provides versatility for the analysis, separation and structural characterization of a variety of chemical compounds with increasing complexity. In particular, examples of TIMS – MS separation for complex biological and heteroatom hydrocarbons will be shown.

4:06PM D1.00007 Measurement of statistical nuclear spin polarization in a nanoscale GaAs sample, FEI XUE, DENNIS WEBER, PHANI PEDDIBHOTLA, MARTINO POGGIO, Department of Physics, University of Basel, Klingelbergstrasse 82, 4056 Basel, Switzerland — We measure the statistical polarization of quadrupolar nuclear spins in a sub-micrometer ($0.6 \mu\text{m}^3$) particle of GaAs using magnetic resonance force microscopy. The crystalline sample is cut out of a GaAs wafer and attached to a micro-mechanical cantilever force sensor using a focused ion beam technique. Nuclear magnetic resonance is demonstrated on ensembles containing less than 5×10^8 nuclear spins and occupying a volume of around $(300 \text{ nm})^3$ in GaAs with reduced volumes possible in future experiments. We discuss how the further reduction of this detection volume will bring the spin ensemble into a regime where random spin fluctuations, rather than Boltzmann polarization, dominate its dynamics. The detection of statistical polarization in GaAs therefore represents an important first step toward 3D magnetic resonance imaging of III-V materials on the nanometer-scale.

4:18PM D1.00008 Carbon nanotube quantum dots as highly sensitive THz spectrometers¹, MOHAMED RINZAN, Physics department, Georgetown university, GREG JENKINS, DENNIS DREW, Physics department, University of Maryland, SERHIL SHAFRANJUK, Department of physics and astronomy, Northwestern university, PAOLA BARBARA, Physics department, Georgetown university — We show that carbon nanotube quantum dots (CNT-Dots) coupled to antennas are extremely sensitive, broad-band, terahertz quantum detectors. Their response is due to photon-assisted single-electron tunneling (PASET)[1], but cannot be fully understood with orthodox PASET models[2]. We consider intra-dot excitations and non-equilibrium cooling to explain the anomalous response. REFERENCES: [1] Y. Kawano, S. Toyokawa, T. Uchida and K. Ishibashi, THz photon assisted tunneling in carbon-nanotube quantum dots, Journal of Applied Physics 103, 034307 (2008). [2] P. K. Tien and J. P. Gordon, Multiphoton Process Observed in the Interaction of Microwave Fields with the Tunneling between Superconductor Films, Phys. Rev. 129, 647 (1963).

4:30PM D1.00009 Ultrafast electro-optic modulation for Terahertz upconversion spectroscopy, MATTHEW DECAMP, ZHIYUAN CHEN, University of Delaware — Traditional time-domain terahertz (THz) spectroscopy techniques require the combination of sub-picosecond laser systems and time-delay stages for spectral analysis, making the design of a portable THz spectrometer challenging. In this work, we demonstrate an alternative method of spectrally resolving coherent THz radiation using narrow band optical light and passive optical spectrum analyzers. This method utilizes THz induced electro-optic modulation of a narrow band laser to upconvert the spectral content of the THz radiation to the visible portion of the electro-magnetic spectrum. This device does not require any movable parts and is well suited for spectrally analyzing both broadband and narrowband THz radiation. The spectral resolution of this technique is limited by the bandwidth of the optical radiation and the non-linear medium. Further advancements will include the development of a portable THz spectrometer, suitable for either research or clinical applications.

4:42PM D1.00010 Detection of internal molecular structural motions using anisotropic spectroscopy¹, ROHIT SINGH, DEEPU GEORGE, Department of Physics, University at Buffalo, SUNY, TIMOTHY KORTER, Department of Chemistry, Syracuse University, ANDREA MARKELZ, Department of Physics, University at Buffalo, SUNY — The far infrared spectroscopy of molecular crystals reveals both intra and inter molecular vibrational modes [1,2]. With the significant increase in complexity of structures, one finds increasing overlap in the internal modes. As an overall strategy to measure the correlated structural motions in protein, we use anisotropic and birefringent behavior of molecular crystals to develop a new technique called MOSTS (Modulated Orientation Sensitive THz Spectroscopy). We achieve high sensitivity and mode separation by using single molecular crystal such as sucrose and rapid modulation of the relative alignment of the terahertz polarization and the crystal axes by rotating the sample. By locking into the signal at the rotation frequency we determine the polarization sensitive signal and map out the optically active vibrational resonances. To illustrate the technique we compare our measured spectra with the calculated and find a close agreement.

4:54PM D1.00011 Ultra-Low Frequency MRI: Novel Imaging Sequences¹, MATTHEW NICHOLS, PAUL SANGIORGIO, JOHN CLARKE, Department of Physics, University of California, Berkeley — Our ultra-low field MRI system operates at a field of 0.132 mT with the signal detected by a Superconducting QUantum Interference Device (SQUID) coupled to an untuned, superconducting, second-derivative gradiometer. Operation at such low fields requires that we prepolarize the protons of our specimen in a field of about 150 mT prior to imaging to increase the sample magnetization. With the ultimate goal of *in vivo* imaging of prostate tissue by taking advantage of the enhanced longitudinal-relaxation-time at low fields, we seek to decrease the imaging time and optimize the signal-to-noise ratio of our imaging pulse sequences to make *in vivo* imaging viable in a clinical setting. To achieve this, we begin with standard imaging sequences used in other frequency domains and adapt them to our specific purposes and requirements, in particular the need to prepolarize. We describe modified inversion recovery and multiple echo imaging sequences, specifically Carr-Purcell-Meiboom-Gill (CPMG) pulse train and fully balanced Steady-State Free Precession (SSFP) sequences. We present the results of applying these sequences to imaging agarose gel phantoms.

5:06PM D1.00012 Millimeter-wave and terahertz spectroscopy for the detection of ionized air and chemical vapor, BENJAMIN GRABER, US. Naval Research Laboratory/Temple University, RONGJIA TAO, Temple University, DONG HO WU, US. Naval Research Laboratory — Our previous work has demonstrated that the time domain terahertz spectroscopy (TDTS) of chemical vapor or ionized air produces characteristic spectrum from which one can identify chemicals or an ionization source, such as nuclear isotopes. While the average power of TDTS is only less than micro-Watts, the peak power of terahertz pulse can exceed kilo-Watts. When terahertz pulse is concentrated within a small area this large peak power produces a very large electric field, exceeding several kV/m. We investigate the field strength dependence of TDTS to see how it affects the detection capability of TDTS for chemical vapor and ionized air when the peak power is varied over the range from a few mW to kW. At the same time we performed similar experiments using a CW millimeter-wave spectroscopy over the frequency range from 75 GHz to 110 GHz and the power strength range from a few micro-Watts to several mW. We will present the details of our experimental results and discuss the merits of both systems for accuracy and long range detection of vapors. We will also examine some theory to understand the data.

Session D2 GMAG: Invited Session: Harnessing Local Atomic Structure to Control Magnetic Interactions in Complex Oxides 204AB

2:30PM D2.00001 Interface engineering in manganites: from diodes to transistors, HAROLD HWANG, Stanford University and SLAC National Accelerator Laboratory — Perovskite manganites show strong coupling between charge, spin, and lattice degrees of freedom as exemplified by 'colossal magnetoresistance'. The recent advances in thin film growth techniques have enabled the generation of novel phases at oxide heterointerfaces, the atomic control of their interface electronic structure, and their incorporation in novel device platforms. We apply these techniques to manganite thin films, first emphasizing the subtleties in optimizing the growth kinetics and stoichiometry [1,2], which has enabled us to create atomically precise heterostructures exhibiting room temperature metallic ferromagnetism in superlattices composed of just 5 unit cell layers [3]. The interface electronic structure was examined using Schottky junctions formed between $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ and Nb-doped SrTiO_3 , where the band offset (Schottky barrier height) can be controlled by the termination layer at the interface [4]. This band engineering technique was applied in making a metal-base transistor [5], which takes advantage of the strong internal electric field at interfaces. An analysis of many devices enables the quantitative understanding of the evolution from a hot-electron transistor to a permeable base transistor. This structure provides a platform for developing devices incorporating the exotic ground states of perovskite oxides and their interfaces.

3:06PM D2.00002 New material design strategies to realize strong coupling in multiferroics and beyond¹, CRAIG FENNIE, Cornell University, School of Applied & Eng. Physics — Perovskite ABO_3 oxides display an amazing variety of phenomena that can be altered by subtle changes in the chemistry and internal structure, making them a favorite class of materials to explore the rational design of novel properties. In this talk I will review a recent advance in which rotations and tilts of the BO_6 octahedra give rise to a novel form of ferroelectricity. Octahedral rotations strongly influence other structural, magnetic, orbital, and electronic degrees of freedom in perovskites and related materials. Thus, I want to discuss the idea that octahedral rotation-driven ferroelectricity has the potential to robustly control emergent phenomena with an applied electric field. As one example, I will show from first principles how these "functional" octahedral rotations simultaneously induce ferroelectricity, magnetoelectricity, and weak ferromagnetism in a class of naturally occurring Ruddlesden-Popper (RP) $(\text{ABO}_3)_2(\text{AO})$ layered perovskites and discuss the challenges to realize electric field switching of magnetism in these RP and in $(\text{ABO}_3)/(\text{A}'\text{BO}_3)$ perovskite superlattice novel multiferroics.

3:42PM D2.00003 Reversal of Magnetic Interactions by Electric field, PHILIP RYAN, Argonne National Laboratory — Direct magneto-electric coupling describes the interaction between magnetic and electric polarization through an intrinsic microscopic phenomenon in a single phase material. Systems which exhibit such coupling are potential candidates for use in a multistate logic memory storage device whereupon magnetic control with electric fields or ferroelectric control with magnetic fields could be used to alter memory bits. I will present x-ray resonant magnetic scattering results providing direct evidence of a magneto-electric cross field effect mediated through strong spin-lattice coupling in a single phase rare earth titanate film. Compressively strained EuTiO_3 is, as in bulk, an antiferromagnetic-paraelectric material, however through strain the balance of the magnetic interactions, both antiferromagnetic and ferromagnetic, shifts whereby the two approach energetic degeneracy. By applying an electric field *in-situ* one can tip the delicate equilibrium and suppress the long range antiferromagnetic order. This is accompanied by the emergence of short range ferromagnetic order. In addition we have qualitatively replicated the microscopic preferential shift from antiferromagnetic to ferromagnetic order with electric field using first principles density functional calculations.

4:18PM D2.00004 Strain-induced oxygen defect formation and interfacial magnetic phase separation in $\text{SrTiO}_3(001)/\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$ ¹, CHRIS LEIGHTON, University of Minnesota — The remarkable functionality and epitaxial compatibility of complex oxides provides many opportunities for new physics and applications in oxide heterostructures. Perovskite manganites and cobaltites provide excellent examples, being of interest for solid oxide fuel cells, catalysis, ferroelectric RAM, gas sensing, resistive switching memory, and oxide spintronics. However, the same delicate balance between phases that provides this diverse functionality also leads to a serious problem - the difficulty of maintaining desired properties close to the interface with other oxides. Although this problem is widespread, manifests itself in several ways, and could present a significant roadblock to the development of heterostructured devices for oxide electronics, there is no consensus as to its origin, or even whether it is driven by electronic or chemical effects. In this work, using $\text{SrTiO}_3(001)/\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$ as a model system, we have combined epitaxial growth via high pressure oxygen sputtering with high resolution x-ray diffraction, atomic resolution electron microscopy and spectroscopy, and detailed magnetic, transport, and neutron scattering measurements to determine the fundamental origin of the deterioration in interfacial transport and magnetism. The effect is found to be due to nanoscopic magnetic phase separation in the near-interface region driven by a significant depletion in interfacial hole doping due to accumulation of O vacancies. This occurs due to a novel mechanism for accommodation of lattice mismatch with the substrate based on formation and long-range ordering of O vacancies, thus providing a fundamental link between strain state and O vacancy density. Further impacts of the O vacancy ordering and interfacial magnetic phase separation, such as formation of a spin-state superlattice and an extraordinary coercivity enhancement, will also be discussed. Work in collaboration with M. Sharma, M. Torija, J. Schmitt, C. He, S. El-Khatib, J. Gazquez, M. Varela, M. Laver and J. Borchers.

¹Work supported by NSF and DOE (neutron scattering).

4:54PM D2.00005 Directly probing the effect of strain on magnetic exchange interactions, KATHRIN DORR, Institute for Physics, MLU Halle-Wittenberg — Thin films of transition metal oxides of the perovskite type ABO_3 ($B = 3d$ or $4d$ metal) have revealed abundant examples for strain-driven changes of magnetic ordering. One most popular is the strain-induced ferromagnetic ferroelectric state of otherwise antiferromagnetic paraelectric EuTiO_3 . Another promising example is the strain control of orbital occupation and magnetic coupling at oxide interfaces of SrRuO_3 with manganites. In spite of strong efforts, the theoretical treatment of magnetic exchange in complex oxides has remained a challenge, and experiments continue to show unpredicted / unexplained large effects of the epitaxial strains in films. In order to provide meaningful experimental data on strain dependences, epitaxial thin films should be grown in various coherent strain states on different substrates without changing anything but the strain. This is inherently difficult: possible problems may arise from a strain-dependent oxidation level or microstructure. As a complementary approach, the in-plane strain of epitaxial oxide films can be controlled reversibly using a piezoelectric substrate, even though the accessible reversible strain of 0.1 – 0.2% is an order of magnitude smaller. In my talk, I will address reversible-strain studies on $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$, $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$ ($x = 0, 0.2, 0.3$) and SrRuO_3 films, showing the strain response of the magnetic Curie temperature, the magnetization and the electrical resistance and discussing the current understanding of the strain effects on magnetic ordering. In $\text{La}_{0.8}\text{Sr}_{0.2}\text{CoO}_3$, a strain-driven phase transition between ferromagnetic and spin-glass-like could be established by combining the piezoelectric substrate with a tuned buffer system providing varied as-grown strain states. In SrRuO_3 , a tetragonal tensile strain state shows a suppression of the ordered magnetic moment. Lattice parameters and symmetries of the films were determined by x-ray diffraction. It is noted that the atomic displacements (bond lengths and angles) under strain in these compounds are yet essentially unknown and subject to present research.

Monday, February 27, 2012 2:30PM - 5:30PM –
Session D3 DCMP: Invited Session: Stripe Order and Fermi-Surface Reconstruction in Cuprate Superconductors 205AB

2:30PM D3.00001 Fermi-surface reconstruction by stripe order in cuprate superconductors, FRANCIS LALIBERTÉ, University of Sherbrooke — The origin of pairing in a superconductor resides in the underlying normal state. In the cuprate high-temperature superconductor YBCO, application of a magnetic field to suppress superconductivity reveals a ground state that appears to break the translational symmetry of the lattice, pointing to some density-wave order [1,2,3]. In another cuprate, Eu-LSCO, the onset of stripe order - a modulation of spin and charge densities - at low temperature is well established [4]. By a comparative study of thermoelectric transport in the cuprates YBCO and Eu-LSCO, we show that the two materials exhibit a very similar process of Fermi-surface reconstruction as a function of temperature and doping [5,6]. This strongly suggests that Fermi-surface reconstruction is caused by stripe order in both cases, compelling evidence that stripe order is a generic tendency of hole-doped cuprates.

Work done in collaboration with J. Chang, N. Doiron-Leyraud, E. Hassinger, R. Daou, D. LeBoeuf, M. Rondeau, B. J. Ramshaw, R. Liang, D. A. Bonn, W. N. Hardy, S. Pyon, T. Takayama, H. Takagi, I. Sheikin, L. Malone, C. Proust, K. Behnia and L. Taillefer.

3:06PM D3.00002 Competition between charge and superconducting orders in underdoped YBCO , MARC-HENRI JULIEN, Laboratoire National des Champs Magnétiques Intenses - Grenoble — We report nuclear magnetic resonance measurements (NMR) showing that high magnetic fields induce a static, unidirectional, modulation of the charge density in the CuO_2 planes of underdoped $\text{YBa}_2\text{Cu}_3\text{O}_y$ [T. Wu et al., Nature 477, 191 (2011)]. The appearance of the charge order coincides with the Fermi surface reconstruction inferred from quantum oscillation and other transport measurements. This charge order appears to be most probably the same $4a$ -periodic stripe modulation as in La-214 cuprates. That it develops only when superconductivity fades away (no charge order is observed under strong fields parallel to the planes) and near the same $1/8$ hole doping as in La-214 suggests that charge order, although visibly pinned by CuO chains in $\text{YBa}_2\text{Cu}_3\text{O}_y$, is an intrinsic propensity of the superconducting planes of high- T_c copper oxides. Since field induced stripe order is also compatible with neutron scattering data in La-214 and with STM data in Bi-2212, charge order could be a generic competitor of high T_c superconductivity.

Work performed with T. Wu, H. Mayaffre, S. Krämer, M. Horvatic, C. Berthier (LNCMI Grenoble), W.N. Hardy, R. Liang, D.A. Bonn (University of British Columbia, Vancouver)

3:42PM D3.00003 The electronic state of underdoped YBCO at high magnetic fields and low temperatures: evidence from quantum oscillatory phenomena¹ , GIL LONZARICH, University of Cambridge — Quantum oscillations in bulk and transport properties have been observed in underdoped $\text{YBa}_2\text{Cu}_3\text{O}_{6+x}$ via a range of techniques and by independent researchers in applied magnetic fields above 20T and temperatures below 10K. The consensus is that the oscillations are periodic in the reciprocal of the magnetic field and consist of a number of components with frequencies (fundamental or otherwise) of below 2kT, nearly an order of magnitude lower than that observed in the overdoped state of $\text{Ti}_2\text{Ba}_2\text{CuO}_{6+x}$. Moreover, the temperature dependence of the amplitude of the strongest oscillatory components that can be measured accurately follows closely that expected for elementary excitations of fermionic character. I will discuss a model of the Fermi surface that can potentially account for each of the periodic components observed, and that appears to be consistent with a number of other known properties in the high-field low-temperature state.

¹Work performed in collaboration with S. E. Sebastian, N. Harrison, R. Liang, D. A. Bonn, and W. N. Hardy.

4:18PM D3.00004 Evidence for competing orders in underdoped $\text{YBa}_2\text{Cu}_3\text{O}_y$, CYRIL PROUST, Laboratoire National des Champs Magnétiques Intenses (CNRS) — 25 years after the discovery of high temperature cuprate superconductors, the observation of quantum oscillations has deeply changed the theoretical landscape relevant to these materials. The measurements of quantum oscillations on both sides of the phase diagram of cuprates confirm the existence of a Fermi surface with sharply defined excitations on the overdoped side and also show that the Fermi surface has suffered a drastic modification on the other side. The small Fermi pockets inferred from quantum oscillations in the underdoped regime combined with the negative Hall and Seebeck coefficients pointing to electrons as dominant charge carriers, greatly strengthen the case that the Fermi surface of underdoped $\text{YBa}_2\text{Cu}_3\text{O}_y$ undergoes a reconstruction because the translational symmetry of its lattice is broken at low temperature. Many studies, such as those of the Hall and Seebeck effects, point to a reconstruction of the Fermi surface due to stripe order. More recently, NMR measurements discover a static, unidirectional, modulation of the charge density in the CuO_2 planes that has the $4a$ -periodic stripe modulation. In this talk, I will show the impact of this charge order on some transport properties, in particular c -axis transport. A crossover to a coherent regime of metallic behavior of the c -axis resistivity at low temperature coincides with the emergence of the charge order. I will also address the topical question of competition between the charge order and superconductivity in high fields.

4:54PM D3.00005 Fermi-surface reconstruction by charge-stripe order in a cuprate superconductor , STEVE KIVELSON, Stanford University — No abstract available.

Monday, February 27, 2012 2:30PM - 5:30PM — Session D4 DAMOP: Long-range Interacting Rydberg and Dipolar Gases 205C

2:30PM D4.00001 Rydberg-Rydberg interactions in ultracold atomic gases , SEBASTIAN HOFFERBERTH, JONATHAN BALEWSKI, STÉPHAN JENNEWEIN, ALEXANDER KRUPP, HUAN NGUYEN, JOHANNES NIPPER, MICHAEL SCHLAGMUELLER, CHRISTOPH TRESP, ROBERT LOEW, TILMAN PFAU, University of Stuttgart — The giant size and large polarizability of Rydberg-atoms make them ideal to study many-body collective effects. We present recent results from the ultra-cold Rydberg experiments in our group. Firstly, we discuss studies of Förster resonances, which appear when two-body-states are tuned into resonance. The resulting strong dipolar interatomic interactions vary in strength and angular dependency based on the magnetic substates involved. We study these interactions in a Ramsey atom interferometer, where the two interferometer arms are atoms in the ground and in the Rydberg state. Using this phase sensitive tool, Förster resonances are studied with unprecedented accuracy. The coherent technique enables to resolve several resonances and study their coherence properties. Secondly, we present our new setup for studying single Rydberg-excitations in optical traps smaller than the Rydberg-blockade sphere. Such ensembles, where all trapped atoms coherently share a single Rydberg-excitation, form a two-level “superatom” whose Rabi-oscillation is collectively enhanced. Our new apparatus combines single ion-detection, sub-micron optical resolution, and highly flexible optical trapping potentials to study coherent dynamics of individual superatoms as well as interactions between superatoms.

2:42PM D4.00002 Towards single-photon optical nonlinearities using cold Rydberg atoms , THIBAUT PEYRONEL, MIT, OFER FIRSTENBERG, Harvard, QIYU LIANG, VLADAN VULETIC, MIT, MIKHAIL LUKIN, Harvard — Effects of the Rydberg blockade in cold atomic clouds have been intensively explored over the last few years. Optical fields can be coherently mapped onto atomic states with a Rydberg component using EIT techniques thanks to the long lifetime of the Rydberg states. As the dipole-dipole interaction between Rydberg atoms prevents several polaritons from propagating simultaneously within a Rydberg volume, it gives rise to strong non-linearities which are mapped back on the probe optical field. We aim at bringing the Rydberg-EIT into the single-photon regime in order to produce non-classical highly correlated states of light. Rubidium atoms are loaded in a far off-resonant (1064nm) optical dipole trap, where densities are typically large enough to reach high optical depths within a single blockade volume. In this regime, the outgoing photon-photon correlation function is expected to exhibit highly non-classical behavior, corresponding to trains of spatially separated single-photons. Moreover, EIT techniques together with a high-resolution imaging system allow the observation of Rydberg excitations in the quasi-1D configuration, and should pave the way to in-situ monitoring of strongly correlated many-body states such as the crystallisation of Rydberg atoms.

2:54PM D4.00003 Altering Photon Statistics using Strong Rydberg Interactions, JOHANNES OTTERBACH, Physics Department, Harvard University, Cambridge, MA, USA, DAVID PETROSYAN, Institute of Electronic Structure and Laser, FORTH, Crete, Greece, ALEXEY V. GORSHKOV, Institute for Quantum Information, California Institute of Technology, Pasadena, CA, USA, THOMAS POHL, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany, MICHAEL FLEISCHHAUER, Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, Germany, MIKHAIL D. LUKIN, Physics Department, Harvard University, Cambridge, MA, USA — The recent advance in coherently controlling and manipulating strong, long-range Rydberg interactions has triggered extensive research in studying interesting many-body effects as, e.g. the use of Rydberg blockade effects for quantum information processing and crystal formation. In this talk I show that Rydberg interactions can be used to alter the photon statistics of a weak probe field after propagating in a coherently prepared atomic Rydberg gas under conditions of Electromagnetically Induced Transparency (EIT). The Rydberg blockade mechanism leads to an effective two-level physics when two photons are separated less than the blockade radius resulting in a strong anti-correlation of two photons separated by an avoided volume. Implications of the formation of such hard-sphere photons for the recent experiment of Pritchard et al. [Phys. Rev. Lett. 105, 193603 (2010)] and the observation of such correlation in future experiments will be discussed.

3:06PM D4.00004 Collective quantum jumps of Rydberg atoms, TONY LEE, California Institute of Technology, HARTMUT HAEFFNER, University of California, Berkeley, MICHAEL CROSS, California Institute of Technology — A quantum system under constant observation may occasionally switch between two metastable states. These quantum jumps are usually observed in a single object, like an atom, electron, or superconducting qubit. We report on a collective type of quantum jump in a group of atoms with long-range Rydberg interaction, laser driving, and spontaneous emission. Over time, the system occasionally jumps between a state of low Rydberg population and a state of high Rydberg population. The jumps are inherently collective and in fact exist only for a large number of atoms. We explain how entanglement and quantum measurement enable the jumps, which are otherwise classically forbidden.

3:18PM D4.00005 Quantum crystals in a trapped Rydberg-dressed Bose-Einstein condensate¹, C.-H. HSUEH, Department of Physics, National Taiwan Normal University, T.-C. LIN, Department of Mathematics, National Taiwan University, T.-L. HORNG, Department of Applied Mathematics, Feng Chia University, W.C. WU, Department of Physics, National Taiwan Normal University — Spontaneously crystalline ground states, called quantum crystals, of a trapped Rydberg-dressed Bose-Einstein condensate are numerically investigated. As a result described by a mean-field order parameter, such states simultaneously possess crystalline and superfluid properties. A hexagonal droplet lattice is observed in a quasi-two-dimensional system when dressing interaction is sufficiently strong. Onset of these states is characterized by a drastic drop of the non-classical rotational inertia proposed by Leggett [Phys. Rev. Lett. 25, 1543 (1970)]. In addition, an AB stacking bilayer lattice can also be attained. Due to an anisotropic interaction possibly induced by an external electric field, transition from a hexagonal to a nearly square droplet lattice is also observed.

¹We acknowledge financial support from NSC, Taiwan.

3:30PM D4.00006 Quantum Magnetism with Polar Molecules: Tunable Generalized t - J Model, ALEXEY GORSHKOV, California Institute of Technology, SALVATORE MANMANA, University of Colorado, Boulder, KEVIN KUNS, California Institute of Technology, KADEN HAZZARD, GANG CHEN, JUN YE, University of Colorado, Boulder, EUGENE DEMLER, MIKHAIL LUKIN, Harvard University, ANA MARIA REY, University of Colorado, Boulder — We show that dipolar interactions between ultracold polar molecules in optical lattices can be used to realize a highly tunable generalization of the t - J model, which we refer to as the t - J - V - W model. The “spin” is encoded in the rotational degree of freedom of the molecules, while the interactions are controlled by applied static electric and continuous-wave microwave fields. We show that the tunability and the long-range nature of the interactions in the t - J - V - W model enable enhanced superfluidity in one dimension and controllable preparation of robust d-wave superfluids in two dimensions. The latter may provide fundamental insights into high-temperature superconductivity. [References: Phys. Rev. Lett. 107, 115301 (2011); Phys. Rev. A 84, 033619 (2011); arXiv:1110.5330]

3:42PM D4.00007 Tunable Superfluidity with Ultracold Polar Molecules on quasi-1D Optical Lattices, SALVATORE R. MANMANA, JILA & CU Boulder, 440 UCB, Boulder, CO 80309, ALEXEY V. GORSHKOV, KEVIN A. KUNS, IQI, CalTech, Pasadena, CA 91125, GANG CHEN, JUN YE, JILA & CU Boulder, 440 UCB, Boulder, CO 80309, EUGENE DEMLER, MIKHAIL D. LUKIN, Physics Department, Harvard University, Cambridge MA 02138, ANA MARIA REY, JILA & CU Boulder, 440 UCB, Boulder, CO 80309 — By selecting two dressed rotational states of ultracold polar molecules on an optical lattice, strong electric dipole-dipole interactions allow to directly emulate spin Hamiltonians and a highly tunable generalization of the t - J model, the t - J - V - W model. We present the phase diagram of the simplest experimentally realizable case, the t - $J_{\perp}$ model with long-range dipolar spin-exchange interactions, on (quasi) one-dimensional chain and ladder systems as obtained from extensive density matrix renormalization group (DMRG) calculations. For the chain, we discuss the possible realization of unconventional quasi-long-range-order caused by the dipolar interactions. While the phase diagram of the dipolar t - $J_{\perp}$ chain is similar at low filling to that of the standard t - J chain, the superconducting region is strongly enhanced. We approach the ladder systems by coupling square plaquettes and comparing the numerical results to a mean-field description. We discuss the possibility to enhance superconductivity in these ladder systems by the presence of the dipolar interactions.

3:54PM D4.00008 Dynamical generation and detection of entangled quantum magnetic states in ultracold polar molecules, KADEN HAZZARD, SALVATORE MANMANA, UC Boulder, JILA, NIST, ALEXEY GORSHKOV, Institute for Quantum Information, California Institute of Technology, ANA MARIA REY, UC Boulder, JILA, NIST — We show that *existing* ultracold polar molecule experiments in optical lattices may generate strongly correlated many-body states by mimicking far-from-equilibrium dynamics of models of quantum magnetism. Recent theory shows that molecules’ rotational states can emulate quantum spins with strong (100-10,000Hz) “spin-spin” interactions. Applying external fields generates a zoo of models: spin-1/2 and larger Heisenberg and XXZ models, and well beyond. We consider the dynamics of the easily prepared fully polarized initial state for the XXZ case predicted to be realized in current experiments. Our analytic and DMRG calculations show that the dynamics can: (i) verify and characterize the spin model (XXZ) description of the system, (ii) generate interesting, entangled states (e.g., cat states, GHZ), and (iii) explore behavior where no quantitative theory is presently possible.

4:06PM D4.00009 Interactions of polar molecules dressed by far-off-resonant light: Entangled dipoles up- or down-holding each other, MIKHAIL LEMESHKO, ITAMP, Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts 02138, USA, BRETISLAV FRIEDRICH, Fritz Haber Institute of the Max Planck Society, Faradayweg 4-6, D-14195 Berlin, Germany, FRIEDRICH TEAM — We show that the electric dipole-dipole interaction between a pair of polar molecules undergoes an all-out transformation when superimposed by a far-off resonant optical field. The combined interaction potential becomes tunable by variation of wavelength, polarization and intensity of the optical field and its dependence on the intermolecular separation exhibits a crossover from an inverse-power to an oscillating behavior. The ability thereby offered to control molecular interactions opens up avenues toward the creation and manipulation of novel phases of ultracold polar gases among whose characteristics is a long-range entanglement of the dipoles’ mutual orientation. We devised an accurate analytic model of such optical-field-dressed dipole-dipole interaction potentials, which enables a straightforward access to the optical-field parameters required for the design of intermolecular interactions in the laboratory.

4:18PM D4.00010 Clustering of cold polar molecules in arrays of one-dimensional tubes, MICHAEL KNAP, Graz University of Technology, EREZ BERG, EUGENE DEMLER, Harvard University — Cold polar molecules allow to study exciting new phenomena which arise from the long-range and anisotropic nature of their mutual interactions. Here, we demonstrate that a Wigner crystal of polar molecules confined in planar arrays of one-dimensional tubes can be made unstable with respect to the formation of clusters of particles. By controlling the orientation of the external electric field which aligns the dipolar moments, increasingly complex structures with a varying number of particles per cluster and thus varying periodicity are formed. The spatial agglomeration of multiple polar molecules results from the interaction and can be described classically. However, we show that the effect survives when quantum fluctuations are present. For systems of a finite number of tubes, the result is a sequence of "clustered" Luttinger liquid states. Finally, we determine the ratio between the interaction and the kinetic energy which is necessary for the spatial agglomeration of polar molecules. We find that the requirements for clustering are reachable in current experiments with cold polar molecules.

4:30PM D4.00011 A dielectric superfluid of polar molecules¹, SETH RITTENHOUSE, ITAMP, Harvard-Smithsonian Center for Astrophysics, RYAN WILSON, JOHN BOHN, JILA and the Department of Physics, University of Colorado — We consider a Bose-Einstein condensate of heteronuclear molecules in an applied electric field. In the strong field regime, the molecules are fully polarized and produce fields that tend to be weak compared to the applied field. However, in weaker applied fields the internal fields due to the polarization of the molecules can become comparable to the applied field, and the system develops a dielectric character. We derive a set of self-consistent mean-field equations that couple the condensate density to its polarization field, leading to the emergence of polarization modes that are coupled to the quasiparticle spectrum of the condensate. While the roton instability is suppressed in this system, the coupling gives rise to a phonon-like instability that is characteristic of a dielectric material with a negative static dielectric function.

4:42PM D4.00012 Dipolar gases in two coupled one-dimensional lattices, MARIANNE BAUER, Cambridge University, MEERA PARISH, University College London — We consider dipolar bosons in two tubes of one-dimensional lattices, where the boson filling fraction is the same in each tube and the dipoles are aligned to be maximally repulsive. In the classical limit of zero inter-site hopping, the bosons arrange themselves into an ordered crystal for any rational filling fraction, forming a complete devil's staircase like in the single tube case [1]. When we turn on hopping within each tube, we obtain a competition between the crystalline Mott phases and a superfluid of defects or solitons. However, in contrast to the single tube case [2], we find that solitons in different tubes can bind into pairs for certain topologies of the filling fraction. This provides an intriguing example of pairing that is purely driven by correlations close to a Mott insulator.

4:54PM D4.00013 Paired Phases of Dipoles in a Bilayer System, ARGHAVAN SAFAVI-NAINI, MIT, SEBNEM GUNES SOYLER, ICTP Trieste, GUIDO PUPILLO, ISIS and IPCMS, Universite de Strasbourg and CNRS, HOSSEIN SADEGHPOUR, ITAMP, BARBARA CAPOGROSSO-SANSONE, University of Oklahoma — By means of large scale quantum Monte Carlo simulations we study a system of dipolar lattice bosons in bilayers geometries and with no hopping between layers. We investigate under which conditions pairing (e.g. paired superfluidity, paired supersolidity) is stabilized and make estimates for current experimental setups. We also study temperature effects and possible experimental signatures of such phases.

5:06PM D4.00014 Bond Order Solid of Two-Dimensional Dipolar Fermions, SATYAN BHONGALE, George Mason University, LUDWIG MATHEY, University of Hamburg, SHAN-WEN TSAI, University of California, Riverside, CHARLES CLARK, NIST, JQI, ERHAI ZHAO, George Mason University — Cold atoms provide a promising platform to solve problems that, although computationally infeasible, are of immense importance to condensed matter physics and material science. Ultra-cold bosonic atoms have been quite successful in emulating the Bose-Hubbard model. Experiments are now underway towards mapping out the unknown phase diagram of the Fermi-Hubbard model. Recent experimental advances in cooling dipolar gases to quantum degeneracy provide an unprecedented opportunity to engineer Hubbard-like models with long range interactions. Here, with the aid of functional renormalization group technique, we show that two new and exotic types of order emerge generically in dipolar fermion systems: bond order solids of p- and d-wave symmetry. Similar, but manifestly different, phases of two-dimensional correlated electronic systems have previously only been hypothesized. Our results suggest that these phases can be constructed flexibly with dipolar fermions, using currently available experimental techniques, providing detectable experimental signatures.

5:18PM D4.00015 Re-entrant first-order phase transitions and anomalous hysteresis of dipolar Bose gases in a triangular optical lattice, DAISUKE YAMAMOTO, Condensed Matter Theory Laboratory, RIKEN, Wako, Saitama 351-0198, Japan, IPPEI DANSHITA, Computational Condensed Matter Physics Laboratory, RIKEN, Wako, Saitama 351-0198, Japan, CARLOS SÁ DE MELO, School of Physics, Georgia Institute of Technology, Atlanta, Georgia 30332, USA — We study the hysteresis behavior of dipolar Bose gases loaded into a triangular optical lattice. A large-size cluster mean-field approximation is applied to the corresponding extended Bose-Hubbard model to take into account metastable states. We find that the phase transition between supersolid (or solid) and superfluid states is always first-order except for the particle-hole symmetric point. In the phase diagram, the supersolid and solid phases are sandwiched in between the superfluid phase, and the system exhibits a re-entrant behavior from superfluid to solid (to supersolid), and back to superfluid with varying the chemical potential. Our most remarkable finding is that in the hysteresis accompanying this "re-entrant" first-order phase transition, the quantum melting transition from supersolid or solid to superfluid can occur while the reverse process is impossible since the superfluid phase remains locally stable for any value of the chemical potential. Moreover, the hysteresis curve of density versus chemical potential does not form a "hysteresis-loop" structure unlike the case of the conventional first-order transition. We show that this anomalous behavior of the hysteresis is a common property of systems exhibiting a re-entrant first-order phase transition.

Monday, February 27, 2012 2:30PM - 5:30PM — Session D5 DCMP: Vanadium Oxides; Metal-insulator Transitions 206A

2:30PM D5.00001 Metal-Insulator Transition in ultrathin CaVO_3 Films, MAN GU, JIWEI LU, STUART WOLF, University of Virginia — Bulk CaVO_3 (CVO) with a $3d^1$ electronic configuration has been found to exhibit metallic and Pauli paramagnetic behavior. We have synthesized epitaxial ultrathin films of CVO on single crystal (100) SrTiO_3 substrates by pulsed electron deposition. The CVO films were capped with 2.5nm SrTiO_3 layer. Compared with single crystal CVO, thin film CVO demonstrated very large resistance ratios (RR), e.g., $R(300\text{K})/R(2\text{K})$ more than 3000. The temperature dependent Hall measurement showed mostly that the large RR determined by the change in mobility, we observed the metal-insulator transition at $\sim 100\text{K}$ in CVO ultrathin films with thickness below 4nm, which was not observed in either thick CVO films or STO films. Above 100K, ultrathin CVO exhibited the metallic behavior, and below 100 K, it became an insulator. The emergence of MIT could be attributed to a pseudogap that appeared at Fermi surface with decreasing film thickness, indicating a transition from 3D metal to 2D insulator transition in ultrathin CVO films at temperatures lower than 100K. A metal-insulator transition was further characterized by I-V measurements, the insulator phase was only observed with driven current below 100K and $2 \times 10^{-6}\text{A}$.

2:42PM D5.00002 Thermoelectric response in the incoherent transport region near Mott transition: the case study of $\text{La}_{1-x}\text{Sr}_x\text{VO}_3$, MASAKI UCHIDA, K. OISHI, Y. ONOSE, J. FUJIOKA, Y. TOKURA, University of Tokyo, M. MATSUO, M. MORI, S. MAEKAWA, JAEA, W. KOSHIBAE, RIKEN ASI, S. MIYASAKA, Osaka University — We report a systematic investigation on the high-temperature thermoelectric response in a typical filling-control Mott transition system $\text{La}_{1-x}\text{Sr}_x\text{VO}_3$. In the vicinity of the Mott transition, incoherent charge transport appears with increasing temperature and the thermopower undergoes two essential crossovers, asymptotically approaching the limit values expected from the entropy consideration, as known as Heikes formula. By comparison with the results of the dynamical mean field theory, we show that the thermopower in the Mott critical state mainly measures the entropy per charge carrier that depends on electronic degrees of freedom available at the measurement temperature. Our findings verify that the Heikes formula is indeed applicable to the real correlated electron systems at practical temperatures ($T > 200$ K).

2:54PM D5.00003 First-principles calculations of phonons in VO_2 ¹, ERIC J. WALTER, HENRY KRAKAUER, TYLER HUFFMAN, M.M. QAZILBASH, College of William and Mary — Vanadium dioxide (VO_2) undergoes a metal-insulator transition at 340K. This is accompanied by a structural transition from a metallic, high-temperature rutile phase to a low-temperature monoclinic insulating phase. Recently, it has become possible to produce single crystal platelets of VO_2 deposited on a oxidized silicon substrate. These micro-crystals are under strain which can potentially alter their properties compared to bulk samples. Infrared micro-spectroscopy on these samples permits accurate measurements of their electronic and phonon properties as the micro-crystals are driven reversibly across the temperature-driven insulator-to-metal transition (IMT). We present *ab-initio* calculations of phonons in the rutile and monoclinic phases of VO_2 . These calculations were performed using first-principles density functional theory using both LDA and LDA+U. The effect of the Hubbard parameters and strain on both phases is discussed. We compare our results to the single crystal measurements and previous experimental results.

¹Supported by ONR

3:06PM D5.00004 Infrared micro-spectroscopy of strained VO_2 micro-crystals, M.M. QAZILBASH, T. HUFFMAN, E.J. WALTER, H. KRAKAUER, Department of Physics, College of William and Mary, JIANG WEI, D.H. COBDEN, Department of Physics, University of Washington, Seattle, H.A. BECHTEL, M.C. MARTIN, Advanced Light Source, Lawrence Berkeley National Laboratory, G.L. CARR, National Synchrotron Light Source, Brookhaven National Laboratory, D.N. BASOV, Department of Physics, University of California, San Diego — The temperature-driven insulator-to-metal transition (IMT) in vanadium dioxide (VO_2) is accompanied by a structural instability (SI). The IMT and SI lead to a drastic change in the electronic properties, crystal structure, and lattice dynamics. We performed infrared micro-spectroscopy on single crystal platelets of VO_2 deposited on oxidized silicon substrate by physical vapor deposition. The firm attachment of these micro-crystals to the substrate causes strain which can alter their properties compared to bulk samples. We report infrared data on these micro-crystals and demonstrate both their electronic and phonon properties in the monoclinic M1 phase and the rutile phase. We also compare their infrared conductivity to that of bulk single crystals and thin films. Finally, we compare infrared-active phonon features to first-principles density functional theory calculations.

3:18PM D5.00005 Ultrafast Pump Probe Transmission Spectroscopy of VO_2 , NATHANIEL BRADY, University of Alabama at Birmingham, KANNATASSEN APPAVOO, Vanderbilt University, MINAH SEO, PRASHANTH UPADHYA, Los Alamos National Laboratory, JOYEETA NAG, RICHARD HAGLUND, Vanderbilt University, ROHIT PRASANKUMAR, Los Alamos National Laboratory, DAVID HILTON, University of Alabama at Birmingham — We have performed nondegenerate pump-probe transmission spectroscopy, pumping with an above the band gap (1.5 eV) 50 fs pulse and probing with a 0.4 eV (below the band gap) pulse to monitor the dynamics of the formation of the metallic phase in vanadium dioxide (VO_2). Below the percolation threshold (< 330 K), we find an initial drop in transmission consistent with electron-hole generation across the band gap, while in the fully metallic phase (< 365 K), we see an initial rise in transmission due to transient heating of electrons at the Fermi surface. In the transitional region, the data show complex time dependence consistent with the nucleation and growth of metallic domains in the semiconducting phase and ultrafast heating of metallic precursors in the insulating phase.

3:30PM D5.00006 Ultrafast Spectroscopy and Optically-Induced Phase Transitions of Single Crystal VO_2 ¹, AARON JONES, JAE PARK, JIM COY, DAVID COBDEN, XIAODONG XU, University of Washington — We investigate the metal-insulator phase transition (MIT) of single crystal VO_2 platelets using non-degenerate optical pump-probe spectroscopy. The pump pulse is at 800 nm and the probe pulse varies between 1.3 μm and 2.4 μm , covering the optical gap (~ 2 μm) of VO_2 . We observe ultrafast carrier relaxation on the timescale of 0.5 ps or less in the insulating phase. Higher pump powers induce coherent acoustic phonon oscillations which we explore by adjusting probe wavelength and pump fluence. At temperatures just below the transition, we observe optically induced MIT at a time scale less than 300 fs (pulse width limited), and we investigate the dependence on crystal size, wavelength, and temperature. The properties of the insulator do not seem consistent with a conventional band semiconductor.

¹Work supported by DoE Grant BES DE-SC0002197 and NSF Grant DGE-0718124

3:42PM D5.00007 THz induced insulator to metal transition in VO_2 metamaterial, MENGKUN LIU, Boston University, HAROLD HWANG, Massachusetts Institute of Technology, HU TAO, Tufts University, ANDREW STRIKWERDA, KEBIN FAN, GEORGE KEISER, AARON STERNBACH, Boston University, KEVIN WEST, SALINPORN KITTIWATANAKUL, JIWEI LU, STUART WOLF, University of Virginia, FIORENZO OMENETTO, Tufts University, XIN ZHANG, Boston University, KEITH NELSON, Massachusetts Institute of Technology, RICHARD AVERITT, Boston University — We use metamaterial enhanced high field terahertz (THz) pulses (up to $\sim 4\text{MV/cm}$) to induce the insulator-to-metal transition in vanadium dioxide (VO_2) thin films at 320K. Ultrafast THz field enhancement in the gaps of metamaterial split ring resonators releases free electrons in VO_2 by the Poole-Frenkel effect. The accelerated hot electrons transfer energy to the lattice via electron phonon coupling inducing the persistent metallic phase. A large nonlinear signature is observed in VO_2 as modulations of the metamaterial resonance on a picosecond time scale. Our results provide insight into electric field induced phase transitions in VO_2 and paves the way for studying nonlinear high THz field effects in many other strongly correlated materials.

3:54PM D5.00008 Optical control of structural evolution of ultrathin VO₂ film following a photoinduced metal-insulator phase transition¹, HAIDAN WEN, X-ray Science Division, Argonne National Laboratory, EFTIHIA BARNES, Department of Materials Science and Engineering, Pennsylvania State University, JUNE H. LEE, YUELIN LI, DONALD A. WALKO, ERIC M. DUFRESNE, X-ray Science Division, Argonne National Laboratory, MARTIN HOLT, Center for Nanoscale Materials, Argonne National Laboratory, DARRELL G. SCHLOM, Department of Materials Science and Engineering, Cornell University, VENKATRAMAN GOPALAN, Department of Materials Science and Engineering, Pennsylvania State University, JOHN W. FREELAND, X-ray Science Division, Argonne National Laboratory, — Using ultrafast x-ray diffraction technique, we have demonstrated that the structural symmetry in VO₂ thin film across the metal-insulator transition (MIT) can be controlled by the optical pump fluence. After an 800 nm, 50 fs laser excitation, the structural evolution of a 13nm-thick, MBE-grown VO₂ film on TiO₂ substrate was monitored by a synchrotron based x-ray diffraction with 100 picosecond (ps) time resolution. By adjusting the pump fluence, the VO₂ film can be prepared in selected structural state 100 ps after excitation, and transits through the known structural phases (tetragonal, monoclinic M2, monoclinic M1) in tens of nanoseconds time scale. When pumping at high fluence (28 mJ/cm²), a new transient state that exhibits lower symmetry than the thermal equilibrium tetragonal phase has been identified and its evolution pathway has been measured.

¹Work at Argonne is supported by the U.S. Department of Energy under Contract No. DE-AC02-06CH11357.

4:06PM D5.00009 In-situ measurements of Stress Relaxation across Metal Insulator Transition in Correlated Oxide Thin Films, VISWANATH BALAKRISHNAN, SHRIRAM RAMANATHAN, Harvard School of Engineering and Applied Sciences — Stress relaxation across the metal-insulator transition in correlated oxide thin films such as VO₂ and SmNiO₃ is of great importance since it could be directly related to the symmetry breaking structural component of the transition and also affects the properties and performance of the electronic devices significantly. We present in-situ stress relaxation measurements across the thermally triggered metal insulator transition and its impact on the transition characteristics and stability. Mesoscopic size effects, micro-patterning and geometrical confinement effects on the metal insulator transition and associated stress relaxation will be addressed. Correspondence between onset of the electrical transition with stress relaxation leads to several interesting observations regarding the transition dynamics and will be discussed.

4:18PM D5.00010 In-Plane Impedance Spectroscopy measurements in Vanadium Dioxide thin films¹, JUAN RAMIREZ, University of California, San Diego, EDGAR PATINO, Universidad de los Andres, RAINER SCHMIDT, Universidad Complutense de Madrid, AMOS SHARONI, Bar-Ilan University, MARIA GOMEZ, Universidad del Valle, IVAN SCHULLER, University of California, San Diego — In plane Impedance Spectroscopy measurements have been done in Vanadium Dioxide thin films in the range of 100 Hz to 1 MHz. Our measurements allows distinguishing between the resistive and capacitive response of the Vanadium Dioxide films across the metal-insulator transition. A non ideal RC behavior was found in our thin films from room temperature up to 334 K. Around the MIT, an increase of the total capacitance is observed. A capacitor-network model is able to reproduce the capacitance changes across the MIT. Above the MIT, the system behaves like a metal as expected, and a modified equivalent circuit is necessary to describe the impedance data adequately.

¹This work has been supported by AFOSR, COLCIENCIAS, CENM and Ramon y Cajal Fellowship.

4:30PM D5.00011 Photoemission Study of VO₂ Above and Below the Transition Temperature¹, LUCA MORESCHINI, Advanced Light Source, YOUNG JUN CHANG, Advanced Light Source and Fritz-Haber Institut, DAVIDE INNOCENTI, Advanced Light Source and Università di Tor Vergata, ANDREW L. WALTER, Advanced Light Source and Fritz-Haber Institut, JONATHAN DENLINGER, AARON BOSTWICK, ELI ROTENBERG, Advanced Light Source — Angle-resolved photoemission (ARPES) experiments on VO₂ have traditionally been hindered by the quality of cleaved single crystals. The lack of a clear metal-insulator transition (MIT) in low photon energy measurements has even lead to the assumption of a surface region with a different electronic structure. With the *in situ* pulsed-laser-deposition (PLD) system available on beamline 7.0.1 at the Advanced Light Source we have grown VO₂(001) films on a TiO₂ substrate and measured the band structure above and below the transition temperature. We discuss our results in comparison with the available calculations, and we show that the MIT is clearly visible for photon energies within the UV range.

¹Work supported by U.S. DOE (DE-AC02-05CH11231 for ALS), the Max Planck Society, and the Swiss National Science Foundation (PBELP2- 125484)

4:42PM D5.00012 Photoemission measurements of strained VO₂¹, JUDE LAVEROCK, ANDREW PRESTON, DAVE NEWBY, KEVIN SMITH, Boston University, SALINPORN KITTIWATANAKUL, JIWEI LU, STUART WOLF, University of Virginia, MATS LEANDERSSON, BALASUBRAMANIAN THIAGARAJAN, MAX-lab, Lund University — The metal-insulator transition of VO₂ has been a textbook example for many years, despite a clear understanding of its microscopic origins proving elusive. Recently, the promise towards novel applications of high-quality thin films, in which the properties of the transition can be tailored by applied strain, has thrust VO₂ back into focus. Here, we report photoemission measurements of strained VO₂ thin films epitaxially grown on TiO₂(110) and TiO₂(100) substrates. The applied strain for these two films lead to moderate and large compressive rutile c-axis strains, respectively. By making use of the incident photon polarization, we observe the changes in polarization anisotropy both across the transition and as a function of applied strain, and demonstrate how we can use this to learn more about the origin of the MIT in VO₂.

¹BU program supported in part by DoE Grant No. DE-FG02-98ER45680.

4:54PM D5.00013 Correlations of local electronic properties in vanadium dioxide thin films¹, ADAM PIVONKA, KEVIN O'CONNOR, ALEX FRENZEL, CHANGHYUN KO, SHRIRAM RAMANATHAN, Harvard University, ERIC HUDSON, Penn State University, JENNIFER HOFFMAN, Harvard University — We probe the local electronic properties of a vanadium dioxide thin film using scanning force microscopy. We scan a conductive cantilever in contact mode across the surface of the sample. At each point, we sweep the voltage applied to the sample, obtaining current versus voltage curves with nanoscale resolution while inducing a transition from the insulating to metallic state. We identify individual grains of ~50-100 nm, and extract the electronic properties of each grain, such as transition voltage, hysteresis, dielectric constant, and metallic state resistance. We discuss the correlations between these properties.

¹This work is supported by the NSF NSEC (PHY 01-17795). Adam Pivonka acknowledges the support of the NSF GRFP and Hertz Foundation.

5:06PM D5.00014 Correlation of Valence State and Transport Properties in VO₂ Films¹, SALINPORN KITTIWATANAKUL, Physics Department, University of Virginia, JUDE LAVEROCK, Physics Department, Boston University, STUART WOLF, Physics Department, University of Virginia, JIWEI LU, Materials Science and Engineering Department, University of Virginia — Vanadium dioxide (VO₂) exhibits a metal semiconductor transition (MST) that is accompanied by the abrupt change in the electrical conductivity, optical transmittance and reflectance in infrared region, which can be used in electronic devices such as temperature sensors and electric switches. VO₂ thin films were grown on c-plane Al₂O₃ substrates with different O₂ flow rates. The XRD scans have been performed to confirm the single phase and highly textured VO₂ films despite the change in the growth parameter, i.e. the oxygen partial pressure. The valence state of vanadium on different films was investigated by soft x-ray spectroscopy. The Hall bars were fabricated for electrical transport and Hall measurements. As the O₂ flow rate increases, the XRD results show decreasing lattice parameter, hence increasing compressive strain along b-axis of monoclinic VO₂; the transport measurements also show the increasing transition temperature (T_{MST}) and the increasing change in resistivity associated with the strain and valence state of vanadium. Hall measurements reveal a sudden increase in carrier concentration from 10²⁰ to 10²⁴ cm⁻³ around T_{MST} , while the mobility remains constant before and after MST. The correlation among the valence state, the strain and MST in VO₂ will be discussed.

¹Authors are thankful to financial supports from VMEC and NRI.

5:18PM D5.00015 Metal-insulator transition in VO₂ macro single domain crystals due to phase boundary motion, HONGLYOU JU, Physics Dept., Yonsei Univ., BONGJIN MUN, Applied Physics Dept., Hanyang Univ., KAI CHEN, Advanced Light Source, LBNL & CAMP-Nano, Xi'an Jiaotong Univ., CATHERINE DEJOIE, NOBUMICHI TAMURA, MARTIN KUNZ, ZHI LIU, SUNG-KWAN MO, Advanced Light Source, LBNL, JOONSEOK YOON, Physics Dept., Yonsei Univ., CHANGWOO PARK, Hanbat National Univ. & Advanced Nano Products — Metal insulator transition (MIT) characteristics of macro-size VO₂ single domain crystals, exhibiting a high resistance ratio of $\sim 10^5$ within as small as 10^{-3} °C in the vicinity of MIT temperature, were investigated by temperature-dependent electrical transport, optical microscopy, and synchrotron-based polychromatic x-ray micro-diffraction measurements. Our results clearly show that MIT initiated via inhomogeneous nucleation, proceeds with the propagation of sharp phase boundary between the metallic (R) and insulating (M1) phases, along the rutile c axis. In this talk, we will present evidences of MIT of single domain VO₂ crystals with sharp phase boundary motion and discuss the implications of our findings on to the origin of MIT and related phenomena.

Monday, February 27, 2012 2:30PM - 5:30PM – Session D6 DMP: Focus Session: Graphene Devices - Bolometers and Optical Response 206B

2:30PM D6.00001 Probing Dirac electron transport in graphene by far-infrared spectroscopy, JIE SHAN, KELIANG HE, LIANG ZHAO, Case Western Reserve University, KIN FAI MAK, NICK PETRONE, JIM HONE, TONY HEINZ, Columbia University — The transport properties of Dirac fermions in graphene are a subject of intense interest. While various scattering mechanisms including impurities, graphene phonons and substrate phonons have been examined by dc transport measurements,¹ direct determination of the scattering rates under different experimental conditions remains challenging.² In this paper we report on the far-infrared optical conductivity spectrum of monolayer graphene samples obtained by Fourier transform infrared spectroscopy. From the frequency dependence of the optical conductivity we determine both the Drude weight and the carrier scattering rate. The dependence of these transport parameters on temperature and electrostatic doping will be presented, and the importance of many-body Coulomb interactions between Dirac electrons will be discussed.

2:42PM D6.00002 Ultrathin dual-gated graphene p-n junction photodetectors, NITYAN NAIR, NATHANIEL GABOR, QIONG MA, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, WENJING FANG, JING KONG, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — Optoelectronic devices composed of atomically thin graphene and boron nitride membranes yield great promise for next-generation photonics and optoelectronic research, yet numerous fabrication challenges remain. We use chemical vapor deposited (CVD) graphene to produce atomically thin, local bottom-gates for high-quality exfoliated graphene optoelectronic devices. By incorporating CVD graphene instead of the more conventional silicon bottom-gate electrodes, we create very low-profile dual-gated field effect p-n junction devices with hexagonal boron nitride as the insulating gate dielectric layer. Combining electron-beam and photolithography techniques, we can shape the bottom-gates to locally modulate the carrier density in the active graphene layer. In addition to avoiding optical transmission through thick top-gate electrodes, our approach allows us to perform temperature dependent photoresponse measurements over various device length scales and with direct control of local electronic carrier densities.

2:54PM D6.00003 Graphene-based Optical Modulator, MING LIU, XIANG ZHANG, UC Berkeley — Data communications have been growing at a speed even faster than Moore's Law, with a 44-fold increase expected within the next 10 years. Data Transfer on such scale would have to recruit optical communication technology and inspire new designs of light sources, modulators, and photodetectors. The past decade has seen the flourish of researches in silicon-based optical modulators. However, their performance is limited by the weak refractive index changes in silicon, and consequently large footprint and stringent fabrication tolerance are required. Here we raise a totally new mechanism for optical modulation. Instead of changing the refractive index in silicon, we use graphene as an active layer and change its absorption coefficient by turning on/off the interband transitions. This turning is realized through shifting the Fermi level by simply a back gate. In this way, we can operate the optical modulator at a relatively high speed (1.2 GHz) over a broad range (1.3 to 1.6 μm), while keep the smallest footprint ($\sim 25 \mu\text{m}^2$). More details of the device will be discussed in the talk.

3:06PM D6.00004 Tunable optical properties of graphene¹, FENG WANG, UC Berkeley — Graphene, a single layer of carbon atoms, exhibits novel two-dimensional electronic behavior. Optical spectroscopy provides a powerful toolkit study graphene physics. In this talk, I will show how we can use infrared spectroscopy to probe gate-dependent interband transitions as well as intraband transitions. I will also discuss how we can use electrical gating to control inelastic light scattering processes in graphene.

¹DOE, ONR, NSF, Packard foundation

3:42PM D6.00005 Photoconductivity of electro-oxidized epitaxial graphene¹, FEIHU WANG, MIKHAIL ITKIS, ELENA BEKYAROVA, ROBERT HADDON, University of California, Riverside, HADDON RESEARCH GROUP TEAM — We report the enhanced photosensitivity of epitaxial graphene (EG) after electrochemical oxidation in nitric acid. The onset of photoconductivity appears at a photon energy of ~ 1.7 eV while the responsivity reaches 200 A/W in the UV spectral range (3.5 eV, 350 nm). The observed photoresponse is attributed to the formation of deep traps at the electro-oxidized EG interface, which release charge carriers under illumination and a significantly prolonged life time of photoexcitations due to the effect of the traps on the recombination dynamics. The enhanced photosensitivity and high selectivity in the UV spectral range make electro-oxidized EG an interesting alternative to the less spectrally selective Si for UV detection, although further optimization of the chemistry is required to shorten the photoresponse time while preserving the high sensitivity.

¹This study was supported by DOD/DMEA under contract H94003-10-2-1003 and NSF-MRSEC through contract DMR-0820382.

3:54PM D6.00006 Photo-controlling electrical properties of graphene-based field-effect transistor with photo-reactive copolymer, CHI-YUAN LIN, Department of Photonics and Institute of Electro-Optical Engineering, National Chiao Tung University, Taiwan, FOREST SHIH-SEN CHIEN, Department of Physics, Tunghai University, Taiwan, CHEN-SHIUNG CHANG, Department of Photonics and Institute of Electro-Optical Engineering, National Chiao Tung University, CHIA-CHEN HSU, Department of Physics, National Chung-Cheng University, Taiwan — Here, we presented a photo-controlling graphene-based FET device. The tri-stable current of graphene device can be achieved in room temperature using the photo-assisted poling (PAP) and photo bleaching (PB) on photo-reactive copolymer PMMA-DR1. PMMA-DR1 was used as a dielectric film between graphene and top gate, where the top gate was the ITO film for applied voltage and excited laser passing. PAP operation created a polarization of PMMA-DR1 film, while the current of graphene FET device was varied due to Fermi energy of graphene was directly influenced by the polarization. The strength of polarization was associated with the gate voltage and laser power during the process of PAP operation. In contrast to the PAP operation, the PB operation was able to destroy the polarization of PMMA-DR1 film, while the current of graphene FET device returned to the initial value. Combining with PAP and PB operations, three current states identified as 1, 0 and -1 states can be achieved in room temperature. The current change ratios were 150% and 50% for 1 state and -1 state, comparing with initial state 0.

4:06PM D6.00007 Imaging of Polarization-dependent Photocurrent in Graphene Photodevices, MINJUNG KIM, DUHEE YOON, Department of Physics, Sogang University, Seoul 121-742, Korea, HO ANG YOON, SANG WOOK LEE, Division of Quantum Phases and Devices, School of physics, Konkuk University, Seoul 143-701, Korea, HYEONSIK CHEONG, Department of Physics, Sogang University, Seoul 121-742, Korea — Recently, a metal-graphene-metal photodetector for high-speed optical communications was reported. In addition, a graphene-based photodetector was reported to be able to absorb broadband light owing to the unique band structure of graphene [Mueller et al., Nature Photonics 4, 297 (2010)]. We investigated the polarization dependence of the photocurrent generated in metal-graphene-metal junctions. The graphene photodevice was fabricated by depositing Pd/Au and Ti/Au electrodes on single-layer graphene samples. When the polarization of incident laser beam is rotated with respect to the metal-graphene-metal junction, the photocurrent is significantly modulated. In addition, we measured the exact positions where the photocurrent is generated by measuring the photocurrent and Raman images of the graphene photodevices simultaneously.

4:18PM D6.00008 Supercollisions and Electron-Lattice Cooling in Graphene, JUSTIN SONG, School of Engineering and Applied Sciences, Harvard and Department of Physics, MIT, MICHAEL REIZER, None, LEONID LEVITOV, Department of Physics, MIT — Hot carrier proliferation is dependent on slow cooling between electron and lattice systems. In graphene, these cooling rates can be slow due to a small Fermi surface size and the momentum-conserving character of electron-phonon scattering. This in concert with the small ratio between the sound velocity, s , and the Fermi velocity, v_F , such that $s/v_F = 1/100$ produces a phase space constrained by the Fermi wavevector, k_F . In each of these first order scattering events, the energy exchanged between electronic and lattice systems is of the order $T_{BG} = \hbar k_F$ which at typical doping densities can be many times smaller than $k_B T$; non-thermal phonons are the dominant contributors to scattering dramatically suppressing cooling power. This constraint can be lifted by considering "supercollisions" that utilize the full thermal distribution of phonons. While the frequency of supercollisions may be lower than the first order process, energy transfer for supercollisions is now on the order of $k_B T$ which is many times larger than the first order process. We will show that this large exchange of energy allows supercollisions to give a dramatic boost to the cooling rate dominating over the first order process.

4:30PM D6.00009 Hot Carrier-Assisted Intrinsic Photoresponse in Graphene, NATHANIEL GABOR, Massachusetts Institute of Technology Physics, JUSTIN SONG, SEAS Harvard University, QIONG MA, NITYAN NAIR, Massachusetts Institute of Technology Physics, THITI TAYCHATANAPAT, Harvard University Physics, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science Japan, LEONID LEVITOV, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology Physics — Graphene is considered an excellent candidate for photodetection and energy harvesting applications due to its broadband optical response and high internal quantum efficiency, yet measurements have not clearly determined the photocurrent generation mechanism. Here, we report on the intrinsic photoresponse of dual-gated monolayer and bilayer graphene p-n junction devices. Local laser excitation of wavelength 850 nm at the p-n interface leads to striking six-fold photovoltage patterns as a function of bottom- and top-gate voltages. These patterns, together with the measured spatial and density dependence of the photoresponse, provide strong evidence that non-local hot carrier transport, rather than the photovoltaic effect, dominates the intrinsic photoresponse in graphene [1,2] The hot carrier regime manifests as a strong photo-thermoelectric effect in which the photogenerated carrier population remains hot while the lattice stays cool. [1] Science v. 334, p. 648-652 (2011). [2] Nano Lett. ASAP 10.1021/nl202318u (2011).

4:42PM D6.00010 Graphene Terahertz Photodetector¹, XINGHAN CAI, GREG JENKINS, ANDREI SUSHKOV, JUN YAN, H.D. DREW, MICHAEL S. FUHRER, Center for Nanophysics and Advanced Materials, University of Maryland, College Park — A graphene photodetector device is fabricated using mechanically exfoliated single layer graphene on SiO₂/Si substrate contacted by two dissimilar metal electrodes (chromium and gold) using standard electron beam lithography. The graphene is etched into a strip shape with specific width and coupled to a bow tie antenna structure to improve coupling to long-wavelength radiation and enhance the electric field in the center of the device. We have observed the response of the graphene photodetector to optical (632.8nm) and infrared laser (118um) radiation as a function of gate voltage and device width. Experimental results and comparison to a model of graphene plasmon-enhanced photodetection will be discussed.

¹This work is supported by CNAM, IARPA, the ONR MURI program, and NSF grants DMR-0804976 and DMR-1105224.

4:54PM D6.00011 Bolometric photo response of dual-gated bilayer graphene¹, JUN YAN, M.-H. KIM, Center for Nanophysics and Advanced Materials and Department of Physics, University of Maryland, College Park, J.A. ELLE, Institute for Research in Electronics and Applied Physics, and Department of Physics, University of Maryland, College Park, A.B. SUSHKOV, G.S. JENKINS, Center for Nanophysics and Advanced Materials and Department of Physics, University of Maryland, College Park, H.M. MILCHBERG, Institute for Research in Electronics and Applied Physics and Department of Physics, University of Maryland, College Park, H.D. DREW, M.S. FUHRER, Center for Nanophysics and Advanced Materials and Department of Physics, University of Maryland, College Park — We study the photo response of dual-gated bilayer graphene devices under infrared radiation. By comparison to Joule heating measurements using a second harmonic transport technique, we determine that the photo response is bolometric instead of photoconductive. The measured large electron-phonon heat resistance of our device is in good agreement with theoretical estimates in magnitude and temperature dependence, and enables our graphene bolometer operating at a temperature of 5 K to have a low noise equivalent power ($33 \text{ fW/Hz}^{1/2}$) and fast response time (sub nanosecond).

¹This work is supported by IARPA, the ONR MURI program, and NSF grants DMR-0804976 and DMR-1105224. J.A.E. and H.M.M. acknowledge the support of NSF.

5:06PM D6.00012 GHz response of bilayer graphene hot electron bolometer, M.-H. KIM, J. YAN, J.A. ELLE, A.B. SUSHKOV, G.S. JENKINS, H.M. MILCHBERG, M.S. FUHRER, H.D. DREW, Center for Nanophysics and Advanced Materials and Department of Physics, University of Maryland, College Park, MD 20742 — An intrinsic GHz speed of a hot-electron bolometer (HEB) based on dual-gated bilayer graphene (BLG) was recently reported (J. Yan, arXiv:1111.1202). The thermal response time is governed by the weak electron acoustic phonon scattering which also results in a high thermal resistance for the lattice cooling of the hot electrons. The time response of BLG HEB was measured as a function of temperature, bias current, and laser power using two time delayed pulses from a $1.03 \mu\text{m}$ pulsed laser. In addition, we probed the energy gap dependence of the time response revealing information about the electron density in gapped BLG. We report the temperature dependence of the heat capacity and thermal resistance obtained from these measurements. This work is supported by IARPA grant #W911NF1010443

5:18PM D6.00013 Non-linear plasma transport in graphene channels and application to the detection of terahertz signals, SERGEY RUDIN, GREG RUPPER, U.S. Army Research Laboratory, Adelphi, Maryland 20783 — The non-linear electron plasma response to electromagnetic signal applied to a gated graphene conduction channel can be used to make a graphene based Dyakonov-Shur terahertz detector. The hydrodynamic model predicts a resonance response to electromagnetic radiation at the plasma oscillation frequency. With less damping and higher mobility, the graphene conduction channels may provide higher quality plasma response than possible with semiconductor channels. Our analysis of plasma oscillations in a graphene channel is based on the hydrodynamic equations which we derive from the Boltzmann equation accounting for both electrons and holes, and including the effects of viscosity and finite mobility.

Session D7 DCMP: Quantum Hall Effect in Mono-, Bi- and Trilayer Graphene 207

2:30PM D7.00001 Correlated random hopping disorder in graphene at high magnetic fields: Landau level broadening and localization properties, ANA L.C. PEREIRA, Universidade Estadual de Campinas, CAIO H. LEWENKOPF, Universidade Federal Fluminense, EDUARDO R. MUCCIOLO, University of Central Florida — Disorder is key to understand the electronic transport properties in graphene, particularly in the quantum Hall regime. There is still some debate on the most relevant disorder mechanisms for transport in graphene. Among those, ripple disorder is believed to play an important role. Static ripples give rise to random correlated hopping disorder, which is the disorder mechanism analyzed in this work. We study the density of states and localization properties of the lowest Landau levels of graphene at high magnetic fields, focusing on the effects caused by correlated long-range hopping disorder. We find that the broadening of the lowest Landau level shrinks exponentially with increasing disorder correlation length. The broadening also grows linearly with magnetic field and with disorder amplitudes. More importantly, we observe that the ratio between the $n=1$ and $n=0$ Landau level widths depends only on the correlation length and is rather insensitive to the disorder strength and to the magnitude of the magnetic field. This allows a closer contact of our results with experiments. In addition, the lowest Landau level peak shows a robust splitting (inferred from the analysis of the participation ratio), whose origin we identify as the breaking of the sublattice (valley) degeneracy.

2:42PM D7.00002 Electrically tunable quantum anomalous Hall effect in graphene decorated by 5d transition-metal adatoms, HONGBIN ZHANG, Forschungszentrum Juelich, Germany, CESAR LAZO, University of Kiel, Germany, STEFAN BLÜGEL, Forschungszentrum Juelich, Germany, STEFAN HEINZE, University of Kiel, Germany, YURIY MOKROUSOV, Forschungszentrum Juelich, Germany — Based on first-principles calculations, we predict that 5d transition-metals on graphene present a unique class of hybrid systems exhibiting topological transport effects that can be manipulated effectively by external electric fields [1]. The origin of this phenomenon lies in the exceptional magnetic properties and the large spin-orbit interaction of the 5d metals leading to significant magnetic moments accompanied with colossal magnetocrystalline anisotropy energies. A strong magneto-electric response is predicted that offers the possibility to switch the spontaneous magnetization direction by moderate electric fields, enabling an electrically tunable quantum anomalous Hall effect.

[1] preprint: <http://arxiv.org/abs/1108.5915>

2:54PM D7.00003 Scanning gate microscopy on graphene in the quantum Hall regime, JAMES HEDBERG, YOICHI MIYAHARA, MICHAEL HILKE, GUILLAUME GERVAIS, PETER GRÜTTER, McGill University, JULIEN RENARD, JOSHUA FOLK, University of British Columbia — Scanning Gate Microscopy was performed on monolayer graphene devices in the quantum hall regime. The devices studied consisted of exfoliated graphene deposited on SiO₂, etched in a Hall Bar configuration, and electrically contacted by standard lithographic techniques. Using a custom built scanning probe microscope (SPM), operating at liquid Helium temperatures and below, in magnetic fields up to 16 T, we spatially mapped the position dependent effects of a movable gate, i.e. the charged tip of the SPM, on the conductivity of the graphene device. Using a global backgate to modulate the carrier density, we can visually observe the transitions between filling factors. Striking features are observed in the resistance versus position maps, offering insights into the microscopic properties of graphene in the quantum Hall regime.

3:06PM D7.00004 Confining potential and Landau level edge states in graphene¹, GUOHONG LI, ADINA LUCAN-MAYER, EVA Y. ANDREI, Department of Physics and Astronomy, Rutgers University — Two-dimensional electron systems in the Quantum-Hall (QH) regime host gapless one-dimensional chiral edge states which are responsible for the quantization of the Hall conductivity. In the regime of the fractional QH effect the edge states form a chiral Luttinger liquid which presents unusual quantum properties such as fractionally charged excitations and interference patterns that could serve as building blocks for QH qubits. Observing and exploiting these properties requires precise control of the edges, but in semiconductor-based 2DES were edge states were studied thus far, achieving the necessary control was difficult. This is because the smooth confinement potential in these systems imposes a length scale which is much larger than the magnetic length leading to incompressible strips and to non-universal behavior. We will show that this limitation is not present in graphene. Using scanning-tunneling-microscopy and spectroscopy to follow the spatial evolution of Landau levels toward an edge, we demonstrated that in graphene it is possible to control the edge states by varying the distance to the screening plane and by controlling the confinement geometry.

3:18PM D7.00005 Unconventional Sequence of Fractional Quantum Hall States in Suspended Graphene, BENJAMIN FELDMAN, Harvard University, BENJAMIN KRAUSS, JURGEN SMET, Max-Planck-Institut für Festkörperforschung, AMIR YACOBY, Harvard University — Graphene provides a unique platform to study many-body correlations due to the relativistic nature of its charge carriers and their fourfold degeneracy. We report local electronic compressibility measurements of a suspended graphene flake performed using a scanning single-electron transistor. Between filling factors $\nu = 0$ and 1, our measurements reveal incompressible fractional quantum Hall states at $\nu = 1/3, 2/3, 2/5, 3/5, 3/7, 4/7$ and $4/9$, which clearly follow the standard composite fermion sequence. In contrast, between $\nu = 1$ and 2, incompressible states occur only at $\nu = 4/3, 8/5, 10/7$ and $14/9$. These fractions correspond to a subset of the composite fermion sequence involving only even numerators, suggesting a robust underlying symmetry. We extract the energy gaps of each fractional quantum Hall state as a function of magnetic field and find that $\nu = 1/3, 2/3, 4/3$, and $8/5$ are strongest at low field, persisting below 1.5 T. Our results provide insight into the interplay between electronic correlations and SU(4) symmetry in graphene.

3:30PM D7.00006 Quantum Hall effect on centimeter scale chemical vapor deposited graphene films, TIAN SHEN, Department of Physics, Purdue University/National Institute of Standards and Technology, WEI WU, QINGKAI YU, Center for Advanced Materials and ECE, University of Houston, CURT RICHTER, RANDOLPH ELMQUIST, DAVID NEWELL, National Institute of Standards and Technology, YONG CHEN, Department of Physics, Purdue University — We report observations of well developed half integer quantum Hall effect on mono layer graphene films of 7 mm by 7 mm in size. The graphene films are grown by chemical vapor deposition on copper, then transferred to SiO₂/Si substrates, with typical carrier mobilities $\approx 4000 \text{ cm}^2/\text{Vs}$. The large size graphene with excellent quality and electronic homogeneity demonstrated in this work is promising for graphene-based quantum Hall resistance standards, and can also facilitate a wide range of experiments on quantum Hall physics of graphene and practical applications exploiting the exceptional properties of graphene.

3:42PM D7.00007 Spin-skyrmion in graphene, WENCHEN LUO, RENÉ CÔTÉ, University of Sherbrooke — In the presence of a magnetic field, the band structure of the two-dimensional electron gas in graphene consists in a series of Landau levels with energy $E_n = \pm \sqrt{2} v_F \sqrt{|n|} \ell$. Each Landau level is 4-fold degenerate including valley and spin degrees of freedom. Working in the Hartree-Fock approximation and a finite Zeeman coupling, we compute the energy required to excite a spin-skyrmion (or antiskyrmion) in Landau levels $n = 1, 2$ at filling factors $\nu = 4, 8$. We show that a skyrmion-antiskyrmion pair has lower energy than an electron-hole pair at these two filling factors. We compare our results with a field-theoretical calculation [1] and with a recent experimental measurement of the transport activation gap in this system.

3:54PM D7.00008 Coulomb impurity under magnetic field in graphene: a semiclassical approach, YUHUI ZHANG, National High Magnetic Field Laboratory and Department of Physics, Florida State University, YAFIS BARLAS, National High Magnetic Field Laboratory, Florida State University, KUN YANG, National High Magnetic Field Laboratory and Department of Physics, Florida State University — We address the problem of a Coulomb impurity in graphene in the presence of a perpendicular uniform magnetic field. We show that the problem can be solved below the supercritical impurity magnitude within the WKB approximation. Without impurity the semiclassical energy correctly reproduces the Landau level spectrum. For values below the supercritical impurity magnitude the energy spectrum still evolves as square root B with a renormalized fine structure constant. For a given Landau level the WKB energy depends on the absolute value of angular momentum in a way which is consistent with the exact diagonalization result. Below the supercritical impurity magnitude, the WKB solution can be expanded as a convergent series in powers of the effective fine structure constant. Relevance of our results to validity of the widely used Landau level projection approximation is discussed.

4:06PM D7.00009 Chern-Simons theory of an anomalous metallic state in half-filled monolayer graphene¹, PALLAB GOSWAMI, BITAN ROY, KUN YANG, National High Magnetic Field Laboratory and Florida State University — The ground state of half-filled monolayer graphene undergoes a novel metal-insulator transition with increasing strength of applied magnetic field. In a weak magnetic field the ground state at half-filling corresponds to a critical metallic state, that governs the $\nu = -2$ to $\nu = 2$ quantum Hall plateau transition. In the strong magnetic field regime this critical state gives way to an interaction driven quantum Hall insulator state. Currently there is no satisfactory theoretical explanation of the insulating phase and the phase transition. Motivated by this issue, we investigate the nature of the ground state in clean half-filled monolayer graphene, using a lattice Chern-Simons theory. In contrast to the results obtained previously by mean-field calculations in the Landau level basis, our analysis in the unpolarized regime shows the existence of an anomalous semimetallic state up to a critical strength of magnetic field, and the critical strength is determined by non-universal details of interaction strength. In the polarized regime the dynamics of the relevant metallic state changes dramatically, and new insulating phases do emerge.

4:18PM D7.00010 ABSTRACT WITHDRAWN —

4:30PM D7.00011 Bilayer graphene as a helical quantum Hall ferromagnet¹, RENE COTE, JEREMIE P. FOUQUET, WENCHEN LUO, Université de Sherbrooke — The two-dimensional electron gas (2DEG) in a graphene bilayer supports a variety of uniform broken-symmetry ground states in Landau level $N = 0$ and at integer filling factors $\nu \in [-3, 4]$. When a bias is applied between the layers at filling factors $\nu = 1, 3$, the ground state evolves from an interlayer coherent state at small bias to a state with orbital coherence at higher bias where *electric* dipoles associated with the orbital pseudospins order spontaneously in the plane of the layers. We show that by further increasing the bias the 2DEG goes first through an electron crystal with an orbital pseudospin texture at each site and then into a helical state where the pseudospins rotate in space. The pseudospin textures in the crystal and the helical states are due to the presence of a Dzyaloshinsky-Moriya interaction in the effective pseudospin Hamiltonian when orbital coherence is present in the ground state. We study in detail the electronic structure these nonuniform states as well as their collective excitations and compute their electromagnetic absorption.

4:42PM D7.00012 Theory of integer quantum Hall effect in bi-layer graphene, BITAN ROY, OSKAR VAFEK, National High Magnetic Field Laboratory and Department of Physics, Florida State University, Tallahassee, Florida 32306, USA — Bi-layer graphene in a quantizing external magnetic field exhibits plateaus of Hall conductivity at various integer fillings. Moreover, electron-electron interactions in suspended doubly gated bi-layer graphene appear sufficiently strong (and short-ranged) to result in a finite gap persisting down to zero magnetic field. In this talk we will demonstrate the competition of various orders within the zeroth Landau level and how their interplay is influenced by the filled Landau levels lying below the Fermi energy. Scaling behavior of the gap at the neutrality point will be discussed. Besides the splitting of the zeroth Landau level, degeneracy lifting of the rest of the Landau levels will be discussed.

4:54PM D7.00013 Electronic transport in ABA trilayer graphene, E.A. HENRIKSEN, D. NANDI, J.P. EISENSTEIN, California Institute of Technology — We present measurements of the electronic transport in ABA trilayer graphene field-effect devices fabricated with both a back and top gate, at zero, low and high magnetic fields. While the zero field resistivity exhibits a saddle point as a function of the two gate voltages that is similar to bilayer graphene, the low-field Hall data are consistent with a two-band system having a band overlap characteristic of semimetals. At high magnetic fields the quantum Hall effect is clearly observed, and displays features which can be traced to the underlying band overlap, as well as a lifting of the lattice mirror symmetry. Overall the transport in ABA trilayers is that of a semimetal in which the band structure can be strongly modified via the electric field effect. This work is supported by the DOE under grant No. DE-FG03-99ER45766 and the Gordon and Betty Moore Foundation.

5:06PM D7.00014 Quantum Hall liquid to Charge density wave phase transitions in ABC-trilayer graphene, YAFIS BARLAS, University of California at Riverside, RENE COTE, MAXINE RONDEAU, University of Sherbrooke, Quebec, Canada — We study interaction driven states within ABC-stacked trilayer graphene's 12-fold degenerate Landau level which appear near the neutral system Fermi level. The 12-fold degeneracy of the zero-energy LL is due to spin and valley degeneracy along with a degenerate set of triplet ($n = 0, 1, 2$) LL orbitals. We predict that at filling factors $\nu = -5, -2, 1, 4$ a quantum phase transition from a quantum Hall liquid state to a triangular charge density wave occurs as a function of the single-particle induced LL orbital splitting. This transition is preceded by a softening of the magneto-roton minima of the quantum Hall liquid which appears at $q l_B \sim 2.4$. The charge density wave is a manifestation of the LL orbital pseudospin textures with nonzero winding numbers. The phase diagrams at other filling factors along with the experimental consequences of our theoretical predictions will also be addressed.

Session D8 GMAG: Organo-metallics: Magnetic and other Properties 208

2:30PM D8.00001 Polymorphism in Low-dimensional Molecule-based Materials: Synthetic Control of Magnetic and Electronic Structure¹, ADORA BALDWIN, JAMIE MANSON, Eastern Washington University, JOHN SCHLUETER, Argonne National Laboratory — Competition for hydrogen bonds in molecule-based materials frequently leads to the stabilization of polymorphic structures with similar energies. Herein, we report that among magnetic coordination polymers selective crystallization of the $[\text{Cu}(\text{HF}_2)(\text{pyrazine})_2]\text{SbF}_6$ and $[\text{Cu}_2\text{F}(\text{HF})(\text{HF}_2)(\text{pyrazine})_4](\text{SbF}_6)_2$ polymorphs can be achieved through control of pressure and temperature during the crystallization process. Through this manner, orbital order and magnetic dimensionality (2D vs. 1D) can be controlled in this system. Similarly, in the analogous $[\text{Co}(\text{HF}_2)(\text{pyrazine})_2]\text{SbF}_6$ system, selective crystallization of the $[\text{CoF}_2(\text{pyrazine})_2]\text{SbF}_6(\text{H}_2\text{O})_3(\text{H}_3\text{O})$ polymorph has been achieved. While these cobalt materials exhibit a 2D magnetic structure, the interlayer coupling is diminished in the hydrated material. Among cation radical salts, five polymorphic phases in the $[\text{bis}(\text{ethylenedithio})\text{tetrathiafulvalene}]_2\text{Ag}(\text{CF}_3)_4(1,1,2\text{-trichloroethane})$ system have been crystallized, four of which have superconducting ground states. Among the superconducting salts, the ones with intercalated charge ordered layers exhibit a five-fold enhancement of T_c .

2:42PM D8.00002 Ground-state properties of $\text{EtMe}_3\text{Sb}[\text{Pd}(\text{dmit})_2]_2$ by many-variable variational Monte Carlo method, SATOSHI MORITA, RYUI KANEKO, MASATOSHI IMADA, Department of Applied Physics, University of Tokyo — The organic Mott insulator $\text{EtMe}_3\text{Sb}[\text{Pd}(\text{dmit})_2]_2$ is a strongly correlated electron system on a nearly-regular triangular lattice and regarded as a spin liquid material. We investigate its effective low-energy model derived from first principles calculations and band+dimensional downfolding. The *ab initio* effective Hamiltonian is given in the form of the two-dimensional single-band extended Hubbard model on an anisotropic triangular lattice with short-ranged Coulomb and exchange interactions. Its ground state is calculated by the many-variable variational Monte Carlo method with quantum-number projection and multi-variable optimization. We draw the ground-state phase diagram as a function of scaling parameters for the interactions and the geometrical frustration by extending the *ab initio* model. We discuss Mott transitions and magnetic properties.

2:54PM D8.00003 Reduced Influence of Electronic Correlations in a Half-Filled System: Metallic Properties and Charge Order Transition in κ -(ET)₂Hg(SCN)₂Cl¹, NATALIA DRICHKO, Johns Hopkins University, REBECCA BEYER, MARTIN DRESSEL, University Stuttgart, Germany, HARALD JESCHKE, University Frankfurt, Germany, JOHN SCHLUETER, Argonne National Laboratory, ELENA ZHILYAEVA, RIMMA LYUBOVSKAYA, Institute of Problems of Chemical Physics, Russia — The family of κ -(ET)₂Hg(SCN)_xCl_{2-x} can be described within a model of a metal with a half-filled conductance band. Our calculations indicate that the value of the on-site Coulomb repulsion U is relatively small in these system. We investigate the effects of lower U on the optical properties of κ -(ET)₂Hg(SCN)₂Cl in the metallic state and below the metal-insulator transition. Optical conductivity spectra in the metallic state above 35 K show a behavior already observed for half-filled metals on the edge of the Mott insulating state: an optical transition between Hubbard bands at frequencies equal to U is present in spectra at all temperatures, being a precursor of a Mott transition, while a coherent carriers response develops below $T^*=150$ K. We note an influence of the lower U value both on the position of the “U-band” and on a relatively high T^* . Untypically for a half-filled system, a metal-insulator transition at 35 K is found that is of a charge-order nature. A possibility of a charge-order ground state in a half-filled system in case of low U and relatively high nearest-neighbor Coulomb repulsion V is discussed.

3:06PM D8.00004 Non-monotonic magnetic field dependence of the staggered-moment in two-dimensional frustrated antiferromagnets, MOHAMMAD SIAHATGAR, BURKHARD SCHMIDT, PETER THALMEIER, Max Planck Institute for Chemical Physics of Solids — We present an efficient method to identify the degree of frustration in quasi-two-dimensional (2D) antiferromagnets described by the J_1 - J_2 quantum Heisenberg model. The frustration ratio J_2/J_1 is commonly obtained from the analysis of magnetic susceptibility, specific heat, and saturation field. We show that the field-induced suppression of quantum fluctuations causes a nonlinear and non-monotonic magnetic field dependence of the staggered moment which depends strongly on the frustration ratio. This serves as a powerful criterion to determine J_2/J_1 using a combination of the exact diagonalization method on finite clusters and the spin-wave analysis. We apply this method to the quasi-2D compound Cu(pz)₂(ClO₄)₂ obtaining an intermediate ratio of $J_2/J_1 \simeq 0.2$ for the frustration.

3:18PM D8.00005 Effects of Pressure on the Magnetic Properties of Prussian Blue Analogues¹, M.K. PEPPRAH, E.S. KNOWLES, M.F. DUMONT, J.S. XIA, M.W. MEISEL, Dept. Physics and NHMFL, Univ. Florida, C.H. LI, D.R. TALHAM, Dept. Chemistry, Univ. Florida — Prussian blue analogues (PBAs) have been shown to exhibit interesting magnetic characteristics under various external stimuli: charge transfer induced spin transition (CTIST),² a temperature effect; persistent photo-induced magnetism (PPIM),³ an optical effect; and pressure induced electron transfer (PIET).⁴ Our research has established that photocontrol of the magnetic response of CoFe-PBA, can be extended to higher temperatures, accompanied by a decrease in magnetization, using heterostructured PBA particles composed of Rb_aCo_b[Fe(CN)₆]_c· m H₂O cores surrounded by shells of K_jNi_k[Cr(CN)₆]_l· n H₂O.⁵ This effect is attributed to strain in the shell, induced by a lattice expansion in the core during illumination. We report a similar effect in the core-shells accompanied by PIET under application of external pressure and probe the similarities between optical and pressure effects.

3:30PM D8.00006 Effect of hydrostatic pressure on a low dimensional S=1/2 gapped quantum antiferromagnet by inelastic neutron scattering¹, TAO HONG, Oak Ridge National Laboratory, C. STOCK, NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, MD 20899, USA., I. CABRERA, C. BROHOLM, Department of Physics and Astronomy, The Johns Hopkins University, Baltimore, Maryland 21218, USA, Y. QIU, J.B. LEO, S.J. POULTON, J.R.D. COPLEY, NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, MD 20899, USA. — We report an inelastic neutron scattering study of a quasi-two-dimensional $S=1/2$ dimer system piperazinium hexachlorodipicrate (PHCC) under hydrostatic pressure up to $P=9.0$ kbar. The spin gap Δ decreases with increasing pressure. The observation of three fold degenerate triplet excitation at $P=6.0$ kbar is consistent with the theoretical prediction and the bandwidth of the dispersion relation is unaffected within the experimental uncertainty. At $P=9.0$ kbar the spin gap is reduced to $\Delta=0.55$ meV from $\Delta=1.0$ meV at ambient pressure [1].

3:42PM D8.00007 Density functional theory study of alkali doped picene, MILAN TOMIC, HUNPYO LEE, ROSER VALENTI, HARALD O. JESCHKE, Institut fuer Theoretische Physik, Goethe-Universitaet Frankfurt, Max-von-Laue-Str. 1, 60438 Frankfurt, Germany — We employ density functional theory methods to determine the equilibrium structures of A_x picene where $A = \text{Na, K, Rb, Cs}$ and $x = 1, 2, 3$. We find that alkali doping with one, two and three alkali ions per picene molecule leads to subsequent filling of the LUMO and LUMO+1 derived bands of picene, leading to quarter, half and three quarter filled systems. We analyse the electronic structures using tight binding methods to derive the kinetic energy part of the underlying Hubbard Hamiltonian. As the interaction strength U on the picene molecules is expected to be large compared to the band width, we also employ manybody methods on the resulting Hamiltonian. We compare our results to photoemission experiments.

3:54PM D8.00008 First principles investigation of the Fabre salts, ANTHONY JACKO, ROSER VALENTI, HARALD O. JESCHKE, Institut fuer Theoretische Physik, Goethe-Universitaet Frankfurt, Max-von-Laue-Str. 1, 60438 Frankfurt, Germany — The Fabre salts (TMTTF)₂X are one dimensional charge transfer salts with a very rich phase diagram including charge ordered, Mott insulating, antiferromagnetic and spin Peierls phases. The structure involves stacks of TMTTF molecules with varying degree of dimerization. Open questions involve the role of the anions in the phase transitions. We investigate the electronic structure of compounds with a number of different anions like $X = \text{AsF}_6, \text{PF}_6$ and Br. We discuss the properties of the underlying Hubbard Hamiltonian for these materials.

4:06PM D8.00009 Scaling Theory of the Mott Transition and Breakdown of the Grüneisen Scaling Near a Finite-Temperature Critical End Point, LORENZ BARTOSCH, University of Frankfurt — We discuss a scaling theory of the lattice response in the vicinity of a finite-temperature critical end point. The thermal expansivity is shown to be more singular than the specific heat such that the Grüneisen ratio diverges as the critical point is approached, except for its immediate vicinity. More generally, we express the thermal expansivity in terms of a scaling function which we explicitly evaluate for the two-dimensional Ising universality class. Recent thermal expansivity measurements on the layered organic conductor κ -(BEDT-TTF) $_2X$ close to the Mott transition are well described by our theory.

4:18PM D8.00010 Tuning the magnetic dimensionality by charge ordering in the molecular TMTTF salts, KAZUYOSHI YOSHIMI, Department of Physics, University of Tokyo, Nanosystem Research Institute "RICS", AIST, HITOSHI SEO, Condensed Matter Theory Laboratory, RIKEN, SHOJI ISHIBASHI, Nanosystem Research Institute "RICS", AIST, STUART BROWN, Department of Physics and Astronomy, UCLA — Low-dimensional (D) organic conductors TMTTF $_2X$ are considered as a prototypical system for investigations of D-crossover phenomena, since the transfer integrals connecting the conduction chains are readily controlled by applied pressure [1]. In addition, recent NMR experiments in TMTTF salts imply the existence of another type of D-crossover which accompanies a multiferroic property; decreasing the ferroelectric-type charge ordering (FCO) by pressure is associated with the suppression of the antiferromagnetic (AF) transition temperature [2]. In this work, we theoretically investigate the interplay between FCO and magnetic states in TMTTF salts [3], and show that FCO increases 2-D AF spin correlation, whereas in the 1-D regime two different spin-Peierls states are stabilized. By performing first-principles band calculations for different salts and comparing our results with experiments, we identify the controlling parameters in the experimental phase diagram to be not only the inter-chain transfer integrals but also the amplitude of the FCO. [1] D. Jerome, *Science* **252**, 1509 (1991). [2] W. Yu *et al.*, *Phys. Rev. B* **70** 121101 (2004). [3] K. Yoshimi, H. Seo, S. Ishibashi, and S. E. Brown, arXiv:1110.3573 and arXiv:1110.3575.

4:30PM D8.00011 Charge dynamics in Mott-insulating and charge-ordered organic crystals: a possibility of the Berezinskii-Kosterlitz-Thouless transition, YAMAGUCHI TAKAHIDE, TOHRU WATANABE, YOSHIHIKO TAKANO, KOUTA KODAMA, SHINYA UJI, National Institute for Materials Science, HIROSHI M. YAMAMOTO, RIKEN — The organic Mott insulator κ -(BEDT-TTF) $_2Cu[N(CN)_2]Cl$ exhibits power-law current-voltage characteristics in a low current range at temperatures below ≈ 10 K. The power-law current-voltage characteristics are similar to those observed in the charge-ordered organic crystals θ -(BEDT-TTF) $_2MzN(SCN)_2$ ($M = Cs$ and Rb) and are accounted for in the same way in terms of exciton excitations: The electric field assists the thermal unbinding of pairs of a doublon and a holon that attract each other due to the two-dimensional long-range Coulomb interaction. The two-dimensional Coulomb interaction arises from the layered structure of the organic crystals and their large dielectric anisotropy. The in-plane dielectric constant can be understood within the context of the same model in terms of polarization of the bound pairs. We discuss a possibility of the Berezinskii-Kosterlitz-Thouless transition in these layered organic crystals. κ -(BEDT-TTF) $_2Cu[N(CN)_2]Cl$ has a much smaller magnetoresistance (25 % in 10 T at 0.3 K) than θ -(BEDT-TTF) $_2CsZn(SCN)_4$ (≈ 10000 % in 10 T at 0.1 K), which probably reflects different spin states of the excitations for the Mott and charge-ordered states. Yamaguchi Takahide *et al.* *PRB* **84**, 035129 (2011)

4:42PM D8.00012 ^1H NMR study on X-ray irradiated κ -(BEDT-TTF) $_2Cu[N(CN)_2]Br$, KAZUYA MIYAGAWA, University of Tokyo, TAKAHIKO SASAKI, Tohoku University, NAOKI YONEYAMA, Yamanashi University, NORIO KOBAYASHI, Tohoku University, KAZUSHI KANODA, University of Tokyo — The κ -(BEDT-TTF) $_2Cu[N(CN)_2]Br$ (κ -Br) is a quasi-two dimensional superconductor with T_c of 12 K. By substituting Cl for Br in the insulating layer, the system becomes a Mott insulator, κ -(BEDT-TTF) $_2Cu[N(CN)_2]Cl$ (κ -Cl), with the Neel temperature of 25 K. So, κ -Br salt is situated close to the Mott transition. Recently, Sasaki *et al.*, have reported the transformation from a metallic (superconducting) state to an insulating state by the x-ray irradiation. The 500h-irradiated thin sample shows insulating behavior in the temperature dependence of resistivity. We report the ^1H NMR studies on the 500h-irradiated κ -Br salt. Below 150 K, where the nuclear relaxation is dominated by electron spins, $1/T_1$ of the irradiated sample increases from that of the non-irradiated sample and is even larger than the value of κ -Cl. Nevertheless, there is no manifestation of magnetic ordering; that is, neither a line broadening nor a divergent peak in $1/T_1$ down to 1.5 K. We will discuss the electronic state of irradiated κ -Br salt based on experimental results.

4:54PM D8.00013 TCP, a new quasi-one-dimensional conducting platinate: DC and NMR studies¹, J.A. ALEXANDER, R.I. LEATHERBURY, O. GAFAROV, A.A. GAPUD, A.P. WEBER, L. PHAM, R.E. SYKORA, A. KHAN, University of South Alabama, A.P. REYES, P. KUHN, National High Magnetic Field Laboratory — $Cs_4[Pt(CN)_4](CF_3SO_3)_2$, or TCP, is the newest member of the family of quasi-one-dimensional conducting platinites that includes the widely studied $K_2[Pt(CN)_4]Br_{0.303}(H_2O)$ (KCP) – best-known for its metal-insulator transition consistent with a Peierls instability. Unlike KCP, however, we have found properties unique to TCP. X-ray diffraction shows longer Pt-Pt separations, and undergoes subtle change with cooling. DC resistivity measurements presented technical challenges that had to be resolved, but in the end revealed a more highly insulating phase at room temperature, and the temperature dependence of resistivity has an anomalous “peak” at around 150 K. NMR also presented a technical challenge in that the ^{195}Pt nucleus, which had been successfully used for NMR studies on KCP, did not produce a usable signal in TCP, wherein we utilized the peripheral ^{133}Cs nuclei instead. Quadrupole splitting of spin states of ^{133}Cs measured as a function of orientation showed consistency with the angular dependence expected of the known symmetry axes of ^{133}Cs . Preliminary measurements of longitudinal relaxation time T_1 also reveal an anomalous temperature dependence in the vicinity of 150 K. All these considerations point to a possible structural transformation, as will be discussed.

¹Funded by an NSF-RUI grant.

5:06PM D8.00014 Experimental and theoretical study of the temperature dependent structural and electronic properties of the spin liquid candidate κ -(BEDT-TTF) $_2Cu_2(CN)_3$, JOHN A. SCHLUETER, Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439, United States, MARIANO DE SOUZA, RUDRA SEKHAR MANNA, MICHAEL LANG, Physikalisches Institut, Goethe-Universität Frankfurt, 60438 Frankfurt, Germany, ROSER VALENTI, HARALD O. JESCHKE, Institut fuer Theoretische Physik, Goethe-Universität Frankfurt, 60438 Frankfurt, Germany — The organic charge transfer salt κ -(BEDT-TTF) $_2Cu_2(CN)_3$ is of great experimental as well as theoretical interest due to the interplay of the effects of electronic correlations, low dimensionality and spin frustration. Besides the spin liquid property at very low temperatures, the material has interesting anomalies at 6K, 60K and 150K. Even though the structure of the material has been determined several times over the past 20 years, complete structural data are only available at room temperature. In our work, we fill this gap by precisely determining the structure at 300K, 250K, 200K, 150K, 100K and 20K. We analyze the structures using density functional theory and tight binding methods. We show that the triangular lattice Hubbard Hamiltonian parameters are temperature dependent, with the interaction strength increasing with decreasing temperature and with the frustration going through a minimum at 150 K. Our results point to the fact that even in the absence of structural phase transitions, experimental determination of structures at various temperatures may be important as a starting point for realistic many-body theoretical investigation of complex materials.

2:30PM D9.00001 Dual microbead-labeled DNA manipulation with magnetic traps in a microfluidic device, M. HOWDYSHELL, M. SIMON, M. POIRIER, R. SOORYAKUMAR, The Ohio State University — Biomolecular responses to mechanical force underlie many critical functions in the context of cellular physiology. In order to develop the technology to apply forces on individual biomolecules, we utilize an array of ferromagnetic disks on a silicon surface to trap and manipulate tethered DNA molecules. The force activation is achieved through remotely controlled programmable weak external magnetic fields that do not damage the biological entity. Moreover, to exploit both hydrodynamic and magnetic forces, the magnetic disks are imprinted within microfluidic channels, while a tethered microbead attached on each end of the DNA strand provides convenient force transmitting handles. Two separate approaches that are utilized involve use of two superparamagnetic beads or a superparamagnetic and nonmagnetic bead pair. The independently controlled hydrodynamic and magnetic forces allow for manipulation of the DNA in all directions within a horizontal plane. Hundreds of magnetic traps are readily patterned onto a single channel, providing the potential to multiplex an ensemble of individual molecules within the device.

2:42PM D9.00002 Testing of a Helmholtz Microcoil in a Diamond Anvil Cell NMR, CHING LIN¹, SAM WEIR², University of California, Davis, SAMUEL WEIR³, Lawrence Livermore National Laboratory, NICHOLAS CURRO⁴, University of California, Davis, LAWRENCE LIVERMORE NATIONAL LABORATORY COLLABORATION — A new designed, multi-turn tungsten Helmholtz micro-coil has been constructed and tested on the solid-state bulk NMR experiment. A Helmholtz micro-coil with diameter 950 μm is embedded on diamond culet and produces a nearly uniform AC magnetic field inside a sample space. A Fluorine polycrystal will be used to test our Helmholtz micro-coil, and the measured NMR data will be compared with the ones produced by other type of diamond anvil cell coils. The Helmholtz micro-coil will be used for high pressure NMR and future investigation of magnetic properties of heavy fermion superconductors.

2:54PM D9.00003 Magneto-mechanical resonant detection of superparamagnetic microbeads trapped by magnetic domain walls¹, ELIZABETH RAPOPORT, DANIEL MONTANA, GEOFFREY BEACH, Massachusetts Institute of Technology — Manipulation of superparamagnetic (SPM) beads with magnetic domain walls (DWs) is of interest for lab-on-chip applications. DWs can trap SPM beads and tagged entities, enabling remote manipulation with nanoscale precision [1, 2]. Previously, we have demonstrated DW driven capture and transport of single microbeads at speeds approaching 1000 $\mu\text{m/s}$ [3]. Here, we demonstrate that the strong magnetostatic bead-DW binding leads to a unique magneto-mechanical resonance [4]. We show experimentally that this resonance can be used to distinguish bead populations based on their size, presenting a new mechanism for bead metrology. Moreover, the bead-DW interaction can be used to sense and characterize magnetic beads without the need for sensor surface functionalization. Exploiting the dual functionality of DWs as both bead carriers and sensors, we present an integrated device capable of high-speed transport and electrical sensing of the magneto-mechanical resonance of individual trapped beads.

3:06PM D9.00004 Cascaded Magneto-Optical Ring Resonator Structures for Tunable Faraday Rotation and Reduced Isolator Footprint, MEHMET CENGIZ ONBASLI, Massachusetts Institute of Technology, JUEJUN HU, University of Delaware, LEI BI, Micron Technology, GERALD F. DIONNE, Massachusetts Institute of Technology Lincoln Laboratory, CAROLINE A. ROSS, Massachusetts Institute of Technology — On-chip optical isolators are indispensable components of integrated optics, and can be modified to enable four-port and multi-port circulators and modulators. We have implemented an on-chip optical isolator by placing a racetrack resonator next to a single mode waveguide and coating half of the resonator with a uniformly magnetized magneto-optical film, which breaks the time-reversal symmetry of light propagation and provides different refractive indices and phase shifts for forward and backward propagating waves. At every pass, the optical mode inside the resonator accumulates Faraday rotation in addition to phase shift due to propagation. The transmission from the output port of the waveguide has a Lorentzian dip due to the resonance peak of the resonator. Light can only propagate in the clockwise direction inside the resonator. Here we model how cascading multiple ring resonators can increase the overall quality factor of the isolator and narrow the resonance linewidth, due to the longer photon lifetime inside the cavity. As a result of better control of Faraday rotation, the isolation ratio is enhanced and the device footprint is reduced with respect to Mach-Zehnder waveguide isolators.

3:18PM D9.00005 On the Energy Transfer Performance of Mechanical Nanoresonators Coupled with Electromagnetic Fields: Applications with magnetic nanoparticles, H. JAVAHERI, B. BARBIELLINI, G. NOUBIR, Northeastern University — The energy transfer performance in electrically and magnetically coupled mechanical nanoresonators is studied [1]. Using the resonant scattering theory, we show that magnetically coupled resonators can achieve the same energy transfer performance as for their electrically coupled counterparts, or even outperform them within the scale of interest. Magnetic and electric coupling are compared in the *Nanotube Radio*, a realistic example of a nano-scale mechanical resonator. The energy transfer performance is discussed for magnetic coupling in magnetite (Fe_3O_4) nanoparticles.

3:30PM D9.00006 Increased Sensitivity of Magnetoelectric Sensors at Low Frequencies Using Magnetic Field Modulation, JONATHAN PETRIE, Army Research Laboratory, DWIGHT VIEHLAND, DAVID GRAY, Virginia Tech University, SANJAY MANDAL, GOLLAPUDI SREENIVASULU, GOPALAN SRINIVASAN, ALAN EDELSTEIN, Oakland University — Magnetoelectric (ME) laminate sensors are vector magnetometers that can detect pT magnetic fields at 1 kHz, although sensitivity may be reduced at lower frequencies. These passive sensors consist of alternating layers of magnetostrictive and piezoelectric materials. A magnetic field causes the magnetostrictive layer to strain the piezoelectric material and create measurable charge. We have shown¹ that since the strain response is a nonlinear function of the bias field, sweeping the magnetic bias on the magnetostrictive layer can modulate the ME response and increase the operating frequency of the sensor. This upward shift lowers the $1/f$ noise and increases the signal amplitude if the new operating frequency is near a mechanical resonance mode of the sensor. Using this modulation technique, the low frequency sensitivity has been improved by more than an order of magnitude and we have achieved a detectivity of 7 pT/ $\sqrt{\text{Hz}}$ at 1 Hz. In addition to increasing the magnetic signal frequency, we can use magnetic modulation to increase the operating frequency of acoustic signals detected by these sensors. This occurs because the ME sensors are nonlinear devices. In these cases using magnetic field modulation, the signal appears as sidebands around the modulation frequency.

¹To be published in Journal of Applied Physics.

3:42PM D9.00007 Bipolar exchange bias modulation in $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{BiFeO}_3$ heterostructure based field effect devices, STEPHEN WU, SHANE CYBART, JAMES PARKER, PU YU, R. RAMESH, R.C. DYNES, University of California, Berkeley / Lawrence Berkeley National Lab — We have fabricated and performed electrical transport measurements on a multiferroic field effect device with a BiFeO_3 (antiferromagnetic/ferroelectric) gate dielectric and a $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ (ferromagnetic) channel to investigate the effect of BiFeO_3 (BFO) polarization on interfacial magnetism by using exchange bias as a diagnostic tool. A reversible static shift in exchange bias through zero applied magnetic field is observed by electrically poling BFO. This bipolar exchange bias modulation behavior strongly suggests that interfacial magnetization is being reversed through the application of electric field. To investigate this phenomenon further we have measured temperature dependent exchange bias, temperature dependent resistivity, and Hall Effect coefficients on multiple devices. Also a comparison to an identical control device using a $\text{Pb}(\text{Zr}_{0.2}\text{Ti}_{0.8})\text{O}_3$ (ferroelectric) gate dielectric and $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ (LSMO) channel is offered, which provides insight into the interfacial magnetic interactions uniquely occurring in the BFO/LSMO system. We analyze these results in the context of proposed models, which suggest that we are modulating both carrier density and interfacial magnetic coupling strengths; both of which have a strong effect on the bipolar modulation of exchange bias.

3:54PM D9.00008 Effect of the exchange bias field on the magnetoimpedance response in multilayered FeNi-IrMn films and CoFeSiB-IrMn ribbons, KERIM TURE, MEHMET YUMAK, GULEN AKTAS, Bogazici University, Department of Physics, JUAN MANUEL FLOREZ, Department of Materials Science and Engineering, MIT, PATRICIO VARGAS, Departamento de Fisica, Universidad Técnica Federico Santa Mara, CAROLINE A. ROSS, Department of Materials Science and Engineering, MIT, CARLOS GARCIA, Bogazici University, Department of Physics — The magnetoimpedance effect (MI) has been widely used in sensitive magnetic field (MF) sensors, but its intrinsic nonlinear properties are disadvantageous for sensor applications near zero field. The combination of ferromagnetic (FM) and antiferromagnetic (AFM) layers produce an asymmetrical MI (AMI) peak positions which are shifted to higher MF as the probe frequency increases, so linear MI behavior can be obtained around zero external field by tuning the frequency. Here, AMI was extensively studied in multilayer strips of exchange-coupled FeNi-IrMn . The effect of the thickness of the FM layer and the angle dependence in three stripe samples with EB induced; parallel, perpendicular and forming an angle of 45 with the direction of the wire were studied. MI ratio raise with increasing thickness of the FM layer is attributed to the stronger pinning of the FM adjacent to the IrMn. Also, a combination of the EB angle affects and direction of the applied MF can tune; the number of peaks in the MI response, the asymmetry between peaks and the shift of the MI response. Besides, an antiferromagnetic layer was deposited on the top of CoFeSiB amorphous ribbons enhancing the MI effect at low frequencies and shifting the MI response at higher frequencies.

4:06PM D9.00009 Tailoring Giant Magneto-impedance Effect in Ultrasoft Ferromagnetic Microwires¹, A. CHATURVEDI, A. RUIZ, P. MUKHERJEE, H. SRIKANTH, M.H. PHAN, Department of Physics, University of South Florida Tampa FL 33620, V.S. LARIN, Microfir Thenologii Industriale, Moldavia — Research on soft ferromagnetic microwires exhibiting giant magneto-impedance (GMI) effect, which is a large change of the ac impedance of a ferromagnetic conductor in a static magnetic field, for advanced magnetic sensor applications is an area of topical interest. In this study we show how the GMI effect and its field sensitivity are optimized in Co-B-Si-Mn microwires by varying the magnetic core to glass shell diameter ratio (d). The microwires have been fabricated by the glass-coated melt spinning method. The largest values of GMI (245%) and its field sensitivity 25%/Oe are achieved at $f = 13\text{MHz}$ for the microwires with $d = 0.86$. The d dependence of the magneto-impedance has been analyzed based on those of the magneto-resistance and magneto-reactance. Our studies indicate that the microwires with optimized GMI response are attractive candidate materials for structural health self-monitoring and magnetic biosensing applications.

¹CIFM and FCASST

4:18PM D9.00010 Soft ferromagnetic microribbons with enhanced GMI effect for advanced magnetic sensor applications¹, A. RUIZ, A. CHATURVEDI, P. MUKHERJEE, H. SRIKANTH, M.H. PHAN, Department of Physics, University of South Florida — Soft ferromagnetic ribbons with giant magneto-impedance (GMI) effect are attractive candidate materials for high-performance magnetic sensor applications. GMI is a large change in the ac impedance of a ferromagnetic conductor subject to a dc magnetic field. There is a need for further improving GMI response of existing materials, as well as reducing the size of a GMI-based sensor for use in micro-sensing systems. In this work, we report the enhancement of GMI in soft ferromagnetic ribbons (Metglas® 2714A) at high frequencies by reducing the width of the ribbon to the micrometer scale. This finding is of practical importance, as sensors with enhanced field sensitivity and reduced size find wider ranging applications. The origin of the enhanced GMI effect in the microribbon is explained in terms of the skin and demagnetization effects. The relative contributions to the magneto-impedance from the magneto-resistance and magneto-reactance have been analyzed and discussed in detail.

¹CIFM and FCASST

4:30PM D9.00011 Designing New Metal-Semiconductor Hybrid Structures With Large Geometric Magnetoresistance¹, LISA PUGSLEY, L.R. RAM-MOHAN, Worcester Polytechnic Institute, S.A. SOLIN, Washington University, St. Louis — The extraordinary magnetoresistance (EMR) in metal-semiconductor hybrid structures was first demonstrated using a four-contact configuration for a circular semiconductor wafer with a concentric metallic inclusion in it. The EMR effect, which is observed at room temperature, is very suitable for use in read heads in magnetic data storage devices. This effect depends on the orbital motion of carriers in an external magnetic field, and the remarkably high magnetoresistance response (the change in resistance with a magnetic field) observed suggests that the geometry of the metallic inclusion can be optimized to significantly enhance the EMR. The theory and simulations to achieve this goal are considered by comparing various 2D structures in an external magnetic field to evaluate the EMR in them using finite element analysis and geometric optimization. For a $10\text{ }\mu\text{m}$ square semiconductor wafer with a square metallic inclusion we see a range in resistance from -400 to $400\text{ }\Omega$ for $-1\text{ T} \leq B \leq 1\text{ T}$. This response can be optimized by changes in contact orientation and the size and shape of the metallic region. Extension to 3D is being investigated at present, which would allow for modeling of magnetic field sensors that also provide the direction of the field.

¹This work was supported by the NSF under grants ECS-0725427 and ECCS-0725538. SAS has a financial interest in PixelEXX, a start-up company whose mission is to market imaging arrays.

4:42PM D9.00012 Ultra wideband, high sensitivity magneto-optic field sensor¹, DONG HO WU, ANTHONY GARZARELLA, Naval Research Laboratory, VINCE FRATELLO, Integrated Photonics Inc. — Using the bismuth rare-earth iron garnet thick films we have demonstrated a magneto-optic (MO) field sensor. The sensor made of all dielectric materials is nearly noninvasive, and is operated at room temperature. The sensor's sensitivity is scalable; the same sensor design can be used for a low-field sensor to measure fields below nano-Tesla or for a high-field sensor to measure several hundred Tesla. The highest sensitivity that we have achieved with the sensor is about $30\text{ pT}/(\text{Hz})^{1/2}$. Presently its frequency range is limited from DC to 2 GHz. We have carried out several different experiments with this sensor to explore a few interesting applications, such as electromagnetic signal interception tests over a very broad frequency range. In this presentation we will report our experimental results obtained from this MO field sensor.

¹This work is supported by DARPA

4:54PM D9.00013 Diamagnetic repulsion, the method of magnetic images & suitability of the solenoid and dipole models¹, MING YIN, Benedict College, Columbia, SC29204, HUAIZHOU ZHANG, TIMIR DATTA, University of South Carolina, Columbia, SC29208 — The repulsion of a permanent magnet from a diamagnetic region was investigated. A magnet of moment m can be described by two models (i) solenoid - a circulating current of appropriate value; second (ii) a magnetic dipole comprising of a pair of north and south poles of separated by a distance. The magnetic field (B) of a permanent magnet was measured. The magnet was modeled as a solenoid with a circulating surface current. The Biot-Savart law field (B) was computed in Matlab. The experimental data of was in excellent agreement with the Matlab results. However, for computing the repulsion force (F) between the magnet and its diamagnetic image by the direct integration of the current-current interaction require detailed knowledge of the two current densities. However such knowledge is not essential if image is modeled as a dipole. When the magnet is a distance z above the diamagnetic interface then the image current I_2 gives rise to a image dipole m_2 and the $F \sim m_2 \text{div } B$, where the div of the holding field is computed at the distance $2z$ below the magnet. In this model F is directly proportional to both m' and the derivative of the field and a negative slope indicates repulsion, all three were confirmed.

5:06PM D9.00014 ABSTRACT WITHDRAWN —

5:18PM D9.00015 Magnetic Field Assisted assembly using programmable array of solenoids - A Manufacturing Approach, VIJAY KASISOMAYAJULA, ANTHONY FIORY, MICHAEL BOOTY, NUGGEHALLI RAVINDRA, New Jersey Institute of Technology — The use of an array of programmable solenoids to implement a magnetic field driven assembly of heterogeneous micro-components onto a substrate is studied. A lower limit of component size, the upper limit of the rate of assembly and the efficiency of the assembly from various perspectives is presented. Various statistical tests are performed on the assembly process to determine its feasibility. A comparison is made between this method of assembly and established assembly techniques in the literature.

Monday, February 27, 2012 2:30PM - 5:30PM —
Session D10 DCOMP: Invited Session: Advancements in Computational Physics using NSF's TeraGrid/XSEDE Resources 210A

2:30PM D10.00001 Benchmark Calculations of Atomic Collision Processes¹, KLAUS BARTSCHAT, Drake University — The rapid development of computational resources has resulted in enormous improvements in the accuracy of numerical calculations of atomic collision processes. This talk will concentrate on recent advances in the computational treatment of charged-particle and intense short-pulse laser interactions with atoms, ions, and small molecules. Examples include electron collisions with heavy complex targets that are of significant importance in many modelling applications in plasma and astrophysics, fundamental studies of highly correlated 4-body Coulomb processes such as simultaneous ionization with excitation, and the accurate solution of the time-dependent Schrödinger equation in the presence of intense femto/attosecond laser fields, which paves the way for quantum dynamic imaging and coherent control.

3:06PM D10.00002 Prediction and Design of Materials from Crystal Structures to Nanocrystal Morphology and Assembly¹, RICHARD HENNIG, Materials Science and Engineering, Cornell University — Predictions of structure formation by computational methods have the potential to accelerate materials discovery and design. Here we present two computational approaches for the prediction of crystal structures and the morphology of nanoparticles. Many materials properties are controlled by composition and crystal structure. We show that evolutionary algorithms coupled to ab-initio relaxations can accurately predict the crystal structure and composition of compounds without any prior information about the system. We will discuss results for various systems including the prediction of unexpected quasi-1D and 2D electronic structures in Li-Be compounds under pressure [1] and of the crystal structure of the superconducting high-pressure phase of Eu [2]. The self-assembly of nanocrystals into mesoscale superlattices provides a path to the design of materials with tunable electronic, physical and chemical properties for various applications. The self-assembly is controlled by the nanocrystal shape and by ligand-mediated interactions between them. To understand this, it is necessary to know the effect of the ligands on the surface energies (which tune the nanocrystal shape), as well as the relative coverage of the different facets (which control the interactions). Density functional calculations for the binding energy of oleic acid-based ligands on PbSe nanocrystals determine the surface energies as a function of ligand coverage. The Wulff construction predicts the thermodynamic equilibrium shape of the PbSe nanocrystals as a function of the ligand coverage. We show that the different ligand binding energies on the 100 and 111 facets results in different ligand coverages on the facets and predict a transition in the equilibrium shape from octahedral to cubic when increasing the ligand concentration during synthesis. Our results furthermore suggest that the experimentally observed transformation of the nanocrystal superlattice structure from fcc to bcc is caused by the preferential detachment of ligands from particular facets, leading to anisotropic ligand coverage [3].

3:42PM D10.00003 Scalable DAG-Based PDE Frameworks for Multi-Scale Multi-Physics Problems¹, MARTIN BERZINS, SCI Institute University of Utah, Salt Lake City, Utah — The task-based approach to software and parallelism is well-known and has been proposed as a potential candidate, named the silver model, for exascale software. This approach is not yet widely used in the large-scale multi-core parallel computing of complex systems of partial differential equations. The central idea is to use a Directed Acyclic Graph (DAG) based approach to express the structure of the underlying software. The aim of this talk is to explore the usefulness of DAG based approaches, using recent developments in the parallel Uintah software framework for partial differential equations to assess how well the DAG type approach works on present-day large-scale architectures for complex multi-physics multiscale applications up to 200K cores. As a result of these investigations, a preliminary and tentative evaluation of the DAG type approach for PDE software infrastructures will be given. The conclusion is that these approaches show great promise for petascale but that considerable algorithmic challenges remain.

¹Support from NSF PetaApps and DOE NETL and INCITE is acknowledged

4:18PM D10.00004 Simulations of Strongly Correlated Systems¹, JUANA MORENO, Louisiana State University

— The field of strongly correlated systems is one of the most active areas in condensed matter physics. This interest is motivated, in part, by a variety of complex emergent phenomena, including high-temperature superconductivity, quantum criticality and complex phases induced by electron-phonon couplings. The recent very rapid development of high performance heterogeneous computer platforms together with a similar emergence of highly accurate many-body algorithms allow the treatment and modeling of complex correlated material systems which were intractable just a few years ago. Important progress has been made by the development of finite size methods, including exact diagonalization and Quantum Monte Carlo techniques. However, due to the minus sign problem, these methods are limited to small lattice sizes. Another successful approach is the dynamical mean field approximation and its cluster extensions, which treat the local or short-ranged dynamical correlations exactly and non-local or long-ranged correlations in a mean field approximation. Due to the effective medium, the Fermion minus sign problem is much milder than that found in finite sized simulations. However, it is still the primary limitation of these methods. To address this problem, multiscale approaches are used which treat only the correlations at the shortest length scales with exact cluster solvers, intermediate length scales are treated using a diagrammatic approach, such as the parquet equations or the dual-fermion formalism and, the longest length scales are captured by the mean field. I will discuss how these new algorithms impact a few model systems including our understanding of quantum criticality in the Hubbard and Anderson model, new phases in ultracold quantum gases, spintronics materials and the role of electron-phonon interaction. I will conclude discussing recent algorithm redesign motivated by the evolution towards hybrid multicore architectures employing graphical processing unit (GPU).

4:54PM D10.00005 Accessing correlated electron motion on the attosecond timescale, JOHANNES FEIST, ITAMP, Harvard-Smithsonian Center for Astrophysics

— In the last decade, there have been tremendous advances in the production of coherent ultrashort light pulses as short as 80 attoseconds ($1 \text{ as} = 10^{-18} \text{ s}$). The availability of these pulses has led to the development of the field of attosecond physics, which aims to follow and control electron motion on its natural timescale (1 atomic unit of time is about 24 attoseconds). One of the major goals of attosecond physics is to access correlated electron dynamics. This requires a description of the target system that goes beyond the commonly used single-active-electron approximation. The large bandwidth of ultrashort pulses and many-photon absorption in strong infrared fields make such a description extremely challenging. I will discuss our work on the full numerical solution of the two-electron Schrödinger equation for helium, which already displays rich correlation effects. I will focus on two applications: The first is attosecond streaking, in which temporal information about the photoionization process in an attosecond pulse is mapped into a momentum shift by a synchronized infrared pulse. This promises to give access to the Eisenbud-Wigner-Smith time delay of photoionization. I will discuss the additional effects that are induced by the infrared field, and how these have to be taken into account for attosecond streaking to fulfill its promise. I will then discuss the possibility of accessing two-electron wave packet dynamics in doubly excited states of helium by an attosecond pump-attosecond probe setup. Such experiments have been called the “holy grail” of attosecond physics and should come within reach in the near future. I will discuss our recent proposal of using two-photon absorption from a single pulse as a coherent reference wave, which can be used to increase the experimental signal by almost two orders of magnitude. This provides direct access to time-dependent observables (e.g., the distance between the two electrons) of the two-electron wave packet.

2:30PM D11.00001 Electronic localization in rotated graphene multi-layer, GUY TRAMBLÉ DE LAIS-

SARDIERE, Cergy-Pontoise University, OMID FAIZY NAMARVAR, DIDIER MAYOU, LAURENCE MAGAUD, Institut Néel CNRS — Rotated graphene bilayers show an interesting electronic structure with a tendency to layer decoupling at large rotation angles and a stronger electronic mixing at small angles, associated with a strong decrease of the velocity ([1] and Refs. therein). These inter-layer mixed states allow us [2] to address the long lasting problem of the origin of the Moiré pattern observed on STM images. For large and intermediate rotation angles, we present analytical and numerical studies of the local density of states in the Moiré that compare well to STM spectra. For very small angles, the inter-layer mixed states ultimately lead to electronic confinement in AA stacking regions in an energy range close to the Dirac point. In graphene multi-layer (up to 10 layers) containing twisted intercalated layers [3], we found both bands with a strong velocity reduction, and bands without velocity reduction. This could explain [2] why velocity renormalization is not observed experimentally in rotated multi-layers on SiC [3,4].

2:42PM D11.00002 Interferences and Fabry-Perot Oscillations in ABA Trilayer Graphene,

LEONARDO CRISTIANO CAMPOS, KAWIN SURAKITBOVORN, Department of Physics, Massachusetts Institute of Technology, Cambridge, MA 02139 USA, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Namiki 1-1, Tsukuba, Ibaraki 305-0044, Japan, PABLO JARILLO-HERRERO, Department of Physics, Massachusetts Institute of Technology, Cambridge, MA 02139 USA, DEPARTMENT OF PHYSICS, MASSACHUSETTS INSTITUTE OF TECHNOLOGY/NATIONAL INSTITUTE FOR MATERIALS SCIENCE TEAM — ABA trilayer graphene (TLG) is a 2D system with multiple sub-bands which can be divided into one monolayer graphene-like sub-band and one bilayer graphene-like sub-band, therefore comprising a system wherein massive and massless bands coexist. Here, we study electronic transmission in the ballistic regime through a 70nm-wide tunable electrostatic potential barrier on exfoliated ABA trilayer graphene encapsulated by hexagonal Boron Nitride. We report Fabry-Perot oscillations of the conductance caused by multiple reflections of the charges in the potential barrier, and we also present a study of their magneto dependence.

2:54PM D11.00003 Quantum Pumping in Graphene Nanoribbons¹, TEJINDER KAUR, Dept. of Physics and

Astronomy, Ohio University, LILIANA ARRACHEA, Dept. de Física, Universidad de Buenos Aires, Argentina, NANCY SANDLER, Dept. of Physics and Astronomy, Ohio University — The interest in the development of devices at the nanoscale has intensified the search for mechanisms that provide control of transport properties while reducing effects of heat dissipation and contact resistance. Charge pumping, in which dc currents are generated in open-quantum systems by applying local de-phased time-dependent potentials, may achieve these goals. We analyze the properties of non-equilibrium zero-bias currents through nano-ribbons using a tight-binding Hamiltonian and the Keldysh formalism beyond the adiabatic and perturbative regimes. Using a numerical implementation with two local single-harmonic time-dependent potentials, we first contrast results for 1d and 2d metallic systems (square lattice). Next, we focus on quasi-1d systems and graphene ribbons, and discuss the role of reservoirs. We analyze the dependence of the dc pumped current as a function of different parameters such as chemical potential, pumping amplitude, and frequency. We observe a considerable increase of pumped current with the dimensionality of the system. Furthermore, we show that lattice mismatch with reservoirs favors the pumping mechanism for graphene ribbons.

3:06PM D11.00004 Conductance fluctuations in graphene as a probe of broken-symmetry and fractional quantum Hall states, JURGEN SMET, Max Planck Institute for Solid State Research — The observation in macroscopic transport studies of the interaction induced broken symmetry and fractional quantum Hall states in graphene normally requires very clean samples and/or strong magnetic fields. Here we report that even when these fragile states are not developed well enough to produce any of the quantum Hall signatures, they are strongly visible in differential conductance fluctuations that appear as a result of charge carrier localization when the system breaks up into compressible islands with incompressible areas in between when the corresponding integer or fractional filling factor is approached. The conductance fluctuations give access to local information even though a macroscopic measurement is performed. The existence of a landscape of compressible islands is unambiguously proved in Coulomb blockade phenomena in the quantum Hall insulating regime where all other conduction channels are switched off. This work has been carried in collaboration with D.S. Lee, V. Skakalova, R.T. Weitz, K. von Klitzing.

3:42PM D11.00005 Interference of electronic states between the two misoriented crossed graphene nanoribbons¹, K.M. MASUM HABIB, ROGER LAKE, Dept of Electrical Engineering, Univ of California Riverside — In a twisted bilayer graphene, where one layer is rotated with respect to the other one, for rotation angles more than 20 degrees each layer remains electronically decoupled even though they are vertically separated by only a fraction of a nanometer. A relative rotation between two graphene nanoribbons (GNRs), with one place on top of the other, creates a crossed GNR (xGNR) with an overlap region that is neither AA nor AB stacking. The geometry of the overlap region of the xGNR is that of a twisted bilayer graphene. Calculations, based on the extended Huckel theory and the non-equilibrium Green's function formalism, show that the electronic states of the individual GNRs of an unbiased xGNR are decoupled from each other similar to the decoupling that occurs in a twisted bilayer graphene. The decoupling occurs due to the quantum mechanical interference between the electronic states of the individual GNRs. This results in a strong suppression of inter-GNR transmission over a large energy of window. The transmission is, however, a strong function of the potential difference between the GNRs and the atomistic geometry of the overlap region which depends on relative translation and rotation angle between the GNRs. Thus, a bias can be used to control the inter-GNR current.

3:54PM D11.00006 Gap opening in graphene by 1D and 2D periodic corrugations, IVAN NAUMOV, ALEXANDER BRATKOVSKY, Hewlett-Packard Laboratories, 1501 Page Mill Road, Palo Alto, California 94304, USA — Using first-principles methods and symmetry arguments, we show that a graphene monolayer, which is periodically corrugated in one or two direction(s), can be either semimetal or semiconductor, depending on how strong corrugation is or how the initial symmetry is broken. In the case of 1D periodic ripples, a gap at the Dirac points opens up only due to (i) breaking of the inversion symmetry or equivalence between A and B sublattices and/or (ii) merging of two inequivalent Dirac points, **D** and **-D**. Since breaking the inversion symmetry has only relatively modest effect, a tangible gap can be mainly induced by mutual annihilation of the Dirac points, which requires large corrugations, close to mechanical breaking point. In contrast to 1D, the 2D ripples can additionally induce a semiconducting gap via mixing of electronic states belonging to two different **K**, **K'** valleys. In this case, a gap on the order of 0.5 eV can be opened up at strains safely lower than the graphene failure strain [1].

4:06PM D11.00007 Electronic structure and energetics of graphene antidot lattice, MASAHIRO SAKURAI, Institute for Solid State Physics, University of Tokyo, SUSUMU SAITO, Department of Physics, Tokyo Institute of Technology, YASUTAMI TAKADA, Institute for Solid State Physics, University of Tokyo — We have made a systematic study of the electronic structure and the energetics of graphene with periodic array of vacancy clusters (graphene antidot lattice) in the framework of the density-functional theory (DFT). We find that the electronic property of the system is well controlled by its lattice periodicity. More specifically, this system can be either metallic or semiconducting, depending on its lattice geometry. Interestingly, some of them are predicted to be direct-gap semiconductors. For example, graphene sheet with high-symmetry arrangements of periodic circle-shape vacancies always has a direct fundamental gap [1]. The DFT total-energy calculations indicate that the geometry of hole edges plays an important role in determining its stability. 4:18PM D11.00008 ABSTRACT WITHDRAWN —

4:30PM D11.00009 Localization and Conductivity of Graphene with Adsorbates, DIDIER MAYOU, Institut Néel, CNRS, GUY TRAMBLAY DE LAISSARDIERE, Cergy-Pontoise University — We compute the conductivity of graphene for two models of resonant and non resonant adsorbates. Away from the Dirac point the conductivity is well given by the semi-classical Drude formula and localization lengths are exponentially large. For some energies, near the Dirac point, the conductivity is well represented by $\sigma \simeq 4e^2/\pi h - \alpha \text{Log}(L_i/L_e)$ as a function of the inelastic scattering length L_i and the elastic mean free path $L_e < L_i$. This implies a magneto-conductivity that varies also linearly with $\text{Log}(B)$ where B is the magnetic field. Our results suggest that the divergence of the localization length which is expected close to the Dirac point affects only a narrow energy region.

4:42PM D11.00010 Effects of disorder on recombination and relaxation processes via acoustic phonons in graphene, FEDIR VASKO, VLADIMIR MITIN, ANDREI SERGEEV, SUNY at Buffalo — Recombination and relaxation processes via acoustic phonons are allowed in a disordered graphene because of violation of the energy-momentum conservation requirements. These processes are analyzed taking into account the interference of electron-phonon and electron-impurity scattering mechanisms. The recombination and relaxation rates are calculated for the cases of intrinsic and heavily-doped graphene. The transient evolution of nonequilibrium carriers is described by the exponential fit dependent on doping conditions and disorder level. The obtained electron recombination and relaxation rates are compared with available experimental data. [1] F. Vasko et al., Phys. Rev. B 84, 155445 (2011).

4:54PM D11.00011 Phase coherent states in graphene heterostructure with chiral asymmetry¹, JUNHUA ZHANG, ENRICO ROSSI, Department of Physics, College of William and Mary — The chiral nature of the fermionic excitations in graphene, bilayer graphene, and topological insulators, induces unique electronic properties in these materials. In bilayer heterostructures the interlayer interaction can induce the formation of an interlayer phase coherent state. An interesting class of heterostructures is constituted by bilayers in which the electrons in the two layers have different chirality. An example of such a system that can be realized experimentally is the heterostructure formed by single layer graphene and bilayer graphene. In this talk I will discuss the conditions for the realization of an interlayer phase-coherent state in chiral-asymmetric heterostructures. In particular I will show how the voltage difference between the two layers affects the conditions for the realization of the phase coherent state, and its properties. I will then discuss the relevance for experiments of our results.

5:06PM D11.00012 Visualizing Electronic Chirality and Berry's Phases in Graphene Systems Using Photoemission with Circularly Polarized Light, YANG LIU, GUANG BIAN, TOM MILLER, TAI-CHANG CHIANG, University of Illinois, Urbana-Champaign — Electronic chirality near the Dirac point is a key property of graphene systems, which is revealed by the spectral intensity patterns as measured by angle-resolved photoemission spectroscopy under various polarization conditions. Specifically, the strongly modulated circular patterns for monolayer (bilayer) graphene rotate by ± 90 degrees (± 45 degrees) in changing from linearly to circularly polarized light; these angles are directly related to the phases of the wave functions and thus visually confirm the Berry's phase of π (2π) around the Dirac point. The details are verified by calculations.

5:18PM D11.00013 Electronic Properties of Curved Graphene-Ring Structures¹, DAIARA FARIA, Ohio University / Universidade Federal Fluminense, Brazil, ANDREA LATGÉ, Universidade Federal Fluminense, Brazil, SERGIO ULLOA, NANCY SANDLER, Ohio University — Recently, deformed graphene in the form of bubbles have been produced on different substrates in a variety of controllable shapes [1]. These findings raise the possibility of changing the electronic properties of these structures allowing for band-structure engineering. We have undertaken a study of the electronic properties of graphene-ring systems with circularly symmetric Gaussian curvature in the Dirac approximation. We obtain energy spectra and wave functions using perturbation theory on the gauge field amplitude describing the curvature. We further analyze the competition between curvature-induced magnetic field and real external fields and the resulting persistent currents generated in their presence. As expected, the results depend on the boundary conditions describing the confined ring edges. In addition, we discuss the effects of the angular asymmetry in the probability density due to the curvature [2] on single rings and more complex confined annular geometries.

Monday, February 27, 2012 2:30PM - 5:30PM – Session D12 DMP: Graphene Transport: Disorder Scattering 210C

2:30PM D12.00001 Theory of 2D Transport in Graphene for Correlated Disorder¹, QIUZI LI, EUYHEON HWANG, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742, USA, ENRICO ROSSI, Department of Physics, College of William and Mary, Williamsburg, Virginia 23187, USA, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742, USA — We theoretically revisit graphene transport properties as a function of carrier density, taking into account possible correlations in the spatial distribution of the Coulomb impurity disorder in the environment. We find that the charged impurity correlations give rise to a density-dependent graphene conductivity, which agrees well qualitatively with the existing experimental data. We also find, quite unexpectedly, that the conductivity could increase with increasing impurity density if there is sufficient interimpurity correlation present in the system. In particular, the linearity (sublinearity) of graphene conductivity at lower (higher) gate voltage is naturally explained as arising solely from impurity correlation effects in the Coulomb disorder.

2:42PM D12.00002 Simultaneous Raman and electrical transport measurements of disordered graphene in situ in ultra-high vacuum¹, JACOB TOSADO, University of Maryland, VINCE BALLAROTTO, Laboratory for Physical Sciences, WILLIAM G. CULLEN, MICHAEL S. FUHRER, University of Maryland — Resonant Raman scattering in graphene gives unique information about disorder, as the D peak is observed only in the presence of disorder which produces intervalley scattering of the electrons. The nature of disorder in graphene prepared by various techniques and on various substrates of the subject of significant research, with significant attention being paid to scattering by charged impurities; resonant scatterers due to vacancies, chemisorbed impurities, etc.; and non-resonant short-range impurities. In order to study the effect of these types of disorder on graphene's electronic properties and Raman spectra simultaneously, we have developed a facility combining thermal deposition, ion bombardment, electrical transport and micro-Raman measurements in an ultra high vacuum environment. We will discuss the capabilities of this facility and present the results of Raman and electrical transport measurements on controllably disordered graphene.

¹This work was supported by the Laboratory for Physical Sciences, and an NRI supplement to the UMD-NSF-MRSEC grant DMR 0520471

2:54PM D12.00003 Creating Vacancies in Supported and Suspended Graphene Field Effect Transistors, SHUREN HU, A.K.M. NEWAZ, ANTHONY HMELO, KIRILL BOLOTIN, Vanderbilt University — We have studied the creation of vacancy defects in both graphene samples supported on SiO₂ substrate and suspended graphene devices. The defects were created by irradiating graphene with a 30KeV Ga⁺ ion beam in UHV; the effect of these defects on electrical transport in graphene was measured *in situ*. We find that the number of defects created in supported devices is dramatically higher in comparison with suspended devices. Using Monte-Carlo and SRIM simulations, we identify the formation of defects by secondary ions in the case of supported devices as a likely explanation of these results. We have also observed that the transport quality degrades drastically with respect to vacancy defect density and follows the same general trend for both supported and suspended graphene. These results may be important in designing devices for high radiation working environments, such as space electronics.

3:06PM D12.00004 Scattering mechanisms in graphene suspended in liquids. II. Flexural phonons (Theory)¹, YEVGENIY PUZYREV, A.K.M. NEWAZ, BIN WANG, KIRILL BOLOTIN, SOKRATES PANTELIDES, Physics and Astronomy Department, VANDERBILT UNIVERSITY COLLABORATION — Recent experiments reported strong scattering of charge carriers by flexural phonons in suspended graphene in vacuum.² Our experimental data (previous talk) show that the carrier mobility observed for devices immersed in non-polar liquids, namely toluene and hexane, are significantly larger than the mobility limitation due to scattering by flexural phonons. We performed molecular dynamics simulations of graphene sheets suspended in hexane, toluene, and in vacuum at room temperature. We find that the interaction of molecules of the liquid with graphene suppresses the amplitude of the phonons by $\sim 50\%$. We show computationally that this suppression is equivalent to an effective increase of the bending rigidity³ of graphene from a free-space value ~ 1.3 eV in vacuum to ~ 3.6 eV in liquids. Therefore, we demonstrated that scattering by out-of-plane flexural phonons is reduced by the presence of liquids.

3:18PM D12.00005 Scattering mechanisms in graphene suspended in liquids. I. Coulomb scattering (Experiment), A.K.M. NEWAZ, YEVGENIY PUZYREV, BIN WANG, SOKRATES PANTELIDES, KIRILL BOLOTIN, Vanderbilt University — Enhanced dielectric screening of charged impurities by high- κ environment of graphene is predicted to improve the electronic quality of graphene devices by suppressing Coulomb scattering. However, experiments reported so far demonstrate that electronic transport in graphene is only modestly modified by a high- κ environment. Here we fabricate large area multiterminal graphene devices suspended in liquids and study electronic transport in graphene as a function of liquid's dielectric constant. We observe a rapid increase of mobility μ with κ due to dielectric screening in non-polar solvents ($\kappa \leq 5$). We also find that charged ions present in polar solvents ($\kappa \geq 18$) cause a drastic drop in mobility counteracting the gains by dielectric screening in polar high- κ liquids. Furthermore, molecular dynamics simulations establish that scattering by out-of-plane flexural phonons is suppressed by the presence of liquids (next talk). We expect that our findings may provide avenues to control and reduce carrier scattering in future graphene-based electronic devices.

3:30PM D12.00006 Short range disorder in Graphene: A Green's function based approach¹, SANKALPA GHOSH², Physics Department, IIT Delhi, New Delhi-110016, India, NEETU AGGARWAL (GARG), MANISH SHARMA, Center for Applied Research in Electronics, IIT Delhi, New Delhi-110016, India — Electrons at the Fermi level in graphene monolayer behave like massless Dirac fermions. Using Green's function based technique we study the transport of such electrons in the presence of randomly located electrostatic impurities in different geometries and compare such transport in graphene with the transport in conventional semiconductors. This study would eventually be used to mimic short range disorder that would be superimposed on a regular structure. Comparison with the optical phenomena will be used to understand such transport. We further extend this technique to study the transport in the presence of magnetic scatterers.

3:42PM D12.00007 Universal conductance fluctuations in Dirac materials in the presence of long-range disorder¹, E. ROSSI, Department of Physics, College of William and Mary, Williamsburg, VA 23187, USA, J.H. BARDARSON, Department of Physics, University of California, Berkeley, CA 94720, USA; Materials Sciences Division, LBNL, Berkeley, M.S. FUHRER, CNAM, Department of Physics, University of Maryland, College Park, MD 20742-4111, USA, S. DAS SARMA, CMTC, Department of Physics, University of Maryland, College Park, MD 20742-4111, USA — We study quantum transport in Dirac materials with a single fermionic Dirac cone (strong topological insulators and graphene in the absence of intervalley coupling) in the presence of long-range disorder [1]. We show, by calculating the conductance fluctuations, that in the limit of very large system size and disorder strength, quantum transport becomes universal. However, a systematic deviation away from universality is obtained for realistic system parameters. By comparing our results to existing experimental data on $1/f$ noise, we suggest that many of the graphene samples studied to date are in a non-universal crossover regime of conductance fluctuations, and provide an explanation for the origin of the $1/f$ noise in Dirac materials and in graphene in particular.

3:54PM D12.00008 Diamagnetism of Graphene with Long-Range Scatterers, MASAKI NORO, Department of Physics, Tokyo Institute of Technology, MIKITO KOSHINO, Department of Physics, Tohoku University, TSUNEYA ANDO, Department of Physics, Tokyo Institute of Technology — We study weak-field orbital susceptibility of graphene containing scatterers with long-ranged potential. The effects of scattering from such impurities are taken up self-consistently by using Green's function technique within a self-consistent Born approximation. To see dependence on the potential range, we consider scatterers with a Gaussian potential and screened charged impurities. Because Green's function or self-energy for long-range impurities strongly depends on wave vector, we have to numerically calculate Green's function and vertex functions. In graphene, the susceptibility diverges at the Dirac point as a delta function of the Fermi energy. For the Gaussian potential, results show that the delta function in the ideal graphene is broadened by disorder, due to the mixing between the states at the Dirac point and other states. The susceptibility as a function of the Fermi energy rapidly decreases away from the Dirac point, with effective width determined by the potential range. As the scattering strength increases, the peak at the Dirac point is less prominent and the susceptibility has a long tail, corresponding to the strong mixing among states due to scattering. These behaviors are obtained only when the vertex corrections are properly taken into account. For charged impurities, the susceptibility shows a double-peak structure caused by the strong variation of the effective scattering strength as a function of the Fermi energy.

4:06PM D12.00009 Current decay rate due to electron-electron scattering in graphene, BEN YU-KUANG HU, The University of Akron — Electron-electron scattering in graphene does not conserve electrical current, because of the linear dispersion of the bands in graphene near the Dirac point. In graphene, when two electrons with initial momenta $\mathbf{k}_1$ and $\mathbf{k}_2$ undergo electron-electron scattering to final states $\mathbf{k}'_1$ and $\mathbf{k}'_2$, in general the total current $\mathbf{v}(\mathbf{k}_1) + \mathbf{v}(\mathbf{k}_2) \neq \mathbf{v}(\mathbf{k}'_1) + \mathbf{v}(\mathbf{k}'_2)$ [see e.g., Li *et al.*, Appl. Phys. Lett. **97**, 082101 (2010)]. We calculate the electric current relaxation rate due to the electron-electron scattering of an electron that is injected into extrinsic graphene at low temperature. When the energy of injected electron relative to the Fermi energy is small compared to the Fermi energy, the current decay rate is small due to phase-space restrictions. The current decay rate grows monotonically as the energy of the injected electron increases.

4:18PM D12.00010 Electron energy relaxation in disordered graphene via e-phonon interaction, WEI CHEN, AASHISH CLERK, McGill University — Motivated by recent experiments, we study theoretically the energy relaxation of hot electrons in disordered graphene via electron-phonon interactions. In contrast to previous treatments [1], we explicitly treat the effects of electronic disorder. Using the Keldysh diagram technique, and including vertex corrections, we identify various mechanisms through which disorder can significantly change the magnitude and temperature dependence of the electronic energy relaxation rate. [1]Felix Von Oppen, Francisco Guinea, Eros Mariani, Phys. Rev.B **80**, 075420 (2009)

4:30PM D12.00011 Electron scattering at graphene edges, S.-J. CHOI, SUNGHUN PARK, H.-S. SIM, Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 305-701, Korea, QUANTUM ELECTRON TRANSPORT THEORY GROUP TEAM — We theoretically study the reflection of electrons at edges in monolayer graphene in a low-energy limit. We consider both of zigzag and armchair edge cases. We find that in the case of zigzag edge, the reflection phase is determined by the rotation of electron pseudospin during the reflection, which is attributed to the chirality between the pseudospin and the electron momentum. On the other hand, in the case of armchair edge, the reflection phase does not contain the information of pseudospin rotation, because of intervalley mixing. The pseudospin rotation can be detected via the measurement of reflection phase in an interferometry setup in graphene with zigzag edge.

4:42PM D12.00012 Highly Defective Graphene: The thinnest insulating membrane¹, AURELIEN LHERBIER², UCL/IMCN/NAPS, STEPHAN ROCHE³, CIN2/ICN-CSIC and Universitat Autònoma de Barcelona, OSCAR A. RESTREPO, UCL/IMCN/BSMA, YANN-MICHEL NIQUET, CEA-UJF/INAC/SP2M/L-Sim, ARNAUD DELCORTE, UCL/IMCN/BSMA, JEAN-CHRISTOPHE CHARLIER, UCL/IMCN/NAPS — The electronic structure and transport properties of two-dimensional highly defective sp² graphene are investigated theoretically. Using classical molecular dynamics, large planes of highly defective graphene-based sheets are first generated. An accurate empirical tight-binding Hamiltonian is then elaborated, allowing the prediction of elastic mean free paths, conductivities, and charge mobilities using a real-space order-N Kubo-Greenwood method. In sharp contrast to pristine graphene, the highly defective sp² carbon sheet displays high density of states close to the Dirac energy. However, the dynamics of the corresponding electronic wavepackets reveals extremely short mean free paths (below 1 nanometer) and quantum interferences, both yielding to particularly strong localization phenomena. Consequently, these highly defective graphene-based sheets, although exhibiting a metallic character through the density of states, are from an electronic transport perspective among the most insulating two-dimensional one-atom-thick membrane ever made.

4:54PM D12.00013 Boundary scattering in quasi-ballistic graphene/hexagonal boron nitride mesoscopic wires, KAZUYUKI IGUCHI, Institute of Industrial Science, University of Tokyo, SATORU MASUBUCHI, IIS and Institute for Nano Quantum Information Electronics, University of Tokyo, TAKEHIRO YAMAGUCHI, MASAHIRO OHNUKI, Institute of Industrial Science, University of Tokyo, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, TOMOKI MACHIDA, IIS and INQIE, University of Tokyo, and PRESTO-JST — In a quasi-ballistic transport regime where the mean free path is larger than the width of conduction channel, diffusive boundary scattering results in an anomalous positive magnetoresistance due to a magnetic commensurability effect between cyclotron motion and sample width. In this work, we fabricate a high-mobility two terminal graphene mesoscopic wire on hexagonal boron nitride with a mean free path comparable to sample width $\sim 1 \mu\text{m}$. Magnetoresistance of the graphene mesoscopic wire shows a peak structure at a magnetic field which scales with the ratio of the cyclotron radius R_c to the wire width w . The peak field increases with back-gate voltage as a consequence that the ratio w/R_c is modified due to the change in R_c . These results indicate the quasi-ballistic transport and diffusive boundary scattering in graphene on hexagonal boron nitride.

5:06PM D12.00014 Effects of disorder induced scattering in chemical vapor deposited Graphene., MING-YANG LI, CHIU-CHUN TANG, Dep. Of Physics, National Tsing Hua University, Taiwan, LAIN-JONG LI, Research Center for Applied Sciences, Academia Sinica, CHENG-CHUNG CHI, JENG-CHUNG CHEN, Dep. Of Physics, National Tsing Hua University, Taiwan — The effect of the short-range scatters in chemical vapor deposited (CVD) graphene on the quantum interference effect of carrier scattering remains to be an interesting question. We study the magneto-resistance and low-frequencies noise of our CVD graphene by varying carrier density and temperature. Unlike previous studies of exfoliated clean graphene flakes, we have found in the vicinity of the Dirac-point (DP) WL signal cannot be fully described in terms of breaking the valley symmetry due to trigonal warping of the bands and atomically sharp disorder [1,2]. The discrepancy regime is coincident with the suppression of noise figures and the vanishing of Hall coefficient. Our data suggest that in low mobility CVD graphene an extra inter-valley elastic scattering process should be considered under the theoretical basis in Ref.1. More detailed experimental results and theoretical analysis will be presented and discussed. Ref[1]: E. McCann, et al., Phys. Rev. Lett. 97 146805(2006) Ref[2]: J.Phys. : Condens. Matter 22 205301 (2010)

5:18PM D12.00015 Efros-Shklovskii Variable Range Hopping in Reduced Graphene Oxide Sheets, DAEHA JOUNG, Nanoscience Technology Center and Department of Physics, University of Central Florida, SAIFUL I. KHONDAKER, Nanoscience Technology Center, Department of Physics, School of Electrical Engineering and Computer Science, University of Central Florida — Reduced graphene oxide (RGO) sheets consist of highly ordered graphene domain and structural defects including oxidized carbon atoms and topological defects. Charge transport properties of RGO sheets are strongly influenced by the degree of disorderliness which can be tuned by varying the amount of the reduction. We studied the hopping conduction of the RGO sheets with different reduction efficiency. We show that the low temperature charge transport properties of the RGO with various reduction efficiency can be well described by Efros-Shklovskii variable range hopping (ES VRH), $\rho \sim \exp[-(T/T)^{1/2}]$. We will discuss how the localization length varies with the degree of reduction. The result indicates that the coulomb interactions between graphene domains play an important role in the charge transport of the RGO sheets.

Session D13 DMP GMAG: Focus Session: Magnetic Nanostructures-Characterization (Scanning Probe, X-ray and Neutron) 211

2:30PM D13.00001 STM Studies of Mn₁₂-Ph on Highly Oriented Pyrolytic Graphite, K. REAVES, Department of Physics and Astronomy, Texas A&M University; WPI-AIMR, Tohoku University, Japan, K. KIM, K. IWAYA, T. HITOSUGI, Y.G. KIM, K. ITAYA, WPI-AIMR, Tohoku University, Japan, H. ZHAO, K.R. DUNBAR, Department of Chemistry, Texas A&M University, H.G. KATZGRABER, Department of Physics and Astronomy, Texas A&M University; ETH Zurich, W. TEIZER, Department of Physics and Astronomy, Texas A&M University; WPI-AIMR, Tohoku University, Japan — Mn₁₂-Ph displays tunneling of quantized magnetization below 3K. In other Mn₁₂ ligand variants this magnetic behavior can alter the electronic behavior of the molecule making it a good candidate for a molecular logic gate. Mn₁₂O₁₂(C₆H₅COO)₁₆ (Mn₁₂-Ph) has a Mn₁₂ core and 16 Phenyl ligands and is deposited onto the surface of highly oriented pyrolytic graphite (HOPG). The samples are then studied via scanning tunneling microscopy in air at 300K and in ultra high vacuum at 300K and 4.2K. At 300K, film formation is studied to optimize samples for subsequent low-temperature studies. Isolated objects are observed via STM on the surface, clearly distinct from the underlying graphite lattice. Topographic data are analyzed in an attempt to correlate apparent features to the internal molecular structure of Mn₁₂-Ph. Voltage spectra of locations thought to be associated with the molecular core are compared to other locations thought to be the HOPG and Phenyl. Spectroscopic data indicate a bias voltage dependence at locations associated with the internal molecular structure thought to be related to the metallic-core of the molecules.

2:42PM D13.00002 Room-temperature spin-polarized scanning tunneling microscopy of antiferromagnetic $\text{Mn}_3\text{N}_2(001)$ nanopylramids¹, KANGKANG WANG, ARTHUR SMITH, Ohio University Nanoscale and Quantum Phenomena Institute — Antiferromagnets play a key role in spintronic applications owing to the exchange bias effect. As devices miniaturize in size and dimension, novel magnetic structures dramatically different from the bulk often emerge. Here we apply spin-polarized scanning tunneling microscopy (SP-STM) at room temperature to study the local magnetization of antiferromagnetic nitride nanostructures. $\text{Mn}_3\text{N}_2(001)$ thin films have been grown on $\text{MgO}(001)$ substrates using molecular beam epitaxy and transferred *in situ* to a home-built SP-STM for magnetic imaging. Results show that the surface consists of alternating chemically in-equivalent atomic terraces. Using SP-STM with dI/dV mapping, different layers can be clearly discriminated due to their different conductances. These differences in conductance are a result of not only the different chemical environments, but also the spin ordering and broken symmetry at the surface. Contrary to expectations, a layer-wise alternating surface anisotropy in these nanopylramids is observed. The presented study enables further investigations of the interplay between growth defects and the formation of intriguing antiferromagnetic domains.

2:54PM D13.00003 Atomic Force Microscopy Incorporated with Magnetic Sample Modulation: a new approach to detect the magnetic nanomaterials, JING-JIANG YU, Nanotechnology Measurements Division, Agilent Technologies, Inc., JAYNE GARNO, Department of Chemistry, Louisiana State University — A new imaging strategy using atomic force microscopy (AFM) for detecting magnetic nanomaterials with much higher spatial resolution and sensitivity than the traditional magnetic force microscopy (MFM) technique is developed [1,2]. This AFM-based imaging mode is referred to as magnetic sample modulation (MSM), since the flux of an AC-generated electromagnetic field is used to induce physical movement of magnetic nanomaterials on surfaces during imaging. The AFM is operated in contact mode using a soft, nonmagnetic tip to detect the physical motion of the sample. By slowly scanning an AFM probe across a vibrating area of the sample, the frequency and amplitude of vibration induced by the magnetic field is tracked by changes in tip deflection. Thus, the AFM tip serves as a force and motion sensor for mapping the vibrational response of magnetic nanomaterials. The investigations are facilitated by nanofabrication methods combining particle lithography with organic vapor deposition and electroless deposition of iron oxide to prepare designed test platforms of magnetic materials at nanometer length scales. Examples of detecting magnetic nanoparticles and magnetic biospecies at single molecular level will be presented [3,4].

3:06PM D13.00004 Uncompensated Magnetization in Antiferromagnets, and New Classification of Exchange Bias Systems, IGOR V. ROSHCHIN, Department of Physics and Astronomy and Materials Science and Engineering Program, Texas A&M University — Exchange bias (EB) is typically observed in a bilayer consisting of a ferromagnet (FM) and an antiferromagnet (AF) as a horizontal shift of the FM hysteresis loop. It is attributed to exchange coupling across the interface. Several experimental findings demonstrate, and most models agree that uncompensated magnetization (UM) in the AF plays an important role in EB. However, the origin of UM remains unknown for most EB systems. Using magnetometry and polarized neutron reflectivity (PNR) we observe UM in antiferromagnet-only, (110)- FeF_2 epitaxially grown on MgF_2 , thin-film samples. The PNR reveals the spatial distribution of the UM. This UM exhibits the so-called “intrinsic exchange bias”: a shift of the hysteresis loop of UM. This effect is similar to the “classical” EB observed in bilayers, except that here, it is observed in a single layer material. The surface is responsible for the macroscopically broken time-reversal symmetry, uncompensated magnetization (UM) in a nominally compensated antiferromagnet [1], and, ultimately, for a new magnetic state. In this magnetic state, zero remanent magnetization cannot be obtained isothermally, because the origin ($M(H=0)=0$) is outside of the major hysteresis loop. Using symmetry group arguments [1] and results of *ab-initio* calculations [2], we argue that it is an equilibrium state. Below T_N , the UM in FeF_2 is coupled to the bulk antiferromagnetic order parameter as supported by several experimental results, including high value of EB field, its temperature dependence, and the absence of the training effect. Based on the proposed origin of the UM and experimental observations for different EB systems, we discuss a new classification of exchange bias systems into two categories, explaining differences in the observed properties.

3:42PM D13.00005 Modeling Scanning SQUID Magnetometry Images of Magnetic Dipoles, LISA QIAN, BEENA KALISKY, BRANNON KLOPFER, BO DWYER, KATHRYN MÖLER, Stanford University — Scanning superconducting quantum interference devices (SQUIDs) with sub-micron sized pick-up loops are the most sensitive detectors of local magnetic flux and can have spin sensitivities down to 100 $\mu\text{B}/\sqrt{\text{Hz}}$. This makes them the ideal candidate for detecting magnetic dipole signals from individual nanomagnets. However, because the image kernel of the SQUID is not usually well known, quantitative analysis of magnetometry images can often be difficult. By using similarly measured SQUID magnetometry of superconducting vortices, we show that it is possible to fit images of magnetic dipoles by combining images of two monopoles. This fitting technique allows us to extract the magnetic moment as well as the information on the spatial extent of the imaged dipole. To quantify the statistical errors of the fit and the systematic errors of the measurement, we fabricated and measured nanomagnet bars of different lengths. This analysis technique, in conjunction with scanning SQUID microscopy, can be used to study individual nanomagnets in a wide variety of fields, ranging from biology to condensed matter physics.

3:54PM D13.00006 ABSTRACT WITHDRAWN —

4:06PM D13.00007 Chemical Segregation in GdFeCo : An X-ray view on Magnetic Coercivity, ALEXANDER REID, SLAC National Accelerator Laboratory, CATHERINE GRAVES, BENNY WU, Dept. of Applied Physics, Stanford University, TIANHAN WANG, Stanford Institute for Materials and Energy Science, Stanford University, ALEXEY KIMEL, ANDREI KIRILYUK, Radboud University Nijmegen, The Netherlands, ARATA TSUKAMOTO, A. ITOH, Nihon University, Japan, JOACHIM STÖHR, SLAC National Accelerator Laboratory, THEO RASING, Radboud University Nijmegen, The Netherlands, HERMANN DÜRR, ANDREAS SCHERZ, SLAC National Accelerator Laboratory — The magnetic coercivity in intermetallic alloys is known to be dominated by microscopic inhomogeneities. These control the characteristics of magnetic switching as they provide nuclei for magnetic domain formation, and the pinning sites governing domain wall propagation. However, such regions exist on nanometer length scales with weak magnetic contrast to their surroundings; their characterization has therefore remained illusive. Here we demonstrate how resonant x-ray scattering is intrinsically sensitive to magnetic changes in a segregated phase. We utilize the fact that magnetic scattering asymmetry directly probes regions where this phase segregation occurs. Our measurements on GdFeCo show strongly temperature dependant magnetic canting in the segregated regions due to local changes in magnetic anisotropy. Understanding the origin and importance of these chemically segregated regions will allow a better understanding of the magnetic switching process in GdFeCo .

4:18PM D13.00008 Using X-Ray Diffraction Microscopy for Imaging Magnetic Domain Structures of Magnetic Thin Films, OLEG KRUPIN, European XFEL GmbH, Germany & SLAC National Laboratory, USA, J.J. TURNER, SLAC National Laboratory, USA, X. HUANG, London Centre for Nanotechnology, University College London, United Kingdom, K.A. SEU, Lawrence Berkeley National Lab, USA, D. PARKS, S. KEVAN, University of Oregon, USA, E. LIMA, K. KISLINGER, Brookhaven National Lab, USA, I. MCNULTY, Argonne National Lab, USA, R. GAMBINO, Material Science and Engineering, Stony Brook University, USA, S. MANGIN, Institut Jean Lamour, CNRS/Nancy-Universite, Nancy, France, S. ROY, P. FISCHER, Lawrence Berkeley National Lab, USA — We report the application of iterative phase retrieval from magnetic x-ray diffraction for imaging magnetic domain structures of magnetic thin films. Using coherent x-ray scattering at the x-ray photon energy corresponding to the $L_{3,2}$ absorption edges of the 3d material Co, we demonstrate that linearly polarized soft x rays can be used to obtain the element specific information about both the amplitude and the phase of magnetic domain structures existing in thin films. We successfully recovered an image of the magnetic structure of an amorphous terbium-cobalt thin film with a spatial resolution of about 75 nm and could differentiate between the magnetization directions, finding qualitative agreement with soft x-ray microscopy images recorded with Fresnel zone plate optics having better than 25 nm spatial resolution.

4:30PM D13.00009 Magnetic order and fluctuations in Fe_3O_4 nanoparticles via coherent X-ray magnetic scattering, KARINE CHESNEL, MATEA TREVINO, YANPING CAI, ANDREW MATTHEW, Physics department, BYU, ROGER HARRISON, Chemistry department, BYU, UT, ANDREAS SCHERZ, SLAC, Stanford, CA — Magnetite (Fe_3O_4) particles exhibit a superparamagnetic behavior when their sizes are in nanometer scale. Such nanoparticles could potentially be used for applications in the medical field. We are interested in investigating the magnetic order and fluctuation dynamics in self-assemblies of such nanoparticles. Our Fe_3O_4 nanoparticles are prepared by an organic route and range from 5 nm to 50 nm in size. They are deposited on membrane where they self-assemble. We have been studying the magnetic order using X-ray resonant magnetic scattering (XRMS) at the SSRL synchrotron facility in Stanford. This unique technique, combined with X-ray Magnetic Circular Dichroism (XMCD), provide information about the spatial distribution of the particles and their magnetic order (1). In addition, the use of coherent light at the SSRL beamline, combined with the application of magnetic field in-situ at different temperatures, allows for studying local magnetic disorder (2) and dynamics of fluctuations near the blocking temperature.

4:42PM D13.00010 Magnetic x-ray scattering, transport and MFM study of strongly correlated $La_{1-x}Sr_xMnO_3$ nanowires¹, XIAOQIAN M. CHEN, TYLER R. NAIBERT, NICK BRONN, JAMES C.T. LEE, SHU WANG, JAMES N. ECKSTEIN, NADYA MASON, RAFFI BUDAKIAN, PETER ABBAMONTE, Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, XIAOFANG ZHAI, None, ANAND BHATTACHARYA, Argonne National Laboratory — Artificial patterning is a promising new approach to studying strongly correlated materials, since a boundary acts as a perturbation that can tip the balance among various competing ground states. We have fabricated large, periodic arrays of 80 nm wide nanowires from epitaxially grown $La_{0.67}Sr_{0.33}MnO_3$ (LSMO) thin films. Their electronic and magnetic properties were studied with resonant soft x-ray scattering (RSXS), transport measurements and magnetic force microscopy (MFM). RSXS measurements revealed a series of structural diffraction peaks that arise from the periodic wire structure. Below the Curie temperature we also observed a series of magnetic superlattice reflections, indicating collective ordering of the magnetic moments into a pattern with a spatial period of five wires. Transport measurements also showed anomalous “telegraph” switching noise at temperatures below 15K, and MFM revealed unusual domain formation. We interpret these results as arising from unusual, boundary-induced magnetic domains interacting via long-ranged, classical magnetic dipole coupling.

4:54PM D13.00011 Local structure and magnetic properties of ultrathin Mn films grown on Si(001), SAMER KAHWAJI, THEODORE MONCHESKY, Dalhousie University, Halifax, Canada, DARYL CROZIER, ROBERT GORDON, Simon Fraser University, Burnaby, Canada — We report on the structural and magnetic properties of ultrathin Mn layers deposited onto Si(001) by molecular beam epitaxy (MBE) at low temperature. X-ray absorption fine structure (XAFS) studies reveal that the structure of the silicide layer that forms depends on the growth temperature of the capping layer. A capping layer grown at 200 °C on 0.35 monolayer (ML) Mn results in a metastable MnSi phase with a B2-like (CsCl) structure, whereas a cap grown at room temperature on 0.5 ML followed by annealing at 200 °C produces a lower coordinated MnSi phase with a B20-like structure. Increasing the Mn thickness from 0.5 to 4 monolayers does not trigger a structural transformation but drives the structure closer to MnSi-B20. Using SQUID magnetometry, we show that the sample with B2-like structure has the largest Mn magnetic moment of $0.33\mu_B/\text{Mn}$ at $T=2$ K, and a Curie temperature T_C above 250 K. MnSi-B20 layers showed lower moments and much lower T_C 's, in-line with those reported for MnSi-B20 thin films.

5:06PM D13.00012 Probing the surface magnetic properties via Auger-photoelectron coincidence spectroscopy, GIAN PAOLO BRIVIO, GUIDO FRATESI, Department of Materials Science, University of Milano Bicocca, Italy, MARIO ITALO TRIONI, CNR- National Research Council of Italy, ISTMI, Milano, Italy, ROBERTO GOTTER, IOM-CNR, Basovizza, Trieste, Italy, GIANNI STEFANI, Department of Physics, University of Roma Tre, Italy — Auger-photoelectron coincidence spectroscopy (APECS) via a dichroic effect is a suitable tool to study complex systems such as magnetic thin films and multilayers. We present clear evidence for such a dichroic effect in the M_{3VV} Auger line shape of Fe films on Cu(001) measured by angle resolved APECS showing final state spin selectivity (triplet vs. singlet components). Using the Fermi Golden rule and the density functional theory formalism, the Auger spectrum and its angular distributions are computed. For magnetic systems, the spin dependence of the Auger matrix elements allows one to work out the individual multiplet contributions to the Auger spectrum. For an accurate interpretation of experiments we also take into account the valence hole-hole interaction affecting the Auger line shape by the Cini-Sawatzky theory but considering a spin dependent on-site interaction U. The calculated angular distribution, in case of a non-spherical ionized core level (e.g. $l=1$, $m=0$), follows a non-trivial behavior in agreement with experiment.

5:18PM D13.00013 Polarized small angle neutron scattering of MnO/Mn_3O_4 nanocrystals, L. DEDON, Y. IJIRI, Department of Physics and Astronomy, Oberlin College, R. BOOTH, Department of Physics, Carnegie Mellon University, K. KRYCKA, J.A. BORCHERS, W.C. CHEN, S. WATSON, NIST Center for Neutron Research, NIST, J.J. RHYNE, Lujan Neutron Scattering Center, Los Alamos National Laboratory, S.A. MAJETICH, Department of Physics, Carnegie Mellon University — Monodisperse magnetic nanoparticles are of great interest for biomedical and data storage applications, particularly in cases where the core and shell can be carefully controlled to alter properties like magnetic anisotropy. However, it is often difficult to determine the underlying moment arrangements and correlations in these systems. Here, we focus on manganese (II) oxide/manganese (II,III) oxide core/shell nanoparticles, using polarized small angle neutron scattering (SANS) to probe the magnetic intra and interparticle interactions. The 30nm diameter particles with 4-5nm shell were prepared by solution chemistry methods and self-assembled into 3D nanocrystals. SANS measurements were conducted in magnetic fields from remanence-1T and temperatures from 10-300K. Magnetic and structural scattering components were separated using an algorithm previously described in [1]. The magnetic signature depended on the field and temperature history of the sample. Modeling work has been done to further quantify the interparticle length scales and the effects of crystal packing. This work was supported in part by NSF grants DMR-0454672, -0704178, -0804779, -1104489, and DOE grant DE-FG02-08ER40481. [1] K.L. Krycka, et al. Phys. Rev. Lett. 104, 207203 (2010).

Monday, February 27, 2012 2:30PM - 5:30PM –

Session D14 DMP GMAG: Focus Session: Spins in Carbon - Spins in Graphene 212

2:30PM D14.00001 Spin transport in graphene, BARBAROS ÖZYILMAZ, Department of Physics, National University of Singapore — Conventional electronic transistors involve the control of electronic charge at the nanoscale to realize memory, logic and communication functions. All these electronic charges, however, also carry a spin that remains unutilized in present commercial devices. This has motivated the search for new materials that propagate spin-polarized currents over large distances. Among the most promising materials for spintronics has been graphene. Micron-scale spin relaxation lengths have been previously demonstrated in single-layer graphene. Recently, we showed that bilayer graphene is a far more interesting candidate for spintronics. By fabricating spin valves on bilayer graphene we have achieved at room temperature spin relaxation times up to 2 nanoseconds, which are an order of magnitude higher than for single layer graphene [1]. Furthermore, the spin-relaxation time scales inversely with the mobility of BLG sample. This indicates the importance of D'yakonov-Perel' spin scattering in BLG. Last not but least, the presence of an electric field tunable band gap in bilayer graphene makes it particularly appealing. Our work provides fundamental insight into the unique properties of bilayer graphene for spintronic applications. Remarkably, a similar difference between single layer and bilayer graphene is also observed in large area graphene grown by the CVD method on copper. These results demonstrate the potential of CVD graphene in realistic spintronics devices [2].

[1] T - Y. Yang et al., Observation of Long Spin-Relaxation Times in Bilayer Graphene at Room Temperature, PRL (2011).

3:06PM D14.00002 Spin Transport in Epitaxial Graphene on SiC (0001), J. ABEL, A. MATSUBAYASHI, University at Albany, C. DIMITRAKOPOULOS, D.B. FARMER, ALI AFZALI, A. GRILL, C.Y. SUNG, IBM T.J. Watson Research Center, V.P. LABELLA, University at Albany — Long spin lifetimes in graphene make it an ideal candidate for the channel material in future spintronic devices. The long spin lifetimes arise due to the small intrinsic spin orbit coupling and low hyper-fine interaction of the electron spins with the carbon nuclei. Spin lifetimes are measured in epitaxially grown graphene on SiC from IBM. The spin lifetime is measured with non-local Hanle measurements to observe spin precession in the graphene. Spin lifetimes are then extracted by fitting to the solution of the Bloch equation with a diffusion term. A comparison will be presented between an injection and detection contact structure with a bare Co/graphene interface and a Co/HfO₂/graphene interface, where it was found that the HfO₂ interface results in an increased spin lifetime. Temperature dependent spin lifetimes and Hall mobilities were measured, and a comparison of the two measurements will also be presented to provide insight into the spin scattering mechanism in epitaxial graphene on SiC.

3:18PM D14.00003 ABSTRACT WITHDRAWN —

3:30PM D14.00004 Spin Dependent Scattering from Gated Obstacles in Graphene Systems¹, MAHMOUD ASMAR, SERGIO ULLÓA, Ohio University — We study scattering of Dirac fermions in the presence of both intrinsic and Rashba spin orbit interactions (SOIs). We use the analytical form of eigenstates in a system with cylindrical symmetry to calculate useful quantities for the scattering of Dirac particles such as phase shifts, and both transport and total cross sections, as well as the corresponding scattering times. At low energies the scattering from a gated obstacle in the absence of SOIs is anisotropic and predominantly forward [1]. In contrast, for energies close to the intrinsic SOI amplitude, the scattering becomes *isotropic*, which can be seen as arising from the effective Dirac mass generated by the SOI interaction. In the presence of Rashba fields we find that the spin-flip scattering is isotropic while it remains anisotropic and predominantly forward for spin-preserving scattering, leading to persistent spin polarization in the forward direction. At high energies, we find a series of resonances in the elastic scattering times, associated with particle trajectories orbiting the obstacle and characterized by long lifetimes. The Rashba SOI is found to double the number of long lived states in both spin-preserving and spin-flip scattering channels. [1]M.Monte Verde et al., PRL **104**,126801 (2010)

¹Supported by NSF-PIRE and NSF-MWN/CIAM.

3:42PM D14.00005 Tunnel spin injection into graphene through ALD-grown tunnel barrier, TAKEHIRO YAMAGUCHI, IIS, Univ. of Tokyo, SATORU MASUBUCHI, IIS and INQIE, Univ. of Tokyo, KAZUYUKI IGUCHI, RAI MORIYA, IIS, Univ. of Tokyo, TOMOKI MACHIDA, IIS and INQIE, Univ. of Tokyo, and PRESTO-JST — Graphene is a promising material for spintronics devices because of its long spin relaxation time due to weak spin-orbit interaction and hyperfine interaction. For the spintronics, it is very essential to develop a reliable method to inject spin polarized electrons into graphene from ferromagnetic electrodes. In this study, between ferromagnetic electrodes and graphene we fabricated a new type of Al₂O₃ tunnel barrier grown by atomic layer deposition (ALD). Before ALD of Al₂O₃, we functionalized the surface of graphene with a self-assembled monolayer of 3, 4, 9, 10 perylene tetracarboxylic acid (PTCA) to improve adhesion and growth of Al₂O₃. Using ALD-Al₂O₃/PTCA composite barrier, large nonlocal magnetoresistance of 30 Ω was observed at 45 K. Nonlocal magnetoresistance reached maximum around charge neutrality point, and *I* – *V* characteristics of the contacts are nonlinear. These results indicate the achievement of tunnel spin injection into graphene, revealing potentially high performance of ALD-Al₂O₃/PTCA tunnel barrier [1]. [1] T. Yamaguchi et al., J. Magn. Magn. Mater. (2011), doi: 10. 1016/j.jmmm. 2011. 09. 031

3:54PM D14.00006 ABSTRACT WITHDRAWN —

4:06PM D14.00007 Spin waves in finite graphene ribbons, ANDREA LATGE, FRANCISCO CULCHAC, ANTONIO COSTA, Instituto de Física, Universidade Federal Fluminense — In a previous work we have shown that the spin excitations of a graphene zigzag ribbon have a dispersion relation predominantly linear for large wave lengths, due to the antiferromagnetic coupling between the magnetizations of the opposite edges. Although the excitations are weakly damped in electrically neutral nanoribbons, the damping can be enhanced by the application of gate voltages. This allows control of the spin relaxation times by purely electrostatic means. Here we investigate spin excitations and also electronic transport in finite zigzag ribbons, connected to graphene-like metallic leads. The ground state is described self-consistently within a mean-field scheme. The spin excitations are extracted from transverse dynamic susceptibility. As a general result we found conductance gaps populated with localized states that are swept out as the length of the conductor increases. The magnetic moment is site dependent, differently from the infinite case, and diverse spin wave excitation modes are exhibited. We study the spin wave behavior and the dynamic susceptibility dependence on the coupling intensity between ribbon and leads. We analyze the role played by the coupling on the spin wave life times and the effects of external doping.

4:18PM D14.00008 GMAG Dissertation Award Talk: Spin Injection and Relaxation in Graphene, WEI HAN, University of California, Riverside — Graphene is a unique and promising candidate for spintronics due to its high mobility, low intrinsic spin-orbit and hyperfine couplings, which should lead to long spin lifetimes and relaxation lengths. Experimentally, the gate-tunable spin transport has been achieved at room temperature. However, the spin injection efficiency has been low and the spin lifetime is still much shorter (50- 200 ps) than expected theoretically (~micro seconds). To fulfill the potential of graphene for spintronics, two major advances are needed to be accomplished; enhance the spin injection efficiency and extend the spin lifetime. In this talk, I will focus on the contributing results for these advancements in graphene spintronics during my Ph. D. study. First, I develop a method to grow atomically smooth MgO tunnel barrier using Ti seeding layer prior the MgO growth on graphene. Then tunneling spin injection into graphene is achieved. The nonlocal spin signal is observed to be as high as 130 ohms at 300 K, with a spin injection efficiency of 30%. Second, using tunneling contacts to suppress the contact-induced spin relaxation, we observed the spin lifetimes as long as 771 ps at 300 K, 1.0 ns at 4 K in SLG, and 6.2 ns at 20 K in bilayer graphene (BLG). Furthermore, contrasting spin relaxation mechanisms are found in SLG and BLG. Third, the spin lifetimes on the same SLG spin valve with tunable mobilities are investigated. These results are important advances for graphene to be used for spin computing or spin logic applications.

4:54PM D14.00009 Magnetism in neutron irradiated graphene samples, YANCEN LI, JOEL THERRIEN, ECE U. Mass Lowell — Recent work in our lab has shown that graphene can become ferromagnetic by way of the addition of hydrogen. The graphene shows a weak but distinct magnetization loop at room temperature. Magnetic force microscopy shows that the magnetic effect can be added and subsequently removed by exposure to a cold hydrogen plasma followed by annealing at 400 Deg C. An outstanding question has been whether the effect observed is due to the interaction of the hydrogen with the graphene, or the addition of defects from the hydrogen. The role of the hydrogen vs. defects was studied using raman microscopy and magnetic force microscopy on graphene samples exposed to neutron irradiation for comparison of a sample containing defects without adatoms.

5:06PM D14.00010 Magnetic Moment Formation in Hydrogenated and Defected Graphene, KATHLEEN MCCREARY, ADRIAN SWARTZ, WEI HAN, ROLAND KAWAKAMI, University of California, Riverside — Recent experimental observations of magnetic moment formation and magnetic ordering in graphene and graphite have excited both theorists and experimentalists. Magnetic ordering in carbon based materials would provide an alternate material to the conventional d and f metals employed in current technologies and could contribute to new applications in nanotechnology, spintronics, medicine, and telecommunications. While still a young and controversial field, previous experimental and theoretical works suggest the presence of magnetic moments in carbon materials is attributed to impurities, boundaries, reduced dimensionality, or defects. In this study, we perform spin transport measurements on graphene devices in order to investigate magnetic moment formation in doped graphene. The graphene surface is modified inside an ultrahigh vacuum chamber through a variety of methods including hydrogen adsorption, Ar sputtering, and molecular beam deposition of transition metals. We observe signatures of paramagnetic moment formation associated with dopants and defects in graphene.

5:18PM D14.00011 Quantum Monte Carlo study of magnetic impurity in bilayer graphene, J.H. SUN, Department of Physics, The Chinese University of Hong Kong, F.M. HU, COMP/Department of Applied Physics, Aalto University, School of Science and Technology, H.K. TANG, HAI-QING LIN, Department of Physics, The Chinese University of Hong Kong — It is expected to observe many different properties in bilayer graphene when compared with single layer graphene due to the differences in crystal structure. Additionally, bilayer system offers a freedom of inducing a gap in the energy band by applying a shift in the electrochemical potential to two graphene layers. In this work, we study the magnetic properties of an Anderson magnetic adatom in Bernal stacking bilayer graphene and compare the results with those of single layer counterpart. Several different cases such as different adatom position and different potential bias of two layers are studied using the quantum Monte Carlo method. In all the cases, we find that the impurity local magnetic moment can be switched between relatively large and small values by tuning the chemical potential. We apply MaxEnT method to compute impurity spectral density and find its behavior to differ from that of an impurity in a single layer graphene. We also calculate various correlation functions and make comparisons.

Monday, February 27, 2012 2:30PM - 5:30PM – Session D15 DMP FIAP GMAG: Focus Session: Spins in Metals - Ultra Fast Dynamics 213

2:30PM D15.00001 Ultrafast Magnetism of Multi-component Ferromagnets and Ferrimagnets on the Time Scale of the Exchange Interaction, ILIE RADU, Radboud University Nijmegen, the Netherlands and Helmholtz-Zentrum Berlin, BESSY II, Germany — Revealing the ultimate speed limit at which magnetic order can be controlled, is a fundamental challenge of modern magnetism having far reaching implications for the magnetic recording industry [1]. Exchange interaction is the strongest force in magnetism, being ultimately responsible for ferromagnetic or antiferromagnetic spin order. How do spins react after being optically excited on a timescale of or even faster than the exchange interaction? Here, we demonstrate that femtosecond (fs) measurements of ferrimagnetic and ferromagnetic alloys using X-ray magnetic circular dichroism provide revolutionary new insights into the problem of ultrafast magnetism on timescales pertinent to the exchange interaction. In particular, we show that upon fs optical excitation the ultrafast spin reversal of GdFeCo - a material with antiferromagnetic coupling of spins - occurs via a transient ferromagnetic state [2]. The latter emerges due to different dynamics of the Gd and Fe magnetic moments: Gd switches within 1.5 ps while it takes only 300 fs for Fe. Thus, by using a single fs laser pulse one can force the spin system to evolve via an energetically unfavorable way and temporarily switch from an antiferromagnetic to a ferromagnetic type of ordering. In order to understand whether the observation of this temporarily decoupled and element-specific dynamics is a general phenomenon or just something strictly related to the case of ferrimagnetic GdFeCo, we have investigated the demagnetization of the archetypal ferromagnetic NiFe alloys. Essentially, we observe the same distinct magnetization dynamics of the constituent magnetic moments: Ni demagnetizes within ~300 fs being much faster than the demagnetization of Fe of ~800 fs. This distinct demagnetization behavior leads to an apparent decoupling of the Fe and Ni magnetic moments on a few hundreds of fs time scale, despite the strong exchange interaction of 260meV (~16 fs) that couples them. These observations supported by atomistic simulations, present a novel concept of manipulating magnetic order on different classes of magnetic materials on timescales of the exchange interaction [3].

3:06PM D15.00002 Uncovering the Ultrafast Angular Momentum Transfer Channels on the Nanoscale in GdFeCo, CATHERINE GRAVES, Stanford University, ALEX REID, Stanford Institute for Materials and Energy Science, BENNY WU, TIANHAN WANG, Stanford University, SANNE DE JONG, Stanford Institute for Materials and Energy Science, ILIE RADU, Radboud University Nijmegen, SASHA EPP, ROBERT HARTMANN, MPG-ASG Hamburg, ARATA TSUKAMOTO, Nihon University, Japan, RYAN COFFEE, MINA BIONTA, JOSHUA TURNER, WILLIAM SCHLOTTER, Linac Coherent Light Source, YVES ACREMANN, ETH Zürich, ALEXEY KIMEL, ANDREI KIRILYUK, Radboud University Nijmegen, JOACHIM STÖHR, Linac Coherent Light Source, THEO RASING, Radboud University Nijmegen, HERMANN DÜRR, ANDREAS SCHERZ, Stanford Institute for Materials and Energy Science — The ultrafast control of electron spins is of both fundamental scientific and technological interest. Recent experiments have shown that femtosecond laser excitation can act as a stimulus to switch the magnetization direction in ferrimagnetic GdFeCo, called all-optical switching. However, how angular momentum is transferred to result in a switched state remains unknown. To further understand this mechanism, we use 80fs x-ray pulses from LCLS to study how angular momentum transfer is triggered in GdFeCo by fs laser excitation using time-, element- and spatially-resolved x-ray resonant magnetic scattering. We present here the first-ever measurement of the fs magnetic response in GdFeCo with spatial resolution down to 10nm. Our results reveal drastically different behaviors on the nanoscale as compared to the bulk and provide insight into the angular momentum transfer channels.

3:18PM D15.00003 Ultrafast Demagnetization Measurements using Extreme Ultraviolet Light: Comparison of Electronic and Magnetic Contributions, CHAN LA-O-VORAKIAT, EMRAH TURGUT, CARSON A. TEALE, HENRY C. KAPTEYN, MARGARET M. MURNANE, JILA/University of Colorado, DENIS LVOVSKY, ROMAN ADAM, PATRIK GRYCHTOL, CLAUS M. SCHNEIDER, Peter Grünberg Institute, Jülich, Germany, STEFAN MATHIAS, MARTIN AESCHLIMANN, University of Kaiserslautern and Research Center OPTIMAS, JUSTIN M. SHAW, HANS NEMBACH, THOMAS J. SILVA, National Institute of Standards and Technology — Ultrashort pulses from high-harmonic generation provide new capabilities for uncovering coupled charge, spin, and phonon dynamics in magnetic materials by combining elemental selectivity with ultrafast time resolution in a tabletop source. In this talk, we address an important question in magneto-optics that has implications for understanding femtosecond magnetism: is the signal from the transverse magneto-optical Kerr effect at the M-shell absorption edges of a magnetic material purely magnetic or perturbed by non-magnetic optical artifacts? We conclusively show that high harmonics sensitively probe the magnetic state, with negligible contributions from electronic effects because of hot-electron dynamics. Finally, our measurements are in excellent agreement with conventional visible-wavelength magneto-optics probes and illustrate the power of high harmonics for probing the dynamics in magnetic materials.

3:30PM D15.00004 Theory of spin hot pockets in laser-induced demagnetization in ferromagnetic nickel¹, GUOPING ZHANG, Department of Physics, Indiana State University, MINGSU SI, Lanzhou University, YIHUA BAI, Center for Instruction, Research and Technology, Indiana State University, THOMAS F. GEORGE, University of Missouri-St. Louis — We will first review the current theory of the demagnetization process, with a particular focus on two distinctive contributions: (a) the optical dipole interaction (ODI) between a laser field and a magnetic system and (b) the spin expectation value change (SEC) between two transition states. We then introduce a new optical spin operator, a product of SEC and ODI between transition states. In ferromagnetic nickel, our first-principles calculation demonstrates that the larger the value of optical spin operator is, the greater the dynamic spin moment change is. This simple operator is very useful, as it directly links the time-dependent spin moment change $\Delta M_z^k(t)$ at every crystal-momentum k point to its intrinsic electronic structure and magnetic properties. Those hot spin pockets should be the focus of future research.

¹Supported by the U. S. Department of Energy under Contract No. DE-FG02-06ER46304, the Office of Science of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231, and DE-AC02-06CH11357, and National Science Foundation of China (NSFC)

3:42PM D15.00005 Ultrafast Transport of Laser-Excited Spin-Polarized Carriers in Metallic Multilayers¹, ALEXEY MELNIKOV, Physical Chemistry Department, Fritz-Haber-Institute of the Max Planck Society, Faradayweg 4-6, 14195 Berlin, Germany — The ultrafast spin dynamics induced by a transport of spin polarized carriers is a hot topic motivated by the fundamental interest in magnetic excitations and applications like spintronics and data storage. To understand underlying elementary processes typically occurring on femtosecond time scales, we have developed a time-of-flight-like approach that probes the spin dynamics induced by hot carriers (HC) and demonstrated a *spin polarized* HC transport through an epitaxial Au/Fe/MgO(001) structure. Using a back pump-front probe configuration, we establish that HC induced in Fe by the pump laser pulse can form a nearly *ballistic* spin current (SC) in Au. Optical second harmonic (SH) generated at the Au surface by the probe pulse monitors the transient surface HC density and spin polarization (SP). Since HC with different SP are excited in Fe to different final energies and consequently have different lifetimes in Au, the HC pulse has steep leading part formed by ballistic HC with the negative SP and shallow trail part formed by diffusive HC with the positive SP. This leads to the SC sign change within the 1 ps overall SC pulse duration. We also make a step towards understanding the origin of laser-induced ultrafast demagnetization overcoming the limited ability of conventional pump-probe schemes to distinguish photon-, electron-, and phonon-mediated effects. Comparing the SH response of Fe to the direct optical excitation with that to the excitation by hot carriers generated in Au, we rule out coherent effects of the pump pulse electromagnetic field and show that the HC-induced spin dynamics is responsible for the ultrafast demagnetization.

4:18PM D15.00006 First-principles dynamical calculation of a pump-probe scenario for the spin flip on NiO, GEORGIOS LEFKIDIS, WOLFGANG HÜBNER, University of Kaiserslautern — Using a fully ab-initio approach we calculate in a dynamic way the time-dependent probe signal of a spin flip scenario on the antiferromagnetic NiO surface. We start from a first-principles calculation of the highly correlated, relativistic, electronic states of a doubly embedded NiO_5^{--8} cluster followed by the time-propagation of the system under the influence of the spin-flipping pump pulse *and* the detecting probe pulse. This way we treat both pulses on equal footing and, for the first time, consider the effects of the electronic non-equilibrium due to the concurrent presence of the pulses. Our time-resolved calculations reveal the subtle influence of the probe pulse itself on the detection signal, which cannot be completely treated solely by the time propagation of the pump pulse and the subsequent calculation of the static susceptibility tensor [1,2]. We also analyze the angular-momentum conservation and its distribution among the system and both laser pulses [3].

4:30PM D15.00007 Non-equilibrium coupling and femto-second oscillatory spin torque in non-collinear F/N/F magnetic multilayers¹, JIANWEI ZHANG, QIANG WANG, Dept. of Physics, Tongji University — By employing time-dependent diffusion theory, we study time-evolution behaviors of spin torque and spin current in non-collinear Ferromagnetic/Normal/Ferromagnetic tri-layers structure. We find in ferromagnetic layer spin torque has femto-second oscillatory in its initio building-up process, which indicates that excited itinerant electron's spin process alone background magnetization in femto-second period near the interfacial region. We also find even mismatch of background magnetization at each F/N interfaces is not enough to compensate discontinuity of spin current near interface, however, by introducing non-equilibrium coupling between two F/N interfaces, one can produce a continuous spin current state across both two interfaces without mandating any boundary conditions. In our study, we find a new universal time-dependent propagator to generate all directions continuous spin current across two F/N interfaces. This new spin propagator is also closely related to spin flip scatter at interface. In addition, we also find the coupling of two N/F interfaces enlarges transverse spin diffusion channels into magnetic layer. Finally, our time-dependent spin current and spin torque states also match our pervious self-consistent steady state results.

4:42PM D15.00008 Probing the timescale of the exchange interaction in a ferromagnetic alloy, EMRAH TURGUT, CHAN LA-O-VORAKIAT, MARK E. SIEMENS, MARGARET M. MURNANE, HENRY C. KAPTEYN, JILA, University of Colorado, Boulder, STEFAN MATHIAS, PATRICK GRANITZKA, STEFFEN EICH, MARTIN AESCHLIMANN, University of Kaiserslautern and Research Center OPTIMAS, Germany, PATRIK GRYCHTOL, ROMAN ADAM, CLAUS M. SCHNEIDER, Peter Grünberg Institute, Research Center Jülich, Germany, JUSTIN M. SHAW, HANS T. NEMBACH, THOMAS J. SILVA, National Institute of Standards and Technology, Boulder — The underlying physics of all ferromagnetic behavior is the cooperative interaction between individual atomic magnetic moments that results in a macroscopic magnetization. In this work, we use extreme ultraviolet pulses from high-harmonic generation as an element-specific probe of ultrafast, optically driven, demagnetization in a ferromagnetic Fe-Ni alloy (Permalloy). We show that for times shorter than the characteristic timescale for exchange coupling, the magnetization of Fe quenches more strongly than that of Ni. Then, as the Fe moments start to randomize, the strong ferromagnetic exchange interaction induces further demagnetization in Ni, with a characteristic delay determined by the strength of the exchange interaction. We can further enhance this delay by lowering the exchange energy by diluting the Permalloy with Cu. This measurement probes how the fundamental quantum mechanical exchange coupling between Fe and Ni in magnetic materials influences magnetic switching dynamics in ferromagnetic materials relevant to next-generation data storage technologies.

4:54PM D15.00009 Driving coherent spin reorientation transition with femtosecond laser pulses, VLADIMIR STOICA, ROY CLARKE, Physics Department, University of Michigan — Ultrafast studies of spin reorientation transition provide insight in magnetization switching processes and are important for the magnetic recording technology. Using femtosecond optical techniques, we demonstrate coherent control of the magnetization vector in epitaxial Fe films. These films feature uniaxial anisotropy that is thermally modulated by an optical pulse. We observe an optically-induced spin reorientation transition of first-order that provides an efficient route to ultrafast coherent magnetization switching. The switching is found to be a three-step temporal process: a coherent reorientation (~ 100 ps) is followed by a spin precession in a newly created metastable state (~ 300 ps), which evolves into a dual domain state that undergoes relaxation within $\sim 2 - 4$ ns. We provide a model to explain the experimental data and predict further applications of this technique. The details of the experiments compare favorably with the simulated magnetization trajectories, opening new pathways for coherent control of magnetic dynamics with pulsed lasers.

5:06PM D15.00010 Theory of the inverse Faraday effect driven by non-coplanar spin structures, KATSUHISA TAGUCHI, GEN TATARA, Tokyo Metropolitan University — We show theoretically that a new mechanism of the inverse Faraday effect exists in the presence of non-coplanar spin structures in metals even without the spin-orbit interaction. The spin density generated by the effect is proportional to the circular polarization of the light, $(\mathcal{E} \times \mathcal{E}^*)$ ($\mathcal{E}$ is the complex amplitude vector of the electric field of the circular light), and $\nabla \times \mathbf{j}_s^\alpha$, where $\mathbf{j}_s^\alpha \equiv (\mathbf{n} \times \nabla \mathbf{n})^\alpha$ is the spin current carried by the spin structure ($\mathbf{n}$ is the unit vector of the localized spin). The effect turns out to be larger than the conventional inverse Faraday effect, and the present mechanism is expected to be useful for the magnetization flip of the Skyrmion.

5:18PM D15.00011 Examination of spin waves in a two-dimensional magnetic superlattice¹, GLADE SIETSEMA, MICHAEL FLATTÉ, University of Iowa — We have studied the properties of spin waves in two-dimensional periodic superlattices of magnetic materials.[1] Frequencies and linewidths are calculated for square and hexagonal symmetry superlattices from the Landau-Lifshitz-Gilbert equations. Large differences in the saturation magnetizations and exchange stiffness constants of the materials are shown to be capable of producing gaps in the magnonic spectrum across the entire superlattice Brillouin zone. For example, with a hexagonal superlattice of Fe and YIG we find gaps of 0.5THz and 1THz within the lowest four bands. Additionally, calculations of the system's Green's functions are used to examine the superlattice's response to pulse excitations, such as from a spin torque oscillator.

2:30PM D16.00001 Local and non-local correlations in nanoscopic systems, GIORGIO SANGIOVANNI, A. VALLI, G. ROHRINGER, A. TOSCHI, K. HELD, Vienna University of Technology, H. DAS, Cornell University, T. SAHA-DASGUPTA, Bose National Centre for Basic Sciences — Tools for reliably treating nanoscopic systems, like coupled quantum-dots, ad-atoms on surfaces, macromolecules, etc., in the presence of electronic correlations are either missing or prohibitively expensive. We have implemented a new computational scheme based on a self-consistently defined set of local problems [1]. Our method scales linearly with the number of sites and allows us to perform large-scale sign-problem free Quantum Monte-Carlo simulations. We have studied the behavior of a single-atom junction formed upon stretching a metallic wire and found that a metal-insulator crossover is induced when the wire is about to break up. The combination with ab-initio techniques allowed us to study size-dependent properties of Manganite nano-clusters [2]. The simplest implementation of our method includes only local self-energy effects. We recently went beyond this and applied the resulting more sophisticated version of our method to an exactly solvable model finding results in remarkable agreement with the exact solution.

2:42PM D16.00002 Quantum impurity solver based on truncated ED (RASCI) wave function expansion¹, DOMINIKA ZGID, EMANUEL GULL, CHRIS MARIANETTI, ANDREW MILLIS, DAVID REICHMAN, Columbia University, GARNET CHAN, Cornell University — Quantum impurity models appear in many applications, including nanoscience and the dynamical mean field approximation (DMFT). Many physically relevant impurity models are too large to be solved by exact diagonalization (ED), lack the interaction and hybridization structure required for quantum Monte Carlo (QMC) simulations, or suffer from a severe sign problem. We present an alternative impurity solver inspired by configuration interaction (RASCI) techniques of quantum chemistry and based on a controlled truncation of a wave function expansion. The method can access larger impurity models (impurities with 5 *d*-orbitals and 20 bath orbitals can be easily calculated on a single processor) than can ED and avoids the sign problems of QMC methods. The performance is demonstrated for a cluster DMFT approximation to the two dimensional Hubbard model and for the problem of a Co adatom on a Cu(111) surface.

