3:42PM T28.00007 The electrical properties of epitaxial p-type ZnO films grown on GaAs (001), WEI-REIN LIU, Research Group, National Synchrotron Radiation Research Center, C.Y. LIN, B.H. LIN, S.T. HSU, Department of Photonics and Institute of Electro-Optical Engineering, National Chiao Tung University, F.S.-S. CHIEN, Department of Physics, Tunghai University, CHEN-SHIUNG CHANG, Department of Photonics and Institute of Electro-Optical Engineering, National Chiao Tung University, CHIA-HUNG HSU, Research Group, National Synchrotron Radiation Research Center, WEN-FENG HSIEH, Department of Photonics and Institute of Electro-Optical Engineering, National Chiao Tung University — Wurtzite ZnO epitaxial layers with both p-type and n-type characteristics are grown on n-type GaAs(001) substrates by pulsed laser deposition (PLD). The local electrical properties of the ZnO layers were investigated by electrostatic force microscope (EFM), Kelvin force microscopy (KFM), and conducting atomic force microscopy (CAFM). Local work function difference of ~125.5 meV was observed on p-type ZnO layer from KFM and EFM measurements due to the un-uniform diffusion of As atoms from the GaAs substrate upon thermal annealing. We also found the work function of p-type ZnO is larger than that of n-type ZnO layer, in which the difference varied from 368.4 to 493 meV. The rectifying junction under p-ZnO/n-GaAs configuration and Ohmic contact under metal probe (Ti)/p-ZnO configuration were both observed by CAFM.

3:54PM T28.00008 Mapping the band profile across the Gd₂O₃/GaAs(100) hetero-interface by using scanning tunneling microscopy, B.C. HUANG, Y.P. CHIU, M.C. SHIH, Department of Physics, National Sun Yat-Sen University, Kaohsiung, 80424, Taiwan, J.Y. SHEN, P. CHANG, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, 30013, Taiwan, C.S. CHANG, Institute of Physics, Academia Sinica, Taipei, 10617, Taiwan, M.L. HUANG, Department of Physics, National Tsing Hua University, Hsinchu, 30013, Taiwan, M.H. TSAI, Department of Physics, National Sun Yat-Sen University, Kaohsiung, 80424, Taiwan, M. HONG, Department of Physics and Graduate Institute of Applied Physics, National Taiwan University, Taipei, 10617, Taiwan, J. KWO¹, Center for Condensed Matter Sciences, National Taiwan University, Taipei, 10617, Taiwan — Direct measurements of atomic-scale electronic structure at nm-thick epitaxial Gd₂O₃ gate oxides on GaAs have been performed using cross-sectional scanning tunneling microscopy and spectroscopy. Both scanning tunneling spectroscopy and analysis of the local electronic states across the gate oxides suggest the Ga-O terminated hetero-interface. In addition, along with the theoretical modeling, the band offsets for both conduction and valence states are identified. A unique combination of STM and STS successfully provides direct information on the interfacial band profile and band offsets across the model high- κ /III-V system in the work.

4:06PM T28.00009 Phase-dependence and manipulation of coherent oscillations of a single-electron wavefunction in a dynamic quantum dot, MATTHEW BENESH, ADAM THORN, MASAYA KATAOKA¹, MICHAEL ASTLEY, CHRIS FORD, CRISPIN BARNES, JONATHAN GRIFFITHS, GEB JONES, IAN FARRER, DAVE RITCHIE, University of Cambridge, UK — Surface acoustic waves (SAWs) in a GaAs heterostructure generate dynamic quantum dots, each capable of carrying a single electron through a gated potential landscape. At the SAW velocity (2800 m/s), the change in potential due to a 100nm surface gate will occur in a period of 40ps in the rest frame of the dot. This high-speed modulation of the potential, far beyond the experimental limit of fast gate-switching, allows for the observation of coherent single-electron dynamics. Previous work has shown that an abrupt shift in dot confinement will cause an electron to oscillate unitarily from side to side. This excitation was measured non-invasively via a tunnel barrier, and good agreement was found between measurements and simulations of the dot dynamics. We present here the results of further work in which we examine the coherence length and phase-dependence of the single-electron oscillations. Through the use of a time-dependent model we also study surface-gate arrangements which may be used to manipulate the electron dynamics mid-stream.

¹Now at NPL Teddington

4:18PM T28.00010 Equi-spin-splitting distribution near the minimum-spin-splitting surface under biaxial strains in bulk wurtzite materials, HSIU-FEN KAO, IKAI LO, JIH-CHEN CHIANG, C.L. WU, W.T. WANG, Department of Physics, Center for Nanoscience and Nanotechnology, National Sun Yat-sen University, Kaohsiung 80424, Taiwan, MENG-EN LEE, Department of Physics, National Kaohsiung Normal University, Yanchao, Kaohsiung 82444, Taiwan, CHUN-NAN CHEN, Department of Physics, Tamkang University, Tamsui, New Taipei City 25137, Taiwan, Y.C. HSU, Department of Physics, Center for Nanoscience and Nanotechnology, National Sun Yat-sen University, Kaohsiung 80424, Taiwan — The spin-splitting energies in biaxially strained bulk wurtzite materials are calculated using the linear combination of atomic orbital method, and the equi-spin-splitting distributions in k -space near the minimum-spin-splitting (MSS) surfaces are illustrated. These data are compared with those derived analytically using the two-band $\mathbf{k} \cdot \mathbf{Dp}$ (2KP) model. It is found the results from these two methods are in good agreement for small k . However, the ellipsoidal MSS surface under compressively biaxial strain predicted by the 2KP model does not exist, due to the data points are far from the Γ point in this case. As a result, from compressively to tensilely biaxial strain, only three types of shapes of the MSS surface exist in the wurtzite Brillouin zone; that is, a hyperboloid of two sheets, a hexagonal cone and a hyperboloid of one sheet.

4:30PM T28.00011 How Hydrogen Terminated Diamond Acquires a Negative Electron Affinity Surface, JONATHAN RAMEAU, JOHN SMEDLEY, ERIK MULLER, Brookhaven National Lab, TIM KIDD, University of Northern Iowa, PETER JOHNSON, Brookhaven National Lab — Electron emission from the negative electron affinity (NEA) surface of hydrogen terminated, boron doped diamond in the [100] orientation is investigated using angle resolved photoemission spectroscopy (ARPES). ARPES measurements using 16 eV synchrotron and 6 eV laser light are compared and found to show a catastrophic failure of the sudden approximation. While the high energy photoemission is found to yield little information regarding the NEA, low energy laser ARPES reveals for the first time that the NEA results from a novel Franck-Condon mechanism coupling electrons in the conduction band to the vacuum. The result opens the door to the development of a new class of NEA electron emitter based on this effect.

4:42PM T28.00012 Laser Phase Separation of Si Rich Oxides: The Role of Composition, EMEL SUNGUR OZEN, ATILLA AYDINLI, SINAN GUNDOGDU, Bilkent University, Department of Physics, Ankara, 06800 — Continuous-wave laser annealing of Si-rich oxide thin films with varying Si content were performed in order to obtain Si nanocrystals (Si_{nc}) embedded in silica. The composition, irradiation times and power densities were investigated as well as the role of hydrogen in phase separation. Si_{nc} in SiO_2 appear to be very promising for the realization of optical function as light emission or optical memory. Nanocrystalline Si finds also important utility in photovoltaics thanks to quantum confinement in the nanostructures offering a wider bandgap material which, in a tandem configuration, can allow a better use of the solar spectrum. Conventional techniques utilize high-temperature processing to obtain Si- SiO_2 phase separation. These processes are not compatible with mass production methods. An alternative approach capable of avoiding high temperature processing is the laser annealing of SiO_x films. The structural effect due to annealing were investigated by Raman and photoluminescence spectroscopy. It has been shown that the size and amount of Si_{nc} depends both on the oxygen content and on the laser power density. PECVD grown hydrogenated SiO_x films were compared with sputtered films without hydrogen to identify its role for the phase separation.

4:54PM T28.00013 A Novel Technique for Detecting Trace Residues of Contamination on GaAs Surfaces before MBE Growth¹, JERRY LEE, KEN WEST, KIRK BALDWIN, LOREN PFEIFFER, Princeton University — To prepare a GaAs substrate for molecular beam epitaxial (MBE) growth, the nominal ~ 3 nm native oxide is typically thermally desorbed in vacuum. To test the completeness of this desorption, we describe a technique, which combines MBE, thermal desorption, atomic force microscopy (AFM), reflection high-energy electron diffraction (RHEED), and secondary ion mass spectroscopy (SIMS), for detecting trace residues of contamination on (100) GaAs surfaces before MBE growth. At all desorption temperatures in the range 600 °C to 665 °C, our RHEED measurements show that the native oxide is largely desorbed within 2 min. However, the SIMS and AFM data indicate that a residue of sub-monolayer oxide invariably remains on the GaAs (100) surface, and tenaciously resists all further attempts at its removal by thermal desorption. Since thermal desorption of the native oxide has long been the standard technique before MBE growth, we suggest that all MBE growth of GaAs heterostructures has been through a partial monolayer of native oxide. We believe that this is the likely reason for the failure of high quality attempts at MBE growth of GaAs after lithographic patterning on a previously grown MBE structure.

5:06PM T28.00014 High-performance substrate-emitting quantum cascade ring lasers, TARIQ MANZUR, Naval Undersea Warfare Center (NUWC, DIVNPT) Newport, RI-02841 — An InP based mid-infrared quantum cascade laser with a ring-shaped cavity is demonstrated in room temperature continuous wave operation. The light is coupled out with a second order distributed feedback grating buried inside the cavity. The device is epilayer-down bonded to a heat spreader and the light is emitted through the substrate. The emission wavelength is around 4.85 μ m with a high power output of 0.51 W. Single mode operation persists up to 0.4 W. Far field exhibits concentric ring features. Modal behavior is analyzed using the coupled mode theory, which suggests that the device operates in an extremely high order mode. Polarization measurement indicates that the beam is azimuthally polarized. This unique polarization state with high power output may find applications in tight focusing, optical tweezers, and material processing.

5:18PM T28.00015 3D Simulation of the Growth of Alloy Semiconductor Quantum Dots Considering Morphological and Compositional Coupling, JUNYAN GUO, YONG-WEI ZHANG, SRIDHAR NARAYANASWAMY, IHPC, Singapore — Fabrication of quantum dots (QDs) with high density may be realized by self-assembly via heteroepitaxial growth of thin films. Since the electronic and optoelectronic properties of QDs are sensitive to size, morphology, strain and especially composition, it is of great importance to control their composition profiles and morphology, and engineer the strain in them. Since the growth is a dynamic process, which carries out via surface diffusion driven primarily by strain relaxation and entropy change due to chemical intermixing, a strong coupling between morphological and composition evolutions during this process leads to a rather complex dynamics, which has not been fully understood. In this work, a 3-D finite element model is developed, which is capable of modeling the formation, self-assembly and coarsening of hetero-epitaxial alloy islands by considering the coupling of morphological and compositional evolution. Several interesting experimental observations, such as fast coarsening kinetics; asymmetries in composition profile and island shape; lateral motion of alloy islands have been observed in our simulations. Our model predictions have painted a rather complete picture for the entire dynamic evolution during the growth of nanoscale heteroepitaxial islands.

Session T29 GQI: Focus Session: Semiconductor Qubits - Coherent Control, Decoherence, and Relaxation 259A

2:30PM T29.00001 Electrical control of single spin dynamics¹, JASON PETTA, Princeton University — Over ten years ago, Daniel Loss and David DiVincenzo proposed using the spin of a single electron as a quantum bit. At the time of the proposal, it was not possible to trap a single electron in a device and measure its spin, let alone demonstrate control of quantum coherence. In this talk I will describe recent progress in the field, focusing on two new methods for single spin control that have been developed by my group at Princeton. The first method is based on quantum interference and implements spin-interferometry on a chip. The second method utilizes the strong spin-orbit coupling of InAs. By shifting the orbital position of the electronic wavefunction at gigahertz frequencies, we can control the orientation of a single electron spin and measure the full g-tensor, which exhibits a large anisotropy due to spin-orbit interactions. Both methods for single spin control are orders of magnitude faster than conventional electron spin resonance and allow investigations of single spin coherence in the presence of fluctuating nuclear and spin-orbit fields. I will also describe recent efforts to transfer these methods to silicon quantum dots, where the effects of fluctuating nuclear fields are much smaller.

¹Research performed in collaboration with Michael Schroer, Karl Petersson, Minkyung Jung, George Stehlik, Hong Lu, and Art Gossard. We acknowledge support from the Sloan and Packard Foundations, ARO, DARPA, and NSF.

3:06PM T29.00002 Harmonic Generation in InAs Nanowire Double Quantum Dots, M.D. SCHROER, M. JUNG, K.D. PETERSSON, J.R. PETTA, Princeton University — InAs nanowires provide a useful platform for investigating the physics of confined electrons subjected to strong spin-orbit coupling. Using tunable, bottom-gated double quantum dots, we demonstrate electrical driving of single spin resonance.^{1,2} We observe a standard spin response when the applied microwave frequency equals the Larmor frequency f_0 . However, we also observe an anomalous signal at frequencies $f_n = f_0/n$ for integer n up to $n \sim 5$. This is equivalent to generation of harmonics of the spin resonance field. While a $f_0/2$ signal has been observed,³ we believe this is the first observation of higher harmonics in spin resonance. Possible mechanisms will be discussed.⁴ Acknowledgements: Research supported by the Sloan and Packard Foundations, the NSF, and Army Research Office.

3:18PM T29.00003 Composite pulse sequences for Z-rotations robust against small magnetic field gradient in singlet-triplet qubits¹, XIN WANG, EDWIN BARNES, LEV S. BISHOP, JASON P. KESTNER, KAI SUN, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park — We design piecewise composite pulse sequences of the exchange interaction in singlet-triplet qubits, suitable for achieving a Z-rotation along the Bloch sphere of arbitrary angle under the influence of a small stray magnetic field gradient. We explicitly show that upon appropriately choosing the pulse parameters, the error arising from the magnetic field gradient can be canceled at least to the third order. Examining the error as a function of the magnetic field gradient, we estimate the magnitude of fluctuation in the magnetic field gradient that can be tolerated under certain quantum error correction threshold.

¹This work is supported by IARPA, LPS-CMTC and CNAM.

3:30PM T29.00004 Composite pulse sequences for robust universal control of singlet-triplet qubits¹, LEV S. BISHOP, Joint Quantum Institute and Condensed Matter Theory Center, University of Maryland, College Park, XIN WANG, EDWIN BARNES, JASON P. KESTNER, KAI SUN, SANKAR DAS SARMA, Condensed Matter Theory Center, University of Maryland, College Park — We consider composite pulse sequences for the exchange interaction in singlet-triplet qubits, in the presence of a finite magnetic field gradient (producing a term in the Hamiltonian similar in magnitude to the exchange interaction). We find pulse sequences achieving arbitrary rotations on the Bloch sphere, for which there is no first-order term in the error arising from fluctuations of the magnetic field gradient. We quantify the range of experimental parameters where our composite sequences can outperform naive uncorrected sequences.

3:42PM T29.00005 Analytically solvable pulses for spin qubit rotations, SOPHIA ECONOMOU, Naval Research Lab — The hyperbolic secant pulse is a well known pulse shape for which the time dependent Schrodinger equation of a two-level system is analytically solvable. It has in the past been proposed [1] for optical spin rotations in quantum dots, and used experimentally to that end [2]. In this talk, a family of pulses will be introduced which can be viewed as the generalization of the sech pulse. These pulses may have skewed temporal profiles and frequency modulation (“chirping”). I will present results for the fidelity of spin rotations using some of these pulses and show that in the case of “Raman-type” control, where an auxiliary excited state is used, it can be advantageous to replace the usual 2π sech pulse.

3:54PM T29.00006 Universal set of single-qubit gates based on geometric phase of electron spin in a quantum dot, VLADIMIR MALINOVSKY, SERGEY RUDIN, Army Research Laboratory, 2800 Powder Mill Road, Adelphi, MD 20783 — The electron spin in a single quantum dot is one of the perspective realizations of a qubit for the implementation of a quantum computer. During last decade several control schemes to perform single gate operations on a single quantum dot spin have been reported. We propose a scheme that allows performing ultrafast arbitrary unitary operations on a single qubit. We demonstrate how to use the geometric phase, which the Bloch vector gains along the cyclic path, to prepare an arbitrary state of a single qubit. It is shown that, the geometrical phase is fully controllable by the relative phase between the external fields. Using the analytic expression of the evolution operator for the electron spin in a quantum dot, we propose a scheme to design a universal set of single-qubit gates based solely on the geometrical phase that the qubit state acquires after a cyclic evolution in the parameter space. The scheme is utilizing ultrafast linearly-chirped pulses providing adiabatic excitation of the qubit states and the geometric phase is fully controlled by the relative phase between pulses.

4:06PM T29.00007 A fast “hybrid” silicon double quantum dot qubit¹, TECK SENG KOH, ZHAN SHI, C.B. SIMMONS, J.R. PRANCE, JOHN KING GAMBLE, YUN-PIL SHIM, University of Wisconsin-Madison, XUEDONG HU, University at Buffalo, SUNY, D.E. SAVAGE, M.G. LAGALLY, M.A. ERIKSSON, MARK FRIESEN, S.N. COPPERSMITH, University of Wisconsin-Madison — We propose a quantum dot qubit architecture that has an attractive combination of speed and fabrication simplicity. It consists of a double quantum dot with one electron in one dot and two electrons in the other. The qubit itself is a set of two states with total spin quantum numbers $S^2 = 3/4$ ($S = 1/2$) and $S_z = -1/2$, with the two different states being singlet and triplet in the doubly occupied dot. The architecture is relatively simple to fabricate, a universal set of fast operations can be implemented electrically, and the system has potentially long decoherence times. These are all extremely attractive properties for use in quantum information processing devices.

¹Work done was supported in part by ARO and LPS (W911NF-08-1-0482), by NSF (DMR-0805045, PHY-1104660, and a graduate fellowship to JKG), and by United States Department of Defense.

4:18PM T29.00008 Theory of Spin Relaxation in Two-Electron Lateral Coupled Quantum Dots¹, MARTIN RAITH, Institute for Theoretical Physics, University of Regensburg, D-93040 Regensburg, Germany, PETER STANO, Institute of Physics, Slovak Academy of Sciences, 845 11 Bratislava, Slovakia, FABIO BARUFFA, German Research School for Simulation Sciences, Forschungszentrum Juelich, D-52425 Juelich, Germany, JAROSLAV FABIAN, Institute for Theoretical Physics, University of Regensburg, D-93040 Regensburg, Germany — We present a global picture of the phonon-induced spin relaxation of two-electron lateral double quantum dots. The analysis covers a wide range of tuning parameters, such as the magnetic field, the exchange coupling, and the electric field (detuning). Our examples cover experimentally important scenarios. Quantitative results were obtained with a highly accurate numerical technique for the two most relevant host materials—GaAs and silicon. We find that in the presence of spin-orbit coupling, the rate becomes anisotropic and its maxima and minima are generated with an in-plane magnetic field parallel or perpendicular to the dots’ alignment dependent on specifics, such as spectral (anti-)crossings (spin hot spots), or the detuning strength. For all regimes, we give qualitative explanations of our observations. By understanding the spin lifetimes (T_1), this work marks a crucial step to the realization of two-electron semiconductor qubits.

4:30PM T29.00009 Dephasing in lateral double quantum dot systems due to evanescent-wave Johnson noise¹, ROBERT JOYNT, MAXIM VAVILOV, LUKE LANGSJOEN, AMRIT POUDEL, University of Wisconsin-Madison — Lateral double quantum dots suffer decoherence due to coupling to the environment. Previous theoretical calculations of dephasing time based on the phonon bath model (Vorojtsov et al. PRB **71**, 2005) and gate-voltage fluctuations (Valente et al. PRB **82**, 2010) are insufficient to explain the short dephasing time observed in experiment with a charge-based double quantum dot system (Petta et al. PRL **93**, 2004). Here we analyze the effect of fluctuating electromagnetic fields in the vicinity of conducting gates on the dephasing rate of charge-based double quantum dot systems.

¹This work was supported by ARO and DOD (W911NF-11-1-0030)

4:42PM T29.00010 Spin relaxation times and spin-dependent transport of silicon 2DEG and donors in high magnetic fields¹, CHEUK CHI LO, C.D. WEIS, J. BOKOR, T. SCHENKEL, Lawrence Berkeley National Laboratory, V. LANG, R.E. GEORGE, J.J.L. MORTON, University of Oxford, A.M. TYRSHKIN, S.A. LYON, Princeton University, J. VAN TOL, National High Magnetic Field Laboratory — We measured the spin-lattice relaxation (T_1) and spin coherence (T_2) times of the two-dimensional electron gas (2DEG) and neutral donors in a silicon field-effect transistor by pulsed electrically detected magnetic resonance at ≈ 3.4 T. The 2DEG T_1 varies between $\approx 200 - 800$ ns depending on the carrier density with an in-plane magnetic field configuration, but remains constant at ≈ 400 ns with an out-of-plane field configuration. On the other hand, $T_2 \approx 50 - 150$ ns for all carrier densities and both field orientations. The neutral donor T_1 and T_2 are found to be similar to that of the 2DEG. At even higher out-of-plane magnetic fields of $8 - 12$ T, Landau levels are clearly resolved in transport measurements and both the 2DEG and donor EDMR signals show corresponding oscillatory behavior as the carrier density is varied. We attribute this behavior to the alignment of the Fermi level with spin-split and different indexed Landau levels.

¹This work was supported by NSA (100000080295) and DOE (DE-AC02-05CH11231).

4:54PM T29.00011 Two-electron dephasing in a single silicon quantum dot¹, JOHN KING GAMBLE, MARK FRIESEN, S.N. COPPERSMITH, Department of Physics, University of Wisconsin-Madison, Madison, WI 53706, USA, XUEDONG HU, Department of Physics, University at Buffalo, SUNY, Buffalo, NY 14260, USA — We study the dephasing of two-electron states in a single silicon quantum dot. Specifically, we consider dephasing due to the electron-phonon coupling and charge noise, treating orbital, valley, and mixed valley-orbit excitations. For phonon-induced dephasing, the intervalley processes are most important and lead to a dephasing rate of about 1 MHz. In an ideal system, dephasing due to charge noise is strongly suppressed due to a vanishing dipole moment. However, introduction of disorder or anharmonicity leads to large effective dipole moments, and hence possibly strong dephasing.

¹This work was supported in part by ARO and LPS (W911NF-08-1- 0482) and by NSF (PHY-1104660).

5:06PM T29.00012 Long Spin Relaxation and Coherence Times of Electrons In Gated Si/SiGe Quantum Dots¹, JIANHUA HE, A.M. TYRSHKIN, S.A. LYON, Princeton University, C.-H. LEE, S.-H. HUANG, C. W. LIU, National Taiwan University — Single electron spin states in semiconductor quantum dots are promising candidate qubits. We report the measurement of $250 \mu\text{s}$ relaxation (T_1) and coherence (T_2) times of electron spins in gated Si/SiGe quantum dots at 350 mK. The experiments used conventional X-band (10 GHz) pulsed electron spin resonance (pESR), on a large area ($3.5 \times 20 \text{ mm}^2$) dual-gate undoped high mobility Si/SiGe heterostructure sample, which was patterned with 2×10^8 quantum dots using e-beam lithography. Dots having 150 nm radii with a 700 nm period are induced in a natural Si quantum well by the gates. The measured T_1 and T_2 at 350 mK are much longer than those of free 2D electrons, for which we measured T_1 to be $10 \mu\text{s}$ and T_2 to be $6.5 \mu\text{s}$ in this gated sample. The results provide direct proof that the effects of a fluctuating Rashba field have been greatly suppressed by confining the electrons in quantum dots. From 0.35 K to 0.8 K, T_1 of the electron spins in the quantum dots shows little temperature dependence, while their T_2 decreased to about $150 \mu\text{s}$ at 0.8 K. The measured 350 mK spin coherence time is 10 times longer than previously reported for any silicon 2D electron-based structures, including electron spins confined in “natural quantum dots” formed by potential disorder at the Si/SiO₂² or Si/SiGe interface, where the decoherence appears to be controlled by spin exchange.

5:18PM T29.00013 Creation of entangled exciton states in coupled quantum dots¹, CELESTINO CREATORE, RICHARD T. BRIERLEY, RICHARD T. PHILLIPS, PETER B. LITTLEWOOD², Cavendish Laboratory, University of Cambridge, JJ Thomson Avenus, CB3 0HE, Cambridge, UK, PAUL R. EASTHAM, School of Physics, Trinity College, Dublin 2, Ireland — Quantum state preparation through external control is fundamental to established methods in quantum information processing and in studies of dynamics. In this respect, systems such as excitons in semiconductor quantum dots (QDs) are of particular interest since they can be easily driven to a particular state through the coherent interaction with a tuned optical field such as an external laser pulse. Here we propose to use adiabatic rapid passage (ARP) to excite entangled states in an ensemble of coupled quantum systems. The ARP protocol makes use of optical pulses with both frequency and temporal modulation and it is an efficient method to achieve population inversion in quantum dot ensembles as it is robust with respect to fluctuations in coupling and detuning. We explore this problem using a generalized t-J Hamiltonian to model an interacting many-dot system described in terms of hard-core bosons. Our quantitative analysis shows that ARP can be successfully implemented to create entangled states in a realistic ensemble of inhomogeneously distributed QDs.

Wednesday, February 29, 2012 2:30PM - 5:30PM – Session T30 GQI: Quantum Algorithms 259B

2:30PM T30.00001 Adiabatic Surface Code Quantum Computing, CHRIS CESARE, CQILC, University of New Mexico, DAVE BACON, Department of Computer Science & Engineering, University of Washington, STEVE FLAMMIA, Perimeter Institute for Theoretical Physics, ANDREW LANDAHL, Sandia National Laboratories, ALICE NEELS, Department of Computer Science & Engineering, University of Washington — There are many approaches to constructing a quantum computer. In addition to the numerous different physical substrates available, there are a plethora of different underlying computational architectures from which to choose. Two major classes of architectures can be distinguished: those requiring a substantial external active control system to suppress errors, and those whose underlying physical construction eliminates much, if not all, of the need for such a control system. Here we focus on the latter class of architectures and address the question: “How does one fault-tolerantly quantum compute on a system protected from decoherence by a static Hamiltonian?” We present a solution that adiabatically interpolates between static Hamiltonians, each of which protects the quantum information stored in its ground space. Since each of these ground spaces can be described as a quantum error-correcting codespace, we call this process adiabatic code deformation. After describing a particular surface code (the toric code) and the way to encode information in code defects, we give explicit adiabatic interpolations that effect braids between defects, allowing for a CNOT gate between encoded qubits. We finish by describing how to extend our procedures to allow for universality.

2:42PM T30.00002 Quantum Random Walks and the Graph Isomorphism Problem¹ , KENNETH RUDINGER, JOHN KING GAMBLE, MARK WELLONS, MARK FRIESEN, ERIC BACH, ROBERT JOYNT, S.N. COPPERSMITH, University of Wisconsin-Madison — We investigate the quantum dynamics of particles on graphs (“quantum walk”), with the aim of developing quantum algorithms for determining whether or not two graphs are isomorphic. We investigate such walks on strongly regular graphs (SRGs), a class of graphs with high symmetry. We explore the effects of particle number and interaction range on a walk’s ability to distinguish non-isomorphic graphs. We numerically find that both non-interacting three-boson and three-fermion continuous time walks have the same distinguishing power on a dataset of 70,712 pairs of SRGs, each distinguishing over 99.6% of the pairs. We also find that increasing to four non-interacting particles further increases distinguishing power on this dataset. While increasing particle number increases distinguishing power, we prove that any walk of a fixed number of non-interacting particles cannot distinguish all SRGs. We numerically find that increasing particle number and increasing interaction range both result in increased distinguishing power of non-SRGs that are designed to be indistinguishable to the hard-core two-boson walk.

2:54PM T30.00003 Hamiltonian Simulation Using Linear Combinations of Unitary Operations , NATHAN WIEBE, ANDREW CHILDS, University of Waterloo — We present a new approach to simulating Hamiltonian dynamics based on implementing linear combinations of unitary operations rather than products of unitary operations. The resulting algorithm has superior performance to existing simulation algorithms based on product formulas and, most notably, scales better with the simulation error than any known Hamiltonian simulation technique. Our main tool is a general method to nearly deterministically implement linear combinations of similar unitary operations, which we show is optimal among a large class of methods.

3:06PM T30.00004 Measurement-Based Quantum Computation with Thermal States and Always-on Interactions , YING LI, Centre for Quantum Technologies, National University of Singapore, DANIEL BROWNE, Department of Physics and Astronomy, University College London, LEONG CHUAN KWEK, Centre for Quantum Technologies, National University of Singapore and Nanyang Technological University, ROBERT RAUSSENDORF, Department of Physics and Astronomy, University of British Columbia, TZU-CHIEH WEI, CN Yang Institute for Theoretical Physics, Stony Brook University — Quantum computation can be achieved by single-qubit measurements on an initial entangled state. It is often implicitly assumed that the interactions between spins can be switched off so that the dynamics of the measured spins does not affect the computation. We propose a model spin Hamiltonian so that measurement-based quantum computation can be accomplished on a thermal state with always-on interactions. Moreover, computational errors induced by thermal fluctuations can be corrected and thus the computation can be executed fault tolerantly if the temperature is below a threshold value.

3:18PM T30.00005 Quantum Computational Universality of the 2D Cai-Miyake-Dür-Briegel Quantum State , TZU-CHIEH WEI, CN Yang Institute for Theoretical Physics, Stony Brook University, ROBERT RAUSSENDORF, Department of Physics and Astronomy, University of British Columbia, LEONG CHUAN KWEK, Centre for Quantum Technologies, National University of Singapore and Nanyang Technological University — Universal quantum computation can be achieved by simply performing single-qubit measurements on a highly entangled resource state, such as cluster states. Cai, Miyake, Dür, and Briegel recently constructed a ground state of a two-dimensional quantum magnet by combining multiple Affleck-Kennedy-Lieb-Tasaki quasichains of mixed spin-3/2 and spin-1/2 entities and by mapping pairs of neighboring spin-1/2 particles to individual spin-3/2 particles [Phys. Rev. A **82**, 052309 (2010)]. They showed that this state enables universal quantum computation by constructing single- and two-qubit universal gates. Here, we give an alternative understanding of how this state gives rise to universal measurement-based quantum computation: by local operations, each quasichain can be converted to a one-dimensional cluster state and entangling gates between two neighboring logical qubits can be implemented by single-spin measurements. Furthermore, a two-dimensional cluster state can be distilled from the Cai-Miyake-Dür-Briegel state.

3:30PM T30.00006 Algorithmic Quantum Cooling , MAN HONG YUNG, SERGIO BOIXO, ALAN ASPURU-GUZIK, Harvard University, HARVARD TEAM — Efficient methods of cooling are essential for exploring the fundamental properties of low temperature physics. A remarkable cooling method is known as the evaporative cooling (or “coffee” cooling), where energetic particles are filtered away so as to lower the mean energy of the rest of the system. Inspired by the idea of evaporative cooling, we developed a method called algorithmic quantum cooling (AQC) for achieving the goal of cooling for any physical system which is simulable by a quantum computer. The novel feature of AQC is that the evolution of the state of the system is modeled as the movement of a one-dimensional classical random walk; the walker plays the role of the motion of the gas particles in an ordinary evaporative cooling. The implementation of this method is analogous to the setting of Maxwell’s demon, where the experimentalist can monitor the heat-up or cool-down of the system, and apply feedback control to the resulting states. Here we cover the results of the connection of AQC with quantum non-demolition measurement, a scaling analysis of AQC, and the application of amplitude amplification to achieve quantum speedup. Experimental realization of AQC can be accomplished with currently available technologies.

3:42PM T30.00007 Progress on exploring practical applications of quantum annealing and D-Wave One , SERGIO BOIXO, USC- ISI, FEDERICO SPEDALIERI, USC - ISI — A D-Wave One quantum optimizer is currently being installed at the newly created USC-Lockheed Martin Quantum Computing Center. This chip implements quantum annealing at finite temperature as a computational resource, with 90 working qubits. Quantum annealing is a particularly simple branch of adiabatic quantum computation. We report work in progress on exploring practical applications of quantum annealing in general, and this chip in particular. Some of this work is done in collaboration with Aspuru-Guzik’s group at Harvard.

3:54PM T30.00008 Adiabatic Quantum Anomaly Detection and Machine Learning¹ , KRISTEN PUDENZ, DANIEL LIDAR, University of Southern California — We present methods of anomaly detection and machine learning using adiabatic quantum computing. The machine learning algorithm is a boosting approach which seeks to optimally combine somewhat accurate classification functions to create a unified classifier which is much more accurate than its components. This algorithm then becomes the first part of the larger anomaly detection algorithm. In the anomaly detection routine, we first use adiabatic quantum computing to train two classifiers which detect two sets, the overlap of which forms the anomaly class. We call this the learning phase. Then, in the testing phase, the two learned classification functions are combined to form the final Hamiltonian for an adiabatic quantum computation, the low energy states of which represent the anomalies in a binary vector space.

¹Research supported by the Lockheed Martin Corporation, the NSF, and NASA Ames Research Center

4:06PM T30.00009 Universal Blind Quantum Computation, JOSEPH FITZSIMONS, National University of Singapore, ELHAM KASHEFI, University of Edinburgh — Blind Quantum Computing (BQC) allows a client to have a server carry out a quantum computation for them such that the client's inputs, outputs and computation remain private. Recently we proposed a universal unconditionally secure BQC scheme, based on the conceptual framework of the measurement-based quantum computing model, where the client only needs to be able to prepare single qubits in separable states randomly chosen from a finite set and send them to the server, who has the balance of the required quantum computational resources. Here we present a refinement of the scheme which vastly expands the class of quantum circuits which can be directly implemented as a blind computation, by introducing a new class of resource states which we term *dotted-complete graph states* and expanding the set of single qubit states the client is required to prepare. These two modifications significantly simplify the overall protocol and remove the previously present restriction that only nearest-neighbor circuits could be implemented as blind computations directly. As an added benefit, the refined protocol admits a substantially more intuitive and simplified verification mechanism, allowing the correctness of a blind computation to be verified with arbitrarily small probability of error.

4:18PM T30.00010 Experimental demonstration of blind quantum computing, STEFANIE BARZ, VCQ, University of Vienna; IQOQI, Austrian Academy of Sciences, Austria, ELHAM KASHEFI, School of Informatics, University of Edinburgh, UK, ANNE BROADBENT, Institute for Quantum Computing, University of Waterloo; Department of Combinatorics & Optimization, University of Waterloo, Canada, JOE FITZSIMONS, Centre for Quantum Technologies, National University of Singapore, Singapore; School of Physics, University College Dublin, Ireland, ANTON ZEILINGER, PHILIP WALTHER, VCQ, University of Vienna; IQOQI, Austrian Academy of Sciences, Austria — Quantum computers are among the most promising applications of quantum-enhanced technologies. Quantum effects such as superposition and entanglement enable computational speed-ups that are unattainable using classical computers. The challenges in realising quantum computers suggest that in the near future, only a few facilities worldwide will be capable of operating such devices. In order to exploit these computers, users would seemingly have to give up their privacy. It was recently shown that this is not the case and that, via the universal blind quantum computation protocol, quantum mechanics provides a way to guarantee that the user's data remain private. Here, we demonstrate the first experimental version of this protocol using polarisation-entangled photonic qubits. We demonstrate various blind one- and two-qubit gate operations as well as blind versions of the Deutsch's and Grover's algorithms. When the technology to build quantum computers becomes available, this will become an important privacy-preserving feature of quantum information processing.

4:30PM T30.00011 Classical Ising Models Realised on Optical Lattices, MAURO CIRIO, G.K. BRENNEN, J. TWAMLEY, S. IBLISDIR, O. BOADA, Macquarie University — We describe a simple quantum algorithm acting on a register of qubits in d spatial dimensions which computes statistical properties of $d + 1$ dimensional classical Ising models. The algorithm works by measuring scattering matrix elements for quantum processes and Wick rotating to provide estimates for real partition functions of classical systems. This method can be implemented in a straightforward way in ensembles of qubits, e.g. three dimensional optical lattices with only nearest neighbor Ising like interactions. By measuring noise in the estimate useful information regarding location of critical points and scaling laws can be extracted for classical Ising models, possibly with inhomogeneity. Unlike the case of quantum simulation of quantum hamiltonians, this algorithm does not require Trotter expansion of the evolution operator and thus has the advantage of being amenable to fault tolerant gate design in a straightforward manner. Through this setting it is possible to study the quantum computational complexity of the estimation of a classical partition function for a 2D Ising model with non uniform couplings and magnetic fields. We provide examples for the 2 dimensional case.

4:42PM T30.00012 Initialization and Readout of Spin Chains for Quantum Information Transport, GURNEET KAUR, PAOLA CAPPELLARO, Massachusetts Institute of Technology, MIT — Linear chains of spins acting as quantum wires are a promising approach to achieve scalable quantum information processors. Nuclear spins in apatite crystals closely emulate a one-dimensional spin chain, thus providing an ideal test-bed for the experimental study of quantum information transport by means of Nuclear Magnetic Resonance techniques. The natural dipolar interaction among the spins can be manipulated via the available collective NMR control to simulate the Hamiltonian capable of driving quantum transport. We present control protocols for initialization and readout of ^{19}F spin chains in Fluorapatite, even in the absence of single-spin addressability. We experimentally prepare and read out desired initial states for transport tasks, such as the simulation of single-spin excitation transport and a two-spin encoded state for quantum information transfer. Our control schemes enable experimental characterization of quantum transport in spin chains and will allow further studies of protocols for perfect fidelity transfer.

4:54PM T30.00013 Dynamical decoupling and quantum error suppression in adiabatic quantum computation, KEVIN YOUNG, Sandia National Laboratories — Adiabatic quantum information processing, like other quantum computing paradigms, is susceptible to noise which can potentially spoil a computation. This talk will address two proposed methods to utilize stabilizer codes to combat such noise: dynamical decoupling and quantum error suppression. A combination of numerical and analytical techniques will illustrate the connections between these two approaches. The talk will conclude with a discussion of the practical advantages of dynamical decoupling over quantum error suppression.

5:06PM T30.00014 Complexity of the Quantum Adiabatic Algorithm, ITAY HEN, A.P. YOUNG, University of California Santa Cruz — The Quantum Adiabatic Algorithm (QAA) has been proposed as a mechanism for efficiently solving optimization problems on a quantum computer. Here, we determine its efficiency by considering several constraint satisfaction (SAT) problems. We do this by studying the size dependence of their typical minimum energy gap using quantum Monte Carlo methods. We find that for most problems this gap decreases exponentially with the size of the problem, indicating that the QAA is not more efficient than existing classical search algorithms. However, for one specific problem, namely, MAX-2-XORSAT, there is evidence to suggest that the gap may be polynomial near the phase transition.

5:18PM T30.00015 Discrete-time quantum walks on the symmetric group (quantum card shuffling), ZLATKO DIMCOVIC, YEVGENIY KOVCHegov, Oregon State University — The next stage in uses of classical stochastic approaches, going beyond Markov chains (random walks on graphs), are walks on algebraic structures. The prime and classic example of such a problem is "card shuffling," a walk on the permutation (symmetric) group. The richness of this non-Abelian group lends itself to modeling of complex phenomena, while it also quickly leads to rather complicated problems. The challenge of studying such quantum processes is no lesser, but the benefits can be expected to even outweigh the classical uses. We study a quantum analog of the classical "top-to-random" shuffle, where the top card is placed at random in the deck. We construct a "coined" DTQW on the permutation group: based on the action of a (unitary) "coin" operator in an additional ("coin") space, (unitary) steps in the group space are taken, resulting in a (quantum) walk over group elements. We use general techniques for the eigenvalue problem of the combined coin and permutation operators, utilizing regularities in the block structure. We have reached preliminary solutions for low-dimensional cases. Currently we are integrating them into a more general solution, which will yield the first step in this deep and far-reaching, while challenging problem.

Wednesday, February 29, 2012 2:30PM - 5:30PM —
Session T31 DMP: Focus Session: Topological Insulators: Synthesis and Characterization - Spin Transport and Superconductivity 260

2:30PM T31.00001 Towards spin injection from silicon into topological insulators¹, CLAUDIA OJEDA-ARISTIZABAL, MICHAEL S. FUHRER, IAN APPELBAUM, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742, USA, IAN APPELBAUM TEAM — Attempts to uncover evidence of spin-momentum coupling in a topological insulator (TI) using transport measurements are hampered by many challenges. Most importantly, injection of a spin polarized current from a ferromagnet that is in contact or close proximity to a topological insulator can easily give rise to anisotropic magnetoresistance signals or planar Hall effect from stray fields, which have the same symmetry and hence are indistinguishable from any signal coming from the spin-momentum-locked surface states. Here we propose a scheme to remove this difficulty by injecting spin-polarized electrons from undoped silicon into the TI surface states. In addition to providing a long-distance transport region to separate the ferromagnetic spin source from the TI by several hundred microns or even millimeters, this approach will also allow spin precession measurements (necessary for unambiguous identification of spin signals) whereas direct injection does not. Detection is provided by differential measurement from two ballistic current contacts on the topological insulator. We will describe our progress in fabrication and measurement of devices with exfoliated crystals of TI Bi₂Se₃, including the determination of the silicon-Bi₂Se₃ Schottky barrier height of 0.34 eV

¹This work is supported by the University of Maryland NSF-MRSEC under Grant No. DMR 05-20471 and the ONR.

2:42PM T31.00002 Spin-momentum helical locking induced spin-valve effects in topological insulator/ferromagnet heterostructures¹, LAN WANG, BIN XIA, CHANG KE, PENG REN, PENG LIU, HAIBIN SU, ALFRED HUAN, Nanyang Technological University — Topological insulator is composed of an insulating bulk state and an odd number of massless spin-helical Dirac cone formed two dimensional surface state. Here we report a novel spin-valve effect in Bi_{1.5}Sb_{0.5}Te_{1.8}Se_{1.2}/CoFe heterostructures. This effect indicates the spin-momentum helical locking on the Bi_{1.5}Sb_{0.5}Te_{1.8}Se_{1.2} topological surface state. It is also indicated that the characteristics of helical surface can be preserved at topological insulator/ferromagnet interface although the ferromagnetism can break the time reversal symmetry and therefore generate an energy gap at the topological Dirac cone.

¹Supports for this work came from Singapore National Research Foundation (RCA-08/018) and MOE Tier 2 (MOE2010-T2-2-059).

2:54PM T31.00003 Spin Transport Experiments in Topological Insulator Bi₂Se₃ Thin Films, JIFA TIAN, ISAAC CHILDRES, HELIN CAO, Department of Physics and Birck Nanotechnology Center, Purdue University, West Lafayette, IN, 47907, IREK MITKOWSKI, Department of Physics, Purdue University, West Lafayette, IN, 47907, YONG P. CHEN, Department of Physics and Birck Nanotechnology Center, Purdue University, West Lafayette, IN, 47907 — Topological insulators are an unusual phase of quantum matter with an insulating bulk gap and gapless spin-momentum locked Dirac surface states. Such a spin-helical surface state provides rich opportunities for potential applications in spintronics. We performed spin valve experiments on exfoliated Bi₂Se₃ thin films (~10 nm thick) with ferromagnetic electrodes using a DC driving current in an in-plane magnetic field. We observed the two-terminal resistances are asymmetric between the large positive (> 0.5 T) and negative (<-0.5 T) in-plane magnetic fields. The high and low resistance states can be reversed by changing the direction of the driving DC current. Furthermore, the measured resistance asymmetry decreases as temperature increases. One interpretation of our observation is related to the spin-momentum helical locking of topological surface states producing a spin-polarized surface current. We also performed the non-local spin valve measurements, and observed an asymmetry in the measured signal between opposite large magnetic fields.

3:06PM T31.00004 Josephson supercurrent through a topological insulator surface state, MENNO VELDHORST, MARIEKE SNELDER, MARCEL HOEK, TIAN GANG, MESA+ Institute for Nanotechnology, University of Twente, The Netherlands, XIAO-LIN WANG, Institute for Superconducting and Electronic Materials, University of Wollongong, Australia, VEERENDRA GUDURU, ULI ZEITLER, High Field Magnet Laboratory, Radboud University Nijmegen, The Netherlands, WILFRED WIEL, MESA+ Institute for Nanotechnology, University of Twente, The Netherlands, ALEXANDER GOLUBOV, HANS HILGENKAMP, ALEXANDER BRINKMAN, MESA+ Institute for Nanotechnology, University of Twente, The Netherlands — The long-sought yet elusive Majorana fermion is predicted to arise from a combination of a superconductor and a topological insulator. An essential step in the hunt for this emergent particle is the unequivocal observation of supercurrent in a topological phase. Here, we present direct evidence for a Josephson supercurrent in superconductor (Nb) - topological insulator (Bi₂Te₃) - superconductor e-beam fabricated junctions by the observation of clear Shapiro steps under microwave irradiation, and a Fraunhofer-type dependence of the critical current on magnetic field. The dependence of the critical current on temperature and electrode spacing shows that the junctions are in the ballistic limit. Shubnikov-de Haas oscillations in magnetic fields up to 30 T reveal a topologically non-trivial two-dimensional surface state. We argue that the ballistic Josephson current is hosted by this surface state despite the fact that the normal state transport is dominated by diffusive bulk conductivity. The lateral Nb-Bi₂Te₃-Nb junctions hence provide prospects for the realization of devices supporting Majorana fermions.

3:18PM T31.00005 Hybrid Superconducting Junctions of Bi₂Se₃ Topological Insulator Nanoribbons, YONG-JOO DOH, Korea University Sejong Campus, HYUNHO NOH, Korea Research Institute of Standards and Science, LEE-SEUL PARK, Sookmyung Women's University, EUN-KYOUNG JEON, Korea Research Institute of Chemical Technology, HONG-SEOK KIM, Korea University Sejong Campus, JEONG-O LEE, Korea Research Institute of Chemical Technology, JIN SEOK LEE, Sookmyung Women's University, JINHEE KIM, Korea Research Institute of Standards and Science — Topological insulators are exotic materials with bulk band gap and metallic edge states which are protected on their own boundary topologically. Here, we report on the fabrication and measurement results of the superconducting proximity junctions of topological insulator nanoribbons of Bi₂Se₃. Single-crystalline Bi₂Se₃ nanoribbons are synthesized using the vapor-liquid-solid method, while the superconducting Al electrodes are formed on top of the nanowire. When a magnetic field (H) is applied along the axial direction, the magneto-resistance data exhibit quasi-periodic oscillations with an average periodicity of $H^* \sim 0.4$ T, which is consistent with the Aharonov-Bohm oscillations. In the superconducting state, the supercurrent branch with a critical current of $I_c \sim 90$ nA is clearly observed in the current-voltage curve as a result of the superconducting proximity effect in Bi₂Se₃ nanoribbon. Quantized voltage steps of the Bi₂Se₃ nanoribbon Josephson junction under the microwave irradiation satisfy the ac Josephson relation.

3:30PM T31.00006 Signature of Majorana Fermions in Josephson Junctions of Bi₂Se₃¹, JAMES WILLIAMS, ANDREW BESTWICK, Stanford University, PATRICK GALLAGHER, Harvard University, JAMES ANALYTIS, IAN FISHER, DAVID GOLDBERGER, Stanford University — At the surface of a three-dimensional topological insulator lie Dirac fermions. Placing a superconductor in proximity to these surface fermions has been theoretically shown to produce Majorana fermions, an as-yet unobserved elementary particle. We report on the fabrication and low-temperature transport of a topological insulator in proximity to two superconductors – a device forming a Josephson Junction with a topological insulator (Bi₂Se₃) as a weak link. Several departures from conventional Josephson Junctions are observed and evaluated in the context of the presence of a one-dimensional wire of Majorana fermions induced in the device.

¹This work is supported in part by the Keck Foundation

3:42PM T31.00007 Superconductivity in the topological semimetal YPtBi, NICHOLAS BUTCH, Lawrence Livermore National Laboratory — Superconductivity was recently discovered in the half Heusler compound YPtBi. Electrical resistivity and Hall data provide compelling evidence that supports the idea that band structure calculations are correct and that YPtBi is indeed a semimetal with nontrivial topology. The low-temperature superconductivity emerges from a remarkable normal state with an extremely low carrier density, no crystalline inversion symmetry, and strong band inversion. I will discuss the normal state properties of YPtBi and details of its superconducting state, and compare them to the characteristics of other potential topological superconductors. This research was performed at the University of Maryland, College Park in collaboration with Paul Syers, Kevin Kirshenbaum, Andrew P. Hope, and Johnpierre Paglione.

4:18PM T31.00008 Superconductivity in Bi₂Te₃ type three dimensional topological compounds induced via pressure, CHANGQING JIN, J. ZHU, P.P. KONG, S.J. ZHANG, J.L. ZHANG, S.M. FENG, H.M. WENG, Q.Q. LIU, X.C. WANG, J.L. ZHU, X.H. YU, L.X. YANG, R.C. YU, Institute of Physics, Chinese Academy of Sciences, L. WANG, W.G. YANG, HPCAT, Geophysical Laboratory, Carnegie Institute of Washington, S.C. ZHANG, Stanford University, X. DAI, Z. FANG, Institute of Physics, Chinese Academy of Sciences — We report experimental updates on pressure induced superconductivity in Bi₂Te₃ type topological compounds. The topological nature of the superconductivity observed will be discussed in conjunction with on site high pressure structure investigations & first principles calculations. A phase diagram of superconductivity as function of pressure will be provided.

4:30PM T31.00009 Proximity-Induced High-Temperature Superconductivity in a Topological Insulator, PARISA ZAREAPOUR, ALEX HAYAT, SHU YANG FRANK ZHAO, ANJAN REIJNDERS, MIKHAIL KRESHCHUK, ACHINT JAIN, Department of Physics and Institute for Optical Sciences, University of Toronto, DANIEL KWOK, NARA LEE, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, ZHIJUN XU, ALINA YANG, G.D. GU, CMP&MS Department, Brookhaven National Laboratory, KENNETH BURCH, Department of Physics and Institute for Optical Sciences, University of Toronto — New topological phases of matter have been proposed to exist at the surface of some materials with spin-orbit coupling called topological insulators. Among the different exotic features of topological insulators, the interface between a topological insulator and a superconductor is of great interest. It is predicted that combining these two materials would lead to the emergence of Majorana fermion excitations which enable several applications in spintronics and quantum computing. Towards this goal, we have investigated Bi₂Sr₂CaCu₂O_{8+δ}(Bi-2212)-Bi₂Se₃ interface junctions made by a new mechanical-bonding technique. Current vs. voltage and differential conductance measurements have been performed in various temperatures ranging from room temperature to 5K. Several anomalies were observed in the Andreev spectra including a zero bias conductance peak appearing below the critical temperature of the superconductor Bi-2212 (85K), a reduced gap in Bi-2212 as well as the intrinsic gap of Bi-2212. These features suggest the induction of high-temperature superconductivity in the Bi₂Se₃ due to proximity to Bi-2212.