2:54PM D16.00003 Modified Iterated perturbation theory in the strong coupling regime and its application to the 3d FCC lattice¹, LOUIS-FRANÇOIS ARSENAULT, (1) Departement de Physique and RQMP, Université de Sherbrooke, Sherbrooke, QC, Canada, PATRICK SÉMON, (1), B. SRIRAM SHASTRY, (2) Physics Department, University of California, Santa Cruz, CA 95064, USA, A.-M.S. TREMBLAY, (1,3) Canadian Institute for Advanced Research, Toronto, Ontario, Canada — The Dynamical Mean-Field theory(DMFT) approach to the Hubbard model requires a method to solve the problem of a quantum impurity in a bath of non-interacting electrons. Iterated Perturbation Theory(IPT)[1] has proven its effectiveness as a solver in many cases of interest. Based on general principles and on comparisons with an essentially exact Continuous-Time Quantum Monte Carlo (CTQMC)[2], here we show that the standard implementation of IPT fails when the interaction is much larger than the bandwidth. We propose a slight modification to the IPT algorithm by requiring that double occupancy calculated with IPT gives the correct value. We call this method IPT- D . We show how this approximate impurity solver compares with respect to CTQMC. We consider a face centered cubic lattice(FCC) in 3d for different physical properties. We also use IPT- D to study the thermopower using two recently proposed approximations[3] S^* and S_{Kelvin} that do not require analytical continuation and show how thermopower is essentially the entropy per particle in the incoherent regime but not in the coherent one.[1]H.Kajueter et al. Phys. Rev. Lett. 77, 131(1996)[2]P. Werner, et al. Phys. Rev. Lett. 97, 076405(2006)[3]B.S. Sriram Shastry Rep. Prog. Phys. 72 016501(2009)

3:18PM D16.00005 Dual fermion dynamical cluster approach for strongly correlated systems, SHUXIANG YANG, Department of Physics & Astronomy, Louisiana State University, HERBERT FOTSO, Department of Physics, Georgetown University, HARTMUT HAFERMANN, Centre de Physique Théorique, Ecole Polytechnique, CNRS, France, KA MING TAM, JUANA MORENO, Department of Physics & Astronomy, Louisiana State University, THOMAS PRUSCHKE, Department of Physics, University of Goettingen, Germany, MARK JARRELL, Department of Physics & Astronomy, Louisiana State University — A multi-scale many-body approach is developed for strongly-correlated electron systems by combining the dynamical cluster approximation (DCA) and the recently introduced dual fermion formalism. This approach systematically incorporates non-local corrections to the DCA by employing an exact mapping from a real lattice to a DCA cluster of linear size L_c embedded in a dual fermion lattice. The Green function in the dual space serves as a small parameter enabling the use of a diagrammatic perturbation calculation on the dual fermion lattice. For example, the dual fermion self-energy calculated with simple second-order perturbation theory scales as $\mathcal{O}(1/L_c^3)$. We demonstrate the effectiveness of the approach by applying it to the 2D Hubbard model.

3:30PM D16.00006 Extended Correlation in Strongly Correlated Systems, Beyond Dynamical Cluster Approximation, HERBERT FOTSO, Department of Physics, Georgetown University, SHUXIANG YANG, Department of Physics and Astronomy, Louisiana State University, HARTMUT HAFERMANN, Centre de Physique Théorique, Ecole Polytechnique, KA-MING TAM, JUANA MORENO, Department of Physics and Astronomy, Louisiana State University, THOMAS PRUSCHKE, Department of Physics, University of Goettingen, MARK JARRELL, Department of Physics and Astronomy, Louisiana State University, LOUISIANA STATE UNIVERSITY COLLABORATION, ECOLE POLYTECHNIQUE COLLABORATION, UNIVERSITY OF GOETTINGEN COLLABORATION — We present a new multi-scale approach for strongly correlated systems that combines the Dynamical Cluster Approximation and the recently introduced dual-fermion formalism. This approach employs an exact mapping from a real lattice to a DCA cluster of linear size L_c embedded in a dual fermion lattice. The short-length-scale physics is addressed by DCA cluster calculations, while the longer-length-scale physics is addressed diagrammatically using dual fermions. The bare and dressed dual fermionic Green functions scale as $\mathcal{O}(1/L_c)$, so perturbation theory on the dual lattice converges very quickly. E.g., the dual Fermion self-energy calculated with simple second order perturbation theory is of order $\mathcal{O}(1/L_c^3)$, with third order and three-body corrections down by an additional factor of $\mathcal{O}(1/L_c)$.

3:42PM D16.00007 Extension of dual-fermion formalism towards disordered systems, HANNA TERLETSKA, Louisiana State University, Brookhaven National Lab, SHUXIANG YANG, ZI YANG MENG, SANDEEP PATHAK, KA MING TAM, JUANA MORENO, MARK JARRELL, Louisiana State University — To study the correlation effects in disordered materials, we extend the recently developed dual fermion approach [1] to include systems with disorder. In particular, we consider the effect of nonlocal disorder-induced correlations in the non-interacting Anderson model. Within this method, such nonlocal effects are included in a systematic way as an expansion to the coherent potential approximation (CPA). The ability to properly treat the nonlocal correlations and provide non-local corrections to the CPA, is crucial for the description of the electron localization. In our analysis, we consider the density of states and localization effects and compare them with the existing results. [1] A.N. Rubtsov, et. al., Phys. Rev. B **79**, 045133 (2009).

3:54PM D16.00008 Application of the Dual Fermion-Dynamical Cluster Approach to the 1D Falicov Kimball Model, SANDEEP PATHAK, ZI YANG MENG, S.-X. YANG, MARK JARRELL, JUANA MORENO, Louisiana State University — The Falicov Kimball model is the simplest model for correlated electrons. It was introduced to study metal-insulator transitions. In one dimension, it is known to possess a charge density wave (CDW) instability at zero transition temperature (T_c). However, finite cluster methods like Dynamical Mean Field Theory (DMFT), Dynamical Cluster Approximation (DCA), Cellular Dynamical Mean Field Theory (CDMFT), etc. show finite temperature CDW transition. In this paper, we study the model using the recently developed Dual Fermion-Dynamical Cluster approach that takes into account large length scale correlations through the auxiliary particles known as dual Fermions. We find that T_c obtained from this method is lower than that obtained from the cluster methods. In particular, we study the scaling behavior of T_c with the linear cluster size and also the scaling of other one-particle and two-particle quantities near the criticality.

4:06PM D16.00009 Phase Separation and Charge-Ordered Phases of the $d = 3$ Falicov-Kimball Model at $T > 0$: Temperature-Density-Chemical Potential Global Phase Diagram from RG Theory¹, A. NIHAT BERKER, Sabanci University and MIT, OZAN S. SARIYER, Koc University and U of North Carolina, MICHAEL HINCZEWSKI, U of Maryland and F Gursay Res Inst — The global phase diagram of the spinless FK model in $d=3$ is obtained by renormalization-group theory, exhibiting 5 distinct phases. Four of these phases are charge-ordered (CO) phases, in which the system forms two sublattices with different electron densities. The CO phases occur near half filling of the conduction electrons, for the entire range of localized electron densities. Phase boundaries are second order, except for the intermediate and large interaction regimes, where a first-order phase boundary occurs in the central region of the phase diagram, resulting in phase coexistence near half filling of both localized and conduction electrons. These two-phase or three-phase coexistence regions are between different charge ordered phases, between charge-ordered and disordered phases, and between dense and dilute disordered phases. The second-order phase boundaries terminate on the first-order transitions via critical endpoints and double critical endpoints. The first-order phase boundary is delimited by critical points. The phase diagram cross-sections with respect to the chemical potentials and densities of the localized and conduction electrons, at all representative interaction strengths, hopping strengths, temperatures, are calculated and exhibit 10 distinct topologies.

4:18PM D16.00010 Collective Excitations and Stability of the Excitonic Phase in the Extended Falicov–Kimball Model, DENIS I. GOLOSOV, Dept. of Physics, Bar-Ilan University, Israel — We consider the excitonic insulator state (often associated with electronic ferroelectricity), which arises on the phase diagram of an extended spinless Falicov–Kimball model (FKM) at half-filling. Within the Hartree–Fock approach, we calculate the spectrum of low-energy collective excitations in this state up to second order in the narrow-band hopping and/or hybridisation. This allows to probe the mean-field stability of the excitonic insulator. The latter is found to be unstable when the case of the pure FKM (no hybridisation with a fully localised band) is approached. The instability is due to the presence of another, lower-lying ground state and *not* to the degeneracy of the excitonic phase in the pure FKM. The excitonic phase, however, may be stabilised further away from the pure FKM limit. In this case, the low-energy excitation spectrum contains new information about the properties of the excitonic condensate (likely including the critical temperature).

4:30PM D16.00011 Propagation of entanglement in one-dimensional models of many-body localization, JENS H. BARDARSON, UC Berkeley & Lawrence Berkeley National Laboratory, FRANK POLLMANN, Max-Planck-Institute for the Physics of Complex Systems, JOEL E. MOORE, UC Berkeley & Lawrence Berkeley National Laboratory — An important and still unanswered fundamental question is whether a closed quantum system of many interacting particles can be localized by disorder. The time evolution of an initially unentangled state is studied for a 1D random-field XXZ Hamiltonian. Even for weak interactions, when the system is thought to be in a many-body localized phase, entanglement shows neither localized nor diffusive behavior: interactions act as a singular perturbation on the truly localized state with no interactions. The logarithmic time dependence of entanglement observed rather suggests a broad range of time scales typical of glassy behavior.

4:42PM D16.00012 Fidelity Spectrum in Quantum Phase Transitions, WING CHI YU, SHI-JIAN GU, HAI-QING LIN, The Chinese University of Hong Kong — A quantum phase transition (QPT) is incarnated by an abrupt change in the qualitative structure in the ground state wavefunction of a many-body system as the external driving parameter varies. The ground state fidelity, which is a measure of similarity between two states, is expected to show a sudden drop across the transition point and its possibility as a witness to QPTs has raised much interest in recent years. However, the ground state fidelity does not capture much information about the contribution of the low-lying excitations. In this presentation, we introduce the concept of fidelity spectrum, i.e. the matrix elements of $M = |\Psi(\lambda)\rangle\langle\Psi(\lambda + \delta\lambda)|$, where λ is the external driving parameter and $\Psi(\lambda)$ is the wavefunction of the system at λ . By studying the fidelity spectrum, we hope to shed light on the role of excited states played in QPTs. We investigate the fidelity spectrum in two many-body systems, namely the one-dimensional transverse-field Ising model and the two-dimensional Kitaev model defined on a honeycomb lattice. We found that in different phases, as well as at the critical points, the fidelity spectrum shows significant different behaviors.

4:54PM D16.00013 ABSTRACT WITHDRAWN —

5:06PM D16.00014 Quantum Monte Carlo calculation of reduced density matrices, LUCAS WAGNER, University of Illinois at Urbana-Champaign — Quantum Monte Carlo (QMC) methods offer an efficient way to approximate the interacting ground state and some excited states of realistic model Hamiltonians based on the fundamental Coulomb interaction between electrons and nuclei. Many highly accurate results have been obtained using this method; however, it is often a challenge to extract the important correlations that the QMC wave function contains. I will describe some new results using the reduced density matrices (RDM's) to understand the electron correlation in the many-body wave function. The RDM's have both informative usage for describing correlation and pragmatic uses in further improving the variational wave function.

Session D17 DMP: Focus Session: Surfaces and Interfaces in Nonoxide Nanostructures: Growth, Structure, and Characterization - Growth Dynamics 252A

2:30PM D17.00001 Factors that control the morphology of ice films on metal surfaces¹, NORMAN BARTELT, Sandia National Laboratories — Examination of the equilibrium nanoscale morphology of ice films provides important clues about the energetics of water-metal interactions [1]. In this talk I compare STM and DFT results for the structure of ice films on Pt(111) and Ni(111). Because the lattice constants of Ni and Pt differ by 10%, this comparison allows us to probe the effect of lattice misfit on ice nucleation and growth. On both substrates, STM suggests a first molecular water layer very different from bulk ice: besides the usual hexagonal rings they also both contain a motif of pentagons and heptagons [2]. Furthermore, at 140K, thicker films on both substrates dewet the substrate to lower interfacial energy by forming 3-dimensional ice crystallites several nanometers thick [3]. However, despite these similarities, there are striking differences in the submonolayer structure and in the kinetics of the dewetting process. Using DFT calculations as a guide, I will discuss how these differences can be related to substrate lattice constant and draw conclusions about the processes that control ice film morphology.

3:06PM D17.00002 Structure and dynamics of water nano-droplets on graphene, MING MA, ANGELOS MICHAELIDES, GABRIEL AEPPLI, London Centre for Nanotechnology, University College London — The wettability of graphene and the diffusion of water droplets across it is of central importance to many emerging applications in nanofluidics. Here we report an extensive set of molecular dynamics simulations for water clusters of varying sizes on graphene (20 to 2,000 water molecules), using force field parameters fitted to recent ab initio quantum Monte Carlo data [J. Ma, A. Michaelides, D. Alfe, L. Schimka, G. Kresse, and E. G. Wang, Phys. Rev. B 84, 033402 (2011)]. The contact angle for the water droplets obtained here, with our ab initio water - carbon interaction, is in very good agreement with experiments. A strong size dependence in the diffusion of the water droplets across the surface is also observed. This work is a step towards understanding surface transportation in carbon based nanofluidics.

3:18PM D17.00003 Large-scale simulations of glancing-angle deposition¹, JACQUES AMAR, XUEJING LIU, University of Toledo — While thin-films grown via glancing-angle deposition have interesting structural, mechanical, and optical properties, the large range of time- and length-scales makes realistic simulations difficult. Accordingly, while activated relaxation processes may be important at long time-scales, here we focus on the deposition process since we expect the effects of shadowing and deposition-induced relaxation to dominate for large deposition angles. In particular, by taking advantage of the speed of recently developed graphical-processing-units (GPUs) we have carried out “large-scale” GPU-enhanced MD simulations of Cu/Cu(100) growth up to 20 monolayers (ML) for deposition angles θ (corresponding to the angle with respect to the substrate normal) ranging from 50° to 85° and for both random and fixed azimuthal angles. In general, we find good agreement with experimental results for the dependence of thin-film porosity on deposition angle and film-thickness. Results for the dependence of the surface roughness, lateral correlation length and microstructure (e.g. defect density, vacancy density, and strain) on the deposition angle and film thickness will also be presented.

3:30PM D17.00004 Shape transitions in strained Cu islands on Ni(100): kinetics versus energetics¹, YUNSHI SHIM, JACQUES AMAR, University of Toledo — We examine the shape transition from compact to ramified islands observed in submonolayer Cu/Ni(100) growth. Recently, it has been argued that this transition is not due to a growth instability but can be understood in terms of energetic arguments. In order to determine the responsible mechanisms we have carried out energetics calculations as well as temperature-accelerated dynamics (TAD) and kinetic Monte Carlo (KMC) simulations. Our results indicate that the shape transition cannot be explained by equilibrium arguments, but is instead due to kinetic effects which are mediated by strain. In particular, by calculating the relevant line-tension and strain energies, we find that the equilibrium critical island-width is at least four orders of magnitude larger than the experimentally observed arm-width. In contrast, our TAD simulations indicate that unexpected concerted motions occurring at step edges are responsible. The energy barriers for these concerted motions decrease with increasing island size and appear to saturate for islands larger than 300 - 400 atoms. By including these strain-induced kinetic processes in our KMC simulations of island-growth, we have been able to explain both the temperature- and coverage-dependence of the island morphology.

3:42PM D17.00005 Dewetting Processes in Ultra-thin Epitaxial Ag Films on Si(111), CHARLOTTE E. SANDERS, JISUN KIM, C.K. SHIH, UT Austin — The authors have recently reported the development of a technique to grow large-area, single-crystal, atomically smooth Ag films on Si(111), and have demonstrated the utility of such films for plasmonics applications: the films support surface plasmon polaritons with extremely low damping. Although the authors have observed that films with thickness on the order of several tens of nanometers can be relatively stable against dewetting—at least on a time scale long enough for fabrication and EOT probing under ambient conditions—they have also seen that very thin Ag films (e.g., 5 nm) start dewetting under ambient conditions within about 24 hours. This raises an important question: how and why does dewetting occur? The authors have now undertaken a detailed and systematic study of the mechanism of dewetting in epitaxial Ag films on Si(111) as a function of film thickness. The current presentation will focus on this work, and will attempt to shed light on the apparent robustness of films grown using their method.

3:54PM D17.00006 Diffusion of a Ga adatom on the GaAs(001)- $c(4 \times 4)$ -heterodimer surface: A first-principles study¹, SANJAY KHARE, JASON ROEHL, SANDEEP ARAVELLI, University of Toledo, RAY PHANEUF, University of Maryland — The adsorption and diffusion behavior of a Ga adatom on the GaAs(001)- $c(4 \times 4)$ -heterodimer surface were studied by employing ab initio density functional theory computations in the local density approximation. Structural and bonding features of the $c(4 \times 4)$ -heterodimer reconstruction surface were examined. A comparison with the $c(4 \times 4)$ -ss reconstruction² was performed. Minimum energy sites (MES) on $c(4 \times 4)$ -heterodimer surface were located by mapping the potential energy surface for a Ga adatom. Barriers for diffusion of a Ga adatom between the neighboring MES were calculated by using top and exchange diffusion mechanisms. We proposed two unique diffusion pathways for a Ga adatom diffusing between the global minimums of two neighboring unit cells. Signature differences between electronic structures of top- and exchange- diffusion mechanisms were studied for relevant atoms. We observed a higher diffusion barrier for exchange mechanism compared to top hopping.³

4:06PM D17.00007 Voronoi Cell Patterns: theoretical model and application to submonolayer growth¹, DIEGO LUIS GONZÁLEZ², T.L. EINSTEIN, U. of Maryland — We use a simple fragmentation model to describe the statistical behavior of the Voronoi cell patterns generated by a homogeneous and isotropic set of points in 1D and in 2D. In particular, we are interested in the distribution of sizes of these Voronoi cells. Our model is completely defined by two probability distributions in 1D and again in 2D, the probability to add a new point inside an existing cell and the probability that this new point is at a particular position relative to the preexisting point inside this cell. In 1D the first distribution depends on a single parameter while the second distribution is defined through a fragmentation kernel; in 2D both distributions depend on a single parameter. The fragmentation kernel and the control parameters are closely related to the physical properties of the specific system under study. We apply our model to describe the Voronoi cell patterns of island nucleation for critical island sizes $i=0,1,2,3$. Experimental results for the Voronoi cells of InAs/GaAs quantum dots are also described by our model.

4:18PM D17.00008 Aberration corrected Low Energy Electron Microscopy for Surface and Interface Studies, RUDOLF TROMP, IBM T.J. Watson Research Center — Correction of spherical and chromatic aberrations of the electron microscope objective lens constitutes one of the most significant and far-reaching breakthroughs in electron optics in the last 20 years. For instance, with the TEAM microscope it is now possible to image atoms with a spatial resolution of 50 picometers, providing a detailed real-space view of the carbon atoms in a single sheet of graphene. Similarly, the resolution on Low Energy Electron Microscopy (LEEM) has improved from a typical value of 5 nm, to less than 2 nm, at an electron energy of just a few eV. Photo Electron Emission Microscopy (PEEM) has recently achieved a resolution of 5 nm. In this talk I will discuss the successful implementation of electron-mirror based aberration correction in LEEM. Some of the details of the electron optical implementation will be discussed, in particular the unique optical properties of the electron mirror, and its mode of operation. Quantitative methods to verify proper control of the optical parameters and successful aberration correction have been developed and implemented in this new instrument. Spatial resolution has improved by more than a factor 2 as compared to the uncorrected instrument, and an ultimate spatial resolution below twice the wavelength of the electron at the sample appears to be achievable. In comparison, the highest resolution Transmission Electron Microscopes have a spatial resolution of about 20 electron wavelengths.

4:54PM D17.00009 LEEM and STM studies of Ag on Ge (110)¹, BRET STENGER, CORY MULLETT, MARSHALL VAN ZIJLL, EMILIE HUFFMAN, DYLAN LOVINGER, SHIRLEY CHIANG, University of California Davis — The growth of Ag deposited on Ge(110) was studied with low energy electron microscopy (LEEM) and scanning tunneling microscopy (STM). The LEEM studies showed the formation of long one dimensional islands as Ag was deposited above 430 °C. Island nucleation proceeded from defects in the Ge substrate. During deposition, the length of the islands increased while the width remained constant. The size and distribution of the islands was dependent on the substrate temperatures during deposition. At 480 °C, islands were 100 nm wide and 1-20 μm long at 9 ML of coverage. At 530 °C, islands were 200nm wide and 1-3 μm long at 9 ML of coverage. STM images showed that the islands were composed of Ag and that the surface regions between the islands exhibited a reconstruction which is characteristic of pure Ge.

5:06PM D17.00010 LEEM Observations of Ag/Ge(111) Structural Phases and Phase Transformations¹, SHIRLEY CHIANG, CORY MULLETT, University of California Davis — We use low energy electron microscopy (LEEM) to study the growth of, and transformations between structural phases of Ag deposited on Ge(111) above and below the Ag desorption temperature. Ag deposited on Ge(111) forms three main surface phases above 100 °C: (4x4), ($\sqrt{3}\times\sqrt{3}$)R30°, and (3x1). For deposition between 540-575 °C, a (3x1) phase grows. Upon the completion of the growth of the (3x1) phase, a ($\sqrt{3}\times\sqrt{3}$)R30° phase grows. For sufficiently high Ag deposition rates, we observed the same growth sequence above the Ag desorption temperature of 575 °C, up to 640 °C. Desorption above 575 °C proceeds with the reverse sequence: the ($\sqrt{3}\times\sqrt{3}$)R30° phase desorbs followed by desorption of the 3x1 phase. Above 640 °C, we observed the growth of the (3x1) phase but not the ($\sqrt{3}\times\sqrt{3}$)R30°. For 4x4 and ($\sqrt{3}\times\sqrt{3}$)R30° surfaces prepared by deposition between 200-500 °C we observe the transformation of these phases to a 1x1 disordered phase at the desorption temperature (575 °C), with desorption proceeding from the edges of disordered 1x1 domains.

5:18PM D17.00011 Crystalline Structure of the Pb/Si(111)7x7 Stable Wetting Layer, M. GRAMLICH, S.T. HAYDEN, YIYAO CHEN, U. Missouri, C. KIM, Kyun Hess U., Korea, M.C. TRINGIDES, Ames Lab-USDOE, P.F. MICELI, U. Missouri — The wetting layer formation in the Pb/Si(111)7x7 system has attracted extensive interest because of anomalously fast kinetics, which enables the formation of quantum size effect (QSE) nanoislands [Jeffrey et al. PRL **96**, 106105 (2006)]. However, previous studies of the wetting layer by x-ray diffraction and scanning-probes have led to *inconsistent* structural models; thus, the structure of this wetting layer has been unsolved. Furthermore, a recent investigation has revealed that the wetting layer is out-of-equilibrium over a surprisingly broad temperature range [Gramlich et al., PRB **84**, 075433 (2011)]. Using *in situ* x-ray scattering methods, we have solved the *stable*, low temperature annealed structure of the wetting layer. It exhibits a strained atomic layer where Pb atoms are in transition, from Si-7x7 sites towards 8x8-sites, with some Pb-atoms vertically closer to the Si-7x7. Interestingly, the Si adatoms shift to the edges of the unit cell. Funding is acknowledged from NSF DMR-0706278 (PFM, MWG, STH, YC, and the Ministry of Knowledge Economy of Korea 2009-F014-01 (CK). The experiments were performed on the 6IDC beam line, supported by the US-DOE (through Ames Lab, W-7405-Eng-82), at the Advanced Photon Source (US-DOE, W-31-109-Eng-38) located at Argonne National Laboratory.

Session D18 DMP: Focus Session: Nanostructures and Metamaterials, Growth, Structure, and Characterization – What is a good conductor for Metamaterials and Plasmonics 252B

2:30PM D18.00001 Manipulating Plasmons Using Graphene for One-Atom-Thick Optical Signal Processing, NADER ENGHETA, University of Pennsylvania — In this talk, we provide an overview of our recent theoretical work on merging the field of graphene with metamaterials and transformation optics. In particular, we show that the control and variation of graphene's conductivity, spatially and temporally, may offer a one-atom-thick platform for manipulation of optical signals propagating along the single sheet of graphene as the surface Plasmon polariton (SPP) surface waves. Since the phase velocity of the SPP surface wave directly depends on the graphene conductivity, tailoring the conductivity can be regarded as a “knob” to control and shape the propagation of such SPP across the graphene. We have shown that such inhomogeneous distribution of conductivity across the graphene gives rise to the notion of one-atom-thick transformation optics and metamaterials—essentially thinnest possible metamaterials [A. Vakil, N. Engheta, *Science*, **332**, 1291 (2011)]. Additionally we have demonstrated, theoretically and using computer simulations, that one can achieve optical signal processing functions such as Fourier transforming across a single layer of graphene [A. Vakil, N. Engheta, “Fourier Optics on Graphene” *ArXiv* 1108.5218 (2011)]. The graphene-based Fourier optics suggests prospects for multilayer signal processing, allowing for design of ultra-compact nanoscale signal processing systems. We are also investigating other optical manipulation, such as waveguiding, field confinement in cavities, graphene antennas, optical spectrometry, and optical mirror reflection, all on one-atom-thick structures. In this talk, we will present some of our results on these topics.

3:06PM D18.00002 Graphene, superconductors, and metals: What is a good conductor for metamaterials and plasmonics?¹, PHILIPPE TASSIN, Vrije Univ. Brussel and Ames Lab/Iowa State Univ. — Recent developments in the field of metamaterials and plasmonics have promised a number of exciting applications, in particular at terahertz and optical frequencies. Most metamaterials consist of carefully designed metallic structures that replace atoms in their role as the basic unit of interaction with electromagnetic radiation. Unfortunately, the noble metals are not particularly good conductors at optical frequencies, resulting in significant dissipative loss in metamaterials. In this communication, we address the question of what is a good conductor for use in metamaterials and in plasmonics. We develop a model based on the quasistatic response of the metamaterial constituents to an incident electromagnetic field in order to derive a figure of merit for conductors. We find (1) it is the resistivity of the material—rather than the conductivity or permittivity—that provides direct information on the dissipative loss in the metamaterial, and (2) the dissipative loss depends on certain geometric aspects of the system, such as the layer thickness. Subsequently, we apply the model to graphene, to superconductors (Nb and YBCO), to several noble and transition metals, and to some conducting oxides (like ITO).

3:42PM D18.00003 Quantum Plasmonics, REINIER HEERES, LEO KOUWENHOVEN, VALERY ZWILLER, TU Delft — Surface plasmon polaritons allow confinement of light to sub-wavelength length-scales. Due to the confinement the electro-magnetic fields involved are stronger, which can be used to enhance optical interactions. We use this fact to realize a plasmonic beam-splitter based on a directional-coupler geometry, i.e. two waveguides close to each other coupled by their evanescent fields. This beam-splitter can be much smaller than conventional dielectric structures. Integrated Niobium-Nitride superconducting single-photon detectors (SSPDs) allow to probe the plasmons directly in the near-field. This makes it possible to study the structure on the quantum level using photon pairs created in a spontaneous parametric down-conversion process. Our aim is to observe Hong-Ou-Mandel interference, a true quantum effect which causes indistinguishable photons arriving at the same time at both inputs to exit through the same port, i.e. bunch. This will prove the quantum nature of surface plasmons and could be used to build sub-wavelength quantum logic gates. We also show that resonant plasmonic antennas can greatly enhance the absorption and therefore detection efficiency of SSPDs.

3:54PM D18.00004 Application of metasurface description for multilayered metamaterials and an alternative theory for metamaterial perfect absorber¹, JIANGFENG ZHOU, University of South Florida, HOU-TONG CHEN, Los Alamos National Laboratory, THOMAS KOSCHNY, Ames Laboratory, Iowa State University, ABUL AZAD, ANTOINETTE TAYLOR, Los Alamos National Laboratory, COSTAS SOUKOULIS, Ames Laboratory, Iowa State University, JOHN O'HARA, Oklahoma State University — Recently, the metamaterial perfect absorber has attracted intense interest in metamaterial community. The impedance matching mechanism based on effective bulk permittivity and permeability is widely used to explain such structures. However, this model has difficulties, in particular, because such systems are usually asymmetric, assigning homogenous effective material parameters to these systems may lead to unphysical results. In our work, we use an effective medium model that treats each layer of the metamaterial as a metasurface with unique effective surface electric and magnetic susceptibility, χ_{se} and χ_{sm} . We then use a transfer matrix method to analyze the overall EM properties of multilayered metamaterials using the effective material parameters (surface susceptibilities) of each layer. We find that the functional mechanism is the Fabry-Perot interference resulting from the multiple reflections in the cavity bounded by two metamaterial layers. This contrasts with previous explanations based on bulk effective medium theory.

¹Los Alamos National Laboratory LDRD Program, Ames Laboratory was supported by the Department of Energy (Basic Energy Sciences) under contract No. DE-AC02-07CH11358. This was partially supported by the U.S. Office of Naval Research, Award No. N000141010925

4:06PM D18.00005 Active Core-Shell Nanowire Optical Antenna Absorbers¹, CARLOS ASPETTI, CHANG-HEE CHO, RITESH AGARWAL, Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia, PA — Core-shell dielectric-metal nanoparticles have demonstrated tunability of their absorption properties due to the size- and shape-dependence of the surface plasmon resonance. Recently, the core-shell semiconductor-insulator-metal nanowire was examined as a platform for manipulating the core emitter lifetimes due to the highly confined and intense electromagnetic fields mediated by whispering gallery surface plasmon polariton modes. Combining these two concepts we realize an active semiconductor-insulator-metal optical antenna, which demonstrates a highly tunable absorption spectrum. By directly contacting the semiconductor core, photocurrent data is coupled with simulations to show highly tunable, significant broad-band absorption enhancement; a general result for a range of material systems.

4:18PM D18.00006 Genetic Optimization of Optical Nanoantennas, CARLO FORESTIERE, ALYSSA PASQUALE, Department of Electrical and Computer Engineering & Photonic Center, Boston University, ANTONIO CAPRETTI, Department of Electrical Engineering, Università degli Studi di Napoli Federico II, SYLVANUS LEE, Department of Electrical and Computer Engineering & Photonic Center, Boston University, GIOVANNI MIANO, Department of Electrical Engineering, Università degli Studi di Napoli Federico II, ANTONELLO TAMBURRINO, DAEIMI, Università degli Studi di Cassino, LUCA DAL NEGRO, Department of Electrical and Computer Engineering & Photonic Center, Boston University — Metal nanostructures can act as plasmonic nanoantennas (PNAs) due to their unique ability to concentrate the light over sub-wavelength spatial regions. However engineering the optimum PNA in terms of a given quality factor or objective function. We propose a novel design strategy of PNAs by coupling a genetic optimization (GA) tool to the analytical multi-particle Mie theory. The positions and radii of metallic nanosphere clusters are found by requiring maximum electric field enhancement at a given focus point. Within the optimization process we introduced several constraints in order to guarantee the physical realizability of the tailored nanostructure with electron-beam lithography (EBL). Our GA optimization results unveil the central role of the radiative coupling in the design of PNA and open up new exciting pathways in the engineering of metal nanostructures. Samples were fabricated using techniques and surface-enhancement Raman scattering measures were performed confirming the theoretical predictions.

4:30PM D18.00007 Plasmonic Anti-Hermitian Coupling for Nano-Manipulation of Light, ZILIANG YE, SHAUNG ZHANG, YUANG WANG, YONGSHIK PARK, GUY BARTAL, XIAOBO YIN, XIANG ZHANG, UC Berkeley — Open quantum systems consisting of coupled bound and continuum states have been studied in a variety of physical systems. In these systems, the effects of the continuum decay channels are accounted for by indirect anti-Hermitian couplings among the bound states. Here we propose a general scheme to control light in a nano-plasmonic system by utilizing the anti-Hermitian coupling between the individually designed resonances of each plasmonic element in the system. As a specific example, we experimentally show a realistic coupled plasmonic dipole antenna array with $\lambda/15$ separations, in which selective excitation of an individual antenna can be achieved by tuning the frequency of the incident light. Without the anti-Hermitian coupling, these antennas are indistinguishable from each other.

4:42PM D18.00008 Broadband scattering reduction using a hybrid inertial metamaterial design¹, THEODORE MARTIN, GREGORY ORRIS, Naval Research Laboratory — The ability to hide an object from an external wave through scattering reduction is one of the most sought-after goals of the metamaterials community. Using transformational optics, Pendry [1] demonstrated that a wave can be bent around an object using a conformal map that reduces the object's scattering cross section to zero. The transformational method has now been extended to transformational acoustics [2], but the traditional inertial method requires infinite mass at the boundary of the hidden object, which cannot be easily approximated in practice. Scattering reduction can also be obtained over a more limited bandwidth using wrapping layers that cancel some of the modal coupling between the object and the exterior environment [3]. Using multiple scattering theory, we demonstrate that a combination of an “imperfect” conformal map with a scattering cancellation layer can achieve improved scattering reduction over a broad bandwidth in an aqueous acoustic environment. Our “hybrid” design is amenable to a parameter-space constrained to within an order of magnitude of the background fluid in order to obtain a solution with realistic material properties. The introduction of a cancellation layer enables us to optimize performance over targeted frequency bands with only a small impact on the overall size of the design.

4:54PM D18.00009 Surface plasmon excitations in multicoaxial metamaterial cables: Zero magnetic field, BAHRAM DJAFARI-ROUHANI, University of Science & Technology of Lille, MANVIR KUSHWAHA, Rice University — By using an elegant response function theory, which does not require matching of the messy boundary conditions, we investigate the surface plasmon excitations in the multicoaxial cylindrical cables made up of negative-index metamaterials in the absence of an applied magnetic field. The multicoaxial cables with *dispersive* metamaterial components exhibit rather richer (and complex) plasmon spectrum with each interface supporting two modes: one TM and the other TE for (the integer order of the Bessel function) $m \neq 0$. The cables with *nondispersive* metamaterial components bear a different tale: they do not support simultaneously both TM and TE modes over the whole range of propagation vector. The computed local and total density of states enable us to substantiate spatial positions of the modes in the spectrum.¹ Such quasi-one dimensional systems as studied here should prove to be the milestones of the emerging optoelectronics and telecommunications systems.

¹M.S. Kushwaha and B. Djafari-Rouhani, *J. Opt. Soc. Am B* **27**, 605 (2010).

5:06PM D18.00010 Surface Plasmon Based Engineering of Semiconductor Nanowire Optics¹, CHANG-HEE CHO, CARLOS O. ASPETTI, Department of Materials Science and Engineering, University of Pennsylvania, MICHAEL E. TURK, JAMES M. KIKKAWA, Department of Physics and Astronomy, University of Pennsylvania, SUNG-WOOK NAM, RITESH AGARWAL, Department of Materials Science and Engineering, University of Pennsylvania — Emission from unthermalized (hot) excitons can be observed from high-quality crystals and quantum-well structures due to decreases in the exciton lifetimes but typically with low yields. By employing a plasmonic nanocavity, we observe efficient hot-exciton emission in core-shell CdS-SiO₂-Ag nanowires with intensities surpassing those from thermalized excitons [1]. These new spectral characteristics are mediated by whispering gallery plasmonic modes that yield highly intense electromagnetic fields. As a result, the exciton radiative lifetime is decreased by several orders of magnitude. The introduction of a high-quality hybrid plasmonic nanocavity structure significantly changes the photophysics of the host material, demonstrating an approach applicable to other material systems.

5:18PM D18.00011 Plasmonic nanostructures for multiscale light amplification, AIQING CHEN, ULRICH WELP, VITALII VLASKO-VLASOV, Argonne National Laboratory, MSD, RYAN MILLER, ELENA SHEVCHENKO, LEONIDAS OCOLA, STEPHEN GRAY, Argonne National Laboratory, CNM, EUGENE DEPRINCEIII, Georgia Institute of Technology — We demonstrate experimentally a multiscale plasmonic design for giant light amplification using gold nanoparticles self-assembled in gratings on a metal mirror with thin dielectric spacer. The successive increase of the light enhancement factors upon addition of individual plasmonic elements in the design is tested by measurement of the Raman signal from R6G and benzenethiol molecules on clusters of nanoparticles, their ordered arrays on dielectric, semiconducting, and metal substrates, and on metal substrate with gratings. High fidelity of our structures as SERS substrates are confirmed by areal maps of the Raman response. FDTD numerical calculations are in a good agreement with our experimental measurements.

Session D19 DCMP DMP: Invited Session: Novel Phases in Strongly Correlated Iridates 253AB

2:30PM D19.00001 Spin orbit coupling, electron correlations and exotic magnetism in 5d complex Ir oxides, HIDENORI TAKAGI, Department of Physics, University of Tokyo and RIKEN ASI — In 5d Iridium oxides, a large spin-orbit coupling of ~ 0.5 eV, inherent to heavy 5d elements, is not small as compared with the width of d bands and often modifies the landscape of the electronic structure substantially. This is distinct from those of 3d transition metal oxides and gives rise to a variety of novel electronic phases. Layered Ir⁴⁺ perovskite Sr₂IrO₄ is recently revealed to be a novel $J_{eff}=1/2$ Mott insulator [1,2], where even a moderate Coulomb U can open up a correlation gap because of the large spin-orbit coupling. In the three dimensional analogue of Sr₂IrO₄, SrIrO₃, the large spin-orbit coupling manifests itself in a contrasted way, where the interplay of strong spin-orbit coupling and lattice distortions brings the system almost to a band insulator. SrIrO₃ is in fact a very low carrier density semimetal with unusual transport and magnetic properties. If $J_{eff}=1/2$ Ir⁴⁺ is placed on a honeycomb lattice or a geometrically frustrated lattice such as pyrochlore lattice, even more exotic states might be anticipated, including a correlated topological insulator [3] and a Kiteav magnet [4]. Our attempt to explore such spin-orbit coupling induced states will be reported.

3:06PM D19.00002 Topological and spin-liquid phases in strongly correlated iridates, YONG BAEK KIM, University of Toronto — Recently, the emergence of topological phases in interacting electron systems such as topological insulators and spin liquid phases, has been a subject of intensive research. In particular, much attention has been given to 5d transition metal oxides where the strong spin-orbit coupling and intermediate strength of the electron interaction provide an ideal playground for the emergence of a number of interesting topological phases. We summarize recent theoretical efforts in this direction in the context of Iridates, or iridium oxides. We make connections to the existing and future experiments on a variety of iridates materials including pyrochlore iridates, honeycomb-lattice iridates, and hyperkagome-lattice systems.

3:42PM D19.00003 Possible proximity of the Iridates $(\text{Na,Li})_2\text{IrO}_3$ to a topologically ordered Mott insulator: Phase diagram of the Heisenberg-Kitaev model, SIMON TREBST, University of Cologne — Motivated by the recent experimental observation of a Mott insulating state for the layered Iridates $(\text{Na,Li})_2\text{IrO}_3$, we discuss possible ordering states of the effective Iridium moments taking into account the extreme sensitivity of these 5d transition metal oxides to crystal field effects and strong spin-orbit coupling. The microscopic exchange has been argued [1,2] to be a combination of isotropic Heisenberg and highly anisotropic Kitaev exchange, which can be tracked back to the spin and orbital components of the effective momenta. Depending on the relative strength of these two couplings, the system exhibits either various types of conventional magnetic order or a more exotic gapless spin-liquid ground state. Carefully studying [3] the stability of these phases at finite-temperatures – and the role of frustration, i.e. a considerable suppression of the ordering temperature from the Curie-Weiss temperature – allows us to connect back to thermodynamic experiments [4] on the Iridates $(\text{Na,Li})_2\text{IrO}_3$ and possibly estimate microscopic coupling parameters. Finally, we discuss the effects of a magnetic field applied in the [111] direction – perpendicular to the hexagonal lattice formed by the Iridium moments – and show that a topologically ordered ground state is found over a small range of coupling parameters [5], also indicating the existence of an exotic critical point whose location might not be far from actual material parameters.

4:18PM D19.00004 Honeycomb lattice spin-orbit Mott insulators¹, PHILIPP GEGENWART, I. Physikalisches Institut, Georg-August University Goettingen — Iridates displaying a Mott insulating state caused by the interplay of electronic correlations and strong spin-orbit coupling have recently attracted considerable attention. We focus on the honeycomb material A_2IrO_3 ($\text{A}=\text{Na, Li}$), in which the topology of the underlying lattice leads to interesting magnetic properties [1]. The strong spin-orbit coupling in this 5d transition metal system is expected to result in orbital-dependent highly anisotropic magnetic in-plane exchange [2]. The combination of $J_{\text{eff}} = 1/2$ and the underlying honeycomb lattice makes A_2IrO_3 a promising candidate for the Kitaev model, which is exactly solvable and has a spin-liquid ground state. Our experimental data on Na_2IrO_3 prove a Mott insulating state of effective $J=1/2$ moments with predominant antiferromagnetic coupling, indicated by a Weiss temperature of $\theta = -120$ K. A bulk antiferromagnetic transition occurs at a much reduced temperature of $T_N = 15$ K and the reduced magnetic entropy suggests strong magnetic frustration and/or low-dimensional magnetic interactions. The nature of the ordered phase has also been studied by resonant x-ray spectroscopy near the Ir-L3 edge, providing evidence for an unconventional, most-likely zig-zag-type spin ordering [3]. The latter may be related to next-nearest neighbour exchange and/or a substantial Kitaev contribution in the Heisenberg-Kitaev model [2]. Upon replacing Na with the smaller Li, one may enhance the relative importance of the Kitaev contribution. For Mott insulating Li_2IrO_3 we observe a similar ordering temperature of 15 K, while the negative Weiss temperature is drastically reduced. These observations are compatible with an enhancement of the Kitaev contribution compared to the Na-system, suggesting that Li_2IrO_3 could be located close to the Kitaev limit [5].

Session D20 FIAP: Invited Session: Advanced Electromagnetic Imaging and Remote Sensing:
From DC to Daylight 253C

2:30PM D20.00001 Advanced EM Modeling in Support of Buried Target Detection and Identification¹, EUGENE LAVELY, BAE Systems — The detection and discrimination of buried unexploded ordnance is essential for restoration of millions of acres of munitions testing grounds to public use. Public safety is paramount so high detection probability is essential, and accurate discrimination is key for economically feasible remediation. Time domain electromagnetic (TDEM) induction methods in principle have the capability to address these criteria. The transmitter loop current pulse generates a magnetic field in the target region. This changing applied field, especially as the pulse terminates, induces currents in the target, generating a scattered magnetic field. The decaying scattered field, following pulse termination, induces the measured voltage in the receiver loop. There are three different regimes that one may identify in the voltage time traces: early, intermediate, and late time. At very early time, immediately following pulse termination, the currents are confined to the immediate surface of the target. The initial diffusion of these currents into the target interior leads to a $1/2$ power law decay for nonferrous targets, ($3/2$ for ferrous targets). At intermediate time, as the currents penetrate the deeper target interior, the power law crosses over to a multi-exponential decay, representing the simultaneous presence of a finite set of exponentially decaying modes. Finally, at late time only the single, slowest decaying mode survives. At intermediate- to late-time our mean field algorithm models the dynamics by computing as large a number as possible of the modes, and determining the excitation level of each. At early time, the power law arises from a superposition of an essentially infinite number of exponentials, and a complementary theory, based on the detailed dynamics of the initial very thin surface current sheet, has been developed instead. We pre-compute intrinsic properties of modes containing all discrimination information of targets, and use this for nearly real-time inversion of TDEM measurement for target properties and subsequent discrimination.

3:06PM D20.00002 Through-wall microwave imaging: some applications of physics to urban reconnaissance¹, PETER WEICHMAN², BAE Systems — I will review some recent physics-based modeling approaches in support of microwave through-wall building tomography. Building layout estimation is a nonlinear inverse problem with a large number of degrees of freedom (geometry, location, and scattering properties of major building elements, such as walls, floors, and ceilings, plus many other smaller elements such as windows, doorways, and stairways). The physics of microwave propagation in such environments is very complex, involving multiple reflection, transmission, and diffraction events. Careful control of measurement protocol, using well-focused and directed transmitter and receiver arrays, can mitigate this to some degree. However, even under the most optimistic scenarios, the number of interactions increases exponentially as the signal penetrates more deeply into the building. Multiple overlapping returns from different building elements quickly overwhelm one's ability to disambiguate their sources. To explore the fundamental limitations on solutions to the inverse problem, efforts to create physics-based models that capture the signal complexity as accurately as possible will be described. These models remain an approximate description of reality, but nevertheless enable one to understand the effects of the explosion of multiple scattering events on the inversion, and quantify the limits of the inversion quality under even the most optimistic scenarios for data diversity and precision.

3:42PM D20.00003 Advanced methods in synthetic aperture radar imaging, THOMAS KRAGH, BAE Systems — For over 50 years our world has been mapped and measured with synthetic aperture radar (SAR). A SAR system operates by transmitting a series of wideband radio-frequency pulses towards the ground and recording the resulting backscattered electromagnetic waves as the system travels along some one-dimensional trajectory. By coherently processing the recorded backscatter over this extended aperture, one can form a high-resolution 2D intensity map of the ground reflectivity, which we call a SAR image. The trajectory, or synthetic aperture, is achieved by mounting the radar on an aircraft, spacecraft, or even on the roof of a car traveling down the road, and allows for a diverse set of applications and measurement techniques for remote sensing applications. It is quite remarkable that the sub-centimeter positioning precision and sub-nanosecond timing precision required to make this work properly can in fact be achieved under such real-world, often turbulent, vibrationally intensive conditions. Although the basic principles behind SAR imaging and interferometry have been known for decades, in recent years an explosion of data exploitation techniques enabled by ever-faster computational horsepower have enabled some remarkable advances. Although SAR images are often viewed as simple intensity maps of ground reflectivity, SAR is also an exquisitely sensitive coherent imaging modality with a wealth of information buried within the phase information in the image. Some of the examples featured in this presentation will include: (1) Interferometric SAR, where by comparing the difference in phase between two SAR images one can measure subtle changes in ground topography at the wavelength scale. (2) Change detection, in which carefully geolocated images formed from two different passes are compared. (3) Multi-pass 3D SAR tomography, where multiple trajectories can be used to form 3D images. (4) Moving Target Indication (MTI), in which Doppler effects allow one to detect and geolocate moving targets within SAR images. (5) Real time video SAR, where one forms a continuously updated SAR image by “staring” at an area of interest.

4:18PM D20.00004 Multiple-input Multiple-output Ground Moving Target Indicator Radar: Theory and Practice, DAN BLISS, Lincoln Laboratory, Massachusetts Institute of Technology — Multiple-input multiple-output (MIMO) extensions to radar systems enable a number of advantages compared to traditional approaches. These advantages include improved angle estimation and target detection. In this paper, an overview of MIMO radar is provided, and the concept of coherent MIMO radar is defined. The principle focus of the paper is the discussion of MIMO ground moving target indication (GMTI). For GMTI radar modes, the advantages of a coherent MIMO architecture include improved angle estimation and enhanced slow speed target detection. To illustrate this, the concept of coherent MIMO radar is introduced and performance comparisons made between MIMO GMTI and traditional radar GMTI. These comparisons are supported by theoretical bounds, simulations, and experimental results for GMTI angle estimation accuracy and minimum detectable target velocity. For some applications, these results indicate significant potential improvements in clutter-mitigation, signal-to-noise ratio (SNR) loss, and reduction in angle-estimation error for slow-moving targets. The important effects of waveform characteristics is addressed.

4:54PM D20.00005 Image Formation in Bio-optical Sensing¹, ERIC MILLER, Tufts University — Over the past two decades a number of optical sensing methods have emerged with potential to provide complementary information to traditional medical imaging modalities in application areas ranging from basic science to disease diagnosis and treatment monitoring. Though still largely in the research and development stage, modalities including diffuse optical tomography (DOT), fluorescence molecular tomography (FMT), photo-acoustic tomography (PAT), and bio-luminescence tomography (BLT) have excited much interest due to their natural functional imaging capability, their relatively low cost, and the fact that none required the use of ionizing radiation. These advantages however are tempered by a number of challenges associated with the processing of these data. Specifically, these data types all rely in one way or another on the interaction of light with tissue. The diffusive nature of this interaction inherently limits the spatial resolution of these modalities. As a result the process of forming an image is a far more delicate task than is the case with more standard imaging modalities such as X-ray computed tomography (CT). Two basic methods have been explored to address the ill-posedness of these problems in order to improve the information content in the resulting images. The optical data may be augmented either through the use of spectral diversity or by attempting to integrate optical data types with information from other modalities such as CT or MRI. Alternatively, a mathematical technique known as regularization can be used to impose physically-based constraints on the reconstruction. In this talk, I shall provide an overview of the work in my group in optical image formation within the contexts of DOT for breast cancer imaging and FMT for small animal imaging. The focus of the talk will be on methods that integrate data augmentation and mathematical regularization. In the case of FMT, we shall discuss our work in combining the optical data with information provided by CT concerning the structural distribution of tissue classes within the region of interest. Here, we have developed a number of spatially-varying regularization methods which use the CT data to help constrain the FMT reconstruction and obtain imaging results that are substantially improved over classical regularization techniques. For DOT, we have recently been considering the use of hyperspectral data sets in which information from over 100 near infrared wavelengths is made available to the processing. When combined with a regularization scheme based on parameterizing the images in a geometric manner, we believe that it will be possible to produce a standalone DOT system with spatial resolution that is today only achieved by combining DOT with e.g., CT.

Monday, February 27, 2012 2:30PM - 5:30PM — Session D21 DCMP: Multiband Superconductivity, mostly MgB₂ 254A

2:30PM D21.00001 STS studies of the pi-band superconductivity in MgB₂ in a transverse field¹, C. GRIGGS, M.R. ESKILDSEN, University of Notre Dame, N.D. ZHIGADLO, J. KARPINSKI, ETH — Since being discovered MgB₂ has become the paradigm for two-band/two-gap superconductivity. Early scanning tunneling spectroscopy (STS) measurements, showed a rapid suppression of the superconductivity in the isotropic π -band for modest applied fields $H \parallel c$. These measurements were performed with the tunnel current (I_t) parallel to the crystalline c -axis which couple, almost exclusively, to the π -band, and with the suppression attributed to vortex core overlap. Here we report STS measurements performed in a transverse field, such that $I_t \parallel c \perp H$. In this configuration no vortices are cutting through the image plane, and instead the superconducting phase is affected by the Meissner currents running within one penetration depth of the sample surface. Within this field orientation we observe far less suppression of the superconducting state in the π -band compared to the earlier measurements with $H \parallel c$. A clear gap is seen up to $H = 0.9$ T.

¹Supported by NSF award no. DMR-0804887.

2:42PM D21.00002 Measurement of penetration depth of MgB_2 using DC SQUID, DANIEL CUNNANE, KE CHEN, X.X. XI, Temple University — Penetration depth is an important parameter for the design of Rapid Single Flux Quantum (RSFQ) circuits. For MgB_2 , different values from 40 nm to 150 nm have been reported by different groups. We have measured the penetration depth of MgB_2 using MgB_2 DC SQUIDS. The SQUID was made using $\text{MgB}_2/\text{MgO}/\text{MgB}_2$ Josephson junctions with epitaxial MgB_2 electrodes deposited via Hybrid Physical-Chemical Vapor Deposition. The MgO was deposited by RF Magnetron Sputtering of an MgO target. The device shows good voltage modulation above 150 μV . The working temperature for these SQUIDS ranges from below 10K to 37K, with the optimum voltage modulation near 35K. The results will be discussed in comparison to the penetration depth reported by other measurement techniques.

2:54PM D21.00003 Effect of scattering on the gap distribution in tunneling spectra of $\text{MgB}_2/\text{I}/\text{Pb}$ junctions, WENQING DAI, QI LI, Department of Physics, Pennsylvania State University, University Park, PA 16802, KE CHEN, XIAOXING XI, Department of Physics, Temple University, Philadelphia, PA 19122 — We fabricated $\text{MgB}_2/\text{Native oxide}/\text{Pb}$ planar tunneling junctions using the MgB_2 films grown by the hybrid physical-chemical vapor deposition technique (HPCVD). Both π (~ 1.8 meV) and σ gaps (~ 7.9 meV) were observed in spectra due to tunneling from side of c -oriented MgB_2 grains on film surface on SiC (0001) substrates. We have previously observed a distribution of energy gap values within both bands in clean HPCVD films with long electron mean free path. Here we report an investigation of the tunneling spectra by systematically varying the MgB_2 film thickness and the thickness of native oxide barrier. We found the MgB_2 π gap distribution range narrows from ~ 1.7 meV to ~ 1.4 meV together with a loss of fine peak structures, as the MgB_2 film thickness decreases from 100 nm to 33 nm, in which the electron mean free path is limited by the thickness. In addition, fine peak structures also smear out when the junction resistance is large. The results show electron scattering from both inside the film and on the surface can smear out the gap distribution structures in tunneling spectra.

3:06PM D21.00004 Vortex Lattice Transition Dynamics in MgB_2 , C. RASTOVSKI, P. DAS, K. SCHLESINGER, M.R. ESKILDSEN, W.J. GANNON, University of Notre Dame, IN, USA, C.D. DEWHURST, Institut Laue-Langevin, France, N.D. ZHIGADLO, J. KARPINSKI, ETH Zurich, Switzerland — We present small-angle neutron scattering (SANS) studies of the vortex lattice (VL) in MgB_2 with $H \parallel c$. This material has three different VL phases, all with triangular symmetry but oriented differently with respect to the crystalline axes. Furthermore, a high degree of metastability between the VL phases of MgB_2 has been observed as the sample is cooled or heated across the equilibrium phase transitions. Here we present detailed studies of how the metastable (MS) VL phases transition to the ground state (GS), either driven by small changes of the DC magnetic field or by a transverse AC field. Our results show that the MS VL is not due to vortex pinning, and results are inconsistent with predictions based on the Bean model. Instead, we speculate that a “jamming” of counter rotated VL domains is responsible for the VL metastability. This is further supported by a power law dependence of the GS VL domain population upon the number of applied AC cycles. This work was supported by the Department of Energy, Basic Energy Sciences under Award No. DE-FG02-10ER46783.

3:18PM D21.00005 Non-linear Time Effects in Superconducting Polycrystalline MgB_2 , MURAT OLUTAS, ATILGAN ALTINKOK, ATILLA KILIC, KIVILCIM KILIC, Abant Izzet Baysal University — The time evolution of the voltage response (V-t curves) to a symmetric bi-directional square wave (BSW) current with long periods (P) applied to the MgB_2 sample was investigated at low dissipation levels. It was observed that regular sinusoidal-like voltage oscillations evolve at certain ranges of the amplitude (I_{BSW}) and period (P_I) of the BSW current, external magnetic field (H), and temperature (T). The regular sinusoidal-like oscillations were interpreted in terms of the dynamic competition between pinning and depinning processes. In this process, the interaction between flux lines and pinning centers could be elastic coupling because of rigidity of flux line lattice in MgB_2 . We suggest that the oscillating mode can be related to the drifting of flux lines which are in motion. In this case, due to the strong pinning and complex relaxation effects, the majority of flux lines traversing the sample does not leave it entirely and remains in an oscillating mode by moving forth and back as a function of time. We suggest that the flux dynamics associated with the oscillating mode is the ordered motion of defective flux line system. Fast Fourier Transform analysis of V-t oscillations showed that the period of oscillations is comparable to that of the BSW current. The oscillating mode was also discussed in terms of sliding charge density waves (CDWs).

3:30PM D21.00006 Study of MgB_2 Films for RF Cavity Applications¹, TENG TAN, CHENGGANG ZHUANG², ALEX KRICK, KE CHEN, XIAOXING XI, Department of Physics, Temple University — Magnesium diboride (MgB_2) is a promising superconducting material for RF cavity applications due to its high critical temperature T_c and large thermodynamic critical field H_c . Using Hybrid Physical-Chemical Vapor Deposition (HPCVD), we have grown 2"-diameter MgB_2 films on sapphire and metal substrates, including molybdenum, niobium, tantalum, and stainless steel. Measured by DC magnetization, the T_c 's of these films were between 38.2 to 39.2 K; the upper critical field H_{c2} 's were about 7 T, in consistent with previously reported value of clean MgB_2 films; the zero-field critical current density J_c 's were above 10^7 A/cm² and were suppressed rapidly by increasing applied magnetic field, indicating a lack of pinning in clean MgB_2 films. Multilayered MgB_2/MgO films were also investigated to prevent vortex penetrating the MgB_2 layer and increase the vortex penetration field (H_{c1}) following Gurevich's theoretical work [1]. The RF properties of these films were studied.

3:42PM D21.00007 Mesoscopic Nonlinear Electrodynamical Response of the Two Band Superconductor MgB_2 ¹, TAMIN TAI, University of Maryland-College Park, TENG TAN, XIAOXING XI, Temple University, BEHNOOD GHAMSARI, STEVEN ANLAGE, University of Maryland-College Park — Multi-gap superconductors are expected to have exotic physics associated with internal coupling between the multiple order parameters. 10 years after its discovery, MgB_2 is a two gap superconductor that still attracts much attention for both fundamental and practical reasons. A microwave measurement of the temperature dependent third harmonic response P_{3f} (T) is performed by applying a strong and localized (mesoscopic) RF magnetic field on high quality MgB_2 films. Comparing to the P_{3f} (T) result on Nb thin films, the low temperature nonlinearity of MgB_2 shows a complete harmonic cancelation at a temperature near the transition temperature of the proximity-induced π band. One possibility is that this phenomenon is due to an additional intrinsic nonlinearity arising from Josephson coupling between the σ and π bands. This nonlinear response then interferes with other nonlinear mechanisms coming from moving vortices and the intrinsic nonlinear Meissner effect of the two-gap system. To investigate further, we measure the magnitude and phase of the nonlinear response and compare to models of the three nonlinearity mechanisms.

3:54PM D21.00008 Superconducting-to-Normal Switching and I-V Experiments showing Multiple Tunneling Channels in a Multi-Gap Superconductor¹, STEVE CARABELLO, JOSEPH LAMBERT, JEROME MLACK, Drexel University, WENQING DAI, YI. SHEN, QI LI, The Pennsylvania State University, DANIEL CUNNANE, C.G. ZHUANG, KE CHEN, X.X. XI, Temple University, ROBERTO RAMOS, Indiana Wesleyan University — Magnesium diboride is a BCS superconductor with many interesting properties, notably its two superconducting energy gaps associated with the disconnected sheets of its Fermi surface. A heterojunction, using the dual-gap MgB₂ and a single-gap superconductor as its superconducting electrodes, provides a system well-suited for exploring the unique properties of MgB₂, by exhibiting multiple tunneling channels. We present data from superconducting-to-normal state switching experiments and tunneling spectroscopy experiments to temperatures as low as 20mK that indicate multiple tunneling channels in this multiple-gap superconductor. We describe features of escape rates and I-V curves that may be consistent with recent published theoretical work on macroscopic quantum tunneling in multi-gap superconductors.

¹This research has been supported by a grant-in-aid from Sigma Xi.

4:06PM D21.00009 ABSTRACT WITHDRAWN —

4:18PM D21.00010 Multilayer Structures in MgB₂ superconducting thin films: influence on doping, pinning, and connectivity¹, MIKE SUMPTION, MIKE SUSNER, SCOT BOHNENSTIEHL, TED COLLINGS, Materials Science Dept, The Ohio State University — Pinning force density, connectivity, and doping were investigated for MgB₂ superconducting thin films. Pulsed Laser Deposition (PLD) was used to produce MgB₂ thin films on Al₂O₃ (0001), MgO (111), YSZ (111), and SiC (0001) substrates. The MgB₂ target was manufactured through high pressure and high temperature induction heating that produced a highly dense material. ZrB₂, SiC, or C targets were alternated with the MgB₂ target to produce films with various levels of doping and/or pinning centers. X-ray diffraction (XRD) was used to determine the substitution, strain, and epitaxy. Surface microstructures and grain sizes were compared via scanning electron microscopy (SEM). Transmission electron microscopy (TEM) was employed on ion-milled samples representing cross-sections of the film to determine the oxide content of the films as well as to confirm if the added dopants modified the superconducting properties of the MgB₂ via atomic substitution or increases in strain. Normal-state resistivity measurements were taken on the films to determine the connectivity as compared to literature single crystal values. Magnetic J_c s were taken of the films to determine the influence of the microstructure on the pinning properties.

4:30PM D21.00011 Effect of Carbon Nanotubes on Transport Properties of MgB₂¹, DEREK CAPLINGER, DANHAO MA, Department of Physics, The Pennsylvania State University, Altoona College, Altoona, PA 16601, USA, RUWANTHA JAYASINGHA, Department of Physics & Astronomy, University of Louisville, Louisville, KY 40292, USA, KOFI ADU, Department of Physics, The Pennsylvania State University, Altoona College, Altoona, PA 16601, USA, GAMINI SUMANASEKERA, Department of Physics & Astronomy, University of Louisville, Louisville, KY 40292, USA — Carbon nanotubes (CNT) and magnesium diboride (MgB₂) are two fascinating materials; with CNT exhibiting unique quantum electrical properties due to its 1-D structure and MgB₂ being a superconducting with transition temperature (T_c) at ~ 40 K. We report preliminary results on the effect of carbon nanotubes on the temperature dependent (300K to 4K) thermoelectric power (TEP) and resistivity of MgB₂. The normalized resistance ($(R-R_{300})/R_{300}$) shows very little dependence on the sample composition; however, the absolute resistance increases with increasing CNT concentration. At high CNT composition, the TEP mimic the characteristic TEP of CNT. However at low CNT composition, we see an upturn at about 30K.

4:42PM D21.00012 Applicability of two-component Ginzburg-Landau model in two-band systems¹, MIHAIL SILAEV, Royal Institute of Technology and Institute for physics of microstructures RAS, EGOR BABAEV, Royal Institute of Technology and University of Massachusetts Amherst — We report a microscopic derivation of the conditions under which the two-band superconductors can be described by a two-component Ginzburg-Landau (GL) field theory. We also investigate the conditions when multicomponent GL-like expansions fail and one should resort to a microscopic description. We show that besides being directly applicable at elevated temperatures, a version of a minimal two-component GL theory in certain cases also gives an unexpectedly accurate description of certain aspects of a two-band system even substantially far from T_c . This shows that two-component GL model can be used for addressing a wide range of questions in multiband systems.

4:54PM D21.00013 Inter-band scattering effects in the Chevrel phase superconductors, ANSON CHEUNG, University of Cambridge — Recent scanning tunneling spectroscopy on the Chevrel phases SnMo₆S₈ and PbMo₆S₈ by Petrović et al. (PRL **106**, 017003 (2011)) demonstrates clear signatures of multi-band superconductivity. In contrast with MgB₂, where there is extremely weak scattering between the σ and π bands, the inter-band scattering rate is relatively high compared to the intra-band scattering rate in the Chevrel phases. We calculate the quasi-classical Green's function in the presence of strong inter-band scattering and derive comparable results to the measured density of states. We make predictions for proposed measurements on the vortex cores.

5:06PM D21.00014 Collective modes in three-band superconductors with repulsive interband interactions¹, VALENTIN STANEV, Materials Science Division, Argonne National Laboratory — I consider a simple model of a three-band superconductor with repulsive interband interactions. In such a system frustration associated with the odd number of gaps leads to the possible existence of intrinsically complex time-reversal symmetry breaking (TRSB) order parameter. I show that in this state the fluctuations of the *different* gaps are strongly coupled and this leads to the development of novel excitations, which mix the phase and amplitude oscillations. This is due to the non-trivial relative phase angle between the gaps. The energy of these excitations is less than 2Δ and thus they are true collective modes of the system.

5:18PM D21.00015 Cryomagnetic STM imaging of the subsurface vortex lattice in the multi-band superconductor $2H\text{-NbSe}_2$ ¹, IGOR FRIDMAN, University of Toronto, V. LUKIC, Stevens Institute of Technology, C. KLOC, Nanyang Technological University, Singapore, C. PETROVIC, Brookhaven National Laboratory, J.Y.T. WEI, University of Toronto and Canadian Institute for Advanced Research — Using cryomagnetic scanning tunneling microscopy (STM) in a novel field geometry, we studied single crystals of the multiband superconductor $2H\text{-NbSe}_2$ under diamagnetically-induced superfluid momentum. Spectroscopy and conductance imaging were performed at 300 mK and in a field of up to 9 T, applied in the ab -plane.[1] Spatial maps of the Doppler effect on the quasiparticle tunneling spectrum revealed distinct stripe patterns that originate from in-plane vortices whose cores are buried in the bulk.[2] The stripe separation varies systematically as a function of the applied field. Our results are interpreted in terms of the interaction between vortical and screening currents, and demonstrate a general method for probing subsurface vortices, especially in emerging multiband superconductors such as the ferro-pnictides/chalcogenides.

Session D22 DMP DCOMP: Focus Session: Fe-based Superconductors - Crystal Growth, Structure, and Properties of $K_x\text{Fe}_{1-y}\text{Se}$ Phases 254B

2:30PM D22.00001 Superconductivity in $K_x\text{Fe}_{2-y}\text{Se}_{2-z}\text{S}_z$ ¹, CEDOMIR PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory — Single crystal alloys $K_x\text{Fe}_{2-y}\text{Se}_{2-z}\text{S}_z$ offer valuable insight into the strength of electronic correlations in the normal state and structural characteristics associated with superconductivity. I will discuss the evolution of the superconducting and magnetic ground states as a function of sulfur concentration z and some noticeable changes in the average and local crystal structure associated with this [1-4]. Conductivity and magnetic properties coincide with stoichiometry changes and with particular local environment of Fe atoms on the two Fe sites in the crystal structure. The ratio of superconducting T_c and Fermi temperature T_F is also suppressed by sulfur doping, indicating the suppression of electronic correlations. The superconductivity persists with relatively high T_c even when electronic correlations in the normal state are greatly reduced. The results for $z = 0$ will be compared with other experimental techniques that probe nanoscale phase separation and degree of vacancy order [5-6]. It will be shown that local structure and population of particular Fe sites is rather important for obtaining the bulk superconducting phase. Superconducting volume fraction and homogeneity of superconducting phase is in direct competition with Fe vacancy order [7].

¹Work at Brookhaven is supported by the U.S. DOE under Contract No. DE-AC02-98CH10886 and in part by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. DOE, Office for Basic Energy Science (H.Lei).

3:06PM D22.00002 Crystal growth and detailed structural characterization of superconducting and non-superconducting phases in the $K_{1-x}\text{Fe}_{2-y}\text{Se}_2$ system, DANIEL SHOEMAKER, DUCK YOUNG CHUNG, MELANIE FRANCISCO, HELMUT CLAUS, SEVDA AVCI, Argonne National Laboratory, ANNA LLOBET, Lujan Neutron Scattering Center, Los Alamos National Laboratory, HEFEI HU, JIAN-MIN ZUO, University of Illinois at Urbana-Champaign, MERCOURI KANATZIDIS, Argonne National Laboratory and Northwestern University — Amid the flurry of activity on $K_{1-x}\text{Fe}_{2-y}\text{Se}_2$ superconductors, it remains established that the stoichiometric compound $K_2\text{Fe}_4\text{Se}_5$ is an antiferromagnetic semiconductor. This raises the question of whether subtle $\text{Fe}^{1+/3+}$ doping causes $K_{1-x}\text{Fe}_{2-y}\text{Se}_2$ to become a bulk superconductor, and if so, is there a structural distinction between superconducting and non-superconducting phases? We have grown $K_{1-x}\text{Fe}_{2-y}\text{Se}_2$ samples that show superconductivity with $T_C = 31$ K, even when growth conditions are starkly different from those reported in the literature. Here we present high-resolution synchrotron X-ray diffraction measurements, alongside single-crystal x-ray and electron diffraction, to elucidate the phase space in this system. Combined with magnetometry, heat capacity, and transport measurements, our structure-property relations help prescribe how chemical composition and heat treatment induce superconductivity and vacancy ordering in the $K_{1-x}\text{Fe}_{2-y}\text{Se}_2$ system.

3:18PM D22.00003 Suppression of superconductivity and spin-glass behavior in Cu-doped $\text{K}_0.8\text{Fe}_2\text{Se}_2$ ¹, RONGWEI HU, JOHNPIERRE PALIONE, SHANTA SAHA, RICHARD GREENE, Center for Nanophysics & Advanced Materials and Department of Physics, University of Maryland — Single crystals with nominal compositions of $\text{K}_0.8\text{Fe}_{2-x}\text{Cu}_x\text{Se}_2$ were grown and studied with low temperature electrical transport and magnetic susceptibility measurements. We show that the superconductivity present in undoped $\text{K}_0.8\text{Fe}_2\text{Se}_2$ crystals with transition temperature of 31 K is very quickly suppressed with Cu doping into the Fe site, and the system very quickly becomes insulating. We discuss anomalous behavior at higher doping, including spin-glass like behavior with further Cu doping.

3:30PM D22.00004 What is the true parent state in alkali-doped Iron Selenides, WEI LI, Fudan University, Shanghai, China, SHUAI DONG, Department of Physics, Southeast University, Nanjing, China, CHEN FANG, JIANGPING HU, Purdue University — By performing first-principles electronic structure calculations and analyzing effective magnetic model of alkali-doped iron selenides, we show that the materials without iron vacancies should approach a novel checkerboard phase in which each four Fe sites group together in tetragonal structure. The checkerboard phase is the ground state with a block antiferromagnetic (AFM) order and a small charge density wave order in the absence of superconductivity. Both of them can also coexist with superconductivity. The results explain mysterious 2 by 2 ordered patterns and hidden orders observed in various different experiments, clarify the missing link between AFM and superconducting phases, suggest that the block-AFM state is the parent state, and unify the understanding of various observed phases in alkali-doped iron selenides. (Reference: Wei Li, *et al.*, arxiv:1110.0372 (2011))

3:42PM D22.00005 Structural and Superconducting Properties of $K_{0.8}Fe_{1.6+x}Se_2$ single crystals, SU JUNG HAN, GENDA GU, QIANG LI, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, New York 11973-5000, USA — We report structural and superconducting properties of $K_{0.8}Fe_{1.6+x}Se_2$ single crystals. Superconducting properties were studied by using transport, specific heat and magnetization measurements, and compared with that of $FeSe_{1-x}Te_x$. We found the *c*-axis resistive transition and specific heat behavior are distinctively different in these two classes of materials. Structural properties were studied via transmission electron microscopy and energy-dispersive X-ray spectroscopy. We found large scale structural and chemical disorder in the $K_{0.8}Fe_{1.6+x}Se_2$ samples. The relationship between structural and superconducting properties in $K_{0.8}Fe_{1.6+x}Se_2$ will be discussed.

3:54PM D22.00006 Imaging the coexistence of superconductivity and a charge density modulation in $K_{0.73}Fe_{1.67}Se_2$ superconductor, PENG CAI, CUN YE, WEI RUAN, XIAODONG ZHOU, State Key Laboratory of Low Dimensional Quantum Physics, Department of Physics, Tsinghua University, AIFENG WANG, MENG ZHANG, XIANHUI CHEN, Hefei National Laboratory for Physical Science at Microscale and Department of Physics, University of Science and Technology of China, YAYU WANG, State Key Laboratory of Low Dimensional Quantum Physics, Department of Physics, Tsinghua University — We report scanning tunneling microscopy studies of the local structural and electronic properties of the iron selenide superconductor $K_{0.73}Fe_{1.67}Se_2$ with $T_C = 32K$. On the atomically resolved FeSe surface, we observe well-defined superconducting gap and the microscopic coexistence of a charge density modulation with $\sqrt{2} \times \sqrt{2}$ periodicity with respect to the original Se lattice. We propose that a possible origin of the pattern is the electronic superstructure caused by the block antiferromagnetic ordering of the iron moments. The widely expected iron vacancy ordering is not observed, indicating that it is not a necessary ingredient for superconductivity in the intercalated iron selenides.

4:06PM D22.00007 Local Atomic and Electronic Structure of $K_{0.8}Fe_{1.6+x}Se_2$: Structural Order and Disorder, TREVOR TYSON, TIAN YU, New Jersey Institute of Technology, SU JUNG HAN, Brookhaven National Laboratory, MARK CROFT, Rutgers University, GENDA D. GU, IVO DIMITROV, QIANG LI, Brookhaven National Laboratory — The local structure of superconducting single crystals of $K_{0.8}Fe_{1.6+x}Se_2$ was studied by x-ray absorption spectroscopy. Near-edge spectra reveal that the average valence of Fe is 2+. The structure about the Se and Fe sites shows a high degree of order in the nearest neighbor Fe-Se bonds. On the other hand, the combined Se and K local structure measurements reveal a very high level of structural disorder in the K layers. The temperature dependence of the Fe-Se atomic correlation follows that of the Fe-As correlation in $LaFeAsO_{0.89}F_{0.11}$. In $K_{0.8}Fe_{1.6+x}Se_2$, the nearest neighbor Fe-Fe bonds has a lower Einstein temperature and higher structural disorder than in $LaFeAsO_{0.89}F_{0.11}$. For higher shells, an enhancement of the second nearest neighbor Fe-Fe interaction is found just below T_C and suggests that correlations between Fe magnetic ion pairs beyond the first neighbor are important in models of magnetic order and superconductivity in these materials. This research is supported by DOE BES Grant DE-FG02-07ER46402 (NJIT) for T.A.T and T.Y. and DOE BES Contract No. DE-AC0298CH10886. (BNL), for S.J.H, G.G, I.K.D, and Q. L.

4:18PM D22.00008 Interplay between structure and properties in $TlFe_{1.6}Se_2$ ¹, ANDREW MAY, HUIBO CAO, MICHAEL MCGUIRE, CLAUDIA CANTONI, BRYAN CHAKOUMAKOS, RADU CUSTELCEAN, BRIAN SALES, Oak Ridge National Laboratory — The degree to which Fe vacancies order greatly influences the properties of intercalated FeSe compounds. In this talk, we will consider the relationship between vacancy ordering and the properties of $TlFe_{1.6}Se_2$. Unlike the alkali-metal based compounds, such as $K_{0.8}Fe_{1.6}Se_2$, $TlFe_{1.6}Se_2$ does not become superconducting and always forms with the Tl-sites fully occupied. This results in reduced complexity and disorder, allowing the role of Fe vacancies to be probed directly. Common to all of these materials is $\sqrt{5}a \times \sqrt{5}a$ superstructure associated with ordering of the Fe vacancies, which appears coupled to a block-checkerboard antiferromagnetic order. Through subtle changes in composition and processing, the vacancies can order more or less completely, and this results in substantial variations in the magnetic properties of $TlFe_{1.6}Se_2$. The electronic behavior is relatively insensitive to these changes, though, as semiconducting behavior is observed in all cases. Finally, high resolution TEM reveals complex local structures, which are markedly different from those observed in $K_{0.8}Fe_{1.6}Se_2$.

4:30PM D22.00009 Defect Structures and nonstoichiometry in the $K_xFe_{2-y}Se_2$ by X-ray diffraction., JOHN CLARIDGE, ALEXEY GANIN, ALEC MCLENNAN, JOHN BACSA, MATTHEW ROSSEINSKY, University of Liverpool, YASUHIRO TAKABAYASHI, KOSMAS PRASSIDES, Durham University — The mechanisms of charge carrier density control in the iron pnictide and chalcogenide superconductors are important as small changes in composition produce metal-insulator transitions and generate superconductivity at temperatures of up to 37K in chalcogenides and 55K in pnictides. All of the reported materials are based on a square FeX ($X = Se, As$) layer built from edge-sharing of FeX_4 tetrahedra. Insertion of alkali metal cations between FeSe layers affords superconductivity in $A_xFe_{2-y}Se_2$ ($A = K, Rb, Cs, Tl$; $0.7 < x < 1$, $0 < y < 0.5$) materials highlights the defect chemistry as the iron charge states close to +2 found in the other Fe-based superconductors require the creation of considerable defect concentrations on either or both iron and alkali metal sites. Ordering of the tetrahedral site vacancies in two crystals of refined compositions $K_{0.93(1)}Fe_{1.52(1)}Se_2$ and $K_{0.862(3)}Fe_{1.563(4)}Se_2$ produces a fivefold expansion of the parent $ThCr_2Si_2$ unit cell in the ab plane which can accommodate 20% vacancies on a single site within the square FeSe layer. The iron charge state is maintained close to +2 by coupling of the level of alkali metal and iron vacancies, doping mechanisms, which can operate at both average and local structure levels will be discussed. These structures will also be considered in terms of their local ordering and with relation to other defect chalcogenide layer structures and possible phase segregation.

4:42PM D22.00010 Local structural disorder and superconductivity in $K_xFe_{2-y}Se_2$, HYEJIN RYU, HECHANG LEI, Brookhaven National Lab, A.I. FRENKEL, Yeshiva University, C. PETROVIC, Brookhaven National Lab — We report significantly enhanced magnetic moment on $K_xFe_{2-y}Se_2$ single crystals after post-annealing and quenching process. In $K_xFe_{2-y}Se_2$ unit cell, there are two Fe sites, Fe1 which has higher symmetry with longer average Fe-Se bond length, and Fe2 which has lower symmetry with shorter average Fe-Se bond length. Temperature dependent X-ray absorption fine structure (XAFS) analysis results on quenched and as grown $K_xFe_{2-y}Se_2$ materials show that quenched $K_xFe_{2-y}Se_2$ materials have increased average Fe-Se bond length and decreased static disorder. This result indicates that occupancy of Fe1 sites increased after post-annealing and quenching process. This result provides clear evidence that Fe1 sites carry higher magnetic moment than Fe2 sites.

4:54PM D22.00011 Novel synthesis method of $K_xFe_{2-y}Se_2$ single crystal, TOSHINORI OZAKI, HIROYUKI TAKEYA, SATOSHI DEMURA, KEITA DEGUCHI, YASUNA KAWASAKI, HIROYUKI OKAZAKI, HIROSHI HARA, TAKAHIDE YAMAGUCHI, HIROAKI KUMAKURA, YOSHIHIKO TAKANO, National Institute for Materials Science — The discovery of superconductivity in $K_xFe_{2-y}Se_2$ with $\sim T_C$ 31 K has triggered a great interest in the field of iron-based superconductors [1]. $K_xFe_{2-y}Se_2$ superconductor has several practical advantages of relatively high T_C , high upper critical field (H_{c2}) and less toxicity compared to FeAs-based superconductors. However, the procedure for producing $K_xFe_{2-y}Se_2$ single crystal is complicated and time-consuming: At first, the FeSe precursor was prepared, and then the single crystals of $K_xFe_{2-y}Se_2$ were grown by the self-flux method. The simplification of the synthesis is really important for applications. We present a novel synthesis method of $K_xFe_{2-y}Se_2$ single crystal, which is very simple and quick. A superconducting transition of this sample appeared at $T \sim 31.6$ K. After quenching the sample, the calculated volume fraction from dc magnetic susceptibility was dramatically increased, consistent with the previous report [2]. We will also report the details of the synthesis, transport properties and microstructures of the samples. 1)J.Guo, *et al*, Phys. Rev. B **82**, 180520 (2010). 2)H. Lei, *et al*, arXiv: 1109.0534.

5:06PM D22.00012 Ordering driven superconductivity in an alkaline iron selenide¹, XIAO-JIA CHEN, Geophysical Laboratory, Carnegie Institution of Washington, Washington, D.C. 20015, QING-ZHEN HUANG, NIST Center for Neutron Research, National Institute of Standards and Technology Gaithersburg, MD 20899, JIAN-XIN ZHU, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM 87545, MINGHU FANG, Department of Physics, Zhejiang University, Hangzhou 310027, China, WEI BAO, Department of Physics, Renmin University of China, Beijing 100872, China, JIAN-BO ZHANG, LING-YUN TANG, Department of Physics, South China University of Technology, Guangzhou 510641, China, JINFU SHU, VIKTOR STRUZHNIKIN, RUSSELL HEMLEY, HO-KWANG MAO, Geophysical Laboratory, Carnegie Institution of Washington, Washington, D.C. 20015 — Combining the resistivity, synchrotron x-ray diffraction, and neutron diffraction measurements, we investigated the evolution of the structural, magnetic, and superconducting properties with pressure up to 37 GPa of superconducting $\text{Rb}_{0.347}\text{Ti}_{0.347}\text{Fe}_{1.752}\text{Se}_2$. Extended phase diagram of temperatures and pressure were established for this material. The results show the superconductivity is in reality driven by ordering.

¹This work is supported by the U.S. DOE under Grants No. DE-SC0001057.

5:18PM D22.00013 Pressure-tuned superconductivity of iron chalcogenides, LILING SUN, Institute of Physics, CAS, XIAO-JIA CHEN, Geophysical Laboratory, Carnegie Institution of Washington, Washington, D.C., JING GUO, PEIWEN GAO, Institute of Physics, CAS, HANGDONG WANG, MINGHU FANG, Department of Physics, Zhejiang University, China, XIAOLONG CHEN, GENFU CHEN, QI WU, DACHUN GU, CHAO ZHANG, XIAOLI DONG, XI DAI, Institute of Physics, CAS, HO-KWANG MAO, Geophysical Laboratory, Carnegie Institution of Washington, Washington, D.C., ZHONGXIAN ZHAO, Institute of Physics, CAS — In this talk, we present our recent progress in effect of pressure on superconductivity of newly discovered iron chalcogenide superconductors. We show that the either positive or negative pressure can tune superconductivity of this new kind of superconductors. Superconductivity with higher superconducting transition temperature T_c can reemerge after elimination of the initial superconducting phase upon compression. We find that the maximum T_c of the reemerging superconducting phase is as high as 48.7 K for $\text{K}_{0.8}\text{Fe}_{1.70}\text{Se}_2$ and 48 K for $\text{Ti}_{0.6}\text{Rb}_{0.4}\text{Fe}_{1.67}\text{Se}_2$, setting a new T_c record for chalcogenide superconductors. The presence of the second superconducting phase is proposed to be related to pressure-induced quantum criticality. Our findings open up the potential route for the exploration of high- T_c superconductivity in iron-based and other superconductors.

Monday, February 27, 2012 2:30PM - 5:18PM — Session D23 DCMP: Metals Theory Oxides Interfaces 255

2:30PM D23.00001 Transferable tight-binding description of the Fe-C interaction, NICHOLAS HATCHER, GEORG K.H. MADSEN, RALF DRAUTZ, ICAMS, Ruhr-Universität Bochum — A coherent transferable tight-binding (TB) parameterization including magnetism has yet to be developed for the Fe-C interaction. Although interatomic potentials have been obtained for this system, recent findings show that the results from these potentials are inconsistent with DFT calculations and do not give an accurate portrayal of chemical bonding in the system. Using dual DFT grid and LCAO calculations within GPAW, we obtain one electron wave functions expanded in a multiple- ζ LCAO basis. This is then down-folded onto an optimal minimal basis, giving a continuous and transferable description of Fe-C bonding. By constructing a TB energy functional using these bond integrals and a parameterized interatomic repulsion, we show how an accurate description of the energy hierarchy of interstitial carbon in Fe-structures can be achieved. Furthermore, we use the model to calculate elastic properties and energies of a variety of Fe-carbides, defects, and carbon diffusion paths. This simple model based on physical insights may be used to study systems containing thousands of atoms.

2:42PM D23.00002 Empirical potentials from a combined density functional theory / genetic algorithm approach: Illustration for Xe in UO₂, ALEXANDER THOMPSON, BRYCE MEREDIG, CHRIS WOLVERTON, Northwestern University — We have developed a new empirical potential for xenon in uranium dioxide with existing UO₂ potentials that achieves accurate xenon defect energetics. This potential was fit to several snapshots of DFT+U molecular dynamics of a single defect configuration using the genetic algorithm code Iterative Potential Refinement (IPR). In IPR, the forces, stresses, and energies from DFT calculations are used to parameterize empirical potentials. Several random sets of parameters are used to compare against DFT and the genetic algorithm minimizes the error of the parameters with respect to the DFT results. We compare this potential and other xenon potentials to DFT+U using a large set of defect calculations of xenon incorporated into sites with high, intermediate, low strain. Despite only being fit to a single configuration, our new empirical potential gives the very good agreement with DFT+U across a range of xenon incorporation sites and vastly outperforms existing xenon potentials.

2:54PM D23.00003 ABSTRACT WITHDRAWN —

3:06PM D23.00004 The dielectric response of single-crystal UO₂ probed by terahertz time-domain spectroscopy, YONG AN, MST-8, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, TREVOR TYSON, Department of Physics, New Jersey Institute of Technology, Newark, NJ 07102, USA, STEVEN CONRADSON, MST-8, Los Alamos National Laboratory, Los Alamos, NM 87545, USA — We measured the complex dielectric function, $\varepsilon = \varepsilon_r + i\varepsilon_i$, of single-crystal UO₂ in the temperature (T) range of 5-500 K by terahertz (THz) time-domain spectroscopy to study its dielectric response. A critical temperature point of 60 K is found for the measured temperature dependence of $\varepsilon_r(T)$. The dispersion of $\varepsilon(\omega)$ in the THz range follows the trend of the damped resonant mode of the transverse optical phonon at $\omega_{TO}=8.4$ THz. Examining the Lyddane-Sachs-Teller relationship reveals mode-softening of ω_{TO} in the temperature range of 60-120 K. We then performed optical-pump THz-probe measurements to study the dynamic dielectric response of UO₂ following photoexcitation. We observe a small pump-induced change in ε that lasts for more than one millisecond, indicating heavy electron behavior of photoexcited 5f electrons resulting from strong electron-lattice interaction. The slow relaxation is attributed to the diffusion of optical phonons generated by photoexcited 5f electrons in the UO₂ crystal.

3:18PM D23.00005 Magnetocaloric Effect of NiFeCoCrPdx High Entropy Alloys¹, DUSTIN BELYEA, University of South Florida, C. BAUER, USF, M. LUCAS, Air Force Research Laboratory, J. HORWATH, AFRL; Wright State University, E. MICHEL, AFRL; UTC inc., CASEY W. MILLER, USF — FeCoCrNi is one of many “high entropy alloys” (HEAs), which are multicomponent alloys with high entropy of mixing. These materials often have high hardness, and resistance to wear and corrosion, making them attractive for applications. Here, we report on the magnetic entropy change and magnetocaloric effect of the FeCoCrNiPdx system. The addition of Pd to FeCoCrNi has been shown to enable the critical temperature to be tuned from 130 K for x=0 to 500 K for x=2. Isothermal magnetization measurements were made on samples with x ranging from 0 to 0.50 as functions of temperature. The magnetic entropy change (ΔS) was calculated using the thermodynamic Maxwell Relation. We find that Pd additions tune the peak ΔS temperature from 130 to 300K, while modestly increasing the peak ΔS magnitude. Interestingly, the addition of Pd leads to an almost doubling of the relative cooling power (RCP), as well as a notable change in the critical behavior of the material. The RCP of ~ 35 J/kg for a 1T field change puts the Pd-containing HEAs in competition with other magnetocaloric materials in the 100-200 K operating range. This alloy system's combination of durability and a tunable Curie temperature without appreciable change in cooling power may make this system interesting for magnetocaloric applications.

3:30PM D23.00006 Magnetic and crystallographic properties of Cr_{1-x}Fe_xGe, YUEN YIU, NIRMAL GHIMIRE, DAVID MANDRUS, University of Tennessee, STEPHEN NAGLER, MICHAEL MCGUIRE, Oak Ridge National Laboratory, DAVID MANDRUS COLLABORATION — According to previously published bulk measurements, Cr_{1-x}Fe_xGe exhibits a quantum critical point at $x=0.75$, where it turns from a paramagnet (for $x > 0.75$) into a ferromagnet (for $x < 0.75$). Cr_{1-x}Fe_xGe is a simple cubic B20 (FeSi) crystal. The endpoints of the alloy are binary compounds that have been studied to some degree. FeGe, the better known of the two, is a spiral ferromagnet similar to MnSi. However, less is known for CrGe, which is thought to be a weakly ferromagnetic paramagnet with bulk properties that may be explained by the paramagnon theory. We report new neutron scattering results on Cr_{1-x}Fe_xGe for $x=0.6, 0.7, 0.75, 0.8$.

3:42PM D23.00007 An *ab-initio* multiscale method to investigate chemical embrittlement of metals, GEORG SCHUSTERITSCH, Harvard University, THOMAS KÜHNE, Johannes Gutenberg University of Mainz, EFTHIMIOS KAXIRAS, Harvard University — We present a multiscale method, coupling a small region treated by first-principles quantum mechanics, to a large classical atomistics region. Our method is based on total energy arguments that are applicable to metals. We employ Kohn-Sham (KS) Density Functional Theory (DFT) in the region of interest and couple this to the classical Embedded Atom Method (EAM). Results for the chemical embrittlement of metals due to segregated impurities at grain boundaries (GB) are presented. We study the average interplanar strain surrounding the GB and use this as a measure of the atomic relaxation. We apply our method to study the chemical embrittlement of Cu by Bi and Pb impurities and compare this to the effect of Ag impurities, which are known to segregate to the GB but not embrittle Cu. We find that Bi and Pb weaken and hence embrittle the Cu GB. In contrast Ag impurities at the GB plane increase cohesion.

3:54PM D23.00008 Molecular dynamics study of the thermopower of Ag, Au, and Pt nanocontacts, F. PAULY, Molecular Foundry, Lawrence Berkeley National Laboratory, USA, J.K. VILJAS, Department of Physics, University of Oulu, Finland, M. BÜRKLE, Institute for Theoretical Solid State Physics, Karlsruhe Institute of Technology, Germany, M. DREHER, P. NIELABA, Department of Physics, University of Konstanz, Germany, J.C. CUEVAS, Departamento de Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, Spain — Using molecular dynamics simulations of many junction stretching processes combined with tight-binding-based electronic structure and transport calculations, we analyze the thermopower of silver (Ag), gold (Au), and platinum (Pt) atomic contacts. In all cases we observe that the thermopower vanishes on average within the standard deviation and that its fluctuations increase for a decreasing minimum cross section of the junctions. However, we find a suppression of the fluctuations of the thermopower for the s-valent metals Ag and Au, when the conductance originates from a single, perfectly transmitting channel. Essential features of the experimental results for Au, Ag, and copper (Cu) of Ludoph and van Ruitenbeek [Phys. Rev. B 59, 12290 (1999)], as yet unaddressed by atomistic studies, can hence be explained by considering the atomic and electronic structure at the disordered narrowest constriction of the contacts. For the multivalent metal Pt our calculations predict the fluctuations of the thermopower to be larger by one order of magnitude as compared to Ag and Au, and suppressions of the fluctuations as a function of the conductance are absent. Main features of our results are explained in terms of an extended single-level model.

4:06PM D23.00009 First-Principles Study of Hydrogen Permeation in Palladium-Gold Alloys, ANGELO BONGIORNO, SHUCHENG XU, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA 30332 — Density functional theory and lattice model calculations are combined to study the permeability of hydrogen in Pd lightly alloyed with Au. This study shows that small amounts of Au substitutions in Pd lead to, respectively, an increase and decrease of the diffusivity and solubility of hydrogen in the alloy. The competition between these two phenomena depends on temperature and can yield dilute PdAu membranes with a hydrogen permeability higher than pure Pd.

4:18PM D23.00010 Hydrogen Embrittlement in Zirconium: a Quasi-Continuum Density Functional Theory Study¹, Q. PENG, Rensselaer Polytechnic Institute — The hydrogen embrittlement in Zirconium becomes a very important and emergent issue for academia, industry and policy makers as a result of the Japan nuclear accident. The hydride formation, diffusion and embrittlement in zircaloy will impact dramatically on the development of advanced nuclear energy systems, the life time extension of the current nuclear fleet and dry storage of spent nuclear fuel. Quasi-Continuum Density Functional Theory (QCDFE) is a powerful concurrent multiscale method based entirely on density functional theory (DFT) and allows quantum simulations of materials properties of a large system with billions of atoms. Using QCDFE modeling, we found that the presents of hydrogen at the cracktip of zirconium, both on crack surface and in-bulk, will form zirconium hydrides and embrittle the system. The concentration of hydrogen and orientation of crack plays important roles in such embrittlement. The mechanism of hydrogen embrittlement under various loading conditions will be discussed.

¹The authors would like to acknowledge the generous financial support from the Defense Threat Reduction Agency (DTRA) Grant # BRBA08-C-2-0130, and the U.S. Nuclear Regulatory Commission Faculty Development Program under contract # NRC-38-08-950.

4:30PM D23.00011 Effects of disorder on the T-dependent bandstructure of purple bronze Li₂Mo₁₂O₃₄, THOMAS JARLBORG, PIOTR CHUDZINSKI, THIERRY GIAMARCHI, DPMC, University of Geneva, 24 Quai Ernest-Ansermet, CH-1211 Geneva 4, Switzerland — The band structures of ordered and disordered Li₂Mo₁₂O₃₄ are calculated by use of *ab-initio* DFT-LMTO method. The unusual band dispersion in the z-direction obtained in previous band calculations is confirmed for the ordered structure, and the overall band structure agree reasonably with existing photoemission data. The T-dependent band broadening is calculated from configurations with thermal disorder of the atomic positions within the unit cell. The band structure shows important band broadening of the two bands at the Fermi energy. The bands are particularly sensitive to in-plane movements of Mo sites. Already disorder due to zero-point motion makes a band broadening of the order of 20 meV and creates a sizable band overlap. The effect of Li vacancies on the two bands is relatively small.

4:42PM D23.00012 Metamagnetic transition self-propelled by the spin injection, ALEXANDER ZYUZIN, University of Waterloo, A.YU. ZYUZIN, A.F. Ioffe Physico-Technical Institute — We study metamagnetic phase transition of itinerant electrons controlled by the spin injection mechanism. The current flow between a ferromagnetic metal and a metamagnetic metal produces the non-equilibrium shift of chemical potential for spin-up and spin-down electrons. This shift acts as an effective magnetic field driving the metamagnetic transition between low and high magnetization states of the metamagnet in the vicinity to the contact with the ferromagnet. We show that high magnetization state of the metamagnet self propels into the bulk of the metamagnet and the length of this state has threshold dependence on the electrical current.

4:54PM D23.00013 Generalized Statistical Thermodynamics Applied to Small Material Systems, ROBERT CAMMARATA, Johns Hopkins University — When characterizing the behavior of small material systems, surface effects can strongly influence the thermodynamic behavior and need to be taken into account in a complete thermal physics analysis. Although there have been a variety of approaches proposed to incorporate surface effects, they are often restricted to certain types of systems (e.g., those involving incompressible phases) and often invoke thermodynamics parameters that are often not well-defined for the surface. It is proposed that a generalized statistical mechanics based on the concept of thermodynamic availability (exergy) can be formulated from which the surface properties and their influence on system behavior can be naturally and rigorously obtained. This availability-based statistical thermodynamics will be presented and its use illustrated in a treatment of nucleation during crystallization.

5:06PM D23.00014 $d + id$ superconductivity on the honeycomb bilayer, MILICA MILOVANOVIC, JAKSA VUCICEVIC, DARKO TANASKOVIC, Institute of Physics Belgrade — We demonstrate that for interlayer attractive interactions on bilayer honeycomb lattice with large interlayer hopping, a time reversal symmetry breaking d -wave topological superconductor is a dominant phase. We find that small momentum order parameter expansion has $d_{x^2-y^2} + id_{xy}$ symmetry around both Dirac points and discuss a possible relevance of this state for experiments on graphene bilayer.

Monday, February 27, 2012 2:30PM - 5:30PM —
Session D24 FIAP: Bionanotechnology and Nanostructured Sensors 256

2:30PM D24.00001 Zirconium tungstate/epoxy resin nanocomposites with negative coefficient of thermal expansion for all-dielectric cryogenic temperature sensors, ERICH SEE, Virginia Tech, VLADIMIR KOCHERGIN, LAUREN NEELY, MADRAKHIM ZAYETNIKOV, MicroXact Inc., GIANLUIGI CIOVATI, Jefferson Lab, HANS ROBINSON, Virginia Tech — The α -phase of zirconium tungstate (ZrW_2O_8) has the remarkable property that its coefficient of thermal expansion (CTE) is negative over its entire range of thermal stability (0-1050K), and through this range it has a nearly constant negative CTE. When ZrW_2O_8 nanoparticles are mixed into a polymer resin, the resulting composite has a reduced CTE when compared with that of the pure polymer. However, previous research on such composites has occurred only near room temperature. We show that at cryogenic temperatures, it is possible to make ZrW_2O_8 /resin nanocomposites with negative CTE. By coating a fiber-optic Bragg grating with such a composite, we were able to create an all-optical temperature sensor without the use of metals, which would be of particular use in superconducting RF cavities. The sensor has sensitivity down to at least 2 K, six times lower than previous fiber-optic temperature sensors.

2:42PM D24.00002 ABSTRACT WITHDRAWN —

2:54PM D24.00003 Strong two-photon-fluorescence from semiconducting polymer nanoparticles for high contrast imaging of cancerous cells, SOUMITRA SATAPATHI, Department of Physics and Applied Physics, University of Massachusetts Lowell, Lowell, MA, 01854, ANOOP PAL, Biomedical Engineering and Biotechnology Program, University of Massachusetts Lowell, Lowell, MA, 01854, LIAN LI, US Army Natick Soldier Research, Development & Engineering Center, Natick, MA, 01760, SURESH GADDE, Nanodelivery Laboratory, Brigham and Women's Hospital, Harvard Medical School, Boston, MA 02115, DHIMITER BELLO, Biomedical Engineering and Biotechnology Program, University of Massachusetts Lowell, Lowell, MA, 01854, LYNNE SAMUELSON, University of Massachusetts Lowell, Lowell, MA, 01854, JAYANT KUMAR, Department of Physics and Applied Physics, University of Massachusetts Lowell, Lowell, MA, 01854 — Strong two-photon-induced fluorescence was observed from a series of novel fluorescent semiconducting polymer nanoparticles using femtosecond laser pulses at 800 nm. The conjugated polymer nanoparticles were fabricated by a simple technique known as the "mini emulsion" technique. The quadratic dependence of the two-photon-fluorescence was confirmed by varying the laser intensity. The two-photon-absorption cross-sections of the nanoparticles were determined in aqueous dispersions by comparing with that of Rhodamine 6G. The deep penetration of the near-infrared laser together with large absorption cross-section demonstrated here, renders these fluorescent polymer nanoparticles as ideal candidates for high contrast in vivo fluorescent imaging of certain tumor cells.

3:06PM D24.00004 Surface Modified Gadolinium Phosphate Nanoparticles as MRI Contrast Agents¹, MATTHIEU F. DUMONT, Dept. Physics. and NHMFL, Univ. Florida, CELINE BALIGAND, Dept. Physiol. Func. Genomics, Univ. Florida, ELISABETH S. KNOWLES, MARK W. MEISEL, Dept. Physics. and NHMFL, Univ. Florida, GLENN A. WALTER, Dept. Physiol. Func. Genomics, Univ. Florida, DANIEL R. TALHAM, Dept. Chem., Univ. Florida — Nanoparticles of $\text{GdPO}_4\cdot\text{H}_2\text{O}$ were synthesized in a water/oil microemulsion using IGEAL CO-520 as surfactant resulting in 50 nm to 100 nm particles that are dispersible and stable in water. Using surface modification chemistry previously established for zirconium phosphonate surfaces,² the particles are directly modified with 5'-phosphate terminated oligonucleotides, and the specific interaction of the divalent phosphate with Gd^{3+} sites at the surface is demonstrated. The ability of the modified nanoparticles to act as MRI contrast agents was determined by performing MR relaxivity measurements at 14 T. Solutions of nanopure water, Feridex® and Omniscan® (FDA cleared contrast agents) in 0.25% agarose were used for comparison and control purposes. MRI data confirm that $\text{GdPO}_4\cdot\text{H}_2\text{O}$ nanoparticles have relaxivities (r_1, r_2) comparable to commercially available contrast agents.³ In addition, biofunctionalization of the surface of the nanoparticles does not prevent their function as MRI contrast agents.

3:18PM D24.00005 ABSTRACT WITHDRAWN —

3:30PM D24.00006 Surface Plasmon Resonance Imaging of the Enzymatic Degradation of Cellulose Microfibrils, KYLE REITER, ADAM RAEGER, Department of Physics, University of Guelph, ANTHONY CLARKE, Department of Molecular and Cellular Biology, University of Guelph, JACEK LIPKOWSKI, Department of Chemistry, University of Guelph, JOHN DUTCHER, Department of Physics, University of Guelph — As the largest component of biomass on Earth, cellulose represents a significant potential energy reservoir. Enzymatic hydrolysis of cellulose into fermentable sugars, an integral step in the production of biofuel, is a challenging problem on an industrial scale. More efficient conversion processes may be developed by an increased understanding of the action of the cellulolytic enzymes involved in cellulose degradation. We have used our recently developed quantitative, angle-scanning surface plasmon resonance imaging (SPRI) device to study the degradation of cellulose microfibrils upon exposure to cellulolytic enzymes. In particular, we have studied the action of individual enzymes, and combinations of enzymes, from the *Hypocrea Jecorina* cellulase system on heterogeneous, industrially-relevant cellulose substrates. This has allowed us to define a characteristic time of action for the enzymes for different degrees of surface coverage of the cellulose microfibrils.

3:42PM D24.00007 Non-destructive method for measuring the Ca/P ratio in human bone, ALEXANDER SLEPKO, ALEXANDER DEMKOV, The University of Texas at Austin — Hydroxyapatite (HA) $[\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2]$ is the main mineral constituent in human bone. It crystallizes in hexagonal and monoclinic phase, which are very similar in structure and properties. A critical measure for healthy bones is the Ca/P ratio which in turn affects the dielectric constant of the mineral constituent. The dielectric constant of HA varies between 5 and 20 depending on the Ca/P ratio in the sample [*J. Mater. Sci.: Mater. Med.* **21**, 399]. We suggest exploiting this large span in the dielectric constant in a non-destructive method to measure the Ca/P ratio in bone by optical spectroscopy. Using density functional theory we calculate the long-range corrected phonon dispersion. We find that only modes around 330 cm^{-1} are strongly affected by the dielectric constant. The shifts in frequency can be up to 20 cm^{-1} as you span the range of the dielectric constant. Thus, by measuring the optical shift and comparing with calibrated samples it is possible to draw conclusions on the Ca/P ratio in the mineral. Importantly, we find the same modes in both the monoclinic and hexagonal phases to be sensitive to changes in the dielectric constant.

3:54PM D24.00008 Surface Functionalized Nanocoax Biosensors¹, BINOD RIZAL, MICHELLE ARCHIBALD, GREGORY MCMAHON, Boston College, NATASHA ERDMAN, Joel USA, Inc., STEPHEN SHEPARD, MICHAEL J. BURNS, THOMAS C. CHILES, MICHAEL J. NAUGHTON, Boston College — We have adapted the nanocoax array architecture for high sensitivity, all-electronic chemical and biological sensing. We previously demonstrated ppb concentration level detection sensitivity to volatile organic compounds in dry air using the nanocoax array with nanoporous coax annuli [1]. Here, we report progress toward modifying/functionalizing the coax metal surfaces to enable specific binding of target molecules (e.g. proteins, toxins, pathogenic organisms), followed by electronic interrogation via capacitance/impedance spectroscopy. As a proxy for target molecules, and in order to confirm the ability to selectively functionalize desired surfaces in our nanopillar / nanocoax geometry, we have selectively attached streptavidin-functionalized core-shell CdSe/ZnS quantum dots to gold nanopillars. Next steps will include substituting antibodies for the quantum dots, and measuring the capacitance and impedance response to the introduction of protein (PSA , CA-125, etc.) in serum. Ref. [1]: H.Z. Zhao, B. Rizal, G. McMahon, H. Wang, P. Dhakal, T. Kirkpatrick, Z.F. Ren, T.C. Chiles, D. Cai and M.J. Naughton (submitted).

4:06PM D24.00009 Magnetic wire trap arrays for biomarker-based molecular detection, GREGORY VIEIRA, The Ohio State University Department of Physics, KALPESH MAHAJAN, GANG RUAN, JESSICA WINTER, The Ohio State University William G. Lowrie Department of Chemical and Biomolecular Engineering, R. SOORYAKUMAR, The Ohio State University Department of Physics — Submicrometer-scale magnetic devices built on chip-based platforms have recently been shown to present opportunities for new particle trapping and manipulation technologies. Meanwhile, advances in nanoparticle fabrication allow for the building of custom-made particles with precise control of their size, composition, and other properties such as magnetism, fluorescence, and surface biomarker characteristics. In particular, carefully tailored surface biomarkers facilitate precise binding to targeted molecules, self-actuated construction of hybrid structures, and fluorescence-based detection schemes. Based on these progresses, we present an on-chip detection mechanism for molecules with known surface markers. Hybrid nanostructures consisting of micelle nanoparticles, fluorescent quantum dots, and superparamagnetic iron oxide nanoparticles are used to detect proteins or DNA molecules. The target is detected by the magnetic and fluorescent functionalities of the composite nanostructure, whereas in the absence of the target these signals are not present. Underlying this approach is the simultaneous manipulation via ferromagnetic zigzag nanowire arrays and imaging via quantum dot excitation. This chip-based detection technique could provide a powerful, low cost tool for ultrasensitive molecule detection with ramifications in healthcare diagnostics and small-scale chemical synthesis.

4:18PM D24.00010 Strategies to enhance the bioavailability of curcumin: a potential antitumor drug, ABHISHEK KUMAR, JOSHNA CHITTIGORI, University of Massachusetts Lowell, LIAN LI, LYNNE SAMUELSON, U.S. Army Natick Soldier Research, Development & Engineering Center, DANIEL SANDMAN, JAYANT KUMAR, University of Massachusetts Lowell — Curcumin is a polyphenol which has elicited considerable interest for its antioxidant and anti tumor properties. Although curcumin may be used as potential therapeutic drug, it is very sparingly soluble in water which makes it less bioavailable under physiological conditions. We report two approaches to make curcumin more bioavailable. The first approach involves fabricating colloidal dispersions of curcumin in the range of tens of nanometers. The second approach involves functionalization of curcumin with polyethylene glycol (PEG) to render it water dispersible or soluble. Since curcumin is a fluorescent molecule as well as a potential drug, its interactions with cells have been investigated using one and two photon confocal fluorescence imaging. We have also observed strong interaction between curcumin and metal ions, which may have physiological implications.

4:30PM D24.00011 Comparison anti-bacterial effect of silver/polystyrene nanocomposites on gram negative and positive bacteria, AKHTAROLMOLOOK KAZEMI, Biochemical and Bioenvironmental Engineering Research Center, Sharif University of Technology, MARYAM RAFTARI, Department of physics and Astronomy, University of Sheffield, Sheffield, UK, SAJJAD TOLLABI-MAZRAEHNO, Johannes Kepler University, Altenberger Str. 69, 4040 Linz, Austria, MOHAMMAD MAHDAVI, Department of Physics, Sharif University of Technology, AZAM IRAJIZAD, Institute for Nanoscience and nanotechnology, Sharif University of Technology — Silver nanoparticles/polystyrene nanocomposites were prepared via casting the solution of polystyrene in a mixture of carbon tetrachloride and acetone containing silver nanoparticles. Colloidal silver nanoparticles in acetone were synthesized by pulsed laser ablation (PLA) of pure bulk silver. Casting the colloidal silver nanoparticles in a solution of polystyrene results in a yellowish transparent polymeric sheet. TEM images show rather spherical nanoparticles with mean diameter of 5 nm. Ag/PS nanocomposites were characterized by UV-VIS spectroscopy. In this study, we also investigated the antimicrobial activity of silver nanocomposites against Escherichia coli (E.coli) and Staphylococcus aureus (S.aureus) as a model for Gram negative and Gram positive bacteria. Antibacterial tests were performed against E. coli and S.aureus, on LB agar plates containing different amount of nanoparticles. Our results showed at all these concentrations, the nanoparticles caused a growth delay of E. coli, increasing the concentration of nanoparticles increased this growth delay.

4:42PM D24.00012 Luminescence of Rare-Earth-Doped Nanoparticles with Aromatic Linker Molecules, TESS SENTRY, MOHITA YALAMANCI, YANWEI ZHANG, ANYA LEACH, MOHINDAR SEEHRA, XIAODONG SHI, ALAN BRISTOW, West Virginia University — Rare-earth-doped vanadate glasses retain their luminescence when formed as shells around magnetic cores [1]. This property has prompted speculation that composite magneto-photoluminescent (CMPL) structures can be used in biological applications. For example, CMPL nanoparticles can be magnetically tuned to separate cells, proteins and nucleic acids [2]. A crucial step in realizing this goal is to attach organic linkers (between the rare-earth-doped shell and bio-probes), which do not affect the luminescence. We demonstrate with IR spectroscopy that Eu:YVO₄ nanoparticles treated with benzoic acid, 3-nitro 4-chloro-benzoic acid and 3,4-dimethoxy benzoic acid all result in the modification of the surface states, replacing the native metal-hydroxyl bond with a longer chain aromatic linker, which can be later functionalized. Photoluminescence spectra under UV-excitation show that the dominant ⁵D₀ → ⁷F₂ transition at ~620 nm is unaffected by the chemical treatment. The result provides a platform to facilitate the attachment of bio-probes to Eu:YVO₄ nanoparticles and related CMPL nanostructures with Fe₂O₄ cores.

4:54PM D24.00013 Light-powered nanoparticle – MEMS hybrid, EVGENIYA MOISEEVA, TOMAS LUCAS, GUANDONG ZHANG, ANDRE GOBIN, CINDY HARNETT, University of Louisville, ELECTRICAL AND COMPUTER ENGINEERING DEPARTMENT TEAM, BIOENGINEERING DEPARTMENT TEAM — This work presents a light-actuated microelectromechanical (MEMS) structure with bistable elements and its applications in cellular-scale actuation. These devices are built using a metal/oxide bilayer with a stress mismatch. In the hybrid design that uses gold nanoparticles for localized heating, a nanoparticle coating is patterned onto the selected part of the device by Parylene micro-stenciling before releasing the structures from the planar substrate. These gold nanoparticles are attractive for use in μ TAS and biotechnology due to their biocompatibility and inertness, the ability to conjugate to the surface via thiol chemistry or electrostatic interaction, and especially their strong tunable absorption in the near infrared region. Integration of the near infrared (IR)-resonant gold nanoparticles with bistable MEMS structures creates light-driven hybrid actuators that quickly respond to narrow-band IR light. The movement of the MEMS device is achieved through controlled thermal expansion, with actuation speed in the millisecond range.

5:06PM D24.00014 Motion observation and SPR measurements of kinesin motility on microtubules, A. SIKORA, D. OLIVEIRA, K. KIM, WPI-AIMR, Tohoku University, Japan, A.L. LIAO, WPI-AIMR, Tohoku University, Japan and Materials Science and Engineering, Texas A&M University, M. UMETSU, T. ADSCHIRI, WPI-AIMR, Tohoku University, Japan, W. HWANG, Materials Science and Engineering, Department of Biomedical Engineering, Texas A&M University, W. TEIZER, WPI-AIMR, Tohoku University, Japan; Materials Science and Engineering and Department of Physics and Astronomy, Texas A&M University — Motor proteins convert chemical energy directly into mechanical work with high efficiency (~50%). One of these proteins, kinesin, is used in the cell to transport organelles. It “walks” along biopolymer tracks called microtubules and, depending on the type, can reach speeds of a few micrometers per second. Kinesin can carry intracellular cargo over long distances against several piconewtons of loads and is barely limited by the cargo size. Motion of streptavidin-coated quantum dots carried by kinesin on microtubules will be presented. We have expressed biotinylated Kinesin-1 using *Escherichia coli*. Attachment to quantum dots was performed using the strong binding affinity between streptavidin and biotin. Microtubules, labeled with rhodamine, allow visualization by fluorescence microscopy. The measured speed of our kinesin fits well with results found in the literature. Surface Plasmon Resonance (SPR) measurements allow the identification and strength evaluation of bonding. Using this technique, we will present results on the binding between our expressed kinesin and microtubule.

5:18PM D24.00015 Construction of Quantum Dot Micro/Nano-track as a Seedbed for Kinesin Motor Proteins, K. KIM, WPI-AIMR, Tohoku University, Japan, A. L. LIAO, WPI-AIMR, Tohoku University, Japan; Materials Science and Engineering, Texas A&M University, A. SIKORA, D. OLIVEIRA, M. UMETSU, T. ADSCHIRI, WPI-AIMR, Tohoku University, Japan, W. HWANG, Materials Science and Engineering, Department of Biomedical Engineering, Texas A&M University, W. TEIZER, WPI-AIMR, Tohoku University, Japan; Materials Science and Engineering and Department of Physics and Astronomy, Texas A&M University — Kinesin is a motor protein engaged in motion on microtubules. It is involved in various subcellular processes such as cell division and transportation of intracellular cargo. The system of (1) kinesin, (2) *in-vitro* polymerized microtubules and (3) specifically functionalized quantum dots has been employed to realize kinesin motility *in-vitro*. Selective attachment of the kinesin motor protein to a surface is an important prerequisite for the development of artificial bio-engineered devices utilizing these dynamic processes in *in-vitro* systems. We will elucidate the feasibility of using a micro/nano-track paved with streptavidin coated quantum dots as fluorescently traceable linkers for biotinylated kinesins. This will be based on results from fluorescence microscopy observations of recent motility assays and quantum dot distributions observed on structured PMMA (polymethyl-methacrylate) surfaces patterned by electron beam lithography.

Monday, February 27, 2012 2:30PM - 5:06PM –
Session D25 DCOMP GSCCM DMP: Focus Session: Matter at Extreme Conditions - New Experimental Capabilities 257A

2:30PM D25.00001 Ultrafast, high resolution, phase contrast imaging of shock response with synchrotron radiation: opportunities and challenges, S.N. LUO, B.J. JENSEN, D.E. HOOKS, K.J. RAMOS, J.D. YEAGER, K. KWIATKOWSKI, T. SHIMADA, D.A. FREDENBURG, Los Alamos National Lab, K. FEZZAA, Argonne National Lab — Designing materials that function at dynamic extremes and predicting dynamic materials response require experimental investigations of their time, rate and microstructure dependences. Key to such experiments are *in situ*, in-volume, temporally and spatially resolved measurements (e.g., x-ray imaging and diffraction). Here we report ultrafast (<100 ps), high resolution (~3 μm), dynamic phase contrast imaging (PCI) measurements during high strain-rate loading (100 ns scale). A gas gun was installed at 32ID beamline of the Advanced Photon Source for dynamic loading, and dynamic PCI measurements were performed with a single x-ray pulse on representative materials/processes, including cylinder impact and penetration, large-cell foam compaction, cerium jet formation and granular material compression. We present overall experimental scheme and opportunities for dynamic materials research as seen from the preliminary results, as well as challenges both for photon sources and detectors.

2:42PM D25.00002 Probing Matter at an Atomic Unit of Pressure using convergent compression, JAMES HAWRELIAK, DAMIAN SWIFT, JON EGGERT, DAVE BRAUN, LLNL, STEVE ROTHMAN, AWE, GILBERT COLLINS, LLNL — Geometric confinement significantly increases the shock pressure as a spherically-converging shock approaches the central focus. Inertial confinement fusion is one area where this technique enables the 100 MBar ablation pressure to multiply to the several-GBar pressure required for fusion. We are using x-ray radiography of a spherically convergent shock wave in a solid sphere to explore material equations of state at pressures which exceed the atomic unit of pressure ($E_h/a_0 = 300\text{MBar}$); the energy density of a hydrogen atom. Measuring materials properties above this pressure will breach yet another significant barrier in our quest to understand extreme states, and will open a completely new realm where the atomic nature of matter is very strongly perturbed. We will discuss initial experiments performed on the Omega laser facility and plans for future experiments on the NIF.

2:54PM D25.00003 High-resolution phase contrast imaging of brittle failure during impact loading, KYLE RAMOS, BRIAN JENSEN, LUO SHENGNIAN, DANIEL HOOKS, JOHN YEAGER, KRIS KWIATKOWSKI, TSUTOMU SHIMADA, Los Alamos National Laboratory, KAMEL FEZZAA, Advanced Photon Source — Heterogeneous processes involved in brittle failure necessitate *in situ*, spatially resolved observation. An impact capability has recently been developed in which synchrotron phase contrast imaging (PCI), at the 32-ID beamline of the Advanced Photon Source, can be used to resolve crack interfaces during dynamic deformation. The imaging is both fast and high-resolution as images with approximately 3 micrometer resolution are obtained from single x-ray pulses (<100 ps duration). Experiments have been performed to investigate questions regarding velocimetry interpretation, the effect of stress states, and whether cracking can occur under uniaxial compression. Uniaxial compression and tension in planar impact configurations and cylindrical impact penetration has been used to vary stress states and observe failure. PCI and velocimetry results from these experiments will be presented for a range of brittle materials spanning glasses and ceramics.

3:06PM D25.00004 Deformation and material dynamics under ultrafast compression, MICHAEL ARMSTRONG, Lawrence Livermore National Laboratory — For decades, dynamic compression experiments have been used to determine the equation of state of materials, and examine material deformation at high strain rates. Within the last 15 years, ultrafast optical methods have been used to characterize deformation at strain rates in excess of $10^{10}/\text{s}$. Recently such experiments have found broad consistency with empirical laws formulated at orders of magnitude lower strain rates, but have also discovered intriguing phenomena on short time scales, such as elastic stress orders of magnitude beyond the yield strength. These experiments explore the ultimate limits of material relaxation via deformation, and the results suggest exciting possibilities for practical and scientific application of ultrafast compression, including nonequilibrium material synthesis, determination of the equation of state with a small scale experiment, and the investigation of ultrahigh density with a table top laser. Here we will talk about our experiments on the ultrafast deformation of metals, including aluminum and iron, and the ultrafast compression of deuterium.

3:42PM D25.00005 High-resolution phase contrast imaging of jet formation in shocked cerium to examine material strength, BRIAN JENSEN, SHENG LUO, FRANK CHERNE, GUY DIMONTE, GUILLERMO TERRONES, DANIEL HOOKS, KYLE RAMOS, JOHN YEAGER, KRIS KWIATKOWSKI, TSUTOMU SHIMADA, Los Alamos National Laboratory, KAMEL FEZZAA, Argonne National Laboratory — Understanding the dynamic properties of metals has been a long-standing scientific challenge. Experiments are needed to locate phase boundaries, to obtain equation-of-state data within those boundaries, and to examine properties such as material strength in the relevant phases. Efforts have been underway in recent years to examine the multiphase equation-of-state for cerium largely because of its complex phase diagram that exists at relatively moderate pressures and temperatures. To date, experiments have been performed to determine the Hugoniot, the shock-melt transition, and to examine the low-pressure phases through the critical point. In the current work, we present novel data that uses ultrafast, high-resolution phase contrast imaging (PCI) to examine jet-formation in cerium for impact stresses that span the alpha-phase up to the melt boundary. These experiments were performed using a recently developed capability at the 32-ID beamline of the Advanced Photon Source that couples the PCI method with an impact system to obtain real-time, spatially resolved images during dynamic compression. Experimental results will be presented and compared with recent efforts that use more traditional shock-release and double-shock loading to examine strength.

3:54PM D25.00006 High Resolution Diagnostics for Simultaneous Measurements of Velocity and Density in Shock-Driven Instabilities, RICARDO MEJIA-ALVAREZ, SRIDHAR BALASUBRAMANIAN, GREG ORLICZ, KATHY PRESTRIDGE, Los Alamos National Laboratory — The interaction between a shock wave and the interface between two fluids of different density might induce macroscopic mixing of the fluids. It is generally accepted that baroclinic vorticity, resulting from misalignments between the density gradient across the interface and the pressure gradient of the shock wave, impels this macroscopic mixing. So far, the Extreme Fluids Team at Los Alamos National Laboratory has conducted the only detailed studies of the structure of the developing instability. These studies encompass simultaneous measurements of velocity and density via combined Particle Image Velocimetry (PIV) and Planar Laser Induced Fluorescence (PLIF). Using this approach, the above mentioned Team has conducted extensive studies over a varicose curtain of heavy gas (SF_6). Since a curtain implies two succeeding interfaces, a new Vertical Shock Tube (VST) was developed for simultaneous characterization of velocity and density fields of single-interface shock-driven flows. This talk is intended to present some of the results obtained for double-interface shock driven flows, as well as describing the characteristics, challenges, and range of possibilities of the laser diagnostics incorporated in the VST.

4:06PM D25.00007 LCLS: A new frontier for time-resolved in situ lattice measurements in materials at extreme conditions, DESPINA MILATHIANAKI, SLAC National Accelerator Laboratory, DAMIAN SWIFT, JAMES HAWRELIAK, Lawrence Livermore National Laboratory, RICHARD LEE, SLAC National Accelerator Laboratory — While laser-based pump-probe experiments have provided significant insights into the processes induced by dynamic loading (e.g. shock-induced phase transitions, elastic-plastic response), the material behavior at the lattice level has been extremely difficult to unveil due to the temporal and signal-to-noise limitations of laser-based x-ray techniques. Here we present recent dynamic x-ray diffraction measurements on the shock-induced behavior of polycrystalline Mg in the 10-40 GPa regime, followed by future experiments in the field of dynamic high pressure science using the free electron laser at LCLS as an ultrafast x-ray probe.

4:18PM D25.00008 Progress towards Single Shot Spectroscopic Techniques for Time-Resolved Measurements in the Diamond Anvil Cell, DOUGLAS ALLEN DALTON, Geophysical Laboratory, Carnegie Institution of Washington, R. STEWART MCWILLIAMS, M.F. MAHMOOD, Howard University and Geophysical Laboratory, ALEXANDER F. GONCHAROV, Geophysical Laboratory — We will discuss how we are bridging the gap between static diamond anvil cell and dynamic shock experiments using various spectroscopic techniques which utilize nonlinear optics. Using pulsed laser techniques, we can achieve extreme temperatures while probing optical and chemical changes on fast time scales. Recent developments incorporating broadband spectroscopy into the laser heated diamond anvil cell have indicated that probing phase transitions while measuring temperature is possible [1]. Various methods for incorporating nonlinear vibrational spectroscopy (such as CARS) into the diamond anvil cell will be discussed. The application of these optical diagnostics to pulsed laser heating and table-top shock experiments [2] will be presented.

4:30PM D25.00009 Phase diagram of shock and ramp-compressed tin, AMY LAZICKI, JONATHON EGGERT, RYAN RYGG, DAMIAN SWIFT, JAMES MCNANEY, GILBERT COLLINS, Lawrence Livermore National Laboratory — We will present powder x-ray diffraction results on laser-ramp-compressed solid tin up to 600 GPa, and discuss new methods for detecting the melting transition. Tin has a complex phase diagram with multiple observed and predicted high pressure phases and a moderate melting temperature, making it an ideal subject for a fundamental study of material properties using new techniques. Ramp compression in the solid allows access to extremely dense condensed phases and in the liquid the possibility for dynamically freezing molten tin. With newly developed x-ray diffraction methods we examine crystal structure, strength and texture in the dynamically compressed phases, and explore the possibility of a new method for mapping out melting curves.

4:42PM D25.00010 Ultrafast Shock Interrogation of Hydrogen Peroxide/Water Mixtures: Thermochemical Predictions of Shock Condition Chemistry¹, JOSEPH ZAUG, MICHAEL ARMSTRONG, SORIN BASTEA, JEFFREY CARTER, I-F. WILLIAM KUO, JONATHAN CROWHURST, CHRISTIAN GRANT, Lawrence Livermore National Laboratory, X-CHEM TEAM — Hydrogen peroxide is a powerful oxidizer and its concentrated aqueous solutions exhibit very high reactivity, even sustaining detonation under strong enough confinement. Due to its simple composition and basic expected decomposition kinetics hydrogen peroxide is very suitable for studying the interplay of high pressures, temperatures and reactivity and their effect on the equation of state, particularly at the boundary between detonating and non-detonating behavior. To this end we performed speed of sound and picosecond time resolved shock measurements on solutions of hydrogen peroxide of concentrations from 30 to 90 percent, and analyzed the results in terms of common assumptions of chemical equilibrium in reactive fluid mixtures. Experimental shock states were achieved up to a maximum pressure of 20 GPa with corresponding shock velocities of 6-7 km/sec.

4:54PM D25.00011 Simulation of Forward and Inverse X-ray Scattering From Shocked Materials, JOHN BARBER, QUINN MARKSTEINER, CRIS BARNES, Los Alamos National Laboratory — The next generation of high-intensity, coherent light sources should generate sufficient brilliance to perform in-situ coherent x-ray diffraction imaging (CXDI) of shocked materials. In this work, we present beginning-to-end simulations of this process. This includes the calculation of the partially-coherent intensity profiles of self-amplified stimulated emission (SASE) x-ray free electron lasers (XFELs), as well as the use of simulated, shocked molecular-dynamics-based samples to predict the evolution of the resulting diffraction patterns. In addition, we will explore the corresponding inverse problem by performing iterative phase retrieval to generate reconstructed images of the simulated sample. The development of these methods in the context of materials under extreme conditions should provide crucial insights into the design and capabilities of shocked in-situ imaging experiments.

Session D26 DCOMP DMP: Focus Session: Physics of Energy Storage Materials - Catalysis and H₂ Storage 257B

2:30PM D26.00001 Design Principles for Oxygen Reduction and Evolution on Oxide Catalysts

, YANG SHAO-HORN, Massachusetts Institute of Technology — Driven by growing concerns about global warming and the depletion of petroleum resources, developing renewable energy production and storage technologies represent one of the major scientific challenges of the 21st century. A critical element in pursuit of this quest is the discovery of efficient and cost-effective catalysts used in solar fuel production via electrochemical energy conversion processes such as oxygen evolution reaction (OER) and oxygen reduction reaction (ORR), both of which are central to the efficiencies of direct solar and electrolytic water-splitting devices, fuel cells, and metal-air batteries. Although the Sabatier's principle provides a qualitative argument in tuning catalytic activity by varying the bond strength between catalyst surface and reactant/product (neither too strong nor too weak leading to the maximum activity at moderate bond strength), it has no predictive power to find catalysts with enhanced activity. Identifying a "design principle" that links catalyst properties to the catalytic activity is critical to accelerate the search for highly active catalysts based on abundant elements, and minimize the use of precious metals. Here we establish a molecular principle that governs the activities of oxygen evolution reaction (OER) and oxygen reduction reaction (ORR) for oxide catalysts, where the activities primarily correlate to the σ^* orbital ("e_g") occupation of surface transition metal cations established by systematic examination of more than ten to fifteen transition metal oxides. The intrinsic ORR and OER activities exhibit a volcano-shaped dependence on the e_g occupancy and the activities peak at an e_g occupancy close to unity. Our findings reflect the critical influence of the σ^* orbital on the energetics of surface reaction intermediates on surface transition metal ions such as the O₂²⁻/OH⁻ displacement and the OH⁻ regeneration, and thus highlight the importance of surface oxide electronic structure in controlling catalytic activities. Using the established molecular principle, we further demonstrate that an alkaline earth cobalt oxide with a chemical formula of Ba_{0.5}Sr_{0.5}Co_{0.8}Fe_{0.2}O_{3δ} (BSCF), catalyzes the OER with intrinsic activity that is at least an order of magnitude higher than the state-of-the-art iridium oxide catalyst in basic solutions.

3:06PM D26.00002 Modeling of hydrogen evolution reaction on the surface of GaInP₂¹, WOON

IH CHOI, BRANDON WOOD, ERIC SCHWEGLER, TADASHI OGITSU, LLNL, QUANTUM SIMULATION GROUP TEAM — GaInP₂ is promising candidate material for hydrogen production using sunlight. It reduces solvated proton into hydrogen molecule using light-induced excited electrons in the photoelectrochemical cell. However, it is challenging to model hydrogen evolution reaction (HER) using first-principles molecular dynamics. Instead, we use Anderson-Newns model and generalized solvent coordinate in Marcus-Hush theory to describe adiabatic free energy surface of HER. Model parameters are fitted from the DFT calculations. We model Volmer-Heyrovsky reaction path on the surfaces of CuPt phase of GaInP₂. We also discuss effects of surface oxide and catalyst atoms that exist on top of bare surfaces in experimental circumstances.

3:18PM D26.00003 ABSTRACT WITHDRAWN —

3:30PM D26.00004 In situ Raman Evidence for Reversible Room-Temperature Hydrogenation

in Pt-doped Carbons¹, XIAOMING LIU, PSU Materials Research Laboratory, YOUJIAN TANG, ENSHI XU, PSU Department of Physics, THOMAS FITZGIBBONS, PSU Department of Chemistry, HUAN-HSIUNG TSENG, MING-SHENG YU, CHENG-SI TSAO, Taiwan Institute of Nuclear Energy Research, JOHN BADDING, PSU Department of Chemistry, VINCENT CRESPI, PSU Department of Physics, ANGELA LUEKING, PSU Department of Chemical Engineering and EMS Energy Institute, ANGELA D. LUEKING TEAM, JOHN V. BADDING TEAM, VINCENT H. CRESPI TEAM, CHENG-SI TSAO COLLABORATION — Atomic hydrogen spillover was investigated by in situ Raman spectroscopy and density functional theory. In the presence of Pt nanoparticles, modes related to Basal plain hydrogenation were observed for activated carbon and graphene, respectively, during Raman measurements in 100 bar H₂. The modes were absent when Pt, carbon, or H₂ were omitted from the experiment. Substituting H₂ with D₂ led to the expected isotopic shift for a hydrogen-dominated vibrational mode. The mode disappeared and reappeared over several cycles of exposure to H₂ or He at room temperature, consistent with room-temperature reversibility of H chemisorbed to the activated carbon in the presence of Pt nanoparticles. Reversibility apparently arises from a facilitated transition of H from a chemisorbed state to a more mobile physisorbed state, followed by recombination and release. Reversibility for Pt/graphene was much less pronounced, suggesting that structural heterogeneities in the sample carbon support and/or catalyst-carbon contact are important factors.

3:42PM D26.00005 Hydrogen storage on calcium coated boron (hetero-)fullerenes: A DFT study

, SULEYMAN ER, Harvard University, GEERT BROCKS, University of Twente, GILLES A. DE WIJS, Radboud University Nijmegen — Using density functional theory (DFT), we investigate hydrogen storage properties of calcium-coated molecular systems of B₈₀ boron fullerene, C₄₈B₁₂ boron-doped heterofullerenes, and well-known C₆₀ fullerene. Here, we consider the most common and low-lying isomers of B₈₀ and C₄₈B₁₂. We find that the Ca-coated molecules have the following properties: (1) The binding of metal atoms to B₈₀ or to C₄₈B₁₂ molecules is much stronger than their binding to a C₆₀ molecule. (2) B₈₀ and C₄₈B₁₂ have larger electron affinities than their carbon only counterpart, and accordingly discharge the surface Ca atoms more efficiently. (3) B₈₀ molecule, however, shows structural deformations upon reacting with Ca atoms. (4) C₄₈B₁₂Ca₆, however, is stable at elevated temperatures. C₄₈B₁₂ has well-exposed, positively charged Ca atoms on its surface, and binds up to six hydrogen molecules per metal center with hydrogen binding energies of 0.17-0.14 eV/H₂, that are suitable for ambient temperature hydrogen storage.

3:54PM D26.00006 Role of nano in catalysis: Pd catalyzed H desorption from MgH₂, WEIYU XIE,

DAMIEN WEST, YIYANG SUN, SHENGBAI ZHANG, Rensselaer Polytech Inst — Magnesium hydride (MgH₂) is promising for on-board hydrogen (H) storage with the major hurdle being the slow desorption kinetics. H desorption from ball-milled MgH₂ peaks at two slightly different temperatures, which further split in the presence of palladium catalyst. It has been experimentally demonstrated that nanostructuring can eliminate the high temperature peak. However, the effect of nanostructuring cannot be explained by thermodynamic destabilization due to quantum size effect. Our first-principles calculation reveals that there exist two reaction pathways for H desorption from MgH₂. One involves H vacancy (SV) diffusion at surface, while the other one involves H atom diffusion in bulk. The SV pathway self-terminates as dehydrogenation eventually eliminates the exposed MgH₂ region. Therefore, it is size-sensitive and fully functions only when the surface-to-bulk ratio is large, which is available only in nanostructures. Our calculation further shows that the SV pathway significantly lowers the desorption barrier, because it decouples the H transport process with the surface liftoff process and benefits from a fact that diffusion of vacancies at surface can have significantly lower barrier than that in bulk.

4:06PM D26.00007 Particle-size dependence of the activation energy for decomposition of lithium amide¹, CHRIS VAN DE WALLE, Materials Department, University of California, Santa Barbara, KHANG HOANG, Naval Research Laboratory, ANDERSON JANOTTI, Materials Department, University of California, Santa Barbara — Lithium amide (LiNH_2) is a promising material for reversible hydrogen storage, yet atomistic mechanisms behind the dehydrogenation process are unknown. The activation energy for LiNH_2 decomposition has been observed to strongly vary with ball milling, suggesting a dependence of the thermodynamics and kinetics of the decomposition on the particle size. We have examined these mechanisms based on first-principles calculations for native point defects and defect complexes in LiNH_2 . We propose that the decomposition of LiNH_2 into lithium imide (Li_2NH) and ammonia (NH_3) occurs through two competing mechanisms, one involving the formation of native defects in the interior of the material and the other at the surface. As a result, the prevailing mechanism and hence the activation energy depend on the surface-to-volume ratio, or the specific surface area, which changes with the particle size. We explain the observed variations of activation energy, and address the role played by LiH in the dehydrogenation of ($\text{LiNH}_2 + \text{LiH}$) mixtures. The relationship between the structure of hydrogen-related defects and the end products in the decomposition reaction can be extended to other complex hydrides.

4:18PM D26.00008 Deliquescence of NaBH_4 computed from density functional theory, PING LI, WISSAM AL-SAIDI, KARL JOHNSON, University of Pittsburgh — Complex hydrides are promising hydrogen storage materials and have received significant attention due to their high hydrogen-capacity. The hydrolysis reaction of NaBH_4 releases hydrogen with both fast kinetics and high extent of reaction under technical conditions by using steam deliquescence of NaBH_4 . This catalyst-free reaction has many advantages over traditional catalytic aqueous phase hydrolysis. The first step in the reaction is deliquescence, i.e. adsorption of water onto NaBH_4 surface and then formation of a liquid layer of a concentrated NaBH_4 solution, which is quickly followed by hydrogen generation. We have used periodic plane wave density functional theory to compute the energetics and dynamics of the initial stages of deliquescence on the (001) surface of NaBH_4 . Comparison of results from standard generalized gradient approximation functionals with a dispersion-corrected density functional show that dispersion forces are important for adsorption. We used DFT molecular dynamics to assess the elementary steps in the deliquescence process.

4:30PM D26.00009 Electronic Structure and Molecular Dynamics Calculations for KBH_4 ¹, DIMITRIOS PAPACONSTANTOPOULOS, ANDREW SHABAEV, KHANG HOANG, George Mason University, MICHAEL MEHL, Naval Research Laboratory, NICHOLAS KIOUSSIS, UC at Northridge — In the search for hydrogen storage materials, alkali borohydrides MBH_4 ($\text{M}=\text{Li}, \text{Na}, \text{K}$) are especially interesting because of their light weight and the high number of hydrogen atoms per metal atom. Electronic structure calculations can give insights into the properties of these complex hydrides and provide understanding of the structural properties and of the bonding of hydrogen. We have performed first-principles density-functional theory (DFT) and tight-binding (TB) calculations for KBH_4 in both the high temperature (HT) and low temperature (LT) phases to understand its electronic and structural properties. Our DFT calculations were carried out using the VASP code. The results were then used as a database to develop a tight-binding Hamiltonian using the NRL-TB method. This approach allowed for computationally efficient calculations of phonon frequencies and elastic constants using the static module of the NRL-TB, and also using the molecular dynamics module to calculate mean-square displacements and formation energies of hydrogen vacancies.

¹The work at GMU is supported by DoE.

4:42PM D26.00010 Dehydrogenation of LiBH_4 nanoclusters: A first-principles study, EBRAHIM HAZRATI, FILIPE VASCONCELOS, ESM, IMM, Radboud University, GEERT BROCKS, CMS, University of Twente, ROBERT DE GROOT, GILLES DE WIJS, ESM, IMM, Radboud University — Recent experimental studies^{1,2} show faster desorption kinetics, improved reversibility and more favorable thermodynamics for confined LiBH_4 nanoparticles than the bulk. Using density functional theory calculations, we first discuss the geometries and energetics of LiBH_4 , LiH , LiB , Li and B clusters. Secondly, we study the effects of particle size on the decomposition pathway of LiBH_4 clusters. Our calculations show that only very small clusters of LiBH_4 (up to 12 formula units) are significantly destabilized relative to the bulk. High stability of small clusters of LiBH_4 originates from the fact that surface energies are very low for bulk LiBH_4 . (100), (010), (101) and (011) surfaces are almost degenerate with surface energies of 0.113, 0.102, 0.115 and 0.097 J/m², respectively. Clusters of LiH , LiB , Li and B are more strongly destabilized than the LiBH_4 clusters upon decreasing the cluster size. We show that, in contrast to the bulk, destabilized clusters of LiBH_4 decompose to $(\text{LiB})_n$ clusters. Finally, we present some of our preliminary NMR chemical shift results for different LiBH_4 surface terminations.

4:54PM D26.00011 First-principles Modeling of Diffusion during Hydrogenation of LiBH_4 , CHAO YU, VIDVUDS OZOLINS, Department of Materials Science and Engineering, University of California, Los Angeles — LiBH_4 has been studied extensively because of its high volumetric and gravimetric hydrogen content. However, experiments show that hydrogen release is very slow at temperatures up to 300 C, which severely limits applications in mobile storage. Using density-functional theory calculations, we systematically study bulk diffusion of defects during solid-state hydrogenation reactions. The defect concentration and concentration gradients are calculated for a variety of defects, including charged vacancies and interstitials. We find that low concentration gradients limit the rate of hydrogen desorption.

5:06PM D26.00012 Bulk diffusion of defects in $\text{LiAlH}_4/\text{Li}_3\text{AlH}_6$, BILJANA ROLIH, VIDVUDS OZOLINS, UCLA — From various experimental studies on decomposition of hydrogen storage materials it has been proposed that bulk diffusion of metal species may be the rate limiting step in hydrogen storage reactions. A recently developed theoretical model uses density functional theory to study the underlying processes involved in bulk diffusion. To date this model has been applied to study dehydrogenation of NaAlH_4 . However further study of alkaline and alkali earth metals merits attention, particularly LiAlH_4 with a high gravimetric hydrogen density, accessible at moderate temperatures. This study uses density functional theory to obtain concentration gradients and diffusivities of native charged and neutral defects in Li_3AlH_6 and LiAlH_4 . The flux of each defect is obtained and thus the activation energy for each defect. Our results show that diffusion of metal species is a possible rate limiting process in the system.

5:18PM D26.00013 First-Principles Study of the Li-Na-Ca-N-H System: Compound Structures and Hydrogen-Storage Properties, PATTANASAK TEERATCHANAN, FEI ZHOU, University of California, Los Angeles, KYLE MICHEL, Northwestern University, VIDVUDS OZOLINS, University of California, Los Angeles — Mixed-metal amides and imides are being widely investigated as potential hydrogen storage materials. Using a combination of first-principle DFT calculations, grand-canonical linear programming, and prototype electrostatic ground state (PEGS) approaches, we predict hydrogen storage reactions in the Li-Na-Ca-N-H system. The enthalpies, entropies, static, zero-point, and $T > 0\text{K}$ vibrational energies of known compounds together with our predictions of some incomplete experimental crystal structures are presented.

Monday, February 27, 2012 2:30PM - 5:30PM – Session D27 DMP GERA: Invited Session: Materials for Energy Applications 258AB

2:30PM D27.00001 The DOE SunShot Initiative: Science and Technology to enable Solar Electricity at Grid Parity, RAMAMOORTHY RAMESH, US DOE / UC Berkeley — The SunShot Initiative's mission is to develop solar energy technologies through a collaborative national push to make solar Photovoltaic (PV) and Concentrated Solar Power (CSP) energy technologies cost-competitive with fossil fuel based energy by reducing the cost of solar energy systems by ~ 75 percent before 2020. Reducing the total installed cost for utility-scale solar electricity to roughly 6 cents per kilowatt hour ($1\$/\text{Watt}$) without subsidies will result in rapid, large-scale adoption of solar electricity across the United States and the world. Achieving this goal will require significant reductions and technological innovations in all PV system components, namely modules, power electronics, and balance of systems (BOS), which includes all other components and costs required for a fully installed system including permitting and inspection costs. This investment will re-establish American technological and market leadership, improve the nation's energy security, strengthen U.S. economic competitiveness and catalyze domestic economic growth in the global clean energy race. SunShot is a cooperative program across DOE, involving the Office of Science, the Office of Energy Efficiency and Renewable Energy and ARPA-E.

3:06PM D27.00002 Integrating the multifunction necessary for electrochemical energy storage into energy- and size-scalable ultraporous nanoarchitectures¹, DEBRA ROLISON², U.S. Naval Research Laboratory — Designing high performance energy-storage devices that combine nanometric feature size with well-wired transport paths requires an architectural perspective. We chose carbon aerogel-like nanofoam papers as attractive plug-and-play electrode substrates because of such desirable properties as high specific surface area, electronic conductivity, and through-connected pore structure. Achieving this blend of desirable properties requires an optimal balance of critical architectural features: (1) open, 3D interconnected macropores sized at 100 to 300 nm (a difficult-to-obtain size range in porous carbons) and (2) pore walls of a size that reduce dead weight and volume (preferably ca. 20-nm wall thickness for 100- to 300-nm voids), yet retain mechanical strength and flexibility without compromising electronic conductivity (preferably ca. 20 S/cm). Carbon nanofoam papers provide a low cost and scalable nanocomposite that exists within this "Goldilocks zone" of desirable properties and which has catalyzed breakthroughs in our work with asymmetric electrochemical capacitors, air cathodes for metal/air batteries, lithium-ion batteries, 3D batteries, and semifuel cells. New charge-storage or catalytic functionality is imparted to internal carbon walls simply by transporting reactants within the 3D macroporous. Self-limiting modification strategies allow us to incorporate conformal, nanoscopic "paints" of metal (Mn, Ti, Ru, Fe) or polymer (redox-active or electron insulating) or to specifically adsorb metal nanoparticles (Pt, Au, Pd, Ag) throughout the macroscopic thickness (0.07 to 0.3 mm) of carbon nanofoam papers as dictated by the requirements of a specific end application. For instance, modification with 10-nm MnO_x increases the mass-, geometric-, and volume-normalized capacitance (2- to 10-fold) relative to the native carbon nanofoam without significantly altering its high-rate character and provides a structure that can be used in an asymmetric electrochemical capacitor or used to an air cathode in a Zn/air cell to electrocatalyze oxygen reduction and provide pulse power. Our redesigned carbon nanofoam offers a versatile design platform for much-needed advances in a broad range of multifunctional energy storage and conversion.

¹This work was supported by the U.S. Office of Naval Research.

²In collaboration with Jeffrey W. Long, Megan B. Sassin, Christopher N. Chervin, Joseph F. Parker, Jean Marie Wallace, Natalie L. Brandell, Bradley T. Willis, and Nathan W. Kucko.

3:42PM D27.00003 Bio-inspired Approaches to Solar Energy Conversion, MICHAEL WASIELEWSKI, Department of Chemistry and ANSER Center, Northwestern University, Evanston, IL 60208-3113 — Natural photosynthesis is carried out by organized assemblies of photofunctional tetrapyrrole chromophores and catalysts within proteins that provide specifically tailored environments to optimize solar energy conversion. Artificial photosynthetic systems for practical solar fuels production must collect light energy, separate charge, and transport charge to catalytic sites where multi-electron redox processes will occur. The primary goal of our research in this field is to understand the fundamental principles needed to develop integrated artificial photosynthetic systems. These principles include how to promote and control: 1) energy capture, charge separation, and long-range directional energy and charge transport, 2) coupling of separated charges to multi-electron catalysts for fuel formation, and 3) supramolecular self-assembly for scalable, low-cost processing from the nanoscale to the macroscale. The central scientific challenge is to develop small, functional building blocks, having a minimum number of covalent linkages, which also have the appropriate molecular recognition properties to facilitate self-assembly of complete, *functional* artificial photosynthetic systems. This lecture will describe our use of ultrafast optical spectroscopy and time-resolved EPR spectroscopy to understand charge transport in self-assembled structures for artificial photosynthesis.

4:18PM D27.00004 Quantum-well and quantum-dot structures for high-efficiency photovoltaics, EDWARD YU, The University of Texas at Austin — Quantum-well and quantum-dot semiconductor heterostructures offer a variety of opportunities for achieving photovoltaic power conversion efficiencies in excess of the Shockley-Queisser limit for single-homojunction solar cells. However, realization of such efficiencies is likely to require a combination of very high quality epitaxial growth or nanostructure synthesis to minimize carrier trapping and recombination, detailed understanding and analysis of optical absorption and nonequilibrium carrier transport processes, and light trapping to enable efficient optical absorption in very thin device layers. We discuss work in which GaAs/InGaAs/InAs semiconductor quantum-well and quantum-dot solar cells are realized in designs that enable efficient collection of photogenerated carriers from quantum-wells and dots, and combined with subwavelength-scale metal and dielectric structures that enable incident photons to be scattered into guided optical modes within a thin-film device, thereby enabling increased absorption efficiency in very thin device layers. Several aspects of this work will be addressed. Measurement of electric-field-dependent photocurrent response enables design of structures in which photogenerated carriers are collected efficiently from quantum-well or quantum-dot structures in the intrinsic region of a p-i-n junction solar cell. Processing to remove epitaxially grown device layers from their original growth substrate enables metal and dielectric nanostructures to be designed and integrated with the semiconductor epitaxial layer structures to scatter incident photons into strongly guided optical modes within the semiconductor. Finally, detailed analysis of quantum-well and quantum-dot optical absorption as well as optical mode structure within the device enables optimization of the absorption and mode profiles to achieve maximum power conversion efficiency. Both computational and experimental results derived from these approaches will be described.

4:54PM D27.00005 Combined conversion of heat and light with Photon Enhanced Thermionic Emission for solar energy harvesting, NICHOLAS MELOSH, Materials Science and Engineering, Stanford University — Recently a new mechanism for solar energy harvesting based on photon-enhanced thermionic emission (PETE) was proposed. This two-step process uses photons to excite carriers into the conduction band, followed by thermionic emission from the conduction band, and electron collection at a low-workfunction anode. This process effectively combines both heat and light, and its efficiency was calculated to exceed ideal single junction photovoltaics since it harvests some of the heat that is normally lost within PV devices. Experimental measurements demonstrated this mechanism in GaN materials, yet the quantum efficiency was very low. Here we discuss the loss mechanisms in the PETE process, and several approaches to overcome them. In particular we focus on surface recombination effects and absorption losses, and demonstrate a heterostructured device that increases the quantum efficiency by two orders of magnitude. Prospects for combined-cycle devices incorporating a PETE converter as a topping cycle on conventional thermal cycles are also analyzed.

Monday, February 27, 2012 2:30PM - 5:30PM –

Session D28 DMP: Focus Session: Dopants and Defects in Semiconductors - Oxides and Interfaces 258C

2:30PM D28.00001 Interdiffusion, Unintentional Doping and Electronic Reconstruction at Polar/nonpolar Oxide Interfaces¹

, SCOTT CHAMBERS, Pacific Northwest National Laboratory — The observation of conductivity at the interface of insulating polar and non-polar perovskites (general form ABO_3) has sparked considerable interest worldwide, with much of the work to date being focused on the $LaAlO_3/SrTiO_3(001)$ heterojunction. Many attribute the interface conductivity to an electronic reconstruction alleviating the polar discontinuity via a film-to-interface charge transfer. However, the possibility of dopant- and/or defect-mediated conductivity cannot be ruled out, especially when the interfaces are not atomically abrupt. Electronic reconstruction requires an electric field within the film to facilitate the charge transfer process. However, x-ray photoemission spectroscopy studies reveal little or no electric field in the LAO film either above or below the critical thickness for conductivity, calling into question the validity of the electronic reconstruction model. In order to gain deeper insight into the electronic properties, it is worthwhile to manipulate the interface by changing the B-site cation in the polar perovskite. There are no low-lying d -derived bands in $LaAlO_3$. Therefore, if conductivity occurs, it ought to be driven by either the wholesale transfer of charge from the $LaAlO_3$ O2p-derived band into the STO (i.e. electronic reconstruction), or unintentional doping and/or defect creation. By replacing Al with a transition metal cation, we inject a new degree of freedom into the band structure – partially occupied d orbitals – and, thus, enable other mechanisms of charge redistribution. We have explored this concept by placing Cr(III) at the B-site and describe the electronic properties of epitaxial $LaCrO_3/STO(001)$ heterojunctions. To minimize defect creation, the films were deposited using molecular beam epitaxy (MBE), in which the incoming atom energies are very low (<0.1 eV). Core-level and valence-band x-ray photoemission spectra measured for MBE-grown $LaCrO_3/SrTiO_3(001)$ yield band offsets and potential gradients within the $LaCrO_3$ sufficient to trigger an electronic reconstruction to alleviate the polarity mismatch. Yet, the interface is insulating. Based on first principles calculations, we attribute this unexpected result to interfacial cation mixing combined with charge redistribution within CrO_2 layers, enabled by low-lying d states within $LaCrO_3$, which suppresses an electronic reconstruction.

3:06PM D28.00002 Calculation of charge transition levels of oxygen vacancies in rutile TiO_2 using the GW method¹

, ANDREI MALASHEVICH, MANISH JAIN, STEVEN G. LOUIE, UC Berkeley and Lawrence Berkeley National Laboratory — Titanium dioxide (TiO_2) is a semiconductor displaying photovoltaic and photocatalytic properties and is widely used in numerous technological applications, such as solar cells, hydrolysis of water, photocatalysis, etc. Defects are important for optical properties of TiO_2 , e.g. they play a crucial role in photocatalytic reactions. Gaining a deep understanding of the influence of intrinsic defects, such as vacancies and interstitials, on the properties of this material is highly desirable. In spite of many theoretical and experimental investigations of defects in TiO_2 , controversies still remain. In this work, the charge transition levels of oxygen vacancies are studied in the rutile form of TiO_2 . For this purpose the GW method is employed for the calculation of the band gap and the position of the defect levels in the gap. The effects of lattice relaxations for systems with various charge states are taken into account. This is done with the help of hybrid functionals, since LDA or PBE mean fields do not describe defect levels properly, which may result in incorrect lattice relaxations. To account for spurious effects due to periodic images of the charged defects, appropriate electrostatic correction techniques are used.

3:18PM D28.00003 Strain effect on diffusion properties of oxygen vacancies in bulk and sub-surface of rutile TiO_2 ¹

, DAJUN SHU, ZHAOWU WANG, MU WANG, School of Physics, Nanjing University — The influences of external strain on diffusion properties of the bulk and subsurface oxygen vacancy (OV) in rutile TiO_2 are systematically studied using first-principle calculations. For OVs in bulk, we find that tensile (compressive) strain applied in the [001] direction or isotropically applied in the equivalent [110] and $[\bar{1}\bar{1}0]$ directions reduces (increases) the energy barriers of diffusion. Anisotropic strain applied in [110] and $[\bar{1}\bar{1}0]$ increases the energy barriers of diffusion in the two directions. Meanwhile it results in anisotropic diffusion behaviors. Between [110] and $[\bar{1}\bar{1}0]$, the bulk OV prefers to diffuse along the one in which more compressive or less tensile strain is applied. From subsurface to surface, the most energetically favorable OV pathway is along the [110] rows terminated with the surface bridging oxygen atoms. The diffusion barrier of the OV in the first trilayer is much lower than that of a bulk OV. External in-plane tensile strain can further reduce the energy barrier of the subsurface OV diffusion, and thus help to improve the diffusion of OVs from bulk to surface.

3:30PM D28.00004 Vibrational spectroscopy of O-H and O-D centers in TiO_2 ¹

, FIGEN BEKISLI, MICHAEL STAVOLA, W. BEALL FOWLER, Lehigh University — While the vibrational properties of O-H centers in TiO_2 have been studied for many years, recent experiments suggest a new picture of their behavior. In the 1970s, Bates and Perkins found a single, sharp, strongly polarized O-H line in TiO_2 , and similarly for O-D and O-T [1]. On the contrary, recent studies by Herklotz *et al.* [2] find three closely spaced O-H (O-D) lines that were assigned to two different charge states of an O-H (O-D) shallow donor. We have in our possession the very TiO_2 samples studied many years ago by Bates and Perkins. We have introduced H and D into these samples and also into TiO_2 samples obtained recently. High-resolution vibrational spectroscopy performed as a function of temperature at Lehigh provides new insight into the different vibrational properties seen for O-H in TiO_2 in the 1970's and in recent studies by Herklotz *et al.* [1] J.B. Bates and R.A. Perkins, Phys. Rev. B **16**, 3713 (1977). [2] F. Herklotz *et al.*, Phys. Rev. B **83**, 235202 (2011)..

3:42PM D28.00005 Intrinsic Spin-Orbit Effects in Strontium Titanate

, CUNEYT SAHIN, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa 52242, USA, GIOVANNI VIGNALE, Department of Physics and Astronomy, University of Missouri, Columbia, Missouri 65211, USA, MICHAEL E. FLATTÉ, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa 52242, USA — We have calculated spin relaxation times via the Elliott-Yafet mechanism for strontium titanate as a function of temperature. The approach uses a low-energy effective spin-orbit Hamiltonian constructed from a tight-binding model with atomic spin-orbit interactions. The intrinsic spin Hall conductivity for strontium titanate has also been calculated from the same low-energy Hamiltonian using a Berry's phase technique. Modifications to the spin relaxation and spin Hall conductivity from elastic strain at an interface will also be described. This work was supported by an ARO MURI.

3:54PM D28.00006 Prediction of a “half semiconductor” for spintronics in non-compensated n-p codoped TiO_2 ¹, WENGUANG ZHU, University of Tennessee & Oak Ridge National Laboratory, XING-QIU CHEN, Institute of Metal Research, CAS, China, HANNO WEITERING, University of Tennessee & Oak Ridge National Laboratory, ZHENYU ZHANG, University of Science and Technology of China & Harvard University, G. M. STOCKS, Oak Ridge National Laboratory — Based on hybrid density functional calculations, we predict that by doping non-compensated Cr-N pairs a normal wide-band-gap semiconductor TiO_2 can be altered to a “half semiconductor”, in which both the top and the valence band and the bottom of the conduction band are fully spin-polarized and exclusively contributed by the same spin component. The underlying formation mechanism of such an unusual band structure is revealed via detailed electronic structure analysis. The magnetic property of the material will also be discussed in this talk. Such a “half semiconductor” material may provide a new twist to generate and manipulate spin currents for spintronics.

4:06PM D28.00007 Charged and neutral oxygen vacancies at MgO surfaces under realistic temperature and pressure conditions, NORINA A. RICHTER, SERGEY V. LEVCHENKO, MATTHIAS SCHEFFLER, Fritz Haber Institute of the Max Planck Society — Surface O vacancies (F-centers) can strongly influence catalytic properties of MgO and metal clusters supported on MgO, but the experimental determination of their concentration at catalytic conditions is difficult. We employ density-functional theory and the *ab initio* atomistic thermodynamics approach to determine concentration and charge states of F-centers at (111) and flat and stepped (100) surfaces of MgO at realistic (T , p) conditions. Slab models and the virtual-crystal approximation [1] are used to model charged defects at surfaces. We find a strong dependence of F^+ and F^{2+} formation energy on the exchange-correlation (XC) functional. Varying the amount of screening and fraction of exact exchange within the HSE functional, we find a linear correlation between defect formation energies and calculated valence-band width of the host material, in line with recent results for bulk systems [2]. Using this correlation and extrapolating to experimental band width, we conclude that only F^{2+} centers can be present in significant concentrations at the (100) terraces at realistic conditions. — [1] L. Vegard, Z. Phys. **5**, 17 (1921); M. Scheffler, Physica **146B**, 176 (1987); [2] R. Ramprasad *et al.*, subm. to Phys. Rev. Lett.

4:18PM D28.00008 Pressure dependence of the large polaron transport in anatase TiO_2 single crystals, JAČIM JAČIMOVIĆ, CRISTIAN VAJU, HELMUTH BERGER, ARNAUD MAGREZ, Laboratory of Physics of Complex Matter Physics, Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland, VIKTOR CEROVSKI, RADOMIR ŽIKIĆ, Institute of Physics, Belgrade, Serbia, RICHARD GAÁL, LÁSZLÓ FORRÓ, Laboratory of Physics of Complex Matter Physics, Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland — Anatase is a TiO_2 polymorph which is a 3.2 eV gap semiconductor interesting for several applications, including catalysis, photocatalysis, and, especially, dye-sensitized solar cells. Surprisingly, transparent single crystals of anatase grown in our laboratory show a metallic resistivity above 60 K which origin is a shallow donor level created by oxygen vacancies. The high value of the resistivity and its T^3 temperature dependence are the result of the polaronic nature of the charge carriers which is supported by the Seebeck coefficient (S). The application of hydrostatic pressure fails to close the donor level and to extend the conducting state to the entire temperature range. Instead, we have found a non-monotonic variation of the low temperature activation energy with applied pressure which is ascribed to the change of polaron's mobility. Thermo-electric power exhibits an unconventional temperature and pressure dependence shedding an additional light on the conductivity mechanism in this compound. The pressure dependence of S is governed by the transport of the large entropy associated with the polaron formation.

4:30PM D28.00009 Revisiting the mechanism of photocatalytic activities in N-doped TiO_2 ¹, NAOITO UMEZAWA, National Institute for Materials Science, JST PRESTO, JINHUA YE, National Institute for Materials Science, MANA — Photocatalysis possesses a great potential for environmental remediation and fuel production [1]. Nitrogen doped TiO_2 is a well-known visible-light sensitive photocatalyst where deep impurity states associated with substitutional nitrogen at oxygen sites (N_O) are believed to be the source of the red shift in photo-absorption edge. However, such a deep level should trap hole carriers, degrading oxidation process. The contradiction between the deep N_O level and rather a high oxidation power of N-doped TiO_2 has been an unsolved puzzle. Here, we propose a convincing mechanism which successfully solves the riddle. N_O strongly binds with a titanium atom at an interstitial site, forming a defect-impurity band, which consists of bonding and anti-bonding states of nitrogen p and titanium d and narrows the band gap. Such a newly formed band, which is connected to the valence band maximum of the host TiO_2 , becomes the migration path of photo-induced hole carriers, assisting carrier transfer to the surface. This clearly explains the photocatalytic activity of N-doped TiO_2 both for the visible-light absorption and the oxidation reaction. [1] Hua Tong, Shuxin Ouyang, Yingpu Bi, Naoto Umezawa, Mitsutake Oshikiri, and Jinhua Ye, Advanced Materials DOI: 10.1002/adma.20110275

4:42PM D28.00010 Femtosecond laser doped and nanostructured TiO_2 for photocatalysis, KATHERINE PHILLIPS, ELIZABETH LANDIS, CYNTHIA FRIEND, ERIC MAZUR, Harvard University — We present a novel method for femtosecond-laser doping of titanium dioxide (TiO_2) for above bandgap absorbance by irradiating titanium metal in the presence of oxygen and dopants. With a bandgap of 3.2 eV for the anatase crystalline phase, TiO_2 most strongly absorbs in the UV range ($\lambda < 387$ nm). However, doping with metals and nitrogen has been shown to create intermediate states in the bandgap. Using femtosecond laser doping techniques on titanium in a gaseous environment, we produce laser-induced periodic surface structures. Altering the gas composition and pressure does not change the surface morphology, but it does impact the chemical composition of the surface. We present compositional data from x-ray photoelectron and Raman spectroscopy and structural data from scanning electron microscopy. Our research presents an innovative approach using laser scanning techniques to alter the structure of TiO_2 and generate a new material for visible-light photocatalysis that has the potential for watersplitting.

4:54PM D28.00011 First-principles study of interstitial hydrogen in yttria-stabilized zirconia.¹, APOSTOLOS MARINOPOULOS, CEMDRX, Physics Department, University of Coimbra, CEMDRX, PHYSICS DEPARTMENT, UNIVERSITY OF COIMBRA TEAM — Hydrogen is a common impurity in oxides and has been known to exhibit a dual behavior: either by being a dopant or alternatively an amphoteric impurity with the transition (pinning) level, $E(+/-)$, lying inside the gap [1]. By means of calculations based on density-functional theory (DFT) and a hybrid-functional scheme (Heyd-Scuseria-Ernzerhof) we have studied the incorporation of hydrogen in yttria-stabilized zirconia. Equilibrium sites and formation energies were determined and the role of intrinsic oxygen vacancies needed to stabilize the cubic phase of the oxide was particularly examined. Whereas, in its positively-charged state, H^+ , hydrogen was found exclusively to form a dative-type bond with O ions, the neutral paramagnetic H^0 displayed a coexistence with deep interstitial configurations with minimal lattice relaxation of the host lattice. A number of atomic-level mechanisms and migration paths were explored in order to understand this site interplay and the dynamics of neutral H^0 in a way that is consistent with the existing experimental data. [1] C.G. Van de Walle and J. Neugebauer, Nature **423**, 626 (2003).

5:06PM D28.00012 Fundamental limits on optical transparency of transparent conducting oxides: free-carrier absorption in SnO_2 ¹, HARTWIN PEELAERS, Materials Department, University of California, Santa Barbara, California, EMMANOUIL KIOUPAKIS, Materials Department, UC Santa Barbara, California; Department of Materials Science and Engineering, University of Michigan, Ann Arbor, Michigan, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara, California — Transparent conducting oxides (TCOs) are a technologically important class of materials used as transparent contacts in optoelectronic devices, such as flat-panel displays, touch screens, solar cells, and light-emitting diodes. These applications are possible because the TCOs combine high electrical conductivity with transparency to visible light. However, the large concentration of free electrons introduces a source of absorption that forms a fundamental limit to the transparency. We evaluated the importance of phonon-assisted free-carrier absorption in SnO_2 completely from first principles. We also provide insight into the mechanisms that govern absorption in different wavelength regimes. Our results show that the absorption is weak in the visible, but it increases by as much as a factor of 5 in the UV. For the infrared region, we show that the absorption increases with the wavelength, and that this increase is proportional to the third power of the wavelength. We also explain this third power dependency.

5:18PM D28.00013 Self-trapping of holes in p-type oxides: Theory for small polarons in MnO ¹, HAOWEI PENG, STEPHAN LANY, National Renewable Energy Laboratory — Employing the *p-d* repulsion to increase the valence band dispersion and the energy of the VBM is an important design principle for p-type oxides, as manifested in prototypical p-type oxides like Cu_2O or CuAlO_2 which show a strong Cu-*d*/O-*p* interaction. An alternative opportunity to realize this design principle occurs for Mn(II) compounds, where the *p-d* orbital interaction occurs dominantly in the fully occupied d^5 majority spin direction of Mn. However, the ability of Mn to change the oxidation state from +II to +III can lead to a small polaron mechanism for hole transport which hinders p-type conductivity. This work addresses the trends of hole self-trapping for MnO between octahedral (rock-salt structure) and tetrahedral coordination (zinc-blende structure). We employ an on-site hole-state potential so to satisfy the generalized Koopmans condition. This approach avoids the well-known difficulty of density-functional calculations to describe correctly the localization of polaronic states, and allows to quantitatively predict the self-trapping energies. We find that the tetrahedrally coordinated Mn is less susceptible to hole self-trapping than the octahedrally coordinated Mn.

Monday, February 27, 2012 2:30PM - 5:30PM — Session D29 GQI: Focus Session: Qubits in Diamond II 259A

2:30PM D29.00001 Quantum information and quantum sensing with NV diamond, PHILIP HEMMER, Texas A&M University — No abstract available.

3:06PM D29.00002 Control of hybrid quantum registers in diamond, TIM HUGO TAMINIAU, TOENO VAN DER SAR, MACHIEL S. BLOK, GIJS DE LANGE, HANNES BERNIEN, WOLFGANG PFAFF, LUCIO ROBLEDO, RONALD HANSON, Kavli Institute of Nanoscience Delft, Delft University of Technology, PO Box 5046, 2600 GA Delft, The Netherlands — Nitrogen Vacancy (NV) centers in diamond provide a robust quantum register consisting of the NV electron spin, the nuclear spin of the associated nitrogen atom and nearby nuclear spins of carbon impurities (^{13}C). The constituents of this hybrid system each have different properties that make them ideal for different roles. For example, the electron spin is readily polarized and read-out optically using spin-dependent fluorescence, whereas long coherence times make the nuclear spins ideal quantum memories. However, because all these systems evolve and decohere on very different time scales, it is challenging to control the register and to protect it from decoherence due to the surrounding environment at the same time. Here we discuss our recent progress in initializing, controlling and reading out all the spins in such few-qubit NV quantum registers. To this end, we combine dynamical decoupling of the electron spin with control of all the nuclear spins, and explore different initialization schemes. These few qubit registers might then be used to implement quantum search algorithms and error correction protocols.

3:18PM D29.00003 Quantum interference of single photons from two remote Nitrogen-Vacancy centers in diamond, ALEXANDER KUBANEK, ALP SIPAHIGIL, EMRE TOGAN, MICHAEL GOLDMAN, YIWEN CHU, NATHALIE DE LEON, ALEXANDER ZIBROV, MIKHAIL LUKIN, Harvard University — The interference of two identical photons impinging on a beam splitter leads to perfect photon coalescence where both photons leave through the same output port. This fundamental effect, known as Hong-Ou-Mandel (HOM) interference [1], can be used to characterize the properties of quantum emitters with high accuracy. This is a particularly useful tool for quantum emitters embedded in a solid state matrix because their internal properties, unlike those of atoms in free space, can vary substantially from emitter to emitter due to interactions with the environment. Here, we demonstrate HOM interference of photons emitted from two single Nitrogen-Vacancy (NV) centers in diamond that are spatially separated by 2 meters. The frequencies of the photons are controlled by tuning individual optical transitions of associated NVs via a DC electric field. The indistinguishability of the photons paves the way for entanglement generation between remote solid state qubits. [1] C. K. Hong, Z.Y. Ou, and L. Mandel, Phys. Rev. Lett. 59, 2044 (1987).

3:30PM D29.00004 Coherent excitation dynamics of single spins in diamond¹, A.L. FALK, G.D. FUCHS², D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106, V.V. DOBROVITSKI, Ames Laboratory and Iowa State University, Ames, IA, 50011 — The spin dynamics of nitrogen vacancy (NV) centers in diamond during non-resonant optical excitation are fundamentally important for both optical initialization and fluorescence-based spin read-out. While such processes rely on the preservation of the longitudinal spin projection, an NV center's lack of orbital coherence at room temperature might suggest that its quantum phase would be destroyed during excitation. We address this question using Ramsey experiments, quantum process tomography and theoretical modeling and establish limits on the coherence loss of an NV center during optical excitation [1]. By treating the excitation and spin precession as a quantum process, we measure a process fidelity of $F = 0.87 \pm 0.03$, which includes excited state dephasing during measurement. Extrapolation to the moment of optical excitation yields $F \approx 0.95$. These results provide a new understanding of NV centers' spin coherence during optical excitation and are crucial for efforts to use coherent evolution in the excited state for spin control.

3:42PM D29.00005 Optimizing the resolution and the sensitivity of a scanning NV magnetometer, SUNGKUN HONG, PATRICK MALETINSKY, MICHAEL GRINOLDS, LAN LUAN, BIRGIT HAUSMANN, MIKHAIL LUKIN, RONALD WALSWORTH, MARKO LONCAR, AMIR YACOBY, Harvard University — A nitrogen-vacancy (NV) center in diamond has been recently considered as an outstanding atomic-scale magnetic field sensor. At the heart of NV based magnetometry is the ability to control the position of an NV within few nanometers to a sample, while preserving its spin coherence and readout fidelity. To this end, we previously developed a fabrication procedure for creating a monolithic scanning diamond nanopillar containing a single NV center. Here we present further optimization of our devices by locating NV centers with nanoscale accuracy as well as improving their magnetic field sensitivity. For locating the NV center, we developed a nanoscale imaging of a NV center in the device via near-field fluorescence quenching, which facilitates post selection of devices with NV centers being closer to the surface. In addition to enhancing photon collection via wave guiding through the nanopillar, we also significantly improved the spin coherence times of our devices via dynamic decoupling. This results in a magnetic field sensitivity of 30 nT/sqrt(Hz), unprecedented for scanning NV centers.

3:54PM D29.00006 High Dynamic Range Magnetometry with a Single Spin in Diamond¹, N.M. NUSRAN, M. UMMAL MOMEEN, M.V. GURUDEV DUTT, University of Pittsburgh — Detection of the weak magnetic fields associated with nanometer sized volumes of spins could allow for non-invasive, element-specific probing of a variety of important physical and biological systems. Averaging out random noise which is the commonly used standard measurement strategy (SM) in most nano-sensors, will at best lead to a field variance that is inversely proportional to the total averaging time. Further, there exists a trade-off between the field sensitivity and the dynamic range in the SM. In this work, we demonstrate an alternative approach for accurate magnetic sensing, using novel phase estimation algorithms (PEA), implemented on a single electronic spin associated with the nitrogen-vacancy (NV) defect center in diamond. The field variance in our approach scales down faster than the SM. The trade-off between the field sensitivity and the dynamic range no longer exists in this approach. Our results show an improvement of $\sim 6.25dB$ in the field sensitivity compared to the SM, over a large field sensing range ($\sim \pm 0.3mT$). Besides their direct impact on applications in demonstrated nanoscale magnetic sensing and imaging, this may also open the way for application of other quantum feedback and control techniques to magnetometry.

¹This work was supported by NSF, DOE and the Alfred P. Sloan Research Fellowship.

4:06PM D29.00007 Room temperature solid-state quantum bit with second-long memory, GEORG KUCSKO, PETER MAURER, CHRISTIAN LATTA, Harvard University, DAVID HUNGER, LMU Munich, LIANG JIANG, Caltech, FERNANDO PASTAWSKI, Max-Planck-Institut für Quantenoptik, NORMAN YAO, STEVEN BENNET, Harvard University, DANIEL TWITCHEN, Element Six, IGNACIO CIRAC, Max-Planck-Institut für Quantenoptik, MIKHAIL LUKIN, Harvard University, LUKIN GROUP TEAM, CIRAC GROUP COLLABORATION — Realization of stable quantum bits (qubits) that can be prepared and measured with high fidelity and that are capable of storing quantum information for long times exceeding seconds is an outstanding challenge in quantum science and engineering. Here we report on the realization of such a stable quantum bit using an individual ¹³C nuclear spin within an isotopically purified diamond crystal at room temperature. Using an electronic spin associated with a nearby Nitrogen Vacancy color center, we demonstrate high fidelity initialization and readout of a single ¹³C qubit. Quantum memory lifetime exceeding one second is obtained by using dissipative optical decoupling from the electronic degree of freedom and applying a sequence of radio-frequency pulses to suppress effects from the dipole-dipole interactions of the ¹³C spin-bath. Techniques to further extend the quantum memory lifetime as well as the potential applications are also discussed.

4:18PM D29.00008 Mechanism for optical initialization of spin in NV⁻ center in diamond¹, SANGKOOK CHOI, MANISH JAIN, STEVEN G. LOUIE, University of California, Berkeley and Lawrence Berkeley National Laboratory — Optical initialization of the negatively charged nitrogen-vacancy (NV⁻) center in diamond, the experimental manipulation of its degenerate mixed ground state into an un-entangled spin state through optical means, makes it one of the best candidates for realization of individually addressable spins in the solid state for quantum computing and other studies under ambient conditions. However, its exact mechanism is still not clear. Based on exact diagonalization of a many-electron Hamiltonian with parameters derived from ab initio GW calculations, the present study elucidates the electronic structure of the NV⁻ center and puts forward a concrete optical initialization mechanism. We calculated the ordering and energy surfaces of the low-energy many-body states and the relaxation processes of photo-excitation responsible for the optical initialization. Intersystem crossings are shown to be essential.

4:30PM D29.00009 Long-range quantum gates using dipolar crystals, HENDRIK WEIMER, Harvard University, ITAMP, NORMAN YAO, Harvard University, CHRIS LAUMANN, Harvard University, ITAMP, MIKHAIL LUKIN, Harvard University — We propose to use the magnetic dipole interaction in high density arrays of nitrogen-vacancy centers to enable long-range quantum logic between distant spin qubits. In our approach, an effective interaction between remote qubits is achieved by adiabatically following the ground state of the dipolar chain across a quantum phase transition [1]. We demonstrate that the proposed quantum gate is particularly robust against disorder and enables coherent coupling between qubits on distances that are compatible with sub-wavelength addressing techniques.

[1] H. Weimer et al., arXiv:1009.1003 (2011).

4:42PM D29.00010 Magnetic imaging of a single electron spin using a scanning NV magnetometer under ambient conditions, MICHAEL GRINOLDS, SUNGKUN HONG, PATRICK MALETINSKY, LAN LUAN, RONALD WALSWORTH, MIKHAIL LUKIN, AMIR YACOBY, Harvard University — It has long been an outstanding challenge to develop a magnetometer capable of detecting individual spins under ambient conditions. Nitrogen-vacancy (NV) centers are an attractive candidate for such a sensor, as even at room temperature their spins can be initialized and read out optically, have long coherence times, and are localized on atomic length scales. Here we present measurements using a scannable NV center to magnetically image the dipole field of a single electron spin. For a target spin, we chose to use an additional NV spin as it can be initialized and driven independently from other proximal spins, allowing us to perform dynamical decoupling schemes on both sensing and target NV spins. Magnetic images are taken under ambient conditions and are achieved through optimizing NV magnetic sensitivity (<60 nT/sqrt(Hz)) as well as minimizing the distance between the NV center and our target spin (<50 nm).

4:54PM D29.00011 Fabrication of thin diamond membranes for quantum information processing, IGOR AHARONOVICH, JONATHAN LEE, ANDREW MAGYAR, EVELYN HU, Harvard University — Coupling of nano-photonic devices to color centers in diamond offers exceptional opportunities to enhance our understanding of light-matter interactions. The formation of thin single crystal diamond membranes containing such centers, is an important prerequisite for the fabrication of diamond based devices. However, there are challenges in forming such membranes in ways that do not compromise the quality of the cavities or the optical properties of the emitters. Here we report the formation of optically active diamond membranes and the subsequent fabrication of optical cavities. In our approach, 1.7 μ m thick diamond membranes were generated by forming a sacrificial layer using ion implantation, followed by thermal annealing. These membranes then served as templates for the epitaxial overgrowth of ~ 300 nm of diamond using CVD. Remarkably, the regrown films reveal the presence of optically active defects which were *not* present in the template, such as silicon-vacancy (SiV) or nitrogen vacancy centers. Microdisk cavities were then formed from the regrown single crystal diamond membranes. Whispering gallery modes (WGMs) with quality factors of ~ 3000 were measured from the diamond cavities. Spectral overlap of WGMs with the zero phonon line of SiV centers was observed and lifetime reduction of the coupled emitter – cavity system was measured. The demonstration of coupling between diamond emitters and a single crystal diamond cavity is a crucial step towards diamond integrated nano-photonic networks.

5:06PM D29.00012 Noises of spin baths for qubits in diamond, ZHIHUI WANG, ANIRBAN DAS, DANIEL LIDAR, SUSUMU TAKAHASHI, University of Southern California — Nitrogen-vacancy (NV) center in diamond is a promising qubit candidate for quantum information processing and high precision magnetometry and is an excellent platform for studying quantum spin dynamics [1,2]. Overcoming spin decoherence of NV centers is critical to the applications. Coupling to spin baths of paramagnetic impurities and nuclei is a major decoherence source for NV centers. Therefore, recent theoretical and experimental efforts have aimed at suppressing the bath noises. In this presentation, we will discuss effects of the spin baths on the qubits at different regimes including high magnetic fields where the degree of the electron spin polarization is almost complete [3]. We will also discuss dynamical decoupling sequences to investigate spin bath noises.

5:18PM D29.00013 Spectroscopy of composite solid-state spin environments for improved metrology with spin ensembles, NIR BAR-GILL, LINH PHAM, CHINMAY BELTHANGADY, DAVID LESAGE, Harvard University, PAOLA CAPPELLARO, MIT, JERONIMO MAZE, Pontificia Universidad Catolica de Chile, MIKHAIL LUKIN, AMIR YACOBY, RONALD WALSWORTH, Harvard University — For precision coherent measurements with ensembles of quantum spins the relevant Figure-of-Merit (FOM) is the product of spin density and coherence lifetime, which is generally limited by the dynamics of spin coupling to the environment. Significant effort has been invested in understanding the causes of decoherence in a diverse range of spin systems in order to increase the FOM and improve measurement sensitivity. Here, we apply a coherent spectroscopic technique to characterize the dynamics of a composite solid-state spin environment consisting of Nitrogen-Vacancy (NV) color centers in room temperature diamond coupled to baths of electronic spin (N) and nuclear spin (¹³C) impurities. For diamond samples with a wide range of NV densities and impurity spin concentrations we employ a dynamical decoupling technique to minimize coupling to the environment, and find similar values for the FOM, which is three orders of magnitude larger than previously achieved in any room-temperature solid-state spin system, and thus should enable greatly improved precision spin metrology. We also identify a suppression of electronic spin bath dynamics in the presence of a nuclear spin bath of sufficient nuclear spin concentration. This suppression could inform efforts to engineer samples with even larger FOM for solid-state spin ensemble metrology and collective quantum information processing.

Monday, February 27, 2012 2:30PM - 5:30PM –
Session D30 GQI: Focus Session: Quantum Information for Quantum Foundations - Entanglement and Causal Structure 259B

2:30PM D30.00001 Quantum measurement bounds beyond uncertainty relations, SETH LLOYD, MIT, VITTORIO GIOVANNETTI, Scuola Normale Pisa, LORENZO MACCONE, University of Pavia — Quantum measurements are limited by bounds such as the Heisenberg uncertainty relations which limit the accuracy of measuring a quantity via the standard deviation of the conjugate one. This talk shows that the accuracy of measuring a quantity such as phase or time is limited by the expectation value of the conjugate quantity. This result proves the long-standing conjecture – recently challenged – that the ultimate phase-precision limit in interferometry is lower bounded by the inverse of the total number of photons employed in the estimation process.

2:42PM D30.00002 Quantum sharability: Entanglement is less monogamous than you think, PETER JOHNSON, Dartmouth College, BENJAMIN SCHUMACHER, Kenyon College, LORENZA VIOLA, Dartmouth College — One of the essential features of entanglement is monogamy. However, it is well known that there are entangled states which are not monogamous. A generalization of the monogamy property is provided by the concept of sharability. For bipartite states, we say a state (or relationship) is $1-n$ sharable if a subsystem can simultaneously share this relationship with n other subsystems. Any state with a limited sharing capacity is entangled, and the strictness of the limit corresponds to how entangled the state is. We present the most interesting findings of sharability of bipartite qubit and qudit states and describe an application to quantum teleportation.

2:54PM D30.00003 New entanglement properties in systems of higher-spin particles, JAY LAWRENCE, University of Chicago and Dartmouth College, MARIO GAETA, ANDREI KLIMOV, University of Guadalajara, Jal., Mexico — We describe a new entanglement property of four-qutrit states that is inaccessible to any number of qubits. In such states, every particle is equally entangled with all others, as in GHZ states, but the entanglement is more robust than that of any four-qubit state. We describe the entanglement properties of related generalized graph states of three-state and five-state particles, and show how these suggest that new entanglement properties will emerge more generally for systems of $p+1$ particles, each having p states, where p is a prime number.

3:06PM D30.00004 Optimal Probabilistic Simulation of Quantum Channels from the Future to the Past, DINA GENKINA, University of Maryland, GIULIO CHIRIBELLA, LUCIEN HARDY, Perimeter Institute — We introduce the study of probabilistic protocols that simulate quantum channels transforming input states in the future into output states in the past. The maximum probability for such a simulation is set by causality and, we claim, depends on the amount and type (classical or quantum) of information the given channel can transmit. In particular, we focus on probabilistic teleportation with multiple copies of input and output. We show that as the number of input copies increases, the maximum probability of successful teleportation increases, a feature that is impossible in classical physics. As the number of input copies tends to infinity, the teleportation probability converges to the maximum probability for the simulation of an ideal classical channel from the future to the past.

3:18PM D30.00005 The asymmetry properties of pure quantum states, IMAN MARVIAN, Institute for Quantum computing & Perimeter Institute for theoretical Physics, Waterloo, Canada, ROBERT SPEKKENS, Perimeter Institute for theoretical Physics, Waterloo, Canada — The *asymmetry properties* of a state relative to some symmetry group specify how and to what extent the given symmetry is broken by the state. Characterizing these is found to be surprisingly useful for addressing a very common problem: to determine what follows from a system's dynamics (possibly open) having that symmetry. We demonstrate and exploit the fact that the asymmetry properties of a state can be understood in terms of information-theoretic concepts. We show that for a pure state ψ and a symmetry group G , they are completely specified by the characteristic function of the state, defined as $\chi_\psi(g) \equiv \langle \psi | U(g) | \psi \rangle$ where $g \in G$ and U is the unitary representation of interest. Based on this observation, we study several important problems about the interconversion of pure states under symmetric dynamics such as determining the conditions for reversible transformations, deterministic irreversible transformations and asymptotic transformations.

3:30PM D30.00006 Equilibration of Global Observables to Microcanonical Measure for Complex Systems, JOSEPH EMERSON, Dept of Applied Math and IQC, University of Waterloo, COZMIN UDUDEC, Dept of Physics, University of Waterloo — In the last few years we have seen significant progress in understanding how the canonical features of quantum statistical mechanics can be derived rigorously from an exact treatment of the underlying quantum mechanical system. Here we consider a related problem: we determine sufficient conditions under which one can derive an effective equilibration to the microcanonical ensemble for the measurement statistics of the global observables of a closed system. Our central assumption is that the unitary time-evolution operator of the system is sufficiently complex when expressed in the eigenbasis of the observable of interest that its eigenstates can be modeled by a typical unitary chosen from the Haar measure (or Circular Unitary Ensemble). This assumption is well-motivated from numerical studies in the field of quantum chaos where this property has been observed for simple model systems whose classical counterparts are globally chaotic. Further, we discuss the time scale on which equilibration occurs in the context of two models for the eigenvalues of the dynamical system. We argue that our results are a natural consequence of an epistemic view of pure quantum states, but may be surprising or even controversial for adherents of other interpretational perspectives.

3:42PM D30.00007 Coarse-graining makes it hard to see micro-macro entanglement¹, SADEGH RAEISI, Institute for Quantum Computing, University of Waterloo, PAVEL SEKATSKI, Université de Genève, CHRISTOPH SIMON, IQIS, University of Calgary — Observing quantum effects such as superpositions and entanglement in macroscopic systems requires not only a system that is well protected against environmental decoherence, but also sufficient measurement precision. Motivated by recent experiments, we study the effects of coarse-graining in photon number measurements on the observability of micro-macro entanglement that is created by greatly amplifying one photon from an entangled pair. We compare the results obtained for a unitary quantum cloner, which generates micro-macro entanglement, and for a measure-and-prepare cloner, which produces a separable micro-macro state. We show that the distance between the probability distributions of results for the two cloners approaches zero for a fixed moderate amount of coarse-graining. Proving the presence of micro-macro entanglement therefore becomes progressively harder as the system size increases.

3:54PM D30.00008 On the quantification of resourcefulness in quantum information¹, YUVAL SANDERS, University of Waterloo, BEN FORTESCUE, Southern Illinois University, GILAD GOUR, University of Calgary — Quantum information processing tasks cannot be performed for free; several types of informational resource must be consumed. Such resources are often expensive: entanglement, for example, is quite difficult to distribute between distant parties. Efficient consumption of informational resources is therefore desirable for practical quantum information processing. Determination of the efficiency of a given protocol requires some method of quantifying the resources present before and after the implementation of a protocol. In the prototypical case of entanglement, one or several entanglement monotones are often used to determine the entanglement cost of a protocol. The mathematical definition of an entanglement monotone has undergone multiple revisions since its formal introduction by Vidal. Currently, a real-valued function of quantum states is considered an entanglement monotone if the function is monotonically decreasing under application of channels that can be enacted using only local operations with classical communication. In this lecture, I argue that even this simple definition is unnecessarily restrictive for fully characterising the entanglement of a state and propose a more general scheme of relative quantifiers of entanglement.

4:06PM D30.00009 Scalar Fields via Causal Tapestries, WILLIAM SULIS, McMaster University/University of Waterloo — Causal tapestries provide a framework for implementing an explicit Process Theory approach to quantum foundations which models information flow within a physical system. We consider event-transition tapestry pairs. An event tapestry O is a 4-tuple (L, K, M, l_p) where K is an index set of cardinality κ , $M = M \times F(M) \times D \times P(M')$ a mathematical structure with M a causal space, $F(M)$ a function space, D a descriptor space, $P(M')$ either a Lie algebra or tangent space on a manifold M' , l_p an event tapestry. L consists of elements of the form $[n] \langle \alpha \rangle \{G\}$, n in K , α in M and G an acyclic directed graph whose vertex set is a subset of L_p . Likewise, a transition tapestry Π is a 4-tuple (L', K', M', l'_p) where $M' = M' \times F(M') \times D' \times P'(M')$. The dynamic generates a consistent succession of $O - \Pi$ pairs by means of a game based on the technique of forcing used in logic to generate models. This dynamic has previously been shown to be compatible with Lorentz invariance. An application of this approach to model scalar fields is presented in which each informon is associated with a function of the form $f(\pi k_1/\sigma_1, \dots, \pi k_N/\sigma_N) \sin(\sigma_1 t_1 - \pi k_1) / (\sigma_1 t_1 - \pi k_1) \dots \sin(\sigma_N t_N - \pi k_N) / (\sigma_N t_N - \pi k_N)$ and the WSK interpolation theorem is used to generate the resulting scalar field on the causal manifold.

4:18PM D30.00010 Topology of Quantum Discord¹, NGA NGUYEN, ROBERT JOYNT, Department of Physics, University of Wisconsin-Madison, Madison, Wisconsin 53706, USA — Quantum discord is arguably a more sensitive measure of quantum correlations than quantum entanglement, and may be able to serve as a resource for quantum computation. All quantum correlations are subject to destruction by external noise. The route by which this destruction takes place depends on the shape of the hypersurface of zero discord in the space of generalized Bloch vectors. In the case of 2 qubits, we show that, except at the origin, this hypersurface is a 9-dimensional manifold with boundary embedded in a 15-dimensional background space. This is done by computing the tangent vectors explicitly and verifying that there are no self-intersections. We discuss the implications for the time evolution of discord in physical models, which contrasts sharply with the evolution of entanglement.

4:30PM D30.00011 ABSTRACT WITHDRAWN —

4:42PM D30.00012 Quantumness versus entanglement in quantum measurements¹, GERARDO ADESSO, School of Mathematical Sciences, The University of Nottingham, MARCO PIANI, Institute for Quantum Computing and Department of Physics and Astronomy, University of Waterloo — We analyze a hierarchy of quantumness measures for composite systems, defined in terms of the entanglement necessarily created between systems and apparatus during local measurements. We prove that the quantumness so defined is always greater than intra-systems entanglement, establishing a firm ordering relation between different non-classical features of correlations. We analyze qualitatively and quantitatively the flow of correlations in iterated measurements, showing that quantumness and entanglement can never decrease along von Neumann chains. Our results provide a comprehensive framework to understand and quantify general signatures of quantumness in multipartite states, and prove how useful the broader study of the quantumness of correlations can be to shed light on issues in quantum information processing, in the quantum theory of measurement and in quantum foundations.

4:54PM D30.00013 Operational interpretation of the G-asymmetry for Abelian groups¹ , MICHAEL SKOTINIOTIS, GILAD GOUR, University of Calgary — In a reference frame alignment protocol the sender, Alice, prepares a quantum system in a state $ket\psi$, that serves as a token of her reference frame, and sends this system to a receiver, Bob, who performs a measurement and learns about the reference frame. We derive the state and measurement that maximize the accessible information in a reference frame alignment protocol. We show that in the limit where a large number of systems are sent, the accessible information per copy equals the Holevo bound. The latter was shown to be equal to the relative entropy of frameness, or G -asymmetry, of the state $ket\psi$, a measure of resourcefulness analogous to the relative entropy of entanglement. We show that for a reference frame alignment protocol, associated with a finite abelian group, Z_N , or the continuous group $U(1)$, associated with the important case of photon number super-selection, the rate of accessible information is quantified by the linearized, regularized G -asymmetry. Our result provides an information theoretic operational interpretation for the G -asymmetry that has been thus far lacking.

5:06PM D30.00014 Considerations of Closed Systems that Measure Particles , MICHAEL STEINER, RONALD RENDELL, Inspire Institute, Inc. — The Measurement Problem has been of fundamental concern since the discovery of Schrodinger's equation. We have been developing a framework for which this problem can be considered under the assumption that the detector is a closed system. Considerations that such systems satisfy will be presented. Questions of whether or not such a framework is possible for which the various considerations can be met will be presented. Related existing work in the literature will be presented.

5:18PM D30.00015 Is entanglement signaling really impossible? , JACK SARFATTI, Retired — Quantum entanglement cannot be used as a communication channel without an auxiliary light speed limited classical key to unlock the message at the receiver? Hermitian observables guarantee orthogonal sender base states that erase any nonlocal influence of the sender settings on the detection probabilities at the receiver. However, this is no longer true when the entangled whole has different macro-quantum coherent Glauber sender states. Glauber states are non-orthogonal eigenstates of the non-Hermitian photon destruction operator. The Born probability interpretation breaks down because of "phase rigidity" (P.W. Anderson's "More is different"). This is a new regime that is to orthodox quantum theory what general relativity is to special relativity. Antony Valentini has argued that the breakdown of the Born probability rule entails "signal non locality" (aka entanglement signals). The space-time interval between the sending and the receiving irreversible measurements is irrelevant depending only on the free will of the local observers. That is, this is a pre-metrical topological information effect. There is asymmetry between the sending and the receiving. Therefore, there is no ambiguity between active (retro) cause and passive effect.

Monday, February 27, 2012 2:30PM - 5:30PM —
Session D31 DMP: Focus Session: Topological Insulators: Synthesis & Characterization - Thin Films 260

2:30PM D31.00001 Epitaxial growth of high quality Bi_2Se_3 thin films on CdS , XUFENG KOU, LIANG HE, University of California, Los Angeles, FAXIAN XIU, Iowa State University, MURONG LANG, University of California, Los Angeles, YONG WANG, The University of Queensland, ALEXEI FEDEROV, Lawrence Berkeley National Laboratory, XINXIN YU, University of California, Los Angeles, JIN ZOU, The University of Queensland, KANG WANG, University of California, Los Angeles, UNIVERSITY OF CALIFORNIA, LOS ANGELES TEAM, IOWA STATE UNIVERSITY COLLABORATION, THE UNIVERSITY OF QUEENSLAND COLLABORATION, LAWRENCE BERKELEY NATIONAL LABORATORY COLLABORATION — We report the experiment of high quality epitaxial growth of Bi_2Se_3 thin films on lattice-matched hexagonal CdS (0001) substrates using a solid source molecular-beam epitaxy system. Layer-by-layer growth of single crystal Bi_2Se_3 has been observed from the first quintuple layer with larger surface triangular terraces. The improved film quality facilitates the characterization of surface states during magneto-transport measurements, such as high Hall mobility of $\sim 6000\text{ cm}^2/\text{Vs}$, a distinct Shubnikov-de Haas (SdH) oscillations and weak anti-localization cusp in the magnetic field dependent longitudinal resistance. These characteristics of Bi_2Se_3 thin films promise a variety of potential applications in ultra-fast, low-power dissipation devices.

2:42PM D31.00002 Fabrication of High Quality Topological Insulator Thin Films and Heterostructures , LI ZHANG, ROBERT HAMMOND, MERAV DOLEV, MAC BEASLEY, AHARON KAPITULNIK, Stanford University, GLAM TEAM — In this talk, I will present a method of fabrication high quality topological insulator thin films and heterostructures with ferromagnet materials using MBE with a RF Selenium cracker cell and pulsed laser deposition. I will also show some preliminary results on the physical properties of those films, including topography, crystal structure and transport properties.

2:54PM D31.00003 MBE growth and transport of the topologically tunable $(Bi_{1-x}In_x)_2Se_3$ system , MATTHEW BRAHLEK, NAMRATA BANSAL, NIKESH KOIRALA, Rutgers University Physics and Astronomy, SUYANG XU, ZAHID HASAN, Princeton University Physics, SEONGSHIK OH, Rutgers University Physics and Astronomy — A current challenge in the field of topological insulators (TI) is identifying a clear transport signal of the surface conduction. The structural similarity between Bi_2Se_3 and In_2Se_3 allowed us to combine the two to obtain $(Bi_{1-x}In_x)_2Se_3$; Bi_2Se_3 has inverted bands, and thus is a non-trivial insulator. In_2Se_3 has no inverted bands and is therefore a trivial band insulator with energy gap 1.3-1.9eV. The mixing ratio x can be thought of as a knob to switch the system from a trivial to a non-trivial state. I will briefly discuss our scheme for producing atomically smooth molecular beam epitaxial grown thin films. I will also discuss our work on transport in the TI-to-non TI regime, and the metal to insulator regime, and compare these results with angle resolved photo emission spectroscopy data.

3:06PM D31.00004 Hybrid Physical-Chemical Vapor Deposition of Bi_2Se_3 Thin films on Sapphire , JOSEPH BROM, YUE KE, RENZHONG DU, JAROD GAGNON, QI LI, JOAN REDWING, The Pennsylvania State University — High quality thin films of topological insulators continue to garner much interest. We report on the growth of highly-oriented thin films of Bi_2Se_3 on c-plane sapphire using hybrid physical-chemical vapor deposition (HPCVD). The HPCVD process utilizes the thermal decomposition of trimethyl bismuth (TMBi) and evaporation of elemental selenium in a hydrogen ambient to deposit Bi_2Se_3 . Growth parameters including TMBi flow rate and decomposition temperature and selenium evaporation temperature were optimized, effectively changing the Bi:Se ratio, to produce high quality films. Glancing angle x-ray diffraction measurements revealed that the films were c-axis oriented on sapphire. Trigon crystal planes were observed in atomic force microscopy images with an RMS surface roughness of 1.24 nm over an area of $2\mu\text{m}\times 2\mu\text{m}$. Variable temperature Hall effect measurements were also carried out on films that were nominally 50-70 nm thick. Over the temperature range from 300K down to 4.2K, the carrier concentration remained constant at approximately $6\times 10^{18}\text{ cm}^{-3}$ while the mobility increased from $480\text{ cm}^2/\text{Vs}$ to $900\text{ cm}^2/\text{Vs}$. These results demonstrate that the HPCVD technique can be used to deposit Bi_2Se_3 films with structural and electrical properties comparable to films produced by molecular beam epitaxy.

3:18PM D31.00005 Pulsed Laser Deposition of Epitaxial Topological Insulator Thin Films: Bi_2Te_3 and $\text{Bi}_2\text{Te}_2\text{Se}$, SHIXIONG ZHANG, LI YAN, JINGBO QI, MUJIN ZHUO, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, YONGQIANG WANG, Materials Science and Technology Division, Los Alamos National Laboratory, ROHIT P. PRASANKUMAR, QUANXI JIA, S. TOM PICRAUX, Center for Integrated Nanotechnologies, Los Alamos National Laboratory — While high quality epitaxial thin films of topological insulators have been achieved by molecular beam epitaxy, there has been little progress using other thin film growth techniques. Here, we report the growth of high quality epitaxial Bi_2Te_3 and $\text{Bi}_2\text{Te}_2\text{Se}$ thin films on silicon (111) and YSZ (111) substrates by pulsed laser deposition (PLD). Systematic structural characterization of the films using x-ray diffraction and transmission electron microscopy has demonstrated that a low laser pulse rate is the key to achieving high quality epitaxial films. Rutherford backscattering spectrometry measurements suggest that the film composition is strongly influenced by the growth temperature and background gas pressure. The electrical transport properties of the films grown at the optimal conditions will also be discussed. Since PLD is an excellent tool to grow a variety of functional oxides, including multiferroics, magnetic semiconductors and high temperature superconductors, the growth of epitaxial topological insulator thin films by the same technique paves the way to synthesize multi-layered heterostructures of the above materials and search for novel physics arising from the resulting interfacial couplings.

3:30PM D31.00006 Growth and properties of half-Heusler DyPdBi ¹, BRIAN MULCAHY, MAO ZHENG, CAROLYN KAN, JAMES ECKSTEIN, University of Illinois Urbana-Champaign — Some half-Heusler phases have been predicted by Chadov, *et al.*, to exhibit topological electronic structure. In addition to providing an exciting new topological system, the breadth of the elemental parameter space for this system opens the door for investigation of the interplay between many novel physical states with the topological system. We have grown thin films of one of these phases, the cubic half-Heusler material DyPdBi , using carefully flux matched molecular beam epitaxy. Crystalline quality was monitored via *in situ* RHEED and verified by *ex situ* x-ray diffraction measurements. Transport measurements indicate the emergence of interesting correlated behavior at low temperature.

¹This work is supported by the NSF.

3:42PM D31.00007 Vacancy Reduction, Structural and Electronic Studies of Epitaxial Films of Topological Insulators¹, F. KATMIS, V. FATEMI, H. STEINBERG, L. ORONA, Department of Physics, MIT, Cambridge, USA, P. WEI, FBML, MIT, Cambridge, USA, P. JARILLO-HERRERO, J. MOODERA², Department of Physics, MIT, Cambridge, USA — We have developed methods for controlling the carrier concentration via a vacancy concentration reduction procedure in the MBE grown epitaxial topological insulator (TI) thin film on various substrates to reach the intrinsic features of TI. Our single crystalline TI thin films allowed us to systematically investigate the nature of coherent transport in this system. For structural characterization of TI thin films, various non-destructive methods, such as x-ray and electron based diffraction techniques, were used as a local probe to understand the long-, short-range atomic ordering and also lattice site occupation. Besides the improved electronic properties of the layers, as grown crystalline films density increased by 20% due to controlled vacancy reduction, determined by *in-situ* x-ray diffraction. Furthermore, correlation of vacancies and Se ion migration was observed to be the likely reason for lowering the carrier concentration. Our study also shows the dependence of carrier mobility and the vacancy concentration which has been optimized.

3:54PM D31.00008 Growth and in-situ ultra-high resolution ARPES studies of the Bi-Te family of topological insulators¹, JAMES LEE, FELIX SCHMITT, ROB MOORE, INNA VISHIK, MING YI, Z.X. SHEN, Stanford University — Topological insulators have received intense focus in the condensed matter community due to their academic and technical potential. The Quantum Anomalous Hall state is an example of the exotic physics that could have a major industry impact if it can be realized and controlled. While the topologically protected states live at interfaces between insulators of two topological classes, investigations of the underlying electronic structure via angle resolved photoemission spectroscopy requires pristine surfaces. Here we present results from *in situ* ultra-high resolution laser ARPES investigations at low temperatures of the doped Bi-Te family of topological insulator thin films grown via molecular beam epitaxy. Electronic structure evolution as a function of dopant, dopant level and thickness will be presented and compared to theoretical predictions.

¹Support given by the DOE and Stanford Graduate Fellowship.

4:06PM D31.00009 Fabrication of Bismuth Selenide Topological Insulating Samples, LUCAS ORONA, HADAR STEINBERG, VALLA FATEMI, FERHAT KATMIS, JAGADEESH MOODERA, PABLO JARILLO-HERRERO, MIT — In this talk, I will discuss fabrication of nanometric topological insulator Bi_2Se_3 devices. Our group uses two fabrication methodologies: Epitaxial thin films and single crystal exfoliation. I will discuss the benefits and drawbacks of each methodology. I will also address the effects on device performance by various steps of the fabrication process.

4:18PM D31.00010 Interfacing 2D and 3D Topological Insulators: $\text{Bi}(111)$ Bilayer on Bi_2Te_3 , TORU HIRAHARA, Department of Physics, University of Tokyo, GUSTAV BIHLMAYER, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, YUSUKE SAKAMOTO, MANABU YAMADA, Department of Physics, University of Tokyo, HIDETOSHI MIYAZAKI, SHIN-ICHI KIMURA, UVSOR Facility, Institute for Molecular Science, STEFAN BLÜGEL, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, SHUJI HASEGAWA, Department of Physics, University of Tokyo — Topological insulators (TI) are insulating materials but have metallic edge states that carry spin currents and are robust against nonmagnetic impurities [1]. While there have been a large number of reports on three-dimensional (3D) TI, only few works have been done in terms of two-dimensional (2D) TI. In the present paper, we report the successful formation of bilayer Bi, which was theoretically predicted to be a 2D TI [2]. We deposited bilayer Bi on a 3D TI Bi_2Te_3 , which the lattice mismatch is very small. From angle-resolved photoemission spectroscopy measurements and *ab initio* calculations, the electronic structure of the system can be understood as an overlap of the band dispersions of bilayer Bi and Bi_2Te_3 . Our results show that the Dirac cone is actually robust against nonmagnetic perturbations and imply a unique situation where the topologically protected one- and two-dimensional edge states are coexisting at the surface [3].

4:30PM D31.00011 Fabrication of Bi_2Te_3 Nanodots by Droplet Epitaxy on GaAs substrates

ZHAOQUAN ZENG, CHEN LI, Department of Physics, University of Arkansas, Fayetteville, AR 72701, DONGSHENG FAN, Department of Electrical Engineering, University of Arkansas, Fayetteville, AR 72701, YUSUKE HIRONO, TIMOTHY MORGAN, XIAN HU, Department of Physics, University of Arkansas, Fayetteville, AR 72701, JIAN WANG, MEENAKSHI SINGH, The Center for Nanoscale Science and Department of Physics, The Pennsylvania State University, University Park, PA 16802, ZHIMING WANG, State Key Laboratory of Electronic Thin Films and Integrated Devices, University of Electronic Science and Technology of China, SHUI-QING YU, Department of Electrical Engineering, University of Arkansas, Fayetteville, AR 72701, AQIANG GUO, GREGORY SALAMO, Department of Physics, University of Arkansas, Fayetteville, AR 72701, GREGORY J. SALAMO TEAM, SHUI-QING YU TEAM, ZHIMING WANG TEAM, JIAN WANG TEAM — Bi_2Te_3 , as a three-dimensional topological insulator, causes wide attention. Here, we report the fabrication of Bi_2Te_3 nanodots on GaAs substrate by droplet epitaxy using molecular beam epitaxy (MBE). Reflection high energy electron diffraction (RHEED), atomic force microscopy (AFM), x-ray photoelectron spectroscopy (XPS), and Raman measurement revealed the existence of Bi_2Te_3 nanodots. Several approaches were developed to control the size and density of as-grown Bi_2Te_3 nanodots. Temperature and density dependent magneto-transport measurements were investigated. This may provide a platform for the interaction investigation among topological insulators, semiconductors, ferromagnets and superconductors.

4:42PM D31.00012 AFM, Raman and electrical transport studies of topological insulating materials subjected to argon plasma etching

ISAAC CHILDRES, JIFA TIAN, IRENEUSZ MIOTKOWSKI, YONG CHEN, Purdue University — Plasma etching is an important tool in nano-device fabrication. We report a study on argon plasma etching of exfoliated flakes of topological insulator materials Bi_2Se_3 , Bi_2Te_3 , Sb_2Te_3 and $\text{Bi}_2\text{Te}_2\text{Se}$. We present data from atomic force microscopy (AFM), Raman spectroscopy and low-temperature magneto-transport measurements. The thickness of our samples measured by AFM is observed to decrease approximately linearly with plasma exposure time. We extract an etching rate for each type of material. For the initial increase in plasma exposure time, we observe increasing intensity and width of the characteristic E_g^2 Raman peak with little change in peak position. The width of this peak for etched flakes becomes larger than those of unetched samples of the same thickness. Additionally, we find that even moderate etching can significantly reduce the conductivity and hall mobility. These results indicate disorder is generated by plasma etching and impedes both phonon and carrier transport. Our findings are valuable for understanding the effects of argon plasma etching on topological insulator materials and using irradiation as a potential method to introduce controlled disorder in such materials.

4:54PM D31.00013 Tuning the spatial location of topological surface states via proximity effects¹

GUANGFEN WU, Univ. of Sci. & Tech. of China, Southeast Univ., China, YAN SUN, Shenyang National Lab for Materials Science, China, HUA CHEN, Univ. of Tennessee, Univ. of Texas at Austin, XIAO GUANG LI, Fudan Univ., Univ. of Sci. & Tech. of China, PING CUI, Univ. of Sci. & Tech. of China, JINLAN WANG, Southeast Univ., China, XINGQIU CHEN, Shenyang National Lab for Materials Science, China, ZHENYU ZHANG, Univ. of Sci. & Tech. of China, Harvard University — In order to exploit promising applications of topological insulators in quantum computing, spintronics, and catalysis, one prerequisite is to gain effective manipulation of the spatial distribution of the topological surface states (TSS). We use first-principles calculations to investigate the interfacial proximity effects on the TSS for hybrid systems consisting of semiconducting thin films with different bandgaps, spin-orbital coupling (SOC) strengths, and lattice mismatches grown on the TI substrate of Bi_2Se_3 . Our results show that the spatial location of the robust TSS can be tuned by the interplay of the effects associated with the SOC strength and the band gap size of the semiconductor. Potential experimental confirmations of these strong predictions are also discussed.

¹Supported by DMSE of USDOE, USNSF, and NNSF of China.

5:06PM D31.00014 Metal-Supported High Crystalline Bi_2Se_3 Quintuple Layers

JEONG HEUM JEON, WON JUN JANG, JONG KEON YOON, SANG-YOUN WEON, SE-JONG KAHNG, Dept. of Physics, Korea University — Atomically flat thin films of Bi_2Se_3 were grown on Au(111) metal substrate using molecular beam epitaxy. Hexagonal atomic structures and quintuple-layer steps were observed at the surfaces of grown films using scanning tunneling microscopy. Multiple sharp peaks from (003) family layers were characterized by X-ray diffraction measurements. The atomic stoichiometry of Bi and Se was considered using X-ray photoemission spectroscopy. Moiré patterns were obtained at the surfaces of one quintuple layer films due to lattice mismatch between Bi_2Se_3 and Au. Our experiments suggest that Au is a reasonable material for electrodes in Bi_2Se_3 devices.

5:18PM D31.00015 Ab initio study of epitaxial graphene on top of Sb_2Te_3 topological insulator

KYUNG-HWAN JIN, Department of Physics, POSTECH, SEUNG-HOON JHI, Department of Physics and Division of Advanced Materials Science, POSTECH — Understanding topological phase as observed in Dirac materials such as graphene and topological insulator (TI) has been a central issue in the field of condensed matter physics. Graphene and TI exhibit unique 2D electronic structures that attract great attention for potential application to spintronic devices. Heterostructures of graphene and TI provide interesting platforms to explore exotic electronic and transport properties of Dirac materials. Electronic structures of graphene in contact with TI were investigated using first-principles methods and tight-binding models. The Dirac cones of graphene on top of TI surface show several interesting features including band-gap opening and band splitting. By fitting first-principles calculations to tight-binding models, we analyzed the origin of the changes in the Dirac cones. We found that both intrinsic and extrinsic spin-orbit couplings are enhanced significantly due to proximity to topological insulator Sb_2Te_3 and that graphene turns into quantum spin-Hall phase. Our results suggest that graphene is also useful as a probe of TI surface states.

Monday, February 27, 2012 2:30PM - 5:30PM —

Session D32 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides
- Lattice Dynamics 261

2:30PM D32.00001 Dynamical couplings in ferroelectrics and multiferroics¹

DAWEI WANG, Xi'an Jiaotong University — First-principle-based molecular dynamics simulations are developed and used to investigate dynamical phenomena in the $\text{Pb}(\text{Zr,Ti})\text{O}_3$ (PZT) ferroelectric solid solutions and in the multiferroic BiFeO_3 system^{2,3}. Several interesting effects are reported, including: (1) the existence of two E modes in PZT in the 50–75 cm^{-1} range for temperatures smaller than $\simeq 200$ K when the system is in its $R3c$ phase. Such existence originates from a *linear* coupling between ferroelectric (FE) motions and tiltings of oxygen octahedra; (2) a Fermi resonance (FR) emerging from a *nonlinear* coupling between FE distortions and oxygen octahedra tilts. This FR manifests itself as the doubling of a nominally-single FE mode in a purely FE phase, when the resonant frequency of the FE mode is close to the first overtone of the oxygen octahedra tiltings; and (3) the prediction of an electromagnon peak, that results from specific interactions between magnetic dipoles, FE motions and oxygen octahedra tiltings, in BiFeO_3 . Some of these results have been confirmed by recent Raman scattering experiments, and analytical models are also developed to better understand such effects.⁴

3:06PM D32.00002 A-site ion vibrational modes in ABO₃ polar perovskites, JIRI HLINKA, Institute of Physics ASCR, Na Slovance 2, 182 21 Prague 8 — It is well known that Pb(B'B'')O₃ family of complex perovskites contains materials with very useful dielectric, piezoelectric and ferroelectric properties. The overall electromechanical response of these system is believed to be related to their characteristic micro-to nanoscale structural correlations (chemical clusters, polar nanoregions or nanotwins). At the level of the ABO₃ unit cell, the remarkable polarizability of these materials originates from lead-ion displacements, and the anharmonic motion of these ions, loosely linked to the core oxygen octahedra network, largely dominates in the low-frequency phonon modes in the system. Therefore, the investigation of the low-frequency phonon modes in these systems is of a great importance. The aim of this contribution is to report recent experimental studies of such low-frequency vibrations by inelastic X-ray, neutron and light scattering techniques, in materials like lead zirconate titanate, lead magnesium niobium titanate or lead titanate. In particular, attention will be paid to our recent inelastic X-ray scattering studies of PZT lattice dynamics.

3:42PM D32.00003 Fully-atomistic first-principles approach to the temperature-dependent lattice-dynamical properties of perovskite oxides, MATHIAS LJUNGBERG, JACEK WOJDEL, JORGE INIGUEZ, ICMAB-CSIC — We present a methodology for the parametrization of effective Hamiltonians for ferroelectric perovskites that provides a fully atomistic description of the materials. The parameters in our effective models are obtained from first-principles calculations; no experimental input is used. The potential energy surface is represented by a truncated Taylor expansion around the ideal cubic perovskite structure, and is, up to second order, exactly equivalent to the first-principles computed one. Higher order terms are determined by fitting to the first-principles energetics and phonon dispersion relations of the relevant low-symmetry phases. By treating all structural degrees of freedom explicitly, our models allow us to investigate the competition between the soft modes that drive the ferroelectric phase transitions in these materials and other, secondary modes. We will show that such an interaction is of significant importance in the prototypical ferroelectric compound PbTiO₃; our method's ability to capture it constitutes a considerable improvement upon earlier approaches. We will also report on our current work to extend this methodology to treat inhomogeneous materials, as e.g. superlattices.

3:54PM D32.00004 Lattice dynamics of cubic PbTiO₃¹, IZUMI TOMENO, Akita University, JAIME A. FERNANDEZ-BACA, KAROL J. MARTY, ORNL, YORIIHIKO TSUNODA, Waseda University, KUNIIHIKO OKA, AIST — The lattice dynamics of cubic PbTiO₃ has been investigated using inelastic neutron scattering. We found four kinds of soft modes in cubic PbTiO₃: (1) the TO modes toward the Γ point, (2) the TA Λ_3 mode toward the R point, (3) the TA Λ_3 mode around the midpoint (1/4,1/4,1/4), and (4) the TA branches in the entire range. Moreover, the TO Σ_4 branch becomes flat away from the zone center. The steep dispersion of the TO modes toward Γ is isotropic and confined to the region $\xi < 0.2$. The temperature dependence of the Γ_{15} mode up to 1173 K is explained by a combination of the Lydanne-Sachs-Teller relation and the Curie-Weiss law. In contrast, the TA Λ_3 modes at the midpoint and R point are weakly temperature dependent. The coexistence of the soft Γ_{15} and R_{25} modes is in agreement with the predicted phonon instability. The midpoint softening suggests the tendency toward forming a fourfold periodicity along the [1,1,1] direction. The energy of the TO Δ_5 branch for cubic PbTiO₃ is considerably higher than that for Pb(Zn_{1/3}Nb_{2/3})O₃. This indicates that the TO modes are dominated by the B-site atom motion.

4:06PM D32.00005 BaTiO₃ nanocrystals studied by Raman spectroscopy¹, A.K. FARRAR, T. ENGMAN, D.A. TENNE, Department of Physics, Boise State University, S. ADIREDDY, G. CARUNTU, Advanced Materials Research Institute, Department of Chemistry, University of New Orleans — Variable-temperature Raman spectroscopy study of BaTiO₃ nanocrystals of varied sizes (from 8 to 20 nm) will be presented. Highly uniform cube-shaped BaTiO₃ nanocrystals have been prepared by solvothermal synthesis at temperatures below 140 °C and characterized by x-ray diffraction and transmission electron microscopy. Raman spectra (measured with ultraviolet and visible excitation) show that all nanocrystals studied are ferroelectric; nanocrystal size effect on the Curie temperature has been investigated. Temperature evolution of Raman spectra (10–600K) demonstrates that the ferroelectric phase of the nanocrystals is different from the bulk BaTiO₃. The transitions from tetragonal to orthorhombic and from orthorhombic to rhombohedral phases, which are characteristic for bulk BaTiO₃, have not been observed in the nanocrystals; the ferroelectric phase in the nanocrystals is the same in the entire temperature range below T_c , and is different from any of the bulk phases. The observed behavior may be explained by complex polarization patterns theoretically predicted for zero-dimensional ferroelectrics.

¹Supported in part by NSF Grants DMR-0705127, DMR-1006136, EPS-1003897 and DMR-1004869, DARPA Grant HR 0011-09-0047, and Research Corporation for Science Advancement Grant 7134.

4:18PM D32.00006 Raman spectra and lattice dynamics of disordered complex perovskite BaMg_{1/3}Ta_{2/3}O₃, SEVERIAN GVASALIYA, DAN HÜVONEN, Laboratorium für Festkörperphysik, ETH Honggerberg, 8093 Zurich, Switzerland, SERGEY LUSHNIKOV, Ioffe Physico-Technical Institute, 194021, St Petersburg, Russia, ELENA POPOVA, St. Petersburg State University, Department of Crystallography, 199034, Russia & Ioffe Physico-Technical Institute, 194021, St Petersburg, Russia, TATIYANA SHAPLYGINA, Ioffe Physico-Technical Institute, 194021, St Petersburg, Russia, ANDREY ZHELUDEV, Laboratorium für Festkörperphysik, ETH Honggerberg, 8093 Zurich, Switzerland — In relaxor ferroelectrics the chemical and the displacive ionic disorders coexist and may cause a relaxation of the selection rules for Raman scattering. We performed a Raman scattering study of BaMg_{1/3}Ta_{2/3}O₃ (BMT), which is chemically disordered cubic perovskite showing no evidences for displacive disorder. Polarized Raman spectra from a single crystal of BMT were collected in the temperature range of 5 — 550 K. We are going to discuss the symmetry assignments of the observed modes and their temperature evolution. Simplified shell-model for the lattice dynamics of BMT will be presented. The results for BMT will be compared to the well-known observations for the Raman spectra from related relaxor ferroelectrics PbMg_{1/3}Ta_{2/3}O₃ and PbMg_{1/3}Nb_{2/3}O₃. In particular, the lowest Raman line observed in BMT is at ~ 110 cm⁻¹, whereas the doublet line in PbMg_{1/3}Ta_{2/3}O₃ is observed around 50 cm⁻¹. Also, we found out that the width of well-isolated A_{1g} line of BMT is approximately two times narrower than that observed in relaxors.

4:30PM D32.00007 Frequency shift of Raman modes due to an applied electric field and domain inversion in LiNbO₃, GREG STONE, BRIAN KNORR, Lehigh University, VENKATRAMAN GOPALAN, Pennsylvania State University, VOLKMAR DIEROLF, Lehigh University — We report changes in the frequency of several Raman modes in congruent and near-stoichiometric lithium niobate that are observed under the application of external applied electric fields parallel to the ferroelectric axis and after domain inversion. A comparison of the direction of the frequency shifts due to an applied electric field and domain inversion reveals that after forward poling there is a reduction of the internal field that is dependent on the intrinsic defect concentration present in the crystal. Upon back poling, the internal field returns to its original state. A further inspection of the Raman peaks reveals that the magnitude of the frequency shift is not consistent between an applied electric field and domain inversion. This indicates that the change in the local internal field introduced by domain inversion is not limited to the ferroelectric axis, but the fields orthogonal to the ferroelectric axis change. Work supported by the grants: NSF-DMR 0602986 and 1008075

4:42PM D32.00008 Infrared phonon anomaly and magnetic excitations in single-crystal $\text{Cu}_3\text{Bi}(\text{SeO}_3)_2\text{O}_2\text{Cl}^1$, KEVIN H. MILLER, C. MARTIN, X. XI, Department of Physics, University of Florida, H. BERGER, Ecole Polytechnique Federal de Lausanne, G.L. CARR, Photon Sciences, Brookhaven National Laboratory, D.B. TANNER, Department of Physics, University of Florida — Infrared reflection as a function of temperature has been measured on the anisotropic single-crystal $\text{Cu}_3\text{Bi}(\text{SeO}_3)_2\text{O}_2\text{Cl}$. The complex dielectric function and optical properties along all three crystal axes of the orthorhombic cell were obtained via Kramers-Kronig analysis and by fits to a Drude-Lorentz model. Below 110 K drastic anomalies in the phonon spectrum (e.g., new modes and splitting of existing modes) are observed along all three crystal axes. Transmission in the terahertz region as a function of temperature has revealed magnetic excitations originating below the ferromagnetic ordering temperature, $T_c=24$ K. The origin of the excitations in the magnetic state will be discussed in terms of their polarization and externally-applied magnetic field dependence.

4:54PM D32.00009 Hydrogen diffusion and tunneling in KTaO_3 from first principles¹, HAZEM ABU FARSACKH, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara — The high proton conductivity in many perovskites has attracted interest for potential applications, such as in fuel cells. A promising approach to increase their conductivity at lower temperatures involves enhancing quantum-mechanical tunneling. In order to determine the role of tunneling for H in KTaO_3 we employ first principles calculations for H interstitial atoms. We identify H binding sites and diffusion channels and calculate the associated activation energies. In addition, we analyze the effect of lattice relaxations on the diffusion barriers. Through calculating the 3D potential energy surface of H, we determine accurate H tunneling rates by numerically solving Schrödinger's equation for H in the 3D potential energy surface. Finally, we examine lattice vibrations and analyze their role in assisting proton tunneling.

5:06PM D32.00010 Scaling of Flat Band Potential and Dielectric Constant as a Function of Ta Concentration in Ta-TiO₂ Epitaxial Films¹, Y.L. ZHAO, A. ROY BARMAN, S. DHAR, A. ANNADI, NUSNNI-NanoCore, NUS, M. MOTAPOTHULA, CIBA,NUS, J.H. WANG, H.B. SU, Material science, NTU, M. BREESE, CIBA,NUS, T. VENKATESAN, NUSNNI-NanoCore, NUS, Q. WANG, Material science, NUS — Electrochemical impedance spectroscopy measurements of pulsed laser deposited single crystal anatase TiO₂ thin films with various concentrations of Ta substituting for Ti were carried out. UV-visible measurements show a systematic increase of the bandgap with Ta incorporation. Corresponding Mott-Schottky plot was applied to obtain a continuous shift of the flat band potential with increasing free charge carrier concentration. This was verified theoretically by ab initio calculation which shows that extra Ta d-electrons occupy Ti t_{2g} orbital with increasing Ta concentration, thereby pushing up the Fermi level. The Mott-Schottky results were consistent when compared with Hall effect and temperature dependent resistivity measurements. From the measured deviation of carrier densities from Hall and Mott-Schottky measurements we have estimated the static dielectric constant of the TiO₂ as a function of Ta incorporation. We are able to estimate the shifts of both the conduction and valence bands from these measurements.

5:18PM D32.00011 Raman spectroscopic studies of $\text{Ti}_{1-x}\text{Ta}_x\text{O}_2$ alloy thin films¹, S. SAHA, A. ROY-BARMAN, NUSNNI-NanoCore, National University of Singapore, C.B. TAY, Department of Electrical and Computer Engineering, National University of Singapore, T. SARKAR, Y. ZHAO, NUSNNI-NanoCore, National University of Singapore, S. TRIPATHY, IMRE, A*STAR, Singapore, S. DHAR, - ARIANDO, NUSNNI-NanoCore, National University of Singapore, S.J. CHUA, Department of Electrical and Computer Engineering, National University of Singapore, T. VENKATESAN, NUSNNI-NanoCore, National University of Singapore — Anatase $\text{Ti}_{1-x}\text{Ta}_x\text{O}_2$ thin films have been of interest not only because of the recently found defect originated room temperature ferromagnetism, but also because of the wide possibilities of its application as transparent conducting oxide in flat panel displays, light emitting diodes and solar cells. The incorporation of a foreign element in a host oxide crystal has conventionally been referred to as doping. However, recently we have experimentally shown that even with as less as 1% Ta incorporation in TiO₂, a totally new alloy system is formed. Here we present a Raman and x-ray diffraction study of anatase $\text{Ti}_{1-x}\text{Ta}_x\text{O}_2$ thin films grown on (100) LaAlO_3 substrate by PLD to understand the crystal structure and defects in the Ta-incorporated TiO₂ thin films. We find that as Ta is incorporated in the TiO₂ lattice the out-of-plane phonons undergo red-shift while the in-plane phonon undergoes a blue-shift, suggesting an expansion of the TiO₂ lattice along the out-of-plane direction with a concomitant in-plane contraction.

Monday, February 27, 2012 2:30PM - 5:18PM – Session D33 GERA: Physics of Batteries and Fuel Cells 106

2:30PM D33.00001 Effect of Iron-based Impurities on the performance of nanostructured C-LiFePO₄ cathode materials for Li ion Batteries, P. VAISHNAVA, Kettering University, A. DIXIT, K. BAZZI, M.B. SAHANA, C. SUDAKAR, Wayne State University, M. NAZRI, Applied Sciences, Inc. Cedarville, Ohio, V. NAIK, University of Michigan - Dearborn, V.K. GARG, A.C. OLIVEIRA, Universidade de Brasilia, Brazil, G.A. NAZRI, R. NAIK, Wayne State University — We report synthesis of pure and C-LiFePO₄ nanoparticles in 20-30 nm size by sol-gel method. Three samples of C-LiFePO₄ were prepared by mixing 0.25M, 0.50M, and 1M lauric acid in the precursor solutions for carbon coating the particles. The samples were characterized by X-ray diffraction (XRD), X-ray photoelectron spectroscopy (XPS), IR spectroscopy, SQUID magnetometry, Raman spectroscopy, and Fe⁵⁷ Mössbauer spectroscopy. All the samples were thoroughly investigated for their electrochemical properties. The XRD measurements showed all the samples are single phase materials with no impurity phase. However, we identified at least three residual non crystalline impurity phases simultaneously using Fe⁵⁷ Mössbauer spectroscopy, XPS, and the magnetic measurements. The elemental chemical states for Fe 2p, P 2p, and O 1s are analyzed using XPS for LiFePO₄ and compared with those of C-LiFePO₄ materials. SQUID magnetometry measurements suggest an antiferromagnetic transition ~50 K in both pure LiFePO₄ and C-LiFePO₄ samples. The role of various phases, such as FeP, Fe₂P, α-Fe and Fe₂O₃ identified and analyzed by Fe⁵⁷ Mössbauer spectroscopy and XPS, will be discussed in relationship to the electrochemical properties of the cathode materials.

2:42PM D33.00002 Role of Ce and In doping in the performance of LiFePO₄ cathode material for Li ion Batteries, BALAJI MANDAL, MARIAM NAZRI, Wayne State University, PREM P. VAISHNAVA, Kettering University, VAMAN M. NAIK, University of Michigan-Dearborn, GHOLAM A. NAZRI, RATNA NAIK, Wayne State University — Recently, the olivine LiFePO₄ has attracted attention as a promising cathode material for Li ion batteries. However, its poor electronic conductivity is a major challenge for its industrial applications. Different approaches have been taken to address this problem. Here, we report a method of improving its conductivity by doping In and Ce ions at the Fe site. We prepared the samples by sol-gel method followed by annealing at 650 °C in Ar (95%) +H₂(5%) atmosphere for 5 hrs. XRD and Raman spectroscopy confirm that the olivine structure remains unchanged upon doping with In and Ce up to 5 wt%. XRD analysis shows the values of the lattice parameters increase with doping as the ionic radii of Ce and In ions are larger than that of the Fe²⁺ ion. This observation also suggests that both Ce and In ions replace Fe ions and not the Li ions in the material. Upon doping, ionic conductivity was found to increase from 10⁻⁹ to 10⁻⁴ Ohm⁻¹cm⁻¹. Interestingly, Ce doped LiFePO₄ showed a higher conductivity than In doped LiFePO₄. SEM measurements show a bigger grain size of ~300-500 nm in doped LiFePO₄ which decreased to ~50 nm when the materials were synthesized using 0.25M lauric acid as a precursor. The electrochemical characteristics of the doped LiFePO₄ along with conductivity and Raman data will be presented.

2:54PM D33.00003 Formation of small polarons in Li₂O₂ and implications for Li-air batteries¹, JOONGGO KANG, National Renewable Energy Laboratory, Golden, Colorado 80401, USA, YOON-SEOK JUNG, Ulsan National Institute of Science and Technology, Ulsan, Korea, SU-HUAI WEI, ANNE DILLON, National Renewable Energy Laboratory, Golden, Colorado 80401, USA — Lithium-air batteries (LABs) have recently been revitalized as a promising electrical energy storage system due to their exceptionally high theoretical energy density. However, its usage is limited by poor rate capability and large polarization in the cell voltage due primarily to the formation of Li₂O₂ in the air cathode. Here, using hybrid density functional theory, we found that the formation of small polarons in Li₂O₂ is the origin that limits the electron transport in Li₂O₂. Consequently, the low electron mobility contributes to the hysteresis in cell voltage and limits the power density of the LABs. We suggest that similar behavior should exist in other peroxides, and p-type doping in Li₂O₂ could significantly improve the performance of LABs at high current densities.

¹This work was funded by the NREL LDRD program (DE-AC36-08GO28308).

3:06PM D33.00004 The Li-induced Conversion Reaction of Ultra-Thin FeF₂ Films¹, RYAN THORPE, SYLVIE RANGAN, ROBERT BARTYNSKI, OZGUR CELIK, LESZEK WIELUNSKI, Rutgers University — Iron (II) fluoride has recently gained interest as a possible cathode material in Li-ion conversion batteries. Conversion materials like this could potentially store 2-3 times more energy than conventional intercalation battery materials by utilizing the full range of charge states in their constituent transition metal ions, i.e., Fe⁽²⁺⁾F₂ + 2Li⁺ + 2e⁻ → Fe⁰ + 2LiF. Using surface science techniques, we are able to observe this reaction at the FeF₂-Li interface. We have grown 5nm films of high-purity polycrystalline FeF₂ in ultra-high vacuum and deposited atomic Li on the surface to simulate the conversion reaction in the absence of external contaminants. Using UV photoemission (UPS), x-ray photoemission (XPS), and inverse photoemission (IPE) spectroscopies, we have measured the composition and charge states of these materials. XPS of the FeF₂ sample after various Li exposures indicate a direct conversion from Fe²⁺ to Fe⁰, with no intermediary phases. The growth of a Fermi edge in UPS and IPE also indicates the formation of metallic Fe, while peaks characteristic of LiF can be seen in UPS after sufficient Li exposure. These results are consistent with those of recent TEM measurements on real electrochemical cells.

¹This material is based upon work supported as part of NECCES, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DE-SC0001294.

3:18PM D33.00005 Electrochemical Performance of Lithium Iron Phosphate Doped with Tungsten, HANU ARAVA, ANDREW TRENCHARD, GAN LIANG, HUI FANG, Sam Houston State University — Due to its high thermal stability, low cost and high theoretical charge capacity, LiFePO₄ has emerged as one of the most promising cathode materials for large-scale lithium ion batteries. In this work, we systematically investigated the effect on structure and electrochemical properties brought by W doping on Fe site of LiFePO₄. LiFe_{1-x}W_xPO₄ (x= 0, 0.01, 0.02, 0.03) samples with and without carbon coating were prepared by using solid-state reaction. The phase and structure of as prepared powders were characterized by X-ray diffraction and scanning electron microscope. Cycling charge and discharge measurement at various C-rates and cyclic voltammetry were employed to reveal the electrochemical properties. Results showed that carbon coating dramatically improved the capacity at fast C-rate. 2 at.% W doping was observed to have the highest charge capacity with 143 mAh/g at 0.1C and a 109 mAh/g for 1C.

3:30PM D33.00006 Model conversion reaction: Li reactivity on iron oxifluorides, SYLVIE RANGAN, RYAN THORPE, OZGUR CELIK, ROBERT BARTYNSKI, Rutgers University — Iron fluorides have gained interest as choice materials for conversion reaction-based batteries. Owing to their large band gaps and their ability to store up to three electrons per formula unit, batteries using these materials operate at high voltages and high energy densities. However the large band gap inhibits charge conduction and thus impedes efficient charging and discharging cycles. Two paths have been taken to overcome this limitation: 1) The use of nanoparticles embedded into a conducting carbon matrix improves both ionic and electronic conduction; and 2) The use of iron oxifluorides, which are characterized by a slightly reduced energy gap that facilitates electronic conduction. It is the latter point that is central to this study as, curiously, relatively little is known about the electronic structure of iron oxifluorides and their interaction with Li, a key aspect of a storage cell's electrochemistry. Model conversion reactions have been studied by evaporating Li on FeF₂ and FeF_xO_y samples. Using X-ray and UV photoemission as well as inverse photoemission spectroscopies, the occupied states and the unoccupied electronic states of the resulting samples have been probed. Transmission electron microscopy has been used in parallel to investigate phase analysis.

3:42PM D33.00007 Shape and volume changes in Lithiated Silicon anodes for batteries, EKIN CUBUK, WEI WANG, EFTHIMIOS KAXIRAS, Harvard University — Silicon is one of the most promising materials for use as an anode for Lithium-ion batteries due to its capacity to hold a large number of Li atoms (up to 4.4 Li per Si atom). One of the biggest challenges in using Silicon as anode material is mechanical failures due to large volume expansion during the lithiation process. Recently detailed experiments have been reported on the dependence of volume change on the crystal orientation, especially for nano-scale structures. We investigate the microscopic mechanisms for shape changes during lithiation of Si by comparing the reaction mechanisms of Li atoms on different surfaces of crystalline Si using first-principles calculations.

3:54PM D33.00008 Effect of carbon support on catalytic efficiency and durability in fuel cells, CECILE MALARDIER-JUGROOT, MICHAEL GROVES, DEBORAH DURBIN, MANISH JUGROOT, Royal Military College of Canada — New nanomaterials already play a key role in several emerging technologies. For instance, in fuel cell technology, catalytic efficiency can be greatly enhanced due to the high surface area of nanomaterials. Improving the durability and efficiency of a platinum catalyst is an important step in increasing its utility when incorporated as the anode or cathode of a proton exchange membrane fuel cell (PEMFC). The authors have shown using Density Functional Theory methods [1] that doping the carbon support of the Pt catalyst can increase the durability and efficiency of the catalyst. This paper will present the effect of doping of the carbon support on the complete reaction path of the Oxygen Reduction Reaction using *ab initio* structural methods as well as a complete *ab initio* molecular dynamics characterization of the reaction. In addition, the electronic structure of the carbon support was shown to improve the metal/CO interaction for the development of a membrane to prevent catalyst poisoning [2]. The paper will also emphasize the effect of the solvent, which is experimentally shown to be crucial. [1] M. Groves, A. Chan, C. Malardier-Jugroot and M. Jugroot, *Chem. Phys. Letters*, 481(4-6), 214-219, 2009 [2] D. Durbin and C. Malardier-Jugroot, *J. Phys. Chem. C*, 115 (3), 808-815, 2011

4:06PM D33.00009 Probing the Reversibility Limit of Lithium Ion Transport in Solid Film Batteries¹, HOWARD WANG, LIWEI HUANG, KAIKUN YANG, Institute for Material Research and Department of Mechanical Engineering, State University of New York, Binghamton, NY 13902, GREGORY DOWNING, Material Measurement Laboratory, National Institute of Standards and Technology, Gaithersburg, MD 20899, ALEC TALIN, PAUL NANEY, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Gaithersburg, MD 20899, JASON ZHANG, Energy and Environment Directorate, Pacific Northwest National Laboratory, Richland, WA 99352, JON OWEJAN, JEFFREY GAGLIARDO, JEANETTE OWEJAN, Electrochemical Energy Research Laboratory, General Motors Company, Honeoye Falls, NY 14472 — Time-resolved neutron depth profiling (TR-NDP) has been used to measure the lithium distribution in electrode layers of thin film batteries during charge/discharge cycles. TR-NDP data demonstrate quantitatively that ionic transport in electrodes follows the electric current in the external circuits under normal charge/discharge conditions whereas deviates upon sudden structural changes. The reversibility limit of ionic transport has been quantified to indicate the onset of battery failure.

¹The NIST/ARRA funding through GM is greatly appreciated

4:18PM D33.00010 Energy Storage and Generation from Thermopower Waves, JOEL ABRAHAMSON, SAYALEE MAHAJAN, WONJOON CHOI, NICOLE SCHONENBACH, JUNGSIK PARK, MICHAEL WALSH, JARED FORMAN, JAE-HEE HAN, Massachusetts Institute of Technology, KOUROSH KALANTAR-ZADEH, RMIT University, MICHAEL STRANO, Massachusetts Institute of Technology — We have demonstrated through simulation and experiment that the nonlinear coupling between an exothermic chemical reaction in a fuel and a nanowire or nanotube with large axial heat conduction accelerates the thermal reaction wave along the nano-conduit. The thermal conduit rapidly transports energy to unreacted fuel regions, and the reaction wave induces a concomitant thermopower wave of high power density, producing electrical current in the same direction. At up to 14 W/g, this can be substantially larger than the power density offered by current micro-scale power sources (e.g. fuel cells, batteries) and even about seven times greater than that of commercial Li-ion batteries. MEMS devices and wireless sensor networks would benefit from such high power density sources to enable functions such as communications and acceleration hampered by present power sources.

4:30PM D33.00011 In-situ TEM observations of the nanoscale electrochemistry in a Li-ion cell, JIANYU HUANG, Sandia National Laboratories, UNIVERSITY OF PITTSBURGH COLLABORATION — The lithiation-delithiation processes of anode materials in lithium ion batteries were observed by in-situ electron microscopy. The lithiation-delithiation was strongly materials, size, and orientation dependent. Upon charging of SnO₂ nanowires, we observed high density of dislocations in the reaction front, while in charging of ZnO nanowires, we observed discrete cracks in the reaction front. In charging Si nanowires, we found the volume expansion was highly anisotropic, resulting in a dumbbell-shaped cross-section and cracking, eventually splitting the single nanowire into sub-wires. Carbon coating not only increases rate performance but also alters the lithiation-induced strain of SnO₂ nanowires. The radial expansion of the coated nanowires was completely suppressed. The lithiation process of individual Si nanoparticles was strongly size-dependent, i.e., there exists a critical particle size with a diameter of ~ 150 nm, below which the particles neither cracked nor fractured upon lithiation, above which the particles first formed cracks and then fractured.

4:42PM D33.00012 Gasoline-powered series hybrid cars cause lower life cycle carbon emissions than battery cars, CHRISTOPH MEINRENKEN, KLAUS S. LACKNER, Columbia University — Battery cars powered by grid electricity promise reduced life cycle green house gas (GHG) emissions from the automotive sector. Such scenarios usually point to the much higher emissions from conventional, internal combustion engine cars. However, today's commercially available series hybrid technology achieves the well known efficiency gains in electric drivetrains (regenerative braking, lack of gearbox) even if the electricity is generated onboard, from conventional fuels. Here, we analyze life cycle GHG emissions for commercially available, state-of-the-art plug-in battery cars (e.g. Nissan Leaf) and those of commercially available series hybrid cars (e.g., GM Volt, at same size and performance). Crucially, we find that series hybrid cars driven on (fossil) gasoline cause fewer emissions (126g CO₂eq per km) than battery cars driven on current US grid electricity (142g CO₂eq per km). We attribute this novel finding to the significant incremental emissions from plug-in battery cars due to losses during grid transmission and battery dis-/charging, and manufacturing larger batteries. We discuss crucial implications for strategic policy decisions towards a low carbon automotive sector as well as relative land intensity when powering cars by biofuel vs. bioelectricity.

4:54PM D33.00013 Design and Characterization of a Microcombustor for Thermophotovoltaic Devices, ABBEY LICHT, MICHAEL MOTOLA-BARNES, METH BANDARA, HAN CHEN, TOM VANDERVELDE, Tufts University — While batteries are currently used to provide power to devices in remote areas, their low energy density (.5MJ/kg) increases carrier weight, limiting the range of applications. Microcombustor systems, on the other hand, rely on hydrocarbon fuels which have a much greater energy density (40MJ/kg) and generate the same power at a fraction of the weight. The microcombustor when paired with a high-efficiency energy extracting device, such as a thermophotovoltaic cell, presents a complete micro-power system. This work describes the fabrication and characterization of a catalytic microcombustor designed specifically to optimize the power production of a thermophotovoltaic cell.

5:06PM D33.00014 Reverse electrowetting – a new approach to high-power harvesting of mechanical energy, TOM KRUPENKIN, J. ASHLEY TAYLOR, SUPONE MANAKASETTTHARN, University Wisconsin - Madison — Over the last decade electrical batteries have emerged as a critical bottleneck in portable electronics development. High-power mechanical energy harvesting can potentially provide a valuable alternative to the use of batteries, but until now, its adoption has been hampered by the lack of an efficient mechanical-to-electrical energy conversion technology. In this talk a novel mechanical-to-electrical energy conversion method is discussed. The method is based on reverse electrowetting (REWOD) – a novel microfluidic phenomenon. Electrical energy generation is achieved through the interaction of arrays of moving microscopic liquid droplets with novel nanometer-thick multilayer dielectric films. Advantages of this process include the production of high power densities, up to 1 KW sq. m; the ability to directly utilize a very broad range of mechanical forces and displacements; and the ability to directly output a broad range of currents and voltages, from several volts to tens of volts. We hope that the REWOD-based energy harvesting can provide a novel technology platform for a broad range of new electronic products and enable reduction of cost, pollution, and other problems associated with the wide-spread battery use.

Session D34 DCP: Focus Session: Nano I – Clusters 107A

2:30PM D34.00001 Cluster Structure and Reactions: Gaining Insights into Catalytic Processes, A. WELFORD CASTLEMAN, Penn State University — To many researchers outside the field of cluster science it comes as a surprise that much can be learned of its relevance to catalysis, even restricting the discussion to ionized systems. The objective of this talk is to present how fundamental insights into reaction mechanisms can be gained through employing alternative approaches that complement rather than supersede more conventional methods in the field of catalysis. In view of the well acknowledged role of defect centers in effecting reactivity, and the preponderance of recent papers presenting evidence of the importance of charged sites, the desire to conduct repetitive experiments is clear. Presented herein are approaches using clusters to accomplish this in order to unravel fundamental catalytic reaction mechanisms, and to use identified superatoms and the concepts of element mimics to tailor catalysts with desired functionality.

3:06PM D34.00002 Photoelectron Angular Distributions of Transition Metal Dioxide Anions - a joint experimental and theoretical study, IVAN IORDANOV, Department of Physics, Pennsylvania State University, DASITHA GUNARATNE, CHRISTOPHER HARMON, Department of Chemistry, Pennsylvania State University, JORGE SOFO, Department of Physics, Pennsylvania State University, A.W. CASTLEMAN, JR, Department of Chemistry, Pennsylvania State University — Angular-resolved photoelectron spectroscopy (PES) studies of the MO_2^- ($\text{M}=\text{Ti}, \text{Zr}, \text{Hf}, \text{Co}, \text{Rh}$) clusters are presented for the first time along with theoretical calculations of their properties. We confirm previously reported non-angular PES results for the vertical detachment energies (VDE), vibrational energies and geometric structures of these clusters and further explore the effect of the 'lanthanide contraction' on the MO_2^- clusters by comparing the electronic spectra of 4d and 5d transition metal dioxides. Angular-resolved PES provides the angular momentum contributions to the HOMO of these clusters and we use theoretical calculations to examine the HOMO and compare to our experimental results. First-principles calculations are done using both density functional theory (DFT) and the coupled-cluster, singles, doubles and triples (CCSD(T)) methods.

3:18PM D34.00003 Stability and Spectroscopic Properties of Singly and Doubly Charged Anions, SWAYAMPRAKASH BEHERA, PURU JENA, Virginia Commonwealth University — Considerable interest currently exists in expanding the pool of hetero-atomic negative ions which have electron affinities much higher than that of halogen atoms. These molecules, called superhalogens, usually consist of a metal atom (M) at the core surrounded by halogen atoms (X) and are represented by the formula MX_{n+1} where n is the maximal valence of the metal atom. We have studied the possibility if pseudohalogens such as CN, which mimic the chemistry of halogen atoms, can be used as building blocks of new superhalogens. Using density functional theory, Moller-Plesset perturbation theory and coupled clusters methods we have studied systematically the structure and spectroscopic properties of $\text{M}(\text{CN})_n$ systems ($\text{M}=\text{Na}, \text{Mg}, \text{Al}$; $n=1-3$ for Na, 1-4 for Mg, and 1-5 for Al) and compared the results to that of corresponding MCl_n clusters. We find that there is a significant difference between these two systems. This is because pseudohalogens have a tendency to dimerize and hence, we find that for these clusters the values of adiabatic detachment energy and the electron affinity may not be the same. Also, we have studied the dianions of $\text{M}(\text{CN})_n$ and MCl_n complexes to determine the critical size required for their stability. We show that CN moieties stabilize a dianion better than halogen atoms do due to the increase in the phase space over which added electrons are delocalized. This could play an important role in interpreting future experimental data on $\text{M}(\text{CN})_n$ complexes.

3:30PM D34.00004 Structure and stability of the $\text{M}_{8-n}\text{N}_n\text{C}_{12}$ ($\text{M}=\text{Ti}, \text{Zr}$; $\text{N}=\text{Sc}, \text{Y}$ and $n=1,2,3$) Met-Cars as building blocks of cluster-assembled materials, CUNEYT BERKDEMIR, SHI-BO CHENG, A. WELFORD CASTLEMAN JR., Department of Chemistry and Physics, The Pennsylvania State University, JORGE O. SOFO, Department of Physics and Materials Research Institute, The Pennsylvania State University — Clusters can be used as building blocks for new materials. However, in order to form a bulk material with clusters, they should be chemically stable. This stability can be characterized by a closed-shell electronic configuration having a large HOMO-LUMO gap. Met-Cars, metal-carbon species composed of early transition metals bonded to carbon, are stable but very reactive. We propose a method to lower their reactivity by metal atom substitution with lower atomic number atoms. We report DFT results on $\text{M}_{8-n}\text{N}_n\text{C}_{12}$ ($\text{M} = \text{Ti}, \text{Zr}$; $\text{N} = \text{Sc}, \text{Y}$, and $n=1,2,3$) Met-Cars in the neutral, cationic and anionic charge states. Our results show that the isoelectronic $\text{M}_6\text{N}_2\text{C}_{12}$, $\text{M}_5\text{N}_3\text{C}_{12}^-$ and $\text{M}_7\text{N}_1\text{C}_{12}^+$ Met-Cars have closed-shell electronic configurations and larger HOMO-LUMO gaps (1.0-1.7 eV) than that of the M_8C_{12} . The intercluster interaction between two isolated neutral $\text{M}_6\text{N}_2\text{C}_{12}$ Met-Cars is relatively weak compared to the M_8C_{12} dimers. Due to the weak interaction of the isolated neutral Met-Cars, their unique properties would be retained during assembly.

3:42PM D34.00005 Interplay of geometric and electronic structure in metalloid gallium clusters, DMITRI SCHEBARCHOV, NICOLA GASTON, Industrial Research Ltd. — Over the last two decades, the so-called "renaissance of main group chemistry" has led to significant advances in the synthesis, isolation and characterization of metalloid gallium clusters. What distinguishes these from other metalloid species (e.g. ligand-protected gold, silver, palladium, etc.) is their structural diversity, with the existence of four different Ga_{22} frameworks being a particularly striking example. To gain more insight into this polymorphism, we carried out electronic structure calculations using density functional theory. Our calculations verify that two of the ligand-protected Ga_{22} isomers can to some degree be viewed as superatom complexes - their respective metalloid cores are more or less close-packed, roughly spherical, and exhibit a well-defined electronic shell structure with a completely filled outer-most shell. The other two frameworks contain a slightly distorted icosahedral Ga_{12} core without a central atom - an unusual arrangement for metals - and the underlying electronic structure is more complex. This talk will serve as a summary of our calculations and illustrate the interplay of geometric and electronic structure in metalloid gallium clusters.

3:54PM D34.00006 Cluster Structure Selection Based on High Vertical Electron Affinity: The Case of TiO_2 Clusters, NOA MAROM, Institute for Computational Engineering and Sciences, The University of Texas at Austin, MINJUNG KIM, Institute for Computational Engineering and Sciences and Department of Chemical Engineering, The University of Texas at Austin, JAMES CHELIKOWSKY, Institute for Computational Engineering and Sciences and Departments of Chemical Engineering and Physics, The University of Texas at Austin — We study the structure and electronic properties of $(\text{TiO}_2)_{2-10}$ clusters using basin hopping based on density functional theory (DFT), combined with many-body perturbation theory in the GW approximation. We show that in photoemission experiments performed on anions the isomers with the high electron affinity are selectively observed rather than those with the lowest energy. These isomers possess a highly reactive Ti^{3+} site. The selectivity for highly reactive clusters may be exploited for applications in catalysis.

4:06PM D34.00007 Growing Ag Clusters in Superfluid He Droplets¹, LUIS F. GOMEZ, Department of Chemistry, University of Southern California, Los Angeles, CA, EVGENY LOGINOV, SICPA SA, Prilly, Switzerland, NAIHAO CHIANG, AVIK HALDER, NICHOLAS GUGGEMOS, VITALY KRESIN, Department of Physics, University of Southern California, Los Angeles, CA, ANDREY F. VILESOV, Department of Chemistry and Department of Physics, University of Southern California, Los Angeles, CA — Here we report on the growth and study of Ag clusters, ranging in size from 10 to 10^7 atoms, in a beam of superfluid He droplets. The droplets were used to capture Ag atoms from a hot oven, which then recombined in the interior of the droplet at sub-Kelvin temperature. The structure of the obtained Ag clusters was studied in situ via laser spectroscopy of their plasmon resonance. Furthermore, the clusters were surface-deposited and studied via transmission electron microscopy. The images have provided for a measure of the cluster flux and size distribution, which is in good agreement with an estimate based on the energy balance of Ag cluster growth in He droplets. The images also reveal an astounding change in shape of the deposited clusters to elongated and track-shaped with increased droplet size. This is ascribed to the formation of vortices within the He droplets whose cores are traced by the Ag atoms and clusters. The possible formation mechanism of the vortices and their stability will also be discussed.

¹This work was supported by NSF grant CHE-1112391.

4:18PM D34.00008 Atomic and Electronic Structure of Ag_n ($n \leq 13$) Clusters and their Reactivity with O_2^1 , GABRIEL U. GAMBOA, ARTHUR C. REBER, SHIV N. KHANNA, Department of Physics, Virginia Commonwealth University. — First principles theoretical studies on the atomic structure, stability, and electronic structure of neutral and anionic Ag_n clusters have been carried out within a gradient corrected density functional approach. It is shown that the clusters are marked by planar or layered structures. For most clusters, the ground state of anions has lowest spin multiplicity. To examine the reactivity of clusters, containing even number of electrons, with O_2 , we calculated the spin excitation energy representing the energy required to excite the cluster to the triplet configuration. It is shown that several of these even electron anionic species and in particular Ag_{13}^- have high spin excitation energy indicating that they should be inert towards reactivity with oxygen. The theoretical predictions are shown to be in agreement with preliminary experimental data on the reactivity of anionic species.

¹We gratefully acknowledge funding by the U.S. Department of the Army through a MURI grant W911NF-06-1-0280.

4:30PM D34.00009 On the Reactivity of $\text{Al}_{13}\text{I}_n^-$ and $\text{Al}_{14}\text{I}_n^-$ Clusters with Methanol¹, M.B. ABREU, A.C. REBER, S.N. KHANNA, Department of Physics, Virginia Commonwealth University — Al_{13} and Al_{14} cluster anions act as halogen or alkaline earth superatoms respectively when bound by I atoms. $\text{Al}_{13}\text{I}_2^-$ and $\text{Al}_{14}\text{I}_3^-$ have enhanced resistance to oxidation by oxygen because of the clusters' closed electronic shells, however the reactivity of aluminum clusters with methanol depends on the presence of complementary active sites. We have examined the reactivity of $\text{Al}_{13}\text{I}_n^-$ and $\text{Al}_{14}\text{I}_m^-$ with methanol to identify if the presence of electronegative iodine may induce active sites on the cluster. The presence of a single iodine atom on Al_{13}^- is insufficient to activate the cluster, however two adjacent ligands induce an active site and makes the cluster highly reactive. The $\text{Al}_{14}\text{I}_m^-$ clusters are found to be reactive with methanol highlighting the importance of geometric shell closures in ligand protected clusters.

¹We gratefully acknowledge financial support from Air Force Office of Scientific Research (AFOSR) through grant #FA9550-09-1-0371.

4:42PM D34.00010 Bonding and Electronic Structure of Cluster Assemblies with Metal Carbonyls¹, MEICHUN QIAN, ARTHUR REBER, SHIV KHANNA, Department of Physics, Virginia Commonwealth University, SUKHENDU MAN-DAL, HECTOR SAAVEDRA, Department of Chemistry, The Pennsylvania State University, PAUL WEISS, Department of Chemistry, The Pennsylvania State University and California Nanosystems Institute, University of California at Los Angeles, AYUSMAN SEN, Department of Chemistry, The Pennsylvania State University — Understanding the factors controlling the band gap energies of cluster-assembled materials is an important step towards creating nano-assemblies with tailored properties. To this end, we have investigated the band gap energies of cluster assemblies involving arsenic clusters bound to metal carbonyl charge-transfer complexes, $[\text{As}_7\text{M}(\text{CO})_3]^{3-}$ $\text{M} = \text{Cr}, \text{Mo}, \text{W}$. The binding of a single charge-transfer complex is shown to have a small effect on the band gap energy as the arsenic lone pair orbital and metal carbonyl orbitals are closely aligned in energy, resulting in a gap similar to the original cluster. The band gap energy is also found to be insensitive to the architecture of the assembled material. In the case where two charge-transfer complexes are bound to the cluster, the bottom of the conduction band is shown to be localized on a solvent molecule bound to the metal carbonyl.

¹We gratefully acknowledge funding by the U.S. Department of the Army through a MURI grant W911NF-06-1-0280.

4:54PM D34.00011 Stability and Shell Magnetism in Transition Metal Doped Calcium clusters¹, VICTOR M. MEDEL-JUAREZ, J. ULISES REVELES, S.N. KHANNA, Virginia Commonwealth University, V. CHAUHAN, P. SEN, Harish-Chandra Research Institute, Chhatnag Road Jhansi, Allahabad 211019, India — Clusters of many metallic elements are known to exhibit enhanced stability at valence electron counts 2, 8, 18, 20, 34, 40, ... that can be understood within a simple spherical confined nearly free electron gas model. In this work we show a magnetic species whose stability is rationalized on a modification of the above shell sequence through deformations of the spherical geometry and through enhanced exchange splitting of the electronic shells via impurity atoms with large atomic orbital exchange splitting. Through first principles theoretical studies of the electronic structure and stability of TMCa_8 ($\text{TM} = \text{Sc}, \text{Ti}, \text{V}, \text{Cr}, \text{Mn}, \text{Fe}, \text{Co}, \text{Ni}, \text{Cu}$ and Zn) clusters we identify a stable magnetic FeCa_8 cluster of 24 valence electrons distributed into a closed 1S2 1P6 1D10 2S2 shell sequence of 20 paired electrons and with 4 electrons occupying the majority $2D_{xy}2D_{x-y}^2$, $2D_{xz}$ and $2D_{yz}$ levels while the unfilled $2D_z^2$ level is separated by a large energy gap of 0.61 eV arising from atomic deformation.

¹We gratefully acknowledge support from U. S. Department of Energy (DOE) through grant DE-FG02-11ER16213.

5:06PM D34.00012 On the stability and oxidation of Pd_n ($n=1-7$) clusters on rutile $\text{TiO}_2(110)$ ¹, S. VINCENT ONG, SHIV KHANNA, Virginia Commonwealth University, DEPT OF PHYSICS, VIRGINIA COMMONWEALTH UNIVERSITY TEAM — First principles theoretical studies of the atomic and electronic structure of Pd_n ($n=1-7$) clusters supported on a $\text{TiO}_2(110)$ surface, and O_2 activation by such clusters, have been carried out within a gradient corrected density functional approach. It is shown that the supported Pd_n cluster geometries are driven by competing effects including intra-cluster interactions favoring compact geometries and cluster support interactions that favor geometries that flatten out in the $\text{TiO}_2(110)$ surface channel. When exposed to O_2 , a single Pd atom only activates the O-O bond while all other clusters energetically favor a broken O-O bond. The differing behavior of the Pd atom is proposed to originate from the minimal amount of charge transferred from Pd to O_2 and its spin excitation energy. For Pd_nO_2 ($n=2-7$), it is shown that while the first O is adsorbed on the Pd_n cluster, the second O occupies a site above a lattice Ti site at the Pd-Ti interface and is indicative of spill over O atoms. The theoretical findings are compared with recent experiments on the structure and oxidation of CO by supported clusters in the presence of O_2 .

5:18PM D34.00013 Strengthening of Au-Au bonds in small gold clusters by adsorbing noble gases, LUCA M. GHIRINGHELLI, SERGEY LEVCHENKO, MATTHIAS SCHEFFLER, Fritz-Haber-Institut, D-14195, Berlin — In state-of-the-art experiments for the vibrational spectra of metal clusters in the gas phase, photodissociation spectroscopy is performed on clusters complexed with noble gas (RG) atoms, where a RG atom is usually expected to form a weak van der Waals bond. By employing DFT (PBE functional with selected comparisons to PBE0, and to MP2 and CCSD(T) calculations), we surprisingly find a partially covalent bond of *neutral* dimers with RG. For $\text{RG} = \text{Ar}, \text{Kr}, \text{Xe}$ one or two RG atoms can bind in a linear molecule with Au_2 . While both Hirschfeld and Mulliken analyses show a small electron transfer from the RG to Au_2 , the Au-Au bond *shortens* and the Au-Au stretch frequency increases. This is inconsistent with the expected effect of electron transfer to the antibonding orbital of the dimer. Electron-density (n) differences between the bonded systems and the isolated fragments show an accumulation of n between RG and the neighboring Au atom, and between the gold atoms. The analysis of the projected density of states reveals that, although only non-bonding orbital interactions and no charge transfer occurs between RG and Au_2 , the d -electrons of Au_2 are redistributed due to the interaction with RG in such a way that the Au-Au σ_s bond is strengthened.

Session D35 DCP: Focus Session: DFT II: Molecular Conductance; Charge Transfer 107B

2:30PM D35.00001 On the derivative discontinuity in molecular junctions¹, CHARLES STAFFORD, University of Arizona — Both the wave and particle aspects of the electron play essential roles in transport through single-molecule junctions. The wave character is implicit both in the Landauer formula used to understand nanoscale transport and in the very chemical bonds holding the junction together, while the particle aspect is manifested in phenomena such as Coulomb blockade and shot noise. The dominant computational paradigm for transport in single-molecule junctions involves local or semilocal approximations to density functional theory combined with nonequilibrium Green's functions. This approach does exceptionally well at describing the wave aspect of the electron, but fails to describe the particle aspect—due to the omission of the derivative discontinuity in the exchange-correlation potential that arises in the limit of vanishing lead-molecule coupling. To understand the role of the derivative discontinuity in molecular junctions, we investigated the transport and occupancy of a simple Anderson model of a molecular junction. We showed² that the exact single-particle Kohn-Sham potential of density functional theory reproduces the linear-response transport of the Anderson model exactly, despite the lack of a Kondo peak in its spectral function. Using Bethe ansatz techniques, we calculated this potential exactly for all coupling strengths, including the cross-over from mean-field behavior to charge quantization caused by the derivative discontinuity. The implications of our results for more complex molecular junctions will be discussed.

3:06PM D35.00002 A density functional that works for transport through Anderson junction¹, ZHENFEI LIU, JUSTIN BERGFELD, KIERON BURKE, Departments of Chemistry and Physics, University of California, Irvine, CHARLES STAFFORD, Department of Physics, University of Arizona — Transport through an Anderson junction can be exactly described by density functional theory, at zero temperature and in the linear response regime. Using Bethe ansatz, we calculate the exact Kohn-Sham potential delivering the exact transmission. We propose a simple parametrization for the Kohn-Sham potential, using a known exact condition. Our parametrization faithfully reproduces numerical results, including the gradual development of the derivative discontinuity that is essential in describing Coulomb blockade correctly.

¹This work is funded by the U.S. Department of Energy (Grant No. DE-FG02-08ER46496).

3:18PM D35.00003 Non-steady state in quantum transport, ELHAM KHOSRAVI, Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle, Germany, STEFAN KURTH, Nano-Bio Spectroscopy Group, Departamento de Física de Materiales, Universidad del País Vasco, Avenida de Tolosa 72, E-20018 San Sebastian, Spain, GIANLUCA STEFANUCCI, Dipartimento di Fisica, Università di Roma Tor Vergata, Via della Ricerca Scientifica 1, 00133 Rome, Italy, E.K.U. GROSS, Max Planck Institute of Microstructure Physics, Weinberg 2, D - 06120 Halle, Germany — The standard approach to quantum transport combines the Landauer-Büttiker (LB) formalism with ground-state density functional theory (DFT). The basic assumption of this approach is that a steady state is achieved after turning on a DC bias. Here we show that this assumption is “not” valid in general and give examples for which no steady state develop within several adiabatic (time-local) approximations as well as in non-interacting systems. In these cases a time-dependent description of transport is essential. For the non-interacting case, the presence of bound states in a biased system is shown analytically and numerically to lead to persistent, localized current oscillations which can be much larger than the steady part of the current (PCCP. 11, 4535(2009)). For the interacting case, the discontinuity of the exchange-correlation potential of DFT in the context of electron transport for an interacting nanojunction attached to biased leads, gives rise to a dynamical state characterized by correlation-induced current oscillations in the Coulomb-blockade regime (PRL. 104, 236801(2010)). In addition, for multistable systems, the time-dependent approach describes if and how a solution can be reached through time evolution.

3:30PM D35.00004 DFT methods for conjugated materials: From benchmarks to functionals, JOHN SEARS, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, Georgia 30332-0400, JEAN-LUC BREDAS, School of Chemistry and Biochemistry, Georgia Institute of Technology — From a theoretical standpoint, many of the problems of interest in the study of pi-conjugated materials for organic electronics applications pose a particular challenge for many modern density functional theory methods. Systematic errors have been observed, for instance, in the description of charge-transfer excitations at donor/acceptor interfaces, in linear and non-linear polarizabilities, as well as in the geometric and electronic properties of conjugated polymers [1,2]. We will discuss recent results in our lab aimed at: (i) understanding the sources of error for some of these problems; (ii) addressing these errors using tuned long-range corrected functionals; and (iii) using these results to guide the development of state-of-the-art methodologies in a new open-source DFT code.

3:42PM D35.00005 Fundamental and excitation gaps in molecules of relevance for organic photovoltaics from an optimally tuned range-separated hybrid functional, SIVAN REFAELY-ABRAMSON, Weizmann Institute of Science, Israel, ROI BAER, Hebrew University, Jerusalem, Israel, LEEOR KRONIK, Weizmann Institute of Science, Israel — The fundamental and optical gaps of relevant molecular systems are of primary importance for organic-based photovoltaics. Unfortunately, whereas optical gaps are accessible with time-dependent density functional theory (DFT), the highest -occupied - lowest-unoccupied eigenvalue gaps resulting from DFT calculations with semi-local or hybrid functionals routinely and severely underestimate the fundamental gaps of gas-phase organic molecules. Here, we show that a range-separated hybrid functional, optimally tuned so as to obey Koopmans' theorem, provides fundamental gaps that are very close to benchmark results obtained from many-body perturbation theory in the GW approximation. We then show that using this functional does not compromise the possibility of obtaining reliable optical gaps from time-dependent DFT. We therefore suggest optimally-tuned range-separated hybrid functionals as a practical and accurate tool for DFT-based predictions of photovoltaically relevant and other molecular systems. For more details, see S. Refaely-Abramson, R. Baer, L. Kronik, Phys. Rev. B 84, 075144 (2011).

3:54PM D35.00006 (1) Modeling emissive charge-transfer states in solution phase functionalized silsesquioxanes. (2) On symmetry hidden charge transfer states: Lessons for the design of functionals¹, BARRY D. DUNIETZ, SHAOHUI ZHENG, HEIDI PHILLIPS, EITAN GEVA, University of Michigan — Range separate hybrid functionals are used to study the charge transfer processes in chromophores attached to silsesquioxanes molecular species. We investigate the experimentally observed red shifting of the emission spectra in comparison to the spectral shift for the individual ligand. Solvent effects are accounted for via a combination of constrained density functional theory and the polarizable continuum (PCM) model. We quantitatively reproduce the experimental red shift and identify the emissive state as a ligand-to-ligand, rather than a ligand-to-silsesquioxane, charge-transfer state. We also find that the enhanced red-shift cannot be explained without accounting for solvation effects and demonstrate the importance of using a range-separated hybrid functional, as opposed to more traditional functionals such as B3LYP, to obtain reliable predictions regarding the emissive state. If time allows we will also discuss the limitations and successes of RSH functionals in treating the case of charge transfer processes that are hidden by system symmetry. We use related models to draw insight for designing improved functionals.

¹This work is pursued as part of the Center for Solar and Thermal Energy Conversion, an Energy Frontier Research Center funded by the US Department of Energy Office of Science, Office of Basic Energy Sciences under 390 Award No. DE-SC0000957.

4:06PM D35.00007 Density Functional Methods and Electronic Processes in Organic Materials¹, QIN WU, Brookhaven National Lab — When modeling the fundamental processes in organic electronic materials, ab initio calculations play an important role because they provide an independent source of information. It is thus critical to use accurate and reliable ab initio methods. In this talk, we will share our experience in using density functional methods to study charge generation and transport in some organic systems. These include prototypical polythiophene and polyfluorene, as well as some newly synthesized conjugated molecules. They all have strong dispersion forces and strong electron-vibration coupling; both are well-known difficult effects for density functional methods to capture accurately. We will describe our effort in exploring ways to do meaningful calculations. Close collaborations with experimental work will also be emphasized.

¹Research is supported by the U.S. Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-98CH10886.

4:18PM D35.00008 Modelling Charge Transfer Reactions and Excitations with Subsystem DFT¹, MICHELE PAVANELLO, Leiden University, JOHANNES NEUGEBAUER, Technical University Braunschweig — The subsystem formulation of DFT known as Frozen Density Embedding (FDE) offers an excellent platform for studying charge transfer reactions in solvated systems, such as biosystems. We present the necessary theory developments for the calculation of the electronic couplings as well as the charge transfer excitations from FDE derived densities. We present preliminary calculations on DNA oligomers radical cations that include donor-bridge, donor-bridge-acceptor, and fully solvated systems.

4:30PM D35.00009 Ab initio molecular dynamics study of the electric double-layer capacitance at solution-electrode interfaces, YASUNOBU ANDO, YOSHIHIRO GOHDA, SHINJI TSUNEYUKI, Department of Physics, The University of Tokyo — Electric double-layer (EDL) is known as an important stage for electrochemical reactions at electrode-liquid interfaces. It has also attracted growing interest for its applications to electronic devices, called EDL capacitors (supercapacitors) and EDL transistors. In efficient development of each device, predicting the EDL capacitance in light of the material features is required. However, Helmholtz capacitance, the part of the EDL capacitance depending on the microscopic structure, has still not been estimated theoretically. Therefore, to evaluate that, we calculated the structure of solution-electrode interfaces by using ab initio molecular dynamics with effective screening medium method. As a result, we made it possible to estimate the Helmholtz capacitance taking the effect of the molecular orientation of the water and the electronic polarization in the water molecules due to the electric field into account. Apparent dielectric constant of the water near the interface can also be calculated. Interestingly, the results reveal that the existence of a first layer of the water molecules near the electrode determines the distance of closest approach of hydrated ions. Moreover, the estimated dielectric constant of the first layer differs from that predicted by the classical theory.

4:42PM D35.00010 Assessing the fitness of various exchange-correlation functionals for TD-DFT studies of charge-transfer excitations in organic dyes¹, PRATIBHA DEV, SAURABH AGRAWAL, NIAL ENGLISH, School of Chemical & Bioprocess Engineering, University College Dublin, SEC STRATEGIC CLUSTER TEAM — Dye Sensitized Solar Cells (DSSCs) are a possible alternative to the more expensive silicon-based cells. Theoretical research in this field has highlighted some of the issues with time-dependent density functional theory (TD-DFT) that is widely used to study electronic excitations of matter. The situation is complicated by the fact that several classes of approximations to the exchange correlation functional can be employed, however, not one of these strictly outperforms the others in its description of charge-transfer excitations. In this work, UV-Vis spectra are calculated using TD-DFT for several organic dyes – alizarin, squaraine, 4-(N, N-dimethylamino) benzonitrile, polyene-linker dyes and triphenylamine-donor dyes. We studied the dyes within three approximations (PBE, B3LYP and CAM-B3LYP) to the exchange-correlation functional. In the dyes considered here, a correlation exists between the functional performance and the spatial overlap of the states involved in the excitations. This overlap can be quantified to provide a good guideline for choosing the right functional when studying intramolecular charge transfer in dyes. It will be an invaluable tool when studying these molecules within more challenging systems, such as dye-titania complexes in DSSCs.

¹We acknowledge the computational support provided by ICHEC. PD acknowledges financial support for this work through EMPOWER fellowship granted by IRCSET. SA is supported by the Science Foundation Ireland under Grant No. [07/SRC/B1160].

4:54PM D35.00011 Electronic density functional theory in the grand canonical ensemble, electrochemistry, and the underpotential deposition of Cu/Pt(111)¹, RAVISHANKAR SUNDARARAMAN, KENDRA WEAVER, TOMAS ARIAS, Physics Department, Cornell University — The study of electrochemical systems within electronic density functional theory requires the handling of non-neutral electronic systems in the plane-wave basis in order to accurately describe charged metallic surfaces; this can be accomplished in joint density functional theory by adding an electrolyte with Debye screening². This capability opens up the opportunity to work in the grand canonical ensemble at fixed chemical potential μ for the electrons, which corresponds directly to the experimental setting in electrochemistry. We present efficient techniques for electronic density functional calculations at fixed μ , and demonstrate the improvement in predictive power over conventional neutral calculations using the underpotential deposition of Cu/Pt(111) as an example: for the first time, we calculate absolute voltages for electrochemical processes in excellent agreement with experiment, instead of voltage shifts alone.

¹This work was supported as a part of the Energy Materials Center at Cornell (EMC2), an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DE-SC0001086.

5:06PM D35.00012 First-Principles Studies of Structure and Energy Level Alignment of Thiophene Assemblies on Methyl-Terminated Si(111), MIN YU, PETER DOAK, JEFFREY NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory — Adsorption of organic molecules on semiconductor photocatalysts has attracted significant attention for energy conversion applications. In this work, we use density functional theory and many-body perturbation theory within the GW approximation to study the geometry, binding energetics, and energy level alignment of a model ligand, thiophene (C₄H₄S), chemisorbed via a C-Si bond on methyl-terminated silicon(111) substrates. We quantify the impact of coverage, interface dipoles, hybridization, and polarization effects on level alignment. For sufficiently weakly-coupled frontier orbitals, we explore the extent to which the self-energy change upon adsorption relative to the gas phase is dominated by nonlocal electrostatic polarization effects [1]. The implications of our results for other thiophene-related ligands, and future spectroscopic experiments, will be thoroughly discussed. We acknowledge DOE for support through JCAP, and NERSC for computational resources.

5:18PM D35.00013 Electronic level alignment at a metal-molecule interface from a short-range hybrid functional, ARIEL BILLER, Weizmann Institute of Science, Israel, ISAAC TAMBLYN, JEFFERY B. NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory, LEEOR KRONIK, Weizmann Institute of Science, Israel — Hybrid functionals often exhibit a marked improvement over semi-local functionals in the description of the electronic structure of organic materials. Because short-range hybrid functionals, notably the Heyd-Scuseria-Ernzerhof (HSE) functional, can also describe the electronic structure of metals reasonably well, it is interesting to examine to which extent they can correctly describe the electronic structure at metal-organic interfaces. Here, we address this question by comparing HSE calculations with many-body perturbation theory calculations in the GW approximation, or with experimental photoemission data, for two prototypical systems: benzene on graphite and benzene diamine on gold. For both cases, we find that while HSE yields results that are somewhat closer to experiment than those of semi-local functionals, the HSE prediction is still lacking quantitatively by ~ 1 eV. We show that this quantitative failure arises because HSE does not correctly capture the fundamental gap of the organic, or its renormalization by the metal. These discrepancies are traced back to missing long-range exchange and correlation components, an explanation which applies to any conventional or short-range hybrid functional.

Session D36 DCP: Focus Session: Environment I: Aerosols and Aqueous Solutions 107C

2:30PM D36.00001 Uncovering the formation mechanism of atmospheric nanoparticles¹, HANNA VEHKAMAKI, University of Helsinki — Atmospheric aerosol affect human health, visibility and radiation budget of the Earth. The current estimate is that 20-80% of aerosols particles are formed in the atmosphere by condensable gases. Experimental and theoretical data indicates that the formation of new particles in the atmosphere in most cases very likely involves sulphuric acid assisted with some base molecules. The role of ions in atmospheric particle formation is has been widely discussed during recent years. The diameter of the forming clusters is 1-2nm, falling between the smallest size where brute force quantum mechanical treatment is possible, and macroscopic size where bulk thermodynamics is applicable. Recent experiments at the CLOUD chamber in CERN have provided molecular-level information on the charged fraction of the nucleating clusters, but the theoretical framework needed to convert this into information on neutral clusters is still lacking. We have used a cost-effective multi-step computational chemistry method involving automated configurational sampling, density functional theory geometry optimizations and coupled-cluster energy calculations, to study the stability of charged and neutral sulfuric acid clusters containing ammonia and dimethylamine. Combined with a cluster dynamics model ACDC, we are able to replicate the formation rates observed in the CLOUD chamber, as well as match observed formation rates in Hyytiälä Smear II station in Finland.

3:06PM D36.00002 Molecular dynamics of binary and ternary nanodroplets with a miscibility gap¹, GERALD WILEMSKI, FAWAZ HRAHSHEH, Missouri University of Science and Technology — The structure of nanodroplets plays an important role in many natural processes including particle nucleation and aerosol formation in the atmosphere. Among other factors, chemical miscibility and surface tension strongly affect the structure of multicomponent nanodroplets at low temperature. Here, we investigate the structure of water/nonane and water/butanol/nonane nanodroplets using molecular dynamics (MD). Our MD results confirm our theoretical predictions of nonspherical nanodroplet (Russian-Doll) structures at low temperatures using density functional and lattice Monte Carlo techniques. We systematically study the variation of the droplet structure with temperature and with butanol concentration.

3:18PM D36.00003 Organization at the Air-Aqueous Interface by Heterodyne-detected Phase-Sensitive Sum Frequency Spectroscopy¹, HEATHER ALLEN, The Ohio State University — Water and ions organize at the air – aqueous interface and the ion distributions within this region give rise to interfacial electric double layers. Geochemical solid-aqueous and atmospheric aerosol relevant air-aqueous interfaces were studied using vibrational sum frequency generation (VSFG), and in some cases, heterodyne-detected VSFG spectroscopy. Solid-aqueous and air-liquid interfaces were also investigated using total internal reflection Raman spectroscopy, infrared reflection absorption spectroscopy (IRRAS), and Brewster angle microscopy (BAM), respectively. Here, we show results from aqueous solutions containing salts such as sulfates and chlorides where surface adsorption and electric field direction reversal was observed. Of the salts studied at the air-aqueous interface with heterodyne-detected VSFG, the magnitude of the electric field in the surface extending to the subsurface regions decreases in the order: $(\text{NH}_4)_2\text{SO}_4 > \text{Na}_2\text{SO}_4 > \text{Na}_2\text{CO}_3 \geq \text{CaCl}_2 > \text{NaCl}$; the electric field is opposite in direction for the sulfates and carbonate relative to the chloride salts.

3:54PM D36.00004 First-principles study of the infrared spectrum of the ice Ih (0001) surface¹, HUANG PATRICK, Lawrence Livermore National Laboratory, Livermore, California, 94550, T. ANH PHAM, University of California, Davis and Lawrence Livermore National Laboratory, Livermore, California, 94550, ERIC SCHWEGLER, Lawrence Livermore National Laboratory, Livermore, California, 94550, GIULIA GALLI, University of California, Davis — Ice particles catalyze a number of processes relevant to atmospheric and environmental chemistry, and the elucidation of these reactions require knowledge of the ice surface structure. Although it is well known that the structure of bulk ice-Ih is proton disordered, the understanding of the microscopic structure of the ice surface is still limited. Recent theoretical studies ^{1,2} suggest that the basal (0001) surface of ice Ih is significantly more proton ordered than the bulk. In this work we compute infrared (IR) spectra of several ordered and disordered models of the (0001) surface of ice, and investigate the sensitivity of these spectra to the microscopic details of the surface structure. In particular we discuss possible signatures of disorder in the computed spectra. [1] D. Pan et al., Phys. Rev. Lett. 101, 155703 (2008); [2] V. Buch et al., Proc. Natl. Acad. Sci. U.S.A. 105, 5969 (2008)

4:06PM D36.00005 1st principle simulations of ions in water solutions: Bond structure and chemistry in the hydration shells of highly charged ions, JOHN WEARE, University of California, San Diego — Methods of direct simulation (Monte Carlo and molecular dynamics) have provided new insights into the structure and dynamics of electrolyte solutions. However, these methods are limited by the difficulty of developing reliable ion-solvent and solvent-solvent potential interactions in the highly perturbed hydration region. To model the interactions in this region methods of simulation that are based on the direct on the fly solution to the electronic Schrödinger equation (ab-initio molecular dynamics, AIMD) are being developed. However, 1st principle methods have their own problems because the solution to the electronic structure problem is intractable unless rather uncontrolled approximations are made (e.g. density functional theory, DFT) and there is high computational cost to the solution to the Schrödinger equation. To test the accuracy of AIMD methods we have directly simulated the XAFS spectra for a series of transition metal ions Ca^{2+} , Cr^{3+} , Mn^{2+} , Fe^{3+} , Co^{2+} , Ni^{2+} , Cu^{2+} , and Zn^{2+} . Despite DFT's well known deficiencies, the agreement between the calculated XAFS spectra and the data is almost quantitative for these test ions. This agreement supports the extension of the interpretation well beyond that of the usual XAFS analysis to include higher-order multiple scattering signals in the XAFS spectra, which provide a rigorous probe of the first shell distances and disorders. Less well resolved features of the spectra can still be analyzed and are related to 2nd shell structure. The combination of XAFS measurements and the parameter free AIMD method leads to new insights into the hydration structure of these ions. While strictly local DFT +gga provides excellent agreement with data, the addition of exact exchange seems to provide slightly better structural agreement. The computational complexity of these calculations requires the development of simulation tools that scale to high processor number on massively parallel supercomputers. Our present algorithm scales to nearly 100,000 processors. However, even with high scaling the time to solution is very long. We are also developing and testing new methods to improve the performance of simulation and new sampling methods that more efficiently explore phase space and can reach longer time frames. Results of calculation of the hydration structure and dynamics of highly charged ions and free energy calculations of ion association will be presented.

4:42PM D36.00006 Reactions of Solvated Electrons Initiated by Sodium Atom Ionization at the Vacuum-Liquid Interface¹, JUSTIN WIENS, University of Wisconsin-Madison, WILLIAM ALEXANDER, Montana State University-Bozeman, GILBERT NATHANSON, University of Wisconsin-Madison, TIMOTHY MINTON, Montana State University-Bozeman — Solvated electrons are powerful reagents in the liquid phase that break chemical bonds and create new reactive species, including hydrogen atoms. Electrons and hydrogen atoms born near the surface, however, behave differently than those created within the liquid. We explore this behavior by exposing liquid glycerol to a beam of sodium atoms. The Na atoms ionize in the surface region, generating electrons that react with deuterated glycerol, $\text{C}_3\text{D}_5(\text{OD})_3$, to produce D atoms, D_2 , D_2O , and glycerol fragments. Surprisingly, 40% of the D atoms desorb into vacuum before attacking C-D bonds to produce D_2 . These D atoms must traverse the interfacial region before desorbing, demonstrating that Na ionization prepares reactive species that reside momentarily at the surface and often escape before reacting with the solvent.

4:54PM D36.00007 Heterogeneous Photochemistry and Optical Properties of Mineral Dust Aerosol, VICKI GRASSIAN, University of Iowa — It is now widely recognized that heterogeneous reactions of mineral dust aerosol with trace atmospheric gases impact the chemical balance of the atmosphere and the physicochemical properties of these particles. Field studies using single particle analysis, have now shown that the chemistry is mineralogy specific and follows the trends expected from laboratory studies. These laboratory studies, which were initiated over a decade ago, have focused on the nighttime chemistry of mineral dust aerosol which is really only "half" the story. This talk will focus on two aspects of solar light interaction with mineral dust aerosol. First, the heterogeneous photochemistry of adsorbed chromophores (e.g. nitrate ion) and light absorbing components of mineral dust (iron oxides and titanium dioxide) is discussed. These heterogeneous photochemical reactions are poorly understood and laboratory studies to better quantify these reactions in order to determine the impact on the chemical balance of the atmosphere are needed, as will be discussed. Second, the optical properties of mineral dust aerosol measured by extinction infrared spectroscopy and visible light scattering show that shape effects are extremely important for mineral dust aerosol.

Monday, February 27, 2012 2:30PM - 5:18PM – Session D37 SPS: SPS Undergraduate Research II 108

2:30PM D37.00001 Low Temperature Resistive Switching Behavior in a Manganite, CHRISTOPHER SALVO, MELINDA LOPEZ, STEPHEN TSUI, California State University San Marcos — The development of new nonvolatile memory devices remains an important field of consumer electronics. A possible candidate is bipolar resistive switching, a method by which the resistance of a material changes when a voltage is applied. Although there is a great deal of research on this topic, not much has been done at low temperatures. In this work, we compare the room temperature and low temperature behaviors of switching in a manganite thin film. The data indicates that the switching is suppressed upon cooling to cryogenic temperatures, and the presence of crystalline charge traps is tied to the physical mechanism.

2:42PM D37.00002 Atomic Steps on Thermally Annealed Oxide Substrates¹, ICON MAZZACCARI, RAFIYA JAVED, AMLAN BISWAS, Department of Physics, University of Florida — Atomically smooth perovskite oxide substrates are necessary for high quality thin-film growth. We have optimized the annealing conditions for the substrates, LaAlO_3 , SrTiO_3 and NdGaO_3 , which are commonly used substrates for growing thin-film perovskite oxides. The optimal annealing temperatures were between 950 °C and 1050 °C and the annealing time for each sample was varied by approximately 20%. Atomic force microscopy was used to compare the surfaces of the annealed substrates with the unannealed ones. These images capture the terrace steps that occur due to the annealing process, and we have confirmed that the heights of the steps are approximately one unit cell (0.4 nm). Currently, we are investigating methods for determining the site termination of the substrates and their effects on thin-film growth.

¹NSF DMR-0804452

2:54PM D37.00003 Field-Induced Phase Transitions in the $S=1/2$ Quasi-1D Antiferromagnet $\text{BaCo}_2\text{V}_2\text{O}_8$ ¹, GIOVANNI FRANCO-RIVERA, University of Puerto Rico at Mayaguez, N.A. FORTUNE, Smith College, S.T. HANNAHS, H.D. ZHOU, National High Magnetic Field Lab, H. TSUJII, Kanazawa University, Y. TAKANO, University of Florida — We have performed magnetocaloric effect and specific heat measurements in the $S=1/2$ quasi-one-dimensional Ising-like antiferromagnet $\text{BaCo}_2\text{V}_2\text{O}_8$ in magnetic fields up to 24 T at temperatures down to 0.3 K. The magnetocaloric effect measurements were made in order to investigate the field-direction dependence of a magnetic transition near 3.7 T. The specific heat and magnetocaloric effect measurements were employed to determine the H-T phase diagram when the field is applied parallel to the *c* axis of the sample. We have found a new antiferromagnetically ordered phase between 19.7 T and 23.1 T, most likely a spin-flop phase. At low fields, our results agree with the known Néel ordered phase boundary.

3:06PM D37.00004 Magnetism in Transition Element Doped In_2O_3 Dilute Magnetic Semiconductors¹, M. LANGHOFF, E. NAHLIK, Department of Physics, Astronomy, and Materials Science, Missouri State University, Springfield, MO 65897, Y. KOLEKAR, Department of Physics, University of Pune, Pune, India, P. KAHOL, K. GHOSH, Department of Physics, Astronomy, and Materials Science, Missouri State University, Springfield, MO 65897 — There is currently a tremendous research effort in the area of dilute magnetic semiconductors (DMS). It is proposed that a DMS exhibiting ferromagnetic properties at room temperature could be used in a new class of devices termed spintronics. Whereas standard electronics work on the principle of manipulation of charge properties of an electron, spintronics work on controlling electron spin. Indium oxide is a wide band gap semiconductor with unique optical and electrical properties. Defect concentrations such as transition metal doping and oxygen vacancies in In_2O_3 can tune the electrical/magnetic behavior from ferromagnetic metal-like to ferromagnetic semiconducting to paramagnetic insulating. Bulk materials of magnetic element (Fe, Co and Cr) doped In_2O_3 have been made using a standard solid state reaction method. Structural and magnetic properties have been measured using standard techniques. XRD analysis confirmed single phase In_2O_3 with no impurity phases due to addition of magnetic elements. Magnetization as a function of applied magnetic field and temperature were collected on all the samples using a SQUID magnetometer. Detailed structural and magnetic properties will be presented in this talk.

3:18PM D37.00005 Magnetic Properties of Ordered Nanoporous Nickel Films¹, JIABIN LIU, HAN-CHANG YANG, X.M. CHENG, Bryn Mawr College — Nanoporous materials have been of great interest for applications such as biosensors and energy storage. Magnetic properties and the magnetization reversal mechanism of nanoporous magnetic materials remain to be fully understood. In this work, we report the fabrication and magnetic properties of ordered nanoporous nickel (Ni) films. The fabrication involved the following steps: self-assembly of monodispersed polystyrene spheres, electrochemical deposition of desired materials, and sphere removal by a dissolution process. Scanning electron microscopy (SEM) images confirmed the highly ordered three-dimensional hexagonal closed pack structures of the Ni films. We characterized magnetic properties of the three-dimensional nanoporous Ni films using vibrating sample magnetometer (VSM). Magnetic hysteresis loops and first-order reversal curves (FORCs) were measured on the nanoporous Ni films of 200 nm pore size with different thicknesses. Analysis on hysteresis loops and FORC distributions shed light on the reversal mechanism of magnetization and magnetostatic interactions of ordered three-dimensional porous structures.

3:30PM D37.00006 Electrical characterization of CVD graphene, YARELY DÁVILA, NICHOLAS PINTO, University of Puerto Rico - Humacao, ZHENG TANG LUO, ALAN JOHNSON JR., University of Pennsylvania — Graphene is a one atom thick carbon sheet that can be obtained via exfoliation of graphite or via chemical vapor deposition (CVD). By using a very simple shadow masking technique, gold contact pads were evaporated over the graphene thereby eliminating chemical etching that is required when using photolithography and often leads to sample contamination. CVD graphene was electrically characterized in a FET configuration under different experimental conditions that include UV exposure, gas sensing and temperature. Our measurements yielded a carrier mobility of up to $3000 \text{ cm}^2/\text{V-s}$ for some devices. Exposure to UV dopes graphene in a controlled manner. The doping level could be maintained indefinitely in vacuum or could be completely reversed by slight heating in air without loss of device performance. The FET's were also tested at different temperatures with little change in the transconductance response. Exposure to ammonia gas *n*-doped graphene while exposure to NO_2 *p*-doped it.

3:42PM D37.00007 Electronic Structure Properties of Graphene/Boron Nitride Layered Systems¹, MAX PETULANTE, University of Maryland, NAM LE, LILIA WOODS, University of South Florida — We explore the properties of systems composed of two or three layers of graphene and hexagonal boron nitride (hBN) using the Vienna Ab-Initio Simulation Package (VASP), a software package for performing first principles simulations based on density functional theory (DFT). Particular attention is given to the contribution of inter-layer dispersion interactions, which are modeled within VASP by the “DFT-D2” method of Grimme. We obtain the binding and van der Waals energies, and inter-layer separations for the most stable stacking configurations of each of the following systems: hBN/graphene, graphene/hBN/graphene, hBN/graphene/hBN, hBN/hBN/graphene, and graphene/graphene/hBN. We observe that the addition of hBN layers to graphene structures induces a band gap, ranging from 0.024 eV, for the graphene/hBN/graphene arrangement, to 0.16 eV, for the hBN/graphene/hBN arrangement. These results, specifically band gaps on the same order as those of silicon and germanium, indicate that graphene/hBN layered structures may have applications in electronics.

¹This work was supported by NSF REU program (award No DMR-1004873).

3:54PM D37.00008 Magnetoresistance of Strained Rare Earth Manganese Oxide Thin Films: Effect of Post-Deposition Thermal Treatment¹, TYLER GOEHRINGER, PARUL SRIVASTAVA, E. KEVIN TANYI, DAVID SCHAEFER, RAJESWARI KOLAGANI, Towson University — We have studied the effects of thermal treatment (annealing) on the properties of thin films of manganese oxide materials $\text{La}_{0.67}\text{Ca}_{0.33}\text{MnO}_3$ and $\text{La}_{0.67}\text{Ba}_{0.33}\text{MnO}_3$, which are known to exhibit colossal magnetoresistance (CMR) and an insulator to metal transition. These materials show properties which are desirable for applications such as magnetic sensors, bolometric infrared sensors, or field effect devices. Two properties of interest, magnetoresistance (MR) and insulator metal transition are especially sensitive to strain because of the relationship between the properties and the symmetry of the crystal. The properties are also sensitive to the oxygen stoichiometry of the film due to changes in the valence state of the manganese which determines the charge carrier density. Recent results from our laboratory have shown a large magnetoresistance in strained films grown on lattice mismatched substrates. The MR continues to increase with decreasing temperature in these films. In order to understand the contribution of strain to the observed MR behavior, in we employ ‘thermal annealing’ to allow for relaxation of strain. Annealing also serves to achieve the optimum oxygen stoichiometry. We will present the results of our annealing studies and their implications for understanding the MR in strained films.

4:18PM D37.00010 Formation of Interfacial Carbide Layers in Multilayer Ti/DLC Thin Films

JASEN SCARAMAZZA, ZACHARY BUCK, TYLER DONATO, BRITTANY CURRAN, C.A. LUNK, S.E. LOFLAND, J.D. HETTINGER, Department of Physics and Astronomy, Rowan University — Titanium (Ti)/Diamond-like-carbon (DLC) and Chromium (Cr)/Carbon (C) multilayer films were prepared on c-axis oriented single crystal sapphire (Al_2O_3) substrates using magnetron sputtering. Interfacial properties of the films were analyzed using x-ray reflectivity and scanning electron microscopy. When DLC is sputtered on a layer of Ti, an interfacial layer of titanium carbide (TiC) forms which is reported for the first time. Energy provided by the substrate bias necessary to facilitate DLC sp^3 bond formation is suspected of allowing TiC to synthesize in a thin layer before DLC forms. It was also found that DLC has difficulty forming on Cr. These results are relevant to biomedical applications where DLC is applied as a low friction/wear film that can be formed on the surface of implants composed mainly of titanium. Further investigation into the medical and tribological effects of TiC interfacial layers is suggested.

4:30PM D37.00011 Properties of Cr_2AlC MAX phase thin films prepared by reactive magnetron sputtering

ZACHARY BUCK, TYLER DONATO, CHRISTOPHER ROTELLA, CARL LUNK, S.E. LOFLAND, J.D. HETTINGER, Department of Physics and Astronomy, Rowan University — $\text{M}_{n+1}\text{AX}_n$ (MAX) phases, where n is 1, 2, and 3, M is an early transition metal, A is an A-group element, and X is either C or N, are ternary carbides with unique properties such as low density, easy machinability, and good oxidation resistance. The MAX phase Cr_2AlC is of particular interest for industrial applications to its excellent high-temperature oxidation resistance and relatively low synthesis temperature. We prepared Cr_2AlC thin films on c-axis oriented single crystal Al_2O_3 , glassy carbon and Si thermal oxide substrates using reactive magnetron sputtering as precursor materials for carbide-derived carbon (CDC) films for “on-chip” supercapacitors. Film deposition was optimized using elemental composition data obtained by WDXRF. Optimized films were characterized using XRD and scanning electron microscopy. It was found that textured Cr_2AlC films only form when the composition was Al-rich allowing the formation of a Cr_5Al_8 interfacial layer. As film composition was optimized, the interfacial layer did not form but the XRD peaks associated with the Cr_2AlC also decreased in magnitude. Extremely high-textured films were grown when a thin buffer layer of CrAl_2 was deposited on the substrate before depositing the Cr_2AlC films. This result suggests that Cr_2AlC films may not be ideal for CDC applications since the films may “lift-off” during conversion due to the existence of the naturally occurring buffer-layer.

4:42PM D37.00012 Fluid-like conducting regions in solid manganite thin films¹

RAFIYA JAVED, HYOUNGJEEN JEEN, AMLAN BISWAS, Department of Physics, University of Florida — Hole-doped manganese oxides (manganites) exhibit a fluid-phase separated state in which the conducting and ferromagnetic phase (FMM) behaves like a fluid embedded in an insulating background phase [1]. While the manganite remains a solid, its local electrical properties behave as a fluid. The fluid behavior of the conducting regions can be tested by observing the effect of an electric field on the shape of the FMM regions. This change in shape is expected to result in anisotropic resistivity. This property was tested by designing microstructures of the manganite film, which simplify the experiment by localizing the electric field to a region the size of the FMM regions. We are testing for possible magnetic anisotropy since the conducting regions are also ferromagnetic. We will also discuss the size effect on the magnetic properties. [1] Dhakal et. al., Phys. Rev. B 75, 092404 (2007)

¹NSF DMR 0804452

4:54PM D37.00013 The intrinsic coupling of polarization with terahertz pulses in a ferroelectric nanowire¹

KIMBERLY SCHULTZ, Carthage College, RYAN HERCHIG, KEVIN MCCASH, INNA PONOMAREVA, University of South Florida — We use first-principles-based molecular dynamics simulations to study the interaction of a terahertz (THz) radiation with polarization in a ferroelectric ultrathin nanowire made of a lead zirconate titanate alloy. In our computational experiment, a 12 nm thick nanowire is first annealed down to temperature of 300 K and then subjected to a wide variety of THz pulses which differ in width, strength and frequency. Such nanowire develops an electrical polarization along the nanowire axial direction which couples strongly with incoming THz radiation. The atomistic resolution of our computational experiments allows us to trace the intrinsic polarization response and energy propagation/dissipation mechanisms that occur at the scale of femtoseconds. Our simulations were carried out under MVE and MVT conditions and the results did not vary significantly between the two ensembles. We further explore how the unique features of such response could be utilized in an ultrafast THz nanoswitches.

¹This work was supported by NSF REU program (award No DMR-1004873)

5:06PM D37.00014 Magnetic Element Doped Transparent Conducting In_2O_3 Thin Films for Spintronic Applications¹

E. NAHLIK, A. LAUDARI, M. LANGHOFF, K. GHOSH, Department of Physics, Astronomy and Materials Science, Missouri State University, Springfield, MO 65897 — Tremendous research efforts are underway to exploit the property of electron spin in spintronics. Spintronic devices critically depend on the availability of a specific materials system for spin injection, manipulation and detection. Transition metal (Cr, Fe, or Co) doped wide band gap oxide semiconductors possess these properties. Indium oxide (In_2O_3) is a wide band gap semiconductor with unique optical and electrical properties. Here, we investigate the effect of Cr, Fe, or Co doping on electrical and optical properties of In_2O_3 thin films. Thin films have been grown on sapphire and quartz substrates using pulse laser deposition method. Electrical and optical characteristics have been measured using UV-VIS spectroscopy and magneto-transport techniques. Optical transmittance and electrical parameters such as carrier concentration and carrier mobility vary with growth parameters such as growth temperature of the substrate and oxygen pressure of the chamber. These details will be discussed during this presentation.

Monday, February 27, 2012 2:30PM - 5:18PM —

Session D39 GQI: Quantum Protocols: Tomography, Communication, and Coding 109B

2:30PM D39.00001 Practical characterization of quantum devices without tomography

OLIVIER LANDON-CARDINAL, U. de Sherbrooke, STEVEN FLAMMIA, IQI, Caltech, MARCUS SILVA, Raytheon BBN Technologies, YI-KAI LIU, NIST, DAVID POULIN, U. de Sherbrooke — Quantum tomography is the main method used to assess the quality of quantum information processing devices, but its complexity presents a major obstacle for the characterization of even moderately large systems. Part of the reason for this complexity is that tomography generates much more information than is usually sought. Taking a more targeted approach, we develop schemes that enable (i) estimating the fidelity of an experiment to a theoretical ideal description, (ii) learning which description within a reduced subset best matches the experimental data. Both these approaches yield a significant reduction in resources compared to tomography. In particular, we show how to estimate the fidelity between a predicted pure state and an arbitrary experimental state using only a constant number of Pauli expectation values selected at random according to an importance-weighting rule. In addition, we propose methods for certifying quantum circuits and learning continuous-time quantum dynamics that are described by local Hamiltonians or Lindbladians.

2:42PM D39.00002 Quantum tomography with small number of copies: a simple estimator for qubit states, HUI KHOON NG, Centre for Quantum Technologies, National University of Singapore, BERTHOLD-GEORG ENGLERT, Centre for Quantum Technologies and the Department of Physics, National University of Singapore — In quantum tomography, one performs repeated measurements on N copies of a given but unknown state and constructs an estimator for the state from the gathered data. A common way of converting the data into an estimator is the maximum-likelihood (ML) method, where the estimator is the state with the largest probability of giving rise to the observed data. ML methods work well for large N , since the likelihood function for large N is sharply peaked around its maximum. For small N , however, there is a significant neighborhood of states around the maximum with nearly equal probability of giving rise to the data. One can then imagine using the likelihood function as a weight to construct an estimator as an average over states. This motivates the introduction of the “mean estimator,” also previously discussed for quantum tomography in the spirit of Bayesian estimation by Blume-Kohout [NJP 12, 043034(2010)]. Here, we extend the mean estimator for a classical die problem to an estimator for qubit states, and demonstrate its advantage over ML estimators. We also discuss a way of overcoming the common complaint of rank-deficiency in ML estimators for our estimator. This simple estimator should be useful as a convenient first estimate for any qubit tomography experiment.

2:54PM D39.00003 Joint quantum tomography of state preparation and measurements using only known quantum operations¹, MARCUS DA SILVA, Raytheon BBN Technologies, JAY GAMBETTA, IBM T.J. Watson Research Center — An important problem in quantum information is the complete characterization of quantum devices, which is usually referred to as “quantum tomography”. Quantum tomography procedures exist for the characterization of quantum states (quantum state tomography), operations (quantum process tomography) and measurements (quantum measurement tomography) — and each of these procedures can be performed using only product states, local unitary operations and local projective measurements. Here we consider the problem of jointly characterizing both the initial state as well as the measurement observable of a system using only well characterized quantum operations. We find that neither local unitaries nor local completely-positive trace-preserving maps are sufficient for obtaining a complete description of the state preparation and measurement of the system, and describe a scheme that uses non-unital trace-reducing physical maps to obtain such a description.

3:06PM D39.00004 Single shot quantum state estimation via continuous measurement in a strong back-action regime, ROBERT COOK, IVAN DEUTSCH, University of New Mexico — Quantum state reconstruction is a fundamental task in quantum information science. The standard approach employs many projective measurements on a series of identically prepared systems in order to collect sufficient statistics of an informationally complete set of observables. An alternative procedure is to reconstruct quantum state by performing weak continuous measurement collectively on an ensemble, while simultaneously applying time varying controls [1]. For known dynamics, the measurement history determines the initial state. In current implementations the shot noise of the probe dominates over projection noise so that measurement-induced backaction is negligible. We generalize this to the regime where quantum backaction can play a significant role, even for small numbers of particles. Using the framework of quantum filtering theory, we model the reconstruction of the state of a qubit through collective spin measurement via the Faraday interaction and magnetic field controls, and develop a maximum-likelihood estimate based on the Fisher information contained in the measurement record.

[1] A. Silberfarb and I. H. Deutsch, “Quantum-state reconstruction via continuous measurement,” Phys. Rev. Lett. 95, 030402 (2005).

3:18PM D39.00005 Beyond maximum-likelihood estimation, BERGE ENGLERT, Natl Univ of Singapore — When the estimators in quantum state tomography or quantum process tomography are obtained by maximizing the likelihood, which has become the method of choice, a unique result is not obtained if the data are informationally incomplete. By combining maximum-likelihood (ML) estimation with Jaynes’s maximum-entropy (ME) principle, a unique estimator can be determined, and this is possible by an efficient iterative algorithm. The resulting estimators, however, can have the familiar deficiencies of maximum-likelihood estimators. Alternative estimation procedures that avoid these drawbacks are wanted. The talk reports on MLME estimation as well as alternative approaches with a Bayesian touch. [References: Phys. Rev. Lett. 107 (2011) 020404; arXiv:1110.1202]

3:30PM D39.00006 Experimental Realization of Adaptive Qubit Tomography, DYLAN H. MAHLER, CQIQ and IOS, Department of Physics, University of Toronto, JOSHUA COMBES, Department of Physics and Astronomy, University of New Mexico, LEE A. ROZEMA, ARDAVAN DARABI, CQIQ and IOS, Department of Physics, University of Toronto, CHRIS FERRIE, Institute for Quantum Computing and Department of Applied Mathematics, University of Waterloo, AEPHRAIM STEINBERG, CQIQ and IOS, Department of Physics, University of Toronto, ROBIN BLUME-KOHOUT, Theoretical Division, Los Alamos National Lab and CQIC, University of New Mexico — In quantum state tomography, an informationally complete set of measurements is made on N identically prepared quantum systems and from these measurements the quantum state can be determined. In the limit as $N \rightarrow \infty$, the estimation of the state converges on the true state. The rate at which this convergence occurs depends on both the state and the measurements used to probe the state. To characterize the quality of a set of measurements the fidelity of the estimation with the true state, averaged over a prior distribution of states, is used as a figure of merit. It is known [1] that for states very close to the surface of the Bloch sphere, the average infidelity $(1 - F)$ goes down with a rate proportional to $\frac{1}{\sqrt{N}}$. It has also been shown that there exists a gap between collective measurement protocols and local measurement protocols, but that local *adaptive* measurement protocols can come close to saturating the collective measurement bound of $\frac{1}{\sqrt{N}}$ [2]. Here we present an experimental demonstration of one qubit tomography that achieves a rate of convergence of $\frac{1}{\sqrt{N}}$ with only a single adaptive step and local measurements.

3:42PM D39.00007 Scalable estimation of computational gate fidelities, EASWAR MAGESAN, University of Waterloo-Institute for Quantum Computing, JAY GAMBETTA, IBM T.J. Watson Research Center — Scalable methods for characterizing the noise affecting a quantum system are of significant interest in theoretical and experimental quantum information theory. Since completely characterizing the noise is exponentially hard in the number of qubits comprising the system, there has been significant effort in developing scalable methods for characterizing particular features of the noise. In particular, “randomized benchmarking” has been shown to be a robust and scalable method for estimating the average error rate over the set of quantum computational gates. We propose a new protocol that allows for benchmarking individual quantum gates rather than the average over the entire set. The protocol consists of a mixture of deterministic and random applications of computational gates and is shown to be scalable in the number of qubits comprising the system. The method is robust against state preparation and measurement errors and is valid provided the average variation of the noise over the gate set can be sufficiently bounded.

3:54PM D39.00008 Quantum controlled paths for perfect discrimination of no-signalling channels, GIULIO CHRIBELLA, Perimeter Institute — A no-signalling channel transforming systems in Alice’s and Bob’s local laboratories is compatible with two different causal structures: one where Alice’s output can be sent to Bob’s input and another where Bob’s output can be sent to Alice’s input. I show that a quantum superposition of circuits operating within these two causal structures enables the perfect discrimination between two no-signalling channels that could not be perfectly distinguished by any ordinary circuit [1]. Such a quantum superposition can be in principle achieved by introducing a qubit that controls the path followed by quantum systems, routing them to different ports of the given no-signalling channel.

[1] G. Chiribella, *Perfect discrimination of no-signalling channels via quantum superposition of causal structures*, arXiv:1109.5154.

4:06PM D39.00009 Experimental characterization of coherent dynamics in a spin chain, CHANDRASEKHAR RAMANATHAN, Dartmouth College, JAMES LEE, Oxford University, PAOLA CAPPELLARO, Massachusetts Institute of Technology, LORENZA VIOLA, Dartmouth College, DAVID CORY, Institute for Quantum Computing and University of Waterloo — We experimentally characterize the coherent room-temperature magnetization dynamics of a spin chain evolving under an effective double-quantum Hamiltonian. Our results indicate that a localized magnetic moment travels down the chain with a group velocity of $6.04 \pm 0.38 \mu\text{m/s}$, corresponding to coherent transport over $N \approx 26$ spins on the timescale of the experiment. We also characterize the influence of the ends of the chains on the magnetization dynamics. Our results are in excellent agreement with a nearest-neighbor-coupled analytical model that predicts that the dynamics are restricted to a Liouville space that only grows quadratically with the number of spins. This suggests that the long-range couplings present in the experimental system only cause a slow leakage out of the subspace. As the double-quantum Hamiltonian is related to the standard one-dimensional XX Hamiltonian by a similarity transform, our results can be directly extended to XX quantum spin chains, which have been extensively studied in the context of both quantum magnetism and quantum information processing

4:18PM D39.00010 Experimental Monte Carlo Quantum Process Certification, LARS STEFFEN, ARKADY FEDOROV, MATTHIAS BAUR, ETH Zurich, MARCUS PALMER DA SILVA, Raytheon BBN Technologies, ANDREAS WALLRAFF, ETH Zurich — Experimental implementations of quantum information processing have now reached a state, at which quantum process tomography starts to become impractical, since the number of experimental settings as well as the computational cost of the post processing required to extract the process matrix from the measurements scales exponentially with the number of qubits in the system. In order to determine the fidelity of an implemented process relative to the ideal one, a more practical approach called Monte Carlo quantum process certification was proposed in Ref. [1]. Here we present an experimental implementation of this scheme in a circuit quantum electrodynamics setup. Our system is realized with three superconducting transmon qubits coupled to a coplanar microwave resonator which is used for the joint-readout of the qubit states. We demonstrate an implementation of Monte Carlo quantum process certification and determine the fidelity of different two- and three-qubit gates such as CPHASE-, CNOT-, 2CPHASE- and Toffoli-gates. The obtained results are compared with the values obtained from conventional process tomography and the errors of the obtained fidelities are determined.

4:30PM D39.00011 Quantum filtering one bit at a time¹, JASON RALPH², NEIL OXTOBY, University of Liverpool, UK — We consider the purification of a quantum state using the information obtained from a continuous measurement record, where the classical measurement record is digitized to a single bit per measurement after the measurements have been made. Analysis indicates that efficient and reliable state purification is achievable for one- and two-qubit systems. We also consider quantum feedback control based on the discrete one-bit measurement sequences.

4:42PM D39.00012 New results in fault-tolerant quantum computing¹, GERALD GILBERT, YAAKOV WEINSTEIN, MITRE Quantum Information Science Group — We compare the accuracy of two methods used to construct a logical zero state appropriate for the $[[7,1,3]]$ CSS quantum error correction code in a non-equiprobable Pauli operator error environment. The first method is to apply error correction, via syndrome measurement, on seven physical qubits all in the state zero, using four-qubit Shor states to implement the syndrome measurements. The second method is to directly implement the $[[7,1,3]]$ encoding gate sequence. We find surprising results that show that even at the most basic level there is still much to be learned about achieving fault tolerance.

¹The authors are grateful for the support provided by the MITRE Innovation Program.

4:54PM D39.00013 On the Use of Shor States for the $[[7,1,3]]$ Quantum Error Correcting Code, YAAKOV WEINSTEIN, MITRE, SIDNEY BUCHBINDER, California Institute of Technology — We explore the effect of Shor state construction methods on logical state encoding and quantum error correction for the $[[7,1,3]]$ Calderbank-Shor-Steane quantum error correction code in a nonequiprobable error environment. We determine the optimum number of verification steps to be used in Shor state construction and whether Shor states without verification are usable for practical quantum computation. These results are compared to the same processes of encoding and error correction where Shor states are not used. We demonstrate that the construction of logical zero states with no first order error terms may not require the complete edifice of quantum fault tolerance. With respect to error correction, we show for a particular initial state that error correction using a single qubit for syndrome measurement yields a similar output state accuracy to error correction using Shor states as syndrome qubits. In addition, we demonstrate that error correction with Shor states has an inherent sensitivity to bit-flip errors.

5:06PM D39.00014 Quantum codes with low weight stabilizers¹, ALEXEY A. KOVALEV, Department of Physics & Astronomy, University of California, Riverside, California 92521, USA, ILYA DUMER, Department of Electrical Engineering, University of California, Riverside, California 92521, USA, LEONID P. PRYADKO, Department of Physics & Astronomy, University of California, Riverside, California 92521, USA — We study quantum cyclic stabilizer codes whose stabilizer can be always defined by one or two stabilizer generators. Our main goal is to construct low-weight stabilizer generators that can yield quantum codes with high code rate and simple error correction. To do so, we apply the classical quaternary representation of stabilizer codes and extend our recent study of one-generator cyclic codes [1]. For any stabilizer generator of weight four or five, we formulate a necessary and sufficient condition for its commutativity. We then proceed with a design of additive cyclic codes with such generators. In some cases, we also extend our commutativity condition and code design to generators of weight six. In particular, quantum cyclic codes with stabilizers of weight four are mapped to the generalized toric codes. Here we also extend the notion of toric codes using a translationally invariant generator and periodic boundary conditions on a two dimensional lattice. Some of our numerically constructed codes can be redefined by means of Code Word Stabilized (CWS) representation [1] as quantum versions of repetition codes. We particularly concentrate on codes with a fixed nonzero rate for which the minimum distance asymptotically grows as the blocklength grows.

Session D40 DBIO GSNP: Focus Session: Systems Biology and Biochemical Networks I 156A

2:30PM D40.00001 Optimal Information Processing in Biochemical Networks, CHRIS WIGGINS, Columbia University — A variety of experimental results over the past decades provide examples of near-optimal information processing in biological networks, including in biochemical and transcriptional regulatory networks. Computing information-theoretic quantities requires first choosing or computing the joint probability distribution describing multiple nodes in such a network — for example, representing the probability distribution of finding an integer copy number of each of two interacting reactants or gene products while respecting the 'intrinsic' small copy number noise constraining information transmission at the scale of the cell. I'll give an overview of some recent analytic and numerical work facilitating calculation of such joint distributions and the associated information, which in turn makes possible numerical optimization of information flow in models of noisy regulatory and biochemical networks. Illustrating cases include quantification of form-function relations, ideal design of regulatory cascades, and response to oscillatory driving.

3:06PM D40.00002 Adaptation at the output of the chemotaxis signaling pathway¹, JUNHUA YUAN, RICHARD BRANCH, BASARAB HOSU, HOWARD BERG, Department of Molecular and Cellular Biology, Harvard University — The chemotaxis signaling pathway allows bacterial cells to sense and respond to changes in concentrations of chemical attractants or repellents. In *E. coli*, the machinery required for bacterial chemotaxis includes two large membrane-embedded multiprotein complexes, one that processes input (receptor clusters) and the other that generates output (flagellar motors). These complexes are coupled by diffusion of a small phosphorylated cytoplasmic protein, CheY-P, which binds to the flagellar motors, increasing the probability that they spin clockwise. Receptor output (the steady-state concentration of CheY-P) varies from cell to cell. However, the motor is ultrasensitive, with a narrow [CheY-P] operating range. How might the receptor output and motor input be matched? By combining various techniques such as FRET, single-motor TIRF, and single-motor bead assay, we showed that the motor shifts its operating range to match the receptor output by changing its composition. The number of FliM subunits in the C-ring increases in response to a decrement in the concentration of CheY-P, increasing motor sensitivity. Such adaptive remodeling is likely to be a common feature in the operation of many molecular machines.

3:18PM D40.00003 The energy cost of accurate adaptation in networks with incoherent type-1 feed-forward loop, GANHUI LAN, YUHAI TU, IBM T. J. Watson Research Center — The incoherent type-1 feed forward loop (I1-FFL) is a common regulatory motif in many biochemical networks, some of which are responsible for accurate sensory adaptation. In this work, we analyze the sensitivity and adaptation function of the I1-FFL type enzymatic reaction networks. We show that detailed balance is broken in I1-FFL and continuous energy dissipation is needed to improve both the sensitivity and the adaptation accuracy of the network. Our study revealed a relation between the performance improvement and the energy dissipation rate. We find that this energy-assisted improvement is bounded (limited) by intrinsic properties of the molecular reaction system. The performance-energy relation in I1-FFL is similar to the recently obtained Energy-Speed-Accuracy relation in networks with negative-feedback-loop, another key motif for accurate sensory adaptation.

3:30PM D40.00004 Noise places constraints on eukaryotic gradient sensing and chemotaxis¹, BO HU, DANNY FULLER, WILLIAM LOOMIS, University of California - San Diego, WEN CHEN, University of Maryland - College Park, WOUTER-JAN RAPPEL, HERBERT LEVINE, University of California - San Diego — Chemotaxis is characterized by the directional cell movement following external chemical gradients. It plays a crucial role in a variety of biological processes including neuronal development, wound healing and cancer metastasis. Ultimately, the accuracy of gradient sensing is limited by the fluctuations of signaling components, e.g. the stochastic receptor occupancy on cell surface. We use concepts and techniques from statistical physics, estimation theory, and information theory to quantify the stochastic and nonlinear information processing in eukaryotic chemotaxis. We mainly address the following questions: (1) What are the physical limits of eukaryotic spatial gradient sensing? (2) How to characterize the movements of chemotactic cells? (3) How much gradient information can be reliably gained by a chemotactic cell? By answering those questions, we expect to derive new insights for general biological signal processing systems.

3:42PM D40.00005 Process-driven inference of biological network structure: feasibility, minimality, and multiplicity¹, CHEN ZENG, Department of Physics, The George Washington University, Washington, DC 20052 — For a given dynamic process, identifying the putative interaction networks to achieve it is the inference problem. In this talk, we address the computational complexity of inference problem in the context of Boolean networks under dominant inhibition condition. The first is a proof that the feasibility problem (is there a network that explains the dynamics?) can be solved in polynomial-time. Second, while the minimality problem (what is the smallest network that explains the dynamics?) is shown to be NP-hard, a simple polynomial-time heuristic is shown to produce near-minimal solutions, as demonstrated by simulation. Third, the theoretical framework also leads to a fast polynomial-time heuristic to estimate the number of network solutions with reasonable accuracy. We will apply these approaches to two simplified Boolean network models for the cell cycle process of budding yeast (Li 2004) and fission yeast (Davidich 2008). Our results demonstrate that each of these networks contains a giant backbone motif spanning all the network nodes that provides the desired main functionality, while the remaining edges in the network form smaller motifs whose role is to confer stability properties rather than provide function. Moreover, we show that the bioprocesses of these two cell cycle models differ considerably from a typically generated process and are intrinsically cascade-like.

4:18PM D40.00006 Communication channels between membrane bound proteins, JAMES SETHNA, BENJAMIN MACHTA, Department of Physics, Cornell University, SARAH VEATCH, Department of Biophysics, University of Michigan, Ann Arbor — Much of what might be called biological computation takes place on the plasma membrane, a 2D liquid composed of a diverse soup of lipids and embedded proteins. Motivated by the recent discovery that these membranes seem to be tuned close to a 2D liquid-liquid critical point, we set out to understand the different channels through which membrane bound proteins can communicate. Diffusing proteins can carry out reactions like phosphorylation when they come in contact with each other. Near criticality, proteins can also exert long-ranged critical Casimir forces on one another by coupling to the local composition order parameter. By modulating the growth and breakdown of the rigid cytoskeleton, they can direct forces on even more distant regions. In addition, proteins can control the release and production of second messengers that diffuse either through the bulk, or in the plane of the membrane itself. By making simple models for these processes we bound functional measures for them as communication channels. These include information theoretic measures of bandwidth, as well as physical measures of energetic efficiency and speed. Our results will likely shed light on the functional role of clustering and other collective behaviors often seen in experiments.

4:30PM D40.00007 Maximum entropy principle for predicting response to multiple-drug exposure in bacteria and human cancer cells, KEVIN WOOD, SATOSHI NISHIDA, Harvard University, EDUARDO SONTAG, Rutgers University, PHILIPPE CLUZEL, Harvard University — Drugs are commonly used in combinations larger than two for treating infectious disease. However, it is generally impossible to infer the net effect of a multi-drug combination on cell growth directly from the effects of individual drugs. We combined experiments with maximum entropy methods to develop a mechanism-independent framework for calculating the response of both bacteria and human cancer cells to a large variety of drug combinations comprised of anti-microbial or anti-cancer drugs. We experimentally show that the cellular responses to drug pairs are sufficient to infer the effects of larger drug combinations in gram negative bacteria, *Escherichia coli*, gram positive bacteria, *Staphylococcus aureus*, and also human breast cancer and melanoma cell lines. Remarkably, the accurate predictions of this framework suggest that the multi-drug response obeys statistical rather than chemical laws for combinations larger than two. Consequently, these findings offer a new strategy for the rational design of therapies using large drug combinations.

4:42PM D40.00008 Robust regulation of oscillatory Min-protein patterns¹, JACOB HALATEK, ERWIN FREY, Arnold Sommerfeld Center for Theoretical Physics and Center for NanoScience, Department of Physics, Ludwig-Maximilians-Universität München — Robust spatial patterning was crucial just from the beginning of cellular evolution, and is key to the development of multicellular organisms. In *E. Coli*, the oscillatory pole-to-pole dynamics of MinCDE proteins functionality prevent improper cell divisions apart from midcell. Min-oscillations are characterized by the remarkable robustness with which spatial patterns dynamically adapt to variations of cell geometry. Moreover, adaption, and therefore proper cell division, is independent of temperature. These observations raise fundamental questions about the underlying core mechanisms, and about the role of spatial cues. With a conceptually novel and universal approach to cellular geometries, we introduce a robust model based on experimental data, consistently explaining the mechanisms underlying pole-to-pole, striped and circular patterns, as well as the observed temperature-dependence. Contrary to prior conjectures, the model predicts that MinD and cardiolipin domains are not colocalized. The key mechanisms are transient sequestration of MinE, and highly canalized transfer of MinD between polar zones. MinD channeling enhances midcell localization and facilitates stripe formation, revealing the potential optimization process from which robust Min-oscillations originally arose.

4:54PM D40.00009 Mathematical Analysis of Biomolecular Network Reveals Connections Between Diseases¹, GUANYU WANG, The George Washington University — Connections between cancer and metabolic diseases may consist in the complex network of interactions among a common set of biomolecules. By applying singularity and bifurcation analysis, the phenotypes constrained by the AKT signaling pathway are identified and mapped onto the parameter space, which include cancer and certain metabolic diseases. By considering physiologic properties (sensitivity, robustness and adaptivity) the AKT pathway must possess in order to efficiently sense growth factors and nutrients, the region of normal responses is located. The analysis illuminates the parameter space and reveals system-level mechanisms in regulating biological functions (cell growth, survival, proliferation and metabolism) and how their deregulation may lead to the development of diseases. The analytical expressions summarize the synergistic interactions among many molecules, which provides valuable insights into therapeutic interventions.

5:06PM D40.00010 Modeling the mammalian circadian clock, CRAIG JOLLEY, HIROKI UEDA, RIKEN Center for Developmental Biology, Laboratory for Systems Biology — In biology, important processes often depend on a temporal schedule. The 24-hour periodicity of solar illumination caused by the earth's rotation has consequences for environmental factors such as temperature and humidity as well as ecological factors such as the presence of food, predators, or potential mates. As a result, many organisms have evolved to develop a circadian clock that allows them to anticipate these environmental changes in the absence of direct temporal cues. In recent years, extensive efforts have been made to deconstruct the biological clockwork from various organisms, develop mathematical models of circadian function, and construct synthetic analogues to test our understanding. My present work has two major foci. First, we have used regulatory principles revealed by recent experimental work to construct a model of the core genetic oscillator of the mammalian circadian system that captures key system-level behaviors. Second, we are exploring the possibility of a post-translational phosphorylation-based oscillator that is coupled to the core oscillator, conferring enhanced robustness and stability on the complete system. A simple model of this post-translational oscillator reveals key design constraints that must be satisfied by any such oscillator.

Session D42 DBIO: Focus Session: Physics of Cancer I – Evolution and Resistance 156C

2:30PM D42.00001 Drug Resistance and the Kinetics of Metastatic Cancer¹, KRASTAN B. BLAGOEV, National Science Foundation — Most metastatic cancers after initial response to current drug therapies develop resistance to the treatment. We present cancer data and a theory that explains the observed kinetics of tumor growth in cancer patients and using a stochastic model based on this theory we relate the kinetics of tumor growth to Kaplan-Meier survival curves. The theory points to the tumor growth rate as the most important parameter determining the outcome of a drug treatment. The overall tumor growth or decay rate is a reflection of the balance between cell division, senescence and apoptosis and we propose that the deviation of the decay rate from exponential is a measure of the emergence of drug resistance. In clinical trials the progression free survival, the overall survival, and the shape of the Kaplan-Meier plots are determined by the tumor growth rate probability distribution among the patients in the trial. How drug treatments modify this distribution will also be described. At the end of the talk we will discuss the connection between the theory described here and the age related cancer mortality rates in the United States.

3:06PM D42.00002 Lattice Boltzmann simulations of lymphatic pumping, CHRISTIAN KUNERT, TIM P. PADERA, LANCE L. MUNN, Massachusetts General Hospital/ Harvard medical school — Lymphatic flow plays an important role in the progress of many diseases, including lymphedema and metastasis. However lymphatic pumping and flow is poorly understood. Here, we present a computer model that is based on biological observations of lymphatic pumping. Fluid flow is simulated by a D2Q9 lattice Boltzmann model. The boundary of the vessels moves according to shear-induced nitric oxide production, and wall motion transfers momentum to the fluid to induce flow. Because the model only includes local properties, it can be highly parallelized. In our case we utilize graphic processors (GPU) to achieve high performance computation. We show that the model provides stable pumping over a wide range of parameter values, with optimum flow achieved in the biological ranges. Furthermore, we investigate the efficiency by analyzing the flow rate and pumping frequency in order to compare the behavior of the model with existing in vivo data.

3:18PM D42.00003 Mechanical and Structural Changes of the Pericellular Coat during Cell Proliferation, LOUIS T. MCLANE, School of Physics, Georgia Institute of Technology, ANNA GRANQVIST, The Renal Center, The Wallenberg Laboratory for Cardiovascular Research, Sahlgrenska University Hospital, PATRICK CHANG, ANTHONY KRAMER, JENNIFER E. CURTIS, School of Physics, Georgia Institute of Technology — The organization of a hyaluronan and proteoglycan-rich pericellular coat at the cell surface has been shown to facilitate cell migration and mitosis. These several microns thick, swollen grafted polymer matrices are directly correlated with efficient proliferation, migration, and in extreme cases have been associated with the metastatic spread of cancer. For example, hyaluronan synthesis is enormously increased when oncogenic viruses transform fibroblasts and elevated levels of hyaluronan are associated with the hyperproliferative and malignant phenotypes in melanoma and various carcinomas. Studies on cancer cell lines have shown that overproduction of hyaluronan and excess proteoglycan enhances their anchorage independent growth, tumorigenicity and metastatic potential. It has long been suspected that the mechanical and structural changes associated with enhanced pericellular matrix are in part responsible for these effects. Here we present measurements of pericellular coat mechanics and structure, investigating how it changes with cell cycle as well as increased or decreased proteoglycan content.

3:30PM D42.00004 Can low energy electrons lead to strand breaks in DNA under realistic conditions?, JORGE KOHANOFF, MAEVE SMYTH, Queens University Belfast — It is widely accepted that low energy electrons produced by ionizing radiation play an important role in causing DNA damage [B. Boudaïffa et al., *Science* **287**, 1658 (2000)]. Understanding the behaviour of DNA components in the condensed phase due to such electrons is a fundamental step towards modelling this damage within a realistic environment. Here we present a computational study of the effect of low energy electrons in condensed phase models of solvated DNA fragments. First we show that excess electrons, which are initially found delocalized, quickly localize around the nucleobases within a 15 fs time scale. Energies and time scales are comparable for each of the bases [M. Smyth and J. Kohanoff, *Phys. Rev. Lett.* **106**, 238108 (2011)]. The phosphodiester bond C_{3'}-O_{3'}, which under normal conditions is very stable, weakens significantly upon electron attachment both, in the gas and in the condensed phase. Computation of free energy profiles show that barriers for bond cleavage are in the region of 5-8 kcal/mol for all the solvated nucleotides, thus suggesting that this kind of event is quite likely at ambient temperature. This supports the notion that ionizing radiation can actually lead to DNA strand breaks in the physiological environment.

3:42PM D42.00005 Emergence of fractal behavior and other changes of cell surface during malignant transformation: AFM study of human cervical epithelial cells, MAXIM DOKUKIN, NATALIYA GUZ, CRAIG WOODWORTH, IGOR SOKOLOV, Clarkson University — Fractal behavior, self-similarity when zooming in or out, is frequently found in natural patterns emerged from chaos or any far from equilibrium systems. While expected and observed for tissues, the emergence of fractal behavior associated with malignant transformations was not observed at the level of single cell. Here report on the appearance of fractal behavior when normal human cervical epithelial cells become malignant. This was found by analyzing the adhesion maps imaged with AFM working in HarmoniX mode. Normal and malignant (a mix of cancerous and precancerous) cells were enzymatic only extracted from cervical tissue of healthy individuals and cancer patients, respectively. A surprising 100% discrimination of malignant and normal cells was observed. Although we previously reported differences in surface (brush) layer of cancer cells, the unambiguous quantitative divergence of the fractal behavior of the adhesion maps is a surprise (in particular, when compared to no difference found in the regular AFM images). The nature of the observed difference in the adhesion behavior will be discussed. These results may suggest that the fractal dimensionality can be treated as a new potential “physicomarker” for detection of individual cervical cancer cells.

3:54PM D42.00006 Improved survival in rats with glioma using MRI-guided focused ultrasound and microbubbles to disrupt the blood-brain barrier and deliver Doxil, MUNA ARYAL, BWH, Harvard Medical School/Department of Physics, Boston College, YONG ZHI ZHANG, NATALIA VYKHODTSEVA, JUYOUNG PARK, CHANIKARN POWER, NATHAN MCDANNOLD, Department of Radiology, BWH, Harvard Medical School — Blood-brain-barrier (BBB) limits the transportation of most neuropeptides, proteins (enzymes, antibodies), chemotherapeutic agents, and genes that have therapeutic potential for the treatment of brain diseases. Different methods have been used to overcome this limitation, but they are invasive, non-targeted, or require the development of new drugs. We have developed a method that uses MRI-guided focused ultrasound (FUS) combined with circulating microbubbles to temporarily open BBB in and around brain tumors to deliver chemotherapy agents. Here, we tested whether this noninvasive technique could enhance the effectiveness of a chemotherapy agent (Doxil). Using 690 kHz FUS transducer and microbubble (Definity), we induced BBB disruption in intracranially-implanted 9L glioma tumors in rat's brain in three weekly sessions. Animals who received BBB disruption and Doxil had a median survival time of 34.5 days, which was significantly longer than that found in control animals which is 16, 18.5, 21 days who received no treatment, BBB disruption only and Doxil only respectively. This work demonstrates that FUS technique has promise in overcoming barriers to drug delivery, which are particularly stark in the brain due to the BBB.

4:06PM D42.00007 Insights into protein – DNA interactions, stability and allosteric communications: A computational study of MutS-DNA recognition complexes¹, LACRAMIOARA NEGUREANU, FREDDIE SALSBURY, Wake Forest University — DNA mismatch repair proteins (MMR) maintain genetic stability by recognizing and repairing mismatched bases and insertion/deletion loops mistakenly incorporated during DNA replication, and initiate cellular response to certain types of DNA damage. The most abundant MMR mismatch-binding factor in eukaryotes, MutS, recognizes and initiates the repair of base-base mismatches and small insertion/deletions. We performed molecular dynamics simulations on mismatched and damaged MutS-DNA complexes. A comprehensive DNA binding site analysis of relevant conformations shows that MutS proteins recognize the mismatched and platinum cross-linked DNA substrates in significantly different modes. Distinctive conformational changes associated with MutS binding to mismatched and damaged DNA have been identified and they provide insight into the involvement of MMR proteins in DNA-repair and DNA-damage pathways. Stability and allosteric interactions at the heterodimer interface associated with the mismatch and damage recognition step allow for prediction of key residues in MMR cancer-causing mutations. A rigorous hydrogen bonding analysis for ADP molecules at the ATPase binding sites is also presented. A large number of known MMR cancer causing mutations among the residues were found.

4:18PM D42.00008 Glycoprotein Mucin Molecular Brush on Cancer Cells and its Correlation with Resistance Against Drug Delivery, XIN WANG, AALOK SHAH, ROBERT CAMPBELL, KAI-TAK WAN, Northeastern University — Uptake of cytotoxic drugs by typical tumor cells is limited by the dense dendritic network of oligosaccharide mucin chains that forms a mechanical barrier. Atomic force microscopy is used to directly measure the force needed to pierce the mucin layer to reach the cell surface. Measurements are analyzed by deGennes' steric repulsion theory. Multi-drug resistant ovarian tumor cells shows significantly larger penetration load compared to the wild type. A pool of pancreatic, lung, colorectal, and breast cells are also characterized. The chemotherapeutic agent, benzyl- α -GalNAc, for inhibiting glycosylation is shown to be effective in reducing the mechanical barrier.

4:30PM D42.00009 Bcl-2 apoptosis proteins, mitochondrial membrane curvature, and cancer, GHEE HWEE LAI, NATHAN SCHMIDT, Physics, UIUC, LORI SANDERS, Materials Science and Engineering, UIUC, ABHIJIT MISHRA, GERARD WONG, Bioengineering, UCLA, OLENA IVASHYNA, ERIC CHRISTENSON, PAUL SCHLESINGER, Cell Biology and Physiology, WUSTL Sch. of Medicine, KIYOTAKA AKABORI, CHRISTIAN SANTANGELO, Physics, U. of Massachusetts — Critical interactions between Bcl-2 family proteins permeabilize the outer mitochondrial membrane, a common decision point early in the intrinsic apoptotic pathway that irreversibly commits the cell to death. However, a unified picture integrating the essential non-passive role of lipid membranes with the contested dynamics of Bcl-2 regulation remains unresolved. Correlating results between synchrotron x-ray diffraction and microscopy in cell-free assays, we report activation of pro-apoptotic Bax induces strong pure negative Gaussian membrane curvature topologically necessary for pore formation and membrane remodeling events. Strikingly, Bcl-xL suppresses not only Bax-induced pore formation, but also membrane remodeling by disparate systems including cell penetrating, antimicrobial or viral fusion peptides, and bacterial toxin, none of which have BH3 allosteric domains to mediate direct binding. We propose a parallel mode of Bcl-2 pore regulation in which Bax and Bcl-xL induce antagonistic and mutually interacting Gaussian membrane curvatures. The universal nature of curvature-mediated interactions allows synergy with direct binding mechanisms, and potentially accounts for the Bcl-2 family modulation of mitochondrial fission/fusion dynamics.

4:42PM D42.00010 Drift, draft, waves, and ratcheting: evolutionary models of cancer progression, CHRISTOPHER MCFARLAND¹, Harvard University, KIRILL KOROLEV², LEONID MIRNY³, MIT — Recent evidence has found that many mutations are detrimental to tumor growth in cancer. These mutations, called *passenger mutations*, are distinguished from the better known cancer-causing *driver mutations*, which increase a tumor cell's proliferative capacity. How passenger mutations arise, despite selection against them, is not well understood nor fully explained by existing theory. Here, we extend several population genetics models to explain their accumulation in a precancerous population of cells and compare our findings against stochastic simulations. We find that passenger mutations alter and can avert progression to cancer. The probability of cancer depended heavily, and non-monotonically, on both the deleteriousness and rate of mutations. Counter-intuitively, high mutation rates decrease the likelihood of cancer—a finding recently corroborated by clinical data[1]. Our models suggest that therapies exploiting passenger mutations can avert cancer and may be more effective than targeting driver mutations.

Session D43 DCMP GSNP: Invited Session: Recent Advances in the Physics of Fractures 157AB

2:30PM D43.00001 Failure of molecules, bones, and the Earth itself, SINAN KETEN, Northwestern University — Materials fail by recurring rupture and shearing of interatomic bonds at microscopic, molecular scales, leading to disintegration of matter at macroscale, and a loss of function. In this talk, the state-of-the-art of investigations on failure mechanisms in materials will be presented, in particular focusing on atomistic origin of deformation and fracture, and the relationships between molecular mechanics and macroscale behavior. Simple examples of fracture phenomena are used to illustrate the significance and impact of material failure on our daily lives. Based on case studies, mechanisms of failure of a wide range of materials are discussed, ranging from tectonic plates to rupture of single molecules, and an explanation on how atomistic simulation can be used to complement experimental studies and theory to provide a novel viewpoint in the analysis of complex systems is provided. Biological protein materials are used to illustrate how extraordinary properties are achieved through the utilization of intricate structures where the interplay of weak and strong chemical bonds, size and confinement effects, and hierarchical features play a fundamental role. This leads to a discussion of how even the most robust biological material systems fail, leading to diseases that arise from structural and mechanical alterations at molecular, cellular, and tissue levels. New research directions in the field of materials failure and materials science are discussed and the impact of improving the current understanding of materials failure for applications in nanotechnology, biotechnology, medicine as well as the built environment.

3:06PM D43.00002 Fast fracture in slow motion: Dynamic fracture and the effect of near-tip elastic nonlinearities in brittle gels, JAY FINEBERG, The Racah Institute of Physics, The Hebrew University of Jerusalem — We present recent results of fracture experiments in poly-acrylamide gels [1]. These gels are soft polymers in which the characteristic sound speeds are on the order of a few meters/sec - thereby slowing down fracture dynamics by 3 orders of magnitude. We first show that the dynamics of rapid cracks are universal; the fracture of gels exhibits characteristic features that are identical with those seen in "classic" materials such as glass. These include:

- Excellent quantitative agreement with the two different equations of motion for single dynamic cracks predicted by Linear Elastic Fracture Mechanics (LEFM) – each for different classes of loading conditions.
- The same branching instabilities, localized waves confined to the crack front, and the characteristic structure formed on the resulting fracture surface as observed in "standard" amorphous brittle materials, such as soda-lime glass.

We utilize the "slow motion" inherent in the fracture of gels to experimentally and theoretically investigate the structure of the deformation fields that surround the tip of highly dynamic cracks. We find that:

- The singular fields predicted by LEFM change their structure due to nonlinear elastic effects that dominate the near-tip region [3].
- This non-linear elastic region provides a quantitative explanation for the oscillatory instability of cracks [2,4] as their speed approaches the Rayleigh wave speed.

These results provide a quantitative first-principles description of how elastic nonlinearity influences the rapid dynamics of a crack.

3:42PM D43.00003 Shapes formed by interacting cracks, KAREN DANIELS, Dept. of Physics, North Carolina State University — Brittle failure through multiple cracks occurs in a wide variety of contexts, from microscopic failures in dental enamel and cleaved silicon to geological faults and planetary ice crusts. In each of these situations, with complicated stress geometries and different microscopic mechanisms, pairwise interactions between approaching cracks nonetheless produce characteristically curved fracture paths. We investigate the origins of this widely observed “en passant” crack pattern by fracturing a rectangular slab which is notched on each long side and subjected to quasi-static uniaxial strain from the short side. The two cracks propagate along approximately straight paths until they pass each other, after which they curve and release a lens-shaped fragment. We find that, for materials with diverse mechanical properties, each curve has an approximately square-root shape, and that the length of each fragment is twice its width. We are able to explain the origins of this universal shape with a simple geometrical model.

4:18PM D43.00004 Fracture Statistics: Universality vs. Nucleation¹, ASHVINI SHEKHAWAT, Cornell University — We reexamine several common assumptions about fracture strength, utilizing large-scale simulations of a fuse network model and applying both renormalization-group and nucleation theory methods. Statistical distributions of fracture strengths are believed to be universal and material independent. The universal Weibull and Gumbel distributions emerge as a consequence of the “weakest-link hypothesis” and have been studied in the classical theory of extreme value statistics. These distributions are also the fixed points of a renormalization group (RG) flow. However, the engineering community often ignores the Gumbel distribution and uses the Weibull form almost exclusively to fit experimental data. Further, such fits are often extrapolated beyond the available data to estimate the probability of rare events in a variety of applications ranging from structural reliability to insurance pricing. Our recent studies of the random fuse network model raises doubts about most of these practices. We find that the emergent distribution of fracture strengths is the Gumbel distribution. However, the extremely slow convergence to the universal Gumbel form renders it unusable at least in this case. On the other hand, we show that a non-universal distribution derived by using a Griffiths type nucleation theory (due to Duxbury et al.) converges rapidly even for moderate system sizes. We find that while extrapolating the RG based universal Gumbel distribution is perilous and gives wildly incorrect predictions, the nucleation based non-universal results can be extrapolated with confidence. It is entertaining that fracture provides wonderful examples of the statistical mechanics tools developed to study both continuous as well as abrupt phase transitions.

4:54PM D43.00005 Avalanches in crack front propagation¹, STEFANO ZAPPERI, National Research Council of Italy CNR — We study avalanches in a model for a planar crack propagating in a disordered medium. Due to long-range interactions, avalanches are formed by a set of spatially disconnected local clusters, the sizes of which are distributed according to a power law. We derive a scaling relation between the local cluster and the global avalanche distributions. For length scales above a crossover length proportional to the Larkin length, the aspect ratio of the local clusters scales with the roughness exponent of the line model. For smaller lengthscales we observe multiscaling in the crack line correlations. Our analysis provides an explanation for experimental results on planar crack avalanches in Plexiglas plates, but the results are applicable also to other systems with long-range interactions such as Barkhausen avalanches in ferromagnetic thin films.

Monday, February 27, 2012 2:30PM - 5:30PM —
Session D44 GQI DCMP: Invited Session: Topological Quantum Computing with Majorana Fermions 157C

2:30PM D44.00001 Non-abelian anyons and topological quantum information processing in 1D wire networks, JASON ALICEA, UC Irvine — Topological quantum computation provides an elegant solution to decoherence, circumventing this infamous problem at the hardware level. The most basic requirement in this approach is the ability to stabilize and manipulate particles exhibiting non-Abelian exchange statistics – Majorana fermions being the simplest example. Curiously, Majorana fermions have been predicted to arise both in 2D systems, where non-Abelian statistics is well established, and in 1D, where exchange statistics of any type is ill-defined. An important question then arises: do Majorana fermions in 1D hold the same technological promise as their 2D counterparts? In this talk I will answer this question in the affirmative, describing how one can indeed manipulate and harness the non-Abelian statistics of Majoranas in a remarkably simple fashion using networks formed by quantum wires or topological insulator edges.

3:06PM D44.00002 Realization and detection of Majorana modes at generic spin-orbit coupled semiconductor/s-wave superconductor interfaces¹, JAY SAU, Department of Physics, Harvard University, Cambridge, MA 02138 — Majorana fermions are hitherto unobserved particles that have been theoretically predicted to have non-Abelian statistics that may be used for Topological Quantum Computation. For over a decade the only candidate systems for observing Majorana fermions were the non-Abelian $\nu = 5/2$ fractional quantum Hall state and chiral p-wave superconductors. More recently, motivated by developments in the area of topological insulators it was realized that a more general class of topological superconductors, some of which may be as simple as the interface of InAs and Al, should support such excitations. This talk will start by explaining why superconductors are a natural host for Majorana fermions. Following this, it will be argued that Majorana fermions should exist in generic semiconductor/superconductor interfaces, both in 1D and 2D, the crucial ingredients being s-wave superconductivity, spin-orbit coupling, and Zeeman splitting. Such Majorana fermions at the end of a nanowire appear as a magnetic-field tunable zero-bias peak in the STM spectrum with quantized conductance. Following this experimental challenges *en route* to realizing Majorana fermions in these structures such as disorder and the required tuning of the chemical potential of the semiconductor, will be discussed. Finally, we will conclude by showing how the spin-orbit coupled nanowires motivate a class of intrinsically number conserving microscopic models for topological superconductor with end Majorana fermions. The bosonization approach used to study this one-dimensional model, directly connects the Majorana fermions, which are typically described as Bogoliubov quasiparticles in mean-field theory, to an emergent Ising order in the one-dimensional nanowire model. The robustness of the topological degeneracy to weak local perturbations can be explicitly demonstrated.

¹Work done at CMTc, UMD in collaboration with Sankar Das Sarma, Sumanta Tewari, Roman Lutchyn and supported by DARPA QuEST, JQI-NSF-PFC, and Microsoft Q. Bosonization work was done in collaboration with B. I. Halperin and K. Flensberg.

3:42PM D44.00003 The Search for Majorana Fermions in Semiconductor Nanowires, LEO KOUWEN-HOVEN, Kavli Institute of NanoScience, Delft, The Netherlands — Majorana Fermions can arise as quasi-particles in specially designed nanoscale, electronic devices. Our approach is to use semiconductor nanowires with strong spin-orbit interaction (InAs or InSb). We induce superconductivity in the nanowires and control the electron density through a nearby gate. Several properties are measured such as the spin-orbit strength (including the dependence on the magnetic field direction), the induced superconducting gap (including magnetic field dependence) and the flow of supercurrents. For the determined experimental values we estimate the temperature scale to be ~ 2 Kelvin as the transition temperature for the reaching the phase of a topological superconductor. Majorana Fermions should be detectable as special features in the tunneling conductance or in the periodicity of an interferometer setup (SQUID geometry).

4:18PM D44.00004 Manipulation of Majorana fermions using superconducting qubits, ANTON AKHMEROV, Leiden University — Majorana fermions are special particles, predicted to appear in certain superconductors. They are extremely useful for quantum computation, due to the possibility to store quantum information in the degenerate ground state of the system. Moreover braiding Majorana fermions around each other allows to implement certain quantum gates in a fault-tolerant manner. I introduce a scheme of quantum computation with Majorana fermions which relies on interplay of charging and Josephson energy to measure, controllably couple, and braid Majorana fermions. The advantage of this scheme is that it fully relies on control elements usual for superconducting circuitry and does not require fine tuning on the scale of Fermi wavelength.

4:54PM D44.00005 Disorder effects in topological quantum wires, and alternative platforms for Majorana Fermion realization, PIET BROUWER, Freie Universitaet Berlin — Spinless p-wave superconducting wires can be in a topological phase in which they harbor Majorana bound states at their ends. Although there are no known spinless p-wave superconductors in nature, several routes to the artificial creation of such systems have been proposed. In this talk, I will discuss how non-idealities in some of the proposed routes, such as potential disorder and deviations from a strict one-dimensional limit, affect the topological phase. In particular, I'll discuss how the topological phase can persist at weak disorder or for multichannel wires, although some of the signatures of the presence of Majorana fermions are obscured.

Monday, February 27, 2012 2:30PM - 5:30PM —

Session D51 DCMP DFD: Liquid Crystals: Chromonics and Nematics Boston Convention Center 154

2:30PM D51.00001 Lyotropic chromonic liquid crystals in the biphasic region, XUXIA YAO, Georgia Institute of Technology, ALEJANDRO REY, McGill University, JUNG PARK, MOHAN SRINIVASARAO, Georgia Institute of Technology — Lyotropic chromonic liquid crystals have a wide coexistence temperature range where the isotropic and nematic phases are in equilibrium. Negative tactoids (isotropic droplets in the nematic medium) or positive tactoids (nematic droplets in the isotropic medium) form and grow as the nuclei of the new phases in the biphasic region. We studied the growth of tactoids as a function of temperature, the prolate shape of tactoids as well as their thermal fluctuation, based on which the viscoelastic properties of chromonic liquid crystals were obtained.

2:42PM D51.00002 Order Parameter measurements of Chromonic Liquid Crystal Benzopurpurin 4B using polarized Raman scattering¹, KARTHIK NAYANI, JUNG OK PARK, MOHAN SRINIVASARAO, Georgia Institute of Technology — Benzopurpurin 4B (BPP4B), a commonly used textile dye, is known to form chromonic liquid crystal phases in aqueous solutions at fairly low concentrations (<0.5 wt%) in comparison with other chromonic liquid crystals. Also the aggregation properties and the structure of the aggregates in aqueous solutions of BPP4B are not well understood. Recently McKitterick et al. reported a study on the aggregation and phase behavior of BPP4B in water.² Further understanding of the behavior of BPP4B in aqueous solutions can be gained by studying how the order parameter of its liquid crystalline phase varies with some relevant parameters. Planar monodomains of BPP4B were obtained using a flat rectangular capillary. Thermal evolution of the order parameter of these aligned monodomains was carried out using polarized Raman scattering measurements. Further, the concentration dependence and the effect of salt on the order parameter were studied. The variation of the order parameter with the above parameters was correlated to the structure of the aggregates using the UV-Vis absorption data.

¹This study was partially supported by NSF (DMR-0706235) and PSE fellowship (Georgia Institute of Technology).

2:54PM D51.00003 Textural transformations in lyotropic chromonic liquid crystals under confinement¹, ALIREZA SHAMS, Department of Chemical Engineering, McGill University, Montreal, Quebec H3A 2B2, Canada, XUXIA YAO, School of Materials Science and Engineering, Georgia Institute of Technology, Atlanta, GA 30332, USA, ALEJANDRO D. REY², Department of Chemical Engineering, McGill University, Montreal, Quebec H3A 2B2, Canada, JUNG OK PARK³, School of Materials Science and Engineering, Georgia Institute of Technology, Atlanta, GA 30332, USA, MOHAN SRINIVASARAO⁴, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA 30332, USA — Lyotropic chromonic liquid crystals under capillary confinement display textural transformations between planar radial and planar polar modes, in which a +1 disclination branches into two +1/2 lines. The texture transformation is characterized by the nature and kinematics of the branch point, the aperture angle, and the shape of the lines. This work presents and validates a model of these four phenomena, which yield the viscoelastic moduli of these novel mesophases.

¹This work is partially supported by a grant from the U.S. Office of Basic Energy Sciences, Department of Energy; grant DE-SC0001412 and McGill Engineering Doctorate Award.

3:06PM D51.00004 Molecular Aggregation in Disodium Cromoglycate¹, GAUTAM SINGH, D. AGRA-KOOIJMAN, Kent State University, P.J. COLLINGS, Swarthmore College, SATYENDRA KUMAR, Kent State University — Details of molecular aggregation in the mesophases of the anti-asthmatic drug disodium cromoglycate (DSCG) have been studied using x-ray synchrotron scattering. The results show two reflections, one at wide angles corresponding to $\pi - \pi$ stacking (3.32 Å) of molecules, and the other at small angles which is perpendicular to the direction of molecular stacking and corresponds to the distance between the molecular aggregates. The latter varies from 35 - 41 Å in the nematic (N) phase and 27 - 32 Å in the columnar (M) phase. The temperature evolution of the stack height, positional order correlations in the lateral direction, and orientation order parameter were determined in the N, M, and biphasic regions. The structure of the N and M phases and the nature of the molecular aggregation, together with their dependence on temperature and concentration, will be presented.

¹Work supported by NSF grant DMR-0806991.

3:18PM D51.00005 Flexopolydispersity of Nematic Liquid Crystals¹, YUE SHI, DONG CHEN, Department of Physics and Liquid Crystal Material Research Center, University of Colorado-Boulder, RIZWAN MAHMOOD, Department of Physics, Slippery Rock University, NOEL CLARK, Department of Physics and Liquid Crystal Material Research Center, University of Colorado-Boulder — Flexopolydispersity is the coupling of gradients in the director field $\mathbf{n}(\mathbf{r})$ of a nematic phase made from a polydisperse mixture of anisotropic particles in solution to the spatial change in variables describing the local mean particle shape, size, and concentration: In solutions of sufficiently polydisperse plates this coupling can lead to a nematic phase with a “blue-phase” like array of +1 defect lines. Such a structure has been observed in the lyotropic nematic phase of solutions of graphene oxide sheets.

¹Supported by NSF MRSEC Grant DMR-0820579.

3:30PM D51.00006 Nematic order in toroidal and higher-genus droplets¹, EKAPOP PAIRAM, JAYA LAKSHMI, ALBERTO FERNANDEZ-NIEVES, Georgia Institute of Technology, GEORGIA TECH TEAM — We generate toroidal and higher-genus droplets filled with nematic liquid crystal which are stabilized inside viscoelastic fluid with a non-zero yield stress. The work presented here is the preliminary observations of our experiments.

¹Georgia Institute of Technology, NSF Career

3:42PM D51.00007 Seeing and Sculpting Nematic Liquid Crystal Textures with the Thom construction, BRYAN CHEN, University of Pennsylvania, GARETH ALEXANDER, University of Warwick — Nematic liquid crystals are the foundation for modern display technology and also exhibit topological defects that can readily be seen under a microscope. Recently, experimentalists have been able to create and control several new families of interesting defect textures, including reconfigurably knotted defect lines around colloids (Ljubljana) and the “toron,” a pair of hedgehogs bound together with a ring of double-twist between them (CU Boulder). We apply the Thom construction from algebraic topology to visualize 3 dimensional molecular orientation fields as certain colored surfaces in the sample. These surfaces turn out to be a generalization to 3 dimensions of the dark brushes seen in Schlieren textures of two-dimensional samples of nematics. Manipulations of these surfaces correspond to deformations of the nematic orientation fields, giving a hands-on way to classify liquid crystal textures which is also easily computable from data and robust to noise.

3:54PM D51.00008 Patterned Liquid Crystal Droplets, JAKUB KOLACZ, ANDREW KONYA, Kent State University Liquid Crystal Institute, JULIO AVILA, California State University, FENG WANG, QI-HUO WEI, Kent State University Liquid Crystal Institute — Geometrical confinement has a significant influence on the structure and properties of liquid crystals. Prior research in this area is mainly on polymer-dispersed liquid crystals and liquid crystals in porous media where the liquid crystal droplets are usually non-uniform in size. Here we use microfabrication techniques to pattern liquid crystals into droplets of different geometrical shapes and sizes, and study the liquid crystal ordering in these liquid crystal droplets. The experimental observations will be compared with simulation results.

4:06PM D51.00009 The mechanism of controlling liquid crystal surface pretilt angle on plasma beam sputtered films¹, RU-PIN PAN, National Chiao Tung University, MENG-CHIOU HUANG, Institute of Atomic and Molecular Sciences, Academia Sinica, WEI-TA WU, CHENG-WEI LAI, HSIN-YING WU, National Chiao Tung University — In liquid crystal (LC) devices, the surface alignment is essential. The polyimide (PI) film is commonly used to make LC molecules parallel to the surface. A rubbing process is usually applied to choose a particular direction on the surface. A pretilt angle is also induced, which is useful but usually very small. In previous works, we have found out that the sputtered ion-oxide films can give a homeotropic alignment to LC, i.e., the LC molecules are perpendicular to the surface. In this work, we combine these two effects by sputtering the ion-oxide particles onto the PI coated glasses. By adjusting the sputtering conditions, the LC alignment are controlled. A wide range of pretilt angles have been achieved, while the rubbing process is no longer required. A thorough study by varying the sputtering conditions, such as voltage, current, and time duration, and observing the pretilt angles is carried out. The sputtered surfaces are examined with scanning electron microscope to see the coverage. By considering the charge distribution and electric field within the sputter, a quantitative model is then developed, which explains how the sputtering conditions affect the pretilt angles almost perfectly.

¹Supported by National Science Council, ROC, under grand number 96-2221-E-009-131-MY3 and Academia Sinica AS-98-TP-A10.

4:18PM D51.00010 Transient Splitting of Conoscopic Isogyres of a Uniaxial Nematic¹, YOUNG-KI KIM, BOHDAN SENUK, LUANA TORTORA, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, Kent, OH, USA, SAMUEL SPRUNT, Physics Department, Kent State University, Kent, OH, USA, MATTHIAS LEHMANN, Institute of Chemistry, Chemnitz University of Technology, Chemnitz, Germany, OLEG D. LAVRENTOVICH, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, Kent, OH, USA — The phase identification is often based on conoscopic observations of homeotropic cells: A uniaxial nematic produces a pattern with crossed isogyres, while the biaxial nematic shows a split of isogyres. We demonstrate that the splitting of isogyres occurs even when the material remains in the uniaxial nematic phase. In particular, in the bent core material J35, splitting of isogyres is caused by change of the temperature. The effect is transient and the isogyres return to a uniaxial (crossed) configuration after a certain time that depends on sample thickness, temperature, and rate of temperature change; the time varies from a few seconds to tens of hours. The transient splitting is caused by the temperature-induced material flow that triggers a (uniaxial) director tilt in the cell. The flows and the director tilt are demonstrated by the CARS microscopy and fluorescent confocal polarizing microscopy (FCPM). This transient effect is general and can be observed even in E7 and 5CB. The effect should be considered in textural identifications of potential biaxial nematic materials.

¹The work was supported by DOE grant DE-FG02-06ER46331 and by SEC.

4:30PM D51.00011 A comparison between “cybotactic” groups in bent-core and rod-like nematic liquid crystals, SAONTI CHAKRABORTY, NICHOLAS DIORIO, WILL CARR, JAMES GLEESON, ANTAL JAKLI, SAMUEL SPRUNT, Kent State University — It is becoming increasingly clear that short-range smectic-CP order is the basis for some of the unusual macroscopic properties of bent-core nematic (BCN) liquid crystals. By analyzing small angle X-ray diffraction patterns taken on a bent-core and a chemically related calamitic (rod-like) nematic, we have attempted to clarify the nature of the “cybotactic groups” (or molecular clusters) contributing to this short-range order in BCNs, and to distinguish their signature from the scattering due to smectic fluctuations normally observed above a nematic to smectic transition. We find that persistent, finite-sized, tilted smectic clusters, with short, temperature-independent correlation lengths, account for the scattering observed from the BCN, while the calamitic material provides a remarkably clear example of temperature-dependent fluctuations in smectic order observed even far above a smectic-C phase. Supported by NSF DMR-0964765

4:42PM D51.00012 Optimizing liquid crystalline properties for bio-sensing at aqueous interfaces¹, WILDER IGLESIAS, Kent State University, NICHOLAS L. ABBOTT, University of Wisconsin, ELIZABETH K. MANN, ANTAL JÁKLI, Kent State University — Recent studies show that surfactant or phospholipid assemblies can be monitored at interfaces between aqueous solutions and thermotropic liquid crystals. The capability of these liquid crystals to change birefringence with the reordering induced by the decorated surface allows to study and characterize dynamical phenomena happening at the interfaces. In this work we tune the surface anchoring and the viscoelastic properties of the liquid crystal mesogens in order to increase sensitivity and optimize the response to events at the surface.

¹This Work was supported by NSF DMR-0907055.

4:54PM D51.00013 Competing Ordering Processes at Liquid Crystal Surfaces Laden with Semifluorinated Alkane Molecules, XUNDA FENG, Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, D-37077 Göttingen, Germany, AHMED MOURRAN, MARTIN MOELLER, DWI an der RWTH Aachen e.V. and Institute for Technical and Macromolecular Chemistry, RWTH Aachen, Forckenbeckstr. 50, D-52056 Aachen, Germany, CHRISTIAN BAHR, Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, D-37077 Göttingen, Germany — Ellipsometric measurements elucidate the interplay between the surface order at the isotropic liquid crystal/air interface and a structural phase transition in a Gibbs film on the same interface. Gibbs films formed by the semifluorinated alkane C18H37–C12F25 exhibit a sharp transition from a dilute state at higher temperatures to a dense state at lower temperatures. The transition temperature can be tuned by controlling the C18H37–C12F25 concentration in the bulk liquid crystal phase. When the transition takes place in the temperature range in which a molecular thin smectic or nematic film exists at the isotropic liquid crystal/air interface, the smectic surface order is destroyed while the nematic surface order is affected by a change of the orientation of the liquid crystal molecules. The ellipsometric data indicate that both behaviors result from a change of the anchoring condition of the liquid crystal molecules in contact with the Gibbs film.

5:06PM D51.00014 Revealing the inner arrangement of cholesteric liquid crystals confined in polymeric electrospun fibers¹, GIUSY SCALIA, Seoul National University, EVA ENZ, MLU Halle-Wittenberg, VERA LA FERRARA, ORONZO CALÓ, ENEA C.R. Portici, JAN LAGERWALL, Seoul National University — Cholesteric liquid crystals, like other types of LCs, can be confined inside polymeric fibers by coaxial electrospinning. In this way the interesting optical properties of cholesterics could be transferred to very long fibers that can form flexible or rigid mats according to the outer sheath material. Selective reflection was easily detected from polymeric fibers with cholesteric LC core. Despite the uniformity of the external morphology of the fibers, evaluated by SEM, defects in the optical texture could be observed in some locations as well as differences in the wavelength of the reflected light. The reason for such differences needs to be clarified in order to achieve a uniform, controlled optical texture. The understanding was achieved by direct observation of the cross section of the LC-filled fibers by cutting and sectioning the fibers by Focused Ion Beam (FIB). This revealed differences in dimensions of the inner cavity correlating them to the observed wavelengths of the selectively reflected light, but also changes in shape, in some parts with strongly varying width that accounts for the defect lines observed. We could also visualize the effect of flow instability of the jet during spinning, inducing the formation of chains of LC droplets.

5:18PM D51.00015 Macroscopic torsional strain and induced molecular conformational deracemization, RAJRATAN BASU, JOEL PENDERY, ROLFE PETSCHKE, Case Western Reserve University, ROBERT LEMIEUX, Queen's University, CHARLES ROSENBLATT, Case Western Reserve University — A macroscopic helical twist is imposed on an achiral nematic liquid crystal by controlling the azimuthal alignment directions at the two substrates. On application of an electric field the director rotates in the substrate plane. This electroclinic effect, which requires the presence of chirality, is strongest at the two substrates and increases with increasing imposed twist distortion. We present a simple model involving a tradeoff among bulk elastic energy, surface anchoring energy, and deracemization entropy that suggests the large equilibrium director rotation at the surfaces induces a deracemization of chiral conformations in the molecules, quantitatively consistent with experiment.

153C

2:30PM D52.00001 Dynamic phase transition in the classical anisotropic XY model on a square lattice¹, WILLIAM BAEZ, The Ohio State University, TRINANJAN DATTA, Augusta State University — Ginzburg-Landau analysis of the anisotropic XY model in a spatially homogeneous oscillating magnetic field on a square lattice suggests the existence of several dynamical phases - Ising symmetry restoring order (Ising SRO), Ising symmetry breaking order (SBO), XY symmetry restoring order (XY SRO), and XY symmetry breaking order (XY SBO). We investigate the presence of these phases and the dynamic phase transition (DPT) between these phases using classical Monte Carlo simulation techniques. We explore the system for a range of values for the external field amplitude, field frequency, and anisotropy parameter. Utilizing the period-averaged magnetization (in both the x- and y- component) as the dynamic order parameter we confirm the presence of multiple DPT transitions in the model. We also construct the probability density histograms of the dynamic order parameter to validate the existence of the four DPT phases.

2:42PM D52.00002 Non-universal local critical exponents at a non-equilibrium phase transition¹, MICHEL PLEIMLING, HYUNHANG PARK, Virginia Tech — We study the dynamic phase transition in the two-dimensional semi-infinite kinetic Ising model in an oscillating field. We focus on the critical regime where the competition between the half-period of the oscillating field $t_{1/2}$ and the metastable lifetime $\langle \tau \rangle$ is most pronounced. We focus on layer-dependent quantities, such as the period-averaged magnetization per layer $Q(z)$ and the layer susceptibility $\chi_Q(z)$, and determine surface critical exponents through finite size scaling. We find that the values of these non-equilibrium exponents are non-universal as they depend on the strength of the surface couplings. Results for the three-dimensional model are also briefly discussed and compared to the two-dimensional case.

3:06PM D52.00004 Extremal Optimization for p-Spin Models¹ , STEFAN FALKNER, STEFAN BOETTCHER,

Emory University — It was shown recently that finding ground states in the 3-spin model on a 2d dimensional triangular lattice poses an NP-hard problem [1]. We use the extremal optimization (EO) heuristic [2] to explore ground state energies and finite-size scaling corrections [3]. EO predicts the thermodynamic ground state energy with high accuracy, based on the observation that finite size corrections appear to decay purely with system size. Just as found in 3-spin models on r -regular graphs, there are no noticeable anomalous corrections to these energies. Interestingly, the results are sufficiently accurate to detect alternating patterns in the energies when the lattice size L is divisible by 6. Although ground states seem very prolific and might seem easy to obtain with simple greedy algorithms, our tests show significant improvement in the data with EO.

3:18PM D52.00005 A novel Kinetic Monte Carlo algorithm for Non-Equilibrium Simulations

, PRATEEK JHA, Northwestern University, VLADIMIR KUZOVKOV, University of Latvia, BARTOSZ GRZYBOWSKI, MONICA OLVERA DE LA CRUZ, Northwestern University — We have developed an off-lattice kinetic Monte Carlo simulation scheme for reaction-diffusion problems in soft matter systems. The definition of transition probabilities in the Monte Carlo scheme are taken identical to the transition rates in a renormalized master equation of the diffusion process and match that of the Glauber dynamics of Ising model. Our scheme provides several advantages over the Brownian dynamics technique for non-equilibrium simulations. Since particle displacements are accepted/rejected in a Monte Carlo fashion as opposed to moving particles following a stochastic equation of motion, nonphysical movements (e.g., violation of a hard core assumption) are not possible (these moves have zero acceptance). Further, the absence of a stochastic “noise” term resolves the computational difficulties associated with generating statistically independent trajectories with definitive mean properties. Finally, since the timestep is independent of the magnitude of the interaction forces, much longer time-steps can be employed than Brownian dynamics. We discuss the applications of this scheme for dynamic self-assembly of photo-switchable nanoparticles and dynamical problems in polymeric systems.

3:30PM D52.00006 How an aggregation process helps us understanding solid fragmentation ,

VLEDOUTS ALEXANDRE, NICOLAS VANDENBERGHE, EMMANUEL VILLERMAUX, IRPHE — We report on an experiment intended to understand the fragmentation of a ring composed of cohesive solid spheres (magnets in dipolar interaction). At initial time, the ring is forced to expand radially and the spheres separate from each other. Because of the dipolar attractive force between the spheres, their uniform angular distribution is unstable and the spheres aggregate with each other to form fragments. We record the full dynamics of the spheres assembly and we show that the final fragment size distribution is the signature of the aggregation process giving birth to it. In particular, we introduce a Weber number We , based on the radial velocity of the ring, the density of the spheres and their magnetization. We find that the final mean fragment size scales like $We^{-1/3}$ and that the standard deviation of the fragments distribution is proportional to it. We will also discuss the relation between our findings and the fragmentation of elastic rings studied by Sir N. Mott.

3:42PM D52.00007 Thermodynamic limit, quasi-stationary states and the range of pair inter-

actions , ANDREA GABRIELLI, Istituto dei Sistemi Complessi - CNR (Rome, Italy), MICHAEL JOYCE, LPNHE - Université Paris 6 (France), BRUNO MARCOS, Lab. J.A. Dieudonné, UMR 6621, Université de Nice (France) — “Quasi-stationary” states are approximately time-independent out of equilibrium states which have been observed in a variety of systems of particles interacting by long-range interactions. We investigate here the conditions of their occurrence for a generic pair interaction $V(r \rightarrow \infty) \sim 1/r^\gamma$ with $\gamma > 0$, in $d > 1$ dimensions. We generalize analytic calculations known for gravity in $d = 3$ to determine the scaling parametric dependences of their relaxation rates due to two body collisions, and report extensive numerical simulations testing their validity. Our results lead to the conclusion that, for $\gamma < d - 1$, the existence of quasi-stationary states is ensured by the large distance behavior of the interaction alone, while for $\gamma > d - 1$ it is conditioned on the short distance properties of the interaction, requiring the presence of a sufficiently large soft-core in the interaction potential.

3:54PM D52.00008 ABSTRACT WITHDRAWN —

4:06PM D52.00009 Numerical study of Potts models with aperiodic modulations: influence

on first-order transitions¹ , NILTON BRANCO, Departamento de Fisica, Universidade Federal de Santa Catarina, Florianopolis, SC, Brazil, DANIEL GIRARDI, National Institute of Science and Technology for Complex Systems, Universidade Federal Fluminense, Volta Redonda, RJ, Brazil — We perform a numerical study of Potts models on a rectangular lattice with aperiodic interactions along one spatial direction. The number of states q is such that the transition is a first-order one for the uniform model. The Wolff algorithm is employed, for many lattice sizes, allowing for a finite-size scaling analyses to be carried out. Three different self-dual aperiodic sequences are employed, such that the exact critical temperature is known: this leads to precise results for the exponents. We analyze models with $q = 6$ and 15 and show that the Harris-Luck criterion, originally introduced in the study of continuous transitions, is obeyed also for first-order ones. The new universality class that emerges for relevant aperiodic modulations depends on the number of states of the Potts model, as obtained elsewhere for random disorder, and on the aperiodic sequence. We determine the occurrence of log-periodic behavior, as expected for models with aperiodic modulated interactions.

4:18PM D52.00010 BREAK —

4:30PM D52.00011 Boundaries Matter for Confined Colloidal Glasses , GARY HUNTER, Emory University,

KAZEM V. EDMOND, New York University, ERIC R. WEEKS, Emory University — We confine dense colloidal suspensions within emulsion droplets to examine how confinement and properties of the confining medium affect the colloidal glass transition. Samples are imaged via fast confocal microscopy. By observing a wide range of droplet sizes and varying the viscosity of the external continuous phase, we separate finite size and boundary effects on particle motions within the droplet. Suspensions are composed of binary PMMA spheres in organic solvents while the external phases are simple mixtures of water and glycerol. In analogy with molecular super-cooled liquids and thin-film polymers, we find that confinement effects in colloidal systems are not merely functions of the finite size of the system, but are strongly dependent on the viscosity of the confining medium and interactions between particles and the interface of the two phases.

4:42PM D52.00012 Dynamics near shear-jamming for a dense granular system¹, JIE REN, JOSHUA DIJKSMAN, ROBERT BEHRINGER, Duke University — This talk will present several systematic experimental studies of a two-dimensional, frictional dense granular system subjected to simple shear deformation. The first experiment consists of linear shear for densities smaller than the isotropic jamming point, and examines both the evolution of the average stress and the evolution of force network. These measures reveal three distinguishable regimes of the granular system with increasing shear strain: unjammed, fragile, and shear-jammed regimes. The second experiment uses small amplitude cyclic shear to probe the dynamical response of the states from the first experiment. For fragile or jammed regimes, cyclic shear drives the system through transient states that evolve towards relatively stable forces networks and system-averaged stress. The timescale of the transient increases rapidly as the system moves deeper into the fragile, or shear-jammed regimes. These experiments also involve particle tracking (displacements and rotations) to search for and characterize non-affine motion and spatial heterogeneity. There is a clear increase in particle diffusion with increasing density and shear strain amplitude, even when the system is still unjammed and experiences only minimal stress. When the system is fragile or jammed, the heterogeneity of particle displacements reveals subtle correlations with the force network.

4:54PM D52.00013 Elasticity of adherent active cells on a compliant substrate¹, SHILADITYA BANERJEE, Department of Physics, Syracuse University, AARON F. MERTZ, ERIC R. DUFRESNE², Department of Physics, Yale University, M. CRISTINA MARCHETTI, Department of Physics and Syracuse Biomaterials Institute, Syracuse University — We present a continuum mechanical model of rigidity sensing by living cells adhering to a compliant substrate. The cell or cell colony is modeled as an elastic active gel, adapting recently developed continuum theories of active viscoelastic fluids. The coupling to the substrate enters as a boundary condition that relates the cell's deformation field to local stress gradients. In the presence of activity, the substrate induces spatially inhomogeneous contractile stresses and deformations, with a power law dependence of the total traction forces on cell or colony size. This is in agreement with recent experiments on keratinocyte colonies adhered to fibronectin coated surfaces. In the presence of actomyosin activity, the substrate also enhances the cell polarization, breaking the cell's front-rear symmetry. Maximal polarization is observed when the substrate stiffness matches that of the cell, in agreement with experiments on stem cells.

5:06PM D52.00014 Differential geometry of the space of Ising models, BENJAMIN MACHTA, RICKY CHACHRA, Department of Physics, Cornell University, MARK TRANSTRUM, Department of Bioinformatics and Computational Biology at the MD Anderson Cancer Center, JAMES SETHNA, Department of Physics, Cornell University — We use information geometry to understand the emergence of simple effective theories, using an Ising model perturbed with terms coupling non-nearest-neighbor spins as an example. The Fisher information is a natural metric of distinguishability for a parameterized space of probability distributions, applicable to models in statistical physics. Near critical points both the metric components (four-point susceptibilities) and the scalar curvature diverge with corresponding critical exponents. However, connections to Renormalization Group (RG) ideas have remained elusive. Here, rather than looking at RG flows of parameters, we consider the reparameterization-invariant flow of the manifold itself. To do this we numerically calculate the metric in the original parameters, taking care to use only information available after coarse-graining. We show that under coarse-graining the metric contracts very anisotropically, leading to a “sloppy” spectrum with the metric's Eigenvalues spanning many orders of magnitude. Our results give a qualitative explanation for the success of simple models: most directions in parameter space become fundamentally indistinguishable after coarse-graining.

5:18PM D52.00015 Seeing and Sculpting Nematic Liquid Crystal Textures with the Thom construction, BRYAN CHEN, University of Pennsylvania, GARETH ALEXANDER, University of Warwick — Nematic liquid crystals are the foundation for modern display technology and also exhibit topological defects that can readily be seen under a microscope. Recently, experimentalists have been able to create and control several new families of interesting defect textures, including reconfigurably knotted defect lines around colloids (Ljubljana) and the “toron,” a pair of hedgehogs bound together with a ring of double-twist between them (CU Boulder). We apply the Thom construction from algebraic topology to visualize 3 dimensional molecular orientation fields as certain colored surfaces in the sample. These surfaces turn out to be a generalization to 3 dimensions of the dark brushes seen in Schlieren textures of two-dimensional samples of nematics. Manipulations of these surfaces correspond to deformations of the nematic orientation fields, giving a hands-on way to classify liquid crystal textures which is also easily computable from data and robust to noise.

Monday, February 27, 2012 2:30PM - 5:30PM –
Session D53 GSNP DFD: Focus Session: Jamming – Nonlinear Acoustics and Vibrational Response 153B

2:30PM D53.00001 Vibrational Modes in Colloidal Crystals, KE CHEN, TIM STILL, Department of Physics and Astronomy, University of Pennsylvania, KEVIN APTOWICZ, Department of Physics, West Chester University, ARJUN YODH, Department of Physics and Astronomy, University of Pennsylvania — We investigate vibrational modes in quasi-two-dimensional colloidal crystals using video microscopy and displacement covariance matrix analysis. Debye scaling in the phonon density of states and the dispersion curve for two-dimensional hexagonal crystals are recovered for both mono-layer and double layer colloidal crystals. Using “soft spots” analysis, low-frequency quasi-localized phonon modes, which were found to coincide with fragile regions in glasses [1] appear to be spatially correlated with structural defects in colloidal crystals. Thus, “soft spots” may be a useful general identifier for defects in both crystalline and amorphous solids. This work is supported by NSF DMR 0804881, MRSEC DMR11-20901, and by NASA NNX08AO0G.

2:42PM D53.00002 Acoustic measurement of a granular density of state, ELI OWENS, KAREN DANIELS, North Carolina State University — Measurements of the vibrational density of states $D(\omega)$ in glasses reveal that an excess number of low-frequency modes is associated with a loss of mechanical rigidity. An excess number of such modes has also been observed in both simulations of idealized granular materials near the jamming point, and in experiments on colloids. We experimentally investigate similar features in a jammed, quasi-two-dimensional granular material. We mimic thermal fluctuations using an electromagnetic driver to inject acoustic white noise, while piezoelectric sensors embedded inside a subset of the particles provide measurements of single-particle velocities. By analogy with conventional thermal techniques, we calculate a $D(\omega)$ -like quantity via the spectrum of the velocity autocorrelation function. We measure $D(\omega)$ as a function of the confining pressure and find that the peak in the density of states shifts to higher frequency with system pressure. At low pressure, disordered systems have more low frequency modes than do hexagonally-packed systems.

2:54PM D53.00003 Elastic weakening of a dense granular medium by acoustic fluidization, XIAOPING JIA, JEROME LAURENT, Université Paris-Est, SIET WILDENBERG, MARTIN VAN HECKE, Universiteit Leiden, LPMDI TEAM, ONNES LAB TEAM — Elastic waves propagating through a dense granular pack provide a unique probe of the elastic properties and internal dissipation of the medium [1], and also allow investigating the irreversible rearrangement of the contact network at large vibration amplitude. In this talk, we describe two distinct types of nonlinearity, i.e. hertzian and frictional, at the grain contact by sound amplitude and velocity measurements, respectively, under different confining pressure [2]. Beyond certain wave amplitude, the sound-matter interaction becomes irreversible, leaving the medium in a weakened and slightly compacted state. A slow recovery of the initial elastic modulus is observed after acoustic perturbation, revealing the plastic creep growth of microcontacts. The cross-correlation function of configuration-specific acoustic speckles highlights the relationship between the macroscopic elastic weakening and the local change of the contact networks, induced by strong sound vibration, in the absence of appreciable grain motion. We show that the softening of elastic modulus is much more pronounced with the shear wave (up to 20%) than with the compressional wave (to 10%).

3:06PM D53.00004 Nonharmonicity in vibrated granular solids, CARL SCHRECK, Yale University — We have shown that granular packings composed of frictionless particles with repulsive contact interactions are strongly nonharmonic. When infinitesimally perturbed along linear response eigenmodes of the static packing, energy leaks from the original mode of vibration to a continuum of frequencies due solely to contact breaking even when the system is under significant compression. Further, vibrated packings possess well-defined equilibrium positions that are different than those of the unperturbed packing. The vibrational density of states obtained using the displacement matrix and velocity autocorrelation function methods exhibit an increase in the number of low-frequency modes over that obtained from linear response of the static packing. The form of the density of states in vibrated granular packings is reminiscent of the low-frequency behavior of the vibrational density of states in fluid systems. We also investigate the effects of inter-particle friction, dissipation, particle shape, and degree of positional order on the density of states and thermal transport properties in driven granular packings.

3:42PM D53.00005 Irreversible Incremental Behavior in a Granular Material¹, LUIGI LA RAGIONE, Cornell University, VANESSA MAGNANIMO, MSM, CTW, University of Twente, 7500EA Enschede (NL), JAMES JENKINS, Cornell University, HERNAN MAKSE, City College New York — We test the elasticity of dense, isotropic, compressed aggregates of frictional spheres using cyclic increments of shear and volume strain in a numerical simulation. For both types of increments, we measure irreversibility in relative displacements and contact forces that is stronger for the increments in shear. The strength of the irreversibility increases as the average number of contacts per particle (the coordination number) decreases. This irreversibility may be associated with the opening of contacts in an increment of loading, pointed out in a recent paper of Schreck et al. (PRL, 2011); such contact opening could lead to irreversible rearrangement of the contact network when the increment is relaxed.

¹Office of Naval Research, Global

3:54PM D53.00006 Experimental Measurements of Force Propagation in Vibrated Photoelastic Disks¹, ALINE HUBARD, MARK SHATTUCK, CUNY Graduate Center and the Benjamin Levich Institute and Physics Department of The City College of New York — We measure and analyze the propagation forces in vibrated disks under constant pressure with different amplitudes and frequencies. We use photoelastic particles to visualize the stress within each particle using a high-speed video camera. From the images we can extract the time dependent force at each contact to determine how force propagates through the contact network. Using mono-disperse particles we focus on force propagation during the phase transition from an ordered solid-like state to a disordered fluid-like state as we change the vibration amplitude. With bi-disperse particles we compare with the transition to a disordered solid-like state.

¹Supported by NSF PREM (DMR-0934206).

4:06PM D53.00007 Nonlinear acoustics of glass bead packings at vanishing static pressures¹, VINCENT TOURNAT, LAUM, CNRS, Université du Maine, Le Mans, France, VITALYI GUSEV, LPEC, CNRS, Université du Maine, Le Mans, France — We present here a set of recent results obtained in three experimental configurations: linear and nonlinear acoustic probing of a granular slab at different compacities, surface acoustic waves in granular layers submitted to gravity, resonances of a granular layer with an in-depth elasticity gradient. We succeeded to overcome the experimental issues associated to the dramatic increase of acoustic wave attenuation when the confining pressure diminishes. Interpretations reveal that the manifestations of nonlinear effects (self-demodulation, nonlinear resonance, second harmonic or subharmonic generation...) allow to isolate the different types of nonlinearities involved (Hertz, clapping, stick-slip, hysteresis...). Also, some discrepancies are observed for the extracted linear elastic parameters scaling laws as a function of vanishing pressure (lower than 100 Pa typically) between the different developed experimental configurations and the theoretical predictions. Explanations for these discrepancies are given. We show that under some conditions, it is necessary to take into account the coupling of grain motion with that of the saturating air. Application of these results to the probing of granular layers under destabilization will be presented.

4:18PM D53.00008 Acoustic Echoes in Model Glasses, JUSTIN BURTON, SIDNEY NAGEL, The University of Chicago — At low temperatures, glasses and crystals behave in qualitatively different ways. In particular, glasses have a great many more low-energy excitations that have traditionally been explained in terms of a distribution of dilute, two-level quantum states that are created by clusters of particles tunneling between two nearly degenerate ground states. Strong evidence for this model has come from the saturation effects and acoustic echoes [1] observed in these excitations. We show that, in contrast to conventional wisdom, the quasi-localized, strongly anharmonic, normal modes of jammed systems [2] can produce acoustic echoes due to the shift in the mode frequency with increasing amplitude. We observe this both in jammed packings of spherical particles with finite-range, Hertzian repulsions, and in model glasses interacting with a Lennard-Jones potential. In contrast to pulse echoes in two-level systems, a distinguishing feature of these “anharmonic echoes” is the appearance of multiple echoes after two excitation pulses, a feature also observed in experiments [1].

4:30PM D53.00009 Extreme Physics and Rearrangements near Jamming, MARTIN VAN HECKE, Leiden University, ZORANA ZERAVCIC, Harvard University, ALEX SIEMENS, JOHANNES SIMON, DANIEL GELEN, Leiden University — Near jamming, linear response becomes irrelevant. I briefly discuss how this gives rise to a range of intrinsically nonlinear, even extreme, phenomena. Moreover, reversibility also breaks down, and I will discuss the nature of rearrangements near jamming.

4:42PM D53.00010 Formation, Propagation, and Attenuation of Shocks Waves in Jammed Matter, LEOPOLDO GOMEZ, Leiden University - Universidad Nacional del Sur - CONICET, VINCENZO VITELLI, Leiden University — We study the formation and propagation of fully non-linear waves in jammed granular media. Close to the jamming point, an arbitrary initial distortion of the media will induce the formation of non-linear finite amplitude waves. There are two regimes in the evolution of these waves. At early times non-linear interactions dominate the propagation, leading to a temporal evolution strongly dependent on the initial distortion. At long times the propagation is characterized by a new universal regime, dominated by hydrodynamical attenuation. Here the non-linear waves evolve in a self-similar fashion, characterized by a power law attenuation whose exponent is weakly dependent on the initial pressure of the system.

4:54PM D53.00011 Jamming of soft spheres at finite temperature : a granular experiment, CORENTIN COULAIS, CEA Saclay, OLIVIER DAUCHOT, ESPCI, ROBERT BEHRINGER, Duke University, GIT - SPEC - CEA SACLAY TEAM, ESPCI TEAM¹, GIT-SPEC-CEA SACLAY / BEHRINGER'S GROUP AT DUKE COLLABORATION — At large packing fraction, disordered packings of particles with repulsive contact interactions jam into a rigid state where they withstand finite shear stresses before yielding. For frictionless particles and at zero temperature, the jamming transition coincides with the onset of iso-staticity and many geometrical and mechanical properties scale with the distance to the jamming point. What are the vestige of jamming at finite temperature and how jamming impacts the thermodynamics of glasses remain open issues. We address these questions experimentally by investigating the dynamics of both the density field and the force network of an horizontally shaken bi-disperse packing of photo-elastic disks. The average number of contact clearly displays an abrupt transition which we interpret as the jamming transition. Besides, dynamical heterogeneities are observed and their amplitude exhibits a maximum, which, in turn, signs a dynamical transition. We discuss in detail the interplay between these two transitions and how they depend on the particle softness and amplitude of the horizontal vibration.

¹The Team is in Saclay and Olivier Dauchot has recently move to ESPCI

5:06PM D53.00012 Density of vibrational modes in partially crystalline granular packings¹, THIBAUT BERTRAND, Yale University, Dpt of Mechanical Engineering, CARL F. SCHRECK, Yale University, Dpt of Physics, MARK SHATTUCK, Benjamin Levich Institute and Physics Department, The City College of the City University of New York, COREY S. O'HERN, Yale University, Dpt of Mechanical Engineering, O'HERN GROUP, YALE UNIVERSITY TEAM — Numerous numerical results have shown that systems of monodisperse frictionless disks crystallize readily and that disordered mechanically stable packings are rarely obtained. We numerically investigate the dependence of the cluster size distribution on system size and quench rate. We also investigate the effect of crystallization on the vibrational response outside the linear response regime. We study changes in the density of vibrational modes due to changes in the average crystallite size and perturbation amplitude in partially crystalline granular packings. In particular we determine how the number of contacts (above the isostatic value) affects anharmonic response in granular packings.

5:18PM D53.00013 Studying the low-frequency quasilocalized modes in disordered colloidal systems, LEI XU, PENG TAN, Physic Dept., The Chinese University of Hong Kong, NING XU, Physic Dept., The University of Science and Technology of China, ANDREW SCHOFIELD, Physic Dept., University of Edinburgh — In disordered colloidal systems, we experimentally measure the normal modes with covariance matrix method, and clarify the origin of low-frequency quasilocalization at single-particle level. We observe important features from both jamming and glass simulations: there is a plateau in the density of states which is suppressed upon ompression, as predicted by jamming; within the same systems, we also find that the low-frequency quasilocalization originates from the coupling between large vibrations of defective structures and transverse excitations, consistent with recent glass simulation. The coexistence of these features demonstrates an experimental link between jamming and glass. Extensive simulations further show that such structural origin of quasilocalization is universally valid for various temperatures and volume fractions.

2:30PM D54.00001 Dynamics of Random Graphs with Bounded Degrees, ELI BEN-NAIM, Los Alamos National Laboratory, PAUL KRAPIVSKY, Boston University — We investigate the dynamic formation of regular random graphs. In our model, we pick a pair of nodes at random and connect them with a link if both of their degrees are smaller than d . Starting with a set of isolated nodes, we repeat this linking step until a regular random graph, where all nodes have degree d , forms. We view this process as a multivariate aggregation process, and formally solve the evolution equations using the Hamilton-Jacobi formalism. We calculate the nontrivial percolation thresholds for the emergence of the giant component when $d \geq 3$. Also, we estimate the number of steps until the giant component spans the entire system and the total number of steps until the regular random graph forms. These quantities are non self-averaging, namely, they fluctuate from realization to realization even in the thermodynamic limit.

2:42PM D54.00002 Influence of Boundary Conditions on Metastable Lifetimes for The Ising Model on the Hyperbolic Plane¹, HOWARD L. RICHARDS, Physics, Marshall University, DIPENDRA SHARMA CHAPAGAIN, Physics, Berea College, JAMES MOLCHANOFF, Math, West Virginia Wesleyan University — Some corals grow in shapes that resemble 3D models of the hyperbolic plane, since this allows them to have greater area for a given growth radius. Each polyp could be represented by an Ising site, with "feeding" = "up" and "retracted" = "down". The mechanisms of metastable decay could be interpreted as how the coral as a whole reacts to changing conditions of food availability or predation. Previous studies have shown that there is a spinodal field for the Ising model on a regular lattice in the hyperbolic plane if it is infinite or has periodic or mean-field boundary conditions. This happens because the size of the boundary grows asymptotically at the same rate as the droplet volume, in clear contrast with droplets in the Euclidean plane. Our simulations show, however, that the spinodal field disappears if more physically relevant open boundary conditions are used instead.

2:54PM D54.00003 Quantifying the complexity of random Boolean networks¹, XINWEI GONG, JOSHUA E.S. SOCOLAR, Department of Physics, Duke University — We study two measures of the complexity of spatially extended systems in the context of random Boolean networks. A measure defined by Shalizi et al. for cellular automata, based on a criterion for optimal statistical prediction [1], does not distinguish between the spatial inhomogeneity of the ordered phase and the dynamical inhomogeneity of the disordered phase. A modification in which complexities of individual nodes are calculated yields vanishing complexity values for networks in the ordered and critical regimes and for highly disordered networks, peaking somewhere in the disordered regime. Individual nodes with high complexity are the ones that pass the most information from the past to the future, a quantity that depends in a nontrivial way on both its own Boolean function and the location of the node within the network.

3:06PM D54.00004 Synchronization in Noisy Networks with Multiple Time Delays¹, DAVID HUNT, GYORGY KORNISS, BOLESŁAW SZYMANSKI, Rensselaer Polytechnic Institute — We expand our previous work of uniform time delays in stochastic, linearly-coupled synchronization problems² by including descriptions of networks with multiple delays. Non-uniform time delays can arise when there are multiple sources of delay, e.g. the time to transmit and the time to process information. In this particular two-delay case³, the primary limitation on the network to synchronize without any centralized direction does not come from restrictions in the transmission of a node's state to its neighbors; rather it depends on the ability for each node to process and respond to the information about itself in the context of its local environment. Furthermore, given a network's structure, there are optimal transmission delays for which the network remains synchronizable for longer processing delays. As a result, synchronization is not always improved—and in some cases it can be totally destroyed—by minimizing the transmission delays. For special cases we also study the scaling function that quantifies the synchronization of the system. This shows the limitation of synchronization in a noisy network

3:18PM D54.00005 Continuous Percolation by Discontinuities, JAN NAGLER, MPI DS, Goettingen — In the very recent article [Science **333**, 322 (2011)], O. Riordan and L. Warnke, state that (i) *any rule based on picking a fixed number of random vertices gives a continuous transition*, and (ii) that therefore *explosive percolation is continuous*. It is equally true that certain percolation processes based on picking a fixed number of random vertices are discontinuous. Here we resolve this seeming paradox. We exemplify this by studying an extremal case of a process that is continuous in the sense of Riordan and Warnke but still exhibits infinitely many discontinuous jumps in arbitrary vicinity of the onset of the continuous phase transition. Moreover, we demonstrate analytically that continuity at the phase transition and discontinuity of the percolation process are compatible and generic for certain competitive percolation systems.

3:30PM D54.00006 Random Transverse Ising Model on Annealed Complex Networks, GINESTRA BIANCONI, Northeastern University — In order to shed light on critical phenomena on cuprates, here we propose a stylized model capturing the essential characteristics of the superconducting-insulator transition of a highly dynamical, heterogenous granular material: the Disordered Quantum Transverse Ising Model (DQTIM) on Annealed Complex Network. We show that when the networks encode for high heterogeneity of the expected degrees described by a power law distribution, the critical temperature for the onset of the superconducting phase diverges to infinity as the power-law exponent γ of the expected degree distribution is less than 3, i.e. $\gamma < 3$. Moreover we investigate the case in which the critical state of the electronic background is triggered by an external parameter g that determines an exponential cutoff in the power law expected degree distribution characterized by an exponent γ . We find that for $g = g_c$ the critical temperature for the superconductor-insulator transition has a maximum if $\gamma > 3$ and diverges if $\gamma < 3$.

3:42PM D54.00007 Dynamical Instability in Boolean Networks as a Percolation Problem, SHANE SQUIRES, MICHELLE GIRVAN, EDWARD OTT, University of Maryland – College Park — Boolean networks, a widely used model of gene regulatory networks, exhibit a phase transition between a stable regime, in which small perturbations die out, and an unstable regime, in which small perturbations grow exponentially. We show that this phase transition can be mapped onto a static percolation problem which predicts the critical point and the long-time Hamming distance between perturbed and unperturbed systems. The results, which apply to Boolean networks with a broad class of topologies and update functions, are confirmed by numerical simulations.

3:54PM D54.00008 Critical Behavior of the Ising Model on Small-world Hanoi Networks¹, TRENT BRUNSON, STEFAN BOETTCHER, Emory University — The addition of small-world bonds on hierarchical lattices changes a typical Ising model ferromagnetic phase transition to one of infinite order, referred to as the inverted-Berezinski-Kosterlitz-Thouless transition. We study this shift in phase behavior on Hanoi networks, which are one-dimensional Ising chains connected by small-world bonds that are self-similar and hierarchical in structure [1]. The phase behavior of the Ising model near T_c on Hanoi networks is studied using an exact renormalization group and Monte Carlo techniques. We show that compared to the Migdal-Kadanoff hierarchical lattice, Hanoi networks possess characteristics in their thermodynamic densities that are more physical. These densities are studied in detail and the behavior of their critical exponents near T_c is described. By introducing a continuous parameter which regulates the strength of small-world bonds in the Hanoi networks, we begin to uncover the essential small-world properties that dictate this change in phase behavior from second- to infinite-order.

4:06PM D54.00009 Popularity versus similarity in growing networks, DMITRI KRIOUKOV, University of California San Diego, FRAGISKOS PAPADOPOULOS, Cyprus University of Technology, MAKSIM KITSACK, University of California San Diego, MARIANGELES SERRANO, MARIAN BOGUNA, University of Barcelona — Preferential attachment is a powerful mechanism explaining the emergence of scaling in growing networks. If new connections are established preferentially to more popular nodes in a network, then the network is scale-free. Here we show that not only popularity but also similarity is a strong force shaping the network structure and dynamics. We develop a framework where new connections, instead of preferring popular nodes, optimize certain trade-offs between popularity and similarity. The framework admits a geometric interpretation, in which preferential attachment emerges from local optimization processes. As opposed to preferential attachment, the optimization framework accurately describes large-scale evolution of technological (Internet), social (web of trust), and biological (E.coli metabolic) networks, predicting the probability of new links in them with a remarkable precision. The developed framework can thus be used for predicting new links in evolving networks, and provides a different perspective on preferential attachment as an emergent phenomenon.

4:18PM D54.00010 Is it really a small world after all , BARUCH BARZEL, ALBERT-LASZLO BARABASI, Northeastern University, THE CENTER FOR COMPLEX NETWORK RESEARCH TEAM — One of the most intriguing revelations in the study of complex networks is the ubiquitous appearance of small worlds, that is networks exhibiting a small, and sometimes even ultra-small, average path length. This suggests that these networks feature globally connected dynamics, where all nodes are affected by all other nodes, given the short distance between them. Nevertheless, empirical data on the dynamics of such networks shows that in practice, such global connectedness is rarely observed. To address this gap between the topology and the observed dynamics of networks we developed the network correlation function method, a framework in which we obtain the patterns of influence between nodes in the network. In simple words we complement the topological description of *who is connected to whom*, by the dynamical description of *who is affected by whom*. Strikingly, using this method, we find that small world topology tends to avoid global dynamics, while non-small worlds could potentially support it. We test our results on a set of networks from various fields, ranging from social to biological networks, and discuss the implications on the dynamical stability of these systems.

4:30PM D54.00011 Metric Structure of Bipartite Networks , MAKSIM KITSACK, UCSD, FRAGKISKOS PADOPOULOS, Cyprus University of Technology., DMITRI KRIOUKOV, UCSD — Many social, biological and technological systems can be conveniently represented as bipartite networks, consisting of two disjoint sets of elements along with edges connecting only elements from different sets. Many of such systems are characterized by high values of bipartite clustering coefficient. We also find that pairs of elements in these bipartite systems tend to have many common neighbors. We present a natural interpretation of these observations. We suggest that elements of the above bipartite systems exist in underlying metric spaces, such that the observed high clustering is a topological reflection of the triangle inequality, the key property of metric space. We propose a simple stochastic mechanism of formation of bipartite networks embedded in metric spaces. We prove that this mechanism is able to reproduce the observed topological properties of bipartite networks. We also discuss the possibility of constructive embedding of real bipartite systems into metric spaces. In my talk I will overview the concept of hidden metric spaces with respect to both unipartite and bipartite networks. I will also discuss existing methods used to infer hidden metric spaces in real networks and possible applications for bipartite networks.