4:42PM T31.00010 Point-contact Andreev Reflection Spectroscopy on Bi₂Se₃ Single Crystal, XUNCHI CHEN, CHAO HUAN, Georgia Inst of Tech, IREK MITKOWSKI, YONG CHEN, Purdue University, ZHIGANG JIANG, Georgia Inst of Tech — Point-contact spectroscopy measurement is carried out on Bi₂Se₃ single crystals via approaching a superconducting niobium tip ($T_c=9.5$ K) to the crystal surface. The tip-sample junction conductance is studied as a function of DC bias voltage, temperature, and magnetic field. The resulting spectra show a conductance dip at zero bias, indicative of ballistic transport. A homebuilt positioning stage enables us to approach the superconducting tip in nanometer accuracy, to precisely control the inter-facial barrier strength. We find that our experimental results cannot be simply described by the standard Blonder, Tinkham and Klapwijk (BTK) model even when the inelastic scattering at the interface is considered. An improved model taking into account the spin-orbit coupling effect is needed to fit our data.

4:54PM T31.00011 Crystal growth and physical property of Bi-Sb-Te-Se topological insulator and CuxBi2Se3 topological superconductor materials¹, GENDA GU, ALINA YANG, JOHN SCHNEELOCH, ZHIJUN XU, JOHN TRANQUADA, J.G. ZHÖA, Z.H. PAN, H.B. YANG, W.D. SI, T. VALLA, CMP&MS, Brookhaven National Laboratory — The discovery of 3D topological insulator and topological superconductor materials opens up a new research field in the condensed matter physics. In order to exploit the novel surface properties of these topological insulators, it is crucial to achieve a bulk-insulating state in these topological insulator crystals. Unfortunately, all available topological insulator crystals are not bulk-insulating. We have grown a number of Bi-Se, Bi-Te, Sb-Te-Se, Bi-Sb-Se, Bi-Sb-Te-Se and Bi-Sb-Te-Se-S topological insulator single crystals by using 5N and 6N pure elements. We have measured the physical properties on these single crystals. We have studied the effect of growth condition and impurity on the bulk electrical conductivity of these single crystals. We try to answer two questions if it is possible to grow the bulk-insulating topological insulator single crystals and which maximum resistivity of these topological insulator single crystals we can grow. We have also grown a number of CuxBi2Se3 topological superconductor single crystals.

¹The work was supported by DOE under contract No. DE-AC02-98CH10886.

5:06PM T31.00012 Crystal structure and superconducting properties in Cu_xBi₂Se₃, YUSUKE SUZUKI, PRADIP DAS, University of Tsukuba, TAKASHI MOCHIKU, NIMS, TAKANARI KASHIWAGI, MASASHI TACHIKI, KAZUO KADOWAKI, University of Tsukuba — The recent discovery of the anomalous superconductivity in Cu_xBi₂Se₃ (0.10<x<0.25) has attracted much attention because of the relation between superconducting state and topological surface state. In order to understand the role of Cu doping in superconducting Bi₂Se₃, we study the doping dependence of the magnetic properties and the characteristics of crystal structures. We made high quality of Cu_xBi₂Se₃ single crystals with several doping level of x by using melt growth technique. We confirmed the superconducting transition from Cu_xBi₂Se₃ for several doping levels and determined the phase diagram of a function of x. The lattice constant increases with increasing Cu doping level, however it saturated around x=0.25 which corresponds to the saturation of T_c as well. We analyzed the crystal structure in detail in explaining the occurrence of superconductivity. Details of the structural and magnetization study will be discussed in the conference.

5:18PM T31.00013 Electrical Transport Properties of Bi₂Te₃ Nanotubes and Nanowires, REN-ZHONG DU, JIAN WANG, QI LI, Department of Physics, The Pennsylvania State University, University Park, PA, USA, YUEWEI YIN, SINING DONG, XIAO GUANG LI, Hefei National Laboratory for Physical Sciences at Microscale, Department of Physics, University of Science and Technology of China, Hefei, China — Electrical transport properties of promising topological insulator, Bi₂Te₃ nanowires and nanotubes are measured at different temperatures and magnetic field and the results are compared with the Bi₂Se₃ thin films. The nanotube and nanowire samples are synthesized by galvanostatic electrodeposition and solution phase methods, with diameters of 70nm (ex) and 50nm (in) for nanotubes and 80~100nm for nanowires, respectively. The contact leads (Pt) are fabricated by using Focusing Ion Beam (FIB). The magnetoresistance of Bi₂Te₃ nanotubes shows linear dependence as a function of magnetic field, with a notable peak around zero field. This is different from Bi₂Se₃ thin films which show quadratic behavior, with a significant dip near zero field. The results will be discussed based on the possible weak localization effect in the nanotubes in comparison with the weak anti-localization effect in the films.

Wednesday, February 29, 2012 2:30PM - 5:30PM —
Session T32 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides - Manganites 261

2:30PM T32.00001 Colossal magnetodielectric effect in DyMn2O5: Electromagnons or rare earth?¹, ANDREI SUSHKOV, DENNIS DREW, MRSEC and CNAM, Department of Physics, University of Maryland, CHRISTIAN KANT, ALEXEY SHUVAEV, ANDREI PIMENOV, ISSP, Vienna University of Technology, Austria, SERGEI ZVYAGIN, Dresden High Magnetic Field Laboratory, Germany, BERND LORENZ, University of Houston, SANG-WOOK CHEONG, Rutgers University — We report on the results of spectroscopic studies of the excitations responsible for the colossal magnetodielectric effect in DyMn2O5 [1]. On one hand, many RMn2O5 compounds have electromagnons capable of inducing large steps in the dielectric constant. On the other hand, rare earth ions can possess electric dipole moments and also can produce dielectric anomalies. Both types of excitations are expected in the experimentally difficult low energy range 0.1-1 meV. We use high frequency dielectric, Fourier transform and back-wave oscillator spectroscopies in combination with low temperature and magnetic field up to 9 T to clarify the origin of the dielectric anomaly in DyMn2O5. [1] N. Hur, S. Park, P. A. Sharma, S. Guha, and S-W. Cheong, Colossal Magnetodielectric Effects in DyMn2O5, PRL 93, 107207 (2004).

¹Work supported in part by NSF-MRSEC under grant DMR-0520471

2:42PM T32.00002 Magnetism-Driven Ferroelectricity in GdMn2O5, NARA LEE, Rutgers University, YOUNG JAI CHOI, Yonsei University, C. VECCHINI, Diamond Light Source Ltd, L. C. CHAPON, ISIS Facility, Rutherford Appleton Laboratory, P. G. RADAELLI, Oxford Physics, A. BOMBARDI, Diamond Light Source Ltd, S-W. CHEONG, Rutgers University — REMn2O5 (RE=rare-earth) is one of the well-studied multiferroics which exhibits the reversible switching of ferroelectric polarization under the application of external magnetic fields. It is known that the ferroelectricity in REMn2O5 originates from the symmetric exchange interaction between Mn ions. However, the role of the rare-earth elements has never been elucidated. In order to reveal the full magnetic structure and the contribution of rare-earth magnetism to the ferroelectricity, we have studied the detailed magnetic and structural properties of high-quality single-crystalline GdMn2O5 (space group, Pbam). We have performed the resonant x-ray scattering experiment, and comprehensive measurements of physical properties of the system, including magnetic susceptibility, dielectric constant and ferroelectric polarization with the variation of temperature and magnetic fields.

2:54PM T32.00003 Raman and Infrared studies of the multiferroics TbMn2O5 and YMn2O5, SABEUR MANSOURI, SERGE JANDL, Université de Sherbrooke, 2500 Boulevard University, Sherbrooke, Quebec J1K 2R1, Canada, P. ORLITA, COLLABORATION¹, M. M. GOSPODINOV, COLLABORATION² — Orthorhombic manganites of the RMnO3 and RMn2O5 families develop an electric polarization induced, flipped and flopped by application of a magnetic field. The Tb(Y)Mn2O5 Anti-ferromagnetic order is incommensurate between $T_N = 42K$ (44K) and $T_C = 38K$ and becomes commensurate between $T_C = 38K$ and $T = 24K$ (18K); at this temperature ferroelectricity appears and remains incommensurate below 24K (18K)[1,2]. We have studied the TbMn2O5 and YMn2O5 Raman active phonons as a function of temperature and compared their behavior to similar multiferroic compounds Bi(Dy)Mn2O5 phonons where the A_g high frequencies modes soften between $T^* \sim 70K$ and T_N and harden below $T_N \sim 42K$ [3]. The over-hardening of the phonon frequencies above anharmonicity at low temperatures confirm that the spin-lattice interaction plays an important role in the magnetoelectric properties. The TbMn2O5 infrared active phonon frequencies are also studied as a function of temperature and under applied magnetic field (up to 10 Tesla). As predicted theoretically the TbMn2O5 infrared-active phonon frequencies soften below T_N . Evolutions of the phonon frequencies under the applied magnetic field are reported and analyzed.

3:06PM T32.00004 Absence of ferroelectricity in hexagonal InMnO3, MARTIN LILIENBLUM, YU KUMAGAI, Department of Materials, ETH Zurich, ALEXEI A. BELIK, International Center for Materials Nanoarchitectonics, NIMS, NAËMI LEO, NICOLA A. SPALDIN, MANFRED FIEBIG, Department of Materials, ETH Zurich — So far, it was believed that hexagonal (h-) InMnO3 exhibit the same type of multiferroic order as the other compounds from the h-RMnO3 family (R = Sc, Y, Dy - Lu), including, in particular, a unit-cell-tripling improper ferroelectric order. Here we present experimental evidence for the absence of ferroelectricity in hexagonal InMnO3 based on three different techniques: x-ray diffraction (XRD), piezoresponse force microscopy (PFM) and optical second harmonic generation (SHG). XRD data are ambiguous because they can be described likewise by the non-ferroelectric $P\bar{3}c$ structure and by the ferroelectric $P6_3cm$ structure present in the other h-RMnO3 compounds. However, PFM at room temperature and SHG measurements at low temperature uniquely reveal the absence of ferroelectric order in InMnO3. We therefore propose that InMnO3 exhibits antiferrodistortive, but non-ferroelectric order according to the $P\bar{3}c$ symmetry. Density functional calculations show that the relative energy between the $P\bar{3}c$ and $P6_3cm$ structures is determined by a competition between electrostatic and covalency effects, with an absence of covalency favoring the ferroelectric structure.

3:18PM T32.00005 Long range order beyond vortices in h-REMnO3, SEUNG CHUL CHAE, NARA LEE, YOICHI HORIBE, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — Fascinating vortices were discovered recently in ferroelectric domain patterns in hexagonal (h-)YMnO3. One of the important ingredients for these vortex domain patterns is mutual interlocking of ferroelectric and structural antiphase domain walls. In contrast to expected vortex domain patterns, we have found intriguing stripe domain patterns in other h-REMnO3 (RE=Ho, Er, Tm, Yb, Lu). These stripe domain patterns appear to indicate the presence of long-range-ordered state as the true ground state in h-REMnO3. On the other hand, vortex domain patterns suggest the presence of a Kosterlitz-Thouless-like transition. We argue that this significant difference stems from very slow kinetics associated the ordering of six possible degrees of freedom.

3:30PM T32.00006 Electronic and Structural Properties Near the Ferroelectric Transition in Multiferroic Hexagonal RMnO3, HAIYAN CHEN, TREVOR TYSON, TAO WU, New Jersey Institute of Technology, JIANMING BAI, Oak Ridge National Laboratory, KEN AHN, New Jersey Institute of Technology, KUMI PANDYA, Brookhaven National Laboratory, S.B. KIM, SANG-WOOK CHEONG, Rutgers University — Combined local and long range structural measurements were conducted on RMnO3 for temperatures extending significantly above the ferroelectric transition temperature, (T_{FE}). We find in hexagonal RMnO3 no large atomic (bond distance or thermal factors) or electronic structure changes on crossing T_{FE} . The born effective charge tensor is found to be highly anisotropic at the O sites indicating very strong hybridization of the charge. The tensor does not change significantly above T_{FE} revealing no charge redistribution and suggests an unusual transition. Molecular dynamic simulations on large supercells are used to provide a general picture of the transition. This work is supported by DOE Grants DE-FG02-07ER46402 (NJIT) and DE-FG02-07ER46382 (Rutgers University).

3:42PM T32.00007 Role of the apical oxygen in RMnO₃ (R = Ho and Lu) low temperature magneto-electric effect , JONATHAN VERMETTE, SERGE JANDL, Département de Physique, Université de Sherbrooke, M. ORLITA COLLABORATION, M. M. GOSPODINOV COLLABORATION — Multiferroic materials are promising candidates for new innovative devices, particularly in the field of memory storage. The strong coupling between magnetic ordering and ferroelectricity characterizing these compounds allows the modulation of the electric polarization (magnetic moment) with an external magnetic (electric) field. Hexagonal RMnO₃ (Ho to Lu) compounds are type-I multiferroics in which ferroelectricity and magnetism have different sources giving a relative weak magneto-electric coupling with a large polarization. In this case ferroelectricity is induced at a relative high temperature ($T_C \sim 800\text{K}$) following a structural transition, while magnetic ordering of Mn³⁺ and R³⁺ occurs at lower temperatures ($T < 100\text{K}$). In order to determine which atoms play a major role in the giant low temperature magneto-electric effect, we study the evolutions of infrared active phonon frequencies in HoMnO₃ and LuMnO₃ under applied magnetic field below $T_{Ho} = 5\text{K}$. By comparing the renormalized force constants and the Born-effective charges, apical oxygen role in Ho³⁺-Mn³⁺ superexchange interaction is particularly underlined.

3:54PM T32.00008 Piezoelectric-response of charged 180° ferroelectric domain walls¹ , EDWARD LOCHOCKI, Department of Physics and Astronomy and Rutgers Center for Emergent Materials, Rutgers University, Piscataway, New Jersey 08854, USA, SOONYONG PARK, Department of Physics, Chung-Ang University, Seoul 156, Republic of Korea, NARA LEE, S-W. CHEONG, WEIDA WU, Department of Physics and Astronomy and Rutgers Center for Emergent Materials, Rutgers University, Piscataway, New Jersey 08854, USA — We report ambient piezoresponse force microscopy (PFM) studies of the multiferroic hexagonal manganite HoMnO₃ performed on the cleaved (110) surface of a single crystal specimen. By changing the sample orientation with respect to the cantilever, we observed an unexpected out-of-plane PFM signal at domain walls which depends on domain wall orientation, in addition to the expected in-plane PFM signal in domains. Further studies confirmed that the domain wall PFM signal results from an out-of-plane displacement, which can be explained by a simple model of local elastic response with conservation of unit cell volume at head-on domain walls.

¹NSF-DMR-0844807 and NSF-DMR-1104484

4:06PM T32.00009 A First Principle exploration of A site ordered Ho_{0.5}A_{0.5}MnO₃ (A=Ge, Sn, Pb, As, Sb, Bi, Se, Te) , SATHYA SHEELA SUBRAMANIAN, National Institute of Technology, Trichy, India, Japan Advanced Institute of Science and Technology, Japan, TAISUKE OZAKI, Japan Advanced Institute of Science and Technology, Japan, KUNHIKO YAMAUCHI, ISIR-SANKEN, Osaka University, Japan, NATESAN BASKARAN, National Institute of Technology, Trichy, India, TAMIO OGUCHI, ISIR-SANKEN, Osaka University, Japan — In this work a first principle attempt has been made to study the structure and properties of doping lone pair cations to ortho-HoMnO₃. Electronic structure calculations were carried out to study Ho_{0.5}A_{0.5}MnO₃ (A=Ge, Sn, Pb, As, Sb, Bi, Se, Te) under the Generalized Gradient Approximation of Density Functional Theory in an attempt to analyze the effect of lone pair cations towards electric polarization and to predict new multiferroics. Under the first principle calculations, Ho_{0.5}A_{0.5}MnO₃ (A=Ge, Sn, As, Sb, Bi, Se, Te) is found to be multiferroic. Doping 50% of Se and Sn to HoMnO₃ is found to highly enhance the electric polarization compared to parent ortho-HoMnO₃. O2p- A valence p orbital hybridization is expected to be the cause of this polarization. Thus Ho_{0.5}Se_{0.5}MnO₃ and Ho_{0.5}Sn_{0.5}MnO₃ are expected to be good candidate multiferroics. A first principle attempt has thus been made to perform an extensive search for new multiferroics in which p-p hybridization is found to have a strong role in causing electric polarization predicting new multiferroics providing a pathway for experimentalists to synthesis new promising multiferroic compounds.

4:18PM T32.00010 Synthesis of Perovskite ScMnO₃ under High Temperature and Pressure¹ , TIAN YU, PENG GAO, Department of Physics, New Jersey Institute of Technology, TREVOR A. TYSON, Dept of Physics, New Jersey Institute of Technology; Dept of Physics and Astronomy & Rutgers Center for Emergent Materials, Rutgers University, H. CHEN, Department of Physics, New Jersey Institute of Technology, J. BAI, Oak Ridge National Laboratory — Perovskite type ScMnO₃ was synthesized under high temperature and pressure starting with hexagonal ScMnO₃. The detail of the structure is examined by synchrotron x-ray diffraction and IR spectroscopy at room temperature. A highly distorted perovskite phase which is similar to the structure of LaMnO₃ is identified by XRD Rietveld Refinement. Due to the small Sc ion radius, each Mn site has a distorted MnO₆ polyhedron. This work is supported by DOE Grant DE-FG02-07ER46402.

¹DOE Grant DE-FG02-07ER46402

4:30PM T32.00011 Low Temperature Structural of ScMnO₃ , PENG GAO, TIAN YU, TREVOR A. TYSON, Department of Physics, New Jersey Institute of Technology, XINGUO HONG, ZHIQIANG CHEN, Mineral Physics Institute, Stony Brook University, SANJIT GHOSE, National Synchrotron Light Source II, Brookhaven National Laboratory, LARS EHM, Mineral Physics Institute, Stony Brook University, ZHENXIAN LIU, Geophysical Laboratory, Carnegie Institution of Washington — We present the temperature dependent structural changes of hexagonal ScMnO₃ probed on multiple length scales. These measurements are compared by IR results. These results are used to assess the structural changes across the Néel temperature which may coincide and couple with the ferroelectric behavior. This work is supported by DOE Grants DE-FG02-07ER46402 (NJIT), by COMPRES, the Consortium for Materials Properties Research in Earth Sciences under NSF Cooperative Agreement EAR 10-43050 (X17B3) and EAR 01-35554 (U2A), and by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-98CH10886 (for use of the National Synchrotron Light Source at Brook Haven National Laboratory).

4:42PM T32.00012 Time-resolved imaging of magnetoelectric switching in MnWO₄¹ , TIM HOFFMANN, PHILIP THIELEN, HISKP, University Bonn, Germany, PETRA BECKER, LADISLAV BOHATY, Institute of Crystallography, University of Cologne, Germany, MANFRED FIEBIG, Department of Materials, ETH Zurich, Switzerland — The interaction of magnetic and ferroelectric order is intrinsically strong in spin-spiral multiferroics. Here the complex magnetic long range order breaks inversion symmetry and induces a spontaneous electric polarization. The interaction allows to switch the magnetic order by an electric field and is thus of great interest for applications. Although such magnetoelectric switching is a major goal in multiferroics, hardly any work was devoted to the dynamic aspects of the actual switching process. Here we report time-resolved optical second harmonic generation measurements of the electric-field-induced reversal of the spin-spiral domains in multiferroic MnWO₄. Ferroelectric and magnetic orders appear to remain rigidly coupled even during the non-equilibrium state of the transition. The switching is governed by domain wall motion on the millisecond time scale. Even though, locally domains can disappear within nanoseconds. The slow global response can be explained by an energy estimate: As the dipole energy in the electric field is much weaker than the magnetic anisotropy energy, the electric field is only a weak lever for manipulating the magnetic system. Therefore magnetoelectric switching in this compound is inherently slow.

¹The authors thank DFG for financial support via SFB 608.

4:54PM T32.00013 Displacement-type ferroelectric transition with magnetic Mn ions in perovskite $\text{Sr}_{1-x}\text{Ba}_x\text{MnO}_3$, HIDEAKI SAKAI, University of St Andrews, JUN FUJIOKA, University of Tokyo, TATSUO FUKUDA, JAEA/SPring8, DAISUKE OKUYAMA, CMRG/CERG, RIKEN, DAISUKE HASHIZUME, RIKEN, FUMITAKA KAGAWA, University of Tokyo, HIRONORI NAKAO, YOUICHI MURAKAMI, CMRC-PF, KEK, TAKAHISA ARIMA, University of Tokyo, ALFRED Q.R. BARON, RIKEN/SPring8, YASUJIRO TAGUCHI, CMRG/CERG, RIKEN, YOSHINORI TOKURA, University of Tokyo — Almost all the proper ferroelectrics with a perovskite structure discovered so far have no *d*-electrons in the off-center transition metal site, as exemplified by BaTiO_3 and $\text{Pb}(\text{Zr,Ti})\text{O}_3$. This empirical *d*⁰ rule is incompatible with the emergence of magnetism and has significantly restricted the variety of multiferroic materials. In this work, we have discovered a displacement-type ferroelectric transition originating from off-center Mn^{4+} ions in antiferromagnetic Mott insulators $\text{Sr}_{1-x}\text{Ba}_x\text{MnO}_3$. As Ba concentration increases, the perovskite lattice shows the typical soft mode dynamics, and the ferroelectricity shows up for $x \geq 0.45$. In addition to the large polarization and high transition temperature comparable to BaTiO_3 , we demonstrate that the magnetic order suppresses the ferroelectric lattice dilation by $\sim 70\%$ and increases the soft-phonon energy by $\sim 50\%$, indicating gigantic magnetoelectric effects [1]. This work was supported by the FIRST program on “Quantum Science on Strong Correlation”.

5:06PM T32.00014 Antiferromagnetic pinning of a phase-like mode below T_N in NdMnO_3 , NESTOR MASSA, LANAIS EFO-CEQUINOR, UNLP, La Plata, Argentina, LEIRE DEL CAMPO, DOMINGOS DE SOUSA MENESES, PATRICK ECHEGUT, CNRS-CEMHTI, Orléans, France, MARIA JESUS MARTÍNEZ-LOPE, JOSE ANTONIO ALONSO, ICMM-CSIC, Madrid, Spain — We report on reflectivity and emission far infrared spectra of NdMnO_3 between 4K and its dissociation temperature. Phonon bands at 300K are in agreement with orthorhombic Pbnm space group assignments. In addition, a broad strong band, reminiscent to a phase-mode in quasi-one dimension metals, is found at very low frequencies that it is understood originating in charge fluctuations in d-orbitals. There is no distinctive behaviors between 1073 K and 1173 K, where orthorhombic O and O' coexist. Beyond ~ 700 K a mid-infrared polaron band turns into a Drude tail suggesting hopping conductivity double exchange due to air heating oxidation $\text{Mn}^{3+} \rightarrow \text{Mn}^{4+} + 1e^-$. Below 300 K phonons are better defined and the low frequency giant dipole acquires strength. Few degrees above the antiferromagnetic transition it broadens as electrons loosing coherence. At $T_N \sim 76$ K we find strong phonon magnetostriction while the band turns asymmetric locking-in to the underlying magnetic order. Preliminary measurements of hexagonal TmMnO_3 , show that asymmetry split due to lower symmetry and the triangular magnetic lattice two exchange integrals J_1 and J_2 in the a-b plane. Similar to a soft mode those two bands and a lower frequency resonance undergo strong hardening down to 4 K.

5:18PM T32.00015 Low temperature Electrical and Magnetic studies of Nsutite, JOHN DISTIN, PAUL YENO, PETER LEMAIRE, Department of Physics and Earth Sciences, Central Connecticut State University, New Britain CT 06050, MELINDA MCNALLY, KELSEY COOLAHAN, Department of Chemistry and BioChemistry, Rowan University, Glassboro NJ 08028 — Nsutite is a naturally occurring Manganese Oxide of the composition $\text{Mn}_{1-x}^{4+}\text{Mn}_x^{2+}\text{O}_{2-2x}(\text{OH})_{2x}$ where $x = 0.06 - 0.07$. D.C. electrical transport measurements were carried out on samples from Nsuta, Ghana between 40 K and 400 K. Non-linear I-V curves were observed below 140 K even at very low currents. The resistivity vs. temperature data suggests electron transport is by the variable range hopping mechanism between 140 K and 400 K. Magnetic moment vs. temperature data were obtained between 5K and 300K at high field (10,000 Oe) and low field (1,000 Oe). Both high and low field data suggest paramagnetic behavior with a possible Neel temperature at about 15K, below which the materials exhibits antiferromagnetic behavior. The electrical and magnetic properties as well as high temperature thermal analysis (DSC) data will be discussed.

Wednesday, February 29, 2012 2:30PM - 4:18PM – Session T35 DCP: Focus Session: Plyler Award Symposium 107B

2:30PM T35.00001 Earle K. Plyler Prize for Molecular Spectroscopy and Dynamics Lecture: 2D IR Spectroscopy of Peptide Conformation, ANDREI TOKMAKOFF, MIT Department of Chemistry — Descriptions of protein and peptide conformation are colored by the methods we use to study them. Protein x-ray and NMR structures often lead to impressions of rigid or well-defined conformations, even though these are dynamic molecules. The conformational fluctuations and disorder of proteins and peptides is more difficult to quantify. This presentation will describe an approach toward characterizing and quantifying structural heterogeneity and disorder in peptides using 2D IR spectroscopy. Using amide I vibrational spectroscopy, isotope labeling strategies, and computational modeling based on molecular dynamics simulations and Markov state models allows us to characterize distinct peptide conformers and conformational variation. The examples illustrated include the beta-hairpin tripp2 and elastin-like peptides.

3:06PM T35.00002 Vibrational spectroscopy of interacting water molecules, JAMES SKINNER, University of Wisconsin — I will discuss a new simulation model for water that includes three-body interactions explicitly, and describe our theoretical approach for calculating OH-stretch spectroscopic observables. I will present illustrative examples, involving pump-probe energy-transfer-induced anisotropy decay in liquid water, IR and Raman line shapes in ice Ih, phase-sensitive SFG spectra of the liquid/vapor interface, and energetics and IR spectra for the different conformations of the water hexamer.

3:42PM T35.00003 Two-dimensional Fourier transform electronic spectroscopy, DAVID JONAS, University of Colorado — Sensitive interference detection of the electric field of femtosecond four-wave mixing signals (stimulated photon echoes) at their point of origin in the sample can be used to record two-dimensional (2D) Fourier transform electronic spectra. In direct analogy to 2D nuclear magnetic resonance, 2D Fourier transform spectra have nearly homogeneous linewidths in each frequency dimension and sort the signal spectrum according to the initial excitation frequency. The initial excitation frequency information is stored in a robust population grating, so 2D spectra can be used to study both coherent and incoherent processes, and have revealed coherent aspects of energy transfer processes. Femtosecond 2D spectra also have the advantage of “freezing out” vibrational motions as inhomogeneities, raising interesting questions about what kinds of broadening can be rephased in 2D spectra recorded with stimulated photon echo pulse sequences. This talk will focus on coherent aspects of non-adiabatic electronic curve crossing and their manifestation in 2D electronic spectra.

Wednesday, February 29, 2012 2:30PM - 4:42PM – Session T37 FEd: Physics Education Research and Resources 108

2:30PM T37.00001 Strength of Student Models of Force and Motion¹ , CECILIA T. MARKES, University of Nebraska at Kearney — With a three-year FIPSE grant, it has been possible to develop and implement activity-based algebra level introductory physics. The Force and Motion Conceptual Evaluation (FMCE) has been given as a pretest and a posttest to both the traditional lecture/lab classes and the activity-based classes. The responses are analyzed to determine the models that students use. The questions are separated into eight groups. Responses are divided into expert model, student model, and null model. Students are categorized as being in an expert state, a mixed state, or a student state. Previous work assumed a particular model if the answers to 70 percent (or more) of the questions in a group fit that model. To determine the strength of the models, the analysis is repeated assuming 85 percent and then 100 percent. The results are analyzed to determine if there is a significant difference from 70 percent to 85 percent to 100 percent. This will indicate the strength of the models in each group of questions.

¹This work was supported by the US DOE's FIPSE Grant No. P116B51449.

2:42PM T37.00002 Project-Based Learning Courses: The Relationship Between Faculty-Intended Course Implementation and Students' Perceptions¹ , JENNIFER A. SIMONOVICH, EMILY TOWERS, YEVGENIYA V. ZASTAVKER, F. W. Olin College of Engineering — Project-based learning (PjBL) has been shown to improve students' performance and satisfaction with their coursework, particularly in science and engineering courses. Specific aspects of PjBL that contribute to this improvement are student autonomy, course scaffolding, and instructor support. This study investigates two PjBL courses required for engineering majors at a small technical school, *Introductory Mechanics Laboratory* and *Introductory Engineering Design*. The three data sources used in this work are classroom observations (one laboratory and four design sessions) and semi-structured in-depth interviews with twelve students and six faculty. Grounded theory approach is used in a two-step fashion by (1) analyzing each data set individually and (2) performing full triangulation of all three data sets. In this talk, we demonstrate the relationship between faculty intentions and student perceptions regarding the three PjBL aspects – student autonomy, course scaffolding, and instructor support – within the context of these two courses. We further discuss implications for the course design and professional development of faculty.

2:54PM T37.00003 Combining Wikis and JiTT to enhance critical thinking abilities , HASHINI MOHOTTALA, University of Hartford, West Hartford, CT 06117 — I report the combine use of Just in Time Teaching (JiTT) and Wikispaces (Wikis) in introductory level, calculus based, physics classes. Over the years, JiTT had been effectively used in teaching physics and some uses on Wikis were also reported in the recent years.¹ Wiki helps students, instructors and technology to interact with one another and JiTT boosts the self-confidence of students to tackle physics problems. Thus, the combine use of Wiki-JiTT is going to be a new experience for both instructors and students. In this experiment, I used Wikis as a platform for JiTT, and conventional JiTT was slightly altered to best fit the combination and to focus on enhancing critical thinking abilities in my students.

3:06PM T37.00004 Student Self-Efficacy in Introductory Project-Based Learning Courses¹ , GEOFFREY PLEISS, YEVGENIYA V. ZASTAVKER, F. W. Olin College of Engineering — This study investigates first-year engineering students' self-efficacy in two introductory Project-Based Learning (PjBL) courses – *Physics (Mechanics) Laboratory* and *Engineering Design* – taught at a small technical institution. Twelve students participated in semi-structured open-ended interviews about their experiences in both courses. Analysis was performed using grounded theory. Results indicate that students had lower self-efficacy in *Physics Lab* than in *Engineering Design*. In *Physics Lab*, students reported high levels of faculty-supported scaffolding related to final project deliverables, which in turn established perceptions of an outcome-based course emphasis. Conversely, in *Engineering Design*, students observed high levels of scaffolding related to the intermediate project deliverables, highlighting process-centered aspects of the course. Our analyses indicate that this difference in student perceptions of course emphases – resulting from the differences in scaffolding – is a primary factor for the discrepancy in self-efficacy between *Physics Lab* and *Engineering Design*. Future work will examine how other variables (e.g., academic background, perception of community, gender) affect students' self-efficacy and perception of scaffolding in these PjBL courses.

3:18PM T37.00005 ABSTRACT WITHDRAWN —

3:30PM T37.00006 The IPAD as a Pedagogical Tool in an Algebra-Based Introductory Physics Class¹ , ANGELA GARRIOTT, LEAH BUSH, ROBERTO RAMOS, Indiana Wesleyan University — We report our experience in using the IPAD as a pedagogical tool for enhancing physics learning in an introductory algebra-based physics laboratory course for primarily pre-med students. We used several applications including (1) video analysis for experiments in accelerated motion (2) virtual oscilloscope for studying wave motion and circuit response to low frequency driving voltages; (3) applications for visualization of electric fields and magnetic fields. We compare student responses to this platform versus more traditional experiments. Using student surveys and polls. We also evaluate the IPAD as a new and familiar interface versus traditional interfaces like the standard oscilloscope. We report on the advantages and disadvantages of using this mobile, popular platform in delivering experimental physics content and promoting student engagement.

¹We acknowledge Indiana Wesleyan University for awarding an IPAD mini-grant to Prof. R. Ramos.

3:42PM T37.00007 Physics: A student's guide through the great texts¹ , KERRY KUEHN, Wisconsin Lutheran College — Although memorizing formulae and learning how to perform calculations is crucial for acquiring a working knowledge of physical theories, the standard pedagogical method employed by many textbooks does not prepare the student to become a practicing scientist precisely because it tends to mask the actual scientific method: the science is presented as an accomplished fact; the prescribed questions revolve largely around technological applications of accepted laws. In this talk, I will describe a two-year general physics curriculum which I have developed and taught for the past decade to undergraduate students at Wisconsin Lutheran College. The curriculum is unique in that it provides students of the natural and mathematical sciences with a comprehensive introduction to physics based on the careful reading and analysis of selections from foundational texts in physics and astronomy. The curriculum is designed to encourage a critical and circumspect approach to the study of natural science, while at the same time developing a suitable foundation for advanced coursework in physics. Through the careful reading and analysis of foundational scientific texts, students learn skills which are essential when considering the practical and philosophical implications of scientific theories.

¹I would like to acknowledge Springer Science+Business Media, LLC for collaborating with me on this project.

3:54PM T37.00008 A student's guide to searching the literature using online databases¹, CASEY W. MILLER, DUSTIN BELYEA, MICHELLE CHABOT, University of South Florida, TROY MESSINA, Centenary College of Louisiana — A method is described to empower students to efficiently perform general and specific literature searches using online resources [Miller et al., Am. J. Phys. 77, 1112 (2009)]. The method was tested on multiple groups, including undergraduate and graduate students with varying backgrounds in scientific literature searches. Students involved in this study showed marked improvement in their awareness of how and where to find scientific information. Repeated exposure to literature searching methods appears worthwhile, starting early in the undergraduate career, and even in graduate school orientation.

4:06PM T37.00009 A jumping cylinder in an incline, RAUL W. GOMEZ, JORGE HERNANDEZ, VIVIANNE MARQUINA, Facultad de Ciencias, UNAM — The problem of a cylinder of mass m and radius r , with its center of mass out of the cylinder axis, rolling in an incline that makes an angle α respect to the horizontal is analyzed. The equation of motion is solved to obtain the site where the cylinder loses contact with the incline (jumps). Several simplifications are made: the analyzed system consists of an homogeneous disc with a one dimensional straight line of mass parallel to the disc axis at a distance $d < r$ of the center of the cylinder. To compare our results with experimental data, we use a Styrofoam cylinder of radius $r = 10.0 \pm 0.05$ cm, high $h = 5.55 \pm 0.05$ cm and a mass $m_1 = 24.45 \pm 0.05$ g, to which a 9.50 ± 0.01 mm diameter and 5.10 ± 0.001 cm long brass rod of mass $m_2 = 30.75 \pm 0.05$ g was imbedded parallel to the disc axis at a distance of 5.40 ± 0.05 cm from it. Then the disc rolls on a 3.20 m long wooden ramp inclined at 30° and 45° respect to the horizontal. To determine the jumping site, the movements were recorded with a high-speed video camera (Casio EX ZR100) at 400 frames per second. The experimental results agree well with the theoretical predictions.

4:18PM T37.00010 Design and operation of an inexpensive far-field laser scanning microscope suitable for use in an undergraduate laboratory course, ARTHUR PALLONE, Northern Kentucky University, ERIC HAWK, None — Scanning microscope applications span the science disciplines yet their costs limit their use at educational institutions. The basic concepts of scanning microscopy are simple. The microscope probe - whether it produces a photon, electron or ion beam - moves relative to the surface of the sample object. The beam interacts with the sample to produce a detected signal that depends on the desired property to be measured at the probe location on the sample. The microscope transforms the signal for output in a form desired by the user. Undergraduate students can easily construct a far-field laser scanning microscope that illustrates each of these principles from parts available at local electronics and hardware stores and use the microscope to explore properties of devices such as light dependent resistors and biological samples such as leaves. Students can record, analyze and interpret results using a computer and free software.

4:30PM T37.00011 Variational Calculations for Hydrogen in Introductory Solid State, JAVIER HASBUN, University of West Georgia — Molecular hydrogen is very important in the introductory solid state physics course because it is used as one of the simplest molecular realistic models where bonding and anti-bonding takes place. This system is one of the first examples in which interactions among the ions and the electrons is incorporated realistically. To this end, we approach the system starting from the hydrogen atom. Here we introduce a numerical approach that reproduces the known analytic result for the ground state. The idea is to expand the hydrogenic wavefunction in terms of Gaussians (four of them) with variational parameters. As the parameters are varied the numerical approach stops when the energy is a minimum. The scheme is consistently extended through the ionized hydrogen molecule and the reproduction of its analytically known ground state energy result. We finally culminate with the hydrogen molecule using a variational wavefunction, a la Hartree, and proceed to repeat the process with a particular flavor of a Hartree-Fock wavefunction [1] and finally obtaining a hydrogen molecule total ground state energy of -31.10 eV with a bond length of 1.37 Bohr radius.

2:30PM T40.00001 Dynamics of focal adhesions modulates active cellular response¹, MOUMITA DAS, SHILADITYA BANERJEE, M. CRISTINA MARCHETTI, Department of Physics, Syracuse University — The cytoskeleton of living cells connects to and senses the extracellular mechanical environment through protein clusters called focal adhesions. We study how the mechanics and dynamics of focal adhesions influence the distribution of mechanical stresses and deformations in a cell which is modeled as an active elastic gel. We carry out our investigations for two types of bond dynamics of focal contacts (a) slip bond dynamics where the bonds are weakened by a tensile mechanical force and (b) catch bond dynamics where they are initially strengthened upon application of a tensile mechanical force, and undergo failure at very large forces. We comment on the effect of different types of focal adhesions on the transmission and regulation of cell traction forces and on cellular mechanosensing.

2:42PM T40.00002 3D Neutrophil Tractions in Changing Microenvironments, JENNET TOYJANOVA, Graduate Student, School of Engineering, Brown University, Providence, RI, ESTEFANY FLORES, Research Assistant, Department of Surgery, Rhode Island Hospital, Providence, RI, JONATHAN REICHNER, Department of Surgery, Rhode Island Hospital and the Warren Alpert Medical School of Brown University, Providence, CHRISTIAN FRANCK, School of Engineering, Brown University, Providence, RI — Neutrophils are well-known as first responders to defend the body against life threatening bacterial diseases, infections and inflammation. The mechanical properties and the local topography of the surrounding microenvironment play a significant role in the regulating neutrophil behavior including cell adhesion, migration and generation of tractions. In navigating to the site of infection, neutrophils are exposed to changing microenvironments that differ in their composition, structure and mechanical properties. Our goal is to investigate neutrophil behavior, specifically migration and cellular tractions in a well-controlled 3D in vitro system. By utilizing an interchangeable 2D-3D sandwich gel structure system with tunable mechanical properties neutrophil migration and cell tractions can be computed as a function of gel stiffness and geometric dimensionality.

2:54PM T40.00003 Force transmission through intercellular fluid transfer, STEVEN ZEHNDER, JOLIE BREAU, ALISON DUNN, GREGORY SAWYER, THOMAS ANGELINI, University of Florida — Cell force generation and transmission play a vital role in controlling cell-to-cell interactions and cell locomotion. Contraction of the cell's cytoskeletal network generates forces that can be transmitted directly to other cells by cell-cell adherens junctions or through a substrate by traction forces. Within monolayers, cytosolic fluid is transferred between cells through gap junctions. The coupling between intercellular fluid movement and contraction can give rise to a different type of cell-cell force transmission. Here we present preliminary results investigating the role of intercellular force transmission through fluid motion across gap junctions.

3:06PM T40.00004 Forcing it on: Cytoskeletal dynamics during lymphocyte activation, ARPITA UPADHYAYA, Department of Physics, University of Maryland, College Park — Formation of the immune synapse during lymphocyte activation involves cell spreading driven by large scale physical rearrangements of the actin cytoskeleton and the cell membrane. Several recent observations suggest that mechanical forces are important for efficient T cell activation. How forces arise from the dynamics of the cytoskeleton and the membrane during contact formation, and their effect on signaling activation is not well understood. We have imaged membrane topography, actin dynamics and the spatiotemporal localization of signaling clusters during the very early stages of spreading. Formation of signaling clusters was closely correlated with the movement and topography of the membrane in contact with the activating surface. Further, we observed membrane waves driven by actin polymerization originating at these signaling clusters. Actin-driven membrane protrusions likely play an important role in force generation at the immune synapse. In order to study cytoskeletal forces during T-cell activation, we studied cell spreading on elastic gels. We found that gel stiffness influences cell morphology, actin dynamics and receptor activation. Efforts to determine the quantitative relationships between cellular forces and signaling are underway. Our results suggest a role for cytoskeleton driven forces during signaling activation in lymphocytes.

3:42PM T40.00005 Aging phenomena in a network model of the cytoskeleton¹, NASRIN AFZAL, MICHEL PLEIMLING, Virginia Tech — Motivated by a series of experiments that study the response of the cytoskeleton in living cells to time dependent mechanical forces, we investigate, through Monte Carlo simulations, a three-dimensional network subjected to perturbations. After having prepared the system in a relaxed state, shear is applied and the relaxation processes are monitored. We measure two-time functions of various quantities such as the Euclidean distance between crosslinks and the energy of the system. We discuss possible implications of our results for relaxation processes taking place in the cytoskeleton.

¹Supported in part by the US National Science Foundation through Grant DMR-0904999.

3:54PM T40.00006 Mechanical interactions may explain synchronized growth of cytoskeletal actin networks in motile cells, ANTONIO DESIMONE, LUCA CARDAMONE, ALESSANDRO LAIO, SISSA-International School for Advanced Studies, SISSA TEAM — Growing networks of actin fibers are able to organize into compact, stiff two-dimensional structures inside lamellipodia of crawling cells. We examine critically the hypothesis that the growing actin network is a critically self-organized system, in which long-range mechanical stresses arising from the interaction with the plasma membrane provide the selective pressure leading to organization. We show that a simple model based only on this principle leads to stochastic protrusion of lamellipodia (growth periods alternating with fast retractions) and several of the features observed in experiments: a growth velocity initially insensitive to the external force; the capability of the network to organize its orientation; a load-history-dependent growth velocity. Our model predicts that the spectrum of the time series of the height of a growing lamellipodium decays with the inverse of the frequency. This behavior is confirmed by optical tweezer measurements performed in vivo on neuronal growth cones. References L. Cardamone et al.: Cytoskeletal actin networks in motile cells are critically self-organized systems synchronized by mechanical interactions. PNAS, vol. 108, no. 34, pp. 13978-13983

4:06PM T40.00007 Investigations of biomechanical activity of macrophages during phagocytosis, DANIEL KOVARI, JENNIFER CURTIS, Georgia Institute of Technology — Phagocytosis has traditionally been investigated in terms of the relevant biochemical signaling pathways that trigger the process and lead to the deformation of the cell as it engulfs a target. Physical changes in the cell include rearrangement and polymerization of actin in the phagocytic cup, large membrane deformations, increased membrane area via exocytosis, and closure of the phagocytic cup through membrane fusion. Hence, phagocytosis is a fine-tuned balance between biophysical cellular events and chemical signaling, which are responsible for driving these materials and mechanical changes. We present a series of assays designed to probe the physical/mechanical parameters that govern a cell during phagocytosis. Custom built micropipette manipulators are used to manipulate individual cells, facilitating high-resolution microscopy of individual phagocytic events. This work has been supported by NSF PoLS #0848797.

4:18PM T40.00008 Collective cell migration during inflammatory response¹, DI WU, KIMBERLY STROKA, HELIM ARANDA-ESPINOZA, Fischell Department of Bioengineering, University of Maryland — Wound scratch healing assays of endothelial cell monolayers is a simple model to study collective cell migration as a function of biological signals. A signal of particular interest is the immune response, which after initial wounding in vivo causes the release of various inflammatory factors such as tumor necrosis alpha (TNF- α). TNF- α is an innate inflammatory cytokine that can induce cell growth, cell necrosis, and change cell morphology. We studied the effects of TNF- α on collective cell migration using the wound healing assays and measured several migration metrics, such as rate of scratch closure, velocities of leading edge and bulk cells, closure index, and velocity correlation functions between migrating cells. We observed that TNF- α alters all migratory metrics as a function of the size of the scratch and TNF- α content. The changes observed in migration correlate with actin reorganization upon TNF- α exposure.

4:30PM T40.00009 Temperature dependence of optically induced cell deformations¹, ANATOL FRITSCH, TOBIAS R. KIESSLING, ROLAND STANGE, JOSEF A. KAES, University of Leipzig, Division of Soft Matter Physics — The mechanical properties of any material change with temperature, hence this must be true for cellular material. In biology many functions are known to undergo modulations with temperature, like myosin motor activity, mechanical properties of actin filament solutions, CO₂ uptake of cultured cells or sex determination of several species. As mechanical properties of living cells are considered to play an important role in many cell functions it is surprising that only little is known on how the rheology of single cells is affected by temperature. We report the systematic temperature dependence of single cell deformations in Optical Stretcher (OS) measurements. The temperature is changed on a scale of about 20 minutes up to hours and compared to defined temperature shocks in the range of milliseconds. Thereby, a strong temperature dependence of the mechanics of single suspended cells is revealed. We conclude that the observable differences arise rather from viscosity changes of the cytosol than from structural changes of the cytoskeleton. These findings have implications for the interpretation of many rheological measurements, especially for laser based approaches in biological studies.

4:42PM T40.00010 ABSTRACT WITHDRAWN —

4:54PM T40.00011 Biomechanical changes in endothelial cells result from an inflammatory response¹, JANINA VAITKUS, KIMBERLY STROKA, HELIM ARANDA-ESPINOZA, Fischell Department of Bioengineering, University of Maryland — During periods of infection and disease, the immune system induces the release of TNF- α , an inflammatory cytokine, from a variety of cell types, such as macrophages. TNF- α , while circulating in the vasculature, binds to the apical surface of endothelial cells and causes a wide range of biological and mechanical changes to the endothelium. While the biological changes have been widely studied, the biomechanical aspects have been largely unexplored. Here, we investigated the biomechanical changes of the endothelium as a function of TNF- α treatment. First, we studied the traction forces applied by the endothelium, an effect that is much less studied than others. Through the use of traction force microscopy, we found that TNF- α causes an increase in traction forces applied by the endothelial cells as compared to non-treated cells. Then, we investigated cell morphology, cell mechanics, migration, and cytoskeletal dynamics. We found that in addition to increasing applied traction forces, TNF- α causes an increase in cell area and aspect ratio on average, as well as a shift in the organization of F-actin filaments within the cell. Combining these findings together, our results show that an inflammatory response heavily impacts the morphology, cell mechanics, migration, cytoskeletal dynamics, and applied traction forces of endothelial cells.

5:06PM T40.00012 Healing of small circular model wounds, OLIVIER COCHET, PHILIPPE MARCQ, JONAS RANFT, Laboratoire Physico-Chimie Curie, UMR168, Institut Curie/CNRS, MYRIAM REFFAY, Laboratoire Matière et Systèmes Complexes, Université Paris Diderot/CNRS, AXEL BUGUIN, PASCAL SILBERZAN, Laboratoire Physico-Chimie Curie, UMR168, Institut Curie/CNRS, BIOLOGY INSPIRED PHYSICS AT MESOSCALE TEAM¹, PHYSICAL APPROACH OF BIOLOGICAL PROBLEMS TEAM² — We develop a new method to produce numerous circular wounds in an epithelial tissue of MDCK cells in a non-traumatic fashion. The reproducibility of the wounds allows for a quantitative study of the dynamics of healing and for a better understanding of the key processes involved in those collective morphogenetic movements. First, we show different mechanisms of closing depending on the initial size of the wound. We then focus on the healing of the smallest wounds from an experimental and theoretical point of view. At the onset of closure, an actomyosin ring is formed around the wound and small protrusions appear and invade the free surface. Using inhibition and laser ablation experiments, we show the relative contribution of both processes to the dynamics of closing. Finally, we develop a theoretical model of the tissue as a whole, combined with the observed forces, in order to better understand the underlying mechanics of this process. We hope that this qualitative and quantitative description will prove useful in the future for the study of epithelial architecture, collective mechanisms in migrating tissues and, on a broader context, cellular invasion in cancerous tissues.

5:18PM T40.00013 Mechanical coupling of smooth muscle cells using local and global stimulations¹, CRAIG COPELAND, Johns Hopkins University, CHRISTOPHER CHEN, University of Pennsylvania, DANIEL REICH, Johns Hopkins University — Mechanical stresses can directly alter many cellular processes, including signal transduction, growth, differentiation, and survival. These stresses, generated primarily by myosin activity within the cytoskeleton, regulate both cell-substrate and cell-cell interactions. We report studies of mechanical cell-cell and cell-substrate interactions using patterned arrays of flexible poly(dimethylsiloxane) (PDMS) microposts combined with application of global stretch or local chemical stimulation. Bovine pulmonary artery smooth muscle cells are patterned onto micropost arrays to create multicellular structures to probe intercellular coupling. Global stimulation is applied by building the micropost arrays on a flexible membrane that can be stretched while allowing simultaneous observation of cell traction forces. Results for triangle wave stretches of single cells show increasing traction forces with increasing strain, and immediate weakening of traction forces as strain is decreased. "Spritzing," a laminar flow technique, is used to expose a single cell within a construct to a drug treatment while cell traction forces are recorded via the microposts. Results will be described showing the response of cells to external stimulation both directly and through intercellular coupling.