4:42PM D54.00012 Topological features of a fractal model for complex networks , LIN BO, HERNAN MAKSE, Levich Institute and Physics Department, the City College of New York — We study the construction and topological features of fractal and non-fractal hierarchical tree-like models generated through an inverse-renormalization growth mechanism with various parameters. These complex networks are characterized by scale-free distribution of connections, clustering coefficient, modular structure, degree correlation and a set of fractal dimensions. We compare the results with analytic expressions and show the dependence of topological properties on growing parameters. Networks with different tendency of hub-hub repulsion are produced and classified in terms of degree correlations. Interloops and intraloops are introduced into growing process to test robustness and stability of networks under attack.

4:54PM D54.00013 Control Centrality and Hierarchical Structure in Complex Networks , YANG-YU LIU, Northeastern University, JEAN-JACQUES SLOTINE, Massachusetts Institute of Technology, ALBERT-LASZLO BARABASI, Northeastern University — We introduce the concept of control centrality (C_c) to quantify the ability of a single node to control a directed weighted network. We map the control centrality into a combinatorial optimization problem. We calculate the distribution of control centrality for several real networks and find that it is mainly determined by the network's degree distribution. We show that the underlying hierarchical structure of a general directed network plays an important role in determining the distribution of control controllability. We rigorously prove that in directed acyclic graphs, i.e. directed networks without loops, a node's control centrality is uniquely determined by its topological position in the underlying hierarchical structure of the network. Our finding on the relation between control centrality and the hierarchical structure inspires us to design an effective random attack strategy against the controllability of malicious networks, without requiring the detailed knowledge of the network structure. We test our random attack strategy on several real networks and find it is indeed effective and even comparable to those targeted attacks which rely on the detailed knowledge of the network structure.

5:06PM D54.00014 A community detection approach to image segmentation and its phases , DANDAN HU, PETER RONHOVDE, ZOHAR NUSSINOV, Department of Physics, Washington University in St. Louis — In this talk, I will discuss "unsupervised" image segmentation that relies on phase diagram structure of the community detection method. Specifically, we apply a replica-inference-based community detection method. "Community detection" describes the general problem of partitioning a complex system involving many elements into optimally decoupled communities of such elements. In our image segmentation analysis, we invoke a multi-resolution community detection variant to ascertain the overall structure of the image at different resolutions. Information based measures (e.g., the normalized mutual information) are used to determine the significant structures at which "replicas" of the systems are strongly correlated. We report on the "easy", "hard", and "unsolvable" phases of the corresponding Potts model at both zero and finite temperatures. The optimal image segmentations are obtained by choosing parameters at the easy phase of the Potts model. The determination of the phase diagram in the analysis of the image segmentation is proved to be highly efficient. We demonstrate in a detailed study of various test cases that our method is fast and accurate and to be especially suited to the detection of camouflaged images.

5:18PM D54.00015 Ordinary Percolation with Discontinuous Transitions¹ , VIJAY SINGH, STEFAN BOETTCHER, Dept. of Physics, Emory University, Atlanta, GA 30322 USA — We study percolation on hierarchical networks using generating functions and renormalization group techniques. Our exact results show the presence of novel features in these networks including the existence of non-trivial critical points, three distinct regimes in the phase diagram and, most importantly, a discontinuity in the formation of the extensive cluster at a critical point $p_c < 1$. At p_c , the order parameter P_∞ describing the probability of any node to be a part of the largest cluster, jumps instantly to a finite value. We present simple examples of small-world networks with various hierarchies of long range bonds, indicating that the presence of discontinuous transitions is generic.

8:00PM G1.00001 The Kitchen as a Lab, FERRAN ADRIA, JOSE ANDRES, World-famous Chef, MICHAEL P. BRENNER, Harvard University — Provocative world-famous Chef Ferran Adria, often associated with originating the modernist cuisine movement, and Washington DC chef Jose Andres, credited with bring the “small plates” movement to North America, will discuss their views on the creative preparation of food with unexpected contrasts of flavor, temperature, and texture. Their discussion will be followed by a talk by Michael P. Brenner, a professor of applied mathematics, who (along with physics professor David A. Weitz) teaches a course at Harvard University on science and cooking. Come learn about the science and the art of food preparation!

Tuesday, February 28, 2012 8:00AM - 11:00AM – Session H1 GIMS: Focus Session: Advances in Scanned Probe Microscopy I: Novel Approaches to Complex Systems 203

8:00AM H1.00001 Hybrid STM/AFM study of half-metallic surface states in cobaltates¹, ALEX W. CONTRYMAN, FRANCIS NIESTEMSKI, MING RUE D. THIAN, CAROLINA PARRA, YULIN CHEN, Stanford University, THORSTEN HESJEDAL, Oxford University, Z.X. SHEN, HARI C. MANOHARAN, Stanford University — Na_xCoO_2 is a well-known compound that has been studied at various Na concentrations, and has drawn much attention for its unconventional superconductivity and antiferromagnetic phase. In its stoichiometric concentration, NaCoO_2 has recently been proposed as a system for observing topological superconductivity when mixed with a superconductor's electronic states through the proximity effect. We examine NaCoO_2 using an ultrahigh-vacuum low-temperature hybrid scanning tunneling and atomic force microscope at 4 K. We use the tuning-fork AFM mode to study the topography of this bulk insulating material when no tunneling is possible, and utilize a special electrical contact scheme to access the electronic surface states for spectroscopy.

¹Supported by DOE, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under contract DE-AC02-76SF00515. Alex W. Contryman is supported by a Dr. Robert M. Noyce Stanford Graduate Fellowship.

8:12AM H1.00002 Trend and novel challenges in spectroscopic imaging scanning tunneling microscopy for correlated electron materials research, JHINHWAN LEE, JIMIN KIM, SEOK HWAN CHOI, CHANHEE KIM, KAIST, HWANSOO SUH, Samsung Advanced Institute of Technology, KAZUHIRO FUJITA, Cornell University, SHIN-ICHI UCHIDA, University of Tokyo, J.C. SEAMUS DAVIS, Cornell University, Brookhaven National Lab — In this presentation we would like to discuss the recent progress of the spectroscopic imaging scanning tunneling microscopy (SI-STM) and how the real- and momentum-space sensitive spectroscopic tool is evolving into a more robust quantum theoretical tool for the phase transition study of the correlated electron materials.

8:24AM H1.00003 Unique vortex states on nanosize superconducting islands observed by LT-STM, TAKAKI SAKAMOTO, TAKAAKI TOMINAGA, Inst. Solid State Phys., Univ. Tokyo, TAKAHIRO NISHIO, RIKEN, TOYOAKI EGUCHI, JST-ERATO/Keio Univ., YASUO YOSHIDA, YUKIO HASEGAWA, Inst. Solid State Phys., Univ. Tokyo — With rapid progress of fabrication methods for nano-size superconductors, many novel properties of their superconductivity have been studied. Several vortex states unique to the nano superconductors, such as, vortex clustering, giant vortex, and anti-vortex, have been reported/predicted on specific size and shape of the islands. In this study we used Pb island structures with atomically flat surface formed on the Si(111) substrate under ultrahigh vacuum conditions as the superconducting sample. We investigate vortex states formed on the Pb islands under magnetic fields using low-temperature scanning tunneling microscopy (LT-STM), which enable us to observe the surface topograph and the superconducting gap (DOS) at atomic scale spatial resolutions simultaneously in real space. We performed precise tunneling spectroscopy on the Pb islands to take two dimensional DOS mapping at the Fermi level and succeeded in observing several kinds of vortex states (ex. multi vortex state and giant vortex state) in real space. The details will be discussed in the presentation.

8:36AM H1.00004 Scanning SQUID microscopy: A powerful tool for probing magnetism and superconductivity in complex oxides, JULIE A. BERT, Stanford Institute for Materials and Energy Science, Stanford University — Magnetic measurements are useful in investigating novel materials because they probe the behavior of electrons and their interactions. Superconducting Quantum Interference Devices (SQUIDS) are ultra-sensitive flux magnetometers and, when used in imaging mode, they become a powerful tool for mapping magnetic fields above a sample. This talk will outline the basics of scanning SQUID microscopy and highlight our recent measurements on a new material system: complex oxide interfaces. Our scanning SQUID technique uncovered the coexistence of superconductivity and magnetism in the LAO/STO oxide system. These measurements highlight many key benefits of the scanning SQUID technique including a 3 micron imaging kernel, excellent flux sensitivity, and an on-chip field coil to simultaneously measure both the intrinsic magnetism and the sample's response to an applied magnetic field.

9:12AM H1.00005 Spatial Dependence of Kondo Screening and Magnetic Anisotropy on Saturated Copper Nitride Islands, M. REYES CALVO, London Centre for Nanotechnology, UCL, London, UK, JENNY C. OBERG, London Centre for Nanotechnology, Dept. of Physics and Astronomy, UCL, London, UK, F. DELGADO, JOAQUIN FERNANDEZ-ROSSIER, International Iberian Nanotechnology Laboratory, Braga, Portugal, CYRUS F. HIRJIBEHEDIN, London Centre for Nanotechnology, Dept. of Physics and Astronomy, Dept. of Chemistry, UCL, London, UK — Co adatoms on a copper nitride surface constitute a unique system for studying the interplay between Kondo physics and anisotropy in a high spin atom ($S=3/2$). By using scanning tunneling spectroscopy techniques, we can determine both the energy scales of the Kondo screening and the spin excitations on a single atom. Here we study the case of Co adatoms on large nitride islands that form as the copper surface is saturated with nitrogen. These islands present a rich spatial variation of their electronic structure. We observe how changes in the electronic structure of the insulator result in dramatic changes in the spectroscopy of the cobalt adatoms: a considerable increase of the anisotropy energy occurs as the Kondo resonance disappears. These results allow us to explore in detail the interplay between these two phenomena.

9:24AM H1.00006 Evolution of the Kondo Resonance for Screened Atoms on Metals and Thin Insulators , JENNY C. OBERG, London Centre for Nanotechnology, UCL, UK; Department of Physics & Astronomy, UCL, UK, M. REYES CALVO, London Centre for Nanotechnology, UCL, UK, CYRUS F. HIRJIBEHEDIN, London Centre for Nanotechnology, UCL, UK; Department of Physics & Astronomy, UCL, UK; Department of Chemistry, UCL, UK — We study the magnetic anisotropy and the Kondo screening of the spin of Co atoms deposited on Cu₂N using scanning tunneling microscopy and spectroscopy. We find that for Co atoms placed on Cu₂N islands the Kondo screening is weaker when the atom is very close to the edge and at the same time has significant changes in the magnetic anisotropy. Furthermore we observe that Co atoms that are placed on the Cu surface but near the Cu₂N islands still show anisotropy and an unusually small Kondo temperature. At larger distances from the Cu₂N islands the usual large Kondo temperature recovers. We examine possible causes for these dramatic changes in the Kondo screening and magnetic anisotropy, including a possible extension of the electronic properties of the Cu₂N islands compared to the topographic influence.

9:36AM H1.00007 Atomic force microscopy as nano-stethoscope to study living organisms, insects , IGOR SOKOLOV, MAXIM DOKUKIN, NATALIYA GUZ, Clarkson University — Atomic force microscopy (AFM) is a known method to study various surfaces. Here we report on the use of AFM to study surface oscillations (coming from the work of internal organs) of living organisms, like insects. As an example, ladybird beetles (*Hippodamia convergens*) measured in different parts of the insect at picometer level. This allows us to record a much broader spectral range of possible surface vibrations (up to several kHz) than the previously studied oscillations due to breathing, heartbeat cycles, coelopulses, etc. (up to 5 -10 Hz). The used here AFM method allows collecting signal from the area as small as ~100nm² (0.0001μm²) with an example of noise level of (2±0.2)×10⁻³ nm r.m.s. at the range of frequencies >50Hz (potentially, up to a MHz). Application of this method to humans is discussed. The method, being a relatively non-invasive technique providing a new type of information, may be useful in developing of what could be called “nanophysiology.”

9:48AM H1.00008 Scanning tunneling microscopy study of the assembly and structure of filamentous virus M13 bound to graphite , PRASHANT SHARMA, Department of Physics, Suffolk University, Boston, MA 02114 — Viruses are an important class of biomaterials used for placing nano particles on inorganic substrates. To accomplish greater control over viral assembly on a substrate it is important to determine the in situ nanoscale structure of the viral protein coat. Scanning tunneling microscopy offers the unique potential for determining the structure and arrangement of the proteins of a virus adsorbed on a conducting substrate. In this work, I develop an experimental technique for isolating and studying M13 viruses that bind to graphite. Using scanning tunneling microscopy in ambient conditions I obtain the correct lateral dimension of the virus and the periodicity of its protein structure when it is bound to graphite. I also analyze the tunneling conductance fluctuations in these measurements and introduce a simple model for tunneling through an assembly of proteins to obtain an accurate estimation of the vertical dimension of a virus bound to a conducting substrate. I discuss broader implications of this scanning tunneling microscopy study for the in situ structure determination of other biomolecules.

10:00AM H1.00009 Nanomechanics of Murine Articular Cartilage Reveals the Effects of Chondroadherin Knockouts¹ , MICHAEL BATISTA, ALAN GRODZINSKY, MIT, CHRISTINE ORTIZ, Massachusetts Institute of Technology, DICK HEINEGÅRD, Lund University, LIN HAN, Massachusetts Institute of Technology — With high resolution nanotechnology tools, quantification of cartilage biomechanical properties provides important insights into the role of low abundance matrix molecules on cartilage function and pathology. In this study, the role of chondroadherin (CHAD) on cartilage mechanical properties was assessed via atomic force microscopy-based nanoindentation (0.1-10 μm/s z-piezo displacement rates) of murine knee cartilage from wild type (WT) and CHAD knockout (KO) animals ages 1 year, 4 month, and 11 weeks (n≥4 joints/age-group). A significant increase in indentation modulus, E, with indentation rate in all specimens (p<0.05, Friedman) suggested poro-viscoelastic behavior. For all age groups, CHAD KO significantly reduced E at all indentation rates (p<0.05, 2-way ANOVA); e.g., at 1-year, E was 0.77±/-0.1 MPa for WT (mean±/-SEM 1μm/s rate) and 0.25±/-0.07 MPa for CHAD KO cartilage. Lack of CHAD appears to delay development of load bearing extracellular matrix. This could affect the effective cross-link density of the tissue network and, hence, decrease local osmotic swelling while increasing the hydraulic permeability of the aggrecan-filled network. Ongoing studies are investigating the biochemical properties and nanostructure of CHAD KO joints.

10:12AM H1.00010 Nanoindenter Stiffness Measurements on a MEMS Sound Sensor¹ , R. DOWNEY, L. BREWER, G. KARUNASIRI, Naval Postgraduate School — We demonstrate a novel technique to extract the various components of the stiffness (or compliance) measured along the surface of a MEMS directional sound sensor. Because the sensor comprises a cantilever beam mounted on torsion springs, the overall stiffness consists of various compliance components added in series. Stiffness measurements made using a nanoindenter are found to agree with an analytical model and a finite element model (FEM) of the sensor. Moreover, by exploiting the differing power-law characteristics of the individual compliance components, we demonstrate extraction of the separate components from a logarithmic plot of the overall stiffness. Finally, we measure the ultimate (failure) strength of the sensor, from which we obtain the maximum acoustic intensity the sensor can tolerate.

¹Supported by NSF

10:24AM H1.00011 Primary electron beam generation in Near-Field-Emission SEM , DANILO ANDREA ZANIN, HUGO CABRERA, LORENZO GIUSEPPE DE PIETRO, URS RAMSPERGER, DANILO PESCIA, Laboratory for Solid State Physics, ETH Zurich, Switzerland — Due to low electron energies used in Near-Field-Emission SEM (NFESSEM), the understanding of the physical phenomena governing the primary electron beam generation is of fundamental relevance. The geometry and the chemical composition of the ultra-sharp field emitter have been therefore investigated by using different well-known electron microscopy techniques. The last hundreds of nanometers of such a field emitter, produced by electrochemical etching of a tungsten wire, can be macroscopically approximated by a cone with angle of aperture of about 6° ± 1°. The shape of the very apex is strongly dependent on the preparation conditions. Moreover, the only remaining contamination after the annealing procedure of the tungsten tips is a tungsten-oxide coating, uniformly distributed on the surface.

10:36AM H1.00012 Chemical contrast in Near-Field-Emission SEM , LORENZO GIUSEPPE DE PIETRO, MANFRED THALMANN, HUGO CABRERA, DANILO ANDREA ZANIN, URS RAMSPERGER, DANILO PESCIA, Laboratory for Solid State Physics, ETH Zurich, Switzerland — In Near-Field-Emission SEM the primary electron beam, of some tens of eV, is generated by cold field emission from a polycrystalline W-tip. Recently, topography images have been obtained by scanning a W(110) sample with a tip at constant height, typically of tens of nm, recording the secondary electron yield and the emission current. We report on the observation of a chemical contrast of a W(110) surface covered by submonolayer of Fe achieved with the NFESSEM technique. The chemical contrast is caused by a significant lower secondary electron yield for Fe with respect to W. The Fe islands with a diameter of 2 nm to 5 nm are clearly distinguishable, giving a direct indication of the microscope lateral resolution. The adsorbate position, size and shape are confirmed by STM. Moreover, this technique shows the presence of Fe growing along the step edges of the substrate, which can not be identified with STM.

10:48AM H1.00013 Electrostatic characterization of Near-Field-Emission SEM, HUGO CABRERA, DANILO ANDREA ZANIN, LORENZO GIUSEPPE DE PIETRO, URS RAMSPERGER, DANILO PESCIA, Laboratory for Solid State Physics, ETH Zurich, Switzerland — The properties of the primary electron beam in Near-Field-Emission SEM (NFEM) are uniquely determined by the actual geometry and position of the conducting components in the experimental apparatus. The reciprocal dependence of the accessible quantities, namely the voltage applied to the emitting tip with respect to the conducting sample surface (V), the relative distance between the tip and the sample (d) and the field-emission current (I), has been thoroughly characterized. In particular, the voltage V needed to produce a given current I has been measured as a function of d ; the values of I have been chosen in the range from 0.05 nA to 1.5 nA, while d has been varied from 4 to 1500 nm. For values of d smaller than a certain threshold $\bar{d}$, dependent on the tip, V turns out to be directly proportional to the distance between the tip and the sample surface. At larger distances, $d > \bar{d}$, we found $V \propto I^a \cdot d^b$, with a and b generally varying from one tip to the another. These results are supported by preliminary theoretical calculations which assume electrostatic geometries directly inspired by the NFEM setup, such as an hyperboloid-shaped emitter with a conduction plane lying at a generic d .

Tuesday, February 28, 2012 8:00AM - 11:00AM –
Session H2 FPS FEd: Invited Session: Novel and Proven Methods of Communicating Science to the Public 204AB

8:00AM H2.00001 Creating Catalytic Collaborations between Theater Artists, Scientists, and Research Institutions¹, DEBRA WISE, Catalyst Collaborative @ MIT — Catalyst Collaborative@MIT (CC@MIT) is a collaboration between MIT and Underground Railway Theater (URT), a company with 30 years experience creating theater through interdisciplinary inquiry and engaging community. CC@MIT is dedicated to creating and presenting plays that deepen public understanding about science, while simultaneously providing artistic and emotional experiences not available in other forms of dialogue about science. CC@MIT engages audiences in thinking about themes in science of social and ethical concern; provides insight into the culture of science and the impact of that culture on society; and examines the human condition through the lens of science that intersects our lives and the lives of scientists. Original productions range from Einstein's Dreams to From Orchids to Octopi – an evolutionary love story; classics re-framed include The Life of Galileo and Breaking the Code (about Alan Turing). CC@MIT commissions playwrights and scientists to create plays; engages audiences with scientists; performs at MIT and a professional venue near the campus; collaborates with the Cambridge Science Festival and MIT Museum; engages MIT students, as well as youth and children. Artistic Director Debra Wise will address how the collaboration developed, what opportunities are provided by collaborations between theaters and scientific research institutions, and lessons learned of value to the field.

¹Would like to acknowledge support from both MIT and Underground Railway Theater.

9:12AM H2.00003 Drawing at the Speed of Talk: doodling complex discussions in real-time to create animated “Conversation Portraits”, FLASH ROSENBERG, Artist in Residence for LIVE from the New York Public Library — What does your research look like as a drawing? Imagine the guy who delivered your pizza understanding the latest paper you delivered. Flash Rosenberg will describe how she “live-draws” discussions between prominent authors and scientists to create lucid animations. She will offer strategies for how to translate the impenetrable into the understandable, convert equations into sensations, and enable everyone to appreciate issues in physics as relevant, intriguing fun. View sample “Conversation Portraits” at <http://vimeo.com/flashrosenberg/videos>

9:48AM H2.00004 The New Wave of Science Festivals and their Establishment, JOHN DURANT, Director of MIT Museum and the Cambridge Science Festival — No abstract available.

10:24AM H2.00005 Celebrating 24 years of Public Outreach of Science and Engineering in Portland Oregon, TERRY BRISTOL, President, Institute for Science, Engineering and Public Policy — There have been several core strategies in our highly successful 24-year Science, Technology and Society outreach program. However, the strategy for each season is also dynamic, requiring innovation and novel coalitions. As Bob Dylan put it so succinctly, “He not busy being born is busy dying.” Public outreach programs - as the Chautauquas of the past - should be positioned in the cultural milieu along with the opera, symphony and theatre. Support for the enterprise needs to be a broad and diverse coalition, based ideally on the creative formation of win-win relationship. You want people to see your success as their success: “Together we can enhance the intellectual environment in ways that none of us could do alone.” Being multi-disciplinary presents challenges but has considerable advantages. For instance, enlightened managers of established organizations recognize the value of exposing their employees to a diversity of problem solving approaches. Instead of inviting speakers for one large lecture we now invite them to be Resident Scholars for two-three days and develop a range of additional smaller public engagements. Science and engineering topics must be relevant - placed in the broader Science, Technology and Society framework. We avoid “gee-whiz” in favor of what stimulates reflection on who we are, where we came from, and our role in the universe. I will briefly review how we have survived and thrived and, finally, what I see as future trends and opportunities.

Session H3 DCMF: Invited Session: Electronic Properties of the Pseudogap Phase in Cuprates 205AB

8:00AM H3.00001 Extremely Correlated Fermi Liquids¹, SRIRAM SHASTRY, University of California Santa Cruz — A new framework is reported for calculating the properties of extremely correlated electronic systems with eliminated double occupancy. Based on Schwinger's approach to field theory, it avoids using auxiliary variables, and leads to a low (particle) density expansion with equations that approximately double the complexity of the standard theory for interacting electrons. Concrete results for the one electron spectral function of the t - J model in 2-dimensions are presented to lowest non trivial order in density. These already show considerable promise in the context of cuprate superconductors. A distinguishing characteristic of this theory is the low energy long wavelength asymmetry between adding holes and particles. Prospects for the experimental observation of this asymmetry are discussed.

8:36AM H3.00002 The new extremely correlated electron perspective of the normal state of high temperature superconductors, GEY-HONG GWEON, UC Santa Cruz — In this talk, two recent angle resolved photoelectron spectroscopy (ARPES) studies on high temperature superconductors are discussed. These studies show the importance of the “extreme electron correlation” a la t-J model. First, we will discuss the normal state single particle spectral function, which has been considered both anomalous and crucial to understand. Here, we report [1] an unprecedented success of applying the new t-J model based “extremely correlated Fermi liquid theory” by Shastry, to describe both laser ARPES data and conventional synchrotron ARPES data on $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ and synchrotron ARPES data on $\text{La}_{1.85}\text{Sr}_{0.15}\text{CuO}_4$. It fits all data sets with the same physical parameter values, satisfies the particle sum rule and successfully addresses two widely discussed kink anomalies in the dispersion. Second, new ARPES investigation [2] of the Fermi surface geometry of $\text{Ca}_{2-x}\text{Na}_x\text{CuO}_2\text{Cl}_2$ from underdoping to overdoping shows that the “weak correlation” Luttinger sum rule, based on Fermi surface only, clearly breaks down in the underdoped case. We note that a t-J model based theory by Yang, Rice and Zhang provides an alternative “extreme correlation” Luttinger sum rule, based on both Fermi surface and “Luttinger surface.” This extreme correlation Luttinger sum rule offers much more natural explanation for the observed ARPES data. These two studies imply that the extreme correlation as embodied in the t-J model is essential for understanding high temperature superconductors over a wide doping range.

9:12AM H3.00003 A Phenomenological Theory of the Anomalous Pseudogap Phase in Underdoped Cuprates, T. MAURICE RICE, Theoretical Physics, ETH Zurich, CH 8093 Zurich Switzerland — A consistent theoretical description of the many anomalous properties that characterize the pseudogap phase in the underdoped region of the cuprate phase diagram has proved challenging. The continuous progress in spectroscopic and other experiments suggests a phenomenological approach. An ansatz based on analogies to the transition to Mott localization at weak coupling in lower dimensional systems, has been proposed by Yang, Rice and Zhang some years back [1]. This ansatz has had success in describing a wide range of experiments [2]. The motivation underlying this ansatz will be described and some of the comparisons to experiment reviewed. The implications for a more microscopic theory will be discussed together with the relation to microscopic theories that start directly from strongly coupled Hamiltonians.

9:48AM H3.00004 Fermi pockets and the pseudogap in underdoped $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8^1}$, HONGBO YANG, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory — The Fermi surface topologies of underdoped samples of the high T_c superconductor $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8$ have been measured with angle resolved photoemission. By examining thermally excited states above the Fermi level, we show that the observed Fermi surfaces in the pseudogap phase are actually components of enclosed hole-pockets. The spectral weight of these pockets is vanishingly small at the magnetic zone boundary, creating the illusion of Fermi “arc”. The area of the pockets as measured in this study is consistent with the doping level, and hence carrier density, of the samples measured. Furthermore, the shape and area of the pockets is well reproduced by phenomenological models of the pseudogap phase as a spin liquid. The demonstration that the pseudogap in the anti-nodal region is a gap symmetric about the chemical potential is a clear indication that singlet pairing takes place in the normal state.

¹The work at Brookhaven is supported in part by the U.S. DOE under Contract No. DE-AC02-98CH10886 and in part by the Center for Emergent Superconductivity (CES), an Energy Frontier Research Center funded by the U.S. DOE, Office of Basic Energy Sciences.

10:24AM H3.00005 Nodal-antinodal dichotomy in underdoped cuprates: a cluster-dynamical mean-field theory perspective., ANTOINE GEORGES, College de France — A distinctive feature of the normal state of underdoped cuprates is the strong dichotomy between nodal and antinodal regions. The nodal regions display well-defined quasiparticle excitations. In contrast, single-particle lineshapes are very broad near the antinodes, where a pseudogap opens. Cluster extensions of dynamical mean-field theory provide an understanding of this phenomenon as a momentum-selective Mott transition. This will be reviewed in this talk and confronted to experiments and to other theoretical approaches.

Tuesday, February 28, 2012 8:00AM - 11:00AM –
Session H4 DAMOP: Spin-orbit Coupling in Ultracold Gases 205C

8:00AM H4.00001 Topological phase transitions in ultra-cold Fermi superfluids: the evolution from BCS to BEC under artificial spin-orbit fields, LI HAN, KANGJUN SEO, CARLOS A.R. SA DE MELO, School of Physics, Georgia Institute of Technology — We discuss topological phase transitions in ultra-cold Fermi superfluids induced by interactions and artificial spin orbit fields. We construct the phase diagram for population imbalanced systems at zero and finite temperatures, and analyze spectroscopic and thermodynamic properties to characterize various phase transitions. For balanced systems, the evolution from BCS to BEC superfluids in the presence of spin-orbit effects is only a crossover as the system remains fully gapped, even though a triplet component of the order parameter emerges. However, for imbalanced populations, spin-orbit fields induce a triplet component in the order parameter that produces nodes in the quasi-particle excitation spectrum leading to bulk topological phase transitions of the Lifshitz type. Additionally a fully gapped phase exists, where a crossover from indirect to direct gap occurs, but a topological transition to a gapped phase possessing Majorana fermions edge states does not occur.

8:12AM H4.00002 BCS-BEC Crossover and Topological Phase Transition in 3D Spin-Orbit Coupled Degenerate Fermi Gases, MING GONG, Department of Physics and Astronomy, Washington State University, Pullman, Washington, 99164, USA, SUMANTA TEWARI, Department of Physics and Astronomy, Clemson University, Clemson, South Carolina 29634, USA, CHUANWEI ZHANG, Department of Physics and Astronomy, Washington State University, Pullman, Washington, 99164, USA, CHUANWEI ZHANG TEAM, SUMANTA TEWARI COLLABORATION — We investigate the BCS-BEC crossover in three-dimensional degenerate Fermi gases in the presence of spin-orbit coupling (SOC) and Zeeman field. We show that the superfluid order parameter destroyed by a large Zeeman field can be restored by the SOC. With increasing strengths of the Zeeman field, there is a series of topological quantum phase transitions from a nontopological superfluid state with fully gapped fermionic spectrum to a topological superfluid state with four topologically protected Fermi points (i.e., nodes in the quasiparticle excitation gap) and then to a second topological superfluid state with only two Fermi points. The quasiparticle excitations near the Fermi points realize the long-sought low-temperature analog of Weyl fermions of particle physics. We show that the topological phase transitions can be probed using the experimentally realized momentum-resolved photoemission spectroscopy. Phys. Rev. Lett. 107, 195303 (2011).

8:24AM H4.00003 BCS-BEC crossover in 2D spin-orbit coupled degenerate Fermi gases¹, CHUANWEI ZHANG, GANG CHEN, MING GONG, Department of Physics and Astronomy, Washington State University, Pullman, WA 99164 — The recent experimental realization of spin-orbit coupling for ultra-cold atoms has generated much interest in the physics of spin-orbit coupled degenerate Fermi gases. Although recently the BCS-BEC crossover in 3D spin-orbit coupled Fermi gases has been intensively studied, the corresponding 2D crossover physics has remained unexplored. In this talk, we discuss the BCS-BEC crossover physics in 2D degenerate Fermi gases in the presence of spin-orbit coupling. We derive the zero temperature mean field gap and atom number equations suitable for the 2D spin-orbit coupled Fermi gases, from which the dependence of the ground state properties (pairing gap, chemical potential, etc.) on the system parameters (e.g., binding energy, spin-orbit coupling strength) is obtained, both numerically and analytically. We characterize the dependence of the BKT transition temperature as well as the vortex-antivortex lattice melting temperature on the spin-orbit coupling strength and the external Zeeman field.

¹This work is supported by DARPA-YFA, ARO, NSF, and AFOSR

8:36AM H4.00004 One-dimensional Ultracold Fermi Gases with Spin-orbit Coupling, YINGFEI GU, HUI ZHAI, Institute for Advanced Study, Tsinghua Univ., Beijing 100084 — We study one-dimensional ultracold Fermi gases with spin-orbit coupling. We use the Bogoliubov-de Gennes equations to determine pairing order parameter, and find out new phases in addition to fully polarized normal phase, fully paired BCS phase and the FFLO phase. We complete the phase diagram in terms of polarization, interaction parameter and strength of spin-orbit coupling.

8:48AM H4.00005 Who is the Lord of the Rings in the Zeeman-spin-orbit Saga: Majorana, Dirac or Lifshitz?¹, CARLOS SA DE MELO, KANGJUN SEO, LI HAN, Georgia Institute of Technology — Zeeman, spin-orbit fields and interactions can be tuned in the context of ultra-cold atoms and allow for the visitation of several different phases. For systems with zero Zeeman field, the evolution from BCS to BEC superfluidity in the presence of spin-orbit effects is only a crossover [1]. In contrast, for finite Zeeman fields, spin-orbit coupling induces a triplet component in the order parameter that produces nodes in the quasiparticle excitation spectrum leading to bulk topological phase transitions of the Lifshitz type [2]. A fully gapped phase also exists, where a crossover from indirect to direct gap occurs. For spin-orbit couplings with equal Rashba and Dresselhaus strengths the nodal quasi-particles are Dirac fermions that live at and in the vicinity of rings of nodes. Transitions from and to nodal phases can occur via the emergence of zero-mode Majorana fermions at phase boundaries, where rings of nodes of Dirac fermions annihilate [3]. Lastly, we characterize different phases via spectroscopic and thermodynamic properties and conclude that Lifshitz is the “Lord of the Rings.”

9:00AM H4.00006 Quantum phases of atomic Fermi gases with spin-orbit coupling¹, MENDERES ISKIN, Koc University, LEVENT SUBASI, Istanbul Technical University — We consider a general anisotropic spin-orbit coupling and analyze the phase diagrams of both balanced and imbalanced Fermi gases for the entire BCS-BEC evolution. First we use the self-consistent mean-field theory at zero temperature, and show that the topological structure of the ground-state phase diagrams is quite robust against the effects of anisotropy. Then we go beyond the mean-field description, and investigate the effects of Gaussian fluctuations near the critical temperature. This allows us to derive the time-dependent Ginzburg-Landau theory, from which we extract the effective mass of the Cooper pairs and their critical condensation temperature in the molecular BEC limit.

9:12AM H4.00007 Low-density molecular gas of tightly-bound Rashba-Dresselhaus fermions, SO TAKEI, CHIEN-HUNG LIN, Condensed Matter Theory Center, The University of Maryland College Park, BRANDON ANDERSON, National Institute for Standards and Technology, VICTOR GALITSKI, Joint Quantum Institute and Physics Department, University of Maryland — We study interacting Rashba-Dresselhaus fermions in two spatial dimensions. First, we present a new exact solution to the two-particle pairing problem of spin-orbit-coupled fermions for arbitrary Rashba and Dresselhaus spin-orbit interactions. An exact molecular wave function and the Green function are explicitly derived along with the binding energy and the spectrum of the molecular state. In the second part, we consider a thermal Boltzmann gas of fermionic molecules and compute the time-of-flight velocity and spin distributions for a single fermion in the gas. We show that the pairing signatures can be observed already in the first-moment expectation values, such as time-of-flight density and spin profiles.

9:24AM H4.00008 Order by Disorder in Spin-Orbit Coupled Bose-Einstein Condensates, RYAN BARNETT, STEPHEN POWELL, Joint Quantum Institute and Condensed Matter Theory Center, University of Maryland, TOBIAS GRASS, ICREA-Institutio Catalana de Recerca i Estudis Avancats, MACIEJ LEWENSTEIN, ICREA-Institutio Catalana de Recerca i Estudis Avancats and ICFO, SANKAR DAS SARMA, Joint Quantum Institute and Condensed Matter Theory Center, University of Maryland — Motivated by recent experiments, we investigate the system of isotropically-interacting bosons with Rashba spin-orbit coupling. At the non-interacting level, there is a macroscopic ground-state degeneracy due to the many ways bosons can occupy the Rashba spectrum. Interactions treated at the mean-field level restrict the possible ground-state configurations, but there remains an accidental degeneracy not corresponding to any symmetry of the Hamiltonian, indicating the importance of fluctuations. By finding analytical expressions for the collective excitations in the long-wavelength limit and through numerical solution of the full Bogoliubov-de Gennes equations, we show that the system condenses into a single momentum state of the Rashba spectrum via the mechanism of order by disorder. We show that in 3D the quantum depletion for this system is small, while the thermal depletion has an infrared logarithmic divergence, which is removed for finite-size systems. In 2D, on the other hand, thermal fluctuations destabilize the system. This work is supported in part by JQI-PFC.

9:36AM H4.00009 Exotic 3D Spin-Orbit Couplings, BRANDON ANDERSON, JQI, NIST and the University of Maryland, GEDIMINAS JUZELIUNAS, Institute of Theoretical Physics and Astronomy and Vilnius University, IAN SPIELMAN, VICTOR GALITSKI, JQI, NIST and the University of Maryland — We describe a scheme for creating an isotropic three-dimensional spin-orbit coupling, dubbed Weyl spin-orbit coupling, in systems of ultracold atoms. This coupling is induced by Raman transitions that link four internal atomic states with a tetrahedral geometry. This spin-orbit coupling gives rise to a Dirac point that is robust against environmental perturbations. We then propose a general procedure for generating exotic three-dimensional spin-orbit couplings with degenerate ground states on more complex manifolds. The procedure is applied to produce a spin-orbit coupling with a toroidal ground state manifold. Finally, we discuss the many-body implications of the exotic spin-orbit couplings.

9:48AM H4.00010 Cold-atom systems with synthetic SU(3) spin-orbit coupling¹, GREG BOYD, RYAN BARNETT, VICTOR GALITSKI, University of Maryland — Recently, the ability to create and control artificial gauge fields in cold gases has been experimentally demonstrated. Here, we propose a scheme to realize synthetic SU(3) spin-orbit interactions and derive an effective single-particle Hamiltonian, parameterized by the Gell-Mann matrices. We then investigate a many-body system of SU(3)-spin-orbit-coupled bosons and derive and analyze numerically the Gross-Pitaevskii equation to describe the effect of interaction on the possible ground states. The time-of-flight density profiles to probe various many-body states in the rich phase diagram of the system are calculated.

10:00AM H4.00011 Superfluidity of Bosons in Optical lattices with Spin-Orbit coupling¹, QINQIN LU, DANIEL SHEEHY, Louisiana State University — Recent experimental and theoretical work has explored artificial spin-orbit coupling induced among two species of boson. Here we examine superfluidity of a cold gas of bosons with spin-orbit coupling in a periodic optical lattice, in the presence of additional short-range interactions. We compute the density distribution after free expansion from the lattice as a probe of superfluidity, and phase transitions, of the trapped gas.

¹This work has been supported by the Louisiana Board of Regents, under grant LEQSF (2008-11)-RD-A-10.

10:12AM H4.00012 Spinor Bose-Einstein Condensates Under Synthetic Gauge Field¹, XIAO-QIANG XU, JUNG HOON HAN, Department of Physics and BK21 Physics Research Division, Sungkyunkwan University, Suwon 440-746, Korea — Due to the recent popularity of synthetic gauge field in ultracold atoms, I will talk about the combined effects of Rashba spin-orbit coupling (SOC) and rotation in spin -1/2 condensates [X.-Q. Xu et al, Phys. Rev. Lett. 107, 200401 (2011)]. Novel features appear in the ground state wave function, such as the existence of a half-quantum vortex or giant vortex, domains of stripe-like phase, suppressed Skyrmion order. Additionally, I will talk about the interesting mapping between pure Rashba BECs and chiral magnets with Dzyaloshinskii-Moriya (DM) interaction.

¹We are supported by the Mid-career Researcher (No. 2010-0008529) and acknowledge helpful interactions with Hui Zhai.

10:24AM H4.00013 BCS-BEC crossover induced by a synthetic non-Abelian gauge field¹, VIJAY B. SHENOY, JAYANTHA P. VYASANAKERE, Indian Institute of Science, S. ZHANG, Ohio State University — We investigate the ground state of interacting spin-*half* fermions(3D) at a finite density ($\rho \sim k_F^3$) in the presence of a uniform non-Abelian gauge field (with magnitude λ) that generates a generalized Rashba spin-orbit interaction. For a weak attractive interaction in the singlet channel described by a small negative scattering length ($k_F|a_s| \lesssim 1$), the ground state in the absence of the gauge field ($\lambda = 0$) is a BCS superfluid with large overlapping pairs. With increasing λ , a non-Abelian gauge field engenders a crossover of this BCS ground state to a BEC ground state of bosons even with a weak attractive interaction. For large gauge couplings ($\lambda/k_F \gg 1$), the BEC attained is a condensate of bosons whose properties are solely determined by the gauge field (and not by the scattering length); we call these bosons "rashbons." In the absence of interactions ($a_s = 0^-$), the shape of the Fermi surface of the system undergoes a topological transition at a critical gauge coupling λ_T . For high symmetry gauge field configurations we show that the crossover from the BCS superfluid to the rashbon BEC occurs in the regime of λ near λ_T .

¹Supported by DST and DAE, India

10:36AM H4.00014 Trapped fermions in a synthetic non-Abelian gauge field¹, SUDEEP KUAMAR GHOSH, JAYANTHA P. VYASANAKERE, VIJAY B. SHENOY, Indian Institute of Science Bangalore — On increasing the coupling strength (λ) of a non-Abelian gauge field that induces a generalized Rashba spin-orbit coupling, the topology of the Fermi surface of a homogeneous gas of non-interacting fermions of density $\rho \sim k_F^3$ undergoes a change at a critical value, $\lambda_T \approx k_F$ [PRB 84, 014512 (2011)]. We analyze how this affects the size/shape of a cloud of fermions trapped in a harmonic potential. We develop an adiabatic formulation, with Pancharatnam-Berry phase terms, for the one particle states in a trap with the gauge field. Local density approximation reveals that the cloud shrinks in a *characteristic fashion with increasing* λ and predicts a spherical cloud for all gauge field configurations. We show, via a calculation of the cloud shape using exact eigenstates, that for certain gauge fields there is systematic anisotropy in the cloud shape that increases with increasing gauge coupling λ . An important spin-off of our adiabatic formulation is that it reveals exciting possibilities for the cold-atom realization of interesting Hamiltonians (eg. quantum hall spherical geometry) by using a non-Abelian gauge field in conjunction with another potential.

¹Supported by DST and DAE, India

10:48AM H4.00015 Effects of the interplay between spin-orbit coupling and interaction on bosons, QI ZHOU, The Chinese University of Hong Kong, XIAOLING CUI, Institute for Advanced Study, Tsinghua University — We show that spin-orbit coupling drastically changes the properties of bosons. The interplay between the spin-orbit coupling and interaction determines the fate of Bose-Einstein condensate, which may even not exist in the presence of isotropic spin-orbit coupling. For anisotropic spin-orbit coupling, condensates survive and are characterized by anisotropic energy spectrum, with a slower sound velocity along the direction of weaker spin-orbit coupling. The spectrum can also be used to distinguish the plane wave phase and the tripe phase.

Tuesday, February 28, 2012 8:00AM - 11:00AM –
Session H5 DMP: Focus Session: Interfaces in Complex Oxides - Polar Interfaces and Ferro-electrics 206A

8:00AM H5.00001 First-principles study of intermixing and polarization at the DyScO₃/SrTiO₃ interface, KOUROSH RAHMANIZADEH, GUSTAV BIHLMAYER, STEFAN BLÜGEL, Peter Gruenberg Institut (PGI-1) & Institute for Advanced Simulation (IAS-1), Forschungszentrum Juelich and JARA, 52425 Juelich, Germany, MARTINA LUYSEBERG, Peter Gruenberg Institut (PGI-5) & Ernst Ruska Centre, Forschungszentrum Juelich and JARA, 52425 Juelich, Germany — Exploring oxide interfaces is an attractive challenge, due to the emerging novel behaviors which don't exist in the corresponding parent bulk compounds. E. g. joining two simple band insulators LaAlO₃ and SrTiO₃ with different polarity can induce conductivity at the interface. We carried out density functional theory (DFT) calculations based on the full potential linearized augmented planewave (FLAPW) method as implemented in the FLEUR code (www.flapw.de) for studying the polar to non-polar interface of DyScO₃ and SrTiO₃. Due to the polar discontinuity, arising from nominally charged DyO or ScO₂ layers, sharp interfaces induce a strong ferroelectric-like polarization in the SrTiO₃, while in off-stoichiometric interfaces this discontinuity is avoided and no such polarization can be found. In both scenarios the interface remains insulating with only a small reduction of the bandgap. Our calculations show that chemically mixed interfaces are energetically more favorable than sharp ones. Our DFT calculations explore also different configurations of the Dy and Sr atoms within the mixed interface plane. The calculated ground state configuration is confirmed by experimental observations.

8:12AM H5.00002 Growth and transport properties of fractionally δ -doped oxide superlattices¹, HO NYUNG LEE, WOO SEOK CHOI, Oak Ridge National Laboratory, SUYOUN LEE, Korea Institute of Science and Technology, VALENTINO COOPER, Oak Ridge National Laboratory — LaTiO₃/SrTiO₃ (LTO/STO) heterostructures are interesting as they show an intriguing 2D conduction, and their bulk counterpart, La_xSr_{1-x}TiO₃ (LSTO), exhibits a filling-controlled insulator-metal transition (IMT). In this study, we investigated the filling controlled IMT in 2D geometry by fabricating monolayer-thick fractionally δ -doped LSTO/STO superlattices (SLs), in order to find ways to enhancing the carrier mobility of two dimensional electron gas (2DEG). Fractional layers of LSTO have been grown in between STO using advanced PLD. It is found that the SLs' transport properties are governed by a multichannel conduction with at least two distinctly different carriers: (1) High-density-low-mobility carriers presenting at the LSTO interface layer and (2) low-density-high-mobility carriers residing in the STO layers away from the δ -doped layer. By optimizing x , we could tune the effective mass and carrier density to enhance the carrier mobility by about an order of magnitude, selectively for the high-density-low-mobility carriers. This proves that the fractional δ -doping is an effective way to controlling the filling controlled IMT, resulting in highly improved transport properties

¹The work was supported by the U.S. Department of Energy, Basic Energy Sciences, Materials Sciences and Engineering Division.

8:24AM H5.00003 Characterization of extreme-concentration 2DEGs at the SrTiO₃/GdTiO₃ interface, CLAYTON JACKSON, POUYA MOETAKEF, TYLER CAIN, UC Santa Barbara, SIDDHARTH RAJAN, Ohio State University, JAMES ALLEN, SUSANNE STEMMER, UC Santa Barbara — Heterostructures of Mott and band insulators exhibit unique interface properties, including two-dimensional electron gases (2DEGs) with extremely high sheet carrier densities due to the polarization discontinuity at the interface. Of paramount importance for the properties is the location, spatial extent and confinement of the 2DEG. Here, we study the 2DEG with carrier densities of $3 \times 10^{14} \text{ cm}^{-2}$ formed at GdTiO₃/SrTiO₃ interfaces grown by MBE. Using a self-consistent Schrödinger-Poisson solver, we estimate the majority of the carriers are confined in a narrow region ($< 3 \text{ nm}$) at the SrTiO₃-side of the interface. Given the large and rapid spatial variation in charge density, experiments are needed to verify the assumptions underlying such models. We measure the admittance as a function of frequency at different fixed DC bias. To extract the carrier distribution in the depletion approximation, a distributed model is used to account for loss and series resistance effects. The resulting CV profile corresponds to a p-type layer. This is explained with a highly conductive space charge layer, resulting in significant depletion only in the p-type GdTiO₃. We report on the carrier distribution near the interface.

8:36AM H5.00004 Dynamical conductivity of the extreme concentration 2DEGs in GdTiO₃/SrTiO₃ heterostructures, DANIEL OUELLETTE, Dept. of Physics, University of CA, Santa Barbara, POUYA MOETAKEF, Materials Dept., University of CA, Santa Barbara, CHRISTOPHER MORRIS, Dept. of Physics and Astronomy, John Hopkins University, MARK SHERWIN, Dept. of Physics and Institute for Terahertz Science and Technology, University of CA, Santa Barbara, S. JAMES ALLEN, Dept. of Physics, University of CA, Santa Barbara, SUSANNE STEMMER, Materials Department, University of CA, Santa Barbara — Metallic conductivity with extremely high 2D carrier concentration is observed at the interface between the Mott insulator GdTiO₃ and the band insulator SrTiO₃. Irrespective of layer thickness or repeats, MBE-grown GdTiO₃/SrTiO₃ heterostructures have carrier density of approximately $1/2$ electron per interface unit cell, or $3 \times 10^{14} \text{ cm}^{-2}$ per interface, in excellent agreement with the polar discontinuity model. To probe the orbital character, confinement, and correlations of carriers in this system we have measured the static (dc) and dynamical conductivity of a variety of heterostructures, using a combination of THz time-domain and FTIR spectroscopies. Samples with SrTiO₃ layers exceeding $\sim 10 \text{ nm}$ thickness exhibit a Drude conductivity that may arise from d_{xz} and d_{yz} electric subbands at the interface. A discrepancy between the measured dynamical and dc conductivity measurements indicates the presence of a few additional carriers with very low scattering rate. By contrast, the Drude response of samples with thinner SrTiO₃ layers shows an increased scattering rate with excellent agreement between the dc and THz frequency dynamical conductivity.

8:48AM H5.00005 Electrostatic carrier doping of GdTiO₃/SrTiO₃ heterostructures, POUYA MOETAKEF, TYLER CAIN, Materials Department, University of California Santa Barbara, DANIEL OUELLETTE, Physics Department, University of California Santa Barbara, JACK ZHANG, CLAYTON JACKSON, Materials Department, University of California Santa Barbara, SIDDHARTH RAJAN, Department of Electrical and Computer Engineering, Ohio State University, JAMES ALLEN, Physics Department, University of California Santa Barbara, SUSANNE STEMMER, Materials Department, University of California Santa Barbara — Two-dimensional electron gases (2DEGs) at interfaces between Mott insulators and band insulators have attracted significant attention because they can exhibit unique properties, such as strong electron correlations, superconductivity and magnetism. At interfaces between SrTiO₃ and the rare earth titanates (Mott insulators) an interfacial fixed polar charge arises due to a polarization discontinuity, which can be compensated by a 2DEG, residing in the bands of the Mott/band insulator. In this presentation, we report on intrinsic electronic reconstructions at a Mott/band insulator interface between stoichiometric GdTiO₃ and SrTiO₃ that were grown using molecular beam epitaxy. The sheet carrier densities of all GdTiO₃/SrTiO₃ heterostructures containing more than one unit cell of SrTiO₃ are approximately $1/2$ electron per unit cell, independent of layer thickness and growth sequence. These carrier densities closely meet the electrostatic requirements for compensating the fixed charge at these polar interfaces. Based on the experimental measurements, insights into the location and confinement of the charge and the influence of different electrostatic boundary conditions are obtained.

9:00AM H5.00006 High mobility electron gas in the surface vicinity of the cubic-perovskite KTaO₃ via Ar⁺-irradiation, SATOSHI HARASHIMA, SLAC National Accelerator Laboratory, The University of Tokyo, CHRIS BELL, YASUYUKI HIKITA, SLAC National Accelerator Laboratory, HAROLD Y. HWANG, SLAC National Accelerator Laboratory, Stanford University — KTaO₃ (KTO), like SrTiO₃ (STO), can be doped to create a high mobility perovskite oxide semiconductor. However, while the low dimensional electronic states of STO have attracted intense interest via spectroscopic [1,2] and transport [3] studies, analogous investigations in KTO have been limited. Of particular interest is the fact that the cubic crystal symmetry in KTO is preserved at low temperatures, in contrast to STO. Here we electron dope KTO via oxygen-vacancy formation by Ar⁺-irradiation [4]. Below $T = 10$ K, the Hall mobility ($> 10^4$ cm²/Vs) of the electrons is significantly higher than in previous studies of STO [4]. The angular dependence of the Shubnikov-de Haas oscillations indicates a Fermi surface without cubic symmetry, in contrast to that expected for bulk KTO. We discuss the possible origins of these data, including the formation of quantum well structures, the coexistence of surface and bulk electrons, and the suppression of cyclotron motion by finite size effects.

9:12AM H5.00007 Memristive behavior of ferroelectric tunnel junctions¹, ALEXEI GRUVERMAN, University of Nebraska-Lincoln — Employment of polarization reversal in ultrathin ferroelectric layers opens new possibilities for development of electronic devices with novel functional properties not available in conventional systems. A particularly promising aspect is realization of resistive switching in the ferroelectric tunnel junctions (FTJ), which can be used as non-charge based logical switches in nonvolatile memory devices. Functionality of FTJs is intrinsically linked to a relationship between polarization orientation and tunneling resistance, which brings about a problem of ferroelectric switching and polarization retention in ultrathin ferroelectric barriers. Here, we demonstrate a giant resistive switching effect of more than 105% at room temperature in the FTJ device structure composed of an epitaxial BaTiO₃ ferroelectric barrier sandwiched between bottom and top electrodes. We provide experimental evidence of the memristive behavior of these FTJs where both the low- and high-resistance states can be tuned by the external voltage by several orders of magnitude. The mechanism of the memristive behavior in our junctions is discussed in terms of the modifications of the tunneling potential profile driven by the charge accumulation in the BaTiO₃ layer.

¹This research was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering (DOE grant DE-SC0004876).

9:48AM H5.00008 Exploring and alleviating detrimental interface dipole effects in ultra-thin all-oxide metal-ferroelectric-metal heterostructures, XIAOHUI LIU, YONG WANG, PAVEL LUKASHEV, J.D. BURTON, EVGENY TSYMBAL, Department of Physics and Astronomy, University of Nebraska-Lincoln — Ultrathin-film metal-ferroelectric-metal heterostructures present an exciting prospect for switchable nanoelectronic memories and devices such as ferroelectric tunnel junctions. The main challenge is to realize ferroelectricity in ultrathin-films where detrimental interface effects become increasingly more pronounced as ferroelectric film thicknesses approach the nanoscale. We studied the ferroelectric polarization of BaTiO₃ in epitaxial SrRuO₃/BaTiO₃/SrRuO₃ junctions by first-principles density functional theory and phenomenological modeling. The calculations show that the presence of a RuO₂/BaO termination sequence at the SrRuO₃/BaTiO₃ interface leads to a pinned interface dipole and is therefore detrimental to the stability of ferroelectricity, leading to the disappearance of switchable polarization under a certain thickness. Here, we propose to alleviate this behavior by depositing a thin layer of SrTiO₃ at this interface to suppress the RuO₂/BaO interface termination sequence, thereby eliminating the associated unfavorable pinned interface dipole. By doing this we find, and experiments confirm, that a switchable ferroelectric state can be stabilized in much thinner heterostructures.

10:00AM H5.00009 ABSTRACT WITHDRAWN —

10:12AM H5.00010 Domains and Electrostatic Coupling in Ferroelectric Superlattices, PAVLO ZUBKO, NOEMIE JECKLIN, CELINE LICHTENSTEIGER, University of Geneva, ALMUDENA TORRES-PARDO, ALEX GLOTER, Université Paris-Sud, PABLO AGUADO-PUENTE, JAVIER JUNQUERA, Universidad de Cantabria, ODILE STEPHAN, Université Paris-Sud, JEAN-MARC TRISCONE, University of Geneva — Superlattices composed of ferroelectric and paraelectric oxides have been the subject of numerous studies, delving into fundamental questions about ferroelectric size effects, revealing novel interfacial phenomena, and opening new possibilities for tailoring the functional properties of these artificially layered ferroelectrics. Here we examine the role of periodic 180 degree ferroelectric nanodomains on the structural and electrical properties of PbTiO₃/SrTiO₃ superlattices. Using a combination of X-ray diffraction and electrical measurements, nanoscale motion of domain walls under applied field has been detected and linked to the large enhancement of the dielectric response. Electrostatic interactions between the ferroelectric layers have been studied in detail, revealing an unexpected decoupling of the ferroelectric layers once the paraelectric layer thickness exceeds just a few perovskite unit cells. Recent advances in transmission electron microscopy allowed us to map out the local structural distortions across the superlattice using electron energy loss spectroscopy with unit-cell resolution, revealing highly inhomogeneous polarization profiles near the interfaces and giving new microscopic insight into the behavior of these fascinating materials.

10:24AM H5.00011 In situ x-ray study of oxide superlattice growth in reactive molecular-beam epitaxy, JUNE HYUK LEE, X-ray Science Division, Argonne National Lab, SEO HYOONG CHANG, Materials Science Division, Argonne National Lab, I-CHENG TUNG, Department of Materials Science and Engineering, Northwestern University, JEFF EASTMAN, DILLON FONG, Materials Science Division, Argonne National Lab, JOHN FREELAND, HAWOONG HONG, X-ray Science Division, Argonne National Lab — Improper ferroelectricity found in ultrashort period PbTiO₃/SrTiO₃ superlattices has attracted interests as one of new 'interfacially engineered' materials.[1] At the interface of PbTiO₃/SrTiO₃ superlattices, the coupling between the ferroelectric mode and antiferrodistortive rotations of oxygen octahedra creates improper ferroelectricity with a large dielectric constant. PbTiO₃/SrTiO₃ superlattices were grown using reactive molecular-beam epitaxy in a chamber with in situ x-ray diffraction capability at the Advanced Photon Source. The use of in situ surface x-ray diffraction allows one to study the evolution of oxide heterostructures. Here we present initial studies of PbTiO₃ and SrTiO₃ single layers as well as superlattices. 10:36AM H5.00012 ABSTRACT WITHDRAWN —

10:48AM H5.00013 The memristive magnetic tunnel junction as a nanoscopic synapse-neuron system¹ , ANDY THOMAS, PATRYK KRZYSTECZKO, JANA MÜNCHENBERGER, GÜNTER REISS, MARKUS SCHÄFERS, Physics department, Bielefeld University — Memristors cover a gap in the capabilities of basic electronic components by remembering the history of the applied electric potentials, and are considered to bring neuromorphic computers closer by imitating the performance of synapses. We used memristive magnetic tunnel junctions based on MgO to demonstrate that the synaptic functionality is complemented by neuron-like behavior in these nanoscopic devices. The synaptic functionality originates in a resistance change caused by a voltage-driven oxygen vacancy motion within the MgO layer. The additional functionality provided by magnetic electrodes enabled a current-driven resistance modulation due to spin-transfer torque. We report on memristive magnetic tunnel junctions characterized by the simultaneous occurrence of resistive switching and tunnel magnetoresistance. Since resistivity provides a natural measure of the synaptic strength, and because of the bipolar nature of the resistance change, long term potentiation and long term depression were emulated. Furthermore, we show that the flux is a good variable for describing voltage-induced resistance variation, which provides the scope for the emulation of spike timing dependent plasticity as well.

Session H6 DMP: Focus Session: van der Waals Bonding in Advanced Material - Methods and Application to Water and Ice 206B

8:00AM H6.00001 van der Waals interactions in water and ice from density functional theory simulations: improvements and challenges¹ , MARIVI FERNANDEZ-SERRA², Stony Brook University — Accounting for long range van der Waals (vdW) type correlations in the description of water and ice has proven to be one of the most important improvements in density functional theory (DFT)-based simulations of water. I will show how our understanding of the network structure in liquid water has changed with the newly available vdW density functionals, derived from the original version of Dion et al. [Phys. Rev. Lett. 92, 246401 (2004)]. In particular I will focus on the links between the density of water and the interplay between the hydrogen bonds and the so called vdW-bonds, easily identifiable in the liquid. These new vdW-DFs have also proven to be very important in the description of ice. In particular I will show how they are capable of accurately describing the anomalous nuclear quantum effects in ice, bringing DFT simulations and experimental results very close together. Our results show that current vdW-DFs are capable of correctly describing the subtle interplay between inter-molecular libration modes and intra-molecular stretching modes in ice, thus reproducing the experimental results once the zero point of these modes is accounted for in the simulations.

8:36AM H6.00002 The Effect of van der Waals Interactions on the Structure of Liquid Water.¹ , ROBERT DISTASIO JR., ZHAOFENG LI, ROBERTO CAR, Princeton University — In this work, we demonstrate the importance of including van der Waals (vdW) interactions in the theoretical prediction of the structure of liquid water. These effects are investigated by computing and analyzing the oxygen-oxygen, oxygen-hydrogen, and hydrogen-hydrogen radial distribution functions (RDFs) obtained from highly accurate *ab initio* molecular dynamic simulations that explicitly account for vdW interactions. In particular, we utilize an efficient order(N) algorithmic implementation of the self-consistent energy and analytical forces of the density functional based vdW correction proposed by Tkatchenko and Scheffler (PRL 102, 073005 (2009)) to demonstrate the importance of vdW interactions in obtaining RDFs that are in close agreement with experiment. In addition, we also provide an analysis of finite size effects in vdW-based liquid water simulations as well as a comparison to several other competitive theoretical methods for treating vdW interactions.

¹NSF CHE-0956500; DOE-DE-SC0005180

8:48AM H6.00003 Van der Waals interactions and vibrational effects in ice from first principles¹ , EAMONN MURRAY, GIULIA GALLI, University of California, Davis — We present a comparative study of the equation of state and of the electronic and vibrational properties of ice XI and VIII, as obtained with *ab-initio* calculations using semi-local (PBE) and nonlocal, van der Waals functionals. The two functionals yield similar electronic properties for both phases, however they perform very differently in describing their vibrational properties, and the transition pressure from the low to the high pressure phase. The latter is overestimated by a factor of about 6 when using PBE and in agreement with experiment when dispersion forces are taken into account. The inclusion of zero point energy contributions does not affect the computed transition pressure, while it substantially affects structural properties, including equilibrium volumes and bulk moduli, especially for the high pressure phase.

9:00AM H6.00004 Hydrogen Bonds and van der Waals Forces in Ice at Ambient and High Pressures , BISWAJIT SANTRA, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany, JIŘÍ KLIMEŠ, London Centre for Nanotechnology and Department of Chemistry, University College London, London, UK, DARIO ALFÈ, Department of Earth Sciences, University College London, London, UK, ALEXANDRE TKATCHENKO, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany, BEN SLATER, Department of Chemistry, University College London, London, UK, ANGELOS MICHAELIDES, London Centre for Nanotechnology and Department of Chemistry, University College London, London, UK, ROBERTO CAR, Department of Chemistry, Princeton University, Princeton, USA, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — The balance between van der Waals (vdW) forces and hydrogen bonding in ambient and high pressure phases of ice has been examined with the first principles approaches, density-functional theory (DFT) and quantum Monte Carlo. At higher pressure, the contribution to the lattice energy from vdW increases and that from hydrogen bonding decreases, leading vdW to have a substantial effect on the transition pressures between the crystalline ice phases. An important consequence, likely to be of relevance to molecular crystals in general, is that the transition pressures obtained from DFT functionals which neglect vdW forces are greatly overestimated [Phys. Rev. Lett. 107, 185701 (2011)].

9:12AM H6.00005 ABSTRACT HAS BEEN MOVED TO Q35.00010 —

9:24AM H6.00006 Higher-order van der Waals coefficients from static multipole polarizability¹

JIANMIN TAO, JOHN PERDEW, ADRIENN RUZSINSZKY, Tulane University — van der Waals interaction is a long-range nonlocal correlation arising from instantaneous charge fluctuations on each fragment. Though very weak, it considerably affects the properties of molecules and solids. Evaluation of van der Waals coefficients is of strong current interest. In this work, we have derived a general expression for these coefficients in terms of static multipole polarizability only. Applications of the present theory to atom as well as molecular pair interactions have been made.

¹This material is based upon work supported by the National Science Foundation under the NSF Cooperative Agreement No. EPS-1003897 with additional support from the Louisiana Board of Regents.

9:36AM H6.00007 Quantum Monte Carlo Simulation of condensed van der Waals Systems¹

ANOUAR BENALI, Argonne National Laboratory, LUKE SHULENBURGER, Sandia National Laboratories, NICHOLS A. ROMERO, Argonne National Laboratory, JEONGNIM KIM, Oak Ridge National Laboratory, O. ANATOLE VON LILIENTFELD, Argonne National Laboratory — Van der Waals forces are as ubiquitous as infamous. While post-Hartree-Fock methods enable accurate estimates of these forces in molecules and clusters, they remain elusive for dealing with many-electron condensed phase systems. We present Quantum Monte Carlo [1,2] results for condensed van der Waals systems. Interatomic many-body contributions to cohesive energies and bulk modulus will be discussed. Numerical evidence is presented for crystals of rare gas atoms, and compared to experiments and methods [3]. Sandia National Laboratories is a multiprogram laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. DoE's National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

9:48AM H6.00008 Van der Waals interactions based on maximally localized Wannier functions

in ABINIT, CAMILO ESPEJO, CINVESTAV-Unidad Querétaro, Universidad Jorge Tadeo Lozano, TONATIUH RANGEL, Université Catholique de Louvain, YANN POUILLON, Nano-Bio Spectroscopy Group - ETSF, ALDO ROMERO, CINVESTAV-Unidad Querétaro, XAVIER GONZE, Université Catholique de Louvain — We review the recent implementation¹ of the method to evaluate van der Waals (vdW) interactions based on maximally localized Wannier functions^{2,3} in the DFT software ABINIT⁴. The implementation allows for the evaluation of vdW interaction energies for molecular and periodic systems on the same grounds and at a low additional computational cost as compared with a normal DFT calculation. Some results on test systems such as Ar₂, benzene dimer and graphene bilayer show both its reliability and performance. Discussion of new defined variables controlling the calculation and guide lines for the user will be presented along with an application to MoS₂ structure.

10:00AM H6.00009 Density-Functional Theory with Screened van der Waals Interactions for the Modeling of Hybrid Inorganic/Organic Systems¹

VICTOR G. RUIZ, WEI LIU, Fritz-Haber-Institut der MPG, EGBERT ZOJER, Institute of Solid State Physics, Graz University of Technology, MATTHIAS SCHEFFLER, ALEXANDRE TKATCHENKO, Fritz-Haber-Institut der MPG — The electronic properties and the function of hybrid inorganic/organic systems (HIOS) are intimately linked to their geometry, with van der Waals (vdW) interactions playing an essential role for the latter. Here we show that the inclusion of the many-body collective response of the substrate electrons inside the inorganic bulk enables us to reliably predict the HIOS geometries and energies. Specifically, dispersion-corrected density-functional theory (the DFT+vdW approach) [*PRL* **102**, 073005 (2009)], is combined with the Lifshitz-Zaremba-Kohn theory [*PRB* **13**, 2270 (1976)] for the non-local Coulomb screening within the bulk. Our method (DFT+vdW^{surf}) includes both image-plane and interface polarization effects. We show that DFT+vdW^{surf} yields geometries in remarkable agreement (≈ 0.1 Å) with normal incidence x-ray standing wave measurements for the 3,4,9,10-perylene-tetracarboxylic acid dianhydride (C₂₄H₈O₆, PTCD) molecule on Cu(111), Ag(111), and Au(111). Similarly accurate results are obtained for xenon and benzene adsorbed on metal surfaces.

10:12AM H6.00010 Stress and Vibrational Properties of non-local van der Waals exchange-correlation functionals

RICCARDO SABATINI, International School for Advanced Studies (SISSA), via Bonomea 265, 34136 Trieste, Italy, STEFANO DE GIRONCOLI, International School for Advanced Studies (SISSA) and CNR-IOM DEMOCRITOS Simulation Center, via Bonomea 265, 34136 Trieste, Italy — Van der Waals interaction is an essential component in the description of soft matter and plays an important role in many other systems, from adsorbates to water interaction. Within the framework of Density Functional Theory in the last years a great effort has been made to overcome the limitations of LDA or GGA functionals, and a new class of non-local functionals is now filling the gap giving interesting results. We present here several new improvements in this field, and some selected applications. In particular, i) we worked out the theoretical formalism needed to define both the stress tensor and the phonon vibrations associated to the non-local functional form proposed by Dion[1], and ii) we developed and implemented in the Quantum ESPRESSO simulation package a new functional inspired by the work of Vydrov and Van Voorhis[2], simple to compute efficiently in plane wave approach and with great performances on the S22 set. Finally we present some results obtained on aminoacid crystal and other simple molecules where these new tools are benchmarked and compared with experimental results and other theoretical approaches.

10:24AM H6.00011 Dispersion interactions in Density Functional Theory, LAMPROS ANDRINOPOULOS, NICHOLAS HINE, ARASH MOSTOFI, Imperial College London — Semilocal functionals in Density Functional Theory (DFT) achieve high accuracy simulating a wide range of systems, but miss the effect of dispersion (vdW) interactions, important in weakly bound systems. We study two different methods to include vdW in DFT: First, we investigate a recent approach [1] to evaluate the vdW contribution to the total energy using maximally-localized Wannier functions. Using a set of simple dimers, we show that it has a number of shortcomings that hamper its predictive power; we then develop and implement a series of improvements [2] and obtain binding energies and equilibrium geometries in closer agreement to quantum-chemical coupled-cluster calculations. Second, we implement the vdW-DF functional [3], using Soler's method [4], within ONETEP [5], a linear-scaling DFT code, and apply it to a range of systems. This method within a linear-scaling DFT code allows the simulation of weakly bound systems of larger scale, such as organic/inorganic interfaces, biological systems and implicit solvation models. 10:36AM H6.00012 A Qbox Implementation of van der Waals Density Functionals with Applications¹, JUN WU, Graduate Group in Applied Science, University of California Davis, Davis CA 95616, FRANCOIS GYGI, Department of Computer Science, University of California Davis, Davis CA 95616 — We present an implementation of the non-local van der Waals correlation functional proposed by Dion et al. [1] in the Qbox code [2]. We develop a simple approach to remove the logarithmic singularity in the kernel function, and derive the non-local potential needed for self-consistent calculations of energies, ionic forces and stress for simulations in arbitrary-shaped unit cells. We compare the performance of five different van der Waals functionals in applications to the benzene-water dimer, the benzene crystal and other organic molecular crystals.

Tuesday, February 28, 2012 8:00AM - 11:00AM — Session H7 DMP: Focus Session: Carbon Nanotube Sensing 207

8:00AM H7.00001 Selective, Reversible Near-Infrared Fluorescence Quenching of Boronic Acid–Single-Walled Carbon Nanotube Complexes in Response to Glucose, KYUNGSUK YUM, JIN-HO AHN, THOMAS MCNICHOLAS, PAUL BARONE, BIN MU, JONG-HO KIM, RISHABH JAIN, MICHAEL STRANO, Massachusetts Institute of Technology — We present the high throughput screening of a library of 30 boronic acid derivatives to form complexes with sodium cholate suspended single-walled carbon nanotubes (SWNTs) to screen for their ability to reversibly report glucose binding via a change in SWNT fluorescence. The screening identifies 4-cyanophenylboronic acid which uniquely causes a reversible wavelength red-shift in SWNT emission. The results also identify 4-chlorophenylboronic acid which demonstrates a turn-on fluorescence response when complexed with SWNTs upon glucose binding in the physiological range of glucose concentration (0 to 30 mM). The mechanism of fluorescence modulation in both of these cases is revealed to be a photo-induced excited-state electron transfer that can be disrupted by boronate ion formation upon glucose binding. This “turn-on” sensing scheme that uses the reversible fluorescence quenching and wavelength shift of the BA–SWNT complex offers a new approach for nIR optical sensing of glucose.

8:12AM H7.00002 The transduction mechanism of carbon nanotube transistors monitoring single molecule protein dynamics, PATRICK C. SIMS, YONGKI CHOI, TIVOLI J. OLSEN, GREGORY A. WEISS, PHILIP G. COLLINS, Depts. of Physics and Astronomy, Chemistry, and Molecular Biology, Univ. of California at Irvine, Irvine, CA 92697 — Recently we have demonstrated high resolution, real-time monitoring of single molecule chemistry using molecules attached to a single-walled carbon nanotube (SWCNT) transistor. The transduction mechanism of SWCNT sensing is often claimed to be due to charge transfer, but here we clearly show the entire effect to be electrostatic. In this study, the chemical system of interest is lysozyme and its enzymatic processing of its binding substrate, peptidoglycan. We investigate the interaction of a lysozyme molecule with the SWCNT conductivity by building devices out of eight different lysozyme variants synthesized by mutagenesis. Each lysozyme variant has a different sequence of surface charges near the SWCNT attachment site, providing a calibrated method of looking at the electrostatic interactions. We observe that positively- and negatively-charged amino acids induce signals of opposite magnitude, while quasi-neutral amino acids like alanine induce little signal at all. The results indicate that careful consideration and manipulation of the charge environment near the attachment site may enhance the signal-to-noise of SWCNT sensors for studying single molecule interactions.

8:24AM H7.00003 Electrical Detection of Resonance in a Helically Coiled Carbon Nanowire, DOYL DICKEL, DEEPIKA SAINI, BALU PILLAI, HERBERT BEHLOW, MALCOLM SKOVE, APPARAO RAO, Clemson University — Helically coiled Carbon Nanowires (HCNWs) are promising elements, both for their promise as components for NEMS devices as well as for fundamental research. This is due primarily to their exotic geometry. We present here the electrostatic excitation of a HCNW cantilever to resonance and an entirely electrical measurement of the same using harmonic detection of resonance (HDR). The correlation between the directly observed resonance and the electrical signal is shown and, in addition to calculating a lateral spring constant from the observed resonance frequency, we examine the nonlinear behavior of the HCNW when driven to large amplitudes of vibration. Specifically, elliptical oscillation is visually evident and we have measured the electrical response of the corresponding combination mode.

8:36AM H7.00004 Arrays of Versatile DNA-Carbon Nanotube Hybrid Chemical Sensor for Vapor Analyte Detection, NICHOLAS KYBERT, MITCHELL LERNER, ZHENGQING JOHN QI, A.T. CHARLIE JOHNSON, University of Pennsylvania, Department of Physics and Astronomy — Large arrays of nanoscale sensors were fabricated for the detection of small molecules based on single-stranded DNA (ssDNA) for chemical recognition and single-walled carbon nanotube field effect transistors (SWNT FETs) for electronic read-out. These versatile sensors are capable of detecting very low concentrations of molecules ranging from volatile organic compounds, whose detection could provide a method for detection or identification of individuals, to noxious compounds designed to harm them. In this work, we deposited enriched semiconducting SWNTs on Si/SiO₂ with an APTES adhesion layer. Photolithographically defined contacts resulted in high yield, high performance arrays of SWNT FETs, which were then individually coated in different ssDNA. The arrays of devices were then simultaneously exposed to analytes down to ppb concentrations. The sensing response of a single device is both analyte and ssDNA sequence dependant. The response and recovery to baseline are both fast (seconds) and repeatable without need for refreshing. By using large arrays of differently functionalized devices, we distinguished similar analytes and established electronic signatures indicative of their presence, paving the way for incorporation of ssDNA/SWNT FET arrays in “electronic nose”-type systems.

8:48AM H7.00005 Environmental Charge Noise in Suspended Carbon Nanotube Biosensors

, TAL SHARF, Oregon State University, JOSHUA W. KEVEK, Cornell University, ETHAN D. MINOT, Oregon State University — Carbon nanotube field effect transistors (CNT FETs) are a promising platform for probing biological systems at nanometer length scales. The sensitivity of a CNT FET sensor is ultimately limited by intrinsic fluctuations in the conductance of the sensor. Our work aims to understand the mechanisms responsible for these conductance fluctuations, and therefore understand the fundamental detection limits of charge-sensitive biosensors. We have measured conductance fluctuations in both surface-bound CNTs and suspended CNTs. Experiments are performed in physiological buffers — the typical environment for real-time biosensing. We compare our measurements to a charge noise model and the Hooke model. We find good agreement with the charge noise model, and find that charge noise is reduced by 10 –fold when CNTs are suspended rather than surface-bound. By measuring conductance fluctuations in a variety of liquid buffers we uncover new clues about the origins of charge noise in electrolyte environments.

9:00AM H7.00006 Generalized Protein Attachment Chemistry for Highly Sensitive Carbon

Nanotube-Based Biosensors, MITCHELL LERNER, Univ. of Pennsylvania, Dept. of Physics and Astronomy, TATIANA PAZINA, MATTHEW ROBINSON, Fox Chase Cancer Center, A.T. CHARLIE JOHNSON, Univ. of Pennsylvania, Dept. of Physics and Astronomy — We developed a label free covalent functionalization procedure for attaching proteins to carbon nanotube field effect transistors (CNTFETs). Biomarker proteins are becoming increasingly useful for early diagnosis of disease, ranging from cancer to arthritis to stress. Current clinical immunoassays for measuring patient protein levels are costly and require significant processing time. Using diazonium salts followed by stabilization of carboxylic acid groups, we can attach a variety of proteins to carbon nanotubes as confirmed by atomic force microscopy. Proteins maintain the integrity of their epitope and bind to their corresponding complementary proteins. Carbon nanotube transistors are superior readout elements for such protein binding events due to their speed and comparable scale. Resulting changes in the electronic transport properties of CNTFETs demonstrate a concentration-dependent response. Binding of osteopontin (OPN), a biomarker for prostate cancer, to its complementary single chain variable fragment (scFv) can be detected down to 1 pg/mL with these methods. Moreover, these devices exhibit selectivity for OPN. Such high sensitivity biosensors could be used in parallel to test a single small volume patient sample for any number of potentially ominous biomarker proteins.

9:12AM H7.00007 Detection of carbon nanotubes in plant roots through microwave-induced

heating, FAHMIDA IRIN, Department of Chemical Engineering, Texas Tech University, BABINA SHRESTHA, JACLYN CANAS, The Institute of Environmental and Human Health, Texas Tech University, MOHAMMAD SAED, Department of Electrical and Computer Engineering, Texas Tech University, MICAH GREEN, Department of Chemical Engineering, Texas Tech University — We demonstrate a novel technique for quantitative detection of CNTs in biological samples by utilizing the thermal response of CNTs under microwave irradiation. In particular, rapid heating of CNTs due to microwave absorption was employed to quantify the amount of CNTs present in alfalfa plant roots. Alfalfa roots were prepared by injecting a known amount of CNTs (single walled and multi walled) and exposed to 30-50 W microwave power to generate calibration curves (temperature rise vs. CNT mass). These calibration curves serve as a characterization tool to determine the unknown amount of CNTs absorbed by alfalfa plant roots grown in CNT-laden soil with superior accuracy and sensitivity. Moreover, the threshold for detectable CNT concentration is much lower than common analytical methods of detecting nanomaterials, such as scanning electron microscopy (SEM), transmission electron microscopy (TEM), and Raman spectroscopy. Considering the lack of effective detection methods for CNT uptake in plants, this method is not only unique but also practical, as it addresses a major problem in the field of nanotoxicology risk assessment.

9:24AM H7.00008 Adsorption of noble gases on individual suspended single-walled carbon

nanotubes, HAO-CHUN LEE, ZENGHUI WANG¹, RICHARD ROY, ERIK FREDRICKSON, OSCAR VILCHES, DAVID COBDEN, Department of Physics, University of Washington — Suspended single-walled carbon nanotubes can act as nanomechanical resonators, offering the ability to detect an adsorbed substance with very high sensitivity via the frequency shift due to the adsorbed mass. By measuring the resonance frequency electrically in the presence of vapors at controlled temperature and pressure we have obtained isotherms for 4He, Ar, Kr and Xe, on multiple nanotubes. The behavior resembles that on graphite but with notable differences, including weaker binding energies. The lower binding allows access to behavior at lower 2D chemical potential than on conventional substrates. For 4He the binding energy is reduced by as much as a factor of two. For Ar the derived two-dimensional phase diagram is similar to that on conventional substrates. For Kr there is variation between nanotubes which may be related to commensurability and area per site on the surface of a cylinder. Work supported by NSF DMR 0907690.

9:36AM H7.00009 Conductance isotherms for adsorption of noble gases on individual single-walled carbon nanotubes¹

, BORIS DZYUBENKO, HAO-CHUN LEE, OSCAR VILCHES, DAVID COBDEN, University of Washington — Using transistors made from suspended carbon nanotubes allows one to probe the interaction of adsorbed atoms and molecules with the carbon substrate electrons. We have studied the effects of adsorbing He, Ne, Ar, Kr, Xe, and other gases on the electrical properties of individual suspended single-walled nanotubes, as a function of pressure and temperature. The conductance changes measurably, and sometimes dramatically, as a monolayer forms and undergoes phase transitions. It yields complementary information to the coverage, which is obtained from the mass shift in the natural vibrational frequency of the nanotube. For example, measurements below the 2D critical point show nonmonotonic features and fluctuations heralding the first-order phase transition. Conductance changes can be measured on a timescale of milliseconds, permitting studies of the dynamics of the monolayer. In the nonlinear regime we observe features in the I-V characteristics as phase transitions are induced by the current and nonequilibrium stationary states occur.

¹Supported by NSF grant DMR 0907690

9:48AM H7.00010 Dependence of adsorption kinetics on the geometry of substrate¹

, DINESH RAWAT, SAIKAT TALAPATRA, VAIVA KRUNGLEVICIUTE, ALDO MIGONE, Department of Physics, Southern Illinois University at Carbondale, IL-62901, USA, DEPARTMENT OF PHYSICS, SOUTHERN ILLINOIS UNIVERSITY AT CARBONDALE, IL-62901, USA TEAM — We report on the results of an adsorption kinetics study of linear alkanes on planar graphite and on aligned multiwalled carbon nanotubes. The kinetics study was performed by monitoring the equilibration times for methane, butane and pentane adsorbed on these two substrates as a function of fractional coverage. For methane, the time required to reach equilibration was found to decrease as the surface coverage increased. However, for butane and pentane, a systematic increase in the equilibration time with increasing fractional coverage was observed. Although similar results were found for both substrates, the waiting times for longer alkanes adsorbed on multiwalled carbon nanotubes, were found to be longer than the ones obtained for planar graphite. We speculate that the observed increase in the equilibration time with coverage for the longer alkanes is due to the rearrangement of the adsorbed molecules. Results of the current study will also be compared to our previous study of adsorption kinetics of linear alkanes on single-walled carbon nanotubes.

10:00AM H7.00011 New concepts in molecular and energy transport within carbon nanotubes: thermopower waves and stochastically resonant ion channels, MICHAEL STRANO, MIT — Our laboratory has been interested in how carbon nanotubes can be utilized to illustrate new concepts in molecular and energy transfer. In the first example, we predict and demonstrate the concept of thermopower waves for energy generation [1]. Coupling an exothermic chemical reaction with a thermally conductive CNT creates a self-propagating reactive wave driven along its length. We realize such waves in MWNT and show that they produce concomitant electrical pulses of high specific power >7 kW/kg. Such waves of high power density may find uses as unique energy sources. In the second system, we fabricate and study SWNT ion channels for the first time [2] and show that the longest, highest aspect ratio, and smallest diameter synthetic nanopore examined to date, a $500\text{ }\mu\text{m}$ SWNT, demonstrates oscillations in electro-osmotic current at specific ranges of electric field, that are the signatures of coherence resonance, yielding self-generated rhythmic and frequency locked transport. The observed oscillations in the current occur due to a coupling between stochastic pore blocking and a diffusion limitation that develops at the pore mouth during proton transport.

10:36AM H7.00012 Neon adsorption on oxidized single-walled carbon nanohorns¹, VAIVA KRUNGLEVICIUTE, ALDO MIGONE, Southern Illinois University Carbondale, MASAKO YUDASAKA, National Institute of Advanced Industrial Science and Technology, Nanotube Research Center, Japan, SUMIO IJIMA, National Institute of Advanced Industrial Science and Technology, Nanotube Research Center; Fundamental Research Laboratory, NEC Corporation, Japan — We will present the results of a study of neon adsorption on oxidized single-walled carbon nanohorns. Our adsorption isotherm measurements were conducted at temperatures below 24.5 K, the triple point for Ne. Results for the effective specific surface area and for the effective pore volume of the nanohorn aggregates will be presented. We will also report on the sorbent-loading dependence of the isosteric heat of neon on the nanohorns, and on the binding energy. Our results for this system will be compared with those obtained for Ne on a sample of dahlia-like nanohorns annealed at 520 K.

¹This work is supported by the NSF through grant DMR-1006428.

10:48AM H7.00013 Carbon dioxide adsorption on open single walled carbon nanohorn aggregates¹, SHREE BANJARA, VAIVA KRUNGLEVICIUTE, ALDO MIGONE, Southern Illinois University Carbondale, MASAKO YUDASAKA, National Institute of Advanced Industrial Science and Technology, Nanotube Research Center, Japan, SUMIO IJIMA, National Institute of Advanced Industrial Science and Technology, Nanotube Research Center; Fundamental Research Laboratory, NEC Corporation, Japan — The adsorption of carbon dioxide was measured on aggregates of single-walled carbon nanohorns treated with H₂O₂. Volumetric adsorption isotherms were conducted at several temperatures between 162 and 212 K (below the triple point for CO₂). Results on adsorption equilibration times, on the substrate-loading dependence of the isosteric heat, and on the binding energy will be presented. The effective specific surface area values obtained in this study will be compared with the ones obtained for other carbon nanohorn samples.

Tuesday, February 28, 2012 8:00AM - 11:00AM — Session H8 DMP GMAG: Focus Session: Frustrated Magnetism - Kagome I 208

8:00AM H8.00001 Confinement transitions of Z2 spin liquids on the kagome lattice¹, MATTHIAS PUNK, Harvard University — Motivated by numerical evidence of a Z₂ spin liquid ground state of the Heisenberg model on the kagome lattice and indications of a proximate valence bond solid (VBS) phase (see S. Yan et al, Science 332, 1173 (2011)), we study quantum phase transitions between Z₂ spin liquids and VBS states, in which the space group of the kagome lattice is broken. These confinement transitions are driven by the condensation of elementary vortex excitations of the Z₂ spin liquid, so called visons. In this talk I will show how a projective symmetry group (PSG) analysis of effective models for the visons can be used to construct quantum field theories for such confinement transitions, which in turn allow for a classification of the spatial symmetries of possible VBS states. Interestingly, the kagome lattice is unique in the sense that the critical properties at the confinement transition are seemingly not described by the Wilson-Fisher fixed point, as is the case for other lattice geometries.

¹Support by the National Science Foundation (DMR-0757145), AFOSR as well as the Austrian Science Fund (J3077-N16) is gratefully acknowledged.

8:36AM H8.00002 NMR study of the spin-1/2 near-kagome system Vesignieite, JEFFREY QUILLIAM, FABRICE BERT, Laboratoire de Physique des Solides, Universite Paris-Sud, ROSS COLMAN, DAVID BOLDRIN, ANDREW WILLS, Department of Chemistry, University College London, PHILIPPE MENDELS, Laboratoire de Physique des Solides, Universite Paris-Sud — The spin-1/2 kagome lattice antiferromagnet is understood to be an ideal setting in which to find novel quantum spin liquid physics. Here, ⁵¹V NMR results are presented on the quantum spin system Vesignieite, which closely approximates such an antiferromagnetic kagome model, possessing a minute 0.7% length difference between inequivalent Cu-Cu bonds. We obtain a measure of the intrinsic magnetic susceptibility of the near-kagome lattice, which shows commonalities with other kagome systems, in particular Herbertsmithite. Meanwhile, the system is found to undergo partial spin freezing at a surprisingly high temperature of $T_C = 9\text{ K} \simeq J/6$. Through a loss of NMR intensity and detailed analysis of the spectral linewidth, we infer a heterogeneous ground state in which 50% of the spins are very weakly frozen, with a moment of $\sim 0.2\text{ }\mu_B$ and the remaining 50% remain dynamic down to very low temperatures. These results are found to be highly consistent with μ SR studies, which find a similar frozen fraction and small size of magnetic moment. We propose that the elevated transition temperature and weakly frozen ground state are explained by the Dzyaloshinskii-Moriya interaction and a proximity to the resulting quantum phase transition.

8:48AM H8.00003 Magnetization Process of Spatially Anisotropic Kagome Heisenberg Model, RYUI KANEKO, TAKAHIRO MISAWA, YUHEI YAMAJI, Department of Applied Physics, University of Tokyo, HIROKI NAKANO, Graduate School of Material Science, University of Hyogo, MASATOSHI IMADA, Department of Applied Physics, University of Tokyo — Motivated by recent experiments on volborthite, a typical spin-1/2 antiferromagnet with a kagome lattice structure, we study magnetization process of a Heisenberg model on a kagome lattice with a spatial anisotropy in applied magnetic fields. First, for the classical Heisenberg model, by using the Monte Carlo method, we find a magnetization step due to the anisotropy at low temperatures and low magnetic fields. The magnetization step signals a first-order transition, between two phases distinguished by distinct and well-developed short-range spin correlations, one characterized by a local 120° structure and the other by a partially spin-flopped structure. These states are also evident in magnon dispersions based on a classical spin configuration for each phase. Then, to clarify how quantum fluctuations affect the magnetization process, we calculate the sublattice magnetization by using the exact diagonalization method. We find that the sublattice magnetization process of the quantum model looks qualitatively similar to that of the classical model, which indicates that the spin structure observed in the classical model also appears in the quantum model. Finally, we point out the relevance of our results to the magnetization steps observed in volborthite.

9:00AM H8.00004 Investigation of fermi-liquid-like specific heat and spin-density-wave signatures in the distorted kagome compound Volborthite, $\text{Cu}_3\text{V}_2\text{O}_7(\text{OH})_2 \cdot 2\text{H}_2\text{O}$, TYLER DODDS, YONG BAEK KIM, University of Toronto — The distorted kagome compound Volborthite shows signatures of spin-density-wave magnetic order and Fermi-liquid specific heat at low temperatures and magnetic fields. A recent density functional study [O. Janson *et al.*, Phys. Rev. B **82**, 104434 (2010)] suggests that Volborthite can be viewed as coupled frustrated Heisenberg spin chains, a model we approach using a slave-fermion representation of the spins. For a certain range of couplings, our mean-field theory finds a Fermi surface of spinons, a portion of which contains nesting. We investigate whether the coexistence of a U(1) spin liquid with a spinon Fermi surface, along with a spinon spin-density-wave, may describe the aforementioned features of the low-field phase. Furthermore, at higher fields, conventional magnetically ordered states are found. We examine if higher magnetic fields can lead to the destruction of the fermi surface, prompting a spinon confinement transition into such a conventionally magnetically ordered state.

9:12AM H8.00005 Experimental signatures of spin liquid physics on the $S=1/2$ kagomé lattice¹, YOUNG LEE, Massachusetts Institute of Technology — I will describe our recent experimental progress on the quest to study novel ground states in frustrated magnets. New states of matter may be produced if quantum effects and frustration conspire to prevent the ground state from achieving classical order. Materials based on the kagomé lattice appear to be ideal hosts for the possibility of a quantum spin liquid ground state in two-dimensions. I will discuss our work which includes single crystal growth, bulk characterization, and neutron scattering measurements of the $S=1/2$ kagomé lattice material $\text{ZnCu}_3(\text{OH})_6\text{Cl}_2$ (also known as herbertsmithite). Recent susceptibility measurements on single crystals yield valuable information on the additional terms in the spin Hamiltonian beyond nearest neighbor Heisenberg exchange, and anomalous x-ray diffraction yields detailed information on the presence of a small amount of atomic impurities. Most interestingly, inelastic neutron scattering measurements of the spin correlations in a single crystal sample reveal a continuum of spinon excitations in this two-dimensional insulating magnet. We will discuss our results in relation to recent theories for spin liquid physics on the $S=1/2$ kagomé lattice.

¹This work was supported by the Department of Energy under Grant No. DE-FG0207ER46134.

9:48AM H8.00006 Spin cluster operator theory for the kagome lattice antiferromagnet¹, KWON PARK, KIAS, KYUSUNG HWANG, Seoul National Univ. and KIAS, YONG BAEK KIM, Univ. of Toronto and KIAS, JAEJUN YU, Seoul National Univ. — The spin-1/2 quantum antiferromagnet on the kagome lattice provides a quintessential example in the strongly correlated electron physics where both effects of geometric frustration and quantum fluctuation are pushed to their limit. Among possible non-magnetic ground states, the valence bond solid (VBS) with a 36-site unit cell is one of the most promising candidates. Improving the bond operator theory, we propose a new approach dubbed as the spin cluster operator theory in which extended clusters of spin are treated as fundamental building blocks of the system. As a result, it is shown that the lowest spin excitation has a gap much lower than the previous value obtained by the bond operator theory, narrowing the difference against exact diagonalization results.

¹National Research Foundation of Korea grant under the Quantum Metamaterials Research Center (K.P.) and the ARP (J.Y.), NSERC of Canada, Canada Research Chair Program, and CIFAR (Y.B.K.)

10:00AM H8.00007 Low Energy Spectrum and Correlation Functions of the $S = 1/2$ Kagome Antiferromagnet, ANDREAS LAUCHLI, Theoretische Physik, University of Innsbruck, Austria, RAINER JOHANNI, Computing Center of the Max Planck Society, Garching, Germany — We report a large scale Exact Diagonalization study of the $S = 1/2$ Heisenberg antiferromagnet on samples of up to 48 sites. The singlet spectrum at low energies involves only energy levels at the Gamma point, indicating the probable absence of spontaneous translation symmetry breaking in the thermodynamic limit. The spin-spin correlations are short ranged as expected, and the dimer-dimer correlation functions reveal traces of diamond-like resonances. We discuss the compatibility of our results with different theoretical proposals for the ground state of the Kagome antiferromagnet.

10:12AM H8.00008 Valence bond crystals in the kagome spin-1/2 Heisenberg antiferromagnet: Symmetry classification and projected wave function study, YASIR IQBAL, Laboratoire de Physique Theorique UMR-5152, CNRS and Universite' de Toulouse, FEDERICO BECCA, CNR Officina dei Materiali and SISSA, DIDIER POILBLANC, Laboratoire de Physique Theorique UMR-5152, CNRS and Universite' de Toulouse — We present a hierarchical group theoretical classification and representation of Valence bond crystal (VBC) phases on the kagome lattice. Starting from the most symmetric parent VBC, we enumerate and give the ansatz for all 6, 12, and 36-site unit cell VBC's in order of increasing number of broken point group symmetry elements. We treat the VBC's within the class of Gutzwiller projected fermionic variational wave functions, which are optimized using a sophisticated implementation of the stochastic reconfiguration method. In particular, for the spin-1/2 quantum Heisenberg antiferromagnetic model, we show that the U(1) Dirac spin liquid is remarkably stable (locally and globally) with respect to all possible VBC patterns enumerated. However, upon addition of a small ferromagnetic next-nearest-neighbor coupling we find that the lowest energy state is a non-trivial generalized 36-site VBC, which can be regarded as being continuously connected to a uniform RVB spin liquid. We also communicate the ground state energy on the kagome 48 site cluster for the nearest-neighbor spin-1/2 quantum Heisenberg antiferromagnetic model, using the technique of application of a few Lanczos steps (within a variational Monte carlo scheme) on the U(1) Dirac spin liquid and the uniform RVB wave function.

10:24AM H8.00009 Neutron Scattering and Thermodynamic Studies of Low Spin Kagome Magnets¹, ROBIN CHISNELL, DANNA FREEDMAN, MIT, JOEL HELTON, NIST Center for Neutron Research, CHRIS STOCK, FRANZ DEMMEL, ISIS Facility - Rutherford Appleton Laboratory, DANIEL NOCERA, YOUNG LEE, MIT — Materials containing low quantum number spins arranged on a kagome lattice are some of the most promising candidates to display spin liquid ground states due to the high degree of geometric frustration. $\text{Cu}(1,3\text{-bdc})$ is a hybrid organometallic compound featuring antiferromagnetically coupled $S=\frac{1}{2}$ Cu^{2+} ions on a kagome lattice. Below $T=1.8$ K the magnetic moments enter a quasi-static phase with no long range magnetic order but extremely slow spin fluctuations. Application of a magnetic field quickly leads to a competing magnetic phase, with a 1 Tesla field able to completely polarize the magnetization below $T=2$ K. We present inelastic neutron scattering measurements of $\text{Cu}(1,3\text{-bdc})$ and note the emergence of low-energy modes in the quasi-static phase. We also present new thermodynamic data on the compound $\text{BaNi}_3(\text{OH})_2(\text{VO}_4)_2$, recently synthesized by our group, which features $S=1$ Ni^{2+} ions on a kagome lattice.

¹This work was supported by the US Department of Energy under Grant No. DE-FG02-07ER46134

10:36AM H8.00010 Magnetic studies of $S=1/2$ kagomé lattice single crystals, TIANHENG HAN, SHAOYAN CHU, MIT, YASU TAKANO, University of Florida, JOSE RODRIGUEZ-RIVERA, NCNR NIST, COLLIN BROHOLM, John Hopkins University, DANIEL NOCERA, YOUNG LEE, MIT — Herbertsmithite $\text{ZnCu}_3(\text{OH})_6\text{Cl}_2$ —one of the most promising quantum spin liquid candidates—presents a promising system for studies of frustrated magnetism on an $S=1/2$ kagomé lattice. Following our recent success in crystal growth, we have measured anisotropies in the magnetic susceptibility and specific heat. The implication on the Hamiltonian will be discussed. Specific heat has been measured at dilution fridge temperatures up to 18 T on a single crystal sample which gives further information on the low temperature phases. In addition, inelastic neutron scattering has been performed and the broad continuum observed is consistent with deconfined 2D spinons which lends further support of herbertsmithite's quantum spin liquid candidacy.

10:48AM H8.00011 Single Crystal NMR Study of Frustrated Spin-Liquid in $S = 1/2$ Kagome Lattice $ZnCu_3(OD)_6Cl_2$, MINGXUAN FU, DAVID. A. TORCHETTI, Department of Physics and Astronomy, McMaster University, Hamilton, ON L8S 4M1, CAN, TAKASHI IMAI, Department of Physics and Astronomy, McMaster University, Hamilton, ON L8S 4M1, CAN; Canadian Institute for Advanced Research, Toronto M5G 1Z8, CAN, TIANHENG HAN, YOUNG. S. LEE, Department of Physics, MIT, Cambridge, Massachusetts 02139, USA — Herbertsmithite $ZnCu_3(OD)_6Cl_2$ is one of the most promising examples for a quantum spin liquid state. Despite the remarkable absence of long range magnetic order down to at least 50mK, understanding the magnetic properties of $ZnCu_3(OD)_6Cl_2$ remains a challenge. This is mainly due to the difficulty in locating the defects, and in understanding the possible role of defects in the physical properties of this material. We have investigated the local magnetic and lattice environment of $ZnCu_3(OD)_6Cl_2$ single crystals¹ using NMR techniques². With successful identification of ^2D NMR signals arising from the nearest neighbors of Cu^{2+} defects substituting Zn, we find that 14(2)% of Zn sites are occupied by these weakly interacting Cu^{2+} defect spins, which contribute to the large Curie-Weiss enhancement of bulk susceptibility at low temperatures. We then discuss the key aspects of nuclear spin-lattice relaxation rate $1/T_1$ measured near the defect and intrinsic sites.

8:00AM H9.00001 Nonlinear conduction phenomena in the Mott insulator Ca_2RuO_4 , RYUJI OKAZAKI, YASUO NISHINA, YUKIO YASUI, ICHIRO TERASAKI, Department of Physics, Nagoya University, FUMIHIKO NAKAMURA, YUSAKU KIMURA, MARIKO SAKAKI, TAKASHI SUZUKI, ADMS, Hiroshima University — The 4d-electron Mott insulator Ca_2RuO_4 has attracted considerable attention because of its rich electronic states dramatically varied by temperature change, pressure, and isovalent Sr substitution. Recently, Nakamura *et al.* reported an intriguing result of current-voltage characteristics in Ca_2RuO_4 and found an E -induced insulator-to-metal transition caused by relatively low electric field $E \sim 50$ V/cm [1]. In this study we investigate the nonlinear conduction phenomena in the Mott insulating phase of Ca_2RuO_4 with a proper evaluation for self-heating effects. By utilizing a non-contact infrared thermometer, sample temperature was accurately determined even in the presence of large Joule heating. The resistivity shows a typical insulating behavior featured by thermal activation with an energy gap, but clearly depends on the applied currents. The result is highlighted by a strong suppression of the energy gap by the electrical currents. A striking similarity to the current dependence of charge-order gap in organic insulators is discussed in terms of the nonequilibrium phase transition.

[1] F. Nakamura *et al.*, (submitted).

8:12AM H9.00002 Emergent electronic and magnetic state in $Ca_3Ru_2O_7$ induced by Ti doping, XIANGLIN KE, Oak Ridge National Laboratory, J. PENG, Tulane University, D.J. SINGH, T. HONG, W. TIAN, C.R. DELA CRUZ, Oak Ridge National Laboratory, Z.Q. MAO, Tulane University — We report an emergent electronic and magnetic state in the bilayer ruthenate $Ca_3Ru_2O_7$ upon doping with a small concentration of Ti on the Ru sites. In contrast to a quasi-two-dimensional metallic state in $Ca_3Ru_2O_7$, which has an antiferromagnetic state formed by ferromagnetic bilayers stacked antiferromagnetically along the c-axis [1,2], we find an insulating state with a “G”-type nearest neighbor antiferromagnetic order in $Ca_3(Ru_{1-x}Ti_x)_2O_7$ for $x \geq 0.03$ [3]. The close proximity of these two distinct electronic and magnetic states demonstrates unique competing magnetic interactions in $Ca_3Ru_2O_7$, which provides a rare opportunity to investigate the interplay between correlated metal physics and Mott physics. Work supported by U.S. DOE.

8:24AM H9.00003 From quasi-2D metal with ferromagnetic bilayers to Mott insulator with G-type antiferromagnetic order in $Ca_3(Ru_{1-x}Ti_x)_2O_7$, JIN PENG, GAOCHAO WANG, Department of Physics and Engineering Physics, Tulane University, New Orleans, LA 70118, XIANGLIN KE, TAO HONG, Neutron Scattering Science Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, ZHIQIANG MAO, Department of Physics and Engineering Physics, Tulane University, New Orleans, LA 70118 — $Ca_3Ru_2O_7$ exhibits unique electronic and magnetic properties, such as giant magnetoresistance, a quasi-2D metallic ground state, and antiferromagnetic (AFM) order comprising of ferromagnetic bilayers coupled antiferromagnetically along the c-axis [1-3]. In this talk, we will show that only a few percent of Ti-doping at Ru sites can tune the ground state to a Mott-insulating state with “G”-type, nearest neighbor AFM order [4]. We have established the electronic and magnetic phase diagram of this doped system to address the underlying physics of such a Mott-transition. We find that a strong scattering effect due to the Ti ions’ empty 3d orbital significantly reduces electrons’ itinerancy, playing a pivotal role in the suppression of the bilayer ferromagnetism and inducing the Mott transition. These findings imply that $Ca_3Ru_2O_7$ involves competition between the antiferromagnetism due to the Mott transition and the itinerant ferromagnetism due to a Stoner instability. [1] X.N. Lin *et al.*, Phys. Rev. Lett. **95**, 017203(2005). [2] W. Bao *et al.*, Phys. Rev. Lett. **100**, 247203 (2008). [3] Y. Yoshida *et al.*, Phys. Rev. B **69**, 220411 (R) (2004). [4] X. Ke *et al.*, Phys. Rev. B **84**, 201102 (R) (2011).

8:36AM H9.00004 Orbital selective phase transition¹, YU-ZHONG ZHANG, Physics Department, Tongji University, Shanghai 200092, P.R. China, HUNPYO LEE, Institut für Theoretische Physik, Goethe-Universität Frankfurt, Frankfurt am Main 60438, Germany, HAI-QING LIN, Beijing Computational Science Research Center, Beijing 100089, China, CHANG-QIN WU, Department of Physics and State Key Laboratory of Surface Physics, Fudan University, Shanghai 200433, China, HARALD JESCHKE, ROSER VALENTI, Institut für Theoretische Physik, Goethe-Universität Frankfurt, Frankfurt am Main 60438, Germany — Orbital selective phase transition (OSPT), proposed to be responsible for the coexistence of localized and itinerant electrons, has attracted extensive interest from both experimentalists and theoreticians, since the observation of an anomalous behavior with a Curie-Weiss-like local spin in the metallic phase of $Ca_{2-x}Sr_xRuO_4$ at $0.2 \leq x \leq 0.5$. Recently, even more attentions have been paid to OSPT since the coexistence of localized and itinerant electrons may reconcile the strong debates on how to understand the origin of magnetism in various iron-based superconductors. Here, various mechanisms for OSPT are reviewed and a new mechanism will be proposed. The distinct band dispersion of different orbitals, which should be generally satisfied in various materials, is identified to be the crucial point for OSPT with magnetic order. Such an OSPT are not sensitive to the strength of Hund’s rule coupling. Heavy doping favors collinear antiferromagnetic state over the OSPT. Discussions are made related to the pnictides.

8:48AM H9.00005 Magnetic order arising from chemical chaos in A_2MnRuO_6 ($A = Sr, Ca$) double perovskites, ROHAN MISHRA, PATRICK WOODWARD, WOLFGANG WINDL, The Ohio State University — Experimentally Sr_2MnRuO_6 is observed to be a c-type antiferromagnetic insulator with a tetragonal structure, while Ca_2MnRuO_6 is found to be a metallic ferrimagnet with an orthorhombic structure. Both compounds display magnetic ordering even in the absence of any recognizable chemical ordering of Mn and Ru ions. In this work, we present first principles calculations to show that the change in properties of the two compounds is only a consequence of pressure and hence can be tuned either by epitaxial growth or by alloying at A-site with Sr^{2+} or Ca^{2+} ions. We find that the Mn e_g -states are highly sensitive to pressure. Compression raises their energy in Sr_2MnRuO_6 , accompanied by a transfer of electrons from the eg states to the Ru-Mn hybridized t_{2g} -states. This results in a transition from c-type antiferromagnetism to ferrimagnetism. Ferrimagnetic ordering in-turn allows for greater delocalization of the up-spin Ru t_{2g} -electrons, hence increasing the conductivity. We also show that in the presence of disorder, the Mn_{Ru} antisites couple ferromagnetically with their neighboring Mn_{Mn} sites. This allows for the interesting possibility of preserving highly spin-polarized conduction even in the absence of chemical ordering.

9:00AM H9.00006 Surface dynamics and electronic properties of parent and Mn doped $Sr_3Ru_2O_7$ ¹, JING TENG, CHEN CHEN, BIAO HU, JIANDI ZHANG, RONGYING JIN, WARD PLUMMER, Louisiana State University — High resolution Electron Energy Loss Spectroscopy has been utilized to measure the temperature dependence of the low energy excitations at the surface of cleaved $Sr_3(Ru_{1-x}Mn_x)_2O_7$ single crystals ($x = 0, 0.16$). Four loss peaks are observed and assigned as the $A_{1g}(2)$, $A_{2u}(3)$, $A_{2u}(2)$, and $A_{1g}(1)$ vibration modes. The continuous electronic excitation spectra, Drude tail, shows that the parent compound is metallic at all temperatures investigated (80K to RT). But the $A_{1g}(1)$ mode splits into two peaks between 145K and 210K indicating a structural transition at the surface. For the 16% Mn doped samples the bulk is insulating and antiferromagnetic below 160K. In contrast, the surface is always metallic. Upon cooling from RT the $A_{1g}(1)$ mode hardens with its width broadening from RT to 160K, and then softens and narrows quickly until 80K. The Drude tail exhibits similar behavior. Evidently the presence of the surface suppresses AF ordering and kills the insulating phase.

9:12AM H9.00007 The Physics of Hunds metals and its relevance for ruthenades, iron pnictides and chalcogenides, KRISTJAN HAULE, Rutgers The State University of New Jersey — I will discuss the physics of Hund's metals. In these systems the Coulomb interaction among the electrons is not strong enough to fully localize them, but it significantly slows them down, such that low-energy emerging quasiparticles have a substantially enhanced mass. This enhanced mass emerges not because of the Hubbard interaction U , but because of the Hund's rule interactions J that tend to align electrons with the same spin but different orbital quantum numbers when they find themselves on the same atom. I will show a few examples of such Hund's metals, including Sr_2RuO_4 , iron pnictides and iron chalcogenides materials. The electronic structure, computed by the Dynamical Mean Field Theory in combination with Density Functional Theory, successfully reproduces several experimental results and explains the key properties of these material: such as the mass renormalizations and anisotropy of quasiparticles, the crossover into an incoherent regime above a low temperature scale, the magnetic moments in iron compounds, etc. While at very low temperature our simulations predict these materials to be Fermi liquids, at finite temperature they strongly deviate from Fermi liquid prediction and can be characterized by self-energy which follows a powerlaw, with non-integer exponents. The origin of this non-Fermi liquid fixed point will be discussed.

9:48AM H9.00008 Anomalous E -type Antiferromagnetism in the ground state of Mn-substituted $Sr_3Ru_2O_7$ ¹, DALGIS MESA, Dept. of Physics, Louisiana State University, Baton Rouge, LA 70802, FENG YE, SONGXUE CHI, JAIME A. FERNANDEZ-BACA, V.O. GARLEA, Neutron Scattering Science Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, BIAO HU, RONGYING JIN, E.W. PLUMMER, JIANDI ZHANG, Dept. of Physics, Louisiana State University, Baton Rouge, LA 70802 — The bi-layer perovskite, $Sr_3Ru_2O_7$, has sparked a lot of interest because of the quantum critical behavior—related to a metamagnetic (magnetic field-tuned) phase transition. One of the key issues is related to the magnetism in the system. Here we report an investigation of the effects on magnetism resulting from chemical substitution in this compound. Our neutron scattering investigation reveals an unusual E -type antiferromagnetic (AFM) structure induced by Mn-substitution in the ground state of $Sr_3(Ru_{1-x}Mn_x)_2O_7$ ($x = 0.16$). The AFM structure exhibits a long-range order in ab -plane but almost only a single bilayer-thickness correlation along the c -direction, thus characterizing the system as a quasi-two-dimensional antiferromagnet while the AFM order parameter shows almost three-dimensional-like scaling character as T approaches T_N (~ 82 K). The magnetic moments are aligned along the c -axis with an upper limit of $\sim 0.70 \mu_B$ /Ru site. The induced AFM order most likely results from the enhancement of super-exchange interactions rather than from structural distortions or from freezing of electronic instabilities due to the nesting character of Fermi surface in the parent compound.

10:00AM H9.00009 Anisotropy of magnetoresistivities in $Sr_3Ru_2O_7$: Evidence for orbital-dependent metamagnetism¹, D. FOBES, G.C. WANG, Z.Q. MAO, Department of Physics and Engineering Physics, Tulane University, New Orleans, LA — $Sr_3Ru_2O_7$ has been studied extensively due to its rich electronic and magnetic ground state properties, such as its quantum criticality and electronic nematic phase [1,2]. In this talk we will present the results of in-plane angle-resolved directional magnetotransport anisotropy measurements, a technique we used previously to elucidate the orbital-selective nature of the itinerant metamagnetism in $Sr_4Ru_3O_{10}$ [3]. We find that the c -axis magnetoresistivity anisotropy undergoes a drastic change in symmetry from fourfold to twofold through the metamagnetic transition, consistent with the behavior expected for the strong spin polarization. In contrast, the in-plane magnetoresistivity anisotropy remains fourfold through the transition accompanied by only a gradual shift in phase, and only trends towards twofold symmetry at fields well above the transition. These findings suggest the $d_{xz,yz}$ bands, should play a pivotal role in the metamagnetic transition.

10:12AM H9.00010 Study of an electronic nematic with precise control of the applied magnetic field vector, JAN BRUIN, SUPA, University of St Andrews, RODOLFO BORZI, Instituto de Investigaciones Fisicoquímicas Teóricas y Aplicadas and Departamento de Física, IFLP, UNLP, ANDREAS ROST, SUPA, University of St Andrews, ROBIN PERRY, SUPA, University of Edinburgh, SANTIAGO GRIGERA, Instituto de Física de líquidos y sistemas biológicos, UNLP and SUPA, University of St Andrews, ANDREW MACKENZIE, SUPA, University of St Andrews — The layered perovskite metal $\text{Sr}_3\text{Ru}_2\text{O}_7$ has gained considerable interest since the discovery of its field tuned quantum criticality [1] and the subsequent discovery of a new electronic phase with a high magnetoresistive anisotropy, consistent with the existence of an electronic nematic fluid [2]. This anisotropy may be oriented by applying a moderate field (H_{ab}) in the plane of the RuO layers. The study of the behaviour of the electronic nematic state requires precise control over both the magnitude and direction of H_{ab} . For this purpose, we operate a 3-axis 9/1/1 tesla vector magnet, which offers full control of the magnetic field vector with a high degree of precision. Here, we present recent magnetotransport data for $\text{Sr}_3\text{Ru}_2\text{O}_7$ measured in the vector magnet. We confirm the two-fold to four-fold rotational symmetry breaking and show that it occurs even in the limit of small values of H_{ab} . Additionally, we address pinning of the anisotropy underlying crystal lattice. Finally, we show the dependence of the anisotropy on magnetic field and temperature, which may help explain its origin at the microscopic scale.

10:24AM H9.00011 Optical Polarization Microscopy of the Electron Nematic Phase in $\text{Sr}_3\text{Ru}_2\text{O}_7$, COLIN HEIKES, DAVID MACNEILL, Cornell University, SAIKAT GHOSH, S N Bose National Centre for Basic Sciences, R. PERRY, J.F. MERCURE, St. Andrews University, E.A. KIM, Cornell University, A. MACKENZIE, St. Andrews University, D.C. RALPH, Cornell University — We report the implementation of a fiber-based optical microscope, capable of operating at temperatures below 100 mK and in magnetic fields in excess of 9 Tesla, with sub-micron spatial resolution. This microscope is integrated into the bore of a dilution refrigerator with an optical fiber coupling light to an external optical table. Bench-top optical elements allow for polarization analysis of the reflected light from a surface and thus the detection of magnetic or other polarization-sensitive properties of mater at low temperature and high fields. As a first application of the instrument, we are studying the proposed electron nematic phase of the $n=2$ Ruddlesden-Popper material $\text{Sr}_3\text{Ru}_2\text{O}_7$, which exhibits a low-temperature phase transition in the form of an in-plane conduction anisotropy. We plan to detect this phase optically by analyzing the polarization rotation of the reflected light through the phase boundary, with the aim of imaging domain structure in the nematic phase.

10:36AM H9.00012 Suppression of An Antiferromagnetic Insulating Phase in $\text{Sr}_3(\text{Ru}_{1-x}\text{Mn}_x)_2\text{O}_7$ by Magnetic Field¹, BIAO HU, E.W. PLUMMER, R. JIN, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803 — Double-layered $\text{Sr}_3\text{Ru}_2\text{O}_7$ is a paramagnetic metal. The partial substitution of Mn for Ru results in metal-insulator transition at T_{MIT} and antiferromagnetic ordering at T_M in $\text{Sr}_3(\text{Ru}_{1-x}\text{Mn}_x)_2\text{O}_7$. Interestingly, both T_{MIT} and T_M can be easily suppressed by the application of magnetic field, especially for low-doping compounds ($x < 0.1$). This behavior can be explained as Mn-doping-induced antiferromagnetic-insulating domains below T_{MIT} . The application of magnetic field suppresses the antiferromagnetic coupling, thus converting the insulating domains back to metallic.

10:48AM H9.00013 The Orbital-Selected Mott Phase of the Nondegenerate Two-Orbital Hubbard Model¹, YUN SONG, Department of Physics, Beijing Normal University — We use the dynamical mean-field theory to study the optical conductivity and orbital susceptibility of the nondegenerate two-orbital Hubbard model in the orbital-selective Mott phase. The optical conductivity of the wide band presents expectedly a nonzero Drude peak, while the localization character is observed for the optical conductivity of the narrow band. Particularly, a rapidly reverse shape in the orbital susceptibility emerges right at Fermi surface, implying the coexistence of the orbital ordering with the orbital-selected Mott phase. We also find that the orbital-selected Mott transition can be suppressed by the negative crystal field splitting. Applying the present findings to compound $\text{Ca}_{2-x}\text{Sr}_x\text{RuO}_4$, we demonstrate that the orbital-selected Mott phase can not survive in wide doping region from $x=0.2$ to 2.0.

Tuesday, February 28, 2012 8:00AM - 11:00AM – Session H10 DAMOP: Invited Session: Strongly Interacting Photons 210A

8:00AM H10.00001 Strong photon-photon interaction in a coupled quantum dot- photonic crystal nanocavity¹, JELENA VUCKOVIC, Stanford University — Quantum dots (QDs) in photonic crystal nanocavities are interesting both as a testbed for fundamental cavity quantum electrodynamics (QED) experiments, as well as a platform for classical and quantum information processing. In addition to providing a scalable, on-chip, semiconductor platform, this system also enables very large dipole-field interaction strengths, as a result of the field localization inside of sub-cubic wavelength volumes (vacuum Rabi frequency is in the range of 10's of GHz). We have demonstrated controlled amplitude and phase modulation between two continuous wave (CW) optical beams at the single photon level (power less than a photon per cavity photon lifetime) interacting via a strongly coupled quantum dot - photonic crystal cavity system, and have subsequently extended this experiment to weak time-varying control field and a CW signal field. Recently, we have performed all-optical switching at the single photon level between two pulsed, resonant optical beams (with 40ps pulses and 80MHz repetition rate). In this experiment, we have measured transmission through the strongly coupled QD-cavity system as a function of delay between the two pulses, and have demonstrated a 22% increase in the transmission at zero delay. The increase in the transmission is a result of the saturation of the strongly coupled QD-cavity system. We have also studied the effects of the photon blockade and photon induced tunneling which result from the anharmonicity of the ladder of dressed states in a strongly coupled QD-nanocavity system. These effects lead to dramatic changes in the transmitted photon statistics, which can be varied from sub-Poissonian to super-Poissonian, and can be employed to generate nonclassical states of light (such as Fock or NOON states) with high efficiency.

¹This work has been supported by the ONR (PECASE Award), DARPA, and ARO.

8:36AM H10.00002 Single-photon nonlinearity¹, VLADAN VULETIC, MIT — Optical nonlinearity at the level of single photons will enable a variety of novel effects and applications, including the possibility of quantum gates between individual photons. We generate such a nonlinearity in an atomic ensemble by replacing the strong (classical) coupling field of electromagnetically induced transparency by the mode of an optical resonator. Then the resonant transmission of light through the atomic ensemble can be substantially altered even by the cavity vacuum. The vacuum induces a group delay of the optical pulse that corresponds to a group velocity of 1600 m/s. We also discuss possibilities for implementing a single-photon switch.

9:12AM H10.00003 Strongly nonlinear optics with plasmonics, PARK HONGKUN, Harvard University — No abstract available.

9:48AM H10.00004 Slow-light polaritons in Rydberg gases, MICHAEL FLEISCHHAUER, Dept. of Physics, University of Kaiserslautern — Slow-light polaritons are quasi-particles generated in the interaction of photons with laser-driven atoms with a Λ - or ladder-type coupling scheme under conditions of electromagnetically induced transparency (EIT). They are a superposition of electromagnetic and collective spin excitations. If one of the states making up the atomic spin is a high lying Rydberg level, the polaritons are subject to a strong and non-local interaction mediated by a dipole-dipole or van-der Waals coupling between excited Rydberg atoms. I will present and discuss an effective many-body model for these Rydberg polaritons. Depending on the detuning of the control laser the interaction potential between the polaritons can be repulsive or attractive and can have a large imaginary component for distances less than the so-called blockade radius. The non-local effective interaction gives rise to interesting many-body phenomena such as the generation of photons with an avoided volume, visible in strongly suppressed two-particle correlations inside the blockade volume. Moreover the long-range, power-law scaling of the interaction can in the repulsive case give rise to the formation of quasi-crystalline structures of photons. In a one dimensional system the low-energy dynamics of the polaritons can be described in terms of a Luttinger liquid. Using DMRG simulations the Luttinger K parameter is calculated and conditions for the formation of a quasi-crystal are derived. When confined to a two-dimensional geometry, e.g. using a resonator with quasi-degenerate transversal mode spectrum, Rydberg polaritons are an interesting candidate to study the bosonic fractional quantum Hall effect. I will argue that the formation of photons with an avoided volume is essential for explaining recent experiments on stationary EIT in Rydberg gases [1,2].

10:24AM H10.00005 Fast optical control of atom-light interactions using quantum dots coupled to photonic crystal cavities, EDO WAKS, University of Maryland — Quantum dots (QDs) are stable, bright, semiconductor based light emitters that exhibit a quantized energy spectrum. For these reasons they are excellent candidates for development of lasers, optoelectronic components, and could serve as basic building blocks for future quantum information technology. By coupling these nanostructures to optical cavities the interaction strength between QDs and light can be significantly increased. Photonic crystals (materials with a periodic index of refraction) are particularly promising for enhancing these interactions due to their ability to guide and confine light on the size scale of an optical wavelength. Photonic crystal based optical cavities have already been shown to enable the strong coupling regime of cavity quantum electrodynamics (cQED). In this regime a significant modification of both the QD emission spectrum and cavity reflectivity can be observed due to quantum mechanical mixing of atom-photon states. Control of QD-photon interactions on fast timescales is an important capability that enables strong nonlinear optical effects, opening up the door for a new class of opto-electronic devices at ultra-low light levels. It could also provide a promising route towards quantum information processing using photons and QDs to store and transmit quantum coherence. Here we describe a method to achieve fast all-optical control of atom-light interactions using indium arsenide (InAs) QDs coupled to photonic crystal cavities. We show that a QD strongly coupled to a photonic crystal cavity can exhibit very large optical Stark shifts due to resonant cavity enhancement of the electromagnetic field. Stark shifts as large as 20 GHz are demonstrated with as few as 10 photons in the cavity. These shifts can be used to control the QD resonant frequency on fast time scales, and therefore modify its interactions with the optical cavity through resonant detuning. Using this approach we demonstrate the ability to perform all optical switching with control pulse energies as small as 400 photons and switching times as fast as 140 ps. The approach can be improved through better cavity coupling methods to approach nonlinear optics near the single photon level.

Session H11 DMP: Focus Session: Graphene Structure, Stacking, Interactions: Interfaces and Adsorbates 210B

8:00AM H11.00001 Confinement of organic solvents by wet transfer of graphene, GREGORY DOIDGE, JOSHUA WOOD, ERIC POP, JOSEPH LYDING, University of Illinois — Transfer of graphene grown by chemical vapor deposition (CVD) on Cu requires a polymer support for the graphene and wet-etching of the Cu growth substrate. After etching, the polymer/graphene film must go through several solvent baths to remove contaminants. Water is commonly used for this cleaning due to its capability as a solvent and its ability to support the polymer/graphene film through high surface tension. By contrast, common organic solvents have lower surface tension, causing the film to tear and fold within the liquid. To bypass this challenge, we have implemented a polymer-bound truss to reinforce the polymer/graphene film, which avoids the need of proper solvent surface tension. We have transferred graphene grown on Cu using common organic solvents like methanol, isopropanol, ethylene glycol, and dimethyl sulfoxide for the final transfer liquids. This process traps the solvents between the graphene and the final substrate. Confinement effects are determined via optical microscopy, atomic force microscopy, and Raman spectroscopy for both the trapped solvent molecules and the graphene. Our procedure opens up the possibility of confining biological materials suspended in organic solvents under graphene.

8:12AM H11.00002 Photo-assisted polymerization of one-dimensional molecular arrays on epitaxial graphene, TEYU CHIEN, APARNA DESHPANDE¹, CHUN-HONG SHAM, JUSTICE ALABOSON, MARK C. HERSAM², Department of Materials Science and Engineering, Northwestern University, Evanston, Illinois 60208 — Self-assembled monolayers provide opportunities to tailor the materials properties of graphene and template subsequent chemical functionalization at molecular length scales. In particular, 10,12 pentacosadiynoic acid (PCA) is found to assemble into one-dimensional arrays on epitaxial graphene on SiC(0001) as revealed by ultra-high vacuum scanning tunneling microscopy (UHV-STM). Furthermore, UV-triggered polymerization of PCA in UHV is achieved, leading to distinct conformational changes at the molecular scale. The sub-5 nm widths of these one-dimensional polymers make them promising candidates for templating the formation of graphene nanoribbons with significant band gaps. Molecular resolution UHV STM characterization of the structure and electronic properties of this nanostructured chemical functionalization strategy will be presented.

8:24AM H11.00003 Chemical reactivity imprint lithography on graphene: Controlling the substrate influence on electron transfer reactions, QING HUA WANG, ZHONG JIN, KI KANG KIM, ANDREW HILMER, GERALDINE PAULUS, CHIH-JEN SHIH, Massachusetts Institute of Technology, MOON-HO HAM, Gwangju Institute of Science and Technology, JAVIER SANCHEZ-YAMAGISHI, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, JING KONG, PABLO JARILLO-HERRERO, MICHAEL STRANO, Massachusetts Institute of Technology — The chemical functionalization of graphene enables control over electronic properties and interactions with other materials. Graphene's chemical reactivity is strongly influenced by the underlying substrate. In this paper, we show a stark difference in the rate of electron transfer chemistry with aryl diazonium salts on monolayer graphene supported on a broad range of substrates. Reactions proceed rapidly when graphene is on SiO₂ and Al₂O₃ (sapphire), but negligibly on alkyl-terminated and hexagonal boron nitride (hBN) surfaces. The effect cannot be explained by the overall graphene doping levels alone, and can instead be described using a reactivity model accounting for substrate-induced electron-hole puddles in graphene. Raman spectroscopic mapping is used to characterize the effect of the substrates on graphene. Reactivity imprint lithography (RIL) is demonstrated as a technique for spatially patterning chemical groups on graphene by patterning the underlying substrate, and is applied to the covalent tethering of proteins on graphene.

8:36AM H11.00004 Graphene on Metals: Interface Structure and Defects, LYUDMYLA ADAMSKA, RAFIK Q. ADDOU, MATTHIAS BATZILL, IVAN I. OLEYNIK, University of South Florida — The epitaxial growth of graphene on metal substrates is one of the major methods of graphene production for electronic applications. Therefore, the metal/graphene interface interactions as well as the graphene defects appeared during the growth affect in a substantial way the electronic properties of both graphene and graphene/metal contacts, which are both important for device applications. Structural and electronic properties of simple and complex graphene/metal as well as graphene/metal-alloy interfaces were investigated using first principles density functional theory. The point defect structures in graphene on metal substrate were studied and compared with those in free standing graphene.

8:48AM H11.00005 Topologically Frustrated Bonding in Dual-sided Adsorption to an Atomically Thin Membrane, CHENG-ING CHIA, VINCENT CRESPI, Department of Physics, Pennsylvania State University — A seamless sp^2 atomically thin layer cuts space in half, and prevents penetration of atoms through the sheet, while still allowing cross-sheet charge transfer. This geometrical frustration separates charge donating (e.g. alkali) and charge accepting (e.g. halogen) ions in opposite subspaces and generates a collective planar dipole. In this unusual geometry we observe new physics and chemistry. For graphene layer the uncompensated Coulomb interactions generate a system with multiple nearly degenerate structures which are either metallic or small-gap semiconductors, in contrast to the insulating behavior of unfrustrated salt crystals. When the layer is changed to h-BN, the collective dipole imposes a large Stark effect on the halogen and alkali-derived valence and conduction bands, resulting in a large band gap tuning with areal adsorbate density.

9:00AM H11.00006 Correlation between adatom adsorption properties and growth morphology of metal on graphene¹, XIAOJIE LIU, Ames Laboratory, Iowa State University and Jilin University, China, C.Z. WANG, M. HUPALO, Ames Laboratory, Iowa State University, WEN-CAI LU, Jilin University, China, Y.X. YAO, P.A. THIEL, K.M. HO, M.C. TRINGIDES, Ames Laboratory, Iowa State University, AMES LABORATORY, IOWA STATE UNIVERSITY TEAM, JILIN UNIVERSITY, CHINA COLLABORATION — We present a systematic study of various metal adatom adsorption on graphene by *ab initio* calculations. The correlation between the adatom adsorption properties and the growth morphology of the metals on graphene is investigated. We show that the growth morphology is related to the ratio of the adsorption energy to the bulk cohesive energy (E_a/E_c) of the metals and the diffusion barrier (ΔE) of the metal adatom on graphene. The growth morphology is also affected by the strain induced by metal adsorption on graphene. We also show that most of the metal nanostructures on graphene are thermally stable against coarsening. The first-principles calculations are consistent well with the observations from recent experiments.

¹Supported by DOE-BES under Contract No. DE-AC02-07CH11358

9:12AM H11.00007 Lithium Intercalation Induced Decoupling of Epitaxial Graphene on SiC(0001): Electronic Property and Dynamic Process, YUANCHANG LI, GANG ZHOU, Department of Physics, Tsinghua University, Beijing, JIA LI, Institute of Advanced Materials, Graduate School at Shenzhen, Tsinghua University, Shenzhen, JIAN WU, BING-LIN GU, WENHUI DUAN, Department of Physics, Tsinghua University, Beijing, CMT TEAM — This work presents first-principles investigations of the dynamic process of lithium (Li) penetration through the buffer layer on 6H-SiC(0001) surface, as well as the Li-insertion induced change of electronic structure. It is found that the penetration is kinetically forbidden for perfect buffer layer, because of the size confinement of its honeycomb structure. From the analysis of rate coefficient under the experimental conditions, topological defects no smaller than 8-membered ring are predicted to be essential for Li intercalation. Along with the Li insertion, the electronic property of the buffer layer is changed from n-type doping (Li-adsorption) to that of quasi-free-standing graphene (Li-intercalation). It is the electron injection by Li that results in the dissociation of the Si-C bonds and the decoupling of Li-intercalated buffer layer from the substrate. Moreover, we demonstrate the influence of such topological defects on the electronic property of epitaxial graphene, which provides some useful hints for understanding the observed gap and midgap state behavior.

9:24AM H11.00008 Single atom doping of graphene – A theoretical study, AMIR NATAN, Department of Physical Electronics, Tel-Aviv University, 69978 Tel-Aviv, Israel, TAMAR SEIDEMAN, Department of Chemistry, Northwestern University, Evanston IL 60208-3113, USA — We present first principles results and analysis for the electronic structure of chemically modified graphene. We show the relationship between different physical parameters and the electronic band structure of the modified material and its doping level. Finally, we discuss the possible effects of a substrate and of charge transfer patterns for device applications.

9:36AM H11.00009 Hydrogen adsorption induced structural and electronic changes in graphene grown on metal substrate, SRIVATS RAJASEKARAN, SARP KAYA, TOYLI ANNIYEV, HIROHITO OGASAWARA, ANDERS NILSSON, Stanford Synchrotron Radiation Lightsource, FAN YANG, DARIO STACCHIOLA, Chemistry Department, Brookhaven National Laboratory, FRANK-ABILD PEDERSON, JENS NORSKOV, SUNCAT, STANFORD SYNCHROTRON RADIATION LIGHTSOURCE TEAM, CHEMISTRY DEPARTMENT, BROOKHAVEN NATIONAL LABORATORY COLLABORATION, SUNCAT COLLABORATION — Graphene hydrogenation proposed to open a band gap has also been shown to be the case for graphene on metal substrates. Our carbon specific soft x-ray (photoelectron, absorption, emission) spectroscopy studies on single and few layer graphene on Pt(111) do not indicate band opening due to hydrogenation. The graphene layer is weakly interacting with the Pt(111) substrate but hydrogenation induces structural changes which lead to observation of density of states at the Fermi level (contrary to band opening hypothesis) due to strong hybridization with substrate. Hydrogenation observed to occur only on the surface atoms of few layers of graphene induces interlayer carbon-carbon bonding due to structural distortions initiated at the surface, i.e. propagation of sp^3 hybridization to underneath carbon layers. This structure is stabilized due to hybridization of the carbon atoms in the bottom layer with the Pt(111) substrate.

9:48AM H11.00010 Vibrational Spectrum of “Crystalline Graphane”, A.I. KOLESNIKOV, Oak Ridge National Laboratory, Oak Ridge, TN, USA, V.E. ANTONOV, I.O. BASHKIN, V.S. EFIMCHENKO, Ins. Solid State Physics RAS, Chernogolovka, Russia, G.E. GRANROTH, Oak Ridge National Laboratory, Oak Ridge, TN, USA, V.I. KULAKOV, Ins. Solid State Physics RAS, Chernogolovka, Russia, T. SHERLINE, Oak Ridge National Laboratory, Oak Ridge, TN, USA, ORNL TEAM, ISSP RAS TEAM — Since the discovery of graphene, a flat monolayer of carbon atoms, a great interest was attracted to synthesis of chemically modified carbon sheets. In particular, it was proposed that graphane, representing a graphene sheet saturated by hydrogen adsorbed from both sides, would be stable [1], and this prediction was confirmed by TEM [2]. Recently, hydrogenated graphite with a composition close to CH has been synthesized by exposing the graphite to gaseous hydrogen at $P=2$ to 7 GPa and $T=350$ to 450°C [3]. The formation of hydrographite is accompanied by a 40% increase in the c -parameter of the unit cell. The IR spectrum shows a strong band near 2850 cm^{-1} due to stretching vibrations of the C-H covalent bonds. In the present work, we studied the vibrational spectrum of hydrographite by inelastic neutron scattering. The obtained spectrum is very similar to that calculated for a single graphane plane [4]. This suggests a weak interaction between the graphane layers in hydrographite, so it could be considered as a “crystalline graphane” material. 1. J.O. Sofo et al., PRB **75**, 153401 (2007). 2. D.C. Elias et al., Sci. **323**, 610 (2009). 3. I.O. Bashkin et al., Int. Symp. Metal-Hydr. Syst., Reykjavik, Iceland, 2008. 4. G. Savini et al., PRL **105**, 037002 (2010).

10:00AM H11.00011 Direct determination of the dominant scatterer in graphene on silicon oxide¹, JYOTI KATOCH, MASA ISHIGAMI, Department of Physics and Nanoscience Technology Center, University of Central Florida, Orlando, FL — Previously the density of native scatterers in graphene on silicon oxide was shown to be proportional to the number of adsorption sites for atomic hydrogen [1]. However, this study provided limited information about the sites in graphene with affinity to atomic hydrogen. We employed a detailed temperature programmed desorption study on hydrogen-dosed graphene sheets. The determined desorption energy is used to reveal the nature of the dominant scatterer in graphene on silicon oxide.

[1] J. Katoch, J.H. Chen, R.Tsuchikawa, C.W. Smith, E.R. Mucciolo, and M. Ishigami, *Uncovering the dominant scatterer in graphene sheets on SiO₂*, Physical Review B Rapid Communications, 82, 081417 (2010).

10:12AM H11.00012 Electron Heat Capacity of Nitrogen Doped Graphene in Low Temperature, DI LUO, WANG-CHUANG KUO, None — We calculate the electron heat capacity of nitrogen doped graphene with a simple method. There are four kinds of bonds to be considered, the pi and anti-pi bonds of C-C and C-N. And the extra electrons are treated as free constituents. We found a small amount of difference in the electron heat capacity between a pure graphene and a thin film CN_x. Nevertheless, with a precise measurement on the electron heat capacity of the thin film or layer structure of CN_x, we can determine the doping concentration of nitrogen.

10:24AM H11.00013 Chemical reactions and thermal stability of oxygen impurities on graphene¹, BIN WANG, Department of Physics and Astronomy, Vanderbilt University, SOKRATES PANTELIDES, Vanderbilt University and ORNL — Oxygen as an impurity is known to degrade conductivity in graphene, but annealing at moderate temperature reverses the effect. Here we report first-principles calculations of oxygen binding and reactions on graphene that elucidate the underlying physics. We find that two O atoms can form an O dimer that can desorb from graphene with an overall activation barrier of 1.3 eV. Oxygen can also be removed in a more complicated reaction in which C atoms in graphene are consumed. We find that structural defects such as Stone-Wales defect and grain boundaries show enhanced binding to O atoms due to the local strain, facilitating the O reaction. If H atoms coexist, an O atom can bind to an H atom forming an OH group, which can also be removed by thermal annealing due to the weak binding, resulting in defect-free graphene.

¹This work was supported by DTRA Grant No. HDTRA1-10-1-0016 and the William A. and Nancy F. McMinn Endowment at Vanderbilt University. The calculations were performed at Air Force Research Laboratory DoD Supercomputing Resource Center.

10:36AM H11.00014 Efficient adsorbate transport on graphene by electromigration, KIRILL VELIZHANIN, Los Alamos National Laboratory, DMITRY SOLENOV, Naval Research Laboratory — Chemical functionalization of the surface of graphene holds promise for various applications ranging from nanoelectronics to surface catalysis and nano-assembling. In many practical situations it would be beneficial to be able to propel adsorbates along the graphene sheet in a controlled manner. We propose to use electromigration as an efficient means to transport adsorbates along the graphene surface. Within the tight-binding approximation for graphene, parametrized by density functional theory calculations, we estimate the contributions of the direct force and the electron wind force to the drift velocity of electromigration and demonstrate that the electromigration can be rather efficient. In particular, we show that the drift velocity of atomic oxygen covalently bound to graphene can reach up to 4 cm/s for realistic graphene samples. Further, we discuss ways to dynamically, i.e., during experiment, control the efficiency of electromigration by charging and/or local heating of graphene.

Tuesday, February 28, 2012 8:00AM - 11:00AM —

Session H12 DMP DCMP: Chemical Doping of Graphene and Applications: Solar Cells, Sensors

210C

8:00AM H12.00001 I-V characteristics of organic molecules coated graphene, SEUNG JAE BAEK, YUNG WOO PARK, Seoul National University — Thin layers of organic molecules, OTS and DMF, are coated on top of graphene which was extracted by the exfoliation. I-V characteristics of the organic molecules coated graphene were investigated at low temperature by varying the gate voltage. P-doping with slight enhancement of mobility was observed with the OTS coating. On the other hand, n-doping with relatively higher enhancement of mobility was obtained with the DMF coating. CNT is nested on top of the organic molecules coated graphene by dielectrophoresis and Coulomb blockade was observed in the sandwich device.

8:12AM H12.00002 Investigation of Electrochemical Gate Controlled Charge Transport in Large Area Boron-Nitrogen Doped Graphene, SUJOY GHOSH, Southern Illinois University, Carbondale, SWASTIK KAR, Northeastern University, Boston, ZHENG LIU, ROBERT VAJTAI, PULICKEL AJAYAN, Rice University, Houston, SAIKAT TALAPATRA, Southern Illinois University, Carbondale, SOUTHERN ILLINOIS UNIVERSITY COLLABORATION, NORTHEASTERN UNIVERSITY COLLABORATION, RICE UNIVERSITY COLLABORATION — We report on the investigation of charge transport measurements of B and N doped graphene C (B,N) under the influence of an electrochemical gate. These C (B,N) systems are expected to have unique electronic properties due to the combination of impurities including both atomistically separated B and N species, as well as hexagonal boron nitride (*h*-BN) units within the graphitic C lattice. Investigations were performed on large area BN doped graphene devices fabricated with different BN doping levels. The electrochemically gate controlled interfacial capacitance and quantum capacitance of BN doped graphene devices were measured. The effect of doping on the quantum capacitance and electron mobility will be discussed.

8:24AM H12.00003 Stable Chemical Doping of Graphene for Low Electrical Resistance and High Optical Transparency, KARA BERKE¹, SEFAATTIN TONGAY², MAX LEMAITRE³, ZAHRA NASROLLAHI⁴, DAVID TANNER⁵, BILL APPLETON⁶, ARTHUR HEBARD⁷, University of Florida — Since becoming experimentally available, graphene has been used in various devices such as field effect transistors (FETs), solar cells and sensing applications. Although graphene based devices with modest characteristics have been reported, in some device geometries a lower graphene resistance with different Fermi level values is still desired. Here, we describe our use of a hydrophobic organic dopant with strong electronegativity, environmental stability and high optical transmittance which is spin cast onto CVD-grown graphene films. We observe a typical 70% reduction in resistance upon chemical modification of the graphene. Magnetoresistance measurements imply that the modified graphene is hole doped, and time-dependent resistance measurements show excellent stability. Using Raman spectroscopy we confirm the doping of graphene sheets from the shifts in G and 2D peak positions and intensity ratios. We show transmittance and SEM characteristics of the graphene sheets before and after doping. These results may serve as a guide for modification of graphene's properties as desired for various applications.

8:36AM H12.00004 Reversible and Robust Carrier Doping in Graphene *via* Mechanical Actuation of Tethered Azobenzene, PHONG NGUYEN, VIKAS BERRY, NIHAR MOHANTY, KABEER JASUJA, Kansas State University, VIVEK SHENOY COLLABORATION — machines – molecules capable of responding to external stimuli - have gained great interest due to their applications in molecular actuation nanodevices. In this talk, we demonstrate that ultrathin graphene exhibits high-sensitivity to orientation, surface-vicinity, electronegativity, and density-of-states of interfaced molecules. This enables the realization of reversible doping of graphene *via* molecular mechanics on its surface. Here, few-layer-graphene (FLG) sheets were functionalized with electronegative and isomerizable azobenzene-molecules. The optical transformation of these azo-molecules from their *trans* conformation to *cis* conformation dopes 7.5×10^3 holes/ μm^2 in the underlying graphene. This corresponds to ~ 20 azobenzene molecules producing 1 hole (hole-mobility of $301 \mu\text{m}^2/\text{V/s}$) in the azobenzene-FLG (AFLG) device. Further, we demonstrate the facile fabrication of the AFLG device and the mechanism of electrical modulation due to molecular mechanics. We also compare the response of the AFLG device with an FLG device directly doped with electronegative perylene tetracarboxylic acid, which led to ~ 3 fold increase in the hole density. -abstract-

8:48AM H12.00005 Tuning the Electrical Properties of Large Area Graphene through Boron-Nitrogen Co-Doping, BALEESWARAIAH MUCHHARLA, ARJUN PATHAK, Southern Illinois University, Carbondale, ZHENG LIU, LI SONG, Rice University, SWASTIK KAR, Northeastern University, Boston, ROBERT VAJTAI, PULICKEL AJAYAN, Rice University, Houston, SAIKAT TALAPATRA, NAUSHAD ALI, Southern Illinois University, Carbondale, SOUTHERN ILLINOIS UNIVERSITY, CARBONDALE TEAM, RICE UNIVERSITY, HOUSTON COLLABORATION, NORTHEASTERN UNIVERSITY, BOSTON COLLABORATION — We report on investigation of low temperature electrical transport measurements of B and N co-doped graphene layers C (B, N). We find that the temperature dependence of resistance ($5\text{K} < T < 400\text{K}$) of pure graphene shows a metallic behavior, whereas the C (B, N) samples show an increasingly semiconducting behavior with increasing doping levels. Within the studied temperature range, at higher temperatures, the doped samples showed a band-gap dominated Arrhenius-like temperature dependence. At the lowest temperatures, the temperature dependence deviates from an activated behavior, and presents evidence for a conduction mechanism that is consistent with Mott's 2D-Variable Range Hopping (2D-VRH).

9:00AM H12.00006 Raman studies of ultra-clean graphene on hexagonal boron nitride with controlled doping, YILEI LI, INANC MERIC, KIN FAI MAK, LEANDRO MALARD, CORY DEAN, PHILIP KIM, KENNETH SHEPARD, TONY HEINZ, Columbia University — Graphene prepared by exfoliation on hexagonal boron nitride (h-BN) provides an ideal platform for studies of the intrinsic properties of Dirac electrons because of its unprecedented charge homogeneity. With this system, many of the fascinating phenomena hidden by charge inhomogeneity in conventional graphene samples have recently been revealed. Here we describe progress in examining both electron-phonon and electron-electron interactions by means of Raman scattering by the G- and the 2D-modes. In our studies, we were able to observe a symmetric energy shift in the Raman 2D peak at low doping levels when the Fermi level was tuned from the electron side to the hole side. This shift is understood as a change in the double-resonance condition induced by the renormalization of the electron and phonon band structures. At the same time, the 2D peak is broadened under electron or hole doping. Additionally, we observed very weak doping dependence of the G peak (both position and width) at Fermi energies less than half of the phonon energy and the subsequent usual removal of non-adiabatic Kohn anomaly with increased doping, which reflects again the extremely homogeneous charge distribution in our samples.

9:12AM H12.00007 Scanning Tunneling Microscope (STM) Study of B-doped Monolayer Graphene, LIUYAN ZHAO, Columbia University, MARK LEVENDORF, Cornell University, CHRISTOPHER GUTIERREZ, THEANNE SCHIRO, GEORGE FLYNN, Columbia University, JIWOONG PARK, Cornell University, ABHAY PASUPATHY, Columbia University, COLUMBIA UNIVERSITY COLLABORATION, CORNELL UNIVERSITY COLLABORATION — Chemical doping is a promising technique to tailor the electronic properties of graphene. Here we focus on an atomic scale characterization of Boron-doped monolayer graphene sheets using primarily STM, assisted by Raman Spectroscopy and X-ray Absorption Spectroscopy (XAS). We will show in topography that there are two major structures that result from B-doping, and in spectroscopy that each of these structures plays different roles in modifying the electronic properties of graphene. Raman Spectroscopy and XAS provide complementary information about the nature of the B-C bonds in the sample.

9:24AM H12.00008 Substituent Effects for the Control of Covalent Electronic Doping of CVD Graphene, GERALDINE L.C. PAULUS, Massachusetts Institute of Technology, MOON-HO HAM, Kyungwon University, QING HUA WANG, ANDREW J. HILMER, KI KANG KIM, CHIH-JEN SHIH, ZACHARY ULISSI, JING KONG, MICHAEL S. STRANO, Massachusetts Institute of Technology — Controlling the electrical properties of graphene is of particular interest for future electronic, optoelectronics and sensing applications. We investigate the doping effect of different chemical functional groups covalently attached to CVD-grown graphene devices with a polymer electrolyte top-gate. The covalent reaction is based on a diazonium chemistry, specifically the type and degree of doping for a diazonium salt with a nitro group, a bromo group or an alkyne group attached are investigated. We use three different approaches to inspect various aspect of the doping in graphene: Gaussian calculations, Raman measurements and transfer-characteristics. The transfer curves show that nitro groups induce p-doping while the bromo- and alkyne groups induce n-doping. A new model that takes into account both coulombic and resonant scattering as well as a asymmetric electron and hole transport is developed to fit the transfer-curves. The graphene transistors are very robust and reproducible, suggesting this is a simple and facile way to control the electronic properties of graphene.

9:36AM H12.00009 Charge transfer and density of states modifications of graphene upon molecular adsorption - Implications for gas and molecular sensors, DAVID CAREY, ALEXANDER SAMUELS, University of Surrey — The adsorption of molecules on single layer graphene can result in significant modifications to the band structure and density of states near the Dirac point and can result in the introduction of scattering centres which can modify the carrier mobility. Understanding how the competing interactions of increased carrier density and density of scattering centres is therefore an important consideration in the description of the properties of graphene. We have used ab initio methods to explore the degree of charge transfer, modification to the band structure and density of states associated with the adsorption of a range of open and closed shell molecules, organometallic molecules and planar organic molecules. We show how the charge transfer can be related to the position of the molecule related energy levels on adsorption relative to the Dirac point. We find low levels ($<0.05e$) of charge transfer for NH_3 , NO and NO_2 molecules but larger values for cobaltocene (n-type, 0.31 e/molecule) and about 0.3 e/molecule for the organic molecules TDAE (n-type) and DDQ (p-type) respectively. These molecules open up ways to dope graphene to high levels and are important considerations in sensing. We also discuss the factors that control the charge transfer.

9:48AM H12.00010 Biochemical Sensing in Solution Gated Graphene Field Effect Transistors¹, MAURICIO D. BEDOYA, JAN SCRIMGEOUR, School of Physics and Petit Institute for Bioengineering and Bioscience, Georgia Institute of Technology Atlanta, GA 30332 (USA), JAMES PALMER, W.A. DEHEER, School of Physics, Georgia Institute of Technology Atlanta, GA 30332 (USA), C. BERGER, School of Physics, Georgia Institute of Technology Atlanta, GA 30332 (USA) and CNRS-Institut Neel, BP 166, 38042 Grenoble, Cedex 9, France, J.E. CURTIS, School of Physics and Petit Institute for Bioengineering and Bioscience, Georgia Institute of Technology Atlanta, GA 30332 (USA) — Epitaxial graphene is a promising material for the construction of label-free chemical and biochemical sensors. In this work, graphene of few-layers is used as a sensor for pH and ionic strength in a solution gated field effect transistor (SGFET). In order to improve the sensitivity of the SGFET to pH and ionic changes the transistor is connected in a four-point (van der Pauw) configuration. Results for the shift in the Dirac point when the pH or ionic strength is changed are shown.

¹This work is supported by the National Science Foundation under Grant No. DMR-0820382

10:00AM H12.00011 Combined transport-Scanning Probe Microscopy study of reduced graphene oxide sensors, CHRISTOPHER KEHAYIAS, JOSEPH RAHAMIM, Physics and Astronomy, Tufts University, SAMUEL MAC-NAUGHTON, SAMEER SONKUSALE, Electrical and Computer Engineering, Tufts University, CRISTIAN STAIL, Physics and Astronomy, Tufts University — We present an in-depth study of the sensing properties of chemically reduced graphene oxide (rGO) based devices. Graphene oxide is an electronically hybrid material that can be controllably tuned from an insulator to a semiconductor material via reduction chemistry. Due to their chemical structure and large surface to volume ratio rGO sensors can detect gas adsorption at very low concentrations. rGO devices are created by dielectrophoretic assembly of rGO platelets onto interdigitated electrode arrays, which are lithographically pre-patterned on top of SiO_2/Si wafers. The gas sensing properties of these devices are characterized using novel combined transport-Scanning Kelvin Probe Microscopy and transport-Electrostatic Force Microscopy measurements in the presence of different gas analytes. These measurements show unique, very sensitive and repeatable responses to various volatile organic compounds and other gases. Maps of the electrostatic potential and charge distribution across these circuits are used to model the dynamics of electronic transport through the rGO system.

10:12AM H12.00012 Biomimetic graphene sensors: functionalizing graphene with peptides¹, MASA ISHIGAMI, Department of Physics and Nanoscience Technology Center, University of Central Florida, Orlando, FL, SANG NYON KIM, RAJESH NAIK, Materials and Manufacturing Directorate, Air Force Research Laboratory, Wright-Patterson Air Force Base, OH 45433, SUREN A. TATULIAN, Department of Physics, University of Central Florida, Orlando, FL, 32816-2385, JYOTI KATOCH, Department of Physics and Nanoscience Technology Center, University of Central Florida, Orlando, FL — Non-covalent biomimetic functionalization of graphene using peptides is one of more promising methods for producing novel sensors with high sensitivity and selectivity. Here we combine atomic force microscopy, Raman spectroscopy, and attenuated total reflection Fourier transform infrared spectroscopy to investigate peptide binding to graphene and graphite. We choose to study a dodecamer peptide identified with phage display to possess affinities for graphite and we find that the peptide forms a complex mesh-like structure upon adsorption on graphene. Moreover, optical spectroscopy reveals that the peptide binds non-covalently to graphene and possesses an optical signature of an α -helical conformation on graphene.

¹This work is based upon research supported by the National Science Foundation under Grant No. 0955625

10:24AM H12.00013 Solution-gated graphene field-effect transistors as local pH sensors in microfluidic systems, WAN LI, Department of Physics, Cornell University, HÉCTOR D. ABRUÑA, Department of Chemistry and Chemical Biology, Cornell University, DANIEL C. RALPH, Department of Physics, Cornell University — We report a study of solution-gated graphene field-effect transistors (SGGFETs) as high-performance local pH sensors in microfluidic devices. Previous experiments have shown that SGGFETs can function as pH sensors for bulk volumes of solutions, and a response of 20 mV/(unit pH) shift in the Dirac point was typically observed. In our study, we investigated SGGFETs micro-fabricated out of CVD graphene grown on copper foil and found a robust pH sensitivity of 50 mV/(unit pH). This value is close to the thermodynamically allowed maximum value, i.e., the Nernst value of 59 mV/(unit pH) at room temperature. We further integrated the SGGFETs into microfluidic systems for lab-on-chip applications. We found the SGGFETs are capable of real-time detection of local pH changes in microfluidic channels, thus providing reliable measurement of the local pH for small volumes of liquids (a few nL). Possible applications of this microfluidic detection system, for example, in monitoring chemical diffusion and reactions in microfluidic channels, will be discussed.

10:36AM H12.00014 A low cost construction method for Graphene based resistive chemical sensors¹, SILPA KONA, CINDY K. HARNETT, University of Louisville — Graphene is a 2D material with distinctive properties and a large surface area that can be exposed to surface adsorbates from a target gas, making it attractive as a sensing material. This enables studies on the interaction of gas molecules with the graphene surface and subsequent changes in its properties. Due to its high electron mobility at room temperature, graphene exhibits high sensitivity, making it a good candidate for environmental and industrial sensing applications. Several models of graphene based sensors have been put forth previously based on high-resolution lithographic techniques and for individual electrode attachment to the sensing film with e-beam lithography. These techniques can produce small numbers of devices that explore the limits of molecular scale sensing, but the methods are currently impractical for large scale production of low cost sensors. We present our graphene based sensor with the focus on designing small, cost effective and reliable sensors with high sensitivity towards the target gas, detailing the assembly of graphene/acrylic devices, their characterization and investigation of their performance as resistive chemical sensors using differential voltage measurements.

¹NSF GRANT AWARD # 0644511

10:48AM H12.00015 Finite temperature quantum transport in nanosensors based on graphene nanoribbons¹, KIRTI KANT PAULLA, AMIR FARAJIAN, Department of Mechanical and Materials Engineering, Wright State University — We study finite temperature quantum conductance of nanosensors based on graphene nanoribbons exposed to carbon and nitrogen oxides. Using ab-initio-based Green's function formalism, the quantum conductance of the nanoribbon with and without adsorbed oxide molecules is calculated. We investigate the effects of molecular vibrations and electron-vibron coupling on conductance modulation. The implication of the results concerning nanosensor functionality under desired environmental temperatures, and the differences with the low-temperature cases, are discussed

¹This research is supported by the National Science Foundation Grant ECCS- 0925939.

Tuesday, February 28, 2012 8:00AM - 11:00AM –
Session H13 DMP GMAG: Focus Session: Low-Dimensional and Molecular Magnetism - Magnetism and Transport of Isolated Molecular Magnets - Molecular spintronics 211

8:00AM H13.00001 Manipulating Molecular Kondo Effect by Chemical Reactions, HOWON KIM, Department of Physics, Korea University, YUNHEE CHANG, Graduate School of Nanoscience and Technology (WCU), KAIST, MIN HUI CHANG, Department of Physics, Korea University, YONG-HYUN KIM, Graduate School of Nanoscience and Technology (WCU), KAIST, SE-JONG KAHNG, Department of Physics, Korea University — Motivated by spintronic applications, the control of Kondo effect arising from spin exchange interaction between isolated spins and conduction electrons of non-magnetic metals, has been explored. A method to control the molecular Kondo effect is demonstrated via chemical reactions. A spontaneous binding between molecules was exploited to control the molecular Kondo effect on Au(111). The Kondo effect was switched back on using local scanning tunneling microscope manipulation. This method relies on the hybridized pairing of unpaired spins two molecules, as supported by our density functional theory calculation results.

8:12AM H13.00002 Electronic readout of a single nuclear spin using a molecular spin transistor, R. VINCENT, Institut Neel, CNRS, Grenoble, S. KLYASTSKAYA, M. RUBEN, INT and KIT, Karlsruhe, Germany, W. WERNSDORFER, F. BALESTRO, Institut Neel, CNRS, Grenoble — Quantum control of individual spins in condensed matter devices is an emerging field with a wide range of applications ranging from nanospintronics to quantum computing [1,2]. The electron, with its spin and orbital degrees of freedom, is conventionally used as carrier of the quantum information in the devices proposed so far. However, electrons exhibit a strong coupling to the environment leading to reduced relaxation and coherence times. Indeed quantum coherence and stable entanglement of electron spins are extremely difficult to achieve. We propose a new approach using the nuclear spin of an individual metal atom embedded in a single-molecule magnet (SMM). In order to perform the readout of the nuclear spin, the quantum tunneling of the magnetization (QTM) of the magnetic moment of the SMM in a transistor-like set-up is electronically detected. Long spin lifetimes of an individual nuclear spin were observed and the relaxation characteristics were studied. The manipulation of the nuclear spin state of individual atoms embedded in magnetic molecules opens a completely new world, where quantum logic may be integrated.

8:24AM H13.00003 DFT calculations of the charged states of N@C60 and {Fe4} single molecule magnets investigated in tunneling spectroscopy, JAVIER NOSSA, FHOKRUL ISLAM, CARLO CANALI, Linnaeus University, Kalmar, Sweden, MARK PEDERSON, Naval Research Laboratory, Washington, USA — For device applications of single molecule magnets (SMMs) in high-density information storage and quantum-state control it is essential that the magnetic properties of the molecules remain stable under the influence of metallic contacts or surface environment. Recent tunneling experiments [1, 2] on N@C60 and {Fe4} SMM have shown that these molecules preserve their magnetic characteristics when they are used as the central island of single-electron transistors. Although quantum spin models have been used extensively to study theoretically tunneling spectroscopy of SMMs, it has been shown recently that the orbital degrees of freedom, which is absent in spin models, can significantly affect the tunneling conductance [3]. In this work we present first-principles calculations of the neutral and charged states of N@C60 and {Fe4} SMMs, and discuss a strategy to include their properties into a theory of quantum transport. We also present results of the magnetic anisotropy for the different charge states of Fe4 and discuss their relevance for experiments [2] in the sequential tunneling and cotunneling regimes.

8:36AM H13.00004 Beller Lectureship: Single Molecular Magnets on Conductive Surfaces¹, ROBERTA SESSOLI, Department of Chemistry & INSTM, University of Florence — For more than a decade molecules showing magnetic bistability, generally known as Single Molecule Magnets, have represented a playground to study quantum effects that appear in magnetism when the nanometer scale is attained. The field is now mature to investigate more complex nanostructures where the interplay between transport and magnetism at the molecular scale can be exploited. The first step along this direction requires to organize SMMs on surfaces rather than as bulk phases. Pursuing this apparently straight forward task has already encountered many difficulties because of the complex nature and fragility of SMMs and of the peculiar origin of their magnetic bistability. Also robust SMMs based on lanthanide ions and phthalocyanine lose most of their SMM properties when the crystalline phase is abandoned. Thanks to a collaboration with Prof. Cornia in Modena, Italy, and Prof. Saintavrit in Paris, France, we have carried out a very low temperature synchrotron investigation showing that a polynuclear SMM cluster, based on a propeller-like tetranuclear iron(III) core, Fe4, retains the typical hysteresis also when the molecules are chemically grafted to a gold surface. The tailoring of the anchoring ligand has allowed the control of the orientation of the molecules on the substrate and has given the possibility to observe the resonant quantum tunneling of the magnetization. Preliminary investigations on Fe4 SMMs thermally evaporated in UHV conditions on a conducting ferromagnetic oxide like Lanthanum Strontium Manganite, have shown an unprecedented phenomenon. While the reported studies of paramagnetic molecules on magnetic substrates have in general shown a sizeable magnetic interaction with the substrate but no evidences of SMM behavior, in our investigation the magnetic hysteresis of Fe4 exceeds in coercive field that of the substrate, recorded at the Mn L3 edge. More interestingly, the zero field step of the hysteresis, typical of quantum tunneling of magnetization that characterizes Fe4 SMMs, disappears when deposited on LSMO, opening the perspective of a novel hybrid magnetism at the nanoscale.

¹The support of the European Research Council through the Advanced Grant MolNanoMaS is acknowledged.

9:12AM H13.00005 Theoretical study of hysteresis in electron transport through spin-crossover molecules, KRISTEN BROWN, KYUNGWHA PARK, Dept. of Physics, Virginia Tech, Blacksburg, VA 24061 — Recent advances in nanoscale molecular systems stimulate experimental studies of electron transport across molecular junctions formed by single molecules or nanoparticles bridged between electrodes, or molecular monolayers adsorbed onto surfaces, using three-terminal set-ups or scanning tunneling microscope. Among them, spin-crossover molecular systems draw attention due to their unusual coupling between spin degrees of freedom and external stimuli. Spin magnetic moments of these molecular systems increase with increasing temperature or pressure, or shining light, and their magnetization shows hysteresis behavior with temperature, pressure, or light. Recent transport measurements across nanoparticles made of such spin-crossover molecules reveal hysteresis behavior in current-voltage characteristics, driven by voltage at a given temperature. In this talk, we present our work on understanding of hysteresis in electron transport through a nanoparticle consisting of Fe-based spin-crossover molecules, using a model-Hamiltonian approach and insight obtained from density functional theory.

9:24AM H13.00006 Individual Magnetic Molecules on Ultrathin Insulating Surfaces, FADI EL HALLAK, London Centre for Nanotechnology, UCL, London, UK, BEN WARNER, London Centre for Nanotechnology, UCL, London, UK; Department of Physics & Astronomy, UCL, London, UK, CYRUS HIRJIBEHDIN, London Centre for Nanotechnology, UCL, London, UK; Department of Physics & Astronomy, UCL, London, UK; Department of Chemistry, UCL, London, UK — Single molecule magnets have attracted ample interest because of their exciting magnetic and quantum properties. Recent studies have demonstrated that some of these molecules can be evaporated on surfaces without losing their magnetic properties [M. Mannini *et al.*, *Nature* 468, 417, (2010)]. This remarkable progress enhances the chances of real world applications for these molecules. We present STM imaging and spectroscopy data on iron phthalocyanine molecules deposited on Cu(100) and on a Cu₂N ultrathin insulating surface. These molecules have been shown to display a large magnetic anisotropy on another thin insulating surface, oxidized Cu(110) [N. Tsukahara *et al.*, *Phys. Rev. Lett.* 102, 167203 (2009)]. By using a combination of elastic and inelastic electron tunnelling spectroscopy, we investigate the binding of the molecules to the surface and the impact that the surface has on their electronic and magnetic properties.

9:36AM H13.00007 Interfacial Electronic and Magnetic Coupling in Organic-metal System Studied by Scanning Tunneling Microscopy, YU-HSUN CHU, C.H. HSU, P.J. HSU, W.J. HSIEH, C.I. LU, S.W. CHEN, C.J. BUTLER, Department of Physics, National Taiwan University, 10617 Taipei, Taiwan, CHAO-CHENG KAUN, Research Center for Applied Sciences, Academia Sinica, Taipei 106, Taiwan, MINN-TSONG LIN, Department of Physics, National Taiwan University, 10617 Taipei, Taiwan — Organic materials have drawn much attention in spintronics studies because of their tunable properties by functional groups and potential to achieve molecular magnets. An important factor influencing these properties is the interfacial effect. In organic-metal systems, different interfaces lead to strong modulation of electronic structures and even magnetic behaviors like spin coupling. In our study, Mn-phthalocyanine (MnPc) deposited on Cu(111) surface have been measured by scanning tunneling microscopy (STM) and spectroscopy (STS) at 4.5 K. With different deposition amount, MnPc are adsorbed as isolated molecules or in an ordered assembled structure. From STS curves, assembled MnPc possess a broadened state near the onset of Cu(111) surface state comparing to isolated ones. According to ab initio calculation, distance between the central Mn atom and the substrate in assembled molecules is reduced due to intermolecular interaction and affects the electronic structures. Magnetic behaviors of MnPc on ferromagnetic metal substrate are further investigated by spin-polarized STM (SP-STM). Spin contrast of isolated molecules on Co nanoislands on Cu(111) is found near the Fermi level in STS maps, which is considered to be ferromagnetic coupling between MnPc and Co islands.

9:48AM H13.00008 The Kondo effect in molecular magnets from first principles, DAVID JACOB, Max Planck Institute of Microstructure Physics Halle, MICHAEL KAROLAK, ALEXANDER I. LICHTENSTEIN, University of Hamburg, MARIA SORIANO, JUAN JOSE PALACIOS, Universidad Autonoma de Madrid — When a magnetic molecule is deposited on a metallic substrate or attached to metallic contacts its magnetic moment may actually be screened by the conduction electrons due to the Kondo effect. In view of possible applications of molecular magnets such as nanoscale spintronics and magnetic storage devices, it is important to being able to predict whether the Kondo effect will take place or not in a given system. Also one would like to understand in detail how the Kondo effect emerges in a given situation and how it is controlled by the various parameters such as the molecular conformation and the type of substrate. Using a recently developed ab initio approach for molecular devices [1,2] that explicitly takes into account the strong electronic correlations that give rise to the Kondo effect, we have calculated the electronic structure and transport properties of different magnetic molecules coupled to nanocontacts [3] and surfaces [4]. Our calculations shed light on the complex nature of the Kondo effect in molecular-scale devices. [1] D. Jacob *et al.*, *PRL* 103, 016803 (2009); [2] D. Jacob *et al.*, *PRB* 82, 195115 (2010); [3] M. Karolak *et al.*, *PRL* 107, 146604 (2011); [4] K. J. Franke *et al.*, *Science* 20 940 (2011)

10:00AM H13.00009 ABSTRACT WITHDRAWN —

10:12AM H13.00010 Electronic transport in Co-based valence tautomeric conjugated polymers¹, MARCO BUONGIORNO NARDELLI, YIFENG CHEN, North Carolina State University, ARRIGO CALZOLARI, Istituto Nanoscienze CNR-NANO-S3, WANDERLA SCOPEL, North Carolina State University — Using first principle density functional theory (DFT) methods combined with maximally localized Wannier function (MLWF), real-space basis sets and a Green's function transport scheme within the Landauer ballistic transport regime, we investigated the electronic structures and electronic transport properties of a Co-based valence tautomeric (VT) conjugated backbone polymeric system. We found that GGA+U induced high-spin structure not in satisfactorily agreement with realistic circumstances from the computed Co projected density of states (PDOS). So we instead employed constrained magnetization calculations to induce the low-spin to high-spin magnetic transition computationally. Transport calculations showed that the high-spin structure is two orders of magnitude more conductive than the low-spin structure, thus supporting the vision that this kind of Co-based VT polymer can function as basis for switchable molecular spintronic devices. Finally, we will briefly discuss the chemisorption of this VT system on metallic substrates the spin transport properties of metal-molecule-metal configurations.

¹NSF Center for Chemical Innovation: Center for Molecular Spintronics (CHE-0943975)

10:24AM H13.00011 Dynamical magnetic anisotropy in spin-1 molecular systems¹, DAVID RUIZ-TIJERINA, Ohio University, PABLO CORNAGLIA, CARLOS BALSEIRO, Centro Atomico Bariloche, e Instituto Balseiro, Argentina, SERGIO ULLOA, Ohio University — We study electronic transport through a deformable spin-1 molecular system in a break junction setup, under the influence of a local vibrational mode. Our study shows that the magnetic anisotropy, which arises due to stretching along the transport axis [Science 328 1370 (2010)], is renormalized by the interactions with vibrations. The coupling induces additional spin-asymmetric hybridizations that contribute to the net molecular anisotropy. We show that the low temperature physics of such device can be described by an anisotropic Kondo model ($J_{\perp} > J_{\parallel}$), with a magnetic anisotropy term, $A_{Net} S_z^2$, negative at zero stretching. A quantum phase transition (QPT) is explored by stretching the molecule, driving A_{Net} into positive values, and changing the character of the device from a non-Fermi-liquid (NFL) to a Fermi liquid (FL) ground state. This transition can be directly observed through the zero-bias conductance, which we find to be finite for negative anisotropy, zero for positive anisotropy, and to reach the unitary limit at $A_{Net} \approx 0$. At that point, an underscreened spin-1 Kondo ground state appears due to the restitution of the spin-1 triplet degeneracy.

¹Supported by NSF-PIRE and NSF-MWN/CIAM.

10:36AM H13.00012 Hot electron spin transport in C₆₀ fullerene¹, LUIS EDUARDO HUESO, CIC nanoGUNE AND IKERBASQUE, Basque Foundation for Science, MARCO GOBBI, AMILCAR BEDOYA-PINTO, FEDERICO GOLMAR, ROGER LLOPIS, CIC nanoGUNE, FELIX CASANOVA, CIC nanoGUNE AND IKERBASQUE, Basque Foundation for Science — Carbon-based molecular materials are interesting for spin transport application mainly due to their small sources of spin relaxation [1]. However, spin coherence lengths reported in many molecular films do not exceed a few tens of nanometers [2]. In this work we will present results showing how hot spin-polarized electrons injected well above the Fermi level in C₆₀ fullerene films travel coherently for hundreds of nanometers. We fabricated hot-electron vertical transistors, in which the current created across an Al/Al₂O₃ junction is polarized by a metallic Co/Cu/Py spin valve trilayer and subsequently injected in the molecular thin film. This geometry allows us to determine the energy level alignment at each interface between different materials. Moreover, the collector magnetocurrent excess 85%, even for C₆₀ films thicknesses of 300 nm. We believe these results show the importance of hot spin-polarized electron injection and propagation in molecular materials. [1] V. Dediu, L.E. Hueso, I. Bergenti, C. Taliani, Nature Mater. 8, 707 (2009) [2] M. Gobbi, F. Golmar, R. Llopis, F. Casanova, L.E. Hueso, Adv. Mater. 23, 1609 (2011)

10:48AM H13.00013 A Copper Nitride Nanotemplate for Individual Magnetic Molecules, BEN WARNER, London Centre for Nanotechnology, Department of Physics & Astronomy, UCL, London, UK, FADI EL HALLAK, London Centre for Nanotechnology, UCL, London, UK, MICHAEL WATERS, School of Chemistry, University of Nottingham, Nottingham, UK, JORIS VAN SLAGEREN, Institut für Physikalische Chemie, Universität Stuttgart, Stuttgart, Germany, CYRUS HIRJIBEHEDIN, London Centre for Nanotechnology, Department of Physics & Astronomy, Department of Chemistry, UCL, London, UK — Molecular magnets hint at a promising future in information technology applications because of their interesting quantum and magnetic properties in the bulk. If these molecules are to be useful for device applications, it may be necessary to place them on surfaces, and work has begun to concentrate in this area. However, the practical issues of isolating and accessing these molecules have yet to be resolved. We present scanning tunnelling microscopy (STM) data on FePc and (DyPc₂) deposited on a (Cu₂N-Cu(100)) surface. (Cu₂N-Cu(100)) forms a quasi-periodic lattice, and has been shown to force porphyrin molecules to sit at specific sites (D. Eciya et al., Appl. Phys. Lett. 92, 223117 (2008)). As with the porphyrins, we find that these molecules sit at the intersection of the copper lines. This spatial separation restrains any potential dipolar or exchange interaction between the molecules, and it allows for individual, independent spins to be addressed. Using data taken with an STM we investigate the properties of these molecules, and furthermore show that the molecules on this surface are immobile up to room temperature.

Tuesday, February 28, 2012 8:00AM - 10:12AM —
Session H14 GMAG DMP FIAP: Focus Session: Spins in Semiconductors - Electrical Spin Injection 212

8:00AM H14.00001 Electrical Spin Injection and Detection in Silicon: Effect of Interface States, JONAS BEARDSLEY, YONG PU, Ohio State University Department of Physics, ADRIAN SWARTZ, PAT ODENTHAL, UC Riverside Department of Physics, ANDREW BERGER, DONGKYUN KO, VIDYA BHALLAMUDI, PETER CHRISTOPHER HAMMEL, Ohio State University Department of Physics, ROLAND KAWAKAMI, UC Riverside Department of Physics, EZEKIEL JOHNSTON-HALPERIN, JON PELZ, Ohio State University Department of Physics — We have observed (using the local Hanle method) electrical spin injection into n and p type Si through a Fe/MgO/Si tunnel, with an effective spin lifetime of ~130ps and an extremely large spin RA product as high as ~0.1 MΩ*μm² at low bias and temperature. Both the spin-RA and the differential resistance decrease exponentially with bias at temperatures below 150K. The effective spin lifetime weakly depends on temperature, decreasing by ~30% from 10K to 300K. We observe the inverse Hanle effect when an external magnetic field is applied parallel to the magnetization, possibly indicating the presence of stray fields near the Si surface. These observations roughly agree with other local Hanle spin injection studies in Silicon and GaAs, but differ strongly from the results expected for injection into bulk Silicon. The two stage tunneling model through localized states (LS) developed by Tran *et al* (PRL 102; p. 036601) can explain the large magnitude of the observed spin RA, and we have developed an extended LS model which can explain the voltage dependence, which will be discussed in another talk.

8:12AM H14.00002 Non-local spin transport and accumulation measurements in Si:AlGaAs with tunable carrier density¹, JENNIFER MISURACA, J.-I. KIM, Florida State University, K.K. MENG, L. CHEN, J. LU, J.H. ZHAO, Institute of Semiconductors, Chinese Academy of Sciences, P. XIONG, S. VON MOLNAR, Florida State University — The spin lifetime in GaAs varies strongly with carrier density near the insulator to metal transition (IMT), possibly peaking at the transition [1]. However, determining the optimal spin lifetime in this material is challenging because many replica samples need to be fabricated and measured. This difficulty can be circumvented by employing Si:Al_{0.3}Ga_{0.7}As, a persistent photoconductor, as the spin transport medium. This material has been characterized and has an effective carrier density which can be tuned *in situ* via photo-excitation from 10¹⁴ to 10¹⁸ cm⁻³ and a critical carrier density for the IMT of 9.0 × 10¹⁶ cm⁻³ at 5K [2]. Heterostructures have been grown by MBE, consisting of 2 μm Si:AlGaAs, a thin epitaxial Fe layer, and an AlGaAs graded junction to create Schottky tunnel barrier contacts. Non-local spin devices have been fabricated and measured. Based on non-local 4 terminal (NL 4T) and local and NL 3T Hanle effect measurements, the initial electrical spin transport and accumulation measurements in this material are reported. The spin lifetimes range from 600 ps to 2.8 ns for multiple carrier densities, ranging from 3.5 × 10¹⁶ to 2.4 × 10¹⁷ cm⁻³. [1] J. M. Kikkawa et al., Phys. Rev. Lett. 80, 4313 (1998). [2] J. Misuraca et al., Phys. Rev. B. 82, 125202 (2010).

8:24AM H14.00003 Electrical spin injection and detection in Fe/MgO/Si: influence of interface states, YONG PU, JONAS BEARDSLEY, Center for Emergent Materials, The Ohio State University, ADRIAN SWARTZ, PATRICK ODENTHAL, Dept. of Physics and Astronomy, University of California-Riverside, ANDREW BERGER, DONGKYUN KO, VIDYA BHALLAMUDI, CHRIS HAMMEL, Center for Emergent Materials, The Ohio State University, ROLAND KAWAKAMI, Dept. of Physics and Astronomy, University of California-Riverside, EZEKIEL JOHNSTON-HALPERIN, JON PELZ, Center for Emergent Materials, The Ohio State University — We report electrical spin injection and detection in Fe/MgO/Si tunnel diodes using a 3-terminal (3T) geometry. Analysis of our Hanle curves yields an effective spin life-time of ~0.1 ns and a spin-RA product ~1 MΩ * μm², both of which are in rough agreement with previous 3T studies. However, according to our analysis the spin-RA is ~ 6 orders of magnitude larger than expectations for bulk Si, and the 0.1 ns effective spin life-time is much smaller than reported value in Si by ESR or non-local methods. Here we provide a detailed analysis of electrical injection and detection in the 3T geometry. We present an alternative expression for the 3T spin signal than is usually used, and we propose that spin is accumulating in localized states (LS) at the MgO/Si interface rather than just in bulk Si. Incorporating a theory of spin accumulation in LS developed by M. Tran *et al* (PRL 102, 036601), we propose an energy distribution for the density of localized states, and introduce a model that agrees well with our anomalously large spin-RA and can explain the strong bias dependence of both spin and charge transport.

8:36AM H14.00004 Spin accumulation in Fe/MgO/Ge heterostructures, A.T. HANBICKI, S.-F. CHENG, R. GOSWAMI, O.M.J. VAN 'T ERVE, B.T. JONKER, Naval Research Laboratory — We have investigated the injection of spins into n-type Ge(001) from Fe through an MgO tunnel barrier using 3-terminal Hanle measurements. While significant progress has been made in Si, spin research in Ge is still at a nascent stage, due in part to the fact that significant Fermi level pinning at the Ge interface makes it difficult to efficiently inject carriers. We observe here precessional dephasing of the spin accumulation in an applied magnetic field (the Hanle effect) in Fe/MgO/Ge structures for both forward and reverse bias. We determine spin lifetimes and corresponding spin diffusion lengths for injection into Ge substrates of varying carrier concentration and see a trend of increasing spin lifetime with decreasing doping density. At room temperature, spin lifetimes range from $\tau_s = 50$ ps to 123 ps as the carrier concentration is reduced from $n=8 \times 10^{17} \text{ cm}^{-3}$ to $2 \times 10^{16} \text{ cm}^{-3}$. We will discuss the spin-RA product as a function of carrier concentration and the role of interface states. The observed room temperature injection of spins shows that despite persistent Fermi level pinning, spin accumulation is possible in the surface of Ge. This work was supported by core programs at NRL.

8:48AM H14.00005 Spin Transfer from a Ferromagnet into a Semiconductor through an Oxide barrier, CLODOALDO IRINEU LEVARTOSKI DE ARAUJO, MILTON ANDRE TUMELERO, ALEXANDRE DA CAS VIEGAS, Laboratorio de Filmes finos e Superfícies (LFFS), Universidade Federal de Santa catarina, NICOLAS GARCIA, Laboratorio de Fisica de Sistemas Pequenos y Nanotecnología, Consejo Superior de Investigacione Cientificas (CSIC), ANDRE AVELINO PASA, Laboratorio de Filmes finos e Superfícies (LFFS), Universidade Federal de Santa catarina — We present results on the magnetoresistance of the system Ni/Al203/n-doped Si/Al2O3/Ni in fabricated nanostructures. The results at temperature of 14K reveal a 75% magnetoresistance that decreases in value up to approximately 30K where the effect disappears. We observe minimum resistance in the antiparallel configurations of the source and drain of Ni. As a possibility, it seems to indicate the existence of a magnetic state at the Si/oxide interface. The average spin diffusion length obtained is of 650 nm approximately. Results are compared to the window of resistances that seems to exist between the tunnel barrier resistance and two threshold resistances but the spin transfer seems to work in the range and outside the two thresholds.

9:00AM H14.00006 Comparing nonlocal and three terminal Hanle experiments in Silicon, OLAF VAN 'T ERVE, CONNIE LI, AUBREY HANBICKI, PHILLIP THOMPSON, BEREND JONKER, Naval Research Laboratory — We have recently shown electrical spin injection in the technologically important material Si up to 500K and demonstrated a dependence of the spin lifetime with carrier concentration. In previous work on GaAs, we have seen excellent agreement between the spin lifetime derived from Hanle data measured directly at the injector contact using a three terminal measurement and the simultaneously measured nonlocal signal outside of the charge path. Unfortunately, simultaneous measurement of three terminal and nonlocal measurements is impractical on the Silicon devices due to the high resistance of the $6 \times 100 \mu\text{m}^2 \text{ Fe/AlO}_x/2\text{e}18$ n-type Si injector contact. Instead we used a separate $150 \times 100 \mu\text{m}^2 \text{ Fe/AlO}_x/\text{Si}$ contact on the same substrate to do three terminal measurements and nonlocal measurements independently. Lorentzian fits to the data shows a spin lifetime of 280 ps measured directly underneath the spin injecting contact. This data is in excellent agreement with the spin lifetime vs. carrier concentration for NiFe/SiO₂/Si contacts, however it is a factor of 3 lower than the spin lifetime of ~ 1 ns measured at the nonlocal contact. We discuss this observed difference and other properties such as temperature dependence and bias dependence of the three terminal vs. nonlocal experiments.

9:12AM H14.00007 Electrical injection and detection of spin accumulation in Si at 500 K with magnetic metal/SiO₂ contacts, CONNIE H. LI, Naval Research Lab — Electrical spin injection into Si (001) from a ferromagnetic metal through an Al₂O₃ tunnel barrier has been demonstrated.¹ However, the utilization of SiO₂ as the tunnel barrier can have significant impact on the development of Si based spintronics. Here we demonstrate the electrical injection, detection and precession of spin accumulation in Si, via injection from ferromagnetic contacts such as Ni_{0.8}Fe_{0.2} and Co_{0.9}Fe_{0.1} through a SiO₂ tunnel barrier.² The injection of spin-polarized carriers produce a net spin polarization and an imbalance in the spin-dependent electrochemical potential under the contact, which is detected as a voltage at the same contact. The decrease of this voltage with increasing out-of-plane magnetic field due to spin dephasing, i.e., Hanle precession of the electron spin, is observed up to 500 K. We observe Hanle precession of electron spin accumulation in Si for a wide range of bias, and demonstrate that the spin lifetime (extracted from the Lorentzian fit to the Hanle data) varies with Si carrier density. Details of the bias and temperature dependence of the spin lifetime and spin diffusion length will also be presented at the meeting. These results confirm spin accumulation in the Si transport channel up to 500 K rather than trapping in localized interface states, and demonstrate the practical aspect of spin-based semiconductor device technology. Supported by ONR.

9:48AM H14.00008 Spin-filter effect of quantum dot with spin-orbit interaction in magnetic field, TOMOHIRO YOKOYAMA, MIKIO ETO, Faculty of Science and Technology, Keio University — We theoretically investigate a spin-polarized current generation in a semiconductor quantum dot (QD) with spin-orbit interaction in a magnetic field. In the absence of magnetic field, a spin-polarized current is generated only when the QD is connected to more than two leads.¹ In the presence of magnetic field, on the other hand, we show that the two-terminal QD works as a spin filter due to the spin-orbit interaction even if the Zeeman effect is negligibly small. First, we focus on the vicinity of current peaks of Coulomb oscillation due to the resonant tunneling, considering the two energy levels around the Fermi level in the leads, and obtain an analytical form of spin-dependent current. The spin-polarization of the current is largely enhanced when the spacing between the two levels is smaller than the level broadening due to the tunnel coupling to the leads. Second, we perform a numerical simulation using a realistic model for the confining potential of the QD. We find more than 40% spin-filtering efficiency around some current peaks.

10:00AM H14.00009 Tailoring Chirp in Spin-Lasers, JEONGSU LEE, SUNY at Buffalo, GUILHEM BOERIS, Ecole Polytechnique, KAREL VYBORNÝ, Institute of Physics ASCR, IGOR ZUTIC, SUNY at Buffalo — The interplay of spin injection in lasers and their nonlinear response leads to novel spintronic devices [1]. Such spin-lasers can enable desirable properties including threshold reduction, bandwidth enhancement, and low chirp [1-3]. These lasers can also be viewed as spin-amplifiers, since high circular polarization in the output can be achieved even with nearly spin-unpolarized injection [2,3]. In the present work, we study chirp in spin-lasers and suggest new modulation schemes to improve their performance. Supported by NSF-ECCS, U.S. ONR, AFOSR-DCT, and NSF-NEB 2020.

Tuesday, February 28, 2012 8:00AM - 11:00AM –

Session H15 DMP FIAP GMAG: Focus Session: Spin and Dynamics in Metal, Spin logic and Spin-Based Devices 213

8:00AM H15.00001 A novel three-terminal spintronics device utilizing the spin Hall effect, CHI-FENG PAI, LUQIAO LIU, HSIN-WEI TSENG, YUN LI, School of Applied and Engineering Physics, Cornell University, DANIEL C. RALPH, Department of Physics, Cornell University, ROBERT A. BUHRMAN, School of Applied and Engineering Physics, Cornell University — Previous work¹ has established that the spin Hall effect (SHE) in certain thin film metallic layers can generate a transverse spin current large enough to effect, through spin transfer torque (STT), the reversible magnetic switching of an adjacent ferromagnetic layer having perpendicular magnetic anisotropy. Here we discuss a new three-terminal spintronics device that utilizes the SHE induced STT to efficiently and reversibly switch the magnetic orientation of a thin free layer electrode of an MgO magnetic tunnel junction having in-plane magnetization. The low write currents ($\leq 1\text{mA}$), large output impedance and good thermal stability ($45\text{k}_B\text{T}$) that has been achieved with this SHE three-terminal device approach, which separates the write and read operations in a manner that is relatively straightforward to fabricate, demonstrate an attractive candidate for application in next generation STT MRAM and non-volatile spin logic circuits.

¹Luqiao Liu *et al.*, arXiv:1110.6846 and Luqiao Liu invited presentation this conference (focus topic 10.1.4)

8:12AM H15.00002 Electric field assisted switching in magnetic tunnel junctions¹, WEIGANG WANG, MINGEN LI, STEPHEN HAGEMEN, C. L. CHIEN, Johns Hopkins University — It is of great interest to acquire large effects of electric field on magnetic properties, partly driven by the premise that voltage-controlled magnetization reversal would be far more energy efficient and be compatible with the ubiquitous voltage-controlled semiconductor devices. Normally the effect of electric field in metallic systems is negligible because the electric field can only penetrate into the materials by a few monolayers due to screening by the free electrons. Here we report the pronounced effects of electric field in magnetic tunnel junctions (MTJs) with very thin CoFeB electrodes, where the magnetic anisotropy originates solely from the CoFeB/MgO interfaces. The MTJs have the key structure of Co₄₀Fe₄₀B₂₀(1.2-1.3nm)/MgO(1.2-2nm)/Co₄₀Fe₄₀B₂₀(1.6nm) and the tunneling magnetoresistance in all junctions is in excess of 100%. Due to the redistribution of electrons among the different 3d orbitals of Fe and Co, the perpendicular magnetic anisotropy of the CoFeB electrodes can be significantly modified by an applied electric field. As a result, the coercivity, the magnetic configuration, and the tunneling magnetoresistance of the MTJs can be manipulated by voltage pulses, such that the high and low resistance states of the MTJ can be reversibly controlled by voltages less than 1.5 V in magnitude and with much smaller current densities.

8:24AM H15.00003 Nanomagnetic triangles for a non-volatile logic applications¹, ALEXANDER KOZHANOV, University of California Santa Barbara, S. JAMES ALLEN, University of California at Santa Barbara — Single domain triangular nanomagnet is a base element in the recently proposed non-volatile logic application [1]. Dependent on the triangle shape and dimensions “Y” or “buckle” magnetization alignment ground states are defined by configurational anisotropy. In the “Y” ground state the local magnetization is aligned to point either towards or away from the triangle vertices. The three triangle vertices are used for information storage while switching between different ground states performs logic operations. In this work we study nanomagnetic triangle ground states and switching between them using micromagnetic simulations. We show that triangle shape engineering within the fabrication method tolerance allows maintaining the “Y” ground state despite the shape distortions typical for fabrication process. We correlate the height and profile of the energy barrier between the triangle ground states with the triangle shape and dimensions. We discuss ground state switching mechanisms and assess the triangle use for non-volatile logic and memory applications.

8:36AM H15.00004 Ultra low-energy hybrid spintronics and straintronics: multiferroic nanomagnets for memory, logic and ultrafast image processing¹, JAYASIMHA ATULASIMHA², Virginia Commonwealth University — We have theoretically shown that multiferroic nanomagnets (consisting of a piezoelectric and a magnetostrictive layer) could be used to perform computing while dissipating $\sim$ few 100 kT/bit (Appl. Phys. Lett. 97,173105, 2010) at clock rates of $\sim$ 1GHz. They can act as memory elements (Appl. Phys. Lett. 99, 063108, 2011), logic gates (Nanotechnology, 22, 155201, 2011, <http://arxiv.org/abs/1108.5758v1>) and associative memory for higher order computing such as ultrafast image reconstruction and pattern recognition (J. Phys. D: Appl. Phys. 44, 265001 (2011), <http://arxiv.org/abs/1109.6932v1>). This talk will provide an overview of our research in:

1. Theoretical study of stress induced magnetization dynamics in isolated multiferroic nanomagnets (memory) and dipole coupled nanomagnetic arrays laid out in specific geometric patterns to implement a universal logic gate.
2. Monte Carlo simulations of the magnetization trajectories in such systems described by the stochastic Landau-Lifshitz-Gilbert (LLG) equation, that show error-free ($>99.99\%$) fast ($\sim 1\text{GHz}$) switching with very low dissipation (few 100kT/bit/magnet).
3. Demonstrating that multiferroic nanomagnets possessing biaxial anisotropy could be used for four-state logic and perform image processing applications such as image reconstruction and pattern recognition.
4. Experimental fabrication of such devices using e-beam lithography and deposition to create $\sim 100\text{nm}$ diameter elliptical nanostructures and study them with magnetic force microscopy.

9:12AM H15.00005 Reliable switching in MRAM and multiferroic logic , KAMARAM MUNIRA, Charles L. Brown Department of Electrical and Computer Engineering, University of Virginia, SUPRIYO BANDYOPADHYAY, Department of Electrical and Computer Engineering, Virginia Commonwealth University, JAYASIMHA ATULASIMHA, Department of Mechanical Engineering , Virginia Commonwealth University, EUGENE CHEN, Grandis, Inc., AVIK W. GHOSH, Charles L. Brown Department of Electrical and Computer Engineering, University of Virginia — Low reliable writing in spintronic devices limits their applicability in the automotive and defense industries. Coupling stochastic macromagnetic simulator with quantum transport, we show how greater reliable switching can be achieved in MRAM and multiferroic logic. Using a combination of spin-transfer torque and small applied perpendicular field in MRAM, the error rate can be considerably reduced for a given voltage pulse. In multiferroic logic, strain plays the role of the magnetic field. Information is passed along an array of nanomagnets (NM) (magnetostrictive + piezoelectric layers) through dipole coupling with neighboring NMs. A low voltage applied to the piezoelectric element causes the NM's magnetization to switch to its hard axis. Upon releasing the stress, the magnetization of the NM relaxes to the easy axis, with its final orientation determined by the dipolar coupling with the left NM, thus achieving a low power Bennett clocked computation. In the face of stagnation points along the potential energy landscape, the success rate of the straintronic switching can be controlled with by how fast the stress is removed from the NM. (Funding: DARPA, GRANDIS, NSF-NEB).

9:24AM H15.00006 Low-energy information transfer between dipolar-coupled magnetic disks observed by time resolved magnetic soft X-ray microscopy¹ , PETER FISCHER, CXRO/LBNL, HYUNSUNG JUNG, KISUK LEE, DAE-EUN JEONG, YOUNG-SEOK CHOI, YOUNG-SANG YU, DONG-SOO HAN, Dept MSE/Seoul Natl U, ANDREAS VOGEL, LARS BOCKLAGE, GUIDO MEIER, IAP/U Hamburg, MI-YOUNG IM, CXRO/LBNL, SANG-KOOG KIM, Dept MSE/Seoul Natl U — The coupling between oscillators allows to mutually transfer energy and also to propagate information signals. Utilizing the concept of coupled oscillators, we experimentally demonstrated a new mechanism for energy transfer between spatially separated dipolar-coupled magnetic disks by stimulated vortex gyration. Direct experimental evidence was obtained by state-of-the-art experimental time-resolved soft X-ray microscopy probe. The rate of energy transfer from one disk to the other was derived from the two normal modes' frequency splitting caused by dipolar interaction. This mechanism provides tunable energy transfer rates, low-power input signals and negligible energy loss in the case of negligible intrinsic damping. Coupled vortex-state disks might find applications in future information-signal processing. H. Jung, et al., NPG - Scientific Reports 1 59 (2011); M.-W. Yoo, et al., Phys. Rev. B 82, 174437 (2010); H. Jung, et al., Appl. Phys. Lett. 97, 222502 (2010); Y.-S. Choi, et al., Phys. Rev. B 80, 012402 (2009); P. Fischer, et al., Phys Rev B 83 212402 (2011).

¹Supported by Basic Science Research Program (NRF Korea) No. 20110000441, DOE/BES No. DE-AC02-05-CH1123, DFG/SFB 668 and GK 1286 and City of Hamburg

9:36AM H15.00007 Four-state straintronics: Ultra low-power collective nanomagnetic computing using multiferroics with biaxial anisotropy¹ , NOEL D'SOUZA, JAYASIMHA ATULASIMHA, SUPRIYO BANDYOPADHYAY, Virginia Commonwealth University — Two-phase multiferroic nanomagnets, consisting of elastically coupled magnetostrictive/piezoelectric layers, can be endowed with four stable magnetization states by introducing biaxial magnetocrystalline anisotropy in the magnetostrictive layer. These states can encode four logic bits. We show through extensive modeling that dipole coupling between such 4-state magnets, combined with stress sequences that appropriately modulate the energy barriers between the stable states through magnetoelastic coupling, can be used to realize 4-state NOR logic (J. Phys. D: Appl. Phys. 44, 265001 (2011)) as well as unidirectional propagation of logic bits along a "wire" of nanomagnets (arXiv:1105.1818). As very little energy is consumed to "compute" in such a system, this could emerge as an ultra-efficient computing paradigm with high logic density. We show, by solving the Landau-Lifshitz-Gilbert (LLG) equation, that such nanomagnet arrays can be used for ultrafast image reconstruction and pattern recognition that go beyond simple Boolean logic. The image processing attribute is derived from the thermodynamic evolution in time, without involving any software. This work is supported by the NSF under grant ECCS-1124714 and VCU under PRIP.

9:48AM H15.00008 GMAG Dissertation Award Talk: All Spin Logic – Multimagnet Networks interacting via Spin currents¹ , SRIKANT SRINIVASAN, School of Electrical and Computer Engineering, Purdue University — Digital logic circuits have traditionally been based on storing information as charge on capacitors, and the stored information is transferred by controlling the flow of charge. However, electrons carry both charge and spin, the latter being responsible for magnetic phenomena. In the last few decades, there has been a significant improvement in our ability to control spins and their interaction with magnets. All Spin Logic (ASL) represents a new approach to information processing where spins and magnets now mirror the roles of charges and capacitors in conventional logic circuits. In this talk I first present a model [1] that couples non-collinear spin transport with magnet-dynamics to predict the switching behavior of the basic ASL device. This model is based on established physics and is benchmarked against available experimental data that demonstrate spin-torque switching in lateral structures. Next, the model is extended to simulate multi-magnet networks coupled with spin transport channels. The simulations suggest ASL devices have the essential characteristics for building logic circuits. In particular, (1) the example of an ASL ring oscillator [2, 3] is used to provide a clear signature of directed information transfer in cascaded ASL devices without the need for external control circuitry and (2) a simulated NAND [4] gate with fan-out of 2 suggests that ASL can implement universal logic and drive subsequent stages. Finally I will discuss how ASL based circuits could also have potential use in the design of neuromorphic circuits suitable for hybrid analog/digital information processing because of the natural mapping of ASL devices to neurons [4].

10:24AM H15.00009 "Spin inverter" as building block of All Spin Logic devices¹ , ANGK SARKAR, SRIKANT SRINIVASAN, SUPRIYO DATTA, School of Electrical and Computer Engineering, Purdue University, W. Lafayette, IN, USA — All-spin logic (ASL) represents a new approach to information processing where the roles of charges and capacitors in charge based transistors are played by spins and magnets, without the need for repeated spin-charge conversion. In our past work, we have presented numerical simulations based on a coupled spin transport and Landau Lifshitz Gilbert model showing that ring oscillators and logic circuits with intrinsic directionality [IEEE Trans. Magn. 47,10, 4026, 2011; Proc. IEDM, 2011]] can be implemented by manipulation of spins in magnetic nanostructures. The aim of this talk is (1) to identify a basic ASL unit that can be interconnected to build up spin circuits analogous to the way transistors are interconnected to build conventional circuits and (2) to present a compact model for this basic unit that can be used to design and analyze large scale spin circuits. We will show that this basic ASL unit is a one-magnet "spin inverter" with gain that can be cascaded to accomplish a spin circuit implementation of almost any logic functionality

10:36AM H15.00010 Ultra low-power straintronics with multiferroic nanomagnets: magnetization dynamics, universal logic gates and associated energy dissipation, MOHAMMAD SALEHI-FASHAMI, JAYASIMHA ATULASIMHA, SUPRIYO BANDYOPADHYAY, Virginia Commonwealth University — Stress induced magnetization dynamics of dipole coupled multiferroic nanomagnet arrays is modeled by solving the Landau-Lifshitz-Gilbert (LLG) equation. We show that in such multiferroic nanomagnets, consisting of magnetostrictive layers elastically coupled to piezoelectric layers, the single domain magnetization can be rotated by a large angle ($\sim 90^\circ$) in ~ 1 ns if a tiny voltage of a few tens of millivolts is applied across the piezoelectric layer [Nanotechnology, 22, 155201, 2011, Appl. Phys. Lett. 99, 063108, 2011]. Arrays of such multiferroic nanomagnets can be laid out in specific geometric patterns to implement combinational and sequential logic circuits by exploiting inter-magnet dipole coupling and Bennett clocked with specific stress cycles to propagate logic bits and implement dynamic logic. In this work, we theoretically demonstrate logic propagation in and fan-out characteristics of a universal NAND gate and discuss energy dissipation in the magnet and in the external clock. We show that this energy dissipation can be 3 orders of magnitude more energy-efficient than current CMOS technology for a reasonable clock speed of 1 GHz. This work is supported by the NSF under grant ECCS-1124714.