Wednesday, February 29, 2012 2:30PM - 5:42PM – Session T41 DFD: Swimming, Motility and Locomotion 156B

2:30PM T41.00001 Undulatory swimming on a free surface¹, RAMIRO GODOY-DIANA, SOPHIE RAMANANARIVO, OLIVIA GANN, BENJAMIN THIRIA, PMMH UMR7636 CNRS; ESPCI ParisTech; UPMC; U. Diderot Paris 7 — A wide variety of swimmers in nature use body undulations to generate a propulsive force, in part owing to the relative insensitivity of the principle of undulatory swimming to the value of the Reynolds number $Re = UL/\nu$, which measures the relative importance of viscous and inertial forces in the flow considered (U and L being the typical speed and length of the animal, and ν the kinematic viscosity of the surrounding fluid). Here we study a flexible filament forced to oscillate by imposing a harmonic motion to one of its extremities (using magnetic interactions) and propelling itself at the surface of a water tank. This experiment serves as a canonical model for studying the interactions between an elastic structure undergoing complex deformations and the surrounding fluid.

2:42PM T41.00002 Geometry, Curvature, and Locomotion, ROSS HATTON, HOWIE CHOSET, Carnegie Mellon University — Many animals and robots locomote by undulating their bodies in traveling waves. Together with the generally inextensible nature of such systems, the large deformations involved in these motions introduce significant nonlinearities into their analysis. As a result, the equations of motion for these systems are often treated as black boxes – the displacement resulting from a given input (e.g., wave amplitude) can be calculated, but the relationship between the inputs and the net displacement over a period of the wave is hidden inside the nonlinearities. Drawing on results from the geometric mechanics community, we have developed an analysis framework for high-deformation locomotion that looks inside this black box, based on three core principles: (1) Working in terms of body curvature provides a linear basis for describing nonlinear high-deformation shapes. (2) Lie bracket analysis (the exploitation of system nonlinearities through oscillatory inputs) captures the nonlinearity of the system interaction with the world. (3) Systematically optimizing the coordinate choice transforms the system nonlinearity into a form that can be geometrically analyzed over the space of body curvatures to characterize the system's ultimate locomotory capabilities.

2:54PM T41.00003 Optimizing turning for locomotion, LISA BURTON, Massachusetts Institute of Technology, ROSS HATTON, HOWIE CHOSET, Carnegie Mellon University, A.E. HOSOI, Massachusetts Institute of Technology — Speed and efficiency are common and often adequate metrics to compare locomoting systems. These metrics, however, fail to account for a system's ability to turn, a key component in a system's ability to move a confined environment and an important factor in optimal motion planning. To explore turning strokes for a locomoting system, we develop a kinematic model to relate a system's shape configuration to its external velocity. We exploit this model to visualize the dynamics of the system and determine optimal strokes for multiple systems, including low Reynolds number swimmers and biological systems dominated by inertia. Understanding how shape configurations are related to external velocities enables a better understanding of biological and man made systems. Using these tools, we can justify biological system motion and determine optimal shape configurations for robots to maneuver through difficult environments.

3:06PM T41.00004 Effect of confinements: Bending in Paramecium, AJA EDDINS, Engineering Science and Mechanics - Virginia Tech, SUNG YANG, Department of Nano-bio Materials and Electronics, GIST, Republic of Korea, CORRIE SPOON, SUNGHWAN JUNG, Engineering Science and Mechanics - Virginia Tech — Paramecium is a unicellular eukaryote which by coordinated beating of cilia, generates metachronal waves which causes it to execute a helical trajectory. We investigate the swimming parameters of the organism in rectangular PDMS channels and try to quantify its behavior. Surprisingly a swimming Paramecium in certain width of channels executes a bend of its flexible body (and changes its direction of swimming) by generating forces using the cilia. Considering a simple model of beam constrained between two walls, we predict the bent shapes of the organism and the forces it exerts on the walls. Finally we try to explain how bending (by sensing) can occur in channels by conducting experiments in thin film of fluid and drawing analogy to swimming behavior observed in different cases.

3:18PM T41.00005 ABSTRACT WITHDRAWN —

3:30PM T41.00006 Enhanced swimming motion of nematode in a non-Newtonian fluid, JIN-SUNG PARK, Department of Physics and School of Engineering and Applied Sciences, Harvard University, DAEYEON KIM, JENNIFER SHIN, School of Mechanical, Aerospace and Systems Engineering, Division of Mechanical Engineering, Korea Advanced Institute of Science and Technology, DAVID WEITZ, Department of Physics and School of Engineering and Applied Sciences, Harvard University — Small organisms navigate their complex terrestrial substrates, which have the property of non-Newtonian complex fluids. Although a large body of literature exists on the locomotion of these organisms, the previous studies are mostly limited in simple Newtonian systems. Here we present experimental results on the locomotion of *Caenorhabditis elegans* (*C. elegans*), especially investigated in colloidal suspensions that exhibit the behavior of shear thinning fluid in the range of shear rate of undulating nematode. Interestingly, we observed that the swimming speed of nematodes was gradually increased with an increase of particle volume fraction in suspensions, and this enhanced motion of nematode is closely related to the shear thinning in the fluid viscosity.

3:42PM T41.00007 Hydrodynamic Optimality in the Bacterial Flagellum, SAVERIO SPAGNOLIE, Brown University, ERIC LAUGA, University of California, San Diego — Most bacteria swim through fluids by rotating helical flagella which can take one of 12 distinct polymorphic shapes, the most common of which is the normal form used during forward swimming runs. To shed light on the prevalence of the normal form in locomotion, we have gathered all available experimental measurements of the various polymorphic forms and computed their intrinsic hydrodynamic efficiencies. The normal helical form is found to be the most efficient of the 12 polymorphic forms by a significant margin—a conclusion valid for both the peritrichous and polar flagellar families, and robust to a change in the effective flagellum diameter or length. Hence, although energetic costs of locomotion are small for bacteria, fluid mechanical forces may have played a significant role in the evolution of the flagellum.

3:54PM T41.00008 Characterisation of metachronal waves on the surface of the spherical colonial alga *Volvox carteri*, DOUGLAS BRUMLEY, MARCO POLIN, CONSTANT MOREZ, RAYMOND GOLDSTEIN, TIMOTHY PEDLEY, University of Cambridge — *Volvox carteri* is a spherical colonial alga, consisting of thousands of biflagellate cells. The somatic cells embedded on the surface of the colony beat their flagella in a coordinated fashion, producing a net fluid motion. Using high-speed imaging and particle image velocimetry (PIV) we have been able to accurately analyse the time-dependent flow fields around such colonies. The somatic cells on the colony surface may beat their flagella in a perfectly synchronised fashion, or may exhibit metachronal waves travelling on the surface. We analyse the dependence of this synchronisation on fundamental parameters in the system such as colony radius, characterise the speed and wavelength of the observed metachronal waves, and investigate possible models to account for the exhibited behaviour.

4:06PM T41.00009 Collective dynamics of active suspensions in confined geometries, DENIS BARTOLO, ESPCI-Paris Diderot University, ERIC LAUGA, UCSD, JEAN-BAPTISTE CAUSSIN, ENS Lyon — We discuss the collective dynamics of suspensions of self-propelled particles confined in confined geometries. First, we revisit the conventional description of the hydrodynamic couplings between swimmers living in thin films or in shallow channels. We show that these hydrodynamic interactions are chiefly set by the particle size and shape irrespective of the microscopic propulsion mechanism. Second, we use kinetic theory to study the phase behavior of dilute suspensions. Finally, we exploit these results to show that the hydrodynamic interactions destabilize isotropic suspensions of polar particles, thereby yielding spontaneous collective motion at large scales. In contrast, suspensions of apolar particles only display weakly cooperative motion at small scales. We also investigate the case of aligned suspensions. Their behavior is very similar to the bulk phase of dipolar swimmer. They display generic instabilities at all scales. Comparisons of our theoretical findings with experiments on artificial swimmers will be shown.

4:18PM T41.00010 Giant number fluctuations in self-propelled particles without alignment¹, YAOUEN FILY, SILKE HENKES, Syracuse University, M. CRISTINA MARCHETTI, Syracuse University and Syracuse Biomaterials Institute — Giant number fluctuations are a ubiquitous property of active systems. They were predicted using a generic continuum description of active nematics, and have been observed in simulations of Vicsek-type models and in experiments on vibrated granular layers and swimming bacteria. In all of these systems, there is an alignment interaction among the self-propelled units, either imposed as a rule, or arising from hydrodynamic or other medium-mediated couplings. Here we report numerical evidence of giant number fluctuations in a minimal model of self-propelled disks in two dimensions in the absence of any alignment mechanism. The direction of self-propulsion evolves via rotational diffusion and the particles interact solely via a finite range repulsive soft potential. It can be shown that in this system self propulsion is equivalent to a non Markovian noise whose correlation time is controlled by the amplitude of the orientational noise.

¹Supported by the NSF through grants DMR-0806511 and DMR-1004789. The computations were carried out on SUGAR, a cluster supported by NSF-PHY-1040231.

4:30PM T41.00011 Chemotactic Self-Organization of Bacteria in Three-Dimensions, YEVGENIY KALININ, DAVID GRACIAS, Chemical and Biomolecular Engineering, Johns Hopkins University — Self-assembly with cellular building blocks represents an important yet relatively unexplored area of research. In this talk, we describe the self-assembly of motile cells using three-dimensional (3D) patterns of chemical (such as chemoattractants) that guide cellular and organization. These 3D chemical patterns are created when chemicals are released via diffusion from lithographically patterned self-assembled polyhedral containers. We show that a number of conceptually different strategies can be utilized for chemical patterns creation. In one such strategy, the overall shape of the container can be chosen to closely match the desired 3D spatial profile. As a part of a different strategy, we discuss how the chemical patterns can be engineered by specific placement of pores on the polyhedral containers. Combining these two strategies allows chemicals to be released in a variety of spatial patterns. To demonstrate applicability of our concept to in vitro organization of living cells in specific 3D geometries, we describe chemotactic self-organization of *E. coli* bacteria in a variety of well-defined shapes and space curves. We link the parameters that characterize the patterns of cells and the patterns of chemicals and describe how one can engineer the spatial shape of the multicellular constructs.

4:42PM T41.00012 Collective Dynamics of a Laboratory Insect Swarm, NICHOLAS OUELLETTE, DOUGLAS KELLEY, NIDHI KHURANA, Dept. of Mech. Eng., Yale University — Self-organized collective animal behavior is ubiquitous throughout the entire biological size spectrum. But despite broad interest in the dynamics of animal aggregations, little empirical data exists, and modelers have been forced to make many assumptions. In an attempt to bridge this gap, we report results from a laboratory study of swarms of the non-biting midge *Chironomus riparius*. Using multicamera stereoimaging and particle tracking, we measure the three-dimensional trajectories and kinematics of each individual insect, and study their statistics and interactions.

4:54PM T41.00013 Dimensional transitions for coupled rotational/translational diffusion in powered nanorotors¹, AMIR NOURHANI, Chem. Eng. Dpt., Penn State Univ, PAUL LAMMERT, Phys. Dpt., Penn State Univ, ALI BORHAN, Chem. Eng. Dpt., Penn State Univ, VINCENT CRESPI, Phys. Dpt., Penn State Univ — Small colloidal particles in fluids are well-known to engage in rotational and translational Brownian motion. Over the past several years, experimentalists have developed a new class of colloidal particles which exhibit autonomous powered motion due to consumption of chemical fuels. Two such classes of nanomotor that have been developed are linear and rotary motors. Nanorotors engage in cyclical motions due to asymmetries in the distribution of force on the surface of the particles. We have analyzed the diffusion of powered rotary motors, considering how the addition of a powered component to their motion affects their diffusional properties.

5:06PM T41.00014 Swimming of bio-inspired micro robots in circular channels, SERHAT YESILYURT, FATMA ZEYNEP TEMEL, Sabanci University — In recent years, bio-inspired micro swimming robots have been attracting attention for use in biomedical tasks such as opening clogged arteries, carrying out minimally invasive surgical operations, and carrying out diagnostic tasks. There have been a number of experimental and modeling studies that address swimming characteristics of micro swimmers with helical tails attached to magnetic heads that rotate and move forward in rotating external magnetic fields. We carried out experimental studies with millimeter long helical swimmers in glass tubes placed in between Helmholtz coils, and demonstrated that swimming speed increases linearly with the frequency of the external field up to the step-out frequency. In order to study interaction of the swimmer with the circular boundary we used a computational fluid dynamics model. In simulations we compared swimming speeds of robots with respect to the frequency of the external magnetic field, wavelength and amplitude of the helical tail, and distance to the channel wall. According to simulation results, as the swimmer gets closer to the boundary swimming speed and efficiency improve. However step-out frequency decreases near the wall due to increased torque to rotate the swimmer.

5:18PM T41.00015 ABSTRACT WITHDRAWN —

5:30PM T41.00016 Bristle-Bots: a model system for locomotion and swarming, LUCA GIOMI, NICO HAWLEY-WELD, L. MAHADEVAN, Harvard University — The term *swarming* describes the ability of a group of similarly sized organisms to move coherently in space and time. This behavior is ubiquitous among living systems: it occurs in sub-cellular systems, bacteria, insects, fish, birds, pedestrians and in general in nearly any group of individuals endowed with the ability to move and sense. Here we address the problem of the origin of collective behavior in systems of self-propelled agents whose only social capability is given by aligning contact interactions. Our model system consists of a collection of Bristle-Bots, simple automata made from a toothbrush and the vibrating device of a cellular phone. When Bristle-Bots are confined in a limited space, increasing their number drives a transition from a disordered and uncoordinated motion to an organized collective behavior. This can occur through the formation of a swirling cluster of robots or a collective dynamical arrest, according to the type of locomotion implemented in the single devices. It is possible to move between these two major regimes by adjusting a single construction parameter.

Wednesday, February 29, 2012 2:30PM - 5:06PM —
Session T42 DBIO GSNP: Focus Session: Evolutionary Systems Biology III - Evolutionary Games 156C

2:30PM T42.00001 Bacterial tower of Babel –How cheating and lying diversify bacterial communication, AVIGDOR ELDAR, Tel-Aviv University, Department of molecular microbiology and biotechnology — In microbial “quorum sensing” (QS) communication systems, microbes produce and respond to a signaling molecule, enabling a cooperative response at high cell densities. Many species of bacteria show fast, intraspecific, evolutionary divergence of their QS pathway specificity—signaling molecules activate cognate receptors in the same strain but fail to activate, and sometimes inhibit, those of other strains. Despite many molecular studies, it has remained unclear how a signaling molecule and receptor can coevolve, what maintains diversity, and what drives the evolution of cross-inhibition. Here I use mathematical analysis to show that when QS controls the production of extracellular enzymes —“public goods”—diversification can readily evolve. Coevolution is positively selected by cycles of alternating “cheating” receptor mutations and “cheating immunity” signaling mutations. The maintenance of diversity and the evolution of cross-inhibition between strains are facilitated by facultative cheating between the competing strains. My results suggest a role for complex social strategies in the long-term evolution of QS systems. More generally, my model of QS divergence suggests a form of kin recognition where different kin types coexist in unstructured populations.

3:06PM T42.00002 Coupling between evolutionary and population dynamics in experimental microbial populations, ALVARO SANCHEZ, JEFF GORE, Department of Physics, Massachusetts Institute of Technology — It has been often been assumed that population dynamics and evolutionary dynamics occur at such different timescales that they are effectively de-coupled. This view has been challenged recently, due to observations of evolutionary changes occurring in short timescales. This has led to a growing interest in understanding eco-evolutionary dynamics of populations. In this context, recent theoretical models have predicted that coupling between population dynamics and evolutionary dynamics can have important effects for the evolution and stability of cooperation, and lead to extremely rich and varied dynamics. Here, we report our investigation of the eco-evolutionary dynamics of a cooperative social behavior, sucrose metabolism, in experimental yeast populations. We have devised an experimental strategy to visualize trajectories in the phase space formed by the population size (N) and the fraction of cooperator cells in the population (f). Our measurements confirm a strong coupling between evolutionary and population dynamics, and allowed us to characterize the bifurcation plots. We used this approach to investigate how sudden environmental changes affect the stability and recovery of populations, and therefore the stability of cooperation.

3:18PM T42.00003 Competition between species can drive public goods cooperation within a species, HASAN CELIKER, EECS department, MIT, JEFF GORE, Physics department, MIT — Costly cooperative strategies are vulnerable to exploitation by cheats. Microbial studies have suggested that cooperation can be maintained in nature by mechanisms such as reciprocity, spatial structure and multi-level selection. So far, however, almost all laboratory experiments aimed at understanding cooperation have relied on studying a single species in isolation. In contrast, species in the wild live within complex communities where they interact with other species. Little effort has focused on understanding the effect of interspecies competition on the evolution of cooperation within a species. We test this relationship by using sucrose metabolism of budding yeast as a model cooperative system. We find that when co-cultured with a bacterial competitor, yeast populations become more cooperative compared to isolated populations. We show that this increase in cooperation within yeast is mainly driven by resource competition imposed by the bacterial competitor. A similar increase in cooperation is observed in a pure yeast culture when essential nutrients in the media are limited experimentally.

3:30PM T42.00004 The emergence of cooperation from a single cooperative mutant, JONAS CREMER, University of California, San Diego, ANNA MELBINGER, ERWIN FREY, Ludwig-Maximilians University Munich, Germany — Population structure is one central condition which promotes the stability of cooperation: If cooperators more likely interact with other cooperators (positive assortment), they keep most of their benefit for themselves and are less exploited by non-cooperators. However, positive assortment can only act successfully if cooperation is already well established in the population such that cooperative individuals can successfully assort. But how can cooperation emerge when starting with a single cooperative mutant? Here we study this issue for a generic situation of microbial systems where microbes regularly form new colonies and show strong population growth. We show how and when the dynamical interplay between colony formation, population growth and evolution within colonies can provoke the emergence of cooperation. In particular, the probability for a single cooperative mutant to succeed is robustly large when colony-formation is fast or comparable to the time-scale of growth within colonies; growth supports cooperation.

3:42PM T42.00005 Coping with stress in a synthetic world, LINGCHONG YOU, Duke University — A major focus of synthetic biology is the engineering of gene circuits to perform user-defined functions. In addition to generating systems of practical applications, such efforts have led to the identification and evaluation of design strategies that enable robust control of dynamics in single cells and in cell populations. On the other hand, there is an increasing emphasis on using engineered systems programmed by simple circuits to explore fundamental biological questions of broad significance. In this talk, I will discuss our efforts along this line of research, whereby we have used engineered gene circuits to examine the evolutionary dynamics of two common bacterial survival strategies in stress response: programmed death and cell-cell communication.

4:18PM T42.00006 Bacterial cheating limits antibiotic resistance, HUI XIAO CHAO, EUGENE YURTSEV, Gore Lab, Department of Physics, Massachusetts Institute of Technology, MANOSHI DATTA, Computational Systems Biology, Massachusetts Institute of Technology, TANYA ARTEMOVA, JEFF GORE, Gore Lab, Department of Physics, Massachusetts Institute of Technology — The widespread use of antibiotics has led to the evolution of resistance in bacteria. Bacteria can gain resistance to the antibiotic ampicillin by acquiring a plasmid carrying the gene beta-lactamase, which inactivates the antibiotic. This inactivation may represent a cooperative behavior, as the entire bacterial population benefits from removing the antibiotic. The cooperative nature of this growth suggests that a cheater strain—which does not contribute to breaking down the antibiotic—may be able to take advantage of cells cooperatively inactivating the antibiotic. Here we find experimentally that a “sensitive” bacterial strain lacking the plasmid conferring resistance can invade a population of resistant bacteria, even in antibiotic concentrations that should kill the sensitive strain. We observe stable coexistence between the two strains and find that a simple model successfully explains the behavior as a function of antibiotic concentration and cell density. We anticipate that our results will provide insight into the evolutionary origin of phenotypic diversity and cooperative behaviors.

4:30PM T42.00007 Bacterial Transformation and Competition Under Antibiotic Stress, JONAS PEDERSON, Danish Technical University, ANDREW BERGMAN, None, CHRIS CLEVELAND, Princeton University, TOLGA CAGATAY, UT Southwestern, ROBERT AUSTIN, Princeton University, GABOR BALASZI, M.D. Anderson Medical Center — Transformation, the process by which bacteria uptake DNA directly from their environment and incorporate it as their own genetic material, is a form of Horizontal Gene Transfer that occurs throughout nature as an important mechanism for spurring on bacterial evolution. We examine the capacity of bacteria to undergo transformation and will discuss work that has been done by the Austin group using Micro-Habitat Patches (MHPs) to examine the emergence of phenotypes due to horizontal gene transfer.

4:42PM T42.00008 Rapid Antibiotic Resistance Evolution of GASP Mutants, QIUCEN ZHANG, Princeton University, HYUNSUNG KIM, NADER POURMAND, UC Santa Cruz, ROBERT AUSTIN, Princeton University — The GASP phenotype in bacteria is due to a mutation which enables the bacteria to grow under high stress conditions where other bacteria stop growing. We probe using our Death Galaxy microenvironment how rapidly the GASP mutant can evolve resistance to mutagenic antibiotics compared to wild-type bacteria, and explore the genomic landscape changes due to the evolution of resistance.

4:54PM T42.00009 Spatial vs. individual variability with inheritance in a stochastic Lotka-Volterra system, ULRICH DOBRAMYSL, UWE C. TAUBER, Department of Physics, Virginia Tech — We investigate a stochastic spatial Lotka-Volterra predator-prey model with randomized interaction rates that are either affixed to the lattice sites and quenched, and / or specific to individuals in either population. In the latter situation, we include rate inheritance with mutations from the particles' progenitors. Thus we arrive at a simple model for competitive evolution with environmental variability and selection pressure. We employ Monte Carlo simulations in zero and two dimensions to study the time evolution of both species' densities and their interaction rate distributions. The predator and prey concentrations in the ensuing steady states depend crucially on the environmental variability, whereas the temporal evolution of the individualized rate distributions leads to largely neutral optimization. Contrary to, e.g., linear gene expression models, this system does not experience fixation at extreme values. An approximate description of the resulting data is achieved by means of an effective master equation approach for the interaction rate distribution.

Session T44 DPOLY: Focus Session: Interparticle Interactions in Polymer Nanocomposites - Grafted Chains 157C

2:30PM T44.00001 Colloidal assembly on soft substrates, JURE DOBNIKAR, TINE CURK, FRANCISCO MARTINEZ VERACOECHEA, DAAN FRENKEL, University of Cambridge, UK — We studied – by Monte Carlo computer simulations - ordering of hard sphere colloidal particles subject to gravity and soft interactions induced by polymer-coated substrates. The polymers are randomly anchored to a flat surface with an average density ranging from very dilute values to a situation where a dense polymer brush with the average height h forms. Studying a single colloid subject to such substrate and the gravity we observed a transition from a regime where it is confined to the hard surface at $z=0$, via a bimodal regime where it is equally likely to find it at the bottom or at the top, to the regime where it lies on top of the brush at $z=h$. In a system of many colloids the polymers induce an effective colloid-colloid interaction of entropic origin. We have performed Grand canonical Monte Carlo simulations and explored the structure formation as a function of the anchoring density and the effective gravity of the colloids. Colloids are initially attracted and grow into elongated assemblies with a well-defined lateral width. At low grafting densities such assemblies form percolated networks, while at high enough grafting densities finite clusters are observed. We discuss the relevance of our results to applications like particle sorting, reactions catalysis and passive diffusion.

2:42PM T44.00002 Molecular Dynamics Simulations on the Thermal and Mechanical Properties of Blend of Polymer and Polymer Grafted Nanoparticles, SANAT KUMAR, DONG MENG, Department of Chemical Engineering, Columbia University, GARY GREST, Sandia National Laboratories — Grafting polymers onto the surface of NPs has become one of the most effective approaches to integrate NPs into polymer melts. It then becomes crucial to be able to understand how the presence of grafted chains affects the effective interactions between NPs as well as the mechanical properties of the resulting composites. Using molecular dynamics simulations we first measure the potential of mean force between grafted NPs from two-particle simulations. Simulations of systems containing many grafted NPs are then performed to determine the phase behavior and structure of grafted NPs in explicit polymer matrices. Finally, we cool the nanocomposites to temperatures below their glass transition and stress the systems to investigate how the presence of grafted NPs changes their mechanical properties.

2:54PM T44.00003 Self Assembly of Tethered Nanoparticle Telechelics, RYAN MARSON, Materials Science and Engineering, University of Michigan, CAROLYN PHILLIPS, Applied Physics, University of Michigan, JOSHUA ANDERSON, SHARON GLOTZER, Chemical Engineering, University of Michigan — Simulations, theory, and experiment predict that aggregating nanoparticles functionalized with polymer tethers can self-assemble to form phases seen in block copolymer and surfactant systems, but with additional nanoparticle ordering and mesophase complexity. Here we consider a novel class of “telechelic” tethered nanoparticle building blocks, where two nanoparticles are connected together by a polymer tether. The architecture is similar to a triblock copolymer, but with additional geometric constraints imposed by the rigid particle end groups. Using Brownian dynamics simulations, we explore the phase diagrams of several examples of this class of nano-building-block, and present predictions of novel phases and their dependence on particle size, tether length, and thermodynamic parameters. We compare our results with recent simulations of di-tethered nanospheres [1, 2] and mono-tethered nanospheres [2, 3].

3:06PM T44.00004 Controlling the Phase Behavior of Gold Nanoparticles within Polymer Matrix by Varying Composition and Length of Ligands, SEYONG KIM, MISANG YOO, Korea University, BUMJOON KIM, Korea Advanced Institute of Science and Technology, JOONA BANG, Korea University — Nanocomposites have been investigated for many years due to their fascinating features. In spite of the captivative properties, compatibility problem has been an obstacle for manufacturing the nanocomposites. To achieve the compatibility between NPs and polymer matrix, thiol-terminated polymeric ligands have been used for tuning the surface property of the NPs. However, in case of Au NPs, Au-thiol bond is unstable above 60 °C. In our recent work, we designed thermally stable Au NPs by using thiol terminated photo crosslinkable block copolymer, PS-b-PSN3-SH. With the thermally stable Au NPs, we demonstrated that Au NPs are stable at high temperature and can serve as compatibilizers for PS/PMMA blends. Herein, we prepared Au NPs using photo crosslinkable polymeric ligands which have various ligand composition and lengths. As the ligands characteristics were changed, the phase behaviors of Au NPs in both homopolymer and block copolymer bulk sample were significantly different. For example, the NPs become more dispersed within the polymer matrix with longer polymer ligands, while they are aggregates when shorter ligands were used. In this work, morphologies of Au NPs within polymer matrix were systematically investigated using the cross-sectional transmission electron microscopy.

3:18PM T44.00005 ABSTRACT WITHDRAWN —

3:30PM T44.00006 Molecular Weight Distribution Effects on the Structure of Strongly Adsorbed Polymers by Monte Carlo Simulation, VIKRAM KUPPA, University of Cincinnati — Monte Carlo simulations are used to investigate the adsorption of polymers from solution onto strongly attractive, perfectly smooth substrates. Using a coarse-grained united atom model for freely rotating polymer chains, three systems with different polydispersities are studied. The structure of the adsorbed layers, exemplified by density profiles, bond orientation order parameters, radii of gyration, and distribution of the adsorbed chain fractions, is shown to be highly dependent on the molecular weight distribution of the polymer phase. The results for the more monodisperse polymer systems are qualitatively similar to experimental and theoretical investigations, but devolve from very different chain conformations and statistics. For the first time ever, equilibrium polymer adsorption on highly attractive surface is studied, with all molecules in the adsorbed layers demonstrated to be indistinguishable from each other. The ergodicity of states explored by the polymer chains is in contrast to the kinetically constrained viewpoint of irreversible adsorption, and the observed behavior is explained in the context of the competition between polymers to make contact with the surface.

3:42PM T44.00007 Role of Stretchable Arms, Grafting Density and Parallel Reformable Bonds in the Self-Healing of Cross-Linked Star Nanogel Particles, BALAJI IYER VAIDYANATHAN SHANTHA, ISAAC SALIB, VICTOR YASHIN, GERMAN KOLMAKOV, University of Pittsburgh, KRZYSZTOF MATYJASZEWSKI, Carnegie Mellon University, ANNA BALAZS, University of Pittsburgh — We investigate the role of stretchable and reformable bonds in the self-healing of a network formed by star-like nanogel particles. The individual particles of the network are composed of a cross-linked gel core and a corona of grafted polymeric arms with sticky end groups. The sticky groups in the coronas of adjacent particles interact to form multiple labile bonds (up to N) that lead to the formation of the nanogel network. Interaction between soft colloids with polymeric arms is combined with the Bell model for rupture and formation of bonds to model the interaction of array of particles. While the stretch of the bonds is captured through the bond spring constant (k) and cutoff radius for bond breaking (rc), the equilibrium distance (req) at which the labile bonds reform is obtained from the corona thickness. We show that the presence of stretchable arms allows for rearrangements leading to either increase or decrease of the strength and ductility of the nanogel network depending on the grafting density. We also show that while the force required to rupture the nanogel network is proportional to the number of parallel bonds (N), the ductility is a more complex function of N.

3:54PM T44.00008 Poly(ethylene-oxide)/clay/silica nanocomposites: Morphology and thermomechanical properties, ENGIN BURGAZ, Materials Sci. and Eng., Ondokuz Mayıs Univ. Samsun, Turkey — Poly(ethylene oxide) PEO/clay/silica nanocomposites were prepared via solution intercalation by exploiting phase separation based on the bridging of particles by polymer chains. The intercalated morphology of nanocomposites was confirmed by XRD. Vibrational modes of the ether oxygen of PEO in the hybrids are shifted due to the coordination of the ether oxygen with the sodium cations of clay and the H-bonding interactions of the ether oxygen with the surface silanols of hydrophilic fumed silica. Based on SEM, the overall density of nanoparticle aggregates in the interspherulitic region was observed to be higher compared to that inside spherulites. PEO/clay/silica hybrids show significant property improvements compared to PEO/clay hybrids and pure PEO. The system containing 10 wt.% clay and 5 wt.% silica has substantially higher modulus and much lower crystallinity compared to the 15 wt.% clay system. The physics behind the reinforcement effect and the reduction of crystallinity as a function of fumed silica loading is discussed based on the morphological characterization of the hybrids. Lastly, PEO/clay/silica hybrids display good thermal stability and are much stiffer compared to pure PEO and PEO/clay nanocomposites.

4:06PM T44.00009 Copolymer mediated interactions in dense nanocomposites: role of chemical heterogeneity and sequence, DEBAPRIYA BANERJEE, KENNETH S. SCHWEIZER, UIUC — Microscopic PRISM integral equation theory is applied to study the structure and dispersion of nanospheres in AB copolymer melts as a function of architecture and chemical heterogeneity of the interfacial attractions spanning the depletion, stabilization and bridging regimes. For a random copolymer (RCP) with coexisting weak and strong monomer-particle attractions, the nanoparticle potential-of-mean-force (PMF) at intermediate copolymer compositions varies non-monotonically between the two homopolymer limits. Non-adsorbing monomers are generically found to be crucial for achieving good filler dispersion in RCP melts. For 50/50 multiblock melts the role of block length, R , has been studied over a wide range ($R=1,2,5,10,25,50$). Filler miscibility dramatically increases when one of the monomers is weakly adsorbing (depletion). Dispersion is also improved for some block lengths when one of the monomers strongly adsorbs (bridging) due to the emergence of a long-ranged repulsive barrier in the PMF just beyond a local non-contact minimum, resulting in a positive second virial coefficient. Strikingly, better stability is predicted as the particle-to-monomer diameter ratio increases from 2 to 10, contrary to the behavior in homopolymer or RCP melts.

4:18PM T44.00010 Effect of bidispersity in grafted chain length on potential of mean force between polymer grafted nanoparticles in a homopolymer matrix, ARTHI JAYARAMAN, NITISH NAIR, University of Colorado at Boulder — In polymer nanocomposites consisting of polymer grafted nanoparticles in a polymer matrix the molecular weight of the grafted polymers plays a key role in dictating the effective inter-particle interactions. Despite the importance of graft molecular weight on effective inter-particle interactions in monodisperse polymer grafted nanoparticles, and evidence of non-trivial polydispersity effects in systems containing polymers grafted on flat surfaces, not much work has been done to explore polydispersity effects in polymer grafted nanoparticles. In this talk we will present self-consistent PRISM theory-Monte Carlo simulation studies showing how bidispersity in grafted chain lengths affects the grafted chain conformations and inter-particle interactions in a dense homopolymer polymer matrix. The value of the potential of mean force (PMF) between bidisperse grafted particles at contact is governed by the short grafts and values at large inter-particle distances are governed by the longer grafts. Our results suggest that by introducing bidispersity in grafted chains one can change the rules seen in monodisperse polymer grafted particles for wetting/dewetting of grafted polymers by matrix polymer.

4:30PM T44.00011 Concentration, Interaction and Temperature Dependent Chain Dynamics in Polybutadiene / Clay Nanocomposites Characterized by Solid State ^1H Double Quantum NMR Spectroscopy, XIAOLIANG WANG, Nanjing University, PINGCHUAN SUN, Nankai University, H. HENNING WINTER, University of Massachusetts, Department of Chemical Engineering, GI XUE, Nanjing University — A concentration, interaction and temperature dependent multimode segmental chain dynamics of carboxy terminated polybutadiene (CTPB) in CTPB/organo-clay (C18-clay) nanocomposite was investigated by solid state ^1H double quantum (DQ) NMR spectroscopy. Here, the measurements were performed on a series of samples of CTPB physically attached to the surface of C18-clay. NMR results showed that the nanocomposite exhibit discrete dynamic component with stepwise increase in their motional freedom with decreasing clay content. A remarkable change of CTPB chain dynamics at organo-clay concentration of 40 wt% was found, indicating a saturation effect of the polymer adsorbed on the clay surface. The transverse magnetization relaxation experiment help us quantitatively analysis the rigid, intermediate, and mobile components. Removal of either the end-group of CTPB or of the modifier on the clay changed the polymer-clay interaction profoundly, and thus changed polymer chain dynamics, especially for chains in proximity to the clay surface. The measurement confirmed our earlier hypothesis that the strong polymer-clay interaction was the key to the synergy effect in polymer/clay nanocomposites.

4:42PM T44.00012 Structural Transitions of Polymer Grafted Magnetic Nanoparticles¹, YANG JIAO, PINAR AKCORA, Stevens Institute of Technology — We decorate iron oxide nanoparticles with polymers to investigate the various interactions between particles and particle-polymer on the formation of different morphologies. We show that very low to intermediate grafting densities (2-20 chains/particle) can be achieved by controlling the concentration of free polymer chains in solution by grafting-to method. Nanostructural transitions of poly(styrene) grafted Fe_3O_4 nanoparticles are investigated upon varying the grafting densities and brush lengths. The roles of these parameters as well as dipolar force in the formation of various aggregates, such as star-like shape and chains, are discussed. This morphological transition is found to be sensitive to small grafting density change in very low to intermediate regime (0.01-0.04 chains/nm²). Interestingly, the matrix shows reverse effects on nanostructures with increment of brush lengths.

4:54PM T44.00013 ABSTRACT WITHDRAWN —

Wednesday, February 29, 2012 2:30PM - 5:30PM —
Session T45 DPOLY: Polymeric Glasses 159

2:30PM T45.00001 Formation of Polymer Glasses Under Stress and Its Influence on Physical Aging, LAURA GRAY, PAUL YOON, CONNIE ROTH, Department of Physics, Emory University — Understanding and controlling the stability and physical aging of polymer glasses is important for many technological applications from gas separation membranes to optical coatings. We investigate the stability of polymer glasses when thermally quenched under different stress conditions. Ellipsometry is used to measure the physical aging rate of polystyrene films supported or transferred onto silicon wafers. We quantify the time-dependent decrease in film thickness that results from the increase in average film density during aging to obtain a physical aging rate. We have observed significant differences between films quenched in a free-standing versus supported state, even though all films were aged in a supported state. Films quenched in a free-standing state exhibit a strong thickness dependence to their physical aging rate at micron length scales, an order of magnitude or two larger than thicknesses where nanoconfinement effects on the glass transition and modulus are typically observed. In contrast, supported films do not display any film thickness dependence to their aging rate at this large length scale. All available evidence suggests that different stress conditions are the underlying cause of this effect. In order to investigate the role of stress during the vitrification of polymer glasses, we have constructed a unique jig to apply a known stress to free-standing films during the thermal quench.

2:42PM T45.00002 Deformation-induced molecular mobility allows polystyrene glasses to flow, MARK EDIGER, BEN BENDING, KELLY CHRISTISON, University of Wisconsin-Madison — Experiments on colloidal glasses show that local rearrangements occur more rapidly during deformation. For polymeric glasses, similar features are expected but cannot be directly imaged. Dye reorientation has been used to measure segmental mobility in polymer glasses during active deformation. In creep deformations, we see a hundred-fold enhancement of mobility occurring in polystyrene glasses lightly cross-linked with 2 and 4 weight percent of divinylbenzene. Qualitatively similar mobility enhancement has been previously reported for lightly cross-linked poly(methyl methacrylate). Data from all three systems superpose on a master plot of the mobility as a function of the local strain rate during creep. Additionally, in the flow regime we see a significant narrowing of the distribution of relaxation times for both the polystyrene and poly(methyl methacrylate) glasses, similar to what has been reported for colloidal systems. Because polystyrene lacks the prominent beta relaxation of poly(methyl methacrylate), we conclude that the changes in mobility during creep deformation are a result of changes in the alpha segmental relaxation time.

2:54PM T45.00003 Temperature Divergence of the Dynamics of a PVAc glass: Dielectric vs. Mechanical Behaviors¹, GREGORY MCKENNA, JING ZHAO, Texas Tech University — The dynamics of glass forming liquids as the glass transition is traversed has become of special interest because of the continuing question as to whether or not these dynamics diverge towards an ideal glass transition/Kauzmann temperature or if the apparent Vogel-Fulcher divergence is lost as one goes below the conventional T_g but remains in equilibrium. Here we examine the response of a PVAc polymer glass-former using both dielectric and mechanical methods in the vicinity of T_g . Isothermal measurements were performed to study the aging behavior of PVAc and to assure that the equilibrium state was achieved and for temperatures to as much as 15 °C below the T_g . Surprisingly, we found that the mechanical response took much longer to age into equilibrium than did the dielectric response. Also, although the dielectric and mechanical responses seem to probe the glassy dispersion, the temperature dependence of the time-temperature shift factors obtained from the two methods are different and the dielectric measurement response shows a turnover to Arrhenius behavior rather than a continuation of the VFT divergence at the lowest temperatures tested.

¹The authors thank the National Science Foundation under grant DMR-0804438 for support of this project.

3:06PM T45.00004 Determination of effective correlation length in a glassy polymer using electrostatic force microscopy, BRANT RUMBERGER, NATHAN ISRAELOFF, Northeastern University — Various fourth-order correlation functions have been used to study the size of dynamically correlated regions in colloidal glasses and simulated glass forming liquids or polymers. However, measuring these correlation functions in molecular glasses has been limited by the small length scales on which the dynamics occur. Electrostatic force microscopy techniques are employed here to probe dielectric noise in polyvinyl acetate. We analyze fourth-order statistical fluctuations in order to determine spatio-temporal correlation lengths and their temperature dependence near the sample's glass transition. The first harmonic response of an applied AC voltage between the conducting AFM tip and the conducting substrate beneath the thin film polymer sample is proportional to the local electric polarization. Noise in this signal is examined and many hours are recorded at various temperatures in order to improve statistical precision. We employ a variety of statistical analysis techniques ranging from power spectrum analysis to variance of autocorrelation functions in order to find deviations from Gaussian statistics. Super-sharp carbon nanotube EFM tips (nominal radius of 10 nm) are employed to probe smaller effective volumes and thus more easily detect these fluctuations.

3:18PM T45.00005 Stable Nanostructured Polymer Films Formed Via Matrix Assisted Pulsed Laser Evaporation, YUNLONG GUO, KIMBERLY SHEPARD, RODNEY PRIESTLEY, Princeton University — Via typical routes to the vitreous state, the ability to significantly alter the properties of amorphous solids is restricted due to the kinetic nature of the glass transition. In this talk, we show that matrix assisted pulsed laser evaporation (MAPLE) can be used to form ultra-stable and nanostructured glassy polymers with significantly reduced densities, enhanced glass transition temperatures, and superior kinetic stability at high temperatures. Relative to the standard poly(methyl methacrylate) glass formed on cooling at standard rates, glasses prepared by MAPLE can be 40 percent less dense and have 40 K higher glass transition temperatures. Furthermore, the kinetic stability in the glassy-state can be enhanced by 2-orders-of-magnitude. The unique combination of properties is a result of the glass morphology, i.e., the glassy films are formed by the assembly of nearly spherical-like polymer nanoglobules.

3:30PM T45.00006 A Scattering Model for Amorphous, Intrinsically Microporous Polymers¹, AMANDA G. MCDERMOTT, Penn State University, PETER M. BUDD, University of Manchester, NEIL B. MCKEOWN, Cardiff University, CORAY M. COLINA, JAMES RUNT, Penn State University — We discuss the development of a scattering model for glassy, porous polymers in which porosity is equivalent to free volume, deriving significant insight from molecular dynamics simulations. Polymers of intrinsic microporosity (PIMs) exhibit high gas permeability and a large concentration of pores smaller than 1 nm; their porosity arises from an unusual chain structure combining rigid segments with sites of contortion, rather than from any templating effect. Although for many porous materials, useful information such as pore sizes and specific surface areas can be extracted from scattering patterns, a successful scattering model for PIMs must account for several unusual features. Simulated structures that reproduce characteristic scattering features are used to test model assumptions, with the ultimate goal of increasing the utility of scattering for studying microporous polymeric membrane processing and physical aging.

3:42PM T45.00007 Non-Equilibrium Water-Glassy Polymer Dynamics, ERIC DAVIS, Drexel University, MATTEO MINELLI, MARCO BASCHETTI, GIULIO SARTI, Università di Bologna, YOSSEF ELABD, Drexel University — For many applications (e.g., medical implants, packaging), an accurate assessment and fundamental understanding of the dynamics of water-glassy polymer interactions is of great interest. In this study, sorption and diffusion of pure water in several glassy polymers films, such as poly(styrene) (PS), poly(methyl methacrylate) (PMMA), poly(lactide) (PLA), were measured over a wide range of vapor activities and temperatures using several experimental techniques, including quartz spring microbalance (QSM), quartz crystal microbalance (QCM), and time-resolved Fourier transform infrared-attenuated total reflectance (FTIR-ATR) spectroscopy. Non-Fickian behavior (diffusion-relaxation phenomena) was observed by all three techniques, while FTIR-ATR spectroscopy also provides information about the distribution of the states of water and water transport mechanisms on a molecular-level. Specifically, the states of water are significantly different in PS compared to PMMA and PLA. Additionally, a purely predictive non-equilibrium lattice fluid (NELF) model was applied to predict the sorption isotherms of water in these glassy polymers.

3:54PM T45.00008 Self-consistent Mixing Rule for the Viscoelasticity of Heterogeneous Systems, FRANCOIS LEQUEUX, ESPCI/SIMM Paris France, PEILUO SHI, HELENE MONTES, None — Heterogeneous systems –like glasses mixtures - can exhibit huge local fluctuations of their viscoelastic modulus. The average viscoelastic modulus is often approximated either as the average modulus, or as the inverse of the average of the inverse of the modulus. Here we test a self-consistent method based on the Olroyd Palierne model for blend viscoelasticity [1]. We test this method on polymer miscible blends, with a very different glass transition temperature. We first deduce from Differential Scanning Calorimetric measurements the distribution of glass transition and thus of local viscoelastic modulus. From that we predict quantitatively the viscoelastic modulus of the polymer blends. It appears thus that the self-consistent averaging for disordered systems is extremely efficient, describing quantitatively systems where the modulus varies locally by at least 3 decades. [1] F. Lequeux, A. Ajdari, "Averaging rheological quantities in descriptions of soft glassy materials" Phys. Rev E 63 R030502 (2001)

4:06PM T45.00009 Understanding failure behavior of polymer glasses: a molecular viewpoint, GREGORY ZARTMAN, SHIWANG CHENG, SHI-QING WANG, The University of Akron — In surveying the vast literature we note that a unified simple picture appears to be lacking to account for all the known facts on failure behavior of polymer glasses. In this work, we first apply the fresh insight we have gained from studying nonlinear extensional rheology of entangled melt to show why a melt-stretched polystyrene turns ductile. We further show that the ductile polycarbonate can also turn brittle upon pre-melt-stretching. Finally, blending oligomeric PC into an originally ductile PC also causes the mixture to become brittle. All these old and new phenomena point to the fact that the strength of the load bearing chain network dictates at a given temperature whether the polymer glass would undergo ductile failure through shear yielding or brittle fracture via crazing. This presentation will provide a description of how the entanglement structure can be altered by melt deformation or the choice of different chemical specificity (that influences the packing length) to affect the strength of polymer glasses. It is this network strength relative to the yield strength associated with the inter-segmental van der Waals interactions that determines how strain localization (shear yielding – necking vs. crazing) takes place.

4:18PM T45.00010 Heterogeneous Dynamics During Creep of Rod Containing Polymer Nanocomposites, GREGORY TOEPPERWEIN, University of Wisconsin, ROBERT RIGGLEMAN, University of Pennsylvania, JUAN DE PABLO, University of Wisconsin — Polymer glasses exhibit regions of locally higher or lower mobility leading to heterogeneous dynamics. While heterogeneous dynamics have been examined in some detail in pure polymers, less is known about polymer nanocomposites (PNCs). We have previously studied PNCs, providing descriptions of how particles alter the network of entanglements, measuring local mechanical heterogeneity, demonstrating strain response under uniaxial deformation, and examining crazing and failure under multiaxial deformation. In the present work, we examine dynamic heterogeneity in rod-containing PNCs by performing creep deformation simulations and monitoring several measures of mobility. We are able to directly probe how dynamic heterogeneity evolves during deformation, and explore the origins of molecular mobility in polymer glasses. Examination of the segmental motion of a PNC undergoing creep reveals that the glassy heterogeneity of these systems decreases significantly following the onset of flow. It is found that the more heterogeneous distribution of relaxation times characteristic of PNCs in the bulk remains unaltered regardless of deformation state. It is found that the mobility and heterogeneity of PNCs are less susceptible to change upon deformation than those for the pure polymer.

4:30PM T45.00011 Molecular dynamics simulations of highly cross-linked polymer networks: prediction of thermal and mechanical properties, NATALIA SHENOGINA, Wright State University, Dayton, OH, MESFIN TSIGE, University of Akron, Akron, OH, SHARMILA MUKHOPADHYAY, Wright State University, Dayton, OH, SOUMYA PATNAIK, Wright-Patterson Air Force Base, Dayton, OH — We use all-atom molecular dynamics (MD) simulations to predict the mechanical and thermal properties of thermosetting polymers. Atomistic simulation is a promising tool which can provide detailed structure-property relationships of densely cross-linked polymer networks. In this work we study the thermo-mechanical properties of thermosetting polymers based on amine curing agents and epoxy resins and have focused on the DGEBA/DETDA epoxy system. At first we describe the modeling approach to construction of realistic all-atom models of densely cross-linked polymer matrices. Subsequently, a series of atomistic simulations was carried out to examine the simulation cell size effect as well as the role of cross-linking density and chain length of the resin strands on thermo-mechanical properties at different temperatures. Two different methods were used to deform the polymer networks. Both static and dynamic approaches to calculating the mechanical properties were considered and the thermo-mechanical properties obtained from our simulations were found in reasonable agreement with experimental values.

4:42PM T45.00012 Heterogeneity: A Solution to the Mysteries of the Glass transition?¹, XIAOJUN DI, GREGORY MCKENNA, Department of Chemical Engineering, Texas Tech Univ — For most phase transitions, dynamic slowdown is accompanied by static structure change. However, in supercooled liquids there is a pronounced dynamic slowdown, i.e. diffusion coefficient, relaxation time and viscosity change 14 orders of magnitude within a small temperature range, without any static structure change. Over the past several decades, extensive research has been performed to understand this dramatic dynamical slowing, i.e., why the glass transition occurs? What exactly is the glass transition? And how molecules move near the glass transition? In the present work, the idea that the large decrease in mobility in supercooled liquids during cooling from above T_g occurs due to the increasing length scale of heterogeneous sub-regions, or the Cooperative Rearranging Regions (CRR) proposed by Adam and Gibbs, is evaluated by analyzing both experiment and computer simulation results. Although the existence of microscopic heterogeneous regions is confirmed, the values of the fitting parameters obtained from both VFT and power law fits of the temperature dependent heterogeneity data suggest that the heterogeneity, itself, might not play in the key role in the T_g and/or tightly connect with the CRRs.

4:54PM T45.00013 The effect of polar interactions on the dynamics in vitreous liquids, ALEXANDER AGAPOV, YANGYANG WANG, PHILIP GRIFFIN, ALEXEI SOKOLOV, Department of Chemistry, University of Tennessee — It is known that in small molecule and polymeric systems the long-range process like diffusion and chain relaxation decouple from the local structural relaxation temperature dependence as system approaches its T_g . Recently, it was shown by Sokolov and Schweizer (*Phys. Rev. Lett.* **2009**, 102, 248301) that these decoupling phenomena seem to have similar underlying mechanism irrespective whether system is a polymeric or a molecular liquid. The degree of decoupling for both polymers and small molecule systems show very similar trend with respect to the fragility of the material. More fragile systems show higher degree of decoupling. However, such behavior was shown only on the example of dynamics in weakly interacting van der Waals systems. On the example of three polymers and one room temperature ionic liquid (RTIL) it is demonstrated that the presence of polar interactions leads to rather steep temperature dependence of large length scale dynamic processes, like chain relaxation and self-diffusion. As a result, the degree of decoupling between large length scale and local dynamic processes in such polar materials is significantly lower than in weakly interacting liquids with comparable fragilities. The microscopic mechanism behind an unusual dynamic behavior seen in polar polymers and RTILs remains unclear. Nevertheless, knowledge of such structure-property relationship can significantly aid in the development of novel materials. Authors are thankful to NSF and (U.S.) DOE, Office of Basic Energy Sciences for the financial support.