10:48AM H15.00011 Hybrid spintronics and straintronics: A paradigm for ultra-low-energy computing¹, KUNTAL ROY, SUPRIYO BANDYOPADHYAY, Electrical and Computer Engg., Virginia Commonwealth University, Richmond, VA 23284, JAYASIMHA ATULASIMHA, Mechanical and Nuclear Engg., Virginia Commonwealth University, Richmond, VA 23284 — We have shown in the past that the magnetization of a two-phase multiferroic single-domain nanomagnet can be electrically switched (flipped) with very little energy dissipation at low temperatures. This heralds a new energy-efficient magnetic logic and memory technology [Appl. Phys. Lett., 99, 063108, 2011, Phys. Rev. B, 83, 224412, 2011, Nanotechnology, 22, 155201, 2011]. Here, we extend our low-temperature result to room temperature where thermal noise can cause switching failures and increase average energy dissipation and switching delay. Using Monte Carlo simulations of switching trajectories described by the stochastic Landau-Lifshitz-Gilbert (LLG) equation, we show that even at room temperature, nearly error-free fast switching is possible with very low dissipation. The energy dissipated to switch an appropriately designed nanomagnet with $> 99.99\%$ probability at room temperature is only ~ 400 kT for a switching delay of sub-nanosecond. This is enabled by the complex interplay between the in-plane and out-of-plane excursions of the magnetization vector which aids switching. This work is supported by the NSF under grant ECCS-1124714.

Tuesday, February 28, 2012 8:00AM - 11:00AM – Session H16 DCMP DAMOP: Quantum Fluids: Mainly Helium, Vortices, and Solitons 251

8:00AM H16.00001 Weak to strong limits in confined superfluid helium¹, STEPHEN R.D. THOMSON, JUSTIN K. PERRON, FRANCIS M. GASPARINI, The State University of New York University at Buffalo — Experiments with ^4He confined in $(2\ \mu\text{m})^3$ boxes connected via a thin film 33 nm thick have shown that the boxes act as isolated entities when spaced $4\ \mu\text{m}$ edge-to-edge [1], whereas when spaced $2\ \mu\text{m}$ edge-to-edge, they are strongly coupled to each other [2]. To investigate the spatial dependence of this coupling we are currently measuring $(2\ \mu\text{m})^3$ boxes spaced $1\ \mu\text{m}$ edge-to-edge. We report measurements of the specific heat and superfluid density of helium confined in this geometry. These new data will help us to map the transition between fully isolated to fully coupled boxes which, in this limit, should behave like a $2\ \mu\text{m}$ thick film. Questions involving our understanding of the correlation length ξ arise, since it is observed that coupling is manifest over much larger distances than ξ .

8:12AM H16.00002 Critical point coupling in liquid helium and the significance of the correlation length¹, JUSTIN K. PERRON, STEPHEN R.D. THOMSON, FRANCIS M. GASPARINI, The State University of New York, University at Buffalo — Recent measurements of liquid helium confined to $(2\ \mu\text{m})^3$ boxes connected through a 33 nm film have shown coupling effects between boxes spaced distances much larger than the correlation length $\xi(t, L)$ [1,2] and proximity effects on the connecting film [3]. An analysis of data suggests that $\xi(t, L)$ is the relevant parameter in these effects. This dependence on $\xi(t, L)$ is used to argue that the enhancement in the specific heat due to coupling is a reflection of the finite-size correlation length in the boxes and hence its scaling function. All this raises some profound questions about our physical understanding of $\xi(t, L)$.

8:24AM H16.00003 Creating Only Isotropic Homogeneous Turbulence in Liquid Helium near Absolute Zero¹, G.G. IHAS, K.J. THOMPSON, G. LABBE, Department of Physics, University of Florida, PO Box 118440, Gainesville, FL 32607, P.V.E. MCCLINTOCK, Department of Physics, Lancaster University, Lancaster LA1 4YB, UK — Flow through a grid is a standard method to produce isotropic, homogeneous turbulence for laboratory study. This technique has been used to generate quantum turbulence (QT) above 1 K in superfluid helium² where QT seems to mimic classical turbulence. Efforts have been made recently³ to make similar measurements near absolute zero, where there is an almost total absence of normal fluid and hence classical viscosity. This presents the difficulty that most motive force devices produce heat which overwhelms the phenomena being investigated. The process of designing and implementing a “dissipation-free” motor for pulling a grid through superfluid helium at millikelvin temperatures has resulted in the development of new techniques which have broad application in low temperature research. Some of these, such as Meissner-affect magnetic drives, capacitive and inductive position sensors, and magnetic centering devices will be described. Heating results for devices which can move in a controlled fashion from very low speed up to 10 cm/s will be presented. Acknowledgement: We thank W.F. Vinen for many useful discussions.

8:36AM H16.00004 Superfluid Onset and 2D phase transitions of Helium-4 on Lithium and Sodium, ANGEL VELASCO, FAWN HUISMAN, University of California, Irvine, ELI VAN CLEVE, Lawrence Livermore National Laboratory, PETER TABOREK, University of California, Irvine — We have fabricated lithium and sodium films on quartz crystal microbalances (QCM) using in situ low temperature pulsed laser deposition. The frequency shift and dissipation of the QCM was measured as a function of helium pressure and chemical potential and used to construct the phase diagram of helium films on these substrates. Pressure measurement techniques based on an RGA mass spectrometer, which provides accurate measurement below 10^{-8} Torr will be described. Lithium and sodium are predicted to be intermediate strength substrates which are strong enough to be wetted by He-4 but weak enough that solid-like layers do not form, so they are candidates for observing sub-monolayer superfluidity in direct contact with a metallic surface. Helium adsorption isotherms and quenches between 0.5K and 1.6K on both lithium and sodium indicated continuous, sub-monolayer helium film growth and superfluid onsets in sub-monolayer films. Features below 1K indicate a collision between a classical 2D liquid/vapor phase transition and the Kosterlitz-Thouless superfluid phase transition. We see no evidence for the pre-wetting step instability predicted for helium on sodium.

8:48AM H16.00005 ABSTRACT WITHDRAWN —

9:00AM H16.00006 Discrepancies Between Theory and Experiment for Field-Dependence and f -wave Interactions in Superfluid $^3\text{He-B}$, C.A. COLLETT, J. POLLANEN, JIA LI, W.J. GANNON, W.P. HALPERIN, Department of Physics and Astronomy, Northwestern University — We have performed transverse acoustics experiments in superfluid $^3\text{He-B}$, exploring the magnetic field splitting of the imaginary squashing mode (ISQ), a collective mode of the order parameter labelled by its total angular momentum $J = 2$. We have compared theoretical calculations¹ of the Zeeman splitting, g_2 , and its dependence on the strength of f -wave pairing interactions, x_3^{-1} , with our recent experimental data, showing unexpected discrepancies. We suggest that the origin of these discrepancies can be traced to limits on the applicability of the theoretical calculations at high magnetic field and at frequencies some distance from the order parameter collective mode. We discuss the analysis done by Davis *et al.* in light of those limitations.² This work was supported by the National Science Foundation DMR-1103625.

9:12AM H16.00007 Role of the order parameter manifold on surface Majorana fermions and spin susceptibility of superfluid $^3\text{He-B}$, TAKESHI MIZUSHIMA, Dept. of Phys., Okayama University, MASATOSHI SATO, ISSP, The University of Tokyo, KAZUSHIGE MACHIDA, Dept. of Phys., Okayama University — Here, we theoretically investigate surface Andreev bound states (SABS) in superfluid $^3\text{He-B}$ confined to a slab geometry. It is known that the Majorana property gives rise to the Ising anisotropy of spin susceptibility on the surface, which reflects the assumption that the order parameter manifold of the B-phase is restricted to the subspace. In this talk, we first demonstrate that the $\text{SO}(3)$ manifold, which describes the relative rotation of spin and orbital, plays a critical role on the various properties associated with the SABS, such as the Majorana nature, gapless dispersion, topological invariant, and spin susceptibility. Then, based on the quasiclassical Eilenberger theory which takes account of the dipole interaction, we quantitatively discuss thermodynamics and the Majorana property of the SABS in superfluid $^3\text{He-B}$ under a magnetic field, where the Majorana property and spin susceptibility is determined by the interplay of the magnetic field and dipole interaction.

9:24AM H16.00008 Macroscopic quantum tunneling of a single vortex in a rotating Bose-Einstein condensate¹, KINJAL DASBISWAS, ALAN T. DORSEY, Department of Physics, University of Florida — A vortex can be created in a metastable state near the center of a harmonically trapped Bose condensate when it is rotated with suitable velocities. This state has a finite lifetime before which the vortex tunnels outwards to the edge of the trap. We estimate this tunneling rate semiclassically with the vortex treated as a point particle. This is followed by a more exact treatment incorporating the dynamics and mass of the vortex. The calculation is based on a Thomas-Fermi approximation, relevant to the typically large atomic densities used in experiments, but we also analyze the low density limit in a “weakly nonlinear” perturbative framework. We discuss the feasibility of detecting this effect with currently achievable experiments.

9:36AM H16.00009 Expansion Dynamics of a Ring Bose-Einstein Condensate¹, MARK EDWARDS, Georgia Southern University and NIST, HADAYAT SEDDIQI, MICHAEL KRYGIER, BRANDON BENTON, Georgia Southern University, CHARLES CLARK, Joint Quantum Institute and NIST — We studied the dynamics of BECs when released from a ring trap under conditions similar to those that obtained in a recent experiment done at NIST. In that experiment a ring-shaped BEC was formed in an all-optical trap created by intersecting a horizontal light sheet and a vertical Laguerre-Gaussian beam. Condensates were created in these traps and then “stirred” by applying Raman pulses having orbital angular momentum (OAM). We modeled the dynamics of condensates formed under these conditions by first solving the 2D time-dependent Gross-Pitaevskii equation (GPE) in imaginary time to obtain the initial condensate shape. We accounted for the OAM by applying a phase imprint to this wave function and then propagated it using the GPE in real time with the trap off. We found that, after release, the condensate expands both inward and outward. When no OAM was applied, this inward expansion causes the hole in the ring to close up entirely in turn causing a buildup of atom density there. Inflow and outflow of atoms from the center caused expanding interference rings to form. With non-zero applied initial OAM similar behavior was observed except that the central hole never closes with hole size increasing with increasing initial OAM. We compare our results with the NIST experiment.

9:48AM H16.00010 Quantum Dynamics of a Bose Superfluid Vortex¹, LARA THOMPSON, Massachusetts Institute of Technology, PHILIP STAMP, University of British Columbia, Pacific Institute of Theoretical Physics — Quantum vortex dynamics remain poorly understood despite decades of theoretical investigation. The vortex is a topological soliton, arising from the same medium as the quasiparticles with which it interacts. Hence the coupling between the vortex “zero mode” and the quasiparticles has no term linear in the quasiparticle variables – the lowest order coupling is quadratic. We present a fully quantum-mechanical derivation of the vortex equation of motion valid at low temperatures where the normal fluid density is small. The resulting equation of motion is naturally expressed as a function of the dimensionless frequency $\tilde{\Omega} = \hbar\Omega/k_B T$. The usual Hall-Vinen/Iordanskii equations are valid when $\tilde{\Omega} \ll 1$ (the “classical regime”), but elsewhere, the equations are strongly memory dependent. We will discuss the experimental implications of this frequency dependence in Bose superfluids and cold atomic gases.

10:00AM H16.00011 Fragmented Many-Body states of definite angular momentum and stability of attractive 3D Condensates , MARIOS C. TSATSOS, ALEXEJ I. STRELTISOV, OFIR E. ALON, LORENZ S. CEDERBAUM, Heidelberg University — We consider a 3D Bose-Einstein Condensate (BEC), with attractive interparticle interactions, embedded in a harmonic, spherically symmetric trap. This system is metastable only if the total number of bosons N and the interaction strength λa_0 do not exceed some critical values. Otherwise the system collapses. Gross-Pitaevskii (GP) theory predicts the maximum (critical) number of bosons N_{cr}^{GP} that, for a given λ_0 , can be loaded to the system, without its collapse. But, what happens to the excited states? To investigate the structure and stability of these states we must go beyond GP theory; these states have definite values of angular momentum (AM) L , are highly fragmented and can support number of bosons much greater than N_{cr}^{GP} . Secondly, we investigate the impact of external rotation of the trap to the AM and stability of the gas. We find that, for all allowed values of rotation frequency no significant stabilization occurs. The symmetry of the ground state does not change and no AM is transferred to the gas. This behaviour is attributed to the attractive nature of the interparticle interaction.

10:12AM H16.00012 Origins of bright soliton transparency to Bogoliubov quasi-particles¹ , ZAIJONG HWANG, MAXIM OLSHANII, University of Massachusetts Boston — Bogoliubov quasi-particles can pass through a one-dimensional bright soliton without reflection at all energies.² Reflectionless properties of this kind usually originate from a supersymmetric structure of the corresponding Hamiltonian.^{3,4} However, we give a strong indication that in this case¹, the mathematical mechanism enabling full spectrum transparency of a scattering object does not fall into any of the conventional paradigms.

10:24AM H16.00013 Supersymmetric Structure of two Families of Solitons¹ , ANDREW KOLLER, MAXIM OLSHANII, University of Massachusetts Boston — Solitons have generated considerable interest in the cold atoms and condensed matter communities. We demonstrate that two families of n -soliton solutions (with n an integer) – one for the attractive nonlinear Schrödinger (NLS) equation, and one for the sine-Gordon (sG) equation – originate from a quantum-mechanical supersymmetric (QM-SUSY) chain connecting a set of reflectionless operators $\hat{H}_n$. The families consist of breather-type solitons for NLS² and multi-(anti)kink solitons with specific velocities for sG. The operators $\hat{H}_n$, which we refer to as Akulin's Hamiltonians³, form reflectionless direct-scattering initial conditions for the inverse scattering method. Such a QM-SUSY chain is analogous to the known connection between QM-SUSY chains of Pöschl-Teller potentials and solitons of the Korteweg-de Vries (KdV) equation⁴. The existence of QM-SUSY chains connecting soliton solutions, now for three different integrable nonlinear equations, sheds light on the underlying mechanisms responsible for soliton generation.

10:36AM H16.00014 From Dark Solitons to Vortex Clusters in Bose-Einstein Condensates , PANAYOTIS KEVREKIDIS, University of Massachusetts, Amherst — In this talk, we'll start by considering the experimental, theoretical and numerical dynamical properties of dark solitons in quasi-one-dimensional trapped Bose-Einstein condensates. We will identify the oscillations and interactions of such coherent structures and we will then aim towards generalizing the corresponding notions to quasi-two-dimensional vortex states. In the latter setting, we will use two approaches: one from the linear limit of the underlying system that will permit us to identify the bifurcations of multi-vortex cluster states, while the second in the large density limit will enable our consideration of the vortices as precessing and interacting particles within the condensate. We will corroborate our analytical predictions within these limits and numerical results bridging the limits with experimental observations for the dynamics of few-vortex clusters.

10:48AM H16.00015 Multifractals in Soliton sea on Fibonacci Lattice¹ , MASAHIRO TAKAHASHI, HOSHO KATSURA, Department of Physics, Gakushuin University, MAHITO KOHMOTO, The Institute for Solid State Physics, The University of Tokyo, TOHRU KOMA, Department of Physics, Gakushuin University — Systems exhibiting Bose-Einstein condensation are suitable for fabricating artificially designed structures, e.g., the bichromatic potentials have attracted much attention. More exotic structures also appear to be experimentally feasible in the optical imaging system with high resolution. We consider one of exotic structures, Fibonacci potential, which is quasiperiodic. On the Fibonacci potential without nonlinear interaction, it is known that the spectrum is singular continuous and all the eigenvectors are called a critical state, in which multifractal states are included. On the other hand, the physical properties of the Bose-Einstein condensates confined in a optical lattice can be described in terms of the Schrödinger equation with nonlinear term via particle-particle interactions. We numerically and mathematically investigated nonlinear Schrödinger equation on Fibonacci potential focusing on the competition between nonlinear fluctuation and criticality [M. Takahashi *et al.*, arXiv:1110.6328]. The conclusion is that the critical states with the spectrum in the Cantor set retains their profile irrespective of the strength of the nonlinearity. The spectrum for the critical states is in a sea of "stationary solitons" which appear as a result of nonlinear effects.

Session H17 DMP GERA FIAP: Focus Session: Thermoelectrics - Characterization/Molecular junctions/Magnetic and Low Temp 252A

8:00AM H17.00001 Strategies for developing optimal thermoelectric metrology protocols , JOSHUA MARTIN, National Institute of Standards and Technology — The Seebeck coefficient is an essential physical property routinely measured to evaluate the potential performance of new thermoelectric materials. These materials facilitate the inter-conversion of thermal and electrical energy and are useful in power generation or solid-state refrigeration applications. However, the diversity in Seebeck coefficient measurement techniques, conditions, and probe arrangements has resulted in conflicting materials data, further complicating the inter-laboratory confirmation of reported higher efficiency thermoelectric materials. In an effort to identify optimal thermoelectric measurement protocols, we have developed a complimentary strategy to both evaluate and compare these different probe arrangements and measurement methodologies: first, through the design of an innovative experimental apparatus, and second, through error modeling of Seebeck coefficient measurements using finite element analysis. This talk will include a discussion of key measurement challenges, example diagnostics, and recommended practices to effectively manage uncertainty in Seebeck coefficient measurements.

8:12AM H17.00002 Experimental Determination of the Lorenz Number¹, KEVIN LUKAS, WEISHU LIU, ZHIFENG REN, Boston College, GANG CHEN, MIT, CYRIL P. OPEIL, Boston College — In an effort to improve the dimensionless thermoelectric figure of merit (ZT), thermal conductivity reduction is imperative. Most efforts are made to reduce the lattice portion of the thermal conductivity through nanostructuring. However there is no direct way to measure the lattice contribution and typically the lattice thermal conductivity is approximated by various methods. By experimentally determining the Lorenz number, the lattice thermal conductivity can be directly calculated. A method for determining the Lorenz number of thermoelectric materials $\text{Bi}_2\text{Te}_{2.7}\text{Se}_{0.3}$ and $\text{Bi}_{0.88}\text{Sb}_{0.12}$ will be presented.

¹s3tec Center

8:24AM H17.00003 Anisotropic Two-band Transverse Thermoelectrics in Zero Magnetic Field, CHUANLE ZHOU, Y. TANG, K. HEINSELMANN, M. GRAYSON, EECS Dept., Northwestern University, S. BIRNER, Walter Schottky Institut, Tech. Univ. Munchen — Narrow gap materials with anisotropic electron and hole band conductance are shown to function as anisotropic two-band transverse (A2T) thermoelectrics, whereby longitudinal electrical currents generate transverse Peltier heat flow. Unlike the Ettingshausen effect which requires external magnetic field, a large transverse Seebeck coefficient in A2T thermoelectric results from the anisotropic electron and hole mass tensors without magnetic field. Compared to synthetic transverse thermoelectrics, A2T thermoelectric coolers can be scaled to nanoscale, and the intrinsic nature of this phenomenon is promising for cryogenic applications. With exponentially tapered coolers, arbitrary ΔT can be reached with sufficiently thick layers and a small electric field. Equations for A2T thermoelectric transport from an electron-hole band model yield the optimal orientation to achieve maximum transverse figure of merit $Z_{\perp}T$. The InAs/GaSb type II superlattice is shown to have the appropriate anisotropic band structure, and bandgaps of order kT are calculated to give a competitive $\Delta T = 14$ K at room temperature. Thermal conductivity of the superlattice is 4 W/m-K at 300 K using 3ω method. Preliminary data on in-plane Seebeck coefficient will also be presented.

8:36AM H17.00004 Magnetotransport in thermoelectric materials.¹, MONA ZEBARJADI, MIT, KEVIN LUKAS, CYRIL OPEIL, Boston College, GANG CHEN, MILDRED DRESSELHAUS, MIT, S3TEC TEAM² — The mechanisms behind the magnetic field and temperature dependent thermoelectric effects that have recently been found experimentally in the electrical resistivity, thermopower and thermal conductivity of nanocomposite samples of Bi_2Te_3 and related compounds is studied. Large deviations in the transport coefficients in the presence of an applied magnetic field, both when the magnetic field is parallel and perpendicular to the transport direction has been observed in Bi_2Te_3 compounds, despite the small electronic mean free paths in these materials. An accurate analysis of the experimentally measured data leads to the estimation of electron mean free path and extraction of lattice thermal conductivity contribution from the total thermal conductivity. We will apply a Boltzmann transport equation based formalism to analyze the experimental data and improve the accuracy of the estimation of electronic and lattice part of the thermal conductivity. A particular attention will be paid to the analysis of the anisotropic effects in these samples.

²an Energy Frontier Research Center funded by the U.S. Department of Energy

8:48AM H17.00005 Separation of Joule Heating and Peltier Cooling via Time-Resolved X-Ray Diffraction in Si/SiGe Superlattice¹, MICHAEL KOZINA, MATTHIAS FUCHS, JIAN CHEN, MASON JIANG, Stanford University PULSE Institute, PICE CHEN, PAUL EVANS, University of Wisconsin-Madison Department of Materials Science and Engineering, BJORN VERMEERSCH, JE-HYEONG BAHK, ALI SHAKOURI, University of California-Santa Cruz Department of Electrical Engineering, DALE BREWE, Argonne National Lab, DAVID REIS, Stanford University PULSE Institute — We present detailed measurements of the thermal profile in a pulsed current SiGe-based thermoelectric micro-cooler. The evolution of heat flow in thermoelectric materials has been previously studied using time-domain thermoreflectance imaging; however, such methods are typically only sensitive to the surface temperature of the device, and the heat flow into the material remains hidden. Using time-resolved x-ray diffraction, we probe the transient temperature change in both the surface gold electrode and the underlying Si/SiGe superlattice using the shift in diffraction pattern caused by thermal expansion. We are also able to resolve Joule heating vs. Peltier cooling taking place in the gold through separation of timescales made possible by the relatively short duration (100ps) of the Advanced Photon Source.

¹This research is supported in part by the DOE Office of Science Graduate Fellowship Program (DOE SCGF), made possible in part by the American Recovery and Reinvestment Act of 2009, administered by ORISE-ORAU under contract no. DE-AC05-06OR23100.

9:00AM H17.00006 Reassessment of the carrier concentration in GeTe-based thermoelectric materials by ¹²⁵Te NMR, E.M. LEVIN, J.D. ACTON, K. SCHMIDT-ROHR, Ames Laboratory US DOE and Iowa State University — $\text{Ge}_{1-x}\text{Ag}_x/2\text{Sb}_{x/2}\text{Te}$ *p*-type thermoelectric materials ("TAGS-*n*") were studied extensively in the 1970s and then again recently. They exhibit an unusual combination of large thermopower, *S*, and high hole concentration, *p*, reported based on the Hall effect data, which has not been explained. To solve this puzzle, we have synthesized GeTe, GeTe:Bi, and TAGS-*n* with *n*= 97, 94, 90, and 85 and studied XRD, thermopower, electrical resistivity, thermal conductivity, and ¹²⁵Te NMR. Most importantly, we have determined the carrier concentrations using ¹²⁵Te NMR spin-lattice relaxation and Knight shift. In GeTe and GeTe:Bi, we found that carrier concentrations generally agree with the values reported from Hall effect. In TAGS-*n*, they are much lower but agree better with the values expected from *S* vs. *p* for GeTe-based materials, solving the puzzle partially. The NMR vs. Hall effect discrepancy in TAGS-*n* can be due to the presence not only of holes but also electrons generated by Sb atoms, which results in artificially high hole concentration from Hall effect. Even though the true hole concentration is lower than reported, the thermopower of TAGS-*n* is still significantly larger than that of GeTe and GeTe:Bi at similar carrier concentration. This can be explained by energy filtering enhanced by potential barriers formed due to Ag-Sb pairs in the TAGS-*n* lattice.

9:12AM H17.00007 Charge and Energy Transport in Molecular Junctions, PRAMOD REDDY, University of Michigan — Charge and energy transport in molecular junctions, created by trapping short organic molecules (~1nm) between inorganic electrodes, is expected to be fundamentally different from transport in bulk materials due to their discrete electronic structure. In fact, numerous computational studies have suggested that it may be possible to utilize the novel thermoelectric and thermal transport phenomenon in nanoscale molecular junctions to create efficient energy conversion devices (e.g. thermoelectric devices). However, a large number of these effects remain to be experimentally verified. We will describe our experimental studies where thermoelectric properties of junctions were studied at the single/few molecule level enabling novel insights into the relationship between molecular structure and the thermoelectric properties of junctions. We will also present our recent experimental efforts to probe thermal transport in nanoscale molecular junctions and point contacts. In order to accomplish this goal, it is necessary to accurately measure heat currents as small as 10 picowatts. Towards this goal, we will present a novel device developed by us that is capable of resolving heat currents as small as 4 picowatts.

9:48AM H17.00008 The impact of electron-vibration interactions on the thermoelectric efficiency of molecular junctions, BAILEY HSU, JI-WEI JIANG, YU-CHANG CHEN, Department of Electrophysics, National Chiao-Tung University — From first-principles approaches, we investigate the thermoelectric efficiency of a molecular junction where a benzene molecule is connected directly to the platinum electrodes. We calculate thermoelectric figure of merits ZT in the presence of electron-vibration interactions with and without local heating under two scenarios: linear response (zero bias) and finite bias (non-zero bias) regimes. In the linear response regime, ZT saturates around the electrode temperature $T_e = 25$ K in the elastic case, while in the inelastic case we observe a non-saturated and a much larger ZT beyond $T_e = 25$ K attributed to the tail of the Fermi-Dirac distribution. In the finite bias regime, the inelastic effects reveal the signatures of the molecular vibrations in the low temperature regime. The normal modes exhibiting structures in the inelastic profile are characterized by large components of atomic vibrations along the current density direction on top of each individual atom. In all cases, the inclusion of local heating leads to a higher wire temperature T_w and thus magnifies further the influence of the electron-vibration interactions due to the increased number of local phonons.

10:00AM H17.00009 Interfacial Interactions in Polymer-Nanocrystal Thermoelectric Composites Provide a Novel Route for Power Factor Enhancement, NELSON E. COATES, Lawrence Berkeley National Laboratory, SHANNON K. YEE, Mechanical Engineering, University of California, Berkeley, BORIS RUSS, Department of Chemical and Biomolecular Engineering, University of California, Berkeley, JEFFREY J. URBAN, Lawrence Berkeley National Laboratory, RACHEL A. SEGALMAN, Department of Chemical and Biomolecular Engineering, University of California, Berkeley — The highest performing thermoelectric materials currently available are fabricated via expensive high-temperature vacuum processing techniques. Recently, there has been an increasing interest in the thermoelectric properties of solution-processable materials, which have the potential to dramatically reduce module fabrication costs. These solution-processed materials however often exhibit poor transport properties, which undermines their competitive advantage over the more traditional expensive thermoelectric materials. Here, we present the thermoelectric transport properties of a new class of solution-processable conducting-polymer/inorganic composite materials as a function of nanocrystal loading. In the Poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) and Tellurium nanowire composite devices fabricated for this study, the thermoelectric performance of the composite exceeds that of either pure organic or inorganic component alone. This result suggests an interface-driven mechanism for this enhanced performance and provides an exciting route for improving the power factors of organic-inorganic hybrid thermoelectrics.

10:12AM H17.00010 Nernst-Ettingshausen Effect in Elemental Rare-Earth Single Crystals¹, AUDREY CHAMOIRE, JOSEPH HEREMANS, The Ohio State University, THERMAL MATERIALS LABORATORY TEAM — The transverse Nernst-Ettingshausen (N-E) coefficient N measurements of the elemental rare-earth (R-E) single-crystal are for the first time presented from 80 to 420 K. Since they have mainly hexagonal symmetry at room temperature, measurements are given with the heat flux along the [100] and the [001] axes. Due to their complex band structure and Fermi surface, their small thermopower (S) and their multicarrier systems involving electron (e) and hole (h) pockets, their N are expected to be large. Indeed, for such systems, both S and N can be expressed as¹ $S = (S_e\sigma_e + S_h\sigma_h)/(\sigma_e + \sigma_h)$ while $N = [(N_e\sigma_e + N_h\sigma_h)/(\sigma_e + \sigma_h) + (S_h - S_e)(R_Hh\sigma_h - R_He\sigma_e)\sigma_e\sigma_h]/(\sigma_e + \sigma_h)^2$, where σ is the electrical conductivity and R_H the Hall coefficient and the subscript correspond to either carriers. Since $S_h > 0$ and $S_e < 0$, the resulting S should be low thus leading to a large N . These solids are useful in single-material thermoelectric N-E coolers. They create a large temperature differences using thermomagnetic effects, without having to be cascaded. This would resolve the problem of contact resistances of actual multi-stage Peltier coolers, especially in the cryogenic temperature range. The dimensionless figure of merit of N-E coolers is $zT_N = B^2 N^2 \sigma(B) T / \kappa(B)$, with B is the magnetic field, T the absolute temperature and κ the thermal conductivity. a.E.H. Putley, *The Hall Effect and Semiconductor Physics*, New York: Dover publication, 1968.

10:24AM H17.00011 Giant Bipolar Nernst Effect in the Quasi-One-Dimensional Metal, $\text{Li}_{0.9}\text{Mo}_6\text{O}_{17}$, JOSHUA L. COHN, University of Miami, BENJAMIN D. WHITE, Montana State University, CARLOS A. M. DOS SANTOS, Escola de Engenharia de Lorena - USP, Brazil, JOHN J. NEUMEIER, Montana State University — The Nernst coefficient for the quasi-one-dimensional metal, $\text{Li}_{0.9}\text{Mo}_6\text{O}_{17}$, is found to be among the largest known for metals ($\nu \simeq 500 \mu\text{V/KT}$ at $T \sim 20$ K), and is enhanced in a broad range of temperature by orders of magnitude over the value expected from Boltzmann theory for carrier diffusion. A comparatively small Seebeck coefficient implies that $\text{Li}_{0.9}\text{Mo}_6\text{O}_{17}$ is bipolar with large, partial Seebeck coefficients of opposite sign. A very large thermomagnetic figure of merit, $ZT \sim 0.5$, is found at high field in the range $T \approx 35 - 50$ K.

¹This material is based upon work supported by an award from Research Corporation (Univ. Miami), the National Science Foundation under grant DMR-0907036 (Mont. St. Univ.), and in Lorena by the CNPq (301334/2007-2) and FAPESP (2009/14524-6).

10:36AM H17.00012 Cryogenic Thermoelectric Properties of the Bismuth-Magnesium and Bismuth-Antimony-Magnesium Systems¹, CHRISTINE OROVETS, HYUNGYU JIN, Department of Mechanical and Aerospace Engineering, The Ohio State University, BARTLOMIEJ WIENDLOCHA, AGH University of Science and Technology, Krakow, Poland, JOSEPH P. HEREMANS, Department of Mechanical and Aerospace Engineering, The Ohio State University — There is a need to increase the Figure of Merit of thermoelectric materials used in low temperature cooling applications. Band structure calculations show that substitutional magnesium in bismuth can form sharp density of states peaks, suggesting the presence of a resonant level. Single crystal samples of $(\text{Bi}_{1-x}\text{Sb}_x)_{1-y}\text{Mg}_y$ ($0 \leq x \leq 12\%$ and $0 \leq y \leq 0.7\%$ nominally) were synthesized in evacuated ampoules. The composition of each ingot was analyzed using x-ray diffraction, and transport properties were measured using a Thermal Transport Option (TTO) in a Physical Properties Measurement System (PPMS) from 300K to 2K. It is apparent that the addition of magnesium strongly influences thermopower; the data for $\text{Bi}_{90}\text{Sb}_{10}\text{Mg}_{0.7}$ shows a second minimum in thermopower at 20K, in addition to the expected minimum at approximately 50-60K. This could be due to the resonant scattering at the cryogenic temperatures which arises from the excess density of states. The addition of magnesium also appears to decrease thermal conductivity below 30K. We present systematic experimental approaches and the results to elucidate the role of magnesium in bismuth and bismuth-antimony systems.

10:48AM H17.00013 Low Temperature Electronic and Magnetic Properties of CePd_3M_x ¹, STEPHEN BOONA, DONALD MORELLI, Department of Chemical Engineering and Materials Science, Michigan State University — The intermediate valence compound CePd_3 is a strong candidate for low temperature thermoelectric applications due to its unusually large Seebeck coefficient which peaks at approximately $115 \mu\text{V/K}$ near 125K. This phenomenon results from a sharp peak in the density of states near the Fermi level due to the hybridization of conduction electrons with those in the partially occupied cerium f-shell, thus making the system highly sensitive to changes in the average cerium valence state. We have systematically studied the structural and thermoelectric properties of various CePd_3M_x compounds, where M is an s- or p-block element and $0 < x < 0.1$, in order to explore the effects of such partial filling on the cerium valence. The results of X-ray diffraction, Seebeck coefficient, and magnetic susceptibility measurements are reported. We have found that incorporating M elements of various valence configurations has similar effects on the electronic and magnetic properties as changing the M concentration, thus establishing an effective new mechanism for tailoring the thermoelectric properties of the system.

Session H18 DMP: Focus Session: Electron, Ion, and Exciton Transport in Nanostructures - Nanowires and Superlattices 252B

8:00AM H18.00001 Energy Transfer of Excitons and Electron-Hole Plasmas between Quasi-two-dimensional Semiconductor Layers¹, S.K. LYO, University of California, Irvine, CA — We study the energy transfer mechanisms of excitons and electron-hole plasmas between two quasi-two dimensional (2D) semiconductor quantum wells. It is shown that dipolar (i.e., Foerster) energy transition (ET) mechanism dominates at a short distance while photon-mediated ET mechanism plays a more important role for transfer over a long distance. The magnitude and the dependence of the transfer rates of plasmas and excitons on the temperature, the well-to-well distance, and the density are compared for both ET mechanisms. The spatial dependence of the 2D-2D transfer rates will be compared with that of the ET rate between two quantum dots.

¹Supported by U.S./DOE/BES under Contract No. DE-AC04-94AL85000.

8:12AM H18.00002 Charge transport physics of individual PbSe Nanowire field effect transistors¹, SOONG JU OH, DAVID KIM, CHERIE KAGAN, University of Pennsylvania — We report the charge transport properties of individual PbSe nanowire (NW) field-effect transistors (FETs) fabricated from single crystalline, PbSe NWs 10 nm in diameter synthesized by wet-chemical methods. PbSe is a particularly interesting semiconductor to study in one-dimension as the diameter of the NWs is smaller than the electron, hole and exciton Bohr radii, allowing study of strongly quantum confined NWs. We investigate the temperature dependent charge transport properties of ambipolar and reversibly, surface, p-doped PbSe NW FETs. We demonstrate that PbSe NW FETs behave as Schottky Barrier (SB) FETs, in which the off current is limited by the SB height and decreases as temperature decreases, while the on current is achieved by gate thinning and increases as temperature decreases. We calculate the SB heights for electron and hole injection in ambipolar and hole injection in p-type PbSe NW FETs. The hole mobility in surface-doped, p-type FETs is temperature dependent, rising monotonically from 200 cm²/Vs at room temperature to 2000 cm²/Vs at 4.5K, without signatures of impurity scattering which commonly limits carrier mobilities at low temperatures in substitutionally doped NWs.

8:24AM H18.00003 Electronic transport in individual, vertical, catalyst free GaN/AlN nanowires, CAMELIA MARGINEAN, SANTINO CARNEVALE, PATRICK PHILLIPS, THOMAS KENT, DENIS PELEKHOV, MICHAEL MILLS, ROBERTO MYERS, The Ohio State University — In the recent years, the advances in the THz technology, for example the development of the quantum cascade laser, promotes the possibility to use resonant tunneling diodes (RTD) to enhance such technologies. Coaxial m-plane AlN/GaN nanowire based resonant tunneling diode structures were formed by plasma assisted molecular beam epitaxy (MBE) using a two-step growth method that allows for control of vertical and lateral growth [1]. They are spontaneously formed MBE nanowires and they are integrated in Si (111). We discuss ongoing work on the electronic transport in these individual, vertical nanowires using two nanoprobe to contact the top of the nanowire and the substrate. The IV characteristics reveal a clear negative differential resistance (NDR) at room temperature (RT). The NDR was observed ~ 4V with a peak-to-valley ratio as high as 10. [1] S.D. Carnevale *et al.*, *Nano Letters*, 11, (2), 2011.

8:36AM H18.00004 Correlated study of individual nanowires with electronic transport and scanning tunneling microscopy, SHENGYONG QIN, TAE-HWAN KIM, Oak Ridge National Laboratory, YANNING ZHANG, University of California, Irvine, HANNO H. WEITERING, The University of Tennessee, Knoxville, CHIH-KANG SHIH, The University of Texas at Austin, WENJIE OUYANG, RUQIAN WU, University of California, Irvine, ARTHUR P. BADDORF, AN-PING LI, Oak Ridge National Laboratory — The electronic conductance in quantum wires is often dictated by quantum instabilities and strong localization at the atomic scale. We present a novel nano-transport technique which combines local nano-contacts and four-probe STM. The approach allows for correlated study of electron transport and scanning tunneling spectroscopy in individual nanowires. We first apply it to the GdSi₂ quantum wires, which show that isolated nanowires exhibit a metal-insulator transition upon cooling, driven by the defect-induced localizations, while wire bundles maintain a robust metallic state, stabilized by interwire electronic coupling. We then demonstrate applications of this transport technique with carbon nanotubes and copper wires in situ. The method bridges the gap between the transport and the local electronic and structural properties down to the atomic scale.

8:48AM H18.00005 The influence of excitonic effects on charge separation at hybrid nanoscale interfaces¹, ZHIGANG WU, HUASHAN LI, MARK LUSK, Colorado School of Mines — Efficient charge separation is critical in nanostructured photovoltaic systems, but the accurate prediction of charge separation rates remains an extremely difficult task. Although considerable progress has been made, reliable theoretical schemes to describe the charge-separation mechanisms and to compute the interfacial charge transfer dynamics have not been fully developed. In this work, we embrace the excitonic effects that are of critical importance in nanoscale geometries to derive a criterion for charge separation at hybrid nanoscale interfaces beyond the traditional quasiparticle energy-level alignment. The approach utilizes calculations from many-body perturbation theory with Green functions to accurately account for self-energy and electron-hole interactions. Four representative interfaces between Si quantum dots and small molecules are considered using this approach, in order to demonstrate that both excitonic and Coulomb stabilization effects are essential for correctly predicting charge separation at nanostructured interfaces. Interestingly, our calculations suggest that preemptory exciton transfer across interfaces only suppresses the subsequent charge separation. We also compute charge separation rates using the Marcus theory and other methods, and their accuracy are

9:00AM H18.00006 QM/EM simulation of Junctionless FinFET, JIE PENG, LINYI MENG, CHIYUNG YAM, GUANHUA CHEN, Department of Chemistry, University of Hong Kong, Hong Kong, China — We present here the simulations of a junctionless transistor. Its source, channel and drain are embedded in a piece of uniformly doped silicon nanowire. In the earlier stage, it has been designed to be a normally “ON” device. Quite reversely, the first experimentally presented junctionless transistor is in the “OFF” state when the applied gate voltage is absent. Simulations show that the depletion occurs between the nanowire and hetero-doped gate. A “P-N junction” is formed in the junctionless transistor, whose direction is perpendicular to the direction of the current flowing. Our simulation considers the depletion effect in the Quantum mechanical calculation. I-V curves of transistors with the gate doped by the same and different type of dopants have been obtained. The results match the experiments.

9:12AM H18.00007 Tuning the hole mobility in InP semiconductor nanowires¹, MARIAMA REBELLO SOUSA DIAS, UFSCar Ohio University, ADALBERTO PICININ, VICTOR LOPEZ-RICHARD, UFSCar, SERGIO E. ULLOA, Ohio University, LEONARDO K. CASTELANO, JOSÉ PEDRO RINO, GILMAR E. MARQUES, UFSCar — Transport properties of holes in InP nanowires were calculated considering the effect of temperature and the presence of realistic strain fields. The mobility of holes is obtained analytically by considering electron-phonon interaction via deformation potential through longitudinal optical (LO) phonons. Using molecular dynamics with realistic force potentials, we simulate nanowire structures and the associated phonon density of states; the structures show effects of LO phonon energy renormalization due to the reduced dimensionality and variation of the phonon lifetimes important for carrier mobility. Our mobility calculations include heavy and light hole subbands in a Luttinger Hamiltonian formalism and consider how the valence band ground state changes between light- and heavy-hole character, as both the strain field configuration and the nanowire size are changed. Depending on the dimensions and characteristics of the nanowire, we find interesting sudden changes in the mobility, which arise with the onset of a resonance between the LO phonon frequencies and the subband separation between the ground and first hole state. We will present the effect of strains and temperature on this resonant behavior and discuss the consequences for carrier mobility in these systems.

9:24AM H18.00008 First-principles study on metal-TaO_x-metal heterostructures: response to applied bias voltages¹, SATOSHI WATANABE, TAKUYA MATSUMOTO, ARIHIRO TAWARA, Dept. of Materials Engineering, The Univ. of Tokyo, TINGKUN GU, School of Electrical Engineering, Shandong Univ., TOMOFUMI TADA, Dept. of Materials Engineering, The Univ. of Tokyo — Metal-TaO_x-metal heterostructures are promising as a novel nonvolatile memory device [1]. The formation of conduction paths in the TaO_x layer is responsible for the low resistance state and the switching mechanism is understood as the electrochemical redox reaction involved with the bias-voltage application. However, microscopic details of the conduction path and switching mechanism have not been clarified yet. We examine electronic states, and electron and ion transport in Cu-TaO_x (x~2.5)-Pt(or Cu) heterostructures from first principles, focusing on the response to applied bias voltages. We show that Cu interstitials in crystalline Ta₂O₅ enhances electronic conduction considerably [2], while does not in amorphous one. We also show that the potential change due to the bias application is sensitive to the structure of TaO_x layer and/or metal-TaO_x interface: in some case, the potential change may be very small near the Cu/TaO_x interface in the TaO_x layer so that the bias application hardly change the mobility of Cu ions in this region. These results will be discussed in terms of electronic states. [1] T. Sakamoto et al., APL 91 (2007) 092110; [2] T. K. Gu et al., ACS Nano 4 (2010) 6477.

9:36AM H18.00009 Theory of spatially inhomogeneous Bloch oscillations in semiconductor superlattices¹, LUIS BONILLA, MARIANO ALVARO, MANUEL CARRETERO, Universidad Carlos III de Madrid — In a semiconductor superlattice with long scattering times, damping of Bloch oscillations due to scattering is so small that nonlinearities may compensate it and Bloch oscillations persist even in the hydrodynamic regime. To demonstrate this, we propose a Boltzmann-Poisson transport model of miniband superlattices with inelastic collisions and derive hydrodynamic modulation equations for the electron density, the electric field and the complex amplitude of the Bloch oscillations. For appropriate parameter ranges, we solve numerically these equations and show that there are solutions having the form of stable Bloch oscillations with spatially inhomogeneous field, charge, current density and energy density profiles. These Bloch oscillations disappear as scattering times become sufficiently short. For sufficiently low lattice temperatures, Bloch and Gunn type oscillations mediated by electric field, current and energy domains coexist for a range of voltages. For larger lattice temperatures (300 K), there are only Bloch oscillations with stationary amplitude and electric field profiles.

9:48AM H18.00010 Stochastic current switching in semiconductor superlattices: observation of non-exponential kinetics¹, YU. BOMZE, Duke University, H.T. GRAHN, R. HEY, Paul-Drude-Institute, Berlin, Germany, S.W. TEITSWORTH, Duke University — We report the experimental measurement of first-passage-time distributions associated with noise-induced current switching in doped, weakly-coupled GaAs/AlAs superlattices, in a regime of nonlinear electronic transport where the static current-voltage ($I - V$) curves exhibit multiple branches and bistability. For applied voltages near the end of each branch, internal shot noise induces switching of measured current to the next branch with a stochastically varying switching time. Switching time distributions are constructed by carrying out up to 10^5 measurements under identical initial conditions. We have implemented a novel, high bandwidth technique that permits measurement of switching times over very large dynamic range of approximately 10^9 , with measured times ranging from 4 ns to 10 s. For relatively small times ($< 10\mu\text{s}$), the switching time distributions show exponential tails, as expected for activated escape from an initial metastable state. However, at larger times ($> 10\mu\text{s}$), the distributions exhibit approximate power law tails that extend over several decades of time, with additional fine structure. A rate equation model indicates the possible role of multiple, nearly degenerate metastable states in producing the long tail behavior.

10:00AM H18.00011 Pseudospin Transfer Torques in Semiconductor Electron Bilayers¹, YOUNGSEOK KIM, Department of Electrical and Computer Engineering, University of Illinois, Urbana, IL, 61801, ALLAN H. MACDONALD, Department of Physics, University of Texas at Austin, Austin, Texas 78712, MATTHEW J. GILBERT², Department of Electrical and Computer Engineering, University of Illinois, Urbana, IL, 61801, MATTHEW J. GILBERT GROUP COLLABORATION — We use self-consistent quantum transport theory to investigate the influence of interactions on interlayer transport in semiconductor electron bilayers in the absence of an external magnetic field. We conclude that even though spontaneous pseudospin ferromagnetism does not occur at zero field, interaction-enhanced quasiparticle tunneling does alter the resultant interlayer I-V curves. We find that the system exhibits a critical bias voltage that is similar to that of the pseudospin ferromagnetic system, but whose properties depend heavily on the charge imbalance between the two layers and their relative spatial separation. When the bias voltage exceeds the critical value, interlayer current is gradually dropped due to the charge imbalance between the layers until the transport current no longer reaches steady state values.

10:12AM H18.00012 Effects of Fermion Flavor on Excitonic Condensation in Double Layer Systems¹, ZACHARY ESTRADA, Department of Electrical and Computer Engineering, University of Illinois, Urbana IL 61801, JOHN SHUMWAY, Department of Physics, Arizona State University, Tempe, AZ 85287, MATTHEW GILBERT, Department of Electrical and Computer Engineering, University of Illinois, Urbana IL 61801 — We perform fermionic path integral quantum Monte Carlo (PIMC) simulations to study the physical properties of dipolar exciton condensates in symmetric double layer systems. Recently, the role of screening of additional fermion flavors has been a source of contention in exciton condensates. A room temperature superfluid state has been predicted in bilayer graphene assuming that the condensate screens out additional fermion flavors.² On the other hand, large-N calculations have resulted in much weaker screening of fermion flavors and have placed the transition temperature far lower, around one millikelvin.³ We demonstrate the effect of added fermion flavor on the Kosterlitz-Thouless transition temperature (T_{KT}) in symmetric electron-hole bilayers by collecting static and dynamic response functions.⁴ We find that the addition of fermion flavors decreases T_{KT} , however, due to strong exciton binding, the decrease we observe is not as drastic as is predicted in the earlier large-N calculations.

10:24AM H18.00013 Magnetic-Field Modulated Josephson Oscillations in a Planar Semiconductor Microcavity¹, GUOJUN JIN, CHUANYI ZHANG, Nanjing University — An exciton-polariton Josephson junction in a planar semiconductor microcavity is studied by considering an external magnetic field applied normal to its plane [1]. Theoretical results show that there is a competition between the Zeeman energy and the interactions of exciton polaritons, and a critical magnetic field can be determined. Below the critical magnetic field, there are time-independent extrinsic and intrinsic Josephson currents which manifest the dc Josephson effect; while above the critical magnetic field, the ac Josephson effect occurs with the oscillating extrinsic and intrinsic Josephson currents. The oscillation frequency and oscillation amplitude of the Josephson currents are modulated by the magnetic field, and also the spontaneous polarization separation and the macroscopic quantum self-trapping of condensate can be realized under an appropriate magnetic field. The physical origin behind is exposed and the analogy with the Josephson effect in a conventional superconducting Josephson junction is discussed. It is suggested that magnetic fields can be used to facilitate the experimental investigations of the exciton polaritons Josephson effect in semiconductor microcavities.

10:48AM H18.00015 Electrolyte Gated Transistors based on Solution Processed Mesoporous Tungsten Trioxide Thin Films, CLARA SANTATO, DILEK ISIK, Ecole Polytechnique Genie Physique, FABIO CICOIRA, Ecole Polytechnique Genie Chimique — Tungsten trioxide (WO₃) is an important material for electrochromic displays, gas sensors, and photoelectrochemical cells. Despite intensive research efforts, the charge transport properties of nanostructured WO₃ films, as well as of other metal oxide films, are still largely undiscovered. Electrolyte gating provides a powerful platform to study the charge transport properties of nanostructured WO₃ films permitting to achieve high charge density regimes. In turn, this opens the possibility to improve the film transport properties for a wide range of applications. Here we report on electrolyte gated transistors making use of WO₃ films as the semiconductor and H₂SO₄(aq) 1M as the gate dielectric. WO₃ films, prepared by sol-gel method, were deposited on source and drain patterned ITO substrates. The liquid electrolyte was confined using a PDMS well. Atomic force microscopy and scanning electron microscopy images show a mesoporous film structure where the electrolyte can easily penetrate. The mesoporous structure permits an efficient electrolyte gating compared to bulk WO₃ films because of the higher surface available for electrical double layers, which are the underpinning of the electrolyte gating. Upon application of gate bias in the 0-1 V range, with an applied drain voltage ranging between 0-1 V, we were able to tune the conductivity in the WO₃ transistor channel: electrolyte gating of the films led to clear transistor behaviour. Electrolyte gating of WO₃ electrochromism is presently under investigation.

Session H19 DCMP GMAG: Invited Session: Current-Driven Spin Textures 253AB

8:00AM H19.00001 Doppler velocimetry of a current driven spin helix, LUYI YANG, UC Berkeley and Lawrence Berkeley National Lab — We present direct observation of the translational motion of spin helices in GaAs quantum wells under the influence of applied electric fields. Previously, the lifetime of such helices was observed by time-resolving the amplitude of light diffracted from the periodic spin polarization [1]. This technique cannot be applied to tracking the motion of current-driven spin helices because diffraction amplitude is insensitive to translation of the center of mass of a periodic structure. In this talk, we describe a new experimental technique, Doppler spin velocimetry, capable of resolving displacements of spin polarization at the level of 1 nm on a picosecond time scale [2]. This is accomplished through the use of heterodyne detection to measure the optical phase of the diffracted light. We discuss experiments in which this technique is used to measure the motion of spin helices as a function of temperature, in-plane electric field, and photoinduced spin polarization amplitude. Several striking observations will be reported – for example, the spin helix velocity changes sign as a function of wavevector and is zero at the wavevector that yields the largest spin lifetime. Another important observation is that the velocity of spin polarization packets becomes equal to the drift velocity of the high-mobility electron gas in the limit of small spin helix amplitude. Finally, we show that spin helices continue propagate at the same speed as the Fermi sea even when the electron drift velocity exceeds the Fermi velocity of 10^7 cm-s⁻¹. In collaboration with J. D. Koralek and J. Orenstein, UC Berkeley and LBNL, D. R. Tibbetts, J. L. Reno, and M. P. Lilly, SNL. Supported by DOE under Contract No. DE-AC02-05CH11231 and DE-AC04-94AL85000.

8:36AM H19.00002 Experimental studies of skyrmion textures and spin torque effects in chiral magnets, ROBERT RITZ, Technical University Munich, Physics Department E21 — Small angle neutron scattering and measurements of a topological Hall signal identify the formation of skyrmion lattices in the non-centrosymmetric B20 compounds MnSi [1], $\text{Mn}_{1-x}\text{Fe}_x\text{Si}$, $\text{Mn}_{1-x}\text{Co}_x\text{Si}$ and the strongly doped semiconductor $\text{Fe}_{1-x}\text{Co}_x\text{Si}$ [2]. This observation has been confirmed by Lorentz force microscopy in thin samples of $\text{Fe}_{1-x}\text{Co}_x\text{Si}$, FeGe and, most recently, MnSi, where even individual skyrmions have been spotted [3]. Because the skyrmion lattices are exceptionally weakly pinned to the crystal lattice, extreme care has to be exercised when studying the precise intrinsic morphology of related spin textures in bulk samples. As a particularly striking property each skyrmion supports precisely one quantum of emergent magnetic flux. This permits a highly efficient coupling between skyrmions and conduction electrons which results in spin torque effects at ultra-low current densities as seen in small angle neutron scattering [4] and the emergent electric field when the skyrmions move [5].

9:12AM H19.00003 Current-induced domain wall motion stabilized by Rashba spin-orbit coupling, IOAN MIRON, Catalan Institute of Nanotechnology (ICN-CSIC) — No abstract available.

9:48AM H19.00004 Current-driven spin dynamics in spin-orbit coupled superconductors¹, GIOVANNI VIGNALE, Department of Physics, University of Missouri-Columbia — The study of the interplay between spin-orbit coupling (SOC) and superconductivity in two-dimensional electron gases (2DEG) has recently gained impetus following the discovery of i) 2DEGs in InAs or GaAs semiconductor heterostructures that are proximized by ordinary s-wave superconducting leads — a class of systems which plays a key role in the quest for Majorana fermions — and ii) 2DEGs that form at interfaces between complex oxides such as LaAlO_3 and SrTiO_3 , which display tunable SOC and, under appropriate conditions, superconductivity. Motivated by this body of experimental and theoretical literature, we investigate the collective spin dynamics of an archetypical 2DEG model Hamiltonian with Rashba SOC in the presence of *repulsive* electron-electron (e-e) interactions. In the absence of superconductivity a Rashba 2DEG exhibits spin oscillations, which, at long wavelength and for weak repulsive interactions, have a frequency $\approx 2\alpha k_F$, α being the strength of SOC and k_F the usual 2D Fermi wavenumber in the absence of SOC. These oscillations, however, are damped and quickly decay due to the emission of (double) electron-hole pairs, which, in the normal phase, are present at arbitrary low energies. In the presence of superconductivity, collective spin oscillations continue to exist in a wide range of parameters, because the Cooper pairs are mixtures of singlet and triplet components. Further, these excitations are undamped because they lie inside the superconducting gap where no other excitation exists. These spin oscillations can be excited by the application of a magnetic field or a supercurrent and can be used to realize persistent spin oscillators operating in the frequency range of 10 GHz — 1 THz.

10:24AM H19.00005 Emergent electrodynamics from moving magnetic whirls in chiral magnets, ACHIM ROSCH, University of Cologne — In chiral magnets a lattice of magnetic whirls — so-called skyrmions — is stabilized in a small temperature and field range by thermal fluctuations [1]. We discuss how electric and spin currents couple to these skyrmions. As the spin of the electrons locally adjusts to the magnetic texture, the electron picks up a Berry phase. The effects of these time-dependent Berry phases are best described by “artificial” electric and magnetic fields of an emergent electrodynamics which couple to the spin and the spin currents. The efficient Berry phase coupling together with a partial cancellation of pinning forces due to the stiffness of the skyrmion lattice allows to explain theoretically experiments [2], which show that skyrmion lattices can be controlled by ultrasmall current densities. Using tiny gradients of temperature or magnetic field it is also possible to induce rotations of the skyrmion lattice. The topologically quantized winding number of the skyrmions induces exactly one quantum of emergent magnetic flux per skyrmion. Therefore one can also determine quantitatively the emergent electric field induced by a moving skyrmion following Faraday’s law of induction as has been measured in recent experiments [3].

Session H20 GSNP DFD: Invited Session: Hydrodynamics and Microstructure: From Single Self-Propelled Particles to Active Soft Matter 253C

8:00AM H20.00001 Swimming & Propulsion in Viscoelastic Media¹, PAULO ARRATIA, University of Pennsylvania — Many microorganisms have evolved within complex fluids, which include soil, intestinal fluid, and mucus. The material properties or rheology of such fluids can strongly affect an organism’s swimming behavior. A major challenge is to understand the mechanism of propulsion in media that exhibit both solid- and fluid-like behavior, such as viscoelastic fluids. In this talk, we present experiments that explore the swimming behavior of biological organisms and artificial particles in viscoelastic media. The organism is the nematode *Caenorhabditis elegans*, a roundworm widely used for biological research that swims by generating traveling waves along its body. Overall, we find that fluid elasticity hinders self-propulsion compared to Newtonian fluids due to the enhanced resistance to flow near hyperbolic points for viscoelastic fluids. As fluid elasticity increases, the nematode’s propulsion speed decreases. These results are consistent with recent theoretical models for undulating sheets and cylinders. In order to gain further understanding on propulsion in viscoelastic media, we perform experiments with simple reciprocal artificial ‘swimmers’ (magnetic dumbbell particles) in polymeric and micellar solutions. We find that self-propulsion is possible in viscoelastic media even if the motion is reciprocal.

¹This work is supported by NSF-CAREER-0954084.

8:36AM H20.00002 Assembly and dynamics of synthetic cilia¹, TIM SANCHEZ, Brandeis University, Physics Department — From motility of simple protists to determining the handedness of complex vertebrates, highly conserved eukaryotic cilia and flagella are essential for the reproduction and survival of many biological organisms. Despite extensive studies, the exact mechanism by which individual components coordinate to produce ciliary beating patterns remains unknown. We describe a novel approach towards studying ciliary beating. Instead of deconstructing a fully functional organelle from the top-down, we describe a process by which synthetic cilia-like structures are assembled from the bottom-up. We find that simple mixtures of microtubules, kinesin clusters, and a bundling agent produce spontaneous oscillations in MT bundles, suggesting that self-organized beating may be a generic feature of internally driven bundles. Furthermore, bundles in close proximity spontaneously coordinate their beating to generate metachronal traveling waves, reminiscent of the waves seen in ciliary fields. These findings and future refinements of the system can potentially provide insights into general design principles required for engineering synthetic cilia as well as understanding the biological analogues.

9:12AM H20.00003 Polar patterns in active fluids¹, M. CRISTINA MARCHETTI, Physics Department & Syracuse Biomaterials Institute, Syracuse University — Active fluids are a new class of soft materials composed of interacting units that consume energy and collectively generate motion and mechanical stress. Examples include bacterial suspensions, mixtures of cytoskeletal filaments and motor proteins, and migrating epithelial cell layers. Due to their elongated shape, active particles can exhibit orientational order at high concentration and have been likened to “living liquid crystals”, with either nematic or polar symmetry. In this talk I will discuss the spatio-temporal dynamics of continuum models of active fluids in two dimensions, focusing on the case of a system with polar symmetry as relevant to bacterial suspensions. Upon increasing activity, the active fluid displays increasingly complex patterns, including traveling bands, traveling vortices and chaotic behavior. The nonlinear hydrodynamic equations can be mapped onto a diffusion-reaction-convection model, highlighting the connection between the complex dynamics of active system and that of excitable systems.

9:48AM H20.00004 Swimming of Paramecium in confined channels, SUNGHWAN JUNG, Virginia Tech — Many living organisms in nature have developed a few different swimming modes, presumably derived from hydrodynamic advantage. Paramecium is a ciliated protozoan covered by thousands of cilia with a few nanometers in diameter and tens of micro-meters in length and is able to exhibit both ballistic and meandering motions. First, we characterize ballistic swimming behaviors of ciliated microorganisms in glass capillaries of different diameters and explain the trajectories they trace out. We develop a theoretical model of an undulating sheet with a pressure gradient and discuss how it affects the swimming speed. Secondly, investigation into meandering swimmings within rectangular PDMS channels of dimension smaller than Paramecium length. We find that Paramecium executes a body-bend (an elastic buckling) using the cilia while it meanders. By considering an elastic beam model, we estimate and show the universal profile of forces it exerts on the walls. Finally, we discuss a few other locomotion of Paramecium in other extreme environments like gel.

10:24AM H20.00005 Helical swimming in viscoelastic and porous media, BIN LIU, School of Engineering, Brown University — Many bacteria swim by rotating helical flagella. These cells often live in polymer suspensions, which are viscoelastic. Recently there have been several theoretical and experimental studies showing that viscoelasticity can either enhance or suppress propulsion, depending on the details of the microswimmer. To help clarify this situation, we study experimentally the motility of the flagellum using a scaled-up model system - a motorized helical coil that rotates along its axial direction. A free-swimming speed is obtained when the net force on the helix is zero. When the helix is immersed in a viscoelastic (Boger) fluid, we find an increase in the force-free swimming speed as compared with the Newtonian case. The enhancement is maximized at a Deborah number of approximately one, and the magnitude depends not only on the elasticity of the fluid but also on the geometry of the helix. In the second part of my talk, I will discuss how spatial confinements, such as a porous medium, affect the flagellated swimming. For clarity, the porous media are modeled as cylindrical cavities with solid walls. A modified boundary element method allows us to investigate a situation that the helical flagella are very close to the wall, with high spatial resolution and relatively low computational cost. To our surprise, at fixed power consumption, a highly coiled flagellum swims faster in narrower confinements, while an elongated flagellum swims faster in a cavity with a wider opening. We try understanding these effects with simple physical pictures.

Session H21 DCMP: Superconductivity: Electronic Structure of BSCCO; ARPES and theory
254A

8:00AM H21.00001 Extraction of Normal Electron Self-Energy and Pairing Self-Energy in $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8$ via Laser ARPES, WENTAO ZHANG, Institute of Physics, Chinese Academy of Sciences, Beijing, China, J.M. BOK, J.H. YUN, Dept. of Physics, SungKyunKwan University, Korea, J.F. HE, G.D. LIU, L. ZHAO, H.Y. LIU, J.Q. MENG, X.W. JIA, Y.Y. PENG, D.X. MOU, S.Y. LIU, L. YU, S.L. HE, X.L. DONG, J. ZHANG, Institute of Physics, CAS, Beijing, China, J.S. WEN, Z.J. XU, Brookhaven National Laboratory, USA, G.D. GU, Brookhaven National Laboratory, USA, C.T. CHEN, Z.Y. XU, Technical Institute of Physics and Chemistry, CAS, Beijing, China, H.-Y. CHOI, Dept. of Physics, SungKyunKwan University, Korea, C.M. VARMA, Dept. of Physics and Astronomy, UC Riverside, USA, X.J. ZHOU, Institute of Physics, CAS, Beijing, China — Super-high resolution laser-based angle-resolved photoemission measurements have been performed on a high temperature superconductor $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8$. The band back-bending characteristic of the Bogoliubov-like quasiparticle dispersion is clearly revealed at low temperature in the superconducting state which gives rise to two peaks in the momentum distribution curves. This makes it possible for the first time to experimentally extract the normal electron self-energy and pairing self-energy in the superconducting state. These information can be used to further determine the Bosonic spectral function that will provide key insight and constraints on the origin of electron pairing in high temperature superconductors.

8:12AM H21.00002 Momentum Dependence of the Self-energy and Fluctuation Spectrum of Bi2212 from High Resolution Laser ARPES, HAN-YONG CHOI, JIN MO BOK, JAE HYUN YUN, SungKyunKwan University, WENTAO ZHANG, X.J. ZHOU, Chinese Academy of Sciences, C.M. VARMA, University of California, Riverside — We report deduction of the Eliashberg function $\alpha^2F(\theta, \omega)$ at energy ω and along momentum cuts at angles θ normal to the Fermi surface from the high resolution laser angle resolved photoemission spectroscopy on slightly underdoped Bi2212 in the normal and superconducting states. Our principle result is that despite the angle dependence of the extracted single-particle self-energy, the Eliashberg function in the normal state collapses onto a single function of ω independent of the angle. It has a peak around 0.05 eV, flattens out above 0.1 eV with the angle dependent cut-off. The cut-off energy is given by the intrinsic value of about 0.4 eV or the energy of the band bottom in direction θ , whichever is lower. These results are consistent only with fluctuation spectra which have the correlation length of the lattice constant or shorter. In the superconducting state, the deduced $\alpha^2F(\theta, \omega)$ exhibits a new peak around 0.015 eV in addition to the 0.05 eV peak and flat spectrum as in the normal state. Both peaks become enhanced as T is lowered or the angle moves away from the nodal direction. The implication of these findings is discussed.

8:24AM H21.00003 Mechanisms for Superconductivity in Cuprates compared with results from the Generalized MacMillan-Rowell Analysis of High Resolution Laser- ARPES, CHANDRA VARMA, University of California, Riverside, CA., HAN-YONG CHOI, Korea Institute for Advanced Study, Seoul 130-722, Korea., WENTAO ZHANG, XINGJIANG ZHOU, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China. — The spectra of fluctuations and their coupling to fermions has been deduced from extensive high resolution laser ARPES in several BISCCO samples and quantitatively analyzed. We ask the question whether some of the theories for superconductivity in Cuprates are consistent or inconsistent with the frequency and the momentum dependence of the deductions. We find that any fluctuation spectra, for example that of Antiferromagnetic Fluctuations, whose frequency dependence depends significantly on momentum dependence are excluded. We consider the quantum-critical spectra of the loop-current order observed in under-doped cuprates and its coupling to fermions and find it consistent with the data.

8:36AM H21.00004 Comparative study of the MDC and two-dimensional analysis of ARPES intensity for Bi2212 bilayer superconductor, JIN MO BOK, HAN-YONG CHOI, SungKyunKwan University, JUNFENG HE, X.J. ZHOU, Chinese Academy of Sciences, C.M. VARMA, University of California — The momentum distribution curve (MDC) analysis is commonly used to analyze the ARPES data. A problem of the MDC analysis, however, is that the matrix elements turn out to be energy dependent. To remedy this we take the two-dimensional (2D) analysis of the ARPES intensity as reported by Meevasana et. al. [1]. We analyze the overdoped Bi2212 superconductor ARPES data by performing both 2D and MDC analysis taking the bilayer splitting into consideration. The deduced self-energy and Eliashberg function from both analysis will be compared and presented.

[1] Meevasana et. al. Phys. Rev. B 77, 104506 (2008).

8:48AM H21.00005 Ultra-High Resolution Time- and Angle-Resolved Photoemission Experiments on High Temperature Superconductor $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8$, WENTAO ZHANG, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA, CHRIS SMALLWOOD, TRISTAN MILLER, Department of Physics, University of California, Berkeley, CA 94720, USA, CHRIS JOZWIAK, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA, HIROSHI EISAKI, Nanoelectronics Research Institute (NeRI), National Institute of Advanced Industrial Science and Technology (AIST) Umezono 1-1-1 Tsukuba, Ibaraki 305, DUNG-HAI LEE, ALESSANDRA LANZARA, Department of Physics, University of California, Berkeley, CA 94720, USA — Ultra-high resolution laser-based time- and angle-resolved photoemission measurements have been carried out on various dopings of $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8$ high temperature superconductor. In this talk, we will report on the study of the dynamical quasiparticle excitation and recombination of the nodal electronic states in cuprate.

9:00AM H21.00006 Momentum-Dependent Ultrafast Quasiparticle Dynamics in Optimally-Doped Bi-2212 Monitored with Time-Resolved ARPES, GEORGI DAKOVSKI, Linac Coherent Light Source, SLAC National Accelerator Laboratory, Menlo Park CA, TOMASZ DURAKIEWICZ, Condensed Matter and Magnet Science, Materials Physics and Applications Division, Los Alamos National Laboratory, Los Alamos NM, JIAN-XIN ZHU, Physics of Condensed Matter and Complex Systems, Theoretical Division, Los Alamos National Laboratory, Los Alamos NM, PETER RISEBOROUGH, Department of Physics, Temple University - Philadelphia PA, GENDA GU, Condensed Matter Physics & Materials Science, Brookhaven National Laboratory, Upton NY, STEVE GILBERTSON, GEORGE RODRIGUEZ, Center for Integrated Nanotechnologies, Materials Physics and Applications Division, Los Alamos National Laboratory, Los Alamos NM — We have employed the novel technique of time- and angle-resolved photoelectron spectroscopy (t-ARPES) to investigate the quasiparticle dynamics in photoexcited, optimally-doped $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8$ superconductor across the superconductor-metal transition. In this talk, we will present and analyze the substantially different ultrafast dynamics, tracked in momentum-dependent fashion, by probing the nodal and antinodal regions of the Brillouin zone, on a 35 femtosecond timescale. The consequences of these findings in terms of reentrant superconductivity will be discussed.

9:12AM H21.00007 Tracking Cooper Pair Formation in a Cuprate Superconductor: An Ultra-fast ARPES Study, CHRISTOPHER SMALLWOOD, JAMES HINTON, Department of Physics, UC Berkeley; Materials Science Division, LBNL, CHRIS JOZWIAK, Advanced Light Source, LBNL, WENTAO ZHANG, JAKE KORALEK, Materials Science Division, LBNL, HIROSHI EISAKI, Nanoelectronics Research Institute, National Institute of Advanced Industrial Science and technology, DUNG-HAI LEE, JOSEPH ORENSTEIN, ALESSANDRA LANZARA, Department of Physics, UC Berkeley; Materials Science Division, LBNL — A basic mystery in high temperature superconductivity is the process that drives quasiparticles to form Cooper pairs, the fundamental charge carriers in any superconductor. We use time- and angle-resolved photoemission spectroscopy (TR-ARPES) to measure the relaxation dynamics of low energy excitations in the optimally doped cuprate superconductor Bi-2212. Results are discussed within the context of the Rothwarf-Taylor model of quasiparticle recombination.

9:24AM H21.00008 Nodal Gap of Heavily Under-doped Bi2201 Revealed by VUV Laser ARPES, YINGYING PENG, JIANQIAO MENG, The Institute of Physics, Chinese Academy of Sciences, CHANGTIAN CHEN, ZUYAN XU, Technical Institute of Physics and Chemistry, Chinese Academy of Science, XINGJIANG ZHOU, The Institute of Physics, Chinese Academy of Sciences — We have carried out VUV laser-based angle-resolved photoemission (ARPES) on heavily under-doped $\text{Bi}_2(\text{Sr}_{2-x}\text{La}_x)\text{CuO}_{6+\delta}$ (abbreviated as La-Bi2201) samples with different dopings from antiferromagnetic insulators to superconductors. We find that, along the $(0,0) - (\pi,\pi)$ nodal direction, there is a gap opening that is strongly dependent on the hole doping level. The momentum and temperature dependence of the gap is investigated and the implication of the observations will be discussed.

9:36AM H21.00009 Doping Dependence of Pair-breaking and Pair-forming Processes in BSCCO, THEODORE REBER, NICHOLAS PLUMB¹, YUE CAO, ZHE SUN, STEPHEN PARHAM, QIANG WANG, University of Colorado, HIDEAKI IWASAWA, Hiroshima Synchrotron Radiation Center, Hiroshima University, SHIMPEI ONO, RIKEN, GENDA GU, Brookhaven National Lab, YOSHIHIRO AIURA, AIST, GERALD ARNOLD, DANIEL DESSAU, University of Colorado — Angle resolved photo-emission spectroscopy (ARPES) provides a direct measure of electronic scattering processes in materials. However traditional methods (e.g. MDC widths) of determining the scattering processes from ARPES fail to discriminate between pairing and non-pairing interactions. Our new analysis technique, the ARPES tunneling spectrum (ATS), isolates the pairing channel from all other processes. We will report doping, angle and temperature dependence of both the pair-forming strength and the pair-breaking rate in BSCCO.

¹Now at PSI

9:48AM H21.00010 Momentum dependence of Fermi surface maps in angle-resolved photoemission spectrum of $\text{Bi}_2\text{Sr}_2\text{CuO}_6$ (Bi2201), SUSMITA BASAK, Northeastern U., J. NIEMINEN, M. LINDROOS, Northeastern U. and Tampere U. Tech., Finland, R. S. MARKIEWICZ, A. BANSIL, Northeastern U. — We have investigated the effect of ARPES matrix element on photointensity for emission from the Fermi energy as a function of photon energy in Bi2201 using first-principles as well as tight-binding model calculations. Our results show that as the photon energy increases and photoemitted electrons are spread over a larger area of momentum space, the highest spectral intensities generally remain pinned to the largest momenta probed at any given photon energy. The tight-binding calculations, which involve a three band Hubbard Hamiltonian based on $\text{Cu } d_{x^2-y^2}$ and $\text{O } p_x, p_y$ orbitals, give insight into the role of the ARPES matrix element in shaping the photointensities. A relatively simple formula is derived for the matrix element, showing how much of the zone-to-zone variation of the photointensity is controlled by the structure factor associated with the Bloch wavefunction.

10:00AM H21.00011 Detecting the minimum gap locus in ARPES spectra of Bi2201¹, MAKOTO HASHIMOTO, SSRL, SLAC National Accelerator Lab, RUIHUA HE, Advanced Light Source, Lawrence Berkeley National Lab, Berkeley, ROB MOORE, SIMES, SLAC and GLAM, Departments Departments of Physics and Applied Physics, Stanford University, DONGHUI LU, SSRL, SLAC National Accelerator Lab, YOSHIYUKI YOSHIDA, Nanoelectronics Research Institute, AIST, MOTOYUKI ISHIKADO, Japan Atomic Energy Agency, HIROSHI EISAKI, Nanoelectronics Research Institute, AIST, ZAHID HUSSAIN, Advanced Light Source, Lawrence Berkeley National Lab, Berkeley, TOM DEVEREAUX, ZHI-XUN SHEN, SIMES, SLAC and GLAM, Departments Departments of Physics and Applied Physics, Stanford University — Recent angle-resolved photoemission (ARPES) studies have reported a direct evidence for the competing nature of the pseudogap by showing that the pseudogap dispersion is not tied to Fermi momentum (k_F) [1,2]. In this study, to get more detailed information on how the competing pseudogap evolves across the pseudogap temperature (T^*), we introduce a new analysis method for spectral weight. We found a clear indication that the pseudogap opens at T^* with the minimum gap locus deviating from k_F , which is completely different manner from the gap opening by simple superconductivity, and strongly supports that the pseudogap is another distinct order. [1] M. Hashimoto and R.-H. He *et al.*, Nature Phys. **6**, 14-418 (2010). [2] R.-H. He and M. Hashimoto *et al.*, Science **331**, 1579-1583 (2011).

10:12AM H21.00012 Evidence for Charge-Density-Wave in Underdoped Bi2201 from ARPES and LEED, J.A. ROSEN, R. COMIN, G. LEVY, D. FOURNIER, Z.-H. ZHU, B. LUDBROOK, C.N. VEENSTRA, D. WONG, P. DOSANJH, Department of Physics & Astronomy, University of British Columbia, Vancouver, British Columbia V6T 1Z1, Canada, Y. YOSHIDA, H. EISAKI, Superconducting Electronics Group, National Institute of Advanced Industrial Science and Technology, Ibaraki 305-8568, Japan, L. PETACCIA, Sincrotrone Trieste, Strada Statale 14 Km 163.5, 34149 Trieste, Italy, A. DAMASCELLI, Quantum Matter Institute and Department of Physics & Astronomy, University of British Columbia, Vancouver, British Columbia V6T 1Z4, Canada — While there is mounting evidence for a broken symmetry in the pseudogap state of the high- T_c cuprates, the identification of a specific phase remains elusive. Through the combination of electronic (ARPES) and structural (LEED) probes, we uncover a temperature dependent evolution of the CuO_2 plane band dispersion in highly-ordered Bi2201, which is directly associated with a hitherto-undetected evolution of the incommensurate superstructure. The quasilinear, continuous variation of the modulation wavelength $2\pi/Q_2$ from ~ 66 to $43\text{\AA}$, below a characteristic $T_{Q_2} \simeq 130\text{K}$, provides evidence for an electronically-driven charge-density-wave ordering. This points to a remarkable electron-lattice coupling, in which the footprint of the BiO -layer-induced superstructure is found in the modulated electronic structure of the CuO_2 plane.

10:24AM H21.00013 Electronic Scattering Rates in the High- T_c Superconductor $\text{Bi}_{2.1}\text{Sr}_{1.9}\text{Ca}(\text{Cu}_{1-y}\text{Fe}_y)_2\text{O}_x$, STEPHEN PARHAM, THEODORE REBER, YUE CAO, JUSTIN WAUGH, University of Colorado, GENDA GU, Brookhaven National Laboratory, DANIEL DESSAU, University of Colorado — We investigate the effects of Fe impurities in bi-layer BSCCO. It is known that substituting Fe for Cu in this material reduces T_c , but the mechanism for this decrease is not well understood. We have developed a technique that utilizes ARPES to quantitatively measure the effects of impurities on electronic scattering. Using this technique we investigate the details of how Fe impurities cause an increase in the pair-breaking scattering rate in bi-layer BSCCO.

10:36AM H21.00014 Universal 115meV Feature and High Energy Spectral Weight Transfer in $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\Delta}$ Superconductor Revealed by Laser ARPES, JUNFENG HE, XINGJIANG ZHOU, The Institute of Physics, Chinese Academy of Sciences — Quasiparticle dispersion and spectral weight transfer have been investigated by laser-based angle-resolved photoemission spectroscopy in $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\Delta}$. A universal energy scale near $\sim 115\text{meV}$ can be clearly identified in superconducting state which is insensitive to momentum and doping levels. A concomitant observation with this energy scale is the spectral weight transfer over a large energy range when the sample goes from the normal state to the superconducting state. The origin and implications of these observations will be discussed.

10:48AM H21.00015 Towards the Standard Model for Fermi Arcs from a Wilsonian Reduction of the Hubbard Model, SEUNGMIN HONG, PHILIP PHILLIPS, University of Illinois, Urbana-Champaign, UNIVERSITY OF ILLINOIS, URBANA-CHAMPAIGN TEAM — Two remarkable features emerge from the exact Wilsonian procedure for integrating out the high-energy scale in the Hubbard model. At low energies, the number of excitations that couple minimally to the electromagnetic gauge is less than the conserved charge, thereby implying a breakdown of Fermi liquid theory. In addition, two charge e excitations emerge in the lower band, the standard projected electron and a composite entity (comprised of a hole and a charge $2e$ bosonic field) which give rise to poles and zeros of the single-particle Green function, respectively. The poles generate spectral weight along an arc centered at $(\pi/2, \pi/2)$ while the zeros kill the spectral intensity on the back-side of the arc. The result is the Fermi arc structure intrinsic to cuprate phenomenology. The presence of composite excitations also produces a broad incoherent pseudogap feature at the $(\pi, 0)$ region of the Brillouin zone, thereby providing a mechanism for the nodal/anti-nodal dichotomy seen in the cuprates.

Tuesday, February 28, 2012 8:00AM - 11:00AM —

Session H22 DMP DCOMP: Focus Session: Fe-based Superconductors - Anisotropic Transport and Anisotropy 254B

8:00AM H22.00001 Temperature-dependent anisotropic resistivity in electron, hole and iso-electron - doped BaFe₂As₂ superconductors¹, M.A. TANATAR, Ames Laboratory USDOE, Ames, Iowa — Anisotropic electrical resistivity, $\rho(T)$, was studied in iron-arsenide superconductors, obtained by doping the parent BaFe₂As₂ compound on three different sites: (1) electron donor transition metal (Co, Ni, Rh, Pd) substitution of Fe [1,2]; (2) hole donor K substitution of Ba [3]; (3) isoelectron P substitution of As. For all three types of dopants a range of T -linear behavior is found at the optimal doping in both the in-plane and the inter-plane $\rho(T)$ above T_c . At some higher temperature this range of T -linear resistivity is capped by a slope-changing anomaly, which, by comparison with NMR, magnetic susceptibility and Hall effect measurements, can be identified with the onset of carrier activation over the pseudogap [1]. The doping-evolution of anisotropic temperature dependent $\rho(T)$ and of the pseudogap are quite different for three types of doping. A three-dimensional $T-H$ phase diagram summarizing our results will be presented. Furthermore, potential correlation of the anisotropic normal state transport and anisotropic superconducting state heat transport will be discussed.

8:36AM H22.00002 Enhanced conductance in the normal state of Fe pnictides & chalcogenides measured by quasiparticle scattering spectroscopy (QPS): evidence of orbital fluctuations, HAMOOD ARHAM, C.R. HUNT, W.K. PARK, L.H. GREENE, U of IL at Urbana, J. GILLET, S.D. DAS, S.E. SEBASTIAN, U. Cambridge, S. RAN, A. THALER, S.L. BUD'KO, P.C. CANFIELD, Ames Lab & ISU, Z.J. XU, J.S. WEN, Z.W. LIN, Q. LI, G. GU, BNL — QPS reveals a conductance enhancement at a temperature, T_{onset} , for RFe₂As₂ (R=Ca, Sr, Ba) and Fe_{1.13}Te. For Ba/Sr Fe₂As₂ and Fe_{1.13}Te the enhancement survives well above the magnetic and structural transition temperatures (Ba: $T_N \sim 132$ K, $T_{onset} \sim 175$ K; Sr: $T_N \sim 192$ K, $T_{onset} \sim 240$ K; Fe_{1.13}Te: $T_N \sim 60$ K, $T_{onset} \sim 75$ K) while for most CaFe₂As₂ junctions it disappears below T_N and T_S (11 junctions tested, only 2 showed weak enhancement above T_N). For Co underdoped BaFe₂As₂ the enhancement coexists with the superconducting Andreev peaks while it is not observed for Co overdoped Ba122. We construct a modified phase diagram for Ba(Fe_{1-x}Co_x)₂As₂ to reflect the presence of this feature for the underdoped regime.¹ We discuss this conductance enhancement in the context of non-Fermi liquid behavior of these compounds due to orbital fluctuations.² This work is supported by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the US DOE, Office of Science, Award No. DE-AC0298CH1088. 8:48AM H22.00003 Nematic order in the vicinity of a vortex in superconducting FeSe, DEBANJAN CHOWDHURY, EREZ BERG, SUBIR SACHDEV, Department of Physics, Harvard University — We present a phenomenological theory of the interplay between nematic order and superconductivity in the vicinity of a vortex induced by an applied magnetic field [1]. Nematic order can be strongly enhanced in the vortex core. As a result, the vortex cores become elliptical in shape. For the case where there is weak bulk nematic order at zero magnetic field, the field-induced eccentricity of the vortex core has a slow power-law decay away from the core. Conversely, if the nematic order is field induced, then the eccentricity is confined to the vortex core. We discuss the relevance of our results to recent scanning tunneling microscopy experiments on FeSe [2].

9:00AM H22.00004 T-matrix Impurity Effects on Nematicity in Iron-Based Superconductors, NACHUM PLONKA, ALEXANDER KEMPER, THOMAS DEVEREAUX, Stanford University and SLAC National Accelerator Laboratory — In iron-based superconductors, nematicity has been reported in transport measurements and a broad range of spectroscopies, including angle-resolved photoemission, neutron scattering, and scanning tunneling microscopy. These observed anisotropies of broken tetragonal symmetry have been attributed to pure spin physics or unequal occupation of the iron d-electron orbitals, referred to as orbital ordering. To address this issue, we use realistic multi-orbital tight-binding Hamiltonians and T-matrix formalism to explore the effects of non-magnetic impurities. In particular, we present a detailed examination of the local density of states around impurities, and highlight the interplay of magnetic and orbital degrees of freedom.

9:12AM H22.00005 Surface Structure of Stripe ordered 1x2 phase on (Ba, Ca)(Fe_{1-x}Co_x)₂As₂¹, GUORONG LI, VON BRAUN NASCIMENTO, XIAOBO HE, AMAR B. KARKI, RONGYING JIN, JIANDI ZHANG, WARD PLUMMER, Louisiana State University — Low energy electron diffraction (LEED) and scanning tunneling microscopy/spectroscopy (STM/S) have been utilized to investigate the geometric structure of the stripe 1x2 surface phase of (Ba, Ca)(Fe_{1-x}Co_x)₂As₂ iron pnictides. STM images show that the surface consists of competing ordered and disordered regions. The 1x2 phase appears on the surface of all compounds but coexist with ($\sqrt{2} \times \sqrt{2}$)R45° phase on the surface of Ba122. Quantitative structural analysis of LEED-I(V) using the fractional spots of the 1x2 phase on both parent compounds as well as Ca(Fe_{0.925}Co_{0.075})₂As₂ gives a similar surface structure with a termination layer of 50% Ca/Ba atoms. The surface Ca/Ba layer has a large inward relaxation ~ 0.5 Å and the underneath As-Fe-As layer displays a buckling distortion. The Pendry Rp factor (~ 0.24) obtained in the structural refinement is excellent for all three systems.

9:24AM H22.00006 Scanning tunneling spectroscopy in Co-doped BaFe₂As₂: what density functional theory can tell us, KLAUS KOEPERNIK, STEVEN JOHNSTON, JEROEN VAN DEN BRINK, IFW Dresden, ERIK VAN HEUMEN, MARK S. GOLDEN, Zeeman Institute, University of Amsterdam, Netherlands — We use density functional theory to simulate the scanning tunneling spectra and topographic images of Co-doped BaFe₂As₂. The matrix element effects are evaluated and the specific contributions of the different surface atoms to the spectra are considered. The results give a better understanding of the measured spectra and assess the resolution of STS measurements in these systems.

9:36AM H22.00007 Scanning tunneling spectroscopic studies of the iron-arsenic superconducting $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$ single crystals, M.L. TEAGUE, H. CHU, R. T.-P. WU, N.-C. YEH, Dept. of Physics, Caltech, Pasadena, CA 91125, USA, P. CHEN, B. SHEN, H.-H. WEN, Institute of Physics, Chinese Academy of Sciences, China — Scanning tunneling spectra of $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$ ($x=0.06, 0.08, 0.12$) single crystals are studied as a function of temperature (T) and magnetic field (H). For $H = 0$, direct evidence for two-gap superconductivity at energies $\omega = \Delta_\beta$ and $\Delta_{\alpha,\gamma/\delta}$ ($\approx 2\Delta_\beta$) and for magnetic resonance modes at $\Omega \approx \Delta_\beta + \Delta_{\alpha,\gamma/\delta}$ are found for all samples at $T < T_c$. Fourier transformation of the tunneling spectra reveals x - and ω -dependent quasiparticle interference (QPI) wave-vectors $\mathbf{q}_2$ near $(\pm\pi,0)/(0,\pm\pi)$ and $\mathbf{q}_1$ near $(\pm 2\pi,0)/(0,\pm 2\pi)$. The spectral intensity of $\mathbf{q}_2$ exhibits strong ω -dependence, peaking sharply at $\omega = \Delta_\beta, \Delta_{\alpha,\gamma/\delta}$ and Ω . This is in stark contrast to the Bragg diffraction peaks that are independent of ω, T and x . For $H > 0$, additional QPI wave-vector $\mathbf{q}_3$ appears near $(\pm\pi,\pm\pi)$. These findings are consistent with the sign-changing s -wave pairing symmetry. Additionally, for the optimally doped sample, a pseudogap at $\omega \sim \Delta_{\gamma/\delta}$ is found inside the vortex core, possibly due to coexisting superconductivity and spin density waves. This result is in contrast to the zero-bias conductance peaks observed inside the vortex core of $(\text{Ba}_{1-x}\text{K}_x)\text{Fe}_2\text{As}_2$, implying asymmetry in the hole and electron-doping of the iron arsenides. This work was supported by NSF DMR-0907251.

9:48AM H22.00008 Examining multiple spectroscopic techniques with multiband Eliashberg theory in $\text{BaCo}_x\text{Fe}_{2-x}\text{As}_2$ ¹, STEVEN JOHNSTON, IFW Dresden, E. VAN HEUMEN, University of Amsterdam, K. KOEPERNIK, IFW Dresden, MASSEE FREEK, J. KAAS, J.B. GOEDKOOP, University of Amsterdam, J. VAN DEN BRINK, IFW Dresden, M.S. GOLDEN, University of Amsterdam — A wealth of experimental data from multiple probes are available for the newly-discovered pnictide superconductors. Here, we exploit this fact and examine a multi-band Eliashberg model for optimal doped $\text{BaCo}_x\text{Fe}_{2-x}\text{As}_2$ assuming a broad spin-fluctuation boson spectrum and retaining the full 3D bandstructure. Our focus is on comparing the model directly with data collected by our group from ARPES, STM and optics experiments performed on samples from the same growth batch. We find that the model captures all of the important aspects of the three probes including the behavior of the gap structure in the dI/dV characteristics and contributions from low-energy interband transitions in the optical conductivity. Our results also indicate the role of matrix elements in establishing the strong particle-hole asymmetry observed in the dI/dV spectra.

¹This work is funded by FOM and the VENI program (both part of NWO).

10:00AM H22.00009 Point-Contact Andreev Reflection Spectroscopy in Pt-Substituted BaFe_2As_2 ¹, STEVEN ZIEMAK, University of Maryland, XIAOHANG ZHANG, National Institute of Standards and Technology, TYLER DRYE, RICHARD GREENE, JOHNPIERRE PAGLIONE, University of Maryland — We have investigated the superconducting order parameter of $\text{BaFe}_{2-x}\text{Pt}_x\text{As}_2$ using point-contact Andreev reflection spectroscopy (PCAR). The samples used were large single crystals with measured Pt concentrations consistent with optimal doping ($x = 0.15$). Junctions were made between gold or lead tips and the c -axis of the superconducting samples. Conductivity spectra were measured over a range of temperatures and fit to curves generated using the Blonder-Tinkham-Klapwijk (BTK) model for two gaps, one isotropic and one angle-dependent gap with nodes.

¹Center for Nanophysics and Advanced Materials, Physics Department, University of Maryland, College Park

10:12AM H22.00010 Scanning tunneling microscopy study of K-doped iron selenide superconductor film by MBE, QI-KUN XUE, WEI LI, HAO DING, PENG DENG, KAI CHANG, SHUIHUA JI, Tsinghua University, KE HE, LILI WANG, XUCUN MA, Chinese Academy of Sciences, JIANG-PING HU, Purdue University, XI CHEN, Tsinghua University — The alkali-doped iron selenide superconductors have generated considerable excitations as well as confusions, regarding the delicate interplay between Fe vacancies, magnetism and superconductivity. We have grown high-quality $\text{K}_x\text{Fe}_{2-y}\text{Se}_2$ thin film with (001) surface orientation on STO substrate by molecular beam epitaxy. The scanning tunneling microscopy (STM) measurement demonstrates that there are two superconducting phases: striped KFe_2Se_2 in adjacent to the phase with $\sqrt{5} \times \sqrt{5}$ Fe vacancy order and doped KFe_2Se_2 with Fe and K vacancies. Both phases have a superconducting gap of 9 meV. These findings elucidate the existing controversies on the role of $\sqrt{5} \times \sqrt{5}$ Fe vacancy order in superconducting $\text{K}_x\text{Fe}_{2-y}\text{Se}_2$. Based on the atomic level information by STM, we will discuss the mechanism of the two different superconducting phases.

10:24AM H22.00011 The Surface Structure of $\text{FeTe}_{1-x}\text{Se}_x$: A LEED/STM Study¹, XIAOBO HE, VON BRAUN NASCIMENTO, GUORONG LI, JIANDI ZHANG, RONGYING JIN, Louisiana State University, Baton Rouge, LA 70803, USA, A.S. SEFAT, M.A. MCGUIRE, B.C. SALES, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, D. MANDRUS, University of Tennessee, Knoxville, TN, 37996, E.W. PLUMMER, Louisiana State University, Baton Rouge, LA 70803, USA — We have utilized low energy electron diffraction (LEED $I - V$) and scanning tunneling microscopy (STM) to investigate the structural properties of $\text{FeTe}_{1-x}\text{Se}_x$ ($x = 0$ and 0.45) surface. The LEED pattern indicates there is no surface reconstruction on both parent and doped compounds. However, the detailed surface structure calculations from LEED $I - V$ show the cleaved surface of FeTe is Te termination with a 0.06 Å compression on the top layer. The STM topography shows the extreme flatness of the FeTe surface with a corrugation of less than 8 pm. The high resolution STM topography indicates that nanoscale chemical phase separation between Te and Se atoms is unambiguously revealed on the surface of $\text{FeTe}_{0.55}\text{Se}_{0.45}$. Chemical phase separation on the nanoscale makes the LEED $I - V$ surface structural analysis of $\text{FeTe}_{1-x}\text{Se}_x$ (001) very challenging. We will discuss the solution of the LEED analysis and the STM observations as a function of x .

10:36AM H22.00012 Cryomagnetic Point-Contact Andreev Reflection Spectroscopy on Single Crystal Iron-Chalcogenide Superconductors¹, Y.T. YEN, University of Toronto, RONGWEI HU, C. PETROVIC, Brookhaven National Laboratory, K.W. YEH, M.K. WU, Institute of Physics, Academia Sinica, Taiwan, J.Y.T. WEI, University of Toronto and Canadian Institute for Advanced Research — We report on cryomagnetic point-contact Andreev reflection spectroscopy performed on single crystals of superconducting $\text{FeTe}_{1-x}\text{S}_x$ and $\text{FeTe}_{1-x}\text{Se}_x$. The samples are cleaved in-situ and the measurements are carried out at temperatures down to 4.2K and in a field up to 9T. At base temperature and zero field, we observe a cone-shaped hump at lower voltages in the conductance spectra with no dips at zero bias and a linear background at higher voltages. The spectral evolution of gap size, zero-bias conductance, and excess spectral area are analyzed as a function of temperature and field. Further spectral analysis is carried out using theoretical models of conductance spectra in multiband superconductors [1,2] and of gap symmetry in Fe-based superconductors [3]. The role of interstitial iron is also considered, by comparison with atomically-resolved scanning tunneling spectroscopy data.

10:48AM H22.00013 Transport properties of disordered iron-pnictides in case of coexistence between superconducting and spin-density wave order¹, DUSHKO KUZMANOVSKI, MAXIM VAVILOV, University of Wisconsin - Madison — We present a theoretical description of the transport properties of a dirty multi-band superconductor in the case when both superconducting and spin-density wave orders coexist. We focus on differential conductance spectra of normal metal-superconductor junctions. In pure SC phase, we demonstrate that the interband impurity scattering broadens the coherent peak near the superconducting gap and significantly reduces its height even at relatively low scattering rates. This broadening is consistent with a number of recent experiments performed for both tunnel junctions and larger diffusive contacts. We further analyze the effect of the SDW order parameter on the differential conductance and other transport properties in the coexistence phase.

8:00AM H23.00001 Cr based Alloy Cr-Y-Mo-W Oxidation Study from First Principals Molecular Dynamics Simulation, LEI ZHAO, SHIZHONG YANG, EBRAHIM KHOSRAVI, Southern University and A&M College, SHENGMIN GAO, Louisiana State University — First principles molecular dynamics simulations have been performed to study the stability and oxidation progress of Cr based alloys at high temperatures. The bulk phase of cubic Cr-based alloys is investigated with density functional theory (DFT) calculations and *ab initio* molecule dynamic (MD) method. Diffusion of oxygen atoms within different densities of Y, Mo, and W doping and temperatures in Cr-Y systems is studied in this research. The effects of Y, Mo, and W doping are also studied. The properties of the optimized Y, Mo, and W co-doped Cr-based alloys also studied by using *ab initio* MD method. Further improvement of the oxidation resistance and surface corrosion of Cr-based alloys will be discussed.

8:12AM H23.00002 Enhancing mechanical toughness of aluminum surfaces by nanoboron implantation: An *ab initio* study¹, ZHEN ZHU, Michigan State University, DAE-GYEON KWON, YOUNG-KYUN KWON, Kyung Hee University, DAVID TOMANEK, Michigan State University — We use *ab initio* density functional theory to study the formation dynamics and equilibrium atomic arrangement in aluminum surfaces exposed to energetic boron aggregates. Results of our molecular dynamics simulations indicate that after using up their excess kinetic energy to locally melt the aluminum surface, boron atoms prefer to remain in subsurface sites. We perform extensive structure optimization studies to identify the optimum structural arrangement and changes in the electronic structure associated with the formation of strong Al-B bonds, which are responsible for the stability enhancement of the compound. Nano-indentation simulations based on constrained optimization suggest that presence of boron atoms enhances the mechanical hardness and wear-resistance of aluminum surfaces.

8:24AM H23.00003 Phase Stability and Deformation Behavior of Mo-Si-B System and effect of alloying¹, OLEG Y. KONTSEVOI, ARTHUR J. FREEMAN, Northwestern University — Molybdenum silicides are promising materials for ultra-high temperature applications above 1300 °C. One of the main drawbacks is their brittleness at low temperatures, which may be improved by additions. We employ first principles calculations with the highly precise FLAPW method to investigate the effect of alloying with 3d, 4d and 5d transition metals on phase stability, cleavage and shear characteristics of the 3-component system Mo – Mo₃Si – Mo₅SiB₂. We determined site preference, phase partitioning of alloying elements, and their effect on shear behavior and preferred deformation modes. We show that in Mo₃Si alloying with 3d transition metals results in a significant reduction of energy barriers to shear deformation (softening effect), while 4d and 5d additions increase shear barriers (hardening effect). In Mo₅SiB₂, 3d transition metals (except for Ti) act as weak softeners, while 4d and 5d show mixed behavior – hardening for early elements and softening for late ones. The softening potency of additions increases with atomic number, but exhibits non-monotonic behavior as a result of a competition between size and electronic effects. The results are discussed in conjunction with possible pathways to ductility enhancement through alloying.

¹Supported by the AFOSR (Grant No. FA 9550-07-1-0174)

8:36AM H23.00004 Structural, elastic and thermal properties of cementite from Modified Embedded Atom Method (MEAM) potential¹, LAALITHA LIYANAGE, Department of physics and astronomy, Mississippi State University, JEFF HOUZE, None, SEONG-GON KIM, Department of physics and Astronomy, Mississippi State University, MARK TSCHOPP, SUNGHO KIM, Center for advanced vehicular systems, Mississippi State University, MIKE BASKES, Los Alamos National Laboratory, MARK HORSTEMEYER, Department of Mechanical Engineering, Mississippi State University — Structural, elastic and thermal properties of cementite were studied using a newly developed MEAM potential for the Fe-C alloy system. The single element potential of C correctly predicts graphite and diamond as the two stable structures. Parameters for the Fe-C alloy potential were constructed based on the structural and elastic properties of elements in the L₁₂ reference structure, calculated from ab-initio simulations. Parameters were further adjusted to reproduce structural properties of cementite and the interstitial energies for Fe correctly. Pair potential parameters were optimized using a method combining Latin hypercube sampling of the N-dimensional parameter space and multi-objective optimization. Elastic constants, surface formation energies, melting temperature and specific heat of cementite were calculated using the potential. The values computed from the Fe-C alloy MEAM potential are in good agreement with DFT calculations and experiments.

¹Department of Energy funded research project

8:48AM H23.00005 High Strain Rate Deformation of BCC Materials: Molecular Dynamics Simulations, CON HEALY, GRAEME ACKLAND, University of Edinburgh — To improve machining processes, a good understanding of plasticity of bulk metals and at high strain rates is required. During machining processes, it is thought that strain rates of $\sim 10^6 \text{s}^{-1}$ are reached. These strain rates are currently not achievable in experimental high strain rate testing techniques. Here we investigate high strain rate deformation of bcc Fe using Molecular Dynamics simulations. Simulations include those of nano-scale single crystal pillars and of a nano-crystalline sample. We show that bcc materials may exhibit different deformation behavior at high strain rates. Under compression at strain rates of $\sim 10^8 \text{s}^{-1}$, nano-scale single crystal pillars may exhibit slip on atypical planes if the direction of maximum resolved shear stress points along that plane. The stress-strain behavior of these pillars is characterized by sudden strain bursts due to slip events. The yield stress required for these slip events can be as high as 2 GPa, much higher than the Peierls stress which is around 25 MPa for an edge dislocation in Fe. The nano-crystalline sample showed stress-strain behavior closer to that of a bulk metal. At high temperatures, pillars exhibit surface premelting. A large portion of the pillar turns amorphous when strained.

9:00AM H23.00006 Effect of lattice vibrations on magnetic phase transition in BCC Iron , JUNQI YIN, MARKUS EISENBACH, AURELIAN RUSANU, DON NICHOLSON, Oak Ridge National Lab — From the first principle calculation of BCC iron, we build a classical Heisenberg model with the interaction coupling as a function of both the distance and local environments (e.g. volume). Using the Johnson potential and Finnis-Sinclair potential, we perform Monte Carlo simulations of BCC iron including the effect of lattice vibrations. The validity of classical Heisenberg model in describing the magnetic phase transition of BCC iron is explained.

9:12AM H23.00007 Phase-Stabilizers in Titanium Alloys , BENGT TEGNER, LINGGANG ZHU, GRAEME ACKLAND, SUPA, School of Physics and Astronomy, The University of Edinburgh — Titanium alloys exhibit three distinct crystal structures: alpha, beta and omega. For various applications alloying elements can be used to stabilize the desired phase. While alloy designers have well established rules of thumb, rigorous theory for non-equilibrium single-phase crystal stability is less well established. Here we tackle this problem using electronic structure calculations. We use two different methods based on density functional theory with pseudopotentials and plane waves, with either explicit atoms or the virtual crystal approximation (VCA). The former is highly reliable, while the latter makes a number of drastic assumptions that typically lead to poor results. Surprisingly, the agreement between the methods is good, showing that the approximations in the VCA are not important in determining the phase stability and elastic properties. This allows us to generalize, showing that the single-phase stability can be related linearly to the number of d-electrons, independent of the actual alloying elements or details of their atomistic-level arrangement. This leads to a quantitative measure of beta-stabilization for each alloying transition metal.

9:24AM H23.00008 Structural properties and phase stability of Ti alloys containing V and Cr by first-principles calculation , LINGGANG ZHU, BENGT TEGNER, GRAEME ACKLAND, SUPA, School of Physics and Astronomy, The University of Edinburgh, QING-MIAO HU, RUI YANG, Shenyang National Laboratory for Materials Sciences, Institute of Metal Research, Chinese Academy of Sciences, Shenyang 110016, China — We apply the first-principles plane-wave pseudopotential method and virtual crystal approximation (VCA), to investigate structural properties and phase stability of ternary titanium alloy Ti-V-Cr. The lattice parameters of the alloy vary almost linearly with the number of d electrons in spite of the different ratio of V to Cr, which agrees with the available experimental results. At 0K, we find that an extra 0.4 electrons per atom can stabilise the beta Ti-V-Cr. Debye approximation is used to consider the temperature effect, and it is found that at 973K, with an extra 0.1 d electron per atom, the beta Ti-V-Cr can be stabilised, compared with 0.15-0.20 d electron required experimentally at 973K. It is shown that V and Cr move the Fermi energy to lower values of the density of the states of the beta phase, which accounts for the stabilisation effect.

9:36AM H23.00009 Dynamics of twinning dislocations in Tantalum¹ , LUIS SANDOVAL, MICHAEL SURH, ALEXANDER CHERNOV, DAVID RICHARDS, Condensed Matter and Materials, Physical and Life Science Directorate, Lawrence Livermore National Laboratory — Twinning is one of the major deformation modes of plastic deformation in crystals, being particularly important in systems under extreme conditions of low temperature or high strain rates. Despite decades of work, the nucleation and growth mechanisms of twinning are still poorly understood, especially in bcc metals. Nucleation of twinning dislocations loops on the coherent twin boundary has been considered a principal mechanism of growth of deformation twins. We have used molecular dynamics simulation to study the behavior of twinning dislocations in Tantalum, in particular the dependence of dislocation velocities on shear stress and temperature. The dynamics of edge and screw twinning dislocations is isolated and analyzed. Finally we show how kinetic parameters extracted from these simulations help inform a multiscale strength model for Tantalum that includes both twinning and slip as deformation mechanisms in the regime of high strain rates.

¹This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344 (LLNL-ABS-513469).

9:48AM H23.00010 Vacancy Assisted Climb in Continuum Dislocation Dynamics , MATTHEW BIERBAUM, YONG CHEN, WOOSONG CHOI, JAMES SETHNA, Cornell University — Using a mesoscale continuum theory of dislocation dynamics, we study the physical effects of vacancy assisted climb. New physics emerges at high temperatures where dislocations are also able to move in the climb direction due to the absorption and emission of vacancies. We investigate this high temperature behavior using our minimal continuum dislocation dynamics model, which produces fractal cell structures in 2 and 3 dimensions. By coupling the dislocation density to a vacancy field we are able to study the effects of vacancies on diffusion-limited dislocation motion. We calibrate our model using measurements of climb velocities for straight, parallel dislocations and check the limit of no climb by freezing out vacancy motion. We use our model to explore applications of vacancy assisted climb, including dislocation creep and absorption of dislocations at grain boundaries.

10:00AM H23.00011 Stacking-fault energy and anti-Invar effect in FeMn alloys at high temperature , ANDREI REYES-HUAMANTINCO¹, PETER PUSCHNIG, CLAUDIA AMBROSCH-DRAXL, Chair of Atomistic Modelling and Design of Materials, University of Leoben, Austria, OLEG PEIL, I. Institute for Theoretical Physics, Hamburg University, Germany, ANDREI RUBAN, Applied Material Physics, Royal Institute of Technology, Stockholm, Sweden — High-Mn steels (20-30at%Mn, 2-4wt%Si and Al) are of interest for the automotive industry due to their outstanding mechanical properties. Their deformation behavior has been empirically correlated to the stacking-fault energy (SFE), an important quantity in steel design that can be calculated *ab-initio*. Using state-of-the-art methods within density-functional theory together with Monte Carlo simulations, we calculate the free energy of the Fe-22.5at%Mn binary alloy between 300-800 K. Experimentally, the alloy is completely random and in the paramagnetic state, which we model via the coherent potential approximation and the disordered local moment approach, respectively. We treat magnetic excitations by including longitudinal spin-fluctuations and find that the FeMn alloy is an itinerant paramagnet. Our calculations confirm the experimentally observed strong magneto-volume coupling, realized in the anti-Invar behavior. We then obtain the structural stability and the SFE from free energy differences and find very good agreement with measurements. Our results demonstrate that the interplay between magnetic excitations and the thermal lattice expansion is the main factor determining the anti-Invar effect, the *fcc-hcp* martensitic transformation temperature and the SFE.

10:12AM H23.00012 Microstructural and mechanical characterization of 0.2mass% Carbon content steel , SAJJAD TOLLABIMAZRAEHNO, Johannes Kepler University, Altenberger Str. 69, 4040 Linz, Austria, CHRISTIAN COMMENDA, None, GUENTER HESSER, Johannes Kepler University, Altenberger Str. 69, 4040 Linz, Austria, ANDREAS PICHLER, None, KURT HINGERL, Johannes Kepler University, Altenberger Str. 69, 4040 Linz, Austria — The microstructures of low carbon content steel are comprised of bainite, martensite, tempered martensite and retained austenite. These structures are obtained by different heat treatments. The effect of heat treatment on microstructure and mechanical properties were investigated using X-ray diffraction, focused ion beam - scanning electron microscope (FIB-SEM), electron backscatter diffraction (EBSD), and nanoindentation. The experimental misorientation distribution revealed most grain boundaries had misorientation range between 50° and 60°. The lattice relation between bainite and parent austenite is Kurdjumov-Sachs ($\langle 111 \rangle_B \parallel \langle 110 \rangle_A$). FIB-SEM images and nanoindentation were revealed the grain size can influence the hardness.

10:24AM H23.00013 ABSTRACT WITHDRAWN —

10:36AM H23.00014 Ab initio-based interatomic potentials for body-centered cubic refractory metals¹, MICHAEL FELLINGER, HYOUNGKI PARK, JEREMY NICKLAS, JOHN WILKINS, The Ohio State University — A fundamental understanding of transformation and deformation processes in the bcc refractory metals (V, Nb, Ta, Mo, and W) is vital for designing new bcc-based commercial alloys with desired properties. Such an understanding is aided by computational methods capable of reaching length and time scales needed for meaningful simulations of phase transformations and extended defects responsible for plastic deformation. Classical interatomic potentials are indispensable for simulating such phenomena inaccessible to first-principles methods. We develop accurate and robust embedded-atom method (EAM) [1] and modified-EAM (MEAM) [2] potentials for the bcc metals by fitting the model parameters to accurate first-principles data. The potentials are applicable for studying mechanical and thermodynamic properties, yielding excellent agreement with both experiments and first-principles calculations.

10:48AM H23.00015 Influence of Nano-Alumina and Micro-Size Copper on Microstructure and Mechanical Properties of Magnesium Alloys AZ31, QUY BAU BOSLEY NGUYEN, SANDAR KHIN TUN, MANOJ GUPTA, National University of Singapore — In this paper, magnesium composites are synthesized through the addition of nano-alumina and micron size copper particulates in AZ31 magnesium alloy using the technique of disintegrated melt deposition. The simultaneous addition of Cu and nano-alumina particulates led to an overall improvement in physical, microstructural characteristics and mechanical response of AZ31. Small size and reasonably distributed second phases were formed. The 0.2% yield strength increased from 180 to 300 MPa (67%), while the ductility increased by almost 24%. The overall tensile properties assessed in terms of work of fracture improved by 66%. An attempt is made to correlate the tensile response of composites with their microstructural characteristics. The results suggest that these alloy composites have significant potential in diverse and wider engineering applications.

Tuesday, February 28, 2012 8:00AM - 11:00AM – Session H24 FIAP: Electrical and Thermal Properties of Semiconductors 256

8:00AM H24.00001 Electrical characterization of SiGeSn grown on Ge substrate using ultra high vacuum chemical vapor deposition, MO AHOUEJJA, University of Dayton, S. KANG, M HAMILTON, Y.K. YEO, Air Force Institute of Technology, ENP, WPAFB, OH, J. KOUVETAKIS, J. MENENDEZ, Arizona State University — There has been recently considerable interest in growing $\text{Si}_y\text{Ge}_{1-x-y}\text{Sn}_x$ alloys for the fabrication of photonic devices that could be integrated with Si technologies. We report temperature dependent Hall (TDH) measurements of the hole concentration and mobility from high quality p-type doped $\text{Si}_{0.08}\text{Ge}_{0.90}\text{Sn}_{0.02}$ layers grown on p-type doped Ge substrates using ultra high vacuum chemical vapor deposition. The TDH measurements show the hole sheet density remains constant at low temperatures before slightly decreasing and dipping at ~ 125 K. It then exponentially increases with temperature due to the activation of shallow acceptors. At temperatures above ~ 450 K, the hole sheet density increases sharply indicating the onset of intrinsic conduction in the SiGeSn and/or Ge layers. To extract the electrical properties of the SiGeSn layer alone, a parametric fit using a multi layer conducting model is applied to the measured hole concentration and mobility data. The analysis yields boron and gallium doping concentrations of $3 \times 10^{17} \text{ cm}^{-3}$ and $1 \times 10^{18} \text{ cm}^{-3}$ with activation energies of 10 meV and 11 meV for the SiGeSn layer and Ge substrate, respectively. Furthermore, a temperature independent hole sheet concentration of $\sim 5 \times 10^{15} \text{ cm}^{-2}$ with a mobility of $\sim 250 \text{ cm}^2/\text{Vs}$, which is believed to be due to an interfacial layer between the SiGeSn layer and the Ge substrate, is also determined.

8:12AM H24.00002 Informatic Strategies for Screening Electron Mobility of Candidate Semiconducting Materials¹, KIM FERRIS, Pacific Northwest National Laboratory, DUMONT JONES, Proximate Technologies, LLC. — While carrier transport properties are critical to semiconductor efficiency, screens for potentially new materials based upon mobility measurements can be problematic. In the early stages of materials development, measured electron mobilities are often unreliable indicators of their eventual performance and serve as a poor basis to assess the longer term potential of candidate materials. In this paper, we describe an information-based approach for estimating an effective upper limit, using the specific case of the II-VI semiconductors. The optical (polaron) electron mobility has been developed as a screening property, supported by informatic estimates of dielectric properties. This mobility represents a practical screen, providing an estimate of the potential bounding value at room temperature. Using this basis, partial screening criteria based on compositional factors can also be constructed.

8:24AM H24.00003 Measurement of Electron Effective Mass in $\text{GaAs}_{1-x}\text{Bi}_x$ ¹, BRIAN FLUEGEL, RAJEEV KINI², AARON PTAK, DAN BEATON, KIRSTIN ALBERI, ANGELO MASCARENHAS, National Renewable Energy Laboratory — Magnetic field and temperature dependent resistivity measurements on n-type $\text{GaAs}_{1-x}\text{Bi}_x$ epitaxially grown films show clear Shubnikov de Haas oscillations in the range $0 \leq x \leq 0.0088$. An overall decrease in the electron effective mass is observed for this range of compositions. Accounting for the known giant bandgap bowing of $\text{GaAs}_{1-x}\text{Bi}_x$, the measured changes in the electron effective mass are in qualitative agreement with perturbation theory applied to the known bandgap reduction for this alloy, confirming that bismuth mainly perturbs the valence band. The stronger compositional dependence of the measured masses is attributed to effects from the bismuth isolated state.

8:36AM H24.00004 Piezo-resistance in n -type $\text{Si}_{1-x}\text{Ge}_x$ alloys as a function of alloy composition and strain¹, FELIPE MURPHY-ARMANDO, STEPHEN FAHY, Tyndall National Institute, University College Cork — We use first-principles electronic structure methods[1,2] to predict the piezoresistance of n -type $\text{Si}_{1-x}\text{Ge}_x$ at various alloy compositions and strain configurations. The gauge factor, $G = d\rho/d\epsilon/\rho$, where ρ is resistivity and ϵ is strain, varies strongly with both composition and strain. Nonlinear changes in resistivity with strain may arise due to changing occupancy of the higher-conductance L valley relative to the lower-conductance Δ valley, coupled to a change in inter-valley alloy and phonon scattering. [1] F. Murphy-Armando and S. Fahy, J. Appl. Phys., accepted for publication (2011). [2] F. Murphy-Armando and S. Fahy, Phys. Rev. Lett., 97, 096606 (2006)

8:48AM H24.00005 Non-diffusive thermal conductivity in semiconductors at room temperature , ALEXEI MAZNEV, JEREMY JOHNSON, JEFFREY ELIASON, KEITH NELSON, AUSTIN MINNICH, KIMBERLEE COLLINS, GANG CHEN, Massachusetts Institute of Technology, JOHN CUFFE, TIMOTHY KEHOE, CLIVIA SOTOMAYOR TORRES, Catalan Institute of Nanotechnology — The “textbook” value of phonon mean free path (MFP) in silicon at room temperature is ~ 40 nm. However, a large contribution to thermal conductivity comes from low-frequency phonons with much longer MFPs. We find that heat transport in semiconductors such as Si and GaAs significantly deviates from the Fourier law at distances much longer than previously thought, ≥ 1 μm at room temperature and above. We use the laser-induced transient thermal grating technique in which absorption of crossed laser pulses in a sample sets up a sinusoidal temperature profile monitored via diffraction of a probe laser beam. By changing the period of the thermal grating we vary the thermal transport distance within the range ~ 1 -10 μm . In measurements performed on thin free-standing Si membranes and on bulk GaAs the thermal grating decay time deviates from the expected quadratic dependence on the grating period, thus providing model-independent evidence of non-diffusive transport. The simplicity of the experimental configuration permits analytical treatment of non-equilibrium phonon transport with the Boltzmann transport equation. Our analysis shows that at small grating periods the effective thermal conductivity is reduced due to diminishing contributions of “ballistic” low-frequency phonons with long MFPs.

9:00AM H24.00006 Thermal conductivity and isotope effect in wide bandgap semiconductors , LUCAS LINDSAY, THOMAS REINECKE, NRL, Washington, DC, ENRICO BELLOTTI, Electrical and Computer Engineering Department, Boston University, DAVID BROIDO, Department of Physics, Boston College — We have calculated the lattice thermal conductivity, k , of wurtzite InN, GaN, and AlN using an exact numerical solution of the phonon Boltzmann transport equation and *ab initio* calculations of interatomic force constants. We find good agreement with experiment for the thermal conductivities around and above room temperature. The large frequency gap between the acoustic and the optic phonon branches in these materials limits anharmonic phonon scattering leading to large enhancements to k with isotopic enrichment. We comment on the roles of various phonon scattering mechanisms on k in these wide bandgap semiconductors.

9:12AM H24.00007 Conductance beyond the Landauer limit and charge pumping in quantum wires driven by linearly polarized radiation , JAY SAU, TAKUYA KITAGAWA, BERTRAND HALPERIN, Department of Physics, Harvard University, Cambridge, MA 02138 — Periodically driven systems, which can be described by Floquet theory, have been proposed to show characteristic behavior that is distinct from static Hamiltonians. Floquet theory proposes to describe such periodically driven systems in terms of states that are indexed by a photon number in addition to the usual Hilbert space of the system. In this work, we propose a way to measure directly this additional state by the measurement of the conductance of a single channel quantum point contact. Specifically, we show that a single channel wire augmented with a grating structure when irradiated with microwave radiation can show a DC conductance above the limit of one conductance quantum set by the Landauer formula. Another interesting feature of the proposed system is that being non-adiabatic in character, it can be used to pump a photo-current even with linearly polarized light. This circumvents the topological restrictions of adiabatic pumping, which necessitate the use of circularly polarized light. J.S. thanks the Harvard Quantum Optics center for support.

9:24AM H24.00008 Positive and Negative Coulomb Drag in a 1D Quantum Circuit , DOMINIQUE LAROCHE, McGill University and Sandia National Laboratories, GUILLAUME GERVAIS, McGill University , MIKE LILLY, JOHN RENO, Sandia National Laboratories — We report Coulomb drag measurements between tunable vertically-coupled quantum wires. The wires are fabricated in a GaAs/AlGaAs double quantum well heterostructure with a 15 nm barrier separating the quantum wells. The Coulomb drag signal is mapped out versus the number of subbands occupied in each wire, and regions of both positive and negative drag are observed (D. Laroche *et. al.* Nature Nanotechnology, doi:10.1038/nnano.2011.182). The observation of negative Coulomb drag at a high one-dimensional electronic density is not predicted by the usual momentum-transfer model for Coulomb drag and shows that the existing picture of the drag effect in one-dimension is incomplete. In order to clarify the origin of this negative signal, temperature dependencies of the Coulomb drag are presented both in the positive and in the negative drag regimes. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:36AM H24.00009 Phonon Mediated Optical Stark Effect for Organic-Semiconductor Heterostructures¹ , QUE HUONG NGUYEN, Marshall University — The system of macroscopic equations of hybrid excitons, photons and phonon is investigated in order to model the optical Stark effect for the hybrid systems with combination of semiconductor and organic materials. The unique properties of the hybrid system will allow tuning the system to get the most preferable outcomes. One of the key points is to study the interaction of different components of the system with each other to get the condition to facilitate the observation of phonon and the phonon-mediated Stark effect.

¹The support from NASA Seed Grant Award 211012 is acknowledged.

9:48AM H24.00010 Electron phonon coupling and carrier lifetimes in III-nitride ternary semiconductors¹ , NANDAN TANDON, P.G. KASSEBAUM, L.R. RAM-MOHAN, Physics Department, Worcester Polytechnic Institute, Worcester, MA, USA — III-nitride semiconductors have a large bandgap and find applications in high power devices, in which the thermal management of energy generated becomes a key issue. The transfer of energy from the energetic carriers to the lattice is determined by the electron-phonon coupling for the crystal. In this work, we present our results on the electron-phonon coupling in ternary and quaternary semiconductors. The full phonon dispersion and electron-phonon coupling is determined using *ab-initio* methods. We then evaluate the carrier lifetimes for the emission of LO phonons by including the full zone and not only the zone center phonons. We expect that the treatment of the electron-phonon coupling effects over the full Brillouin zone could be critical for III-nitride thermal management, and will be directly compared to the results where only the zone center phonons are considered.

10:00AM H24.00011 Vibrational structure of defect luminescence bands in GaN from electronic structure calculations , AUDRIUS ALKAUSKAS, CHRIS G. VAN DE WALLE, Materials Department, University of California Santa Barbara, CA 93106-5050 — Optical methods are among the most powerful to characterize defects in materials. The study of optical signatures based on state-of-the-art electronic structure methods is therefore very important. In this work we investigate the vibrational structure of luminescence bands pertaining to deep defect levels in GaN. Since luminescence lineshapes depend sensitively on defect geometries and vibrational frequencies, these should be described accurately. The latter is achieved through the use of hybrid density functionals. Both quasi-localized and bulk phonons are included in our description. In the case of transitions accompanied by very large lattice relaxations, anharmonic effects become sizeable, and these are also accounted for. For the defects studied a very good agreement with available experimental data is achieved. For instance, in the case of wide luminescence bands the resulting line widths are within 0.05 eV of the experimental values. This work was supported by the Swiss NSF and by NSF.

10:12AM H24.00012 Ultrafast Carrier Dynamics in GaAs(110) Studied by Time- and Angle-Resolved Photoelectron Spectroscopy, SHUOLONG YANG, JONATHAN SOBOTA, Stanford University, PATRICK KIRCHMANN, Fritz Haber Institute of the Max Planck Society, ZHI-XUN SHEN, Stanford University — Ultrafast carrier dynamics in GaAs is of particular importance to optoelectronic devices and solar cell technologies. We employ Time- and Angle-Resolved Photoelectron Spectroscopy to elucidate the dynamics of both the occupied and unoccupied states of GaAs(110) upon femtosecond infrared laser excitation. We observe in the conduction band an optically excited population and energy shift, which both decay in ~ 10 ps. The valence band also exhibits energy shifting dynamics which encompasses multiple temporal regimes. More intriguingly, valence band dynamics are also observed for negative pump-probe delays. We explain these observations by a carrier-transport-induced electrostatic potential change within a Drude-like picture.

10:24AM H24.00013 Intraexcitonic Autler-Townes effect in terahertz-driven semiconductor quantum wells, M. WAGNER, D. STEHR, H. SCHNEIDER, S. WINNERL, Helmholtz-Zentrum Dresden-Rossendorf HZDR, Dresden, Germany, A. ANDREWS, S. SCHARTNER, G. STRASSER, TU Vienna, Austria, M. HELM, HZDR — When a two-level system is resonantly driven by intense light non-perturbative phenomena such as Rabi oscillations and their frequency equivalent, the AC Stark or Autler-Townes effect, can be observed. The latter one manifests itself in an absorption line splitting where the magnitude is linear in the light field strength and where the symmetry of the splitting is determined by the detuning from resonance. Known from molecular spectroscopy [1], the effect has also been observed in solid state structures with its much broader line widths, e.g. for intersubband transitions [2]. Here, we present the first unambiguous evidence of this effect in undoped GaAs/AlGaAs quantum wells using the hydrogen atom like intraexcitonic 1s and 2p states of the heavy-hole exciton. These states with a transition energy of 9 meV are resonantly coupled by strong terahertz light from a free-electron laser. For low fields our findings are qualitatively explained by a simple two-level model whereas deviations occur in the 10 kV/cm field range where the rotating-wave approximation of the simplified model breaks down and exciton ionization occurs. Due to the small Rydberg energy we can easily reach a highly non-trivial regime where the Rabi energy and the transition energy become comparable to the photon energy.

10:36AM H24.00014 Raman Spectroscopy and Scanning Electron Microscopy of the Bismuth Sillenites $\text{Bi}_{25}\text{InO}_{39}$ and $\text{Bi}_{25}\text{FeO}_{39}$ ¹, DANIEL J. ARENAS, THEO JEGOREL, LEV GASPAREOV, University of North Florida, HIDEO KOHNO, Osaka University, CATALIN MARTIN, DAVID B. TANNER, University of Florida, MICHAEL W. LUFASO, University of North Florida — The Raman spectrum of $\text{Bi}_{25}\text{InO}_{39}$, a new type of bismuth sillenite, is reported along with the spectra of $\text{Bi}_{25}\text{FeO}_{39}$. Their spectra are remarkably similar to each other and to other bismuth sillenites reported in the literature. The similarities show that the new samples were successfully grown in the sillenite structure. The parameters of each Raman mode were obtained by fitting the spectra to a Lorentzian oscillator model, and the modes were assigned to symmetry-allowed modes of the I23 space group. The assignments were made by comparison to other materials with the sillenite structure. Scanning Electron Microscope images of the samples are also presented.

¹Work at UNF was supported by NSF under Grant No. DMR-0805073. Work at UF was supported by the US DOE through contract DE-FG02-02ER45984.

10:48AM H24.00015 Two-dimensional Fourier-Transform spectra of PbS semiconductor quantum dots, DENIS KARAISKAJ, PRASENJIT DEY, JASON BYLSMA, Department of physics, University of South Florida — Investigating the correlations of multiple excitons in semiconductor quantum dots is a challenging many-body problem that has drawn considerable experimental and theoretical attention over the last two decades. Nonlinear four-wave mixing experiments have long been known to provide direct probes for the many-body effects in the ultrafast dynamics of excitons in semiconductor nanostructures. With the advent of two-dimensional Fourier-transform (2DFT) spectroscopy many-body contributions can be isolated and identified. 2DFT spectra of colloidal quantum dots will be presented, providing new understanding of the role of many-body interactions in the excitonic decoherence of these nanomaterials.

Tuesday, February 28, 2012 8:00AM - 11:00AM —

Session H25 DCOMP GSCCM DMP: Focus Session: Simulation of Matter at Extreme Conditions - Shock Compression of Metals 257A

8:00AM H25.00001 Invariance of the Dissipative Action at Ultrahigh Strain Rates above the Strong Shock Threshold¹, JONATHAN CROWHURST, MICHAEL ARMSTRONG, KIMBERLY KNIGHT, JOSEPH ZAUG, ELAINE BEHYMER, Lawrence Livermore National Laboratory — We have directly resolved shock structures in pure aluminum in the first few hundred picoseconds subsequent to a dynamic load, at peak stresses up to 43 GPa and strain rates of in excess of 10^{10} s^{-1} . For strong shocks we obtain peak stresses, strain rates, and rise times. From these data, we directly validate¹ the invariance² of the dissipative action in the strong shock regime, and by comparing with data obtained at much lower strain rates show that this invariance is observed over at least 5 orders of magnitude in the strain rate. Over the same range, we similarly validate the fourth-power scaling of strain rate with peak stress (the Swegle-Grady relation). 1. J. C. Crowhurst, M. R. Armstrong, K. B. Knight, J. M. Zaug, E. M. Behymer, Phys. Rev. Lett. 107, 144302 (2011). 2. D. E. Grady, J. Appl. Phys. 107, 013506 (2010). This work was also supported by the EFree, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Grant No. DESC0001057.

¹This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract No. DE-AC52-07NA27344 with Laboratory directed Research and Development funding (11ERD039)

8:12AM H25.00002 Ultrashort elastic and plastic shock waves in nickel generated by femtosecond laser pulses, NAIL INOGAMOV, Landau Institute for Theoretical Physics, BRIAN DEMASKE, VASILY ZHAKHOVSKY, University of South Florida, CARTER WHITE, Naval Research Laboratory, IVAN OLEYNIK, University of South Florida — The structure and evolution of ultrashort shock waves generated by femtosecond laser pulses in thin nickel films were investigated by molecular dynamics and two-temperature hydrodynamics simulations. Ultrafast laser energy deposition results in the formation of a highly-pressurized 100-nm-thick layer below the surface of the film. Relaxation of the stress-confined state leads to the creation of a strong compression wave that later transforms into an ultrashort shock wave. Analysis of experimental data shows that such a shock wave, generated by low absorbed laser fluence, can exhibit a pure elastic structure despite an amplitude exceeding the conventional Hugoniot elastic limit. For absorbed fluences above $\sim 0.6 \text{ J/cm}^2$, two independent processes of elastic and plastic wave breaking are observed with the elastic precursor appearing before formation of the plastic wave. It is found that the amplitude of the elastic precursor is almost independent of the absorbed fluence, but closely related to the pressure at the melting front. The decay rate of the plastic wave amplitude is much higher than that of the elastic wave, which may result in the complete disappearance of the plastic wave within the metal film.

8:24AM H25.00003 Molecular dynamics simulations of steady shock waves in nickel, BRIAN DEMASKE, VASILY ZHAKHOVSKY, University of South Florida, CARTER WHITE, Naval Research Laboratory, IVAN OLEYNIK, University of South Florida — Shock waves in single-crystal nickel samples were investigated by molecular dynamics (MD) simulations. Standard piston simulations were used to investigate the elastic-plastic split-shock-wave regime, whereas regimes having a single steady shock-wave structure were studied by a novel moving window (MW-MD) technique. Two distinct regimes were investigated, including the regimes of split elastic and plastic shock waves and the steady two-zone elastic-plastic single wave. Split shock waves were shown to form at moderate piston velocities out of a metastable high-pressure elastic state that decays into a two-wave structure consisting of a slow plastic wave and fast elastic precursor. At higher piston velocities, the plastic wave overtakes the elastic precursor but does not overrun it. Instead, both waves were found to move in tandem with the same average speed while maintaining a finite, and in some cases strongly fluctuating, separation width that may extend to several microns. The dependence of shock wave structure on crystallographic orientation and concentration of defects was investigated.

8:36AM H25.00004 A Molecular dynamics study of a Richtmyer-Meshkov instability¹, FRANK CHERNE, GUY DIMONTE, TIMOTHY GERMANN, VIRGINIE DUPONT, Los Alamos National Laboratory — We simulated a single-mode Richtmyer-Meshkov instability (RMI) using the SPaSM (Scalable Parallel Short-range Molecular-dynamics) code on the RoadRunner supercomputer and its Cerrillos counterpart. The simulations consisted of approximately 60 million atoms shocked along the $\langle 111 \rangle$ direction. The single crystal simulations had a sinusoidal groove with a wavelength of 257 nm. We conclude from the simulations that the RMI interfaces shows an inversion for most of the conditions we studied. For certain amplitudes and stresses, we observe the spike saturating. Simulations have been carried out at shock strengths both above and below the melt transition. A discussion of the spike and bubble characteristics will be discussed.

¹Support for this work was done under US DOE contract DE-AC52-06NA25396.

8:48AM H25.00005 Orientation dependence of shock-induced melting in crystalline aluminum, IVAN OLEYNIK, MIKALAI BUDZEVICH, VASILY ZHAKHOVSKY, University of South Florida, CARTER WHITE, Naval Research Laboratory — The complete evolution of metastable states during shock-induced solid-liquid phase transitions in crystalline aluminum was observed in moving window molecular dynamics simulations. The orientation-dependent transition pathways towards orientation-independent final equilibrium states include both “cold melting” followed by resolidification in $[110]$ - and $[111]$ -oriented shock waves, and crystal overheating followed by melting in $[100]$ shock waves. Such orientation-dependent dynamics of solid-liquid phase transitions takes place within an extended zone up to hundreds of nanometers behind the shock front, which makes it accessible for experimental observation.

9:00AM H25.00006 Strain rate influence on the Hall-Petch effect in Cu, VIRGINIE DUPONT, TIMOTHY C. GERMANN, Los Alamos National Laboratory — The increased strength of materials with a decreasing grain size has been known for several decades as the Hall-Petch effect. This trend is true down to a specific grain size below which the strength starts decreasing again, due to a change in the underlying plasticity mechanisms caused by the increased grain boundary network density. We are interested in the strain rate influence on the Hall-Petch and “reverse Hall-Petch” effects. We use molecular dynamics simulations to study polycrystalline samples of copper of different grain sizes between 5 nm and 30 nm, and under uniaxial compression at a wide range of strain rates (10^8 to 10^{11} s⁻¹). We verify that the yield stress of the material increases with the strain rate, due to the time scale required to generate plasticity. Moreover, we observe that the grain size for which the yield stress is highest depends on the strain rate studied. These results are of particular importance for high strain rate loading conditions, such as shock compression.

9:12AM H25.00007 High Strain Rate and Shock-Induced Deformation in Metals¹, RAMON RAVELO², University of Texas-El Paso — Large-scale non-equilibrium molecular Dynamics (MD) simulations are now commonly used to study material deformation at high strain rates (10^9 - 10^{12} s⁻¹). They can provide detailed information— such as defect morphology, dislocation densities, and temperature and stress profiles, unavailable or hard to measure experimentally. Computational studies of shock-induced plasticity and melting in fcc and bcc single, mono-crystal metals, exhibit generic characteristics: high elastic limits, large directional anisotropies in the yield stress and pre-melting much below the equilibrium melt temperature for shock wave propagation along specific crystallographic directions. These generic features in the response of single crystals subjected to high strain rates of deformation can be explained from the changes in the energy landscape of the uniaxially compressed crystal lattice. For time scales relevant to dynamic shock loading, the directional-dependence of the yield strength in single crystals is shown to be due to the onset of instabilities in elastic-wave propagation velocities. The elastic-plastic transition threshold can accurately be predicted by a wave-propagation stability analysis. These strain-induced instabilities create incipient defect structures, which can be quite different from the ones, which characterize the long-time, asymptotic state of the compressed solid. With increase compression and strain rate, plastic deformation via extended defects gives way to amorphization associated with the loss in shear rigidity along specific deformation paths. The hot amorphous or (super-cooled liquid) metal re-crystallizes at rates, which depend on the temperature difference between the amorphous solid and the equilibrium melt line. This plastic-amorphous transition threshold can be computed from shear-waves stability analyses. Examples from selected fcc and bcc metals will be presented employing semi-empirical potentials of the embedded atom method (EAM) type as well as results from density functional theory calculations.

9:48AM H25.00008 Metallurgical Effects Upon the Shock Response of Tantalum: Cold Work and Dilute Alloying, JEREMY MILLETT, AWE — The response of the body centred cubic metal tantalum to shock loading has been studied for several decades, due to its use by the military in explosively formed projectiles. It can also be considered as an ideal body centred cubic metal, thus rendering it ideal for studies of fundamental mechanical and microstructural behaviour. Previous studies on well controlled, annealed specimens has shown that deformation is controlled by the motion of rather than the generation of $a/2\langle 111 \rangle\{110\}$ screw dislocations in straight segments, which result in little if any post shock hardening. In situ-shear strength measurements have also shown a significant strength reduction behind the shock front, suggesting that the motion of these dislocations acts as a stress relief mechanism. Similar effects have also been noted in tungsten and its alloys, but very recently, measurements in niobium and molybdenum show shear strength to be near constant behind the shock front. Other factors, such as variation of Peierls stress effecting ease of dislocation generation and the propensity to twin also have a strong effect upon the shock response. In this presentation, we return to tantalum, investigating the differences in shock response between a low dislocation density (annealed) and high dislocation density (cold rolled) material. We also examine the effects of dilute alloying through the addition of 2.5wt% tungsten to tantalum. Results are discussed in terms of the shear strength and its variation with time behind the shock front.

10:00AM H25.00009 High Strain Rate Behavior of Nanoporous Tantalum¹, CARLOS J. RUESTES, Instituto de Ciencias Basicas, Univ. Nac. Cuyo., EDUARDO M. BRINGA, CONICET - Instituto de Ciencias Basicas, Univ. Nac. Cuyo., ALEXANDER STUKOWSKI, Lawrence Livermore National Laboratory, JOAQUIN F. RODRIGUEZ NIEVA, Massachusetts Institute of Technology, GRACIELA BERTOLINO, CONICET - Centro Atomico Bariloche, YIZHE TANG, MARC A. MEYERS, University of California, San Diego — Nano-scale failure under extreme conditions is not well understood. In addition to porosity arising from mechanical failure at high strain rates, porous structures also develop due to radiation damage. Therefore, understanding the role of porosity on mechanical behavior is important for the assessment and development of materials like metallic foams, and materials for new fission and fusion reactors, with improved mechanical properties. We carry out molecular dynamics (MD) simulations of a Tantalum (a model body-centered cubic metal) crystal with a collection of nanovoids under compression. The effects of high strain rate, ranging from $10^7 s^{-1}$ to $10^{10} s^{-1}$, on the stress strain curve and on dislocation activity are examined. We find massive total dislocation densities, and estimate a much lower density of mobile dislocations, due to the formation of junctions. Despite the large stress and strain rate, we do not observe twin formation, since nanopores are effective dislocation production sources. A significant fraction of dislocations survive unloading, unlike what happens in fcc metals, and future experiments might be able to study similar recovered samples and find clues to their plastic behavior during loading.

¹Research funded by PICT2008-1325, PICT2009-0092 and SeCTyP.

10:12AM H25.00010 High-Pressure Strength Determination via Quasi-Elastic Optimization Analysis, JUSTIN BROWN, TRACY VOGLER, JIM ASAY, Sandia National Laboratories — The analysis of unloading profiles from ramp wave experiments on Sandia's Z machine for the purposes of extracting strength information can be greatly influenced by the presence of a window. An impedance mismatch between the sample and the window generates a reflected ramp wave which perturbs the incoming wave, particularly at later times when, during unloading, the material strength becomes evident. In an effort to analyze the waveforms for an accurate estimate of the strength, the experimental data is coupled with optimized numerical simulations. Simulations were performed with LASLO, a one-dimensional magneto-hydrodynamics code. The deviatoric response was calculated using a modified rate-independent Steinberg - Guinan model in which a quasi-elastic response was implemented during unloading by linearly varying the shear modulus. A best fit of relevant parameters in this strength model along with the magnetic field at the drive surface were estimated over the course of thousands of simulations using the Dakota optimization package. These results may then be used to estimate the in situ wave profiles from which the strength can be extracted. Initial results will be presented for ramp wave compression of tantalum with a lithium fluoride window to peak stresses of ~ 120 GPa. Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin company, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

10:24AM H25.00011 Calculation of diffusivity and viscosity of Al-Cu molten mixtures using molecular dynamics¹, ROBERT RUDD, WILLIAM CABOT, KYLE CASPERSEN, JEFF GREENOUGH, TOMORR HAXHIMALI, PAUL MILLER, DAVID RICHARDS, FREDRICK STREITZ, Lawrence Livermore National Lab — We use equilibrium classical molecular dynamics and Green-Kubo techniques to calculate the diffusivity and viscosity of Al-Cu molten mixtures. We calculate both the self-diffusivities and the Maxwell-Stefan diffusivities, and evaluate the validity of the Darken relation for this system. We compare the results with those from experiments reported in the literature. We have constructed an analytic model that is fit to the MD results. This transport model has been implemented in a continuum hydrodynamics code. Both the continuum code and extremely large-scale molecular dynamics have been used to simulate the development of vortices due to the Kelvin-Helmholtz instability in a shear layer, and we discuss the results of that comparison.

¹This work was performed under the auspices of the US Dept. of Energy by Lawrence Livermore National Security, LLC under Contract DE-AC52-07NA27344.

10:36AM H25.00012 Mechanical Behaviour of Light Metal Alloys at High Strain Rates. Computer Simulation on Mesoscale Levels, VLADIMIR SKRIPNYAK, EVGENIYA SKRIPNYAK, Tomsk State University, LOTHAR W. MEYER, NORMAN HERZIG, Nordmetall GmbH, NATALIYA SKRIPNYAK, Tomsk State University, TOMSK STATE UNIVERSITY TEAM, NORDMETALL GMBH TEAM — Researches of the last years have allowed to establish that the laws of deformation and fracture of bulk ultrafine-grained and coarse-grained materials are various both in static and in dynamic loading conditions. Development of adequate constitutive equations for the description of mechanical behavior of bulk ultrafine-grained materials at intensive dynamic influences is complicated in consequence of insufficient knowledge about general rules of inelastic deformation and nucleation and growth of cracks. Multi-scale computational model was used for the investigation of deformation and fracture of bulk structured aluminum and magnesium alloys under stress pulse loadings on mesoscale level. The increment of plastic deformation is defined by the sum of the increments caused by a nucleation and gliding of dislocations, the twinning, meso-blocks movement, and grain boundary sliding. The model takes into account the influence on mechanical properties of alloys an average grains size, grain sizes distribution of and concentration of precipitates. It was obtained the nucleation and gliding of dislocations caused the high attenuation rate of the elastic precursor of ultrafine-grained alloys than in coarse grained counterparts.

10:48AM H25.00013 Estimation of spectral characteristics of particles ejected from free surfaces of metals and liquids under shock wave effect, ALLA GEORGIEVSKAYA, VICTOR RAEVSKY, RFNC-VNIIEF — The authors present approximated relations for estimations of the basic characteristics of flow of particles ejected from free surface of substance after shock wave arrival (shock-wave ejecta). The problem is considered as a particular case of the Richtmayer-Meshkov instability. Periodic perturbations on free surface, which are sinusoidal and having triangular shape, are considered as the initial perturbations causing formation of jets and particles. The medium is assumed to be liquid with surface tension. The role of viscosity is estimated. In the work, the authors obtained equations for estimations of the following characteristics of the particle flow: - dependence of integral mass of ejected substance on time; - space-time distribution of density of ejected substance; - space-time distribution of velocity of ejected substance; - distribution of particles in sizes; - correlation of sizes and velocities of particles. Estimations are presented concerning influence of shear strength and plasticity on substance ejecta. Analytical relations are compared with results of numerical calculations and experiments."

Session H26 DCOMP GSNP: Focus Session: Friction, Fracture and Deformation Across Length Scales - Friction Across Length Scales 257B

8:00AM H26.00001 Rock Friction from the Nanoscale to the San Andreas Fault, DAVID L. GOLDSBY, Brown University — Nucleation of earthquakes (EQs) and the resistance of faults to shearing during EQs are determined by nano-to-micro- scale frictional processes that occur on tectonic-scale faults. A first-order observation from rock-friction studies is that of ageing, i.e., the linear increase in friction with the log of the time of stationary contact, manifest as a positive or negative dependence of friction on sliding rate. A necessary condition for EQ nucleation is a negative rate dependence of friction. In spite of the success of friction 'laws' which encapsulate the rate and time dependences of friction in fitting experimental data and reproducing natural phenomena in EQ models, these laws lack a physical basis. Atomic force microscope (AFM) experiments on silica-silica contacts explore the physics of ageing, more specifically increases in adhesion of nanometers-sized contacts with time (Li et al., *Nature*, 2011). The experiments reveal prominent ageing which increases with humidity, as in rock friction tests, without increases in contact area due to creep (the canonical explanation for ageing in rock-friction tests). Ageing in the AFM tests is in fact much larger than in rock-friction tests, a discrepancy explained with a simple multi-asperity contact model. At EQ slip rates (≥ 1 m/s) a variety of dynamic fault-weakening mechanisms may decrease the shear resistance of faults, which would have important consequences for the magnitudes of EQ stress drops, strong ground motions and accelerations, for the EQ energy budget, and for the state of stress on faults. Experiments on rocks found in the Earth's crust for slip rates up to ~ 0.4 m/s over ~ 40 mm of slip, reveal a dramatic $1/V$ decrease in frictional strength above a characteristic weakening velocity V_w of ~ 0.1 m/s (Goldsby and Tullis, *Science*, 2011). Friction is also revealed to be a nearly pure function of slip rate, i.e., it adjusts to the ambient slip rate over only microns of slip. The observations are explained by 'flash heating', whereby microscopic asperity contacts become intensely frictionally heated and weakened above V_w . Dramatically lower friction due to flash heating may explain why heat flow along active faults like the San Andreas Fault is much lower than expected. Strong velocity-weakening friction and the rapid strength recovery with decreasing slip rate from flash heating may explain why EQ ruptures propagate as slip pulses rather than as cracks.

8:36AM H26.00002 Avalanche Distributions and the Effect of Inertia in Strained Amorphous Solids¹, K. MICHAEL SALERNO, MARK O. ROBBINS, Johns Hopkins University, CRAIG MALONEY, Carnegie Mellon University — We present results from two and three-dimensional simulations of a disordered, binary Lennard-Jones solid under quasi-static, steady-state shear. The solid responds to the applied shear strain with bursts of particle movement and plasticity. The energy E of these avalanches spans a wide range and follows a power-law distribution $N(E) \propto E^{-\tau}$ with three distinct exponents, depending on the importance of inertia. In the limit of overdamped dynamics, or no inertia, we find $\tau \approx 0.8$, consistent with previous energy minimization simulations. As inertia becomes more important, the system approaches an unstable critical point where $\tau = 1$. In the underdamped limit, where inertia plays a large role, the distribution of avalanches follows a power-law with exponent $\tau = 1.4$ with an excess of system-spanning events. The three regimes have distinct finite-size-scaling exponents. The fact that consistent exponents are found in two and three dimensions indicates that both may be in the mean-field limit. Spatial correlations in avalanches under different damping regimes will be contrasted.

8:48AM H26.00003 Dynamic Phase Diagram and Jamming for Driven Dislocation Assemblies, CHARLES REICHHARDT, CYNTHIA REICHHARDT, CAIZHI ZHOU, IRENE BEYERLEIN, Los Alamos National Laboratory — By using large scale numerical simulations for driven dislocations in 2D, we show that the resulting dynamic phase diagram has the same features found for driven vortex matter and charge density waves in the presence of random disorder. For low loads the system is pinned or jammed. Just above the onset of motion we observe strong velocity fluctuations with $1/f$ noise properties and bimodal velocity distributions associated with rapidly fluctuating dislocation structures. At higher loads there is a dynamic reordering into a state of partially ordered domain walls with a pronounced drop in the velocity fluctuations as well as a reduction in the noise power. These features have all the hallmarks observed for dynamic phases such as the pinned, fluctuating, and dynamical reordering transitions found in driven vortex matter. We discuss the implications of work in terms of dynamic phase transitions at the onset of motion and the onset of the dynamical ordering.

9:00AM H26.00004 Scale invariant avalanches: a critical confusion, OSVANNY RAMOS, Laboratoire PMCN, University Lyon 1, 43 bd. du 11 novembre 1918, 69622 Villeurbanne, France — In the last decades considerable efforts have been devoted to understanding single events related to friction, fracture and unjamming transition, commonly denominated avalanches. However, in many different natural scenarios -from subcritical fracture to earthquake dynamics- these events are of all scales; a situation that has often been interpreted within the formalism of critical phenomena, and having as a relevant consequence the inherently unpredictability of scale-invariant avalanches. A revision of this interpretation which departs from standard ideas is presented here, resulting in [1]: (i) critical systems are not necessarily unpredictable; (ii) slowly driven systems evolving through power-law distributed avalanches are not necessarily critical; and (iii) scale-invariant avalanches are not necessarily unpredictable. Simple simulations and granular experiments [2] confirm the findings.

9:12AM H26.00005 Unjamming of amorphous films probed with a transverse shear ultrasonic oscillator, JULIEN LEOPOLDES, GUILLAUME CONRAD, XIAOPING JIA, Université Paris Est, France, LPMDI TEAM — Friction between solids depends essentially on the response of the interfacial amorphous layer to shear and compressive stresses. Hence, the transition from static to dynamic friction corresponds to the unjamming transition of confined amorphous materials [1]. With a shear ultrasonic oscillator, we study the boundary lubrication due to molecular films confined between a plane and a sphere [2]. We observe a linear viscoelastic behaviour at low oscillation amplitude and a nonlinear frictional microslip regime at high amplitude. In a new set of experiments, the system is brought near the unjamming transition by applying a static force. The interfacial layer softens before unjamming, as indicated by the linear response of the oscillator. We suggest an interpretation based on a stress-induced decrease of the free volume, and propose a corresponding heuristic model. Last, we show how ultrasonic in-plane oscillations of ~ 10 nm amplitude can trigger unjamming, and we discuss the possible related mechanisms.

9:24AM H26.00006 Universality of Deformation Down to the Nanoscale, NIR FRIEDMAN, Department of Physics, University of Illinois at Urbana-Champaign, ANDREW T. JENNINGS, Division of Engineering and Applied Sciences, Caltech, GEORGIOS TSEKENIS, Department of Physics, University of Illinois at Urbana-Champaign, JU-YOUNG KIM, Division of Engineering and Applied Sciences, Caltech, MOLEI TAO, Department of Computing and Mathematical Sciences, Caltech, JONATHAN T. UHL, None, JULIA R. GREER, Division of Engineering and Applied Sciences, Caltech, KARIN A. DAHMEN, Department of Physics, University of Illinois at Urbana-Champaign — Deformation on macroscopic scales is often modeled as a continuous process, which in reality occurs via a sequence of nanometer-sized discrete slips. We report statistical analyses of slip size distributions obtained by uniaxial compression experiments on nano-crystals of different crystal structures and sizes down to 75 nm. We show that a simple mean field theory (MFT) correctly predicts the statistical behavior by collapsing data using the MFT exponents and scaling function. This study demonstrates that a simple model captures the statistics and universality class of discrete deformation events in a variety of metallic nano-crystals down to the smallest experimentally accessed length scales.

9:36AM H26.00007 Boundary lubrication under pressure: could the friction jump down, instead of up? , ANDREA VANOSI, SISSA & CNR-IOM DEMOCRITOS, Trieste, Italy, ANDREA BENASSI, CNR-IENI, Milano, Italy, NICOLA VARINI, ICHEC, Dublin, Ireland, ERO TOSATTI, SISSA & CNR-IOM DEMOCRITOS, ICTP, Trieste, Italy — The sliding friction during pressure squeezeout of a boundary lubricated contact has been shown [1,2] to undergo upward jumps every time a lubricant atomic layer is expelled. Here we ask the question whether the jump could not be downward. Whereas most studies focus on the layered structure which the confined lubricant takes in the normal direction, the element we wish to consider is a possible change of parallel periodicity occurring at the squeezeout transition. Such changes have been reported in simulations [3], but their effect has not been discussed so far. One possible effect could be a transition of the slider-lubricant interface commensurability, producing a switch of the frictional mechanism, from lubricant melting-freezing in a commensurate state, to superlubric in an incommensurate one – in this case with a drop of friction for increasing load. We exemplify this effect by MD simulations, where we replace for convenience the open squeezeout system with a closed system, where the lubricant is sealed between the sliders. As the number of layers drops under pressure, the planar lubricant structural lattice parameter also drops. This change reflects in a sliding friction jump, which is easily observed to be downwards. The potential observability of load-induced friction drops will be discussed.

9:48AM H26.00008 Plasticity as a Depinning Phase Transition , GEORGIOS TSEKENIS, University of Illinois at Urbana-Champaign, PAK YUEN CHAN, None, THOMAS FEHM, Ludwig-Maximilians-Universität Muenchen, JONATHAN T. UHL, None, JONATHAN DANTZIG, NIGEL GOLDENFELD, KARIN DAHMEN, University of Illinois at Urbana-Champaign — Crystalline materials deform in an intermittent way via slip-avalanches, which exhibit a variety of scale-invariant behaviors that have been interpreted as a pinning-depinning transition. We use discrete dislocation dynamics at zero temperature to resolve the temporal profiles of slip-avalanches and extract the finite-size scaling properties of the dislocation system, thus going beyond gross aggregate statistics. We provide a comprehensive set of scaling exponents, which establishes that the dynamics of plasticity, in the absence of hardening, is consistent with the mean field interface depinning universality class, even though there is no quenched disorder. Finally, we show how Phase Field Crystal simulations shed light on the effect of temperature on intermittent dislocation dynamics and its critical scaling behavior.

10:00AM H26.00009 Tribo-induced melting and temperature gradients at sliding asperity contacts , J. KRIM, L. PAN, D.J. LICHTENWALNER, North Carolina State University, A.I. KINGON, Brown University — Tribo-induced nanoscale surface melting mechanisms have been investigated by means of a combined QCM-STM technique [1] for a range of Au and Au-Ni alloys with varying compositional percentages and phases. The QCM-STM setup allows studies to be performed at sliding speeds of up to m/s, and also reveals valuable information concerning tip-substrate temperature gradients.[3] A transition from solid-solid to solid-“liquid like” contact was observed for each sample at sufficiently high asperity sliding speeds. Pure gold, solid-solution and two-phase Au-Ni (20 at.% Ni) alloys were compared, which are materials of great relevance to MEMS RF switch technology.[2] The transition points agree favorably with theoretical predictions for their surface melting characteristics. We acknowledge NSF and AFOSR support for this research.

10:12AM H26.00010 Formation of Stable Metallic Nanocontacts by mechanical annealing¹ , CARLOS SABATER, Dep. of Applied Physics University of Alicante, Spain, CARLOS UNTIEDT, Dep. App. Phys. Univ. Alicante, SP, JUAN JOSE PALACIOS, Dep. of Condensed Matter Physics, Univ. Autonoma de Madrid, MARIA JOSE CATURLA, Dep. App. Phys. Univ. Alicante, SP — Metallic nanocontacts (NC) can be fabricated using STM or related techniques. In these experiments the size of the NC can be followed, down to the atomic contact, by measuring its electrical conductance. Such evolution will normally differ for each experimental realization and therefore conductance histograms are used to identify preferential configurations. It can be shown that occasionally there are some atomic configurations that can be repeated during consecutive cycles of mechanical deformation of the contacts. Here we report experiments for gold NC where the same trace of conductance can be obtained for hundreds of cycles of formation and rupture. We have studied the process leading to such repetitiveness of the traces and found that this is obtained when limiting the indentation depth between the two surfaces to a conductance value of approximately 5-6 G_0 . Using molecular dynamics simulations we have obtained the same behaviour and observed how, after repeated indentations, the two metallic contacts are shaped into a stable configuration by mechanical annealing. This confirms and explains the fact that repeated indentation of a tip into a metallic substrate can be used as a method to sharpen or clean STM tips, but only when such indentation does not exceed a limit.

10:24AM H26.00011 Scaling in earthquake models with inhomogeneous damage¹ , RACHELE DOMINGUEZ, Randolph-Macon College, KRISTY TIAMPO, University of Western Ontario, C.A. SERINO, W. KLEIN, Boston University — We study the scaling of earthquake models that are variations of Olami-Feder-Christensen and Burridge-Knopoff models, in order to explore the effect of spatial inhomogeneities on earthquake-like systems when interaction ranges are long, but not necessarily longer than the distances associated with the inhomogeneities of the system. For long ranges and without inhomogeneities, such models have been found to produce scaling similar to GR scaling found in real earthquake systems. In the earthquake models discussed here, damage is distributed inhomogeneously throughout and the interaction ranges, while long, are not longer than all of the damage length scales. We find that the scaling depends not only on the amount of damage, but also on the spatial distribution of that damage.

10:36AM H26.00012 Stress Corrosion Fracture of Silicate Glasses: How Far Can Water Penetrate? , ELISABETH BOUCHAUD, CEA-Saclay ESPCI ParisTech, CINDY ROUNTREE, FABRICE COUSIN, CEA-Saclay, FREDERIC LECHENAULT, ENS Paris, STEPHANE CHAPULIOT, AREVA, LAURENT PONSON, I D Alembert Paris, JEAN-PHILIPPE BOUCHAUD, CFM Paris — Although glass can be considered as homogeneous at scales as small as a few tens of nanometers, since it exhibits no density fluctuations beyond, its amorphous structure makes it a disordered material with respect to fracture properties. Fluctuations of the orientations of Si-O bonds with respect to the external stress make it unlikely that bonds closest to the crack tip break first, despite the high stress concentration. As a consequence, glass behaves in a quasi-brittle manner rather than in a purely elastic way. *In situ* Atomic Force Microscopy experiments tracking the slow progression of a stress corrosion crack seemed to show indeed the opening and growth of nano size flaws ahead of the tip. However, these results are controversial, because of artifacts which may seriously affect the observations. Furthermore, the low diffusion coefficient of water in silica should forbid hydrolysis at a distance from the crack tip, except at the free surface. Nevertheless, our recent neutron reflectivity experiments show that water actually penetrates into the material during stress corrosion fracture. Comparing two experiments performed for different crack velocities shows that the diffusion coefficient is hugely increased under stress, allowing for bond breakings at ~ten nanometers ahead of the main crack tip.

10:48AM H26.00013 Magnetic friction: From Stokes to Coulomb behavior¹, MARTIN MAGIERA, SEBASTIAN ANGST, ALFRED HUCHT, DIETRICH E. WOLF, Faculty of Physics and CeNIDE, University of Duisburg-Essen, D-47048 Duisburg, Germany — We demonstrate that in a ferromagnetic substrate, which is continuously driven out of equilibrium by a field moving with constant velocity v , at least two types of friction may occur when v goes to zero: The substrate may feel a friction force proportional to v (Stokes friction), if the field changes on a time scale which is longer than the intrinsic relaxation time. On the other hand, the friction force may become independent of v in the opposite case (Coulomb friction). These observations are analogous to e.g. solid friction. The effect is demonstrated in both, the Ising (one spin dimension) and the Heisenberg model (three spin dimensions), irrespective which kind of dynamics (Metropolis spin-flip dynamics or Landau-Lifshitz-Gilbert precessional dynamics) is used. For both models the limiting case of Coulomb friction can be treated analytically. Furthermore we present an empiric expression reflecting the correct Stokes behavior and therefore yielding the correct cross-over velocity and dissipation. arXiv:1111.2494

Tuesday, February 28, 2012 8:00AM - 11:00AM –
Session H27 GMAG DMP FIAP: Invited Session: McGroddy Prize, Adler Lectureship, and Pake Prize: Superconductivity and Spin Transport 258AB

8:00AM H27.00001 Assembling, understanding, auguring phase diagrams for Fe-based superconductivity¹, PAUL CANFIELD, Ames Laboratory and Department of Physics, Iowa State University — The quest for improved examples of novel, potentially useful, superconductors reached another milestone in 2008 with the discovery of Fe-based superconductivity in wide range of structurally related arsenide and selenide compounds. In particular, the AFe_2As_2 ($\text{A} = \text{Ba}, \text{Sr}, \text{Ca}$) compounds proved to have the highly desirable combination of intriguing properties that imply intimate coupling between electronic, magnetic and structural degrees of freedom, exceptionally high and relatively isotropic upper critical field curves and readily grown, homogeneous single crystals. Over the past three years the CMP community has been able to develop a broad and deep empirical understanding of substitutional and pressure based phase diagrams of these materials that is leading to theoretical as well as synthetic insights. In this talk I will broadly review some of our key findings and speculate about future directions for research in this field.

¹Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

8:36AM H27.00002 James C. McGroddy Prize for New Materials Lecture: New Superconductors and other Research in New Materials¹, ROBERT CAVA, Department of Chemistry, Princeton University — Superconductors and other electronic materials can often display subtle relationships between their structural characteristics and their electronic properties. Though the primary interest in these relationships is within the condensed matter physics community, often at their foundation are the concepts of bonding and structure familiar to inorganic and solid state chemists. Thus a hybridized view, combining physics and chemistry, is one way of approaching the discovery and characterization of new materials. In this talk I will describe some of our research in this context and comment on some broader aspects of interdisciplinary research in new materials.

¹The authors work on superconductivity and new materials has been supported by DOE, NSF, and AFOSR.

9:12AM H27.00003 David Adler Lectureship Award in the Field of Materials Physics: Racetrack Memory - a high-performance, storage class memory using magnetic domain-walls manipulated by current, STUART PARKIN, IBM Almaden Research Center, San Jose, California — Racetrack Memory is a novel high-performance, non-volatile storage-class memory in which magnetic domains are used to store information in a “magnetic racetrack” [1]. The magnetic racetrack promises a solid state memory with storage capacities and cost rivaling that of magnetic disk drives but with much improved performance and reliability: a “hard disk on a chip”. The magnetic racetrack is comprised of a magnetic nanowire in which a series of magnetic domain walls are shifted to and fro along the wire using nanosecond-long pulses of spin polarized current [2]. We have demonstrated the underlying physics that makes Racetrack Memory possible [3,4] and all the basic functions - creation, and manipulation of a train of domain walls and their detection. The physics underlying the current induced dynamics of domain walls will also be discussed. In particular, we show that the domain walls respond as if they have mass, leading to significant inertial driven motion of the domain walls over long times after the current pulses are switched off [3]. We also demonstrate that in perpendicularly magnetized nanowires there are two independent current driving mechanisms: one derived from bulk spin-dependent scattering that drives the domain walls in the direction of electron flow, and a second interfacial mechanism that can drive the domain walls either along or against the electron flow, depending on subtle changes in the nanowire structure. Finally, we demonstrate thermally induced spin currents are large enough that they can be used to manipulate domain walls.

9:48AM H27.00004 George E. Pake Prize Lecture: Pulsed Laser Deposition and the Oxide Electronics Revolution, T. VENKATESAN, NUSNNI-NanoCore, National University of Singapore — The discovery of the Pulsed Laser Deposition (PLD) Process at Bellcore was followed by a stream of advances in the epitaxial growth of oxides and a variety of heterostructures and interfaces. Today Oxide Electronics is a fascinating field with a great deal of new Science and potential for applications. Following a discussion of these events, my talk will focus on the adventure involved in creating a new company, Neocera, and, at the same time, pushing ahead in the evolving field of oxide electronics. There, electron spin, pairing, and alignment to create superconductivity and magnetism have opened up new frontiers for research and materials development.

10:24AM H27.00005 A New Avenue towards Colossal Magnetoresistance in Organic Tunneling Junctions, JIAN SHEN, Department of Physics, Fudan University, Shanghai, China and Department of Physics and Astronomy, The University of Tennessee — A major challenge for the field of organic spintronics is how to achieve large magnetoresistance (MR) in a reliable manner. We have developed a new approach that dramatically improves MR of organic spin valves. Our approach involves using buffer layer assisted growth to prepare magnetic nanodot layers on top of the organic spacer layer. Interdiffusion between magnetic electrode and organic spacer layer has been largely suppressed in devices prepared by this method. Consequently, devices become highly reliable and large magnetoresistance up to a few hundred percent has been obtained. Moreover, we have attempted to insert a single magnetic nanodot layer inside the organic spacer layer. In such a tunneling junction device, even when the electrodes are nonmagnetic, a colossal MR up to 100000% has been achieved at relatively high temperatures. The underlying mechanism has been discussed based on temperature-dependent I-V curves and resistivity measurements.

8:00AM H28.00001 Reliability of III-V electronic devices – the defects that cause the trouble¹

, SOKRATES T. PANTELIDES, Department of Physics and Astronomy and Department of Electrical Engineering and Computer Science, Vanderbilt University, Nashville, TN — Degradation of electronic devices by hot electrons is universally attributed to the generation of defects, but the mechanisms for defect generation and the specific nature of the pertinent defects are not known for most systems. Here we describe three recent case studies [1] in III-V high-electron-mobility transistors that illustrate the power of combining density functional calculations and experimental data to identify the pertinent defects and associated degradation mechanisms. In all cases, benign pre-existing defects are either depassivated (irreversible degradation) or transformed to a metastable state (reversible degradation). This work was done in collaboration with R.D. Schrimpf, D.M. Fleetwood, Y. Puzyrev, X. Shen, T. Roy, S. DasGupta, and B.R. Tuttle. Devices were provided by D.F. Brown, J. Speck and U. Mishra, and by J. Bergman and B. Brar.

8:36AM H28.00002 Near-Interface Defects in SiO₂/SiC MOS Devices¹, A.F. BASILE, P.M. MOONEY, Simon

Fraser University — The implementation of SiO₂/SiC MOSFETS for high power applications has been hindered by the high density of near-interface states. We have developed a method to distinguish both the energy and spatial distribution of defect states near insulator-semiconductor interfaces through a comparison of the thermal emission energy extracted from constant capacitance transient spectroscopy (CCDLTS) measurements and the interface Fermi energy (F_P). The dependence of F_P on trap filling voltage at the CCDLTS peak temperature is determined from temperature-dependent 1MHz C-V curves. Capture by tunneling into oxide traps is detected in 4H- and 6H-SiC capacitors fabricated by oxidation followed by NO-annealing, with the difference in thermal emission energies consistent with the conduction band offsets of the two polytypes at the SiO₂/SiC interface. Comparison with results from first principles calculations suggests that the observed oxide traps are $C_O=C_O$ and interstitial Si [1]. SiC defects having energies close to the SiC conduction band are suggested to be carbon di-interstitial defects, $(C_2)_i$, introduced during standard oxidation [1]. Well-known traps introduced in SiC by ion-implantation are observed in 4H-SiC MOS capacitors fabricated by N-implantation followed by standard oxidation, thus validating this new method [2].

8:48AM H28.00003 Doping in Si/SiO₂ Structures: A first-principles metadynamics study ,

NICHOLAS LANZILLO, Rensselaer Polytechnic Institute, PHILIP SHEMELLA, IBM Research - Zurich, SAROJ NAYAK, Rensselaer Polytechnic Institute, WANDA ANDREONI, ALESSANDRO CURIONI, IBM Research - Zurich, RENSSELEAR POLYTECHNIC INSTITUTE COLLABORATION, IBM RESEARCH - ZURICH COLLABORATION — Dopant diffusion in semiconductor devices is a field of study with tremendous technological importance. We have performed first-principles metadynamics simulations of the diffusion of n-type dopants at the Si/SiO₂ interface using the ab-initio MD method. After the generation of a vacancy in the Si region, arsenic, phosphorus and silicon atoms show varying mechanisms of diffusion, including both substitutional and interstitial. Although at the near-interface silicon region arsenic is the first to diffuse interstitially, its interstitial position is more stable and thus less likely to diffuse across the interface relative to phosphorus and silicon. As arsenic crosses the interface, however, its relative stability decreases with respect to phosphorus and silicon and diffusion into the oxide becomes unfavorable. This is in agreement with experimentally observed arsenic pile-up at the Si/SiO₂ interface. We quantify the diffusion mechanisms by comparing free energy barriers in the silicon region as well as at the interface. We find the largest barriers exist for silicon, while the smallest barriers exist for arsenic.

9:00AM H28.00004 The lifetime recovery puzzle in intermediate band materials: A new experimental approach ,

MARK WINKLER, Massachusetts Institute of Technology, DANIEL RECHT, JACOB KRICH, MICHAEL AZIZ, Harvard University, TONIO BUONASSISI, Massachusetts Institute of Technology — We have recently observed that deep-level impurities in silicon – such as the chalcogens S and Se – can drive an insulator-to-metal transition. The existence of this transition has potential ramifications for the development of intermediate band (IB) solar cells, and significant progress has recently been made toward explaining the origin of this transition. Recently, however, theoretical disagreement has arisen regarding whether impurity concentrations beyond the insulator-to-metal transition should result in increased non-radiative recombination rates or instead yield “lifetime recovery.” Very few measurements of carrier lifetime in IB-candidates have been reported that could help clarify this issue, which has important impacts on the selection of IB-materials and the design of IB solar cells. We have developed a technique based on transient optical absorption to measure the trapping rate of the intermediate states and will discuss the results of these measurements in the hyperdoped silicon system (Si doped with chalcogens to concentration $>10^{20}\text{cm}^{-3}$). We will also discuss the impact of these measurements on the current theoretical disagreement.

9:12AM H28.00005 Single-Electron Capacitance Spectroscopy of Individual Dopants in Silicon ,

MATTHEW DENINNO, MOREWELL GASSELLER, JAMES HARRISON, STUART TESSMER, Michigan State University, SVEN ROGGE, Centre for Quantum Computation and Communication Technology, School of Physics, The University of New South Wales, ROGER LOO, MATTY CAYMAX, IMEC, Belgium — Motivated by recent transport experiments and proposed atomic-scale semiconductor devices, we present measurements that extend the reach of scanned-probe methods to discern the properties of individual dopants tens of nanometers below the surface of a silicon sample. Using a capacitance-based approach, we have both spatially resolved individual subsurface boron acceptors and spectroscopically detected single holes entering and leaving these minute systems of atoms. A resonance identified as the B^+ state is shown to shift in energy from acceptor to acceptor. The resonance is absent in a control sample that does not contain the boron acceptors. By directly measuring the quantum levels and testing the effect of dopant-dopant interactions, this method represents a valuable tool for the development of future atomic-scale semiconductor devices.

9:24AM H28.00006 Charge States of Individual Group V Donors on n-doped Si(111)-(2x1)

Surface¹, VERONIKA BRAZDOVA, PHILIPP STUDER, CYRUS F. HIRJIBEHDIN, STEVEN SCHOFIELD, NEIL J. CURSON, DAVID R. BOWLER, University College London — Functionality of semiconductor devices now relies upon only a few atoms and study of individual dopants in silicon has thus been rapidly growing in importance. Group V donors are especially interesting due to their potential applications in quantum computing and spintronics. The charge state of the dopants is of fundamental importance for conventional semiconductor devices as well as in concept QIP and spintronic devices. We combine density functional theory simulations and ion implantation and cross-sectional scanning tunneling microscopy (XSTM) to study individual Group V donors in cleaved n-doped Si(111)-(2x1) surface. We present a detailed analysis of the dopant-induced charging effects and discuss the surface charge dependence on the local reconstruction induced by the individual dopants.

9:36AM H28.00007 First-principles calculations for Er impurities in Si

LARS BJAALIE, LARS ISMER, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara — Erbium-doped Si is a promising material for the development of silicon-based light sources that can interface with CMOS technology, optical fiber, and spin centers for quantum computing. Using density functional theory with a screened hybrid functional we examine the structural and electronic properties of Er(III) impurities in Si, focusing on the site preference and the Er effects on the electrical properties of the Si host. We find that Er is stable either at the tetrahedral interstitial site or at the substitutional site, depending on the Fermi-level position; Er sitting at the hexagonal interstitial site is higher in energy at all Fermi levels, in agreement with experimental observations. In p-type Si, i.e., for Fermi levels near the valence band, Er prefers the tetrahedral interstitial site and acts as a donor. In n-type Si, i.e., for Fermi levels near the conduction band, Er prefers the substitutional site and acts as an acceptor. We will also discuss the impurity-to-band optical transitions determined from calculated configuration coordinate diagrams.

9:48AM H28.00008 Deactivation of deep level impurities in hyperdoped silicon

CHRISTIE SIMMONS, MARK WINKLER, JOSEPH SULLIVAN, Massachusetts Institute of Technology, DANIEL RECHT, MICHAEL AZIZ, Harvard School of Engineering and Applied Sciences, TONIO BUONASSISI, Massachusetts Institute of Technology — Extremely high concentrations of deep level impurities in silicon have exhibited unique properties of interest for optoelectronic and photovoltaic applications. For example, silicon hyperdoped with chalcogens demonstrates significant infrared absorption at wavelengths longer than the band edge of silicon. Hyperdoped silicon is fabricated by high-dose ion implantation followed by pulsed laser melting and rapid re-solidification. The result is a metastable supersaturated solid solution with doping concentrations orders of magnitude above the room temperature solubility limit. Thermal annealing results in a deactivation of the sub-gap absorption in this material, suggesting that the precise chemical state of the deep level impurities is a critical component of the enhanced absorption. To gain further insight to the absorption mechanism and the stability this material, we present a detailed investigation of the deactivation induced by rapid thermal annealing of silicon hyperdoped with sulfur.

10:00AM H28.00009 Single crystal silicon hyperdoped with transition metals

DANIEL RECHT, Harvard University, MATTHEW SMITH, JOSEPH SULLIVAN, Massachusetts Institute of Technology, SUPAKIT CHARNVANICHBORIKARN, Australian National University, MARK WINKLER, Massachusetts Institute of Technology, JAMES WILLIAMS, Australian National University, TONIO BUONASSISI, SILVIJA GRADEČAK, Massachusetts Institute of Technology, MICHAEL AZIZ, Harvard University — Silicon hyperdoped with sulfur and selenium by ion implantation and pulsed laser melting has recently been shown to undergo an insulator to metal transition. While experimental and theoretical investigations have begun to unravel the nature of this transition, little has been done to generalize this work to other dopants. This talk will discuss recent progress in hyperdoping silicon with transition metal dopants focusing on challenges not present in the silicon-chalcogen system. In particular, experimental results (e.g., SIMS, RBS, TEM) on the role of dopant selection and resolidification velocity in preventing segregation and cellular breakdown of the solidification front will be addressed in detail. In addition, measurements of the optoelectronic properties of silicon hyperdoped with transition metal dopants will be reported.

10:12AM H28.00010 Theoretical and Experimental Framework of an Insulator-to-Metal Transition in Selenium-Hyperdoped Silicon

ELIF ERTEKIN, University of Illinois, MARK WINKLER, Massachusetts Institute of Technology, DANIEL RECHT, AURORA SAID, MICHAEL AZIZ, Harvard University, TONIO BUONASSISI, JEFFREY GROSSMAN, Massachusetts Institute of Technology — Following the discovery of black silicon in 1998, hyperdoping - doping to concentrations orders of magnitude larger than the solubility limit - has emerged as a promising method for designing semiconductors with unique optical and electronic properties. Black silicon (silicon hyperdoped with chalcogens), synthesized by pulsed laser techniques, has recently received substantial interest owing to its broad, sub-band gap absorption down to photon energies as low as 0.5 eV, suggesting applications towards infrared detection and intermediate band photovoltaics. Until now, there has not been a clear explanation of these properties. In this presentation, we combine computational and experimental evidence to probe the origin of sub-band gap optical absorption and metallicity in black silicon. Temperature-dependent conductivity measurements show that black silicon undergoes an insulator-to-metal transition at a critical dopant concentration. Our computational analysis based on density functional theory and quantum Monte Carlo methods suggest that the enhanced optical properties result from this insulator-to-metal transition that appears to be a classic impurity-driven Mott transition, driven largely by many-body effects.

10:24AM H28.00011 Optical Absorption Mechanisms in Sulfur Hyper-doped Silicon

JOSEPH SULLIVAN, Department of Mechanical Engineering, Massachusetts Institute of Technology, DANIEL RECHT, Harvard School of Engineering and Applied Sciences, CHRISTIE SIMMONS, Department of Mechanical Engineering, Massachusetts Institute of Technology, MICHAEL AZIZ, Harvard School of Engineering and Applied Sciences, TONIO BUONASSISI, Department of Mechanical Engineering, Massachusetts Institute of Technology — Silicon that is doped with sulfur, a deep-level donor, to concentrations approaching 1% at. demonstrates sub-band gap optical absorption, and has potential applications as an intermediate band solar cell material and a short-wavelength infrared (SWIR) photodetector. Understanding the nature of the absorption mechanism will aid in creating future devices with this exciting material. To elucidate the absorption mechanism, the reflectivity and absorption coefficient have been measured to photon energies down to 75 meV. We report on these new measurements as well as data fitting that give insight into absorption mechanism within these materials.

10:36AM H28.00012 Atomistic study of heavy doping in Si nanowires¹

MAHESH NEUPANE, University of California, Riverside, CA 92506, RAJIB RAHMAN, Sandia National Laboratories, Albuquerque, NM 87185, USA, ROGER LAKE, University of California, Riverside, CA 92506 — Dopant atoms are becoming increasingly important in the nanoscaled field-effect transistors (FET) because of their tendency to influence device parameters such as sub-threshold current-voltage characteristics and gate-to-channel electrostatic coupling. Achieving high doping concentrations is essential for the realization of Si nanowire FET where low resistance contacts or tunnel junctions and narrow depletion widths are needed. In an effort to understand the dopants effect on these devices as a function of scaling parameters, we use self-consistent field (SCF) tight-binding (TB) method as implemented in NEMO3D to obtain an accurate quantitative description of the band structure, confinement geometries and valley-orbit interaction from a full band-structure technique as a function of dopant location, concentration and applied electrical field. Our method solves the Poisson equation iteratively coupled with the atomistic TB Hamiltonian for charge self-consistency to provide an accurate description of the electrostatics. Our simulations show how the band structure of the nanowire is affected by the presence of few impurities.

10:48AM H28.00013 Femtosecond-laser hyperdoping: controlling sulfur concentrations in silicon for band gap engineering, MENG-JU SHER, MARK WINKLER, YU-TING LIN, BENJAMIN FRANTA, ERIC MAZUR, Harvard University — Doping silicon to concentrations above the metal-insulator transition threshold yields a novel material that has potential for photovoltaic applications. By focusing femtosecond laser pulses on the surface of a silicon wafer in a sulfur hexafluoride (SF₆) environment, silicon is doped with 1% atomic sulfur. This material exhibits near-unity, broadband absorption from the visible to the near infrared (< 0.5 eV, deep below the silicon band gap), and metallic-like conduction. These unusual optical and electronic properties suggest the formation of an intermediate band. We report on the femtosecond laser doping techniques we employ and the resulting material properties. By changing the laser parameters and ambient environment we can control the dopant profiles, crystallinity, and surface morphology. We perform optical absorption and temperature-dependent Hall measurements to investigate electron transport and to identify the energy states of the sulfur donors.

Tuesday, February 28, 2012 8:00AM - 11:00AM —

Session H29 GQI: Focus Session: Superconducting Qubits: Amplifiers and Read-out 259A

8:00AM H29.00001 Frequency tunable non-degenerate Josephson amplifier for qubit readout¹, FLAVIUS SCHACKERT, MICHAEL HATRIDGE, KATRINA SLIWA, BALEEGH ABDO, LUIGI FRUNZIO, MICHEL DEVORET, Yale University, Dept. of Applied Physics — We have developed a new ultra low noise microwave amplifier based on the Josephson parametric converter (JPC), which overcomes a practical weakness of devices of previous generations: having sufficient frequency tunability to easily match the qubit readout frequency. The JPC consists of two superconducting microwave resonators that are coupled to each other through a ring of four Josephson junctions, threaded by a magnetic flux and providing the non-linearity for the amplification process. The non-linearity is of the trilinear form involving the minimal number of modes, and allows ideal non-degenerate parametric amplification at the quantum limit of noise. In our new tunable version, the junctions responsible for amplification are shunted by a cross of four larger junctions, which for our purpose can be regarded as linear inductors, as in the work of Roch et al.[1]. The JPC has now a unique bias point at any applied flux and is tunable over more than half a gigahertz. We are currently using this amplifier in conjunction with a quantum non-demolition measurement of a transmon qubit and have observed quantum jumps with fidelity larger than 90%. [1] N. Roch, E. Flurin, F. Nguyen, P. Morfin, P. Campagne-Ibarcq, M. H. Devoret, and B. Huard, in preparation.

8:12AM H29.00002 Microstrip SQUID amplifiers for quantum information science, M.P. DEFEO, B.L.T. PLOURDE, Syracuse University — Recent progress in SQUID amplifiers suggests that these devices might approach quantum-limited sensitivity in the microwave range, thus making them a viable option for measurement of superconducting quantum systems. In the microstrip SQUID amplifier configuration, gains of around 20dB are possible at frequencies of several hundred MHz, and the gain is limited by the maximum voltage modulation available from the SQUID. One route for increasing the voltage modulation involves using larger resistive shunts, however maintaining non-hysteretic device operation requires smaller junction capacitances than is possible with conventional photolithographically patterned junctions. Operating at higher frequencies requires a shorter input coil which reduces mutual inductance between the coil and washer and therefore gain. We have fabricated microstrip SQUID amplifiers using submicron Al-AIO_x-Al junctions and large shunts. The input coil and SQUID washer are optimized for producing high gain at frequencies in the gigahertz range. Recent measurements of gain and noise temperature will be discussed as well as demonstrations of these devices as a first stage of amplification for a superconducting system.

8:24AM H29.00003 Measurement of the phase non-reciprocity of the Josephson parametric converter¹, BALEEGH ABDO, KATRINA SLIWA, ARCHANA KAMAL, FLAVIUS SCHACKERT, MICHAEL HATRIDGE, LUIGI FRUNZIO, MICHEL DEVORET, Applied Physics - Yale University — Non-reciprocal devices such as circulators and isolators play a pivotal role in many microwave experiments on quantum superconducting circuits. However, non-reciprocity in these devices is achieved using ferrites and permanent magnets which are not suitable for on chip integration. We have built a symmetric two port device by pairing two Josephson parametric converters (JPCs) working in pure conversion mode, each of which is driven with an independent pump tone. We observed a non-reciprocal phase shift between the two ports, which depends on the phase difference between the two pumps. The present noiseless system constitutes an important step towards the implementation of a noiseless gyrator, the main building block of an on-chip circulator for back-action free quantum measurement.

¹Work supported by IARPA, ARO and NSF

8:36AM H29.00004 Performance of the doubly pumped four-wave Josephson parametric amplifier¹, KATRINA SLIWA, ANIRUDH NARLA, MICHAEL HATRIDGE, FLAVIUS SCHACKERT, SHYAM SHANKAR, ARCHANA KAMAL, BALEEGH ABDO, LUIGI FRUNZIO, MICHEL DEVORET, Applied Physics Dept., Yale University — The degenerate Josephson Parametric Amplifier (JPA) is a promising quantum-limited amplifier for the measurement of mesoscopic systems. In the single pump scheme, the amplification process utilizes two photons at the drive frequency to produce a signal and an idler photon. However the large reflected pump tone at the drive frequency strongly acts back on the measured system. Several circulators prevent this back action, but come at a non-negligible cost in system noise temperature. Two drive tones symmetrically detuned from the original drive frequency provide the necessary pump energy but with the reflected tones now far removed from the signal frequency. We have investigated the performance of the doubly pumped JPA with pump detunings from 50 to 1000 MHz. The expected gain profile has been measured with at least 20 dB of gain and no loss of bandwidth. A gigahertz range of tunability, no degradation in noise temperature, and improvements in dynamic range are also expected.

¹Work Supported by IARPA, ARO, and NSF

8:48AM H29.00005 Analytical Calculation of Gain and Noise of DC SQUID Microwave Amplifier, ARCHANA KAMAL, MICHEL DEVORET, Departments of Physics and Applied Physics, Yale University, JOHN CLARKE, Department of Physics, University of California, Berkeley — The dc SQUID microwave amplifier, based on Josephson junctions, is employed in a wide spectrum of applications ranging from dark matter detection to the readout of superconducting qubits. A crucial advantage offered by this device is the separation of input and output channels, unlike conventional Josephson parametric amplifiers, so that it does not require a nonreciprocal device such as a circulator for its operation. The mechanism underlying the directional gain in the SQUID microwave amplifier, however, has so far remained elusive. We present a first principles, analytical calculation, based on scattering theory, of a practical SQUID amplifier which elucidates the underlying nonlinear mode mixing responsible for the directional operation of the device. The gain and quantum noise characteristics of a SQUID operated as a microwave voltage amplifier are discussed. Work supported by IARPA and ARO (AK, MHD and JC) and NSF (AK and MHD).

9:00AM H29.00006 Observing quantum jumps of a transmon qubit with a Josephson parametric converter¹, S. SHANKAR, M. HATRIDGE, F. SCHACKERT, K. GEERLINGS, T. BRECHT, K. SLIWA, B. ABDO, L. FRUNZIO, R.J. SCHOELKOPF, M.H. DEVORET, Applied Physics Dept., Yale University — A high fidelity linear quantum non-demolition (QND) readout of a superconducting qubit opens up the possibility of observing quantum jumps and is a prerequisite for quantum feedback and error correction. This readout is challenging since the qubit, the readout resonator and the following amplifier chain have to be simultaneously optimized to achieve the desired performance. We fabricated a superconducting transmon qubit at 5.7 GHz coupled to a compact resonator at 7.5 GHz, designed to produce a dispersive shift (χ) of 6 MHz of the resonator frequency when the qubit is excited. The resonator linewidth matches χ to produce maximum readout contrast in a transmission measurement, while maintaining a Purcell limited T_1 of about 3 μ s. Using a Josephson parametric converter that is tuned to match the resonator frequency, we achieved a system noise temperature of the following amplifier chain of about 0.5 K, roughly thrice the standard quantum limit. Using these optimized parameters, we measured the qubit state with about 5 photons in the readout resonator and observed quantum jumps with fidelity above 90 %. Further, by looking at the statistics of the jumps and the evolution of the qubit population in single shot traces, we find that the average qubit T_1 during the readout matches the Purcell limited T_1 , as expected for a QND measurement.

¹Work supported by IARPA, ARO and NSF.

9:12AM H29.00007 Quantum measurement in action with the transmon qubit¹, M. HATRIDGE, S. SHANKAR, F. SCHACKERT, K. GEERLINGS, T. BRECHT, K. SLIWA, B. ABDO, L. FRUNZIO, R.J. SCHOELKOPF, M.H. DEVORET, Applied Physics Dept., Yale University — High fidelity, rapid quantum non-demolition readout of superconducting qubits greatly facilitates tests of single qubit measurement theory. We have realized such readout in an experiment comprised of a transmon coupled to a compact resonator, which is in turn connected via an isolator and circulator to a tunable Josephson parametric converter (JPC) operated as a phase-preserving parametric amplifier. When the qubit state is measured with an rf tone corresponding to an average cavity circulating power of 5 photons, fidelity exceeds 90% for a measurement duration of 240 ns ($\sim 0.1 T_1$). This performance allows the observation of quantum trajectories of the qubit, showing discrete jumps and a bimodal distribution of measurement results, despite the linear character of the amplifier. This provides further support for the quantum nature of superconducting artificial atoms. We have conducted Stern-Gerlach type experiments, in which the qubit is repeatedly measured along different axes. Results are in good agreement with theoretical predictions of the effect of partial measurement on qubit state evolution.

¹Work supported by IARPA, ARO, and NSF.

9:24AM H29.00008 Monitoring the state of a superconducting quantum bit using weak measurements¹, CHRIS MACKLIN, R. VIJAY, D.H. SLICHTER, STEVEN WEBER, KATER MURCH, R. NAIK, UC Berkeley, QNL, ALEXANDER N. KOROTKOV, Department of Electrical Engineering, University of California, Riverside, CA 92521, USA, I. SIDDIQI, UC Berkeley, QNL — We demonstrate continuous weak measurement of the state of a superconducting transmon qubit in the circuit QED architecture using a Josephson parametric amplifier. The near quantum-limited noise performance of the amplifier enables us to obtain a high-fidelity measurement record which can be used to reconstruct the qubit state evolution during measurement by employing the quantum Bayesian formalism. While simultaneously driving the qubit at its Larmor frequency and measuring it weakly, we are able to resolve the spectral signature of Rabi oscillations present in the measurement record with a high signal-to-noise ratio (SNR). We discuss current limitations in this measurement scheme and suggest ways to further optimize the SNR. Our results suggest a route to implement quantum feedback to steer the state of a superconducting qubit.

¹This research is supported by the ARO QCT program.

9:36AM H29.00009 Stabilizing Rabi oscillations in a superconducting qubit using quantum feedback¹, R. VIJAY, CHRIS MACKLIN, D.H. SLICHTER, STEVEN WEBER, KATER MURCH, R. NAIK, UC Berkeley, QNL, ALEXANDER N. KOROTKOV, Department of Electrical Engineering, University of California, Riverside, CA 92521, USA, I. SIDDIQI, UC Berkeley, QNL — Recent progress in the development of quantum-noise-limited superconducting parametric amplifiers has enabled high-fidelity, continuous measurements of superconducting quantum bits (qubits). We exploit this functionality while leveraging improved coherence times in transmon qubits to show that it is now possible to obtain a faithful record of real-time qubit dynamics during measurement. We weakly measure the qubit while it is continuously driven at the Larmor frequency. The phase of the resulting Rabi oscillations diffuses slowly, primarily due to the measurement. We monitor this phase diffusion and correct for it by feeding back on the qubit drive amplitude. This locks the Rabi oscillations to a classical reference signal and the oscillations persist indefinitely with a reduced visibility set by the feedback efficiency. We perform tomography on the feedback stabilized state and suggest routes to further optimize the feedback efficiency. Such capabilities suggest a measurement based route for implementing continuous quantum error correction.

¹This research is supported by the ARO QCT program

9:48AM H29.00010 High fidelity readout of a superconducting qubit using heralded state preparation¹, J.E. JOHNSON, UC Berkeley, C. MACKLIN, D.H. SLICHTER, R. VIJAY, UC Berkeley, QNL, E. WEINGARTEN, JOHN CLARKE, UC Berkeley, I. SIDDIQI, UC Berkeley, QNL — We report measurements of a superconducting flux qubit, coupled via a shared inductance, to a quasi-lumped element 5.78-GHz readout resonator formed by the parallel combination of an interdigitated capacitor and a meander line inductor. A Josephson parametric amplifier with near-quantum-limited noise performance is used to increase the measurement sensitivity. We demonstrate a continuous, high-fidelity readout with sufficient bandwidth and signal-to-noise ratio to resolve quantum jumps in the flux qubit. We achieve a readout fidelity of 91%, limited primarily by T_1 decay between state preparation and measurement. The fast, high-visibility, QND character of the readout allows for many successive readouts within a time T_1 . We exploit this capability to herald pure ground and excited state ensemble populations by post-selecting only for certain states after an initial readout. This method enables us to eliminate errors due to imperfect state preparation, increasing the fidelity to 94%. We also present a precise budget of fidelity loss and an analysis of the readout backaction.

¹This work was funded in part by the U.S. Government and by BBN Technologies.

10:00AM H29.00011 Experimental approaches to improve the single shot measurement fidelity of a superconducting charge qubit, YANBING LIU, SRIKANTH SRINIVASAN, ANTHONY HOFFMAN, ANDREW HOUCK, Princeton University — We discuss various experimental approaches to improve the single shot measurement fidelity of a superconducting charge qubit. Dispersive readout is optimized on a transmon coupled to a superconducting coplanar waveguide resonator. Measurement parameters, such as microwave power and frequency are varied. Also control theory is adapted to construct a genetic algorithm which optimizes the shape of the drive pulse. Additionally, we attempt to reduce noise and increase SNR by employing a SLUG amplifier. Using these techniques, we discuss the feasibility of reaching the measurement fidelity needed for scalable quantum computation with superconducting circuits.

10:12AM H29.00012 Multiplexed dispersive readout for the superconducting phase qubit, DANIEL SANK, R. BARENDs, J. BOCHMANN, B. CHIARO, Y. CHEN, J. KELLY, M. LENANDER, E. LUCERO, M. MARIANTONI, A. MEGRANT, C. NEILL, P. O'MALLEY, P. ROUSHAN, A. VAINSENCHEr, J. WENNER, T. WHITE, Y. YIN, ANDREW CLELAND, JOHN M. MARTINIS, UC Santa Barbara — Scaling to multiple qubit circuits requires state readout with maximum reliability and the minimum number of readout lines. Here, we introduce a multiplexed readout scheme for superconducting phase qubits. We replace our standard readout SQUIDs with inductively coupled resonators so that the measured state of the qubit (left or right side of the potential well) is read out as a shift of the resonator frequency. We connected several readout resonators to a single feedline and use a multi-tone microwave reflection measurement to simultaneously read out the states of multiple qubits using a single cable. Together with the compact lumped LC resonator design, the efficiency of chip space usage is greatly improved.

10:24AM H29.00013 Ground State Misidentification in Superconducting Qubits, JAMES WENNER, Y. CHEN, J. KELLY, H. WANG, E. LUCERO, B. CHIARO, R. BARENDs, M. LENANDER, M. MARIANTONI, A. MEGRANT, C. NEILL, P. O'MALLEY, P. ROUSHAN, D. SANK, A. VAINSENCHEr, T. WHITE, Y. YIN, J. ZHAO, A.N. CLELAND, JOHN M. MARTINIS, UC Santa Barbara — To achieve fault tolerant quantum computation, it is necessary to maximize measurement fidelity and minimize readout-induced measurement errors. A new protocol was developed to measure $P_1(|g\rangle)$, the probability of measuring the excited state without exciting the qubit, while not including stray tunneling present in superconducting phase qubits. We have confirmed the expected trend in $P_1(|g\rangle)$ with device temperature. We then compared $P_1(|g\rangle)$ for phase qubits with different readout mechanisms and found that it is $\sim 3\%$ for our dispersive readout scheme and $\sim 1.5\%$ for our prior SQUID-based readout scheme. We have further applied microwave power to the flux bias and microwave drive lines to understand the source of this difference.

10:36AM H29.00014 Autoresonant readout of a high Q resonator coupled to a superconducting quantum bit¹, KATER MURCH, STEVEN WEBER, R. VIJAY, UC Berkeley, QNL, ERAN GINOSSAR, Physics Department, University of Surrey, STEVEN M. GIRVIN, Physics Department, Yale University, I. SIDDIQI, UC Berkeley, QNL — The frequency of a nonlinear oscillator changes with oscillation amplitude. When a high-Q, nonlinear oscillator is excited with a frequency chirped drive, the system can respond at either low or high oscillation amplitude depending on whether the drive excitation is below or above a critical value, respectively – a phenomenon known as autoresonance. We exploit this nonlinear phenomenon to read out the state of a superconducting transmon qubit coupled to a high-Q nonlinear resonator. Because the excitation is non-equilibrium, the resonator can be read out faster than its energy decay time. The fidelity for mapping the qubit state onto the oscillator can be as high as 80% and is limited by the T_1 lifetime of the qubit, and readily achievable pulse parameters.

¹This research was supported by the IARPA CSQ program.

10:48AM H29.00015 Qubit Measurement with a Nonlinear Cavity Detector Beyond Linear Response, CATHERINE LAFLAMME, AASHISH CLERK, McGill University — We consider theoretically the use of a driven, nonlinear superconducting microwave cavity to measure a coupled superconducting qubit. This is similar to setups studied in recent experiments.^{1,2} In a previous work, we demonstrated that for weak coupling (where linear response theory holds) one misses the quantum limit on QND detection in this system by a large factor proportional to the parametric gain.³ Here we calculate measurement backaction beyond linear response by using an approximate mapping to a detuned degenerate parametric amplifier having both linear and dispersive couplings to the qubit. We find surprisingly that the backaction dephasing rate is far more sensitive to corrections beyond linear response than the detector response. Thus, increasing the coupling strength can significantly increase the efficiency of the measurement. We interpret this behavior in terms of the non-Gaussian photon number fluctuations of the nonlinear cavity. Our results have applications to quantum information processing and quantum amplification with superconducting microwave circuits.

8:00AM H30.00001 Screening of charged impurities with multi-electron singlet-triplet spin qubits in quantum dots¹, JASON KESTNER, EDWIN BARNES, NGA NGUYEN, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland - College Park — Charged impurities in semiconductor quantum dots comprise one of the main obstacles to achieving scalable fabrication and manipulation of singlet-triplet spin qubits. We theoretically show that using dots that contain several electrons each can help to overcome this problem through the screening of the rough and noisy impurity potential by the excess electrons [1]. We demonstrate how the desired screening properties turn on as the number of electrons is increased, and we characterize the properties of a double quantum dot singlet-triplet qubit for small odd numbers of electrons per dot. We show that the sensitivity of the multi-electron qubit to charge noise may be an order of magnitude smaller than that of the two-electron qubit.

8:12AM H30.00002 Measurements of undoped accumulation-mode SiGe quantum dot devices, KEVIN ENG, MATHEW BORSELLI, KEVIN HOLABIRD, IVAN MILOSAVLJEVIC, ADELE SCHMITZ, PETER DEELMAN, BIQIN HUANG, MARKO SOKOLICH, LESLIE WARREN, THOMAS HAZARD, ANDREY KISELEV, RICHARD ROSS, MARK GYURE, ANDREW HUNTER, HRL Laboratories, LLC — We report transport measurements of undoped single-well accumulation-mode SiGe quantum dot devices with an integrated dot charge sensor. The device is designed so that individual forward-biased circular gates have dominant control of dot charge occupancy, and separate intervening gates have dominant control of tunnel rates and exchange coupling. We have demonstrated controlled loading of the first electron in single and double quantum dots. We used magneto-spectroscopy to measure singlet-triplet splittings in our quantum dots: values are typically ~ 0.1 meV. Tunnel rates of single electrons to the baths can be controlled from less than 1 Hz to greater than 10 MHz. We are able to control the (0,2) to (1,1) coupling in a double quantum dot from under-coupled ($t_c < kT \sim 5\mu\text{eV}$) to over-coupled ($t_c \sim 0.1$ meV) with a bias control of one exchange gate. 8:24AM H30.00003 Fabrication of dual-gated devices on undoped Si/SiGe heterostructures¹

Y. DOVZHENKO, K. WANG, C. PAYETTE, Department of Physics, Princeton University, Princeton, New Jersey 08544, C.-H. LEE, C. W. LIU, Department of Electrical Engineering, National Taiwan University, Taipei, Taiwan, ROC, J. R. PETTA, Department of Physics, Princeton University, Princeton, New Jersey 08544 — Undoped accumulation mode Si/SiGe heterostructures have recently emerged as a promising platform for the fabrication of few-electron silicon spin qubits. Spin blockade has been observed in an accumulation mode double dot [1] and a record mobility of $1.6 \text{ million cm}^2/(\text{Vs})$ has been achieved in undoped wafers grown at National Taiwan University [2]. We develop a fabrication process for dual-gated accumulation mode structures and form a stable two-dimensional electron gas by applying positive bias to a global top gate. The resulting 2DEG has charge densities of $2 - 5 \times 10^{11}/\text{cm}^2$ and mobilities up to $200,000 \text{ cm}^2/(\text{Vs})$. We present preliminary data from quantum point contacts fabricated in this geometry.

8:36AM H30.00004 Optimization of realistic silicon double quantum dots through simulation

, ERIK NIELSEN, SUZEY GAO, RALPH YOUNG, RICHARD MULLER, Sandia National Laboratories — We present results obtained using a newly developed semiclassical and Poisson-Schrodinger simulation tool which is able to simultaneously optimize many solution parameters. We discuss the benefit this capability has on realistic device design, and report general trends seen when targeting few-electron quantum dots in silicon and silicon-germanium structures. This work was supported by the Laboratory Directed Research and Development program at Sandia National Laboratories. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

8:48AM H30.00005 Anatomy of the exchange gate action in undoped accumulation-mode SiGe quantum dot devices

, A.A. KISELEV, R.S. ROSS, M.G. BORSELLI, K. ENG, K.S. HOLABIRD, T.M. HAZARD, M.F. GYURE, HRL Laboratories LLC, 3011 Malibu Canyon Road, Malibu CA 90265 — We discuss simulations of an undoped accumulation-mode SiGe device containing an electrostatically formed double quantum dot in its active area. We validate our virtual model by extensive device characterization (in terms of gate actions, dot addition energies, etc.) and quantitative comparisons to concurrent experimental data. Next, we trace and map in detail the turn-on of the inter-dot exchange interaction by the exchange gate located between the dot gates. Of primary interest is the ability to control (i.e., both to completely shut off and to gradually modulate in the neV to μeV range) the exchange energy between the two separated electrons. We identify a potential obstacle to proper device operation, the formation of additional dot states under the progressively more forward-biased exchange gate. This effect is limited, however, to the case of large dot gate diameter and/or large dot-dot separation. Lastly we quantify and analyze the consequences of cross-capacitance between adjacent exchange and dot gates. Sponsored by the United States Department of Defense. Approved for public release, distribution unlimited.

9:00AM H30.00006 Effect of fixed charge gate oxide defects on the exchange energy of a multi-valley silicon double quantum dot¹

, RAJIB RAHMAN, ERIK NIELSEN, RICK MULLER, MALCOLM CARROLL, Sandia National Laboratories — Exchange interaction at the MOS interface has been proposed as a qubit coupling approach for both MOS quantum dots and donor qubits. An intrinsic source of disorder in the MOS system is the charge defects in silicon dioxide, nanometers away from the interface and qubit electrons. The presence of a charge defect so near the qubit can significantly perturb the confinement potential and alter the intended coupling. Using a large-scale atomistic tight-binding method coupled to a full configuration interaction technique, we investigate the role of these defects on the two-electron coupling of a double quantum dot (DQD) as a function of detuning bias. We show how the multi-valley character of silicon is manifested in the two-electron spectrum, and hence in the exchange energies of excited triplet states corresponding to different valley configurations. Our results show that defects near the tunnel barrier can adversely affect the tunability of the DQD, while defects distributed asymmetrically relative to the two dots can act as an additional detuning source.

9:12AM H30.00007 Modeling split gate tunnel barriers in lateral double top gated Si-MOS nanostructures

, AMIR SHIRKHORSHIDIAN, University of New Mexico, NATHANIEL BISHOP, RALPH YOUNG, JOEL WENDT, MICHAEL LILLY, MALCOLM CARROLL, Sandia National Labs — Reliable interpretation of quantum dot and donor transport experiments depends critically on understanding the tunnel barriers separating the localized electron state from the 2DEG regions which serve as source and drain. We analyze transport measurements through split gate point contacts, defined in a double gate enhancement mode Si-MOS device structure. We use a square barrier WKB model which accounts for barrier height dependence on applied voltage. This constant interaction model is found to produce a self-consistent characterization of barrier height and width over a wide range of applied source-drain and gate bias. The model produces similar results for many different split gate structures. We discuss this models potential for mapping between experiment and barrier simulations. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE, Office of Basic Energy Sciences user facility. The work was supported by the Sandia National Laboratories Directed Research and Development Program. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. DOE's National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:24AM H30.00008 Enhancement-mode buried strained-silicon channel double quantum dot

, T.M. LU, N.C. BISHOP, T. PLUYM, J. MEANS, P.G. KOTULA, J. CEDERBERG, L.A. TRACY, J. DOMINGUEZ, M.P. LILLY, M.S. CARROLL, Sandia National Laboratories — We demonstrate a relaxed-SiGe/strained-Si enhancement-mode gate stack for quantum dots. The devices were fabricated within a 150 mm Si foundry setting that uses implanted ohmics and chemical-vapor-deposited dielectrics. Thermal budget was minimized to prevent Ge/Si interdiffusion and strain relaxation. A mobility of $1.6 \times 10^5 \text{ cm}^2/\text{Vs}$ at $5.8 \times 10^{11}/\text{cm}^2$ is measured in Hall bars that witness the same device process flow as the quantum dot. Periodic Coulomb blockade measured in a double-top-gated lateral quantum dot nanostructure terminates with open diamonds up to $\pm 10 \text{ mV}$ of dc voltage across the device. Charge sensing indicates a lithographically defined double quantum dot with tunable coupling. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE, Office of Basic Energy Sciences user facility. The work was supported by the Sandia National Laboratories Directed Research and Development Program. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:36AM H30.00009 Hybrid Donor-Dot Devices made using Top-down Ion Implantation for Quantum Computing, EDWARD BIELEJEC, NATHAN BISHOP, MALCOLM CARROLL, Sandia National Laboratories — We present progress towards fabricating hybrid donor – quantum dots (QD) for quantum computing. These devices will exploit the long coherence time of the donor system and the surface state manipulation associated with a QD. Fabrication requires detection of single ions implanted with 10's of nanometer precision. We show in this talk, 100% detection efficiency for single ions using a single ion Geiger mode avalanche (SIGMA) detector integrated into a Si MOS QD process flow. The Nanoimplanter (nl) a focused ion beam system is used for precision top-down placement of the implanted ion. This machine has a 10 nm resolution combined with a mass velocity filter, allowing for the use of multi-species liquid metal ion sources (LMIS) to implant P and Sb ions, and a fast blanking and chopping system for single ion implants. The combination of the nl and integration of the SIGMA with the MOS QD process flow establishes a path to fabricate hybrid single donor-dot devices. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:48AM H30.00010 Computer assisted design of poly-silicon gated enhancement-mode, lateral double quantum dot devices for quantum computing, NATHANIEL BISHOP, RALPH YOUNG, Sandia National Labs, CARLOS BORRAS PINILLA, HAROLD STALFORD, University of Oklahoma, Norman, ERIK NIELSEN, RICHARD MULLER, RAJIB RAHMAN, LISA TRACY, JOEL WENDT, MICHAEL LILLY, MALCOLM CARROLL, Sandia National Labs — We discuss trade-offs of different double quantum dot and charge sensor lay-outs using computer assisted design (CAD). We use primarily a semi-classical model, augmented with a self-consistent configuration interaction method. Although CAD for quantum dots is difficult due to uncontrolled factors (e.g., disorder), different ideal designs can still be compared. Comparisons of simulation and measured dot characteristics, such as capacitance, show that CAD can agree well with experiment for relevant cases. CAD results comparing several different designs will be discussed including a comparison to measurement results from the same designs. Trade-offs between poly-silicon and metal gate lay-outs will also be discussed. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE, Office of Basic Energy Sciences user facility. The work was supported by the Sandia National Laboratories Directed Research and Development Program. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

10:00AM H30.00011 Correlation functions of the electric and magnetic fields in the vicinity of a metal surface¹, LUKE LANGSJOEN, ROBERT JOYNT, MAXIM VAVILOV, AMRIT POUDEL, University of Wisconsin - Madison — The Johnson noise-induced relaxation rate of a charge or spin qubit for a transition at a particular frequency in the vicinity of a metal boundary is proportional to the temporal Fourier component at that frequency of the electric or magnetic correlation function evaluated at the position of the qubit. These correlation functions are shown to be greatly enhanced compared to the blackbody result in the near vicinity of the metal due to the contribution of evanescent waves. As such, we expect a measurable enhancement of qubit decoherence due to the contribution of evanescent waves. We use a Green's dyadic approach to calculate the correlation functions of the fluctuating electric and magnetic fields in the vicinity of a conducting surface. In a local treatment of the dielectric properties of the metal this enhancement diverges as the inverse cube of the distance from the boundary, and for distances less than the order of the Fermi wavelength of the metal a nonlocal treatment is necessary to obtain an accurate result. We present a calculation of the correlation function for the full range of distances.

¹DOD, ARMY W911NF-11-1-0030

10:12AM H30.00012 Fabrication and measurement of quantum dots in double gated, dopantless Si/SiGe heterostructures, DANIEL WARD, ROBERT MOHR, JONATHAN PRANCE, JOHN GAMBLE, DON SAVAGE, MAX LAGALLY, SUSAN COPPERSMITH, MARK ERIKSSON, University of Wisconsin-Madison — Significant progress has been made towards quantum dot spin qubits in Si/SiGe single and double quantum dots. In the past, these structures have been created by depleting a modulation-doped 2DEG that forms at the Si/SiGe interface. The modulation doping in such devices is believed to be a source of charge noise. Recently, undoped structures have been explored for the formation of both 2DEGs and quantum dots in Si/SiGe. Here we discuss measurements on double gated, dopantless quantum dots in Si/SiGe heterostructures. The devices are based on a new "island mesa" design incorporating micro-ohmic contacts. We present transport measurements on a double quantum dot showing a smooth transition from single dot to double dot behavior.

10:24AM H30.00013 Unintentional Quantum Dots in Silicon: Deducing the Location and Cause, TED THORBECK, NIST and University of Maryland: JQI, CNAM, NEIL M. ZIMMERMAN, NIST — When attempting to use local gates to electrostatically define quantum dots in silicon, additional unintentional quantum dots (U-QDs) that are not defined by the gates are often observed. U-QDs are typically blamed on random charged defects such as dopants or interface traps. We use measured gate capacitances and a capacitance simulator to determine the location of the U-QDs with a precision of a few nanometers. Since we have observed U-QDs in similar locations in multiple devices, we suggest that some U-QDs are not caused by random charged defects instead are a systematic but unanticipated consequence of the fabrication. We will discuss strain as a potential cause of the U-QDs. This allows us to suggest methods to reduce the frequency of U-QDs in future devices. Given the variety of groups suffering from U-QDs and the simplicity of this technique, we think that many groups might benefit from our methods.

10:36AM H30.00014 The divacancy in SiC: A new solid-state qubit, LUKE GORDON, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, University of California, Santa Barbara — The nitrogen-vacancy center in diamond has attracted interest due to promising applications as a room-temperature solid-state qubit (the basic unit of a quantum computer). It is, however, desirable to identify defects that possess similar properties, but in alternative semiconductors that are either cheaper or more technologically mature. One notable defect system is the divacancy in 4H-SiC, which has recently been the subject of extensive experimental investigation. In this work, we employ advanced computational methods, particularly density functional theory using a hybrid functional, to investigate the stability and excitation energies of multiple forms of the divacancy in the various polytypes of silicon carbide. The hybrid functional gives band gaps and lattice parameters that are in excellent agreement with experiments. This allows for quantitative predictions of defect levels and zero-phonon line energies for excitation and emission processes, aiding in experimental identification of these defects.

10:48AM H30.00015 Large Stark effect for Li donor spins in Si, LUKE PENDO, ERIN HANDBERG, South Dakota School of Mines, VADIM SMELYANSKIY, NASA Ames Research Center, ANDRE PETUKHOV, South Dakota School of Mines — We study the effect of a static electric field on lithium donor spins in silicon. The anisotropy of the effective mass leads to the anisotropy of the quadratic Stark susceptibility, which we determined using the Dalgarno-Lewis exact summation method [1]. The theory is asymptotically exact in the field domain below Li-donor ionization threshold, relevant to the Stark-tuning Electron Spin Resonance (ESR) experiments [2]. With the calculated Stark susceptibilities at hand, we were able to predict and analyze several important physical effects. In particular, we demonstrate that the Stark effect anisotropy, combined with unique valley-orbit splitting of a Li donor in Si, spin-orbit interaction and specially tuned external stress, may lead to a very strong modulation of the donor spin g-factor by the electric field. Also we investigate the influence of random strains on the g-factor shifts and quantify the random strain limits and requirements to Si material purity necessary to observe the ESR-Stark shifts experimentally. Finally, we discuss possible applications of our results to quantum information processing with Li spin qubits in Si.

Tuesday, February 28, 2012 8:00AM - 11:00AM –
Session H31 DMP: Focus Session: Topological Insulators: Synthesis and Characterization:
Bulk Crystals 260

8:00AM H31.00001 Low carrier concentration crystals of the topological insulator $\text{Bi}_2\text{Te}_2\text{Se}$, SHUANG JIA, HUIWEN JI, E. CLIMENT-PASCUAL, M.K. FUCCILLO, M.E. CHARLES, Department of Chemistry, Princeton University, JUN XIONG, N.P. ONG, Department of Physics, Princeton University, R.J. CAVA, Department of Chemistry, Princeton University — We report the characterization of $\text{Bi}_2\text{Te}_2\text{Se}$ crystals obtained by the modified Bridgman and Bridgman-Stockbarger crystal growth techniques. X-ray diffraction study confirms an ordered Se-Te distribution in the inner and outer chalcogen layers, respectively, with a small amount of mixing. The crystals displaying high resistivity ($> 1 \Omega\text{cm}$) and low carrier concentration ($\sim 5 \times 10^{16}/\text{cm}^3$) at 4 K were found in the central region of the long Bridgman-Stockbarger crystal, which we attribute to very small differences in defect density along the length of the crystal rod. Analysis of the temperature dependent resistivities and Hall coefficients reveals the possible underlying origins of the donors and acceptors in this phase.

8:12AM H31.00002 Structural study of topological insulator $\text{Bi}_2(\text{Se}_{3-x}\text{Te}_x)$, KEESEONG PARK, University of Virginia, Charlottesville, Virginia 22904, USA., DESPINA LOUCA, University of Virginia, Charlottesville, Virginia 22904, USA, ANNA LLOBET, Lujan Neutron Scattering Center, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — With neutron diffraction, we systematically investigated the local and average structures of topological insulator $\text{Bi}_2(\text{Se}_{3-x}\text{Te}_x)$ ($x=0, 1, 1.5, 2$, and 3) from 5 to 500 K. The average crystal structure of Bi_2Se_3 is rhombohedral R-3m symmetry with 2 unique chalcogen sites. This gives rise to 2 types of Bi-(Se/Te) bonds in quintuple layer composed of Se1-Bi-Se2 –Bi-Se1 layers, covalent Se1-Bi bond with the bonding length of 2.85 Å and ionic Se2-Bi bond with the bonding length of 3.07 Å at 5 K. The Se1-Se1 bonds between quintuple layers are governed by Van der Waals of the length of 3.47 Å at 5 K. With increasing temperature, it is observed that the quintuple layer unit contracts from the anti-parallel motion of the Bi-(Se1)₃ tetrahedra toward the Se2-center layer. Also such a contraction implies the Van der Waals bonding between quintuple layers weakens with temperature. A similar temperature dependence of atomic structure is observed on Bi_2Se_3 .

8:24AM H31.00003 Hole doping of p-type thin topological insulators, INNA KORZHOVSKA, LUKAS ZHAO, ZHIYI CHEN, HAIMING DENG, LIMIN HUANG, City College of New York - CUNY, SIMONE RAOUX, JEAN JORDAN-SWEET, IBM Research - Yorktown, MYRIAM SARACHIK, STEPHEN O'BRIEN, LIA KRUSIN, City College of New York - CUNY — Recent studies of intrinsically n-type topological insulator (TI) Bi_2Se_3 demonstrated that doping with Cu introduces electrons into this system, and that in the narrow range of doping $\text{Cu}_x\text{Bi}_2\text{Se}_3$ becomes a superconductor below Tc 5 K. It is presumed that Cu intercalates into Van der Waals gaps in the tetradymite structure of layered Bi_2Se_3 , although this remains to be confirmed. We report on hole doping experiments on the naturally p-type Te-based TIs: thin films of Bi_2Te_3 and nanocrystalline plates of Sb_2Te_3 . The samples were iodine doped either during the growth or by the exposure to iodine vapor. Transport measurements on films indicate a very unusual T³ temperature dependence of longitudinal resistivity. It drops significantly below 30 K with decreasing temperature, although the drop appears arrested by a metal-insulator transition in the 300 mK range. Magnetization measurements on nanoplates indicate the development of large diamagnetic signal. These results will be discussed in comparison with the superconductivity obtained by Cu doping in Bi_2Se_3 . * Supported in part by NSF-DMR-1122594.

8:36AM H31.00004 Synthesis and Characterization of New Topological Insulators¹, KOUJI SEGAWA, Institute of Scientific and Industrial Research, Osaka University — In this talk, I will show detailed information on synthesizing process and characterization results of new topological insulator (TI) materials with interesting properties. Among the synthesized materials, TlBiSe_2 was the first ternary TI and has the largest bulk band gap [1], $\text{TlBi}(\text{S}_{1-x}\text{Se}_x)_2$ presents a topological phase transition with unexpected Dirac mass [2], BiTe_2Se presents a large bulk resistivity [3], and $\text{Bi}_{1.5}\text{Sb}_{0.5}\text{Te}_{1.7}\text{Se}_{1.3}$ has finally achieved the surface-dominated transport in bulk single crystals [4]. It is essentially easy to grow single crystals of all the chalcogenides above, because those compounds melt congruently at relatively low temperatures. Therefore, the melt-growth method is applicable if the raw materials are in a sealed condition, e.g., in a quartz tube. However, crucial techniques for obtaining high-quality samples vary between the systems. Besides the growth method, characterizations of the transport properties, ARPES, the X-ray diffraction, and quantitative chemical analysis will also be presented.

This work is in collaboration with A. A. Taskin, S. Sasaki, Zhi Ren, K. Eto, T. Minami, and Y. Ando (Osaka Univ.), and T. Sato, S. Souma, H. Guo, K. Sugawara, K. Kosaka and K. Nakayama, and T. Takahashi (Tohoku Univ.).

¹This work was supported by JSPS(KAKENHI 19674002 and 20371297, and Next-Generation World-Leading Researchers Program), MEXT (Innovative Area “Topological Quantum Phenomena” KAKENHI 22103004), and AFOSR (AOARD 10-4103).

9:12AM H31.00005 Transport properties of new Pb-based Topological Insulators¹, KAZUMA ETO, SATOSHI SASAKI, KOUJI SEGAWA, YOICHI ANDO, Institute of Scientific and Industrial Research, Osaka University — A topological insulator (TI) has a gapped insulating bulk and a gapless metallic surface. So far, such materials as $\text{Bi}_{1-x}\text{Sb}_x$, Bi_2Se_3 , and TlBiSe_2 are known to be TIs. Recently, several theoretical predictions have been made for new TI materials. In this work, we focus on the Pb-based ternary chalcogenides as new candidate TIs. We have grown a number of single crystals in the systems of Pb-Bi-Se, Pb-Bi-Te, Pb-Sb-Te and Pb-(Sb,Bi)-Te. After selecting single-phase samples, we measured the transport properties to check for their bulk-insulating nature. It was found that $\text{Pb}(\text{Sb}_x\text{Bi}_{1-x})_2\text{Te}_4$ shows a change in the carrier type at around $x=0.55$ as inferred both by the thermopower and by the Hall effect, but the temperature dependences of the resistivity remained metallic in all the samples studied. We discuss the prospect of making a bulk-insulating material in the Pb-based TIs.

¹This work was supported by JSPS (KAKENHI 23-4376 and NEXT Program), MEXT (Innovative Area “Topological Quantum Phenomena”) and AFOSR-AOARD. KE expresses his special thanks for the Research Fellowship for Young Scientists by JSPS.

9:24AM H31.00006 Millikelvin transport of high quality Bi_2Se_3 crystals at high pressure, KEVIN KIRSCHENBAUM, Center for Nanophysics and Advanced Materials, Physics Dept., University of Maryland, JASON JEFFRIES, NICHOLAS BUTCH, Lawrence Livermore National Laboratory, PAUL SYERS, Center for Nanophysics and Advanced Materials, Physics Dept., University of Maryland, JAMES HAMLIN, BRIAN MAPLE, University of California at San Diego, JOHNPIERRE PAGLIONE, Center for Nanophysics and Advanced Materials, Physics Dept., University of Maryland — In this study we present electronic transport in Bi_2Se_3 single crystals in a diamond anvil pressure cell. Reaching temperatures down to 20 mK and pressures exceeding 30 GPa we measure changes in electrical resistivity, magnetoresistance, and the Hall effect and discuss the results as they pertain to topologically interesting behavior.

9:36AM H31.00007 Entropy transport in Bi_2Se_3 , BENOÎT FAUQUÉ, AURELIE COLLAUDIN, KAMRAN BEHNIA, LPEM (UPMC-CNRS), ESPCI, 75005 Paris, France, NICK BUTCH, JOHNPIERRE PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park, Maryland 20742, USA, STEFFEN WIEDMANN, High Field Magnet Laboratory, Institute for Molecules and Materials, Radboud University Nijmegen, 6525 ED Nijmegen, The Netherlands — Bi_2Se_3 and Bi_2Te_3 are well known compounds in the thermoelectricity community as they present a high figure of merit [1]. Although the thermoelectric power of Bi_2Se_3 has been extensively studied at high temperature, little is known about its behaviour at the low temperature limit. In this presentation, we will report the results of our entropy measurement of Bi_2Se_3 at low temperature and high magnetic field for a bulk carrier concentration from 10^{17}cm^{-3} to 10^{19}cm^{-3} . In all compounds we show significant quantum oscillations in the Seebeck and Nernst responses. Based on the bulk Fermi surface, we propose a simple description of the entropy transport measurement in Bi_2Se_3 (in the range of concentrations studied). Indeed, Bi_2Se_3 (non compensated system) appears as a complementary system of bismuth [2] and graphite [3] (compensated systems) to understand the entropy transport in the low carrier concentration limit.

9:48AM H31.00008 Search and Design of Topological Insulators by High-throughput Method, KESONG YANG, WAHYU SETYAWAN, SHIDONG WANG, Department of Mechanical Engineering and Materials Science, Duke University, JEFF MULLLEN, MARCO BUONGIORNO-NARDELLI, Department of Physics, North Carolina State University, STEFANO CURTAROLO, Department of Mechanical Engineering and Materials Science, Duke University, DUKE TEAM, NCSU TEAM — Topological insulators (TIs) have attracted enormous interest because of their novel surface conduction effects which are protected by time-reversal symmetry. A high-purity TI with a highly insulating bulk is necessary to realize the potential practical applications of this class of materials. Therefore, numerous attempts are being made to search for TIs with desired properties (e.g., a large band gap and amenability to high-quality crystal growth). In this presentation, we will introduce an effective high-throughput approach to search and design TIs from a vast electronic structure database such as Inorganic Crystal Structure Database (ICSD) and Heusler alloys.

10:00AM H31.00009 Effects of Intrinsic Defects on Topological Insulator Behavior: Theory and Experiments on Ternary Tetradymite Compounds¹, DUANE D. JOHNSON, LIN-LIN WANG, AFTAB ALAM, MIANLIANG HUANG, SRINIVASA THIMMAIAH, TOM LOGRASSO, ADAM KAMINSKI, None, PAUL C. CANFIELD, Division of Materials Science and Engineering, Ames Laboratory and Iowa State University — Ternary tetradymites $\text{Bi}_2\text{Te}_{3-x}\text{Se}_x$ are predicted to be topological insulators via density functional theory (DFT) surface band structure calculations. Experimentally, we find that Bi_2Se_3 and Bi_2Te_3 form a continuous solid solution at the two non-equivalent group VI sites with different site preferences for Se and Te. The DFT formation energies for ordered and partially ordered compounds agree well with experimental data. Importantly, we calculated the intrinsic defect formation energies of binary and ternary tetradymites, and find they correlate well with the bulk conductivity measurement. Angle resolved photoemission spectroscopy confirms the existence of the Dirac cone in the surface band of $\text{Bi}_2\text{Te}_2\text{Se}$.

¹Supported by DE-AC02-07CH11358 at the Ames Laboratory operated by Iowa State University

10:12AM H31.00010 Transport properties of chalcogenide and related topological insulator bulk crystals, R.B. LILLIANFELD, HELIN CAO, TAI-LUNG WU, IREK MIOTKOWSKI, YONG P. CHEN, Purdue University — Three-dimensional (3D) topological insulators (TIs) have attracted strong theoretical and experimental interest in the condensed matter community. We have used the Bridgman method to synthesize various chalcogenide and related 3D TI crystals. We present an experimental survey of a group of binary, tertiary, and quaternary bulk crystals of various compositions of Bi, Sb, Ge, Se, Te, and S. Our survey includes systems without intentional doping, as well as systems doped with magnetic and non-magnetic impurities. We present magnetotransport data over a range of temperatures. We also measure thin films exfoliated from these bulk crystals to examine efficacy of carrier modulation through an applied gate voltage. We discuss the results of these measurements in the context of TI properties, with the ultimate goal of identifying systems that display electronic transport properties consistent with an insulating bulk and spin-helical Dirac fermion surface states.

10:24AM H31.00011 Bulk Excitations in single crystal Bi_2Se_3 : Electron Energy Loss Spectroscopy Study, SZ-CHIAN LIQU, F.T. HUANG, R. SANKAR, M.-W. CHU, F.C. CHOU, C.H. CHEN, Center for Condensed Matter Sciences, National Taiwan University, CENTER FOR CONDENSED MATTER SCIENCES, NATIONAL TAIWAN UNIVERSITY COLLABORATION — Bi_2Se_3 with larger figure of merit has been used in room-temperature thermoelectric applications. Furthermore, it is also one of a handful known topological insulators. Most of recent studies were focused on the topological surface states of Bi_2Se_3 while few of them studied the electronic excitations of bulk Bi_2Se_3 . Here, we report studies of electronic excitations of single-crystal Bi_2Se_3 by electron energy-loss spectroscopy (EELS). EELS spectrum in bulk Bi_2Se_3 reveals several spectral features at ~ 7 , ~ 16.8 , ~ 26.4 and ~ 28.4 eV. The peaks at ~ 26.4 and ~ 28.4 eV are due to excitations from Bi 5d electrons. The ~ 7 and ~ 16.8 eV peaks are easily identified as bulk-plasmon excitations according to the frequency-dependent complex dielectric function derived from experimental spectrum with Kramers-Krönig analysis. Furthermore, momentum (q)-dependent EELS spectra along [110], [300] and [001] directions were also performed in this study. When momentum transfer q is parallel [110] and [300] directions, the 16.8 eV-peak (bulk plasmon) significantly shift to higher energy (up to 23 eV) with increasing q values, while this peak shifts less than 1 eV when momentum transfer q is parallel to [001] direction, revealing the distinct anisotropy of bulk plasmon dispersions. Detailed characteristics of this anisotropic behavior will also be discussed.

10:36AM H31.00012 Insights on the electronic and vibrational properties of Bi(111) from first principles¹, MARISOL ALCANTARA ORTIGOZA, ROLF HEID, KLAUS-PETER BOHNEN, Karlsruhe Institute for Technology, IRINA SKLYADNEVA, Donostia International Physics Center, NEHA NAYYAR, TALAT S. RAHMAN, University of Central Florida, EUGENE CHULKOV, Donostia International Physics Center — Bi(111) is known to have surface electron carriers close to Γ as well as hole carriers at Γ and along the ΓM directions. The lattice dynamics of Bi(111) is however largely unknown. We investigate both the electronic structure and lattice dynamics of Bi(111) films via density-functional-theory and density-functional-perturbation-theory calculations taking into account the spin-orbit coupling (SOC). While the splitting of the branches is dominated by the SOC almost everywhere along the ΓM direction, around the zone boundary (M), the delocalized character of this state plays an important role. Reducing the thickness of a film decreases the band gap progressively. At ~ 3 -nm thickness, the highest valence band re-crosses the Fermi level and creates extra electron pockets. We find, however, that the lattice dynamics of Bi(111) is robust with respect to film thickness. Bi(111) has a number of “high-lying” surface modes in the optical band almost everywhere along the ΓKM and ΓM directions, most notably, a vertical mode slightly above the bulk band. Surface acoustic modes are also present as well as some “low frequency” optical modes in small regions of the zone. A comparison with recent measurements will be presented, as well as the possible implications on the electron-phonon coupling.

¹Work supported in part by DOE-BES grant DE-FG02-07ER46354

10:48AM H31.00013 Electron beam irradiation effect on Bi_2Se_3 topological insulator nanodevices¹, ZHIYONG WANG, PENG WEI, XINFEI LIU, JING SHI, Department of Physics and Astronomy, University of California Riverside — Nanofabrication is found to introduce excess charge carriers and results in a strong metallic state in Bi_2Se_3 . The uncontrolled carrier density causes the Fermi level to rise to the conduction band. To verify the effect of the electron beam lithography (EBL), we have measured the carrier density of Bi_2Se_3 nanodevices before and after EBL with a range of electron beam energies and doses and find that the Fermi level rises in both n- and p-type devices. To effectively control the position of the Fermi level, we have developed a nanofabrication-free technique for Bi_2Se_3 nanodevices, with which the initial state of the bulk materials can be well preserved. We deliberately choose p-type Ca-doped Bi_2Se_3 devices and systematically introduce more electrons using successive EBL. Resistivity temperature dependence shows that the Fermi level position is gradually tuned from the valence band into the band gap. Further fine tuning of the Fermi level is accomplished by applying a gate voltage to the devices. An increase of a factor of 10 in mobility has been observed in the device as the Fermi level is brought into the band gap, which is consistent with the suppressed backscattering of the surface states in topological insulators.

Session H32 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides - Conducting Domain Walls and Conduction Mechanisms 261

8:00AM H32.00001 Conduction of topologically-protected charged ferroelectric domain walls¹, WEIDA WU, YOICHI HORIBE, NARA LEE, S-W. CHEONG, Department of Physics and Astronomy and Rutgers Center for emergent materials, Rutgers University, Piscataway, NJ 08854 USA, JEFFERY GUEST, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, Illinois 60439 USA — We report on the observation of nanoscale conduction at ferroelectric domain walls in hexagonal HoMnO_3 protected by the topology of multiferroic vortices using *in situ* conductive atomic force microscopy, piezo-response force microscopy, and kelvin-probe force microscopy at low temperatures. Conductance spectra reveal that only negatively charged tail-to-tail walls, in contrast to positively charged head-to-head walls, exhibit ohmic-like conduction in addition to Schottky-like rectification. Our results pave the way for understanding the semiconducting properties of the domains and domain walls in small-gap ferroelectrics.

¹NSF-DMR-0844807, NSF-DMR-1104484 and DE-AC02-06CH11357

8:12AM H32.00002 Electrical dressing of domain walls in hexagonal ErMnO_3 , DENNIS MEIER, JAN SEIDEL, UC Berkeley, ANDRES CANO, European Synchrotron Radiation Facility, KRIS DELANEY, UC Santa Barbara, YU KUMAGAI, ETH Zuerich, MAXIM MOSTOVOY, University of Groningen, NICOLA A. SPALDIN, MANFRED FIEBIG, ETH Zuerich, RAMAMOORTHY RAMESH, UC Berkeley — Domain walls are natural mobile nanoscale objects that can exhibit structural, physical, and chemical properties which drastically differ from the surrounding bulk material. This applies to a large variety of phenomena including chemical/electrical transport, multiferroicity, or superconductivity. Unfortunately, in contrast to bulk materials, very little is known about involved length scales and control parameters when it comes to domain walls and experimental evidence is highly desirable. Here, we report on electrical dressing of trimerization-polarization walls in ErMnO_3 . Using piezoforce-response microscopy and conductive atomic force microscopy we reveal that two characteristic length scales are to be distinguished: A first one corresponding to the structural / ferroelectric changes occurring at the wall and a second one referring to the associated electric properties. Furthermore, we demonstrate the response of the electrically dressed walls to external electric fields and develop a model that explains this response. Our results are expected to generally apply to domain walls in ferroelectric semiconductors and provide new insight into the interplay of charge and lattice degrees of freedom at domain walls.

8:24AM H32.00003 Anisotropic conductance at improper ferroelectric domain walls, JAN SEIDEL, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA, DENNIS MEIER, Department of Physics, University of California, Berkeley, CA 94720, USA, ANDRES CANO, European Synchrotron Radiation Facility, 6 Rue Jules Horowitz, 38043 Grenoble, France, KRIS DELANEY, Materials Research Laboratory, University of California, Santa Barbara, CA 93106, USA, YU KUMAGAI, Department of Materials, ETH Zurich, Wolfgang-Pauli-Strasse, 8093 Zurich, Switzerland, MAXIM MOSTOVOY, Zernike Institute for Advanced Materials, University of Groningen, 9747 AG Groningen, The Netherlands, NICOLA SPALDIN, MANFRED FIEBIG, Department of Materials, ETH Zurich, Wolfgang-Pauli-Strasse, 8093 Zurich, Switzerland, RAMAMOORTHY RAMESH, Department of Materials Science and Engineering, University of California, Berkeley, CA 94720, USA — Domain walls in ferroelectric oxides hold great potential for the development of new device paradigms in oxide nanoelectronics due to their field-tunable functionality. They are also of fundamental interest for studies of ferroic and low-dimensional systems physics. We investigate the electronic conductance of ferroelectric domain walls in the improper ferroelectric ErMnO_3 . We show that the conductance is a continuously tunable function of the domain wall orientation, with a range of an order of magnitude. We explain the observed behavior using first-principles density functional and phenomenological theories, and relate it to the extraordinary stability of the inherent head-to-head and tail-to-tail domain walls in hexagonal manganites, which is a direct consequence of the improper ferroelectric character of these materials.

8:36AM H32.00004 Conduction at domain walls in insulating $\text{Pb}(\text{Zr}_{0.2}\text{Ti}_{0.8})\text{O}_3$ thin films, JILL GUYONNET, IAROSLAV GAPONENKO, STEFANO GARIGLIO, PATRYCJA PARUCH, DPMC, University of Geneva — Ferroic domain walls are intrinsically nanoscale and often present functional properties beyond those of their parent material. One of the most striking examples is the recent discovery of electrical conduction¹ at domain walls in multiferroic BiFeO_3 . Different scenarios have been proposed to explain the observed conduction, generally relating it to the complex nature of domain walls specific to BiFeO_3 .² Here, we report on scanning probe microscopy studies of domain-wall-specific conduction in thin films of tetragonal ferroelectric (PZT). Our measurements show nonlinear asymmetric current-voltage characteristics with strong thermal activation at $T > 150$ K. Moreover, the average current signals remain stable over the duration of measurement (up to four days). In light of recent transmission electron microscopy measurements at 180° domain walls in PZT,³ we discuss the possible conduction mechanisms, highlighting the role of electrode asymmetry and microscopic domain wall structure promoting local defect segregation.

8:48AM H32.00005 Interplay between polarization and conductivity in BiFeO_3 thin films, SAEEDH FAROKHIPOOR, BEATRIZ NOHEDA PINUAGA, Zernike Institute for Advanced Materials, Netherlands — BiFeO_3 (BFO) is a rhombohedrally distorted, ferroelectric, antiferromagnetic perovskite and one of the few room temperature multiferroics. We've previously reported on conduction at 71° domain walls in BFO thin films grown on SrRuO_3 -buffered SrTiO_3 substrates. For clarifying the origin of conductivity in domain/domain walls, the conduction mechanisms have been extensively studied. The large current regime is determined by Schottky emission from the tip. The migration of oxygen vacancies to the domain walls lowers the Schottky barrier heights at the interface with the metallic tip compared to that in the domains, which results in the observed difference of conductivity in domains and domain walls. In this work we investigate the tunability of the conductivity upon changes in the electrode's work function, as well as the interplay between polarization and conductivity in BFO thin films.

9:00AM H32.00006 Tunable Metallic Conductivity in Ferroelectric Nanodomains, P. MAKSYM-MOVYCH, Oak Ridge National Laboratory, Oak Ridge, TN, A.N. MOROZOVSKA, Institute for Semiconductor Physics, National Academy of Science of Ukraine, P. YU, Department of Materials Science and Engineering, University of California, Berkeley, CA, E.A. ELISEEV, Institute for Problems of Materials Science, National Academy of Science of Ukraine, Y.-H. CHU, Department of Materials Science and Engineering, National Chiao Tung University, R. RAMESH, Department of Materials Science and Engineering, University of California, Berkeley, CA, A.P. BADDORF, S.V. KALININ, Oak Ridge National Laboratory, Oak Ridge, TN — Domain wall conductivity in ferroelectric and multiferroic oxides is an essential example of new electronic properties created by topological defects. So far electron transport through domain walls in canonical BiFeO₃ and PbZr_{0.2}Ti_{0.8}O₃ (PZT) ferroelectrics has been dominated by thermally activated hopping, concealing the enabling physics and limiting potential applications. We will present a pioneering observation of metallic conductivity in nanoscale ferroelectric domains in PZT, that unambiguously identifies a new conduction channel created through the bulk of the oxide film [1]. From a corollary theoretical analysis, we conclude that metallic conductance is enabled by the interplay of charging and flexoelectric effects at tilted and curved walls of the nanodomain. Furthermore, both type and density of carriers can be tuned by manipulation of the order parameter. Thus, a new family of electronic properties may be found in multiferroic and topologically nanostructured complex oxides. [1] Maksymovych et al, *Nano Lett.* in review (2011). Research conducted at the Center for Nanophase Materials Sciences, sponsored by BES, U. S. DOE.

9:12AM H32.00007 Ultrafast p-d charge-transfer carrier dynamics of multiferroic BiFeO₃, Y.M. SHEU, S.A. TRUGMAN, Y.-S. PARK, Center for Integrated Nanotechnologies, LANL, Los Alamos, NM 87545, S.-W. CHEONG, Department of Physics and Astronomy, Rutgers University, NJ 08854, Q. JIA, A.J. TAYLOR, R.P. PRASANKUMAR, Center for Integrated Nanotechnologies, LANL, Los Alamos, NM 87545 — We report first comprehensive understanding of ultrafast carrier dynamics in bulk single crystal BiFeO₃. From a wavelength dependent optical pump-probe measurement, we find that the photoexcited carriers relax to the bottom of band through electron-phonon coupling with a ~ 1 ps time constant that does not significantly change across the antiferromagnetic transition. Following relaxation, carriers leave the conduction band or original excited electronic configuration and decay via radiative recombination, which is supported by our photoluminescence spectroscopy, reported for the first time.

9:24AM H32.00008 Photocurrent effect of epitaxial tetragonal-like BiFeO₃ thin film, KANGHYUN CHU, CHANG-SU WOO, SEUNG JIN KIM, Department of Physics, KAIST, JI HO SUNG, WONMO LEE, MOON-HO JO, Department of Materials Science and Engineering, POSTECH, CHAN-HO YANG, Department of Physics, KAIST — Photovoltaic effect in ferroelectrics has recently received many attentions due to potential applications related to optoelectronic devices and solar cells. Here we report photocurrent effect of highly elongated “tetragonal-like” BiFeO₃ thin films grown on LaAlO₃ (001) substrates using pulsed laser deposition technique. Spatially resolved photocurrent measurements are performed with varying photon wavelength and polarization. Being combined with local ferroelectric domain structure by piezoresponse force microscopy, the spatially resolved techniques make a pathway to explore inter-relation between electric polarization and photon polarization. This study might deepen our understating of light induced conduction phenomena in ferroelectrics.

9:36AM H32.00009 Intrinsic defects in BiFeO₃: Energetics and implication for magnetism, TULA R. PAUDEL, SITARAM S. JASWAL, EVGENY Y. TSYMBAL, University of Nebraska, Lincoln — We investigate energetics of the intrinsic defects in bulk multiferroic BiFeO₃ and explore their implication for magnetization in this compound using a first-principles approach based on density functional theory. We find that dominant defects in oxidizing conditions are Bi and Fe vacancies and in reducing conditions are O and Bi vacancies. When enforcing charge neutrality, the calculated carrier concentration shows that the BiFeO₃ grown in oxidizing conditions has p-type conductivity. The conductivity decreases with oxygen partial pressure and the material becomes insulating with tendency for n-type conductivity. We find that the Bi and Fe vacancies produce a magnetic moment of $\sim 1 \mu_B$ and $\sim 5 \mu_B$ per vacancy, respectively, for p-type BiFeO₃ and none for insulating BiFeO₃. O vacancies do not introduce any moment for both p-type and insulating BiFeO₃. Calculated magnetic moments due to intrinsic defects are consistent with those reported experimentally for the bulk BiFeO₃, however do not explain the large magnetization observed in some experiments on thin-film BiFeO₃.

9:48AM H32.00010 Dielectric screening enhanced Hall mobility in doped ferroelectrics, WOLTER SIEMONS, MICHAEL A. MCGUIRE, VALENTINO R. COOPER, MICHAEL D. BIEGALSKI, ILIA N. IVANOV, GERALD E. JELLISON, LYNN A. BOATNER, BRIAN C. SALES, HANS M. CHRISTEN, Oak Ridge National Laboratory — A low electron mobility is the key limitation that prevents widespread device applications of complex oxide materials. However, in some perovskites, for example SrTiO₃ and KTaO₃, high mobilities in excess of $10,000 \text{ cm}^2 \text{ s}^{-1} \text{ V}^{-1}$ are measured. Together with this dramatic increase in mobility as temperature is lowered, their dielectric constants also increase from a few hundred at room temperature to near 20,000 at low temperatures, suggesting a correlation between the dielectric constant and the mobility. By using electron-doped ferroelectric crystals of composition KTa_{1-x}Nb_xO₃, where the ferroelectric transition temperature can be tuned by changing the Ta:Nb ratio, we demonstrate an enhancement of the Hall mobility by a factor of 2-3 at the Curie temperature up to room temperature. We conclude that the mobility in these doped ferroelectrics peaks at the Curie temperature due to the increased dielectric constant, which reduces charge carrier scattering by impurities. Enhanced mobility could result in faster oxide transistors, boost the performance of thermoelectric devices, and enable more efficient photovoltaic materials. Supported by ORNL's LDRD program (W.S., H.M.C., V.C., G.E.J.), U.S. DOE, BES, MSED (M.A.M., B.C.S.) and SUFD (M.D.B., I.N.I.).

10:00AM H32.00011 The persistence of ferroelectric distortions in electron-doped BaTiO₃: microscopic origins and critical behavior, YONG WANG, JOHN BURTON, SITARAM JASWAL, EVGENY TSYMBAL, University of Nebraska - Lincoln — To explore possible novel applications of the prototypical ferroelectric oxides we perform theoretical studies of electron-doping in BaTiO₃. The presence of conduction electrons in a ferroelectric opens the possibility of bi-stable behavior directly in a conducting material which may lead to new functionalities. It is known, however, that conduction electrons screen the long range Coulomb interactions responsible for polar instabilities. Interestingly though, our first-principle density functional calculations reveal that ferroelectric distortions can persist in electron-doped BaTiO₃ up to 0.01 e/unit cell, consistent with experimental results [1], suggesting that ferroelectricity and conductivity can coexist. To elucidate the competition between the long range Coulomb interactions and the short range bonding effects we have developed an adequate electrostatic model. Using this model, we reproduce the polarization vs. doping behavior obtained from first-principles and derive an analytical expression for the critical doping above which ferroelectric distortions disappear. [1] T. Kolodiazhnyi et al, Phys. Rev. Lett. 104, 147602 (2010).

10:12AM H32.00012 Multiphysics model of semiconducting ferroelectrics and its application to memory devices, NATHANIEL NG, KAUSHIK BHATTACHARYA, California Institute of Technology — Ferroelectrics are used in many electronic devices, in particular as transistors for ferroelectric memory devices. The behavior of these materials are often described via the classic time-dependent Ginzburg Landau model, where they are treated as insulators. However, it is well known that ferroelectrics are in fact wide band-gap semiconductors. It then follows that capturing the key aspects of semiconductor physics—band bending at the interface, Fermi levels, depletion layers, require ferroelectrics to be treated as semiconductors. In this work, we introduce a model that addresses these difficulties, yet at the same time is consistent with both the time-dependent Ginzburg Landau model and the classic drift-diffusion model in semiconductors. Unlike other models, our model makes no a priori assumptions on the space charge and polarization distributions and is not restricted to equilibrium profiles. We first demonstrate that charge carriers migrate to neutralize electric fields across 90° domain walls. Finally, we attempt a full simulation of a ferroelectric transistor and model current flow, electric field and polarization distributions.

10:24AM H32.00013 Conduction mechanism in $\text{BiFeO}_3\text{-CoFe}_2\text{O}_4$ columnar nanostructure, YI-CHUN CHEN, Department of Physics, National Cheng Kung University, YING-HUI HEISH, CHEN-WEI LIANG, Department of Materials Science and Engineering, National Chiao Tung University, JIA-MING LIOU, Department of Physics, National Cheng Kung University, YA-PING CHIU, Department of Physics, National Sun Yat-Sen University, QING HE, Advanced Light Source, Lawrence Berkeley National Laboratory, QIAN ZHAN, Department of Materials Physics and Chemistry, University of Science and Technology Beijing, YING-HAO CHU, Department of Materials Science and Engineering, National Chiao Tung University — Multiferroic materials, which possess interaction between more than one ferroic ordering parameters, had attracted great scientific and technological interests. Among the bi-phase magneto-electric nanostructures, $\text{BiFeO}_3\text{-CoFe}_2\text{O}_4$ (BFO-CFO) is a model system with ferroelectricity and ferrimagnetism coupling to each other through stress mediation. In this study, we investigated the electron transport behavior and the leakage-current mechanism in high quality nano-composite BFO-CFO thin films. The CFO nanopillars were heteroepitaxially embedded in a BFO matrix grown on SrTiO_3 substrates. Macroscopic vertical transport result showed the interface limit model was the dominant mechanism of the large leakage. Local conduction in epitaxial BFO-CFO nanostructures was studied by conducting atomic force microscope (C-AFM) while the nature of band structure variation was demonstrated by scanning tunneling microscope (STM). This study provides a basic explanation of leakage mechanism in self-assembled composite material system.

10:36AM H32.00014 Current-Controlled Negative Differential Resistance Due to Joule Heating In TiO_2 , A.M. BRATKOVSKY, Hewlett-Packard Laboratories, Palo Alto, A.S. ALEXANDROV, S.E. SAVEL'EV, Loughborough Inst. Technology, UK, D.B. STRUKOV, UC Santa Barbara, Santa Barbara, R.S. WILLIAMS, Hewlett-Packard Laboratories, Palo Alto — We show that Joule heating causes current-controlled negative differential resistance (CC-NDR) in TiO_2 memristive systems by constructing an analytical model of the current-voltage characteristics based on polaronic transport for Ohm's law and Newton's law of cooling and fitting this model to experimental data. This threshold switching is the "soft breakdown" observed during electroforming in TiO_2 and other transition-metal oxide based memristors, as well as a precursor to "ON" or "SET" switching of unipolar memristors from their high to their low resistance states. The shape of the V-I curves is a sensitive indicator of the nature of the polaronic conduction, which apparently follows an adiabatic regime [1].

[1] A.S. Alexandrov, A.M. Bratkovsky, B. Bridle, S.E. Savel'ev, D. Strukov, and R.S. Williams, Appl. Phys. Lett. 99, xxx (2011).

10:48AM H32.00015 Physical and Electrical Characterization of HfO_2 , HfSiO_4 , and ZrSiO_4 Memristors Based on Sol-Gel Synthesis, J.L. TEDESCO, WALTER ZHENG, S. POOKPANRATANA, A.A. HERZING, P.P. KAVURI, O.A. KIRILLOV, N.V. NGUYEN, C.A. RICHTER, National Institute of Standards and Technology — To date, most memristive devices have been fabricated by using TiO_2 or TaO_x dielectric films. In order to explore the possible advantages of other high- κ dielectrics in memristive devices, memristors were fabricated with HfO_2 , HfSiO_4 , and ZrSiO_4 layers synthesized from sol-gels. X-ray photoelectron spectroscopy measurements are consistent with reported spectra of HfO_2 , HfSiO_4 , and ZrSiO_4 films, but contain significant amounts of carbon. The films also have low densities and are flat, as measured by vacuum ultraviolet spectroscopic ellipsometry and optical profilometry measurements, respectively. This flat morphology is different from previous solution-processed dielectric films that exhibited rough surfaces [1]. Transmission electron microscopy measurements were also used to characterize these dielectric films. Current-voltage measurements indicate that, despite the contamination, the memristors exhibit nonvolatile bipolar resistive switching. The retention times measured for these memristors are $\sim 10^6$ s. Capacitance and conductance measurements of these memristors indicate differences between the ON and OFF states, which will be discussed further. [1] J.L. Tedesco, et al., ECS Trans. 35, 111 (2011).

Tuesday, February 28, 2012 8:00AM - 11:00AM – Session H33 GERA FIAP: Focus Session: Scaleable Technologies for Photovoltaics 106

8:00AM H33.00001 Solar Glitter – Microsystems Enabled Photovoltaics, GREGORY N. NIELSON, Sandia National Laboratories — Many products have significantly benefitted from, or been enabled by, the ability to manufacture structures at an ever decreasing length scale. Obvious examples of this include integrated circuits, flat panel displays, micro-scale sensors, and LED lighting. These industries have benefited from length scale effects in terms of improved performance, reduced cost, or new functionality (or a combination of these). In a similar manner, we are working to take advantage of length scale effects that exist within solar photovoltaic (PV) systems. While this is a significant step away from traditional approaches to solar power systems, the benefits in terms of new functionality, improved performance, and reduced cost for solar power are compelling. We are exploring scale effects that result from the size of the solar cells within the system. We have developed unique cells of both crystalline silicon and III-V materials that are very thin (5-20 microns thick) and have very small lateral dimensions (on the order of hundreds of microns across). These cells minimize the amount of expensive semiconductor material required for the system, allow improved cell performance, and provide an expanded design space for both module and system concepts allowing optimized power output and reduced module and balance of system costs. Furthermore, the small size of the cells allows for unique high-efficiency, high-flexibility PV panels and new building-integrated PV options that are currently unavailable. These benefits provide a pathway for PV power to become cost competitive with grid power and allow unique power solutions independent of grid power.

8:36AM H33.00002 Perspective on the Practical Limits and Roadmap for Nanostructured Photovoltaics, RICHARD R. LUNT, Michigan State University, VLADIMIR BULOVIC, Massachusetts Institute of Technology — The practical efficiency limits for nanostructured photovoltaics including organic small molecule, dye-sensitized, polymer, and colloidal-quantum-dot architectures are assessed *a posteriori*. Five decades since Shockley and Queisser derived the theoretical power conversion efficiency limit of single-junction photovoltaic cells, researchers have still not demonstrated such high performance for any photovoltaic device system. Hence, in evaluating the achievable performance of a comparatively new photovoltaic technologies, such as nanostructured PVs, it is prudent to estimate the upper limit of achievable efficiencies based on trends of the best technical demonstrations across the nanostructured platforms. This analysis is utilized to give a clear perspective on the potential market viability of these technologies in the near future and outline the challenges necessary to overcome this threshold. These technologies are compared and contrasted to provide an overview for the potential of each for reducing thermal losses with "Third Generation" concepts accessible to nanostructured PVs that can subsequently impact cost structures.

8:48AM H33.00003 Role of radiative recombination in 1 eV GaInNAs solar cells, IAN R. SELLERS, University of Oklahoma, WEI-SIN TAN, KATHERINE SMITH, STEPHEN DAY, STEWART HOOPER, MATTHIAS KAUER, Sharp Laboratories of Europe — High quality GaInNAs p-i-n solar cells with depletion widths in excess of $1\mu\text{m}$ for material absorbing in the practically important 1eV band gap regime are presented [1]. This is achieved through optimization of post-growth rapid thermal annealing at a temperature of $\sim 910^\circ\text{C}$. Despite the improvements in material quality evidenced by a low background impurity concentration and improved minority carrier collection, the external quantum efficiency remains limited to $\sim 50\%$. This is attributed to losses due to efficient radiative recombination in the bulk GaInNAs intrinsic region enhanced via localization of carriers in alloy fluctuations.

[1] Sellers *et al.* Applied Physics Letters 99, 151111 (2011)

9:00AM H33.00004 Device architectures for efficient photovoltaics from hard-to-dope semiconductors, STEVEN BYRNES, WILLIAM REGAN, WILL GANNETT, ALEX ZETTL, FENG WANG, Department of Physics, University of California at Berkeley, Berkeley, CA, and Materials Sciences Division, Lawrence Berkeley National Laboratory — In the search for cheap and efficient next-generation solar cells, much attention and effort has focused on semiconductor absorber materials which are difficult to dope both p and n, because of self-compensation, trap creation, or other effects. Such materials include oxides, sulfides, nanoparticles, organics, and so on. Even when the material itself has desirable electrical and optical properties for photovoltaic performance, the lack of a p-n homojunction architecture hampers device efficiency. Heterojunctions are a frequent solution, but compatible semiconductors are often unavailable or suboptimal. Therefore, we have explored new, cost-effective device architectures that promise performance comparable to a p-n homojunction, but which require neither bipolar doping nor compatible materials for heterojunctions. These architectures have the potential to bring emerging hard-to-dope semiconductors into technological and commercial relevance.

9:12AM H33.00005 Efficiency Analysis and Demonstration of Split-Junction Photovoltaic Solar Cells, HAN CHEN, EMIR MAGDEN, CHANDLER DOWNS, THOMAS VANDERVELDE, Tufts University — Recently, it has been proposed that separating solar radiation with a split-junction solar cell can result in higher overall conversion efficiencies, than are possible for monolithic designs. This hypothesis is investigated by simulating and analyzing 2+1 split junction cells for efficiency comparisons with theoretical and actual multi-junction cells. Ideal band-gaps for simultaneously operating photovoltaic and thermophotovoltaic cells have been determined. With the new configuration, it is shown that the efficiency achievements previously set by Ge/InGaAs/InGaP cells can be surpassed. A total increase in power output is observed during field tests using a Cassegrain split-junction concentrator with a dichroic lens (1.1 micron cutoff wavelength). Proposed benefits such as reduced heat load on the solar cell and ease of lattice constant matching in cell design are also validated. Additionally, with the flexibility of the concentrator assembly, it is shown that similar split-junction configurations with matching dichroic lenses allow for significant improvements in high efficiency solar cell technology.

9:24AM H33.00006 Electronic structure and optical spectra of Bulk and Nanocrystalline CuInS_2 ¹, MICHAEL MEHL, ALEXANDER EFROS, Naval Research Laboratory, Washington DC, ANDREW SHABAEV, George Mason University, Fairfax VA — Chalcopyrite CuInS_2 is a promising candidate for semiconductor photovoltaic devices. Here we study the behavior of the electronic structure and optical spectra of nanocrystalline CuInS_2 . We determine the bulk band structure using the HSE06 Hybrid Density Functional as implemented in the Vienna Ab-initio Simulation Package (VASP). We find an equilibrium structure in good agreement with experiment, and a direct band gap of 1.2 eV, as compared to the experimental value of 1.5 eV. The band gap is extremely sensitive to the position of the sulfur atoms, which suggests that it can be controlled in part by the doping of the In site with Ga. CuInS_2 is nearly cubic, so we fit the first-principles band structure to a k.p Hamiltonian with invariants consistent with the departure for cubic symmetry. This Hamiltonian is then used to describe the hole spectra in a CuInS_2 nanocrystal. We show the symmetry breaking inherent in the chalcopyrite structure can activate the optically passive ground hole state in the nanocrystal, and discuss the resulting optical behavior of the nanocrystal.

¹Work supported by the US Office of Naval Research

9:36AM H33.00007 Impact of a high resistivity transparent (HRT) layer on ultra-thin CdTe devices¹, HASITHA MAHABADUGE, KRISTOPHER WIELAND, The University of Toledo, ALVIN COMPAAN, The University of Toledo; Xunlight 26 Solar, LLC — Pushing the limits of the absorber layer thickness to submicron levels without compromising the efficiency in CdTe devices is important for several reasons. Reducing the thickness of the CdTe layer can increase the manufacturing speed and lower the material usage, production time, cost and energy needed for production. Thickness fluctuations in these submicron devices can lead to shunting when these fluctuations are comparable to the absorber layer thickness. Introducing a high resistivity transparent (HRT) layer in the device structure can reduce such shunting. We find that the impact of the HRT layer is higher for ultra-thin absorber layers. In this study, the effect of using sputtered ZnO as the HRT layer was investigated for devices with a 0.2 μm CdTe layer. Our results show a 40% increase in efficiency in the CdTe devices with the HRT layer compared to the devices without the HRT layer. The increase in efficiency is primarily from improved fill factor due to an increase in shunt resistance from 0.15 kohm-cm² to 0.32 kohm-cm². As a result of increased shunt resistance there is an increase in the efficiency as well as a substantial increase in the yield for small dot cells.

9:48AM H33.00008 Solution-based synthesis of crystalline silicon thin films from liquid silane inks, GANJIGUNTE R.S. IYER, GURUVENKET S., JUSTIN M. HOEY, KENNETH J. ANDERSON, DOUGLAS L. SCHULZ, ORVEN F. SWENSON, S. ELANGO VAN, P. BOUDJOUK, ERIK K. HOBBIE, North Dakota State University — Silicon (Si) dominates the photovoltaics industry and there is a need for new approaches that can significantly reduce fabrication cost. In this context, we report a non-vacuum, solution-based process for the synthesis of crystalline silicon (c-Si) thin films from liquid cyclohexasilane (CHS) in a platform that is readily applicable to large-area flexible devices. UV-polymerization during spin coating leads to the formation of thin films, which were crystallized via thermal and laser annealing. Structural changes in the films were examined using SEM, AFM and Raman spectroscopy. Subsequent chemical annealing through atmospheric-pressure hydrogen plasma treatment led to a four-decade enhancement in film conductivity, which we attribute to a disorder-order transition in a bonded Si network.

10:00AM H33.00009 Device modeling for organic solar cells¹, LUNMEI HUANG, ROBERT KRASNY, Department of Mathematics, University of Michigan, KYLE RENSHAW, Department of Physics, University of Michigan, STEPHEN FORREST, Department of Physics, Department of Electrical Engineering and Computer Science, and Materials Science and Engineering, University of Michigan — Organic solar cells (OSCs) are expected to play an important role in addressing our future energy needs due to their low cost and low processing requirements compared to inorganic solar cells (ISCs). However the efficiency of OSCs is still too low in comparison with ISCs for widespread applications. The biggest loss of quantum efficiency (QE) in OSCs is due to the limited free carrier generation occurring at the donor-acceptor (D-A) interface. Excitons (bound electron-hole pairs) are generated in the bulk by photo-absorption, but only a portion of them reach the D-A interface where they can dissociate into free charge carriers. Therefore, better understanding and control of exciton diffusion, free carrier generation and recombination are critical in order to improve QE for OSCs. To elucidate the physics of OSCs and aid in experimental studies, we developed a drift-diffusion model to describe the dynamics of excitons and free charge carriers. Our model predicts the performance of OSC devices by calculating their QE and current-voltage curves (I-V), as well as many other important physical quantities, such as the internal electric field, and the concentration and flux of excitons and free carriers. The effect of exciton and free carrier mobility, device temperature, and layer thickness, will be discussed. Furthermore, the exciton dissociation mechanism widely described by Onsager's model, will be investigated in detail.

10:12AM H33.00010 Combined Photo and Thermionic Energy Conversion with Doped Diamond Electron Emitters, TIANYIN SUN, FRANZ KOECK, ROBERT NEMANICH, Arizona State University — Conversion of heat into electrical energy has been demonstrated using low effective work function diamond films achieved with n-type doping and surface hydrogen termination. Recently, visible light photo-electron emission has been demonstrated from the same diamond, and this work suggests that this effect could be utilized for a new approach to solar energy conversion namely combined photo and thermionic energy conversion. This work presents a spectroscopic study of photo- and thermionic electron emission from nitrogen doped diamond films on silicon substrates. In this experiment the diamond samples are heated from 100 °C to 500 °C, while being illuminated with light from 240 to 600 nm. The emission spectra show a significant increase of photo-emission intensity with elevated temperature and a lowering of the effective work function. The results are discussed in terms of the photo and thermal excitation, the carrier transport and the electron statistics. The results indicate the potential of diamond films in a combined photo and thermionic energy conversion solar cell. This research is supported through the Office of Naval Research.

10:24AM H33.00011 Metal nanoparticle-graphene superstructures as electrodes for solar cells¹, ANNA ZANIEWSKI, MARIA SCHRIVER, GLORIA LEE, A. ZETTL, Dept. of Physics, UC Berkeley — We present metal nanoparticle and graphene superstructures as a potential electrode for solar cells. We show the effect of various metallic nanoparticles on the work function, sheet resistance, and optical properties of graphene layers. The geometries studied include nanoparticles on single layer graphene, and embedded in a graphene sandwich. We discuss the application of these electrodes to organic and silicon solar cells.

10:36AM H33.00012 Study of the crystalline phases in paste coating deposition of CIGS, IVAN DAVOLI, IVAN COLANTONI, Università di Roma Tor Vergata, Dipartimento di Fisica, SURFACE ANALYSES LABORATORY COLLABORATION — One or two microns of CIGS can absorb most of the incident solar radiation because $\text{CuIn}_{1-x}\text{Ga}_x\text{Se}_2$ have a direct band gap with a high absorption coefficient. The theoretical predictions explain that the optimum photovoltaic performance should be provided by a high gallium concentration, but experimentally is observed that above 30% of Ga the efficiency is reduced. This contradictory behaviour is not completely understood. Using paste coating technique for CIGS deposition, we have recently shown a strong correlation among Ga concentration, structural properties and compound stoichiometry. The desired stoichiometric compound will be obtained varying the concentration of the basic elements in the paste. Our diffraction data show that the maximum of the crystalline phase is reached when CIGS have a Ga concentration higher. Furthermore the SEM EDX quantitative analysis performed on the same samples have shown the presence of different phases. Such a phases separation find a theoretical explanation as ODC (Ordered Defect Compound) in Cu-poor system. X-ray absorption spectroscopy reveals the structure around a specific atomic species and allow us to understand the type of phases in chalcopyrite structure.

10:48AM H33.00013 A large-area, LED-based spectral response measurement system for solar PV device characterization, BEHRANG HAMADANI, JOHN ROLLER, HOWARD YOON, BRIAN DOUGHERTY, National Institute of Standards and Technology — Accurate and reliable measurement of the spectral responsivity (SR) of a solar cell is an important step in evaluating the electrical performance of competing photovoltaic (PV) technologies. We have investigated ways to measure the spectral responsivity, and hence the external quantum efficiency, of solar cells using measurement techniques that employ light emitting diodes (LEDs). Our setup includes one or more plates of compactly-installed, high-powered LEDs each containing up to 32 different LEDs that span the wavelength range of 375 nm to 1200 nm. Each LED plate is placed at the entrance of a tapered, highly reflective light guide for light mixing and large-area projection. Two unique measurement techniques have been investigated at NIST. The first technique consists of an LED sweep algorithm where a pulsed signal is applied to a given LED and the photogenerated current from the device under test is recorded using a lock-in technique. In the second SR technique, 32 variable-frequency, pulsed signals are applied to all LEDs at the same time, while recording the photogenerated current by a spectrum analyzer in the frequency domain. We will describe the uniqueness and advantages offered by each technique in detail and compare the accuracy of the two methods. A scheme for providing light bias and its impact on the SR measurements will be reported.

Tuesday, February 28, 2012 8:00AM - 11:00AM –
Session H34 DCP: Focus Session: Nano II: Nanoscale Materials and Properties I 107A

8:00AM H34.00001 Nanoelectronics Meets Biology, CHARLES LIEBER, Harvard University, Dept. of Chemistry and Chemical Biology — Nanoscale materials enable unique opportunities at the interface between the physical and life sciences, and the interface between nanoelectronic devices and biological systems makes possible communication between these two diverse systems at the length scale relevant to biological function. In this presentation, the development of nanowire nanoelectronic devices and their application as powerful tools for the life sciences will be discussed. First, a brief introduction to nanowire nanoelectronic devices as well as comparisons to other electrophysiological tools will be presented to illuminate the unique strengths and opportunities enabled at the nanoscale. Second, illustration of detection capabilities including signal-to-noise and applications for real-time label-free detection of biochemical markers down to the level of single molecules will be described. Third, the use of nanowire nanoelectronics for building interfaces to cells and tissue will be reviewed. Multiplexed measurements made from nanowire devices fabricated on flexible and transparent substrates recording signal propagation across cultured cells, acute tissue slices and intact organs will be illustrated, including quantitative analysis of the high simultaneous spatial and temporal resolution achieved with these nanodevices. Specific examples of subcellular and near point detection of extracellular potential will be used to illustrate the unique capabilities, such as recording localized potential changes due to neuronal activities simultaneously across many length scales, which provide key information for functional neural circuit studies. Last, emerging opportunities for the creation of powerful new probes based on controlled synthesis and/or bottom-up assembly of nanomaterials will be described with an emphasis on nanowire probes demonstrating the first intracellular transistor recordings, and the development of “cyborg” tissue. The prospects for blurring the distinction between nanoelectronic and living systems in the future will be highlighted.

8:36AM H34.00002 Charge Retention by Monodisperse Gold Clusters on Surfaces Prepared Using Soft Landing of Mass Selected Ions, GRANT JOHNSON, Pacific Northwest National Laboratory, THOMAS PRIEST, University of Louisville, JULIA LASKIN, Pacific Northwest National Laboratory — Monodisperse gold clusters have been prepared on surfaces in different charge states through soft landing of mass-selected ions. Gold clusters were synthesized in methanol solution by reduction of a gold precursor with a weak reducing agent in the presence of a diphosphine capping ligand. Electrospray ionization was used to introduce the clusters into the gas-phase and mass-selection was employed to isolate a single ionic cluster species which was delivered to surfaces at well controlled kinetic energies. Using in-situ time of flight secondary ion mass spectrometry (SIMS) it is demonstrated that the cluster retains its 3+ charge state when soft landed onto the surface of a fluorinated self assembled monolayer on gold. In contrast, when deposited onto carboxylic acid terminated and conventional alkyl thiol surfaces on gold the clusters exhibit larger relative abundances of the 2+ and 1+ charge states, respectively. The kinetics of charge reduction on the surface have been investigated using in-situ Fourier Transform Ion Cyclotron Resonance SIMS. It is shown that an extremely slow interfacial charge reduction occurs on the fluorinated monolayer surface while an almost instantaneous neutralization takes place on the surface of the alkyl thiol monolayer. Our results demonstrate that the size and charge state of small gold clusters on surfaces, both of which exert a dramatic influence on their chemical and physical properties, may be tuned through soft landing of mass-selected ions onto selected substrates.

8:48AM H34.00003 Transitioning the Superfluid Helium Droplet Assembly into a Technology: Synthesis of Nanometer Scale Energetic Films using SHeDA, S.B. EMERY, K.B. RIDER, B.K. LITTLE, R. CLEAVER, C.M. LINDSAY, Air Force Research Laboratory Energetic Materials Branch — Since the pioneering work of the Toennies, Scoles, and Northby groups in the early 1990's, dozen of instruments around the world have been constructed to produce and study beams of superfluid helium nanodroplets. The technique has been exploited to shed light on a wide range of topics in chemical physics such as atomic scale manifestations of superfluidity, chemistry at ultra-low temperatures, and the assembly of exotic Van der Waals complexes to name a few. The helium droplet method has been considered for more applied use as a tool for isotope enrichment, low-fragmentation ionization mass spectrometry, and synthesizing/depositing core-shell spintronic nanoparticles. Indeed, the helium droplet methodology is in the midst of transitioning from a novel cryogenic nano-scale matrix in which to perform fundamental research into a technology for synthesizing, characterizing, and manipulating material. This talk describes our efforts to engineer a robust, user-friendly, broadly-tunable helium droplet apparatus capable of synthesizing composite nanoparticles and depositing them into films. This device is now being used to assemble and deposit metallic nanoparticles, and the efficiency of the process is being investigated. The physical details of the design, performance of the instrument, and our progress at understanding the deposition process will be presented. Distro 96ABW-2011-0266.

9:00AM H34.00004 Screened Charge Model in the Treatment of Electrostatic Interactions¹, BO WANG, HANNAH LEVERENTZ, Department of Chemistry, University of Minnesota, DONALD TRUHLAR, Department of Chemistry and Supercomputing Institute, University of Minnesota — Partial atomic charges play an important role in molecular simulations of complex systems, and they are widely used to compute the electrostatic interactions in various methods. We propose a screened charge model to include charge penetration and screening effects in electrostatic modeling. In the screened charge model, the atomic charge density of an atom in a molecule is represented by a spherical smeared charge plus a point charge at the nucleus. The new model is illustrated for the electronically embedded combined quantum mechanical and molecular mechanical (QM/MM) calculations and for the electrostatically embedded many-body (EE-MB) method. For a test set of 40 complexes, the mean unsigned error of QM/MM electrostatic interactions between QM and MM regions is reduced from 8.1 to 2.8 kcal/mol and that for QM/MM induction interactions from 1.9 to 1.4 kcal/mol. In a test of five water hexamers, the mean unsigned error of the EE-MB binding energies of the clusters is decreased by a factor of 2 at both the pairwise additive (PA) and three-body (3B) levels. Moreover, we have found that the charges derived by fitting electrostatic potentials with the screened charge method are less sensitive to the positions of the fitting points, and the quality of the fit to the electrostatics is improved.

9:12AM H34.00005 Magnetic Superatom Assemblies and their Transport Properties¹, LIN ZHU, J. ULISES REVELES, V. MENDEL, A. REBER, SHIV KHANNA, Department of Physics, Virginia Commonwealth University — We had recently shown that magnetic superatoms can be formed by embedding 3d transition metal atoms in metallic clusters of otherwise non-magnetic elements. The hybridization between the localized exchange split atomic orbitals in 3d elements with superatomic orbitals can help stabilize the magnetic state. Through first principles studies on the electronic structure and magnetic moment of $Mg_n TM$ ($TM = Sc, Ti, V, Cr, Mn, Fe, Co, \text{ and } Ni$) clusters, we had identified $Mg_8 Fe$ to be a stable magnetic superatom. In this work, we will present our investigations on the magnetic properties of the assemblies of such superatoms and the nature of electronic transport through such assemblies with various electrodes. The effects of the contact geometry and gate voltage on the conductance are also studied.

¹We gratefully acknowledge support from U. S. Department of Energy (DOE) through grant DE-FG02-11ER16213.

9:24AM H34.00006 Fabrication and Characterization of Electrodeposited Nanoporous Alloys¹, KYLA KOBOSKI, NATHAN GRABER, EVAN NELSEN², JENNIFER HAMPTON, Hope College — Nanoporous Ni and NiFe thin films were created by electrodeposition of NiCu and NiFeCu followed by electrochemical dealloying to remove the Cu component. The structure and composition of the resulting materials, before and after the dealloying step, was characterized using scanning electron microscopy and energy dispersive spectroscopy. The electrochemical double-layer capacitance was measured to estimate the active surface area. The catalytic behavior of these complex nanoporous materials was investigated using hydrogen evolution as a model reaction.

¹This material is based upon work supported by the National Science Foundation under NSF-RUI Grant No. DMR-1104725, NSF-REU Grant No. PHY/DMR-1104811, and NSF-MRI Grant No. CHE-0959282.

9:36AM H34.00007 Strongly Size-Dependent High-Temperature Behavior of Bismuth Oxide Nanoparticles, GERRIT GUENTHER, Technische Universität Darmstadt, Materials Science, Petersenstr. 23, 64287 Darmstadt, Germany, RALF THEISSMANN, EINAR KRUIS, Nanostructures and Technology, University Duisburg-Essen, Bismarckstr. 81, 47057 Duisburg, Germany, OLIVIER GUILLON, Institute for Materials Science, Friedrich-Schiller-Universität Jena, Löbdergraben 32, 07743 Jena, Germany — Oxide nanostructures show very strong size-dependent changes in their thermal and chemical stability and reactivity. The degree of these changes depends on the type and strength of bonds at the surface: The higher the surface energy the stronger the size-dependence. Inorganic compounds are governed by strong and long ranging bonds which result e.g. in generally high melting points and surface energies. So the properties of such nanostructures could shed more light on the role that the material's surface plays. This is demonstrated here by experiments with size-selected bismuth oxide nanoparticles between 5 and 60 nm ($\pm 5\%$). Characterization of the particles revealed a metastable $\beta - Bi_2O_3$ structure. That testifies a size-driven crossover in phase stability below a critical particle size. Heating experiments up to the evaporation point were performed inside the synthesis-chamber as well as with in-situ TEM, in-situ XRD and a high-temperature nanocalorimeter. Different atmospheres were used. For the first time a melting point reduction in oxide nanoparticles was directly shown: For example 10 nm particles melted max. 40% and evaporated 12% below the bulk values which is a considerably stronger size-effect than for metals ($\leq 5\%$).

9:48AM H34.00008 Borane derivatives: A New Class of Superhalogens, DEVLEENA SAMANTA, Virginia Commonwealth University, BISWARUP PATHAK, RAJEEV AHUJA, Uppsala University, PURUSOTTAM JENA, Virginia Commonwealth University — Halogens have the largest electron affinities of all elements in the periodic table, that of Cl being the highest, namely 3.6 eV. Superhalogens have electron affinities that far exceed that of halogens. Based on density functional theory calculations, we show that the Wade-Mingo's rule, well known for describing the stability of closo-boranes ($B_n H_n^{2-}$), can be used to design a new class of superhalogens by tailoring the size and composition of borane derivatives. These superhalogens do not have to have either a metal or a halogen atom unlike conventional superhalogens. We show this by taking $B_{12}H_{13}$ and $CB_{11}H_{12}$ as examples. Also, these superhalogens can be used as building blocks of hyperhalogens of the form $M(B_{12}H_{13})_2$ and $M(CB_{11}H_{12})_2$ ($M=Li, Na, K, Rb, Cs$). This finding opens the door to an untapped source of superhalogens and weakly coordinating anions with potential applications.

10:00AM H34.00009 Configurational thermodynamics of alloyed nanoparticles: a first-principles cluster expansion study¹, LIN-LIN WANG, Division of Materials Science and Engineering, Ames Laboratory, DUANE D. JOHNSON, Division of Materials Science and Engineering, Ames Laboratory and Iowa State University — Transition-metal, alloyed core-shell nanoparticles (NPs) continue to be studied as heterogeneous catalysts because they are found to improve catalytic activity and selectivity for many energy-conversion processes. However, thermodynamic investigations have been limited mostly to NP core-shell preference, rather than both geometric structure and its chemical decoration. Here, by extending cluster expansion methods to treat alloyed nanoparticles, we study the configurational thermodynamics of bimetallic NPs, using databases from density functional theory calculations. We find that the interplay between the ordering tendency and the core-shell segregation tendency can induce site-specific preferences around the NP, as we exemplify, e.g., in AgAu. Such simulations will provide information needed for further understanding of the structure-function relationships in NP catalysis.

¹Supported by the DOE/BES under DE-FG02-03ER15476 (Catalysis) and DE-AC02-07CH11358 at the Ames Laboratory operated by Iowa State University

10:12AM H34.00010 Sintering of multi-metallic nanoparticles, VINEETHA MUKUNDAN, Purdue University, BIRGID WANJALA, RAMESHWORI LOUKRAKAM, JIN LUO, JUN YIN, CHUAN-JIAN ZHONG, Binghamton University, OANA MALIS, Purdue University — During the thermal treatment employed to activate the Pt-based nano catalysts used in fuel cell applications, the particles undergo structural transformations that affects their chemical performance. The mechanisms of coalescence and grain growth in bimetallic/trimetallic nanoparticles supported on planar silica on silicon are investigated using in-situ synchrotron based X-ray diffraction in the temperature regime 400-900C. The sintering process was found to be accompanied by lattice contraction and L10 chemical ordering. The mass transport involved in sintering is attributed to grain boundary diffusion and its corresponding activation energy is estimated from data analysis.

10:24AM H34.00011 Temperature dependence of Raman spectroscopy of molecular iodine trapped in zeolite crystals, WENHAO GUO, DINGDI WANG, JUANMEI HU, ZIKANG TANG, SHENGWANG DU, Physics Department, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong — Molecular iodine has been pursued for many practical applications, such as molecular clock, molecule-based quantum information processing, due to its narrow-linewidth hyperfine optical transitions. But because of its low vapor pressure, the experimental setup employing a free-space-based iodine vapor cell is very space-consuming. Recently, it is reported that the iodine molecule can be loaded into the channels of zeolite crystals, the density there could be orders improved and its space orientation can be precisely controlled. It may drastically reduce the size of molecular iodine experiment setup, and have many potential applications in microchip technology. We have studied the Raman spectroscopy of iodine molecule confined in zeolite crystals, AlPO₄-5 (AFI) and AlPO₄-11 (AEL), under different temperatures. The results show that in AEL, where the molecules are intensely confined, the ground vibrational states are close to that of an ideal 1D harmonic oscillator, while in AFI, where the molecules have a bit more freedom, they vibrate like in the free space, but with a loosened spring. And we come up a reasonable theoretical model to explain the Raman width dependence on temperature for these systems

10:36AM H34.00012 Single molecule thermodynamics and nanopore-based thermometry, JOSEPH E. REINER, Physics Department, Virginia Commonwealth University, JOSEPH W.F. ROBERTSON, Physical Measurement Laboratory, NIST, LISA K. BURDEN, Biology Department, Wheaton College, DANIEL L. BURDEN, Chemistry Department, Wheaton College, JOHN J. KASIANOWICZ, Physical Measurement Laboratory, NIST — The nanopore-based resistive pulse method measures the reduction in ionic current caused by the interaction of single molecules with the pore. It has great promise in addressing problems across a range of fields that include biomedicine and genomics. The technique requires the residence time of the molecules in the pore to exceed the inverse bandwidth of the detection system ($\sim 10 \mu s$). Efforts are underway to improve this by molecular modification of the pore wall, but little effort has focused on modifying the solution conditions in and around the pore. We address this issue by precisely controlling the solution temperature around a protein ion channel (alpha hemolysin) via laser-induced heating of gold nanoparticles. In this technique, the nanopore serves dual roles as both a highly local thermometer and single molecule sensor. Preliminary data suggests that the solution temperature can be controlled over a wide range, the nanopore conductance can be used to directly measure rapid changes in temperature, and the temperature change can dramatically alter the interaction kinetics of single molecules with the nanopore. The method will improve the development of biochip sensors and lead to a new platform for single molecule thermodynamic studies.

10:48AM H34.00013 On the Stability and Dynamics of Atmospheric Pre-Nucleation Clusters, VILLE LOUKONEN, University of Helsinki, Department of Physics, Helsinki, FI-00014 University of Helsinki, Finland, I-FENG W. KUO, Lawrence Livermore National Laboratory, Chemical Sciences Division, Livermore, CA 94550 USA, MATTHEW J. MCGRATH, Department of Biophysics, Graduate School of Science, Kyoto University, Kyoto 606-8502, Japan, HANNA VEHKAMAKI, University of Helsinki, Department of Physics, Helsinki, FI-00014 University of Helsinki, Finland — Atmospheric new-particle formation is a complex physical phenomenon with far-reaching consequences: currently, the role of aerosols is one of the main uncertainties in predicting the climate change. However, the molecular-level particle formation mechanisms are poorly understood. It is believed that sulfuric acid is the key player with possible contributions from various base molecules, ions or organics. Here we present results from first-principles molecular dynamics simulations of molecular clusters of sulfuric acid and two atmospherically relevant bases, ammonia and dimethylamine. The dynamics and stability of the studied clusters (sulfuric acid)_n•(ammonia)_{n-1} and (sulfuric acid)_n•(dimethylamine)_n where $n = 2, 3, 4$ were probed for 45 ps at T=300K at BPE/TZV2P level of theory. The stability of the clusters is largely dependent on the H-bonding patterns and in most cases the equilibrium patterns emerged within the first 10 ps. Curiously, even after the equilibrium was reached the clusters showed pronounced bond rearrangement: the number of bonds remained the same, but the individual atoms forming the bonds changed. Regardless of this behavior, the clusters remained bound together.

Tuesday, February 28, 2012 8:00AM - 11:00AM —
Session H35 DCP: Focus Session: DFT III: Weak Bonding and Liquid Phase Systems 107B

8:00AM H35.00001 Weakly Interacting Subsystems in DFT, TROY VAN VOORHIS, MIT Department of Chemistry — In chemistry, one is frequently interested in systems that are composed of weakly interacting fragments: a solute dissolved in a solvent phase, the base pairs in DNA, molecules in a crystal. In all these cases, our physical picture is that electronic states of the assembly emerge from small perturbations of states localized on the fragments. In frustrating fashion, standard functionals completely fail to reproduce this qualitative picture: the excited states of molecular assemblies are dominated not by local, valence excitations, but by spurious charge transfer states; weak van der Waals forces that hold molecules together are typically absent; excess spin and charge tend to be strongly delocalized even when the physical coupling between centers is extremely weak. In this talk we will discuss how truly nonlocal density functionals can mollify these trends. In particular, we will highlight the recent derivation and implementation of nonlocal van der Waals density functionals that account for long-range correlation in terms of two-point density interactions.

8:36AM H35.00002 Towards Efficient and General Method for Many-Body van-der-Waals Interactions, ALEXANDRE TKATCHENKO, Fritz-Haber-Institut der MPG, Berlin — Van der Waals interactions are intrinsically many-body phenomena, arising from collective electron fluctuations in a given material. Adiabatic connection fluctuation-dissipation theorem (ACFDT) allows to compute the many-body vdW interactions accurately. However, the ACFDT computational cost is prohibitive for real materials, even when the random-phase approximation is employed for the response function. We show how the problem of computing the long-range many-body vdW energy for real systems can be solved efficiently by mapping the system (molecule or condensed matter) onto a collection of quantum harmonic oscillators. Currently, our method, which couples density-functional theory with the many-body dispersion energy (DFT+MBD), is developed for non-metallic system [A. Tkatchenko, R. A. DiStasio Jr., R. Car, M. Scheffler, submitted]. The DFT+MBD method includes the hybridization effects by using the Tkatchenko-Scheffler approach [PRL 102, 073005 (2009)], the long-range Coulomb screening through classical electrodynamics [B. U. Felderhof, Physica 29, 1569 (1974)], and the many-body vdW energy from the coupled-fluctuating dipole model [M. W. Cole et al., Mol. Simul. 35, 849 (2009)]. The successes of the DFT+MBD approach and the many challenges that lie ahead will be discussed.

8:48AM H35.00003 Dispersion Interactions with Density-Functional Theory: Benchmarking Semiempirical and Interatomic Pairwise Corrected Density Functionals, LEEOR KRONIK, Weizmann Institute of Science, Israel, NOA MAROM, University of Texas at Austin, Austin, TX, ALEXANDRE TKATCHENKO, MARIANA ROSSI, VIVEKANAND V. GOBRE, Fritz-Haber-Institut, Germany, ODED HOD, Tel Aviv University, Israel, MATTHIAS SCHEFFLER, Fritz-Haber-Institut, Germany — We present a comparative assessment of the accuracy of two approaches for evaluating dispersion interactions: inter-atomic pair-wise corrections and semi-empirical meta-generalized-gradient-approximation (meta-GGA) based functionals. This is achieved by employing conventional (semi-)local and (screened-)hybrid functionals, as well as semi-empirical hybrid and non-hybrid meta-GGA functionals of the M06 family, with and without pair-wise Tkatchenko-Scheffler corrections. All those are tested against the benchmark S22 set of weakly bound systems, a representative larger molecular complex, and a representative dispersively bound solid. We also compare our results with those obtained from Grimme's pair-wise correction (DFT-D3) and Langreth-Lundqvist functionals (vdW-DF1/2). We find that the semi-empirical kinetic-energy-density dependence of the M06 functionals mimics some of the non-local correlation needed to describe dispersion. However, long-range contributions are still missing. Pair-wise corrections provide for a satisfactory level of accuracy irrespectively of the underlying functional.

9:00AM H35.00004 *Ab-initio* liquid water with hybrid functionals and dispersion interactions¹, ZHAOFENG LI, Princeton University, XIFAN WU, Temple University, ROBERT DISTASIO JR., ROBERTO CAR, Princeton University — We report *ab-initio* molecular dynamics simulations of liquid water using the hybrid PBE0 functional plus self-consistent dispersion forces based on the scheme of Ref.² Simulations were performed at T=300K and at T=330K to approximately account for nuclear quantum effect on the oxygen-oxygen(O-O) RDF, as suggested by previous path integral simulations. Focusing on O-O RDF, we find that the combined effect of the hybrid functional and of the dispersion interactions significantly improves the agreement of the simulated structure with experiment.

9:12AM H35.00005 Understanding the role of London dispersion forces in molecular surface processes, VALENTINO R. COOPER, Oak Ridge National Laboratory — The interactions and dynamics of molecules at surfaces and within pores are essential to many chemical processes, ranging from molecular storage to catalysis and self-assembly. A molecular level understanding of molecule-surface interactions is crucial for tuning surface/pore selectivity and reactivity. While it is clear that strong chemisorption bonds facilitate these interactions, the role of weaker van der Waals (vdW) forces, which include London dispersion and π - π stacking interactions, are often unknown or overlooked. Recent advances in density functional theory (DFT) have now made it possible to reliably account for London dispersion interactions. In this paper, I will discuss the use of one such technique, the Rutgers-Chalmers vdW non-local correlation functional,^{1,2} to demonstrate how the inclusion of London dispersion forces is critical for a truly first principles understanding of processes sensitive to molecule-surface interactions, such as the loading of H₂ within porous materials and the chemisorption of organic molecules at surfaces. These works highlight the fundamental importance of London dispersion interactions in the broader context of chemical physics. This work was supported by the Department of Energy, BES, Materials Sciences and Engineering Division.³

9:48AM H35.00006 First principles Monte Carlo simulations of vapor-liquid equilibria: Density functionals, basis sets, and dispersion corrections¹, J. ILJA SIEPMANN, University of Minnesota, MATTHEW J. MCGRATH, Kyoto University, I-F. WILLIAM KUO, Lawrence Livermore National Laboratory, CHRISTOPHER J. MUNDY, Pacific Northwest National Laboratory — Gibbs ensemble Monte Carlo simulations are used to compute the vapor-liquid equilibria for water, methanol, and methane using Kohn-Sham density functional theory. Results for BLYP and PBE functionals, BLYP with Grimme D2 and D3 dispersion corrections, and various basis sets are compared. Although none of the combinations of functional, dispersive correction, and basis set is found to yield highly accurate predictions for liquid densities, vapor pressures, and heats of vaporization for all three compounds, the results for dispersion corrected BLYP with large basis set are promising.

¹Research support from the National Science Foundation is gratefully acknowledged.

10:00AM H35.00007 Incorporation of an Improved Radial Distribution Function into Classical DFT, JOOST DE GUSSEM, ERIN MCGARRITY, Delft Technical University — An expression for the radial distribution function $g(\vec{r})$ for a fluid can be found using classical density functional theory. We use this expression in place of the mean-field value (*e.g.*, $g = 1$ for Lennard Jones fluids) in the excess Helmholtz free energy functional for the pair interactions to achieve self-consistent density profiles. We will discuss the differences found with this improved choice for $g(\vec{r})$ compared to other, simpler approximations. We will show results for liquid-vapor systems containing hard-sphere fluids with Lennard-Jones and dipolar interactions.

10:12AM H35.00008 Solvation of the chloride anion in water: ab initio simulations, CUI ZHANG, Department of Chemistry, University of California, Davis, DAVIDE DONADIO, Department of Chemistry, University of California, Davis and Max Planck Institute for Polymer Research, 55128 Mainz, Germany, FRANCOIS GYGI, Department of Computer Science, University of California, Davis, GIULIA GALLI, Department of Chemistry, University of California, Davis and Department of Physics, University of California, Davis — We studied the structural, vibrational and electronic properties of the chloride anion in water using ab initio molecular dynamics. Our investigation has three main objectives: understand the range of perturbation exerted by the anion on the water hydrogen bonded network; identify signatures of the anion perturbation in infrared spectra of the solution and study the extent of charge localization on the anion, as predicted by semi-local (PBE) and hybrid functionals (PBE0). In agreement with recent experiments, we find that the presence of the anion substantially affects only the hydrogen bonding in the first solvation shell, due to a decrease of the dipole moment of the first shell water molecules and thus a weakening of the hydrogen bonds. Such a weakening leads to a slightly blue shifted band in the computed IR spectra. While structural and vibrational properties of the solution are similar within PBE and PBE0, the electronic properties exhibit marked differences.

10:24AM H35.00009 Entropy of Liquid Water from Ab Initio Molecular Dynamics, LEONARDO SPANU, CUI ZHANG, Chemistry Department University of California Davis, GIULIA GALLI, Chemistry Department and Physics Department University of California Davis — The debate on the structural properties of water has been mostly based on the calculation of pair correlation functions. However, the simulation of thermodynamic and spectroscopic quantities may be of great relevance for the characterization of liquid water properties. We have computed the entropy of liquid water using a two-phase thermodynamic model and trajectories generated by ab initio molecular dynamics simulations [1]. In an attempt to better understand the performance of several density functionals in simulating liquid water, we have performed ab initio molecular dynamics using semilocal, hybrid [2] and van der Waals density functionals [3]. We show that in all cases, at the experimental equilibrium density and at temperatures in the vicinity of 300 K, the computed entropies are underestimated, with respect to experiment, and the liquid exhibits a degree of tetrahedral order higher than in experiments. We also discuss computational strategies to simulate spectroscopic properties of water, including infrared and Raman spectra.

10:36AM H35.00010 Mean-field Density Functional Theory of Triple Junction¹, CHANG-YOU LIN, MICHAEL WIDOM, ROBERT F. SEKERKA, Department of Physics, Carnegie Mellon University, Pittsburgh, PA 15232, USA — A triple junction in a three-phase fluid system is modeled by a mean-field density functional theory. We use a variational approach to find the Euler-Lagrange equations. Analytic solutions are obtained in the two-phase regions at large distances from the triple junction. We employ a triangular grid and use a successive over-relaxation method to find numerical solutions in the entire domain for the special case of equal interfacial tensions for the two-phase interfaces. We use the Kerins-Boiteux formula to obtain a line tension associated with the triple junction. This line tension turns out to be negative. We associate line adsorption with the change of line tension as the governing potentials change.

¹We appreciate the support of Department of Physics, Carnegie Mellon University for this work.

10:48AM H35.00011 Structural and vibrational properties of sulphate-water clusters from ab-initio calculations, QUAN WAN, LEONARDO SPANU, Department of Chemistry, University of California, Davis, GIULIA GALLI, Department of Chemistry and Department of Physics, University of California, Davis — Hydrated clusters of sulfuric acid derivatives play an important role in many processes of interest, e.g. environmental sciences and electrochemistry. Determining their structural and electronic properties is a challenging task: they exhibit a complex free energy landscape and there is no direct experimental measurement of their geometry, which is usually inferred from spectral signatures obtained, e.g. by infrared (IR) measurements [1]. We have used *ab initio* molecular dynamics simulations to investigate the stability, electronic properties and IR of sulphate-water clusters containing 12 and 13 water molecules. We discuss how the entire hydrogen bonded network of the cluster may be affected by the presence of a single, additional water molecule, leading to geometrical arrangements not yet identified in experiments. We also show that clusters with different structures may have similar IR spectra, thus making it difficult to use spectral signatures to unequivocally determine the cluster geometry. Finally we discuss the electronic properties of the clusters and in particular differences obtained in the computed ionization potentials when using semi-local and hybrid functionals.

Tuesday, February 28, 2012 8:00AM - 11:00AM – Session H36 DCP: Focus Session: Environment II: Green Processes 107C

8:00AM H36.00001 Using Molecular Simulation to Develop New Materials for Energy and Environmental Applications¹, EDWARD MAGINN, University of Notre Dame — We face two enormous challenges in the coming decades. First, we must find ways to provide clean, affordable energy to an ever-growing population. Second, as underdeveloped countries advance, we must find ways to provide access to advanced technologies that enhance human wellbeing. What makes these two challenges even more daunting is that they both must be met using sustainable technologies; simply relying on old dirty technologies is not an option. In this talk, I will show how approaches rooted in chemical physics are being used to develop new materials that can be used to meet these challenges. In particular, I will give examples where molecular-based simulations are being used in three areas: 1) the discovery of new ionic liquid solvents for capturing CO₂ produced from fossil fuel combustion; 2) the development of new refrigerants that have better performance and significantly lower global warming potentials than existing refrigerants; and 3) fundamental investigations of actinide ions in solution, with the objective of developing new separation processes for nuclear waste remediation and fuel reprocessing technologies.

8:36AM H36.00002 Highly Selective CO₂/CH₄ Gas Uptake by a Halogen-Decorated Borazine-Linked Polymer, THOMAS REICH, SWAYAMPRAKASH BEHERA, KARL JACKSON, PURU JENA, HANI EL-KADERI, Virginia Commonwealth University — We report herein a synergistic approach that combines synthesis and characterization of a new borazine-linked polymer, BLP-10(Cl), and theoretical calculations based on density functional theory to investigate its performance in small gas storage and separation. We focus on the binding of H₂, CO₂, and CH₄. The choice of these gases is motivated by their impact on energy and the environment. Given the relatively small and similar kinetic diameter of the CH₄ and CO₂ molecules, their efficient separation remains a nontrivial task. In the case of a dihydrogen molecule interacting with the chlorinated borazine, we find the H₂ to be bound molecularly with a bond length of 0.75 Å and at a distance of 2.76 Å from the boron site. CO₂ and CH₄, on the other hand, interact with the central ring system of borazine at a distance of 3.12 Å and 3.33 Å respectively. The bond length between the carbon and oxygen atoms of CO₂ is 1.16 Å while the distance between the carbon and hydrogen of CH₄ is 1.10 Å. The binding affinities of all gases with the chlorinated borazine rings obtained from using the M06 exchange-correlation potential agree very well with experimental data collected from pure gas component isotherms. Theoretical investigations also indicate that all of the gas molecules preferentially interact with the borazine ring rather than the phenyl substituent of the nitrogen atoms which highlight the significance of including polarizable building blocks in adsorbent materials.

8:48AM H36.00003 Carbon dioxide intercalation in Na-fluorohectorite clay at near-ambient conditions¹, JON OTTO FOSSUM², Department of Physics, Norwegian University of Science and Technology, HENRIK HEMMEN, ERLEND G. ROLSETH, DAVI FONSECA, ELISABETH LINDBO HANSEN, Department of Physics, Norwegian University of Science and Technology - NTNU, TOMAS PLIVELIC, MAX IV Laboratory, Lund University, Sweden — A molecular dynamics study by Cygan et al.[1] shows the possibility of intercalation and retention of CO₂ in smectite clays at 37 °C and 200 bar, which suggests that clay minerals may prove suitable for carbon capture and carbon dioxide sequestration. In this work we show from x-ray diffraction measurements that gaseous CO₂ intercalates into the interlayer space of the synthetic smectite clay Na-fluorohectorite. The mean interlayer distance of the clay when CO₂ is intercalated is 12.5 Å at 20 °C and 15 bar. The magnitude of the expansion of the interlayer upon intercalation is indistinguishable from that of the dehydrated-monohydrated intercalation of H₂O, but this possibility is ruled out by careful repeating the measurements exposing the clay to nitrogen gas. The dynamics of the CO₂ intercalation process displays a higher intercalation rate at increased pressure, and the rate is several orders of magnitude slower than that of water or vapor at ambient pressure and temperature.

9:00AM H36.00004 Monoethanolamine adsorption on TiO₂ (110) for solid supported CO₂ capture¹, DEYU LU, KATHRIN MULLER, Center for Functional Nanomaterials, Brookhaven National Laboratory, SANJAYA SENANAYAKE, Chemistry Department, Brookhaven National Laboratory, DAVID STARR, Center for Functional Nanomaterials, Brookhaven National Laboratory — Solid supported CO₂ capture materials are drawing substantial attention as a promising, cost-effective and environmentally friendly alternative to aqueous amine based CO₂ capture. Recently CO₂ capture was observed from monoethanolamine (MEA) adsorbed TiO₂ powders. In order to facilitate the rational design of future solid CO₂ capture materials, it is very important to understand the interaction between MEA and the TiO₂ surface at the atomic level and how it affects the CO₂ capture capabilities. In this work, we report a combined experimental and theoretical study of MEA adsorption on rutile TiO₂ (110). We found that 1 ML of MEAs can form a stable and ordered pattern on TiO₂ (110). However, the amine group in MEA (the CO₂ capture site) binds preferably to the TiO₂ surface in the gauche mode. The binding energy of the gauche mode is about 0.8 eV larger than the trans mode, where the amine group is free, causing the present MEA/TiO₂ system unable to capture CO₂. We found that this large binding energy difference is originated from a combination of surface donor-acceptor bonds, H-bonds, and dipole-induced dipole interaction. Our study suggests that these effects are key factors to design future amine-based solid supported CO₂ capture materials.

9:12AM H36.00005 Investigation of nanoparticle transformations to guide the design of greener products and processes¹, JAMES HUTCHISON, University of Oregon — Nanoscale particles and products containing nanoparticles hold promise as higher performance materials; however, there are concerns that the production and use of nanoparticles might negatively impact human health or the environment. Within the context of greener nanoscience we aim to maximize the benefits, while minimizing hazards, of nanoscale products. A significant gap in the knowledge needed to develop greener products and processes is our understanding of the formation and transformation of nanoparticles. Such studies of nanoparticle dynamics are technically challenging and few studies have been reported. In this presentation, I will describe convenient methods to monitor nanoparticle dynamics and show how knowledge of nanoparticle transformations can guide the design of greener products and processes. In one example, chemically-modified transmission electron microscopy (TEM) grids are used to directly visualize silver nanoparticle transformations on surfaces. By indexing the TEM grids, it was possible to examine the same nanoparticles repeatedly throughout exposure to different environments. These studies show that larger particles can act as a source of smaller nanoparticles and that much larger particles also produce nanoparticles. With this knowledge, an improved design of nanoparticle coatings for antimicrobial fabrics was developed. A second example involves the use of small angle x-ray scattering (SAXS) to monitor nanoparticle formation reactions in solution in real-time. A combination of beam-line and lab-scale SAXS measurements, combined with simultaneous optical studies, showed that particle growth and coalescence compete under typical synthesis conditions, leading to loss of structural definition of the product. This mechanistic insight, in turn, guided the design of efficient and greener syntheses of well-defined nanoparticles.

9:48AM H36.00006 Ceria Nanoparticles: Environmental Impacts on Particle Structure and Chemistry¹, DONALD BAER, PRABHAKARAN MUNUSAMY, AJAY KARAKOTI, SUNTHARAMPILLAI THEVUTHASAN, EMSL Pacific Northwest National Laboratory, SATYA KUCHIBHATLA, Battelle Science and Technology India, SUDIPTA SEAL, University of Central Florida — Ceria nanoparticles are widely studied for catalytic, energy, environmental and bio-medical applications. The performance of ceria often depends on the ability of Cr to switch between +3 and +4 oxidation states. This paper summarizes observations of the impact that synthesis route, processing conditions, storage and environmental conditions have on the chemical and physical properties of ceria nanoparticles. Particles less than 10 nm in diameter are highly dynamic and change their oxidation state not just as a function of size, but also as a function of aging (time) and environmental conditions. During particle nucleation and growth, both particle size and oxidation state change with time. These observations suggest that interpretations of experimental results based primarily on particle size may be misleading. Raman and microXRD studies indicate that these changes can be more complex than anticipated. Because synthesis, analysis and relevant operational conditions often place particles in different environments, understanding how particles change with time in operational conditions is essential to predicting their properties. Time and environmentally induced changes may also play a significant role in the discrepancies reported in various studies.

10:00AM H36.00007 Solubility and transport of cationic and anionic patterned nanoparticles, JIAYE SU, HONGXIA GUO, Beijing National Laboratory for Molecular Sciences, Joint Laboratory of Polymer Sciences and Materials, MONICA OLVERA DE LA CRUZ, Department of Materials Science, Northwestern University — Diffusion and transport of nanoparticles (NPs) through nanochannels is important for desalination, drug delivery, and biomedicine. Their surface composition dictates their efficiency separating them by reverse osmosis, delivering into cells, as well as their toxicity. We analyze bulk diffusion and transport through nanochannels of NPs with different hydrophobic-hydrophilic patterns achieved by coating a fraction of the NP sites with positive or negative charges via explicit solvent molecular dynamics simulations. The cationic NPs are more affected by the patterns, less water soluble, and have higher diffusion constants and fluxes than their anionic NPs counterparts. The NP-water interaction dependence on surface pattern and field strength explains these observations. For equivalent patterns, anionic NPs solubilize more than cationic NPs since the Coulomb interaction of free anionic NPs, which are much stronger than hydrophobic NP-water interactions, are about twice that of cationic NPs.

10:12AM H36.00008 Hydrogen bond density and strength analysis on hydrated Rutile (110) and Cassiterite (110) surfaces, NITIN KUMAR, Department of Physics, Penn State University, PAUL KENT, Center for Nanophase Materials Sciences and Chemical Sciences Division, Oak Ridge National Laboratory, ANDREI BANDURA, St. Petersburg State University, DAVID WESOLOWSKI, Chemical Sciences Division, Oak Ridge National Laboratory, JAMES KUBICKI, Department of Geosciences, Penn State University, JORGE SOFO, Department of Physics, Penn State University — We study the dynamics of water on the surface of cassiterite (110) and rutile (110) using ab-initio molecular dynamics simulation. Water adsorbs and dissociates on these surfaces. This dynamic equilibrium is dominated by the hydrogen bond (h-bond) network at the surface. The h-bond density analysis shows that adsorbed water molecules form higher average number of h-bonds on rutile (~2.3) as compared to the cassiterite surface (~2.1). On the other hand, bridging oxygen atoms form higher average number of h-bonds on cassiterite (~1.4) than rutile surface (~1.2). Dissociated species are found to have same average number of hydrogen bonds on both surfaces. As a consequence, the rutile surface has higher density of h-bonds at the surface than cassiterite, however, their strength is lower [N. Kumar et al., J. Chem. Phys. 134, 044706 (2011)]. This delicate balance is responsible for the different dynamical properties of both surfaces.

10:24AM H36.00009 Microfluidics and Stimulus-Responsive Materials – The Key to Next Generation Chemical Sensors for Widely Distributed Environmental Monitoring¹, DERMOT DIAMOND, Dublin City University — The fields of chemical sensing and microfluidics have promised much, but in terms of functional devices, have delivered relatively little. Issues like biofouling and surface degradation mean that sensor characteristics change rapidly in real samples. Consequently, chemical sensors must be regularly recalibrated to ensure the information they send is reliable. This results in complex and very costly devices that must integrate fluidics, standards, and waste storage, as well as sampling and analytical procedures. The fundamental challenge for realizing sensors for widely distributed environmental monitoring is this - how can we produce low cost sensing platforms that can function reliably in an autonomous manner for periods up to years? The key to progress lies in new, and more sophisticated materials that can respond to external stimuli, and communicate with the external world. For example, materials that can be activated from a passive state, reversibly bind and release targeted guest molecules, and return to a passive form. Activation and deactivation happen as part of an external control system, which can be local (chemical in nature) or external (e.g. photonic), and the material reports its status (passive, activated-free, activated-occupied) optically materials can be incorporated into more sophisticated platforms, such as micelles, beads, or complete fluidic systems that are much more biomimetic in nature than current platforms. They include polymer actuators that expand and contract dramatically under an external stimulus (e.g. light), enabling valve and pumping functions to be fully integrated into the microfluidic device. This lecture, I will present some of the exciting possibilities for chemical sensing that are now beginning to emerge through breakthroughs in fundamental materials science.

¹Science Foundation Ireland - 07/CE/I1147 - “CLARITY: Centre for Sensor Web Technologies.”

Tuesday, February 28, 2012 8:00AM - 11:00AM – Session H37 SPS: SPS Undergraduate Research III 108

8:00AM H37.00001 Fabrication of Micromirror Templates Using a Focused CO₂ Laser¹, SONIA PEREZ, Henderson State University, BEN PETRAK, KUMARASIRI KONTASINGHE, ANDREAS MULLER, University of South Florida — Micromirrors are an important component in quantum optics, for example in Fabry-Perot microcavities, where light can be recirculated within small volumes. Recently, a CO₂ laser method has been demonstrated as a way to fabricate micromirror templates with an exceptionally high surface quality. However, these templates typically vary in size significantly, which is undesirable in many applications, for example when arrays are needed. Here we address this problem by implementing a feedback method, which uses the light emitted by the sample during the ablation process. By measuring the intensity of the light emitted and correcting, in real time, the laser intensity, we can control the feature size to be less than 5 percent.

¹This work was supported by NSF REU program (award No DMR-1004873).

8:12AM H37.00002 High-power, narrow-bandwidth laser based on a tapered amplifier¹, MICHAEL YANAKAS, ANTHONY VIVONA, MICHAEL LIM, Dept. of Physics and Astronomy, Rowan University — We have constructed a high-power, tunable, narrow-bandwidth, cw laser based on a semiconductor tapered amplifier at a wavelength of 780 nm. Bandwidth narrowing to less than 1 MHz is accomplished with an intra-cavity interference filter, while 10 GHz of continuous tuning is possible with a cavity mirror mounted on a PZT stack. The laser output has a slope efficiency of 0.5 W/A, optical output power of 0.7 W, and will be used for laser cooling of atomic rubidium.

¹Supported in part by NSF PHY0613659.

8:24AM H37.00003 Depth of focus in digital holography using spatial partially coherent light¹, KRISTEN BINZ, Wake Forest University, XIAO YU, DAVID CLARK, MYUNG K. KIM, University of South Florida — Digital holography is a powerful, but young, imaging technology that has a vast array of applications; its strength lies in the ability to numerically focus on any plane within a sample from a single hologram and to use both amplitude and phase information from the intensity field to reconstruct the sample's 3D characteristics on a computer. The quality of many holograms, however, is compromised by speckle and other interference noise associated with the high-coherence lasers often used to illuminate the sample. Speckle noise may be diminished by lowering the coherence length of the source. In our experiments, partially coherent light was created by directing a laser beam through a rotating ground glass. We aimed to discern whether the coherence of the source could be systematically altered by changing the position of the ground glass within the focused laser beam. We anticipated that altering the coherence length would also systematically change the depth of focus. Initial results support our hypotheses.

¹This work was supported by NSF REU program (award No DMR-1004873)

8:36AM H37.00004 Photocatalytic properties of nanostructured TiO₂ surfaces¹, LAUREN MOORE, Northeastern University, TIMOTHY LUTTRELL, MATTHIAS BATZILL, University of South Florida — Photocatalytic chemical reactions are actively explored for direct production of chemical fuels from sun light through electrolysis or for the clean-up of organic pollutants through photocatalysis. Titanium dioxide is a prototypical photocatalyst which has been studied extensively. However, there are still unanswered questions regarding the relationship between surface morphology and photocatalytic properties. In this study, we used ion beam assisted surface nanopatterning and UV-catalysis to investigate the dependence of photoreactivity on surface nanostructures. Energetic argon gas ions were used to induce self-formation of nanopatterns on TiO₂ surfaces and the structure formation was characterized by atomic force microscopy. The influence of the surface structure on the photochemical properties was assessed through photocatalytic degradation of methyl orange in aqueous solution with a flat sample and a nanopatterned sample of TiO₂, respectively. The resulting absorbance spectrums were then compared.

¹This work was supported by NSF REU program (award No DMR-1004873).

8:48AM H37.00005 Pushing the Limits of Nanoscale Imaging in Atomic Force Microscopy , JACOB CVETICH, VASUDEVA RAO ARAVIND, BENJAMIN LEGUM, Clarion University, CLARION UNIVERSITY TEAM — The invention of scanning probe microscopy has revolutionized the field of nanotechnology. Atomic force microscopy is a branch of scanning probe microscopy in which an extremely sharp tip (~ 50 nm diameter) is held in contact with a sample surface. By maintaining constant force between the tip and the sample, the topography of a sample surface can be measured with high precision. The lateral resolution in this technique is however limited by the size of the tip. In this presentation, we present a method to deconvolve the effect of tip size and obtain higher resolution than presented by the experimentally obtained topographic image.

9:00AM H37.00006 Scanning Tunneling Microscopy of Fe Doped $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+x}$, BRIAN KOOPMAN, Clark University, W.D. WISE, KAMALESH CHATTERJEE, MIT, GENDA GU, Brookhaven National Laboratory, E.W. HUDSON, Penn State University, M.C. BOYER, Clark University — We will present a low temperature scanning tunneling microscopy (STM) study of the high-temperature superconductor $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+x}$ (Bi-2212) which has been intentionally doped with magnetic (Fe) impurities in order to locally disrupt superconductivity around the impurities. We examine spatial variations in the density of states in the vicinity of Fe impurities, and compare our results with previous STM studies of Ni doped Bi-2212. Notable differences between Fe and Ni impurities include differences in the number and energy locations of the impurity peaks. Our analysis shows that Fe is a weaker magnetic impurity than Ni and that the particle-hole symmetry present in the spectra of Ni impurities is not as obvious in Fe impurities. By studying how these impurities interact with superconductivity in Bi-2212 we hope to understand more about the superconducting mechanism in high-temperature superconductors.

9:12AM H37.00007 Theoretical & Experimental Design & Optimization of Multilayer Mirrors for Soft X-Ray Reflection , BAKARI HASSAN, FRANCK DELMOTTE, EVGUENI MELTCHAKOV, None — The reflection of soft X-rays is relevant for the development of ultra fast attosecond cameras, X-ray lithography, and the study of solar storms. Soft X-rays are typically absorbed, as opposed to reflected, due to all materials' absorptive nature. Co/C-am multilayers composed of 40 layers were deposited on Si & SiO_2 substrates by Magnetron Sputtering technique and were characterized by grazing-incidence diffraction. Theoretical interfacial roughness and layer thicknesses were simulated using the commercial software IMD, while experimental values were estimated by fitting the reflectivity data. Low reflectivity values were observed at the locations of Bragg peaks. However, through deposition optimization, reflectivity values could potentially reach values above 60%.

9:24AM H37.00008 Domain Coarsening Within the Ising Model on the Hyperbolic Plane¹ , JAMES MOLCHANOFF, Math, West Virginia Wesleyan University, HOWARD L. RICHARDS, Physics, Marshall University — In spite of its simplicity, both the dynamics and equilibrium statistics of the Ising model are nontrivial. Previous studies in this REU have shown that the dynamics of metastable decay is very different in the hyperbolic plane than in the Euclidean plane. Here we perform Monte Carlo simulations of domain coarsening in the hyperbolic plane. We find that domain coarsening occurs more slowly than in the Euclidean plane.

¹Research performed at Marshall University's REU in scientific computing, supported by National Science Foundation grant OCI-1005117.

9:36AM H37.00009 Quantum chaos: an introduction via chains of interacting spins-1/2 , AVIVA GUBIN, LEA SANTOS, Yeshiva University — We discuss aspects of quantum chaos by focusing on spectral statistical properties and structures of eigenstates of quantum many-body systems. Quantum systems whose classical counterparts are chaotic have properties that differ from those of quantum systems whose classical counterparts are regular. One of the main signatures of what became known as quantum chaos is a spectrum showing repulsion of the energy levels. We show how level repulsion may develop in one-dimensional systems of interacting spins-1/2 which are devoid of random elements and involve only two-body interactions. We present a simple recipe to unfold the spectrum and emphasize the importance of taking into account the symmetries of the system. In addition to the statistics of eigenvalues, we analyze also how the structure of the eigenstates may indicate chaos. This is done by computing quantities that measure the level of delocalization of the eigenstates.

9:48AM H37.00010 Solving the Feynman–Gell-Mann Equation for the Electron , GRAHAM MILLER, DANIEL FINKENSTADT, U.S. Naval Academy, Physics Department — There are very few cases for which the Dirac equation can be solved exactly. Moreover, the techniques familiar from undergraduate quantum mechanics provide little help in solving its linear differential equations. Working instead with a two-component formalism, the transformed Dirac equation can be solved for cases of constant electric and magnetic fields for an electron. This approach was recommended in the famous 1958 paper by Feynman and Gell-Mann and has the form: $(i\hbar \frac{\partial}{\partial t} - V)^2 = -\hbar^2 c^2 |\nabla - i\frac{e}{\hbar} \vec{A}|^2 - e\hbar c \vec{\sigma} \cdot (\vec{B}c + i\vec{E}) + (mc^2)^2$, when acting on a two component spinor φ . We will show the solution of this equation for the cases of parallel E & B fields, perpendicular fields, perhaps oblique fields and finish with a discussion of the Hydrogen atom. Through taking the nonrelativistic limits, these solutions can be verified for well-known conditions.

10:00AM H37.00011 Second harmonic generation and non-linear corrections to the high frequency susceptibility of a multiferroic material , PHILIP JAVERNICK, TRINANJAN DATTA, Augusta State University — We consider the effects of non-linear (second order) corrections to the high-frequency susceptibilities of a material that is simultaneously ferroelectric and a canted antiferromagnet (multiferroic). The non-linear corrections introduce a second harmonic term in the magnetic, electric, and multiferroic susceptibilities. Using the Landau-Lifshitz equation of motion for the magnetic components and the Landau-Khalatnikov relaxation equation for the electric polarization we theoretically compute the non-linear corrections to the susceptibilities for the optic antiferromagnetic mode, the acoustic mode, and the electric susceptibilities up to second order. Using realistic material parameters we find that the corrections have either a noticeable or negligible effect on the first order susceptibility values.

10:12AM H37.00012 Aluminum Nitride Nanofibers fabricated using Electrospinning and Nitridation¹ , XENIA BARBOSA, University of Puerto Rico at Humacao, EVA CAMPO, JORGE SANTIAGO, University of Pennsylvania, IDALIA RAMOS, University of Puerto Rico at Humacao, UPPEN-UPR PREM COLLABORATION² — Aluminum Nitride (AlN) and other nitride semiconductors are important materials in the fields of optoelectronics and electronics. AlN nanofibers were synthesized using electrospinning and subsequent heating under N_2 and NH_3 atmospheres. The precursor solution for electrospinning contains aluminium nitrate and cellulose acetate. The electrospun nanofibers were heated in N_2 to eliminate the polymer and produce Al_2O_3 , and then nitridized at a temperature of 1200°C under NH_3 flow. Scanning Electron Microscopy (SEM) observations demonstrate the production of fibers with diameters ranging from a few nanometers to several micrometers. X-Ray Diffraction and UV-VIs analyses show the production of AlN nanofibers with hexagonal wurzite structure and a band gap of approximately approximately 6 eV. Current-Voltage measurements on a single AlN fiber with gold electrodes suggest the formation of a Schottky contact The fabrication method and results from the fibers characterization will be presented.

10:24AM H37.00013 Formation of Nanostructures at Gold Surfaces Exposed to Femtosecond Laser Pulses, KELSIE NIFFENEGGER, Auburn University, BRIAN DEMASKE, VASILY ZHAKHOVSKY, IVAN OLEYNIK, University of South Florida — The evolution of free-standing gold film irradiated by ultrashort laser pulses was simulated using molecular dynamics. The spatially non-uniform deposition of laser energy was modeled by a two-dimensional temperature profile applied during time of electron-ion energy exchange. Our simulations show that the ultrafast two-dimensional heating results in the melting and pressurization of a thin surface layer. Due to a non-uniform stress distribution, this molten layer expands to form a jet-like protrusion at the laser pulse's focal point. Above some critical stress, many voids start to nucleate forming a foam-like material covered by a thin liquid shell/cupola. The still expanding cupola may rupture forming a rim around the newly-developed crater. All these processes lead to complicated surface morphology, which becomes frozen at the nanosecond time scale. Geometrical characteristics of simulated surface profiles, including crater depth and size of frozen bubbles, agree well with experiment. Our simulations help to provide better insight into the atomistic mechanisms of nanostructure formation.

10:36AM H37.00014 Gold coated nanoparticles on silicon substrate, SIRAK MELAKU, None — The study of Gold nanoparticles is very captivating because of their significance and applications as catalysts in restructuring technologies that are used for manufacturing medicine, energy production, transportation, computation, communication, and environmental changes. In this experiment, I have analyzed the morphology of gold nanoparticles using different techniques. A sputter coating technique was used to deposit gold on silicon substrate. During the process, depositions were performed using varying plasma coating times and voltages. The Gold nanoparticles were then analyzed using the Atomic Force Microscopy (AFM) and Scanning Electron Microscopy (SEM). The AFM and SEM data revealed that the coating surface morphology was dependent upon deposition conditions.

10:48AM H37.00015 Simulations of surface plasmons launched on gold nanogratings, IAN WHITE, JENNIFER STEELE, Department of Physics and Astronomy, Trinity University — A gold nanograting with a dielectric coating containing fluorescent molecules can enhance the intensity of fluorescence at certain frequencies due to the excitation of surface plasmons. Fluorescence is enhanced by two mechanisms: (1) an enhanced electromagnetic field at the excitation frequency of the fluorophores and (2) surface plasmon modes providing extra decay channels for fluorophores. Previous studies on corrugated film gratings show that coupling to higher diffraction order plasmons occur with lower efficiency. We find that for wire gratings, fluorophores couple to higher order plasmon modes on both sides of the gold wires with uniform efficiency. We also measure directional enhanced fluorescence on both the active (reflection) and substrate (transmission) side of the gratings. In this work, gold nanogratings with a dielectric coating were modeled using COMSOL Multiphysics software, which solves Maxwell's equations in the region of the grating. As the thickness of the dielectric layer containing the fluorophores is increased, the plasmon modes shift. The behavior of the gratings was simulated as a function of height of the gold wires and thickness of the dielectric coating. These simulations will inform future experiments.

Tuesday, February 28, 2012 8:00AM - 11:00AM – Session H39 Electronic Structure: Calculations II 109B

8:00AM H39.00001 Variational investigations of the electronic structure and energy of finite hydrogen systems with the Gutzwiller wave function within local correlation matrix renormalization approximation¹, YONGXIN YAO, JUN LIU, CAI-ZHUANG WANG, KAI-MING HO, Iowa State University and Ames Laboratory-U.S. DOE — We introduce the correlation matrix renormalization Hartree-Fock (CMR-HF) method in which the many-body Hamiltonian of a multi-electronic system is solved using a variational Gutzwiller-type wave-function. The Gutzwiller approximation is generalized to renormalize the one-electron density matrix and two-electron correlation matrix of the system. To achieve a clear presentation of the concept and methodology, we describe the detailed formalisms for a finite hydrogen system with minimal basis set. The resulting expectation value of the Hamiltonian have clear parallels to terms in the standard uncorrelated Hartree-Fock method, allowing an iterative self-consistent field solution of the many-electron problem analogous to the Hartree-Fock solution. We have applied the method to a series of hydrogen clusters to compare with the results of several other quantum chemical calculation methods.

¹Work at Ames Laboratory was supported by the US Department of Energy, Basic Energy Sciences, Division of Materials Science and Engineering.

8:12AM H39.00002 Real-time time-correlation approach for x-ray absorption and emission spectra¹, F.D. VILA, A.J. LEE, J.J. REHR, Dept. of Physics, U. of Washington, Seattle, WA 98195 — We present a real-time approach for calculations of X-ray absorption (XAS) and emission spectra (XES) from deep core-levels, based on time-correlation functions. XAS and XES have traditionally been calculated using Fermi's golden rule in frequency space, and alternatively, using real-space Green's function (RSGF) methods. Recently, however, with the advent of very high brightness pulsed x-ray sources, calculations of time-dependent response have become a focus of attention. Here we obtain the time-correlation functions by propagating the initial, dipole-excited wavefunction with a Crank-Nicolson time-evolution operator.² The initial state is obtained using projector augmented wave (PAW) transition matrix elements and, for XAS, the propagation is carried out in the presence of a core hole. The approach is implemented using an extension of SIESTA and can be applied both to molecular and extended systems. Illustrative examples are presented for several systems, and yield results in good agreement with RSGF and Fermi golden rule approaches using FEFF and StoBe respectively. Finally, we discuss improvements in order to include dynamic many-body effects.

8:24AM H39.00003 Calculation of Phonon Satellites in Electron Spectral Functions¹, SPENCER WILLIAMS, J.J. KAS, J.J. REHR, University of Washington, M. VERSTRAETE, Universite de Liege — We describe a first principles approach for calculations of phonon satellites in the electron self-energy and spectral function. The method is based on cumulant expansion techniques [1] applied to the self-energy model of Eiguen and Ambrosch-Draxl [2] with the dynamical matrix and electron-phonon couplings obtained from ABINIT [3]. In particular, the electron-phonon couplings are calculated from the Eliashberg functions as in [4], and the phonon DOS is obtained from a many-pole/Lanczos representation of the phonon Green's function [5]. The method is illustrated with results for a number of systems.

8:36AM H39.00004 Atomic Multiplets in X-ray spectroscopies revisited¹, BERNARD DELLEY, Paul Scherrer Institut, CMT, WHGA123, CH-5232, Villigen PSI, FRANÇOIS VERNAY, University of Perpignan, France, ANNE-CHRISTINE ULDREY, Paul Scherrer Institut, CMT, WHGA123, CH-5232, Villigen PSI — Atomic multiplets are known since a long time to produce specific, crystal field dependent, fingerprints of open d- and f- shells in X-ray spectroscopies. Older computer programs originating from gas-phase optical spectroscopy of atoms tend to be difficult to apply to crystal field environments with lower symmetries. In order to study changes of X-ray absorption near edge spectra and resonant inelastic X-ray scattering (RIXS) across symmetry lowering phase transitions, a new multiplet program was developed. Starting from a Dirac-Slater spherical atom calculation we evaluate electron-electron interaction and crystal field in the Hilbert space spanned by the open shells by diagonalization. The crystal field can be simply defined by nominal charges and cartesian atomic positions relative to the core-hole atom. To overcome limitations of the model and for fitting known spectra, spin-orbit splitting, el-el interaction and crystal-field can be scaled independently. The nominal charges may be taken as further crystal field parameters. Various XAS and RIXS examples will be discussed, in particular in view of the polarisation dependence and symmetry of the crystal.

¹Supported by grant SNF 200021-129970.

8:48AM H39.00005 Simulation of electron-energy-loss spectra including both diffraction and solid-state effects¹, MICAH PRANGE, MARK OXLEY, Vanderbilt University and ORNL, MARIA VARELA, ORNL, STEPHEN PENNYCOOK, ORNL and Vanderbilt University, SOKRATES PANTELIDES, Vanderbilt University and ORNL — Aberration-corrected scanning transmission electron microscopes yield probe-position-dependent electron-energy-loss spectra (EELS) that can potentially provide spatial mapping of the underlying electronic states. EELS calculations, however, typically describe excitations by a plane wave travelling in vacuum, neglecting diffraction and interference effects. Here we report the development and initial application of a methodology that combines a full electronic-structure calculation with beam propagation in a thin film. The simulations are based on PAW plane-wave calculations of the excitation spectrum of the material and Bloch wave simulations of the probe propagation.

9:00AM H39.00006 Precise all-electron response functions from a combined spectral sum and Sternheimer approach: application to EXX-OEP, MARKUS BETZINGER, CHRISTOPH FRIEDRICH, STEFAN BLÜGEL, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — The optimized-effective-potential (OEP) method is used to construct local potentials from non-local, orbital-dependent functionals, e.g., exact exchange (EXX). The method involves two response functions, which have to be converged to very high precision to obtain smooth and stable local potentials. Usually, this requires an exceptionally large orbital basis, leading to very costly calculations, especially for all-electron methods such as FLAPW [1]. In this work, we propose a scheme that combines the usual spectral sum from standard perturbation theory with a radial Sternheimer approach. It also comprises a, albeit small, Pulay-type correction, which refines the results especially for small basis sets. We demonstrate that with this new approach already the conventional minimal LAPW basis set is sufficient to yield precise response functions. Furthermore, very few unoccupied states are required, which reduces the computational cost considerably. The numerically important Sternheimer contribution arises from the potential dependence of the LAPW basis functions and is constructed by solving inexpensive radial differential equations. We show results for complex transition-metal oxides.

9:12AM H39.00007 Electronic band structure of lanthanum bromide and strontium iodide from many-body perturbation theory calculations¹, DANIEL ABERG, Lawrence Livermore National Laboratory, PAUL EHART, Chalmers University of Technology, BABAK SADIGH, Lawrence Livermore National Laboratory — Rare-earth based scintillators represent a challenging class of scintillator materials due to pronounced spin-orbit coupling and subtle interactions between d and f states that cannot be reproduced by standard electronic structure methods such as density functional theory. In this contribution we present a detailed investigation of the electronic band structure of LaBr₃ using the quasi-particle self-consistent GW (QPscGW) method. This parameter-free approach is shown to yield an excellent description of the electronic structure of LaBr₃. Specifically we reproduce the correct level ordering and spacing of the 4f and 5d states, which are inverted with respect to the free La atom, the band gap as well as the spin-orbit splitting of La-derived states. We furthermore present electronic structure calculations using G₀W₀ for the important scintillator material SrI₂. We explicitly take into account spin-orbit coupling at all levels of the theory. Our results demonstrate the applicability and reliability of the GW approach for rare-earth halides and complex halides. They furthermore provide an excellent starting point for investigating the electronic structure of rare-earth dopants such as Ce and Er.

9:24AM H39.00008 First-principles studies of Ce and Eu doped inorganic materials as candidates for scintillator gamma ray detectors¹, ANDREW CANNING, Lawrence Berkeley National Laboratory, UC Davis, SLIM CHOUROU, STEPHEN DERENZO, Lawrence Berkeley National Laboratory — We have performed high-throughput DFT based (GGA+U) band structure calculations for new Ce and Eu doped wide band gap inorganic materials to determine their potential as candidates for gamma ray scintillator detectors. These calculations are based on determining the 4f ground state level of the Ce and Eu relative to the valence band of the host as well as the position of the Ce and Eu 5d excited state relative to the conduction band of the host. We find many classes of candidate materials where the 5d is in the conduction band preventing scintillation. Even when the Eu and Ce 4f and 5d levels are placed well in the gap of the host, traps on the host can also prevent the energy of the gamma ray transferring to the Eu or Ce. We therefore also performed calculations for host hole traps and electron traps to compare their energies to the Ce and Eu 4f and 5d levels.

9:36AM H39.00009 Test of Variational Methods for Molecular and Solid State Properties by Application to Hyperfine Interaction in Phosphorous Atom, T.P. DAS, R.H. PINK, S.R. BADU, Department of Physics, University at Albany, SUNY, ARCHANA DUBEY, Department of Physics, University of Central Florida, R.H. SCHEICHER, Department of Physics, Uppsala University, LEE CHOW, Department of Physics, University of Central Florida — As part of our program for testing the accuracy of variational methods for studying energy and wave-function dependent molecular and solid state properties, namely the Variational Hartree-Fock Many Body Perturbation Theory (VHFMBPT) and Variational Density Functional Theory (VDFT), we have studied the magnetic hyperfine interaction for ^{31}P nucleus in the ground state. Our investigations provide hyperfine constants of +35.2MHz by the VHFMBPT and -11.2 MHz by VDFT procedures as compared to +55.055 MHz from experiment [1]. The VHFMBPT procedure provides the same signs for one-electron and many-body contributions as obtained earlier [2] by the HFMBPT procedure which uses the needed one-electron atomic wave-functions for the occupied and unoccupied states obtained by solving the Hartree-Fock equations through numerical integration, and not variationally as in the VHFMBPT procedure. Possible avenues for improved agreement by both variational procedures will be suggested. [1] N.C. Dutta, C. Matsubara, R.T. Pu and T.P. Das, Phys. Rev. 9:48AM H39.00010 Sharp transition for single polarons in one-dimensional models with non-diagonal Su-Schrieffer-Heeger coupling, DOMINIC J.J. MARCHAND, PHILIP C.E. STAMP, University of British Columbia, NIKOLAY V. PROKOF'EV, University of Massachusetts, MONA BERCIU, University of British Columbia — Ever since Landau pointed out the possibility of an electron becoming self-trapped in its own lattice distortion, people have looked for sharp transitions in polaronic states. Gerlach and Löwen [1] proved the absence of such a transition in the case of a gapped (i.e. optical) phonon branch and an electron-phonon coupling $g(q)$ depending only on the phonon momentum q . Whether a sharp transition could be found in other models remained an open question for the last twenty years. By presenting both unbiased Diagrammatic Monte Carlo results for the single polaron with Su-Schrieffer-Heeger (SSH) coupling to optical phonons, and supporting results from no less than three other numerical and analytical approximations, we believe our previous work and that of our collaborators [2] to be the first unequivocal demonstration of a sharp transition in a polaronic system. Here we expand this work to more general models that include either an additional diagonal Holstein coupling to optical phonons, or a SSH coupling to acoustic phonons. The survival of the sharp transition in these models is investigated using the Bold Diagrammatic Monte Carlo method and the Momentum Average approximation. References: [1] Rev. Mod. Phys. 63, 63 (1991) [2] Phys. Rev. Lett. 105, 266605 (2010)

10:00AM H39.00011 Many-Pole Model Calculations of Inelastic Losses in XPS¹, J.J. KAS, J.J. REHR, University of Washington, M. GUZZO, L. REINING, Ecole Polytechnique — Inelastic losses such as satellites in x-ray photo-emission spectra (XPS) are difficult to treat theoretically due to the importance of many-body effects beyond the quasi-particle approximation. Here we present an approach based on an exponential (i.e., cumulant) representation² of the one-particle Green's function, together with³ a many-pole model of the dielectric function, which incorporates dynamic effects beyond the GW approximation. In this method the photo-electron is treated as in inverted LEED state which couples to the system via neutral, quasi-boson excitations. The approach yields an approximation to the XPS in terms of a convolution of a quasi-particle calculation and a spectral function that includes contributions from both intrinsic and extrinsic excitations,⁴ as well as interference between them. The method is illustrated with recent experimental results.⁵

10:12AM H39.00012 Low Energy Positron Interactions with Biological Molecules, INDIKA WAN- NIARACHCHI, CAROLINE MORGAN, Physics Department, Wayne State University, BERNHARD SCHLEGEL, Chemistry Department, Wayne State University, GARY KEDZIORA, AFRL/DSRC, Wright-Patterson AFB, LARRY BURGGRAB, Engineering Physics, Air Force Institute of Technology, MICHAEL PAK, SHARON HAMMES-SCHIFFER, Chemistry Department, Penn State University — There is some experimental evidence that positrons can produce distinctive molecular fragmentation patterns. It is known that tuning the incident positron energy to near resonance with molecule vibrations can strongly enhance the positron annihilation probability for a molecule.¹ This suggests that fragmentation induced by slow positrons may provide valuable complementary information to existing techniques for identification and study of proteins. In order to study this concept, we are developing a general quantum method for reliably calculating the density distribution for positrons bound to large biological molecules using NEO/GAMESS. We developed transferrable atom-centered positron basis sets for first-principles calculations for molecules containing O, N, C, and H. The positron density in the bound state is concentrated near the most electronegative atomic sites so that e^-e^+ annihilation will be most likely to occur in these regions for low incident positron energies leading to positron trapping in the bound state. Using the basis sets and approximations we have tested to predict where annihilation occurs can ultimately help us understand the resulting fragmentation patterns of larger biological molecules.

10:24AM H39.00013 Atomic Probing Structures of Electrolytes at Graphene Surface: Insights from X-ray Scattering and Molecular Dynamics, HUA ZHOU, PAUL FENTER, Argonne National Laboratory, PANCHAPAKESAN GANESH, PAUL KENT, DEEN JIANG, ARIEL CHIALVO, PASQUALE FULVIO, SHENG DAI, Oak Ridge National Laboratory, GUANG FENG, MICHAEL ROUHA, PETER CUMMINGS, Vanderbilt University, VOLKER PRESSER, JAKE MCDONOUGH, YURI GOGOTSI, MATTHEW WANDER, KEVIN SHUFORD, Drexel University — The interactions of electrolyte fluids with carbon-based electrodes control many complex interfacial processes encountered in electrochemical energy storage systems. However, our knowledge of the atomic/nanoscale reactivity at interfaces of electrolytes with electrodes remain scares due to the incomplete understanding of interfacial structures and processes in-situ and real-time encountered in real operation conditions. In this talk, we will present our efforts to obtain a molecular-scale perspective of the interactions of electrolytes with carbon surfaces near “real world” conditions. Structures of various electrolytes including slat aqueous and ionic liquids on atomically flat graphene (epitaxially grown on a SiC substrate), an ideal model fluid-solid interface system, were investigated by coupling high-resolution interface X-ray scattering techniques with molecular modeling-simulation approaches. These results provide a base-line for understanding relevant electrolyte/carbon interactions and will lead to fundamentally new insights and provide unique tests of atomistic fluid-solid interface models for energy storage systems.

10:36AM H39.00014 Charge Transfer Resistance of a Pristine Graphitic Carbon Interface, BRAD CORSO, ISRAEL PEREZ, PHILIP COLLINS, University of California, Irvine — Electron transfer to and from graphitic carbons is highly sensitive to the chemistry of the graphitic carbon surface. It is known that pristine graphitic carbon has a much higher interfacial resistance than defective carbon; however, a quantitative measure of the difference is limited by the difficulty of preparing truly pristine, defect-free surfaces. Here, we use an individual single-walled carbon nanotube (SWNT) and its single defect sensitivity to ensure that the graphitic carbon surface is pristine. The interfacial charge transfer resistance is measured in the context of a MnO₂-coated SWNT, a pseudocapacitor device whose charge cycling performance is found to be limited by the chemistry of the carbon interface. In our devices, the SWNT is uniformly coated with 250-350 nm of MnO₂ and cyclic voltammetry is analyzed using an equivalent circuit model to determine the charge transfer resistance. We prove that the defect-free carbon interface is less active than disordered interfaces of carbon or of metallic electrodes. This research is supported by the NEES Energy Frontier Research Center of the U.S. DOE Office of Basic Energy Sciences (#DESC0001160).

10:48AM H39.00015 Applications of Light Element X-ray Raman Spectroscopy and Hard X-ray Emission Spectroscopy to the Electronic Structure of Energy Storage Materials: Prospects and Initial Results from the Spectroscopy Program at SSRL, DENNIS NORDLUND, WENG TSU-CHIEN, DIMOSTHENIS SOKARAS, SLAC National Accelerator Laboratory, STANFORD SYNCHROTRON RADIATION LABORATORY TEAM — We present the applicability of x-ray raman spectroscopy of light elements and hard x-ray emission to probe the electronic structure of energy storage materials under in-situ conditions. In particular, recent advances in resolution and throughput of x-ray raman spectroscopy (XRS) offer the capability to measure 1s x-ray absorption profiles of light elements such as lithium, boron, carbon, nitrogen and oxygen with less than 0.3eV resolution in the order of 10s of minutes. Initial results from the Spectroscopy program at SSRL and collaborations with groups in various energy storage fields will be presented, with an emphasis on Lithium Batteries and Hydrogen Storage applications.

Tuesday, February 28, 2012 8:00AM - 11:00AM —
Session H40 DBIO DPOLY: Focus Session: Protein Association II: Aggregation and Fibril Formation 156A

8:00AM H40.00001 The Physics of Amyloid Aggregation and Templating in Prions¹, DANIEL COX, Dept. of Physics, UC Davis — The problem of self-assembled amyloid aggregation of proteins in structures with beta-strands perpendicular to a one dimensional grown axis is interesting at a fundamental level (is this the most generic end state of proteins?), from a biological level (if the self-assembly can be regulated it is of use in contexts like spider silk and bacterial colony formation), for human public health (aggregation unregulated induces diseases like mad cow and Alzheimer's), and for possible materials applications (e.g., in tissue scaffolding). In this presentation, I will review the work of my group in examining the possibility that the left-handed beta helix (LHBH) structure can be the building block of the aggregates of mammalian prion and yeast prion proteins. I will also discuss our efforts to assess the possibility of a novel pH driven structural switch between LHBH and alpha-helical forms in the ordered half of the mammalian prion protein, and now the possibly pH stabilized LHBH structure can template aggregate growth of the disordered half of the protein, identified in numerous experimental studies as most relevant to disease.

¹Support from US NSF I2CAM International Materials Institute Award, Grant DMR-0844115 is gratefully acknowledged

8:36AM H40.00002 Early-Aggregation Studies of Polyglutamine in Solution, AARON FLUITT, JUAN DE PABLO, University of Wisconsin-Madison — Several neurodegenerative diseases, notably Huntington's disease, are associated with certain proteins containing extended polyglutamine tracts. In all polyglutamine diseases, the age of onset is inversely correlated with the length of the polyglutamine domain beyond some pathological threshold. Diseased cells are characterized by intranuclear inclusions rich in aggregated polyglutamine. Experimental evidence suggests that oligomeric aggregate species, not mature amyloid fibrils, are the species most toxic to the cell. Little is known about the structures and aggregation dynamics of polyglutamine oligomers due to their short lifetimes. A better understanding of the pathway through which polyglutamine peptides form oligomeric aggregates will aid the design of therapies to inhibit their toxic activity. In this work, we report structural characterization of polyglutamine monomers and dimers from atomistic molecular dynamics simulations in explicit water. Umbrella sampling simulations reveal that the stability of the dimer species with respect to the disassociated monomers is an increasing function of the chain length.

8:48AM H40.00003 Search for Length Dependent Stable Structures of Polyglutamine Proteins with Replica Exchange Molecular Dynamic¹, ALEXANDER KLUBER, ROBERT HAYRE, DANIEL COX, University of California Davis — Motivated by the need to find beta-structure aggregation nuclei for the polyQ diseases such as Huntington's, we have undertaken a search for length dependent structure in model polyglutamine proteins. We use the Onufriev-Bashford-Case (OBC) generalized Born implicit solvent GPU based AMBER11 molecular dynamics with the parm96 force field coupled with a replica exchange method to characterize monomeric strands of polyglutamine as a function of chain length and temperature. This force field and solvation method has been shown among other methods to accurately reproduce folded metastability in certain small peptides, and to yield accurately de novo folded structures in a millisecond time-scale protein. Using GPU molecular dynamics we can sample out into the microsecond range. Additionally, explicit solvent runs will be used to verify results from the implicit solvent runs. We will assess order using measures of secondary structure and hydrogen bond content.

¹Research supported by NSF grant DMR-0844115

9:00AM H40.00004 Lysozyme Aggregation and Fibrillation Monitored by Dynamic Light Scattering, LOUIS NEMZER, BRET FLANDERS, JEREMY SCHMIT, CHRISTOPHER SORENSEN, Department of Physics - Kansas State University — The aggregation of amyloidogenic proteins provides a rich phase space with significant biomedical implications, including a link with several age-related diseases. We employed dynamic light scattering to monitor the aggregation of lysozyme, a model protein, from a monomeric state until the formation of micron-sized fibrils. For an aqueous lysozyme solution buffered at pH 2, the auto-correlation function of the scattered light intensity was found to be well-fit by a single exponential function with decay time $\tau = 1/(2Dq^2) = 0.25$ ms, which corresponds to a mean hydrodynamic radius (R_H) of 2.2 nm, very likely generated by monomers. Ethanol (4% v/v final concentration) induced a partial unfolding, to $R_H = 4.6$ nm. The subsequent addition of 70 mM KCl was found to shrink the size back to $R_H = 2.5$ nm, as expected when a denatured protein refolds due to partial screening of the intramolecular repulsion. However, further aggregation was not observed. At pH 4, using a low-salt acetate buffer, more ethanol (10% v/v) was required to initiate unfolding, but once it occurred, larger aggregates formed. These results are consistent with the model that partial unfolding, which exposes beta-motif secondary structure, is a prerequisite for aggregation and fibrillation, but the aggregation fate depends on the protein charge state (pH) and screening (salt concentration).

9:12AM H40.00005 Primary nucleation and linear aggregation: novel methods take us further

, GONZALO GARCIA, Department of Chemistry, University of Cambridge — Understanding linear aggregation has long been of interest in the study of proteins, as it is relevant in several human diseases such as Alzheimer's Disease. While much work has been carried out experimentally and numerically, relatively little has been done to develop an analytical model for the time evolution and scaling behaviour of such systems. Here, we present a novel mathematical framework, guided by physical insight, for approaching these problems. We then apply this to derive an exact expression for the evolution of the polymer length distribution of an amyloid system, driven by primary nucleation, taking into account both elongation and depolymerisation. This is presented in terms of a perturbative expansion, and is valid for negligible monomer depletion. We then apply a similar framework to solve a similar system that also includes an arbitrary number of conformational intermediates before reaching the final conformation - we uncover the time evolution of the total mass of polymers in the final conformational state, and demonstrate various properties about its time-scaling behaviour. We then apply self-consistent iterative schemes, starting from these solutions, to derive a series of approximate analytical models for these systems, taking monomer depletion into account.

9:24AM H40.00006 The Mechanisms of Aberrant Protein Aggregation

, SAMUEL COHEN, Harvard University, University of Cambridge, MICHELE VENDRUSCOLO, CHRIS DOBSON, TUOMAS KNOWLES, University of Cambridge — We discuss the development of a kinetic theory for understanding the aberrant loss of solubility of proteins. The failure to maintain protein solubility results often in the assembly of organized linear structures, commonly known as amyloid fibrils, the formation of which is associated with over 50 clinical disorders including Alzheimer's and Parkinson's diseases. A true microscopic understanding of the mechanisms that drive these aggregation processes has proved difficult to achieve. To address this challenge, we apply the methodologies of chemical kinetics to the biomolecular self-assembly pathways related to protein aggregation. We discuss the relevant master equation and analytical approaches to studying it. In particular, we derive the underlying rate laws in closed-form using a self-consistent solution scheme; the solutions that we obtain reveal scaling behaviors that are very generally present in systems of growing linear aggregates, and, moreover, provide a general route through which to relate experimental measurements to mechanistic information. We conclude by outlining a study of the aggregation of the Alzheimer's amyloid-beta peptide. The study identifies the dominant microscopic mechanism of aggregation and reveals previously unidentified therapeutic strategies.

9:36AM H40.00007 Amyloid growth: combining experiment and kinetic theory

, TUOMAS KNOWLES, SAMUEL COHEN, MICHELE VENDRUSCOLO, CHRISTOPHER DOBSON, University of Cambridge — The conversion of proteins from their soluble forms into fibrillar amyloid nanostructures is a general type of behaviour encountered for many different proteins in the context of disease as well as for the generation of a select class of functional materials in nature. This talk focuses on the problem of defining the rates of the individual molecular level processes involved in the overall conversion reaction. A master equation approach is discussed^{1 2} and used in combination with kinetic measurements to yield mechanistic insights into the amyloid growth phenomenon.

9:48AM H40.00008 Scaling exponents report on changes in the mechanism of filamentous

growth, LUKE RAJAH, SAMUEL COHEN, Department of Chemistry, University of Cambridge, SARA LINSE, ERIK HELLSTRAND, Chemistry Department and Molecular Protein Science, Lund University, CHRIS DOBSON, TUOMAS KNOWLES, Department of Chemistry, University of Cambridge — We analyse the scaling behaviour in the proliferation and growth of protein nanostructures. We show that changes in scaling exponents that govern the lag time of the reaction within a given system can be identified with mechanistic changes that affect a molecular step in the assembly pathway. In this study, we focused on fibril growth from a representative protein, insulin, and an unstructured peptide, A β 42. Our results reveal that the scaling exponent contains contributions not only from the dominant secondary nucleation mechanism in the systems studied, but also from the primary nucleation step even in cases where the generation of nuclei from the primary pathway is significantly smaller than from the secondary pathway. These results shed light on the origin of the scaling behaviour of filamentous growth.

10:00AM H40.00009 Control the kinetics and pathway of insulin fibril formation

, ZHONGLI ZHENG, BENXIN JING, Y. ELAINE ZHU, University of Notre Dame — Protein fibrils have been proposed as possible toxic agents for many amyloid related diseases, such as Alzheimer's disease, however the reaction pathway toward the amyloid fibrillation remain inadequately understood. In this work, we examine the conformational transition of human insulin as the model amyloid protein by single-molecule fluorescence spectroscopy and imaging. By controlling the pH cycling, insulin monomer and oligomers are indentified at given pH variation condition. Furthermore, low frequency ac-electric fields are employed to control the insulin aggregation from its monomers in a microchannel. It is observed that lag time to induce insulin fibrillation can be significantly shortened, in compasson to the commonly used cooling and seeding methods, and exhibits a strong dependence on applied ac-field strength. Additionally, the structure of insulin aggregates under ac-electric fields is observed to be drastically different from that under the temperature control.

10:12AM H40.00010 Time-Dependent and Low Temperature Studies of Amyloidogenic and Non-amyloidogenic Proteins by Dielectric Relaxation Spectroscopy

, DONALD BARRY, SHAUN MARSHALL, SHELBY HUNT, Worcester Polytechnic Institiute, FLORIN DESPA, University of California, Davis, IZABELA STROE, Worcester Polytechnic Institiute — We present dielectric relaxation spectroscopy measurements of amyloidogenic Abeta (1-42) and non-amyloidogenic Abeta (42-1) proteins over a frequency range of 10 mHz to 10 MHz. Measurements were performed as a function of time from 0 to 24 h and temperature range of 193K-283K. Two relaxation peaks, alpha and beta, were observed at temperatures above 193 K. These peaks are attributed to the bulk and bound water. As a function of time, the dielectric signal of the Abeta (1-42) shifts towards the dielectric signal of the solvent while for the Abeta (42-1) the dielectric signal does not change. The activation energies of Abeta (1-42) and Abeta (42-1) were calculated and significant differences were found. We attribute these variations to structural changes that affect the hydration map of Abeta (1-42) aggregates. Our results are in agreement with theoretical predictions.

10:24AM H40.00011 Applying microfluidic techniques in quantitative studies of protein aggregation

, THERESE HERLING, University of Cambridge — Protein aggregation and fibrillation is involved in a number of devastating diseases, of which we have a limited understanding at present. Microfluidic techniques can be used in developing quantitative assays to study individual aspects of protein aggregation. Under certain conditions bovine insulin aggregates to give spherulites; spherical structures with fibrils growing and branching out from a central core. Drawing a parallel to actin polymerisation of the cell's cytoskeleton, fibril growth generates force. The force generated by polymerisation at fibril ends during spherulite growth can be measured in a microfluidic environment (TPJ Knowles et al, PNAS, 2009). By measuring the bending of four polydimethylsiloxane walls by a growing spherulite positioned in the centre, the force generated by polymerisation at fibril termini can be calculated. By growing the spherulites with a constant flow of monomer, the maximum force able to be generated by fibril growth, the stall force, can be calculated. This gives insight into the energy landscape of protein aggregation.

10:36AM H40.00012 Anomalous Formation of Multilayer Protein Aggregates on the Surface of Nanotubular TiO_2 ¹, JACOB FORSTATER, ALFRED KLEINHAMMES, YUE WU, Department of Physics and Astronomy, University of North Carolina at Chapel Hill — Significant evidence links protein aggregation to the pathology and progression of most protein misfolding diseases. Protein aggregation also poses a significant problem for the safe and cost-effective production of therapeutic proteins. A comprehensive understanding of these problems requires both a detailed understanding native protein-protein interactions as well as an understanding of how protein-material interactions may alter protein aggregation phenomenon. Here we report on the anomalous formation of multilayered protein aggregates of globular proteins on the surface of TiO_2 nanotubes. Our findings suggest that minor alterations of the surface hydration properties of the nanotubes may drastically alter protein aggregation phenomenon. We further highlight the role of electrostatic and Van der Waals forces in this aggregation process.

10:48AM H40.00013 Effect of Lipid Bilayer on Human Islet Amyloid Polypeptide Self Assembly, CHI-CHENG CHIU, SADANAND SINGH, JUAN J. DE PABLO, University of Wisconsin-Madison — Aggregates of human islet amyloid polypeptides (hIAPP, also known as human amylin) are commonly found in the pancreatic β -cells of type II diabetes patients. Experimental studies have shown that small aggregates of hIAPP, that arise during the assembly process, lead to membrane leakage and are highly cytotoxic. Due to the fast assembly kinetics, it is difficult to study the early aggregation of hIAPP experimentally. In this work, we use molecular simulation with a coarse grained (CG) model to investigate the oligomerization of hIAPP with and without the presence of lipid bilayers. We develop a CG protein model that reproduces the three thermodynamically stable structures of hIAPP, namely α -helix, β -hairpin, and unstructured coil, and the corresponding free energy differences calculated by atomistic molecular simulations. The aggregated structure of hIAPP also agrees with that proposed by NMR experiments. We further investigate the assembly of hIAPP in the presence of a lipid bilayer and its effect on the membrane leakage. Comparing our results with the mechanism proposed based on experimental data provides a better understanding of the origins of hIAPP self assembly and its toxicity.

Session H43 DBIO: Invited Session: Physics of Systems Biology 157AB

8:00AM H43.00001 Robustness of Biological Circuits, MARC KIRSCHNER, Department of Systems Biology, Harvard Medical School, Boston MA, USA — In responding to inputs biological systems do many types of calculations, some of which serve to maximize the signal and suppress noise. Physiology faces similar requirements and to fulfill these many sensory systems such as vision and hearing are designed to respond logarithmically to the fold change over initial conditions, a property known as “Weber’s Law.” Mathematical modeling of the ancient Wnt signaling circuit suggested that a key design feature of that pathway was to provide a robust logarithmic output and as a consequence it does not respond robustly in a linear or hyperbolic way. We confirmed this behavior in *Xenopus* embryos and in human colorectal cells in culture. However, to read a robust logarithmic output from the Wnt pathway in the form of fold change in the levels of beta catenin, the responding transcriptional circuit must be able to compare initial and final levels of beta catenin accurately. This is exactly what we found in *Xenopus* embryos. What kind of transcriptional pathway has this property? Examination of the detailed promoter of a classic wnt responsive gene showed that two domains contribute to the calculation: the well known TCF/LEF sites that bind beta catenin near the coding sequence and a functional DNA feature upstream, which is unresponsive to beta catenin. The TCF/LEF sites on their own respond in a linear mode to the beta catenin concentration. The upstream functional feature confers the logarithmic response. Knowledge of the pathway structure should allow us to define a “Weber’s Law” circuit that allows transcriptional systems to suppress noise by responding to fold change rather than to simple saturation.

8:36AM H43.00002 Epigenetic switches and network transitions, MASAKI SASAI, Nagoya University — We investigate dynamics of gene networks which are regulated by both the fast binding/unbinding of transcription factors to/from DNA and the slow processes of chromatin structural change or histone modification. This heterogeneous dynamics consisting of different time scales is analyzed by the mean-field approximation and the stochastic simulation to show that the network exhibits multiple metastable states and is characterized by transitions among them. We discuss distribution and fluctuation of states of the core gene network of embryonic stem cells as an example of such heterogeneous dynamics and the simulated transitions are compared with the experimental data on the distribution of stem cell states.

9:12AM H43.00003 Specificity and Self Recognition in Immunity, ARUP K. CHAKRABORTY, Massachusetts Institute of Technology — No abstract available.

9:48AM H43.00004 Landscape and Flux Framework for Non-Equilibrium Networks: Kinetic Paths and Rate Dynamics, JIN WANG, Stony Brook University — We developed a general framework to quantify three key ingredients for dynamics of nonequilibrium systems through path integrals in length space. First, we identify dominant kinetic paths as the ones with optimal weights, leading to effective reduction of dimensionality or degrees of freedom from exponential to polynomial so large systems can be treated. Second, we uncover the underlying nonequilibrium potential landscapes from the explorations of the state space through kinetic paths. We apply our framework to a specific example of nonequilibrium network system: lambda phage genetic switch. Two distinct basins of attractions emerge. The dominant kinetic paths from one basin to another are irreversible and do not follow the usual steepest descent or gradient path along the landscape. It reflects the fact that the dynamics of nonequilibrium systems is not just determined by potential gradient but also the residual curl flux force, suggesting experiments to test theoretical predictions. Third, we have calculated dynamic transition time scales from one basin to another critical for stability of the system through instantons. Theoretical predictions are in good agreements with wild type and mutant experiments. We further uncover the correlations between the kinetic transition time scales and the underlying landscape topography: the barrier heights along the dominant paths. We found that both the dominant paths and the landscape are relatively robust against the influences of external environmental perturbations and the system tends to dissipate less with less fluctuations. Our theoretical framework is general and can be applied to other nonequilibrium systems.

10:24AM H43.00005 Experimental evolution in budding yeast, ANDREW MURRAY, Harvard University — I will discuss our progress in analyzing evolution in the budding yeast, *Saccharomyces cerevisiae*. We take two basic approaches. The first is to try and examine quantitative aspects of evolution, for example by determining how the rate of evolution depends on the mutation rate and the population size or asking whether the rate of mutation is uniform throughout the genome. The second is to try to evolve qualitatively novel, cell biologically interesting phenotypes and track the mutations that are responsible for the phenotype. Our efforts include trying to alter cell morphology, evolve multicellularity, and produce a biological oscillator.

Session H44 DPOLY: Focus Session: Nano to Mesoscale Structure in Ordered Systems: Liquid Crystal Topology and Defects 157C

8:00AM H44.00001 Polymer Physics Prize Break —

8:36AM H44.00002 Chiral Self-Assembly¹, ROBERT MEYER², Physics Department, Brandeis University, Waltham, MA 02454 — Chirality, the lack of reflection symmetry, at the molecular level has a profound influence on the ordering of molecular assemblages at the macroscopic scale. The example discussed here is the self-assembly of monolayers of rod-like fd virus particles, with the virus particles oriented on the average perpendicular to the plane of the layer, like a single layer of a smectic-A liquid crystal. Because these virus particles are chiral, they would prefer a twisted packing, which is incompatible with the layer structure. The twisted packing can only appear locally, at layer edges or in isolated defects in the interior of the layer. As chirality increases, the twisted regions achieve lower energy, until they can drive remarkable transformations to structures with longer edges and/or a greater number of defects.

9:12AM H44.00003 Pillar-Assisted Epitaxial Assembly of Focal Conic Domain Arrays in Smectic-A Liquid Crystals, DANIEL BELLER, APIRADEE HONGLAWAN, MARCELLO CAVALLARO, RANDALL KAMIEN, KATHLEEN STEBE, SHU YANG, University of Pennsylvania — We demonstrate a versatile approach to tailor the spacing and symmetry of periodic arrays of toric focal conic domains (TFCDs) over a large area via confinement of smectic-A liquid crystals (SMA LCs) in patterned substrates. Arrays of pillars with variable dimensions are employed to direct the assembly of TFCDs, determining both the domain positions and the size of the defects. Highly ordered square and hexagonal arrays of TFCDs result from topographical confinement of the LC in square and hexagonal arrays of pillars. Focal conic domains are shown to form only when the confined geometry provides sufficient area so that substrate-induced planar alignment of LC molecules is energetically favorable. Since the spacing and symmetry of the TFCD array can be readily pre-determined by the arrangement of the directing pillars, this pillar-assisted assembly technique serves as a model study for directed assembly of liquid crystals in three dimensions and offers improvements to the capability of LC-based templates for device fabrication and lithography.

9:24AM H44.00004 Shape and chirality transitions in twisted nematic elastomer ribbons: Finite element simulation studies, VIANNEY GIMENEZ-PINTO, Liquid Crystal Institute, Kent State University, FANGFU YE, University of Illinois, Urbana, BADEL MBANGA, University of Massachusetts, Amherst, JONATHAN SELINGER, ROBIN SELINGER, Liquid Crystal Institute, Kent State University — We use finite element simulation studies to explore transitions of shape and chirality in nematic elastomer ribbons with a twisted director configuration. Recent experimental and theoretical studies demonstrated that these fascinating materials show reversal of macroscopic chiral sense under a change of temperature, and explored shape selection as a function of the sample's aspect ratio. We explore these phenomena via three dimensional finite element simulation studies. For ribbons with width/thickness ratio above a threshold value, we find that on heating the sample undergoes a sequence of shape transitions from right handed helix – right handed twisted ribbon – flat ribbon – left handed twisted ribbon – left handed helix. Ribbons with width/thickness ratio below the threshold show fewer shape transitions, from right handed twisted ribbon – flat ribbon – left handed twisted ribbon. These results are in qualitative agreement with theoretical predictions, provide insight into experimental observations, and demonstrate the value of finite element methods for future engineering design of nematic elastomer devices.

9:36AM H44.00005 Frustrated orientational order on extrinsic geometries¹, BADEL L. MBANGA, GREGORY M. GRASON, Department of Polymer Science and Engineering, University of Massachusetts, Amherst, CHRISTIAN D. SANTANGELO, Department of Physics, University of Massachusetts, Amherst — The ground state of an anisotropic liquid on a curved surface has topological defects due to the surface's Gaussian curvature. The extrinsic geometry of the surface, however, frustrates the ground state arising from Gaussian curvature alone, changing the defect configurations in the ground state or expelling them from the surface altogether. We study nematic order on unduloids - a family of undulated cylinders with constant mean curvature spanning from the cylinder to a chain of spherical droplets - arising in systems ranging from liquid bridges to fluid membranes. We identify structural transitions in which pairs of disclinations of opposite signs are nucleated as the unduloid progresses from cylinder to spheres, explicitly separating the role of intrinsic geometry, which nucleates disclinations to screen Gaussian curvature, and extrinsic geometry, which expels defects from the neck. We describe some implications for the pinching off of a cylinder.

9:48AM H44.00006 Topology of knots and links in chiral nematic colloids, SLOBODAN ZUMER, University of Ljubljana and Jozef Stefan Institute, SIMON COPAR, University of Ljubljana, IGOR MUSEVIC, University of Ljubljana and Jozef Stefan Institute, MIHA RAVNIK, University of Oxford, UROS TKALEC, Jozef Stefan Institute — Nematic braids formed by disclinations entangling colloidal particles in chiral and achiral nematic liquid crystals are geometrically stabilized and restricted by topology. We report how self-linking number enables a classification of entangled defect lines [1, 2] and how a simple rewiring scheme for the orthogonal crossing of two half integer disclinations, based on a tetrahedral rotation of two relevant disclination segments allows us to predict nematic braids and their self-linking numbers. We further describe how using of laser micromanipulation enable the knotting of defect lines in chiral nematic colloids into knots and links of arbitrary complexity [3]. Colloids stabilized by nematic braids based on all knots and links with up to six crossings, including Hopf link, Star of David, Borromean rings are realized. We demonstrate how topology leads to the engineering of complex soft materials.

10:00AM H44.00007 Modeling texture transitions in cholesteric liquid crystal droplets¹, ROBIN SELINGER, VIANNEY GIMENEZ-PINTO, SHIN-YING LU², JONATHAN SELINGER, ANDREW KONYA, Kent State University — Cholesteric liquid crystals can be switched reversibly between planar and focal-conic textures, a property enabling their application in bistable displays, liquid crystal writing tablets, e-books, and color switching “e-skins.” To explore voltage-pulse induced switching in cholesteric droplets, we perform simulation studies of director dynamics in three dimensions. Electrostatics calculations are solved at each time step using an iterative relaxation method. We demonstrate that as expected, a low amplitude pulse drives the transition from planar to focal conic, while a high amplitude pulse drives the transition from focal conic back to the planar state. We use the model to explore the effects of droplet shape, aspect ratio, and anchoring conditions, with the goal of minimizing both response time and energy consumption.

10:12AM H44.00008 Necklaces of Liquid Crystal Beads: Nematic Drops Constrained on Thin Cellulosic Fibers, PEDRO ALMEIDA, YONG GENG, FCT/UNL, EUGENE TERENTJEV, University of Cambridge, MARIA HELENA GODINHO, FCT/UNL, CENIMAT COLLABORATION, CAVENDISH LABORATORY COLLABORATION — Liquid crystal droplets dispersed in a continuous matrix have important applications in electro-optical devices. They also produce intriguing topological defect structures due to the confinement of the liquid crystal by closed boundaries that impose alignment at the interface. In this work we use a simple method to generate stable liquid crystal droplets topologically equivalent to a toroid by depositing tiny volumes of a nematic liquid on cellulosic micro-fibers (1 μm diameter) suspended in air. This system can exhibit non-trivial point topological defects which can be energetically unstable against expanding into ring defects, depending on the fibers constraining geometries. By changing temperature, the system remains stable and allows the study of the defects evolution near the nematic-isotropic transition showing qualitatively different behavior on cooling and heating processes. The necklaces of such liquid crystal drops constitute excellent systems for fundamental studies and open new perspectives for applications. This work was sponsored by Air Force Office of Scientific Research, Air Force Material Command, USAF, under grant number FA8655-10-1-3020. 10:24AM H44.00009 Controlling the location of defects in nematic shells, ALBERTO FERNANDEZ-NIEVES, Georgia Tech, TERESA LOPEZ-LEON, MAURIZIO NOBILI, CHRISTOPHE BLANC, University of Montpellier 2 — We study nematic shells with four $s=+1/2$ defects and vary the elastic constant anisotropy of the liquid crystal by approaching the nematic-to-smectic phase transition temperature. We find the defects ultimately arrange themselves along a great circle, consistent with recent expectations. Changing the elastic constant anisotropy provides an alternative route to changing the shell thickness inhomogeneity for controlling the defects location.

10:36AM H44.00010 Structures in liquid crystalline shells at a nematic-smectic transition¹, JAN LAGERWALL, Seoul National University, Grad. School of Convergence Science & Technology, Korea, HSIN-LING LIANG, Inst. of Organic Chemistry, Johannes Gutenberg University Mainz, Mainz, Germany, PER RUDQUIST, Chalmers University of Technology, Dept. for Microtechnology & Nanoscience, Goteborg, Sweden — Liquid crystalline shells display phenomena that are fascinating from a fundamental physics point of view and they also hold promise for innovative applications e.g. for advanced colloids. The key feature of these shells is the unavoidable presence of topological defects, the types and numbers of which depend on the phase as well as the geometrical features of the shell. Here we present our investigation of the complex internal reordering phenomena occurring in a liquid crystalline shell undergoing a transition between the nematic and smectic phases. In the smectic phase, the topological and geometrical constraints of a spherical shell with symmetric boundary conditions imposed on the developing 1D quasi-long-range order create a conflict that triggers a series of buckling instabilities, resulting in two different characteristic defect patterns. We will also show very recent results on shells with asymmetric boundary conditions, giving rise to beautiful complex patterns, some transitory, some stable. The phase transition between nematic and smectic order yields varying textures depending on the shell size and thickness, and on the specific alignment types at the shell in- and outside, respectively.

10:48AM H44.00011 Visualizing, manipulating, and imprinting π -wall defects in self-assembled colloidal membranes, MARK ZAKHARY, THOMAS GIBAUD, C. NADIR KAPLAN, EDWARD BARRY, Brandeis University, RUDOLF OLDENBOURG, Marine Biology Laboratory, ROBERT B. MEYER, ZVONIMIR DOGIC, Brandeis University — Geometric frustration and the resulting topological defects play an important role in determining the structural, mechanical and optical properties of materials. Here we describe the behavior of a new type of defect, called a π -wall, in a model system of colloidal membranes composed of chiral rod-like *fd* viruses. We use complimentary optical microscopy techniques to study the structure and energetics of π -walls, and develop a model based on the analogy between liquid-crystals and superconductors to determine the structure and energetics of π -walls. We then focus on π -wall formation, showing that π -walls naturally assemble through a unique coalescence process in which chiral frustration plays an essential role. π -walls can also be artificially created and engineered using externally applied optical forces.

Tuesday, February 28, 2012 8:00AM - 11:00AM —

Session H45 DPOLY: Focus Session: Thin Film Block Copolymers - Phase Behavior 159

8:00AM H45.00001 Polymer Physics Prize Break —

8:36AM H45.00002 Controlling the Orientation of Block Copolymer Thin Films with Selective and Neutral Nanoparticles, MISANG YOO, SEYONG KIM, Korea University, BUMJOON J. KIM, Korea Advanced Institute of Science and Technology, JOONA BANG, Korea University — The bottom up approach using self-assembly of block copolymers (BCP) have been considered as a powerful technique which can resolve the limitations of conventional nanolithograph. For practical applications, the perpendicular orientation of microdomains with respect to the substrate is a prerequisite. However in most cases, one of the domains has a preferential interaction with the substrate and this interaction induces parallel orientation of the microdomains. To overcome the preferential interaction and to obtain vertically orientated BCP microdomains, diverse approaches have been developed. Previously, we synthesized thermally stable core-shell gold nanoparticles using UV cross-linkable BCP and also precisely tuned the surface property of nanoparticles which are selective and neutral to PS and PMMA by adjusting the composition of polymeric ligand. Moreover, we demonstrated the effect of selective and neutral gold nanoparticles on the orientation of PS-PMMA thin films. Herein, we further investigated the effect of selective and neutral gold nanoparticles on the orientation of BCP thin films of lamellar and cylindrical BCP according to the film thickness. The thin film morphologies were characterized with AFM and SEM.

8:48AM H45.00003 Assembly and Photo-Induced Disorder in Block Copolymer-Additive Systems¹, LI YAO, JAMES WATKINS, University of Massachusetts Amherst — Additives that hydrogen bond selectively to one block of a weakly ordered or disordered block copolymer can drive phase segregation to yield well ordered materials. Here we show that the addition of D- or L-tartaric acid to low molecular weight, weakly segregated poly(ethylene oxide-block-tert-butyl acrylate), PEO-b-PtBA, induces strong segregation and well ordered morphologies as evidenced by Small Angle X-ray Scattering. This strong interaction between enantiopure tartaric acid and the PEO block also suppresses PEO crystallinity at room temperature. While the addition of racemic tartaric acid does not strengthen segregation nor does it suppress PEO crystallization. The UV-exposure of well ordered films of PEO-b-PtBA/tartaric acid blends containing a photo acid generator followed by a post-exposure bake results in the deprotection of the tert-butyl acrylate block to yield poly(acrylic acid) (PAA). Since PAA and PEO are miscible and tartaric acid can interact strongly with either block, the system becomes disorder, resulting in a photo-induced disordering transition which can be exploited to pattern the surfaces. The kinetic behavior of the disordering transition upon deprotection of PtBA to PAA was studied using Grazing-Incidence Small-Angle X-ray Scattering.

¹Funding from Center for Hierarchical Manufacturing (CHM); Facility support from Materials Research Science and Engineering Center at University of Massachusetts Amherst (MRSEC UMASS) and Cornell High Energy Synchrotron Source (CHESS)

9:00AM H45.00004 Diblock copolymer morphologies in ultra thin films under shear, MARCO PINNA, ANDREI ZVELINDOVSKY, University of Central Lancashire, XIAOHU GUO, Daresbury Laboratory, CHRISTINE STOKES, University of Central Lancashire — We demonstrate that the shear alignment and the shear-induced transitions in sphere-forming diblock copolymer single layer and bilayer films observed experimentally can be explained by cell dynamics simulation, a simple model with a Ginzburg-Landau Hamiltonian. In two layer films the spheres align in various arrangements, like (100) or (110) bcc plains, or transform to cylinders depending on the shear rate and the temperature. We present a nontrivial alignment mechanism of a single layer of spherical domains in shear via slug-like movement of transient cylindrical micelles. In addition, we clarify the formation of the perpendicular cylinders, found in the recent particle based simulation. We also present results on lamellae shearing in ultra-thin films.

9:12AM H45.00005 Structure and dynamics of random block copolymers in the bulk and thin films, MARCUS MÜLLER, BIRGER STEINMÜLLER, Georg-August University, Göttingen, Germany, KEITH H. HAMBRECHT, GRANT D. SMITH, DMITRY BEDROV, University of Utah, Salt Lake City — Using a soft, coarse-grained model and a Lennard-Jones bead-spring model, we study the morphology of random block copolymers in the bulk and in contact with a hard wall that preferentially attracts one component. We show that both coarse-grained models yield similar equilibrium morphologies at intermediate and long length scales, and identify a mapping between the parameters of the two models. For most parameters we observe a disordered, microemulsion-like morphology. We study the single-chain dynamics in the bulk and in contact with a preferential surface. The relaxation times of the soft, coarse-grained model is about two orders of magnitude faster than the Lennard-Jones bead-spring model. In both models the relaxation time increases with segregation but the Lennard-Jones bead-spring model is additionally slowed down by the densification of the local packing at low temperatures. We employ the soft, coarse-grained model to generate starting configurations for the bead-spring model. Then, the bead-spring model is quenched below its glass transition temperature, and we investigate the local mechanical properties of the disordered, yet structured morphology.

9:24AM H45.00006 Macrophase Separation of Block Copolymer Blends in Thin Films, LANCE WILLIAMSON, PAUL NEALEY, University of Wisconsin — The behavior of macrophase-separating blends of symmetric polystyrene-*b*-poly(methyl methacrylate) block copolymers in thin films on non-preferential surfaces was characterized with respect to the blends' molecular weights and composition. When the molecular weight ratio of block copolymers is at least five, the blends segregate into a domain of nearly pure small block copolymer with a small lamellar period and a domain of about equal volume fraction of each block copolymer with a larger lamellar period. The composition and structure of these blends was determined by analyzing the period and area fraction of each phase from plan-view scanning electron micrographs. The lamellae propagate through the thickness of the film. The use of block copolymer blends has potential in block copolymer lithography as a strategy to pattern different period structures in the same film.

9:36AM H45.00007 Phase segregation at the sub-5-nm scale using high χ Poly(ethylene oxide-*b*-dimethylsiloxane) copolymers, DAMIEN MONTARNAL, GLENN FREDRICKSON, EDWARD KRAMER, CRAIG HAWKER, Materials Research Laboratory, UCSB — Silicon containing block copolymers, such as Poly(styrene-*b*-dimethylsiloxane) (PS-PDMS), have recently received significant attention for nanolithographic applications [Jung et al., Nano Letters 2010, 10, 1000]. PDMS provides indeed a robust and highly selective mask to oxygen reactive ion etching. In addition, the high Flory-Huggins $\chi_{PS-PDMS}$ parameter (about 0.3 at room temperature) favors the segregation of low molecular weight (16 kg/mol) block copolymers (BCPs) into well-organized structures with pitch as small as 17 nm. In an effort to downscale further the size of structures formed by BCP, we decided to turn to copolymers with even higher χ parameters. Copolymers of Poly(ethylene oxide) (PEO) and PDMS are known to have extremely high χ parameters (0.4 -1.1) [Galin et al., Macromolecules, 1981, 14, 677], but their bulk and thin film properties have not been investigated in detail. PEO-PDMS BCPs were synthesized by chain coupling via a versatile copper-activated azide-alkyne click reaction. The unusually high χ parameter between EO and DMS allowed strong phase segregation to occur in copolymers with molecular weight as low as 5kg/mol. The full pitch were found to be less than 10 nm and we report on their bulk and thin film characteristics.

9:48AM H45.00008 Decoupling Bulk Thermodynamics and Wetting Characteristics of Block Copolymer Thin Films¹, SANGWON KIM, University of Minnesota, Twin Cities, PAUL NEALEY, University of Wisconsin, Madison, FRANK BATES², University of Minnesota, Twin Cities — The incorporation of a random copolymer molecular architecture has been known to induce notable changes in the physical properties, often with commercial implications. In this presentation, the consequences of controlled degrees of epoxidation on both bulk and thin-film properties of poly(isoprene) blocks in poly(styrene-*b*-isoprene) (PS-PI) diblock copolymers and poly(isoprene) (hPI) homopolymers have been studied, where the products after epoxidation are denoted as hPI_{xn} and PS-PI_{xn}. Small angle X-ray scattering and dynamic mechanical spectroscopy were conducted on PS-PI_{xn} to calculate the effective interaction parameters χ_{eff} between the PS and PI_{xn} blocks in bulk (3-D) while the surface energy of thin-film PI_{xn} (2-D) was estimated based on contact angle measurements on hPI_{xn} and lamellar orientations of thin-film PS-PI_{xn}. A non-linear change with a minimum at the intermediate degrees of modification is observed for χ_{eff} in bulk whereas thin-film experiments suggest that the surface energy of PI_{xn} increases linearly with epoxidation. This decoupling of bulk and thin-film thermodynamic behaviors is attributed to the different roles that a random copolymer architecture plays in establishing 3-D order versus wetting at a 2-D surface.

10:00AM H45.00009 Continuity and connectivity of lamellar-forming block copolymers in thin films, IAN CAMPBELL, MARK STOYKOVICH, University of Colorado, Boulder — Thin films of block copolymers are emerging as a low-cost lithographic material. In order to effectively utilize this class of materials, the structure of the self-assembled morphologies in thin films must be well understood. In this work, the network structure formed by a lamellar diblock copolymer of polystyrene (PS) and poly(methyl methacrylate) (PMMA) was explored as the compositional symmetry was varied through homopolymer addition. The volume fraction of PMMA was varied from 0.45 to 0.55. The long-range connectivity of the PS and PMMA domains, as well as the branch and endpoint density, was characterized. Increasing the compositional asymmetry of the copolymer system leads to interconnected networks that span arbitrarily large areas, increased branch density, and decreased endpoint density. The network structure for each copolymer system also depends on annealing time, annealing temperature, and surface chemistry of the substrate. Improved understanding of the variability in lamellar morphologies will enable the selection of copolymers, annealing conditions, and surface chemistries to fabricate lithographic masks by self-assembly.

10:12AM H45.00010 Theoretical and Experimental Investigations of Contact Hole Shrink using PS-PMMA Block Copolymers, VALERIY GINZBURG, PHILLIP HUSTAD, JEFFREY WEINHOLD, RAHUL SHARMA, VIVIAN CHUANG, PETER TREFONAS, The Dow Chemical Company — One possible application of block copolymer directed self-assembly (DSA) involves rectification or "shrink" of contact holes in a polarity switched photoresist (see, e.g., J. Cheng et al., ACS Nano 8, 4815 [2010]). The block copolymer (e.g., PS-PMMA) undergoes ordering inside the cylindrical hole; the central (PMMA) domain is then etched out so that the hole diameter is effectively reduced. We utilize strong segregation theory (SST) and numerical self-consistent field theory (SCFT) to calculate the phase behavior of the block copolymers as function of their molecular weight and composition, as well as the contact hole diameter and the surface chemistry of the walls. The model predictions were compared with experimental data, and a good agreement was found. The results illustrate how modeling can serve to guide block copolymer selection for DSA contact hole rectification application.

10:24AM H45.00011 Tailoring block copolymer morphology via control of topographical surface: A self consistent field theoretic study, XIANGGUI YE, BRIAN J. EDWARDS, BAMIN KHOMAMI, Materials Research and Innovative Laboratory, Department of Chemical and Biomolecular Engineering, University of Tennessee, Knoxville, TN 37996 — It is well known that chemically patterned or topologically complex substrates can direct self-assembly of adsorbed layers or thin films of block copolymers. In this study we have examined the self-assembly of a lamella-forming diblock copolymer guided by topological complexity, namely, substrates composed of trenches with different heights and widths. In general, when the substrate is neutral to both blocks of the copolymer, the perpendicular lamella morphology is obtained. However, when the substrate has a preferred affinity to one of the blocks, a host of novel morphologies including different bi-continuous network structures can be created by judiciously manipulating the trench height and width. Overall, this study clearly demonstrates the impact of this class of simulations in rational design of morphologies in thin multi-component polymeric films with application to technologies such as filtration, and high-surface area membranes.

10:36AM H45.00012 Silicon patterning using self-assembled PS-b-PAA diblock copolymer masks for anti-reflective black silicon fabrication via plasma etching, XIN ZHANG, CHRISTOPHER J. METTING, SEAN FACKLER, ROBERT M. BRIBER, Department of Materials and Engineering, University of Maryland, College Park, MD 20742, USA, ANDREI B. SUSHKOV, H. DENNIS DREW, Department of Physics, University of Maryland, College Park, MD 20742, USA — The diblock copolymer of poly(styrene-b-acrylic acid) is a novel self-assembling mask material for pattern transfer applications. This material system has high dry etch selectivity and can produce a variety of feature types and size scales. Different vertical profiles were produced by altering the etch recipes and diblock copolymer or SiO₂ mask processing. This patterning technique is used to fabricate antireflective silicon metamaterials that show broadband anti-reflection properties in the visible and infrared wavelength range (<5% total reflection). These materials are potentially useful for solar cell and light sensing applications. Similar surface roughening by chemical etch, porous silicon, nanowires and other methods have been used previously to reduce reflectance from material interfaces for photovoltaics and antireflection applications. Unlike these methods, the BCP self-assembled pattern transfer via RIE produces robust patterns that are tunable in both the horizontal and vertical directions without harsh chemicals or expensive catalysts. This simple and rapid process can also be applied to semiconductors other than silicon.

10:48AM H45.00013 Assembly of block copolymer films between chemically patterned and chemically homogeneous surface, JEONG IN LEE, HUIMAN KANG, HYO SEON SUH, CHRISTOPHER THODE, University of Wisconsin, LEI WAN, HGST, ABELRADO HERNANDEZ, University of Wisconsin, YASUHIKO TADA, HIROSHI YOSHIDA, Hitachi Ltd., JUAN DE PABLO, PAUL NEALEY, University of Wisconsin — Many technologically useful block copolymer systems other than poly(styrene-block-methylmethacrylate) are currently not amenable for directed assembly because one of the blocks has a lower surface energy, segregates to the free surface of the film, and disrupts directed assembly of the film (at least with respect to realizing perpendicularly oriented through-film domains) on the underlying chemical pattern. Cross-linkable random copolymer mats were developed as well as methods to deposit them on the surfaces of block copolymer films. The chemistry of these “top coats” can be tuned to impart preferential and non-preferential wetting properties towards the blocks of the block copolymer films. The three-dimensional morphology of block copolymers assembled between lithographically-defined chemically patterned surfaces and top coats of varying wetting properties were characterized using specialized sample preparation techniques and cross-sectional scanning electron microscopy. The resulting structures compare favorably with molecular simulations. A primary technological objective of the top coat strategy is to direct the assembly of block copolymer systems that allow for sub-10 nm patterning and perpendicularly oriented domains.

Tuesday, February 28, 2012 8:00AM - 11:00AM — Session H46 DPOLY: Invited Session: Polymer Physics Prize 160ABC

8:00AM H46.00001 Polymer Physics Prize Lecture: Polyelectrolyte complexes: New routes to useful soft materials, MATTHEW TIRRELL, University of Chicago — Mixtures of oppositely charged polyelectrolytes may form precipitates (phase-separated solids) or coacervates (phase-separated fluids). Coacervates have been known for a long time to have interesting properties such as very low interfacial tension with water and a resultant ability to coat surfaces, engulf particles and invade porous media. Most prior work on coacervate complexes has been done with structurally complex (e.g., gum Arabic), biologically derived macromolecules (e.g., gelatin). Our work is focusing on phase behavior and self-assembly in classes of structurally simpler polymers. Polypeptides are one such class, where we can produce anionic, cationic and neutral, water-soluble polymers all with the same backbone and varying in small side-group structures. We are able to demonstrate very general patterns in phase behavior over different members of this class of polymers. Coacervate formation is the rule rather than the exception in these materials, with such formation quite strongly peaked at balanced stoichiometry of the polyelectrolyte components. One molar salt is usually sufficient to dissolve the coacervate phases that form. Block copolymer mixtures containing oppositely charged blocks can form self-assembled structures: micelles with diblocks and hydrogels with triblocks. The structure and properties of these assemblies can be tuned based on knowledge of the bulk phase behavior response to molecular weight, stoichiometry and salt concentration. Examples of phase behavior and structure-property relationship will be discussed.

8:36AM H46.00002 Physical and Biological Properties of Engineered Protein Hydrogels, DAVID TIRRELL, California Institute of Technology — Injectable hydrogels show substantial promise for use in minimally invasive tissue engineering and drug delivery procedures. A new injectable hydrogel material, developed from recombinant telechelic proteins expressed in *E. coli*, demonstrates shear thinning by three orders of magnitude at large strains. Large amplitude oscillatory shear illustrates that shear thinning is due to yielding within the bulk of the gel, and the rheological response and flow profiles are consistent with a shear-banding mechanism for yielding. The sharp yielding transition and large magnitude of the apparent shear thinning allow gels to be injected through narrow gauge needles with only gentle hand pressure. After injection the gels reset to full elastic strength in seconds due to rapid reformation of the physical network junctions, allowing self-supporting structures to be formed. The shear thinning behavior is largely independent of the midblock length, enabling genetic engineering to be used to control the equilibrium modulus of the gel without loss of the characteristic yielding behavior. The shear-banding mechanism localizes shear stresses during flow into narrow regions of the gel, allowing more than 95% of seeded cells to survive the injection process.

9:12AM H46.00003 Enhancing Biopolymer Dynamics through Destruction, JENNIFER ROSS, University of Massachusetts Amherst — Microtubules are cytoskeletal filaments that organize intracellular space structurally and through active transport along their lengths. They need to be organized and remodeled quickly during development of differentiated cells or in mitosis. Much work has focused on remodeling from the ends because these long polymers can stochastically disassemble through dynamic instability or be actively disassembled. Microtubule-severing enzymes are a novel class of microtubule regulators that create new ends by cutting the filament. Thus, these proteins add a new dimension to microtubule regulation by their ability to create new microtubule ends. Interestingly, despite their destructive capabilities, severing has the ability to create new microtubule networks in cells. We are interested in the inherent biophysical activities of these proteins and their ability to remodel cellular microtubule networks. Interestingly, despite their destructive capabilities, severing has the ability to create new microtubule networks in cells. We use two-color single molecule total internal reflection fluorescence imaging to visualize purified severing enzymes and microtubules *in vitro*. We have examined two families of severing enzymes to find that their biophysical activities are distinct giving them different network-regulating abilities.

9:48AM H46.00004 Cellular Reconstitution: Building Biomolecular Systems from the Bottom Up, DANIEL FLETCHER, University of California, Berkeley — No abstract available.

Tuesday, February 28, 2012 8:00AM - 11:00AM — Session H48 DPOLY: Polymer Gels and Solutions 161

8:00AM H48.00001 Polymer Physics Prize Break —

8:36AM H48.00002 Phase Segregation and Dynamics in Strongly Interacting Small Molecule Additive - Block Copolymer Surfactant Complexes , ROHIT KOTHARI, Polymer Science and Engineering, University of Massachusetts Amherst (UMASS Amherst), AHMED KHALIL, H. HENNING WINTER, Chemical Engineering, UMASS Amherst, JAMES J. WATKINS, Polymer Science and Engineering, UMASS Amherst — Rheology and Small Angle X-Ray Scattering (SAXS) were used to investigate order to disorder transitions (ODTs) and disorder to order transitions (DOTs) of poly(ethyleneoxide-*b*-propyleneoxide-*b*-ethyleneoxide) block copolymer surfactants mixed with hydrogen-bond-donating small molecule additives. A series of additives having a core benzene ring and systematic variation in the number of carboxylic or hydroxyl groups attached to the ring were of particular interest. Ordered cylindrical morphologies, confirmed using SAXS, were obtained only in a certain additive concentration region. ODTs were characterized by sudden changes in the linear viscoelastic properties in low frequency region upon increasing temperature. The locations of ODTs varied widely with hydrogen-bond-donating ability of the functional group and were found to be strongly dependent on the number of functional groups attached to the ring. For a given additive, the temperature at which ODT occur was strong function of the additive loading, whereas the linear viscoelastic properties of the ordered state were little changed upon varying additive concentration in ordered region. The location and dynamics of DOTs upon cooling were comparable to the ODTs upon heating. Studies using these model systems provide insight into the design of well-ordered hybrid materials.

8:48AM H48.00003 Using Mesoscopic Models to Design Strong and Tough Biomimetic Polymer , ISAAC G. SALIB, University of Pittsburgh, Pittsburgh, PA 15261, USA , GERMAN V. KOLMAKOV, New York City College of Technology, CUNY, New York, NY 11201, USA, BENJAMIN J. BUCIOR, University of Pittsburgh, Pittsburgh, PA 15261, USA, ORIT PELEG, MARTIN KROGER, THIERRY SAVIN, VIOLA VOGEL, ETH Zurich, CH-8093 Zurich, Switzerland, KRZYSZTOF MATYJASZEWSKI, Carnegie Mellon University, Pittsburgh, PA 15213, USA, ANNA C. BALAZS , University of Pittsburgh, Pittsburgh, PA 15261, USA — Using computational modeling, we investigate the mechanical properties of polymeric materials composed of coiled chains, or globules, which encompass a folded secondary structure and are crosslinked by labile bonds to form a network. In the presence of an applied force, the globules can unfold into linear. Our goal is to determine how to tailor the labile intra- and inter-molecular bonds within the network to produce material exhibiting both toughness and strength. We use the lattice spring model (LSM) to simulate the globules and the crosslinked network. We utilize our modified Hierarchical Bell model (MHBM) to simulate the rupture and reforming of N parallel bonds. We demonstrate that the mechanical properties of the system are sensitive to the values of N_{in} and N_{out} , the respective values of N for the intra- and inter-molecular bonds. We find that the strength of the material is mainly controlled by the value of N_{out} , with the higher value of N_{out} providing a stronger material. We also find that if N_{in} is smaller than N_{out} , the globules can unfold under the tensile load before the sample fractures and thus, can increase the ductility of the sample.

9:00AM H48.00004 Synthesis and Characterization of Poly(hydroxyethyl methacrylate) Hydrogels Bearing Reversibly Associating Side Groups¹ , CHRISTOPHER LEWIS, JIAHUI LI, MITCHELL ANTHAMATTEN, University of Rochester — Poly(hydroxyethyl methacrylate) (poly(HEMA)) is a technologically important hydrogel that can be processed into different shapes and is best known for its role in contact lenses. However, applications of water swollen polyHEMA are limited by its poor mechanical properties. We are studying the influence of reversibly associating side groups on the behavior of poly(HEMA) hydrogels. In non-polar media, it is well known that ureidopyrimidinone (UPy) groups self-associate to form hydrogen bonded dimers (DDAA); however their behavior in water-swollen hydrogels is unclear. A series of poly(HEMA) linear polymers of controlled molecular weight with varying UPy content have been prepared using a reversible addition-fragmentation chain transfer (RAFT) polymerization technique. UPy content significantly reduces water swelling and improves mechanical properties. The degree of hydrogen bonding within water swollen hydrogels is studied, and properties of functional hydrogel polymers and networks are compared to an unswollen hydrophobic analog.

9:12AM H48.00005 Thermoreversible Supramolecular Ion Gels via Hydrogen Bonding , YU LEI, TIMOTHY LODGE, Department of Chemistry, University of Minnesota — Ion gels are a novel class of functional materials of broad interest for advanced applications. We have developed a thermoreversible supramolecular ion gel system consisting of a poly(2-vinylpyridine-*b*-ethylene oxide-*b*-2-vinylpyridine) (P2VP-PEO-P2VP) triblock copolymer, a poly(4-vinylphenol) (PVPh) linear homopolymer, and an ionic liquid, 1-ethyl-3-methylimidazolium bis(trifluoromethylsulfonyl)amide ([EMI][TfSA]), where a highly inter-connected transient polymer network is formed by hydrogen bonding between the P2VP endblocks and PVPh cross-linkers. This system exhibits novel physical properties, such as interesting dynamics and homopolymer clustering in the cross-links. The applicability of time-temperature superposition to this system is striking, resulting in a master curve that extends over 20 orders of magnitude in reduced frequency. The hydrogen-bonded phase can arrange into a hexagonally packed cylindrical morphology with long-range ordering, which reveals very slow kinetics and is thermodynamically stable only within a narrow temperature window. The highly tunable relaxation dynamics as well as shear modulus might enable materials design for specific applications.

9:24AM H48.00006 Hydrogen Bonding Based Layer-by-Layer Assembly of Poly(vinyl alcohol) with Weak Polyacids , HYOMIN LEE, REMY MENSIRE, ROBERT COHEN, MICHAEL RUBNER, Massachusetts Institute of Technology — Multilayer thin films that consist of poly(vinyl alcohol) (PVA) and weak polyacids such as poly(acrylic acid) (PAA) and poly(methacrylic acid) (PMAA) were prepared by hydrogen bonding interactions. Both the degree of hydrolysis and molecular weight of PVA were investigated in terms of their influence on growth behavior and pH stability. Multilayer films containing PVA and PAA could be assembled successfully only by using partially hydrolyzed PVA and low pH solutions. By comparing films containing PAA with those containing a more strongly interacting partner, PMAA, it was shown that the extent of PVA hydrolysis becomes significant only when weak hydrogen bonding pairs such as PVA and PAA were used. pH-triggered dissolution experiments demonstrated that the degree of hydrolysis can be used as an additional parameter by which to tune the pH stability of the film. Also, the presence of an abundance of free hydroxyl and carboxylic acid groups in the multilayer allowed enhanced pH stability to be obtained by thermal and chemical methods as well as numerous opportunities for post-assembly functionalization.

9:36AM H48.00007 Gelation in a model 1-component system with adhesive hard-sphere interactions, JUNG MIN KIM, University of Delaware, AARON EBERLE, National Institute of Standards and Technology, JUN FANG, Arkema Inc., NORMAN WAGNER, University of Delaware — Colloidal dispersions can undergo a dynamical arrest of the disperse phase leading to a system with solid-like properties when either the volume fraction or the interparticle potential is varied. Systems that contain low to moderate particulate concentrations form gels whereas higher concentrations lead to glassy states in which caging by nearest neighbors can be a significant contributor to the arrested long-time dynamics. Colloid polymer mixtures have been the prevalent model system for studying the effect of attraction, where attractions are entropically driven by depletion effects, in which gelation has been shown to be a result of phase separation [1]. Using the model 1-component octadecyl coated silica nanoparticle system, Eberle et al. [2] found the gel-line to intersect the spinodal to the left of the critical point, and at higher concentrations extended toward the mode coupling theory attractive driven glass line. We continue this study by varying the particle diameter and find quantitative differences which we explain by gravity.

9:48AM H48.00008 Concentration Fluctuations in Polymer Solutions under Extensional Flow, MICHAEL VILLET, MICHAEL CROMER, GLENN FREDRICKSON, GARY LEAL, University of California, Santa Barbara, ROMAN STEPANYAN, MARKUS BULTERS, DSM Ahead, Geleen, Netherlands — Polymer solutions under flow are known to exhibit stress-concentration coupling that can anisotropically amplify concentration fluctuations. This phenomenon has been extensively studied for shear flow, but is less well understood for extensional flows. Using a two-fluid model, we study concentration fluctuation amplification in polymer solutions under a variety of extensional flows, including mixed shear and extension.

10:00AM H48.00009 Crossover length scale for viscosity experienced by Gold nanoparticles in semi dilute polymer solution, INDERMEET KOHLI, RAMI OMARI, ASHIS MUKHOPADHYAY, Wayne State University — Gold nanoparticles (Au NPs) were used as a probe to characterize the crossover length scale for viscosity in semi dilute poly (ethylene glycol) (PEG)-water solutions. Fluctuation correlation spectroscopy (FCS) was used to measure the diffusion of these NPs as a function of their size (5-20 nm), PEG concentration (0 to 40%w/w) and PEG molecular weight (5 kDa to 35 kDa). Our results indicate that for particles with radius $R > R_g$, usual hydrodynamic conditions can be applied, but for particles with radius $R \leq R_g$, the diffusion is approximately an order of magnitude faster than that predicted by Stokes Einstein (SE) relation. The results imply that radius of gyration R_g of the polymer gives the crossover length scale from nanoviscosity to macroviscosity. The relative viscosity experienced by the particles was scaled as $\eta/\eta_0 = \exp(b(R_g/\xi)^a)$, where η_0 is the water viscosity, ξ is the correlation length, $a = 0.70 \pm 0.03$ and $b = 1.59 \pm 0.07$.

10:12AM H48.00010 Kinetics of Narrowly dispersed Latex Formation in a Surfactant-free Emulsion Polymerization of Styrene in Acetone-Water Mixture¹, HE CHENG, ZHIYONG LI, CHARLES HAN, Intitue of Chemistry Chinese Academy of Sciences — The kinetics of narrowly dispersed latex formation in a surfactant-free emulsion polymerization of styrene in acetone-water was studied by a combination of transmission electron microscopy and light scattering. The critical nuclei were experimentally observed and the formation of narrowly dispersed PS latex is proved to be originated from competitive growth kinetics. Spherical nuclei were regenerated via a microphase inversion of PS oligomer in 50% volume fraction acetone-water mixture at 70°C. They follow a polydispersed log-normal distribution and the smallest nucleus with $R_s 1.1\text{nm}$ is similar to critical nuclei. Note the spherical nuclei are not necessarily narrowly dispersed. Competitive growth kinetics makes smaller nuclei grow much faster than large nuclei in the subsequent polymerization process, resulting in narrowly dispersed PS latex. Two kinds of PS seed particles were added, separately, into two parallel surfactant-free emulsion polymerization batches of styrene in acetone-water mixture at 70°C. It was found that the size of seed particles almost does not change, but the small size PS latex grows rapidly. Our fitting results proves competitive growth kinetics proposed by Vanderhoff and coworkers.

10:24AM H48.00011 Cluster Growth in Aqueous Sugars Observed by Dynamic Light Scattering¹, TRI TRAN², DAVID SIDEBOTTOM, Creighton University — Dynamic light scattering of aqueous sugar solutions as a function of sugar concentration and temperature reveal the development of sugar clusters occurring in two stages. At low volume fractions of sugar, a so-called cluster phase consisting of nearly monodisperse clusters forms with a mean cluster mass that increases in proportion to the volume fraction. At a critical volume fraction, near where the clusters begin to overlap, a second stage ensues wherein cluster-cluster aggregation forces a more rapid, power law growth in advance of a percolation threshold observed near 83 wt% sugar.