5:06PM T45.00014 The Twinkling Fractal Theory of the Glass Transition: Applications to Soft Matter, RICHARD WOOL, Chemical Engineering, University of Delaware — The Twinkling Fractal Theory (TFT) of the glass transition has recently been demonstrated experimentally [J.F. Stanzione et al., *J. Non Cryst. Sol.*, (2011), 357,311]. The hard to-soft matter transition is characterized by the presence of solid fractal clusters with liquid-like pools that are dynamically interchanging via their anharmonic intermolecular potentials with Boltzmann energy populations with a characteristic temperature dependent vibrational density of states $g(\omega) \sim \omega^{d_f}$. The twinkling fractal frequencies ω cover a range of 10^{12} Hz to 10^{-10} Hz and the fractal solid clusters of size R have a lifetime $\tau \sim R^{d_f/d_f}$, where the fractal dimension $D_f \approx 2.4$ and the fracton dimension $d_f = 4/3$. Here we explore its application to a number of soft matter issues. These include (a) Confinement effects on T_g reduction in thin films of thickness h , where by virtue of large cluster exclusion, $\Delta T_g \sim 1/h^{D_f/d_f}$; (b) T_g gradients near bulk surfaces, where the smaller clusters on the surface have a faster relaxation time; (c) Effect of twinkling surfaces on cell growth, where at $T \approx T_g + 20$ C, there exists a twinkling fractal range that leads to bell-shaped enhancement of cell growth and chemical up-regulation via the twinkling surfaces “communicating” with the cells through their vibrations; and (d) adhesion above and below T_g where topological fluctuations associated with $g(\omega)$ promotes the development of nano-nails at the interface.

5:18PM T45.00015 Nano-indentation of Polycarbonate and Diamine Blends, SURESH AHUJA, Retired — Nanoindentation of complex surfaces is of great interest from academic and industrial point of view. There are unique properties such as indentation effects resulting in strain softening and strain hardening. There is a differentiation in structure with the depth exhibited with variation of T_g . Hertzian and non-linear deformation models including usage of FEM offer opportunity in analyzing nano-indentation. In polycarbonate, the effective elastic modulus and the hardness decreases as the applied load is increased. As the hold time was increased, the effective elastic modulus and the hardness also decreased. The contact stress increases as the contact strain rate is increased. Presence of diamine(MTBD) in polycarbonate results in making the surface and bulk brittle and acts as an anti-plasticizer by increasing its modulus and reducing yield stress (hardness) and strain to break. Data on modulus and hardness of polycarbonate and blends of diamine as function of depth (strain) and strain rate are presented and compared with those of composites with silica.

Session T46 GIMS: Invited Session: Keithley Award Session: Photoacoustic and Photothermal Measurement Science 160AB

2:30PM T46.00001 Joseph F. Keithley Award For Advances in Measurement Science Lecture: Thermophotonic and Photoacoustic Radar Imaging Methods for Biomedical and Dental Imaging¹

, ANDREAS MANDELIS, Center for Advanced Diffusion-Wave Technologies, MIE, Univ. of Toronto — In the first part of this presentation I will introduce thermophotonic radar imaging principles and techniques using chirped or binary-phase-coded modulation, methods which can break through the maximum detection depth/depth resolution limitations of conventional photothermal waves. Using matched-filter principles, a methodology enabling parabolic diffusion-wave energy fields to exhibit energy localization akin to propagating hyperbolic wave-fields has been developed. It allows for deconvolution of individual responses of superposed axially discrete sources, opening a new field: depth-resolved thermal coherence tomography. Several examples from dental enamel caries diagnostic imaging to metal subsurface defect thermographic imaging will be discussed. The second part will introduce the field of photoacoustic radar (or sonar) biomedical imaging. I will report the development of a novel biomedical imaging system that utilizes a continuous-wave laser source with a custom intensity modulation pattern, ultrasonic phased array for signal detection and processing coupled with a beamforming algorithm for reconstruction of photoacoustic correlation images. Utilization of specific chirped modulation waveforms (“waveform engineering”) achieves dramatic signal-to-noise-ratio increase and improved axial resolution over pulsed laser photoacoustics. The talk will conclude with aspects of instrumental sensitivity of the PA Radar to optical contrast using cancerous breast tissue-mimicking phantoms, super paramagnetic iron oxide nanoparticles as contrast enhancement agents and in-vivo tissue samples.

¹With N. Tabatabaei, S. Telenkov, and R. Alwi

3:06PM T46.00002 Photoacoustics and Photothermal instrumentation in the study of thermal properties of liquids and semisolids

, JUAN JOSE ALVARADO-GIL, Applied Physics Department, Cinvestav-Unidad Merida, Carretera antigua a Progreso Km. 6, Merida, Yucatan, Mexico, 97217 — The fundamentals of the measurements of the thermal properties of solids and semisolids using photoacoustics and photothermal techniques are presented. It is shown that photoacoustics is a high stability technique which allows the monitoring of complex process in which the physical properties of the liquid can evolve. Additionally, it is shown that the methodology known as thermal wave cavity can be used successfully in high accuracy measurements for a wide variety of materials. In particular the case of magnetic fluids in which the viscosity can be varied, using an external magnetic fluid, is presented. It is also shown that the thermal wave cavity permits the study of magnetic fluids in which high aspect ratio particles are introduced in the fluid matrix. The effect of the orientation of non-magnetic particles inside the magnetic fluid generated by external magnetic field is also investigated. The possible applications and consequences in the development of windows of controlled thermal conductivity are discussed.

3:42PM T46.00003 Photoacoustic and Photothermal Effects in Periodic Structures and Acoustic Resonators

, GERALD DIEBOLD, Brown University — Laser excited photoacoustic and photothermal waves can be generated in one-dimensional structures whose acoustic or thermal properties vary sinusoidally in space. The wave equations describing the pressure or the temperature in such structures can be shown to reduce to inhomogeneous Mathieu equations. Solutions of the Mathieu equation are obtained based on both the method of variation of parameters and expansion of the pressure or temperature in a summation over eigenfunctions. The solutions for the photoacoustic effect show the space equivalent of subharmonic generation where resonances occur at one half of the period of the structure. The positions of the band gaps and the dispersion relations for any modulation depth of the acoustic properties of the structure can be found directly from the Mathieu characteristic exponent. Since the photoacoustic effect is governed by an inhomogeneous differential equation, excitation within forbidden gaps is possible. For excitation within a finite region of the structure, the Mathieu equation equivalent of Hankel functions are defined. From these functions the properties of the photoacoustic waves excited within or outside of the band gaps are found. For thermal waves, the character of the waves and the dispersion relation can be found as well, however no band gaps result from the periodicity of the thermal properties of the structure. The generation of sound by continuous, unmodulated irradiation of an absorbing gas in a resonant cavity is discussed. A longitudinal resonance of the cavity is predicted to be excited since any pressure increase from optical absorption is accompanied by a density increase, the latter resulting in additional energy deposition by the laser beam. Thus, on each return of the pressure pulse to the window of the resonator where laser beam enters the acoustic signal is amplified. Calculations show that for a strongly absorbing gas, the acoustic modes of the resonator become mode locked.

4:18PM T46.00004 Linear and Nonlinear Laser-Based Guided Acoustic Waves Propagating at Surfaces (2D) and Edges (1D)

, PETER HESS, University of Heidelberg — In recent years photoacoustics opened the door to many new applications of 2D linear surface acoustic waves (SAWs), e.g., nondestructive evaluation (NDE) of surface-breaking cracks. Real partially-closed cracks of micrometer size have been analyzed. More recently also pulsed laser excitation of solitary elastic surface pulses and their detection with a continuouswave probe laser has been achieved, by generating dispersion with a thin film coating that introduces a length scale. In addition, such laser-based pump-probe experiments allow the excitation of short nonlinear SAW pulses developing steep shock fronts that fracture brittle materials such as silica or silicon. With this method it is possible to measure the fracture strength of materials and compare the critical failure stress with ab initio calculations of the ideal strength of the corresponding perfect single crystal. The excitation and detection of 1D edge or wedge waves propagating along a wedge formed by two planar surfaces that meet at the apex of the wedge or wedge tip has been performed by laser irradiation. The characteristic features of the non-dispersive linear wedge waves such as their small phase velocity below the Rayleigh velocity, the very high degree of localization of the displacement field at the wedge tip, and their existence for certain geometries in anisotropic media such as silicon could be verified by photoacoustic experiments. Despite the strong nonlinearity of certain edge-localized modes, as expected from theoretical considerations, 1D solitary waves and nonlinear wedge waves with steep pulse profiles could not be detected up to now. The latest progress will be discussed.

4:54PM T46.00005 Understanding climate: the role of photoacoustic spectroscopy at NIST¹

, KEITH GILLIS, National Institute of Standards and Technology — Sophisticated climate models predict that soot aerosols have a significant impact on Earth's energy budget; however, the uncertainty of these predictions is large, in part, because soot in the atmosphere and in the laboratory is poorly characterized. In the atmosphere, soot's optical and physical properties change as it combines with water vapor and sulfuric acid. We will describe a novel photoacoustic spectrometer system that measures the optical absorption cross section of various soots as they age in diverse environments. We also measure the albedo (optical scattering) of aerosols ranging from black-carbon-like to brown-carbon-like using simultaneous photoacoustic spectroscopy and cavity ring-down spectroscopy. Lastly, we developed a photoacoustic spectrometer system that measures the concentration of carbon dioxide in atmospheric air with sub-ppm uncertainty. We will report results of field tests of this spectrometer.

Session T47 DPOLY: Focus Session: Heterogeneous Colloids I 160C**

2:30PM T47.00001 Janus and Multiblock Colloids¹, STEVE GRANICK, University of Illinois — This talk surveys emerging areas opened up by the directional interactions presented by the specially-designed spheres known as Janus. The “diblock” motif, mutually attractive on one domain and repulsive on another, makes this a prototypical system for elucidating, on a mechanistic level, how concepts of chemical reaction kinetics explain the development of stable and highly ordered nonequilibrium structures. With the “triblock” motif, spheres that attract one another on two polar regions but repel at the middle band, we go beyond this to demonstrate the self-assembly of a useful low-density lattice of spheres, the colloidal Kagome lattice, and visualize its aqueous assembly dynamics on the single-particle level. A newer area of opportunity is “dynamic self-assembly,” in which energy fed into the system as a control variable generates big surprises. The generalization of these design rules will be discussed.

¹Work performed with Erik Luijten, Qian Chen, Jing Yan, Nobuhiro Yanai, Jie Zhang, Jonathan K. Whitmer, and Sung Chul Bae.

3:06PM T47.00002 Synchronized Dancing of Magnetic Janus Particles, JING YAN, Department of Materials Science and Engineering at University of Illinois at Urbana-Champaign, MOSES BLOOM, Department of Materials Science and Engineering at Northwestern University, SUNGCHUL BAE, Department of Materials Science and Engineering at University of Illinois at Urbana-Champaign, ERIK LUIJTEN, Department of Materials Science and Engineering at Northwestern University, STEVE GRANICK, Department of Materials Science and Engineering at University of Illinois at Urbana-Champaign — With Janus particle coated with magnetic material on one side, we demonstrate here first a complicated dance of single particle under external field. Then we show various quasi-one dimensional and two dimensional assembly from synchronized motion of a collection of these microspheres. With combination of experiment and simulation, we show how they are phase-locked in motion and self-organize into unexpected structures. By exploring a range of parameters, we also demonstrate fine control of the phase behavior of such dynamic self-assembled materials. We provide an vivid example here how synchronization in both time and space could lead to a new class of responsive materials.

3:18PM T47.00003 Hierarchical assemblies and cluster growth regimes of bipolar Janus nanoparticles: effect of particle characteristics, MAHDY MALEKZADEH MOGHANI, Materials Research and Innovative Laboratory (MRIL), Department of Chemical and Biomolecular Engineering, University of Tennessee, BAMIN KHOMAMI, Department of Chemical and Biomolecular Engineering, University of Tennessee — Numerous current and potential applications have motivated fundamental understanding of self assembly of colloidal Janus particles (JP). Experimental studies on nano and micron sized JPs have demonstrated a plethora of simple and complex structures. However, computational approaches to date have lacked the sophistication required to capture the rich free energy landscape of suspension of JPs especially for nanoscale particles and hence have been unable to elucidate the underlying principles that govern their complex self assembly. In this study, molecular dynamic simulation of a restricted primitive model, which also includes long range coulombic interaction, has been performed in order to elucidate the underlying physics in the self assembly of bipolar JP at different surface charge density ($0.2\sim 1.3$ e/nm²), salt concentration ($0\sim 3$ mM) and particle sizes. Our results clearly indicate formation of two distinct sub structures in very low JP concentration, namely: strings and rings. As the concentration of JP increases these sub structures joins and/or hierarchically assemble into larger clusters. Furthermore, the interconnection between the ionic cloud around a single JP and sequential cluster growth in JPS as a function of surface charge density, particle size and steric hindrance of surface ions has been elucidated.

3:30PM T47.00004 Stability of helical Janus clusters, CONNOR L. ECK, Northwestern University, JONATHAN K. WHITMER, University of Wisconsin–Madison, QIAN CHEN, STEVE GRANICK, University of Illinois at Urbana–Champaign, ERIK LUIJTEN, Northwestern University — Recent experimental and computational work has elucidated the importance of kinetic pathways in the formation of helical structures by hydrophobic-charged Janus particles.¹ Motivated by these findings, we perform free-energy calculations to investigate the equilibrium structure and relative stability of helical aggregates as a function of cluster size and Janus balance. These results simultaneously aid in the interpretation of experimental observations and in the design of building blocks for specific structures.

3:42PM T47.00005 Hierarchical Self-assembly of Triblock Janus Spheres, QIAN CHEN, SUNG CHUL BAE, STEVE GRANICK, University of Illinois at Urbana-Champaign — We show how monodisperse triblock Janus spheres in aqueous suspension, whose poles are attractive and middle band repulsive, self-assemble into hierarchical supracolloidal structures, on two sequential levels. Based upon the delicate dependence of interactions on ionic strength, we first activate attraction between larger patches, obtaining finite-sized 3D clusters. These clusters, now concrete objects themselves, are triggered later to be linked through topologically determined orientations. A family of unprecedented, complex structures is produced, with order over multiple length scales.

3:54PM T47.00006 Janus particles at fluid-fluid interfaces: the third face of Janus particles, DAEYEON LEE, TERESA BRUGAROLAS, BUM JUN PARK, MYUNG HAN LEE, University of Pennsylvania — Janus spheres are asymmetric particles with polar and apolar hemispheres. In this work, we study the interactions and assembly of Janus spheres – bubbles and solid particles – at fluid-fluid interfaces. Both the Janus bubbles and the Janus particles have strikingly different interfacial behaviour compared to their homogeneous counterparts. Janus spheres at a fluid-fluid interface interact with each other via long-ranged attractions. We show that the attractive interactions between interface-trapped Janus spheres are induced by the presence of diffuse boundary between the two hemispheres. Three phase contact line anchored around the rugged Janus boundary deforms that the fluid interface leading to attractive interactions between the spheres. The orientation and fluid deformation caused by Janus spheres are directly observed using a gel trapping method. We also show that the surface chemistry of Janus spheres plays a critical role in determining their interfacial behaviour. Potential implications of the observed long-range attractions will be discussed.

4:06PM T47.00007 Self Assembly of Hard, Space-Filling Polytopes¹, BENJAMIN SCHULTZ, University of Michigan, Dept. of Physics, PABLO DAMASCENO, University of Michigan, Dept. of Applied Physics, MICHAEL ENGEL, SHARON GLOTZER, University of Michigan, Dept. of Chemical Engineering — The thermodynamic behavior of systems of hard particles in the limit of infinite pressure is known to yield the densest possible packing [1,2]. Hard polytopes that tile or fill space in two or three spatial dimensions are guaranteed to obtain packing fractions of unity in the infinite pressure limit. Away from this limit, however, other structures may be possible [3]. We present the results of a simulation study of the thermodynamic self-assembly of hard, space-filling particles from disordered initial conditions. We show that for many polytopes, the infinite pressure structure readily assembles at intermediate pressures and packing fractions significantly less than one; in others, assembly of the infinite pressure structure is foiled by mesophases, jamming and phase separation. Common features of these latter systems are identified and strategies for enhancing assembly of the infinite pressure structure at intermediate pressures through building block modification are discussed.

4:18PM T47.00008 Self Assembly of Colloids¹, STEFANO SACANNA, New York University — We are exploring the self assembly of colloidal matter using building blocks with complex shapes and functionalities. Our toolbox includes particles with tunable cavities and protrusions, particles with flexible ball-and-socket joints, colloidal cubes and particles with magnetic patches. Using these building blocks and a variety of interactions, including chemical, steric, magnetic and lock-and-key shape recognition, we aim to develop new assembly schemes to build structures with a reconfigurable structural arrangement.

¹This work was supported by a MURI grant (W911NF-10-1-0518).

4:54PM T47.00009 Surface Roughness directed Self-Assembly of Patchy Particles into Colloidal Micelles, DANIELA KRAFT, Center for Soft Matter Research, New York University, RAN NI, FRANK SMALLENBURG, MICHEL HERMES, Soft Condensed Matter, Utrecht University, KISUN YOON, DAVID WEITZ, Experimental Soft Condensed Matter Group, Harvard University, ALFONS VAN BLAADEREN, Soft Condensed Matter, Utrecht University, JAN GROENEWOLD, Van 't Hoff Laboratory for Physical and Colloid Chemistry, Utrecht University, MARJOLEIN DIJKSTRA, Soft Condensed Matter, Utrecht University, WILLEM KEGEL, Van 't Hoff Laboratory for Physical and Colloid Chemistry, Utrecht University — Self-assembly of colloidal particles into larger structures bears potential for creating materials with unprecedented properties, such as full photonic band gaps in the visible spectrum. Colloidal particles with site-specific directional interactions, so called “patchy particles,” are promising candidates for bottom-up assembly routes towards such complex structures with rationally designed properties. Here we present an experimental realization of patchy colloidal particles based on material independent surface roughness specific depletion interactions. Smooth patches on rough colloids are shown to be exclusively attractive due to their different overlap volumes. We discuss in detail the case of colloids with one patch that serves as a model for molecular surfactants both with respect to their geometry and their interactions. These one-patch particles assemble into clusters that resemble surfactant micelles. We term these clusters “colloidal micelles.” Similarities as well as differences between the colloidal model system and molecular surfactants are discussed and quantified by employing computational and theoretical models.

5:06PM T47.00010 Entropic selection of patchy particle assemblies¹, XIAOMING MAO, University of Pennsylvania, QIAN CHEN, STEVE GRANICK, University of Illinois at Urbana-Champaign — We explore the statistical physics of triblock patchy colloids with degenerate valency, i.e., particles with excessively large attractive areas on two opposite sides, via analytic theory, which has the advantage of revealing fundamental laws of self-assembly more easily compared to the usual “trial-and-error” approach taken in experiments and simulations. From calculations of the free energy of multiple possible ground states, we conclude that the rotational entropy of individual particles favors certain bond angles, whereas vibrational entropy favors open rather than close-packed structures. Our analytic calculation is readily generalizable to other types of patchy particles and provides guidelines for new designs. We conclude that whereas the seemingly unfavorable degenerate valency of patchy colloids can lead to multiple energetic ground states and difficulties in selecting a unique ordered state, it also opens doors to surprising ordering phenomena. This shares pleasing commonalities with the “order-from-disorder” effect in frustrated magnets.

5:18PM T47.00011 Assembling Colloidal Clusters from Spherical Codes¹, CAROLYN PHILLIPS, ERIC JANKOWSKI, MICHELLE MARVAL, SHARON GLOTZER, University of Michigan — Anisotropic building blocks assembled from colloidal particles are attractive building blocks for self-assembled materials because their complex interactions can be exploited to drive self-assembly. In this work we consider the thermodynamically driven self-assembly of terminal clusters of particles. We predict that clusters related to spherical codes, a mathematical sequence of points, can be synthesized via self-assembly. These anisotropic clusters, which derive from packing solutions of spheres around a sphere, can be tuned to different anisotropies via the ratio of sphere diameters and temperature. Structural and dynamical analysis of these tiny systems reveal rich and sometimes surprising properties.

¹Supported by DOE-BES, under award DE-FG02-02ER46000

Wednesday, February 29, 2012 2:30PM - 5:30PM —
Session T48 DPOLY DBIO: Focus Session: Advanced Optical Probes of Soft Matter - Microrheology, Microbiography 161

2:30PM T48.00001 Colloidal Diffusion and Hydrodynamic Interactions near Boundaries, BHASKAR JYOTI KRISHNATREYA, DAVID G. GRIER, Department of Physics and Center for Soft Matter Research, New York University, New York, NY 10003, CENTER FOR SOFT MATTER RESEARCH, NEW YORK UNIVERSITY TEAM — Holographic optical tweezers allow trapping of colloidal spheres in fluid in three dimensions. In-line digital holographic microscopy yields time-resolved information on the three dimensional distribution of material in a sample. Analysis of in-line holographic images of diffusing colloidal spheres provides their three dimensional positions with nanometer resolution. We studied diffusion of colloidal spheres in three dimensions as a function of distance from boundary by analyzing particle trajectories generated by blinking optical tweezers and digital holographic microscopy. From the trajectories we calculated the particle-particle and particle-wall hydrodynamic interactions as a function of distance from the boundary. The results will help in understanding interactions between micron-sized colloidal particles near a boundary.

2:42PM T48.00002 Non-contact microrheology at the air-water interface¹, THOMAS BOATWRIGHT, University of California, Irvine, ROIE SHLOMOVITZ, ALEX LEVINE, University of California, Los Angeles, MICHAEL DENNIN, University of California, Irvine — Mechanical properties of biological interfaces, such as cell membranes, have the potential to be measured with optical tweezers. We report on an approach to measure air-water interfacial properties through microrheology of particles near, but not contacting, the surface. An inverted optical tweezer traps beads of micron size or greater in the bulk, and can then translate them perpendicular to the interface. Through the measurement of thermally driven fluctuations, the mobility of the particle is found to vary as a function of submerged depth and the boundary conditions at the interface. Near a rigid wall, the mobility is confirmed to decrease in a way consistent with Faxén's law. Very close to the free air-water interface, the mobility changes with the opposite sign, increasing by about 30% at the surface, consistent with recent calculations by Shlomovitz and Levine. In addition, the presence of a Langmuir monolayer at the interface is found to significantly change the mobility of the particle close to the interface. With an accurate theory, it should be possible to infer the shear modulus of a monolayer from the fluctuations of the particle beneath the interface. Since particles are not embedded in the monolayer, this technique avoids impacting the system of study.

2:54PM T48.00003 Competing effects of inertia in passive microrheology¹, TSUTOMU INDEI, JAY

SCHIEBER, ANDRÉS CÓRDOBA, Department of Chemical and Biological Engineering, Illinois Institute of Technology — Single-point passive microrheology is generalized to account for both bead and medium inertia, and to incorporate a nonlinear optical trap or elastic trap. We first show that inertial motion of the bead couples with the elasticity of the viscoelastic material, resulting in a resonant oscillation of the mean-square displacement (MSD) of the bead well beyond the time scales of bead inertia. However, this prediction is rather different from both the original result of GSER and what is typically observed for viscoelastic materials. We next show that medium inertia tends to attenuate the oscillations because it dissipates bead energy by radiation of transverse sound waves through the Basset force. Thus, bead inertia competes with medium inertia for the MSD's oscillation. We find that it is sufficient to damp bead oscillations via Basset forces when the bead density is $> 4/7$ of the fluid density, independent of most other details in the system. We also show that the non-conservative forces that exist in an optical trap [Roichman et al., PRL, **101**, 128301 (2008)] also result in circulation in a viscoelastic medium. However, the rates are not sufficiently rapid to excite elastic modes.

3:06PM T48.00004 High bandwidth linear viscoelastic properties of complex fluids from the measurement of their free surface fluctuations, BASILE POTTIER, LAURENCE TALINI, CHRISTIAN FRÉTIGNY, PPM-D-SIMM

— We present a new optical method to measure the linear viscoelastic properties of materials, ranging from complex fluids to soft solids, within a large frequency range (about $0.1\text{--}10^4$ Hz). The surface fluctuation specular reflection technique is based on the measurement of the thermal fluctuations of the free surfaces of materials at which a laser beam is specularly reflected. The propagation of the thermal surface waves depends on the surface tension, density, and complex viscoelastic modulus of the material. For known surface tension and density, we show that the frequency dependent elastic and loss moduli can be deduced from the fluctuation spectrum. Using a viscoelastic solid (a cross-linked PDMS), which linear viscoelastic properties are known in a large frequency range from rheometric measurements and the time-temperature superposition principle, we show that there is a good agreement between the rheological characterization provided by rheometric and fluctuation measurements. We also present measurements conducted with complex fluids that are supramolecular polymer solutions. The agreement with other low frequency and high frequency rheological measurements is again very good, and we discuss the sensitivity of the technique to surface viscoelasticity.

3:18PM T48.00005 Holographic microrefractometer, HAGAY SHPAISMAN, BHASKAR J. KRISHNATREYA, DAVID G.

GRIER, Department of Physics and Center for Soft Matter Research, New York University, New York, NY 10003 — In-line holographic microscopy of micrometer-scale colloidal spheres yields heterodyne scattering patterns that may be interpreted with Lorenz-Mie theory to obtain precise time-resolved information on the refractive index of the suspending medium. We demonstrate this method's efficacy with measurements on calibrated refractive index standards, and apply it to measurements of varying Sucrose concentration in a microfluidic channel. Using commercial colloidal spheres as probe particles and a standard video camera for detection yields volumetric refractive index measurements with a resolution approaching 10^{-3} RIU for each probe particle in each holographic snapshot. The combination of spatial resolution, temporal resolution, multi-point *in situ* access and technical simplicity favor this approach for cost-effective lab-on-a-chip applications.

3:30PM T48.00006 Studying colloidal particles on an emulsion droplet with digital holographic microscopy, JEROME FUNG, Harvard University, Dept. of Physics, REBECCA W. PERRY, Harvard University, School of Engineering and Applied Sciences, THOMAS G. DIMIDUK, Harvard University, Dept. of Physics, VINOTHAN N. MANOHARAN, Harvard University, Dept. of Physics and School of Engineering and Applied Sciences

— Interactions between colloidal particles at a curved liquid-liquid interface remain poorly understood. We study how the interactions between micron-sized polymethyl methacrylate (PMMA) particles bound to the surface of $\sim 5\text{ }\mu\text{m}$ decane droplets dispersed in an aqueous continuous phase influence the particle dynamics. We track the 3D position of up to 6 particles moving on a droplet by imaging particle-laden droplets with digital holographic microscopy and fitting the recorded holograms with Lorenz-Mie scattering calculations. We demonstrate particle tracking with ~ 10 nm precision in all directions at up to millisecond frame rates, which allows the study of rapid particle motions. In addition, we use negative dielectrophoresis to keep the droplets far away from the walls of our sample holders during imaging. Our measurements probe the interparticle interactions and allow us to determine particle contact angles *in situ*.

3:42PM T48.00007 Brownian motion goes ballistic¹, ERNST-LUDWIG FLORIN, University of Texas at Austin

— It is the randomness that is considered the hallmark of Brownian motion, but already in Einstein's seminal 1905 paper on Brownian motion it is implied that this randomness must break down at short time scales when the inertia of the particle kicks in. As a result, the particle's trajectories should lose its randomness and become smooth. The characteristic time scale for this transition is given by the ratio of the particle's mass to its viscous drag coefficient. For a $1\text{ }\mu\text{m}$ glass particle in water and at room temperature, this timescale is on the order of 100 ns. Early calculations, however, neglected the inertia of the liquid surrounding the particle which induces a transition from random diffusive to non-diffusive Brownian motion already at much larger timescales. In this first non-diffusive regime, particles of the same size but with different densities still move at almost the same rate as a result of hydrodynamic correlations. To observe Brownian motion that is dominated by the inertia of the particle, i.e. ballistic motion, one has to observe the particle at significantly shorter time scales on the order of nanoseconds. Due to the lack of sufficiently fast and precise detectors, such experiments were so far not possible on individual particles. I will describe how we were able to observe the transition from hydrodynamically dominated Brownian motion to ballistic Brownian motion in a liquid. I will compare our data with current theories for Brownian motion on fast timescales that take into account the inertia of both the liquid and the particle. The newly gained ability to measure the fast Brownian motion of an individual particle paves the way for detailed studies of confined Brownian motion and Brownian motion in heterogeneous media.

4:18PM T48.00008 Imaging dynamics and transitions in colloidal clusters¹, REBECCA W. PERRY, Harvard

University, School of Engineering and Applied Sciences, THOMAS G. DIMIDUK, Harvard University, Dept. of Physics, JESSE W. COLLINS, Harvard University, School of Engineering and Applied Sciences, JEROME FUNG, GUANGNAN MENG, Harvard University, Dept. of Physics, VINOTHAN N. MANOHARAN, Harvard University, Dept. of Physics and School of Engineering and Applied Sciences — We use digital holographic microscopy to measure the relative motions of particles in colloidal clusters containing micron-sized spherical particles interacting through short-range attractions. These clusters explore many configurations as they approach their equilibrium states. Furthermore, clusters formed with weak interactions continue to transition between equal-energy configurations. We solve the challenge of tracking closely-packed, thermally-driven colloidal spheres in three dimensions by fitting the holograms using an exact solution for the scattering from multiple spheres. The method allows us to track each sphere with 10 nm precision in all three dimensions with millisecond time resolution.

4:30PM T48.00009 Holography of Cells fitted to DDA scattering solutions, THOMAS DIMIDUK, JEROME FUNG, REBECCA PERRY, Harvard, RYAN MCGORTY, UCSF, VINOTHAN MANOHARAN, Harvard — Understanding the dynamics of cells is important to many areas of biophysics. Digital Holography offers a way to observe these dynamics at high speed, in 3D, in relatively native conditions. I will present work studying single cell dynamics through in-line digital holography. To quantify the motion of subcellular components, we fit our holograms to models of scattering based on the Discrete Dipole Approximation. In particular, we apply the technique to determine the fluctuations of the cell membrane. The technique allows us to interrogate the cells over a broad range of time scales, from 10^{-3} s up to the time scale for cell division.

4:42PM T48.00010 Holographic deconvolution microscopy for high resolution particle tracking¹, LISA DIXON, FOOK CHIONG CHEONG, DAVID GRIER, New York University — Rayleigh-Sommerfeld back-propagation can be used to generate a volumetric reconstruction of the light field responsible for the recorded intensity in an in-line hologram. Deconvolving the three dimensional light intensity with an optimal kernel derived from the Rayleigh-Sommerfeld propagator itself emphasizes the objects responsible for the scattering pattern while suppressing undesired artifacts. Bright features in the deconvolved volume may be identified with such objects as colloidal spheres and nanorods. Tracking their thermally-driven Brownian motion through multiple holographic video images provides estimates of the tracking resolution, which approaches 1 nm in all three dimensions.

4:54PM T48.00011 Measuring Nanoparticle Dynamics with Real-Time, 3D Tracking, KAN DU, Center for Nanoscale Science and Technology at National Institute of Standard and Technology, University of Maryland, ANDREW BERGLUND, Center for Nanoscale Science and Technology at National Institute of Standard and Technology — Nanoparticles in liquids are an important platform for nanofabrication and nanomanufacturing processes. Few *in situ* methods are available for measuring the time-resolved dynamics of individual nanoparticles at nanoscale spatial resolution. Drawing on recent advances in real-time single-particle feedback control, we have developed an apparatus that enables us to measure the 3D motion and dynamics of individual fluorescent nanoparticles in liquid environments. Real-time feedback control methods enable us to monitor the dynamics of individual nanoparticles by locking them in focus in an optical microscope, which enhances both the temporal and spatial resolution of our instrument. We applied the technique to study diffusion dynamics of polystyrene nanoparticles adsorbed at liquid-liquid interfaces. This tool can also be applied to study nanoparticle binding, self-assembly processes, and single-molecule biophysics.

5:06PM T48.00012 Nano-domains of high viscosity and stiffness mapped in the cell membrane by thermal noise imaging, YUNHSIANG HSU, ARND PRALLE, University at Buffalo, SUNY — The cell membrane is thought to contain spatial domains, created by cholesterol-lipid clusters and by interactions with the membrane cytoskeleton. The influence of these domains on membrane protein mobility and cell signaling has clearly been demonstrated. Yet, due to their small size and transient nature, the cholesterol stabilized domains cannot be visualized directly. We show here that thermal noise imaging (TNI) which tracks the diffusion of a colloid labeled membrane protein with microsecond and nanometer precision, can visualize cholesterol stabilized domains, also known as lipid rafts, in intact cells. Using TNI to confine a single membrane protein to diffuse for seconds in an area of 300nm x 300nm provides sufficient data for high resolution maps of the local diffusion, local attraction potentials and membrane stiffness. Using a GPI-anchored GFP molecule to probe the membrane of PtK2 cells we detect domains of increased membrane stiffness, which also show increased viscosity and are the preferred location for the GPI-anchored protein. These domains are further stabilized by addition of ganglioside cross linking toxins and disappear after removal of the cholesterol.

5:18PM T48.00013 Fluorescence correlation spectroscopy enumerate the number of nanoparticles in optical confinement, YI HU, XUANHONG CHENG, H. DANIEL OU-YANG, Lehigh University — In the presence of an optical trap, both the concentration and diffusion dynamics of the nanoparticles near the center of the laser focus are affected. This phenomenon could affect the interpretation of the result from fluorescence correlation spectroscopy (FCS) where highly focused laser is often used. A recent Monte Carlo simulation study shows, for non-interacting particles under trapping energy up to 2 kT, the zero-time autocorrelation function $G(0)$ can be used to enumerate the mean number of particles N in the trap. It is not clear, however, how particle interactions or higher trapping will affect this prediction. To address these issues, we conducted FCS experiments to examine $G(0)$ as a function of trapping energy and particle interaction strength. We discovered that $G(0) = 1/N$ is true up to 6 kT as long as the particle interactions are negligible. As the particle interaction is increased, the validity of the above relation quickly breaks down. We interpret our experimental finding based on the consideration of Poisson statistics.

Session T49 DMP DPOLY: Focus Session: Organic Electronics and Photonics: Structure - Property Correlations 162A

2:30PM T49.00001 Correlating the efficiency and nanomorphology of polymer blend solar cells utilizing resonant soft x-ray scattering, HONGPING YAN, BRIAN COLLINS, ELIOT GANN, NCSU, CHENG WANG, ALS, HARALD ADE, NCSU, CHRISTOPHER MCNEILL, Monash Univ — Enhanced scattering contrast afforded by resonant soft x-ray scattering (R-SoXS) is used to probe the nanomorphology of all-polymer solar cells based on blends of the donor poly(3-hexylthiophene) (P3HT) with the acceptor either poly((9,9-dioctylfluorene)-2,7-diyl-alt-[4,7-bis(3-hexylthien-5-yl)-2,1,3-benzothiadiazole]-2',2''-diyl) (F8TBT) or poly([N,N'-bis(2-octyldodecyl)-11 naphthalene-1,4,5,8-bis(dicarboximide)-2,6-diyl]-alt-5,5'-(2,2'-12 bithiophene)) (P(NDI2OD-T2)). A bimodal distribution of domain sizes is observed for P3HT:P(NDI2OD-T2) blends with small domains of ~ 5 - 10 nm that evolve with annealing and larger domains of ~ 100 nm insensitive to annealing. P3HT:F8TBT blends in contrast show a broader distribution but with the majority structured on 10 nm length scale. For both blends an evolution in device performance is observed, correlated with a coarsening and purification of domains on the 5 - 10 nm length scale. Grazing-Incidence Wide Angle X-ray Scattering (GI-WAXS) reveals 25 - 40 nm thick P(NDI2OD-T2) crystallites embedded in the larger domains observed by R-SoXS. A higher degree of P3HT crystallinity is observed in blends with P(NDI2OD-T2) compared to F8TBT. The propensity of the polymers to crystallize in P3HT:P(NDI2OD-T2) blends is also observed to hinder the morphological development on the sub-10 nm length scale. More broadly, this work also highlights the complementarity of R-SoXS and GI-WAXS.

2:42PM T49.00002 Hierarchical Nanomorphologies Promote Exciton Dissociation in Polymer: Fullerene Bulk Heterojunction Solar Cells¹, WEI CHEN, SETH DARLING, Center for Nanoscale Materials, Argonne National Laboratory — In the last fifteen years, research efforts have led to organic photovoltaic (OPV) devices with power conversion efficiencies (PCEs) up to ~8%, but these values are still insufficient for the devices to become widely marketable. To further improve solar cell performance a thorough understanding of the complex structure-property relationships in the OPV devices is required. In this work, we demonstrated that the OPV active layer of PTB7:fullerene bulk heterojunction (BHJ) solar cells, which set a historic record of PCE (7.4%), involves hierarchical nanomorphologies ranging from several nanometers of crystallites to tens of nanometers of nanocrystallite aggregates in PTB7-rich and fullerene-rich domains, themselves hundreds of nanometers in size. These hierarchical nanomorphologies with optimum crystallinity and intermixing of PTB7 with fullerenes are coupled to significantly enhanced exciton dissociation, which consequently contribute to photocurrent, leading to the superior performance of PTB7:fullerene BHJ solar cells. New insights of performance-related structures afforded by the current study should aid in the rational design of even higher performance polymeric solar cells.

¹W. Chen gratefully acknowledges financial support from Argonne Director's Postdoctoral Fellowship. This work is partially supported by a University of Chicago-Argonne Strategic Collaborative Initiative Seed Grant.

2:54PM T49.00003 Unexpected Morphological Traits of Bulk Heterojunction Organic Solar Cells with Exceptional Power Conversion Efficiencies, JOHN TUMBLESTON, BRIAN COLLINS, North Carolina State University, ANDREW STUART, University of North Carolina, ZHE LI, Monash University, HONGPING YAN, North Carolina State University, CHRISTOPHER MCNEILL, Monash University, WEI YOU, University of North Carolina, HARALD ADE, North Carolina State University — The synthesis of new polymers for polymer/fullerene bulk heterojunction solar cells has boosted the power conversion efficiency (PCE) of these devices to levels now exceeding 5%. Even with these advancements in efficiency, relatively little is known of the morphological characteristics of the active layer including domain size and purity, material crystallinity and orientation, and miscibility of the bulk heterojunction components. Herein, we employ a suite of soft and hard x-ray scattering and microscopy techniques to probe defining traits of the morphology for the high-performing polymers, poly[4,8-(3-butylthiophenyl)benzo[1,2-b:4,5-b']dithiophene-*alt*-2-(2-butyloctyl)-5,6-difluoro-2H-benzo[d][1,2,3]triazole] (BnDT-FTAZ) and thieno[3,4-b]thiophene-*alt*-benzodithiophene (PTB7) blended with phenyl-C61-butyric acid methyl ester (PC₆₁BM) and PC₇₁BM, respectively. PCEs of 7.4% for BnDT-FTAZ and 5.3% for PTB7 based solar cells are achieved when processing methods result in smaller, more mixed polymer/fullerene phases where non-zero miscibility is measured for each system. Furthermore, the polymers do not strongly crystallize in the active layer and average domain sizes larger than 50 nm are noted for both systems.

3:06PM T49.00004 Correlating Free-Carrier production in P3HT with Solid-State Microstructure using Time-Resolved Microwave Conductivity¹, GARRY RUMBLES, NREL — The nature of the primary photoexcitation in conjugated polymers has been a subject of interest for a number of years, and two models have emerged: neutral excitons and free charge carriers. While excitons are recognized as the dominant of the two species, there are a small fraction of carriers that appear directly upon photoexcitation that have been detected experimentally either spectroscopically or through conductivity measurements. The fraction of near-instantaneous free charge carriers produced depends both on the chemical structure of the polymer and on the time-scale on which the study is performed. For example, poly(3-hexylthiophene) (P3HT) thin films have been reported to have free carrier yields as high as 15%, when measured on a fast time scale, but as low as 3% when measured on a slow time scale. It is unclear why these numbers are so different, and from where these carriers originate. This presentation will report studies using flash photolysis, time-resolved microwave conductivity (fp-TRMC) to probe carriers produced in a number of thin films of P3HT of differing molecular weights. By correlating the free carrier yield with the solid-state microstructure of the polymer, and the corresponding electronic absorption spectra, we will propose a model that explains the origins of these carriers.

3:42PM T49.00005 Controlling Active Layer Morphology in Polymer/Fullerene Solar Cells, SUCHANUN MOUNGTHAI, NIKHILA MAHADEVAPURAM, GILA STEIN, University of Houston — The active layer in most polymer solar cells is based on the bulk heterojunction (BHJ) design. BHJs are prepared by arresting the phase separation of a polymer/fullerene blend to produce a nanoscale, interpenetrating network. Such non-equilibrium structures are very difficult to control and reproduce, posing a significant challenge for fundamental structure-property investigations. We demonstrate a new approach to control the active layer morphology with a simple two-step process: First, a thin film of poly(3-hexylthiophene) (P3HT) is cross-linked into stable nanostructures or microstructures with electron-beam lithography [1]. Second, a soluble fullerene is spun-cast on top of the patterned polymer to complete the heterojunction. Significantly, irradiated P3HT films retain good optoelectronic properties and bilayer P3HT/fullerene heterojunctions yield power-conversion efficiencies near 0.5%. We have performed preliminary studies with model nanostructured devices and we find that efficiency increases with interfacial area [2]. These model devices are very valuable for fundamental studies because the interfacial area is accurately measured with small-angle X-ray scattering, and the active layer can be “deconstructed” for imaging with atomic force microscopy.

3:54PM T49.00006 The Miscibility of PCBM in Low Band-Gap Conjugated Polymers in Organic Photovoltaics, HUIPENG CHEN, Department of Chemistry, University of Tennessee, WEI YOU, Department of Chemistry, University of North Carolina, JEFF PEET, Konarka Technologies, JASON AZOULAY, GUILLERMO BAZAN, Center for Polymers and Organic Solids The University of California, Santa Barbara, MARK DADMUN, Department of Chemistry, University of Tennessee — Understanding the morphology of the photoactive layer in organic photovoltaics (OPVs) is essential to optimizing conjugated polymer-based solar cells to meet the targeted efficiency of 10%. The miscibility and interdiffusion of components are among the key elements that impact the development of morphology and structure in OPV active layers. This study uses neutron reflectivity to correlate the structure of low band gap polymers to their miscibility with PCBM. Several low band gap polymers that exhibit power conversion efficiencies exceeding 7%, including PBnDT-DTfBT were examined. The intermixing of low band-gap polymer and PCBM bilayers was monitored by neutron reflectivity before and after thermal annealing, providing quantification of the miscibility and interdiffusion of PCBM within the low band gap polymer layer. These results indicate that the miscibility of PCBM ranges from 3% to 26% with the low band-gap polymers studied. The correlation between low band gap polymer structure and miscibility of PCBM will also be discussed.

4:06PM T49.00007 Self-assembly Columnar Structure in Active Layer of Bulk Heterojunction Solar Cell¹, CHENG PAN, JENNIFER SEGUI, YINGJIE YU, HONGFEI LI, Stony Brook University, BULENT AKGUN, SUSHIL K. SATIJA, National Institute of Standards and Technology, DILIP GERSAPPE, Stony Brook University, CHANG-YONG NAM, Brookhaven National Laboratory, MIRIAM RAFAILOVICH, Stony Brook University — Bulk Heterojunction (BHJ) polymer solar cells are an area of intense interest due to their flexibility and relatively low cost. However, due to the disordered inner structure in active layer, the power conversion efficiency of BHJ solar cell is relatively low. Our research provides the method to produce ordered self-assembly columnar structure within active layer of bulk heterojunction (BHJ) solar cell by introducing polystyrene (PS) into the active layer. The blend thin film of polystyrene, poly (3-hexylthiophene-2,5-diyl) (P3HT) and [6,6]-phenyl C₆₁ butyric acid methyl ester (PCBM) at different ratio are spin coated on substrate and annealed in vacuum oven for certain time. Atomic force microscopy (AFM) images show uniform phase segregation on the surface of polymer blend thin film and highly ordered columnar structure is then proven by etching the film with ion sputtering. TEM cross-section technology is also used to investigate the column structure. Neutron reflectometry was taken to establish the confinement of PCBM at the interface of PS and P3HT. The different morphological structures formed via phase segregation will be correlated with the performance of the PEV cells to be fabricated at the BNL-CFN.

4:18PM T49.00008 Dissipative Particle Dynamics Studies of Rod-Coil Polymer Nanocomposites¹, CHARLES STARBIRD, DONGSHENG ZHANG, ARTHI JAYARAMAN, University of Colorado at Boulder — Organic solar cell efficiency depends strongly on the morphology within the active layer consisting of donor (e.g. conjugated polymer) and acceptor (e.g. fullerene derivative) materials. Higher device efficiency can be obtained if the donor-acceptor morphology has high interfacial area, small domains, and continuous pathways. One way to control donor-acceptor morphology is via copolymerization of the conjugated “rod” polymer and an acceptor “coil” block. Past theory and experimental studies have characterized the phase behavior of pure rod-coil block copolymers. In this talk we will present dissipative particle dynamics simulation studies of composites of symmetric rod-coil block copolymers and nanoscale additives of varying selectivity (rod-, coil- and non-selective). With increasing volume fraction of non- and rod- selective nanoadditives we see a shift in the liquid crystalline and microphase transitions to lower temperatures, and new morphologies (e.g. helical twists in rod block domain and zig-zag lamellae) not seen in pure symmetric rod-coil polymers. These shifts in phase transition are explained by where the nanoadditives reside, which in turn is dictated by where the system can maximize enthalpic gain and minimize loss of nanoadditive translational entropy.

4:30PM T49.00009 Model Hamiltonian for predicting the bandgap of conjugated systems, ANDRE LEITAO BOTELHO, YONGWOO SHIN, XI LIN, Division of Materials Science and Engineering, Boston University — We calculate the bandgaps for conjugated systems using the adapted Su-Schrieffer-Heeger Hamiltonian and find good agreement with 130 independent experimental points. The 2D version of the model correctly demonstrates the decrease in bandgap from the addition of vinylene bridges to both poly(*p*-phenylene) and polythiophene indicating that planarization is not a significant effect. Expanding the model to 3D shows that interchain interactions systematically reduces the bandgap. In fused rings sharing dissimilar bonds, such as in isothianaphthene, the bond length dimerization along the carbon backbone decreases leading to a decrease in the bandgap. In contrast, when fusing two of the same rings along equivalent bonds, for example thienoacene, the bandgap change is less than 10% at best when normalized by the number of carbon atoms in the conjugation path. From porphyrin and pyrrole-benzothiadiazole we learn that tautomerization significantly affects the bandgap, as the ϵ value for NH had to be used for both NH and N, indicating that H is being shared by both. In modeling donor-acceptor co-polymers we accurately calculate the reduction in the bandgaps when compared to their parent homopolymers.

4:42PM T49.00010 The Effect of Side-Chain Length on the Solid-State Structure and Optical Properties of F8BT: A DFT Study¹, MOHAMMAD JAVAD ESLAMIBIDGOLI, JOLANTA B. LAGOWSKI, Memorial University of Newfoundland — Using the long-range corrected hybrid density functional theory (DFT/B97D) approach, we have performed bulk solid state calculations to investigate the influence of side-chain length on the molecular packing and optical properties of poly (9,9-di-n-octylfluorene-alt-benzothiadiazole) or F8BT. Two different packing structures, the lamellar and nearly hexagonal, were obtained corresponding to longer and shorter side-chains respectively. This behavior can be attributed to the micro-phase separations between the flexible side-chains and the rigid backbones and is in agreement with previous investigations for other hairy-rod polymers. In addition, as a result of the efficient inter-chain interactions for the lamellar structure, the dihedral angle between the F8 and BT units is reduced providing a more planar configuration for the backbone which leads to the decreased band gap (by 0.2-0.3 eV) in comparison to the hexagonal phase and the gas phase with no side-chain. Time-dependent DFT (TDDFT/B3LYP) was also used to study the excited states of the monomer of F8BT optimized in solid-state structures with different side-chain lengths. It is found that the absorption spectrum is red shifted for the polymers with lamellar structure relative to the polymers in hexagonal and gas phases.

¹Sun Microsystems Canada Inc (Graduate Fellowship administrated by ACEnet at Memorial University)

4:54PM T49.00011 Polymer blend photovoltaics with conjugated block copolymers as surfactants, CHANGHE GUO, MATTHEW WITMAN, KIARASH VAKHSHOURI, Pennsylvania State University, RAFAEL VERDUZCO, Rice University, ENRIQUE GOMEZ, Pennsylvania State University — Conjugated polymer blend photovoltaics are a class of devices where the active layer is composed of a polymer acceptor and a polymer donor. These devices suffer from macrophase separation in the active layer, where it is challenging to kinetically trap domains with characteristic sizes below micron length scales. Thus, for mixtures of poly(3-hexylthiophene) (P3HT) and poly((9,9-dioctylfluorene)-2,7-diyl-alt-[4,7-bis(thiophen-5-yl)-2,1,3-benzothiadiazole]-2',2''-diyl) (PFOTBT), we have synthesized a conjugated block copolymer to act as an A/B surfactant and stabilize a microstructure. The performance of devices where the active layer is composed of P3HT, PFOTBT, and P3HT-PFOTBT block copolymer blends is found to depend on the composition of the mixture and processing conditions. In addition, we have utilized energy-filtered transmission electron microscopy to characterize the morphology of the blends and correlated the microstructure with device performance.

5:06PM T49.00012 ABSTRACT WITHDRAWN —

5:18PM T49.00013 Self-assembly and characterization of two-component films of semiconducting nanoparticles, YIPENG YANG, NAGARJUNA GAVVALAPALLI, HARIHARA VENKATRAMAN, MINA BAGHGAR, MICHAEL BARNES, DHANDAPANI VENKATARAMAN, ANTHONY DINSMORE, University of Massachusetts Amherst — Polymer-based semiconducting materials are promising candidates for large-scale, low-cost photovoltaic devices. To date, the efficiency of these devices has been low in part because of the challenge of optimizing molecular packing while also obtaining a bicontinuous structure with a length scale of approximately 10nm. Here we demonstrate an alternative approach to solving this problem by packing nanoparticles of electron- and hole-transporting semiconductors into a two-component film. We first make nanoparticles of semiconducting materials (P3HT, PCBM, CdSe, etc) suspended in liquid. Then a binary suspension of nanoparticles is dried onto a non-volatile liquid surface to form a solid, two-component film with uniform thickness. The absorbance, photoluminescence, structure, and charge mobility of the films are measured. For a range of stoichiometries, we obtain bicontinuous structures and significant luminescence quenching, indicating charge transfer. This study shows that two-component nanoparticulate films may be an effective route toward bulk heterojunctions with controlled morphology. We acknowledge support from the US Department of Energy, Office of Basic Energy Sciences, through grant DE-SC0001087.

Wednesday, February 29, 2012 2:30PM - 5:30PM –

Session T50 DPOLY: Focus Session: Phase Behavior and Structure in Copolymers 162B

2:30PM T50.00001 Self-assembly of semiflexible-flexible block copolymers, ARUN KUMAR, VENKAT

GANESAN, The University of Texas at Austin — We apply self-consistent Brownian dynamics simulations to study the self-assembly behavior of semiflexible-flexible block copolymers. A Maier-Saupe interaction model was applied for the orientational interactions between the semiflexible polymers, while the enthalpic interactions between semiflexible and flexible polymers were modeled through a standard Flory-Huggins approach. To develop a physical understanding of the phases and their regimes of occurrence as a function of varying persistence length of the semiflexible block, we computed the 2D phase diagram for our model. We quantify the progression of the self-assembly morphologies in transitioning from coil-coil block copolymers on the one hand to rod-coil block copolymers on the other hand. The results obtained are in qualitative agreement with the existing experimental and numerical results.

2:42PM T50.00002 Effect of chain shape on the self-assembly of bioinspired block copolymers

, ADRIANNE M. ROSALES, HANNAH K. MURNEN, University of California, Berkeley, RONALD N. ZUCKERMANN, Lawrence Berkeley National Laboratory, RACHEL A. SEGALMAN, University of California, Berkeley — Polymer chain shape has been shown to affect both polymer properties and block copolymer self-assembly. Polypeptoids, a class of sequence-specific bioinspired polymer, have a chain shape that can be tuned by the introduction of monomers with bulky, chiral side chains, allowing one to change the polymer conformation while preserving the chemical nature of the side chains. Here, it is shown that introducing chiral, aromatic monomers into the polypeptoid chain increases the glass transition by 20 C for a chiral, helical polypeptoid compared to its achiral, non-structured analog. Incorporation of these polypeptoids into block copolymers with poly(methyl acrylate) enables a systematic study of the effect of chain shape while maintaining similar enthalpic interactions. For two otherwise analogous block copolymers, conformational asymmetry is shown to affect both the morphological domain spacing and the order-disorder transition temperature. Future work will focus on interfacial segregation experiments to determine the effect of conformational asymmetry on the Flory-Huggins parameter.

2:54PM T50.00003 Processing-Dependent Self-Assembly of Protein-Polymer Diblock Copolymers

, C.S. THOMAS, L. XU, B.D. OLSEN, MIT — Self-assembly of globular protein-polymer diblock copolymers is a novel method for nanopatterning protein-based materials which maintains a high fraction of protein activity as well as the folded protein structure. By subjecting these copolymers to different processing conditions, long range ordering and the fraction of active protein can be controlled. Here, self-assembly of model mCherry-b-poly(N-isopropyl acrylamide) (PNIPAM) block copolymers is induced by water evaporation from dilute aqueous solutions of conjugate material, and followed by solvent annealing of the resulting nanostructures. Different pathways towards self-assembly are accessed by orthogonally manipulating the solvent quality for each block of the copolymer using temperature and pH. Small-angle scattering and transmission electron microscopy show nanostructure depends heavily on PNIPAM coil fraction and solvent annealing condition, with solution self-assembly reflected in the solid state structure under certain conditions. Protein structure is unaffected by the processing pathway, while protein activity levels in the nanodomains depend strongly on processing conditions and can retain up to 80% of the initial activity.

3:06PM T50.00004 Helical Ordering in Chiral Block Copolymers, WEI ZHAO, SUNG WOO HONG, DIAN CHEN,

GREGORY GRASON, THOMAS RUSSELL, University of Massachusetts Amherst — Introducing molecular chirality into the segments of block copolymers can influence the nature of the resultant morphology. Such an effect was found for poly(styrene-*b*-L-lactide) (PS-*b*-PLLA) diblock copolymers where hexagonally packed PLLA helical microdomains (H* phase) form in a PS matrix. However, molecular ordering of PLLA within the helical microdomains and the transfer of chirality from the segmental level to the mesoscale is still not well understood. We developed a field theoretic model to describe the interactions between segments of chiral blocks, which have the tendency to form a “cholesteric” texture. Based on the model, we calculated the bulk morphologies of chiral AB diblock copolymers using self-consistent field theory (SCFT). Experiments show that the H* phase only forms when microphase separation between PS and PLLA block happens first and crystallization of PLLA block is suppressed or happens within confined microdomain. Hence, crystalline ordering is not necessary for H* phase formation. The SCFT offers the chance to explore the range of thermodynamic stability of helical structures in the phase diagram of chiral block copolymer melts, by tuning parameters not only like the block segregation strength and composition, but also new parameters such as the ratio between preferred helical pitch to the radius of gyration and the Frank elastic constant for inter-segment distortions.

3:18PM T50.00005 Phase Behavior of Binary Blends of AB+AC Block Copolymers with compatible B and C blocks

, VICTOR PRYAMITSYN, VENKAT GANESAN, University of Texas at Austin — Recently the experimental studies of phase behavior of binary blends of PS-*b*-P2VP and PS-*b*-PHS demonstrated an interesting effect: blends of symmetric PS-*b*-P2VP and shorter symmetric (PS-*b*-PHS) formed cylindrical HEX and spherical BCC phases, while each pure component formed lamellas. The miscibility of P2VP and PHS is caused by the hydrogen bonding between P2VP and PHS, which can be described as a negative Flory χ -parameter between P2VP and PHS. We developed a theory of the microphase segregation of AB+AC blends of diblock copolymers based on strong stretching theory. The main result of our theory is that in the copolymer brush-like layer formed by longer B chain and shorter C chains, the attraction between B and shorter C chains causes relative stretching of short C chains and compression of longer B chains. The latter manifests in an excessive bending force towards the grafting surface (BC|AA interface). Such bending force causes a transition from a symmetric lamella phase to a HEX cylinder or BCC spherical phases with the BC phase being a “matrix” component. In a blend of asymmetric BCC sphere forming copolymers (where B and C segments are the minor components), such bending force may unfold BCC spherical phase to a HEX cylinder phase, or even highly uneven lamella phases.

3:30PM T50.00006 Universality in block copolymers: a corresponding states hypothesis

, JENS GLASER, JIAN QIN, PAVANI MEDAPURAM, DAVID MORSE, Dept. of Chemical Engineering and Materials Science, University of Minnesota — Phase behavior and fluctuations of very long block copolymers are well described by self-consistent field theory, and by the random-phase (RPA) approximation for concentration fluctuations. The SCF / RPA predicts behavior that depends on only a few dimensionless parameters. More sophisticated coarse-grained theories instead suggest an extended form of this principle of corresponding states, in which the behavior is predicted to depend on one additional parameter, the independent degree of polymerization $\bar{N}$. We are testing this prediction by comparing extensive computer simulations of several different coarse-grained simulation models of AB diblock copolymer melts. We utilize a novel simulation methodology based on graphical processing unit (GPU) accelerated hybrid molecular dynamics / Monte Carlo replica exchange simulations on a cluster of many GPUs. We present data for off-lattice models with soft- and hard-core non-bonded interactions, and a lattice model, comparing simulations of different models that are designed to have matched values of $\bar{N}$. The results provide extremely strong evidence for the corresponding states hypothesis, which is found to remain accurate even for chains that are much too short to be accurately described by SCFT or the RPA.

3:42PM T50.00007 Manipulating triblock copolymer morphology using tapered block interfaces

, WEI-FAN KUAN, THOMAS H. EPPS, III, University of Delaware — Tapered block copolymers offer the opportunity to manipulate copolymer segregation strengths independently of the molecular weight and chemical constituents. This independent control allows the design of materials with designer interactions and improved mechanical properties, while retaining the desired self-assembled nanostructures. The tapered interfaces between blocks have been shown to significantly decrease the effective interaction parameters between blocks, leading to lower order-to-disorder transition temperatures relative to corresponding non-tapered block copolymers. In this work, we synthesized a series of tapered triblock copolymers using a combination of anionic polymerization, atom transfer radical polymerization, and click chemistry. Comparing the morphologies of our tapered and non-tapered triblock copolymers suggests that the phase behavior of the tapered materials can differ from the non-tapered triblock materials due to the manipulated interfacial profile.

3:54PM T50.00008 Manipulating the morphological behavior of ABA triblock copolymers with block polydispersity, ADAM SCHMITT, MAHESH MAHANTHAPPA, University of Wisconsin-Madison — As an extension of our ongoing efforts to understand the effects of middle B segment polydispersity on the melt-phase behavior of ABA triblock copolymers, we describe the morphological consequences of block polydispersity in the context of poly(lactide-*b*-1,4-butadiene-*b*-lactide) (LBL) triblock copolymers. The complete melt-phase behavior of 52 well-defined LBL triblock copolymers was evaluated using a combination of synchrotron small-angle X-ray scattering (SAXS) and transmission electron microscopy (TEM). Through careful comparisons with monodisperse copolymer control samples, we show that block polydispersity causes large shifts in the composition-dependent phase windows in a manner consistent with previous reports. However, these polydisperse LBL triblocks do not exhibit the substantial domain dilation observed in more weakly segregated SBS triblock copolymers. Based on these observations, we discuss the possibility of using block polydispersity as a new means of tailoring the morphological behavior of microphase separated ABA triblock copolymers.

4:06PM T50.00009 Phase Behavior of Linear ABC Tri Block-Random Copolymers with a Semicrystalline Endblock, BRYAN BECKINGHAM, RICHARD REGISTER, Princeton University — The solid-state structure of semicrystalline block copolymers is set either by block incompatibility or by crystallization of one or more blocks. A variety of solid-state morphologies may be observed depending on the block interaction strength, ranging from spherulitic to confined crystallization within preexisting microphase-separated domains. We aim to explore crystallization from both homogeneous and microphase-separated melts and to characterize the resulting solid-state structure of linear ABC "block-random" copolymers that incorporate a semicrystalline polyethylene endblock. Linear triblock copolymers, poly[butadiene-*b*-isoprene-*b*-(isoprene-*r*-styrene)], are synthesized via anionic polymerization. Two hydrogenation schemes are then applied, either complete saturation of all double bonds or a selective saturation of only diene units. Both schemes yield semicrystalline polyethylene endblocks but dissimilar interblock segregation strengths. In both derivatives of a 30-14-14 kg/mol triblock-random copolymer, small-angle x-ray scattering reveals the formation of a well-ordered three-domain lamellar melt from which crystallization of the polyethylene endblock proceeds. Crystal orientation within the lamellae has been determined by wide-angle x-ray scattering after lamellar orientation in a channel die. We are currently varying relative block and overall molecular weights, and the block sequence to further explore these materials.

4:18PM T50.00010 Discovering Complex Ordered Phases of Block Copolymers, AN-CHANG SHI, McMaster University — Block copolymers with their rich phase behavior and ordering transitions have become a paradigm for the study of structured soft materials. Understanding the structures and phase transitions in block copolymers has been one of the most active research areas in polymer science in the past two decades. One of the achievements is the self-consistent field theory (SCFT), which provides a powerful framework for the study of ordered phase of block copolymers. I will present a generic strategy to discover complex ordered phases of block copolymers within the SCFT framework. Specifically, a combination of real-space and reciprocal-space techniques is used to explore possible ordered phases in multiblock copolymer melts. These candidate phases can then be used to construct phase diagrams. Application of this strategy to linear and star ABC triblock copolymers has led to the discovery of a rich array of ordered phases.

4:54PM T50.00011 Thermodynamic Behavior of Poly(1,4-isoprene-*b*-DL-lactide) Diblock Copolymers, TIMOTHY M. GILLARD, SANGWOO LEE, FRANK S. BATES, University of Minnesota — The phase behavior of a series of poly(1,4-isoprene-*b*-DL-lactide) (IL) diblock copolymers near the order-disorder transition temperature (T_{ODT}) was investigated using a combination of dynamic mechanical spectroscopy (DMS), small angle x-ray scattering (SAXS) and differential scanning calorimetry (DSC). IL copolymers of relatively low molecular weight ($\sim 2.5 - 6$ kg/mol) formed ordered phases with experimentally accessible T_{ODTs} due to the large segment-segment interaction parameter (χ_{IL}). The order-disorder transitions were accompanied by distinct signatures in the DSC traces, where the magnitude of the latent heat of the ODT (ΔH_{ODT}) depends strongly on the ordered phase morphology. Symmetric compounds exhibited almost no hysteresis in the onset temperature for ordering and disordering, indicative of an absence of a nucleation barrier, while asymmetric IL diblocks displayed considerable hysteresis. These findings will be discussed in the context of composition fluctuation effects in the disordered melt near T_{ODT} .

5:06PM T50.00012 Direct Comparisons among Fast Off-Lattice Monte Carlo Simulations, Integral Equation Theories, and Gaussian Fluctuation Theory for Disordered Symmetric Diblock Copolymers, DELIAN YANG, JING ZONG, QIANG WANG, Department of Chemical and Biological Engineering, Colorado State University — Based on the same model system of symmetric diblock copolymers as discrete Gaussian chains with soft, finite-range repulsions as commonly used in dissipative-particle dynamics simulations, we directly compare, without any parameter-fitting, the thermodynamic and structural properties of the disordered phase obtained from fast off-lattice Monte Carlo (FOMC) simulations¹, reference interaction site model (RISM) and polymer reference interaction site model (PRISM) theories, and Gaussian fluctuation theory. The disordered phase ranges from homopolymer melts (i.e., where the Flory-Huggins parameter $\chi = 0$) all the way to the order-disorder transition point determined in FOMC simulations, and the compared quantities include the internal energy, entropy, Helmholtz free energy, excess pressure, constant-volume heat capacity, chain/block dimensions, and various structure factors and correlation functions in the system. Our comparisons unambiguously and quantitatively reveal the consequences of various theoretical approximations and the validity of these theories in describing the fluctuations/correlations in disordered diblock copolymers. [1] Q. Wang and Y. Yin, *J. Chem. Phys.*, **130**, 104903 (2009).

5:18PM T50.00013 The power spectrum of thermal composition fluctuations in a lamellar mesophase, AUGUST BOSSE, Polymers Division, NIST — We derive an analytic expression for the power spectrum of Gaussian thermal composition fluctuations in an ordered lamellar mesophase. We compare this expression to the power spectrum measured in stochastic simulations of a two-dimensional diblock copolymer melt based on the Leibler-Brazovskii Hamiltonian. The analytic expression fits the simulation data with zero adjustable fitting parameters over a relatively wide range of model parameters. This expression will facilitate line-edge roughness (LER) modeling in block copolymer directed self-assembly applications, and it can serve as a model component in a scattering-based LER metrology framework.

Wednesday, February 29, 2012 2:30PM - 5:30PM –
Session T52 GSNP: Non-equilibrium Systems, Especially using Fluctuation Theorems and Fluctuation-Dissipation Relations 153C

2:30PM T52.00001 Transient and steady state behavior of full counting statistics in thermal transport, BIJAY AGARWALLA, BAOWEN LI, JIAN-SHENG WANG, National University of Singapore — We study the statistics of heat transferred in a given time interval t_M , through a finite harmonic system, which is connected with two heat baths, maintained at two different temperatures. We calculate the cumulant generating function (CGF) for heat transfer using non-equilibrium Green's function method. The CGF can be concisely expressed in terms of Green's functions of the system and the self-energy of the lead with shifted arguments, $\Sigma^A(\tau, \tau') = \Sigma_L(\tau + \hbar x(\tau), \tau' + \hbar x(\tau')) - \Sigma_L(\tau, \tau')$, where $\Sigma_L(\tau, \tau')$ is the contour-ordered self-energy of the left lead. The expression of CGF is valid in both transient and steady state regimes. We present a transient result of the first four cumulants of a graphene junction. It is found that measurement causes the energy to flow into the leads. In the steady state we show that the CGF obey “*steady state fluctuation theorem*”. We also study the CGF for the joint probability distribution of left and right lead heat flux $P(Q_L, Q_R)$, which is important to calculate the correlations between Q_L and Q_R , and also the total entropy that flows into the leads. We also discuss the CGF for the total entropy production for two lead system without the center part.

2:42PM T52.00002 Langevin dynamics beyond the weak coupling limit, ALEXANDER PLYUKHIN, Saint Anselm College — Many popular results of non-equilibrium statistical mechanics hold only in leading order in a small parameter λ which controls the strength of the system-environment coupling. In this approximation the equations for the first two moments $\langle v \rangle$ and $\langle v^2 \rangle$ of the Brownian particle's velocity are closed and describe exponential relaxation to thermal equilibrium. To higher orders in λ these equations are not closed but coupled to higher moments $\langle v^n \rangle$. This may result in much richer dynamics (both transient and stationary) and non-trivial ergodic properties. Generalized fluctuation-dissipation relations are derived microscopically and shown to ensure convergence to thermal equilibrium to any order in λ . One exception is the regime of superlinear diffusion, characterized by zero integral friction (vanishing integral of the memory kernel), when the generalized Langevin equation may have non-ergodic solutions that do not relax to equilibrium values. Also, for specific memory kernels the equation may have non-dissipative (non-stationary) solutions even if the integral friction is finite and diffusion is normal.

2:54PM T52.00003 Jarzynski equality for spin glasses and its application, MASAYUKI OHZEKI, Department of Systems Science, Graduate school of Informatics, Kyoto University, KOJI HUKUSHIMA, Department of Basic Science, Graduate School of Arts and Sciences University of Tokyo, HIDETOSHI NISHIMORI, Department of Physics, Tokyo Institute of Technology — We study an application of Jarzynski equality to spin glasses with gauge symmetry. It is shown that the exponentiated free-energy difference appearing in the Jarzynski equality reduces to a simple analytic function written explicitly in terms of the initial and final temperatures if the temperature satisfies a certain condition related to gauge symmetry. This result can be used to derive a lower bound on the performed work during the nonequilibrium process by changing the external magnetic field as well as a pseudo work done during changing temperature. The latter case serves as useful information to implement the population annealing developed in numerical use of the Jarzynski equality to equilibrate the many-body system. We also prove several exact identities that relate equilibrium and nonequilibrium quantities. These identities show possibility of the population annealing to evaluate equilibrium quantities from nonequilibrium computations, which may be useful for avoiding the problem of slow relaxation in spin glasses.

3:06PM T52.00004 Thermodynamic reversibility in feedback processes¹, JORDAN HOROWITZ, JUAN PARRONDO, Universidad Complutense de Madrid — The information acquired during a thermodynamic process with feedback can be converted into useful work. However, the second law of feedback restricts the amount of useful work that can be obtained from this information. In this presentation, I will discuss optimal thermodynamic processes with feedback, where all the information is converted into work. Utilizing the detailed fluctuation theorem for feedback, I will demonstrate that such processes are feedback-reversible: they are indistinguishable from their time-reversal, thereby extending the notion of thermodynamic reversibility to feedback processes.

3:18PM T52.00005 Entropy production in non-equilibrium steady states¹, DANIEL BEN-AVRAHAM, Clarkson University, SVEN DOROSZ, University of Luxembourg, MICHEL PLEIMLING, Virginia Tech — We discuss entropy production in non-equilibrium steady states by focusing on paths obtained by sampling at regular (small) intervals, instead of sampling on each change of the system's state. This allows us to directly study entropy production in systems with microscopic irreversibility. The two sampling methods are equivalent otherwise, and the fluctuation theorem also holds for the different paths. We focus on a fully irreversible three-state loop, as a canonical model of microscopic irreversibility, finding its entropy distribution, rate of entropy production, and large deviation function in closed analytical form, and showing that the observed kink in the large deviation function arises solely from microscopic irreversibility [1].

3:30PM T52.00006 Information, entropy, and heat far from equilibrium¹, SEBASTIAN DEFFNER, University of Maryland — For equilibrium states, the Shannon entropy, $H = - \int d\Gamma p(\Gamma) \ln p(\Gamma)$, coincides with the thermodynamic entropy. It has lately been recognized that for systems in nonequilibrium steady states a thermodynamic description based on H becomes feasible, as well. In the present work we derive various generalizations of the second law for nonequilibrium processes with additional information supplied from an external or an internal memory. We will show that the irreversible entropy production is bounded from below by the information transferred from the memory to the system.

¹This work was funded by the DAAD.

3:42PM T52.00007 Effective temperature determines density distribution in a slowly varying external potential beyond linear response, GRZEGORZ SZAMEL, MIN ZHANG, Department of Chemistry, Colorado State University — We consider a sheared colloidal suspension under the influence of an external potential that varies slowly in space in the plane perpendicular to the flow and acts on one selected (tagged) particle of the suspension. Using a Chapman-Enskog type expansion we derive a steady state equation for the tagged particle density distribution. We show that for potentials varying along one direction only, the tagged particle distribution is the same as the equilibrium distribution with the temperature equal to the effective temperature obtained from the violation of the Einstein relation between the self-diffusion and tagged particle mobility coefficients. We thus prove the usefulness of this effective temperature for the description of the tagged particle behavior beyond the realm of linear response. We illustrate our theoretical predictions with Brownian dynamics computer simulations.

3:54PM T52.00008 ABSTRACT WITHDRAWN —

4:06PM T52.00009 Dynamic phase transitions in large work production of linear diffusion systems, HYUNGGYU PARK, Korea Institute for Advanced Study, CHULAN KWON, Myongji University, JAE DONG NOH, University of Seoul — We present the theoretical study on non-equilibrium (NEQ) fluctuations for diffusion dynamics in high dimensions driven by a linear drift force. We find the time-dependent probability distribution function exactly as well as the NEQ work production distribution $P(W)$ in terms of solutions of nonlinear differential equations. In two dimensions, we find analytically a sequence of dynamic phase transitions in the exponential tail shape of $P(W)$. Their implications and origins are discussed.

4:18PM T52.00010 Driven Langevin dynamics: heat, work and pseudo-work, DAVID SIVAK, Lawrence Berkeley National Laboratory, JOHN CHODERA, University of California, Berkeley, GAVIN CROOKS, Lawrence Berkeley National Laboratory — Common algorithms for simulating Langevin dynamics are neither microscopically reversible, nor do they preserve the equilibrium distribution. Instead, even with a time-independent Hamiltonian, finite time step Langevin integrators model a driven, nonequilibrium dynamics that breaks time-reversal symmetry. Herein, we demonstrate that these problems can be resolved with a Langevin integrator that splits the dynamics into separate deterministic and stochastic substeps. This allows the total energy change of a driven system to be divided into heat, work, and pseudo-work – the work induced by the finite time step. The extent of time-symmetry breaking due to the finite time step can be measured and true equilibrium properties recovered. This interpretation of discrete time step Langevin dynamics as a driven process provides new insights into the practical use of stochastic integrators for molecular simulation.

4:30PM T52.00011 Statistical interpretation of heat and work and the adiabatic theorem in irreversible processes, PURU GUJRATI, University of Akron — By generalizing the traditional concept [1] of heat and work to include their irreversible components allows us to express them in statistical terms so that dW is the *isentropic* energy change; this generalizes the equilibrium adiabatic theorem. Then dQ is then nothing but the energy change solely due to the change in the microstate probability. Accordingly $dQ=TdS$ [2] so that *all powerful aspects of the equilibrium formulation are preserved*, a quite remarkable but unexpected result. The traditional formulation of the first law of thermodynamics, which uses the fields (temperature, pressure, etc.) of the medium can be *equivalently* written as $dE=dQ-dW$ using the fields of the system. This makes the two descriptions using the fields of the medium or the system equivalent and settles the long existing dispute in the literature regarding the proper choice of the fields. Moreover, the use of system fields (including affinities) allows us to analyze non-equilibrium processes such as free expansion between non-equilibrium states, which cannot be analyzed in the traditional approach.

4:42PM T52.00012 Application of the generalized fluctuation-dissipation theorem on a sheared suspension¹, EMMANOUELA FILIPPIDI, ALEXANDRE FRANCESCHINI, DAVID PINE, Center for Soft Matter Research, New York University — We explore the validity of the generalized fluctuation-dissipation theorem for steady-state systems (proposed by Prost, Joanny and Parrondo, PRL 103, 090601 2009) in an experimental system: a suspension of non-colloidal spheres under slow periodic strain. The system is out-of-equilibrium and typically undergoes a phase transition from an active fluctuating to an absorbing state as the strain amplitude is decreased. It is a good candidate for applying the proposed theory since it has Markovian dynamics and fluctuating steady states. The control parameters are the applied strain amplitude and its volume fraction and fluctuations of proper observables such as the individual particle locations can be readily measured. Perturbations of the control parameter of strain can lead in new steady states after a transient response, which in turn can be correlated with the fluctuating observable, thus providing a way of verifying the validity of the proposed version of the generalized fluctuation-dissipation theorem.

4:54PM T52.00013 Entropy rate of non-equilibrium growing networks, ARDA HALU, KUN ZHAO, Northeastern University, SIMONE SEVERINI, University College London, GINESTRA BIANCONI, Northeastern University — In order to quantify the complexity of networks, new entropy measures have recently been introduced. Most of these entropy measures pertain to static networks or to dynamical processes defined on static complex networks. In this talk, we will discuss the entropy rate of growing network models, which quantifies how many labeled networks are typically generated by those growing network models. We will present an analytical evaluation of the difference between the entropy rate of growing tree network models and the entropy of tree networks that have the same asymptotic degree distribution. We will outline our finding that growing networks with linear preferential attachment generated by dynamical models are exponentially less in number than the static networks with the same degree distribution for a large variety of relevant growing network models. We will also discuss the entropy rate for growing network models that show structural phase transitions, including models with non-linear preferential attachment. We will conclude by presenting numerical simulations showing that the entropy rates above and below the structural phase transitions follow a different scaling with the network size.

5:06PM T52.00014 Persistency and Uncertainty Across the Academic Career, ALEXANDER PETERSEN, MASSIMO RICCABONI, IMT Lucca Institute for Advanced Studies, H. EUGENE STANLEY, Boston University, FABIO PAMMOLLI, IMT Lucca Institute for Advanced Studies — Recent shifts in the business structure of universities and a bottleneck in the supply of tenure track positions are two issues that threaten to change the longstanding patronage system in academia and affect the overall potential of science. We analyze the longitudinal publication rate $n_i(t)$ on the 1-year scale for 300 physicists $i = 1...300$. For most careers analyzed, we observe cumulative production acceleration $N_i(t) \approx A_i t^{\alpha_i}$ with $\alpha_i > 1$, reflecting the benefits of learning and collaboration spillovers which constitute a cumulative advantage. We find that the variance in production scales with collaboration radius size S_i as $\sigma_i^2 \sim S_i^\psi$ with $0.4 < \psi < 0.8$. We develop a preferential growth model to gain insight into the relation between career persistency and career uncertainty. This model shows that emphasis on nonstop production, a consequence of short-term contract systems, results in a significant number of “sudden death” careers that terminate due to unavoidable negative production shocks. Hence, short-term contracts may increase the strength of “rich-get-richer” mechanisms in competitive professions and hinder the upward mobility of young scientists.

5:18PM T52.00015 A Random Walk Picture of Basketball, ALAN GABEL, SIDNEY REDNER, Boston University — We analyze NBA basketball play-by-play data and found that scoring is well described by a weakly-biased, anti-persistent, continuous-time random walk. The time between successive scoring events follows an exponential distribution, with little memory between events. We account for a wide variety of statistical properties of scoring, such as the distribution of the score difference between opponents and the fraction of game time that one team is in the lead.

Session T53 GSNP: Focus Session: Wave Propagation in Strongly Scattering Media 153B

2:30PM T53.00001 Fluctuations in Intensity in disordered media as a New Sub-wavelength Microscopy Tool , GABRIEL CWILICH, Department of Physics, Yeshiva University, JUAN JOSE SAENZ, Departamento de Física de la Materia Condensada, Universidad Autonoma de Madrid — The intensity-intensity correlations of waves that propagate coherently through a disordered system are discussed, in the mesoscopic scale. Since many of the properties of those correlations are independent of the transport regime (ballistic, diffusive or localized) they can be discussed using the macroscopic approach of random matrix theory [1]. In that framework we have considered the problem of multiple sources emitting simultaneously in a disordered medium, and we will show that the correlations and even the intensity fluctuations at a fixed point outside the turbid system can provide useful information about both the relative position of the sources and their coherence. Moreover, the information obtained is relevant at subwavelength lengths, opening the possibility of new applications to fluorescence studies, communications and image processing in turbid environments, complementary to traditional techniques.

2:42PM T53.00002 Photon localization in a nematic liquid crystal¹ , JIM MCCLYMER, MATT LUDDEN, University of Maine, Dept. of Physics and Astronomy, JESSE WERTHEIM, None — The nematic liquid crystal MBBA, due to director fluctuations, is a highly scattering material with low absorption. We previously² reported that the transmission coefficient for laser light at 633 nm decays exponentially with a decay length of approximately 0.8 mm while the absorption length is over 30 times larger which we interpret as evidence for photon localization. The data does not fit a model of diffusion or diffusion with absorption. We have extended this work by measuring the decay coefficient for incoherent light from 475 to 825 nm. We find that the absorption remains low over this range, with absorption lengths ranging from 8 mm at the blue end of the spectrum to 12 mm in the near IR. The transmission coefficient in the nematic phase shows an exponential decrease with decay constants an order of magnitude smaller than the absorption length, 0.4 mm, in the blue end while increasing to 3 mm in the near IR. The data indicates that photon localization is observed throughout the visible region into the near IR.

2:54PM T53.00003 Light Transport in Disordered Media with PT-symmetry¹ , SAMUEL KALISH, ZIN LIN, TSAMPIKOS KOTTOS, Wesleyan University — The localization properties of randomly layered optical media with $\mathcal{PT}$ -symmetric refraction index are studied both theoretically and numerically using the transfer-matrix method. The transmission coefficient decays exponentially as a function of the system size, with a rate $\xi_\gamma(W)^{-1} = \xi_0(W)^{-1} + \xi_\gamma(0)^{-1}$, where $\xi_0(W)$ is the localization length of the equivalent passive disordered system and $\xi_\gamma(0)$ is the attenuation/amplification length of the corresponding perfect system with combined gain/loss refraction index profile. While transmission processes are reciprocal to left and right incident waves, one-sided reflection is found.

3:06PM T53.00004 New perspectives on waves in random media: Speckle, modes, transmission eigenchannels, and focusing¹ , AZRIEL GENACK, Queens College of the City University of New York — The understanding of electron localization and conductance fluctuations has been advanced by utilizing notions of speckle, modes, and transmission eigenchannels. These concepts cannot be probed directly for electronic systems but can be explored for classical waves utilizing spectra of field transmission coefficients between arrays of points on the incident and output surfaces of ensembles of random samples. This is illustrated in microwave measurements of transmission through random waveguides in the Anderson localization transition. These experiments supply the link between the statistics of intensity and conductance and show that transmitted wave can be decomposed simultaneously into the underlying quasi-normal modes and transmission eigenchannels of the sample. The power of each of these approaches and the richness of the links between them will be illustrated by examples that reveal new aspects of wave propagation. The delayed onset of transmission following pulse excitation is shown to be the result of destructive interference between highly correlated speckle patterns of neighboring modes, while the falling decay rate at later times reflects the incoherent decay of increasingly prominent long-lived modes. We determine the individual eigenvalues τ_n of the transmission matrix and achieve nearly complete transmission in opaque diffusive samples. We demonstrate that when reflection at the sample interface is taken into account, the spacing between average values of $\ln\tau_n$ is equal to the inverse of the bare conductance, in accord with predictions by Dorokhov [1]. We find that the distribution of total transmission relative to the conductance is determined by the effective number of transmission eigenvalues, $N_{eff} = (\sum_{n=1}^N \tau_n)^2 / \sum_{n=1}^N \tau_n^2$, which provides the link between the statistics of intensity and conductance. For diffusive waves, N_{eff} is the inverse of the degree of intensity correlation. The contrast between the peak and background of maximally focused radiation in the transmitted wave, achieved when the incident is phase conjugated relative to the selected focal point, is equal to $(1 + N_{eff})$.

3:42PM T53.00005 Experimental Observation of Brachistochrone Wave Dynamics in PT Symmetric Structures¹ , JOSEPH SCHINDLER, HAMIDREZA RAMEZANI, ANG LI, MEI ZHENG, TSAMPIKOS KOTTOS, FRED ELLIS, Wesleyan University, Middletown, CT — Mutually coupled modes of a pair of active LRC circuits, one with amplification and another with an equivalent amount of attenuation, provide an experimental realization of a wide class of systems where gain and loss mechanisms break the Hermiticity while preserving parity-time (PT) symmetry. For a value γ_{PT} of the gain and loss strength parameter the eigenfrequencies undergo a spontaneous phase transition from real to complex values, while the normal modes coalesce, acquiring a definite chirality. A dramatic manifestation of PT symmetry is observed in the brachistochrone wave dynamics. Experimental findings support the theoretical prediction of arbitrarily small energy transfer times between the LRC elements of the circuit. We envision that realization of such design strategies can have applications in telecommunications and metamaterial structures.

¹Wesleyan Project Grant, AFOSR No. FA 9550-10-1-0433

3:54PM T53.00006 Experimental studies of PT-scattering in arrays of active LRC elements¹ , ZIN LIN, JOSEPH SCHINDLER, HAMID RAMEZANI, FRED ELLIS, TSAMPIKOS KOTTOS, Wesleyan University, WAVE TRANSPORT IN COMPLEX SYSTEMS TEAM — One of the fundamental tasks in antenna theory is getting an antenna to radiate by removing mismatch losses between the loaded antenna and the transmission line that delivers the power. We will present experimental data suggesting that $\mathcal{PT}$ -symmetric antenna structures, where active elements associated with the real part of impedance ($\pm R$) are involved, can lead to a broadband, reflectionless behavior. The suggested *optimal matching* strategy can potentially be superior to the existing one which uses active LC elements in order to balance the reactance. Along these lines, we also envision antenna arrangements with unidirectional ultrafast communication capabilities, where the signal will transfer faster (or slower) between the active elements of the $\mathcal{PT}$ -structure depending on the entrance point of the incident wave.

¹We acknowledge AFOSR No. FA 9550-10-1-0433 grant and a NSF ECCS-1128571 grant.

4:06PM T53.00007 Measurement of the Probability Distribution of Optical Transmittance on the Crossover to Anderson localization, ZHOU SHI, JING WANG, AZRIEL GENACK, Department of Physics, Queens College of the City University of New York — We report measurements of spectra of the field transmission matrix t for microwave radiation propagating through waveguide filled with randomly positioned dielectric scattering spheres in the Anderson localization transition. Diagonalizing the matrix product $tt^\dagger$ gives the transmission eigenvalues τ_n , which yields the optical transmittance, $T = \sum_{a,b=1}^N |t_{ba}|^2 = \sum_{n=1}^N \tau_n$. The ensemble average of the transmittance is equal to the dimensionless conductance, $g = \langle T \rangle$. We show the probability distribution of transmittance $P(T)$ changes from Gaussian to log-normal as the value of g decreases. The distribution $P(T)$ is analyzed in terms of the underlying transmission eigenvalues τ_n . For random samples with $g \sim 3.9$, we found $P(T)$ follows a Gaussian distribution. For $g \sim 0.37$, we observe a highly asymmetric distribution for $-\ln T$. The sharp drop for high values of T is attributed to the restriction that $\tau_n < 1$ and the repulsion between transmission eigenvalues even for localized samples. For $g \sim 0.04$, the distribution of transmittance is nearly log-normal. The variance of $-\ln T$, σ^2 , scales linearly with $\langle -\ln T \rangle$ as predicted by single parameter scaling even for weakly localized waves.

4:18PM T53.00008 Mode Statistics in Random Media¹, JING WANG, AZRIEL GENACK, Department of Physics, Queens College, The City University of New York — The nature of transport through a material is determined by the spectrum of modes or energy levels. We have analyzed the frequency variation of the transmitted microwave field speckle pattern for quasi one-dimensional random samples to obtain the central frequencies, linewidths and speckle patterns of the modes for an ensemble of samples at lengths of two and three times the localization length. The number of modes can be determined unambiguously from the spectrum of the goodness of fit. From these results we obtain the statistics of mode spacings and widths. The distribution of spacings between adjacent modes is close to the Wigner surmise predicted for diffusive waves exhibiting strong level repulsion. However, deviations from the Wigner surmise can be seen in the distribution of spacings beyond nearest modes. A weakening in the rigidity of the modal spectrum is observed as the sample length increases because of reduced level repulsion for more strongly localized waves. In contrast to residual diffusive behavior for level spacing statistics, the distribution of level widths are log-normal as predicted for localized waves.

¹The research was supported by the NSF under Grant No. DMR-0907285 and a PSC-CUNY grant.

4:30PM T53.00009 A Random Matrix Approach for Understanding Wave Statistics from Wireless Communications to Quantum Dots¹, JEN-HAO YEH, EDWARD OTT, THOMAS ANTONSEN, STEVEN ANLAGE, University of Maryland — Complexity of a wave propagation environment is advantageous from the perspective of wave chaos theory because, in the semiclassical limit, the corresponding ray trajectories of the wave propagation have chaotic dynamical behavior, and a statistical description is most appropriate. Random matrix theory (RMT) successfully describes universal properties of the system. We combine RMT with our random coupling model that includes non-universal effects, such as the radiation impedance of the ports and the effect of short ray trajectories in the system, and we establish a first-principles model for wave statistical properties such as the fading amplitude in wireless communications, the scattering matrix, the impedance matrix, and the thermopower of quantum dots. We also report experimental tests on two ray-chaotic microwave cavities with different degrees of loss. In the high loss regime the results demonstrate that our RMT model agrees with traditional fading models (Rayleigh fading and Rice fading) and provides a more general understanding of the models and a detailed physical basis for their parameters. Moreover, in the low loss regime the RMT approach describes the data better.

¹This work is funded by the ONR/Maryland AppEl Center Task A2 (contract No. N000140911190), the AFOSR under grant FA95500710049, and Center for Nanophysics and Advanced Materials (CNAM).

4:42PM T53.00010 Quantifying Volume Changing Perturbations to a Wave Chaotic System¹, BINIYAM TADDESE, Department of Electrical & Computer Engineering, University of Maryland, College Park, MD 20742-3285, USA, GABRIELE GRADONI, Department of Physics, University of Maryland, College Park, MD 20742-4111, USA, FRANCO MOGLIE, Dip. di Ingegneria dell'Informazione, Università Politecnica delle Marche, Ancona, Italy, THOMAS ANTONSEN, EDWARD OTT, STEVEN ANLAGE, Department of Physics, University of Maryland, College Park, MD 20742-4111, USA — The Loschmidt Echo and Fidelity decay are used to measure perturbations on a quantum wave chaotic system. We extended these concepts to classical waves to detect perturbations. [1]. In this work, we show that volume changing perturbations to a classical wave chaotic cavity can be quantified with a sub-wavelength sensitivity. This is demonstrated both numerically and experimentally. A wave chaotic quasi-1D star graph model [2], was initially used to show the results. The quantification of electrical-volume changing perturbations to a one cubic meter aluminum box will be demonstrated experimentally; the experimental results are also supported by a finite difference time domain simulation of the box. Finally, the approach to quantify these perturbations will be shown to apply to a generic wave chaotic system by using a time domain version of our Random Coupling Model.

4:54PM T53.00011 Nonlinear Time-Reversal in a Wave Chaotic System¹, MATTHEW FRAZIER, BINIYAM TADDESE, EDWARD OTT, THOMAS ANTONSEN, STEVEN ANLAGE, University of Maryland — Time reversal mirrors are particularly simple to implement in wave chaotic systems and form the basis for a new class of sensors [1-3]. These sensors work by applying the quantum mechanical concepts of Loschmidt echo and fidelity decay to classical waves. The sensors make explicit use of time-reversal invariance and spatial reciprocity in a wave chaotic system to remotely measure the presence of small perturbations to the system. The underlying ray chaos increases the sensitivity to small perturbations throughout the volume explored by the waves. We extend our time-reversal mirror to include a discrete element with a nonlinear dynamical response. The initially injected pulse interacts with the nonlinear element, generating new frequency components originating at the element. By selectively filtering for and applying the time-reversal mirror to the new frequency components, we focus a pulse only onto the element, without knowledge of its location. Furthermore, we demonstrate transmission of arbitrary patterns of pulses to the element, creating a targeted communication channel to the exclusion of 'eavesdroppers' at other locations in the system. [1] Appl. Phys. Lett. 95, 114103 (2009) [2] J. Appl. Phys. 108, 1 (2010) [3] Acta Physica Polonica A 112, 569 (2007)

5:06PM T53.00012 Low-Diffracting Modes in Surface Plasmon Metamaterials, SANDEEP INAMPUDI, Department of Physics and Applied Physics, University of Massachusetts Lowell, IGOR SMOLYNONOV, Department of Electrical and Computer Engineering, University of Maryland, VIKTOR PODOLSKIY, Department of Physics and Applied Physics, University of Massachusetts Lowell — Plasmonic structures, with periodic arrays of thin PMMA ridges on metal substrates have been shown experimentally to overcome the diffraction limit. Here we present a theoretical description of this phenomenon. We use mode matching technique to analyze the dynamics of the electromagnetic waves in the periodic systems, taking into account the extended 3D-geometry and the finite thickness of the PMMA ridges. Specifically, we focus on the behavior of plasmonic mode and its non-trivial coupling to the free space waves and to the other guided modes of the system. The eigen states of the periodic system dominated by the surface waves are identified and their dispersion is analyzed via generalization of mode-matching formalism and Bloch-periodic approach. An analytical approximation, adequately describing the behavior of the system is derived and is used to explain the suppression of diffraction in the system.

5:18PM T53.00013 Nonsymmorphic Phononic Metamaterials: shaping waves over multiple length scales¹, CHEONGYANG KOH, DSO National Laboratories, S118230, Singapore, EDWIN THOMAS, School of Engineering, Rice University, P.O. Box 1892, Houston, Texas 77251, USA — The vector nature of the phonon makes rational design of phononic metamaterials challenging, despite potential in unique wave propagation behavior, such as negative refraction and hyper-lensing. While most designs to date focus on the “meta-atom” (building block) design, their “spatial arrangement” (non-locality) is equally instrumental in dispersion engineering. Here, we present a generalized design framework (DF) for PMM design, utilizing both “global” and “local” symmetry concepts. We demonstrate, utilizing specific properties of nonsymmorphic plane groups, PMMs possessing i) a low-frequency in-plane complete spectral gap (ICSG) of 102% (CSG of 88%), ii) a set of polychromatic ICSGs totaling over 100% in normalized gap size. Within the same DF, we further integrate broken symmetry states (BSS) (edge states, waveguides, etc) with designed polarization, (de)localization and group velocities. In particular, we demonstrate how these BSS may be utilized to elucidate signatures of complex polarization fields through phonon-structure interactions, leading to interesting applications in elastic-wave imaging, as well as information retrieval by probing polarization states of scattering bodies over multiple scales.

Wednesday, February 29, 2012 2:30PM - 5:18PM – Session T54 DCMP: Superconductivity: Mostly Spectroscopy and Pairing 152

2:30PM T54.00001 Probing the Photoresponse of Superconducting Materials and Devices by Laser Scanning Microscopy¹, STEVEN ANLAGE², BEHNOOD GHAMSARI, University of Maryland — We present the results of photoresponse experiments on superconducting rf/microwave devices, including Niobium and Cuprate resonators and metamaterials, by means of laser scanning microscopy. The spatially inhomogeneous photoresponse of these devices reveals the distribution of rf/microwave currents. Moreover, it will be discussed that the dependence of the phase of the photoresponse to the exciting microwave frequency may be used to bifurcate the kinetic and resistive parts of the photoresponse mechanism, which, in turn, could be used to probe the evolution of the local order parameter at different temperatures. Furthermore, we will examine the possibility of imaging the anisotropy of superconducting properties, as in the anisotropic Meissner effect, by investigating the photoresponse of a working superconducting resonator to visible light. While most of the aforementioned devices consist of thin films and cast into resonant structures, we will further discuss the techniques through which these measurements can be extended to bulk materials as well as non-resonant structures. These results are particularly useful for identifying the sources of quench and hot spots in a variety of superconducting devices including superconducting RF cavities.

2:42PM T54.00002 Far infrared study of magnetic field induced normal states of $\text{La}_{1.94}\text{Sr}_{0.06}\text{CuO}_4$, THOMAS TIMUSK, Department of Physics and Astronomy, McMaster University, Hamilton ON, Canada, TOOMAS RÖÖM, URMAS NAGEL, DANIEL HÜVONEN, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia, DAVID HAWTHORN, Department of Physics University of Waterloo, Waterloo, ON, Canada, S. WAKIMOTO, H. ZHANG, Department of Physics, University of Toronto, Toronto, ON, Canada, JUNGSEOK HWANG, Department of Physics and Astronomy, McMaster University, Hamilton ON, Canada — We report on the ab-plane optical properties of the magnetic field induced normal state of $\text{La}_{1.94}\text{Sr}_{0.06}\text{CuO}_4$ ($T_c = 5.5\text{K}$), the first such study. We apply strong magnetic fields (4 T and 16 T) along the c-axis. We find that at 4 T fields, which are strong enough to destroy superconductivity, the normal state at 1.4 K is very similar to the normal state at 20 K in zero field. However at higher fields we observed a gap-like depression in the optical conductivity at low frequency along with parallel growth of a broad absorption peak centered at higher frequency. The spectral weight loss in the depression at low frequency is recovered by the spectral weight in the broad peak. We attribute the magnetic field induced gap-like depression and the broad peak to a competing charge order to superconducting order or charge localization in ab-plane of the system.

2:54PM T54.00003 Electron energy loss spectroscopy study of superconducting Nb and its native oxides, RUNZHE TAO, R. TODOROVIC, J. LIU, R. MEYER, A. ARNOLD, University of Illinois at Chicago, W. WALKOSZ, P. ZAPOL, ANL, A. ROMANENKO, L. COOLEY, FNAL, ROBERT KLIE, University of Illinois at Chicago — Niobium has attracted increasing attention in recent years due to its usage in superconducting RF-cavities in next generation particle accelerators. In particular, the possible role of oxidation or the presence of oxygen vacancies on the superconducting properties of niobium metals used in superconducting RF cavities has been the focus on many recent studies. Here, we present a series of electron energy-loss spectroscopy (EELS) studies on niobium (Nb) and its oxides (NbO , NbO_2 , Nb_2O_5) to develop a reliable method for quantifying the oxidation state in mixed niobium oxide thin films. Our approach utilizes a combination of transmission electron microscopy and EELS experiments with density functional theory calculations to distinguish between metallic niobium and the different niobium oxides. Based on these observed changes in the core-loss edges, we propose a linear relationship that correlates the peak positions in the Nb M- and O K-edges with the Nb valence state. The methods developed in this paper will then be applied to ultrathin niobium oxide films to examine the effects of low-temperature baking on the films' oxidation states. In addition to oxides, Niobium hydrides are considered as one of the main reasons for Q-decrease under high field. The different phases of Nb hydride can be identified directly using electron diffraction and EELS, which allows for the local hydrogen concentration to be examined at room temperature as well as 95 K.

3:06PM T54.00004 Strong-Field Pulsed THz Study of Superconductivity Breakdown in NbN ¹, G.L. CARR, Y. SHEN, Y. HIDAKA, J.B. MURPHY, X. YANG, X.-J. WANG, Photon Sciences, Brookhaven National Laboratory — We report the ultra-fast breakdown of the superconducting state in a NbN thin film ($T_c \approx 14\text{K}$) when exposed to an intense single-cycle THz pulse. The THz pulse's transform-limited spectral content was kept below the NbN pair-breaking energy threshold near $2\Delta/\hbar c = 35\text{ cm}^{-1}$ (i.e., $<1\text{ THz}$). Thus, the initial electronic response was dominated by the inductive behavior of the pair condensate. At low THz E-field strength, the NbN film transmitted less for the superconducting state than for the normal state, as expected. As a function of increasing THz E-field strength, the film transmittance remained constant until a threshold range was reached, after which the transmittance changed over to its normal state value. Through this threshold range we also observed a significant non-linear response in the form of THz upconversion to frequencies approaching 3 times the optical gap, corresponding to time scales well below 1 picosecond.

3:18PM T54.00005 ABSTRACT WITHDRAWN —

3:30PM T54.00006 Spatial Complexity Due to Bulk Electronic Liquid Crystals in Superconducting Dy-Bi2212, ERICA CARLSON, BENJAMIN PHILLABAUM, Purdue University, KARIN DAHMEN, University of Illinois at Urbana-Champaign — Surface probes such as scanning tunneling microscopy (STM) have detected complex electronic patterns at the nanoscale in many high temperature superconductors. In cuprates, the pattern formation is associated with the pseudogap phase, a precursor to the high temperature superconducting state. Rotational symmetry breaking of the host crystal (i.e. from C4 to C2) in the form of electronic nematicity has recently been proposed as a unifying theme of the pseudogap phase [Lawler Nature 2010]. However, the fundamental physics governing the nanoscale pattern formation has not yet been identified. Here we use universal cluster properties extracted from STM studies of cuprate superconductors to identify the fundamental physics controlling the complex pattern formation. We find that due to a delicate balance between disorder, interactions, and material anisotropy, the rotational symmetry breaking is fractal in nature, and that the electronic liquid crystal extends throughout the bulk of the material.

3:42PM T54.00007 Search for order parameter domains in single crystal flakes of chiral p -wave superconductor Sr_2RuO_4 using micrometer size Josephson junctions, YIQUN YING, YING LIU, Department of Physics, The Pennsylvania State University, DAVID FOBES, TIJIANG LIU, ZHIQIANG MAO, Department of Physics, Tulane University — Even though the odd-parity, spin-triplet superconductivity in Sr_2RuO_4 is supported by many experimental studies, the existence of order parameter domains and domain walls remains to be an open question. In addition, how these domains can be controlled experimentally is not understood. We fabricate small Al- Sr_2RuO_4 Josephson junctions using flakes of singlecrystalline Sr_2RuO_4 prepared by mechanical exfoliation, using Ti as an interlayer for adhesion purpose. The $3\text{ }\mu\text{m}$ wide junctions defined by photolithography on a natural ac plane was found to show Josephson coupling. Experiments on the effect of domain walls on Josephson coupling and the control of domain walls are being explored. The work is supported by DOE under Grant No. DE-FG02-04ER46159 and Penn State nanofabrication lab.