²first year graduate student will present

10:36AM H48.00012 Boson peak in L-cysteine: a Raman scattering study, THAMIRES LIMA, HERCULANO MARTINHO, Universidade Federal do ABC — The Boson peak is a distinctive feature of many glassy and disordered crystalline solids. Recently it has been suggested that similar feature may be correlated to anharmonic transitions observed in macromolecules like DNA and proteins. In the present work we studied the low frequency ($15 - 600 \text{ cm}^{-1}$) Raman scattering response of L-cysteine and L-Cysteine hydrochloride with different hydration levels in the $15 - 270 \text{ K}$ temperature range. Our analyzes will be concerned to understand the water rule in the Boson peak inelastic light signal, its correlation to the dynamic transitions at $T^* \sim 80 \text{ K}$ and $T_D \sim 280 \text{ K}$, and its microscopic origin as well.

10:48AM H48.00013 Low temperature dynamic transitions of L-cysteine and L-proline amino acids: a specific heat study, MARIANA ISHIKAWA, THAMIRES LIMA, HERCULANO MARTINHO, Universidade Federal do ABC — Studies have shown that several macromolecules present two dynamic transitions at $T^* \sim 80 \text{ K}$ and $T_D \sim 280 \text{ K}$ which have intrinsic correlation to their biological activity. The present work concerns the detailed analysis of the low temperature transition at T^* by specific heat. This transition is usually described as originated on the CH₂SH dynamics. We compared the experimental results with simulations based on rigid rotor specific heat model by Caride and Tsallis [J. Stat. Phys. **35**, 187 (1984)] and we found an excellent agreement.

Tuesday, February 28, 2012 8:00AM - 11:00AM –
Session H49 DPOLY: Focus Session: Fluctuation-Induced Forces in Soft Matter & Polymeric Systems - Casimir and Interfacial Forces 162A

8:00AM H49.00001 Polymer Physics Prize Break –

8:36AM H49.00002 Casimir Interaction at Soft Interfaces , EHSAN NORUZIFAR, JEF WAGNER, University of California, Riverside, HSIANG-KU LIN, University of California, Riverside / MIT, UMAR MOHIDEEN, ROYA ZANDI, University of California, Riverside — We study Casimir interaction due to the thermal fluctuations between colloidal particles on the membranes and fluid interfaces. To calculate the Casimir energy we employ the scattering formalism. In this technique the shape and material properties of the colloids are encoded in their scattering matrices. The energy is calculated by combining the scattering matrices with the universal translation matrices, which convert between the bases used to compute scattering for each colloid, but otherwise are independent of the physical and chemical properties of the colloids and the interface. We show that in the scattering formalism one can easily implement various geometries and material properties and more importantly calculate the energy for all separation regimes.

8:48AM H49.00003 Critical Casimir Interactions: New fluctuation forces in colloidal science , PETER SCHALL, Institute of Physics, University of Amsterdam — Casimir forces arise from the confinement of fluctuations between two walls. Critical Casimir forces provide thermodynamic analogues of quantum-mechanical Casimir forces and arise from the confinement of concentration fluctuations of a critical solvent. These forces act also between colloidal particles that are suspended in this solvent, giving rise to temperature-dependent attractive interactions between the particles. We use these temperature-dependent forces to control colloidal phase transitions. In this talk, I will present a new index and density-matched model system that allows direct observation of these phase transitions with confocal microscopy. In three dimensions and real time, we follow how a colloidal gas freezes into a colloidal liquid, and the colloidal liquid freezes into a solid, all driven by critical Casimir forces. We measure the critical Casimir particle pair potential directly from the pair correlation function, and use Monte Carlo simulations to map the complete gas-liquid-solid phase diagram. Excellent agreement with the experimental observations is obtained. Our measurements include microgravity experiments on board the International Space Station (ISS) to elucidate non-equilibrium assembly of the particles achieved by controlled temperature quench.

9:00AM H49.00004 Thermodynamic Casimir effect in the large- n limit: Exact results for slabs with free surfaces , F.M. SCHMIDT, Fakultät für Physik, Universität Duisburg-Essen, 47048 Duisburg, Germany, M. HASENBUSCH, Institut für Physik, Humboldt-Universität zu Berlin, 12489 Berlin, Germany, A. HUCHT, S. RUTKEVICH, D. GRÜNEBERG, H.W. DIEHL, Fakultät für Physik, Universität Duisburg-Essen, 47048 Duisburg, Germany — The $O(n)$ ϕ^4 -model for a three-dimensional slab of thickness L and infinite lateral extension is investigated in the large- n limit. The effective (Casimir-like) forces that are induced between the two confining boundary planes by thermodynamic fluctuations in such systems at and near bulk criticality are studied. While systems with periodic or antiperiodic boundary conditions perpendicular to the planes are translationally invariant and thus can be treated analytically, the physical relevant case of free boundary conditions leads to a breaking of translational invariance perpendicular to the boundary planes. In the large- n limit one arrives at a spherical model with separate constraints for each layer parallel to the confining surfaces. The resulting self-consistent Schrödinger-type equation is solved numerically at and near the bulk critical temperature to obtain the large- n limit of the scaling functions of the Casimir force and the excess free energy. The Casimir amplitude is calculated with high accuracy to take the value $\Delta_C = -0.01077340685025(10)$. The Casimir force scaling function shows a minimum below the bulk critical temperature similar to the $n = 2$ result.

9:12AM H49.00005 Fluctuation-induced forces in a fluid membrane under tension , ROYA ZANDI, University of California, Riverside — We develop an exact method to calculate thermal Casimir forces between inclusions of arbitrary shapes and separation, embedded in a fluid membrane whose fluctuations are governed by the combined action of surface tension, bending modulus, and Gaussian rigidity. Each object's shape and mechanical properties enter only through a characteristic matrix, a static analog of the scattering matrix. We calculate the Casimir interaction between two elastic disks embedded in a membrane. In particular, we find that at short separations the interaction is strong and independent of surface tension.

9:48AM H49.00006 The Casimir forces between inclusions in a fluid membrane , HSIANG-KU LIN, ROYA ZANDI, UMAR MOHIDEEN, LEONID PRYADKO, University of California at Riverside — We discuss the fluctuation-induced force, a finite-temperature analogue of the Casimir force, between two foreign inclusions embedded in a stretchable fluid membrane. Specifically, we suggest a Green's-function-based method to calculate the Casimir interaction in cases where the fluctuations of a planar membrane are governed by Helfrich Hamiltonian, including the surface tension σ and both bending κ and Gaussian $\bar{\kappa}$ rigidities. For two circular inclusions in a fluid membrane, the Casimir energy scales as the inverse power law of the separation and is greatly reduced beyond the characteristic length $\ell_0 = \sqrt{\kappa_0/\sigma_0}$. The impact of line tension is also discussed.

10:00AM H49.00007 Aspect-ratio dependence of thermodynamic Casimir forces , ALFRED HUCHT, DANIEL GRUENEBERG, FELIX M. SCHMIDT, Fakultät für Physik, Universität Duisburg-Essen, 47058 Duisburg, Germany — We consider the three-dimensional Ising model in a $L_\perp \times L_\parallel \times L_\parallel$ cuboid geometry with finite aspect ratio $\rho = L_\perp/L_\parallel$ and periodic boundary conditions along all directions. For this model the finite-size scaling functions of the excess free energy and thermodynamic Casimir force are evaluated numerically by means of Monte Carlo simulations [1]. The Monte Carlo results compare well with recent field theoretical results for the Ising universality class at temperatures above and slightly below the bulk critical temperature T_c . Furthermore, the excess free energy and Casimir force scaling functions of the two-dimensional Ising model are calculated exactly for arbitrary ρ and compared to the three-dimensional case. We give a general argument that the Casimir force vanishes at the critical point for $\rho = 1$ and becomes repulsive in periodic systems for $\rho > 1$.

10:12AM H49.00008 Field-Theoretic Simulations of Bicontinuous Microemulsions in Polymer Blends , KRIS DELANEY, GLENN FREDRICKSON, UC Santa Barbara — Long diblock copolymers introduced into a blend of thermodynamically incompatible homopolymers can act as a surfactant to suppress macroscopic phase separation of the blend. As the fraction of diblock copolymer is varied, an isotropic Lifshitz tricritical point is observed in the mean-field equations, demarking the crossover from macrophase to microphase separation. Close to the Lifshitz point, fluctuations are strong enough to suppress the low-temperature formation of a well-ordered microphase leading to the appearance of a long-lived bicontinuous microemulsion characterized by micron-scale continuous domains. In this work, we discuss computational strategies for simulating the equilibrium formation of the microemulsion using field-theoretic methods. We address the challenges involved with accurately localizing the order-disorder transition in a fluctuating theory, and the handling of strong fluctuations close to the Lifshitz point.

10:24AM H49.00009 Looking Down at Adsorption Dynamics: Filament Height Measurements with TIRFM , DAVID WELCH, ZVONIMIR DOGIC, Brandeis University — Polymer adsorption is important in several contexts such as chromatography, colloid stabilization, and bio-fouling. Despite a cross-disciplinary interest in the subject, there are not many techniques to observe single-molecule adsorption events in real time. We use TIRF microscopy to accomplish this using the biological polymer f-actin adsorbed to a microscope slide via the well-known depletion interaction. We find TIRFM is able to quantitatively measure filament height, and we compare our results to theoretical predictions and previous results obtained from other systems.

10:36AM H49.00010 Partial osmotic compressibility of binary mixtures of colloidal nanoparticles and PEG, JINXIN FU, MELISSA GOLEB, H. DANIEL OU-YANG, Lehigh University — Proposed originally by Oosawa and Asakura, polymer crowding-induced attractive force between colloidal particles is being used in a variety of applications ranging from protein crystallization to nanoparticle sorting. While the force has been well studied for a pair of micro particles in the presence of polymers, direct measurement of such force between nanoparticles is very difficult. To investigate effects of crowding polymers, we propose an approach to measure the colloidal osmotic compressibility and virial coefficients in the presence of polymers and compare experimental results with theoretical models. The materials we investigated are binary mixtures of fluorescent polystyrene nanospheres (100 – 210 nm in diameter) and polyethylene glycol (PEG). Using fluorescence microscopy to examine the change of the particle concentration in an optical trap, which exerts no force upon PEG, allows us to measure the partial osmotic compressibility of the particles. The measured partial compressibility and its virial expansion are compared with theoretical calculations to elucidate the competing effects of polymer crowding and adsorption.

10:48AM H49.00011 ABSTRACT WITHDRAWN —

Tuesday, February 28, 2012 8:00AM - 11:00AM —
Session H50 DPOLY: Polymer Melts 162B

8:00AM H50.00001 Polymer Physics Prize Break —

8:36AM H50.00002 Coil-Globule Transition of Polymer – Tricriticality of Theta, ASHOK DASMAHA-PATRA, Department of Chemical Engineering, Indian Institute of Technology Guwahati, Guwahati-781039, Assam — We demonstrate the tricriticality of the theta point in the coil-to-globule transition of a single flexible polymer chain by dynamic Monte Carlo (DMC) simulation. For homopolymer, at the tricritical point, the second order theta transition line approaches the first order collapse transition line as the chain length approaches the thermodynamic limit. Theta point of homopolymer has been estimated by following the ideal behavior of chain at the theta point. Temperature at which the constant volume specific heat (C_v) shows a peak is considered as the collapse temperature and the transition is of first order. In T-N plane, collapse temperature approaches towards the theta temperature as the chain length approaches to the thermodynamic limit. For copolymer (with periodic distribution of comonomer along the chain), the collapse temperature increases with increasing the stickiness parameter (viz., higher solvophobicity of the comonomers relative to monomers) and approaching towards the theta as the value of the stickiness parameter increases. Theta points of copolymers have been estimated from the theta point of homopolymer under the condition of the ideality of the theta point. The collapse temperatures for copolymer have been in a manner similar to homopolymers. Theta temperature vs. stickiness parameter represents a second order line whereas collapse temperature vs. stickiness parameter represents a first order line. We demonstrate that as the stickiness parameter increases, these two lines meet each other, close to the “tricritical” theta temperature.

8:48AM H50.00003 Microscopic Theory of Nanoparticle Diffusivity in Entangled and Unentangled Polymer Melts, UMI YAMAMOTO, KENNETH SCHWEIZER, University of Illinois, Urbana-Champaign — We present a statistical dynamical theory at the level of forces for the violation of the Stokes-Einstein (SE) diffusion law of a spherical nanoparticle in entangled and unentangled polymer melts. Based on a combination of mode-coupling and polymer physics ideas, the non-hydrodynamic friction coefficient is related to microscopic structure and the length-scale-dependent polymer melt collective density fluctuation dynamics. When local packing correlations are neglected, analytic expressions are derived for the non-hydrodynamic diffusivity as a function of particle size, polymer radius-of-gyration, tube diameter, degree of entanglement and temperature; local packing effects are numerically investigated under athermal and attractive conditions. The conditions for the recovery of the SE law are qualitatively distinct for unentangled and entangled melts, and entanglement effects are the origin of large SE violations consistent with recent experiments. The influences of melt packing fraction and interfacial attraction strength are also qualitatively different depending on whether the polymers are entangled or not. The anomalous time-dependence of the nanoparticle mean square displacement is studied using a self-consistent Generalized Langevin Equation approach.

9:00AM H50.00004 Effect of Secondary Structure on the Persistence Length of a Poly N-substituted Glycine, HANNAH K. MURNEN, ADRIANNE M. ROSALES, University of California Berkeley, STEVEN R. KLINE, National Institute of Standards and Technology, RONALD N. ZUCKERMANN, Lawrence Berkeley National Laboratory, RACHEL A. SEGALMAN, University of California Berkeley — A polymer containing helical secondary structure is shown to be nearly as flexible as a chemically analogous polymer containing no structure. Polypeptides or poly N-substituted glycines are a class of sequence specific polymers in which chain shape can be controlled via monomer choice involving both sterics and chirality. In this study, a polypeptoid containing aromatic chiral sidechains was synthesized. Classical measurements such as circular dichroism and NMR have shown previously that the bulky chiral side chains cause the polypeptoid to adopt a helical conformation. However, small angle neutron scattering demonstrated that in acetonitrile, the persistence length of the helical polypeptoid was approximately 1 nm, only about 15% of the fully extended helical length. This small persistence length indicates that the chain likely adopts several conformations in solution and is not rigidly locked into its helical shape throughout the entire length of the polymer

9:12AM H50.00005 Gibbs Ensemble Calculations of Phase Coexistence in Supramolecular Assembly of Block Copolymers, ZOLTAN MESTER, NATHANIEL LYND, GLENN FREDRICKSON, University of California Santa Barbara — We propose a new self-consistent field theory method for calculating phase behavior in reversibly bonded supramolecular polymer melts. Previous studies formulated models for supramolecular assembly in the grand canonical ensemble to make use of the constraints imposed on the chemical potentials of the products from chemical equilibrium. Instead, we formulate the model in the canonical ensemble by including a term in the Hamiltonian that accounts for the reaction favorability/penalty. The chemical equilibrium statement is obtained by optimizing the Hamiltonian with the amount of reacted polymer. The canonical partition function can be easily adapted to the Gibbs ensemble whereby phase boundaries between coexisting phases can be conveniently simulated. As an illustration of our method, we examine a blend of AB diblock and B homopolymer with the ability to reversibly bond to form ABB diblock. In the limits of infinite reaction favorability and penalty, the system approaches cases of an ABB diblock-B homopolymer blend when the AB diblock is the limiting reactant and an AB diblock-B homopolymer blend, respectively. The interplay between reactant ratios (stoichiometry) and reaction favorability/penalty is explored for intermediate values of reactivity.

9:24AM H50.00006 Pressure-induced structural transition in an one-component polymer poly(4-methyl-1-pentene) in its melted state, AYANO CHIBA, Keio University, Japan, NOBUMASA FUNAMORI, KAZUYA NAKAYAMA, University of Tokyo, Japan, YASUO OHISHI, Japan Synchrotron Radiation Research Institute (Spring-8), Japan, STEPHEN M. BENNINGTON, Rutherford Appleton Laboratory, UK, SANJAY RASTOGI, Loughborough University, UK, ANUJ SHUKLA, European Synchrotron Radiation Facility, France, KAZUHIKO TSUJI, Keio University, Japan, MIKIHITO TAKENAKA, Kyoto University, Japan — Liquid-liquid transitions or amorphous-amorphous transitions are well-known in systems with small molecular or structural units, such as those seen in water, phosphorus, and silica glass. We studied pressure-induced structural change for isotactic poly(4-methyl-1-pentene) in its melted state, and found a structural transition for this one-component polymer melt. High-pressure in-situ x-ray diffraction and specific-volume measurements on the polymer melt have uncovered discontinuities in the pressure dependences of microscopic structure as well as those of macroscopic density. The results suggest the occurrence of a liquid-liquid phase transition.

9:36AM H50.00007 Anomalous diffusion of a polymer chain in an unentangled melt, JEAN FARAGO, Universite de Strasbourg, HENDRIK MEYER, ALEXANDER SEMENOV, CNRS — Contrary to common belief, the hydrodynamic interactions (HI) in polymer melts are not screened beyond the monomer length and are important in transient regimes. We show that the viscoelastic HI effects (VHI) lead to anomalous dynamics of a tagged chain in an unentangled melt at $t < t_N$ (t_N , the Rouse time). The chain centre-of-mass (CM) mean-square displacement is enhanced (as compared to the Rouse diffusion) by a large factor increasing with chain length. We develop an analytical theory of VHI-controlled chain dynamics yielding negative CM velocity autocorrelation function which quantitatively agrees with our MD simulations without any fitting parameter. It is also shown that the Langevin friction force, when added in the model, strongly affects the short- t CM dynamics which, however, can remain strongly enhanced. The transient VHI effects thus provide the dominant contribution to the subdiffusive CM motion universally observed in simulations and experiments on polymer melts.

9:48AM H50.00008 Representation of Polymer melts as soft liquids with effective pair interactions, ANTHONY CLARK, MARINA GUENZA, University of Oregon — Descriptions at various levels of coarse-graining are of great interest in understanding the complex structure and dynamics of polymer liquids, as relevant processes take place at a wide variety of length and time scales. In this talk we present and analytically characterize effective interaction potentials to map a polymer melt onto a liquid of soft spheres or soft-colloid chains, with each soft colloid representing the center of mass of a chain or large subsection of a chain. The thermodynamics of the coarse-grained system using the effective potentials can be shown to agree with the thermodynamics of monomer-level descriptions across a range of thermodynamic states. The scaling of the effective pair potentials beyond the physical extent of the polymer with increasing chain interpenetration is shown to be essential to capturing the contribution to the thermodynamics of the melt due to many-polymer interactions in the soft coarse-grained description, despite its vanishingly small effect on structural correlations. Further development of the theory will consider its extension from soft-colloid chains to lower level bead and spring level descriptions with the aim of gaining insight into the thermodynamic properties of these widely used models.

10:00AM H50.00009 Entropy of Mixing: Rigid vs. Flexible Molecules: Effect of Varying Solvent on Dissolution Temperature, ERIC B. SIROTA, ExxonMobil Research and Engineering Company, HASNAIN RANGWALLA, ExxonMobil Chemical Company, PAWEL PECZAK, ExxonMobil Research and Engineering Company — We report a study of the dissolution temperature of n-hexacontane, as a function of concentration, with 52 different solvents, aimed at understanding the effect of molecular flexibility on the entropy-of-mixing. The entropy-of-mixing of rigid molecules is commonly expected to go as $\ln(\text{mole fraction})$, while for flexible polymers it is expected to follow Flory-Huggins $\ln(\text{volume fraction})$. By isolating the entropy-of-mixing, we have experimentally found that rigidity, through ring structures, causes deviations from the Flory-Huggins behavior; and we have proposed and derived a cross-over form for the entropy-of-mixing which varies between $\ln(\text{volume fraction})$ and $\ln(\text{mole fraction})$ according to molecular rigidity.

10:12AM H50.00010 Polymeric Fluid Flow Over Superhydrophobic Surfaces, LUCAS LANDHERR, STEVEN HUDSON, KALMAN MIGLER, National Institute of Standards and Technology — Superhydrophobic (SHP) surfaces are characterized by their exceptionally low surface energies and distinct surface roughnesses that create a vapor layer between the fluid and the surface. The reduced contact area at the interface can create a dewetted state resulting in slip, drag reduction, and improved flow of fluids. Most previous superhydrophobic studies have utilized simple liquids (e.g. water) in focusing on characterization of the quiescent interface and on drag reduction or slip modifications of fluid flow. As polymeric fluid flows have exhibited similar slip and drag reduction phenomena, this study attempts to utilize SHP surfaces to improve the flow behavior of more complex multi-component fluids, such as polymer solutions. By merging the research fields of SHP surfaces and polymer fluids, we investigate the potential to enhance slip and drag reduction effects as a result of surface interactions. Microfluidic channels, interfacial rheometry and goniometry are used to evaluate slip length and fluid flow.

10:24AM H50.00011 Reconstructing Polymer Melt Dynamics Sped up due to Large-Scale Coarse-Graining, IVAN LYUBIMOV, MARINA GUENZA, University of Oregon — A theoretical approach to rescale the artificially fast dynamics of highly coarse-grained polymer melts is extended to chains represented as soft particles. The effective pair potential derived from first-principles to represent polymer chains with soft interactions is used to perform mesoscale molecular dynamics simulations of coarse-grained melts. This potential ensures the reproduction of the correct global structure and thermodynamics, but entropic and frictional corrections are necessary to reconstruct realistic dynamics. The behavior of the system is described by generalized Langevin equations derived for different levels of coarse-graining. The explicit analytical dependence on the thermodynamic and molecular parameters enhances the predictive power of the reconstruction method. The dynamics, reconstructed from mesoscale simulation, is in quantitative agreement with experiments and atomistic simulations.

10:36AM H50.00012 Steric Constraints in Fractal-Regime Star Polymers, GREGORY BEAUCAGE, DURGESH RAI, RAMANTH RAMACHANDRAN, University of Cincinnati, KEDAR RATKANTHAR, NIKOS HADJICHRISTIDIS, University of Athens, HONG KUNLUN, DAVID UHRIG, Oak Ridge National Laboratory — Star polymers at high functionality, f , and high arm length, z_{arm} , display a collapsed core structure described by Daoud and Cotton in a colloidal regime (CR). At lower functionality ($f < \sim 8$) and relatively low arm length, stars display a polymeric structure in a fractal regime (FR). For FR stars in good solvents the arms display steric interactions analogous to polymer chains tethered to a surface. We have used small-angle neutron scattering to quantify, for the first time, this steric interaction so as to understand the approach to the CR as a function of z_{arm} and f as well as temperature and solvent type. Experimental data from model star polymers and literature data from polyurethane stars are considered as examples.

10:48AM H50.00013 Capillary break-up, gelation and extensional rheology of hydrophobically modified cellulose ethers, VIVEK SHARMA, SIMON HAWARD, Massachusetts Institute of Technology, OLIVIA PESSINET, Ecole des Mines, ASA SODERLUND, PHIL THRELFALL-HOLMES, AkzoNobel, GARETH MCKINLEY, Massachusetts Institute of Technology — Cellulose derivatives containing associating hydrophobic groups along their hydrophilic polysaccharide backbone are used extensively in the formulations for inks, water-borne paints, food, nasal sprays, cosmetics, insecticides, fertilizers and bio-assays to control the rheology and processing behavior of multi-component dispersions. These complex dispersions are processed and used over a broad range of shear and extensional rates. The presence of hydrophobic stickers influences the linear and nonlinear rheology of cellulose ether solutions. In this talk, we systematically contrast the difference in the shear and extensional rheology of a cellulose ether: ethylhydroxyethyl-cellulose (EHEC) and its hydrophobically-modified analog (HMEHEC) using microfluidic shear rheometry at deformation rates up to 10^6 inverse seconds, cross-slot flow extensional rheometry and capillary break-up during jetting as a rheometric technique. Additionally, we provide a constitutive model based on fractional calculus to describe the physical gelation in HMEHEC solutions.

Tuesday, February 28, 2012 8:00AM - 11:00AM –

Session H51 DCMP DFD: Colloids II: Crystals and Phase Transitions Boston Convention Center 154

8:00AM H51.00001 Effects of vacancies and interstitials on the phonon modes in a 2D colloidal crystal¹, LICHAO YU, SUNGCHEOL KIM, Brown University, DI YIN, Wuhan University and Brown University, ALEXANDROS PERTSINIDIS, Sloan-Kettering Institute, New York, XINSHENG LING, Brown University — We report a study of the effects of vacancies and interstitials on the phonon modes in a 2D colloidal crystal. By applying the equi-partition theorem, we extract the dispersion relation of the lattice vibrations in a two-dimensional colloidal crystal using real-time video microscopy. We find that both longitudinal and transverse modes in the spectrum are softened by the existence of vacancies and interstitials.

¹This work was supported by a grant from NSF-DMR.

8:12AM H51.00002 Normal modes of various colloidal crystals¹, FENG WANG, YI PENG, ZIREN WANG, YILONG HAN, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China, SOFT MATTER AND VIDEO MICROSCOPY LAB TEAM — We measured the vibrational normal modes from particle displacements in various microgel colloidal crystals including monolayers, multi-layer thin films, three-dimensional normal and superheated crystals by video microscopy. Their density of states all agree with the Debye's theory in the low-frequency regime, but the fluctuation of the frequency is similar to that of the eigenvalues of random matrices: the distributions of the frequency spacings between successive normal modes are the Wigner surmise, the spectral rigidities are logarithmic, and the distributions of vibrational amplitudes in the majority of modes are Gaussian. In addition, the first a few low-frequency modes are plane waves and dominate the thermal vibration, and the majority of modes are delocalized.

¹This work was supported by Hong Kong GRF Grants No. 601208 and No. 601911.

8:24AM H51.00003 Microscopic observation of dynamics and structure in microgel suspensions¹, MELAKU MULUNEH, Harvard University, JORIS SPRAKEL, Wageningen University, The Netherlands, HANS WYSS, Eindhoven University of Technology, The Netherlands, JOHAN MATTSSON, University of Leeds, UK, DAVID WEITZ, Harvard University — We use 3D confocal microscopy to understand the packing dynamics and structure of fluorescently labeled p(NIPAm-co-AAc) microgel colloidal particles. Such systems respond to changes in temperature, pH, and polymer content by changing size, morphology, and interaction behavior. We conduct experiments to understand this behavior in detail: our results show that the dynamics are dominated by attraction driven crystallization and concentration at low pH and concentration only at high pH. Crystal nucleation occurs homogeneously in the suspensions and does not appear to be restricted to geometric boundaries. The growth of crystals is nucleation-limited and can complete on the order of hours. Structural analysis of the crystals formed indicates that the stacking style is insensitive to charge, concentration, size, and stiffness of the particles and remains FCC.

¹This work is supported by the Harvard MRSEC (DMR-0820484), and the NSF (DMR-1006546)

8:36AM H51.00004 Homogeneous Melting of 3D Superheated Colloidal Crystals¹, ZIREN WANG, FENG WANG, YI PENG, YILONG HAN, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong, SOFT MATTER & VIDEO MICROSCOPY LAB TEAM — We locally superheated the interior of thermal-sensitive microgel colloidal crystals and measured the homogenous melting by video microscopy. The nucleation was typically started from a local strong-vibrating region instead of precursor defects. We found that the nucleation time $t \sim (\phi - \phi_m)^{-2}$ and critical nucleus size $r^* \sim (\phi - \phi_m)^{-1}$ as predicted by the classical nucleation theory, while the observed non-spherical critical nuclei and the merging of subcritical nuclei are beyond the classical nucleation theory. At the superheated limit where the incubation time vanishes, the Lindemann parameter approaches 0.18 which just equals to that at the liquid-solid interface. Beyond the superheated limit, the melting becomes like a spinodal decomposition rather than a nucleation process.

¹This work was supported by Hong Kong SAR GRF Grants No. 601208 & 601911.

8:48AM H51.00005 Polyhedral assembled colloids (PACs); a new family of colloids with facets, NOBUHIRO YANAI, JING YAN, QIAN CHEN, STEVE GRANICK, University of Illinois at Urbana Champaign — We introduce a new class of colloids with polyhedral morphology that self-assemble into well-defined clusters and crystals by means of directional attraction between facets. These micron-sized particles are prepared by controlled crystallization of metal ions and organic bridging ligands in solution. They are characterized by distinct polyhedral morphology, rhombic dodecahedra in this work. Unlike spheres that isotropically interact along a curved surface, rhombic dodecahedra particles in suspension associate in a directional facet-to-facet fashion, forming clusters whose elemental units are orderly not only in interparticle distance but also mutual orientation. Furthermore, by changing the particle concentration during the self-assembly, we observe two types of hexagonal arrangement of these rhombic dodecahedra.

9:00AM H51.00006 Measuring every particle's size in a confocal microscopy experiment, ERIC WEEKS, Physics Dept., Emory University, REI KURITA, Institute of Industrial Science, University of Tokyo — We have developed a technique to estimate the radius of every particle observed in a confocal microscopy experiment. From simulations, we verify that the particle radii are estimated to high accuracy in a variety of samples: dense colloidal suspensions, colloidal gels, and binary samples. This method allows us to determine *in situ* the particle size distribution. Furthermore, this method lets us find relationships between individual particle size and dynamical behaviors. First, crystal nucleation occurs in regions that are locally more monodisperse. Second, in dense samples, particle mobility is well correlated with the local volume fraction, defined as the true particle volume divided by the particle's Voronoi volume.

9:12AM H51.00007 Vibrational Phonon Modes of Two-Dimensional Soft-Particle Colloidal Crystals with Hard-Particle Dopants¹, MATTHEW GRATALE, PETER YUNKER, KE CHEN, Department of Physics and Astronomy, University of Pennsylvania, KEVIN APTOWICZ, Department of Physics, West Chester University, ARJUN YODH, Department of Physics and Astronomy, University of Pennsylvania — We study the phonon modes of two-dimensional colloidal crystals consisting of random distributions of "soft" NIPA microgel particles and "hard" polystyrene particle dopants. Thus, the effective springs connecting nearest-neighbors are very stiff, very soft, or of intermediate stiffness, corresponding to three possible inter-particle potentials present in the crystals. We employ video microscopy to derive the phonon modes of corresponding "shadow" crystals with the same geometric configuration and interactions as the experimental colloidal system, but absent damping [1,2,3]. Long wavelength, Debye-like behavior is found at low frequencies, regardless of the number of hard polystyrene particles present in the crystal. Hard particles are primary participants at high frequencies, while soft spheres are primary participants at intermediate frequencies. [1] Chen *et al.*, PRL **105**, 025501 (2010). 9:24AM H51.00008 Direct observation of the nucleation in colloidal solid-solid transitions¹ , YI PENG, FENG WANG, ZIREN WANG, YILONG HAN, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China — We studied the solid-solid transitions between square and triangular lattices in thermal sensitive microgel colloidal thin films by video microscopy. A novel two-step nucleation process was observed in a locally heated single crystalline domain: typically a ~60-particle liquid nucleus was first from the square lattice and then rapidly transformed to a solid nucleus with triangular lattice. Such a post-critical triangular-lattice nucleus grew linearly and induced grain boundaries around it. Nuclei were triggered by the merging of stronger vibrating areas instead of precursor defects. The critical nucleus size was measured from the mean first passage time of the nucleus size.

¹This work was supported by GRF grants 601208 and 601911.

9:36AM H51.00009 Colloidal gas-liquid transition: tuning nucleation and growth by Critical Casimir forces , DUC NGUYEN, PhD, PETER SCHALL, Dr — The nucleation and growth of the liquid phase has been well studied in simulations, but direct experimental observations remain challenging. Here we present a detailed study of the colloidal gas-liquid transition induced by Critical Casimir forces that allow direct control over particle interactions via temperature-dependent solvent fluctuations. We show that with the direct control over particle interactions we can “freeze” a dilute colloidal gas into a dense colloidal liquid. By using dynamic light scattering to follow the evolution of liquid aggregates we observe three clearly distinct regimes: nucleation, interface limited- and diffusion limited growth. We elucidate these regimes directly in real space by using confocal microscopy. In the nucleation regime, we determine the Gibbs free energy, interfacial tension and chemical potential of the liquid aggregates directly from their size distribution. In the growth regime, we can directly follow the attachment of particles, and the collapse of liquid aggregates to large drops. Our critical Casimir colloidal system allows us to control all stages of nucleation and growth with temperature, thereby providing unprecedented insight into this gas-liquid transition.

9:48AM H51.00010 Temperature control of colloidal phases by Critical Casimir forces – a simulation study , MINH TRIET DANG, VAN DUC NGUYEN, Van der Waals-Zeeman Institute, University of Amsterdam, Netherlands, ANA VILA VERDE, PETER BOLHUIS, Van't Hoff Institute for Molecular Science, University of Amsterdam, Netherlands, PETER SCHALL, Van der Waals-Zeeman Institute, University of Amsterdam, Netherlands, VAN DER WAALS-ZEEMAN INSTITUTE, UNIVERSITY OF AMSTERDAM, NETHERLANDS COLLABORATION, VAN'T HOFF INSTITUTE FOR MOLECULAR SCIENCE, UNIVERSITY OF AMSTERDAM, NETHERLANDS COLLABORATION — Critical Casimir forces arising from the confinement of critical solvent fluctuations between the surfaces of colloidal particles have recently been shown a promising route to control colloidal assembly. Such forces are strongly temperature dependent, and thus allow for direct temperature control of colloidal interactions. However, colloidal phase transitions controlled by this highly temperature-dependent potential are still poorly understood. Here, we report Monte Carlo simulations of critical Casimir-driven colloidal phase behavior using input potentials directly measured in experiments. We map the gas-liquid coexistence region using Gibbs ensemble simulations and the solid-fluid coexistence boundaries using Gibbs-Duhem integration, and determine the gas-liquid critical point by applying scaling theory. The constructed gas-liquid-solid phase diagram agrees quantitatively with that observed in experiments. Remarkably, the simulated gas-liquid coexistence curve exhibits 3D Ising scaling despite the strong temperature dependence of the pair potentials.

10:00AM H51.00011 Colloidal aggregation in microgravity by critical Casimir forces¹ , SANDRA VEEN, PETER SCHALL, OLEG ANTONIUK, Van der Waals Zeeman Institute - University of Amsterdam, MARCO POTENZA, MATTEO ALAIMO, University of Milan, STEFANO MAZZONI, European Space Agency, GERARD WEGDAM, Van der Waals Zeeman Institute - University of Amsterdam, VAN DER WAALS ZEEMAN INSTITUTE - UNIVERSITY OF AMSTERDAM COLLABORATION, OPTICS AND MICROGRAVITY RESEARCH LABORATORY - UNIVERSITY OF MILAN COLLABORATION, PHYSICAL SCIENCE UNIT HUMAN SPACEFLIGHT AND OPERATIONS - EUROPEAN SPACE AGENCY COLLABORATION — We study aggregation and crystal growth of spherical Teflon colloids in binary liquid mixtures in microgravity by the critical Casimir effect. The critical Casimir effect induces interactions between colloids due to the confinement of bulk fluctuations (density or concentration) near the critical point of liquids. The strength and range of the interaction depends on the length scale of these fluctuations which increase as one approaches the critical point. The interaction potential can thus be tuned with temperature. We follow the growth of structures in real time with Near Field Scattering. Measurements are performed in microgravity in order to study pure diffusion limited aggregation, without disturbance by sedimentation or flow.

¹NWO/NSO/ESA

10:12AM H51.00012 Light transport through soft colloidal glasses , SOFIA MAGKIRIADOU, Harvard Physics Department, Cambridge, MA, USA, JIN-GYU PARK, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, USA, YOUNG-SEOK KIM, Korea Electronics Technology Institute, S.Korea, GI-RA YI, Department of Engineering Chemistry, Chungbuk National University, S. Korea, VINOTHAN N. MANOHARAN, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, USA — We have developed a novel colloidal system for the fundamental study of light propagation through disordered media. Our colloids contain core-shell particles with scattering cores and transparent shells which are self-assembled into amorphous, glassy configurations. The core-shell structure of the particles allows us to independently control two key parameters for light propagation: their scattering cross-section, which is determined by the cores, and their spacing, which is determined by the shells. Thus, our system is ideally suited for the study and manipulation of the optical properties of disordered materials. In particular, we aim to investigate how photonic stop bands arise in disordered media and how near-field coupling between scatterers affects light transport. We intend to use this knowledge to make amorphous colloids with various angularly-independent structural colors.

10:24AM H51.00013 3D Dynamic Light Scattering of Microgel Suspensions , JOHN HYATT¹, ALBERTO FERNANDEZ-NIEVES², Georgia Institute of Technology, GEORGIA TECH TEAM — We use 3D cross-correlated dynamic light scattering to investigate suspensions of microgels. We will discuss some of the theory behind this technique and present results from size- and pH-tunable pNIPAM microgels cross-linked with PEG and copolymerized with acrylic acid.

10:36AM H51.00014 Using colloidal packings as templates for structuring drugs , JAMES WILKING, Harvard University, ANDRÉ STUDART, ETH, SEBASTIAN KOLTZENBURG, BASF, RODRIGO GUERRA, ESTHER AMSTAD, Harvard University, JENS RIEGER, BASF, DAVID WEITZ, Harvard University — Many pharmaceutical compounds are poorly soluble in water; this is problematic because most pharmaceuticals are delivered orally and must dissolve in the gastrointestinal fluid in order to be taken up by the body. We introduce a simple method for increasing the dissolution rates of poorly water-soluble organic actives. We demonstrate that by structuring the compounds within the interconnected, nanoscale pore space of a colloidal packing we create composites which rapidly disintegrate in water, exposing the nanostructured organic active and leading to improved dissolution rates.

10:48AM H51.00015 Spin coating of superparamagnetic colloids with applied magnetic fields¹

, WENCESLAO GONZÁLEZ-VIÑAS, MOORTHY PICHUMANI, University of Navarra — We report experimental results on the behavior of dilute superparamagnetic colloids under shear stresses (using a commercial spin-coater and varying its rate of rotation) with applied magnetic fields. For the case of zero field, we compare the results obtained for different kind of particles (non-magnetic [1] vs PS based [2] vs silica based [3]) and solvents by analyzing the dried deposits obtained from the spin coating. All the data collapse in a single curve, when the appropriate scaling for the film thickness is performed. This agreement allows us to define a reference to measure the relative change in viscosity, when a magnetic field is applied during the spin coating. Thus, we show the magnetorheological properties of colloidal dispersions. These results shed light into the aggregation and clustering dynamics for colloids under external fields with shear and provide a new method to study the rheological properties of colloids.

Tuesday, February 28, 2012 8:00AM - 11:00AM — Session H52 GSNP DFD: Focus Session: Extreme Mechanics - Rods 153C

8:00AM H52.00001 Dynamic curling of a naturally curved Elastica¹, BASILE AUDOLY, Institut Jean le Rond d'Alembert, University Paris 6 and CNRS — We consider the motion of a naturally curved Elastica that has been flattened onto a hard surface. When it is released from one end, the Elastica lifts off the surface and curls dynamically into a moving spiral. The motion is governed by inertia, bending and geometric nonlinearity. At long times, the dynamics follows a self-similar regime: the size of the spiral grows like the cubic root of time, while the velocity of the front reaches a constant value. The asymptotic velocity is derived analytically, and compared to numerical simulations and to experiments.

8:36AM H52.00002 The Mechanics of Curly Hair, JAMES MILLER, Massachusetts Institute of Technology, ARNAUD LAZARUS, BREANNA BERRY, MIT, BASILE AUDOLY, Institut d'Alembert (University Paris 6), PEDRO REIS, MIT — We explore the oft-neglected role of intrinsic natural curvature on the mechanics of elastic rods. Our testbed, a hanging hair, is a deceptively simple system that exhibits complex mechanics and geometrically nonlinear behavior. Through a combination of precision desktop-scale experiments, numerical simulations, and theoretical analysis, we seek physical insight into the nontrivial configurations adopted by a naturally curved elastic rod that is suspended under its own weight. In particular, we aim to gain predictive understanding of the transition from planar to non-planar solutions as well as the localization of torsion in the non-planar configurations. The experimentally observed behavior of our custom-fabricated naturally curved rods is captured well by simulations and is rationalized through scaling arguments.

8:48AM H52.00003 The Shape of a Ponytail and the Statistical Physics of Hair Fiber Bundles, RAYMOND E. GOLDSTEIN, University of Cambridge, PATRICK B. WARREN, Unilever R&D Port Sunlight, ROBIN C. BALL, University of Warwick — From Leonardo to the Brothers Grimm our fascination with hair has endured in art and science. Yet, a quantitative understanding of the shapes of a hair bundles has been lacking. Here we combine experiment and theory to propose an answer to the most basic question: What is the shape of a ponytail? A model for the shape of hair bundles is developed from the perspective of statistical physics, treating individual fibers as elastic filaments with random intrinsic curvatures. The combined effects of bending elasticity, gravity, and bundle compressibility are recast as a differential equation for the envelope of a bundle, in which the compressibility enters through an "equation of state." From this, we identify the balance of forces in various regions of the ponytail, extract the equation of state from analysis of ponytail shapes, and relate the observed pressure to the measured random curvatures of individual hairs.

9:00AM H52.00004 Following the equilibria of slender elastic rods, ARNAUD LAZARUS, JAMES MILLER, PEDRO REIS, Massachusetts Institute of Technology — We present a novel continuation method to characterize and quantify the equilibria of elastic rods under large geometrically nonlinear displacements and rotations. To describe the kinematics we exploit the synthetic power and computational efficiency of quaternions. The energetics of bending, stretching and torsion are all taken into account to derive the equilibrium equations which we solve using an asymptotic numerical continuation method. This provides access to the full set of analytical equilibrium branches (stable and unstable), a.k.a bifurcation diagrams. This is in contrast with the individual solution points attained by classic energy minimization or predictor-corrector techniques. We challenge our numerics for the specific problem of an extremely twisted naturally curved rod and perform a detailed comparison against a precision desktop-scale experiments. The quantification of the underlying 3D buckling instabilities and the characterization of the resulting complex configurations are in excellent agreement between numerics and experiments.

9:12AM H52.00005 The elasticity of magnetic chains: From self-buckling to self-assembly, DOMINIC VELLA, EMMANUEL DU PONTAVICE, CAMERON HALL, ALAIN GORIELY, OCCAM, University of Oxford — Spherical neodymium magnets have become a popular toy in recent years. In this talk, we present the results of some experimental and theoretical investigations into the peculiar elastic-like behaviour exhibited by chains of these magnetic spheres. We show how the dipole-dipole interactions between spheres penalise deformation, and we find that the form of this penalty is different for a long chain compared to a short chain. Finally, we investigate the dynamic self-assembly of these chains into cylindrical structures.

9:24AM H52.00006 Spontaneous and Deterministic Three-dimensional Curling of Pre-strained Elastomeric Strips: From Hemi-helix to Helix, JIANGSHUI HUANG, JIA LIU, BENEDIKT KROLL, KATIA BERTOLDI, ZHIGANG SUO, DAVID CLARKE, Harvard University — A variety of three dimensional curls are produced by a simple generic process consisting of pre-straining one elastomeric strip, joining it to another and then releasing the bi-strip. The hemi-helix, one kind of three dimensional curls, consists of multiple, alternating helical sections of half wavelength in opposite chiralities and separated by perversions. The hemi-helix wavelength and the number of perversions are determined by the strip cross-section, the constitutive behavior of the elastomer and the value of the pre-strain. Topologically, the perversions also separate regions of the helix deforming principally by bending from those where twisting dominates. Changing the prestrain and the ratio between the thickness and the width induce a phase separation of hemi-helical structure, helical structure and hybrid structure which have similarities to coiled polymer molecules and plant tendrils.

9:36AM H52.00007 Snakes Out of the Plane¹, ANDREW MCCORMICK, BRUCE A. YOUNG, L. MAHADEVAN, Harvard University — We develop a new computational model of elastic rods, taking into account shear and full rotational dynamics, as well as friction, adhesion, and collision. This model is used to study the movement of snakes in different environments. By applying different muscular activation patterns to the snake, we observe many different patterns of motion, from planar undulation to sudden strikes. Many of the most interesting behaviors involve the snake rising out of the horizontal plane in the vertical direction. Such behaviors include a sand snake sidewinding over the hot desert sand and a cobra rearing up into a defensive striking position. Experimental videos of live snakes are analyzed and compared with computational results. We identify and explain a new form of movement previously unobserved: “collateral locomotion.”

9:48AM H52.00008 Analysis of the fluid mechanical sewing machine, PIERRE-THOMAS BRUN, Institut Jean le Rond d'Alembert/Lab. FAST, UPMC, Univ Paris-Sud, CNRS, BASILE AUDOLY, Institut Jean le Rond d'Alembert, UPMC, CNRS, NEIL RIBE, Lab FAST, UPMC, Univ Paris-Sud, CNRS — A thin thread of viscous fluid falling onto a moving belt generates a surprising variety of patterns, similar to the stitch patterns produced by a traditional sewing machine. By simulating the dynamics of the viscous thread numerically, we can reproduce these patterns and their bifurcations. The results lead us to propose a new classification of the stitch patterns within a unified framework, based on the Fourier spectra of the motion of the point of contact of the thread with the belt. The frequencies of the longitudinal and transverse components of the contact point motion are locked in most cases to simple ratios of the frequency Ω_c of steady coiling on a surface at rest (i.e., the limit of zero belt speed). In particular, the “alternating loops” pattern involves the first five multiples of $\Omega_c/3$. The dynamics of the patterns can be described by matching the upper (linear) and the lower (non-linear) portions of the thread. Following this path we propose a toy model that successfully reproduces the observed transitions from the steady dragged configuration to sinusoidal meanders, alternating loops, and the translated coiling pattern as the belt speed is varied.

10:00AM H52.00009 Microfabrication of a spider-silk analogue through the liquid rope coiling instability¹, FREDERICK P. GOSSELIN, DANIEL THERIAULT, MARTIN LEVESQUE, Ecole Polytechnique de Montreal — Spider capture silk outperforms most synthetic materials in terms of specific toughness. We developed a technique to fabricate tough microstructured fibers inspired by the molecular structure of the spider silk protein. To fabricate microfibers (with diameter $\sim 30\mu m$) with various mechanical properties, we yield the control of their exact geometry to the liquid rope coiling instability. This instability causes a thread of honey to wiggle as it buckles when hitting a surface. Similarly, we flow a filament of viscous polymer solution towards a substrate moving perpendicularly at a slower velocity than the filament flows. The filament buckles repetitively giving rise to periodic meanders and stitch patterns. As the solvent evaporates, the filament solidifies into a fiber with a geometry bestowed by the instability. Microtraction tests performed on fibers show interesting links between the mechanical properties and the instability patterns. Some coiling patterns give rise to high toughness due to the sacrificial bonds created when the viscous filament loops over itself and fuse. The sacrificial bonds in the microstructured fiber play an analogous role to that of the hydrogen bonds present in the molecular structure of the silk protein which give its toughness to spider silk.

10:12AM H52.00010 Buckling Instability and Stress Propagation in Rods with Elastic Support, ZI CHEN, Biomedical Engineering, Washington Univ. in St. Louis, WANLIANG SHAN, Mechanical & Aerospace Engineering, Princeton Univ., ANKITA GUMASTE, Neuroscience & Behavioral Biology, Emory Univ., WINSTON SOBOYEJO, Mechanical & Aerospace Engineering, Princeton Univ., CLIFFORD BRANGWYNNE, Chemical & Biological Engineering, Princeton Univ. — The cytoskeleton of living cells is a composite material consisting of a network of biopolymers including f-actin and microtubules (MTs). MTs are able to bear significant compressive loads in cells as a result of reinforced short wavelength buckling, due to the surrounding actin network. However, the length scale of compressive force propagation, even for macroscopic rods, remains poorly understood. Here we propose a minimal theory that incorporates elastic restoring forces from the surrounding network, elucidating the compressive force-dependence of the buckled rod shape. We identify a threshold length as the effective distance stresses can propagate in such network, and show that the decay length is tunable by modifying the longitudinal mechanical coupling coefficients. We test these predictions with experiments in macroscopic rods, and show that the degree of mechanical coupling directly controls the penetration depth of buckling, in agreement with theoretical and numerical predictions. Our results suggest that the length scale over which mechanical signals are transduced in cells may be actively controlled, and could provide design principles for novel types of fiber composite materials based on biomimetic control of the longitudinal coupling coefficients.

10:24AM H52.00011 Undulatory buckling of a rod constrained by an elastic matrix, JIA LIU, TIANXIANG SU, Harvard University, OSCAR LOPEZ-PAMIES, UIUC, PEDRO REIS, MIT, KATIA BERTOLDI, Harvard University — Elastic instabilities of rods constrained by an elastic matrix and subjected to axial compression have long been recognized as essential for structural applications in the context of failure mitigation and, more recently, towards exploitation of functionality. Relevant fields for this class of problems include drilling, biomedical instrumentation and root growth in plants. We explore the two possible scenarios observed when, above a threshold load, compression is applied to a rod constrained by a matrix: i) the rod can develop a planar oscillatory solution (sinusoidal buckling) or ii) it can take the configuration of a helix (helical buckling). We identify the principal parameters of this system, perform a systematic parametric study and rationalize the phase diagram through a hybrid of theoretical and numerical analyses. Particular attention is devoted to the effect of the mechanical properties of the constraining matrix which is found to have a critical influence on this buckling scenario.

10:36AM H52.00012 Slack, stress, and noisy structures in inertial strings, JAMES HANNA, CHRISTIAN SANTANGELO, Department of Physics, University of Massachusetts - Amherst — Strings and chains are inextensible filaments with negligible bending and twist resistance. Local arc length conservation is enforced by the stress, a Lagrange multiplier field screened by curvature. Uniform stress fields are generated by a wide class of inertial motions that includes travelling waves of curvature and torsion, while gradients in stress result in more complicated dynamics. We will discuss a theoretical example inspired by experimental and numerical observations of the growth of an arch in a straightening chain, involving the amplification, rectification, and advection of slack.

10:48AM H52.00013 Sinusoidal to helical buckling of an elastic rod under a cylindrical constraint, TIANXIANG SU, Harvard University, JAMES MILLER, ARNAUD LAZARUS, Massachusetts Institute of Technology, NATHAN WICKS, JAHIR PABON, Schlumberger-Doll Research, KATIA BERTOLDI, Harvard University, PEDRO REIS, Massachusetts Institute of Technology — We investigate the buckling and post-buckling behavior of an elastic rod loaded under cylindrical constraint. Our precision desktop-scale experiments comprise of axially compressing a hyper-elastic rod inside a transparent acrylic pipe. These experiments are also modeled using a discrete elastic rod simulation that includes frictional effects. Under imposed displacement, the initially straight rod first buckles into a sinusoidal mode and eventually undergoes a secondary instability into a helical buckling regime. The buckling and post-buckling behavior is found to be highly dependent on the systems' geometry, in particularly the aspect ratio of the rod to pipe diameter. We quantify the wavelength and pitch of the periodic patterns through direct digital imaging and record the reaction forces at both ends of the pipe. The observed behavior is rationalized through scaling arguments and captured by numerical simulations.

Session H53 GSNP: Focus Session: Continuum Descriptions of Discrete Materials 153B

8:00AM H53.00001 Failure of a loose packing of grains , GREG FARRELL, NARAYANAN MENON, UMass-Amherst

— One-sided repulsive interactions and history-dependent friction forces can cause the mechanics of real granular systems to deviate significantly from that of cohesive solids. Marked deviations from elastic behavior can be seen in the mechanical response and structure of sedimented loose packings of frictional spheres even for very delicate perturbations. In our experiments, particles' displacements are observed with 3D fluorescent imaging as a shear plane is displaced through the packing. As anticipated, we find the shear force is approximately linear with the displacement between discrete yielding events. However, even in this apparently linear region, structural aging continues to occur for the smallest displacements that we can apply. This suggests the inaccessibility of a reversible shear deformation regime in loose packings of granular material. We present a spatial characterization of the particle motion that distinguishes between these continuous instances of irreversibility and the larger discrete failure events.

8:12AM H53.00002 Jamming in Hopper Flows: Analysis of Survival Times¹ , MICHAL DICHTER, Brandeis

University, SHUBHA TEWARI, Western New England University, BULBUL CHAKRABORTY, Brandeis University — Many granular systems experience a transition from a fluid-like state to a solid-like state characterized by a sudden arrest in dynamics, or “jamming.” Recent experiments by the Behringer Group at Duke University suggest a probabilistic model of jamming in hopper flows. We will show the results of numerical simulations of dense, gravity-driven, granular flows in a two-dimensional hopper with a tapered outlet [PRE 79, 011303 (2009)]. We will present results for the statistics of mass flow at the outlet, and the probability of survival without a jam. We will correlate the survival times with velocity and density distributions near the hopper opening.

¹This project is funded by NSF.

8:24AM H53.00003 Experimental analysis on how grain properties affect the performance of jammed granular systems for variable stiffness robotic applications¹ , NADIA CHENG, KARL IAGNEMMA, ANETTE HOSOI, KATY GERO, Massachusetts Institute of Technology

— Jamming of granular media has become increasingly utilized as a variable stiffness mechanism for industrial and robotic applications. The goal of our work is to better understand how grain properties affect jamming so that granular systems can be designed to fulfill the requirements of a given application. We have primarily focused on experimental studies to analyze how certain grain properties—such as shape, surface roughness, size distribution, and shape distribution—affect the performance of granular systems. Potential applications that utilize jamming would typically require that a contained granular system transition between effective solid states (e.g., when particular shape or strength needs to be maintained) and effective liquid states (e.g., when the system needs to be compliant such that it can be shaped or actuated by its environment). Therefore, we are interested in quantifying 1) the strength of compacted granular systems in their effective solid states and 2) the “ease of flow” and compliance of granular systems in their effective liquid states.

8:36AM H53.00004 Shear-Transformation-Zone Theory of Glassy Diffusion, Stretched Exponentials, and the Stokes-Einstein Relation , JAMES LANGER, University of California, Santa Barbara

— The success of the shear-transformation-zone (STZ) theory in accounting for broadly peaked, frequency-dependent, glassy viscoelastic response functions is based on the theory's first-principles prediction of a wide range of internal STZ transition rates. Here, I propose that the STZ's are the dynamic heterogeneities frequently invoked to explain Stokes-Einstein violations and stretched-exponential relaxation in glass-forming materials. I find that, to be consistent with observations of Fickian diffusion near T_g , an STZ-based diffusion theory must include cascades of correlated events, but that the temperature dependence of the Stokes-Einstein ratio is determined by an STZ-induced enhancement of the viscosity. Stretched-exponential relaxation of density fluctuations emerges from the same distribution of STZ transition rates that predicts the viscoelastic behavior.

9:12AM H53.00005 A granular flow law based on nonlocal fluidity , KEN KAMRIN, MIT, GEORG KOVAL, INSA Strasbourg

— A general, three-dimensional law to predict granular flow in an arbitrary geometry has been an elusive goal for decades. Recently, an elasto-plastic continuum model has shown the ability to approximate steady flow and stress profiles in multiple inhomogeneous flow environments. However, the model does not capture some phenomena observed in the slow, creeping flow regime. As normalized flow-rate decreases, granular stresses are observed to become largely rate-independent and a dominating length-scale emerges in the mechanics. This talk attempts to account for these effects using the notion of nonlocal fluidity, which has proven successful in treating nonlocal effects in emulsions. The idea is to augment the usual granular fluidity law with a diffusive second-order term scaled by the particle size that spreads flowing zones accordingly. Below the yield stress, the local contribution vanishes and the fluidity becomes rate-independent, as we require. We implement the modified law in multiple geometries and validate its predictions for velocity, shear-rate, and stress against discrete particle simulations.

9:24AM H53.00006 Rheology of discontinuously shear thickening suspensions beyond simple shear , PAWEL ZIMOCZ, GARETH MCKINLEY, ANETTE HOSOI, Massachusetts Institute of Technology

— The behavior of discontinuously shear thickening suspensions in flows other than simple shear is not well understood, in part due to unresolved experimental challenges. For example, such suspensions thicken most easily close to rigid boundaries due to the no-slip condition. This makes experiments highly dependent on the shape and size of the container used. We show that by placing a lubricating layer of oil between the suspension and the container we can generate flows where thickening is nearly independent of rigid boundaries. This method is particularly useful in creating quasi one- and two-dimensional flows, which can be easily visualized. We use this method to conduct capillary breakup experiments with thickening suspensions of silica and cornstarch particles, in which we observe the formation of beads-on-a-string morphologies with multiple satellite and sub-satellite bead generations, similar to the morphologies observed in breakup of viscoelastic fluids. Using a one-dimensional continuum model, we show how nonlinear rheology of thickening suspensions results in the creation of these complex morphologies.

9:36AM H53.00007 Activated processes in a stress landscape: a rheological model for dense driven granular materials¹ , BULBUL CHAKRABORTY, DAPENG BI, Brandeis University

— We model (Phil. Trans. R. Soc. A 2009 367) the rheological behavior of granular materials based on a stress-based statistical ensemble and the Soft Glassy Rheology framework (SGR). It takes into account the disordered nature of granular packings and the metastability of jammed states, as well as spatial heterogeneity and intermittency. In this model, mesoscopic subregions of a driven granular material undergo activated processes in a *stress* landscape with a broad distribution of barrier heights. Due to the athermal nature of granular materials, the activated processes are induced not by the thermodynamic temperature, but by a temperature-like quantity which is a measure of the fluctuation of stresses. Results and predictions of the model have been successfully applied to analyze experiments in a Couette geometry. We will discuss applications of the stress-activated framework in, for example, recent experiments that study non-local rheology in dense flows (PRL 106 108301(2011)).

9:48AM H53.00008 Shear-transformation-zone theory of plasticity in hard-sphere materials, CHARLES K.C. LIEOU, JAMES S. LANGER, AHMED E. ELBANNA, JEAN M. CARLSON, Department of Physics, University of California, Santa Barbara — The dynamics of sheared, dense granular materials exhibits features, such as a dynamic yield stress and a glass transition, similar to those of other amorphous solids. However, strictly granular, hard-sphere systems fundamentally differ from traditional glassy and colloidal systems because at microscopic scales their dynamics and interaction energies are insensitive to thermal temperature. In this talk we present a theory of plasticity for sheared, granular materials that combines Shear Transformation Zone (STZ) theory with Edwards' statistical theory of granular materials. We find that the dynamics of a strictly granular system, like other amorphous solids, can be captured statistically in terms of entropic mechanisms. In our analysis of sheared hard spheres, the volume V replaces the energy E as a function of entropy S in conventional statistical mechanics. In place of an effective disorder temperature, a central feature of the STZ theory for traditional glassy systems, the compactivity $X = \partial V / \partial S$ characterizes the internal state. We derive the STZ equations of motion for a granular material accordingly, and predict its macroscopic properties such as shear viscosity and macroscopic frictional coefficient under different shearing conditions.

10:00AM H53.00009 Width of Shear Zones in Gravity-Driven Granular Flows, SHUBHA TEWARI, Western New England University, BULBUL CHAKRABORTY, Brandeis University — Gravity-driven granular flow in a vertical hopper exhibits a flow profile that consists of a plug near the center and a shear zone near the boundary walls. It has been observed that the width of the shear zone is a few particle diameters and is independent of the channel width, however, the mechanism by which the width is selected remains unclear. Using event-driven simulations of granular flow in a two-dimensional hopper, we investigate the width of the shear zone as a function of the channel width and the boundary conditions at the wall. We focus on the role played by fluctuations in the stress as the source of activated slips near the wall as a candidate mechanism for the shear zone.

10:12AM H53.00010 From streamline jumping to strange eigenmodes: Learning from simple continuum models of granular mixing¹, IVAN C. CHRISTOV², JULIO M. OTTINO, RICHARD M. LUEPTOW, Robert R. McCormick School of Engineering and Applied Science, Northwestern University — Simple continuum models of granular flow can provide fundamental insight into how and why granular materials mix. Though a similar kinematic framework can be used to study both fluid and granular mixing, there are striking differences that we explore through a computational-experimental study of granular flow in a slowly rotating quasi-two-dimensional polygonal container. In the Lagrangian frame, for small numbers of revolutions, we show that the mixing pattern is captured by a model termed "streamline jumping." This minimal model, arising at the limit of a vanishingly-thin surface flowing layer, possesses no intrinsic stretching or streamline crossing in the usual sense, yet it can lead to complex particle trajectories that resemble chaos. In the Eulerian frame, meanwhile, we show the presence of naturally-persistent granular mixing patterns ("strange" eigenmodes) for intermediate numbers of revolutions. Unlike fluid mixing, however, strong diffusive effects (due to particle collisions in granular flows) result in fast decay of these transient patterns in monodisperse mixtures. Meanwhile, segregation leads to permanent excitation of eigenmodes in bidisperse mixtures.

10:24AM H53.00011 From liquid to stone: a polydispersive colloidal model for cement setting¹, ENRICO MASOERO, ROLAND PELLENG, FRANZ-JOSEF ULM, SIDNEY YIP, Massachusetts Institute of Technology, EMANUELA DEL GADO, ETH Zurich — The main binding phase of cement is the nano-porous C-S-H gel, (calcium-silicate-hydrate). Here we investigate the temporal evolution of the mechanical properties of cement across the rigidity transition from liquid paste to solid stone, due to the precipitation of C-S-H. This transition is named "setting" and occurs several hours after mixing cement powder with water. We present a numerical model of random insertion of colloidal C-S-H nano-particles in the Monte Carlo framework. The particles interact with each other according to a generalized Lennard-Jones potential. Depending on the particle size polydispersity, the packing fraction of the final assemblies ranges between 0.64 and 0.73. The mechanical properties of the assemblies indicate that the packing fraction is the key parameter for continuum mechanics models at larger scales. In fact, both the stiffness and the strength of the assemblies increase with the packing fraction, while the ductility decreases. On the other hand, the evaluation of the specific surface requires an additional parameter fixing the length scale, for example, the characteristic size of the nano-pores. We finally show the relevance of our results for cement setting with a simple semi-analytical model of micro-pore filling.

10:36AM H53.00012 Effect of randomness on wave propagation in granular systems, MOHITH MANJUNATH, AMNAYA P. AWASTHI, PHILIPPE H. GEUBELLE, Department of Aerospace Engineering, University of Illinois at Urbana-Champaign — Granular systems have been shown to possess energy absorbing and potential wave mitigation characteristics due to the flexibility in tuning the properties of the particles. The present study focuses on the impact of randomness on wave propagation in 1D and 2D lattices of spherical particles where the randomness is associated with either the mass, Young's modulus or radius of the spheres. The 1D study (motivated by M. Manciau et. al. (2001)) reveals the presence of two distinct regimes of decay in peak compressive force with distance for any level of randomness. The transition between the regimes of exponential and power-law decay is shown to occur when the amplitude of the leading pulse reduces below that of the scatter. Investigation into the ensemble kinetic and potential energies of the system as a function of time shows the gradual transfer of energy from potential to kinetic with increase in the level of randomness. In 2D square packed systems simulated with a modified version of the molecular dynamics package LAMMPS, we note that the decay in peak compressive force is present due to dimensionality as well as randomness. Normalization is then used to quantify the decay due to randomness alone and we investigate the anisotropy of the randomness induced decay.

10:48AM H53.00013 Continuum Representation of the Mechanics of Random Fiber Networks, ALI SHAHSAVARI, CATALIN PICU, Rensselaer Polytechnic Institute — Solving boundary value problems over large domains of random fiber networks is important in the design of fiber-based engineering materials and in the understanding of the biophysics of biological materials. In most of these applications, systems contain a very large number of fibers, which renders nearly impossible solving boundary value problems while resolving every fiber in the problem domain. Therefore, developing a continuum model for the discrete system is desirable. This presentation focuses on conditions under which this mapping can be performed and the minimum size of the problem beyond which the continuum representation is valid. Random fiber networks are highly heterogeneous and exhibit non-affine deformation with correlated fields at different observation length scales. The scale of transition from the discrete to the continuum model must be large enough to capture all the statistically independent subdomains of the network. This scale cannot be determined exclusively based on geometric considerations (e.g. based on fiber density). These considerations, along with a constitutive model for the small deformation of continuum models of fiber networks are discussed in this talk.

Tuesday, February 28, 2012 8:00AM - 11:00AM —

Session H54 GSNP: Focus Session: Complex and co-evolving networks - Dynamics on Networks

8:00AM H54.00001 Robustness and Assortativity for Diffusion-like Processes in Scale-free Networks¹, ANTONIO SCALA, CNR-ISC, Uos “La Sapienza”, GREGORIO D’AGOSTINO, ENEA - CR “Casaccia”, VINKO ZLATIĆ, Theoretical Physics Division, Rudjer Boskovic Institute, GUIDO CALDARELLI, IMT Lucca Institute for Advanced Studies — By analyzing the diffusive dynamics of epidemics and of distress in complex networks, we study the effect of the assortativity on the robustness of the networks. We first determine by spectral analysis the thresholds above which epidemics/failures can spread; we then calculate the slowest diffusional times. Our results show that disassortative networks exhibit a higher epidemiological threshold and are therefore easier to immunize, while in assortative networks there is a longer time for intervention before epidemic/failure spreads. Moreover, we study by computer simulations a diffusive model of distress propagation (financial contagion). We show that, while assortative networks are more prone to the propagation of epidemic/failures, degree-targeted immunization policies increases their resilience to systemic risk.

¹FET Open Project “FOC” nr. 255987, European project “MOTIA” JLS-2009-CIPS-AG-C1-016

8:12AM H54.00002 Time scales and dynamical processes in activity driven networks, NICOLA PERRA, BRUNO GONCALVES, Northeastern University, ROMUALDO PASTOR-SATORRAS, UPC, ALESSANDRO VESPIGNANI, Northeastern University — Network science has undergone explosive growth in the last ten years. This growth has been driven by the recent availability of huge digital databases, which has facilitated the analysis and construction of large-scale networks from real data and the identification of statistical regularities and structural principles common to many systems. Network modeling has played an essential role in this endeavor; however models are chiefly constructed by considering as relevant ingredients only the connectivity and statistical properties of the networks, while disregarding the actual agents' behavior. Here we address this challenge by measuring the agents' interaction activity in real-world networks and defining a minimal model capable of reproducing the intrinsically additive nature of connectivity patterns obtained from time-aggregated network representations. Additionally, we demonstrate that processes such as epidemic and information spreading in highly dynamical networks can be better characterized in terms of agent social activity than by connectivity based approaches

8:24AM H54.00003 Network growth dynamics of fire ant (*Solenopsis invicta*) nests, NICK GRAVISH, School of Physics, Georgia Tech, MICHAEL A.D. GOODISMAN, School of Biology, Georgia Tech, DANIEL I. GOLDMAN, School of Physics, Georgia Tech — We study the construction dynamics and topology of fire ant (*Solenopsis invicta*) nests. Fire ants in colonies of hundreds to hundreds of thousands create subterranean tunnel networks through the excavation of soil. We observed the construction of nests in a laboratory experiment. Workers were isolated from focal colony and placed in a quasi 2D, vertically oriented arena with wetted soil. We monitored nest growth using time-lapse photography. We found that nests grew linearly in time through tunnel lengthening and branching. Tunnel path length followed an extended power law distribution, $P(l - l_0)^\beta$. Average degree of tunnel nodes was $k = 2.17 \pm 0.40$ and networks were cyclical. In simulation we model the nest growth as a branching and annihilating levy-flight process. We study this as a function of dimensionality (2D and 3D space considered) and step length distribution function $P(l_s)$. We find that in two-dimensions path length distribution is exponential, independent of the functional form of $P(l_s)$ consistent with a poisson spatial process while in three-dimensions $P(l) = P(l_s)$. Comparing simulation and experiment we attribute the slower than exponential tail of $P(l)$ in experiment as a result of a behavioral component to the ant digging program.

8:36AM H54.00004 The Impact of Time Delays in Network Synchronization in a Noisy Environment¹, G. KORNISS, RPI — Coordinating, distributing, and balancing resources in networks is a complex task and it is very sensitive to time delays. To understand and manage the collective response in these coupled interacting systems, one must understand the interplay of stochastic effects, network connections, and time delays. In synchronization and coordination problems in coupled interacting systems individual units attempt to adjust their local state variables (e.g., pace, orientation, load) in a decentralized fashion. They interact or communicate only with their local neighbors in the network, often with explicit or implicit intention to improve global performance. Applications of the corresponding models range from physics, biology, computer science to control theory. I will discuss the effects of nonzero time delays in stochastic synchronization problems with linear couplings in an arbitrary network. Further, by constructing the scaling theory of the underlying fluctuations, we establish the absolute limit of synchronization efficiency in a noisy environment with uniform time delays, i.e., the minimum attainable value of the width of the synchronization landscape.² These results have also strong implications for optimization and trade-offs in network synchronization with delays.

9:12AM H54.00005 Predicting the origin of contagion processes on complex, multi-scale networks, RAFAEL BRUNE, CHRISTIAN THIEMANN, DIRK BROCKMANN, Northwestern University — Contagion phenomena in space often exhibit complex, multiscale spatio-temporal patterns driven by the interaction of non-local dispersal and nonlinear dynamics. A key challenge is the prediction of dynamic patterns based on information on human interactions, mobility and initial conditions. The development of computational models has thus received considerable attention. However, in many realistic situations, a process has already evolved for some period before detection and identifying the spatial origin is difficult. Surprisingly, this “inverse problem” has received little attention in the past. We show in a paradigmatic model for human disease dynamics that despite the spatial complexity of dynamic patterns, the origin of outbreak can be predicted with high fidelity. Based on the technique of shortest path trees in strongly heterogeneous, multi-scale human mobility networks we show that at any point in time the spatial origin can be reconstructed reliably. This novel perspective on complex spatio-temporal dynamics can be applied to systems beyond human disease dynamics for instance the reconstruction of neolithic diffusion of agriculture into Europe and related migration driven historic phenomena.

9:24AM H54.00006 Influence and structural balance in social networks, P. SINGH, S. SREENIVASAN, B. SZYMANSKI, G. KORNISS, RPI — Models on structural balance have been studied in the past with links being categorized as friendly or antagonistic [Ref- T. Antal et al., Phys. Rev. E 72, 036121 (2005)]. However no connection between the nature of the links and states of the nodes they connect has been made. We introduce a model which combines the dynamics of the structural balance with spread of social influence. In this model, every node is in one of the three possible states (e.g. leftist, centrist and rightist) [Ref- F. Vazquez, S. Redner, J. Phys A, 37 (2004) 8479-8494] where links between leftists and rightists are antagonistic while all other links are friendly. The evolution of the system is governed by the rules of structural balance and opinion spread takes place as a result of structural balance process. The dynamics can lead the system to a number of fixed points (absorbing states). We study how the initial density of centrists n_c affects the dynamics and probabilities of ending up in different absorbing states. We also study the scaling behavior of the expected time to converge to one of the absorbing states as a function of the initial density of centrists and under some variations of our basic model.

9:36AM H54.00007 Majority-vote model on a dynamic small-world square lattice, THOMAS E. STONE, Husson University, SUSAN R. MCKAY, University of Maine — Majority-vote models are often used to study consensus building, coarsening dynamics, and phase transitions, among other phenomena. In addition to the microscope rules governing a particular model, it is well known that the relevant properties of each system depend crucially on the underlying lattice structure. Here we investigate a majority-vote with noise model on a square lattice with dynamic small-world rewiring via Monte Carlo simulation and finite size scaling analyses. We construct the order-disorder phase diagram and find the critical exponents associated with the continuous phase transition. We compare our results to those obtained from two-dimensional static small-world networks, as well as the isotropic lattice and mean-field limiting cases.

9:48AM H54.00008 Underlying mechanisms for commuting and migration processes , FILIPPO SIMINI, ALBERT-LASZLO BARABASI, Northeastern University, JAMES BAGROW, Northwestern University — Both frequent commuting and long-term migration are complex human processes that strongly depend on socio-demographic, spatial, political, and even economic factors. We can describe both processes using weighted networks, in which nodes represent geographic locations and link weights denote the flux of individuals who commute (or migrate) between locations. Although both processes concern the movements of individuals, they are very different: commuting takes place on a daily (or weekly) basis and always between the same two locations, while migration is a rare, one-way displacement. Despite these differences, a recently proposed stochastic model, the Radiation model, provides evidence that both processes may be successfully described by the same underlying mechanism. For example, quantities of interest for either process, such as the distributions of trip length and destination populations, appear remarkably similar to the model's predictions. We explore the similarities and differences between commuting and migration both empirically, using census data for the United States, and theoretically, by comparing these commuting and migration networks to the predictions given by the Radiation model.

10:00AM H54.00009 A quantitative measure for organization of complex and co-evolving networks , GEORGI GEORGIEV, Assumption College and Tufts University — To define evolution and self-organization in complex networks a quantitative measure for organization is necessary. Two systems should be numerically distinguishable by their degree of organization and their rate of self-organization. Here we apply as a measure for quantity of organization the inverse of the average sum of physical actions of all elements in a system per unit motion multiplied by the Planck's constant. The meaning of quantity of organization here is the number of quanta of action per one unit motion of an element. For example, a unit motion for electrons on a computer chip is the one necessary for one computation. This definition can be applied to the organization in any complex system. Systems self-organize to decrease the average action per element per unit motion in them. This is the attractor for a dynamical, nonlinear system evolving in time. Constraints increase this average action, so constraint minimization is a basic mechanism for action minimization. Increase of quantity of elements in the network, leads to faster constraint minimization through grouping, decrease of average action per element and motion and therefore faster self-organization and evolution.

10:12AM H54.00010 Identification of Interventions to Control Network Crises , JIE SUN, SAGAR SAHASRABUDHE, ADILSON MOTTER, Northwestern University — Large-scale crises in financial, social, infrastructure, genetic and ecological networks often result from the spread of disturbances that in isolation would only cause limited damage. Here we present a method to identify and schedule interventions that can mitigate cascading failures in general complex networks. When applied to competition networks, our method shows that the system can often be rescued from global failures through actions that satisfy restrictive constraints typical of real-world conditions. However, under such constraints, interventions that can rescue the system from a propagating cascade exist over specific periods of time that do not always include the early postperturbation period, suggesting that scheduling is critical in the control of network cascades.

10:24AM H54.00011 Effect of degree correlations on controllability of complex networks , MARTON POSFAI, YANG LIU, Center for Complex Network Research and Department of Physics, Northeastern University, Boston, Massachusetts 02115, USA, JEAN-JAQUES SLOTINE, Non-linear Systems Laboratory, Massachusetts Institute of Technology, Cambridge, Massachusetts, 02139, USA, ALBERT-LASZLO BARABASI, Center for Complex Network Research and Department of Physics, Northeastern University, Boston, Massachusetts 02115, USA — While significant effort was made during the past decade to understanding the structure, evolution and function of complex networks, little is known about our ability to control them. A system is considered controllable if by imposing appropriate external signals on a set of its nodes, called driver nodes, the system can be driven from any initial state to any desired final state in finite time. The controllability of a network can be quantified by calculating the minimal number of driver nodes needed to obtain complete control. We study the effect of degree correlations on network controllability via both numerical simulations and analytical calculations. Numerical simulations are performed by systematically adding correlations to model networks using appropriate rewiring schemes inspired by simulated annealing. Analytical results are derived using the cavity method originally developed in spin glass theory. The numerical and analytical results enable us to give qualitative predictions of controllability for any networks based on their degree correlation profiles. We test our predictions on several real networks and find consistent results.

10:36AM H54.00012 Control Capacity in Complex Networks , TAO JIA, YANG-YU LIU, CCNR, Northeastern University, JEAN-JACQUES SLOTINE, Massachusetts Institute of Technology, ALBERT-LASZLO BARABASI, CCNR, Northeastern University — By combining tools from control theory and network science, an efficient methodology was proposed to identify the minimum sets of driver nodes, whose time-dependent control can guide the whole network to any desired final state. Yet, this minimum driver set (MDS) is usually not unique, but one can often achieve multiple potential control configurations with the same number of driver nodes. Given that some nodes may appear in some MDSs but not in other, a crucial question remain unanswered: what is the role of individual node in controlling a complex system? We first classify a node as critical, redundant, or ordinary if it appears in all, no, or some MDSs. Then we introduce the concept of control capacity as a measure of the frequency that a node is in the MDSs, which quantifies the importance of a given node in maintaining Controllability. To avoid impractical enumeration of all MDSs, we propose an algorithm that uniformly samples the MDS. We use it to explore the control capacity of nodes in complex networks and study how it is related to other characteristics of the network topology.

10:48AM H54.00013 Controlling Complex Networks with Compensatory Perturbations , SEAN CORNELIUS, Northwestern University, Department of Physics and Astronomy, WILLIAM KATH, Northwestern University, Department of Engineering Sciences and Applied Mathematics, ADILSON MOTTER, Northwestern University, Department of Physics and Astronomy — The response of complex networks to perturbations is of critical importance in areas as diverse as ecosystem management, power system design, and cell reprogramming. These systems have the property that localized perturbations can propagate through the network, causing the system as a whole to change behavior and possibly collapse. We will show how this same mechanism can actually be exploited to prevent such failures and, more generally, control a network's behavior. This strategy is based on counteracting a deleterious perturbation through the judicious application of additional, compensatory perturbations—a prospect recently demonstrated heuristically in metabolic and food-web networks. Here, we introduce a method to identify such compensatory perturbations in general complex networks, under arbitrary constraints that restrict the interventions one can actually implement in real systems. Our method accounts for the full nonlinear time evolution of real complex networks, and in fact capitalizes on this behavior to bring the system to a desired target state even when this state is not directly accessible. Altogether, these results provide a new framework for the rescue, control, and reprogramming of complex networks in various domains.

Tuesday, February 28, 2012 11:15AM - 2:15PM –
Session J1 GIMS: Focus Session: Advances in Scanned Probe Microscopy II: High Frequencies & Optical Techniques 203

11:15AM J1.00001 Towards Magnetic Resonance Imaging of Semiconducting and Biological Nanostructures, D.P. WEBER, FEI XUE, P. PEDDIBHOTLA, M. POGGIO, University of Basel, Switzerland — In recent years a technique combining nuclear magnetic resonance (NMR) and sensitive force microscopy has emerged as a viable method for doing magnetic resonance imaging (MRI) on the nanometer scale [1]. This method, known as magnetic resonance force microscopy (MRFM), has the potential to create three-dimensional (3D), non-destructive, sub-surface images of the density of particular nuclear magnetic moments with isotopic contrast. Resolution better than 10 nm has been achieved with ^1H in a single virus particle [2]. Here we discuss the application of this technique to nanobiological samples, such as viruses, small bacteria, or cell membranes, and to various semiconductor nanostructures including quantum wells (QWs) and nanowires (NWs). In particular, we focus on the sample preparation challenges presented by these samples. Transfer and attachment of these sub-micrometer samples to our micrometer-sized force sensor includes the use of a focused ion beam (FIB) technique and manual micromanipulators used together with optical microscopy.

11:27AM J1.00002 Nanoscale MRI of electron spins at millikelvin temperatures, GEERT WIJTS, ANDREA VINANTE, OLEKSANDR USENKO, ARTHUR DEN HAAN, LAURENS SCHINKELSHOEK, TJERK OOSTERKAMP, Leiden University — Magnetic Resonance Imaging by Atomic Force Microscopy (MRI-AFM) combines the non-destructive subsurface sensitivity of an MRI scanner with the high spatial resolution of an Atomic Force Microscope. It is a powerful technique to detect a small number of spins that relies on force detection by an ultrasoft, magnetically tipped cantilever and selective magnetic resonance manipulation of the spins. In order to minimize the thermomechanical noise of the cantilever and to increase spin polarization, MRI-AFM should be carried out at ultralow temperatures. Therefore, we developed a SQUID-based detection technique, which avoids heating of the cantilever and the spin sample. Using this technique, we demonstrate the manipulation and detection of dangling bond paramagnetic centers on a silicon surface at temperatures as low as 30 millikelvin. The fluctuations of these unpaired electron spins are supposedly linked to $1/f$ magnetic noise and decoherence in SQUIDs as well as in several superconducting and single spin qubits. We find evidence that spin diffusion plays a key role in the dynamics of spins at low temperatures.

11:39AM J1.00003 ESR induced anomalous polarization in Magnetic Resonance Force Microscopy, LEI CHEN, ERIC MOORE, JONILYN LONGENECKER, JOHN MAROHN, Cornell University — Mechanically detecting electron spin resonance has opened up new avenues of performing magnetic resonance detection and imaging to an individual spin-labeled macromolecule. The large gradient field from the magnetic tipped cantilever creates selective resonance conditions for each spin label in the macromolecule. The detection is made through the shifts in the cantilever self-oscillating frequency due to the back action on to the cantilever from the resonating spin polarization. In order to improving the detection sensitivity, great efforts have been made to transfer polarization of electron spins to nearby nuclear spins. Here, we reported an anomalous frequency shift in our mechanically detected ESR experiment. This ESR induced anomalous frequency shift, however is larger in amplitude and slower in relaxation time than ESR frequency shift. We will discuss that this anomalous polarization are potentially due to the dynamic nuclear polarization (DNP) mechanism.

11:51AM J1.00004 Nanomechanical detection of nuclear magnetic resonance using a silicon nanowire oscillator, JOHN NICHOL, University of Illinois at Urbana-Champaign — “Bottom-up” nanomechanical devices such as nanowires, nanotubes, and grapheme oscillators have previously been proposed as next-generation scanning probe force and mass sensors because of their potential for ultralow mechanical dissipation. Here, we report the use of a radio frequency silicon nanowire mechanical oscillator as a nuclear magnetic resonance force sensor to detect the statistical polarization of ^1H spins in polystyrene. Using a specialized scanning probe microscope, as well as a polarization-enhanced fiber-optic interferometer, we operate the nanowire as a force sensor at cryogenic temperatures. Nanowires of the type we study have very low intrinsic dissipation, and they experience negligible increase in dissipation as close as 10 nm from a surface. In order to couple the ^1H spins to the nanowire oscillator, we have developed a magnetic resonance force detection protocol which utilizes a nanoscale current-carrying wire to produce large time-dependent magnetic field gradients as well as the rf magnetic field. Under operating conditions, the nanowire exhibited an ultralow force noise of $1.9 \text{ aN}^2/\text{Hz}$ in the measurement quadrature. Further progress toward nanometer scale magnetic resonance imaging using this technique is discussed.

12:27PM J1.00005 Mechanism for Edge-enhanced Optical Response of Tip Induced Plasmonic Emission¹, GUO LI, Univ. of Sci. & Tech. of China; Institute of Physics, CAS, China, LIUGUO CHEN, CHAO ZHANG, ZHENCHAO DONG, Univ. of Sci. & Tech. of China; ZHENYU ZHANG, Univ. of Sci. & Tech. of China; Harvard University — In the investigation of tip induced plasmonic emission supplemented by STM, molecular layers are always viewed as spacers suppressing the induced emission. However, our nanoscale photo mapping of $\text{H}_2\text{TBPP}/\text{Ag}(111)$ strikingly showed enhanced emission at the molecule-island edge, which is even remarkable higher than that on the bare Ag surface. To understand this intriguing phenomenon, DFT calculations have been carried out. We found that when an organic molecule is adsorbed on Ag surface, its HOMO couples with the Ag states around the Fermi level, and forms an inelastic tunneling channel. The involved states of this channel accumulate in the interface and around the phenyl groups. Therefore, when the STM tip locates at the edge of the molecular island, the proportion of the inelastic tunneling current increases and the photo emission is enhanced. We also found that this edge-enhanced photo response is generic; the investigations of other molecule/metal systems demonstrate similar results.

12:39PM J1.00006 Adiabatic Plasmon Nanofocusing for Ultrashort Pulses and Spectroscopy, JOANNA ATKIN, SAMUEL BERWEGER, ROBERT OLMON, XIAOJI XU, MARKUS RASCHKE, University of Colorado at Boulder — The simultaneous control of optical fields on both nanometer spatial and femtosecond time scales would enable direct spectroscopic access to the elementary electronic and vibrational excitations in matter. Here, we utilize adiabatic surface plasmon polariton (SPP) nanofocusing on free-standing 3D tapered metal tips in order to generate nanometer confined field localization at the tip apex. Using the second harmonic generation (SHG) at the tip apex we perform MIIPS pulse optimization and frequency-resolved optical gating (FROG) characterization of the nanofocused pulses. With the combination of high bandwidth coupling using a chirped grating, pulse-shaping, and low-dispersion nanofocusing, we can achieve full optical control on the nanoscale, from $< 16 \text{ fs}$ pulse duration to arbitrary optical waveforms. This technique enables linear and non-linear plasmon-enhanced spectroscopy, with the simultaneous temporal control over ultrashort pulses opening the possibility for true time-resolved scanning-probe imaging. We demonstrate this capability for background-free probing of individual molecular and nanocrystalline systems.

12:51PM J1.00007 Near-Field Enhanced UV Resonance Raman Spectroscopy Using an Aluminum Bow-tie Nano-antenna, LING LI, SHUANG FANG LIM, ROBERT RIEHN, HANS HALLEN, North Carolina State University — An aluminum bow-tie nano-antenna is combined with the resonance Raman effect in the deep UV to dramatically increase the sensitivity of Raman spectra to a small volume of material, such as benzene used here. By carefully choosing the right geometric parameters for the nano-antenna, we achieved a gain of a half million in signal intensity from the near field enhancement due to the surface plasmon resonance in the aluminum nanostructure. The on-line resonance enhancement contributes another factor of several thousands, limited by the laser line width. Thus, an overall gain of billions is achieved. We also demonstrated that the strong electric field gradients inside the bow-tie gap induce gradient-field Raman peaks for several strong IR modes.

1:03PM J1.00008 Multimodal Imaging of Heterogeneous Materials, WEI LIU, JIANYONG YANG, WITec Instruments, THOMAS DIENG, UTE SCHMIDT, WITec GmbH — New materials for highly specified applications can either have mono-atomic flat surfaces or a roughness of several hundred micro- or millimeter. In the past two decades, AFM was the main techniques used to characterize the morphology of nano-materials. On the other hand, Raman spectroscopy is known to be used to unequivocally determine the chemical composition of a material. By combining Raman spectroscopy with high resolution confocal optical microscopy, the analyzed material volume can be reduced below $0.02 \mu\text{m}^3$, thus leading to the ability to acquire Raman images with diffraction limited resolution. The combination of confocal Raman microscopy with Atomic Force Microscopy (AFM) is a breakthrough in microscopy. Using such a combination, the high spatial and topographical resolution obtained with an AFM can be directly linked to the chemical information provided by confocal Raman microscopy. True Surface Microscopy, allows confocal Raman imaging guided by the surface topography obtained by an integrated non-contact optical profilometer. Large-area topographic coordinates from the chromatic confocal profilometer can be precisely correlated with the large area confocal Raman imaging data. This allows true surface Raman imaging on heavily inclined or rough surfaces, with the sample surface held in constant focus, while maintaining highest confocality. In summary, the combination of confocal Raman microscopy with AFM and true surface microscopy allows the characterization of materials at high, submicron resolution, as well as on mm-rough surfaces across large areas.

1:15PM J1.00009 Local 2D-2D tunneling in high mobility electron systems, MATTHEW PELLICCIONE, ADAM SCIAMBI, JOHN BARTEL, DAVID GOLDBERGER-GORDON, Stanford University, LOREN PFEIFFER, KEN WEST, Princeton University, MICHAEL LILLY, Sandia National Laboratory, SETH BANK, University of Texas, Austin, ARTHUR GOSSARD, University of California, Santa Barbara — Many scanning probe techniques have been utilized in recent years to measure local properties of high mobility two-dimensional (2D) electron systems in GaAs. However, most techniques lack the ability to tunnel into the buried 2D system and measure local spectroscopic information. We report scanning gate measurements on a bilayer GaAs/AlGaAs heterostructure that allows for a local modulation of tunneling between two 2D electron layers. We call this technique Virtual Scanning Tunneling Microscopy (VSTM) [1,2] as the influence of the scanning gate is analogous to an STM tip, except at a GaAs/AlGaAs interface instead of a surface. We will discuss the spectroscopic capabilities of the technique, and show preliminary results of measurements on a high mobility 2D electron system.

1:27PM J1.00010 Infrared Phonon Fingerprinting of Nanocrystals through Broadband Near-Field Spectroscopy, ALEXANDER S. MCLEOD, University of California, San Diego, GERARDO DOMINGUEZ, California State University, San Marcos, PRISCILLA KELLY, MARK THIEMENS, University of California, San Diego, LINGFENG M. ZHANG, University of California, San Diego; Boston University, ALEX RODIN, MICHAEL M. FOGLER, University of California, San Diego, FRITZ KEILMANN, Max Planck Institute of Quantum Optics and Center for NanoScience, D.N. BASOV, University of California, San Diego — Near-field infrared spectroscopy has recently been demonstrated with the capability to resolve optical properties of sub-wavelength sample areas across a broad range of infrared frequencies. This method holds promise for the direct identification of sub-wavelength chemical composition in nanostructured and heterogeneous samples. We apply this technique to the study of phonon-resonant silicon carbide nanocrystals tens of nanometers in size using an apertureless scanning near-field optical microscope (SNOM) coupled to a pulsed broadband infrared laser source and FTIR spectrometer. We present measurements of nanocrystal near-field spectra in the range of $700\text{--}1200 \text{ cm}^{-1}$ evaluated in comparison with the near-field spectra of bulk silicon carbide, calibrated using ellipsometry. A detailed analytic model of the probe-sample near-field interaction is applied for the identification of nanoscale resonant size effects. These techniques provide a powerful method for identifying and characterizing sub-wavelength nanocrystals in heterogeneous samples via near-field infrared “phonon fingerprinting.”

1:39PM J1.00011 Creation of Electron Trap States in Silicon Dioxide By Local Electron Injection¹, DUSTIN WINSLOW, CLAYTON WILLIAMS, University of Utah — Over a decade ago, the Scanning Tunneling Microscope was shown capable of desorbing single hydrogen atoms from the surface of hydrogen terminated silicon.² The resultant dangling bonds can act as atomic scale quantum dots.³ Electrons trapped in such dangling bond states at the surface of crystalline silicon have short retention times at room temperature, due to the proximity of the occupied state energy level to the conduction band. Here we report on a method for creating electron trap states at the surface of a silicon dioxide film by electron injection from a metalized Atomic Force Microscope probe tip. Single Electron Tunneling Force measurements⁴ are employed to examine the existence of trap states in the silicon dioxide surface before and after the electron injection. Evidence for electron trap state creation, without topographic modification of the silicon dioxide surface, will be presented. The trap states created by this process have electron retention times which are greater than one second at room temperature. The methodology for trap state creation and detection will be presented.

1:51PM J1.00012 Nm-scale Mapping of Thermally-Activated Trap Emission in an AlGaIn/GaN High Electron Mobility Transistor, D. CARDWELL, A.R. AREHART, S.A. RINGEL, J.P. PELZ, The Ohio State University — AlGaIn/GaN high electron mobility transistors (HEMTs) are intrinsically ideal for high frequency and high power applications, but have degraded performance due to charge trapping. Nm-scale AFM-based electrical measurements sensitive to the emission of trapped charge, such as scanning Kelvin probe microscopy (SKPM), can, in principle, be used to determine the energies, cross sections, and densities of electrically-active traps with high spatial resolution. Using SKPM, we obtain nm-scale surface potential transient (SPT) maps over the entire surface of an AlGaIn/GaN HEMT. Surprisingly, we find significant SPTs near the edges of the device that are similar to conductance transients, and whose time constants vary with temperature, indicating thermally-activated emission. Comparison of nm-scale measurements and electrostatic simulations will be discussed to quantify the spatial distribution of trapped charge near the edge of the device. Work supported by ONR-DRIFT (P. Maki).

2:03PM J1.00013 Stochastic switching of microcantilever motion¹, WARNER VENSTRA, HIDDE WESTRA, HERRE VAN DER ZANT, Kavli Institute of Nanoscience — Fluctuation-induced transitions between two stable states of a strongly driven microcantilever are studied. Intrinsic geometric and inertial nonlinearities of the cantilever give rise to an amplitude-dependent resonance frequency, and at a critical point bifurcation occurs. Two states are stable, represented by vibration at a low and a high amplitude. Adding noise facilitates transitions between the states. The transition rate rises upon increasing noise intensity, as expected for noise-activated escape from a dynamic double well. Further increasing the noise intensity causes a parametric change in the dynamic double well, and results in a decay of the switching rate. Close to the onset of spontaneous transitions, the bistable cantilever is very sensitive. We demonstrate the noise-enhanced detection of weak modulations of the bistable cantilever, resulting in an optimum signal-to-noise ratio at non-minimum noise intensity.

Tuesday, February 28, 2012 11:15AM - 2:15PM –

Session J2 FEd: Invited Session: K-12 Science Education: Closing the Gap with the Leading Nations 204AB

11:15AM J2.00001 A Framework for K-12 Science Education, HELEN QUINN, Stanford University — I will discuss the content and purpose of the NRC study report “a framework for K-12 science education” and report on the ongoing project led by Achieve, in which over 20 states are engaged to develop science standards based on this document.

11:51AM J2.00002 The Globalization of Science Education, GEORGE DEBOER, AAAS Project 2061 — Standards-based science education, with its emphasis on clearly stated goals, performance monitoring, and accountability, is rapidly becoming a key part of how science education is being viewed around the world. Standards-based testing within countries is being used to determine the effectiveness of a country's educational system, and international testing programs such as PISA and TIMSS enable countries to compare their students to a common standard and to each other. The raising of standards and the competition among countries is driven in part by a belief that economic success depends on a citizenry that is knowledgeable about science and technology. In this talk, I consider the question of whether it is prudent to begin conversations about what an international standards document for global citizenship in science education might look like. I examine current practices to show the areas of international agreement and the significant differences that still exist, and I conclude with a recommendation that such conversations should begin, with the goal of laying out the knowledge and competencies that international citizens should have that also gives space to individual countries to pursue goals that are unique to their own setting.

12:27PM J2.00003 Physics For All – yes, it's real physics, ARTHUR EISENKRAFT, University of Massachusetts Boston — Can “all” students learn “real” physics? We want to provide instruction to a wider segment of the population including those students who will not go into STEM (Science, Technology, Engineering, Math) careers. We also want to maintain the integrity of physics, challenge all students, and not compromise the rigor of our courses. Accomplishing this requires a research guided approach to instruction, curriculum and assessment. Physics First and Physics for All have become a success story for thousands of students in urban, suburban, and rural districts. At the same time, the International Physics Olympiad and other competitions have raised the expectation of what the most motivated students can achieve. Many physics educators are exploring ways to set higher goals for our most gifted students while also providing physics instruction to students previously excluded from our physics classes. Many of the same issues that K-12 educators are struggling with are equally important to the college community as colleges try to educate both future physicists and an educated citizenry. Great novels and symphonies are accessible to people of different backgrounds and levels of expertise. We should develop strategies that enable us to share an understanding of physics with all students because everyone deserves an opportunity to reflect on the wondrous workings of our universe.

1:03PM J2.00004 An Introduction to the new AP Physics algebra-based program: A new focus on best practices¹, GAY STEWART, University of Arkansas, Fayetteville — Advanced Placement (AP) credit was always designed to represent good college courses. After a call from the NRC, the College Board undertook a redesign of the AP Science courses to improve the quality of teaching and learning in the nation's high schools, modeling best practices at the college level. The Physics Redesign has focused on the AP Physics B course, the equivalent of the algebra-based introductory college physics course. This talk will focus on the background to this undertaking, the process that was followed, and the resulting courses. The impact these changes will have on current teaching practices will be discussed. Currently, Physics B is supposed to follow a preparatory course. Now, the material is divided up and deepened to make each year a stand-alone, rigorous, conceptual and problem-solving course. The significantly deeper conceptual level for the newly designed course allows teachers more time for inquiry-based, student-centered learning. Because of the two-course design, the first year will be accessible to more students. These can be placed flexibly into a school's curriculum; examples will be discussed. Examples from the new curriculum framework for these courses will be presented.

¹Thanks to the NSF for support in the early phases of the redesign.

1:39PM J2.00005 The Role of Pre-College Preparation in College Physics Success¹, PHILIP SADLER, Harvard-Smithsonian Center for Astrophysics — There is no shortage of, often contradictory, opinions concerning how best to prepare students for college physics, but personal experience is a poor substitute for rigorous investigation. After collecting data from 11,000 science students and their instructors at randomly chosen colleges and universities, we can offer a more universal picture of the middle school to college learning progression in physics. Using epidemiological methods to mine the backgrounds of students taking introductory physics courses, we find predictors of performance and persistence while controlling for demographic differences. I will report on our findings on the value of middle school physical science preparation, lab experiences, technology use, classroom demonstrations, coverage, block scheduling, Advanced Placement, Physics First, project work, and facility in mathematics.

¹The work has been supported by NSF projects: GSE/RES 624444 Persistence Research in Science and Engineering and 635090, Synthesis of Research on Advanced High School Coursework in Science and Mathematics.

Tuesday, February 28, 2012 11:15AM - 2:15PM –

Session J3 GQI DCMP: Invited Session: Quantum Computing with Superconducting Circuits 205AB

11:15AM J3.00001 Continuous High-Fidelity Monitoring of a Superconducting Qubit: From Quantum Jumps to Feedback¹, I. SIDDIQI, QNL, University of California, Berkeley — Great advances have been made in superconducting qubit technology since the first demonstration of coherent oscillations more than 10 years ago. Continuous, high-fidelity monitoring of the qubit state, however, has remained an elusive target. We demonstrate this functionality by using a wide-bandwidth superconducting parametric amplifier operating near the quantum noise limit to read out the state of a transmon qubit coupled to a linear resonant cavity. Depending on the qubit-cavity detuning and the cavity photon occupation, two different measurement regimes can be accessed. In the strong measurement regime, the qubit states are fully resolved in a time much shorter than T_1 . This permits the observation of quantum jumps between qubit states in real time, and enables the study of the quantum Zeno effect and measurement non-idealities. In the weak measurement regime, information is extracted slowly and the measurement is no longer projective on short time scales. However, the measurement record is still highly correlated with the qubit dynamics and can be used to steer the qubit state using feedback. We demonstrate this idea by phase-locking Rabi oscillations to a classical reference. This allows the oscillations to persist indefinitely, albeit with a reduced amplitude indicative of the efficiency of the feedback protocol.

¹This research is supported by the ARO QCT program.

11:51AM J3.00002 Observation of the dynamical Casimir effect in a superconducting circuit, CHRISTOPHER WILSON, Chalmers University — Modern quantum theory predicts that the vacuum of space is not empty, but instead teeming with virtual particles flitting in and out of existence. While initially a curiosity, it was quickly realized that these vacuum fluctuations had measurable consequences, for instance producing the Lamb shift of atomic spectra and modifying the magnetic moment for the electron. This type of renormalization due to vacuum fluctuations is now central to our understanding of nature. 40 years ago, Moore suggested that a mirror undergoing relativistic motion could convert virtual photons into directly observable real photons. This effect was later named the dynamical Casimir effect (DCE). Using a superconducting circuit, we have observed the DCE for the first time. The circuit consists of a coplanar transmission line with an *electrical length* that can be changed at a substantial fraction of the speed of light. The length is changed by modulating the inductance of a superconducting quantum interference device (SQUID) at high frequencies (> 10 GHz). In addition to observing the creation of real photons, we observe two-mode squeezing of the emitted radiation, which is a signature of the quantum character of the generation process.

12:27PM J3.00003 Towards a scalable superconducting qubit architecture, MATTHIAS STEFFEN, IBM — I will review IBM's current approach towards building a scalable superconducting qubit architecture. The goal is to build a system using quantum error correction schemes based on two-dimensional surface codes, which are predicted to have a remarkably low fault tolerant threshold. I will briefly outline the particular skew-square lattice configuration and describe the concept of logical qubits and gates. On the experimental side, I will show recent advances towards implementing such surface code. This includes improvements in qubit coherence times, now exceeding $T_1=5\mu s$ reliably, achieved by shielding the sample from infrared radiation confirming other recent results. Additional approaches leading to even longer coherence times are reviewed. With improved coherence times we show improved gate fidelities of two-qubit gates based the cross-resonance effect – an all microwave approach towards implementing two-qubit gates. I will conclude by reviewing some interesting future engineering challenges that should be addressed on our way towards building a quantum computer.

1:03PM J3.00004 The Photon Shell Game and the Quantum von Neumann Architecture with Superconducting Circuits¹, MATTEO MARIANTONI, Department of Physics and California NanoSystems Institute, University of California, Santa Barbara, CA 93106-9530, USA — Superconducting quantum circuits have made significant advances over the past decade, allowing more complex and integrated circuits that perform with good fidelity. We have recently implemented a machine comprising seven quantum channels, with three superconducting resonators, two phase qubits, and two zeroing registers. I will explain the design and operation of this machine, first showing how a single microwave photon $|1\rangle$ can be prepared in one resonator and coherently transferred between the three resonators. I will also show how more exotic states such as double photon states $|2\rangle$ and superposition states $|0\rangle + |1\rangle$ can be shuffled among the resonators as well [1]. I will then demonstrate how this machine can be used as the quantum-mechanical analog of the von Neumann computer architecture, which for a classical computer comprises a central processing unit and a memory holding both instructions and data. The quantum version comprises a quantum central processing unit (quCPU) that exchanges data with a quantum random-access memory (quRAM) integrated on one chip, with instructions stored on a classical computer. I will also present a proof-of-concept demonstration of a code that involves all seven quantum elements: (1), Preparing an entangled state in the quCPU, (2), writing it to the quRAM, (3), preparing a second state in the quCPU, (4), zeroing it, and, (5), reading out the first state stored in the quRAM [2]. Finally, I will demonstrate that the quantum von Neumann machine provides one unit cell of a two-dimensional qubit-resonator array that can be used for surface code quantum computing. This will allow the realization of a scalable, fault-tolerant quantum processor with the most forgiving error rates to date.

1:39PM J3.00005 Realization of Three-Qubit Quantum Error Correction with Superconducting Circuits, MATTHEW REED, Yale University — Quantum computers promise to solve certain problems exponentially faster than possible classically but are challenging to build because of their increased susceptibility to errors. Remarkably, however, it is possible to detect and correct errors without destroying coherence by using quantum error correcting codes. The simplest of these are the three-qubit codes, which map a one-qubit state to an entangled three-qubit state and can correct any single phase-flip or bit-flip error of one of the three qubits, depending on the code used [1]. The fidelity of a process in which errors can occur on all qubits, where there is the possibility of an uncorrectable double or triple error, should therefore decrease only quadratically with error probability. I will first introduce how the three-qubit encoded state can be produced in our superconducting architecture by employing interactions with non-computational qubit states, as previously demonstrated [2]. I will then discuss how these non-computational interactions can be generalized to produce a novel three-qubit conditional-conditional NOT (CCNot) or Toffoli gate, which implements the correcting step of an error correction algorithm. Finally, I will explain how, by combining these ingredients, we have performed a single pass of both quantum bit- and phase-flip error correction and have demonstrated the predicted first-order insensitivity to errors.

Tuesday, February 28, 2012 11:15AM - 2:15PM – Session J4 DAMOP: Non-Equilibrium Dynamics with Quantum Gases 205C

11:15AM J4.00001 Non Equilibrium Quantum Criticality: an intuitive approach, EMANUELE DALLA TORRE, EUGENE DEMLER, Department of Physics, Harvard University, THIERRY GIAMARCHI, DPMC-MaNEP, University of Geneva, Switzerland, EHUD ALTMAN, Department of Condensed Matter Physics, Weizmann Institute of Science, Israel — Since their discovery in 1976, equilibrium quantum critical points have attracted continuous interest, due to their universality (i.e. the independence from the microscopic details of the systems). In two recent papers [1,2] we have extended these concepts to non-equilibrium systems, by studying the universal properties of quantum systems driven by time-dependent noise. We were able to demonstrate that [1] they can show a new class of non-equilibrium quantum criticality, and [2] small perturbations around the critical point lead to new physical phenomena, such as the spontaneous generation of an effective temperature and an effective dissipation. To this end, we developed a real-time renormalization group (RG) in the Keldysh path-integral formalism, which may however appear cryptic to the non-experts. In this talk, I will show how the main conclusions of the RG approach can be understood by simpler arguments based on circuit theory and fluctuation-dissipation relations.

11:27AM J4.00002 Dynamics of noise correlations of ultracold bosons in an optical lattice, KHAN W. MAHMUD, EITE TIESINGA, Joint Quantum Institute, NIST and University of Maryland, USA — We study second order correlations of ultracold bosons in an optical lattice for superfluid and Mott insulating phases. Starting with a superfluid ground state, a sudden increase in the lattice depth projects it into a non-equilibrium state. We examine the subsequent dynamics of the system - analyzing noise correlations of the atomic cloud after time-of-flight expansion. We also investigate the effects of three and higher-body interactions on noise correlations in deep lattices.

11:39AM J4.00003 Stability of Counterflow Superfluidity¹ , NOAH BRAY-ALI, CARL WILLIAMS, Joint Quantum Institute, NIST and University of Maryland, 100 Bureau Drive, Stop 8423, Gaithersburg, MD 20899-8423, USA, EUGENE DEMLER, Department of Physics, Harvard University, Cambridge MA 02138 — We examine the stability of the counterflow superfluid state in two component mixtures of ultracold atoms in optical lattices. Using a Gutzwiller mean-field approach, we find a sharp boundary separating stable counterflow from a dynamically unstable regime. As the inter-component interaction strength increases, the critical counterflow rate drops, falling to zero when interactions are strong enough to induce phase separation of the two components. Going beyond mean-field theory, we compute the decay rate of counterflow within the stable regime due to phase slips. The results agree well with numerically exact simulations and are calculated in a regime of parameters relevant to current experiments on mixtures of ultracold alkali atoms.

11:51AM J4.00004 Fermion Dynamics from Gross-Pitaevskii-like Equations , MICHAEL FORBES, Institute for Nuclear Theory, University of Washington, RISHI SHARMA, TRIUMF — The dynamics of condensed fermions (i.e. the Unitary Fermi Gas) play a key role in understanding a range of physical systems, from dynamics in rotating traps of cold atoms, to explaining pulsar glitches in neutron stars. Density functional theory (DFT) provides a powerful tool for modeling these dynamics, but unfortunately, simulating even a few vortices requires the use of leadership class computing. This talk will address the efficacy of using modified Gross-Pitaevskii (GP) like equations to model the dynamics of Fermi systems. These GP-like equations are significantly easier to solve, yet still capture much of the relevant physics. We shall advocate an approach of using fermionic DFT to adjust the form of the modified GP-like equations, and then using the latter to model more complicated phenomena beyond the capability of the fermionic DFT. The dynamics of vortices pinned on defects will serve as an example.

12:03PM J4.00005 Expansion of Bose-Hubbard Mott insulators in optical lattices¹ , MARK JREIS-SATY, Department of Mechanical Engineering, Columbia University, New York NY 10025, USA, JUAN CARRASQUILLA, Department of Physics, Georgetown University, Washington DC 20057, USA, F. ALEXANDER WOLF, Theoretical Physics III, Center for Electronic Correlations and Magnetism, Institute of Physics, Augsburg University, D-86135 Augsburg, Germany, MARCOS RIGOL, Department of Physics, Georgetown University, Washington DC 20057, USA — We present a study of the expansion of bosonic Mott insulators in the presence of an optical lattice after switching off a confining potential. We use the Gutzwiller mean-field approximation and consider two different setups. In the first one, the expansion is restricted to one dimension. We show that this leads to the emergence of two condensates with well-defined momenta, and argue that such a construct can be used to create atom lasers in optical lattices. In the second setup, we study Mott insulators that are allowed to expand in all directions in the lattice. In this case, a simple condensate is seen to develop within the mean-field approximation. However, its constituent bosons are found to populate many nonzero momentum modes. An analytic understanding of both phenomena in terms of the exact dispersion relation in the hard-core limit is presented.

12:15PM J4.00006 Protection of dissipative quantum state preparation by interlacing the control with dynamical decoupling pulses¹ , Z.R. GONG, WANG YAO, Department of Physics, and Center for Theoretical and Computational Physics, The University of Hong Kong — Various dissipative processes have recently been exploited for preparing quantum state with multipartite entanglement between many qubits. Most such schemes are applicable only to an ensemble of identical qubits, and inhomogeneous broadening will reduce the state preparation fidelity. Here we show that by interlacing the dynamical decoupling pulse sequence with the dissipative state preparation control, the errors resulting from the inhomogeneous broadening can be suppressed up to certain order of the pulse interval and the desired entangled states can be prepared with high fidelity. We give two examples where sequence of π pulses interlaced with dissipative control realize high fidelity preparation of cluster states and many-body singlets of atomic qubits.

12:27PM J4.00007 ABSTRACT MOVED TO L4.00008 —

12:39PM J4.00008 Periodically and almost periodically driven quantum system , LUCA D'ALESSIO, ANATOLI POLKOVNIKOV, Boston University — When a quantum system is driven periodically in time it can display dynamical localization, i.e its energy grows extremely slowly and may saturate at a value smaller than the infinite temperature limit. We show that by making the period of the perturbation longer this phenomenon is destroyed and the energy of the system grows quickly and saturates at the infinite temperature limit. We argue that this process is related to the breaking down of a particular form of perturbation theory (in the duration in of driving) and can be interpreted as a transition from a local to a long-range effective Hamiltonian. We discuss how robust our findings are against small aperiodicity in the driving. We finally discuss how realize this interesting non-equilibrium physics in cold atom experiments.

12:51PM J4.00009 Cold bosons in noisy optical lattices , JOHANNES SCHACHENMAYER, Department of Physics and Astronomy, University of Pittsburgh, HANNES PICHLER, PETER ZÖLLER, Institute for Theoretical Physics, University of Innsbruck, and Institute for Quantum Optics and Quantum Information, Innsbruck, ANDREW DALEY, Department of Physics and Astronomy, University of Pittsburgh — Cold atoms in optical lattices open the possibility to experimentally study strongly interacting many-body quantum systems with controllable parameters. A key challenge to prepare interesting quantum states in these systems is to achieve sufficiently low temperatures. At these temperatures a deep theoretical understanding of possible heating processes and how they affect the characteristics of the quantum state becomes essential. In every realistic experiment there exist many sources of noise that cause phase and amplitude fluctuations in the standing laser waves that form the optical lattice potential. This classical noise can lead to heating and a significant change of the quantum state. We study the stochastic many-body non-equilibrium dynamics of bosons in an optical lattice and determine how the state changes depending on the characteristics of the noise. We do this by solving time-dependent stochastic many-body Schrödinger equations, both analytically and numerically.

1:03PM J4.00010 Many-body Landau-Zener Transition in Cold Atom Double Well Optical Lattices , YINYIN QIAN, MING GONG, CHUANWEI ZHANG, Washington State University — Ultra-cold atoms in optical lattices provide an ideal platform for exploring many-body physics of a large system arising from the coupling among a series of small identical systems whose few-body dynamics are exactly solvable. Using Landau-Zener (LZ) transition of bosonic atoms in double well optical lattices as an experimentally realizable model, we investigate such few to many body route by exploring the relation and difference between the few-body (in one double well) and many-body (in double well lattice) non-equilibrium dynamics of cold atoms in optical lattices. We find the many-body coupling between double wells greatly enhances the LZ transition probability, while keeping the main features of the few-body dynamics. Various experimental signatures of the many-body LZ transition, including atom density, momentum distribution, and density-density correlation, are obtained.

1:15PM J4.00011 Quasi steady-states, spin statistics, and interaction-induced transport of ultra-cold atoms in 1D optical lattices¹, CHIH-CHUN CHIEN, Los Alamos National Laboratory, MICHAEL ZWOLAK, Oregon State University, MASSIMILIANO DI VENTRA, University of California, San Diego — We consider several non-equilibrium scenarios where ultra-cold atoms are initially loaded into the ground state of a 1D optical lattice. The system is then set out of equilibrium either by inducing a density imbalance or by imposing time-dependent inhomogeneous interactions. To monitor the dynamics, we have implemented the micro-canonical approach to transport [1] which has been previously used to study electron dynamics in nanoscale systems. We have found that by removing particles on the right half of the lattice, fermions form a quasi steady-state current, which can be observed as a plateau in the current as a function of time. In contrast, the bosonic current oscillates and decays to zero in the thermodynamic limit [2]. The difference appears in uniform lattices as well as lattices with a harmonic trap. Further, when light-induced interactions are applied to half of the lattice, we have found, using a Hartree-Fock approximation, a conducting-nonconducting transition in the fermionic case as the interaction increases. Our studies are relevant to recent experiments on transport of ultra-cold atoms and address fundamental issues in nanoscale electronic transport.

1:27PM J4.00012 Spin Caloritronics in Noncondensed Bose Gases, CLEMENT WONG, HEDWIG VAN DRIEL, RAKPONG KITTINARADORN, HENK STOOF, REMBERT DUINE, Utrecht University — We consider coupled spin and heat transport in a two-component, atomic Bose gas in the noncondensed state. We find that the transport coefficients show a temperature dependence reflecting the bosonic enhancement of scattering, and discuss experimental signatures of the spin-heat coupling in spin accumulation and total dissipation. Inside the critical region of Bose-Einstein condensation, we find anomalous behavior of the transport coefficients, and in particular, an enhancement for the spin caloritronics figure of merit that determines the thermodynamic efficiency of spin-heat conversion.

1:39PM J4.00013 Universal energy fluctuations in thermally isolated driven systems, GUY BUNIN, Department of Physics, Technion, LUCA D'ALESSIO, Department of Physics, Boston University, YARIV KAFRI, Department of Physics, Technion, ANATOLI POLKOVNIKOV, Department of Physics, Boston University — When an isolated system is brought in contact with a heat bath, its final energy is random and follows the Gibbs distribution—this finding is a cornerstone of statistical physics. The system's energy can also be changed by performing non-adiabatic work using a cyclic process. Almost nothing is known about the resulting energy distribution in this set-up, which is in particular relevant to recent experimental progress in cold atoms, ion traps, superconducting qubits and other systems. Here we show that when the non-adiabatic process consists of many repeated cyclic processes, the resulting energy distribution is universal and different from the Gibbs ensemble. We predict the existence of two qualitatively different regimes with a continuous second-order-like transition between them. We illustrate our approach by performing explicit calculations for both interacting and non-interacting systems.

1:51PM J4.00014 Lie-algebraic Approach to Dynamics of Closed Quantum Systems and Quantum-to-Classical Correspondence¹, VICTOR GALITSKI, Joint Quantum Institute and Physics Department, University of Maryland — I will briefly review our recent work on a Lie-algebraic approach to various non-equilibrium quantum-mechanical problems, which has been motivated by continuous experimental advances in the field of cold atoms. First, I will discuss non-equilibrium driven dynamics of a generic closed quantum system. It will be emphasized that mathematically a non-equilibrium Hamiltonian represents a trajectory in a Lie algebra, while the evolution operator is a trajectory in a Lie group generated by the underlying algebra via exponentiation. This turns out to be a constructive statement that establishes, in particular, the fact that classical and quantum unitary evolutions are two sides of the same coin determined uniquely by the same dynamic generators in the group. An equation for these generators - dubbed dual Schrödinger-Bloch equation - will be derived and analyzed for a few of specific examples. This non-linear equation allows one to construct new exact non-linear solutions to quantum-dynamical systems. An experimentally-relevant example of a family of exact solutions to the many-body Landau-Zener problem will be presented. One practical application of the latter result includes dynamical means to optimize molecular production rate following a quench across the Feshbach resonance.

2:03PM J4.00015 Visibility of the Amplitude (Higgs) Mode in Condensed Matter and Cold Atomic Systems, DANIEL PODOLSKY, ASSA AUERBACH, Physics Department, Technion - Israel Institute of Technology, DANIEL P. AROVAS, Department of Physics, University of California at San Diego — The amplitude mode is a ubiquitous collective excitation in condensed matter systems with broken continuous symmetry. It is expected in antiferromagnets, short coherence length superconductors, charge density waves, and lattice Bose condensates. Its detection is a valuable test of the corresponding field theory, and its mass gap measures the proximity to a quantum critical point. However, since the amplitude mode can decay into low energy Goldstone modes, its experimental visibility has been questioned. Here we show that the visibility depends on the symmetry of the measured susceptibility. We discuss various experimental setups for measuring the scalar susceptibility. We show that the optical conductivity of the O(2) theory (relativistic superfluid) displays a threshold behavior at the Higgs mass.

Session J5 DMP: Focus Session: Interfaces in Complex Oxides - Electronic Structure 206A

11:15AM J5.00001 Angle resolved photoemission spectroscopy of the electronic structure of complex oxide interfaces, KYLE SHEN, Cornell University — Engineering interfaces between complex oxides has proven to be a powerful technique for tuning their electronic and magnetic properties. To fully understand how these interfaces can control these electronic properties, one requires advanced spectroscopic tools to uncover their electronic structure. Angle-resolved photoemission spectroscopy (ARPES) is the leading tool for probing energy and momentum resolved electronic structure. To understand the physics of these complex oxide interfaces, we have developed an approach which combines state-of-the-art oxide molecular beam epitaxy with high-resolution ARPES. As one example, we describe our work on oxide superlattices $[\text{LaMnO}_3]_{2n} / [\text{SrMnO}_3]_n$ with alternating LaMnO_3 and SrMnO_3 blocks. Our ARPES measurements reveal that as a function of separation between the LaMnO_3 - SrMnO_3 interfaces, the interfacial quasiparticle states evolve from a quasi-three-dimensional ferromagnetic metal, to a two-dimensional spin-polarized electron liquid, and ultimately to a pseudogapped ferromagnetic insulator with increasing superlattice thickness, n . I will also describe our work on other oxide thin films SrTiO_3 and Sr_2TiO_4 -based interfaces where the quasiparticle interactions can be tuned as a function of dimensionality, and work on cuprate and ruthenate thin films.

11:51AM J5.00002 Spectral and spatial redistribution at the $\text{LaAlO}_3/\text{SrTiO}_3$ interface, T. GUENTER, A. RUBANO, T. FINK, HISKP, University Bonn, Germany, D. PAPARO, F. MILETTO GRANOZIO, U. SCOTTI DI UCCIO, L. MARRUCCI, Dip. di Scienze Fisiche, University Naples, Italy, J. MANNHART, MPI for Solid State Research, Stuttgart, Germany, M. FIEBIG, Materials Department, ETH Zürich, Switzerland — A conductive two-dimensional electron liquid (2DEL) appears at the $\text{LaAlO}_3/\text{SrTiO}_3$ (LAO/STO) interface for a LAO thickness of $n \geq 4$ unit cells. Despite the tremendous research interest, many questions regarding the origin and characteristics of the 2DEL have to be addressed yet. In particular, this includes the electronic structure of the “buried interface.” Optical second harmonic generation (SHG) is an ideal tool for studying interfaces, since it is sensitive to the interfacial symmetry breaking along the stacking direction. Using SHG with frequency-tunable amplified femtosecond laser pulses we obtain information about the structural reorganization of the interfacial STO conduction band for SHG photon energies up to 6.2 eV. A massive spectral weight redistribution is present for $n \geq 3$, indicating a global reorganization of the conduction band structure. At low temperatures the spectral resolution is enhanced which alleviates the distinction of interfacial electronic transitions. Additionally, we discuss the modification of the interfacial states by variation of the STO surface termination. Our data are supported by a theoretical framework based on symmetry selection rules that allows a specific assignment of interfacial $\text{O}(2p)\text{-Ti}(3d)$ transitions to the SHG spectrum.

12:03PM J5.00003 Electronic properties of $\text{LaAlO}_3/\text{SrTiO}_3$ superlattices: interface charge density, Fermi surfaces, plasmon and optical spectra¹, SE YOUNG PARK, ANDREW J. MILLIS, Columbia University — We present calculations of the charge density profile, Fermi surface topology, plasmon and optical excitation spectra of the electron gas at the $\text{LaAlO}_3/\text{SrTiO}_3$ interface. The calculations are based on a self-consistent Hartree/RPA approximation and a tight binding parametrization of the band structure. The subband occupancy is determined as a function of polar discontinuity magnitude and dielectric constant. The number of occupied xy bands changes significantly whereas for all reasonable polar discontinuity and dielectric constant profiles only one yz and one xz bands are occupied. These yz and xz band give dominant contributions to the long-distance tail of the interface charge. The plasmon and optical absorption spectra are determined. The results are compared with experimental data.

¹Support: DOE ER-046169 and the Kwanjeong education foundation

12:15PM J5.00004 Direct observations of the band alignment of $\text{LaAlO}_3/\text{SrTiO}_3$ using scanning tunneling microscopy, Y.P. CHIU, B.C. HUANG, P.C. HUANG, Department of Physics, National Sun Yat-sen University, Kaohsiung, 804, Taiwan, V.T. TRA, J.Y. LIN, Institute of Physics, National Chiao Tung University, Hsinchu, 300, Taiwan, J.C. YANG, Y.H. CHU, Department of Materials Science and Engineering, National Chiao Tung University, HsinChu, 300, Taiwan — In this work, by using cross-sectional scanning tunneling microscopy, local and direct evidence of the electronic information across the $\text{LaAlO}_3/\text{SrTiO}_3$ hetero-interfaces are investigated. A combination of scanning tunneling spectroscopy and analysis with atomic resolution across the hetero-interface reveals how the oppositely charged atomic planes undergo electronic reconstructions and introduce a built-in electric field across the polar LaAlO_3 thin films grown on SrTiO_3 substrates. With the consideration of the tip-induced band bending effect, the magnitude of the built-in field across LaAlO_3 , the band bending on SrTiO_3 side, and the decay length of the band downshift of SrTiO_3 side at the hetero-interface are directly observed.

12:27PM J5.00005 Multi-orbital subband structure of transition-metal oxide 2DEGs, PHIL D.C. KING, University of St Andrews, W. MEEVASANA, Suranaree University of Technology, H.Y. HWANG, Z.-X. SHEN, Stanford University, F. BAUMBERGER, University of St Andrews — We demonstrate the creation and control of two-dimensional electron gases (2DEGs) in the 3d and 5d transition metal oxides SrTiO_3 and KTaO_3 . These 2DEGs, of the form usually generated by interface engineering, are created here at the bare oxide surfaces. This permits their detailed spectroscopic investigation using angle-resolved photoemission (ARPES), and we employ this to directly image the d-orbital subband structure of the 2DEGs. We find that quantum confinement lifts the degeneracy of the bulk band structure, driving orbital ordering of the 2DEG. We measure the resulting ladder of light d_{xy} subbands, which co-exist at lower binding energies with heavy d_{xz}/d_{yz} -derived states. The electronic structure revealed by ARPES is in quantitative agreement with our model tight-binding calculations. While the strong spin-orbit coupling of KTaO_3 promotes substantial orbital mixing, our calculations predict only a small Rashba splitting of the 2DEG states, consistent with our experimental measurements where any spin splitting is too small to be resolved. The polar nature of the $\text{KTaO}_3(100)$ surface plays a striking role in mediating formation of the 2DEG as compared to non-polar $\text{SrTiO}_3(100)$, reminiscent of the polar catastrophe at $\text{LaAlO}_3/\text{SrTiO}_3$ interfaces.

12:39PM J5.00006 A Universal Critical Density Underlying the Physics of Electrons at the $\text{LaAlO}_3/\text{SrTiO}_3$ Interface, ARJUN JOSHUA, S. PECKER, J. RUHMAN, E. ALTMAN, S. ILANI, Weizmann Institute of Science — The two-dimensional electron system formed at the interface between the insulating oxides LaAlO_3 and SrTiO_3 exhibits ferromagnetism, superconductivity, and a wide range of unique magnetotransport properties. A key challenge is to find a unified microscopic mechanism that underlies these emergent phenomena. Here we show that a universal Lifshitz transition between d-orbitals lies at the core of the observed transport phenomena in this system. Our measurements find a critical electronic density at which the transport switches from single to multiple carriers. This density has a universal value, independent of the LaAlO_3 thickness and electron mobility. The characteristics of the transition, its universality, and its compatibility with spectroscopic measurements establish it as a transition between d-orbitals of different symmetries. A simple band model, allowing for spin-orbit coupling at the atomic level, connects the observed universal transition to a range of reported magnetotransport properties. Interestingly, we also find that the maximum of the superconducting transition temperature occurs at the same critical transition, indicating a possible connection between the two phenomena. Our observations demonstrate that orbital degeneracies play an important role in the fascinating behavior observed so far in these oxides. Ref: arxiv.org/abs/1110.2184

12:51PM J5.00007 Localization of the Two-dimensional Electron Gas in $\text{LaAlO}_3/\text{SrTiO}_3$ Heterostructures, TOMAS HERNANDEZ, CHUNG WUNG BARK, CHANG-BEOM EOM, MARK S. RZCHOWSKI, University of Wisconsin-Madison — We use low temperature magnetotransport measurements to compare the quasi 2-dimensional electron gas (2DEG) at the $\text{LaAlO}_3/\text{SrTiO}_3$ interface in heterostructures grown on $(\text{LaAlO}_3)_{0.3}\text{-(Sr}_2\text{AlTaO}_6)_{0.7}$ (LSAT) substrates to the 2DEG at the $\text{LaAlO}_3/\text{single crystal SrTiO}_3$ interface. All heterostructures were grown by pulsed laser deposition with *in-situ* reflection high-energy electron diffraction. For the samples on LSAT, we find that increasing the carrier concentration by growing at lower oxygen partial pressures changes the conductivity mechanism, from strongly localized transport at low carrier concentrations to metallic conductivity with indications of weak localization at higher concentrations. We interpret this as an increasing occupation of Ti 3d bands of layers near the interface, changing the spatial extent of the conduction region and its susceptibility to localization by disorder and point defects at the interface. On the other hand, the 2DEG of similarly grown LaAlO_3 on single crystal SrTiO_3 shows metallic behavior and low temperature measurements display Kohler scaling of the out-of-plane magnetoresistance, consistent with classical orbital transport.

1:03PM J5.00008 Localized electron states and phase separation at the $\text{LaAlO}_3/\text{SrTiO}_3$ interface, S. SATPATHY, K.V. SHANAVAS, Department of Physics & Astronomy, University of Missouri — Even though the 2D electron gas at the polar interfaces of LAO/STO has been studied extensively, an explanation for the observed magnetic centers or the coexistence of magnetism and superconductivity is still lacking. Earlier density-functional calculations have indicated the presence of multi-bands and two types of electrons at the interface [1]. Here we propose that a combination of lattice disorder, octahedral rotations, and Jahn-Teller distortion can lead to some of these electrons to be localized near the interface and form lattice polarons. Evidence for this is presented from detailed density-functional calculations, which indicate that the energy gain associated with JT distortion and impurity or disorder induced local potentials can offset the kinetic energy cost of localization. Our model studies [2] also show the possible existence of a phase separation, thereby providing a natural explanation for the coexistence of magnetism and superconductivity [3].

1:15PM J5.00009 Electronic structure, Fermi surfaces, and electron-phonon coupling in La-doped Sr_2TiO_4 and SrTiO_3 ¹, YUEFENG NIE, SHOUVIK CHATTERJEE, BULAT BURGANOV, ERIC MONKMAN, JOHN HARTEY, DANIEL SHAL, Laboratory of Atomic and Solid State Physics, Department of Physics, Cornell University, Ithaca, NY 14853, USA, CHE-HUI LEE, DARRELL SCHLOM, Department of Materials Science and Engineering, Cornell University, Ithaca, New York 14853, USA, KYLE SHEN, Laboratory of Atomic and Solid State Physics, Department of Physics, Cornell University, Ithaca, NY 14853, USA — Sr_2TiO_4 is a quasi-two-dimensional Ruddlesden-Popper structure analogue to SrTiO_3 , and is isostructural with the cuprate parent compound La_2CuO_4 . Although the electronic structure of SrTiO_3 has been well-explored due to its importance in oxide electronics, little is known about the electronic properties of Sr_2TiO_4 . To investigate this, we synthesized epitaxial La doped Sr_2TiO_4 and SrTiO_3 films on (100) LSAT substrates by molecular beam epitaxy (MBE) and investigated the electronic structure using angle-resolved photoemission spectroscopy (ARPES). The electronic structure of 5% La doped Sr_2TiO_4 shows a single electron like band with mostly Ti-3d_{xy} character dispersing across the Fermi surface which corresponds well with LDA calculations. This is in contrast to doped SrTiO_3 where all three t_{2g} bands are degenerate. We also observed signatures of strong electron-phonon coupling in the quasi-two-dimensional Sr_2TiO_4 materials which appear to be absent in three-dimensional SrTiO_3 .

¹The work is supported by the Cornell Center for Materials Research through the National Science Foundation.

1:27PM J5.00010 Theory of SrTiO_3 2DEGs, GURU KHALSA, ALLAN MACDONALD, The University of Texas at Austin — There has been much recent interest in oxide 2DEGS - in particular those involving SrTiO_3 . In spite of the simple conduction band structure of the parent material, there has been no quantitative understanding of the physical properties of these systems. We have built a model, informed by experiment, that is sufficiently realistic to describe defect free surface/interface states in SrTiO_3 . The model is able to account for non-local dielectric screening and the orbital dependence of quantum confinement effects. Preliminary results of the model will be compared with experiment.

1:39PM J5.00011 Conducting band structure in $\text{LaTiO}_3/\text{SrTiO}_3$ interfaces¹, YOUNG JUN CHANG, Advanced Light Source (ALS), LBNL & Fritz-Haber-Institut, LUCA MORESCHINI, AARON BOSTWICK, Advanced Light Source (ALS), LBNL, ANDREW L. WALTER, Advanced Light Source (ALS), LBNL & Fritz-Haber-Institut, KARSTEN HORN, Fritz-Haber-Institut, ELI ROTENBERG, Advanced Light Source (ALS), LBNL — Oxide interfaces between insulating hosts show unexpected conducting carriers, which can be useful for next-generation electronic applications. However, the fundamental understanding of the conducting interfaces remains elusive. Here we report *in situ* angle-resolved photoemission spectroscopy (ARPES) studies in the $\text{LaTiO}_3/\text{SrTiO}_3$ heterostructures, of which layer thicknesses were precisely prepared by pulsed laser deposition in the BL7.0, ALS. We found that the interface generates a high-density electron gas over few unit cells from the junction. We further discuss the orbital characteristics of the interface electronic states with comparison to the recent theoretical calculations. Based on the unit-cell layer resolved electronic structure of the $\text{LaTiO}_3/\text{SrTiO}_3$ interface, we discuss the conducting carriers comparing to the $\text{LaAlO}_3/\text{SrTiO}_3$ interfaces.

Tuesday, February 28, 2012 11:15AM - 2:15PM –
Session J6 DMP: Focus Session: van der Waals Bonding in Advanced Materials - Layered Structures & Mechanical Properties 206B

11:15AM J6.00001 Improved Description of Soft Layered Materials with van der Waals Density Functional Theory, GABRIELLA GRAZIANO, London Centre for Nanotechnology and Department of Chemistry, University College London, ISIS Facility, Rutherford Appleton Laboratory, JIRI KLIMES, London Centre for Nanotechnology and Department of Chemistry, University College London, FELIX FERNANDEZ-ALONSO, ISIS Facility, Rutherford Appleton Laboratory, Department of Physics, University College London, ANGELOS MICHAELIDES, London Centre for Nanotechnology and Department of Chemistry, University College London — The accurate description of dispersion forces with approaches based on density functional theory has long been a coveted goal and is currently one of the most active areas of research in computational physics/chemistry. We have tested two new functionals, the optimized Becke88 van der Waals (optB88-vdW) and optimized PBE van der Waals (optPBE-vdW) [1, 2] to describe materials where van der Waals interactions dominate. Structural (bond length and interlayer distance) and energetic parameters (atomization and interlayer binding energies) of graphite and hexagonal-boron nitride have been calculated using these functionals and we show that our calculations are in very good agreement with experiments and higher level theoretical calculations. From these calculations it is possible to conclude that optB88- vdW and optPBE-vdW are promising functionals for the accurate description of systems held together mainly by dispersion forces.

11:27AM J6.00002 Moiré pattern of a single layer MoS₂ grown on Cu(111)¹, DUY LE, TALAT S. RAHMAN, University of Central Florida — We present results of first principles calculations of the geometric and electronic structures of a single layer of Molybdenum disulfide (MoS₂) on Cu(111) utilizing the van der Waals density functional [1]. The lowest energy Moiré structure consists of (4 × 4) MoS₂ on (5 × 5) Cu(111), in agreement with experimental observation [2]. Examination of the local density of electronic states and charge redistribution shows that the layer is not purely physisorbed on the surface, rather there exists a chemical interaction between it and the Cu surface atoms. Interestingly the MoS₂ film is found to be not appreciably buckled, while the atoms in the top Cu layer gets reorganized and vertically disordered. The sizes of Moiré patterns for a single layer of MoS₂ adsorbed on several other close packed metal surfaces are estimated by minimizing the lattice mismatch between the film and the substrate.

11:39AM J6.00003 Observation of tightly bound charged excitons in monolayer MoS₂, KELIANG HE, Case Western Reserve University, KIN FAI MAK, Columbia University, CHANGGU LEE, Sumgkyunkwan University, Suwon, Korea, JIM HONE, TONY HEINZ, Columbia University, JIE SHAN, Case Western Reserve University — Recent advances in the development of atomically thin layers of materials have opened up many new research opportunities. In particular, the transition metal-dichalcogenide molybdenum disulfide (MoS₂) has been shown to cross over from a dark indirect semiconductor to a highly luminescent direct gap material in the limit of monolayer thickness.¹ Here we report results of studies of the optical absorption and photoluminescence of a monolayer MoS₂ field-effect transistor (FET) at 10 K. In the limit of very low doping, the optical properties are dominated by an excitonic feature at ~ 1.9 eV. As the doping density is increased, a new resonance emerges on the low-energy side of the exciton. This feature has been identified as a trion, the bound state of an exciton and an additional electron (or hole). The absorbance and photoluminescence of both the trion and exciton can be tuned by electrostatic doping. A large trion binding energy, exceeding room temperature, is inferred. Our observation can be understood in terms of the dynamical many-body response of a 2D electron gas to the optically created hole and reflects the unusually strong many-body interactions in this 2D system.

11:51AM J6.00004 Beyond graphene: atomic scale structure of quasi-2D van der Waals materials, CHRISTOPHER GUTIERREZ, LIUYAN ZHAO, KIN FAI MAK, PAUL CADDEN-ZIMANSKY, DMITRI EFETOV, TONY F. HEINZ, GEORGE W. FLYNN, PHILIP KIM, ABHAY PASUPATHY, Columbia University, ROBERT J. CAVA, Princeton University — Graphene, a single atomic layer of graphite, has attracted much attention for its unique electronic and mechanical properties. But what role does reduced dimensionality play in other 2D atomic crystals? In this talk we present scanning tunneling microscopy (STM) measurements of the atomic scale structure and spectroscopy of related quasi-2D materials including the transition metal dichalcogenides (TMDs), and their heterostructures with graphene.

12:03PM J6.00005 Here to stay: Stability and structure of (6√3×6√3)-R30° graphene on SiC(111) by all-electron DFT including van der Waals effects, VOLKER BLUM, LYDIA NEMEC, PATRICK RINKE, MATTHIAS SCHEFFLER, Fritz-Haber-Institut, D-14195 Berlin, Germany — SiC is a favorite growth substrate for mono- and few-layer graphene by Si sublimation. On the Si side, large ordered graphene areas can be obtained as commensurate (6√3×6√3)-R30° ("6√3") periodic films [1]. From a thermodynamic perspective, graphene formation competes with several other phases, including graphite on one side, and several Si-rich reconstructions on the other. The question whether 6√3 graphene on SiC(111) is thermodynamically or just kinetically stabilized could be answered by density functional theory (DFT) calculations but for two challenges: (1) The needed surface slab systems are extremely large (up to 2000 atoms in this work), and (2) most standard DFT functionals do not include van der Waals effects. We here show by all-electron DFT including van der Waals effects (PBE+vdW [2]) that the 6√3 graphene-like phases on SiC(111) are thermodynamically stable compared to competing surface phases, and obtain the full structure including the substrate-induced graphene corrugation. The impact of strain in smaller-cell approximants and that of possible graphene defects is discussed. [1] K. Emtsev *et al.*, Nature Materials **8**, 203 (2009). [2] A. Tkatchenko, M. Scheffler, PRL **102**, 073005 (2009).

12:15PM J6.00006 Edge-Edge interactions in stacked graphene, EDUARDO CRUZ-SILVA, University of Massachusetts Amherst, XIAOTING JIA, Massachusetts Institute of Technology, MAURICIO TERRONES, The Pennsylvania State University, MILDRED DRESSELHAUS, Massachusetts Institute of Technology, VINCENT MEUNIER, Rensselaer Polytechnic Institute — Graphene is often considered as the ultimate material for nanoscale electronics due to its unique structure-dependent properties. It has recently been shown that edge reconstruction and reshaping using combined electron irradiation and Joule heating could be used to control graphene properties towards nanodevice design. For instance, HRTEM experiments on few-layered graphene have revealed the presence of small graphene patches and platelets over larger graphene domains. While these platelets usually move freely over the larger graphene surface, they sometimes get locked in positions close to the edges of the larger sheet, thereby modifying the local electronic environment. We modeled this behavior with extensive density functional calculations using the van der Waals functional of Dion *et al.* Local interactions at the edges are found to be sufficiently strong to explain the presence of stacking configurations (e.g. AA) that are known to be energetically unfavorable in 2D graphene. Our results explain the observed dynamics of these stacked platelets and provide a deeper understanding of graphene edge reconstruction.

12:27PM J6.00007 Influence of water on the electronic structure of metal supported graphene: Insight from van der Waals density functional theory¹, JI FENG, XIAO LI, ENGE WANG, Peking University, China, SHENG MENG, Institute of Physics, China, JIRI KLIMES, ANGELOS MICHAELIDES, University College London — We investigate the interaction between water and metal supported graphene through van der Waals density functional theory calculations. Our results show a systematic increase in the adsorption energy of water on graphene in the presence of underlying metal substrates. In addition, we find that the electronic nature of the graphene-metal contacts behave differently upon water adsorption: in the case of a weak, physical graphene-metal contact, the charge carrier doping level of graphene is tuned by water, resulting in a Fermi level shift on the order of 100 meV. In the case of a strong chemical graphene-metal contact, the ? and ?* bands of graphene are hardly perturbed by water adsorption. These results illustrate the correlated nature of the interactions between water, graphene, and metal substrates, and show that the electronic structure and the doping level of graphene can be controlled by water deposition.

12:39PM J6.00008 Alkanes adsorbed on graphene: a vdW-DF study, ELISA LONDERO, EMMA KARLSON, MARCUS LANDAHL, DIMITRI OSTROVSKII, JONATAN RYDBERG, ELSEBETH SCHROEDER, Chalmers University of Technology — Studies of small chains of molecules adsorbed on graphene are important for application of graphene in possible devices, not least its use as a gas sensor for the detection of single molecules. In this work we present a density functional theory study of the first ten n-alkanes adsorbed on graphene using the vdW-DF functional. We compare our adsorption energies to temperature programmed desorption measurements finding a similar linear scaling with the number of carbon atoms in the chain. The presence of an offset when extrapolating to the case of no molecules on the surface is also confirmed.

12:51PM J6.00009 To wet or not to wet? Dispersion forces tip the balance for water ice on metals, JAVIER CARRASCO, Instituto de Catal sis y Petroleoqu mica, CSIC, Marie Curie 2, E-29049 Madrid, Spain, BISWAJIT SANTRA, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, D-14195 Berlin, Germany, JIRI KLIMES, ANGELOS MICHAELIDES, London Centre for Nanotechnology and Department of Chemistry, University College London, London WC1E 6BT, UK — For almost 30 years now, density functional theory (DFT) has been used to explore the molecular level details of water-metal interfaces. However, since the typical generalized gradient approximation exchange-correlation functionals used in these studies do not account for van der Waals (vdW) dispersion forces, the role dispersion plays in water adsorption remains unclear. Here, we tackle this issue head on applying a newly developed non-local functional [J. Klimeš *et al.*, J. Phys.: Condens. Matter **22**, 022201 (2010)] to two of the most widely studied water-ice adsorption systems, namely water on Cu(110) and Ru(0001). We show that non-local correlations contribute substantially to the water-metal bond and that this is an important factor in governing the relative stabilities of wetting layers and 3D bulk ice [J. Carrasco *et al.*, Phys. Rev. Lett. **106**, 026101 (2011)]. Due to the greater polarizability of the substrate metal atoms, non-local correlations between water and the metal exceed those between water within ice. This sheds light on a long-standing problem, wherein common DFT exchange-correlation functionals incorrectly predict that none of the low temperature experimentally characterized ice-like wetting layers are thermodynamically stable.

1:03PM J6.00010 Understanding the magnetic properties present at hybrid organic-ferromagnetic interfaces and the role of the van der Waals interaction, NICOLAE ATODIRESEI, VASILE CACIUC, Peter Gr nberg Institut (PGI) and Institute for Advanced Simulation (IAS), Forschungszentrum J lich and JARA, 52425-J lich, Germany, PREDRAG LAZIĆ, Massachusetts Institute of Technology, Cambridge, 02139 Massachusetts, USA, STEFAN BL GEL, Peter Gr nberg Institut (PGI) and Institute for Advanced Simulation (IAS), Forschungszentrum J lich and JARA, 52425-J lich, Germany — The design of nanoscale spintronic elements in multifunctional devices relies on a clear theoretical understanding of the physics at the electrode-organic system interfaces and in particular, the functionality of specific molecules in a given organic-metal surface environment. The density functional theory provides a framework where a realistic understanding of these systems with predictive power can be expected. However, only very recent functionals describe the exchange correlation of the organic molecule-metal interface reliably including the van der Waals interaction. We show that this has a great influence in particular on specific flat adsorbed π -conjugated electron systems. Our first-principles calculations performed for several organic molecules containing $\pi(p_z)$ electrons adsorbed onto a magnetic substrate show that the magnetic properties such as the local spin polarization, molecular magnetic moments and their spatial orientation can be specifically tuned by using substituents with different electronegativities. 1:15PM J6.00011 Simultaneous conductance and mechanical measurements on single molecule junctions reveal enhanced binding due to van der Waals interactions¹, SRIHARSHA V. ARADHYA, MICHAEL FREI, Columbia University, MARK S. HYBERTSEN, Brookhaven National Laboratory, LATHA VENKATARAMAN, Columbia University — Quantitative measurement of Van der Waals (vdW) interactions at the single molecule level remains challenging in experiments and its accurate inclusion in first principles theory is also complex. Here we report simultaneous measurement of force and electrical conductance across Au-molecule-Au junctions using a conducting atomic force microscope (AFM) for 4,4'-bipyridine (BP) and 1,2-bis(4-pyridyl)ethylene (BPE) molecules. For each of these molecules two distinct molecular junction structures are observed with characteristic conductances, consistent with previous studies utilizing scanning tunneling microscopy (STM). These two structures are found to have very different mechanical properties. Specifically, we find that the higher conductance junctions have a significantly larger rupture force and stiffness than those that show the lower conductance. They also have a larger rupture force than Au point contacts, suggesting multiple points of contact. Density functional theory (DFT) calculations suggest that the rupture force for the low conductance structure is well characterized as arising from N-Au donor acceptor interaction. However, the large rupture force and stiffness of the high conductance structure is most naturally explained as being due to the vdW contributions.

¹Support: NSF CHE 07-44185 and The Packard Foundation

1:27PM J6.00012 Mechanical properties of van der Waals interactions at compositionally graded interfaces between metals and organic semiconductors¹, HUARUI SUN, Department of Mechanical Engineering, University of Michigan, VLADIMIR STOICA, Department of Physics, University of Michigan, MAX SHTEIN, Department of Materials Science and Engineering, University of Michigan, ROY CLARKE, Department of Physics, University of Michigan, KEVIN PIPE, Department of Mechanical Engineering, Department of Electrical Engineering and Computer Science, University of Michigan — Interfacial bonding plays an important role in energy transfer (e.g., electrical conduction, thermal transport, or acoustic coupling) in composite materials as well as electronic and optoelectronic devices. In this work we use an ultrafast laser to excite vibrational modes in a thin aluminum film that is in contact with a small molecular organic semiconductor (copper phthalocyanine, CuPc). From the measured acoustic dynamics, we derive the fundamental mechanical properties of the van der Waals bonding at the Al/CuPc interface, and further study how these mechanical properties change in a series of samples as the interface is compositionally graded. The implications of these results are discussed in the contexts of interfacial thermal resistance, organic optoelectronic devices, and thermoelectric energy conversion.

1:39PM J6.00013 Benchmark data base for accurate van der Waals interaction in inorganic fragments¹, JAN BRNDIAR, IVAN STICH, Institute of Physics, Slovak Academy of Sciences — A range of inorganic materials, such as Sb, As, P, S, Se are built from van der Waals (vdW) interacting units forming the crystals, which neither the standard DFT GGA description as well as cheap quantum chemistry methods, such as MP2, do not describe correctly. We use this data base, for which we have performed ultra accurate CCSD(T) calculations in complete basis set limit, to test the alternative approximate theories, such as Grimme [1], Langreth-Lundqvist [2], and Tkachenko-Scheffler [3]. While none of these theories gives entirely correct description, Grimme consistently provides more accurate results than Langreth-Lundqvist, which tend to overestimate the distances and underestimate the interaction energies for this set of systems. Contrary Tkachenko-Scheffler appear to yield surprisingly accurate and computationally cheap and convenient description applicable also for systems with appreciable charge transfer.

1:51PM J6.00014 Interlayer binding energy of graphite: A mesoscopic determination from deformation¹, ZHE LIU, Department of Mechanical and Aerospace Engineering, Monash University, VIC 3800, Australia, ZE LIU, QUANSHUI ZHENG, Department of Engineering Mechanics and Center for Nano and Micro Mechanics, Tsinghua University, Beijing 100084, China, COMPUTATIONAL MATERIALS SCIENCE COLLABORATION, CENTER FOR NANO AND MICRO MECHANICS COLLABORATION — Despite the interlayer binding energy (BE) being one of the most important material properties of graphite, direct experimental determination is yet to be reported. In this talk, we present a novel experimental method to directly measure the interlayer BE of HOPG. By employing the self-retraction motion of a graphite flake in a graphite island (Phys. Rev. Lett. 100, 067205 (2008)), we assembled a graphite top flake spanning a graphite step, yielding a contact area ($\sim \mu\text{m}^2$) with a graphite platform. STM scan showed that the interface was atomically smooth. The deformation of the top flake should be determined by the BE with the graphite platform. Thus using a finite element model to simulate the top-flake height profiles measured by AFM, we determine the graphite BE as $0.19(\pm 0.01)\text{J/m}^2$, which can serve as a benchmark for other theoretical and experimental works. Our proposed method can be easily extended to measure the BEs between graphite/graphene and other types of substrates. It can also be used in other systems, particularly lamellar materials and thin films.

2:03PM J6.00015 Helium atom diffraction from a monolayer solid with a beam that penetrates to the substrate, LUDWIG BRUCH, Physics Dept; University of Wisconsin-Madison, FLEMMING HANSEN, Chemistry Dept., Technical University of Denmark — Diffraction of a thermal energy helium atomic beam is evaluated in the situation that the target monolayer lattice is so dilated that the atomic beam penetrates to the region between the monolayer and the substrate. Parameters are chosen to be representative of a hypothetical $p(1 \times 1)$ commensurate monolayer solid of $\text{H}_2/\text{KCl}(001)$. Depending on the spacing between the monolayer and the substrate and on the angle of incidence, there are cases where part of the incident beam is trapped in the interlayer region for times exceeding 50 ps. The methodology is a direct extension of the wave-packet propagation used for the scattering of helium from the quantum monolayer solid $\text{H}_2/\text{NaCl}(001)$.¹

Tuesday, February 28, 2012 11:15AM - 2:15PM – Session J7 DMP: Focus Session: Graphene Devices 207

11:15AM J7.00001 Graphene-Superconductor based Bolometers, HELI VORA, PIRANAVAN KUMARAVADIVEL, BENT NIELSEN, XU DU, Department of Physics & Astronomy, Stony Brook University — Due to its small volume and linear energy dependence of electron density of states, graphene has very low electronic heat capacitance compared to what is found in metals with achievable volume. This makes it a promising material for applications requiring bolometric sensing of radiation with a fast response without compromising sensitivity. Here we report fabrication of graphene-superconductor tunnel junctions and characterization of their bolometric response. When radio frequency radiation is shone onto the junction, the electrons in graphene heat up and dynamic resistance within the superconducting gap changes. The relation between absorbed power and temperature rise is used to characterize heat conductance and thermal noise equivalent power.

11:27AM J7.00002 Microwave transport and noise in graphene devices, BERNARD PLACAIS, ANDREAS BETZ, EMILIANO PALLECCHI, GWENDAL FÈVE, JEAN-MARC BERROIR, Ecole Normale Supérieure, CHRISTIAN BENZ, ROMAIN DANNEAU, Karlsruhe Institute of Technology, ANTONELLA CAVANNA, ALI MADOURI, Laboratoire de Photonique et Nanostructures, MESOSCOPIC PHYSICS GROUP TEAM, PHY NANO TEAM, ANR MIGRAQUEL COLLABORATION — We report on microwave transport and noise in graphene sheets, capacitors and transistors. We achieved a transit frequency of 80 GHz in graphene-on-sapphire transistors [1]. This is close to the state-of-the art for a 200nm gate length. In order to investigate electronic diffusion in graphene we have realized 10 GHz bandwidth experiments in metal-oxide-graphene capacitors. The crossover from capacitor to skin-effect limited cavity regimes provides an accurate and direct measurement of the diffusion constant $D(\varepsilon)$. We find D to be energy independent, which points to a mass-disorder scenario [2]. Finally, we have measured the shot noise of CVD graphene in a broad range of bias up to 1V drain-source voltage. In our GHz-frequency measurements we observe a Fano factor exhibiting the three characteristic regimes of electron-impurity, electron-electron and electron-phonon interactions.

[2] E. Pallecchi et al, Phys. Rev. B 83, 125408 (2011)

11:39AM J7.00003 Anomalous noise characteristics in graphene p-n junctions¹, JANICE WYNN GUIKEMA, ATIKUR RAHMAN, NINA MARKOVIC, Johns Hopkins University — Graphene p-n junctions provide an interesting platform to study the Dirac nature of charge carriers, which gives rise to phenomena such as Klein tunneling and electron lensing. p-n junctions also play an important role in graphene nanodevices, but the ubiquitous low-frequency noise typically limits the device performance. It has been observed that the low-frequency noise for back-gated single layer and bilayer graphene decreases at the Dirac point, even though the resistance is maximal there. This decrease has been attributed to the effects of spatial charge inhomogeneity, and the noise in such devices decreases with decreasing temperature. We will present noise characteristics of dual-gated graphene p-n junction devices. At the Dirac point, the noise shows an “M” shape as a function of top gate voltage. Away from the Dirac point the shape changes depending on the back gate and top gate voltage. Unlike the low-frequency noise in graphene nanodevices, noise across the p-n junction decreases with increasing temperature. We also observed that the noise amplitude is larger in p-n-p or n-p-n devices than in p-p-p or n-n-n devices. We will discuss the mechanism that explains this anomalous noise behavior in graphene p-n junction.

11:51AM J7.00004 Incidence Angle-dependent Transport across a Single Graphene $p-n$ Junction Formed by Buried Split-gates¹, SURAJIT SUTAR, EVERETT COMFORT, JIAN LIU, CNSE, University at Albany (SUNY), TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Tsukuba, Japan, JI UNG LEE, CNSE, University at Albany (SUNY), CNSE, UNIVERSITY AT ALBANY (SUNY) TEAM, NATIONAL INSTITUTE FOR MATERIALS SCIENCE COLLABORATION — Due to electron chirality effects, carrier transport across Graphene $p-n$ junctions (GPNJ) is predicted to have strong angular dependence [1]. This work reports evidence of such effects in a single GPNJ for various geometries created by the use of buried split-gates (SG). Standard processes are used to fabricate 2-terminal Graphene devices aligned to buried Polysilicon SG at different angles to the junction. Sweeping the SG biases V1 and V2 allows mapping the doping-dependent device resistance (R_t). For doping levels (V1,V2), subtracting the average unipolar resistance $R_t(V1,V1)$ from the bipolar resistance $R_t(V1,V2)$ gives the average junction resistance $R_j(V1,V2)$, subtracting out both contact and channel resistances. For bipolar doping, R_j shows a sharper peak for tilted channels than one that is normal to the junction, the peak being sharpest for 45° , the largest angle probed. This trend is observed for both exfoliated and CVD Graphene, especially for higher mobility and lower widths, consistent with theory. The ratio of the maximal R_j for 45° and 0° devices is about 2.5, significant for the modest Graphene mobilities of our devices. [1] V. Cheianov et al., **Science**, **315**, 2007, pp 1252.

12:03PM J7.00005 Gate-Controlled P-I-N Junction Switching Device with Graphene Nanoribbon, SHU NAKAHARAI, TOMOHIKO IJIMA, SHINICHI OGAWA, National Institute of Advanced Industrial Science and Technology, HISAO MIYAZAKI, SONGLIN LI, KAZUHIITO TSUKAGOSHI, National Institute for Materials Science, SHINTARO SATO, NAOKI YOKOYAMA, National Institute of Advanced Industrial Science and Technology — The concept of a novel graphene P-I-N junction switching device with a nanoribbon is proposed, and its basic operation is demonstrated in an experiment. The concept aims to optimize the operation scheme for graphene transistors toward a superior on-off property. The device has two bulk graphene regions where the carrier type is electrostatically controlled by a top-gate, and these two regions are separated by a nanoribbon which works as insulator. As a result, the device forms a (P or N)-I-(P or N) junction. The off state is obtained by lifting the band of the bulk graphene of the source side and lowering that of the drain side, so that the device forms a P-I-N junction. In this configuration, the leakage current is reduced more effectively than the conventional single gate transistors due to a high barrier height and a long tunneling length in the nanoribbon. The on state is obtained by flipping the polarity of the bias of either top-gate to form a P-I-P or N-I-N junction. An experiment showed that the drain current was suppressed in the cases of P-I-N and N-I-P compared to P-I-P and N-I-N, and all of the behaviors were consistent with what was expected from the device operation model. This research is granted by JSPS through FIRST Program initiated by CSTP.

12:15PM J7.00006 Fabrication of suspended graphene heterojunctions for exploring the intrinsic transport of Dirac fermions, PIRANAVAN KUMARAVADIVEL, XU DU, Stony Brook University — With linear energy dispersion and chirality, the quasiparticles in graphene differs from the conventional electrons in solid state systems in that the motions of the quasiparticles are governed by the Dirac Weyl equation. High quality of suspended graphene has made it possible to reach lower carrier densities and longer mean free paths and therefore has opened up the possibility of studying some of the unique, intrinsic properties of this Dirac electron system, which cannot otherwise be observed in conventional graphene devices on various substrates. To retain and exploit such properties of suspended graphene in heterojunction devices requires fabricating a contactless air top gate over the suspended graphene channel. Here we report on fabrication of such a device, which enable us to explore further, some interesting physics and transport of these Dirac fermions in graphene.

12:27PM J7.00007 Transport Properties of Gate Tunable Graphene-Based Tunnel Diodes, DAMON FARMER, VASILI PEREBEINOS, PHAEDON AVOURIS, IBM T.J. Watson Research Center — Due to its linear dispersion relation and unique physical properties, graphene has become a material of intense experimental and theoretical investigation. There has been rapid progress in the fabrication and understanding of graphene devices, particularly those based on the field effect transistor (FET) configuration. These three-terminal switches rely on a gate field to control electronic transport (diffusive or quasi-ballistic) in the graphene channel, where the field is perpendicular to the current flow. Here, a different type of three-terminal graphene device is demonstrated, one based on quantum tunneling. These devices build upon the convention two-terminal metal-insulator-metal (MIM) tunnel diode configuration by replacing one of the metal electrodes with graphene. Incorporation of a third (gate) electrode allows for modulation of the accessible density of states in the graphene electrode, thereby tuning the threshold voltage for tunneling in the diode. This tunable diode concept, where the gate field is parallel to the tunneling direction, is novel for a purely solid-state system. The device characteristics owing to the unique properties of graphene will be discussed, as will the underlying physics of device operation.

12:39PM J7.00008 Drain Current Saturation in Sub- μm Graphene Field Effect Transistors, SHU-JEN HAN, IBM TJ Watson Research Center, DHARMENDAR PALLE, IBM Research Labs, Austin, AARON FRANKLIN, ALBERTO VLADES-GARCIA, IBM TJ Watson Research Center — Recently, graphene field-effect transistors (FET) with high cut-off frequencies (f_T) were reported; however, the devices showed very weak drain current saturation, leading to an undesirably high output conductance. A crucial figure-of-merit for analog/RF transistors is the intrinsic gain (gm/gds). In this work, we show that by employing an embedded gate structure with an equivalent oxide thickness less than 2 nm, strong drain current saturation can be obtained for graphene FETs with short channels. The mechanism was not entirely due to velocity saturation, but rather the combination of a shift of the Dirac point in the voltage domain and a strong bias-dependent gate capacitance. The mechanisms are also verified with models.

12:51PM J7.00009 Self-aligned high transconductance CVD graphene transistor, YUCHI CHE, ALEXANDER BADMAEV, ZHEN LI, CHONGWU ZHOU, University of Southern California — Exceptional electronic properties of graphene make it a highly promising material for high-speed electronics. However, the design and practical realization of graphene transistors are still challenging, which limit the potential of graphene. In this work, we present a novel, practical, and highly scalable method for the fabrication of self-aligned graphene transistors. Large-area single-layer graphene films were grown on copper foil and were transferred onto 12 inch Si wafers. Furthermore, in order to achieve wafer-scale fabrication of graphene transistors with high yield, we developed a self-aligned fabrication approach by standard lithographical methods. The fabricated transistors with gate lengths in the range of 110 to 170 nm showed excellent performance with the peak current density of $1.3 \text{ mA}/\mu\text{m}$. The peak transconductance reaches $0.5 \text{ mS}/\mu\text{m}$, which is one of the best transconductance for CVD graphene transistor published up to date. Our novel fabrication method shows great potential toward practical implementation of graphene in high frequency devices and circuits.

1:03PM J7.00010 Graphene Enabled Vertical Field Effect Transistors, EVAN P. DONOGHUE, Physics, University of Florida, Gainesville, FL, MAXIME G. LEMAITRE, Material Science and Engineering, University of Florida, Gainesville, FL, MITCHELL A. MCCARTHY, BO LIU, Physics, University of Florida, Gainesville, FL, BILL R. APPLETON, MS&E, NIMET, Univrsity of Florida, Gainesville, FL, ANDREW G. RINZLER, Physics, University of Florida, Gainesville, FL — Vertical field effect transistors (VFETs) using a carbon nanotube source electrode have recently demonstrated state-of-the-art current densities at low operating voltages from comparatively low mobility organic semiconductors. Unlike in conventional thin film transistors, transconductance arises from a gate field modulation of the contact barrier at the organic semiconductor/nanotube interface (with the performance enhanced by nanotube Fermi level shifts allowed by their low density of electronic states). Graphene's low density of states near the Dirac point similarly makes it a good candidate source electrode in VFETs. We have now demonstrated such devices, facilitated by the use of a novel transfer technique that improves areal yields while avoiding both polymeric residue and the particulates that necessitate the use of thicker channel layers in nanotube VFETs. Critical to high performance is a facile method developed for perforating the graphene sheet with holes of a tunable size and density, allowing for a direct assessment of the role of self-screening effects in VFETs. These initial graphene enabled VFETs achieve on-current densities exceeding $250\text{mA}/\text{cm}^2$ at drive voltage swings of less than 4V with on/off current ratios larger than 10^6 .

1:15PM J7.00011 Transport/magnetotransport of high-performance graphene transistors on organic molecule-functionalized substrates, SHAO-YU CHEN, Academia Sinica, PO-HSUN HO, National Taiwan University, REN-JYE SHIUE, Academia Sinica, CHUN-WEI CHEN, National Taiwan University, WEI-HUA WANG, Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan — We present the transport and magnetotransport of high-quality graphene transistors on conventional SiO_2/Si substrates by modification with organic molecule self-assembled monolayers (SAMs). Graphene devices on organic SAM-functionalized substrates exhibit high carrier mobility, low intrinsic doping, suppressed carrier scattering, and reduced thermal activation of resistivity at room temperature. Magnetotransport of graphene devices with pronounced quantum Hall effect and Shubnikov-de Haas oscillations also confirms the high quality of graphene on this ultrasmooth organic SAM-modified platform. The high-performance graphene transistors on the solution-processable SAM-functionalized SiO_2/Si substrates are promising for the future development of large-area and low-cost fabrications of graphene-based nanoelectronics.

1:27PM J7.00012 Quantum transport simulation of graphene transistors, YANG LU, JING GUO, University of Florida, COMPUTATIONAL NANOTECHNOLOGY TEAM — Owing to its unique electrical and thermal properties, graphene has attracted great interests as potential building blocks of next generation electronics, especially for RF applications. Due to lack of band gap, Klein tunneling plays an important role in sub-100nm graphene transistors. Inelastic phonon scattering introduced by intrinsic phonons of graphene and polarized substrate also affect device performance. We show that coupling between inelastic phonon scattering and Klein tunneling leads to different device physics of graphene transistors from common nanoscale transistors. The electron-phonon interaction and quantum transport in graphene transistors are modeled by the non-equilibrium green's function method within the self-consistent Born approximation. We evaluate the effect of inelastic process on both DC and RF performance of graphene transistors. We also briefly discuss the self-heating effects in graphene transistors introduced by inelastic phonon scattering.

1:39PM J7.00013 Pulse gating on graphene quantum dots, CHRISTIAN VOLK, CHRISTOPH NEUMANN, SEBASTIAN KAZARSKI, STEFAN FRINGES, STEPHAN ENGELS, BERNAT TERRES, JAN DAUBER, STEFAN TRELLENKAMP, UWE WICHMANN, CHRISTOPH STAMPFER, JARA-FIT and II. Institute of Physics B, RWTH Aachen, Aachen and Peter Gruenberg Institut (PGI-8/9), Forschungszentrum Juelich, Juelich, Germany — Graphene quantum devices have received increasing attention over the last years. Graphene quantum dots (QDs) are interesting systems for implementing spin qubits. Compared to well-established GaAs-based QDs, their smaller hyperfine and spin-orbit coupling promises more favorable spin coherence times. However, while the preparation, manipulation, and read-out of single spins have been demonstrated in GaAs, research on graphene QDs is still at an early stage. Although Coulomb blockade phenomena and excited state spectroscopy is now well established, experimental signatures allowing the identification of relaxation times have been hard to trace. Here we report on the current status of pulse gating experiments on graphene quantum devices and in particular we will present measurements of the charge relaxation rates in single-layer graphene QDs. The investigated devices consist of an island with a diameter of 120 nm, 4 lateral graphene gates and 2 charge detectors. From so-called diamond measurements we extract a charging energy of 11 meV and excited state level spacings on the order of 2-4 meV. The gates allow to individually tune the tunnelling-in and -out rates down to low MHz regime. Low-bias pulse gate measurements allow finally to extract relaxation rates on the order of 50 ns.

1:51PM J7.00014 Ultrafast conductivity measurements in CVD graphene¹, JAMES HEYMAN, YILIKAL AYINO, ROLAN MANDERSON-JONES, JACOB STEIN, Macalester College, Department of Physics and Astronomy — We study carrier dynamics in CVD graphene films on Al_2O_3 using time-resolved THz spectroscopy (TRTS). Excitation with a 50fs, 800nm pulse produces a conductivity change $\Delta\sigma$ which we measure as a decrease in transmission of an ultrafast THz pulse. Ongoing work seeks to investigate TRTS in a magnetic field to directly probe scattering rates of photogenerated carriers. At present we report zero field measurements. We observe different recovery dynamics for low ($\Delta\sigma \ll \sigma_0$) and high ($\Delta\sigma > \sigma_0$) pump powers. For pump fluence $\varphi < 10^{12}\text{photons cm}^{-2}$ ($\Delta\sigma \ll \sigma_0$) we find $\Delta\sigma \propto \varphi$ and observe a nearly exponential decay $\Delta\sigma \propto e^{-t/\tau}$ with decay time $\tau \approx 2\text{ps}$. At higher powers ($\Delta\sigma > \sigma_0$) $\Delta\sigma$ is sublinear in φ , and the decay rate decreases, with $\tau \approx 4\text{psat } \varphi \approx 5 \cdot 10^{13}\text{photons cm}^{-2}$. Graphene's unusual conductivity relation, $\sigma \propto \sqrt{n}$, predicts the observed behavior, since $\Delta\sigma \propto \sqrt{n_0 + n_{\text{photo}}} - \sqrt{n_0}$ is approximately linear for $n_0 \gg n_{\text{photo}}$, while $\Delta\sigma \propto \sqrt{n_{\text{photo}}}$ for $n_{\text{photo}} \gg n_0$. Here n_0 and σ_0 are the equilibrium carrier density and conductivity in these p-type films. At high pump powers we also observe a rapid initial recovery on $\sim 500\text{fs}$ timescale which is not described by this simple model.

¹Work supported by the National Science Foundation under Grant Nos. DMR-1006065 and DMR-0959341

2:03PM J7.00015 Delay Analysis of Graphene Field Effect Transistors and T-Gate Self-Aligned GFETs¹, HAN WANG, ALLEN HSU, KI KANG KIM, JING KONG, TOMAS PALACIOS, Massachusetts Institute of Technology — In this paper, we propose a new method for extracting the carrier transit delays in radio-frequency (RF) graphene field effect transistors (GFETs). This delay analysis not only gives deep physical insight into the carrier transport in the channel, but also provides valuable information that can guide the device engineers in optimizing the design of high performance RF GFETs. The contribution of this work is three-fold. First, GFETs are fabricated on sapphire substrate to reduce the parasitics from the GSG pads. This minimizes the error in measuring the S-parameter of the device and allows small-signal capacitances to be accurately extracted. Second, we present for the first time a detailed delay analysis of high frequency graphene transistors. Lastly, the simple and robust method proposed can accurately extract the intrinsic transit delay of the GFETs - the delay purely associated with the carrier transiting across the intrinsic gate region – and allows a new method for direct experimental extraction of the average carrier velocity in the channel. Based on the analysis, we propose a self-aligned device structure to minimize the parasitic delays in GFETs. This GFET structure uses a T-shape gate as the mask to allow the source and drain metals to be aligned to the edge of the gate. A T-gate self-aligned GFET with gate head of 300 nm and foot 50 nm is fabricated and its DC and RF characteristics are reported.

Session J8 DCMP GMAG: Quantum Magnetism, BEC, and Disorder 208

11:15AM J8.00001 Finite- T spectral function of the BEC quantum magnets¹, SUHAS GANGADHARIAH, University of Basel, Switzerland, SASHA CHERNYSHEV, UC Irvine — We discuss the momentum, frequency, and temperature dependence of the spectral function of interacting 3D bosonic excitations in the vicinity of the BEC quantum critical point. The relaxation rate is demonstrated to have a highly non-trivial ω -dependence with several asymptotic regimes that are studied in some detail. The spectral function is shown to exhibit, in a wide range of temperatures, an asymmetric quasiparticle peak and a shoulder, originating from the behavior of the self-energy. These spectral features should be readily observable in neutron-scattering experiments in the BEC quantum magnets. We also argue that this behavior of the spectral function must persist throughout the strong-coupling limit.

11:27AM J8.00002 ABSTRACT WITHDRAWN —

11:39AM J8.00003 Theory of magnetic Bose glass in Br-doped dichloro-tetrakis-thiourea-nickel (DTN)¹, STEPHAN HAAS, University of Southern California, RONG YU, Rice University, TOMMASO ROSCILDE, Ecole Normale Supérieure de Lyon - France — We will review here the microscopic model allowing to describe quantitatively the physics of Br-doped DTN. The magnetic Hamiltonian of Br-DTN describes $S=1$ spins coupled through bimodally distributed antiferromagnetic bonds, and with a correlated bimodal distribution of single-ion anisotropies. A spin-boson mapping leads to a description in terms of a Bose-Hubbard-like model with random hoppings and random on-site interactions for magnetic quasiparticles, whose density is controlled by the applied magnetic field. This model features an extended gapless and compressible Bose-glass phase in low fields, extending down to zero field, at which the compressibility vanishes, corresponding to a Mott-glass phase. We will present extensive quantum Monte Carlo results for the thermodynamic signatures of the Bose glass, and for the quantum critical signatures of the magnetic ordering transition occurring at stronger field, which corresponds to a remarkable realization of the Bose-glass/superfluid transition.

¹Numerical calculations have been supported by an INCITE award from the DOE.

11:51AM J8.00004 Magnetization and Specific Heat Investigations of the Bose Glass: Br-doped $\text{NiCl}_2\text{-4SC}(\text{NH}_2)_2$, FRANZISKA WEICKERT, CORNELIU MICLEA, ROMAN MOVSHOVICH, VIVIEN ZAPF, Los Alamos National Laboratory, RONG YU, Rice University Houston, TOMMASO ROSCILDE, ENSL, Lyon, France — $\text{NiCl}_2\text{-4SC}(\text{NH}_2)_2$ (DTN) is an insulating material, which shows field induced XY-AFM order between $H_{c1} = 2.1$ T and $H_{c2} = 12.6$ T. In boson language, the ground state of DTN can be described as a Mott insulator, and the ordered state as a Bose-Einstein condensation of magnons. Bond disorder is introduced by substituting Br atoms on Cl positions, which simultaneously changes the super exchange interaction along the c -direction on a local scale and leads to a Mott-glass ground state in zero field. Furthermore, the system develops a gapless Bose glass for magnetic fields $0 < H < H_{c1}$ and $H > H_{c2}$, followed by a Mott insulating state above the saturation field H_{sat} . Note, that the critical fields $H_{c1,2}$ and H_{sat} are shifted compared to those of pure DTN. In this talk, we report on measurements of the magnetization and specific heat at very low temperatures between 50 mK and 3 K in high magnetic fields up to 14 T on an 8% Br-doped single crystal DTN. We compare our data with the local gap model, which reduces the low-temperature and low-field behavior to those of an ensemble of individual three level systems with local magnetization $M_S = 0, \pm 1$ and a finite energy gap for $H = 0$.

12:03PM J8.00005 Magnetic Bose glass in Br-doped $\text{NiCl}_2\text{-4SC}(\text{NH}_2)_2$: Magneto-Electric Effect, LIANG YIN, JIAN-SHENG XIA, NEIL SULLIVAN, University of Florida, VIVIEN ZAPF, LANL, ARMANDO PADUAN-FILHO, Universidade de Sao Paulo — $\text{NiCl}_{1.85}\text{Br}_{0.15}\text{-4SC}(\text{NH}_2)_2$ is a candidate for Bose glass state of the magnetism at low temperatures, which is the bosonic analog of Anderson localization. Here we explore the glassy dynamics of the magnetization taking advantage of magneto-electric coupling in this material. We report measurements of the magneto-electric effect in $\text{NiCl}_{1.85}\text{Br}_{0.15}\text{-4SC}(\text{NH}_2)_2$ using two different experimental setups: (i) magnetic field-induced polarization and (ii) electric-field-induced magnetization. Both measurements show that the proposed Bose glass state in a high magnetic field is sensitive to the applied frequencies of AC magnetic and electric fields, with a maximum response between 700Hz and 1000Hz. This frequency-dependent behavior could provide information about the characteristic response time and the size of magnetic clusters.

12:15PM J8.00006 Disorder in a two-dimensional quantum spin liquid, DAN HUVONEN, MARTIN MANS-SON, SEVERIAN GVASALIYA, SHUANGYI ZHAO, ETH Zurich, TATIANA YANKOVA, Moscow State University, VASILIIY GLAZKOV, Kapitza Institute for Physical Problems, ERIC RESSOUCHE, Institut Laue-Langevin, CHRISTOF NIEDERMAYER, MARK LAVER, Paul Scherrer Institut, GEORG EHLERS, Oak Ridge National Laboratory, ANDREY ZHELUDEV, ETH Zurich — We discuss magnetic field induced phase transition to magnon Bose-Einstein condensate state in a disordered two-dimensional spin gap antiferromagnet. Disorder was introduced into piperazinium hexachlorodipicrate (PHCC) by chemically substituting up to 10% of exchange interaction mediating Cl ions for Br. We present specific heat, magnetization, susceptibility, elastic and inelastic neutron scattering results in fields up to 14T. Data reveals that disorder enlarges significantly the spin gap and induces nonzero susceptibility in the gapped phase. Reduction of magnon bandwidth and lifetime are evident from inelastic neutron scattering measurements. Although the phase transition seems to survive, the condensate wavefunction acquires a history dependence. In contrary to theoretical expectations, the extracted critical exponents show no changes within experimental accuracy.

12:27PM J8.00007 Dynamics of the Random-Field Ising Model, SPENCER TOMARKEN, DANIEL SILEVITCH, THOMAS ROSENBAUM, Department of Physics, The University of Chicago — Ising magnets with long, needle-like domains can be treated as single extended spins which interact via dipole-dipole forces. Typically such dipole interactions cancel out due to spatial symmetry, but the combination of randomly packed grains and the application of a magnetic field transverse to the easy axis of magnetization can break the symmetry. This results in a site-random-magnetic field that points along the easy axis and varies from grain to grain, described by the Random-Field Ising Model (RFIM). We report a series of magnetization measurements in longitudinal and transverse magnetic fields that demonstrate RFIM behavior in the room-temperature, rare-earth ferromagnet $\text{Nd}_2\text{Fe}_{14}\text{B}$, and analyze our data in terms of predicted scaling relations.

12:39PM J8.00008 Strong Disorder Renormalization Group for the Many Body Localization Transition, GIL REFAEL, California Institute of Technology, VADIM OGANESYAN, City University of New York, SHANKAR IYER, California Institute of Technology — The strong disorder renormalization group, originally devised by Ma and Dasgupta to study the random Heisenberg antiferromagnet, has subsequently been used to investigate the low energy physics and quantum phase transitions of a variety of strongly disordered systems. However, recent work by Basko, Aleiner, and Altshuler has focused attention on the many body localization transition, a dynamical quantum phase transition that involves the localization of highly excited eigenstates of a many body system in Fock space. Numerical results from an exact diagonalization study by Pal and Huse suggest that the many body localization transition may exhibit so-called infinite-randomness, a property that implies that a strong disorder renormalization group may be well-suited to study this transition. With the many body localization transition in mind, we therefore outline a strong disorder renormalization procedure that targets the least-localized eigenstate of a model. We then apply this procedure to study disordered quantum Ising and XXZ models. The latter model is similar to the one investigated by Pal and Huse and is expected to contain a dynamical transition between localized and ergodic phases; our principal aim is to use the strong disorder RG to characterize this transition.

12:51PM J8.00009 Evolution of magnetic order and fluctuations in Ni-V close to the disordered ferromagnetic quantum critical point¹, ALMUT SCHROEDER, RUIZHE WANG, S. UBAID-KASSIS, Kent State University, P.J. BAKER, F.L. PRATT, ISIS, S.J. BLUNDELL, T. LANCASTER, I. FRANKE, J.S. MOELLER, Oxford University — Muon spin rotation and magnetization data of the d-metal alloy $\text{Ni}_{1-x}\text{V}_x$ are presented at several vanadium concentrations x below and above the critical $x_c \approx 11\%$ where the onset of long-range ferromagnetic (FM) order is suppressed. Bulk magnetization shows signatures of a disordered quantum phase transition (QPT), most clearly in the paramagnetic regime: Above x_c the temperature dependence of the magnetic susceptibility is best described by simple non-universal power laws marking a quantum Griffiths phase. But the deviations from a clean FM in the ordered phase are more subtle to recognize in the bulk magnetization and are noticed only close to x_c . Muon data reveal a broad field distribution in the FM regime at even small x ($x \geq 4\%$). The evolution of the magnetic cluster distribution and dynamics from the pristine FM towards the paramagnetic regime will be presented. This adds new insight in this model system at a disordered QPT.

1:03PM J8.00010 Unconventional spin-Peierls state in the quantum magnet TiOBr ¹, J.-P. CASTEL-LAN, Argonne National Laboratory, J.P. CLANCY, University of Toronto, J.P.C. RUFF, Advanced Photon Source, S. ROSENKRANZ, R. OSBORN, Argonne National Laboratory, B.D. GAULIN, McMaster University, F.C. CHOU, S.H. HUANG, National Taiwan University — The discovery of spin-Peierls transitions in inorganic materials such as CuGeO_3 with T_{sp} of 14K allowed for the growth of large single crystals. With the availability of large single crystals the opportunity arises to introduce both magnetic and nonmagnetic impurities and study the resulting perturbations from the ground state. Recently a new class of unconventional spin-Peierls materials were discovered TiOBr and TiOCl . TiOBr and TiOCl have been shown to exhibit dimerized singlet ground states and undergo not one but two successive phase transitions. We have performed x-ray scattering measurements on single crystals of TiOBr . These measurements reveal both commensurate and incommensurate spin-Peierls phases; below $T_{c2} \sim 48\text{K}$ incommensurate super-lattice reflections arise at $Q=[H\pm\delta, K+1/2\pm\epsilon, L]$ which persists down to the lock in transition at $T_{c1} \sim 27\text{K}$. We will report on the details of these successive transitions and the destruction of the long-range ordered spin-Peierls state with introduction of magnetic vacancies by doping with Sc.

1:15PM J8.00011 Ashkin-Teller criticality and pseudo-first-order behavior in a frustrated Ising model on the square lattice¹, SONGBO JIN, ARNAB SEN, ANDERS SANDVIK, Boston University — We consider the square-lattice frustrated Ising model with first- and second-neighbor interactions, $J_1 < 0$ and $J_2 > 0$. Its thermal phase transition to “stripe” order when $g = J_2/|J_1| > 1/2$ has remained controversial despite many past studies. Using Monte Carlo simulations to investigate the order-parameter distribution and its Binder cumulant, we demonstrate Ashkin-Teller criticality for $g \geq g^*$, i.e., the critical exponents vary continuously between those of the 4-state Potts model at g^* and the Ising model for $g \rightarrow \infty$. The Potts point, below which the transition is first-order, is $g^* = 0.67 \pm 0.01$, much lower than previously believed. The system exhibits *pseudo first-order* behavior for $g^* \leq g \leq g'$ ($g' \approx 0.9$), which was previously misinterpreted as actual first-order behavior.

¹NSF Grant No. DMR-1104708.

1:27PM J8.00012 Quantum phase diagram of the spin ladder model with next-nearest neighbor interactions, YANCHAO LI, HAIQING LIN, Beijing Computational Science Research Center, Beijing 100084, People's Republic of China — By using the density matrix renormalization group technique, we investigate the quantum phase diagram of a two-leg spin-1/2 ladder with diagonal and in-chain next-nearest neighbor interactions for both anti-ferromagnetic and ferromagnetic frustrated cases. Through analyzing the correlation function and four-site entropy, the existence of the controversial columnar dimer phase is confirmed, and the phase transitions caused by the in-chain next-nearest neighbor interaction are presented for the anti-ferromagnetic frustrated case; meanwhile, for the ferromagnetic frustrated case, we find that the system possesses a tetramer phase, a ferromagnetic phase, and the states I and II, and the spin arrangements for I and II are determined.

1:39PM J8.00013 Majorana Spin Liquids on a two-leg ladder¹, HSIN-HUA LAI, OLEXEI MOTRUNICH, California Institute of Technology — We realize a gapless Majorana Orbital Liquid (MOL) using orbital degrees of freedom and also an $\text{SU}(2)$ -invariant Majorana Spin Liquid (MSL) using both spin and orbital degrees of freedom in Kitaev-type models on a 2-leg ladder. The models are exactly solvable by Kitaev's parton approach, and we obtain long-wavelength descriptions for both Majorana liquids. The MOL has one gapless mode and power law correlations in energy at incommensurate wavevectors, while the $\text{SU}(2)$ MSL has three gapless modes and power law correlations in spin, spin-nematic, and local energy observables. We study the stability of such states to perturbations away from the exactly solvable points. We find that both MOL and MSL can be stable against allowed short-range parton interactions. We also argue that both states persist upon allowing $\mathbb{Z}_2$ gauge field fluctuations, in that the number of gapless modes is retained, although with an expanded set of contributions to observables compared to the free parton mean field.

¹National Science Foundation through grant DMR-0907145 and A. P. Sloan Foundation.

1:51PM J8.00014 Static and dynamic properties of a strong-leg spin ladder, DAVID SCHMIDIGER, SEBASTIAN MUEHLBAUER, SEVERIAN GVASALIYA, ANDREY ZHELUEV, Neutron Scattering and Magnetism Group, ETH Zurich, Laboratory for Solid State Physics, PIERRE BOUILLLOT, DPMC-MaNEP, University of Geneva, CORINNA KOLLATH, Departement de Physique Theorique, University of Geneva, THIERRY GIAMARCHI, DPMC-MaNEP, University of Geneva — Static and dynamic properties of the strong-leg $S = 1/2$ Heisenberg spin ladder system $(\text{C}_7\text{H}_{10}\text{N})_2\text{CuBr}_4$ are studied using inelastic neutron scattering and neutron diffraction experiments, as well as bulk magneto-thermodynamic measurements. The leg-odd excitation channel is dominated by long-lived single-magnon states in the entire Brillouin zone, which supports a symmetric-ladder model for this material [1]. In the leg-even channel, a considerable fraction of the spectral weight is contained in a novel long-lived two-magnon bound state. Contrary to reports by other authors, in applied magnetic fields we observe a Bose-Einstein condensation of magnons that manifests itself if 3D long-range antiferromagnetic ordering. The latter emerges beyond $H_c=2.8$ T and is due to weak inter-chain interactions. The field-temperature phase diagram showing the spin liquid, Tomonaga-Luttinger spin liquid and BEC phases is mapped out. The experimental results are in spectacular agreement with DMRG calculations. The latter provide additional insight on certain spin ladder properties specific to the strong-leg regime.

2:03PM J8.00015 Sign problem free quantum Monte Carlo simulations of spin density wave transitions in metals, EREZ BERG, Harvard University, MAX METLITSKI, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, SUBIR SACHDEV, Harvard University — We present a version of the spin-fermion model for spin density wave (SDW) transitions in metals, which can be simulated using the determinant quantum Monte Carlo method with no sign problem. The sign problem is eliminated by generalizing the model to include two orbitals which are coupled through the SDW field. The resulting model has a pseudo-time reversal symmetry that guarantees that the minus signs resulting from integrating out the fermions cancel, resulting in a real effective action for the SDW bosonic field. We present preliminary results for the SDW and pairing susceptibilities and the fermion Green's function near the quantum critical point.

Session J9 GMAG DMP: Focus Session: Magnetic Oxide Thin Films And Heterostructures -
Multiferroic Thin Films 209

11:15AM J9.00001 Electric-field induced magnetization reversal using multiferroics, MORGAN TRASSIN, Department of Materials Science and Engineering, University of California, Berkeley, CA 94720 — Controlling magnetism using solely electric fields is interesting not only from a fundamental standpoint, but presents great potential for ultimately low energy consumption logic and memory. The evidence of the electrically controllable antiferromagnetic ordering in the multiferroic magnetoelectric bismuth ferrite (BiFeO₃) drew an increasing interest in the pursuit for new emerging devices. To use such functionality for device applications, deterministic control not only of antiferromagnetism, but also ferromagnetism is essential. To achieve this goal, a ferromagnet/multiferroic heterostructure has been proposed based on the combination of magnetoelectric coupling in BiFeO₃ and exchange coupling between magnetic materials and offers a new pathway for the electrical control of magnetism. By combination of a piezoresponse force microscopy, photoemission electron microscopy and anisotropic magnetoresistance measurements, we demonstrated the non-volatile reversal of a CoFe layer magnetization induced solely by the application of an electric field at room temperature. This 180 degree rotation of the magnetization of the ferromagnetic layer is mediated by a strong interfacial coupling. The correlation between the ferroelectric state in the multiferroic layer and the CoFe ferromagnetic domain architecture is evidenced. The projection of this strong magnetoelectric coupling in an out-of-plane configuration, allowing the reduction by an order of magnitude of voltage required, will be discussed. Our results show the high potential of magnetoelectric-based heterostructures for future low energy consumption data storage devices.

11:51AM J9.00002 Properties of LuFe₂O₄ Films Grown by Molecular-Beam Epitaxy, R. MISRA, C.M. BROOKS, The Pennsylvania State University, University Park, PA, J.A. MUNDY, T. HEEG, Cornell University, NY, J. SCHUBERT, Peter Grunberg Institute (PGI 9-IT), Julich, Germany, Z.K. LIU, The Pennsylvania State University, University Park, PA, D. MULLER, D.G. SCHLOM, Cornell University, NY, P. SCHIFFER, The Pennsylvania State University, University Park, PA — LuFe₂O₄ is an exotic material with a simultaneous existence of ferroelectricity and ferrimagnetism at the highest temperature (240 K) of any known material [1]. 25 nm thick films of this unusual multiferroic were grown by MBE on MgAl₂O₄, MgO, and SiC substrates. XRD shows that the LuFe₂O₄ films are single-phase and epitaxial. Film stoichiometry was regulated using an adsorption controlled growth process by depositing LuFe₂O₄ in an iron rich environment at pressures and temperatures where the excess iron desorbs from the film surface during growth. STEM images reveal the layered structure of LuFe₂O₄ and a clean substrate-film interface free of second phases. The magnetization data exhibits a rapid increase in magnetization below 240 K consistent with the bulk paramagnetic to ferrimagnetic phase transition. On further cooling, the zero field cooled (ZFC) branch of the magnetization displays a peak at 205 K that is suggestive of a glassy transition, which is also seen in bulk samples. At 100 K and 70 kOe, we observe a saturation magnetization of 2.4 μ_B /f. u. (theoretical value of 3 μ_B /f. u.)

[1] Ikeda *et. al.*, Nature **436** (2005) 1136–1138.

12:03PM J9.00003 Growth and Characterization of Magnetoelectric Fe₂TeO₆ Thin Films¹, JUNLEI WANG, PETER DOWBEN, CHRISTIAN BINEK, University of Nebraska-Lincoln — Promising spintronic concepts such as Cr₂O₃ based voltage-controlled exchange bias systems [1] employ electric controlled boundary magnetization. Symmetry arguments reveal that equilibrium boundary magnetization is a generic property of magnetoelectric antiferromagnets [2]. However, experimental evidence of boundary magnetization is scarce and microscopic evidence has only been provided for the Cr₂O₃ (0001) surface [3]. In order to bring the concept of boundary magnetization into a broader experimental context we prepare the magnetoelectric antiferromagnet Fe₂TeO₆ with tri-rutile structure. We use two distinct approaches for the thin film growth, RF sputtering and pulsed laser deposition (PLD). Both methodologies start from targets which we prepare from sintered powder of Fe₂TeO₆ produced in a solid-state reaction. We characterize the magnetoelectric thin film of Fe₂TeO₆ structurally, magnetically and magnetoelectrically using XRD, SQUID, RHEED, LEED and MOKE. Our investigation aims on an experimental test of the predicted generality of the equilibrium boundary magnetization in magnetoelectric antiferromagnets.

12:15PM J9.00004 Probing of ferroelectric and antiferromagnetic orders of multiferroic YMnO₃ via second harmonic generation¹, SRINIVAS POLISETTY, MIKEL HOLCOMB, CAMERON KEENAN, FELIO PEREZ, DAVID LEDERMAN, West Virginia University — The ferroelectric and antiferromagnetic properties of epitaxial, hexagonal (0001) YMnO₃ thin films grown on GaN/Al₂O₃ substrates were studied using second harmonic generation. A Ti:sapphire laser with a 15 W Nd:YVO₄ pump was used to generate the second harmonic signal. Above the Néel temperature, ferroelectric ordering was clearly observed as deduced from angular plots of the incoming and outgoing polarization of the second harmonic generation (SHG) signals. Additional antiferromagnetic order was identified below the Néel temperature. The ferroelectric-magnetic coupling studied via SHG will be discussed.

12:27PM J9.00005 Investigation of Electric Field Control of Antiferromagnetic Domains in Epitaxial BiFeO₃ Thin Films Using Neutron Diffraction, W. RATCLIFF, National Institute of Standards and Technology, Gaithersburg, MD 20899, V. ANBUSATHIAH, T. GAO, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20424, P.A. KIENZLE, National Institute of Standards and Technology, Gaithersburg, MD 20899, I. TAKEUCHI, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20424 — BiFeO₃ (BFO) is a multiferroic which displays both ferroelectric and magnetic order at room temperatures. Thin films possess a simple G-type antiferromagnetic order. In the bulk, this ordering takes on an additional long-wavelength modulation in the form of a spiral [1]. Recent neutron diffraction results have revealed that it is possible to recover a modulated magnetic structure in thin films which is strongly dependent on the orientation of the substrate on which the film is grown [1]. Based on this, BFO thin films were deposited on a vicinal SrTiO₃ substrate. PFM measurements demonstrate that a ferroelectric monodomain was achieved. New neutron diffraction results show that it is possible to change the population of magnetic domains in such films through the application of an electric field (which also switches the ferroelectric domain state). Based on these results, magneto optic Kerr effect (MOKE) measurements were performed on patterned pads of exchanges coupled Co film deposited on top of the BFO films. The results of these measurements will be discussed in the context of device applications. [1] Lee Seongsu; Choi Taekjib; Ratcliff W. II; *et al.*, Phys. Rev. 12:39PM J9.00006 Antiferromagnetic and structural phase transitions in tetragonal-like BiFeO₃, H.M. CHRISTEN, G.J. MACDOUGALL, W. SIEMONS, Oak Ridge National Laboratory, J.H. NAM, Korea Institute of Ceramic Engineering and Technology, J.L. ZARESTKY, M.D. BIEGALSKI, S. LIANG, E.R. DAGOTTO, S.E. NAGLER, Oak Ridge National Laboratory — The recent observation that strain stabilizes a tetragonal-like (“T-like”) polymorph of BiFeO₃ has illustrated how epitaxial constraints can fundamentally alter the properties of this multiferroic material. We performed detailed temperature-dependent neutron and x-ray scattering experiments on epitaxial BiFeO₃ films on different substrates (SrTiO₃, LaAlO₃, YAlO₃) to study the nature of the monoclinic crystal structure and of the antiferromagnetic (AFM) order. In agreement with Monte Carlo simulations for a classical Heisenberg model, we observe a much lower Néel temperature in the T-like morph ($T_N \simeq 325\text{K}$) than in less-strained (“R-like”) films ($T_N \simeq 645\text{K}$), and additionally a low-temperature coexistence of C-type and G-type AFM. Independent of the antiferromagnetic transition, at $T \simeq 375\text{K}$ we also observe a structural phase transition from one type of monoclinic distortion to a different one. In combination, these measurements shed light on the complexity of the phase diagram of BFO, and provide routes to explore how the material’s properties can be tuned by external parameters. Research supported by the U.S. DOE, BES, MSED (H.M.C., W.S., S.L., E.D., H.M.C) and SUFD (M.D.B., G.J.M, J.L.Z, S.E.N.).

12:51PM J9.00007 Reversible switching of magnetic easy axis in Co/BiFeO₃ thin film heterostructures¹, TIEREN GAO, ANBUSATHIAH VARATHARAJAN, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20424, WILLIAM RATCLIFF, NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, USA, ICHIRO TAKEUCHI, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20424, UNIVERSITY OF MARYLAND TEAM, NIST COLLABORATION — We are investigating the magnetic properties of a thin Co layer deposited on top of and exchange coupled to (001) BiFeO₃ (BFO) thin films. 5 nm Co layer is evaporated and patterned into 100 micron x 100 micron pads. We measure angular dependent magnetic hysteresis loop of the Co layer using the magneto-optical Kerr effect and by sweeping the direction of the external magnetic field. We find that exchange-coupled Co layer always develops a magnetic easy axis along the [100] or [010] direction of BFO. As electric field pulses are applied between the Co pad and the bottom electrode (SrRuO₃), non-volatile changes in the magnetic properties are observed in the Co layer. For a particular Co/BFO configuration, application of an electric field corresponding to the ferroelectric coercive field of the BFO film switches the magnetic easy axis by 45°. Upon application of the opposite electric field pulse, the easy axis switches back to the original direction. Subsequent applications of the alternating electric field pulses result in repeating reversible switching between the initial easy axis direction and the 45° rotated direction.

¹This work is funded by NSF MRSEC at UMD.

1:03PM J9.00008 Probing interface reconstructions in multiferroic BiFeO₃ and charge ordered La_{0.5}Ca_{0.5}MnO₃ heterostructures, GUNEETA SINGH-BHALLA, MORGAN TRASSIN, YING-HAO CHU, RAMMAMOORTHY RAMESH, Berkeley — Spurred by the potential for device structures with multiple tuning parameters, recent explorations of carefully engineered oxide interfaces have highlighted intriguing possibilities. A famous example includes the LaAlO₃/SrTiO₃ heterostructure where the individual layers are insulating but an electron gas appears at the interface. In similar fashion, the atomically engineered interface between antiferromagnetic BiFeO₃ and ferromagnetic manganite [La,Sr]MnO₃ results in the formation of a ferromagnetic state in BiFeO₃ at the interface. Here we explore the interface between BiFeO₃ and the charge ordered manganite, La_{0.5}Ca_{0.5}MnO₃. The insulating nature of La_{0.5}Ca_{0.5}MnO₃ and BiFeO₃ allows us to directly probe the electronic properties of the interface via transport measurements. A combination of capacitance and field effect measurements combined with structural probes shed new light on the charge ordered manganite and multiferroic interface. We explore the effects of cross-plane ferroelectric switching in BiFeO₃ on charge ordering in La_{0.5}Ca_{0.5}MnO₃, and hence the electronic and magnetic properties of La_{0.5}Ca_{0.5}MnO₃ near the interface. We discuss our results and implications.

1:15PM J9.00009 Promise of new multiferroics: Synthesis and characterization of epitaxial NiTiO₃ films, TAMAS VARGA, EMSL at PNNL, Richland, WA, TIMOTHY DROUBAY, PNNL, Richland, WA, MARK BOWDEN, EMSL at PNNL, Richland, WA, SCOTT CHAMBERS, PNNL, Richland, WA, BERND KABIUS, WILLIAM SHELTON, PONNUSAMY NACHIMUTHU, VAITHIYALINGAM SHUTTHANANDAN, EMSL at PNNL, Richland, WA, EMSL INTRAMURAL TEAM — In a search for new multiferroic materials where the direction of magnetization can be switched by an applied electric field, we have looked for materials in which polarization and magnetization are strongly coupled. Recent theory calculations predicted that the family of compounds MTiO₃ (M = Mn, Fe, Ni), in a certain polymorphic structure (acentric *R3c*), are promising candidates where a polar lattice distortion can induce weak ferromagnetism. Guided by these insights, a rhombohedral phase of NiTiO₃ has been prepared in epitaxial thin film form, whose structure is very close to that predicted to be a multiferroic. The synthesis of such new epitaxial films, their full structural characterization and physical property measurements along with our first-principles DFT calculations to predict the desired NiTiO₃ structure and its stability are reported.