3:54PM T54.00008 T-linear resistivity and hot Fermi surface from spin-density wave quantum critical fluctuations¹, DOMINIC BERGERON, A.-M. S. TREMBLAY, Universite de Sherbrooke — The linear dependence in temperature T of the resistivity observed in the normal phase of unconventional superconductors is often attributed to quantum critical behavior. We use the two-particle self-consistent (TPSC) approach to the Hubbard model to study this problem. The quantum critical point is associated with a spin-density wave (SDW) phase transition at zero-temperature on the 2D square lattice at finite doping. Our approach satisfies the Mermin-Wagner theorem, the Pauli principle and conservation laws, and is valid from weak to intermediate coupling. We take into account vertex corrections. For the model with nearest neighbors only and also with t' and t'' , we compute, as a function of T , contributions to the conductivity coming from different directions in the Brillouin zone. Our results show that the low temperature resistivity is linear because the whole Fermi surface is hot down to the lowest temperatures studied. This occurs because the SDW correlation length and the thermal de Broglie wavelength both scale as $1/T$.

4:06PM T54.00009 Controlled Intergrowth of 248 and 247 Phases of Y-Ba-Cu-O in Epitaxial Films and Heterostructures¹, H. ZHANG, University of Toronto, N. GAUQUELIN, G.A. BOTTON, Canadian Centre for Electron Microscopy and McMaster University, J.Y.T. WEI, University of Toronto and Canadian Institute for Advanced Research — Recent studies have shown that superconductivity in the Y-Ba-Cu-O (YBCO) family of cuprates can also be rooted in the quasi-1D Cu-O chains [1], even when the CuO_2 planes are not conducting [2]. The critical temperature (T_c) depends on the phase of YBCO present, such as $\text{Y}_2\text{Ba}_4\text{Cu}_8\text{O}_{16}$ (248) and $\text{Y}_2\text{Ba}_4\text{Cu}_7\text{O}_{15}$ (247). Recent studies have also shown that heterostructuring YBCO with other oxides such as $\text{La}_{2/3}\text{Ca}_{1/3}\text{MnO}_3$ (LCMO) can strongly influence the former's T_c [3]. This talk reports on a reexamination of these issues, by probing and controlling the intergrowth of the various YBCO phases in thin films and heterostructures. The samples were grown epitaxially by pulsed laser-ablated deposition, and characterized by electrical transport, XRD and high-resolution TEM with in-situ EELS. We observed the presence of 248 and 247 phases in YBCO/LCMO heterostructures. We also observed conversion between different phases of YBCO depending on the thermodynamics of the growth and annealing conditions. The implication of our results on the T_c variation in YBCO/LCMO heterostructure is discussed.

4:18PM T54.00010 Quantitative measurements of the magnetic field profile in superconductors¹, VLADIMIR KOZHEVNIKOV, Tulsa Community College, ANDREAS SUTER, Paul Scherrer Institute, Switzerland, HELMUT FRITZSCHE, NRC-CNRC Chalk River Laboratories, Canada, KRISTIAAN TEMST, Katholieke Universiteit Leuven, Belgium, THOMAS PROKSCHA, ELVEZIO MORENZONI, Paul Scherrer Institute, Switzerland, MARGRIET VAN BAEI, CHRIS VAN HAESENDONCK, JOSEPH INDEKEU, Katholieke Universiteit Leuven, Belgium — Measurement of the magnetic field profile $B(z)$, z being the distance from the sample surface, in the Meissner state of superconductors is one of the longest standing problems of experimental superconductivity. Importance of $B(z)$ follows, in particular, from the fact, that it provides a direct way to determine the key intrinsic parameters, such as the London penetration depth at zero temperature $\lambda_L(0)$ and the Pippard coherence length ξ_0 . None of these parameters is known with justified uncertainty for *any* superconductor. $B(z)$ can be measured using Low-Energy Muon Spin Rotation spectroscopy (LE- μ SR) and Polarized Neutron Reflectometry (PNR). To verify abilities of these techniques for quantitative measurements of $B(z)$ in unconventional superconductors and to examine the nonlocal electrodynamics effect predicted by Pippard in 1953, we performed an extensive series of cross LE- μ SR and PNR measurements of $B(z)$ with two extreme type-I superconductors, In and Sn. Results obtained at the initial stage of this project were reported last year. Now the project is completed. Results unambiguously validate the nonlocal effect. Conditions which have to be met to use LE- μ SR and/or PNR for measurements of $\lambda_L(0)$ and ξ_0 will be discussed.

¹Supported by NSF, DMR 0904157

4:30PM T54.00011 The critical magnetic field in the intermediate state of a Pippard superconductor¹, VLADIMIR KOZHEVNIKOV, Tulsa Community College, RINKE WIJNGAARDEN, JESSE DE WIT, VU University Amsterdam, The Netherlands, BERT VAN SCHAEYBROECK, Koninklijk Meteorologisch Instituut, Belgium, CHRIS VAN HAESENDONCK, Katholieke Universiteit Leuven, Belgium — One of the fundamental problems of unconventional superconductivity is the magnetic structure of vortices. In order to contribute to the solution of this problem and to address number of unsolved questions of the intermediate state (IS) we undertook an experimental and theoretical study of IS in an extreme type-I superconductor focusing on the critical field of the IS-N (normal) transition. Results shed new light on the structure and evolution of the magnetic flux density in normal domains and may lead to new insights in the structure of vortices in type-II materials. A 2.5 μm thick indium film with mean free path 11 μm was placed in the superconducting vector (3D) magnet. Magneto-optical images were taken simultaneously with measurements of the sample resistance using a small low frequency AC current. The equilibrium domain structure of the IS state was investigated as a function of independently controlled in- and out-of-plane magnetic fields and/or DC transport current applied to the sample. The observed critical field varied in a range from 100% down to 40% of the thermodynamic critical field. A theoretical model based on the classical Landau laminar structure quantitatively accounts for the experimental results for both ordered and disordered domain patterns.

¹Supported by NSF

4:42PM T54.00012 Evidence for s+d wave pairing in copper oxides superconductors from an analysis of NMR and NQR data, ANNETTE BUSSMANN-HOLDER, Max-Planck-Institute for Solid State Research — Knight shift and spin-lattice relaxation rate data of high temperature copper oxide superconductors are analyzed within a two-band model for superconductivity with coupled s+d wave superconducting gaps. The two-gap approach leads to substantial modifications of the coherence factors, which reflects itself in the Knight shift and the relaxation rate $1/T_1T$. From the analysis it is concluded that the data are consistent with 40% s-wave and 60% d-wave gap admixtures in agreement with earlier penetration depth data.

4:54PM T54.00013 Pseudogap studied by optical conductivity spectra of Zn-substituted $\text{YBa}_2\text{Cu}_3\text{O}_y$ ¹, ECE UYKUR, TAKAHIKO MASUI, KIYOHISA TANAKA, SHIGEKI MIYASAKA, SETSUKO TAJIMA, Dept. of Physics, Osaka University, Osaka 560-0043, JAPAN — The pseudogap and the superconducting gap cause a similar suppression of the low energy optical conductivity, but the behaviors of the spectral weight transfers are different, which enables us to distinguish these two gaps. In the c-axis spectra of $\text{YBa}_2\text{Cu}_3\text{O}_y$, however, it is difficult to discuss these spectral weight transfers because of the additional structures due to a transverse Josephson plasma mode [1]. To overcome this problem, we substituted Zn for Cu, which is known to suppress those supplementary structures [2]. In this study, we performed temperature dependent reflectivity measurements in Zn-substituted $\text{YBa}_2\text{Cu}_3\text{O}_y$ system. We have revealed the continuous transfer of the low energy spectral weight to the higher energy region even below T_c , which suggests the coexistence of the pseudogap and the superconducting gap. [1]C. Bernhard et al. Phys. Rev. B, 61 (2000) 618. [2]R. Hauff et al., Phys. Rev. Lett., 77 (1996) 4620.

5:06PM T54.00014 Evidence of gate-tunable topological excitations in two-dimensional electron system, R. KOUSHIK, Department of Physics, Indian Institute of Science, Bangalore, MATTHIAS BAENNINGER¹, VIJAY NARAYAN, Cavendish Laboratory, University of Cambridge, J.J.Thomson Avenue, Cambridge; UK, SUBROTO MUKERJEE, Department of Physics, Indian Institute of Science, Bangalore, MICHAEL PEPPER, Department of Electronic and Electrical Engineering, University College London, Torrington Place, London, IAN FARRER, DAVID RITCHIE, Cavendish Laboratory, University of Cambridge, J.J.Thomson Avenue, Cambridge; UK, ARINDAM GHOSH, Department of Physics, Indian Institute of Science, Bangalore — We report experimental observation of a new mechanism of charge transport in two-dimensional electron systems (2DES) in the presence of strong Coulomb interaction and disorder. We show that at low enough temperature the conductivity tends to zero at a non-zero carrier density, which represents the point of essential singularity in a Berezinskii-Kosterlitz-Thouless (BKT)-like transition. Our experiments with many 2DESs in GaAs/AlGaAs heterostructures suggest the charge transport at low carrier densities to be due to the melting of an underlying ordered ground state through proliferation of topological defects. Independent measurement of low-frequency conductivity noise supports this scenario.

Session U18 Meet the NSF-DMR Program Director and Learn About Funding Opportunities at NSF 252B

5:45PM U18.00001 Meet the NSF-DMR Program Director and Learn About Funding Opportunities at NSF, JANICE HICKS, NSF/DMR Deputy Division Director — The session will include a presentation on the mission and programs of the Division of Materials Research (DMR) of the National Science Foundation (NSF), as well as a description of ongoing and forthcoming research funding opportunities. In addition, attendees will have the opportunity to interact “one on one” with NSF Program Directors present.

Wednesday, February 29, 2012 5:45PM - 7:45PM –
Session U20 DCMP: Town Hall Meeting: Mesoscopic Materials and Chemistry 253C

5:45PM U20.00001 Introduction to Mesoscale Science, JOHN SARRAO, Los Alamos National Laboratory, GEORGE CRABTREE, Argonne National Laboratory — BESAC seeks community input for a forthcoming report on Mesoscale Materials and Chemistry, where classical, microscale and nanoscale science meet. The report, to be released in Fall 2012, will identify the most promising research opportunities in two areas:

- new mesoscale materials, phenomena and functionality
- facilities, instruments and tools needed to make, characterize and describe mesoscale materials, phenomena and functionality.

You may contribute to the Town Hall through oral comments or by completing and uploading a Priority Research Direction quad chart through the Meso website, meso2012.com. If you upload a Priority Research Direction quad chart in advance, it can be projected at the Town Hall to illustrate your oral comments. Please see the Mesoscale Materials and Chemistry website for additional background and details: meso2012.com

6:05PM U20.00002 Community Input —

Wednesday, February 29, 2012 7:30PM - 9:00PM —

Session U60 “Trends” in the APS Publication Physics Westin Boston Waterfront Grand Ballroom A/B

7:30PM U60.00001 Spin Caloritronics: spin-dependent thermoelectrics and beyond, GERRIT E.W. BAUER, IMR, Tohoku University and Kavli Institute, TU Delft — Condensed matter physicists hope to alleviate the various energy crises that threaten our way of life through research into the management and recycling of waste heat by solid state structures and devices. In particular, spin caloritronics investigators study the role of the electron's spin in the flow, control, and transformation of heat currents in magnetic materials in order to add new functionalities and increase the efficiency of existing thermoelectric technology. In this talk I will give an overview of spin caloritronics and explain our present understanding of the underlying physics.

8:00PM U60.00002 Animalcules Redux: The fantastic world of microswimmers, RAYMOND GOLDSTEIN, University of Cambridge — Antony van Leeuwenhoek, the master microscopist, discovered many of the microorganisms that are now so familiar to us. His so-called “animalcules” such as bacteria and algae have been central to the study of problems in biological physics ranging from locomotion to evolution. Recent advances in microscopy, micromanipulation, high-speed imaging, and colloidal physics have led to renewed interest in natural, as well as synthetic, swimming microorganisms – microswimmers. In this talk I will give an overview of some fascinating recent developments, including collective behavior and anomalous transport in suspensions of swimmers, synchronization of flagella and colloidal oscillators, and light-driven multicellular locomotion (phototaxis).

8:30PM U60.00003 Metamaterials, Transformation Optics, and the Science of Invisibility, JOHN PENDRY, Imperial College London — Refractive materials give limited control of light: we can fashion lenses, and construct waveguides, but complete control is beyond simple refracting materials. Ideally we might wish to channel and direct light as we please as if diverting the flow of a fluid. Manipulation of Maxwell's equation using transformation optics shows that we can achieve just that, and metamaterials open the door to this new design paradigm for optics, providing the properties required to give almost complete control of light down to sub wavelength scales. One potential application would be to steer light around a hidden region, creating a cloak of invisibility.

Thursday, March 1, 2012 8:00AM - 11:00AM —

Session V1 GIMS: Focus Session: Advances in Scanned Probe Microscopy III: SPM of Single Atoms & Molecules 203

8:00AM V1.00001 Non-contact friction and the relaxational dynamics of surface defects, JIAN-HUANG SHE, ALEXANDER V. BALATSKY, Los Alamos National Lab — When a cantilever oscillates near a sample surface, it experiences a dissipative force. Such non-contact friction is of great practical importance to the ultrasensitive force detection measurements. Previous theories predict the friction coefficient to be six orders of magnitude smaller than the experimental value. Here, inspired by the recent experiments reported in *Phys. Rev. Lett.* 105, 236103 (2010), we propose two new mechanisms to explain the magnitude, as well as the distance, temperature and frequency dependence of the friction. We assume that the surface defects couple to the cantilever tip either in the spin or charge channel, and their relaxational dynamics gives rise to the observed behavior of both the friction coefficient and the induced spring constant. Nice agreement is found with the experiments.

8:12AM V1.00002 Dissecting an organic-metal bond by molecular manipulation, CHRISTIAN WAGNER, NORMAN FOURNIER, CHRISTIAN WEISS, RUSLAN TEMIROV, F. STEFAN TAUTZ, Peter Gruenberg Institut (PGI-3), Forschungszentrum Juelich, Germany

Scanning probe microscopy with a dynamic AFM has been able to answer some fundamental questions of surface science, like the force necessary to move an atom[1]. Recently, we demonstrated the gradual removal of a single 3,4,9,10-perylenetetracarboxylic-dianhydride (PTCDA) molecule from Ag(111) using a dynamic AFM [2]. The continuous force gradient measurement allowed the structural control over the junction. Here, we show how to extract details of the molecule-surface bonding (physisorption, chemisorption, bonding via functional groups) from such an experiment. The importance of a full-fledged simulation of the lifting -including tip oscillation- is emphasized. We point out the necessity of, and fundamental problems related to, a curved tip trajectory. We study PTCDA on Au(111) and Ag(111) and find qualitatively and quantitatively different binding potentials and adsorption energies. The data represents an ideal benchmark for existing and future ab-initio calculations on these systems. Our method should be applicable to various substrate-adsorbate systems and hence has the potential to answer many open questions in the field.

8:24AM V1.00003 Multi-frequency amplitude modulated non-contact atomic force microscopy for nanoscale dielectric measurements¹, BHARAT KUMAR, JOSEPH BONVALLET, SCOTT CRITTENDEN, University of South Carolina — Multi-frequency non-contact atomic force microscopy with amplitude feedback in air was used to obtain the dielectric constant of ultra-thin films on metallic substrates. The cantilever was excited at its second bending mode by applying an AC electric field between the substrate and cantilever. The capacitance gradient between the cantilever tip and sample substrate was obtained by measuring the capacitive force driving the cantilever at its second bending mode. An analytic expression relating capacitance and dielectric constant of thin film was then used to fit the experimental data and the dielectric constant was obtained from the fit parameters. The method was validated by obtaining the dielectric constants of self-assembled monolayers of thiol molecules (2.0 ± 0.1) on gold substrate, and sputtered SiO₂ (3.6 ± 0.07) thin film. The high Q-factor of the second bending mode of the cantilever increases the accuracy of capacitive measurements while the low applied potentials minimize the likelihood of variation of dielectric constants at high field strength and of damage from dielectric breakdown of air.

8:36AM V1.00004 Anomalously large g -factor of single atoms adsorbed on a metal substrate, JENS WIEBE, ALEXANDER A. KHAJETOORIANS, BRUNO CHILIAN, ROLAND WIESENDANGER, Institute of Applied Physics, Hamburg University, Jungiusstrasse 11, D-20355 Hamburg, Germany, SAMIR LOUNIS, Forschungszentrum Jülich, Peter Grünberg Institut and Institute for Advanced Simulation, 52425 Jülich, Germany, ANTONIO T. COSTA, Instituto de Física, Universidade Federal Fluminense, 24210-340 Niterói, Rio de Janeiro, Brazil, DOUGLAS L. MILLS, Department of Physics and Astronomy, University of California Irvine, California, 92697 USA — We performed magnetic field dependent inelastic scanning tunneling spectroscopy (ISTS) on individual Fe atoms adsorbed on different metal surfaces. ISTS reveals a magnetization excitation which is shifting linearly to higher energies in the magnetic field. The data is used to extract the magnetic anisotropies and the g -factors of the Fe atoms, as well as the lifetimes of the excitations. We find lifetimes of hundreds of femtoseconds limited by coupling to electron-hole pairs in the substrate and decreasing linearly upon application of the magnetic field. As expected, the magnetic anisotropy strongly depends on the substrate. Astoundingly, we find that the g -factor is $g \approx 3.1$ for Ag(111) instead of the regular value of 2 which is observed for the Cu(111) substrate [1]. This very large g -shift can be understood when considering the complete electronic structure of both the Ag(111) surface state and the Fe atom, as shown by *ab initio* calculations of the magnetic susceptibility.

8:48AM V1.00005 Spin Parity effects in STM single magnetic atom manipulation, FERNANDO DELGADO, JOAQUÍN FERNÁNDEZ-ROSSIER¹, International Iberian Nanotechnology Laboratory (INL), Av. Mestre José Veiga, 4715-330 Braga, Portugal — Recent experimental work shows that a spin polarized scanning tunneling microscopy tip can be used both to read and write the spin orientation of a single magnetic spin [1]. Inelastic electron tunneling spectroscopy (IETS) shows that spin of the magnetic atom is quantized [2], like the spin of a molecular magnet. Here we discuss two fundamental problems that arise when a bit of classical information is stored on a quantized spin: quantum spin tunneling and back-action of the readout process. Quantum tunneling is responsible of the loss of information due to the relaxation of the spin coupled to the environment, while the detection induced back-action leads to an unwanted modification of the spin state. We find that fundamental differences exist between integer and semi-integer spins when it comes to both, read and write classical information in a quantized spin.

9:00AM V1.00006 Magnetic Particle Imaging with a Cantilever Detector, JACOB ALLDREDGE, JOHN MORELAND, NIST — We present a novel method for the measurement of the magnetic moment of single micrometer scale particles as a function of the applied field. Our technique is based on magnetic force microscopy (MFM) with a hard magnetic tip in a uniform opposing field. By moving the tip position and using a simple model we can extract the magnetic properties of isolated particles and precisely measure subsurface particle locations in 3D.

9:12AM V1.00007 Scanning Probe Microscopy and Spectroscopy of Molecules on Thin Insulating Films, JASCHA REPP, University Regensburg — Ultrathin insulating films on metal substrates facilitate the use of the scanning tunneling microscope (STM) to study the electronic properties of single atoms and molecules, which are electronically decoupled from the metallic substrate. The ionic relaxations in a polar insulator lead to a charge bi-stability in some adsorbed atoms and molecules. It is shown that control over the charge-state of individual molecules in such systems can be obtained by choosing a substrate system with an appropriate work function. The distribution of the additional charge is studied using difference images. These images show marked intra-molecular contrast [1]. We discuss how atomic-force-microscopy (AFM) in a combined STM/AFM based on the qPlus-sensor [2] reveals additional information that is truly complementary to the STM data set. In the case of a non-planar molecule that shows two different adsorption geometries, only the AFM channel provides reliable information on the conformation of the molecule. In another example of an artificially formed molecule-metal-molecule complex, the AFM channel provides information on the bonding that is important to understand the STM results.

9:48AM V1.00008 Tailoring Dirac Fermions in Molecular Graphene, KENJIRO K. GOMES, WARREN MAR, WONHEE KO, CHARLIE D. CAMP, DOMINIK K. RASTAWICKI, Stanford University, FRANCISCO GUINEA, ICMM CSIC Madrid, HARI C. MANOHARAN, Stanford University — The dynamics of electrons in solids is tied to the band structure created by a periodic atomic potential. The design of artificial lattices, assembled through atomic manipulation, opens the door to engineer electronic band structure and to create novel quantum states. We present scanning tunneling spectroscopic measurements of a nanoassembled honeycomb lattice displaying a Dirac fermion band structure. The artificial lattice is created by atomic manipulation of single CO molecules with the scanning tunneling microscope on the surface of Cu(111). The periodic potential generated by the assembled CO molecules reshapes the band structure of the two-dimensional electron gas, present as a surface state of Cu(111), into a “molecular graphene” system. We create local defects in the lattice to observe the quasiparticle interference patterns that unveil the underlying band structure. We present direct comparison between the tunneling data, first-principles calculations of the band structure, and tight-binding models.

10:00AM V1.00009 Synthesizing and Observing Electric and Magnetic Gauge Fields in Molecular Graphene¹ , DOMINIK RASTAWICKI, CHARLIE D. CAMP, KENJIRO K. GOMES, MING RUE D. THIAN, ALEX W. CONTRYMAN, HARI C. MANOHARAN, WONHEE KO, WARREN MAR, Stanford University — Molecular graphene is an artificial analogue of graphene that can be built using a scanning tunneling microscope (STM). It is realized by constraining surface-state electrons to a honeycomb lattice, which we have shown reproduces the Hamiltonian of natural graphene. We experimentally demonstrate that creating strains within the honeycomb lattice modifies the Hamiltonian in the same way that true laboratory-frame electric and magnetic fields do. In our experiments we have created artificial magnetic fields that can reach values as high as 60 T, and which can change their magnitude significantly over a distance as short as 2 nm. Some of the new physical phenomena we have been able to observe include: gauge invariance for lattices with very different real-space strains but the same artificial fields, emergence of Landau levels due to constant artificial magnetic fields, occurrence of a confined state at an interface straddling a sign-inversion of the effective magnetic field, and effective chemical doping and potential changes associated with applied electric gauge fields.

10:12AM V1.00010 Topologically protected chiral edge state realized on molecular graphene , WONHEE KO, WARREN MAR, KENJIRO K. GOMES, DOMINIK K. RASTAWICKI, CHARLIE D. CAMP, HARI C. MANOHARAN, Stanford University — Graphene has many interesting topological properties arising from the hexagonal lattice shape and sublattice symmetry. Although its edge state is known to be extremely sensitive to the shape of the edge, and is non-topological, it has been shown that graphene with an energy gap produced by broken sublattice symmetry can possess different topologies due to different sign of the carrier mass. By making a junction of two gapped graphene regions with opposite mass, we can realize a topologically protected edge state at the mass domain wall junction, with chirality emerging from the valley degeneracy. Molecular graphene is an artificial honeycomb lattice built by atom manipulation, and due to its extreme tunability, we have realized a topological edge state between gapped molecular graphene regions with opposite signs of Dirac fermion mass. Enhanced density of states restricted only to the junction clearly shows the existence of the edge state. Also, its robustness to the geometrical detail is observed from its persistence over various edge structures, and chirality is revealed by selective scattering at the intersection of edges.

10:24AM V1.00011 Measuring Electronic Properties of Topological Defects in Molecular Graphene , CHARLIE CAMP, DOMINIK RASTAWICKI, KENJIRO GOMES, WONHEE KO, WARREN MAR, MING RUE THIAN, FRANCIS NIESTEMSKI, ALEX CONTRYMAN, CAROLINA GONZALEZ, HARI MANOHARAN, Stanford University — With the development of artificial “molecular” graphene, it is possible to create a two-dimensional electron system very similar to graphene by assembling molecules in the appropriate geometry on surface states using a scanning tunneling microscope (STM) tip. Using this same system, we recreate many lattice defects that occur naturally in graphene. Such defects have a significant effect on the electronic and transport properties of natural graphene, and are thus of notable interest in the development of nanoelectronics. In particular, we study rotational grain boundaries, which are formed by the rotation of a region of graphene with respect to the rest of the lattice. These include the Stone-Wales defect, the simplest with two adjacent carbon sites rotated by 90 degrees, as well as a common larger topological defect recently identified as the flower defect. Using STM, we examine the electronic properties of these defects in molecular graphene, paying particular attention to the emergence of new states close to the Dirac point and the quasiparticle scattering. These geometries are also studied in hole- and electron-doped variants.

10:36AM V1.00012 Scanning Vibronic Spectroscopy of Single Molecules¹ , MING RUE D. THIAN, WARREN MAR, WONHEE KO, KENJIRO K. GOMES, DOMINIK K. RASTAWICKI, CHARLIE D. CAMP, ALEX W. CONTRYMAN, HARI C. MANOHARAN, Stanford University — The dynamics of a single molecule within a quantum point contact or tunnel junction can be quite complex, exhibiting motion over frequency scales ranging from kHz to THz. In this work, we examine in detail the dynamic motion of single molecules by using low-temperature scanning inelastic tunneling, isotopic sorting, and isotopic labeling. Carbon-based molecules such as carbon monoxide, C₆₀, and diamondoids function as prototype homonuclear and heteronuclear molecules. Target structures are assembled on surfaces via atomic manipulation or self-assembly in order to tailor local THz-scale vibrational modes and to control kHz-scale molecular motion. In addition we functionalize a scanning tunneling microscope tip and use its own THz-scale vibrational modes as a probe and a tunable perturbation. These techniques reveal structure not visible in traditional STM data. We compare this data to expected local quantum forces.

10:48AM V1.00013 Pitfalls in normalizing scanning tunneling spectroscopy and how to do it “right” (from an experimentalist perspective) , MICHAEL DREYER, RAMI DANA, ANITA ROYCHOWDHURY, University of Maryland — Scanning tunneling spectroscopy is widely used to probe the local density of states (LDOS) by measuring dI/dV typically using a lock in amplifier. According to theory, the data has to be normalized by (I/V) to reveal the true LDOS - of cause still convoluted with the tip density of states. This process can induce its own artifacts and has to be done carefully. In our case the algorithm includes finding the true bias offset (if any), correct any offset in the measured current, rescale the measured dI/dV curves using the calculated version $(\Delta I/\Delta V)$, replacing $I(V)$ around $V_{\text{bias}} = 0$ by a polynomial and finally performing the normalization. The motivation and consequences of each step will be discussed using example data.

Session V2 GMAG: Invited Session: Spin Caloritronics of Magnetic Structures and Devices
204AB

8:00AM V2.00001 Thermal creation of stronger spin-transfer torque in oscillators and memories, JOHN SLONCZEWSKI, formerly with IBM Research Division — Oscillators and magnetic random-access memories (MRAMs) investigated today rely on spin-transfer torque (STT) carried by an electric current flowing through a magnetic tunnel junction (MTJ) having barrier composition MgO.¹ Experiments confirm the theoretical upper bound $\tau_e=1/2$ on the torque yield (defined as dimensionless torque per unit supplied electric current). This bound limits the performance potential of STT-MRAM in which current supplied by one transistor within each cell switches the information bit. Replacement of electric current with heat flow (supplied by a Joule heater) carried by magnons may provide a greater torque yield τ_h .² The essential structure for this *thermagnonic* spin transfer (TMST) comprises a stack of three nano layers: a spontaneously magnetized insulator (*ferrite* for brevity), a non-magnetic metallic spacer, and the free metallic magnet responding to the transferred torque. Phonons carry most of the heat flowing through the ferrite. But spin-1 magnons also carry a portion of it and deposit pure spin polarization into the spacer whose free electrons transport it to the free magnet. Ferrite-metal interfaces also occur in a spin-Seebeck effect.³ Principles of spin relaxation provide estimates of τ_h based on existing data for sd-exchange, superexchange, and non-magnetic interfacial thermal resistance; τ_h may exceed τ_e by one order of magnitude.⁴ Related results of an FMR spin-pumping experiment⁵ and DFT computations⁶ support the potential of TMST-MRAM. In the case of an oscillator, TMST could increase its efficiency and enable largely independent controls of frequency and output voltage.

8:36AM V2.00002 Spin pumping and spin Seebeck effect, EIJI SAITOH, Institute for Materials Research, Tohoku University — Utilization of a spin current, a flow of electrons' spins in a solid, is the key technology in spintronics that will allow the achievement of efficient magnetic memories and computing devices. In this technology, generation and detection of spin currents are necessary. Here, we review inverse spin-Hall effect and spin-current-generation phenomena recently discovered both in metals and insulators: inverse spin-Hall effect, spin pumping, and spin Seebeck effect. (1) Spin pumping and spin torque in a Mott insulator system We found that spin pumping and spin torque effects appear also at an interface between Pt and an insulator YIG. This means that we can connect a spin current carried by conduction electrons and a spin-wave spin current flowing in insulators. We demonstrate electric signal transmission by using these effects and interconversion of the spin currents [1]. (2) Spin Seebeck effect We have observed, by using the inverse spin-Hall effect [2], spin voltage generation from a heat current in a NiFe, named the spin-Seebeck effect [3]. Surprisingly, spin-Seebeck effect was found to appear even in insulators [4], a situation completely different from conventional charge Seebeck effect. The result implies an important role of elementary excitation in solids beside charge in the spin Seebeck effect. In the talk, we review the recent progress of the research on this effect. This research is collaboration with K. Ando, K. Uchida, Y. Kajiwara, S. Maekawa, G. E. W. Bauer, S. Takahashi, and J. Ieda.

9:12AM V2.00003 Computational spin caloritronics, KE XIA, Department of Physics, Beijing Normal University — Recent experimental and theoretical studies focused on spin-mediated heat currents in at interfaces between metals and insulators, where the latter can be either the barrier in a magnetic tunnel junction or a ferromagnetic insulator. A crucial parameter is the efficiency of spin injection and spin-transfer torque. In this talk, we will report realistic electronic structure calculations for two material systems. 1) The pertinent material parameter governing spin transfer and spin Seebeck effect is the spin mixing conductance that we calculate for the Silver-YIG (Yttrium-Iron-Garnett) interface. This turns out to be much larger than expected from the Stoner model. We find mixing conductance comparable to intermetallic interfaces, a surprising result that can be rationalized in terms of magnetic local moments at the interface. These results imply that the spin-mediated energy and information transmissivity of magnetic insulators is potentially much better than has been measured in early experiment, a result that has been experimentally corroborated very recently by several groups. 2). We demonstrate that the thermal spin-transfer torque (TST) in a junction Fe-MgO-Fe tunnel junctions with ultra thin barriers can amount to 10^{-7} J/m²/K at room temperature, which is estimated to cause magnetization reversal for temperature differences over the barrier of the order of 10 K. The large TST for ultrathin barriers can be explained by multiple scattering due to interface states. Direct evidence for the existence of these states can be obtained by comparing shot noise calculations with recent experiments for high-quality junctions [Arakawa et al., Appl. Phys. Lett. 98, 202103(2011)]. *This work was carried out in collaboration with Xingtao Jia, Kai Liu and Gerrit E.W. Bauer.

9:48AM V2.00004 Magneto-Seebeck effect and thermal torques in magnetic tunnel junctions¹, MARKUS MUENZENBERG, I. Phys. Institute, Georg-August-University Goettingen — Creating temperature gradients in magnetic nanostructures has resulted in a new research direction, i.e., the combination of magneto- and thermoelectric effects. Magnetic tunnel devices, known for application as magnetic sensor in hard disc drives or magnetic random access memories (MRAM) show large magnetoresistance. We show that in nanoscale magnetic tunnel junctions, the Seebeck voltage in a heat gradient can be controlled via the magnetization. The Seebeck coefficient changes during the transition from a parallel to an antiparallel magnetic configuration in a tunnel junction – the magneto-Seebeck effect. In that respect, it is the analog to the tunneling magnetoresistance and thus is called tunneling magneto-Seebeck effect (or tunneling magnetothermopower). The change in Seebeck coefficients is in the order of the voltages known from the charge-Seebeck effect in semiconductors (up to 100 μ V/K). Their size and sign can be delicately controlled by the composition of the electrodes' atomic layers adjacent to the barrier and the temperature and we observe a characteristic sign change from positive to negative magneto-Seebeck effects as theoretically predicted. It is known that generally strong electronic asymmetry at around the Fermi level results in a large Seebeck effect. Here the magnetization dependence of the charge-Seebeck coefficients varying up to >100% for the parallel and the antiparallel originates from the half-metallic like transmission of the tunnel junction. Using heating with ultrafast laser pulses, these thermal gradients can be of up to 20 K across the tunnel barrier. We demonstrate that we can achieve the parameters predicted, where by thermal torques magnetization switching is expected. This allows to conceptually think of MRAM's driven by heat gradients only.

10:24AM V2.00005 Thermomagnonic spin transfer and Peltier effects in insulating magnets¹

ALEXEY A. KOVALEV, University of California at Riverside — The recent discovery of the spin Seebeck effect [1] in metals, insulators and semiconductors stimulated development of spincaloritronics [2]. The possibility of measuring the Onsager reciprocal spin Peltier effect has been investigated recently as well. In our theoretical work [3], we study the fictitious electromagnetic fields induced by magnetic textures which may offer an alternative route for observing the spin Peltier effect. Particularly, in an insulating ferromagnet a moving magnetic texture should effectively drive the spin (wave) current which in turn should lead to the heat current by the spin Peltier effect. We further study the coupled magnon energy transport and collective magnetization dynamics in ferromagnets with magnetic textures. We conclude that the analogy between the fictitious electromagnetic fields and real fields should lead to magnonic counterparts of such effects as the Hall effect, the Ettingshausen effect, the Nernst effect, and the Righi-Leduc effect. By constructing a phenomenological theory based on irreversible thermodynamics, we describe motion of domain walls by thermal gradients and generation of heat flows by magnetization dynamics. From microscopic description based on magnon kinetics, we estimate the transport coefficients and analyze the feasibility of energy-related applications (e.g. nanoscale heat pumps [4]) in insulating ferromagnets, such as yttrium iron garnet and europium oxide. Our estimates show that the viscous coupling effects between magnetization dynamics and magnon flows can be strong in materials with low spin densities (e.g. dilute magnetic systems) and narrow domain walls, which can allow the magnonic manipulation of magnetization dynamics and heat pumping.

Session V3 DCMP: Invited Session: Spin Fluctuations and Cooper Pairing in Unconventional Superconductors 205AB

8:00AM V3.00001 Linear- T scattering and pairing from spin fluctuations in organic supercon-

ductors, NICOLAS DOIRON-LEYRAUD, Université de Sherbrooke — The (TMTSF)₂X series of organic superconductors, with X=PF₆ or ClO₄, are clean single-band metals that exhibit unconventional superconductivity in the vicinity of a pressure-induced spin-density wave (SDW) quantum critical point. As such, they epitomize the interplay between magnetism and superconductivity observed in heavy fermion, cuprate, and iron-pnictide superconductors. We have recently examined the electrical resistivity $\rho(T)$ of (TMTSF)₂X materials as a function of temperature and pressure. At the SDW quantum critical point, we observed a strictly linear temperature dependence of the resistivity over two decades in temperature [1,2]. Moving away from SDW order with increasing pressure, this linear resistivity was found to decrease in parallel with the weakening superconductivity, such that A , the coefficient of the linear contribution to $\rho(T)$, directly correlates with the superconducting T_c [1,2]. This shows that linear- T scattering and superconducting pairing share a common origin. A similar correlation was also found between A and the spin fluctuations seen by NMR experiments [2]. Owing to the quasi-1D nature of the (TMTSF)₂X system, this connection between spin fluctuations, scattering, and superconductivity is well described theoretically by a model that considers the hitherto overlooked mutual reinforcement of SDW and pairing correlations [3]. In particular, the feedback of pairing correlations on SDW fluctuations appears to be decisive for the strength of the linear resistivity and its extent in temperature and pressure. The fact that the same empirical correlation between linear- T resistivity and T_c is observed in the hole-doped [4,5] and electron-doped [6] cuprates, as well as in iron-pnictides [1,4], shows that the same mechanism is at play in these materials. This points to a common, magnetic origin to the superconducting pairing. Work done in collaboration with S. René de Cotret, P. Auban-Senzier, D. Jérôme, C. Bourbonnais, K. Bechgaard, and L. Taillefer.

8:36AM V3.00002 Link between spin fluctuations and Cooper pairing in copper oxide superconductors¹

KUI JIN, Center for Nanophysics & Advanced Materials, Department of Physics, University of Maryland, College Park — Although it is generally accepted that superconductivity is unconventional in the high- T_c cuprates, the relative importance of phenomena such as spin and charge (strip) order, superconductivity fluctuations, proximity to Mott insulator, a pseudogap phase and quantum criticality are still a matter of debate. In electron-doped cuprates, the absence of “anomalous” pseudogap phase in the underdoped region of the phase diagram and weaker electron correlations suggest that Mott physics and other unidentified competing orders are less relevant and that antiferromagnetic (AFM) spin fluctuations are the dominant feature. In this talk, I will report results of low temperature magnetotransport experiments in optimal to overdoped (non-superconducting) thin films of the electron-doped cuprate La_{2-x}Ce_xCuO₄ (LCCO). We find that a linear-in- T scattering rate is correlated with the superconductivity (T_c). Our results show that an envelope of such scattering surrounds the superconducting phase, surviving to 20 mK (the limit of our experiments) when superconductivity is suppressed by magnetic fields [1]. Comparison with similar behavior found in organic superconductors [2] strongly suggests that the linear-in- T resistivity in the electron-doped cuprates is caused by spin-fluctuation scattering. Because linear-in- T scattering has also been linked to T_c in some hole-doped cuprates [2], our results suggest a fundamental connection between AFM spin fluctuations and the pairing mechanism of high temperature superconductivity in all cuprates. In addition, I will discuss how quantum criticality plays a significant role in shaping the anomalous properties of the electron-doped cuprate phase diagram. We identify quantum critical scaling in LCCO with a line of quantum critical points that surrounds the superconducting phase as a function of magnetic field and charge doping [3].

9:12AM V3.00003 Intense paramagnon excitations in a large family of high-temperature superconductors, MATHIEU LE TACON, Max Planck Institute for Solid State Research — Motivated by the search for the mechanism of high-temperature superconductivity, an intense research effort has been focused on the evolution of the spin excitation spectrum upon doping from the antiferromagnetic insulating to the superconducting states of the cuprates. Because of technical limitations, however, the experimental investigation of doped cuprates has been largely focused on excitations with energies ≤ 100 meV in a small range of momentum space [1]. Here we take advantage of the recent developments of high-resolution resonant inelastic x-ray scattering [2,3] to show that a large family of superconductors, encompassing the model compounds $\text{YBa}_2\text{Cu}_4\text{O}_8$ and $\text{YBa}_2\text{Cu}_3\text{O}_7$, exhibits damped spin excitations - or paramagnons - with dispersions and spectral weights closely similar to those of magnons in undoped, antiferromagnetically ordered cuprates over much of the Brillouin zone. The results are in excellent agreement with the spin excitations obtained by exact diagonalization of the $t - J$ Hamiltonian on finite-sized clusters. A numerical solution of the Eliashberg equations based on the experimental spin excitation spectrum of $\text{YBa}_2\text{Cu}_3\text{O}_7$ reproduces its superconducting transition temperature T_c within a factor of two. The discovery of a well-defined, surprisingly simple spin excitation branch over a wide range of doping levels thus strongly supports magnetic Cooper pairing models for the cuprates [4].

9:48AM V3.00004 Magnetically driven superconductivity in CeCu_2Si_2 , OLIVER STOCKERT, Max Planck Institute for Chemical Physics of Solids, Dresden — The origin of unconventional superconductivity, including high-temperature and heavy-fermion superconductivity, is still discussed controversially. Spin excitations instead of phonons are thought to be responsible for the formation of Cooper pairs. Unconventional superconductivity is quite often observed in the vicinity of a magnetic quantum critical point (QCP), i.e., a continuous magnetic phase transitions occurring at $T = 0$. Such a QCP can be approached when tuning a continuous finite temperature phase transition to $T = 0$ by means of a non-thermal control parameter like doping, pressure or magnetic field. As a result of the quantum-critical spin fluctuations unusual low-temperature properties are observed. The heavy-fermion compound CeCu_2Si_2 displays unconventional superconductivity and is already at ambient pressure located in the vicinity of a QCP where long-range antiferromagnetism vanishes. Using elastic and inelastic neutron scattering we studied in detail the antiferromagnetic order and the spin excitations spectrum around the QCP. Antiferromagnetism and superconductivity exclude each other on a microscopic scale. While for magnetically ordered samples critical slowing down of the spin fluctuations above T_N is observed, shows the normal state response of superconducting CeCu_2Si_2 an almost critical slowing down for $T \rightarrow 0$. Its temperature dependence and scaling behavior are in line with the expectations for an itinerant spin-density-wave QCP. This interpretation is substantiated by an analysis of specific heat data and the momentum dependence of the magnetic excitation spectrum. The magnetic response in the superconducting state is characterized by a transfer of spectral weight to energies above a spin excitation gap. Compared to the condensation energy there is a larger saving of magnetic exchange energy as the system condenses into a superconducting state. Our results strongly imply that the coupling of Cooper pairs in CeCu_2Si_2 is mediated by overdamped spin fluctuations.

10:24AM V3.00005 2012 IUPAP C10 Young Scientist Prize on the Structure and Dynamics of Condensed Matter Lecture: Spin Fluctuations and Pairing in Fe-based Superconductors, A.D. CHRISTIANSON, Oak Ridge National Laboratory — The origin of superconductivity in the Fe-based superconductors, like that in other unconventional superconductors, remains shrouded in mystery. How the pairing bosons emerge either due to or in spite of the strong magnetic interactions found in the Fe-based superconductors is one of the most thoroughly investigated questions in the field. A prominent example of the interplay of superconductivity and magnetism is the dramatic shift of spectral weight from the low energy spin excitations to an energy which is related to the superconducting gap resulting in a peak in the spin excitation spectrum localized in both momentum and energy which occurs at the onset of superconductivity. The appearance of the new peak in the spin excitation spectrum below the superconducting transition temperature is referred to as s spin resonance and is most commonly interpreted as indicating a sign change of the superconducting order parameter on different portions of the Fermi surface and thus is consistent with an extended s-wave or $s_{\pm}$ pairing symmetry in many Fe-based superconductors. We will review the observations and implications of the spin resonance across the Fe-based superconductors. In particular we will examine the relationship between the resonance energy and the superconducting transition temperature as a function of chemical doping and pressure. While the spin resonance provides important information about pairing symmetry, there does not appear to be sufficient spectral to explain the pairing strength. Thus the remainder of the spin excitation spectrum must be examined to determine if spin fluctuations are ultimately responsible for pairing in the Fe-based materials. Consequently, we will discuss in detail the way in which the spin excitations evolve from the nonsuperconducting compounds to their superconducting relatives as a function of chemical doping.

Thursday, March 1, 2012 8:00AM - 10:36AM – Session V4 DAMOP: Bosons and Fermions in Optical Lattices 205C

8:00AM V4.00001 Doublon production rate by optical lattice modulation for strongly correlated Fermionic atoms, AKIYUKI TOKUNO, DPMC-MaNEP, University of Geneva, EUGENE DEMLER, Harvard University, THIERRY GIAMARCHI, DPMC-MaNEP, University of Geneva — Currently lattice modulation spectroscopy technique is applied to experiments. [1] In this spectroscopy, the number of doubly occupying atom (doublon) produced by amplitude modulation of an optical lattice potential is probed. Theoretically, it allows us to access a kinetic energy correlation function. [2] We discuss doublon excitations of strongly correlated fermionic atoms in a high-temperature regime relevant to current experiments of fermionic atoms in an optical lattice. [3] We employ a slave particle representation, and the self-energy is estimated by using non-crossing approximation based on a spin-incoherent assumption. Furthermore, this formalism is applied to calculation of the doublon production rate as a function of the lattice modulation frequency, chemical potential and temperature. Using parameters given in the experiment [1], a fit to the experimental data is implemented, and quantitatively good agreement is obtained.

8:12AM V4.00002 Superfluid to normal phase transition in strongly correlated bosons in two and three dimensions, JUAN CARRASQUILLA, MARCOS RIGOL, Georgetown University — Using quantum Monte Carlo simulations, we investigate the finite temperature phase diagrams of hardcore bosons in two- and three-dimensional lattices. To determine the phase boundaries, we perform a finite-size-scaling analysis of the condensate fraction and/or the superfluid stiffness. We then discuss how these phase diagrams can be measured in experiments with trapped ultracold gases, where the systems are inhomogeneous. For that, we introduce a method based on the measurement of the zero-momentum occupation, which is adequate for experiments dealing with both homogeneous and trapped systems, and compare it with previously proposed approaches.

8:24AM V4.00003 Double occupancy as a universal probe for antiferromagnetic correlations and entropy in cold fermions on optical lattices, NILS BLUEMER, ELENA GORELIK, DANIEL ROST, Institute of Physics, Johannes Gutenberg University, Mainz, Germany, THEREZA PAIVA, Instituto de Física, Universidade Federal do Rio de Janeiro, Brazil, RICHARD SCALETTAR, Department of Physics, UC Davis, USA, ANDREAS KLUEMPER, University of Wuppertal, Wuppertal, Germany — We study antiferromagnetic (AF) order and correlations in the half-filled Hubbard model using dynamical mean-field theory, determinantal quantum Monte Carlo (in dimensions $d = 2, 3$), and Bethe Ansatz (in $d = 1$). We establish a low-temperature enhancement of the double occupancy D at strong coupling as a local probe of strong AF correlations accessible in cold-atom experiments [1]. As a function of entropy $s = S/(Nk_B)$, D is nearly universal with respect to dimensionality, with a minimum in $D(s)$ at $s \approx \log(2)$ [2]. The quantum AF Heisenberg regime at $s \lesssim \log(2)$, driven by an abrupt gain in kinetic energy and with clear signatures also in the next-nearest neighbor correlation function, should be in immediate experimental reach. Long-range order appears hardly relevant for the current search of AF signatures in cold fermions. Thus, experimentalists need not achieve $s < \log(2)/2$ (on a cubic lattice) and should consider lower dimensions, for which the AF effects are larger, or even use dimensionality as a tunable parameter.

8:36AM V4.00004 Tunable Phases of Fermionic Cold Atoms Systems in Mixed Dimensions, KYLE IRWIN, SHAN-WEN TSAI, University of California, Riverside — We investigate a system with two species of fermions. One species, f-fermions, moves on a two-dimensional square lattice. Another species, c-fermions, is constrained to move on a one-dimensional lattice embedded in the square lattice of f-fermions. The phases of the effective one-dimensional system whose interactions are mediated by the two-dimensional system can be tuned by manipulating the two-dimensional density. We explore effective theories, quantum phases, correlations, and relevant energy scales for various fillings of the mixed dimensional system using a functional renormalization group approach.

8:48AM V4.00005 Pairing and Density-Wave Phases of Population Imbalanced Fermi-Fermi Mixture on Optical Lattice, CHEN-YEN LAI, CHUNTAI SHI, SHAN-WEN TSAI, University of California Riverside — We study a two species fermion mixture with different populations on a square lattice, which can be modeled by a Hubbard Hamiltonian with on-site inter-species interaction. Such a model can be realized in a cold atom system with fermionic atoms in two different hyperfine states loaded on an optical lattice, and with interaction strength that can be tuned by an external magnetic field. When one of the fermion species is close to half-filling, the system is highly affected by lattice effects. We find several correlated phases for this system, including spin density wave state, d-wave charge density wave state, and p-wave superfluid state for the minority species. We study this system using a functional renormalization group method, determining its phase diagram and providing an estimate for the critical temperature of each phase. These phases emerge from a combination of interaction, population imbalance, and lattice effects. Lattice effects in particular lead to a much richer phase diagram than that of a imbalanced mixture of fermionic gas.

9:00AM V4.00006 ABSTRACT WITHDRAWN —

9:12AM V4.00007 Finite-temperature Properties of the Fermi-Hubbard Model on the Honeycomb Lattice, BAOMING TANG, EHSAN KHATAMI, Georgetown University, THEREZA PAIVA, Universidade Federal do Rio de Janeiro, MARCOS RIGOL, Georgetown University — We study thermodynamic properties of the Fermi-Hubbard model on the honeycomb lattice utilizing the numerical linked-cluster expansion, which is exact in the thermodynamic limit, and quantum Monte Carlo simulations. We obtain the equation of state, double occupancy, entropy and spin correlations for a wide range of temperatures, chemical potentials, and interaction strengths. Employing a local density approximation, we study properties of the system in the presence of a harmonic trapping potential and compare the efficiency of various adiabatic cooling schemes to those obtained for such model on the square lattice.

9:24AM V4.00008 Realizing a fermionic superfluid state from a band insulator in an optical lattice¹, YOGESHWAR P. SARASWAT, AMAL MEDHI, VIJAY B. SHENOY, Indian Institute of Science Bangalore — We propose a route to realizing a fermionic superfluid state in an optical lattice starting from a band insulator. We show that by increasing the strength of attractive interaction between the fermions in the singlet channel, a band insulator can be driven to a superfluid state in an optical lattice. The band structure is suitably designed to avoid other competing states. We estimate the Kosterlitz-Thouless transition temperature of such a superfluid. The proposal could help the realization of a superfluid state of fermions in an optical lattice circumventing the cooling problem.

¹Supported by CSIR, DST and DAE, India

9:36AM V4.00009 A Boson Core Compressibility Measure for Optical Lattices¹, YASAMIN KHORRAMZADEH, FEI LIN, V.W. SCAROLA, Virginia Tech — Trapping in experiments on cold atomic gases in optical lattices leads to inhomogeneity and different phases within the trap. We model a global measure, the boson core compressibility, that can be used to access local properties of a single phase at the center of the trap using observations of double occupancy. We test this measure on the trapped Bose-Hubbard model using mean field theory and quantum Monte Carlo. We find that the boson core compressibility focuses on the core region of the system and eliminates edge effects. We use the core compressibility to identify the transition from Mott insulator to superfluid and show that it is essentially the same as local compressibility in the core region when the system has doubly occupied sites. We generalize the definition of core compressibility to study systems with large densities at the trap center.

9:48AM V4.00010 Numerical studies of exotic paired states in optical lattices¹, SIMONE CHIESA, College William & Mary, SHIWEI ZHANG, College of William & Mary, GEORGE BATROUNI, Institut Non-Linéaire de Nice — Ultracold atoms are a unique tool that allows the exploration of phases of matter not easily accessible in condensed matter systems. Two interesting possibilities are spin-imbalanced systems and spin dependent optical lattices with Fermi surfaces that differ for the two hyperfine species. We use mean-field theory and quantum Monte Carlo simulations of Hubbard-like models with an attractive contact interaction to study the FFLO state and, by rotating the two Fermi surfaces by 90 degrees with respect to each other, a recently proposed exotic paired state [Feiguin and Fisher, 2009].

¹Supported by ARO and NSF.

10:00AM V4.00011 Competing instabilities in a two band Hubbard model on a square lattice, CHUNTAI SHI, SHAN-WEN TSAI, Department of Physics and Astronomy, University of California Riverside — We study a two band Hubbard model on a two dimensional square lattice. In particular, we focus on the cases wherein one band is doped to have a small electron pocket while the other band is doped to have a hole pocket and the Fermi lines of these two pockets are nearly nested. Similar models have been studied extensively in the context related to the Iron-based material where the interactions between electrons are always repulsive. Here we investigate the generalized cases that the interactions between the fermions within the same band U_1 and U_2 and the interactions between electrons in different bands U_{12} can be tuned independently. Such models can potentially be realized in a cold atom system where the manipulation of the interaction is possible by taking advantage of the Feshbach resonance. The freedom of tuning the strength and the sign (repulsive or attractive) of the interactions, combined with the nearly nested Fermi lines, allows both the density wave phases and the pairing phases to be potential candidates for the ground state. We employ the functional renormalization group approach so that we can investigate the competition between these possible instabilities on an equal footing.

10:12AM V4.00012 Condensate Properties for Strongly Repulsive Bosons in a Double Well, JOEL CORBO, UC Berkeley, JONATHAN DUBOIS, LLNL, BIRGITTA WHALEY, UC Berkeley — We present path integral ground state (PIGS) quantum Monte Carlo calculations for the ground state ($T = 0$) properties of repulsively interacting bosons in a three-dimensional external double well potential over a range of interaction strengths and potential parameters. We focus on calculation of ground state number statistics in order to understand the level of squeezing that the system may exhibit as a function of interaction strength. For weak interactions (i.e. where the standard two-mode model of a BEC in a double well is applicable) we produce results consistent with the two-mode model. However, for stronger interactions, we find a novel and somewhat surprising relationship between squeezing and interaction strength. We find that these new features are qualitatively consistent with squeezing calculations carried out using an improved, recently-proposed eight-mode model, although this model is insufficient to quantitatively predict the results of the full quantum Monte Carlo simulation.

10:24AM V4.00013 A Quantum Plasmonic Circuit for Cold Atoms, MICHAEL GULLANS, Harvard University, DARRICK CHANG, California Institute of Technology, JOHANNES FEIST, TOBIAS TIECKE, JEFF THOMPSON, Harvard University, IGNACIO CIRAC, Max-Planck-Institut für Quantenoptik, PETER ZOLLER, Institute for Quantum Optics and Quantum Information of the Austrian Academy of Sciences, MIKHAIL LUKIN, Harvard University — We propose a new architecture for quantum simulation with atoms using a two dimensional lattice of plasmonic nanoparticles to both trap the atoms and mediate interactions between them. This proposal combines existing technologies from ultracold atoms and plasmonics to exploit the unique coherence properties of atoms and the strong light-matter interaction and subwavelength confinement provided by plasmonic systems. We first show that this system allows to increase the energy scales of Hubbard models by two orders of magnitude compared to optical lattices. We then show how this system can realize a dissipative quantum simulator to prepare a wide range of many-body entangled states.

Thursday, March 1, 2012 8:00AM - 11:00AM –
Session V5 DCMP: Surface Electronic & Lattice Properties: Structure, Surface States, & Adsorption 206A

8:00AM V5.00001 Surface energy anisotropy for FCC metals: Functional forms, YAN-JIUN CHEN, MIHIR KHADILKAR, JAMES P. SETHNA, LASSP, Cornell University — The energy of a crystalline surface depends on the angle of the surface normal with respect to the crystalline axes (i.e. the Miller index). We show that the surface energy as a function of angle is surprisingly easy to describe with a simplistic broken bond model including only a few parameters. In particular, this model is successful at capturing the cusps at high symmetry surfaces. We will use our fitted functional form as a characteristic continuum description of material surface energies for FCC metals. The anisotropy of these surface energies can then be utilized in the study of many material properties- equilibrium shapes (Wolff plots) of crystals and voids, fracture mechanics, cleavage and faceting. We calculate the surface energies using ab initio calculations and various interatomic potentials, providing a measure of the fitness of the potentials for studying physical systems with surfaces. Furthermore, we assemble systematic tables of these results, available to the community through the Knowledgebase of Interatomic Models (KIM, <https://openkim.org/>).

8:12AM V5.00002 Explicit consideration of surface structures for work function calculations, SEUNGCHUL KIM, ANDREW M. RAPPE, Department of Chemistry, University of Pennsylvania — We investigate the effects of atomic structure of surfaces on work functions, using density functional theory (DFT) calculations. Despite the well-known orientation dependence of work functions, the effect of geometric structure of surfaces on work functions is rarely considered. To examine whether the atomic structure of a surface is important to the work function, we perform DFT calculations of thick slabs in the periodic supercell. We then extract the energy levels of the occupied states relative to the vacuum level. Surfaces of oxides, such as BaTiO_3 (001), SrTiO_3 (001), and TiO_2 (110), are especially well-tested because of their various reconstructed structures. Our calculations show that, even for the same surface orientation, the difference in stoichiometry and geometry of the surface gives rise to substantially different work functions. This finding strongly implies that the atomic structures of surfaces must be explicitly taken into account in predicting work functions of materials.

8:24AM V5.00003 The role of surface states in inelastic electron tunneling into metal surfaces¹, MINGHU PAN, QING LI, PETER MAKSYMOWYCH, Center of Nanophase Materials Sciences, Oak Ridge National Laboratory, TN, USA 37831 — Inelastic electron tunneling spectroscopy is a highly capable technique to explore dynamic properties of material surfaces, particularly the phonon spectrum. Presently, many of the so-called “propensity” rules that determine the strength of the measured inelastic loss in STM experiments are still unknown or controversial. We have carried out systematic IETS of surface phonons on a Au(111) surface, and spatially-resolved variations in the vibrational spectrum of an adsorbate on the STM tip. In both cases, the IETS intensity markedly dropped at the step edges. At the same time, the IETS intensity exhibits long-range oscillations, the wavelength of which coincided with the Friedel oscillations of the surface state in the vicinity of the defects. All the observations combined, attest to the important role of the surface state in electron-phonon coupling. We will rationalize the observed effects by invoking the symmetry of the tunneling states, with particular emphasis on the effect of the projected band-gap of the gold surface.

¹This research was conducted at the Center for Nanophase Materials Sciences (CNMS), which is sponsored at Oak Ridge National Laboratory by the Office of Basic Energy Sciences, U.S. Department of Energy.

8:36AM V5.00004 Anisotropic Surface State Mediated RKKY Interaction Between Adatoms on a Hexagonal Lattice¹, THEODORE EINSTEIN, University of Maryland, College Park, PAUL PATRONE, University of Maryland, College Park; and NIST Gaithersburg — Motivated by recent numerical studies of Ag on Pt(111), we derive a far-field expression for the RKKY interaction mediated by surface states on a (111) FCC surface, considering the effect of anisotropy in the Fermi edge. The main contribution to the interaction comes from electrons whose Fermi velocity v_F is parallel to the vector $\mathbf{R}$ connecting the interacting adatoms; we show that in general, the corresponding Fermi wave-vector $\mathbf{k}_F$ is not parallel to $\mathbf{R}$. The interaction is oscillatory; the amplitude and wavelength of oscillations have angular dependence arising from the anisotropy of the surface state band structure. The wavelength, in particular, is determined by the component of the aforementioned $\mathbf{k}_F$ that is parallel to $\mathbf{R}$. Our analysis is easily generalized to other systems. For Ag on Pt(111), our results indicate that the RKKY interaction between pairs of adatoms should be nearly isotropic and so cannot account for the anisotropy found in the studies motivating our work.

¹Supported by NSF-MRSEC DMR 05-20471 and NIST-ARRA Grant 70NANB10H026, with ancillary support from CNAM at UMD.

8:48AM V5.00005 Inverse photoemission and LEED investigation of the ion-bombarded Ni(110) surface, BENJAMIN YOUNG, JIM WARNER, DAVID HESKETT, University of Rhode Island — Ion bombardment of the clean Ni(110) surface is investigated by a combination of Inverse Photoemission Spectroscopy (IPES) with a Geiger-Muller detector and Low Energy Electron Diffraction (LEED) with a homebuilt video capture system. Disorder of the surface is induced by argon ion bombardment with various combinations of argon pressure and sputtering time. The intensity of the unoccupied surface state at $\sim 2\text{eV}$ above the Fermi level at the $\bar{Y}$ point of the surface Brillouin zone decreases with increasing surface bombardment. Simultaneously, intensity profiles of diffraction spots in LEED exhibit broadening and a rising background level for increasing surface disorder. Multiple attempts at correlation between the results of the two techniques are presented.

9:00AM V5.00006 Electronic structure of the indium-adsorbed Au/Si(111)- $\sqrt{3} \times \sqrt{3}$ surface: a first-principles study, FENG-CHUAN CHUANG, CHIA-HSIU HSU, WEN-HUAN LIN, Department of Physics, National Sun Yat-sen University, Taiwan, VIDVUDS OZOLINS, Department of Materials Science and Engineering, University of California, Los Angeles, Los Angeles, CA 90095-1595, USA — Electronic structures of the indium-adsorbed Au/Si(111)- $\sqrt{3} \times \sqrt{3}$ surface were examined using first-principles calculations at In coverages range from 0.15 ML to 1 ML. The band structures of the various proposed models were analyzed in detail. Our results show that the calculated bands for the identified atomic models for indium-adsorbed on conjugate honeycomb-chained-trimer model at In coverages of 1/3 ML and 2/3 ML are in agreement with the identified bands in the angle-resolved photoemission study [Phys. Rev. B **80** 075312 (2009)].

9:12AM V5.00007 Lattice relaxation as the origin of the insulating nature of the alkali/Si(111):B surface, LAURENT CHAPUT, CEDRIC TOURNIER-COLLETTA, LOUIS CARDENAS, BERTRAND KIERREN, YANNICK FAGOT-REVURAT, DANIEL MALTERRE, Institut Jean Lamour, PATRICK LEFEVRE, FRANCOIS BERTRAN, synchrotron soleil, ANTONIO TEJEDA, Institut Jean Lamour, AMINA TALEB, synchrotron soleil — *Ab initio* density-functional theory calculations, photoemission spectroscopy (PES), scanning tunneling microscopy, and spectroscopy (STM, STS) have been used to solve the $2\sqrt{3} \times 2\sqrt{3}R30$ surface reconstruction observed previously by LEED on 0.5 ML K/Si:B. It is found that the large K-induced vertical lattice relaxation obtain in the calculations and occurring only for 3/4 of Si adatoms is shown to quantitatively explain both the chemical shift of 1.14 eV and the ratio 1/3 measured on the two distinct B 1s core levels. A gap is observed between valence and conduction surface bands by ARPES and STS which is shown to have mainly a Si-B character using the *ab initio* calculations. Finally, the calculated STM images agree with our experimental results. Therefore, the insulating character of alkali/Si:B interfaces has been captured to an excellent accuracy, from the low lying 1s state of boron, to the unoccupied states above the gap, within a one-electron approach. This work solves the controversy about the origin of the insulating ground state of alkali-metal/Si(111):B semiconducting interfaces which were believed previously to be related to many-body effects

9:24AM V5.00008 First-Principles Study of One-Dimensional Metal-Molecule Hybrid Chains Self-Assembled on Ag Substrate, BON-GIL KOO, YOUNG-KYUN KWON, Department of Physics and Research Institute for Basic Sciences, Kyung Hee University — We explore the formation mechanism and the structural and electronic properties of one-dimensional metal-molecule hybrid chain self-assembled on Ag(111) substrate using *ab initio* density functional theory. It is observed that such a hybrid chain is formed by spontaneous transformation from 4,4''-dibromo-*p*-terphenyl (DBTP) molecules when deposited on Ag(111) substrate at room temperature. We find that the chain is composed of *p*-terphenyl (TP) connected through an Ag atom to form (TP-Ag)_n. Our study shows that Ag(111) surface plays a catalytic role removing two Br atoms (DB) from DBTP and connecting the remaining TP through an Ag atom, which is a similar phenomenon as the Ullmann cross coupling reaction occurred on Cu surface. We find that those Br atoms detached from DBTP play important roles for spontaneous formation of well-aligned pattern. Our calculated electronic structures and simulated scanning tunneling microscopy (STM) images of (TP-Ag)_n hybrid chain exhibit remarkably different charge distributions depending on the energy values, which are related to the tip voltage in STM experiments. We also investigate the end state of the hybrid chain, which can be spatially resolved.

9:36AM V5.00009 Quantum Monte Carlo studies of surface adsorptions, CHING-MING WEI, CHENG-RONG HSING, IAMS, Academia Sinica, Taipei 10617, Taiwan — Surface adsorption is the first step to the study of surface catalytic reaction. The most common used tool is the Density Functional Theory (DFT) based on exchange-correlation approximations and the accuracy usually has not been checked carefully by highly accurate quantum many-body approaches. We have performed calculations of the surface adsorptions using the state-of-the-art diffusion quantum Monte Carlo (QMC) method to examine the accuracy of LDA and GGA (PBE) functionals in the study of surface adsorptions. The systems examined include the H₂O and OH adsorptions on various types of surfaces such as NaCl(100), MgO(100), TiO₂(110), graphene, Si(100)-(2x2) and Al(100). By comparing GGA (PBE) results with DMC, our results indicate that (i) for the H₂O adsorption, PBE predicts the correct adsorption energies; (ii) for the OH adsorption, PBE has predicted a large over-binding effect except on graphene and Si(100) surfaces. This fact indicates that one needs to be cautious when using DFT to study the surface adsorptions of OH free radical.

9:48AM V5.00010 Resistivity of thin gold films on mica induced by electron-surface scattering from a self-affine fractal surface¹, RAUL C. MUNOZ, CLAUDIO GONZALEZ-FUENTES, RICARDO HENRIQUEZ, MARCOS FLORES, Department of Physics, University of Chile — We present a rigorous comparison between resistivity data and theoretical predictions involving the theory of Palasantzas [G. Palasantzas et al., *Phys. Rev. B* **56** 7726 (1997)], and the mSXW-fractal theory [R. C. Munoz et al., *Phys. Rev. B* **66** 205401 (2002)], regarding the resistivity arising from electron scattering by a self affine fractal surface on gold films *using no adjustable parameters*. We find that both theories lead to an approximate description of the temperature dependence of the resistivity data. However, the description of charge transport based upon fractal scaling seems oversimplified, and the predicted increase in resistivity arising from electron-surface scattering seems at variance with other experimental results. If the samples are made up of grains such that the mean grain diameter $D > L(300)$, the electronic mean free path in the bulk at 300 K, then the predicted increase in resistivity at 4 K is of the order of a few percent. This contradicts published measurements of magnetomorph effects arising from size effects where *electron-surface scattering is the dominant electron scattering mechanism at 4 K*. On the contrary, if the samples are made out of grains such that $D < L(300)$, then *the dominant electron scattering mechanism controlling the resistivity is not electron-surface scattering but rather electron-grain boundary scattering, and the latter electron scattering mechanism is not included in either theory*.

¹Funded by FONDECYT 1085026.

10:00AM V5.00011 Electronic confinement imposed by a nanoporous network: Band formation from coupled quantum dots, KATHRIN MUELLER, MEIKE STOEHR, University of Groningen, The Netherlands, MANFRED MATENA, University of Basel, Switzerland, JORGE LOBO-CHECA, Centre d'Investigacio en Nanociencia i Nanotecnologia, Spain, THOMAS JUNG, Paul-Scherrer-Institut, Switzerland, LUTZ GADE, University of Heidelberg, Germany — The electronic and optical properties of crystalline solids exhibit characteristics that derive to a large extent from the periodic arrangement and interactions of their component quantum systems, such as atoms or molecules. Quantum effects due to confinement of electronic states have been extensively studied for surface states of noble metals which are characterized by a quasi 2D electron gas. The design of such periodic 2D structures on surfaces is more readily achieved using molecular self-assembly from building blocks instead of atom by atom manipulation. We chose a perylene derivative (DPDI) as organic building block which is known to form a highly ordered porous network on Cu(111) upon thermal dehydrogenation. To study the interaction between the electronic surface state and our porous network structure, scanning tunneling spectroscopy (STS) and angle-resolved photoemission (ARPES) was used. Each pore of our porous network confines the surface state of the Cu substrate what can be described as a 0D quantum dot. This work can lead to artificially created electronic structures by modification of the dimensions of the molecular network periodicities together with the appropriate choice of the substrate and the building block.

10:12AM V5.00012 ABSTRACT WITHDRAWN —

10:24AM V5.00013 First-Principles Investigations of Oxygen Vacancies on SnO₂ Nanofilms¹, DANIEL CELLUCCI, STEVEN LEWIS, University of Georgia — In recent years multiple critical advances in nanofabrication have allowed for the well-controlled formation of nanocrystals of the n-type semiconductor tin oxide (SnO_2). Because gas sensing in SnO_2 involves changes in surface resistivity as a function of gas concentration, the high surface-to-volume ratio of SnO_2 nanocrystals could be leveraged to produce a gas sensor with significantly enhanced sensitivity. A key feature of the sensing mechanism is the facile formation and destruction of oxygen vacancies at (or near) the surface. In this talk I will discuss our ongoing first-principles investigations of surface oxygen vacancies in SnO_2 nanofilms. We have focused on vacancy formation among the so-called bridging oxygen atoms on the (110) surface of rutile SnO_2 as a function of vacancy concentration and film thickness and have studied the effect on local atomic and electronic structure. From a set of first-principles Density Functional Theory calculations on ordered vacancy structures, we have parametrized and tested a lattice-gas model describing vacancy-vacancy interactions. Using this model we have conducted extensive Monte Carlo simulations to investigate the oxygen vacancy phases on SnO_2 (110) as a function of temperature and oxygen vapor pressure.

¹National Science Foundation, Grant #CMMI-0856719.

10:36AM V5.00014 Orbital tomography: Deconvoluting photoemission spectra of organic molecules¹, PETER PUSCHNIG, University of Leoben, EVA-MARIA REINISCH, THOMAS ULES, GEORG KOLLER, University of Graz, Austria, SERGEY SOUBATCH, Forschungszentrum Juelich, Germany, MARKUS OSTLER, University Erlangen-Nuernberg, Germany, LORENZ ROMANER, University of Leoben, Austria, F. STEFAN TAUTZ, Forschungszentrum Juelich, Germany, CLAUDIA AMBROSCH-DRAXL, Humboldt University Berlin, Germany, MICHAEL G. RAMSEY, University of Graz, Austria — We study the interface of an organic monolayer with a metallic surface, *i. e.*, PTCDA (3,4,9,10-perylene-tetracarboxylic-dianhydride) on Ag(110), by means of angle-resolved photoemission spectroscopy (ARPES) and *ab initio* electronic structure calculations. We present a tomographic method which uses the energy and momentum dependence of ARPES data to deconvolute spectra into individual orbital contributions beyond the limits of energy resolution. This provides an orbital-by-orbital characterization of large adsorbate systems without the need to invoke sophisticated theory of photoemission, allowing us to directly estimate the effects of bonding on individual orbitals. Moreover, this experimental data serves as a most stringent test necessary for the further development of *ab initio* electronic structure theory.

10:48AM V5.00015 Two-Dimensional Band Structure Study of Bi_{1-x}Sb_x Thin Films, SHUANG TANG, MILDRED DRESSELHAUS, Massachusetts Institute of Technology, DRESSELHAUS GROUP TEAM — Alloys of Bi_{1-x}Sb_x, are considered as one of the best thermoelectric materials for low temperature applications below 200 K. The band structure of Bi_{1-x}Sb_x varies as a function of stoichiometry. At a temperature below 77 K, it does not change with temperature. At a certain Sb composition ($x=0.04$), the conduction band and the valence band touch each other at the L point, and the band-crossing occurs. The electronic dispersion relation becomes linear at the L point, which implies that a Dirac cone is formed at each of the three L points. By making the alloys of Bi_{1-x}Sb_x into thin films, we have two more parameters to vary the band structure, namely film thickness and growth orientation. In our present work, the rich variety of band structure configurations, as well as various phases, of Bi_{1-x}Sb_x thin films has been revealed.

Thursday, March 1, 2012 8:00AM - 11:00AM —

Session V6 DMP: Focus Session: Carbon Nanotube Optics I: Spectroscopy and Excitons 206B

8:00AM V6.00001 High Throughput Optical Imaging and Spectroscopy of Individual Carbon Nanotubes, JIWOONG PARK, Cornell University — Laser-based imaging and characterization of individual carbon nanotubes provides a number of significant advantages over other imaging techniques, including its high throughput, spectral characterization capability, and relatively simple sample preparation. We recently reported a novel on-chip Rayleigh imaging technique using widefield laser illumination to measure optical scattering from individual single-walled carbon nanotubes (SWNTs) on a solid substrate with high spatial and spectral resolution. This method accurately measures the resonance energies and diameters for a large number of SWNTs in parallel. This technique can be used for fast mapping of key SWNT parameters, including the electronic-types and chiral indices for individual SWNTs, position and frequency of chirality-changing events, and intertube interactions in both bundled and distant SWNTs. Further Rayleigh characterization showed that SWNTs can form ideal optical wires. Interestingly, the spatial distribution of the radiation scattered by the nanotubes is determined by their shape, but the intensity and spectrum of the scattered radiation are determined by exciton dynamics and other intrinsic properties. Moreover, the nanotubes display a uniform peak optical conductivity, suggesting universal behavior similar to that observed in nanotube conductance. Finally, two other high-throughput optical imaging techniques, widefield Raman imaging and confocal absorption microscopy, and their applications in nanotube imaging will be discussed.

8:36AM V6.00002 Plasmon Nanooptics with Pristine and Hybrid Nanotube Systems¹, IGOR BONDAREV, North Carolina Central University, USA, MAXIM GELIN, WOLFGANG DOMCKE, Technical University of Munich, Germany — In general, plasmons cannot be excited by light in optical absorption since they are longitudinal excitations while photons are transverse. In small-diameter (~ 1 nm) semiconducting carbon nanotubes (CNs), light polarized along the CN axis excites excitons which, in turn, can couple to the nearest (same-band) interband plasmons [1,2]. Both of these collective excitations originate from the same electronic transitions and, therefore, occur at the same (low) energies ~ 1 eV, as opposed to bulk semiconductors where they are separated by tens of eVs. They do have different physical nature and properties. Their coexistence at the same energies in CNs is a unique feature of confined quasi-1D systems where the transverse electronic motion is quantized to form 1D bands and the longitudinal one is continuous. We discuss how low-energy interband plasmon excitations can efficiently mediate enhanced electromagnetic absorption in pristine semiconducting CNs and bipartite entanglement in hybrid metallic CN systems. We develop a theory for (non-linear) optical monitoring and control of the phenomena above.

8:48AM V6.00003 Photoluminescence from suspended individual ¹³C-enriched nanotubes¹, T. SHIMADA, A. YOKOYAMA, A. ISHII, J. SHIOMI, S. MARUYAMA, Y.K. KATO, The University of Tokyo — We investigate isotope effects on the electronic structure of single-walled carbon nanotubes by photoluminescence microscopy. In order to suspend nanotubes for luminescence measurements, trenches are formed on SiO₂/Si substrates by electron beam lithography and dry etching processes. No-flow chemical vapor deposition is used to grow carbon nanotubes with small amounts of isotopically enriched ethanol with 99% ¹³C. Optical measurements are done in air at room temperature using a laser scanning confocal microscope with a wavelength tunable Ti:sapphire laser as an excitation source. We have successfully identified suspended ¹³C-enriched nanotubes by photoluminescence imaging and assigned their chirality with excitation spectroscopy.

¹This work is supported by the Mitsubishi Foundation, Ogasawara Foundation, Ishikawa Carbon Foundation, KAKENHI, and Global COE Program of MEXT, Japan.

9:00AM V6.00004 Circular dichroism in air-suspended single-walled carbon nanotubes¹, A. YOKOYAMA, A. ISHII, M. YOSHIDA, T. SHIMADA, Y.K. KATO, The University of Tokyo — Chiral carbon nanotubes lack inversion symmetry and are expected to show circular dichroism. We have investigated the helicity dependence of absorption in air-suspended single-walled carbon nanotubes by using photoluminescence intensity for detection. Patterned chemical vapor deposition is used to grow carbon nanotubes over trenches etched on SiO₂/Si substrates. We identified suspended carbon nanotubes by taking photoluminescence images with a home-built laser-scanning confocal microscope and characterized them by excitation spectroscopy. A quarter-wave plate is inserted in the excitation laser path, and the photoluminescence intensity is measured as a function of the angle of the wave plate. We observe differences in the luminescence intensity between left- and right-circularly polarized light.

¹This work is supported by KAKENHI and the Photon Frontier Network Program of MEXT, Japan.

9:12AM V6.00005 Visible fluorescence from 5-Angstrom single-wall carbon nanotubes, YASUMITSU MIYATA, TOSHIYA NAKAMURA, MIHO FUJIHARA, HONG EN LIM, RYO KITaura, HISANORI SHINOHARA, Nagoya University — We report the observation of visible fluorescence from the ultrathin single-wall carbon nanotubes (SWCNTs) with diameters of less than 5-Angstrom. Such ultrathin nanotubes were prepared by extracting the inner shells of double-wall carbon nanotubes using ultrasonication [1]. The extracted sample shows two visible photoluminescence (PL) peaks at 700 and 720 nm under light excitation at 410 and 540 nm, respectively. These peaks can be assigned, respectively, as the PL of (4,3) and (5,3) SWCNTs by comparison with the experimental Kataura plot proposed by Weisman et al. [2]. The present findings provide an important insight for the studies of the structural stability and electric structure of ultrathin SWCNTs. [1] Y. Miyata et al. ACS Nano. 4, 5807 (2010), [2] R. Weisman et. al., Nano Lett. 3, 1235 (2003).

9:24AM V6.00006 Symmetry-breaking of carbon nanotubes vibrational modes induced by transversal deformations, NEWTON M.B. NETO, Universidade Federal de Uberlândia, HELIO CHACHAM, ADO JORIO, SABRINA S. CARARA, JAQUELINE SOARES, Universidade Federal de Minas Gerais, RONALDO J.C. BATISTA, Universidade Federal de Ouro Preto, ERNESTO JOSE-LEVICH, Weizmann Institute of Science, MILDRED DRESSSELHAUS, PAULO ARAUJO, Massachusetts Institute of Technology — In this work we combine an atomic force microscope (AFM) with a setup to perform confocal Raman spectroscopy to follow, *in situ*, the evolution of the G-band feature of a Single Wall Carbon Nanotube (SWNT) with transversal pressure applied to the nanotube via the AFM probe. We observe a previously elusive and fundamental symmetry-breaking effect of the totally symmetric tangential optical TO modes in the G-band feature which exhibits two distinct Raman active modes with an anomalous frequency behavior with increasing applied pressure, while the totally symmetric longitudinal optical LO component remains unaltered. We propose a simple analytical model based on a mass-spring ring system, which satisfactorily explains the main observed effects and shows that the pressure effects change with tube flattening.

9:36AM V6.00007 Non-Radiative Exciton Decay in Single-Walled Carbon Nanotubes, MARK HARRAH, JUDE SCHNECK, Boston University, ALEXANDER GREEN, Wyss Institute, Harvard University, MARK HERSAM, Northwestern University, LAWRENCE ZIEGLER, ANNA SWAN, Boston University — We report on the exciton dynamics for an ensemble of individual, suspended (6,5) single-walled carbon nanotubes via single color E_{22} pump-probe spectroscopy for a wide range of pump fluences. The calculated initial exciton population ranges from ~ 5 to 120 excitons per ~ 725 nm long nanotube, putting the high fluence experiment well into the nonlinear regime. The pump-probe data is not well described by multi-exponential decay or by power law behavior for all fluences. We have developed a single model that describes all data, ranging over two decades of pump fluence and three decades of delay times. The signal decay at low fluence is dominated by a stretched exponential that is consistent with the distribution of relaxation rates resulting from diffusion-limited contact quenching for a nanotube ensemble. The change in dynamics as a function of increasing pump intensity is attributed to exciton-exciton Auger de-excitation in the E_{11} subband and, to a lesser extent, in the E_{22} subband. The initial sub-picosecond decay of the observed response is attributed to E_{22} excitons rapidly acquiring non-zero momentum while remaining in the E_{22} subband.

9:48AM V6.00008 Fine structure of exciton levels in carbon nanotubes: A semianalytical approach¹, SERGUEI GOUPALOV², Jackson State University — We propose a new approach [1] toward excitons in carbon nanotubes whereby the matrix elements of the electron-hole Coulomb interaction are expanded into a series over the nanotube's one-dimensional reciprocal lattice vectors. We show that only a few terms of this expansion give a non-vanishing contribution to the Coulomb matrix elements. The proposed approach allows one to single out Fourier components of the Coulomb potential responsible for the intervalley coupling and formation of the exciton fine structure for each particular nanotube chirality.

10:00AM V6.00009 Dynamical crossovers, universality and long-range interactions of excitons on carbon nanotubes, JEREMY ALLAM, TARIQ SAJJAD, RICHARD SUTTON, SOPHIA SIDDIQUE, ZHONGYANG WANG, KONSTANTIN LITVINENKO, University of Surrey, QUAN-HONG YANG, Tianjin University, TOM BROWN, University of Southampton, WEI LOH, University of Southamp — Simple microscopic interactions in non-equilibrium systems give rise to complex emergent macroscopic phenomena. There has been much theoretical work to understand dynamics of different systems, and equilibrium concepts of scaling, criticality and universality have proved useful. However there is a noted lack of experimental studies. Here we show that exciton reactions on carbon nanotubes display the rich kinetics of the prototypical 1D coalescence reaction $A+A \rightarrow A$. An Auger-like exciton interaction¹ and anomalous kinetics² have already been reported. Here we demonstrate the existence of four distinct dynamical regimes: (1) early dynamics determined by spatial ordering of excitons due to Pauli repulsion at high concentrations; (2) a classical mean-field region with exciton population n decaying as t^{-1} ; (3) a self-organized critical state with anomalous reaction kinetics limited by diffusion and characterized by $n \sim t^{-1/2}$, which we show to be universal with respect to the initial population; and (4) an exponential approach towards an absorbing state corresponding to one exciton per nanotube. The abrupt crossover between regimes indicates a long-range exciton interaction, which introduces a non-scaling dimension that breaks universality at intermediate length-scales.

10:12AM V6.00010 Exciton transport and exchange self-energy in semiconducting carbon nanotubes, JARED CROCHET, Los Alamos National Laboratory, JAY SAU, Harvard University, MARVIN COHEN, University of California at Berkeley and Lawrence Berkeley National Laboratory, JUAN DUQUE, Los Alamos National Laboratory, LAURENT COGNET, Universite de Bordeaux and CNRS, STEPHEN DOORN, Los Alamos National Laboratory — We present direct measurements of S_1 exciton transport in (6,5) carbon nanotubes. Exciton diffusion lengths associated with end quenching, photoluminescence lifetimes, and homogeneous emission linewidths provide a basis for determining an intrinsic diffusion constant of $5 \text{ cm}^2\text{s}^{-1}$ within the dispersion of light. Exciton diffusion is modeled in terms of an anomalous dispersion within a marginal Fermi liquid description of the exciton exchange self-energy and acoustic phonon scattering.

10:24AM V6.00011 Quantum Interference Between the Third and Fourth Excitonic States in Semiconducting Carbon Nanotubes, HAGEN TELG, JUAN G. DUQUE, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, HANG CHEN, ANNA K. SWAN, Department of Electrical and Computer Engineering, and Photonics Center, Boston University, Boston, MA 02215, U.S.A., XIAOMIN TU, MING ZHENG, Polymers Division, National Institute of Standards and Technology, 100 Bureau Drive, Gaithersburg, MD 20899-8540, U.S.A., ANDREW P. SHREVE, STEPHEN K. DOORN, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, Los Alamos, NM 87545, USA — We exploit an energy level cross-over effect¹ to probe quantum interference in the resonance Raman response from carbon nanotube samples highly enriched in the single semiconducting chiralities of (8,6), (9,4), and (10,5). UV Raman excitation profiles of G-band spectra reveal unambiguous signatures of interference between the third and fourth excitonic states (E33 and E44). Both constructive and destructive responses are observed and lead to anomalous intensity ratios in the LO and TO modes. Especially large anomalies for the (10,5) structure result from nearly identical energies found for the two Eii transitions. The interference patterns demonstrate that the sign of the exciton-phonon coupling matrix elements changes for the LO mode between the two electronic states, and remains the same for the TO mode. Significant non-Condon contributions to the Raman response are also found.²

10:36AM V6.00012 New Fundamental Optical Behaviors of Single-Wall Carbon Nanotubes at Cryogenic Temperatures: Closer to their Intrinsic Behavior¹, JUAN DUQUE, CHRISTOPHER HAMILTON, JARED CROCHET, ANDREW DATTELBAUM, SCOTT CROOKER, STEPHEN DOORN, Los Alamos National lab — Development of single walled carbon nanotube (SWNT) materials for optoelectronics and nanophotonics has been especially challenging in that SWNT optical properties are highly sensitive to environmental interactions, which can be particularly severe in composite matrices. Here, we present for the first time an innovative approach to obtain highly photoluminescent (PL) solid-state SWNT-nanocomposites, which provides access to novel photophysical properties. Strongly blue-shifted spectral features, and significant increase ($\sim 3\times$) in PL intensities at cryogenic temp in comparison to room temp or previous reports. This difference can be understood as arising from a significantly slower relaxation of excitons from bright to dark states in our SWNTs, as a result of much weaker interaction with the environment. That is, the bright/dark exciton distribution is highly non-thermal, even at the lowest temperatures. In our SWNT-nanocomposites, environmental interactions are minimized, thus bright excitons *cannot* relax efficiently to the dark state, causing a highly non-equilibrium exciton distribution and a correspondingly large PL intensity, even at low temperatures.

10:48AM V6.00013 Coherent anti-stokes spectroscopy as a probe of chemical disorder in isolated carbon nanotubes, TATYANA SHEPS, JORDAN BROCIOS, ERIC O. POTMA, PHILIP G. COLLINS, University of California, Irvine — We use a third-order coherent anti-stokes (CAS) optical technique to study chemical disorder in individual carbon nanotubes. The CAS response is highly sensitive to this disorder, to the extent that a few chemical defects can appreciably decrease the overall signal. The experiments are performed on individual single- and multi-walled carbon nanotubes (SWNTs and MWNTs) connected in a transistor geometry and subjected to varying degrees of controlled, electrochemical oxidation. The overall CAS intensity can be used to probe the extent of chemical modification, and inhomogeneities along a nanotube resolve local coherent electron density fluctuations. We find that the CAS signal is also strongly affected by substrate interactions: aligned SWNTs grown on single crystal quartz are quenched compared to SWNTs on fused quartz. Finally, CAS spectroscopy on individual SWNTs and MWNTs using picosecond pulses resolves the third-order vibrational signal component at the G-band frequency. The ratio of electronic to vibrational CAS signal components is diameter dependent and in small diameter SWNTs the vibrational component is dominated by the electronic CAS signal. However, in MWNTs, this technique is a first step toward chemically sensitive CARS imaging on a single nanotube level.

Session V7 DMP DCOMP: Focus Session: Computational Design of Materials - Engineering of Electronic Structure Materials 207

8:00AM V7.00001 Band-edge engineering of Silicon by Surface Functionalization: a Combined Ab-initio and Photoemission Study¹, YAN LI, Computational Science Center, Brookhaven National Laboratory, LESLIE OLEARY, NATHAN LEWIS, Department of Chemistry, California Institute of Technology, GIULIA GALLI, Department of Chemistry and Department of Physics, University of California, Davis — The electrode material choice is limited in solar to fuel formation devices because of the requirement of band-edge matching to the fixed fuel formation potential. This limitation can be relieved via band-edge engineering. The changes of band-edge positions of Si electrodes induced by the adsorption of H-, Cl-, Br- and short-chain alkyl groups were investigated by combining density functional (DFT), many-body perturbation theory (MBPT), and ultraviolet photoelectron spectroscopy. The band edge shifts are related to the formation of surface dipole moments, and determine the barrier height of electrons and holes in doped silicon surfaces. We find that the trends of the sign and magnitude of the computed surface dipoles as a function of the adsorbate may be explained by simple electronegative rules. We show that quasi-particle energies obtained within MBPT are in good agreement with experiment, while DFT values may exhibit substantial errors. However computed band edge differences are in good agreement with spectroscopic and electrical measurements even at the DFT level of theory. [1] Y. Li and G. Galli, Phys. Rev. B 82, 045321 (2010). 8:12AM V7.00002 Genetic engineering of band-edge optical absorption in Si/Ge superlattices¹, MAYEUL D'AVEZAC, JUN-WEI LUO, NREL, THOMAS CHANIER, University of Iowa, ALEX ZUNGER, University of Colorado — Integrating optoelectronic functionalities directly into the mature Silicon-Germanium technology base would prove invaluable for many applications. Unfortunately, both Si and Ge display indirect band-gaps unsuitable for optical applications. It was previously shown (Zachai *et al.* PRL 64 (1990)) that epitaxially grown $[(\text{Si})_n(\text{Ge})_m]_p$ (i. e. a single repeat unit) grown on Si can form direct-gap heterostructures with weak optical transitions as a result of zone folding and quantum confinement. The much richer space of *multiple-period* superlattices $[(\text{Si})_{n_1}(\text{Ge})_{n_2}(\text{Si})_{n_3}(\text{Ge})_{n_4} \dots \text{Ge}_{n_N}]_p$ has not been considered. If $M = \sum n_i$ is the total number of monolayers, then there are, roughly, 2^M different possible superlattices. To explore this large space, we combine a (i) genetic algorithm for effective configurational search with (ii) empirical pseudopotential designed to accurately reproduce the inter-valley and spin-orbit splittings, as well as hydrostatic and biaxial strains. We will present multiple-period SiGe superlattices with large electric dipole moments and direct gaps at Γ yielded by this search. We show this pattern is robust against known difficulties during experimental synthesis.

8:24AM V7.00003 New mechanism for work-function tuning: ZnO surfaces modified by a strong organic electron acceptor, YONG XU, OLIVER T. HOFMANN, RINKE PATRICK, MATTHIAS SCHEFFLER, Fritz Haber Institute Berlin, RAPHAEL SCHLESINGER, NORBERT KOCH, Humboldt University Berlin, ANTJE VOLLMER, Helmholtz-Zentrum Berlin — A key task for optimizing optoelectronic devices comprising hybrid inorganic/organic systems is to control the energy level alignment at interfaces. The use of interlayers provides a pathway to solve this challenge. To demonstrate the concept we investigated the polar surfaces of ZnO, modified by the prototypical organic electron acceptor 2,3,5,6-tetrafluoro-7,7,8,8-tetracyanoquinodimethane (F4TCNQ) theoretically and experimentally. DFT-PBE Δ SCF calculations of the O 1s surface core-level shifts combined with XPS measurements suggest that ZnO(000-1)/ZnO(0001) are H/OH covered. Depositing F4TCNQ on these surfaces considerably increases the work function that is shown to be insensitive to the doping level in PBE+vdW. F4TCNQ on ZnO(0001) exhibits an extraordinary high work function due to the appearance of upright adsorption. The PBE+vdW results are in line with the UPS data that shows work-function increases up to 1.4/2.8 eV on ZnO(000-1)/ZnO(0001). In contrast to F4TCNQ on metals, where pronounced bidirectional charge transfer occurs, the charge transfer from ZnO to F4TCNQ is small, pinning the LUMO close to the Fermi level. The polarization of the system, caused by strong charge rearrangement within the adsorbate, is the main mechanism for the large work-function increase.

8:36AM V7.00004 Quantum Monte Carlo Characterization of Excited States and Energy-Level Alignment at Oligomer/Quantum-Dot Interfaces, YOSUKE KANAI, The University of North Carolina, Chapel Hill / Lawrence Livermore National Laboratory, JONATHAN L. DUBOIS, DONGHWA LEE, Lawrence Livermore National Laboratory — Charge separation of excitons in materials is one of the most important physical processes that need to take place in excitonic solar cells and in photocatalytic devices. Heterogeneous interfaces with the so-called type-II character are often employed for inducing the exciton dissociation through interfacial charge transfer. As the simplest criterion for designing such an interface, the energy alignment of the quasi-particle states is often discussed in literature, together with the exciton binding energy of electron-donating materials. Therefore, accurate characterization of the interfacial energy-level alignment and the exciton binding energy using first principles calculations is important for making systematic progresses in designing better materials for solar energy conversion. However, Density Functional Theory calculations need to be employed with caution in this context. First principles calculations such as Many-Body Perturbation Theory and Quantum Monte Carlo are promising alternatives for accurate characterization, but much more work is needed in this area to assess how well these methods perform in practice. In this talk, we will discuss our preliminary results using diffusion Quantum Monte Carlo on calculating the excited states and energy-level alignment of popular Oligomer/Quantum-Dot interfaces.

8:48AM V7.00005 Shape managing the cross-section of a semiconductor nanowire as a method for fine tuning electro-optical properties¹, OSMAN BARIS MALCIOGLU, JEAN-YVES RATY, University of Liege, SORIN MELINTE, Université Catholique de Louvain — Geometry design in nanowire and nanopillar arrays is used to create photon managing structures in a number of optical applications ranging from photovoltaics to field emission devices. The diameter dependence of the intrinsic properties of the material at the nanoscale provides further tunability and significantly improved performance. Using ab-initio methods (TDDFT), we explore the additional possibility of tuning and enhancing the optical properties by fine structuring the cross-sectional geometry.

¹The authors acknowledge support from the FNRS (FRFC grant 2.4509.09) and the Belgian Federal Government.

9:00AM V7.00006 Dimensional Reduction: A design tool for new semiconductor compounds for radiation detection¹, B.W. WESSELS, J.A. PETERS, Z. LIU, Dept. of Materials Science and Engineering, Northwestern University, J. ANDROULAKIS, M.G. KANATZIDIS, Dept. of Chemistry, Northwestern University, H. JIN, A.J. FREEMAN, Dept. of Physics, Northwestern University, Evanston, IL 60208 — To address the need for new wide gap semiconductors for efficient radiation detection, we present a new design tool called *dimensional reduction* (DR). The method is based on reducing the dimensionality of highly dense but low bandgap (<1 eV) compounds to create comparably dense wide bandgap (>1.6 eV) semiconductors without compromises on their mass density. We utilize electronic band structure calculations of bandgap and effective mass to aid in the selection among the wide variety of compounds that can be formed by DR. As a proof of the concept, we report on computational design as well as optical characterization of three such dimensionally reduced materials based on β -HgS, HgSe, and CdTe compounds. These compounds, namely, Cs₂Hg₆S₇, Cs₂Hg₃Se₄, and Cs₂Cd₃Te₄, show great promise as detector materials. Band structure calculations show that they have direct bandgaps of 1.28, 1.97, and 2.35 eV, respectively, in good agreement with experimental values of 1.63, 2.2 and 2.5 eV, respectively. Measured electrical resistivity values of $\sim 10^6$, 10^7 , and 10^9 Ω -cm, respectively, are high enough for further evaluation of these materials for hard radiation detection. Computational design of other wide gap semiconductors is underway.

¹This work is supported by the Defense Threat Reduction Agency through grant no. HDTRA1 09-1-0044.

9:12AM V7.00007 First principles study of LaGaO₃/MgAl₂O₄ (001) polar interfaces¹, ALEJANDRO REBOLA, PETER ZAPOL, JEFFREY EASTMAN, Argonne National Laboratory, SERDAR OGUT, University of Illinois at Chicago — Materials with high oxygen ion conductivity have been the center of much attention due to both fundamental interest and technological applications. One of the most remarkable ionic conductors and an excellent candidate for future solid oxide fuel cells is LaGaO₃ (LGO), as it exhibits very high ionic conductivity when doped with Sr or Mg. To achieve enhanced ionic transport in this system, where oxygen vacancies (V_O) are the dominant carriers, we propose a negatively charged interface as a way of inducing a V_O enrichment layer. In this study, the interface is comprised of LGO and the spinel MgAl₂O₄, both of which exhibit nominally charged (001) planes. We consider an interface where the (GaO₂)¹⁻ layer of LGO is in contact with the (AlO₂)¹⁻ layer of the spinel. Such negatively charged interfaces require compensating defects, providing a strong driving force for enhancing the V_O concentration, and hence, the in-plane ionic conductivity in the space charge region adjacent to the boundary. We report results from first-principles calculations which provide information on the structure and relative stability of these polar interfaces, compensation mechanisms, and defect formation energies as a function of distance from the interface.

9:24AM V7.00008 Theory-driven design of hole-conducting transparent oxides¹, G. TRIMARCHI, H. PENG, IM J., A.J. FREEMAN, V. CLOET, A. RAW, K.R. POEPELMEIER, Northwestern University, Evanston, IL 60208, K. BISWAS, S. LANY, NREL, Golden, CO 80401, A. ZUNGER, University of Colorado, Boulder, CO 80309 — The design of *p*-type transparent conducting oxides (TCOs) aims at *simultaneously* achieving transparency and high hole concentration and hole conductivity in one compound. Such design principles (DPs) define a multi-objective optimization problem that is to be solved by *searching* a large set of compounds for optimum ones. Here, we screen a large set of ternary compounds, including Ag and Cu oxides and chalcogenides, by calculating via first-principles methods the design properties of each compound, in order to search for optimum *p*-type TCOs. We first select Ag₃VO₄ as a case study of the application of *ab-initio* methods to assess a compound as a candidate *p*-type TCO. We predict Ag₃VO₄ (i) to have a hole concentration of $\approx 10^{14}$ cm⁻³ at room temperature, (ii) to be at the verge of transparency, and (iii) to have lower hole effective mass than the prototype *p*-type TCO CuAlO₂. We then map the hole effective mass *vs.* the band gap in the selected compounds and determine those that best meet the DPs by having simultaneously minimum effective mass and a band gap large enough for transparency.

¹Funded by the DOE Energy Frontier Research Center for Inverse Design.

9:36AM V7.00009 Screw Dislocated ZnO and Si Nanostructures Studied with Objective Molecular Dynamics, EVGENIYA AKATYEVA, ILIA NIKIFOROV, DONG-BO ZHANG, TRAIAN DUMITRICA, University of Minnesota — Objective molecular dynamics [1] coupled with tight-binding density functional-based models makes it possible to investigate the stability and electronic structure of ZnO and Si nanotubes [2] and nanowires [3] containing axial screw dislocations. The dislocated structures adopt twisted configurations that stabilize the dislocation at the center despite the close vicinity of surfaces, in excellent agreement with Eshelby's elasticity model of cylinders containing an axial screw dislocation. Coupled to this elasticity model, our simulations represent a new efficient method of calculating the core energy of a dislocation and allow to rationalize the stability of chiral hollow nanowires. The uncovered mechanical and electronic behaviors have implications for a broad class of nanomaterials grown by engaging a screw dislocation. 1. T. Dumitrica and R.D. James, J. Mech. Phys. Sol. 55, 2206-2236 (2007). 2. D.-B. Zhang, E. Akatyeva, and T. Dumitrica, Phys. Rev. B 84, 115431 (2011). 3. I. Nikiforov, D.-B. Zhang, and T. Dumitrica, J. Phys. Chem. Lett. 2, 2544 (2011).

9:48AM V7.00010 Tunable band gaps in transition metal dichalcogenides, ASHWIN RAMASUBRAMANIAM, University of Massachusetts Amherst, DORON NAVEH, ELIAS TOWE, Carnegie Mellon University — We investigate band-gap tuning in transition-metal dichalcogenide bilayers by external electric fields applied perpendicular to the layers. Using density functional theory, we show that the fundamental band gap of MoS₂, MoSe₂, MoTe₂, and WS₂ bilayer structures continuously decreases with increasing applied electric fields, eventually rendering them metallic. We interpret our results in the light of the Giant Stark Effect and obtain a robust relationship, which is essentially characterized by the interlayer spacing, for the rate of change of band gap with applied external field. Our study expands the known space of layered materials with widely tunable band gaps beyond the classic example of bilayer graphene and suggests potential directions for fabrication of novel electronic and photonic devices.

10:00AM V7.00011 Growth of Monolayer Boron Sheet on Metal and Metal Boride Surface, YUANYUE LIU, QINGBO YAN, Dept. of Mech. Eng. & Mat. Sci., Rice U., HOONKYUNG LEE, Dept. of Mech. Eng. Mat. Sci., Rice U., BORIS YAKOBSON, Dept. of Mech. Eng. & Mat. Sci., Rice U., COMPUTATIONAL MATERIALS SCIENCE TEAM — Monolayer boron (B) sheet has attracted lots of interests recently due to its metallic conductivity. However, their experimental synthesis has not been achieved so far, which calls for theoretical investigation. Using first principles calculations, we study the possibility of growing monolayer B sheets on metal (Ag, Au) and metal boride (MgB₂, TiB₂) surface as catalytic substrate. It is shown that after decomposition from precursor, B atoms will aggregate to cluster, then to sheets, while three dimensional bulky B is prohibited due to high nucleation barrier. Charge transfer between substrate and B sheet shifts its stability dependence on hexagon vacancy density. B sheet with specific vacancy density can have cleavage energy as small as graphite thus should be easily peeled off. This work suggests promising approach to synthesize B sheets and would possibly pave the way towards their applications to electronic, optic, and mechanic nano-devices.

10:12AM V7.00012 Understanding the properties of hexagonal Semiconducting Nanomembranes, RODRIGO AMORIM, XIAOLIANG ZHONG, SAIKAT MUKHOPADHYAY, RAVINDRA PANDEY, Michigan Tech, SHASHI KARNA, Army Research Laboratory — Nanomembranes are an interesting material with novel applications, such as their integration into electronic devices. We can highlight the high degree of bendability of nanomembranes that can be important to device integration and the possibility of modifying electronic properties by changing the roughness. Using density functional theory (DFT) combined with non-equilibrium green's function (NEGF) theory, we investigate different hexagonal semiconducting nanomembranes (e.g. BN, AlN and GaN). We will show the stability, electronic and transport properties of these nitride membranes and look into their possible integration with graphene.