1:27PM J9.00010 Structural Control of Magnetic Anisotropy in a Multiferroic EuTiO₃ Thin Film, J.W. FREELAND, Argonne National Laboratory, X. KE, Oak Ridge National Laboratory, P.J. RYAN, J.W. KIM, J.-H. LEE, Argonne National Laboratory, R. MISRA, P. SCHIFFER, Pennsylvania State University, T. BIROL, C.J. FENNIE, D.G. SCHLOM, Cornell University — Strain control of EuTiO₃ has been shown under tensile strain the system converts to a multiferroic groundstate with ferromagnetic and ferroelectric order[1]. Here we present a study of the magnetic order in thin films of EuTiO₃ grown on DyScO₃(110) substrates by reactive molecular-beam epitaxy (MBE). Neutron scattering and magnetic measurements show the magnetic moment orders with an easy axis along only one of the (110) pseudocubic axis of the unit cell. Such an easy axis is connected to the uniaxial crystal structure that evolves from cubic to tetragonal with octahedral tilting, which agrees well with the strain dependent structure predicted under biaxial tensile strain. The magnetic anisotropy for Eu is attributed to an asymmetric crystal field due to the uniaxial symmetry of the Eu-O coordination. Work at Argonne, including the Advanced Photon, is supported by the U.S. Department of Energy, Office of Science, and Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357. [1] J.-H. Lee et al. Nature 466, 954 (2010).

1:39PM J9.00011 Growth and Optical Properties of Multiferroic LuFe₂O₄ Thin Films, R.C. RAI, A. DELMONT, A. SPROW, Department of Physics, SUNY College at Buffalo, NY 14222, B. CAI, M. NAKARMI, Department of Physics, Brooklyn College and Graduate Center of the CUNY, Brooklyn, NY 11210 — We present surface, structural, electronic, and optical properties of multiferroic LuFe₂O₄ thin films grown on single crystal (0001) sapphire, (111) YSZ, and (001) LiNbO₃ substrates using electron-beam deposition. LFO thin films have been deposited on substrates at temperature 750 °C in an oxygen environment and post-deposition annealed at temperatures ranging from 600 to 800 °C to improve the stoichiometry and the crystal quality. We have used AFM and XRD for surface and structural characterization of the LFO thin films. To investigate the charge order phenomenon and the electronic properties, we carried out variable temperature (78 – 450 K) optical and resistivity measurements on the LFO thin films. The absorption spectra of LFO thin films show strong electronic excitations with the energy gap of ~2.18 eV at 300 K. Further, the energy gap of LFO displays strong temperature dependence, exhibiting a ferrimagnetic transition at ~240 K and a charge-order transition at ~350 K, respectively. We will also discuss the electronic excitations of the LFO thin film in the energy range 0.5 – 5.0 eV and their correlations with different magnetic and charge-ordered states.

1:51PM J9.00012 Exchange bias in BiFeO₃/CoFe₂O₄ heterostructure, YONGHANG PEI, Physics Department, University of Virginia, JIWEI LU, RYAN COMES, Department of Materials Science and Engineering, University of Virginia, STUART WOLF, Physics Department, University of Virginia — Room temperature multiferroics BiFeO₃ (BFO), both ferroelectric and antiferromagnetic, has been extensively investigated as a part of exchange bias structures since it promises the electrical field control over the exchange bias. This work focuses on the exchange interaction between ferromagnet CoFe₂O₄ (CFO) and BFO. Bilayer films CFO and BFO were first grown on SrTiO₃ (STO) by Pulsed Electron Deposition (PED) and then field cooled in magnetic field. XRD showed single phase CFO and BFO were grown epitaxially on STO single crystal substrates, and the typical thickness was 21nm for BFO and 3.6~18nm for CFO. In the bilayer structure, we observed that the coercive field increased 100% at 300K and 30 % at 50K, comparing to these of CFO single layer. Also in the bilayer structure, a noticeable exchange bias field (Hex) increased from ~30 Oe at 300 K to ~ 60 Oe at 50 K. We will discuss the impact of the film thickness and the roughness of interface on exchange bias.

2:03PM J9.00013 Magnetic and ferroelectric properties of patterned multiferroic CoFe₂O₄-BiFeO₃ nanocomposites¹, RYAN COMES, University of Virginia, Department of Materials Science and Engineering, MIKHAIL KHOKHLOV, Guilford College, HONGXUE LIU, JIWEI LU, STUART WOLF, University of Virginia, Department of Materials Science and Engineering — CoFe₂O₄ (CFO) offers unique properties as a magnetoelectric material due to its large magnetoelastic response when strained. Previous work has shown that when CFO is co-deposited with BiFeO₃ (BFO) nanostructured phase segregation occurs with CFO pillars forming in a BFO matrix and electrical control of the magnetic anisotropy is possible.[1] Such a system offers unique possibilities for an electrically-controlled spintronic logic scheme.[2] We have recently demonstrated the ability to control the location of the CFO pillars in CFO-BFO nanocomposites using e-beam lithography patterning of uniform CFO films grown on Nb-doped SrTiO₃. Square arrays of pillars with spacings as small as 100 nm have been grown in nanocomposites using pulsed electron deposition. Piezoresponse force microscopy (PFM) measurements show clear ferroelectric response in the BFO matrix. The out-of-plane piezoelectric response, d_{33} , has been measured via PFM within the BFO matrix and is in good agreement with published results for BFO. Magnetic force microscopy (MFM) shows in-plane magnetic anisotropy in the pillars due to compressive in-plane strain. [1] F. Zavaliche, et al. *Nano Lett.* **7** (2007). [2] S.A. Wolf, et al. *Proc. IEEE* **98** (2010).

Session J10 DCOMP: Invited Session: How Reliable are Computed Electronic Properties? 210A

11:15AM J10.00001 Validation of Atomic, Molecular and Condensed Matter Calculations, ERIC SHIRLEY, NIST — The advances in calculational techniques have brought first-principles calculations to a state of frequently having their results for various physical properties agreeing well with measured results for the same properties. Validation of computational results can therefore be an important undertaking in the overall scheme of first-principles work. Along these lines, such validation does not refer to the appropriateness of approximations made in calculations which are necessary to have a practicable methodology. Rather, such validation refers to whether calculations are implemented correctly given whatever approximations one assumes. Three areas are to be discussed in turn to illustrate issues that may arise. These include density-functional total-energy calculations in atoms and ions, in which as many as four atomic-structure programs were tested (and corrected) to permit reasonably high-precision comparisons of results. Second, calculations of dielectric properties and excitation spectra of solids shall be discussed, to illustrate the myriad of choices one might be required to make in terms of approximations, and how various approximations' results can only be compared if numerical methodologies used in conjunction with the respective approximations are sufficiently similar. Third, as a point of reference, brief consideration shall be given to the progress in the calculational validation area made within the quantum chemistry community.

11:51AM J10.00002 New Tools for the Verification and Validation of Electronic Structure Calculations¹, FRANCOIS GYGI, Department of Computer Science, University of California Davis, Davis CA 95616 — First-principles electronic structure calculations are playing an increasingly important role in the prediction of materials properties and in the interpretation of experimental data. Numerous simulation codes including various levels of approximations and various numerical approaches are now readily available to users. The complexity of first-principles calculations and the large number of input parameters needed in a simulation make it challenging to obtain high quality, reproducible data. Results obtained with different electronic structure codes are difficult to compare as they involve a multitude of data formats, making the process of verification and validation (V&V) of electronic structure data complex and error prone. In order to facilitate V&V activities, we have introduced ESTEST [1,2], a web-based framework that allows for automatic comparison and post-processing of results obtained with six electronic structure codes. Recent developments make it possible to extend this functionality to a decentralized network of servers. We discuss general issues related to the process of verification and validation of electronic structure data and outline requirements for the development of future V&V tools.

12:27PM J10.00003 Single-electron excitations of molecules and solids — reliability and robustness of density-functional theory and *GW* calculations, MATTHIAS SCHEFFLER¹, Fritz-Haber-Institut der MPG — State-of-the-art theory addresses single-electron excitations in molecules and condensed matter by linking density-functional theory (DFT) with many-body perturbation theory. Experimentally such results correspond to measurements by direct or indirect photoemission. In actual calculations it is common to employ the pseudopotential approach, where pseudo-wave-functions enter the calculation of the selfenergy, and the core-valence interaction is treated at the DFT level. Furthermore, calculations are typically not done selfconsistently but as a first-order perturbation on some starting point. The latter may be DFT with LDA, GGA, LDA+*U*, HF, or hybrid functionals. Unfortunately, these different starting points can give noticeably different results. In this talk I will evaluate the various approximations, by comparing and analyzing pseudopotential and all-electron calculations. I will also emphasize the need for selfconsistency either by an iterative solution of the Dyson equation or by properly adjusting the zero-th order exchange-correlation functional.

1:03PM J10.00004 Role of Validation and Predictions in Modeling: Specific Examples from Semiconductor Industry Applications, SADASIVAN SHANKAR, Intel Corporation Santa Clara, California, USA — With the advent of newer non-Silicon materials, using modeling to estimate properties are becoming necessary for process technology development. Since these materials are integrated as part of larger devices, interfaces and material domains are increasingly modulating properties of materials. Unlike in bulk materials, electronic and thermodynamic properties are difficult to characterize in these material structures as the device sizes overlap with material domains. We will illustrate specific cases from semiconductor processing and property estimation on the importance of verification of models for internal consistency and validation with experimental data. Given the discrepancy of scales between predictions and measurement, techniques need to bridge them. In addition, models that are developed need to be modular with open interfaces for cross-checking and integration across scales as indicated in the recently announced Materials Genome Initiative.

Tuesday, February 28, 2012 11:15AM - 2:15PM —

Session J11 DMP: Focus Session: Graphene Structure, Stacking, Interactions: Density Functional Theory 210B

11:15AM J11.00001 Electronic structure, electron-phonon coupling and superconductivity in metal-doped few-layer graphene, SERDAR OGUT, University of Illinois at Chicago, XUHUI LUO, University of Illinois at Chicago & National Institute of Standard and Technology, TANER YILDIRIM, National Institute of Standard and Technology & University of Pennsylvania — We systematically investigate from first-principles how the electronic properties and electron-phonon (el-ph) coupling change in metal (Ca, Li) doped graphene as we tune the number of graphene layers from single layer to three layers and to the case of bulk graphite. We find that the Fermi level and el-ph constant can be tuned by the number of layers. In particular, the number of graphene layers has a large effect on the inter-layer metal free-electron-like states, which give rise to large el-ph constant in these systems. Surprisingly, the el-ph coupling in Ca intercalated tri-layer graphene system is stronger than one in the superconducting Ca-doped graphite. Our results suggest the possibility of high T_c superconductivity in metal doped few-layer graphene for nanodevice applications.

11:27AM J11.00002 First-principles investigation of lithium doped of bilayer graphene and Lithium Intercalated Carbon Nanotubes, OGUZ GULSEREN, HUSEYIN SENER SEN, Bilkent University — We have performed first-principles calculations based on density-functional theory for understanding of the structural and electronic properties of Li doped bilayer graphene and Li intercalated CNTs especially addressing the controversial charge transfer state between Li and C. We have checked the possible adsorption, substitution and intercalation of Li by using a bilayer graphene system both with AB stacking (12 different initial configurations) and AA stacking (8 different initial configurations). All calculations are repeated both with LDA and GGA exchange-correlation potential, even though the values of binding energies are different, their order and corresponding physical picture are same from both of the functionals as well as the stackings. In conclusion, we can summarize that Li prefers the hollow site adsorption geometry and it prefers intercalation but not the substitution. In these adsorption modes, almost 0.9 electron of Li atom is transferred to neighboring carbon atoms network leaving positively charged core behind.

11:39AM J11.00003 Ab Initio Study of the Interactions between Dopant Atoms in Graphene¹, IGOR VASILIEV, NABIL AL-AQTASH, TAREK TAWALBEH, KHALDOUN AL-TARAWNEH, New Mexico State University — We present a first-principles computational study of the interactions between the boron (B) and nitrogen (N) dopant atoms in graphene. Our calculations are carried out using density functional theory combined with the generalized gradient approximation for the exchange-correlation functional. The total energies, equilibrium geometries, electronic charge distributions, and densities of states of doped graphene sheets are examined in cases of B-B, N-N, and B-N co-doped graphene. We find the B-B and N-N interactions to be repulsive and the B-N interaction to be attractive. In all cases studied, dopant-dopant interactions appear to have a relatively short range. The interaction energy between the two dopant atoms is found to be inversely proportional to the square of the separation distance. We interpret these results in terms of structural relaxation and electronic charge transfer.

¹Supported by NSF CHE-1112388.

11:51AM J11.00004 Ab Initio Study of the Interactions between Dopant Atoms and Point Defects in Graphene¹, TAREK TAWALBEH, IGOR VASILIEV, New Mexico State University — We apply a first-principles computational method based on density functional theory to study the interaction of substitutional boron and nitrogen atoms with Stone-Wales defects and vacancies in graphene. Our calculations are carried out using a pseudopotential technique combined with the generalized gradient approximation for the exchange-correlation functional implemented in the SIESTA electronic structure package. Graphene sheets are modeled by periodic supercells containing up to 160 atoms. The equilibrium geometries, total energies, electronic structures, and densities of states of doped and defective graphene sheets are examined as a function of the separation distance between dopant atoms and point defects in graphene. The results of our study demonstrate the presence of attractive interaction between dopant atoms and point defects in graphene. The interaction energy decreases rapidly with increasing the dopant-defect separation distance.

¹Supported by NSF CHE-1112388.

12:03PM J11.00005 Many-body study of cobalt adatoms adsorbed on graphene¹, YUDISTIRA VIRGUS, WIRAWAN PURWANTO, HENRY KRAKAUER, SHIWEI ZHANG, College of William and Mary — Interest in the adsorption of transition metal adatoms on graphene has grown rapidly. The interaction between magnetic adatoms and graphene may have applications in designing spintronics devices. Several theoretical and experimental studies have examined Co adatoms on graphene. Calculations of Co-graphene systems have largely been done at the density functional theory (DFT) level, with local or semi-local functionals and with an empirical Hubbard on-site repulsion U (LDA+ U). We use auxiliary-field quantum Monte Carlo (AFQMC), in combination with DFT and quantum chemistry methods, to examine the effects of electron correlation in Co-graphene systems, without adjustable parameters. Binding energy curves for Co-graphene and model structures will be presented, and their implications on the electronic and structural properties will be discussed.

¹DOE, ONR, and NSF

12:15PM J11.00006 Adsorption of group VA atoms in single and double vacancy of graphene, SHYAM KATTEL, BORIS KIEFER, Physics Department, New Mexico State University, PLAMEN ATANASSOV, Chemical and Nuclear Engineering Department, University of New Mexico — Dopants can greatly affect the electronic structure of graphene. In this study we report on the effect of group VA elements associated with single vacancy (SV) and double vacancy (DV) on the electronic structure of graphene. The results of our density-functional-theory (DFT) computations predict strong and exothermic chemisorption of group VA atoms to SV and DV in graphene ($M@SV/DV$, where $M=N, P, As, Sb, \text{ or } Bi$) which leads to large, systematic and diverse effects on its electronic structure. We find that $N@SV$ has a small band gap below Fermi level (E_F) and $P@SV$ has semiconducting and magnetic properties consistent with previous studies. Our preliminary band structure computations show that $As@SV$ induces $\sim 100\%$ spin polarization close to E_F while $Sb@SV$ and $Bi@SV$ are metallic. In contrast, $N@DV$ has a large spin polarization near E_F while all other DV defects are predicted to be metallic. These results suggest that especially $As@SV$ and $N@DV$ may have interesting applications in spintronics and nanoelectronics.

12:27PM J11.00007 ABSTRACT WITHDRAWN —

12:39PM J11.00008 Stability and electronic structure of the functionalized graphene layers¹, JACEK A. MAJEWSKI, KAROLINA MILOWSKA, MAGDALENA BIROWSKA, MAGDALENA WOJNSKA, University of Warsaw — We present results of extensive ab initio calculations in the framework of the density functional theory of the graphene layers (GLs) doped with nitrogen and boron, and also functionalized with simple OH, COOH, NH_n , and CH_n molecules. We calculate binding energies, heat of formation, resulting local deformations (characteristic sp^3 rehybridization of the bonds induced by fragments), electronic structure, elastic properties (Young's modulus and Poisson ratio), and conductance of doped and functionalized GLs as a function of the density of the functionalizing systems. Generally, the stability of the functionalized graphene layers decreases with the growing concentration of functionalizing molecules and we determine the critical density of the molecules that can be chemisorbed on the surface of GLs. We find out that the GLs functionalization leads in many cases to the opening of the graphene band gap and can be therefore utilized in graphene devices. In particular, the zero band gap in K-point of the pristine single GL increases to 0.11, 0.12, 0.25, and 0.24 eV for the GL functionalized with OH, NH, NH_2 , and COOH, respectively.

¹The studies were carried out within the SiCMAT Project financed under the European Funds for Regional Development (Contract No. UDA-POIG.01.03.01-14-155/09).

12:51PM J11.00009 Band Structures of bilayer graphene with experimentally measured twisting angles, HOULONG L. ZHUANG, Department of Materials Science and Engineering, Cornell University, ROBIN W. HAVENER, School of Applied and Engineering Physics, Cornell University, JIWOONG PARK, Department of Chemistry and Chemical Biology, Cornell University, RICHARD G. HENNIG, Department of Materials Science and Engineering, Cornell University — Using density functional theory (DFT) and tight binding calculations, we study the band structure of bilayer graphene as a function of twisting angles and compare the results to spectroscopic measurements. To test the accuracy of DFT, we first compare the band structure with DFT and the G_0W_0 approximation for several bilayer graphene systems with special twisting angles. Our DFT results agree with previous DFT calculations for the weak coupling between the two layers and the band structure. Calculations of the quasiparticle dispersion using the G_0W_0 approximation show that DFT underestimates the Fermi velocity of bilayer graphene and the bandgap away from the K' point. Scaling of the DFT band structure by an empirical parameter that depends on the twist angle accounts for most of the difference between the DFT and the G_0W_0 approximation. Based on the G_0W_0 calculations, we fit a set of tight-binding parameters for the interlayer coupling Hamiltonian. Using this tight-binding model we study the band structure of bilayer graphene for twist angles that closely match experimental systems and have larger unit cells. The results of these band structure calculations explain the experimentally observed G band resonance in Raman spectroscopy for specific twist angles.

1:03PM J11.00010 From graphene to graphite: A first-principles study¹, BI-RU WU, Department of Nature Science, Center for General Education, Chang Gung University — The multilayer graphene and graphite are systematic studied via a first-principles method based on density functional theory and general gradient approximation. The hexagonal, Bernal and rhombohedral stacking types are considered. The total energy, the electronic structure and the strength of the multilayer graphene and graphite are analyzed to study the process of graphene to graphite. We predict the number of graphene multilayers shall be greater than 15 layers to behave as a graphite bulk.

¹This work was supported by the National Science Council of the Republic of China and Chang Gung University.

1:15PM J11.00011 Accurate computational studies of carbon doped two-dimensional boron-nitride¹, HYOUNGKI PARK, AMITA WADEHRA, JOHN W. WILKINS, Department of Physics, The Ohio State University, ANTONIO H. CASTRO NETO, Graphene Research Centre, National University of Singapore, Singapore and Department of Physics, Boston University — Advances in development of atomic-layer crystals with a plethora of new materials are greatly extending the range of possible applications of these two-dimensional (2D) materials. One of these materials is the hexagonal structure of boron nitride (h-BN). Hexagonal BN has a wide band gap and a lattice constant similar to that of graphene. We show that even small quantities of C atoms can offer new functionalities and transform h-BN to be an amazing playground for 2D physics. Large-scale accurate density-functional-theory calculations with the Heyd-Scuseria-Ernzerhof (HSE) hybrid functional reveal the electronic and the magnetic properties of h-BN with substitutionally embedded carbon atoms. Results of local magnetic moments induced by substitution and their interactions are presented for low C concentrations. We also show the electronic structures of quantum dots made of carbon nano-domains for applications in optics and opto-electronics.

1:27PM J11.00012 Electronic and Structural Properties of Graphene Dots in h-BN, ZHAOHUI HUANG, JAMES CHELIKOWSKY, University of Texas at Austin — A major challenge for graphene-based applications is the creation of a tunable electronic band gap as would be present for traditional semiconductor alloys. Since hexagonal boron nitride has a very similar structure to graphene, it is a natural candidate to modify the electronic structure of graphene by forming a hybrid phase sheet containing domains of graphene and hexagonal boron nitride, as has been done experimentally. Here we investigate the properties of such hybrid sheets by using pseudopotential-density functional theory implemented in real space. We find for a graphene dot comparable in size to those observed in experiment, the band gap of the sheet is not significantly modified. Moreover, when the size of graphene dot decreases below $\sim 13\text{\AA}$, strong structural instabilities of the graphene domain occur.

1:39PM J11.00013 Hybrid density functional study of 2D graphene-boron nitride (BCN) nanostructures¹, AMITA WADEHRA, HYOUNGKI PARK, JOHN W. WILKINS, The Ohio State University, ANTONIO H. CASTRO NETO, Graphene Research Centre, National University of Singapore and Boston University — Graphene has attracted enormous research interest in the last few years because of its intriguing physics as well as application potential. Recent synthesis of BCN nanostructures by doping graphene with a wide bandgap insulator boron nitride (BN) has unveiled new possibilities for this material [1]. BCN nanostructures are semiconductors and possess interesting properties that are distinct from the parent compounds. Reliable theoretical estimates can predict the feasibility and usefulness of still largely unexplored BCN nanostructures, and provide a route to engineer their properties. We study electronic structures of a variety of 2D BCN nanostructures using hybrid functional HSE in density functional theory (DFT). We show that their properties can be gradually tuned and are sensitive to composition and the type of configurations. In agreement with experimental observation, a strong tendency to phase-segregate exists for low concentration of BN in graphene. We also investigate magnetic properties of graphene containing substitutional nitrogen atoms, and their suitability for magnetic devices.

1:51PM J11.00014 First-principles and Tight-binding Investigations of Graphene-like Systems¹, X.W. SHA, E.N. ECONOMOU, D.A. PAPACONSTANTOPOULOS, George Mason University, M. PEDERSON, M.J. MEHL, Naval Research Laboratory, M. KAFESAKI, University of Crete — We have performed first-principles calculations of graphene-like systems with large unit cells of the order of 100 atoms. These are mostly quasi-circular pieces of graphene with or without hydrogen atoms to passivate dangling bonds. We have also introduced nitrogen replacements of carbon atoms to explore possibilities of creating a quantum-mechanical analog of the split-ring resonator used in negative refractive index metamaterials. In addition, vibrational spectra were calculated to check the stability of the small flakes. Furthermore, we have used the NRLMOL DFT code with extensions to treat an AC magnetic field coupled to spin and orbital moments. We simulate the graphene-like system to a circuit model to show the cancellation of individual loop currents and the emergence of an edge ballistic current. A tight-binding Hamiltonian was fitted to our NRLMOL results using the NRLTB method. The TB approach starts with an exact fit to the benzene molecule and the resulting TB parameters are transferable to the larger molecules matching well the HOMO-LUMO gap found by the DFT. The NRLTB scheme allows to calculate the electronic spectra of much bigger systems, and examples with results for systems with more than a thousand atoms will be presented.

2:03PM J11.00015 Quasiparticle Band Gaps of Graphene and Graphene on Hexagonal Boron Nitride Substrate, NEERAV KHARCHE, SAROJ NAYAK, Computational Center for Nanotechnology Innovations, Department of Physics, Rensselaer Polytechnic Institute — Graphene holds great promise for post-silicon electronics; however, it faces two main challenges: opening up a band gap and finding a suitable substrate material. Graphene on hexagonal boron nitride (hBN) substrate provides a potential system to overcome these challenges. While theoretical studies suggested a possibility of a finite band gap of graphene on hBN, recent experimental studies find no band gap. We have studied graphene-hBN system using the first-principles density functional method and the many-body perturbation theory within GW approximation [1]. A Bernal stacked graphene on hBN has a band gap on the order of 0.1 eV, which disappears when graphene is misaligned with respect to hBN. The latter is the likely scenario in realistic devices. In contrast, if graphene supported on hBN is hydrogenated, the resulting system (graphene) exhibits band gaps larger than 2.5 eV. The graphene band gap is due to chemical functionalization and is robust in the presence of misalignment, however, it reduces by about 1 eV due to the polarization effects at the graphene/hBN interface.

Session J12 DMP: Focus Session: Graphene: Growth, Mechanical Exfoliation, and Properties
- Strain and Structure 210C

11:15AM J12.00001 Growth-induced electronic properties of epitaxial graphene¹, PHILLIP FIRST, School of Physics, Georgia Institute of Technology — The growth of epitaxial graphene on silicon carbide is challenging to understand and control, yet rife with scientific and technological opportunities. This is due in part to different growth-induced structures such as the “moiré” alignment of graphene layers in multilayer epitaxial graphene on SiC(0001) and the formation of sidewall ribbons at natural and lithographically-defined SiC(0001) step-bunches (nanofacets). We apply scanning tunneling microscopy (STM) and spectroscopy (STS) to probe the local energy bands of such growth-induced structures. STS at cryogenic temperatures and large magnetic fields creates a comb of discrete Landau level energies that we use to quantitatively characterize the local electronic properties.

¹Work done in collaboration with NIST-CNST; supported by NSF and NRI-INDEX.

11:51AM J12.00002 Colossal Corrugations in Freestanding Graphene Observed with STM¹, P.M. THIBADO, P. XU, Y. YANG, S.D. BARBER, M.L. ACKERMAN, J.K. SCHOELZ, SALVADOR BARRAZA-LOPEZ, L. BELLAICHE, Department of Physics, University of Arkansas, IGOR A. KORNEV, Propriétés et Modélisation des Solides, France — The discovery of graphene, a unique two-dimensional electron system with extraordinary physical properties, has ignited tremendous research activity in both science and technology. Graphene interactions with a substrate, such as SiO₂/Si, are known to significantly degrade the electrical performance of graphene devices. Alternatively, suspending a graphene device eliminates the substrate interaction, thereby yielding a 10-fold increase in mobility. However, a detailed investigation on the microscopic scale explaining the origin of these improvements has yet to be completed. In this talk, we present for the first time atomic-resolution STM images of a freestanding graphene membrane. Samples were prepared by direct CVD growth and by large graphene sheet transfer, both onto a 2000-mesh copper grid. Atomic-scale corrugation amplitudes were observed in perfect registry with, yet 50 times larger than the expected electronic corrugations. Density functional theory revealed that charge localization occurs directly beneath the STM tip due to bond angles rotating away from sp² hybridization as graphene flexes in response to the electrostatic attraction. A detailed model of the 3-way interaction which accounts for the observed behavior will be discussed.

¹Support provided by ONR N00014-10-1-0181, N00014-08-1-0915, NSF 0855358, 0701558, DoE 46612.

12:03PM J12.00003 Melon: A carbon-nitride analog to graphene, JOEL THERRIEN, YANCEN LI, ECE U. Mass Lowell, DANIEL SCHMIDT, Plastics Eng U Mass Lowell — Although graphene remains the premier 2-D material, many others have been shown to exist. A close analog to graphene would be a two-dimensional sheet composed of carbon and nitrogen, known as melon. Bulk melon, also known as graphitic carbon-nitride, has been successfully synthesized and shown to be an organic semiconductor with a band-gap around 2.7 eV. We report on the successful synthesis of single layer and few layer melon. The physical and electrical characteristics of this close cousin to graphene will be presented along with the synthesis method.

12:15PM J12.00004 AB-stacked multilayer graphene synthesized via chemical vapor deposition: a characterization by hot carrier transport, DEBTANU DE, CARLOS DIAZ-PINTO, Department of Physics and the Texas Center for Superconductivity, University of Houston, Houston, Texas 77204, VIKTOR HADJIEV, The Texas Center for Superconductivity, University of Houston, Houston, Texas 77204, HAIBING PENG, Department of Physics and the Texas Center for Superconductivity, University of Houston, Houston, Texas 77204 — We report the synthesis of AB-stacked multilayer graphene via ambient pressure chemical vapor deposition on Cu foil. Four-terminal devices were fabricated from such graphene and characterized by hot carrier transport at temperatures down to 240 mK and in magnetic fields up to 14 T. The differential conductance (dI/dV) shows a characteristic dip at longitudinal voltage bias $V=0$ at low temperatures, indicating the presence of hot electron effect due to a weak electron-phonon coupling. Under magnetic fields, the magnitude of the dI/dV dip diminishes through the enhanced intra-Landau level cyclotron phonon scattering. Our results provide new perspectives in obtaining and understanding AB-stacked multilayer graphene, important for future graphene-based applications.

12:27PM J12.00005 Signatures of indentation strain in graphene conductance, MATTHEW BARR, MARIO BORUNDA, ERIC HELLER, Harvard University — We investigate effects on the conductance of a graphene sheet of electron scattering from a localized indentation. Strain in graphene creates effective magnetic fields, and the scattering from a radial strain profile is distinct from other short range scatterers. Through tight-binding calculations, we examine the expected conductance in several experimental geometries, including within graphene nano-ribbons and suspended graphene.

12:39PM J12.00006 Transport in Suspended graphene under strain, HANG ZHANG, JHAO-WUN HUANG, JAIRO VELASCO, DAVID DUNG TRAN, KEVIN MYHRO, ZENG ZHAO ADAM, FENGLIN WANG, YONGJIN LEE, WENZHONG BAO, CHUN NING (JEANIE) LAU, None — Suspended graphene devices with graphene flakes were fabricated using acid etching approach, and strained via application of gate voltage. The stretching procedure was observed and verified by in situ SEM imaging. We observe a change in the devices' minimum conductance and mobility values. Latest experimental results will be compared with theoretical models.

12:51PM J12.00007 Suppression of Weak-Localization Effect in Strained CVD -grown Graphene¹, XIAOCHANG MIAO, SEFAATTIN TONGAY, ARTHUR F. HEBARD, Department of Physics, University of Florida, Gainesville, FL 32611 — We investigate the magnetic field and temperature-dependent transport properties of CVD-grown graphene subjected to different strains. The graphene is transferred to kapton substrates to which a blending force can be applied. In zero magnetic field, the prefactor to the logarithmic-in-temperature conductivity correction decreases by an approximate factor of 3 for strains as high as 0.6 %. There is also a concomitant decrease in diffusivity by a factor of 7. At 5 K we observe negative magnetoresistance for fields up to 0.2 Tesla followed by positive magnetoresistance at higher fields. We attribute the low field negative magnetoresistance to weak-localization and find that it is well described by theory. The strains resulting from the applied blending force inhibit the intervalley scattering rate more than an order of magnitude, thereby leading to a suppression of weak-localization.

¹This work is funded by NSF and ONR.

1:03PM J12.00008 Probing Mechanical Properties of Chemical Vapor Deposition Graphene Membranes Using Indentation Methods, GWAN-HYOUNG LEE, Department of Mechanical Engineering, Columbia University, (And) Samsung-SKKU Graphene Center (SSGC), RYAN COOPER, SUNGJOO AN, AREND VAN DER ZANDE, NICHOLAS PETRONE, Department of Mechanical Engineering, Columbia University, SUNWOO LEE, Department of Electrical Engineering, Columbia University, ALEX HAMMERBERG, Department of Mechanical Engineering, Columbia University, CHANGGU LEE, Department of Mechanical Engineering, Sungkyunkwan University, BRYAN CRAWFORD, Nanomechanics Inc., JEFFREY KYSAR, JAMES HONE, Department of Mechanical Engineering, Columbia University — Recent experimental studies have shown that two-dimensional pristine graphene is the strongest material ever measured. We used Atomic Force Microscopy (AFM) and Agilent G200 nanoindenter to measure the mechanical properties of graphene films obtained by Chemical Vapor Deposition (CVD). CVD graphene with different grain size and number of layers were produced in controlled synthetic conditions and transferred onto silicon dioxide substrate with holes of various diameters. Nano-indentation measurement revealed that stiffness and fracture strength of CVD graphene membranes are similar to those of pristine graphene membranes under the condition that suspended graphene membrane is within a single grain boundary without defects. Furthermore, elastic modulus and fracture strength of multi-layer graphene membranes increase with respect to the number of layers.

1:15PM J12.00009 Electron transport measurement of graphene under one-dimensional local strain, A. KANDA, H. TOMORI, Y. NUKUI, Y. TOYOTA, H. KARUBE, S. NIHEI, University of Tsukuba and CREST-JST, Y. OOTUKA, University of Tsukuba, K. TSUKAGOSHI, MANA-NIMS and CREST-JST, M. HAYASHI, Akita University, H. YOSHIOKA, Nara Women's University — Introducing a nonuniform strain is a promising technique for controlling electron transport in graphene. Theories have predicted the formation of band gaps with properly designed strain; however, reports on experimental transport properties of strained graphene are quite limited. In this presentation, we report the measurement of electron transport in graphene under one-dimensional local strain. The local strain was introduced by inserting a one-dimensional dielectric nanorod between a graphene film and its substrate, using a technique reported in [1]. We found that the conductivity across the strained region decreases around the Dirac point in comparison with the unstrained graphene attached to the substrate, although the mobility far from the Dirac point is almost unchanged. The results cannot be explained by the change of the capacitance between the graphene film and the gate electrode, indicating that the strain affects the electron transport. The experimental results on strained and unstrained graphene devices from the same graphene film as well as the numerical results will be discussed.

[1] H. Tomori *et al.*, Appl. Phys. Express 4, 075102 (2011).

1:27PM J12.00010 Introducing designed local strain to graphene using dielectric nanostructures, H. TOMORI, A. KANDA, H. GOTO, Y. NUKUI, Y. TOYOTA, H. KARUBE, S. NIHEI, University of Tsukuba and CREST-JST, Y. OOTUKA, University of Tsukuba, K. TSUKAGOSHI, MANA-NIMS and CREST-JST, M. HAYASHI, Akita University, H. YOSHIOKA, Nara Women's University — Strain engineering is a promising method for controlling electron transport in graphene. In this presentation, we report a simple and easy method for inducing designed local strain in graphene films [1]. Nanostructures made of a dielectric material (electron beam resist) are placed between graphene and the substrate, and graphene sections between nanostructures are attached to the substrate. The strength and spatial pattern of the strain can be controlled by the size and the separation of nanostructures. Application of strain is confirmed by the Raman spectroscopy as well as from scanning electron microscope (SEM) images. The Raman 2D peak shows spatially nonuniform downshift, which corresponds to the positions of the resist nanostructures. From SEM images, the maximum stretch of the graphene film reaches about 20%. This technique can be applied to formation of band gaps in graphene.

1:39PM J12.00011 ABSTRACT WITHDRAWN —

1:51PM J12.00012 Mechanical-Electric-Magnetic Coupling Effects in Black and White Graphenes, WANLIN GUO, Key Lab of Intelligent Nano Materials and Devices of MOD, Institute of Nano Science, Nanjing University of Aeronautics & Astronautics — Nanoscale multifield couplings can turn very common materials such as carbon and boron nitride into promising functional materials for many device applications. We recently found that the magnetism in graphene nanoribbons on silicon substrates can be tuned linearly by applied bias voltage (*Phys.Rev.Lett.* **103**, 187204, 2009), and this novel magnetoelectric effect is robust to material and geometry variations. Adsorbed graphene nanoribbons can also create tunable magnetism on silicon surface (*Phys.Rev.B* **82**, 235423, 2010). Strain tunable magnetism has also been found in defect graphene (*ACS Nano* **4**, 2124, 2010; *Phys. Rev. B* **82**, 085425, 2010). Contrast to the zero-gap graphene, Hexagon-BN layers (white graphene) and rolled-up nanotubes are generally insulating, we show that the wide gap in them can be tuned into semiconducting range, even closed in BN nanoribbons by electric fields and narrowed by reduced tube diameter or local curvature radius (*Nano Lett.* **10**, 5049, 2010; *Phys. Rev. B* **82**, 035412, 2010). What is more, our recent experiments have demonstrated that flow-induced-voltage in graphene can be 20 folds higher than in graphite (*Appl.Phys.Lett.* **99**, 073103 (2011)). Such extraordinary mechanical-electric-magnetic coupling effects in graphene and BN systems open up new vistas in functional devices compatible with silicon-based technology for efficient energy conversion and novel functional systems.

Tuesday, February 28, 2012 11:15AM - 2:15PM –
Session J13 DMP GMAG: Focus Session: Magnetic Nanostructures - Thin Films, Surfaces and Interfaces 211

11:15AM J13.00001 A Symmetry Microscope for Disordered Materials, DANIEL PARKS, Department of Physics, University of Oregon, KEOKI SEU, Advanced Light Source, Lawrence Berkeley National Lab, RUN SU, Department of Physics, University of Oregon, ERIC FULLERTON, ERIK SHIPTON, Electrical and Computer Engineering, UC San Diego, SUJOY ROY, Advanced Light Source, Lawrence Berkeley National Lab, STEVE KEVAN, Department of Physics, University of Oregon — We use position-resolved coherent speckle patterns in concert with rotational x-ray autocorrelation analysis to uncover “hidden” ordering at specific length scales in labyrinthine magnetic domains. Central to this measurement is understanding how finite-size effects influence the statistics of rotational cross-correlations. To this end, we present numerical simulations of domain configurations whose speckle patterns display rotational ordering similar to experimental candidates, and examine how the real-space structure of ordered and disordered domains differs. In a scanning measurement, we observe what appears to be an island of ordering in an otherwise disordered perpendicular magnetic thin film.

11:27AM J13.00002 New Magnetic State In Thin-Film Antiferromagnets and Uncompensated Magnetization¹, IGOR V. ROSHCIN, K.E. BADGLEY, Texas A&M University, K.D. BELASHCHENKO, University of Nebraska-Lincoln, MIKHAIL ZHERNENKOV, MICHAEL R. FITZSIMMONS, Los Alamos National Laboratory — We observe a new magnetic state, for which the origin ($M(H=0)=0$ point) is outside the major hysteresis loop, which means that zero magnetization at zero applied field cannot be reached isothermally. We observe this in antiferromagnet-only, (110)-FeF₂ grown on MgF₂ samples. The surface is responsible for the macroscopically broken time-reversal symmetry, uncompensated magnetization (UM) in a nominally compensated antiferromagnet, and, ultimately, for the new magnetic state. We argue that it is an equilibrium state. Magnetometry and polarized neutron reflectivity (PNR) measurements indicate that the UM is present in this AF. We report rather unusual properties of this UM, including the “intrinsic exchange bias.” While its manifestation in a shift of the hysteresis loop is similar to that of the “classical” exchange bias observed in bilayers, here, it is observed in a single layer material. We discuss the implications of the origin of the UM on the exchange bias mechanism.

¹Work is supported by Texas A&M University, TAMU-CONACYT Collaborative Research Program, DOE.

11:39AM J13.00003 Existence of Ferromagnetism in Stacked Bilayers of Pd/C₆₀¹, SIDDHARTHA GHOSH, SEFAATTIN TONGAY, ARTHUR F. HEBARD, Department of Physics, University of Florida, Gainesville, FL 32611 USA, HASAN SAHIN, SALIM CIRACI, UNAM-Institute of Materials Science and Nanotechnology, Bilkent University, 06800 Ankara, Turkey — We report on an experimental and theoretical study of the magnetic properties of multilayer structures fabricated by alternating layers of sputter-deposited Pd and thermally-sublimated C₆₀. Auger Electron Spectroscopy and SEM techniques have been used to characterize samples for which magnetic measurements in a commercially available SQUID have been made. The magnetization measurement reveals ferromagnetism in the Pd/C₆₀ system, which has Curie temperature $T_C \sim 450K$, modified Bloch coefficient $P \sim 2.7$ and a temperature-independent coercive field of 50 Oe. The observed ferromagnetism is surprising since both C₆₀ and Pd are non-ferromagnetic in the non-interacting limit. Density functional theory (DFT) calculations show that while the C₆₀ molecules are nonmagnetic unless polymerized, Pd films have a degenerate ground state that can become ferromagnetic with a weak perturbation. Though the calculated charge transfers of ~ 0.06 e between C₆₀ and Pd are not the cause of ferromagnetism, DFT shows that ferromagnetism can be associated with Pd clusters or an interaction of C₆₀ molecules with sharp edges of the Pd thin film.

11:51AM J13.00004 Spin-Wave Transmission in Ferromagnetic Thin Films: Flexoelectric Control and Spin-Wave Drag¹, TIANYU LIU, GIOVANNI VIGNALE, University of Missouri, Columbia, MICHAEL FLATTE, University of Iowa — Spin waves in insulating ferromagnets have recently emerged as an effective low-dissipation carrier of spin currents. In this work we explore a novel form of control of spin waves by *flexoelectric interactions*, which couple an electric field to the spatial gradient of the magnetization. We show that not only the short-wavelength exchange spin waves, but also the long-wavelength magnetostatic spin waves in a thin-film of magnetic insulator can be effectively controlled by an electric field. In fact, the relative electric-field-induced phase shift is even larger for magnetostatic spin waves than for exchange spin waves. We further show that spin waves in an insulating ferromagnetic film can excite a spin current in an adjacent conducting or insulating film, by way of long-ranged dipole-dipole interaction between the layers, in a magnetic analogue of the electronic Coulomb drag.

12:03PM J13.00005 Impact of preparation conditions on the magnetocaloric properties of Gd thin films, H.F. KIRBY, D.D. BELYEA, J.T. WILLMAN, University of South Florida, C.J. HENDRYX, Newsome High School, C.W. MILLER, University of South Florida — The impact of the deposition temperature and gettering were investigated on Ta(5nm)/Gd(30nm)/Ta(5nm) thin films' magneto caloric(MCE) properties. The samples were grown by magnetron at temperatures up to 600 °C, with and without gettering. Structure of the samples was investigated by X-ray diffraction and ray reflectivity. The isothermal magnetization of the samples was above and below the Curie temperature of the Gd. The entropy change associated with the second order phase was calculated from M(H,T) using the thermodynamic Maxwell. Increasing the deposition temperature generally improves entropy peak (magnitude, FWHM, and temperature of the peak), but leads to significant oxidation. The ungettered sample grown at 00 °C was purely GdO (111). Gettering the chamber by sputtering the walls of the chamber for 30 minutes prior to deposition this oxidation issue, and increased the relative cooling power RCP) of films grown at elevated temperatures. The RCP values of the sample set were increased by as much as 42% over ungettered. Supported by AFOSR and NSF.

12:15PM J13.00006 Chiral modulations in MnSi thin films, THEODORE MONCHESKY, ERIC KARHU, Dalhousie University, ULRICH RÖBLER, ALEXEI BOGDANOV, Institut für Festkörper- und Werkstoffforschung Dresden, SAMER KAHWAJI, Dalhousie University, BRIAN KIRBY, NIST Center for Neutron Research, HELMUT FRITZSCHE, Canadian Neutron Beam Centre, Chalk River, MICHAEL ROBERTSON, Acadia University, CHARLES MAJKRZAK, NIST Center for Neutron Research — We present an investigation of the magnetic textures present in MnSi thin films grown on Si(111) by molecular beam epitaxy. The magnetic structure is investigated with SQUID magnetometry and polarized neutron reflectometry (PNR). For an out-of-plane magnetic field, a conical phase is formed with a reduced wavelength of $2\pi/Q = 13.9$ nm that has both left-handed and right-handed chirality due to the presence of inversion domains in the films. We show that the epitaxially induced tensile stress in the MnSi thin films creates an easy-plane uniaxial anisotropy. The magnetoelastic coefficient is obtained from SQUID measurements in combination with transmission electron microscopy and x-ray diffraction data. The agreement between density functional calculations of the coefficient with the experimental value support the conclusion that the uniaxial anisotropy originates from the magnetoelastic coupling. For an in-plane magnetic field, theoretical calculations based on a Dzyaloshinskii model that includes an easy-plane anisotropy predict a variety of modulations to the magnetic order that are not observed in bulk MnSi crystals. Evidence for these states is found in the SQUID and PNR measurements.

12:27PM J13.00007 Stabilization of surface magnetism by organic-acid adsorption¹, J. GÁZQUEZ, Instituto de Ciencia de Materiales Barcelona, Spain, J. SALAFRANCA, Universidad Complutense de Madrid, Spain, N. PÉREZ, A. LABARTA, Universitat de Barcelona, Spain, S.T. PANTELIDES, Vanderbilt University, TN, S.J. PENNYCOOK, Oak Ridge National Laboratory, TN, X. BATLLE, Universitat de Barcelona, Spain, M. VARELA, Oak Ridge National Laboratory, TN — Magnetically-disordered layers at the surface of nanoparticles and low dimensionality magnetic oxides significantly reduce the magnetization density with respect to bulk values. However, high crystal quality Fe₃O₄ nanoparticles capped with non-magnetic organic acid molecules display a surprisingly high magnetization, of unknown origin. Here, we present a real space structural, chemical and magnetic characterization of oleic-acid-capped Fe₃O₄ nanoparticles with nanometer resolution, demonstrating the presence of a strong magnetic surface layer. In combination with theoretical calculations, we establish the key role of the nanoparticle/organic-acid bond. Magnetization is restored in the surface layer because the bonding with the acid's O atoms partially lifts the surface reconstruction, resulting in surface O-Fe atomic configuration and distances close to the bulk values. Our findings have implications for the optimization of magnetic properties of nanoparticles and thin films.

12:39PM J13.00008 Surface Structure of L1₀-MnGa(111) Ultra-Thin Films Studied Using Scanning Tunneling Microscopy and First Principles Calculations¹, REYES GARCIA DIAZ, KANGKANG WANG, Ohio University Nanoscale and Quantum Phenomena Institute, NOBORU TAKEUCHI, Centro de Nanociencias y Nanotecnología, Universidad Nacional Autónoma de México, ARTHUR SMITH, Ohio University Nanoscale and Quantum Phenomena Institute — Manganese gallium alloys have drawn lots of attention recently for their many desirable properties such as high spin polarization and low damping terms. Furthermore, the magnetic properties depend sensitively on the Mn:Ga stoichiometry, ranging from ferromagnetic for MnGa, to ferrimagnetic for Mn₂₋₃Ga, and antiferromagnetic for Mn₃Ga, giving this material great magnetic tune-ability. In this talk, we will focus on the stoichiometric L1₀-structured MnGa(111) surface and study its atomic, electronic, and magnetic properties. Ultra-thin MnGa films (< 10 nm) are grown on GaN(0001) substrates using molecular beam epitaxy, and transferred *in-situ* to the analysis chamber for room-temperature scanning tunneling microscopy studies. Atomic resolution images reveal the existence of both 1×1 and 2×2 surface structures. We investigate these structures using periodic, spin-polarized density functional theory with the generalized gradient approximation (GGA), Vanderbilt ultra-soft pseudo-potentials, and a repeated slab geometry. The parameters are optimized to achieve the lowest-energy configuration. Results from these calculations and their comparison with the STM images will be reported.

¹Authors gratefully acknowledge support from the U.S. DOE and the NSF.

12:51PM J13.00009 Surface Ferromagnetism in Pt films, PUSHKAL THAPA, Dept. of Physics, Wayne State University, Detroit, MI 48201, USA, PARASHU KHAREL, Dept. of Physics, Univ. of Nebraska, Lincoln, Nebraska 68588, USA, RENAT SABIRIANOV, Nebraska Center for Materials and Nanoscience, Univ. of Nebraska, Lincoln, Nebraska 68588, USA, MOHAMMAD FAIZ, Dept. of Physics, Wayne State University, Detroit, MI 48201, USA, JULIE BORCHERS, NIST Center for Neutron Research, Gaithersburg, MD, 20899, USA, DAVID SELLMYER, Dept. of Physics and Astronomy, Univ. of Nebraska, Lincoln, Nebraska 68588, USA, BORIS NADGORNÝ, Dept. of Physics, Wayne State University, Detroit, MI 48201, USA — It has long been recognized that Pt as well as some other noble metals are on the verge of being magnetic, with ferromagnetism in these metals readily detected in nanoparticles. Here we report the observation of surface ferromagnetism in Pt thin films. Both sputtered and e-beam evaporated Pt films of various thicknesses (from 10 ~ 100 nm) have been studied. Detailed SQUID measurements indicate that the film magnetization is largely independent of its thickness. This result is consistent with the neutron scattering data, indicating the presence of a magnetic moment near the top Pt surface, and with the spin polarization measurements by point contact Andreev reflection spectroscopy, demonstrating a sizable spin polarization. Our experimental observations are supported by the first principle density functional calculations showing that certain configurations of Pt atoms on Pt (111) surface exhibit a magnetic moment of up to 1.1 μ_B per Pt atom. We argue that magnetism in this system is due to band narrowing, related to reduced coordination numbers of Pt atoms located at the surface.

1:03PM J13.00010 TiO₂ as an electrostatic template for epitaxial growth of EuO on MgO(001) by reactive molecular beam epitaxy, ADRIAN SWARTZ, JARED WONG, IGOR PINCHUK, ROLAND KAWAKAMI, UC Riverside — Interfacial electrostatics play a key role in determining epitaxial quality in the heteroepitaxy of ionic rock salt materials. We investigate the initial growth modes and the role of interfacial electrostatic interactions of EuO epitaxy on MgO(001) by reactive molecular beam epitaxy. A TiO₂ interfacial monolayer is employed to alleviate electrostatic interactions between the ions of the EuO and MgO to produce high quality epitaxial growth of EuO on MgO(001) with a 45 degree in plane rotation. For comparison, direct deposition of EuO on MgO, without the TiO₂ layer, is discussed. A key difference of EuO epitaxy on TiO₂/MgO is the ability to form EuO by substrate assisted oxidation and without the introduction of external oxygen to the interface. Such ultrathin films are shown to have bulk like magnetic properties

1:15PM J13.00011 Magnetic Thin Films of Inorganic Nanosheets, TAKASHI YAMAMOTO, HIROAKI NAMBA, YASUAKI EINAGA, Department of Chemistry, Keio University, JST-CREST TEAM — Molecule-based magnets have been fascinating materials because of the potential applications in information storage, electronic and spintronic devices. However, such applications would require arraying the active materials on a substrate or interfacing with other components. Here, we focus on fabricating multi-functional magnetic films using inorganic nanosheets as a building block. The thin films could be prepared by the modified Langmuir-Blodgett, LB, technique or the layer-by-layer, LbL, method, which are representative wet-processings for film preparation. As the magnetic LB film, we chose semiconductive titania nanosheets and magnetic Prussian Blue. Upon band gap excitation of titania nanosheets, electron injection into Prussian Blue was achieved with scavenging interlayer water molecules, leading to photoreduction to Prussian White. As the magnetic LbL film, we chose magnetic layered double hydroxide, LDH, nanosheets and non-magnetic smectite nanosheets. In powdered LDH, a coercivity increased with expanding the interlayer spacing. On the other hand, despite the larger interlayer spacing for the LbL film, a coercivity was less than that of the comparative powdered LDH. It is indicated LDH nanosheets are integrated in an anisotropic manner in the LbL films.

1:27PM J13.00012 Suppression and Revival of Magnetic Correlations at Interfaces, AXEL EUVERTE, FREDERIC HEBERT, GEORGE BATROUNI, Institut Non-Lineaire de Nice, SIMONE CHIESA, College of William & Mary, RICHARD SCALETTAR, UC Davis — We study a model of metal-insulator interfaces consisting of a multilayer, repulsive Hubbard Hamiltonian in which the interaction is nonzero on one set of layers and zero on another. As the interface hybridization is tuned, the magnetism and spectral functions in the correlated layers undergo an evolution in which the signatures of strong interaction are first reduced and subsequently revived due to the formation of an interfacial spin liquid phase. The penetration into the correlated layers of the suppression of magnetic order is found to be 4-6 layers.

1:39PM J13.00013 Effects of inhomogeneous strain on the magnetization behavior of magnetic nanostructures in $\text{BiFeO}_3/\text{CoFe}_2\text{O}_4$ composite, NICOLAS AIMON, MARK MASCARO, FRANK LIU, MIT DMSE, MARKUS BUEHLER, MIT Mechanical Engineering Department, CAROLINE ROSS, MIT DMSE — In $\text{CoFe}_2\text{O}_4/\text{BiFeO}_3$ (CFO/BFO) nanostructured thin films, where ferromagnetic nanopillars are embedded in a ferroelectric matrix, electric field induced rotation of the easy axis of the ferrimagnetic nanopillars has been demonstrated experimentally [Zavaliche et al. 2005]. However, for applications where the magnetic pillars would be used to store information, electric control of the magnetization has to be achieved at the scale of a single pillar, without disturbing the neighbors, and the effects of local strain on the magnetic reversal is therefore of interest. We carried out finite element simulations of the strain state of an arrangement of CFO pillars when the BFO matrix surrounding one of them is under piezoelectric strain. Because of stress relaxation at the top free surface of the thin film, the strain is highly inhomogeneous along the pillar. The position-dependent strain was imported into a micromagnetic simulation, giving a position-dependant magnetoelasticity, to predict the switching behavior of the CFO pillars and estimate the feasibility of electric control of a single magnetic bit in this system. The reversal of the pillars was found to be highly incoherent, showing that the pillars cannot be treated as a macrospin.

1:51PM J13.00014 Magnetic field dependencies of dielectric and ferroelectric properties in $\text{PbZr}_{0.52}\text{Ti}_{0.48}\text{O}_3/\text{La}_3/8\text{Ca}_5/8\text{MnO}_3$ multiferroic thin films, YI-PING YAO, YU-KUAI LIU, SI-NING DONG, XIAO-GUANG LI, University of Science and Technology of China — In this work, the temperature and magnetic field dependencies of dielectric and ferroelectric properties were investigated for $\text{Au}/\text{PbZr}_{0.52}\text{Ti}_{0.48}\text{O}_3/\text{La}_3/8\text{Ca}_5/8\text{MnO}_3$ (PZT/LCMO) thin films grown on (001)-oriented SrTiO_3 substrates. The results indicate there exists a large magnetodielectric effect up to 30% at $T = 220$ K, $f = 1$ MHz and $H = 0.8$ T in these multi-layer films, which is promising for practical application as compared with conventional multiferroics demanding large magnetic fields and low temperatures. From the electric polarization hysteresis loops, it is found that with increasing temperature at $H = 0$ T the coercive field E_c of PZT decreases at low temperature range, and then starts to increase till the Curie temperature of LCMO ($T_c \sim 220$ K) where a maximum appears. This peak is obviously suppressed and shifted to a higher temperature with increasing magnetic fields, which may be related to the depolarization field which is affected by the change of the carrier concentration in LCMO. As for the variation of remnant polarization P_r , it increases with increasing temperatures from 50 K to 300 K, but decreases with increasing magnetic fields around T_c . This magnetoelectric effect implies that the strain effect due to the magnetostriction of LCMO may also have some impact on the variation of hysteresis loops. These findings provide potential for multifunctional devices in spintronics.

2:03PM J13.00015 Tailored inter and intra layer exchange coupled superlattices for optimized magnetocaloric effect¹, TATHAGATA MUKHERJEE, S. MICHALSKI, R. SKOMSKI, D.J. SELMYER, CH. BINEK, Department of Physics & Astronomy and the Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, NE, 68588-0111 — We explore Magnetocaloric (MC) properties of Fe/Cr superlattices with tailored inter- and intra-layer interaction using simple 3d metals. Our multilayers are fabricated by pulsed-laser deposition with emphasis on maximizing magnetic entropy changes near room temperature. Nanostructuring² allows tailoring ferromagnetic and antiferromagnetic coupling. This in concert with finite size scaling of the ferromagnetic Fe films has the potential to lead to optimized MC materials. Thermodynamic and MC properties of such Fe/Cr superlattices are studied with the help of SQUID magnetometry. Entropy changes are deduced via the Maxwell relation in single phase regions, X-ray diffraction and X-ray reflectivity are used to correlate structural data with the magnetic properties.

Tuesday, February 28, 2012 11:15AM - 2:15PM — Session J14 GMAG DMP FIAP: Focus Session: Spins in Semiconductors - Spin-Orbit Coupled Electrons and Holes in Semiconductors 212

11:15AM J14.00001 Spin-dependent transport of spin-orbit coupled holes in GaAs nanostructures, ALEX HAMILTON, University of New South Wales — In undergraduate physics, we are often taught that holes in the valence band are just positively charged heavy electrons. But valence band holes are spin-3/2 particles, and this gives them very different properties to spin-1/2 electrons, particularly when confined to low dimensions. These differences show up as highly anisotropic spin properties, which can be directly probed with conventional transport measurements. We have fabricated high quality hole quantum wires that show clean and stable quantized conductance plateaus [1]. In contrast to 1D electron quantum systems, the spin-splitting in these hole wires is highly anisotropic [2], and depends only on the orientation of the in-plane magnetic field relative to the quantum wire [3]. However the orientation and k -dependence of the spin-splitting cannot be reconciled with existing theories, suggesting that more theoretical work is needed before we understand the physics of spin-3/2 holes, even on “simple” (100) surfaces. We have also studied spin-3/2 holes in quantum dots, which show characteristic signatures of Kondo physics. A clear zero-bias peak is observed in the differential conductance, which splits with an applied in-plane magnetic field. The splitting is twice as large as the splitting for the lowest one-dimensional subband, consistent with Kondo physics. Unlike electrons this splitting is highly anisotropic with magnetic field, due to the strong spin-orbit coupling [4].

11:51AM J14.00002 Quantum-confined holes: More spin for your buck!¹, ULRICH ZUELICKE, Victoria University of Wellington, New Zealand — The physical properties of charge carriers in crystalline solids are dictated largely by the material's band structure. Typically, band electrons from the (lowest) conduction band behave very similarly to free electrons in vacuum, only with parameters such as their mass and g -factor adjusted. In contrast, holes from the (upper-most) valence band show a much richer behavior owing to their intrinsic spin-3/2 degree of freedom and this spin's strong coupling to the crystal momentum of holes. In a two-dimensional (2D) quantum well, size quantisation induces an energy splitting between heavy-hole (HH) and light-hole (LH) subbands. The existence of this HH-LH *splitting* makes it tempting to consider HH and LH degrees of freedom separately, in particular in situations where only the highest (generally HH-like) 2D hole subband is occupied. In my talk, I will focus on how such an approach overlooks intriguing differences in the mesoscopic and many-particle properties exhibited by quantum-confined holes as compared with their conduction-electron counterparts. Recent results on the density response [1] and spin susceptibility of 2D holes will be presented to illustrate the ramifications of ubiquitous HH-LH *mixing*. I will also discuss how the temporal modulation of Rashba spin splitting in hole nanostructures generates larger-magnitude spin currents than in corresponding band-electron systems [2]. Finally, Andreev reflection of holes in a p-type-semiconductor – superconductor hybrid system will be considered [3], which also exhibits novel behavior due to band mixing.

12:27PM J14.00003 Spin-electric stripes: electric voltage generated by spin current¹, YULI LYANDAGELLER, Department of Physics Purdue University — At the boundaries of the two-dimensional conductor, stripes arise with an electric field transverse to the flowing electric current, and with 100% electron spin polarization perpendicular to the 2D plane. In these boundary stripes, the magnitudes of spin polarizations are the same, the magnitudes of transverse electric fields are the same, but the directions of electric fields and orientations of spins are opposite. If the spin relaxation is negligible, the magnitudes of the electric fields are directly related to the spin current. The stripes at boundaries are separated by a center-stripe, in which the magnitude and direction of the electric field depend on the ratio of the skew scattering and side jump spin currents. The spin polarization is zero on the centerline and reaches +1 or -1 at the boundaries between the central and periphery stripes if spin relaxation of the z-component of spin normal to the 2D plane is absent. Weak spin relaxation modifies the magnitudes of the spin polarization and electric fields, with +1 or -1 spin polarization persisting at the edges of the sample. Favorable experimental settings, in which electron or hole spin relaxation of the z-component of spin is suppressed but the spin current is not, are discussed.

12:39PM J14.00004 Spin-orbit or Aharonov-Casher edge states in semiconductor two-dimensional systems, L.L. XU, J.J. HEREMANS, Virginia Tech, C.K. GASPE, S. VIJAYARAGUNATHAN, T.D. MISHIMA, M.B. SANTOS, University of Oklahoma — In semiconductors with spin-orbit interaction we experimentally search for edge states induced by the Aharonov-Casher vector potential or Rashba-type spin-orbit interaction. The Aharonov-Casher effect is electromagnetically dual to the Aharonov-Bohm effect and is predicted to lead to a possibly helical edge state structure at two-dimensional sample edges. We use InGaAs/InAlAs heterostructures patterned into mesoscopic side-gated channel structures, where the edge states can be induced, and where backscattering between edge states can be experimentally measured in the resistance. Sweeping side-gate voltage, low temperature resistances are measured across such mesoscopic closed-path structures at either low applied magnetic field, in-plane or normal to the plane, or at fixed magnetic filling factors of 5, 6, 7, and 8 to obtain states of defined spin. Resistance oscillations are observed at low magnetic fields and around filling factor 6 as function of side-gate voltage, and we analyze the oscillations in the light of the search for the edge states (DOE DE-FG02-08ER46532, NSF DMR-0520550).

12:51PM J14.00005 Spin orbit coupling induced splitting in excitations of high mobility 2DESs¹, ALBERT F. RIGOSI, URSULA WURSTBAUER, ARON PINCZUK, Columbia University, JOHN WATSON, SUMIT MONDAL, MICHAEL J. MANFRA, Purdue University, KEN W. WEST, LOREN N. PFEIFFER, Princeton University — Spin orbit interaction (SOI) induces a splitting of the conduction bands in two-dimensional electron systems (2DES) in GaAs. We study the impact of zero-field spin-splitting on excitations of ultra high mobility 2DESs by resonant inelastic light scattering experiments. To distinguish between splitting caused by bulk inversion asymmetry (Dresselhaus) and structure inversion asymmetry (Rashba), we studied symmetric (two-side modulation doped) and asymmetric (single-side modulation doped) quantum wells grown along (001) and (110) crystallographic directions. We probe the excitation modes as a function of transferred momentum for different crystallographic directions in the plane of the QW. At large wave vectors we find a complex splitting of the single-particle intersubband excitation mode that is strongly dependent on the combination of Dresselhaus and Rashba SOI. The observed mode splitting is a result of effective SOI fields in both, ground and first excited subband. Suitable choices of crystallographic orientations yield Dresselhaus and Rashba terms.

1:03PM J14.00006 Current-induced spin polarization along spin orbit fields in strained InGaAs¹, BENJAMIN M. NORMAN, C.J. TROWBRIDGE, Department of Physics, University of Michigan, Ann Arbor, J. STEPHENS, A.C. GOSSARD, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, V. SIH, Department of Physics, University of Michigan, Ann Arbor — Current-induced spin polarization is a phenomenon in which electron spins undergo a momentum-dependent net spin polarization², but the mechanism and how material parameters govern the magnitude of this effect remains an open question. Conductive channels are etched into strained n-doped InGaAs samples along the [110], $\bar{1}\bar{1}0$, [100] and [010] crystal axes with ohmic contacts at either end to allow control of electrical current. While the spin polarization direction is found to align along the direction of the measured spin-orbit effective magnetic fields³, the magnitude of the spin polarization is not proportional to the magnitude of the spin-orbit fields. Surprisingly, crystal axes with the smallest spin-orbit fields appear to have the largest net spin polarization. Our measurements suggest that the longer spin dephasing time for smaller spin-orbit interactions may play a significant role.

1:15PM J14.00007 Thermodynamic compressibility and spin-splitting in one-dimensional quantum wires, LUKE W. SMITH, University of Cambridge, U.K., A.R. HAMILTON, University of New South Wales, Australia, K.J. THOMAS, Sungkyunkwan University, Korea, M. PEPPER, University College London, U.K., I. FARRER, D. ANDERSON, G.A.C. JONES, D.A. RITCHIE, University of Cambridge, U.K. — We study spin-splitting and the much-debated 0.7 structure in GaAs quantum wires using compressibility measurements that directly probe the thermodynamic density of states. Two quantum wires are simultaneously defined in the upper and lower well of a GaAs/AlGaAs double quantum well heterostructure, using midline-gated split-gate devices [1]. The lower wire probes the ability of the upper wire to screen the electric field from a biased surface gate. The technique is sensitive enough to resolve spin splitting of the 1D subbands in the presence of an in-plane magnetic field. The compressibility response of the 0.7 structure is measured, and its evolution with increasing temperature and magnetic field is studied [2]. Despite the sensitivity of our measurements we see no evidence of the formation of the quasibound state predicted by the Kondo model of the 0.7 structure. Instead our data are more consistent with theories which predict that the 0.7 structure arises as a result of spontaneous spin polarization.

1:27PM J14.00008 Spin-orbit effects in two-dimensional hole systems on hydrogen-terminated silicon (111) surfaces, BINHUI HU, TOMASZ M. KOTT, BRUCE E. KANE, University of Maryland — We have studied spin-orbit effects in two-dimensional hole systems (2DHSs) on hydrogen-terminated Si(111) surfaces using Shubnikov-de Haas (SdH) oscillations. The device has a vacuum field-effect transistor structure [1], and the 2DHS is induced on the H-Si(111) surface. Hole concentrations up to $8 \times 10^{11} \text{ cm}^{-2}$ are obtained, and the peak hole mobility is about $15,000 \text{ cm}^2/\text{Vs}$ at $T = 1.5 \text{ K}$. SdH oscillations show that the heavy hole subband is spin split due to spin-orbit effects. Both frequencies and beating node locations of the SdH oscillations are used to characterize the spin-orbit effects. The spin-splitting energy is measured as a function of the hole concentration, and the underlying physics will be discussed. Heavy-hole effective mass is determined by the temperature dependence of the SdH oscillations, and the relationship between the effective mass and the hole concentration will be presented. [1] K. Eng, R. N. McFarland, and B. E. Kane, Appl. Phys. Lett. 87, 052106 (2005)

1:39PM J14.00009 Quasiparticle velocities in 2D electron/hole liquids with spin-orbit coupling¹, DAVID AASEN, STEFANO CHESI, BILL COISH, McGill University — We study the influence of spin-orbit interactions on quasiparticle dispersions in two-dimensional electron and heavy-hole liquids in III-V semiconductors. To obtain closed-form analytical results, we work within the screened Hartree-Fock approximation, valid in the high-density limit. For electrons having a linear-in-momentum spin-orbit interaction, we confirm known results based on the random-phase approximation and we extend those results to higher order in the spin-orbit coupling. For hole systems, with a leading nonlinear-in-momentum spin-orbit interaction, we find two important distinctions. First, the group velocities associated with the two hole-spin branches acquire a significant difference in the presence of spin-orbit interactions, allowing for the creation of spin-polarized wavepackets in zero magnetic field. Second, we find that the interplay of Coulomb and spin-orbit interactions is significantly more important for holes than for electrons and can be probed through the quasiparticle group velocities. These effects should be directly observable in magnetotransport, Raman scattering, and femtosecond-resolved Faraday rotation measurements.

¹preprint arXiv:1110.6661v1

1:51PM J14.00010 Spin Coulomb drag and optical excitations in low dimensional systems, IRENE D'AMICO, University of York, CARSTEN ULLRICH¹, University of Missouri — Within the remit of new quantum technologies, an intense effort is devoted to improving our understanding of spin dynamics, with the aim of building novel spintronics devices. In this context the theory of spin Coulomb drag (SCD) was recently developed. It shows that Coulomb interactions are an intrinsic decay mechanism for spin currents. As confirmed by experiments, SCD can be substantial in semiconductors, and it is bound to become one of the most serious issues in spin polarized transport, since, due to its intrinsic nature, it cannot be avoided even in the purest material. More recently the influence of SCD on optical spin-injection and spin-resolved optical experiments has been considered. Here we report on SCD effects on intersubband optical spin excitations in III-V quantum wells, where SCD may contribute substantially to the linewidth of spin plasmons. By going beyond the usual local density functional approximation and properly including the effects due to the inhomogeneity of the system in the growth direction, we show that the quantization of states in the growth direction may strongly reduce the intrinsic plasmon linewidth.

2:03PM J14.00011 Theory of Helical Fermi liquids, ALI ASHRAFI, DMITRII MASLOV, University of Florida — We extend the Landau Fermi Liquid (FL) theory to include spin-orbit coupling (SOC). In particular, the Rashba SOC is chosen as an example. It is shown that although “charge-part” quantities, such as the charge susceptibility and effective mass, are determined solely by the quasi-particles, “spin-part” quantities, such as the spin susceptibility, have contributions from the damped states in between the two Fermi surfaces induced by the SOC. However, contributions to the lowest order in the SOC can still be extracted from the theory. The nature of the instabilities of such spin-orbit coupled FL is discussed.

11:15AM J15.00001 An Alternative Approach for Fabricating Ring-shaped Spin-transfer Torque RAM Devices, ROBERT BURKE, ALAN EDELSTEIN, Army Research Laboratory — Several techniques have been investigated to fabricate spin-torque transfer RAM (STT RAM) devices with ring-shaped geometries. In-plane STT RAM devices with ring-shaped geometries are advantageous in that the magnetization is confined to the ring structure, eliminating the demagnetization field. This, in turn, reduces the critical current needed to switch the magnetization. To date, the most popular fabrication technique of ring-shaped STT RAM involves a combination of electron beam lithography and ion beam milling. A significant issue with ion beam milling, however, involves the redeposition of the MTJ material on the ring-shaped surface, which leads to shorting of the devices. In our study, we seek an alternative method for forming the ring-shaped devices which eliminates the shorting problem. As a result, we are using a nanopillar and cap structure template to define the ring-shaped geometry of the devices. The nanopillar and cap structure template is fabricated using a combination of a bilayer resist and electron beam lithography to either create a mold for the deposition of a nanopillar and cap structure via ion beam deposition or a resist-based nanopillar and cap structure. This study will report on the results of this process and its prospects as an alternative to ion beam milling.

11:27AM J15.00002 Spin dependent tunneling and possible spin torque effects in magnetic nanoparticle tunnel junctions , CHEN WANG, HSIN-WEI TSENG, ROBERT A. BUHRMAN, DANIEL C. RALPH, Cornell University — It has been predicted that electron tunneling between two magnetic electrodes via a magnetic nanoparticle can exhibit enhanced magnetoresistance at low temperature due to a coherent tunneling mechanism in the Coulomb blockade regime. This has been qualitatively demonstrated for large ensembles of nanoparticles. It has also been predicted that the tunneling current in such a system might exert spin transfer torque with quantum behaviors associated with the discrete energy level of the nanoparticles. Here we report the fabrication and measurement of sub-100 nm nano-pillar tunnel junctions with the layer structure CoFeB/MgO/(CoFeB nanoparticles)/MgO/CoFeB with the dual goal of 1) probing the spin-dependent coherent tunneling associated with the magnetization of a single or very few nanoparticles and 2) exploring the potential for magnetization switching and current-driven dynamics in the nanoparticles induced by spin transfer torque.

11:39AM J15.00003 What determines the sign of magnetoresistance in a molecular tunnel junction? , SUBHASISH MANDAL, RANJIT PATI, Michigan Technological University — The recent observations of both positive and negative sign of tunneling magnetoresistance (TMR) in the same organic spin-valve structure has mystified researchers working in organic spintronics. In this article, we resolve this puzzle by exploring the role of interfacial metal-molecule coupling on TMR in a single molecular spin-valve junction. A planar organic molecule sandwiched between two nickel electrodes is used to build a prototypical spin-valve junction. A parameter-free, single particle Green's function approach in conjunction with a posteriori density functional theory involving a hybrid orbital dependent functional is used to calculate the spin-polarized current. The effect of external bias is explicitly included to investigate the spin-valve behavior. Our calculations show that only a 3% change in the interfacial distance at the metal-molecule junction can alter the sign of the TMR from a positive to a negative value.

11:51AM J15.00004 Spin-dependent inertial force and spin current in accelerating systems , MAMORU MATSUO, Kyoto university, JUN'ICHI IEDA, Japan Atomic Energy Agency, EIJI SAITOH, Tohoku university, SADAMICHI MAEKAWA, Japan Atomic Energy Agency — In the frontier of spintronics, much attention is paid on the control of spin currents. Due to the recent progress of nanoelectromechanics, mechanical manipulation of spins will increase in importance. We discuss theoretically the generation of spin currents in both rotationally and linearly accelerating systems. The explicit form of the spin-dependent inertial force acting on electrons in accelerating systems in the presence of electromagnetic fields is derived from the generally covariant Dirac equation. It is shown that the force is responsible for the generation of spin currents by mechanical rotation and vibration in the first order of the spin-orbit coupling. We also investigate $SU(2) \times U(1)$ gauge theory in accelerating systems, which allows us to extend the spintronic theory in inertial frame to non-inertial frame.

12:03PM J15.00005 Anomalous Magneto Transport in amorphous TbFeCo thin films¹ , NATTAWUT ANUNIWAT, Physics Department, University of Virginia, MARC COSTANTINE, JIWEI LU, Materials Science Department, University of Virginia, MANLI DING, JOSEPH POON, Physics Department, University of Virginia — TbFeCo has attracted some interests because of its high perpendicular anisotropy and tunable magnetic properties for nanomagnetic and spintronics application. In this study, we report a strong size dependence of the coercive field in 30 nm-thick $Tb_{30}Fe_{63.5}Co_{6.5}$ films with MgO capping. Magneto Optical Kerr effect (MOKE) and Vibrating Sample Magnetometer are performed on unpatterned films. The films exhibited strong PMA characteristics with $M_S \sim 200$ emu/cc, $H_C \sim 6000$ Oe, and $K_U \sim 5 \times 10^6$ erg/cc. The films were then fabricated into Hall bars with 500 nm, 50 μm and 500 μm in width. From anomalous Hall effect (AHE), H_C was determined for these patterned films. For Hall bars with the width less than 50 μm , an increase in the coercivity field (~ 1.4 Tesla) was observed at room temperature. The temperature dependent of AHE was characterized from 50K to 300K. The thickness and composition dependent will also be studied and discussed.

12:15PM J15.00006 Anisotropic Magnetoresistance in single-crystalline Ag/NiO/Fe₃O₄/MgO(001) sample , JIA LI, ALI SUCIPT TAN, JIM SON, ERIC JIN, ZI Q. QIU, Department of Physics, University of California at Berkeley — Anisotropic Magnetoresistance (AMR) is a well-known phenomenon in ferromagnetic (FM) materials that the resistivity exhibit different values as the electric current flows parallel and perpendicular to the magnetization direction, respectively. Recognizing that the AMR depends on the spin axis rather than spin direction, we propose that AMR effect should also exist in antiferromagnetic (AFM) materials. In this presentation, we will report the AMR effect in single crystalline Ag/Fe₃O₄/NiO/MgO(001) films in which the electrical current is mainly carried by the nonmagnetic Ag film. By changing the FM Fe₃O₄ magnetization direction with an external magnetic field, the AFM NiO spin axis direction can be changed through the Fe₃O₄/NiO coupling. We observe a non-zero AMR effect in Ag and that the AMR value depends sensitively on the Ag thickness, suggesting that the observed AMR comes from the spin-dependent NiO/Ag interfacial scattering. Moreover, the magnitude of the AMR effect at 1nm thick Ag in Ag/Fe₃O₄/NiO/MgO(001) is comparable to the AMR value from single Fe film.

12:27PM J15.00007 AIP Prize for Industrial Applications of Physics Lecture: Controlled exchange in recording media and spintronic devices , ERIC FULLERTON, University of California, San Diego — Controlled exchange in recording media and spintronic devices Eric Fullerton University of California, San Diego New functionality and performance advantages have been achieved in magnetic recording media by the formation of complex heterostructures and have helped delay predicted recording limits that arise from thermal instabilities in the media [1]. Example media structures include antiferromagnetically coupled (AFC) media [2] and exchange-spring media structures [3, 4] which emerged in longitudinal and perpendicular recording products and have helped to extend recording densities [1]. In this presentation I will review the implementation of exchange-coupled media, the surprising physics that emerged and its impact on hard-drive products. I will further discuss how similar approaches can be used in emerging recording technologies such as heat assisted magnetic recording [4] and bit patterned media [5, 6] as well as many spintronic devices [7,8].

1:03PM J15.00008 Influence of the exchange bias on the magnetic losses in CoFeB/MgO/CoFeB tunnel junctions¹, RYAN STEARRETT, W.G. WANG, XIAOMING KOU, L.R. SHAH, J.Q. XIAO, E.R. NOWAK, University of Delaware — We report the influence of the exchange bias on the low-frequency magnetic losses of the reference layer in CoFeB/MgO/CoFeB tunnel junctions near maximum resistance susceptibility. The phase lag associated with the magnetic losses in the reference layer, ε , is field-dependent during its magnetic reversal, being largest around the antiparallel state and slowly decreasing with higher applied fields. Such behavior would indicate a direct influence of the exchange bias strength. Its strength is determined by the magnitude of the reference layer switching field, H_{ref} . This is defined as the field at which the magnetoresistance-sensitivity product exhibits its maximum. Devices with the strongest exchange bias tend to have the thickest seed layers and exhibit elevated values for H_{ref} and ε . However, ones with weakened exchange bias due to prolonged annealing show a reduction in H_{ref} and ε with increased annealing time. A comparison between top and bottom pinning configurations is also discussed along with its impact on double-barrier magnetic tunnel junctions.

1:15PM J15.00009 ABSTRACT WITHDRAWN —

1:27PM J15.00010 Magneto-optical properties of Fe thin films in an external electric field¹, KOHJI NAKAMURA, TORU AKIYAMA, TOMONORI ITO, Mie University, MICHAEL WEINERT, University of Wisconsin - Milwaukee, ARTHUR FREEMAN, Northwestern University — Controlling magnetic properties by an external electric field (E -field) is a key challenge in magnetic physics. Previously, from first-principles calculations,² we demonstrated the E -field-driven magnetocrystalline anisotropy modification in Fe thin films and at the Fe/MgO interface. Here, we extend our investigations to treat the magneto-optical properties of Fe thin films in an E -field. Calculations were carried out using the film-FLAPW method³, in which an E -field is incorporated and the conductivity tensor is obtained by applying the Kubo formula of linear response theory. Results predict that for an Fe monolayer, when the E -field is introduced over $1\text{V}/\text{\AA}$, the calculated interband conductivity in the low energy region (less than about 2eV from E_F) are modified compared to that in zero field, due to a magnetization reorientation from out-of-plane to in-plane. The calculated plasma frequency is also found to be reduced by 7%, which suggests an E -field-driven magnetoresistance.

1:39PM J15.00011 Spin transport in metal-oxide switching devices, CURT A. RICHTER, Semiconductor and Dimensional Metrology Div, NIST Gaithersburg, MD, H.-JAE JANG, Semiconductor and Dim. Metrology Div, NIST and Dept. of Physics, Wake Forest University, OLEG KIRILLOV, Semiconductor and Dimensional Metrology Div, NIST Gaithersburg, MD, OANA JURCHESCU, Department of Physics, Wake Forest University, Winston-Salem, NC — Metal-oxide-based devices in which resistive switching occurs, often referred to as memristors or resistive-RAM (random oxide memory), show promise for use in technologically exciting applications such as high-density non-volatile memories, electronically reconfigurable logic, and neural networks. We report on electron spin transport through electrochemically precipitated copper filaments formed in TaO_x memristive devices consisting of $\text{Co}(60\text{ nm})/\text{TaO}_x(16\text{ nm})/\text{Cu}(5\text{ nm})/\text{Py}(60\text{ nm})$ with crossbar-type electrode geometry. These metal-oxide switching devices with ferromagnetic electrodes show memristive behavior having a typical OFF/ON resistance ratio of 10^5 . Magnetoresistance measurements performed by sweeping an external magnetic field display evidence of spin transport in the low-resistance ON-state at 77 K. Spin transport vanishes in the OFF-state. These data are strong evidence that the fundamental switching mechanism in these metal-oxide devices is the creation of Cu filaments in the ON-state that completely span the 16 nm thick TaO_x and form a continuous metallic conduction path. In addition to helping elucidate the conduction pathway in these intriguing structures, our findings can advance electronics combining spintronic and electronic functions.

Session J16 DCMF: Vanadium Dioxide; Nano and Devices 251

11:15AM J16.00001 M2 phase in free-standing single-crystalline nanostructures of VO_2 at ambient conditions¹, E. STRELCOV, Southern Illinois University Carbondale, Carbondale, IL, A. TSELEV, I.N. IVANOV, Oak Ridge National Laboratory, Oak Ridge, TN, J. ZHANG, Southern Illinois University Carbondale, Carbondale, IL, J.D. BUDAI, J.Z. TISCHLER, S.V. KALININ, Oak Ridge National Laboratory, Oak Ridge, TN, A. KOLMAKOV, Southern Illinois University Carbondale, Carbondale, IL — A significant drawback of a promising material for realization of an ultrafast switch based on a metal-insulator transition (MIT) - VO_2 - is the inherent linkage between the MIT and lattice transformation from tetragonal to monoclinic with a lattice contribution in the band gap formation in the stable monoclinic M1 structure. On the other hand, the metastable M2 phase exhibits a pure Mott MIT and was shown to be driven metallic without the structural change. Existence of this phase at ambient conditions was reported for Cr and Al-doped VO_2 and nanostructures doped with oxygen vacancies. Here we report stabilization of the M2 phase in VO_2 single-crystalline nanoplatelets (NPLs) doped with Al during the growth process via two new methods. Development of these methods came from our recent in situ studies of the NPL growth mechanism. We reconstructed temperature-doping phase diagram for the NPLs. Electrical properties of the NPLs were also studied as functions of doping level and temperature.

¹Work at SIUC was funded through NSF 772 ECCS-0925837 and SISGR-DOE ERKCM67. Work at ORNL's CNMS was sponsored by DSUF OBES, U.S. DOE. J.D.B. and J.Z.T. were supported by MSED OBES, U.S. DOE.

11:27AM J16.00002 Photocurrent in Vanadium Dioxide¹, T. SERKAN KASIRGA, DONG SUN, JAE H. PARK, JAMES COY, XIAODONG XU, DAVID H. COBDEN, University of Washington — We investigate the photoresponse of VO_2 using scanning photocurrent microscopy below and above the metal-insulator transition at 67°C . To avoid complications of nonuniform strain and twinning boundaries we focus on single-crystal suspended nanobeams, where the strain is either minimal or well controlled. At intermediate temperatures the metallic and insulating phases coexist and a photocurrent and photoconductance associated with the boundary between them is seen. The magnitude and profile of the photoresponse above and below the transition demonstrates a photothermal mechanism, with fast electron-lattice relaxation and absence of built-in electric fields in the insulating phase consistent with strong electron-electron correlations and a short screening length.

11:39AM J16.00003 Electronic phases in vanadium dioxide nanowires observed by scanning tunneling spectroscopy, JOHN HATCH, Department of Physics, SUNY at Buffalo, LUISA WHITTAKER, Department of Chemistry, SUNY at Buffalo, TAI-LUNG WU, ADAM STABILE, G. SAMBANDAMURTHY, Department of Physics, SUNY at Buffalo, SARBAJIT BANERJEE, Department of Chemistry, SUNY at Buffalo, HONG LUO, Department of Physics, SUNY at Buffalo — The electronic behavior of vanadium dioxide around its metal-insulator transition has been the focus of many experimental and theoretical investigations, concerning transition mechanisms. In this work, we present our experimental investigation of the temperature driven metal-insulator transition in individual single crystal vanadium dioxide nanowires with scanning tunneling spectroscopy. The local density of states is studied at temperatures around the transition temperature. We observe three distinct electronic phases: the insulating phase and two metallic phases with different density of states, both in terms of conductivity and in the complexity of the density-of-states spectra. Vanadium dioxide nanowires doped with tungsten were also studied and will be discussed.

11:51AM J16.00004 Current-induced metastable states in single-crystalline VO₂ nanoplatelets¹, ALEXANDER TSELEV, J.D. BUDAI, Oak Ridge National Laboratory, Oak Ridge, TN, E. STRELCOV, Southern Illinois University Carbondale, Carbondale, IL, J.Z. TISCHLER, Oak Ridge National Laboratory, Oak Ridge, TN, A. KOLMAKOV, Southern Illinois University Carbondale, Carbondale, IL, S.V. KALININ, Oak Ridge National Laboratory, Oak Ridge, TN — The metal-insulator transition (MIT) in VO₂ occurs close to ambient temperature, $T_c = 68^\circ\text{C}$, which can be reduced by doping. The phase transition results in a few orders of magnitude change of electrical conductivity and is accompanied by a change of the lattice from tetragonal to monoclinic, which is associated with lattice expansion of $\sim 1\%$ along the tetragonal c-axis of the metallic phase. We observed that, in suspended single-crystalline VO₂ nanoplatelets (NPLs) carrying a sufficiently strong electrical current, Joule heating leads to formation of metal-semiconductor domains, which are self-organized in chains providing a path for the current flow. This results in NPL bending depending on the current strength, which can be used for electrically controlled actuator action. The observed domain structures should be interpreted as distinct metastable states in freestanding and end-clamped quasi-1D VO₂ samples. We analyze the stability conditions for the heterophase domains patterns and main prerequisites for the realization of current-controlled nanoactuators based on the proposed concept.

¹Work at SIUC was funded through NSF 772 ECCS-0925837 and SISGR-DOE ERKCM67. Work at ORNL's CNMS was sponsored by DSUF OBES, U.S. DOE. J.D.B. and J.Z.T. were supported by MSED OBES, U.S. DOE.

12:03PM J16.00005 Hydrogen stabilization of metallic VO₂ in single-crystal nanobeams¹, JIANG WEI, HENG JI, WENHUA GUO, ANDRIY NEVIDOMSKYY, DOUGLAS NATELSON, Rice University — Vanadium dioxide (VO₂) is a strongly correlated material with a metal-insulator transition at 67°C from a high temperature, rutile metal to a lower symmetry insulating state. Substitutional doping can alter the properties of VO₂, but is irreversible. Using individual microcrystals and nanobeams, we show that spillover may dope VO₂ reversibly with atomic hydrogen. Raman and optical microscopy show a stabilized metallic state, consistent with single-crystal electron diffraction and scanning electron microscopy that demonstrate a post-hydrogenation structure similar to the rutile state. Electronic transport shows that the energy band gap of insulating phase can be reversibly tuned towards the metallic phase upon different hydrogenation conditions and the metallic state may be stabilized down to cryogenic temperatures. Electronic structure calculations agree that a hydrogen-containing distorted rutile structure is energetically favored over the monoclinic state.

12:15PM J16.00006 Identifying the Role of Domains in Metal-Insulator Transitions in Individual Nanowires of Tungsten-Doped VO₂, ADAM STABILE, SUJAY SINGH, TAI-LUNG WU, Department of Physics, SUNY at Buffalo, LUISA WHITTAKER, Department of Chemistry, SUNY at Buffalo, PAYAM TAHERIROSTAMI, Department of Physics, SUNY at Buffalo, SARBAJIT BANERJEE, Department of Chemistry, SUNY at Buffalo, G. SAMBANDAMURTHY, Department of Physics, SUNY at Buffalo — Though it is well known that the metal-insulator transition (MIT) in VO₂ can be achieved by a variety of external parameters, an understanding of how different parameters drive such a transition has remained relatively unknown. We report transport and Raman spectroscopic characteristics on voltage (V)- and temperature (T)-driven MIT in individual, single-crystal, tungsten-doped VO₂ nanowires. From transport analyses we discuss the T -dependent features in I vs V curves; specifically hysteresis gaps and resistance jump features seen in sub-micron devices. From Raman spectroscopic analyses we discuss the Raman intensity of A_g modes while driving the temperature and voltage across the transition. We conclude that driving T supports a slow transition to the rutile (R) metallic phase with a wide temperature range of mixed insulating, monoclinic (M1) and R states due to the population of metallic domains. V -driven transition does not appear evolve via the formation of domains, but is activated when V is sufficiently large above a T -dependent threshold.

12:27PM J16.00007 Ionic Liquid Gated Vanadium Oxide Three Terminal Devices: Chemical Stability and Field Effect¹, YOU ZHOU, ZHENG YANG, SHRIRAM RAMANATHAN, Harvard University — Understanding electrostatic field effect in correlated oxides is one approach to uncovering mechanisms leading to metal-insulator transition and further is of great interest in oxide-based device technologies. We have fabricated ionic liquid gated VO₂ three-terminal devices. The VO₂/IL interface properties were systematically studied with emphasis on electrochemical stability, gate capacitance and charging/discharging using photoelectron spectroscopy, impedance spectroscopy and other electrical characterization. We have observed a large modulation of VO₂ channel conductance at room temperature with polarity dependence. Interestingly, the conductance modulation also exhibits a time-dependent response to external gate bias and possible mechanisms will be discussed.

¹We acknowledge Office of Naval Research Grant N00014-10-1-0131 for financial support

12:39PM J16.00008 Gating Effect on VO₂ nanowire by Ionic Liquid¹, HENG JI, JIANG WEI, DOUGLAS NATELSON, Rice University — VO₂ is a well-known strongly correlated material with insulator-to-metal phase transition at 68°C . Below this temperature, VO₂ is an insulating material whose temperature dependence behaves like a semiconductor with 0.6 eV band gap. However, such material cannot be gated by traditional method. In our experiment, we applied a new technique, using ionic liquids, to provide a much stronger transverse electric field on the VO₂ nanowire. We did not observe obvious gating effect on VO₂, but in the meantime, we found that VO₂ is sensitive to hydrogen. The hydrogen produced by electrochemistry when applying voltage on the electrolyte (an ionic liquid with water contamination, in this case) can dramatically change the conductance of VO₂.

¹Robert A. Welch Foundation and Department of Energy award DE-FG02-06ER46337

12:51PM J16.00009 Strain control of the metal-insulator transition in vanadium dioxide nanobeams¹, JAE HYUNG PARK, SERKAN KASIRGA, JAMES COY, XIAODONG XU, DAVID COBDEN, University of Washington, NANODEVICE LAB COLLABORATION — To be able perform systematic studies at the metal-insulator transition in VO₂, we have developed a platform for applying axial strain to suspended single-crystal nanobeams while carrying out optical and transport measurements. The nanobeams are positioned on a piezo-actuated silicon structure using a nanomanipulator. The strain can be used to control the transition temperature, because the metallic and insulating phases have different c-axis lattice constants, or to move the interphase boundary between metal and insulator in coexistence. We report transport, Raman and photoconductance measurements as the transition is tuned in this way.

¹Supported by Department of Energy grant BES DE-SC0002197 and Army Research Office grant 956073-PH.

1:03PM J16.00010 Investigation of switching behavior of two-terminal devices on VO₂¹, IULIANA P. RADU, Katholieke Universiteit Leuven and IMEC, Belgium, KOEN MARTENS, BOGDAN GOVOREANU, SOFIE MERTENS, XIAOPING SHI, MALGORZATA JURCZAK, IMEC, Belgium, STEFAN DE GENDT, Katholieke Universiteit Leuven and IMEC, Belgium, ANDRE STESMANS, Katholieke Universiteit Leuven, JORGE A. KITTL, IMEC, Belgium, MARC HEYNS, Katholieke Universiteit Leuven and IMEC, Belgium — Vanadium dioxide undergoes an insulator to metal transition at about 68 °C. Two-terminal devices fabricated on VO₂ show a steep decrease of resistance when the current or voltage applied are large enough. This switching has been largely attributed to a field effect even in two-terminal devices but controversy still exists. We fabricate devices with an array of electrode separations and widths and study how the dc switching voltage and current depend on device size. The data obtained from these devices are most consistent with a Joule heating mechanism governing the switching. Additionally we perform an ac investigation of these devices and find that the switching to the low resistance state can happen faster than 5ns (the time resolution of the measurement set-up) while the switching to the high resistance state is of the order of hundreds of nanoseconds, consistent with the estimated heat dissipation time. In spite of the Joule heating mechanism which is expected to induce device degradation, we find that the devices can be switched for more than 10¹⁰ cycles making VO₂ a promising material for memory applications.

¹We acknowledge support from the IMEC core partners program, FWO, and a Marie Curie grant.

1:15PM J16.00011 Local thermal heating in VO₂ electric-field-induced metal insulator transition, A. ZIMMERS, L. AIGOUY, Laboratoire de Physique et d'Etude des Matériaux (LPEM), ESPCI-ParisTech-UPMC-CNRS, Paris, France, A. SHARONI, Dept. of Physics and Institute of Nanotechnology, Bar Ilan University, Ramat Gan, Israel, S. WANG, Department of Physics and Materials Science and Engineering and Center for Advanced Nanoscience, UCSD, La Jolla, CA, USA, J.G. RAMIREZ, Department of Physics and Center for Advanced Nanoscience, UCSD, La Jolla, CA, USA, I.K. SCHULLER, Department of Physics and Materials Science and Engineering and Center for Advanced Nanoscience, UCSD, La Jolla, CA, USA — Over recent years, the insulator to metal transition (IMT) of the vanadium dioxide (VO₂) Mott insulator has been revisited revealing an electric-field-induced resistance switching. Whether this feature is purely due to an electrical field effect or due to some Joule heating is still under debate. Here we report a local temperature measurement in a 10μm and a 20μm VO₂ junction while going through the resistance switching. The sample was placed at ΔT=15K below 340K (the thermally induced insulator to metal transition). When ramping up the voltage across the junction we find that the local heating inside the VO₂ junction is close to 15K. This data suggests that in these temperature, current and voltage ranges, the field induced IMT can be explained by local Joule heating. Work supported by the French ANR-09-BLAN-0388-01 and the US DOE and AFOSR.

1:27PM J16.00012 Electrical properties of vanadium dioxide – dielectric – metal structures and the metal-insulator transition¹, KOEN MARTENS, KULeuven ESAT department / IMEC, IULIANA RADU, KULeuven Physics department / IMEC, SOFIE MERTENS, XIAOPING SHI, MARC SCHAEKERS, IMEC, STEFAN DE GENDT, KULeuven Chemistry department / IMEC, MARC HEYNS, KULeuven Materials Science department / IMEC, JORGE KITTL, IMEC — VO₂ and its metal-to-insulator transition (MIT) are of interest for memory and logic nanoelectronic devices due to its very fast transition, its full volume transition implying good scalability and reliability and relatively large resistance on/off ratio of 2-5 orders of magnitude. In this work the equivalent of the heart of MOS (metal-oxide-semiconductor) technology, the MOS capacitor is investigated for the VO₂ case in which the Si is replaced by VO₂. Thermally oxidized VO₂ with a HfO₂ or Al₂O₃ dielectric grown on top with Atomic Layer Deposition were used to form MOS structures. The MOS capacitor electrical properties are analyzed such as the gate current and capacitance behavior with special regard to the MIT. The influence of the MIT on gate dielectric tunneling is shown and modeled as well as RRAM phenomena and an evaluation of the field effect. Implications for the field-induced metal-insulator transition and for device applications are discussed.

¹The FWO is acknowledged for funding.

1:39PM J16.00013 Field-effect modulation of conductance in VO₂ nanobeam transistors with HfO₂ as the gate dielectric, SHAMASHIS SENGUPTA, Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research, Mumbai, KEVIN WANG, KAI LIU, Department of Materials Science and Engineering, University of California, Berkeley, AJAY BHAT, SAJAL DHARA, Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research, Mumbai, JUNQIAO WU, Department of Materials Science and Engineering, University of California, Berkeley, MANDAR M. DESHMUKH, Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research, Mumbai — Field-effect transistors have been fabricated from VO₂ nanobeams using HfO₂ as the gate dielectric. When heated up from low to high temperatures, VO₂ undergoes an insulator-to-metal transition. We observe a change in conductance (6 %) of our devices induced by gate voltage when the system is in the insulating phase. The response is reversible and hysteretic, and the area of the hysteresis loop becomes larger as the rate of gate sweep is slowed down. A phase lag exists between the response of the conductance and the gate voltage. This indicates the existence of a memory of the system involving a timescale of a few minutes. The origin of such slow processes may lie in the coupling between the dipolar arrangement and the strain state of the VO₂ crystal.

1:51PM J16.00014 Metal-to-insulator transition in a columnar nanocomposite oxide¹, ZHAOLIANG LIAO, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70810, USA, PENG GAO, Department of Materials Science and Engineering, University of Michigan, Ann Arbor, MI 48109, USA, SHANE STADLER, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70810, USA, XIAOQING PAN, Department of Materials Science and Engineering, University of Michigan, Ann Arbor, MI 48109, USA, RONGYING JIN, E. WARD PLUMMER, JIANDI ZHANG, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70810, USA — The capability of tuning lattice strain, composition, and dimensionality in epitaxial film growth provide a new avenue of exploring new functionality in correlated electron materials. Here we demonstrated a chemical ratio controlled metal-insulator transition in the nanocomposite films of V₂O₃-La_{2/3}Sr_{1/3}MnO₃ (LSMO) grown on LaAlO₃ (111) substrate through alternative deposition of LSMO and V₂O₃. A V-Mn ion exchange between V₂O₃ and LSMO occurs during the growth and results in the formation of nanoscale and vertically columnar-like insulating Mn₂O₃ and metallic La_{1-x}Sr_xVO₃ composite, as qualitatively revealed by scanning transmission electron microscopy. As determined by transport measurement, a metal-insulator transition is found in the composite films, which depends on the ratio of deposition time of V₂O₃ to LSMO.

¹Supported by U.S. DOE under Grant No. DOE DE-SC0002136.

2:03PM J16.00015 Avalanches in sub-micron V_2O_3 devices¹, SIMING WANG, Department of Physics and Center for Advanced Nanoscience, Materials Science and Engineering Program, University of California San Diego, GABRIEL RAMIREZ, Department of Physics and Center for Advanced Nanoscience, University of California San Diego, IVAN SCHULLER, Department of Physics and Center for Advanced Nanoscience, Materials Science and Engineering Program, University of California San Diego — Systematic resistance versus temperature measurements were performed on micron and sub-micron V_2O_3 devices. Instead of smooth R-T curves reported previously, multiple jumps in resistance are observed through the temperature driven metal-insulator transition. These jumps range over 3 orders of magnitude in resistance. A power law distribution of the jump sizes indicates that the metal-insulator transition in V_2O_3 occurs through a series of avalanches. The power law exponent in V_2O_3 devices is very close to that found in similar VO_2 devices.² This indicates that the phase transition in VO_2 and V_2O_3 are similar and occur through phase separation, percolation and avalanches. The effect of magnetic field on the avalanches in V_2O_3 will be discussed.

¹This work has been supported by the US Department of Energy, Office of Basic Energy Sciences, and Division of Materials Sciences under Award FG03-87ER-45332.

Tuesday, February 28, 2012 11:15AM - 2:15PM – **Session J17 DMP: Focus Session: Surfaces and Interfaces in Nonoxide Nanostructures: Growth, Structure, and Characterization - Organic/Inorganic Interfaces & Quantum Dots 252A**

11:15AM J17.00001 Current at Metal-Organic Interfaces, KLAUS KERN, Max Planck Institute for Solid State Research, Heisenbergstr. 1, D-70569 Stuttgart + Ecole Polytechnique Federale de Lausanne - EPFL, CH-1015 Lausanne — Charge transport through atomic and molecular constrictions greatly affects the operation and performance of organic electronic devices. Much of our understanding of the charge injection and extraction processes in these systems relies on our knowledge of the electronic structure at the metal-organic interface. Despite significant experimental and theoretical advances in studying charge transport in nanoscale junctions, a microscopic understanding at the single atom/molecule level is missing. In the present talk I will present our recent results to probe directly the nanocontact between single molecules and a metal electrode using scanning probe microscopy and spectroscopy. The experiments provide unprecedented microscopic details of single molecule and atom junctions and open new avenues to study quantum critical and many body phenomena at the atomic scale. Implications for energy conversion devices and carbon based nanoelectronics will also be discussed.

11:51AM J17.00002 Temperature dependence in metal/organic heteroepitaxy, GEOFFREY ROJAS, XUMIN CHEN, DONNA KUNKEL, University of Nebraska-Lincoln, MATHIAS BODE¹, Argonne National Laboratory, AXEL ENDERS, University of Nebraska-Lincoln, UNIVERSITY OF NEBRASKA-LINCOLN COLLABORATION, ARGONNE NATIONAL LABORATORY COLLABORATION — The nucleation and growth of 2D single layers of tetraphenyl porphyrin molecules on Ag(111) are studied with variable temperature scanning tunneling microscopy. The heteroepitaxy of the organic/metal thin film occurs in strict analogy with known processes of metal heteroepitaxy. A similar hierarchy of energetic barriers to diffusion along edges and around corners is established. Temperature is the key component to selectively activating these barriers and determining shape of the adislands, from fractal-like shapes at low temperature to compact shape at high temperatures. Using existing models of metal heteroepitaxy, the terrace diffusion and binding energies of tetraphenyl porphyrin are approximated from measurement of island size as a function of temperature. This study provides evidence of the validity of using existing models of metal heteroepitaxy for the description of organic/metal heteroepitaxial systems.

¹now at Universität Würzburg

12:03PM J17.00003 Scanning Tunneling Microscopy investigation of the assembly of diF-TES-ADT on Ag(111)¹, SHAWN HUSTON, Appalachian State University, JIUYANG WANG, North Carolina State University, MARSHA LOTH, JOHN ANTHONY, University of Kentucky, BRAD CONRAD, Appalachian State University, DANIEL DOUGHERTY, North Carolina State University — Over the past two decades organic molecules have shown increasing promise as active layers in electrical devices such as field effect transistors, organic light emitting diodes, and organic photovoltaic devices. The suitability of organic molecules for use in these devices is governed by several properties, chief among them being the ability to self-organize into a film showing high carrier mobility. Organic thin film transistors (OTFT) partially composed of solution processed 2,8-difluoro-5,11-bis(triethylsilyl)ethynyl-anthradithiophene have shown high performance. To date these OTFTs have been constructed solely by solution processing. As such, we have chosen to investigate the possibility of vapor deposition as an alternative. Our investigation of the viability of vapor deposition of this promising molecule begins with deposition on Ag(111) as a model system. Preliminary STM results will be presented and discussed.

¹BC wishes to acknowledge the Ralph E. Powe Junior Faculty Enhancement Award for generous support.

12:15PM J17.00004 DFT study of metal/organic interfaces; optimizing morphology and energy levels for maximum Voc, MICHELLE TOMASIK, ALEXIE KOLPAK, JEFFREY GROSSMAN, MIT — Metal/organic interfaces are important for understanding the electronic properties of any device incorporating organic molecules, although these interfaces have been much less studied than their metal/inorganic counterparts. Using density functional theory, we examine the electronic structure of the interfaces of three metals: silver, aluminum, magnesium, and an organic molecule, Alq3, which is utilized in organic light emitting diodes. We calculate properties of interfaces with a clean metal surface as well as ones with small metal particles injected close to the organic. The effects of the different metals are to charge the Alq3 to varying degrees and perturb the energy levels as the metal states mix with the organic molecule. Insights into the energy level alignment and morphology at these interfaces as a function of the electrode workfunction will be discussed, with the goal of maximizing the open circuit voltage through the choice of metal and deposition process.

12:27PM J17.00005 DFT based modeling of C₆₀/Dichloropentacene/Au OPV heterojunctions, JUN WANG, JIAN-MING TANG, KARSTEN POHL, University of New Hampshire — The co-assembly of functionalized pentacenes (electron-donor materials) and fullerenes (electron-acceptor materials) on metal substrates provides a model for studying the structural and electronic properties for novel organic photovoltaic (OPV) heterojunctions. Our previous STM experimental results show C₆₀ to form single, double and triple nano chains on an intact single-domain, brick-wall structured 6,13-dichloropentacene (DCP) monolayer adsorbed on stepped Au(788). Here, we present theoretical DFT calculations of the geometric and electronic structure, and the charge transfer in this interacting three-component system. Our calculations show that single C₆₀ molecules prefer to either absorb on top of the DCP molecules (slightly shifted off the Cl center) or in between the DCP rows of the brick-wall structure. When adsorbing chains of C₆₀ they will align with either the troughs in between the DCP rows or the top of the DCP rows, in agreement with experiment. Compared to the isolated DCP molecules, the HOMO and LUMO levels move up towards the vacuum level by about 1 eV upon monolayer formation, resulting in charge transfer to C₆₀.

12:39PM J17.00006 Acetophenone on Si(001) with STM and DFT¹, STEVEN SCHOFIELD, ADAM RAHNEJAT, London Centre for Nanotechnology and Department of Physics and Astronomy, UCL, London, UK, OLIVER WARSCHKOW, Centre for Quantum Computation and Communication Technology, University of Sydney, Australia, DANIEL BELCHER, MARIAN RADNY, PHILLIP SMITH, School of Mathematical and Physical Sciences, University of Newcastle, Australia — Organic molecules are likely to play an important role in future technologies, e.g., in novel devices where individual molecules are incorporated as active elements, and in extending the functionality of existing technologies. A detailed, atomic-scale understanding of the structural and electronic properties of molecules on surfaces is key to the development of these technologies. Here we present scanning tunnelling microscopy (STM) and density functional theory (DFT) data of the surface binding configurations of acetophenone adsorbed to Si(001). Topographic and spectroscopic tunnelling experiments were performed at 77 K and room temperature in the limit of very low coverage. We find in analogy to other similar molecules such as acetaldehyde [1], acetone [2,3] and acetic acid [4], acetophenone molecules covalently bond to the Si(001) surface in a variety of configurations that can be directly manipulated using the STM tip. In its most stable configuration, the adsorbate stands upright on the surface, attached via the C and O atoms of its acetyl group, producing a geometry that is robust and attractive for molecular electronics applications. 12:51PM J17.00007 Contact Angle Behavior for Fullerene/Porphyrin Mixtures on Si surfaces¹, MIRIAM CEZZA, ROMAINE A. ISAACS, Department of Materials Science and Engineering, University of Maryland, MD, 20742, QIAN SHAO, Department of Chemistry and Biochemistry, University of Maryland, College Park, MD, 20742, SHY-HAUH GUO², LOURDES G. SALAMANCA-RIBA, Department of Materials Science and Engineering, University of Maryland, MD, 20742, JANICE REUTT-ROBEY, Department of Chemistry and Biochemistry, University of Maryland, College Park, MD, 20742, RAYMOND J. PHANEUF, Department of Materials Science and Engineering, University of Maryland, MD, 20742 — Fullerene/porphyrin mixtures are of great interest in bulk heterojunction organic solar cells. Here we study the morphology of the phase separation which occurs when [6,6]-phenyl-C₆₁-butyric acid methyl ester (PCBM) and tetranitro-zinc phthalocyanine (tn-ZnPc), are deposited onto silicon (111) substrates, including the individual domain length scales, shapes and wetting angles. tn-ZnPc forms small clusters on the Si surface with a contact angle of approximately 15°, while PCBM forms compact clusters on broad (~0.5 µm diameter) “wetting-layer” disks, with the cluster contact angle of ~19°. Interestingly, a 50% mixture shows topography qualitatively similar to that for PCBM, but with a larger contact angle of 22°, indicating that the mixture wets the interface less than either pure component alone.

1:03PM J17.00008 ABSTRACT WITHDRAWN —

1:15PM J17.00009 Molecular nanostructures on graphite, ANDREAS RIEMANN, LINDA GRABILL, BRANDON OWENS, ERIC KREBS, Western Washington University — The self-assembly of different amino acids on graphite has been studied using Scanning Tunneling Microscopy. Experiments involving the amino acid methionine have shown that the molecules arrange themselves in well-ordered molecular wires with equidistant spacing tunable by the amount of adsorbate concentration on the surface. This behavior can be explained by an attractive interaction of the amino and carboxyl groups with each other, whereas the side chains exhibit repulsive interactions. Experiments using other amino acids with different side chains, like tyrosine and histidine, show adsorption behavior which lead to densely packed films of well-ordered amino acids, but no molecular wire structure. The repulsive interactions of the side chains can not be experimentally observed. This interesting phenomenon of inter-molecular interaction was further investigated using molecular mechanics calculations for these molecules.

1:27PM J17.00010 Spontaneous Formation of Quantum Height Manganese Gallium Islands and Atomic Chains on N-polar Gallium Nitride (0001)¹, ARTHUR R. SMITH, ABHIJIT CHINCHORE, KANGKANG WANG, MENG SHI, YINGHAO LIU², Ohio University Nanoscale and Quantum Phenomena Institute — Significant interest has been shown over the last 15+ years in the growth of 2-D island nanostructures of special heights on semiconductor surfaces due to quantum size effects, often referred to as ‘electronic growth.’ Recently, there has been much interest in growth of magnetic metal layers on gallium nitride surfaces, but electronic growth in this system was not reported, until now. Surprisingly, we find that deposition of manganese onto gallium-rich, GaN(0001) results in the spectacular formation of 2-D quantum-height MnGa island structures. Two unique island heights, differing by just one atomic layer, are observed - one being 0.93 nm (5 atomic layers), the other 1.13 nm (6 atomic layers). The 0.93 nm high islands are unstable against the completion of the next atomic layer (0.93 + 0.20 nm), so a single quantum thickness is preferred (1.13 nm). A row structure at the surface of the islands is also revealed, with atomic resolution images suggesting a mixture of Mn and Ga. Auger electron spectroscopy confirms a significant surface Mn content. In addition, growth of 1-D atomic chains at the surface of the completed 1.13 nm high islands is also seen, indicating strongly anisotropic diffusion. The observed behavior is consistent with a quantum size effect driven growth.

1:39PM J17.00011 Wavelength tunable high quality positioned InAs quantum dots grown on patterned GaAs (001) substrates, AYESHA JAMIL, University of Cambridge, JOANNA SKIBA-SZYMANSKA, Toshiba Research Europe Ltd., IAN FARRER, University of Cambridge, MARTIN WARD, Toshiba Research Europe Ltd., JONATHAN GRIFFITHS, GEB JONES, University of Cambridge, ANDREW SHIELDS, Toshiba Research Europe Ltd., DAVE RITCHIE, University of Cambridge, TOSHIBA RESEARCH EUROPE LTD. COLLABORATION — Semiconductor quantum dots serve as ideal contenders in the domains of quantum optics, quantum cryptography and quantum information processing. The decisive factor about their possible applications is their peak emission energy. Naturally grown quantum dots suffer from the problem of random nucleation behavior and non-uniform dot sizes. Here we report on the growth of site-controlled InAs quantum dots on pre-patterned GaAs(001) substrates with adjustable wavelengths. Interplay of the dot growth parameters, particularly growth temperature and Indium deposition amount, as well as the size of the initial template has been employed. With a 20 nm thick GaAs spacer layer grown between the regrowth interface and the quantum dot layer, uniform arrays of quantum dots have been achieved with emission wavelengths covering a spectral window ranging from 900 nm to 1200 nm. This has been achieved without risking the single dot occupancy per nucleation site measured to be > 60% for all of the investigated samples. To ensure better quality of dots, wafer cleanliness is monitored throughout the process. The dots thus show bright emission lines with no spectral jittering.

1:51PM J17.00012 Investigation of spatial correlation of type-II ZnTe quantum dots embedded in ZnCdSe barriers, UTTAM MANNA, ISMAIL NOYAN, GERTRUDE NEUMARK, APAM, Columbia University, SIDDHARTH DHOMKAR, BIDISHA ROY, IGOR KUSKOVSKY, Queens College of CUNY, The Graduate Center of CUNY, RICHARD MOUG, City College of CUNY, LE PENG, MARIA TAMARGO, City College of CUNY, The Graduate Center of CUNY — Doped and undoped multilayered structures of ZnTe type-II quantum dots (QDs) embedded in a ZnCdSe matrix have been grown in order to investigate the formation of an intermediate band, lying within the ZnCdSe band gap, with the aim of absorbing photons with energies below ZnCdSe bandgap. These materials may be useful for intermediate bandgap solar cells. The reciprocal space map (RSM) of the ZnTe/ZnCdSe multilayer QD structure consisting of periodic superlattice peaks in the q_x direction have been studied for two different ZnCdSe spacer thicknesses ($d_A \approx 3.5$, $d_B \approx 1.5$ nm). The ZnTe QDs give rise to diffuse scattering in RSM, which is found to be elongated in the q_x direction for both samples indicating a vertical correlation of the QDs. From the widths of the diffuse maxima in the q_z direction, we found that 16% and 40% of QDs are correlated vertically for $d_A \approx 3.5$ nm and $d_B \approx 1.5$ nm, respectively. With increasing correlation, the pairing probability of the dots increases, leading to a larger average QD size. This conclusion is supported by a smaller blue-shift (26 vs 36 meV) of the photoluminescence peak position with increasing excitation intensity, over five orders of magnitude, for the structure with narrower spacers.

2:03PM J17.00013 Characterization of quantum dot chains using transmission electron microscopy, TYLER PARK, JOHN COLTON, JEFFREY FARRER, Brigham Young University, HAEYEON YANG, South Dakota School of Mines and Technology — We report on the growth and characterization of InGaAs self-assembled quantum dots which form into chains through an altered Stranski-Krastanov method. The methods we are using to study these quantum dot chains include imaging and chemical analysis using a transmission electron microscope (TEM). In order for the quantum dot chains to be characterized using the TEM, the samples must be cut and thinned to allow enough electrons to pass through the sample for our techniques. We are making cross-section and plan view cuts which allow us to get information about the chemical composition, indium segregation, size and spacing, contaminants and other aspects of the dots.

Tuesday, February 28, 2012 11:15AM - 2:15PM –

Session J18 DMP: Focus Session: Nanostructures and Metamaterials, Growth, Structure, and Characterization – New Fabrication Techniques 252B

11:15AM J18.00001 Large Area 3D Negative Index Metamaterials Formed by Printing, JOHN ROGERS, University of Illinois — Negative index metamaterials (NIMS) are man-made structures with values of permittivity and permeability that are simultaneously negative over some range of frequencies. Although advanced lithographic techniques can form the necessary three dimensional (3D) nanoscale features for NIMS, such methods can be applied only over small areas (100's of μm^2) on specialized substrates, with low throughput. This talk summarizes a 3D transfer printing method that can yield 3D-NIMS with excellent optical characteristics, in ways that are scalable to arbitrarily large areas and are compatible with manufacturing. We demonstrate 3D-NIMS with 11-layers and sub-micron unit cell dimensions, over areas $> 75 \text{ cm}^2$, corresponding to $> 10^5 \times 10^5$ unit cells, all with excellent uniformity and minimal defects. These areas and numbers of unit cells both correspond to increases of more than 2×10^7 times, over previous results. Multiple cycles of printing with a single stamp demonstrate use in a manufacturing mode at throughputs that are $\sim 10^8$ times higher than those possible with state-of-the-art focused-ion beam lithography systems (~ 2.5 s per unit cell). Optical measurements show negative index of refraction in the NIR spectral range, with values as large as $\text{Re}(n) \sim -7$ at $\lambda = 2.4 \mu\text{m}$ and high figures of merit (FOM) of ~ 8 at $\lambda = 1.95 \mu\text{m}$ indicating low loss operation. Related approaches can be used to form similar classes of 3D-NIMS with operation in the visible regime.

11:51AM J18.00002 Optical metamaterials with different metals and wedge demonstration of negative refraction with fishnet metamaterials at visible wavelengths¹, NIAN-HAI SHEN, THOMAS KOSCHNY, Ames Lab/Iowa State University, MARIA KAFESAKI, FORTH, COSTAS M. SOUKOULIS, Ames Lab/Iowa State University and FORTH — We investigate the influence of different metals on the electromagnetic response of fishnet metamaterials in the optical regime. We found that, instead of using a Drude model, metals with a dielectric function from experimentally measured data should be applied in order to correctly predict the behavior of optical metamaterials. Through comparison of the performance for fishnet metamaterials made with different metals, i.e., gold, copper, and silver, we found silver is the best choice for the metallic parts compared to other metals, because silver allows for the strongest negative-permeability resonance and, hence, for optical fishnet metamaterials with a high figure-of-merit. We push the negative-index metamaterials to the visible regime and our improved wedge setup provides an unambiguous demonstration of negative refraction for the designed optical metamaterial.

12:03PM J18.00003 Subwavelength imaging of plasmonic nano-bubble cavity probed by Cathodoluminescence, JUN XU, MIT, HYUNGJIN MA, UIUC, NICHOLAS FANG, MIT — Concentrating light into a deep-subwavelength volume is big challenge in conventional optics due to the diffraction limit. In recent years, plasmonics, the interaction of light and metallic nanostructures, offers new opportunities in manipulating light-matter interaction at a subwavelength scale. Because of a strong localized resonant response of the, the field can be confined in a plasmonic cavity with an ultra-small mode volume and a high Purcell factor. Plasmonic light sources at the nanoscale have been demonstrated by utilizing an active medium. However, such light sources are characterized based on either a diffraction-limited technique or a spatially-averaged lifetime measurement, neither of which show subwavelength information. Here, we present a method, cathodoluminescence (CL) that shows a subwavelength resolution image of nanoscale air bubbles trapped in between thin amorphous silicon and silver. A novel multiple-fringe pattern, with a strong dependence on the air gap width, is observed due to an enhanced luminescence. A simple model, based on an oscillating electric dipole, is applied to explain the phenomena. Both the plasmonic and conventional cavity effect of the light interacting with the novel nano-bubble system are considered. The plasmonic nano-bubbles may provide a new approach to generate localized light from a continuous thin film layer with high efficiency, for the application in ultra-compact optical device, molecular imaging, etc.

12:15PM J18.00004 Direct laser writing of three dimensional metal nanostructures using a femtosecond laser and various chemistries, SEUNGYEON KANG, KEVIN VORA, SHOBHA SHUKLA, ERIC MAZUR, Harvard University — Metal nanostructures play important role in various areas such as catalysts or in plasmonics and especially for metamaterial applications. To generate these structures, most fabrication techniques can allow mass production but are either non-controllable, suffer from high cost and low throughput or are limited in two dimensions. Direct laser writing technique resolves these problems but has been mainly used to fabricate polymeric structures. We direct laser write 3D metal structures of tunable dimensions ranging from hundreds of nanometers to micrometers. With computer-controlled translation stage and by utilizing nonlinear optical interactions between chemical precursors and femtosecond pulses, we can limit the metal-ion photo-reduction process to a focused spot smaller than that of the diffraction-limit to create metal nanostructures in a focal volume. We study the chemistry that effects the photo induced metal growth to generate desirable metal structures. By varying the types of solvent, polymer and the concentration ratios of chemicals, we demonstrate our control over the morphology of the resulting metal structures and other features such as flexibility and conductivity. We plan to create diverse metal nanostructures for a wider range of metamaterial applications.

12:27PM J18.00005 Self-assembly of metallic nanoparticles into macroscopic, high-density, monolayer films, JAKE FONTANA, NRC-NRL Postdoctoral Resident at Naval Research Laboratory, RON RENDELL, JAWAD NACIRI, BANAHALLI RATNA, Naval Research Laboratory — A vital element of bringing pragmatic optical metamaterials to fruition is the ability to produce and characterize macroscopic, self-assembled, high-density, ensembles of nanoparticles. We have developed a method that functionalizes metallic nanoparticles with thiol-ene ligands, self-assembles the nanoparticles into high-density, monolayer, centimeter size domain films using phase separation, transports the films onto substrates using surface tension gradients, and crosslinks, via click chemistry, the nanoparticles together into a solid film. We have determined the real and imaginary parts of the phase shift for the films using a Mach-Zehnder interferometer and spectrophotometer and compare the measurements to simulations. We discuss the implications of this self-assembly process for the construction of macroscopic optical metamaterials.

12:39PM J18.00006 Designing Phoxonic Metamaterials with Fractal Geometry, SISI NI, Institute for Soldier Nanotechnologies, Department of Materials Science and Engineering, Massachusetts Institute of Technology, CHEONG YANG KOH, Defense Science Organization, Singapore, STEVE KOOL, EDWIN THOMAS, Institute for Soldier Nanotechnologies, Department of Materials Science and Engineering, Massachusetts Institute of Technology, — Recently, the concepts of fractal geometry have been introduced into electromagnetic and plasmonic metamaterials. With their self-similarity, structures based on fractal geometry should exhibit multi-band character with high Q factors due to the scaling law. However, there exist few studies of *phoxonic* metamaterials based on fractal geometry. We use COMSOL to investigate the wave propagation in two dimensional systems possessing fractal geometries. The simulations of these systems, guided by our recently developed general design framework, help to understand the role of design in determining the phononic properties of the structures. Proposed structures are being fabricated via standard lithographic or 3D printing techniques. The wave behavior of the structures can be characterized using Brillouin Light Scattering, Scanning Acoustic Microscope and Near-field Scanning Optical Microscopy. Due to their sparse spatial distribution, fractal phononic structures show potential for "smart skin", where multifunctional components can be fabricated on the same platform.

12:51PM J18.00007 Plasmon Enhanced Transparency of a Metallic Film on Silicon, TIANYI SUN, Department of Physics, Boston College, YANG WANG, School of Physics and Telecommunication Engineering, South China Normal University, ZHIFENG REN, KRZYSZTOF KEMPA, Department of Physics, Boston College — Low electrical resistivity and high optical transparency are highly desirable for thin films employed in various applications in electronics, optics, solar photovoltaics. In subwavelength scales, plasmon resonance can help electromagnetic waves to propagate through porous metallic films. In this work, we first employ a theory of effective dielectric response, and then quantitative simulations based on finite-difference-frequency-domain (FDFD) and finite-difference-time-domain (FDTD) methods, to understand and demonstrate physics of this effect. We show, that a nanoscopically perforated, yet continuous planar metallic film on silicon, can be designed to be highly transmissive in the entire visible range.

1:03PM J18.00008 Enhancing optical gradient forces with metamaterials¹, VINCENT GINIS, Vrije Univ. Brussel, PHILIPPE TASSIN, Vrije Univ. Brussel and Ames Lab/Iowa State Univ., IRINA VERETENNICOFF, Vrije Univ. Brussel — The transfer of linear momentum from electromagnetic waves to matter and the associated optical forces allow to dynamically manipulate the geometry of nanophotonic components with electromagnetic fields. In recent years, it has been proposed to use optical gradient forces for all-optical actuation of nanophotonic systems. This would open up the possibility for information processing inside nanoscale devices. Despite many efforts to increase these forces in integrated systems, they remain too small for most practical applications. In this contribution, we demonstrate how optical gradient forces can be enhanced significantly with the use of metamaterials. By implementing the techniques of transformation optics, we show how a metamaterial slab allows for the magnification of optical forces over several magnitudes, even when realistic losses are included.

¹Work at VUB was supported by the Research Foundation Flanders (FWO-Vlaanderen) and the Belgian Science Policy Office (Grant No. IAP VI/10). Work at ISU was supported by Ames Laboratory (U.S. DOE).

1:15PM J18.00009 Terahertz composite right/left-handed transmission-line metamaterial surfaces¹, ZHIJUN LIU, PHILIP HON, AMIR TAVALLAEI, TATSUO ITOH, BENJAMIN WILLIAMS, Electrical Engineering Department, University of California, Los Angeles, California 90095, USA, UCLA TERAHERTZ DEVICES AND INTERSUBBAND NANOSTRUCTURES LABORATORY TEAM, UCLA MICROWAVE ELECTRONICS LAB TEAM — We present terahertz metamaterial waveguides based on the concept of composite right/left-handed (CRLH) transmission-lines implemented in a metal-dielectric-metal geometry. The waveguides are fabricated with spin-coated Benzocyclobutene sandwiched between a ground plane and photolithographically defined top capacitive metal pads. Angle-resolved reflection spectroscopy measurement is used to map the dispersion of this metamaterial surface, which reveals strong resonant absorptions for both right-handed and left-handed (backward wave) propagating modes within the leaky-wave bandwidth. Tuning of the waveguide dispersion is demonstrated by varying the integrated lumped element capacitive geometry. The incident polarization provides selection of different waveguide modes, exhibiting either fully right/left handed, or right-handed only propagation. Analysis based on full-wave finite element method simulations as well as lumped circuit models will be presented.

¹This work was supported by NSF under Grant No. ECCS-0901827.

1:27PM J18.00010 Metamaterial Single Polarization Grid: Moving Towards the Dynamic Selective Polarizer, COREY SHEMELYA, THOMAS VANDERVELDE, Tufts University — Ongoing interest in active metamaterial devices has increased due to their scalability, tunability, and, more importantly, the ability to turn them on or off. A dynamic metamaterial polarizer has unique applications for identifying manmade objects anywhere in the IR. This work describes a single layer metamaterial polarization grid. The metamaterial grid is immediately scalable to many different wavelengths. The polarization grid has been designed for conversion to a dynamic metamaterial polarizer with simulated on/off ratios of 9 to 1. To this end, samples have been fabricated using varying doping concentrations of Si in GaAs grown epitaxially on Sapphire. Au metamaterials along with contact grids were then patterned and deposited. This design allows for potential dynamic responses as well as monolithic integration to create an active, metamaterial-stack, selective polarizer.

1:39PM J18.00011 A new theoretical model for enhanced optical transmission through thin films¹, ELI LANSEY, ISROEL MANDEL, Department of Physics, Graduate Center and City College of the City University of New York, JONAH GOLLUB, Phoebus Optoelectronics, DAVID CROUSE, Department of Electrical Engineering, City College of the City University of New York — We present a new theoretical approach for modeling the resonant properties and transmission through subwavelength apertures penetrating metal films. We show that standard cavity mode theory can be applied to an effective resonant cavity whose dimensions are determined by the aperture dimensions in conjunction with the evanescent decay lengths of the diffracted waves. This method predicts the dependence on variation in both the periodicity of the holes and the film thickness over a wide range of values. It further provides a physical mechanism for the enhanced transmission observed in periodic aperture arrays.

¹This material is based upon work supported by the DOD/DARPA SBIR PROGRAM under Contract No. W31P4Q-10-C-0074. It has been approved for public release, distribution unlimited.

1:51PM J18.00012 Enhanced second harmonic generation from aperiodic arrays of gold nanoparticles, ANTONIO CAPRETTI, ECE Dept. and Photonics Center Boston University & DIETL University of Naples Federico II, GARY WALSH, ECE Dept. and Photonics Center Boston University, JACOB TREVINO, Div. of MSE Boston University, GIOVANNI MIANO, DIETL University of Naples Federico II, LUCA DAL NEGRO, ECE Dept. and Photonics Center Boston University & Div. of MSE Boston University — Second harmonic generation (SHG) from planar arrays of metal nanoparticles has been investigated in the last years for several configurations of particle shape and excitation-collection directions. In particular L-shaped particles have been employed to remove centrosymmetry. In this work we study SHG dependence on the array geometry, by comparing the generation efficiency of periodic arrays with that of deterministic aperiodic ones, namely Fibonacci and Golden Angle Spiral, lacking planar centrosymmetry. Two excitation-collection configurations are employed to test fabricated arrays. The whole range of average particle separation is explored, from closed spaced particles (plasmonic regime) to far spaced particles (photonic regime). We observe that SHG efficiency can be increased by arranging centrosymmetric particles in aperiodic arrays without inversion symmetry, both in the plasmonic regime and in the photonic one. We also demonstrate that Fibonacci and Golden Angle Spiral arrays perform differently in respect of the average interparticle separation and the collection direction, allowing the tunability of SHG extraction.

2:03PM J18.00013 Plasmonic Coupling Effects in Large-area High-enhancement, Periodically-Arrayed Nanopillars, FRANCISCO BEZARES, JOSHUA CALDWELL, OREST GLEMBOCKI, Naval Research Laboratory, MAARIT KARINIEMI, JAAKKO NIINISTÖ, TIMO HATANPÄÄ, University of Helsinki, RONALD RENDELL, Naval Research Laboratory, MARAIZU UKAEGBU, Howard University, MIKKO RITALA, University of Helsinki, SHARKA PROKES, Naval Research Laboratory, CHARLES HOSTEN, Howard University, MARKKU LESKELA, University of Helsinki — Periodically arrayed Si nanopillars, coated with a thin layer of Ag, have been shown to produce large-area (~1 mm or more), uniform enhancement of the electromagnetic (EM) field near the surface of such arrays, thus suggesting suitability for the development of next-generation chem/bio-sensors. Although short-range plasmonic coupling effects are expected to increase the enhancement factor of these arrays several orders of magnitude, limitations in current lithographic techniques prohibit the fabrication of closely spaced nanopillars where such coupling effects become significant. Here we show experimentally that the use of Atomic Layer Deposition of Ag allows for the fabrication of Ag-coated Si nanopillar arrays with interpillar spacings of a few nanometers (~2 nm) resulting in 1-2 orders of magnitude increase in EM enhancement observed throughout the whole array area. Experimental observations that provide insight into the nature of the different coupling phenomena contributing to the overall enhancement of the EM field in these systems will also be discussed.

Tuesday, February 28, 2012 11:15AM - 2:15PM – Session J19 DCMP DAMOP: Invited Session: Strongly Interacting Cold Fermi Gases 253AB

11:15AM J19.00001 From ultracold Fermi Gases to Neutron Stars, CHRISTOPHE SALOMON, LKB, Ecole Normale supérieure — Ultracold dilute atomic gases can be considered as model systems to address some pending problem in Many-Body physics that occur in condensed matter systems, nuclear physics, and astrophysics. We have developed a general method to probe with high precision the thermodynamics of locally homogeneous ultracold Bose and Fermi gases [1,2,3]. This method allows stringent tests of recent many-body theories. For attractive spin 1/2 fermions with tunable interaction (^6Li), we will show that the gas thermodynamic properties can continuously change from those of weakly interacting Cooper pairs described by Bardeen-Cooper-Schrieffer theory to those of strongly bound molecules undergoing Bose-Einstein condensation. First, we focus on the finite-temperature Equation of State (EoS) of the unpolarized unitary gas. Surprisingly, the low-temperature properties of the strongly interacting normal phase are well described by Fermi liquid theory [3] and we localize the superfluid phase transition. A detailed comparison with theories including recent Monte-Carlo calculations will be presented. Moving away from the unitary gas, the Lee-Huang-Yang and Lee-Yang beyond-mean-field corrections for low density bosonic and fermionic superfluids are quantitatively measured for the first time. Despite orders of magnitude difference in density and temperature, our equation of state can be used to describe low density neutron matter such as the outer shell of neutron stars.

11:51AM J19.00002 Spin-Imbalance in One and Three-Dimensional Fermi Gases¹, RANDALL HULET², Rice University — The FFLO modulated superconductor state was independently proposed by Fulde and Ferrell, and Larkin and Ovchinnikov, as a way of accommodating the excess spin in a spin-polarized superconductor. The pairs in the FFLO state have non-zero center-of-mass momentum, which can produce a periodic structure with a spatially-modulated order parameter. Although there is some evidence for FFLO pairing in certain heavy fermion compounds that are able to accommodate both magnetic and superconducting order, conclusive experimental proof remains elusive. Motivated by the search for exotic paired states, we have performed experiments with spin-imbalanced ultracold atomic Fermi gases in both 3D and 1D. We use two hyperfine levels of ^6Li to emulate the spin-up and down states. The *s*-wave pairing interactions are controlled via a magnetically-tuned collisional (Feshbach) resonance. In 3D, we find that the gas phase separates into an evenly paired BCS-like core, surrounded by the excess spin-up atoms [1]. For the 1D experiment, a two-dimensional optical lattice was used to create an array of 1D tubes that are each filled with ~200 atoms. The weak axial confinement again produces a phase separation, but in contrast to 3D we find a partially-polarized central core surrounded by either fully-paired or fully-polarized wings, depending on the degree of overall spin-polarization [2]. Theory predicts that the partially-polarized phase is an FFLO superfluid. We are currently trying to obtain direct evidence for FFLO pairing, which may be revealed in the pair momentum distribution found by releasing the atoms axially and allowing them to expand in time-of-flight. We are also exploring the 1D-3D dimensional crossover that occurs when the coupling between tubes is reduced.

12:27PM J19.00003 Many-body physics with ultracold alkali-earth fermions in optical lattices, JUN YE, University of Colorado at Boulder and NIST — No abstract available.

1:03PM J19.00004 Onset of a Pseudogap Regime in Ultracold Fermi Gases¹, AUREL BULGAC, University of Washington — We show, using an ab initio approach based on Quantum Monte Carlo technique, that the pseudogap regime emerges in ultracold Fermi gases close to the unitary point. We locate the onset of this regime at a value of the interaction strength slightly to the BCS side of the unitary point. We determine the evolution of the gap as a function of temperature and interaction strength in the Fermi gas around the unitary limit and show that our results exhibit a remarkable agreement with the recent wave-vector resolved radio frequency spectroscopy data. Our results indicate that a finite temperature structure of the Fermi gas around unitarity is complicated and involves the presence of preformed Cooper pairs, which however do not contribute to the long range order.

1:39PM J19.00005 Strongly Repulsive Quantum Gases¹ , TIN-LUN HO, Physics Department, The Ohio State University — Advances in cold atom experiments have shown that the properties of repulsive Fermi and Bose gases are far more intricate than generally expected, as these systems can produce molecules even in the weakly interacting regime. Recent experiments, however, reveal some general yet puzzling properties of these gases in the strongly repulsive regime. In this talk, we show that these properties are direct consequences of statistics, and are fundamental properties of quantum gases [1]. We shall also discuss the related issue of itinerant ferromagnetism, and discuss the physical settings in which ferromagnetism can be found.

Session J20 COM CSWP: Invited Session: Sexual and Gender Diversity Issues in Physics 253C

11:15AM J20.00001 The State of Higher Education for STEM LGBTQQ Faculty/Staff¹ , SUSAN RANKIN, The Pennsylvania State University — It has long been understood—an understanding that has been well supported by research-based evidence—that institutional “climate” has a profound effect on any academic community’s ability to carry out its tripartite mission of teaching, research, and service (Bauer, 1996; Boyer, 1990; Peterson & Spencer, 1990; Rankin, 1998; 2003; 2010; Rankin & Reason, 2008; Tierney & Dilley, 1996). With the acknowledgment that institutions differ in the level of attention and emphasis on issues campus climate, it is safe to say that a campus climate offering equitable learning opportunities for all students, academic freedom for all faculty, and fairness in employment for all staff and administrators is one of the primary responsibilities of institutions of higher education. The research also suggests that a challenging campus climate exists for LGBTQQ students, faculty and staff. Based on the literature, a challenging climate leads to decreased productivity, decreased sense of value to the community, decreased retention, and negatively influences educational outcomes (Settles, et al. 2006; Trower & Chait (2002); Pascrell & Terenzini, 2005; Whitt, Edison, Pascarella, Terenzini, & Nora, 2001). Little is available in the literature on LGBTQQ faculty in the STEM fields. This program will engage participants in a review of the results of the 2010 project with regard to the experiences of LGBTQQ faculty and staff in the STEM fields.

¹Project supported by Campus Pride.

11:51AM J20.00002 Shattering the Lavender Ceiling: Sexual Minorities in Physics , MICHAEL RAMSEY-MUSOLF, University of Wisconsin-Madison — I will discuss some of the challenges experienced by sexual minorities in physics, from both a personal and broader perspective. I will also comment on the opportunities for the field to become more inclusive, supportive, and scientifically stronger by addressing these challenges.

12:27PM J20.00003 Why Awareness of LGBT issues in the Physics Community Makes Sense , JANICE HICKS, National Science Foundation — A thriving innovation ecology requires diversity of perspective and knowledge. We want to attract and retain the best possible talent to Science and Engineering, particularly after expensive investments in training of faculty, postdoctoral fellows and students. Participants who bring their authentic identity to work are much more efficient, as it takes a lot of energy to stay in the closet. It is a concern that so few S&E faculty are out of the closet – we don’t know the numbers and they are difficult to obtain. This makes it difficult for the younger generation of students to relate as they do not see sexual orientation as an obstacle. It is also important for LGBT people to be visible in order to benefit from workplace policies such as family leave and other benefits. There are some activities to promote a positive view of LGBT people in S&E. The National Organization of Gay and Lesbian Scientists and Technical Professionals (NOGLSTP) has been in existence since 1983, and holds receptions and symposia at the AAAS meeting and other professional society meetings, as well as a symposium called “Out to Innovate,” next to be held October 13-14, 2012 at Ohio State University. The American Chemical Society started an LGBT subdivision of its Division of Professional Relations in 2010. Much more needs to be done to educate leaders so they can speak knowledgeably about LGBT issues. Their ability to do so can affect their success in hiring and retaining top talent.

1:03PM J20.00004 Physics Climate as Experienced by LGBT+ Physicists , ELENA LONG, Kent State University — In 2009, Elena Long created the LGBT+ Physicists website (<http://lgbtphysicists.x10hosting.com>) as a warehouse for resources useful for sexual and gender minorities working in physics. This resource has grown to include networking resources, lists of LGBT-friendly universities and localities, recommendations for enacting positive change in physics communities, and out-reach to other STEM-oriented LGBT organizations. This has been possible in large part by the dynamic community of LGBT+ physicists and allies looking to make physics more welcoming towards our community. In 2011, Elena used her position as Member at Large on the executive committee of the Forum of Graduate Student Affairs (FGSA) to conduct a climate survey that included, among other things, the first serious look at LGBT+ demographics in physics. The survey focused particularly on issues of language heard and harassment experienced by physicists and was broken down into categories based on race, physical and mental ability, gender, and sexuality. Furthermore, it examined the outcomes of experienced harassment and the reasons for when harassment was not reported. Due to the nature of the study, overlapping demographics, especially “multiple minorities,” were also explored. This talk will give a brief history of the LGBT+ Physicists resource as well as an overview of the FGSA study.

1:39PM J20.00005 TBA , THEODORE HODAPP, American Physical Society APS — No abstract available.

Tuesday, February 28, 2012 11:15AM - 2:03PM –

Session J21 DMP: Focus Session: Search for New Superconductors: New Theories and Experiments 254A

11:15AM J21.00001 The Challenge of Unconventional Superconductivity¹ , MICHAEL NORMAN, Materials Science Division, Argonne National Laboratory — In the past few decades, several new classes of superconductors have been discovered. Most of these are unconventional in that they do not appear to be related to traditional superconductors where the order parameter is more or less spatially isotropic. As a consequence, it is felt by many (but not all!) that the cause of superconductivity arises from a different source than the electron-ion interactions that are at the heart of conventional superconductivity. But developing a rigorous theory for any of these classes of materials has proven to be a difficult challenge, and will continue to be one of the major problems in physics in the decades to come. This is particularly true in that if history is any guide, even more dramatic discoveries of unconventional superconductors await us in the future.

¹Work supported by the US DOE, Office of Science, under Contract No. DE-AC02-06CH11357 and by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the US DOE, Office of Science, under Award No. DE-AC02-98CH10.

11:51AM J21.00002 Transport properties of layered Ba(Pb,Bi)O₃ thin films, G.W.J. HASSINK, K. MUNAKATA, R.H. HAMMOND, M.R. BEASLEY, Geballe Laboratory for Advanced Materials, Stanford University, Stanford, CA 94305 — Doped BaBiO₃ is a 3D oxide superconductor with a maximum T_c of 30 K for Ba_{0.6}K_{0.4}BiO₃. There has been a lot of discussion on whether this high T_c can be explained purely by electron-phonon coupling with a high coupling constant λ . In addition, the presence of real-space paired 6s² electrons in the parent compound raise intriguing questions about whether there is an electron-electron coupling interaction as well. This possible negative-U interaction might be used to implement the suggestion by Berg, Orgad and Kivelson [Phys.Rev.B 78, 094509] that for a two-layer system where one layer provides electron pairing interaction and the other layer is conducting, the whole can be superconducting with a high T_c. Here we discuss the transport properties of BaPbO₃/BaBiO₃ bilayers, where the BaBiO₃ layer is thought to act as the pairing layer, while the BaPbO₃ acts as the conducting layer. The transport behavior changes to insulating upon decreasing the metallic BaPbO₃ layer thickness at values that single films are expected to still be metallic.

12:03PM J21.00003 Control of Two-Dimensional Multi-Component Superconductivity in SrTiO₃ Heterostructures by Interlayer Coupling, HISASHI INOUE, MINU KIM, SLAC National Accelerator Laboratory, University of Tokyo, CHRISTOPHER BELL, YASUYUKI HIKITA, SLAC National Accelerator Laboratory, HIROSHI OKAMOTO, University of Tokyo, HAROLD HWANG, Stanford University, SLAC National Accelerator Laboratory, University of Tokyo — Two-dimensional (2D) superconductivity (SC) in the clean limit is of particular interest since novel phases such as the Fulde-Ferrell-Larkin-Ovchinnikov state [1,2], and Landau-quantized SC [3] are suggested theoretically. In an attempt to approach this limit experimentally, SC was confined in a narrow δ -doped region of SrTiO₃ [4]. 2D subbands (SBs) were observed as well as 2D SC. Building on these results, we have explored the coupling between two 2D superconducting layers in structures with two δ -doped layers, with variable interlayer coupling controlled by their spacing. We observe multiple components of the SC in the temperature and angular dependent upper critical field plots. These data suggest that the SB structure in the doped and interlayer regions directly impact the SC, and may play an important role for the design and investigation of multi-component SC. [1] P. Fulde *et al.*, *Phys. Rev.* **135**, A550 (1964). [2] A. I. Larkin *et al.*, *Sov. Phys. JETP* **20**, 762 (1965). [3] M. Rasolt *et al.*, *Rev. Mod. Phys.* **64**, 709 (1992). [4] Y. Kozuka *et al.*, *Nature* **462**, 487 (2009).

12:15PM J21.00004 Electric field induced superconductivity in a layered transition metal chalcogenide, J.T. YE, Y.J. ZHANG, Y. MASTUHASHI, Y. IWASA, Department of Applied Physics, The University of Tokyo — Recent developments in electric double layer transistors (EDLTs) are attracting growing interests because of its stronger field effect orders of magnitude larger than other transistor techniques. This method provides unique abilities to reach the high carrier densities required for inducing superconductivity in several kinds of materials. Among them, layered materials are convenient examples to work with since high quality surface suitable for transistor channel could be easily obtained after mechanical cleavage. Especially, after the introduction of graphene techniques, high quality atomically flat surface can be routinely fabricated on a broad range of layered materials. Combining EDL with novel materials processing techniques on layered materials provides new opportunities in manipulating their electronic properties. We can achieve high carrier density up to 10¹⁴ cm⁻² electrostatically in layered materials and induce metal insulator transitions. Superconductivity, similar as that shown in ZnI EDL transistor, could be observed when we cool down the system to low temperature after inducing a metal insulator transition with large amount of accumulated carriers. The versatility of this combination shows its potential as a protocol to study varieties of layered materials for broader scope of possibilities in accessing their superconductivities. And hopefully, this method could also facilitate to induce superconductivity in new materials.

12:27PM J21.00005 Fano resonances in multigap Fe based superconductors and complexity for material design, ANTONIO BIANCONI, Physics Dept., Sapienza University of Rome — The Fano resonance in the superconducting gaps (or “shape resonance” or “Feshbach resonance”) in multigap superconductors [A Bianconi *Sol. State Commun.* **89**, 933 (1994)] has been proposed as the mechanism for high T_c in Fe-based superconductors and related compounds [D Innocenti *et al Supercond. Sci. Technol.*, 015012 (2011)] near the Lifshitz transition for a vanishing Fermi surface in a superlattice of layers or wires, in the proximity of a lattice, electronic, magnetic instability with competing interactions that give complex systems. The multiscale phase separation from nano-scale to micron scale in K0.8Fe1.6Se2. [A Ricciet *al Phys. Rev.B* **84**, 060511 (2011)] has been detected by a mixed real space and momentum space probe: scanning nano focused X-ray diffraction like in La2CuO4+y [M. Fratini, *et al Nature* **466**, 841 (2010) and [N. Poccia *et al Nature Materials* **10**, 733 (2011)] showing scale free structural organization of dopants favoring in the high T_c phase. The results on KFeSe show phase separation, percolating superconductivity, competing with percolating magnetism and shape resonances in the superconducting gaps.

12:39PM J21.00006 Ordering of dopants and potential increase of Tc to near room temperature, STUART WOLF, University of Virginia, VLADIMIR KRESIN, Lawrence Berkeley Laboratory — This talk will describe a novel method to increase the resistive Tc of cuprate superconductors to values that might approach room temperature, especially if applied to the underdoped region of the Tc versus carrier concentration phase diagram. This is the part of the so-called pseudogap region that exhibits energy gaps and a small Meissner effect well above the maximum resistive transition [1]. The method proposed here involves ordering of the dopants that provide the itinerant holes in the copper oxygen planes. These dopants also act as pair breakers since they are defects in the structure. The strategy we are proposing here is to separate the regions with dopants which provide the itinerant carriers in the cuprate planes from the metallic but dopant free regions nearby, but far enough away to be not seriously affected by the proximity effect. If this separation can be carried out appropriately and we will describe how this will be done in the talk, there will be fully connected high Tc regions that can fully span a sample and present a very high temperature resistive transition, approaching room temperature for some of the cuprates.

[1] V.Z. Kresin and S.A. Wolf, ArXiv 1109.0341

12:51PM J21.00007 Inhomogeneous superconducting state and the intrinsic Tc: Near room temperature superconductivity in the cuprates, VLADIMIR KRESIN, Lawrence Berkeley National Laboratory, STUART WOLF, University of Virginia — Doped cuprates are inhomogeneous superconductors and exhibit properties strongly affected by this inhomogeneity. The notion of an intrinsic critical temperature whose value greatly exceeds the resistive Tc is supported by a number of experimental studies and these will be reviewed in this talk. In particular the anomalous diamagnetism observed above the resistive transition is a manifestation of the presence of superconducting clusters embedded in a normal metallic matrix. The value of intrinsic critical temperature, that reflects the onset of superconductivity in the highest transition temperature clusters, is in some cuprates near room temperature. The transition to the fully superconducting state is percolative in nature and is strongly dependent on the inhomogeneities. Some consequences of such a system, including the ac response will be described.

1:03PM J21.00008 A Kohn Luttinger perspective on topological superconductivity¹, RONNY THOMALE, Stanford University, CHRISTIAN PLATT, WERNER HANKE, Universitaet Wuerzburg — On the basis of an orbital angular momentum and point group symmetry analysis, we argue that electron-driven fluctuations from the viewpoint of a Fermi surface instability generically provide a propensity towards topological superconductivity when the irreducible lattice representations associated with the Cooper pairs are multi-dimensional. For illustration, we explicate our generation recipe of topological superconductivity for the cases of ruthenates, cobaltates, and graphene doped to van Hove filling, i.e. representatives for square, triangular, and honeycomb lattice pairing.

¹Ronny Thomale acknowledges support by the SITP postdoctoral fellowship at Stanford. The authors are supported by DFG-SPP 1458/1.

1:15PM J21.00009 X-ray photoelectron spectroscopy of Single Crystals of intercalated Bismuth Selenide¹, SOMADITYA SEN, JOHN A. DUDEK, University of Wisconsin Milwaukee, WI, YING ZOU, Shanghai Institute of Applied Physics, China, MARY SEVERSON, MARK BISSEN, Synchrotron Radiation Center, Stoughton, WI, PRASENJIT GUPTASARMA², University of Wisconsin Milwaukee, WI — The possibility of superconductivity in topological insulators is likely to yield new physics, especially because the insulating normal state is highly unconventional. However, before moving on to microscopic theory, it is important to characterize and study basic systems available today. Here, we present XPS studies of intercalated single crystals of Bi₂Se₃ and Sb₂Se₃. Core level spectroscopy, combined with infra-red and Raman spectroscopy, yield details of the nature of bonding of atoms at the cleaved surface.

1:27PM J21.00010 Search for Superconductivity in Single Crystals of Topological Insulators¹, PRASENJIT GUPTASARMA², SOMADITYA SEN, JOHN DUDEK, University of Wisconsin Milwaukee, WI, MARY SEVERSON, MARK BISSEN, Synchrotron Radiation Center, Stoughton, WI — Observation of superconductivity in Cu-intercalated Bi₂Se₃, and in Bi₂Te₃ under pressure, open up the possibility of occurrence of superconductivity in other similarly modified structures. Here, we present detailed studies from a comprehensive search for superconductivity in selenides and tellurides of Bismuth and Antimony. High-quality single crystals were intercalated with a number of different elements using both in situ and ex situ techniques, then scanned for a resistive or magnetic transition to superconductivity. With an intent to understand the nature of intercalation in these compounds, we discuss results from our search for superconductivity, together with crystal structure analysis and detailed optical and x-ray photoelectron spectroscopy studies of the cleaved surface.

1:39PM J21.00011 Surface Andreev Bound States of Topological Superconducting Phase in Doped Semiconductors: Application to Cu_xBi₂Se₃¹, TIMOTHY HSIEH, MIT, LIANG FU, Harvard — The recently discovered superconductor Cu_xBi₂Se₃ is a candidate for three-dimensional time-reversal-invariant topological superconductors, which is predicted to have robust surface Andreev bound states hosting massless Majorana fermions. In this work, we present an analytical and numerical study of the surface Andreev bound state wavefunction and dispersion. We find the topologically protected Majorana fermions at $k = 0$, as well as a new type of surface Andreev bound states at finite k . We relate our results to a recent point-contact spectroscopy experiment.

1:51PM J21.00012 Functional renormalization group and variational Monte Carlo studies of the electronic instabilities in graphene near 1/4 doping, FA WANG, Department of Physics, MIT, QIANG-HUA WANG, National Lab of Solid State Microstructures, Nanjing University, China, FAN YANG, Department of Physics, Beijing Institute of Technology, China, DUNG-HAI LEE, Department of Physics, UC Berkeley; Materials Sciences Division, LBNL — We study the electronic instabilities of near 1/4 electron doped graphene using the functional renormalization group (FRG) and variational Monte-Carlo method. A modified FRG implementation is utilized to improve the treatment of the von Hove singularity. At 1/4 doping the system is a chiral spin density wave state exhibiting the anomalous quantized Hall effect, or equivalently a Chern insulator. When the doping drops below 1/4, the $d_{x^2-y^2} + id_{xy}$ Cooper pairing becomes the leading instability. Our results suggest near 1/4 electron- or hole-doped graphene is a fertile playground for the search of Chern insulators and superconductors.

Tuesday, February 28, 2012 11:15AM - 2:15PM –
Session J22 DMP DCOMP: Focus Session: Fe-based Superconductors - Nodal and Nodeless Superconductivity 254B

11:15AM J22.00001 Evolution of symmetry and structure of the gap in Fe-based superconductors with doping and interactions, ANDREY CHUBUKOV, SAURABH MAITI, University of Wisconsin-Madison, MAXIM KORSHUNOV, Russian Academy of Sciences, Siberian branch, THOMAS MAIER, Oak Ridge National Lab., PETER HIRSCHFELD, University of Florida — We present a detailed study of the symmetry and structure of the pairing gap in Fe-based superconductors. We treat them as quasi-2D systems, decompose the pairing interaction into s -wave and d -wave channels and into contributions from scattering between different Fermi surfaces and analyze how each scattering evolves with doping and input parameters. We verify that each interaction is well approximated by the lowest angular harmonics and use this simplification to analyze the interplay between the interaction with and without spin-fluctuation components, the origin of the attraction in the $s\pm$ and $d_{x^2-y^2}$ channels, the competition between them, the nature of angular dependence of the $s\pm$ gaps along the electron Fermi surface, the conditions under which $s\pm$ gap develops nodes, and the origin of superconductivity in heavily electron- or hole-doped systems, when only Fermi surfaces of one type are present. In particular, we find that with increased electron and hole doping, the competition from d -wave grows. In the case of strong hole doping, there is some ambiguity over the leading solution, but in the case of strong electron doping, d -wave emerges as clear winner.

11:27AM J22.00002 Non-Fermi liquid behavior in overdoped iron-pnictides, JOHNPierre PAGLIONE, KEVIN KIRSHENBAUM, SHANTA SAHA, TYLER DRYE, University of Maryland — Electrical transport, magnetic susceptibility and heat capacity data are presented on a series of single-crystal iron-based intermetallic compounds with the ThCr₂Si₂ structure with transition metal substitution used to heavily over-dope the system. We will present observations of unusual temperature dependences in transport, susceptibility and electronic specific heat that indicate an unexpected deviation from Fermi liquid behavior that persists to milliKelvin temperatures.

11:39AM J22.00003 Probing the Superconducting Order Parameter of Co-doped BaFe₂As₂ by Josephson Interferometry¹, JUAN ATKINSON, DALE VAN HARLINGEN, University of Illinois at Urbana-Champaign, PAUL CANFIELD, Ames Laboratory and Iowa State University — We probe the superconducting order parameter in Co-doped BaFe₂As₂ (Ba122) single crystals via measurements of the critical current of Josephson junctions fabricated on polished faces orthogonal to the c-axis. The modulation of the critical current as a function of magnetic flux applied along the c-axis is different for junctions fabricated on different points on a circularly polished face of the Ba122 crystal since each junction probes an effective order parameter of the crystal through an angle in k-space. These modulations map the phase anisotropy and test for the proposed $\pm$ mode pairing symmetry. We will present preliminary results of these studies and compare to existing theoretical models.

¹Work supported by the Department of Energy grant BNL-150252 through the DOE- Energy Frontier Research Center for Emergent Superconductivity.

11:51AM J22.00004 Nodal structure and quantum critical point beneath the superconducting dome of BaFe₂(As_{1-x}P_x)₂, YUJI MATSUDA, Kyoto University — Among BaFe₂As₂ based materials, the isovalent pnictogen substituted system BaFe₂(As_{1-x}P_x)₂ appears to be the most suitable system to discuss many physical properties, because BaFe₂(As_{1-x}P_x)₂ can be grown with very clean and homogeneous, as evidenced by the quantum oscillations observed over a wide doping range even in the superconducting dome giving detailed knowledge on the electronic structure. We investigate the structure of the superconducting order parameter in BaFe₂(As_{0.67}P_{0.33})₂ ($T_c = 31$ K) with line nodes by the angle-resolved thermal conductivity measurements in magnetic field. The experimental results are most consistent with the closed nodal loops located at the flat part of the electron Fermi surface with high Fermi velocity. The doping evolution of the penetration depth indicates that nodal loop is robust against P-doping. Moreover, the magnitude of the zero temperature penetration depth exhibits a sharp peak at $x=0.3$, indicating the presence of a quantum phase transition deep inside the superconducting dome.

This work has been done in collaboration with T. Shibauchi, K. Hashimoto, S. Kasahara, M. Yamashita, T. Terashima, H. Ikeda (Kyoto), A. Carrington (Bristol), K. Cho, R. Prozorov, M. Tanatar (Ames), A.B. Vorontsov (Montana) and I.Vekhter (Louisiana).

12:27PM J22.00005 London penetration depth in single crystals SrFe₂(As_{0.65}P_{0.35})₂, CHARLES P. STREHLOW, K. CHO, M.A. TANATAR, R. PROZOROV, Ames Laboratory, T. KOBAYASHI, S. MIASAKA, S. TAJIMA, Dept. of Physics, Osaka University, Osaka, Japan — In a contrast to a fully-gapped charge-doped (Ba,K)Fe₂As₂ and Ba(Fe,T)₂As₂ [1], isoelectron - substituted BaFe₂(As,P)₂ exhibit nodal superconducting gap [2]. To explore possible universality, low-temperature variation of the London penetration depth, $\Delta\lambda(T)$, was measured in optimally - doped SrFe₂(As_{0.65}P_{0.35})₂ with $T_c=29$ K. $\Delta\lambda(T)$ revealed notable deviations from the exponential temperature dependence, expected for a fully-gapped superconductors. Instead the data are best fit with a power-law function, $\Delta\lambda = AT^n$. The analysis of the data below $1/3T_c$ over a variable fitting temperature range produced exponents $n \leq 2$ which suggests the presence of nodes in the superconducting gap, similar to the P - doped Ba122 compounds.

[2] K. Hashimoto, *et. al.* Phys. Rev. B **81**, 220501(R) (2010).

12:39PM J22.00006 London penetration depth in heavily over-doped Ba(Fe_{1-x}Co_x)₂As₂, JASON MURPHY, H. KIM, M.A. TANATA, A. THALER, P.C. CANFIELD, The Ames Laboratory, U. WELP, W.K. KWOK, Argonne National Laboratory, R. PROZOROV, The Ames Laboratory — The low-temperature variation of London penetration depth, $\Delta\lambda(T)$, has been previously studied in heavily over-doped Ba(Fe_{1-x}Ni_x)₂As₂ [1] and the authors suggested the development of line nodes. Similar conclusion was made from thermal conductivity measurements in Ba(Fe_{1-x}Co_x)₂As₂ [2]. However, $\Delta\lambda(T)$ in this system has only been measured for $x \leq 0.102$ [3], which is not far enough from optimal doping. Here we report tunnel - diode resonator (TDR) measurements in heavily overdoped single crystals of Ba(Fe_{1-x}Co_x)₂As₂ with Co content of $x = 0.108$ ($T_c=14.8$ K) and $x = 0.127$ ($T_c=9$ K). We found a robust power-law behavior of $\Delta\lambda = AT^n$ with $n = 2.5$ and $n = 2.11$ respectively. To test whether the nodes are symmetry imposed or accidental, samples were irradiated with heavy ions. The produced disorder, leads to a decrease in T_c and of the exponent n . These results effects will be discussed in a context of unconventional pairing in Fe-based superconductors.

[2] J.-Ph. Reid *et. al.*, Phys. Rev. B **82**, 064501 (2010).

[3] R.T. Gordon *et.al.* Phys. Rev. B **82**, 054507 (2010).

12:51PM J22.00007 Specific Heat To H_{c2}: Evidence for Nodes or Deep Minima in the Superconducting Gap of Under- and Overdoped BaFe_{2-x}Co_xAs₂¹, G.R. STEWART, J.S. KIM, Department of Physics, Univ. Florida, Gainesville, FL, K. GOFRYK, F. RONNING, Los Alamos National Laboratory, Los Alamos, NM, A.S. SEFAT, Oak Ridge National Laboratory, Oak Ridge, TN, K.Y. CHOI, K.H. KIM, Department of Physics and Astronomy, Seoul National Univ., Seoul, South Korea — Low temperature specific heat, C , in magnetic fields up to H_{c2} is reported for BaFe_{1.91}Co_{0.09}As₂ (underdoped, H_{c2} $\approx$ 16 T, T_c=8 K), BaFe_{1.79}Co_{0.21}As₂ (overdoped, H_{c2} $\approx$ 27 T, T_c=17 K), and - for comparison - BaFe_{1.95}Ni_{0.05}As₂, which should have properties similar to the underdoped Co-sample. Previous measurements of thermal conductivity (as a function of temperature and field) and penetration depth on comparable composition samples gave some disagreement as to whether there was fully gapped/nodal behavior in the under-/overdoped materials respectively. The present work shows that the measured behavior of the specific heat γ ($\propto C/T$ as $T \rightarrow 0$, i. e. a measure of the electronic density of states at the Fermi energy) as a function of field obeys $\gamma \approx H^{0.6 \pm 0.1}$, similar to the Volovik effect for nodal superconductors, over the entire field range for both under- and overdoped Co samples as well as for the underdoped Ni sample. By comparison to theory, the possibility of two bands, one with line nodes and one fully gapped, being present in these materials is discussed.

¹Work at Florida supported by US DOE, contract no. DE-FG02-86ER45268, at Los Alamos by US DOE and LANL LDRD, at Oak Ridge by US DOE, at Seoul by NCRI grant no. 2010-0018300

1:03PM J22.00008 Nodal versus nodeless order parameters in LiFeP and LiFeAs superconductors, T. SHIBAUCHI, K. HASHIMOTO, S. KASAHARA, R. KATSUMATA, Y. MIZUKAMI, M. YAMASHITA, H. IKEDA, T. TERASHIMA, Y. MATSUDA, Kyoto University, A. CARRINGTON, University of Bristol — There is growing evidence that the superconducting gap structure is not universal in the iron-based superconductors. It is essential to determine experimentally what causes nodal and nodeless states. The 111 materials, LiFeAs and LiFeP provide a unique route to study this problem as both materials are superconducting, nonmagnetic, and importantly very clean, with long electronic mean-free paths. Here we report on high-precision measurements of magnetic penetration depth λ in clean single crystals of LiFeAs and LiFeP superconductors, which reveal contrasting low-energy excitations of quasiparticles. In LiFeAs the low-temperature $\lambda(T)$ shows a flat dependence indicative of a fully gapped state, which is consistent with previous studies. In contrast, LiFeP exhibits a T -linear dependence of superfluid density $\propto \lambda^{-2}$, indicating a nodal superconducting order parameter. A systematic comparison of quasiparticle excitations in the 1111, 122, and 111 families of iron-pnictide superconductors implies that the nodal state is induced when the pnictogen height from the iron plane decreases below a threshold value of ~ 1.33 Å.

1:15PM J22.00009 Inter-Layer Superconducting Pairing Induced c-axis Nodal Lines in Iron-based Superconductors, CHANDAN SETTY, Purdue University, YUEHUA SU, Yantai University, ZIQIANG WANG, Boston College, JIANGPING HU, Purdue University — A layered superconductor with a full pairing energy gap can be driven into a nodal superconducting (SC) state by inter-layer pairing when the SC state becomes more quasi-3D. We propose that this mechanism is responsible for the observed nodal behavior in a class of iron-based SCs. We show that the intra- and inter-layer pairings generally compete and the gap nodes develop on one of the hole Fermi surface pockets as they become larger in the iron-pnictides. Our results provide an explanation of the c-axis gap modulations and gap nodes observed by angle resolved photo emission spectroscopy. In addition, we predict that an anti-correlated c-axis gap modulations on the hole and electron pockets should be observable in the $s\pm$ -wave pairing state.

1:27PM J22.00010 Thermal-transport measurement of the nodal superconductor KFe_2As_2 , MINORU YAMASHITA, DAIKI WATANABE, TAKYUYA YAMASHITA, TAKASADA SHIBAUCHI, YUJI MATSUDA, Department of Physics, Kyoto University, HIDETO FUKAZAWA, TAKU SAITO, YOH KOHORI, Department of Physics, Chiba University, KUNIHIRO KIHIO, AKIRA IYO, HIROSHI EISAKI, AIST, Tsukuba — Hole-doped Fe-based superconductors, $(\text{Ba}_{1-x}\text{K}_x)\text{Fe}_2\text{As}_2$, possess two different superconducting gap structures; a fully-gapped state near the optimally doped ($x \sim 0.5$) and a nodal gap state at the hole-dope end ($x = 1$). To investigate the detail gap structure, we performed thermal-transport measurements of KFe_2As_2 with very high purity ($\text{RRR} \sim 1,600$) down to 80 mK. From the temperature dependence of thermal conductivity at zero field, we find a finite residual of κ/T in the zero-temperature limit. This residual increases by magnetic field as $\propto \sqrt{H}$ in low fields, followed by a rapid increase near H_{c2} . Thermal conductivity measurements of different dopes ($x = 0.88, 0.93$) will be reported.

1:39PM J22.00011 Microwave Surface Impedance Measurements of $\text{SrFe}_2(\text{As,P})_2$ Single Crystals, HIDEYUKI TAKAHASHI, YOSHINORI IMAI, ATSUTAKA MAEDA, Department of Basic Science, the University of Tokyo, KENTARO KITAGAWA, KAZUYUKI MATSUBAYASHI, MASASHI TAKIGAWA, YOSHIYA UWATOKO, Institute for Solid State Physics, the University of Tokyo — Various pairing symmetries have been proposed concerning Fe-based superconductors both theoretically and experimentally. It was reported that LaFePO [1] and $\text{BaFe}_2(\text{As,P})_2$ [2] have line nodes in their superconducting gap. It is in sharp contrast to other Fe-based compounds such as LiFeAs [3] and $\text{Fe}(\text{Se,Te})$ [4]. To confirm whether line nodes in gap function is a common feature among P doped systems, we measured the microwave surface impedances of $\text{SrFe}_2(\text{As,P})_2$ single crystals ($T_c \sim 30\text{K}$). Single crystals were grown by self-flux method. The surface impedances were measured using a cavity perturbation technique. The imaginary part of surface impedance, which is proportional to London penetration depth in the superconducting state, shows a power law, $\lambda(T) - \lambda(0) \propto T^n$. The power law indicates low-energy quasiparticle excitation, and an exponent slightly smaller than 2 does not exclude the possibility of the existence of line nodes.

1:51PM J22.00012 Doping-induced line nodes in the superconducting gap of the iron arsenide $\text{Ba}_{1-x}\text{K}_x\text{Fe}_2\text{As}_2$ from thermal conductivity, R.T. GORDON, J.-PH. REID, X.G. LUO, H. SHAKERIPOUR, S. RENÉ DE COTRET, A. JUNEAU-FÉCTEAU, N. DOIRON-LEYRAUD, J. CHANG, LOUIS TAILLEFER, University of Sherbrooke, Canada, H. KIM, M.A. TANATAR, R. PROZOROV, Ames Laboratory and Iowa State University, USA, B. SHEN, H.-H. WEN, Nanjing University, China — The thermal conductivity κ of $\text{Ba}_{1-x}\text{K}_x\text{Fe}_2\text{As}_2$ was measured down to 50 mK in magnetic fields up to 15 T, for heat current both parallel and perpendicular to the tetragonal c axis, across a range of K concentrations from optimal doping ($T_c = 38\text{K}$) down to $T_c = 7\text{K}$, deep into the region of coexistence with antiferromagnetic order. From optimal doping down to $T_c \simeq 15\text{K}$, well into the coexistence region, there is no residual linear term in $\kappa(T)$ as $T \rightarrow 0$, showing that there are no nodes in the superconducting gap anywhere on the Fermi surface. For concentrations in a narrow range such that $9\text{K} < T_c < 13\text{K}$, a large residual linear term appears, signaling the onset of nodes in the superconducting gap, most likely vertical line nodes running along the c axis. For $T_c < 9\text{K}$, the gap is again nodeless. We propose that these changes in the superconducting gap structure are triggered by changes in the Fermi surface as it is reconstructed by the growing antiferromagnetic order.

2:03PM J22.00013 Evidence for line nodes in the energy gap of overdoped $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$: A low-temperature specific heat study¹, GANG MU, Department of Physics, Graduate School of Science, Tohoku University, Japan, JUN TANG, YOICHI TANABE, JINGTAO XU, World Premier International Research Center, Tohoku University, Japan, SATOSHI HEGURI, Department of Physics, Graduate School of Science, Tohoku University, Japan, KATSUMI TANIGAKI, Department of Physics, Graduate School of Science and World Premier International Research Center, Tohoku University, Japan — We report the low-temperature specific heat (SH) study on $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$ single crystals in a wide doping region under different fields. For the overdoped sample, we find the clear evidence for the presence of T^2 term in the electronic SH data, suggesting the presence of line nodes in the energy gap. This term is absent both for the underdoped and optimal doped samples. Moreover, the field induced electronic SH coefficient $\Delta\gamma(H)$ increases more quickly with the field for the overdoped sample than the underdoped and optimal doped ones, showing a large anisotropy of the gap for the overdoped sample. Our results suggest that the energy gap(s) in the present system may have different structures strongly depending on the doping regions.

11:15AM J23.00001 Phonon dispersions and structural transitions of CrO_2 under high pressure, SOORAN KIM, KYOO KIM, CHANG-JONG KANG, B.I. MIN, POSTECH — Phonon dispersions of chromium dioxide (CrO_2) are calculated to investigate the structural phase transitions as a function of pressure. The structural phase transition has been confirmed from the ground state tetragonal CrO_2 of rutile-type ($t\text{-CrO}_2$) to the orthorhombic CrO_2 of CaCl_2 -type ($o\text{-CrO}_2$). The ferromagnetic and half-metallic property is preserved even in $o\text{-CrO}_2$. The softening of Raman-active B_{1g} phonon mode, which is relevant to the above structural transition, is also obtained. We will discuss the possible more structural phase transitions from $o\text{-CrO}_2$ and the related phonon and magnetic properties at much higher pressure.

11:27AM J23.00002 Optimizing plasmonic properties of supported silver nanocube monolayers¹, ANATOLI IANOUL, ADAM BOTTOMLEY, NUR AHAMAD, Carleton University — The refractive index (RI) sensitivity of extinction spectra was compared experimentally for silver nanocubes in solution and in supported monolayers prepared by the Langmuir technique. The size of the nanocubes, RI of supporting dielectric substrate, and the monolayer surface pressure were used as variables in refractive index sensing (RIS) optimization. The dipolar plasmon modes of the colloidal nanocubes were found to have the highest RIS values of 176, 361 and 480 nm/RI units for 40, 80, and 130 nm cubes respectively. The largest figure of merit (FOM) of 4.55 was measured for a quadrupolar mode of 130 nm nanocubes. When compared to suspensions, RIS of supported nanocubes were reduced by ~50% and decreased with increasing monolayer surface pressure. RIS of 40 nm cube monolayers appeared to be sensitive to the substrate RI due to the RI dependent plasmon mode hybridization resulting in dipolar (D) and quadrupolar (Q) modes. RIS sensitivities of D and Q modes for silicon- supported nanocube monolayer were found to be 78 and 170 nm/RI units respectively. The FOM for the Q mode appeared to be 5.5. Intensity of this Q peak was found to increase with the angle of incident light. This work shows the use of high refractive index dielectric substrates, a passive molecular spacer, and large angles of incidence can significantly improve the detection of plasmonic response by supported nanocube monolayers.

11:39AM J23.00003 Isotropic Structural Color of Nanostructured Metal Surfaces, SYLVANUS Y. LEE, Dept of Mechanical Engineering, Boston University, CARLO FORESTIERE, ALYSSA J. PASQUALE, GARY F. WALSH, Dept of Electrical and Computer Engineering, Boston University, MARCO ROMAGNOLI, PhotonIC Corp., LUCA DAL NEGRO, Dept of Electrical and Computer Engineering, Boston University — Engineering angularly insensitive (i.e., isotropic) structural coloration in metals without employing extrinsic materials have been a challenge due to the strong absorption properties of metals in the visible range. In this study, by combining plasmonic resonances of metallic nanoparticles and incoherent light scattering from deterministic arrays with isotropic and diffuse Fourier space, we demonstrate isotropic structural coloration of metal films with spatial uniformity and angular insensitivity. Specifically, we explore the angular scattering properties of aperiodic gold nanoparticle arrays with Pinwheel geometry and their hyperuniform counterpart (Delaunay-triangulated Pinwheel centroid, DTPC). The structures are designed by electromagnetic simulations based on the Coupled Dipole Method in partnership with three dimensional Finite Difference Time Domain modeling of plasmonic resonant nanoparticles on gold films. The experimental characterization is performed by measuring the far-field scattering spectra of the proposed arrays using angle-resolved reflection spectroscopy under white light illumination. The measured radiation diagrams of the fabricated plasmonic arrays demonstrate controllable and isotropic coloration of gold films. The proposed approach can potentially advance plasmonic applications to display, tagging and colorimetric sensing technologies.

11:51AM J23.00004 Ab-initio study of the free liquid Hg surface, LAZARO CALDERIN, Research Computing and Cyberinfrastructure, Penn State, University Park 16802, PA, USA, LUIS E. GONZALEZ, DAVID GONZALEZ, University of Valladolid, Valladolid, Spain — The free surface of liquid Hg at two temperatures (T=300 and 450 K) has been studied by using first principles molecular dynamics simulations. The calculated longitudinal ionic density profile shows an oscillatory shape extending several atomic diameters into the bulk and its wavelength is in good agreement with experiment. The associated self-consistent valence electronic density profile shows much weaker oscillations which are somewhat out of phase with the ionic ones. The calculated X-ray reflectivity shows a marked maximum at a wavevector transfer of $q_z \approx 2.2 \text{ \AA}^{-1}$ whose origin is related to the surface layering. Moreover, it shows a good agreement with the experimental reflectivity data.

12:03PM J23.00005 Noncontact technique for measuring the electrical resistivity and magnetic susceptibility of electrostatically levitated melts¹, G.E. RUSTAN, N.S. SPYRISON, A. KREYSSIG, R. PROZOROV, A.I. GOLDMAN, Iowa State University — Over the last two decades the popularity of levitation methods for studying equilibrium and supercooled melts has increased steadily. Measurements of density, viscosity, surface tension, and atomic structure have become well established. In contrast, measurements of electrical resistivity and magnetic susceptibility of levitated melts have been very limited. To fill this void, we have combined the tunnel diode oscillator (TDO) technique with electrostatic levitation (ESL) to perform inductively coupled measurements on levitated melts. A description of the basic operating principles of the TDO and ESL will be given, as well as a description of the implementation and performance characteristics of this technique. Preliminary measurements of electrical resistivity in the solid and liquid state will be presented for samples of Zr, Si, and Ge, as well as the measurements of ferromagnetic transitions in Fe and Co based alloys.

12:15PM J23.00006 Orientational ordering of tetrahedral clusters in CaCd_6 alloy, WOOSONG CHOI, Cornell University, MAREK MIHALKOVIC, Slovak Academy of Sciences, CHRIS HENLEY, Cornell University — In icosahedral CaCd quasicrystals and related alloy structures, each icosahedral cluster contains an innermost tetrahedral shell that is loosely coupled with its shell. We extract an effective potential for the pair interaction $V(\Omega, \Omega')$ of the orientations Ω of neighboring clusters, as mediated by the intervening atoms. Using the EAM potentials of Brommer et al., ¹we relax all atoms, with each tetrahedron constrained to a chosen (continuously variable) overall orientation but allowing distortions. Using singular value decomposition, the relaxed energies are represented as $V(\Omega, \Omega') = \sum_j A_j f_j(\Omega) f_j'(\Omega')$ where only a few terms are important and the f_j 's have simple sinusoidal forms (which can be understood physically). We thus obtain a fit with only a few parameters, in place of the 46-parameter fit of Brommer et al¹ based on 12 discrete orientations. By Monte Carlo simulations with the obtained interaction, we determine the pattern of the orientationally ordered state seen experimentally below ~90K, and check the ordering transition previously simulated only in small system sizes¹.

12:27PM J23.00007 Electronic structure of Sr_2IrO_4 and its doped materials measured by angle-resolved photoemission spectroscopy, QIANG WANG, YUE CAO, J.A. WAUGH, S.R. PARK, University of Colorado at Boulder, TONGFEI QI, OLEKSANDR KORNETA, GANG CAO, University of Kentucky, D.S. DESSAU, University of Colorado at Boulder — The electronic structure of iridate Sr_2IrO_4 and its doped materials $\text{Sr}_2\text{Ir}_{1-x}\text{Rh}_x\text{O}_4$ and $(\text{Sr}_x\text{La}_{1-x})_2\text{IrO}_4$ were investigated by angle-resolved photoemission spectroscopy. For Sr_2IrO_4 , which is a $J_{\text{eff}}=1/2$ Mott insulator driven by strong spin-orbit coupling, the dispersion of the predominant Ir 5d bands has been successfully resolved and compared with theoretical calculations. The overall band structure is in line with LDA calculations with strong spin-orbit coupling and moderate electron correlation effects included. The detailed electronic structures of isovalent-doped $\text{Sr}_2\text{Ir}_{1-x}\text{Rh}_x\text{O}_4$ and electron-doped $(\text{Sr}_x\text{La}_{1-x})_2\text{IrO}_4$ are also obtained and compared with the electronic structure of the mother compound. These results help reveal the delicate interplay between charge, spin, orbit, and lattice degrees of freedom in iridates and other correlated electron systems.

12:39PM J23.00008 Electronic Structures of Oxygen-deficient PtO_2 ¹, YONG YANG, National Institute for Materials Science, 1-2-1 Sengen, Tsukuba, 305-0047, Japan, OSAMU SUGINO, 1. National Institute for Materials Science; 2. Institute for Solid State Physics, University of Tokyo, 5-1-5 Kashiwanoha, Kashiwa 277-8581, Japan, TAKAHISA OHNO, National Institute for Materials Science, 1-2-1 Sengen, Tsukuba, 305-0047, Japan — We studied the electronic properties of beta-platinum dioxide ($\beta\text{-PtO}_2$), a catalytic material, based on density functional theory. Using the GGA+U method whose predicted band gap is verified by GW calculations, we found that the creation of an oxygen vacancy will induce local magnetic moment on the neighboring Pt and O atoms. The magnetism originates not only from the unpaired electrons that occupy the vacancy induced gap state, but also from the itinerant valence electrons. Because of antiferromagnetic (AF) coupling and the localized nature of gap states, the total magnetic moment is zero for charge-neutral state (V_{O}^0) and is $\sim 1 \mu_B$ for singly-charged states ($V_{\text{O}}^{\pm}$). Calculation of grand potential shows that, the three charge states (V_{O}^0 , $V_{\text{O}}^{\pm}$) are of the same stability within a small region, and the negatively charged state (V_{O}^-) is energetically favored within a wide range of the band gap. On this basis we discussed the implication on catalytic behavior.

¹Work is supported by the Global Research Center for Environment and Energy based on Nanomaterials Science (GREEN) at Natl. Institute for Materials Science (NIMS). First-principles calculations were carried out by the supercomputer (SGI Altix) of NIMS.

12:51PM J23.00009 Theory of Non-Fermi Liquids, PATRICK O'BRIEN, Binghamton University — The focus of this project is to understand the simplest model needed to explain the physics of the material FeCrAs. The geometry of the FeCrAs crystal is used to perform crystal field splitting calculations, which in turn indicates a model that we will attempt to use to describe two of the main trends in the experimental data collected for the material. The model that we believe captures the physical character of FeCrAs for the resistivity and heat capacity measurements is the double exchange model. Next, we must find a way to describe an antiferromagnetic transition at 125K.

1:03PM J23.00010 Evolution between metastable strain glass state and stable martensitic phase in TiNi alloy, YUANCHAO JI, XIAOBING REN, National Institute for Materials Science, XIANGDONG DING, Los Alamos National Laboratory — Phase transitions occur when the thermodynamic free energy of one phase is not lowest for varying some external conditions, such as temperature, pressure, and others. However, metastable glass states that falls out of equilibrium may be observed on continued cooling. Some frozen metastable states can be further spontaneously transformed into thermodynamic stable ones. The corresponding inverse process, from low temperature stable phase to glass state then to another high temperature stable phase upon heating, seems proving the glass state like the metastable state like in chemical reactions. Here we report the inverse freezing (strain glass state) does not occur for the first time. The lower temperature B19' martensite directly transforms into the higher temperature B2 parent phase and the strain glass also transforms B2 phase in the heating process, although the glass state is in the intermediate between B2 and B19' phases in the cooling process in TiNi single crystal. Completely different transformation sequence reveals the inverse glass transition is not necessary between two stable phases and helps us further deepen the understanding of glass transition.

1:15PM J23.00011 Ab Initio Study of Phase-Change Materials Doped with magnetic Impurities, RICCARDO MAZZARELLO, YAN LI, RWTH Aachen University — Chalcogenide Phase-change materials are of great technological importance due to their ability to undergo reversible and fast transitions between the amorphous and crystalline phases upon heating. Recently, it was shown experimentally that $\text{Ge}_2\text{Sb}_2\text{Te}_5$ doped with Fe atoms exhibits phase-change behavior for low concentrations of Fe and that both the amorphous and the crystalline phases are ferromagnetic at low enough temperatures. Moreover, the two phases were found to have different saturation magnetization. This finding opens up the possibility of exploiting the phase-change behavior for fast magnetic switching in e.g. spintronic devices. We have investigated the structural, electronic and magnetic properties of Fe-doped $\text{Ge}_2\text{Sb}_2\text{Te}_5$ by first-principles simulations based on Density Functional Theory. Both amorphous and crystalline (hexagonal and cubic rocksalt) phases of $\text{Ge}_2\text{Sb}_2\text{Te}_5$ were considered. Our results show that in the amorphous phase, the magnitude of the magnetic moments of the Fe impurities is reduced with respect to the crystalline phases, due to the different local geometries and chemical environments, which explains the experimentally observed magnetic contrast between the two phases.

1:27PM J23.00012 Crystallization Times of $\text{Ge}_2\text{Sb}_2\text{Te}_5$ Nanostructures as a Function of Temperature, FARUK DIRISAGLIK, KADIR CIL, MAREN WENNBORG, ADRIENNE KING, MUSTAFA AKBULUT, University of Connecticut, YU ZHU, CHUNG LAM, IBM T. J. Watson Research Center, ALI GOKIRMAK, HELENA SILVA, University of Connecticut — Phase-change memory is a promising non-volatile memory technology in which a small volume of a phase change material is reversibly and rapidly switched between amorphous and crystalline phases by a suitable electrical pulse. Amorphization is achieved by fast cooling after a melting pulse while crystallization is achieved through electrical breakdown of the amorphous element that leads to heating above the crystallization temperature for a sufficient period. Significant difference between the crystallization behavior of phase-change materials in bulk, thin films and in nanostructures have been observed[1,2]. We have studied the crystallization times of nanoscale $\text{Ge}_2\text{Sb}_2\text{Te}_5$ line structures using 50-500 ns voltage pulses with a baseline offset in the 500 K to 625 K range under high-vacuum. The baseline voltage allows measurement of resistance before and after the pulse and crystallization time. Current and voltage were recorded with high time-resolution for amorphizing pulse and very long periods of time to observe the crystallization time. The crystallization time decreases for increasing temperature but it remains on the order of seconds even at elevated temperatures. [1] H. Wong et al., Proc IEEE 98, 2201, 2010. [2] T. Zhang et al., Scr. Mater. 58, 977, 2008.

1:39PM J23.00013 Electrical Resistivity of Liquid $\text{Ge}_2\text{Sb}_2\text{Te}_5$ in Patterned Nanostructures, KADIR CIL, FARUK DIRISAGLIK, MAREN WENNBORG, ADRIENNE KING, MUSTAFA AKBULUT, University of Connecticut, YU ZHU, CHUNG LAM, IBM T.J. Watson Research Center, HELENA SILVA, ALI GOKIRMAK, University of Connecticut — Phase change memory devices are based on the electrical resistivity contrast between the amorphous and the crystalline phases of chalcogenide materials [1]. Since melting is required to amorphize the material, knowledge of the liquid state properties is critical for device design. $\text{Ge}_2\text{Sb}_2\text{Te}_5$ (GST) is the most studied phase change material. However, the two experimental values reported to date for electrical resistivity of liquid GST (one on a thin film [2], the other in bulk [3]) differ by an order of magnitude. We have extracted the electrical resistivity of liquid GST from single pulse measurements on a large number of encapsulated GST line structures with varying lengths, widths and thicknesses. Each structure is self-heated to melt by the microsecond voltage pulse while voltage and current are monitored using an oscilloscope. The liquid state resistivity is calculated from slopes of liquid state resistance versus $1/\text{width}$, fitted as a function of length. The results we obtained for the liquid resistivity of GST in nanostructures are close to those obtained from measurements on bulk GST [3]. 1. H. Wong et al., Proc IEEE 98, 2201, 2010. 2. T. Kato and K. Tanaka, Jap. J. Appl. Phys. 44, 7340, 2005. 3. R. Endo et al., Jap. J. Appl. Phys. 49, 5802, 2010.

1:51PM J23.00014 3-D Numerical Study of Switching Dynamics in Nanoscale Phase Change Memory Devices¹, IBRAHIM CINAR, GULSEN KOSOGLU, OZGUR BURAK ASLAN, GULEN AKTAS, OZHAN OZATAY, Bogazici University, Department of Physics — Phase change memory (PCM) is currently regarded as a strong candidate technology to replace Flash memory in the market. In this work we report a detailed numerical study of the switching process in a nanoscale PCM cell, namely its switching dynamics during SET (turn on) and RESET (turn off) operations. A comprehensive picture of the electrical, thermal and phase change dynamics is obtained using a multiphysics approach with coupled differential equations in the framework of a three dimensional finite element model. The complexity of the problem was handled by constructing separate submodels; an electrical model which involves a temperature and phase dependent electrical conductivity, a thermal model where the joule heating from the electrical current serves as the heat source and involves temperature and phase dependent thermal conductivity and a phase change model. In this presentation we will concentrate on the electrical and thermal submodels in detail. The results of the phase change model taking into account homogeneous and heterogeneous nucleation kinetics will be discussed in another presentation. We will compare the numerical results with experimental data on GST based nanoscale phase change devices with various contact sizes and shapes.

¹This work has been supported by the European Commission FP7 Marie Curie IRG grant: PCM-256281, Bogazici University Infrastructure Research Fund: 6121, Turkish Academy of Sciences TUBA-GEBIP award.

2:03PM J23.00015 3-D Simulation Model of Phase Change and Percolation in Phase Change Memory¹, OZGUR BURAK ASLAN, IBRAHIM CINAR, GULSEN KOSOGLU, GULEN AKTAS, OZHAN OZATAY, Bogazici University, Department of Physics — Even though phase change memory (PCM) appears as a promising nonvolatile solid state memory with its high signal to noise ratio and superior scalability compared to other memory technologies, the complex nature of the phase change process necessitates advanced numerical modeling to optimize the performance of nanoscale memory cells. The phase change and the percolation processes of a nanoscale PCM cell during SET (turn on) and RESET (turn off) operations have been simulated based on a three dimensional finite element model. A multiphysics approach with coupled differential equations is used to observe and understand the phase change and percolation dynamics. The model to represent the PCM is divided into submodels consisting of an electrical, a thermal and a phase change model that affects nucleation kinetics of crystallites. Coupling the submodels in the framework of the multiphysics approach, this model allows us to predict threshold voltage and recrystallization temperature for switching by detecting the critical conditions for the formation of a conductive percolation path in phase change process. These results will be compared to the experimental results to be carried on. The subject of electrical and thermal model will be mentioned in another presentation.

Tuesday, February 28, 2012 11:15AM - 2:15PM –

Session J24 DMP: Focus Session: Dopants and Defects in Semiconductors - Si and III-V 256

11:15AM J24.00001 Dislocation nucleation in Si – effect of Ge and vacancies, ZHI LI, CATALIN PICU, Rensselaer Polytechnic Institute — The presence of dislocations in Si devices is detrimental for their function. However, dislocations may nucleate during device processing from interfaces and from imperfections of the surface. In this work we study the conditions under which this may take place. Specifically, the activation energy for dislocation nucleation in pure Si is evaluated using an atomistic model and considering a corner stress concentrator. At lower temperatures, 60° dislocations nucleate in the shuffle set as half-hexagonal loops. The activation energy depends on the step height and on the spacing between steps. The effect of Ge on nucleation is evaluated using the same model and it is observed that the energy barrier decreases slightly in presence of these substitutional atoms. The presence of vacancies in the glide plane also decreases the activation energy. A low concentration of vacancies (0.5%) decreases the barrier for nucleation similarly with a large concentration of Ge (30%).

11:27AM J24.00002 Surface Charge Distribution on Hydrogen-Passivated Silicon Measured by UHV Kelvin Probe Microscopy, PAVEL NAGORNYKH, KRISTEN BURSON, WILLIAM CULLEN, BRUCE KANE, University of Maryland — A few years ago hydrogen-passivated silicon (H:Si) surfaces were used to observe high-mobility in FETs (100,000 cm²/Vs) [1]. This result is expected since chemical passivation of silicon produces an atomically flat surface with low density of defects. As chemical preparation can lead to creation of fixed charges on H:Si surface, one needs a method to get information about their distribution to further improve the quality of a process. This can be done by measuring electrostatic forces created by such charges with Kelvin Probe Microscopy (KPM), which obtains a voltage distribution map with a resolution of a few nm. We have used UHV KPM for our measurements, since UHV conditions are important for avoiding oxidation of H:Si surface as well as achieving its further depassivation/annealing. By annealing samples above depassivation temperature (500C), we have obtained data that provides more information about depassivation effect on charges that come from chemical residue on hydrogen and silicon itself. Preliminary results show standard deviations of voltage much smaller (by an order of magnitude) than ones measured previously on silicon oxide, consistent with high quality expected from chemical preparation.

11:39AM J24.00003 Magnetic resonance characterization of silicon nanowires¹, MARCO FANCIULLI, Department of Material Science, University of Milano-Bicocca, Italy and MDM Laboratory, IMM-CNR, Agrate Brianza, Italy, MATTEO BELLI, ANTONIO VELLEI, MDM Laboratory, IMM-CNR, Agrate Brianza, Italy, CARMEN CANEVALI, DAVIDE ROTTA, STEFANO PALEARI, MARTINA BASINI, Department of Material Science, University of Milano-Bicocca, Italy — Silicon nanowires (SiNWs) have been extensively investigated in the last decades. The interest in these nanostructures stems from both fundamental and applied research motivations. The functional properties of one- and zero-dimensional silicon structures are significantly different, at least below a certain critical dimension, from those well known in the bulk. The key and peculiar functional properties of SiNWs find applications in nanoelectronics, classical and quantum information processing and storage, optoelectronics, photovoltaics, thermoelectric, battery technology, nano-biotechnology, and neuroelectronics. We report our work on the characterization by continuous wave (CW) and pulse electron spin resonance (CW, FT-EPR) and electrically detected magnetic resonance (EDMR) measurements of silicon nanowires (SiNWs) produced by different top-down processes. SiNWs were fabricated starting from SOI wafers using standard e-beam lithography and anisotropic wet etching or by metal-assisted chemical etching. Further oxidation was used to reduce the wire cross section. Different EDMR implementations were used to address the electronic wave function of donors (P, As) and to characterize point defects at the SiNWs/SiO₂ interface.

¹The support of Fondazione Cariplo, ELIOS Project is acknowledged.

11:51AM J24.00004 Ab initio study of confinement effects and hyperfine structure in chalcogen doped Silicon nanostructures¹, ALBERTO DEBERNARDI, CNR-IMM, MDM laboratory Agrate Brianza, GUIDO PETRETTO, ANDREA MASSE, MARCO FANCIULLI, CNR-IMM, MDM laboratory Agrate Brianza, University Milano-Bicocca — In recent years, increasing interest has been focused on Si nanostructures as building blocks for ultra-scaled electronic devices where quantum mechanic effects are relevant. We have investigated the atomic and electronic structures of a single chalcogen donor in H passivated Si nanostructures of different size by means of the plane-wave pseudopotential techniques we used in Ref. [1] to study Se doped Si (001) nanowires (NW). Our results showed an increase in the gap with diminishing diameter of Si NW. We studied the size dependence of electronic properties and hyperfine constant of single substitutive chalcogen impurity in Si-NWs (001) and (111) oriented, and Si-dots and their dependence on the distance from the NW axis or the centre of the dot. We show that the hyperfine parameters are strongly dependent on the impurity position: we proved that surface effects can lead to strong differences in the hyperfine parameters depending on the chalcogen location inside the nanowire, suggesting a way to determine experimentally the position of the defect on the basis of electron paramagnetic resonance spectra. Preliminary results on chalcogen doped Ge nanowires complete the work. [1] G. Petretto, A. Debernardi, and M. Fanciulli, Nano Letters, Vol. 11, 4509 (2011).

12:03PM J24.00005 Segregation and diffusion of boron dopants in the Si/SiO₂ interface, YOUNG JUN OH, HYEON-KYUN NOH, GEUN-MYUNG KIM, K.J. CHANG, Department of Physics, Korea Advanced Institute of Science and Technology — Boron dopants in metal-oxide-semiconductor field-effect transistors exhibit very peculiar behavior such as transient enhanced diffusion, clustering, and segregation. Especially, B segregation to the Si/SiO₂ interface significantly affects the dopant distribution and thereby the device performance. However, there is a lack of studies on the mechanism for B segregation and diffusion in the Si/SiO₂ interface. In this work, we perform first-principles density-functional calculations to understand how B dopants diffuse and segregate to SiO₂. We generate two Si/SiO₂ interface structures, in which crystalline alpha-quartz and amorphous SiO₂ are placed on Si. Among various B configurations, we find that an interstitial B is energetically more favorable in the oxide, compared with a substitutional B and a self-interstitial-B complex in Si. We examine the effect of point defects such as a floating bond and an oxygen vacancy in SiO₂ on B segregation and also investigate B diffusion pathways across the Si/SiO₂ interface.

12:15PM J24.00006 Hybrid functional calculations for native defects and dangling bonds in α -Al₂O₃¹, MINSEOK CHOI, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara, CA 93106-5050 — Al₂O₃ is a promising material for use as a gate dielectric in III-V-based MOS devices, including in GaN-based transistors. Recent developments indicate that despite the relatively high structural quality, the presence of charge traps and fixed-charge centers near the interface between the oxide and nitride still poses serious problems for device performance. Native defects and dangling bonds in the Al₂O₃ dielectric or in the vicinity of the interface are the most likely causes. To aid in the identification of these centers, we perform density functional calculations with a hybrid functional for point defects and dangling bonds in α -Al₂O₃. We determine the position of the defect transition levels in the gap of the oxide, and analyze the level positions with respect to the nitride band edges. Our results show that O vacancies and Al dangling-bonds can produce charge traps and Al interstitials act as fixed charges in GaN-based *n*-MOSFETs.

12:27PM J24.00007 Role of oxygen-related defects in hafnia¹, MANISH JAIN, Department of Physics, University of California, Berkeley and Lawrence Berkeley National Laboratory, JAMES R. CHELIKOWSKY, University of Texas, Austin, STEVEN G. LOUIE, Department of Physics, University of California, Berkeley and Lawrence Berkeley National Laboratory — Hafnia has recently received much attention because of its potential application as high-k dielectric material replacing silica in microelectronic devices. Point defects in hafnia - in particular oxygen vacancies and interstitials - can play an important role as traps or sources of fixed charge. In this study, we perform electronic structure calculations on oxygen-related defects in monoclinic hafnia using a combined density functional theory (DFT) and GW formalism. We have previously shown that upon including quasiparticle defect levels and the appropriate electrostatic corrections within a supercell calculation, this formalism corrects for the error in calculating formation energy and charge transition levels using standard DFT. In this study, we calculate the formation energy of these defects as a function of the Fermi level and the chemical potential of oxygen to determine which of these defects are most stable.

12:39PM J24.00008 Vibrational spectroscopy of cast Si used to fabricate solar cells: microscopic properties of nitrogen and oxygen impurities¹, HAOXIANG ZHANG, MICHAEL STAVOLA, Lehigh University, MIKE SEACRIST, MEMC Electronic Materials — Cast Si with grain sizes from a few mm to a few cm is commonly used for the fabrication of solar cells. Nitrogen impurities are introduced into cast Si by the SiNx coating of the crucible used for casting. Much is known about N and O centers in single-crystal Si used in microelectronics [1]. We have used vibrational spectroscopy to probe the concentration and defect configurations of nitrogen centers in cast Si used to fabricate solar cells. The interaction of N with O impurities that are present has also been investigated. The dominant N center in cast Si is a N-N interstitial pair. N-O complexes are also formed. Which defect complexes are present depends on the impurity content of the multi-crystalline Si sample, which can vary widely, and its thermal history. [1] H. Ch. Alt and H. E. Wagner, J. Appl. Phys. **106**, 103511 (2009) and the references contained therein..