10:24AM V7.00013 Single-atom Magnetic Anisotropy on a Surface, CHIUNG-YUAN LIN, JING-NENG YAO, Department of Electronics Engineering, National Chiao Tung University — Studying single-atom magnetic anisotropy on surfaces enables the exploration of the smallest magnetic storage bit that can be built. In this work, magnetic anisotropy of a single rare-earth atom on a surface is studied for the first time, both computationally and theoretically. The substrate surface is chosen to be a copper-nitrite surface, where single transition-metal magnetic atoms on the same surface were previously studied one atom at a time by STM.¹ We propose unconventional *f* and *d* subshell symmetries so that following first-principles calculations, simple pictorial analyses of such anisotropy can be performed for the first time, independently for both rare-earth and transition-metal adatoms. The analyses explain the spin-density distribution of a single adatom, and derive the spin orientation of its largest spin-orbit coupling. The magnetic anisotropy energy of the present study is calculated to be a factor of five larger than the previous highest one.

10:36AM V7.00014 Computer Simulated Cold Welding of Metal Nanowires, EDISON DA SILVA, ZENNER PEREIRA, Institute of Physics "Gleb Wataghin", UNICAMP, 13083-970, Campinas - SP, Brazil — Metallic contacts are of great importance in electronic devices, the ability of welding them without temperature change is quite remarkable and of interest. Recently cold welding was achieved in gold and silver nanowires (NWs) with diameters in the range of 4 to 10 nm [1]. In the present work we use computer simulations to produce cold welding in gold, silver and silver-gold NWs at room temperature. We used molecular dynamics with many body effective potentials based on the embedded-atom method EAM using the LAMMPS code to simulate first the braking of gold and silver NWs. The two produced NWs are then cold welded and similarly as occurred in the experiments the newly welded NWs showed fcc structures as the printine samples. The structural analysis is done with two independent methods [2] and strain stress curves of the breaking and welding are present. Our computer simulation compare very well with the experiments. This work is supported by CNPq CAPES and FAPESP and FAEPEX. ZSP is supported by CAPES. CENAPAD-SP and IFGW are acknowledged for computer time.

Thursday, March 1, 2012 8:00AM - 11:00AM – Session V8 DMP GMAG: Focus Session: Frustrated Magnetism - Kagome II 208

8:00AM V8.00001 Monte Carlo simulations of the fcc Kagomé lattice¹, VAHID HEMMATI, MARTIN PLUMER, JOHN WHITEHEAD, Memorial University of Newfoundland, BYRON SOUTHERN, University of Manitoba — For many years, Ir-Mn alloys have been widely used by the magnetic storage industry in thin-film form as the antiferromagnetic pinning layer in GMR and TMR spin valves [1]. Despite the technological importance of this structure, it has not previously been noted that the magnetic Mn-ions of fcc IrMn₃ reside on Kagomé layers ABC stacked along <111> axes normal to the film plane [2,3]. Results of Monte Carlo simulations will be reported on the bulk fcc Kagomé lattice for both XY and Heisenberg models including the eight NN exchange interactions. Degeneracies persist in the 3D case and there is strong evidence for a fluctuation-driven first-order transition to well-defined long-range order characterized as the layered “*q*=0” 120-degree spin structure. Effects of varying the inter-layer coupling are also examined.

8:12AM V8.00002 Phase Control of Magnetic Order in (Y,Lu)BaCo₄O₇, JOHN MITCHELL, SEVDA AVCI, OMAR CHMAISSEM, Argonne National Laboratory, LAURENT CHAPON, Institut Laue Langevin, DMITRY KHALYAVIN, ISIS Facility, Rutherford Laboratory — The RBaCo₄O₇ (R=Ca, Y, Tb-Lu) system provides a novel topology for studying geometric frustration, in which face-sharing tetrahedra of magnetic ions link to form trigonal bipyramids on a Kagomé lattice. Here we describe the structural and magnetic behavior of the Lu member and the solid solution joining Lu to Y as a chemical means to tune between magnetically ordered and disordered ground states. Mean-field models of the generic magnetic phase diagram of RBaCo₄O₇ determined recently by our group (D. D. Khalyavin *et al.* Physical Review B **82**, 094401 (2010)) show a variety of magnetic states as a function of two exchange parameters: *J_{ab}* and *J_c*, where *J_{ab}* links Co ions in the Kagomé planes and *J_c* links Co ions from the Kagome plane to the interleaving triangular layer. Experimentally, we find that YBaCo₄O₇ has a long-range ordered antiferromagnetic ground state, while LuBaCo₄O₇ appears to be disordered above 2 K with very slow dynamics measured by neutron scattering. We use the solid solution to interpolate between these endpoints and discuss these results with respect to the mean-field phase diagram.

8:24AM V8.00003 Spin dynamics in the extended kagomé $\text{YBaCo}_4\text{O}_{7.1}$ ¹, MICHAEL HOCH, PHILIP KUHN, TIGLET BESARA, ARNEIL REYES, National High Magnetic Field Laboratory at Florida State University, Tallahassee, FL, JOHN MITCHELL, Argonne National Laboratory, Argonne, IL — The extended kagomé system YBaCo_4O_7 consists of antiferromagnetically coupled Co^{2+} and Co^{3+} ions arranged in stacks with alternating kagomé and triangular layers in ab planes in the orthorhombic lattice. The oxygen-stoichiometric material orders below 110 K. The system exhibits interesting exchange topology with both trigonal bipyramids and triangular kagomé clusters of Co ions. Model calculations and neutron scattering experiments, made by other workers, have provided considerable information on the magnetic structure. Ordered chains are found for the apical ions along the c-axis with neighbor chains having oppositely directed polarizations perpendicular to c in an antiferromagnetic configuration. Only short range order is present in the kagomé planes at temperatures as low as 2 K. The present pulsed NMR measurements, made on a single crystal, both in zero magnetic field and in low applied fields, distinguish the Co ion sites and provide information on the evolution of the spin dynamics for the plane and chain sites as a function of temperature in the range 1.7 - 50 K above which signal wipe-out occurs. A dramatic change in the spin dynamics is found below 5 K.

8:36AM V8.00004 Spectral Signature of Neodymium Dopants in Frustrated Gadolinium Gallium Garnet Lattice¹, CHRISTOPHER FERRI, MICHAEL TENNENBAUM, SAYANTANI GHOSH, University Of California, Merced, 95348, School Of Natural Sciences — We investigate the spectral emission of Nd^{3+} dopant ions (1% at. wt) in the frustrated magnet Gadolinium gallium Garnet (GGG) as a function of temperature and magnetic field. We concentrate on the low energy excitations centered at 1064 nm and 935 nm, which show a multiplet structure at room temperature. As temperature decreases the emission spectra demonstrate changes in relative intensities that undergo a cross-over at 122 K under zero field cooled conditions. This cross-over is magnetic field dependent and changes as we field-cool the sample. Typically, with decreasing temperature the line widths of the spectral peaks decrease, as is expected. However, when cooled below 10 K selective peaks start exhibiting broadening, even when zero-field cooled. We follow this line broadening as a function of magnetic field and dopant concentration and speculate it is a result of the dopant ions coupling to the internal magnetic fields of the host lattice.

¹We acknowledge funding from NSF CAREER DMR-1056860.

8:48AM V8.00005 Investigating the nature of magnetic correlations in the anti-ferromagnetic hyper-kagome material, $\text{Yb}_3\text{Ga}_5\text{O}_{12}$, KATE ROSS, KATHARINA FRITSCH, McMaster University, ROBERT BEWLEY, TATIANA GUIDI, ISIS, Rutherford Appleton Laboratory, YIMING QIU, CNR, NIST, CHRIS WIEBE, University of Winnipeg, HAIDONG ZHOU, Florida State University, HANNA DABKOWSKA, BRUCE GAULIN, McMaster University — The magnetic Yb^{3+} ions in $\text{Yb}_3\text{Ga}_5\text{O}_{12}$ (YbGG) reside on a hyper-kagome lattice, which has the same connectivity as the planar kagome lattice but in higher dimensions. For anti-ferromagnetically (AFM) coupled spins the hyper-kagome lattice provides a highly-frustrated geometry in three-dimensions. YbGG is isostructural with the well-studied $\text{Gd}_3\text{Ga}_5\text{O}_{12}$ (GGG), which enjoys an exotic magnetic phase diagram. In GGG, the effects of geometric frustration manifest as a disordered, partial spin-glass ground state down to 25mK in zero-field. The application of an external magnetic field first induces an intermediate spin liquid state, then a long range AFM ordered phase. Much less is known about YbGG, though all experimental evidence indicates a lack of LRO in zero-field down to 30mK. We have recently produced single crystals of YbGG and have performed neutron scattering experiments over a range of temperatures (80mK - 10K) and magnetic field strengths (0T - 8T). The results indicate low-energy, fluctuating spin correlations at 80mK, 0T, as well as a dramatic response to an applied magnetic field. At zero-field, we also observe a low-energy dispersionless spin excitation that softens as the temperature is increased above the Schottky anomaly in the specific heat.

9:00AM V8.00006 Spatially anisotropic kagome antiferromagnet with Dzyaloshinskii-Moriya interaction, VLADIMIR A. ZYUZIN, GREGORY A. FIETE, University of Texas at Austin — We theoretically study the spatially anisotropic spin-1/2 kagome antiferromagnet with Dzyaloshinskii-Moriya (DM) interaction using a renormalization group analysis in the quasi-one-dimensional limit. We identify the various temperature and energy scales for ordering in the system. For very weak DM interaction, we find a low-temperature spiral phase with the plane of the spiral selected by the DM interaction. This phase is similar to a previously identified phase in the absence of the DM interaction. However, above a critical DM interaction strength we find a transition to a phase with coexisting antiferromagnetic and dimer order, reminiscent of one-dimensional antiferromagnetic systems with a uniform DM interaction. Our results help shed light on the fate of two dimensional systems with both strong interactions and significant spin-orbit coupling.

9:12AM V8.00007 ABSTRACT WITHDRAWN —

9:24AM V8.00008 Dimensional reduction, avalanches and disorder in artificial kagome spin ice¹, REMO V. HUGLI, GERARD DUFF, HANS-BENJAMIN BRAUN, University College Dublin — In collaboration with an experimental team at the Swiss Light Source we have recently demonstrated that emergent monopoles and associated Dirac strings can directly be observed in real space via x-ray circular dichroism in a kagome lattice geometry. Here we build on the fact that the experimental results are in excellent agreement with MC simulations of a lattice of point dipoles with disorder realized in the form of random switching fields. We demonstrate that within a large range of physical parameters such as interdipolar coupling and randomness, magnetization reversal proceeds via a novel 1D avalanche behaviour whose hallmark is an exponential avalanche size distribution. After presenting simple arguments for the origin of such dimensional reduction we demonstrate that such 1D avalanche behavior also occurs in a model where the dipoles are stretched into magnetic charge dumbbells which provides a more realistic model for nanolithographic islands. Finally we demonstrate how a judicious design of the island anisotropy can be used to achieve controlled switching and avalanche propagation which paves the way for spintronic applications

9:36AM V8.00009 Propagation of monopole defects and flux channels in an artificial square spin-ice lattice, YIMEI ZHU, V.V. VOLKOV, SHAWN POLLARD, Brookhaven National Laboratory — The recent development of artificial lattices of magnetic islands in which competing interactions give rise to macroscopic analogs of atomically frustrated spin ices has opened up a new field of research, in which the interaction, frustration and evolution of individual magnetic elements can be directly observed in real space. We investigate the magnetic reversal along the (11) symmetry axis of permalloy islands in an artificial “square” spin-ice geometry with in-situ Lorentz transmission electron microscopy. Novel differential transport-of-intensity allows for the identification of “monopole”-like defects and flux channels, similar to Dirac strings, that link them. We track the growth and propagation of these defects and flux channels throughout the reversal process. Simulations are used to compare with experiment to show how nucleation and propagation of defects affect the reversal of the lattice as a whole. We find that interactions between defects and flux channels can explain the saturation of defect populations at low net magnetizations. This work was supported by U.S. Department of Energy, Office of Basic Energy Science, Material Sciences and Engineering Division, under Contract No. DE-AC02-98CH10886.

9:48AM V8.00010 Magnetization dynamics in artificial spin ice lattices¹, OLLE HEINONEN, SEBASTIAN GLIGA, Argonne National Laboratory — Artificial spin ice lattices (ASIL) consist of regular arrays of single-domain nanomagnets displaying ice rule ordering. Frustration is introduced through shape anisotropy. ASILs have been shown to exhibit complex behavior, with rich phase diagrams and quasi-static magnetization reversal. In particular, topological defects, such as Dirac monopoles and Dirac strings, play a fundamental role in the quasi-static behavior of ASILs. In this work, we use micromagnetic simulations to investigate the resonant frequencies of square lattice ASILs consisting of stadium-shaped nanomagnets. We calculate the evolution of the fundamental modes of a single element when elements are combined in four-stadia configurations and large lattices. In a cross-shaped four-stadium configuration for example, the Dirac monopole splits the frequencies of the lowest (near)-degenerate symmetric and antisymmetric edge modes of a single stadium. This splitting increases in a 24-stadium system with two monopoles. We also calculate the evolution of the spectral characteristics as the monopoles move farther apart in the lattice, but stay connected through a Dirac string. Our work suggests that these topological defects have distinct spectral signatures that can be detected experimentally.

10:00AM V8.00011 Study of system-size effects on the emergent magnetic monopoles and Dirac strings in artificial kagome spin ice¹, ALEJANDRO LEON, Universidad Diego Portales — In this work we study the dynamical properties of a finite array of nanomagnets in artificial kagome spin ice at room temperature. The dynamic response of the array of nanomagnets is studied by implementing a "frustrated cellular automata" (FCA), based in the charge model. In this model, each dipole is replaced by a dumbbell of two opposite charges, which are situated at the neighbouring vertices of the honeycomb lattice. The FCA simulations, allow us to study in real-time and deterministic way, the dynamic of the system, with minimal computational resource. The update function is defined according to the coordination number of vertices in the system. Our results show that for a set geometric parameters of the array of nanomagnets, the system exhibits high density of Dirac strings and high density emergent magnetic monopoles. A study of the effect of disorder in the arrangement of nanomagnets is incorporated in this work.

10:12AM V8.00012 Magnetic reversal of an artificial square ice: dipolar correlation and charge ordering, JASON MORGAN, University of Leeds, AARON STEIN, Center for Functional Nanomaterials, SEAN LANGRIDGE, ISIS,, CHRISTOPHER MARROWS, University of Leeds — Artificial spin ices are lithographically patterned arrays of single domain nanomagnets [1-4]. The elongated elements form a 2D system of interlinked vertices at which Ising-like dipole moments meet with incompatible interactions. They are directly analogous to 3D bulk spin ice materials [5]. We report on the magnetic reversal of an athermal artificial square ice pattern subject to a sequence of magnetic fields applied slightly off the diagonal symmetry axis, investigated via magnetic force microscopy of the remanent states that result [1]. From an initial diagonally polarised state, sublattice independent reversal is observed via bulk-nucleated incrementally-pinned flipped moment chains along parallel channels of magnetic elements, as evident from analysis of vertex populations and dipolar correlation functions. Weak dipolar interactions between adjacent chains favour antialignment and give rise to weak charge ordering of "monopole" vertices during reversal.

10:24AM V8.00013 Experimental Realization of Isotropic Ising Spins in Frustrated and Unfrustrated Artificial Spin Ice with Perpendicular Anisotropy¹, SHENG ZHANG, JIE LI, IAN GILBERT, YU PAN, PAUL LAMMERT, KRITI KOHLI, RAJIV MISRA, VINCENT CRESPI, NITIN SAMARTH, PETER SCHIFFER, Department of Physics and Materials Research Institute, Pennsylvania State University, University Park, PA 16802, USA, CRISTIANO NISOLI, Theoretical Division and Center for Nonlinear Studies, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, MIKE ERICKSON, CHRIS LEIGHTON, Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN 55455, USA — We have studied lithographically defined arrays of magnetostatically interacting single domain ferromagnetic islands with moments normal to the plane, leading to fully isotropic magnetostatic interactions. Probing both frustrated kagome and unfrustrated honeycomb array geometries, we find that the spin configurations can be reproduced with models based on only nearest-neighbor correlations. While the honeycomb geometry displays ordering of moments in well-defined domains, the kagome geometry has only short range correlations that show striking similarities to those of analogous in-plane systems and are closely comparable to expectations for a simple Ising system.

10:36AM V8.00014 Hysteresis and Return Point Memory in Artificial Spin Ice Systems, CYNTHIA REICHHARDT, Los Alamos National Laboratory, ANDRAS LIBAL, Babes-Bolyai University, CHARLES REICHHARDT, Los Alamos National Laboratory — We investigate hysteresis loops and return point memory for artificial square and kagome spin ice systems by cycling an applied bias force and comparing microscopic effective spin configurations throughout the hysteresis cycle. Return point memory loss is caused by motion of individual defects in kagome ice or of grain boundaries in square ice. In successive cycles, return point memory is recovered rapidly in kagome ice. Memory is recovered more gradually in square ice due to the extended nature of the grain boundaries. Increasing the amount of quenched disorder increases the defect density but also enhances the return point memory since the defects become trapped more easily.

10:48AM V8.00015 Collective Magnetic Behavior of Geometrically Frustrated Arrays with Perpendicular Anisotropy, Y. PAN, K.K. KOHLI, R. FRALEIGH, A.L. BALK, D. FINKEL, S. ZHANG, J. LI, I. GILBERT, P.E. LAMMERT, R. MISRA, V.H. CRESPI, P. SCHIFFER, N. SAMARTH, Dept. of Physics, Penn State University, University Park PA 16802, M. ERICKSON, C. LEIGHTON, Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN 55455 — We use the magneto-optical Kerr effect (MOKE) to study the global and local magnetic behavior of geometrically frustrated arrays of single domain ferromagnetic islands with perpendicular anisotropy. MOKE measurements over macroscopic length scales probe the global properties of arrays with different lattice geometries and island spacings. The variation of switching field as a function of island spacing gives us insight into the influence of local frustration on the collective magnetic response of the arrays. The experimental results are compared with mean field calculations. Finally, we use spatially resolved Kerr microscopy to probe nucleation and domain propagation in the magnetization reversal process. Supported by U.S. Department of Energy Award DE-SC0005313. Transport Properties 209

8:00AM V9.00001 Scaling of the anomalous Hall effect in SrRuO_3 , NOAM HAHAM, YISHAI SHPERBER, MOTY SCHULTZ, NETANEL NAFTALIS, EFRAT SHIMSHONI, Department of Physics, Nano-magnetism Research Center, Institute of Nanotechnology and Advanced Materials, Bar-Ilan University, Ramat-Gan 52900, Israel, JAMES REINER, Department of Applied Physics, Yale University, New Haven, CT 06520-8284, LIOR KLEIN, Department of Physics, Nano-magnetism Research Center, Institute of Nanotechnology and Advanced Materials, Bar-Ilan University, Ramat-Gan 52900, Israel — Being one of the most intriguing manifestations of a transport phenomenon that is sensitive to spin and topology, the anomalous Hall effect (AHE) is at the focus of considerable theoretical and experimental efforts. SrRuO_3 has played a pivotal role in the study of the AHE and numerous attempts have been made to elucidate its complicated behavior. By using SrRuO_3 films with a wide range of thicknesses that vary considerably in the temperature-dependence of their resistivity, we show that the AHE scales with resistivity. The scaling provides a compelling piece of evidence that resistivity, *irrespective of its sources or nature (elastic or inelastic)*, determines the AHE of SrRuO_3 in the entire ferromagnetic phase. This observation strongly suggests that changes in Berry phase due to assumed temperature-dependent exchange splitting cannot explain the complicated temperature dependence of the AHE. On the other hand side jumps mechanism combined with Karplus-Luttinger (Berry phase) mechanism that takes into account effects of finite scattering time may explain the observed behavior.

8:12AM V9.00002 Optical spectroscopy of magnetic exchange splitting above the Curie temperature in ferromagnetic SrRuO_3 thin film, D.W. JEONG, C.H. KIM, C.H. SOHN, S.H. CHANG, H.J. PARK, T.D. KANG, Seoul National University, Y.S. LEE, Soongsil University, J.J. YU, T.W. NOH, Seoul National University — SrRuO_3 is a representative itinerant ferromagnetic material with the Curie temperature about 150K. To investigate the relation between magnetism and electronic structure, we measured temperature dependent optical spectra of SrRuO_3 thin film on SrTiO_3 substrate. With decreasing temperature, spectral weight transfer between 2.5eV and 3.2eV transition was observed. Comparing to the first-principles calculation, we attributed the weight transfer as a magnetic exchange splitting due to the Stoner transition. Interestingly, the exchange splitting remained above the Curie temperature, and destroyed near the room temperature. This observation indicates the long range magnetic ordering of SrRuO_3 is destroyed at the Curie temperature due to the transverse spin fluctuation not a Stoner transition. Moreover, using the optical sum rule of optical spectra, we systematically and quantitatively studied the ferromagnetic property of SrRuO_3 thin film.

8:24AM V9.00003 Electronic and magnetic properties of $\text{Ca}_{2-x}\text{Sr}_x\text{RuO}_4$ epitaxial thin films¹, LUDI MIAO, WENYONG ZHANG, PUNAM SILWAL, XIAOLAN ZHOU, ILAN STERN, JIN PENG, Tulane University, LEONARD SPINU, University of New Orleans, ZHIQIANG MAO, DAEHO KIM, Tulane University — Strongly correlated $\text{Ca}_{2-x}\text{Sr}_x\text{RuO}_4$ (CSRO) has attracted much attention for its rich physical properties such as Mott metal-insulator (MI) transition, antiferromagnetism (AFM), and spin-triplet superconductivity. We have grown epitaxial CSRO thin films on LaAlO_3 (001) substrates using a pulsed laser deposition method and investigated their electronic and magnetic properties. Ca_2RuO_4 thin films show strong compressive strain leading to an itinerant ferromagnetic (FM) phase coexisting with insulating AFM phase in the ground state and a suppressed broad and gradual MI transition. This is in sharp contrast to bulk Ca_2RuO_4 , which exhibits an AFM Mott-insulating ground state and sharp MI transition. While the $x=0.1$ and 0.5 CSRO films also exhibit coherent strain, the MI transition and itinerant ferromagnetism are partially suppressed in the $x=0.1$ film and fully suppressed in the $x=0.5$ film. In contrast, Sr_2RuO_4 thin films are not susceptible to strain on any perovskite substrates including LaAlO_3 ; superconductivity in these films is suppressed due to disorders resulting from strain relaxation.

¹This research is supported by DOD ARO under Grant No. W911NF0910530 and the LA-SIGMA program

8:36AM V9.00004 Optical properties of ferrimagnetic NiFe_2O_4 thin films, DIPANJAN MAZUMDAR, Center for Materials for Information Technology, University of Alabama, QI SUN, KEN O NEAL, BRIAN HOLINSWORTH, HUNTER SIMS, Chemistry Department, University of Tennessee, JIANXING MA, ARUNAVA GUPTA, WILLIAM BUTLER, JANICE MUSFELDT, Center for Materials for Information Technology, University of Alabama, U ALABAMA TEAM, U TENNESSEE TEAM — Magnetic insulators like NiFe_2O_4 are attracting attention due to the high Curie temperature (850 K), which is rare among oxides. We recently demonstrated the growth of high-quality NiFe_2O_4 thin films practically down to room temperature, which permits investigation of the optical properties over wide growth temperatures. Our spectroscopic work reveals that NiFe_2O_4 displays both direct and indirect band gaps. A plot of $(\alpha E)^2$ vs. energy places the 300 K direct gaps for the highest quality films at 2.77 and 2.36 eV for the majority and minority channels, respectively whereas a plot of $(\alpha E)^{0.5}$ vs. energy places the indirect band gap at 1.64 eV. For the indirect case, we extract a coupling phonon energy of ~ 50 meV (400 cm^{-1}), which corresponds to an infrared active O-Fe-O bending mode. The difference between the direct and indirect gap energies reveals an opportunity to obtain spin-polarized carriers via optical excitation. These features have strong overlap with the solar spectrum.

8:48AM V9.00005 Effects of Strain in Highly Ordered $\text{Sr}_2\text{CrReO}_6$ Epitaxial Films¹, A.J. HAUSER, J.R. SOLIZ, M. DIXIT, R.E.A. WILLIAMS, M.A. SUSNER, B. PETERS, L.M. MIER, T.L. GUSTAFSON, M.D. SUMPTION, H.L. FRASER, P.M. WOODWARD, F.Y. YANG, The Ohio State University — $\text{Sr}_2\text{CrReO}_6$, a double-perovskite ferrimagnet, has attracted much attention because of its Curie temperature well above room temperature and predictions of half-metallicity. We have deposited pure-phase $\text{Sr}_2\text{CrReO}_6$ epitaxial films on several (001)-oriented substrates and buffer layers by ultrahigh vacuum off-axis magnetron sputtering, in order to study tensile and compressive strain effects due to lattice mismatches up to 1.5%. Triple-axis x-ray diffractometry was used in tandem with direct observations via HAADF STEM to confirm film epitaxy, phase purity, Cr/Re ordering, and strain via film lattice constants. Magnetic characterization shows a marked effect on the saturation magnetization due to strain, with slight changes in the Curie temperatures. Finally, electrical and optical characterization suggest that $\text{Sr}_2\text{CrReO}_6$ is a gapped material under both unstrained and strained systems, and will be discussed in detail as well.

¹This work is supported by the Center for Emergent Materials at the Ohio State University, a NSF Materials Research Science and Engineering Center (DMR-0820414).

9:00AM V9.00006 Probing of polarization reversal and charge conduction in epitaxial (Ga,Fe)₂O₃ thin films on conducting oxide SrRuO₃, R.H. SHIN, S.H. OH, J.H. LEE, W. JO¹, Department of Physics, Ewha Womans University, Korea, C. LEFEVRE, A. TOMASSON, F. ROULLAND, C. MENY, N. VIART, Institut de Physique et Chimie des Matériaux de Strasbourg, France — Ga_{2-x}Fe_xO₃ (GFO) thin films are the promising room-temperature multiferroics since their magnetic T_C has been reported up to 370 K at x=1.4. However, most polarization hysteresis loops of the GFO thin films have been showed lossy behaviors due to the large leakage current. The origin probably lies on charge movement between Fe³⁺ and Fe²⁺ sites which is generated by oxygen vacancy. We report the large reduced leakage current of the GFO thin films by chemical doping to reduce Fe²⁺. The doped GFO thin films were deposited by pulsed laser deposition at 750°C for 15 min in oxygen partial pressure of 200 mTorr on SrRuO₃/SrTiO₃ substrates with various doping concentration. Epitaxy of b-axis orientation in out-of plane was confirmed by x-ray diffraction. The leakage current was reduced up to 5~6 order of magnitude depending on doping concentration. In order to investigate their conduction mechanism, temperature dependent macroscopic I-V curves were measured. Ferroelectric polarization and switching of the films were acquired over a wide range of temperature as well. Scanning probe microscopy has been used to measure local leakage currents as well as polarization reversal as a mode of conductive atomic force microscopy and piezoelectric microscopy, respectively. Local investigation of their electrical properties alludes to ferroelectricity in GFO.

9:12AM V9.00007 Manipulating magnetic phase competition in manganites¹, T. ZAC WARD, ZHENG GAI, XIAOSHAN XU, Oak Ridge National Laboratory, HANGWEN GUO, WENBIN WANG, University of Tennessee — We will discuss recent investigations attempting to isolate single order parameters in the spin-charge-orbital-lattice hierarchy in order to further understand how these complex interactions govern macroscopic electronic and magnetic properties. Specifically, we will present recent findings on strongly correlated thin films of [LaCa]MnO₃, [LaSr]MnO₃, and [LaPrCa]MnO₃. We have developed new experimental methods that allow for both spin engineering and strain engineering at an interface to be tested on these materials; this has allowed us a glimpse at the interplay driving emergent phenomena. We have found that it is possible to exert a measure of control over the electronic phase competition leading to colossal magnetoresistance and the metal-insulator transition in manganites. This work has also been coupled with novel confinement techniques that allow us to observe single domain transitions using basic resistivity measurements which has led to several new discoveries on the formation and dynamics of electronic domains. These studies offer new means to quantitatively investigate the balanced energetics that drive complex materials and promise an ability to tune critical temperatures and desired electronic/magnetic properties.

9:24AM V9.00008 Role of Interface Transport in the Magnetoresistance of Strained Rare Earth Manganite Thin Films¹, PARUL SRIVASTAVA, TYLER GOEHRINGER, CACIE HART, GILLES DONGMO-MOMO, EKEMBU KEVIN TANYI, GRACE YONG, VERA SMOLYANINOVA, DAVID SCHAEFER, RAJESWARI KOLAGANI, Towson University — We are studying the temperature and field dependence of magnetoresistance in epitaxial thin films of rare earth manganites which are subject to lattice mismatch strain, with the goal of investigating the possible role of transport across strain-induced internal interfaces. We will present our results, comparing La_{0.67}Ca_{0.33}MnO₃ (LCMO) thin films grown on by Pulsed laser deposition on different substrates with varying degrees of compressive or tensile lattice mismatch. Strained films of thickness ~ 10 nm, show a large magnetoresistance in fields < 1 Tesla, which continues to increase with decrease in temperature, similar to magnetoresistance associated with grain boundary transport. The temperature dependence of MR in these films does not correlate with the temperature dependence of resistivity and thus seems to originate from effects other than Mn spin alignment. Lattice mismatch strain is known to suppress the insulator-metal transition and enhance charge and orbital ordering, leading to the coexistence of insulating and ferromagnetic metallic phases. Our results suggest possible contributions to the magnetoresistance from transport across the interfaces between the different phases.

¹TG,CH and GD acknowledge support from Undergraduate Research grants from Fisher College of Science and Mathematics and Towson University Undergraduate research Committee.

9:36AM V9.00009 Correlation between the transport properties, atomic structure and oxygen vacancies of perovskites thin films, JUAN RUBIO-ZUAZO, PILAR FERRER, IGOR MADARIAGA, JONANDER GALLASTEGUI, GERMAN R. CASTRO, CRG SpLine at the ESRF, CRG SPLINE-BM25 TEAM — We present a study of the role of the oxygen vacancies on the atomic structure and the transport properties of a 20 nm thick La_{0.7}Ca_{0.3}MnO₃ thin film grown by the pulsed laser deposition method on a SrTiO₃ (001) substrate. The results show that the manganite lattice can accommodate up to 13% of oxygen vacancies maintaining high crystalline order. Under such conditions the atomic structure is characterized by the movement of the La/Ca cations to the perovskite regular position, by the absence of the MnO₆ basal plane rotation, and by a cooperative tilting of the octahedra along the out-of-plane direction. The metal-to-insulator transition temperature decreases from 265K for the fully oxygenated sample to 28 K for the sample with 13% of oxygen deficiency..

9:48AM V9.00010 The metal-insulator transition in a phase-separated manganite studied by in situ STS¹, P.C. SNIJDERS, ORNL, M. GAO, IOP, CAS, Beijing, China and ORNL, H. GUO, ORNL, Univ. of Tennessee, T.Z. WARD, ORNL, H.-J. GAO, IOP, CAS, Beijing, China, J. SHEN, Univ. of Tennessee and Fudan Univ. Shanghai, China, Z. GAI, ORNL — Electronic phase separation (EPS) is a key feature at the heart of the wide variety of electronic and magnetic properties in complex oxides. One consequence of EPS is that electronic transport experiments in bulk materials or 2D films mostly probe the low resistivity electronic phases due to the percolative path of the current. We study oxygen deficient La_{5/8-x}Pr_xCa_{3/8}MnO₃ (LPCMO) thin films using both *in situ* scanning tunneling spectroscopy (STS) and *ex situ* transport experiments. The oxygen deficiency is known to decrease the metal-insulator transition (MIT) temperature or even completely suppress the MIT in conventional transport experiments. We show that *in situ* STS is able to detect the MIT even in systems where conventional transport experiments do not show an MIT at zero magnetic field.

10:00AM V9.00011 Electroresistance and Joule heating effects in manganite thin films, BENJAMIN MARTINEZ, LUIS PENA, REGINA GALCERAN, ZORICA KONSTANTINOVIC, ALBERTO POMAR, BERNAT BOZZO, LLUIS BALCELLS, FELIP SANDIUMENGE, ICMAB-CSIC. Campus de Bellaterra, Bellaterra-08193. SPAIN, NANOSTRUCTURED MAGNETIC MATERIALS TEAM — Electroresistance (ER), i.e. electric field- and/or current-induced resistance switching, has attracted much attention recently because of the possibility of using it for the implementation of resistance random access memories (ReRAM). Although ER is a quite common phenomenon in transition metal oxides, that has been extensively studied both theoretically and experimentally, the precise mechanism involved is not clear yet. In this work we report on the ER measurements in patterned La_{2/3}Sr_{1/3}MnO₃ (LSMO) thin films prepared by sputtering. In order to analyze Joule heating effects we have evaporated a Pt layer on top of the LSMO path to have access to the actual temperature of the sample while measuring resistance of LSMO path or I(V) characteristic curves. I(V) curves have been measured at different temperatures and the corresponding resistance values are compared with that of the R(T) curve taking into account the actual temperature of the sample in order to clarify the role of Joule heating in the observed change of the resistance.

10:12AM V9.00012 Anisotropic magnetoresistance in thin films of the Mott metal CaVO_3 ¹, JIWEI LU, MAN GU, University of Virginia — Bulk CaVO_3 (CVO) is a Pauli paramagnetic metal with a single 3d electron. Some unusual drastic changes in the magneto-resistance, magnetic susceptibility and the Hall effect have been reported in single crystal CVO. We have simultaneously synthesized epitaxial CVO films grown on three differently oriented SrTiO_3 substrates. Colossal magneto-resistance (MR) as well as large crystalline anisotropic was observed at low temperatures. The maximum MR, defined as $(R(7\text{ T})-R(0\text{ T}))/R(0\text{ T})*100\%$, was over 1,000% at 2 K and 35 Tesla (parallel magnetic field) on the CVO films deposited on a (110) SrTiO_3 single crystal substrate, and didn't show any sign of saturation. When the magnetic field was perpendicular, MR was dropped to 6,000%. The MR ratio was much larger than that of single crystal CVO. We have also investigated the magneto-transport behaviors of CVO films deposited on (111) and (100) STO and will discuss the dependence of MR in CVO on the crystal orientation as well as the orientation of external magnetic field.

¹We are thankful to the support from ARO

10:24AM V9.00013 Magnetoelectric effects in Fe_3O_4 thin films, JARED WONG, ADRIAN SWARTZ, RENJING ZHENG, ROLAND KAWAKAMI, Dept. of Physics and Astronomy - University of California, Riverside — Recently, there has been great interest in voltage-induced manipulation of magnetic properties inside magnetic materials. One attractive avenue is using magnetic oxides, which could be susceptible to manipulation of magnetic properties by electric fields at the interface and/or directly altering the electronic behavior within strongly correlated systems, for example. Magnetite (Fe_3O_4) is quite interesting because it exhibits many interesting properties such as ferrimagnetism, ferroelectricity (at low temperatures) and a metal-insulator phase transition near 120 K known as the Verwey transition. Single crystal Fe_3O_4 samples are deposited through reactive molecular beam epitaxy (MBE) on MgO (001) substrates and the structural quality is confirmed through XRD, RHEED, and LEED. Magnetic properties are examined through magneto-optic Kerr effect (MOKE) measurements and 4-probe I-V / Van Der Pauw measurements were used to determine the electronic properties. Samples are incorporated into an electrically gated structure by the addition of a dielectric layer and metallic top electrode and we report our results and observations of voltage-induced manipulation of the magnetic properties inside thin films of Fe_3O_4 .

10:36AM V9.00014 Dynamics of multiple phases in manganite as revealed by dielectric spectroscopy¹, ZHIGAO SHENG, CERG, ASI-RIKEN, Japan, MASAO NAKAMURA, CERG & CMRG ASI-RIKEN, Japan, MASASHI KAWASAKI, YOSHINORI TOKURA, CERG & CMRG ASI-RIKEN, Japan; University of Tokyo, Japan — Phase separation is a very important feature in correlated electron oxides. The coexistence and competition of multiple phases give rise to gigantic response to tiny stimuli, producing dramatic changes in magnetic, transport, and other properties in these compounds [1]. It is crucial to probe the physical properties of each phase separately for a comprehensive understanding of correlated electron oxide materials and their phase separation, but it is difficult due to their nano-scale distribution. Here we report dynamic properties of multiple phases in manganite thin films by using dielectric spectroscopy with a unique $p-N$ junction configuration. The multiple dielectric relaxations have been detected and we distinguished their corresponding multiple phases. The activation energy and dielectric properties of different phases have been deduced separately. We also elucidated their phase evolution with changing of temperature or applied magnetic field from viewpoint of dielectric response. These results provide a guideline to explore the electronic phase separation phenomena in correlated electron oxides.

10:48AM V9.00015 Interface induced giant magnetoelectric coupling in multiferroelectric superlattices, HONGWEI WANG¹, LIXIN HE², Key Laboratory of Quantum Information, University of Science and Technology of China, XIFAN WU³, Department of Physics and Institute for Computational Molecular Science, — AMnO_3 ($A=\text{Ca}, \text{Sr}, \dots$) are good candidates as building blocks for the multiferroic superlattices, because they have several competing instabilities coupled to the magnetic ordering. The coupling between the spin, the AFD modes and the FE modes depends on the relative energetics of these instabilities. Unfortunately in bulk AMnO_3 , there is a strong AFD instability associated with a large oxygen octahedral rotation that suppresses the FE mode. As a result, the linear magnetoelectric (spin-ferroelectricity) coupling is usually found to be weak. We take the $\text{CaMnO}_3(\text{CMO})/\text{BaTiO}_3(\text{BTO})$ SLs as our model systems. We find that the MnO_6 octahedral rotation will be strongly suppressed by the neighboring BaO layers, leading to the enormous enhancement of magnetoelectric coupling and the local electric polarizations in the CMO layers are significant, comparable to that in the BTO layers. This enhancement will be strengthened with the increasing density of interfaces and reaches its maximum at the shortest SL, (i.e., $n=1$) where one observes a huge change of electric polarization between the antiferromagnetic (AFM) and ferromagnetic (FM) states.

Session V10 GQI DAMOP: Invited Session: Quantum Entanglement in Many-Body Systems

210A

8:00AM V10.00001 Entanglement, teleportation and memory in atomic spin ensembles, EUGENE POLZIK, Niels Bohr Institute, Copenhagen University — Recent experimental progress with entanglement generation and processing in macroscopic atomic spin ensembles will be reviewed. It includes atomic entanglement maintained for an unlimited time via engineered collective dissipation mediated by light and teleportation of collective atomic spin states. A proposal for quantum memory assisted detection of strongly coupled systems will be presented.

8:36AM V10.00002 Entanglement and real-space renormalization group methods for quantum field theories, FRANK VERSTRAETE, University of Vienna — We will demonstrate how the reformulation of the density matrix renormalization group as a variational method within the class of matrix product states has led to a wide class of novel applications and insights into strongly correlated quantum systems in 1 dimension. The discussion will detail the crucial role of entanglement and area laws, and then focus on the generalization of matrix product state methods to quantum field theories and the prospects of simulating experiments with cold gasses. Joint work with I. Cirac, J. Haegeman, T. Osborne.

9:12AM V10.00003 Entangled States of Trapped Ions¹, DIETRICH LEIBFRIED, National Institute of Standards and Technology — Entangled states of the internal degrees of freedom are an important resource in Quantum Information Processing (QIP) and Quantum Simulation (QS) with trapped ions. Most basic requirements for QIP and QS have been demonstrated for trapped ions, with two big challenges remaining: Improving operation fidelity and scaling up to larger numbers of qubits. In the last few years, steady progress has been achieved with laser-based entanglement schemes with demonstrated fidelities of deterministically produced Bell states of 99.3% and up to 14 ion-qubits entangled in generalized GHZ-states. Scalable architectures have been proposed; one scheme, where ion-qubits are moved through a multi-zone trap array, is studied in several laboratories. Sympathetic cooling with a second ion species, which initializes the motional states for multi-qubit operations, has been demonstrated in an experiment where arbitrary operations on two qubits were implemented. Micro-fabrication approaches to ion-trap-arrays have yielded structures that should be capable of holding and manipulating large numbers of ions. Recently, with the use of microwaves, single-qubit rotations with fidelities of 99.998% per gate operation were demonstrated and two ion-qubit gates have been implemented. Microwave control could potentially be easier to scale by directly integrating microwave-lines on micro-fabricated trap devices. It also eliminates several sources of decoherence that are present in laser-based schemes by exclusively coupling to long lived hyperfine ground states.

¹NIST work has been supported by IARPA, DARPA, NSA, ONR and the NIST Quantum Information Program.

9:48AM V10.00004 Topological order and long range quantum entanglements, XIAO-GANG WEN, Dept. of Physics, MIT — What is the origin of fractional charges and fractional statistics in FQH states? What is the origin of light? It turns out that long range entanglement is the reason why fractional charges and fractional statistics can appear FQH state. Long range entanglement is also the reason why waves that satisfy Maxwell equation can appear in some qubit (spin) systems. Long range entanglement also lead to a deeper understanding of gapped quantum phases. It allows us to obtain a classification of interacting topological insulators/superconductors, as well as the much more general symmetry protected topological phases, and intrinsic topological phases.

10:24AM V10.00005 Entangled states as resources in quantum complexity theory, SCOTT AARONSON, MIT Dept. of Electrical Engineering and Computer Science — No abstract available.

Thursday, March 1, 2012 8:00AM - 11:00AM –
Session V11 DMP: Focus Session: Graphene Structure, Stacking, Interactions: Edges and Grain Boundaries 210B

8:00AM V11.00001 Theory and hierarchical calculations of [0001] tilt grain boundaries in graphene, JOHAN CARLSSON, Accelrys Ltd, Cambridge (UK) and Fritz-Haber-Institut, D-14195, Berlin, LUCA M. GHIRINGHELLI, Fritz-Haber-Institut der MPG, D-14195, Berlin, A. FASOLINO, Institute for Molecules and Materials, Radboud University Nijmegen, The Netherlands — Several experiments have revealed the presence of grain boundaries in graphene that may change its electronic and elastic properties. Here, we present a general theory for the structure of [0001] tilt grain boundaries in graphene based on the coincidence site lattice (CSL) theory. We show that the CSL theory uniquely classifies the grain boundaries in terms of the misorientation angle θ and periodicity d . The structure and formation energy of a large set of grain boundaries generated by the CSL theory for $0^\circ < \theta < 60^\circ$ (up to 15 608 atoms) were optimized by a hierarchical methodology and validated by density functional calculations. We find that low-energy grain boundaries in graphene can be identified as dislocation arrays. In contrast to three-dimensional materials, the strain created by the grain boundary can be released via out-of-plane distortions that imply to an effective attractive interaction between dislocation cores. This leads to a (secondary) minimum structure at $\theta = 32.2^\circ$, where the grain boundary is made of a flat zigzag array of only 5- and 7-rings. We discuss the importance of these findings for the interpretation of recent experimental results.

8:12AM V11.00002 Localized states at grain boundaries in graphite¹, ADINA LUCAN-MAYER, GUOHONG LI, Department of Physics and Astronomy, Rutgers University, GABRIEL AUTES, OLEG YAZYEV, Ecole Polytechnique Federale de Lausanne (EPFL), Switzerland, EVA Y. ANDREI, Department of Physics and Astronomy, Rutgers University — Scanning Tunneling Microscopy and Spectroscopy at low temperature and in magnetic field was used to characterize the electronic states near grain boundaries on the surface of graphite. Topographic surface maps show the grain boundaries as narrow stripes within which the lattice is reconstructed into a periodic pattern whose period is determined by the relative orientation between adjacent grains. In spectroscopy the grain boundaries produce sharp peaks in the density-of-states at energies that are characteristic of the misorientation between adjacent grains. Spatial maps of the density-of-states at these peak energies show that the peaks correspond to electronic states that are localized on the grain boundaries. We will present measurements of these localized electronic states, their evolution with magnetic field and misorientation angle between grains. The experimental results will be compared with theoretical calculations.

8:24AM V11.00003 Altering graphene line defect properties using chemistry¹, SMITHA VASUDEVAN, George Washington University, CARTER WHITE, DANIEL GUNLYCKE, Naval Research Laboratory — First-principles calculations are presented of a fundamental topological line defect in graphene that was observed and reported in Nature Nanotech. 5, 326 (2010). These calculations show that atoms and smaller molecules can bind covalently to the surface in the vicinity of the graphene line defect. It is also shown that the chemistry at the line defect has a strong effect on its electronic and magnetic properties, e.g. the ferromagnetically aligned moments along the line defect can be quenched by some adsorbates. The strong effect of the adsorbates on the line defect properties can be understood by examining how these adsorbates affect the boundary-localized states in the vicinity of the Fermi level. We also expect that the line defect chemistry will significantly affect the scattering properties of incident low-energy particles approaching it from graphene.

¹This work was supported by the Office of Naval Research, directly and through the Naval Research Laboratory.

8:36AM V11.00004 Imaging the Structure of Grains, Grain Boundaries, and Stacking Sequences in Single and Multi-Layer Graphene¹, DAVID MULLER, Cornell University — Graphene can be produced by chemical vapor deposition (CVD) on copper substrates on up to meter scales [1, 2], making their polycrystallinity [3,4] almost unavoidable. By combining aberration-corrected scanning transmission electron microscopy and dark-field transmission electron microscopy, we image graphene grains and grain boundaries across six orders of magnitude. Atomic-resolution images of graphene grain boundaries reveal that different grains can stitch together via pentagon-heptagon pairs. We use diffraction-filtered electron imaging to map the shape and orientation of several hundred grains and boundaries over fields of view of a hundred microns. Single, double and multilayer graphene can be differentiated, and the stacking sequence and relative abundance of sequences can be directly imaged. These images reveal an intricate patchwork of grains with structural details depending strongly on growth conditions. The imaging techniques enabled studies of the structure, properties, and control of graphene grains and grain boundaries [5].

9:12AM V11.00005 Experimentally Controlling the Edge Termination of Graphene Nanoribbons, XIAOWEI ZHANG, OLEG YAZYEV, University of California, Berkeley and Lawrence Berkeley National Laboratory, JUANJUAN FENG, University of California, Berkeley and Lanzhou University, Lanzhou, China, CHENGGANG TAO, YEN-CHIA CHEN, University of California, Berkeley and Lawrence Berkeley National Laboratory, LIMING XIE, Stanford University, Stanford, STEVEN LOUIE, ALEX ZETTL, University of California, Berkeley and Lawrence Berkeley National Laboratory, HONGJIE DAI, Stanford University, Stanford, MICHAEL CROMMIE, University of California, Berkeley and Lawrence Berkeley National Laboratory — The edges of graphene exhibit several unique features, such as the presence of localized edge states, and are anticipated to be a powerful means of controlling the electronic properties of this two-dimensional material. Understanding such properties, however, requires a precise knowledge of the atomic-scale structure and chemical composition of the edge. In this work, the edges of graphene nanoribbons (GNRs) are controlled by hydrogen plasma and are investigated through a combination of high-resolution scanning tunneling microscopy (STM) and first-principles calculations. We recover the atomic structure of the edge termination in atom-by-atom fashion and establish the chemical nature of terminating functional groups at graphene edge segments of different orientation – (i.e., zigzag, armchair and chiral). These results allow us to conclude that the edges of hydrogen-plasma-etched GNRs are generally free of structural reconstructions and are terminated by hydrogen atoms with no rehybridization of the outermost carbon edge atoms. Both zigzag and chiral edges show the presence of edge states.

9:24AM V11.00006 Tunable magnetism at graphene edges, MANUEL SCHMIDT, RWTH Aachen, Institute for Theoretical Solid State Physics — Electron-electron interactions drive clean graphene zigzag edges to a ferromagnetic state, known as edge magnetism. In this state, the spin of specific one-dimensional electronic modes, that are localized at the edge (the so-called edge state), is fully polarized. I will discuss a mechanism by which the edge magnetism can be manipulated via electric fields. One possible realization of this mechanism is based on graphene/graphane interfaces. As the field strength is varied, the graphene edge undergoes two phase transitions: (1) from fully polarized edge magnetism to a ferromagnetic Luttinger liquid (fLL) and (2) from the fLL to an ordinary Luttinger liquid. The intermediate phase (fLL) is a realization of the unusual itinerant one-dimensional ferromagnet and is therefore in seeming contradiction with the Lieb-Mattis theorem, which forbids such one-dimensional magnetism. The resolution of this seeming contradiction is shortly discussed.

9:36AM V11.00007 Dynamics of Graphene Edges Interaction under Joule-heating, XU ZHANG, Department of Electrical Engineering and Computer Science, MIT, Cambridge, MA, XIAOTING JIA, Department of Materials Science and Engineering, MIT, Cambridge, MA, EDUARDO CRUZ-SILVA, Department of Physics, Rensselaer Polytechnic Institute, Troy, NY, LEE-PING WANG, Department of Chemistry, MIT, Cambridge, MA, JESSICA CAMPOS-DELGADO, Laboratory for Nanoscience and Nanotechnology Research (LINAN), México, PAULO ANTONIO ARAUJO, Department of EECS, MIT, Cambridge, MA, VINCENT MEUNIER, Department of Physics, Rensselaer Polytechnic Institute, NY 12180, MAURICIO TERRONES, Department of Physics, Pennsylvania State University, PA, TOMAS PALACIOS, Department of Electrical Engineering and Computer Science, MIT, Cambridge, MA, MILDRED DRESSELHAUS, Department of Electrical Engineering and Computer Science, Department of Physics, MIT, Cambridge, MA — The edge physics of graphene plays an essential role in the electronic properties of nanometer scale graphene. Studying the Joule-heating of a graphene sample supported by an integrated TEM-STM instrument is an effective way to sharpen graphene edges, and therefore produce smooth graphene nanoribbons, which will be studied in this work. Through observation of the movement of graphene platelets heat-treated within a crystalline domain of graphene substrate underneath, we advance our understanding about the mechanism of edge reconstruction, edge-edge interaction, in addition to the graphene substrate interaction for single layer graphene.

9:48AM V11.00008 Structure, Stability and Electronic Properties of Graphene Edges on Co(0001), DEBORAH PREZZI, S3 CNR-Nano, IT, DAEJIN EOM, Columbia University, NY, KWANG T. RIM, Columbia University, HUI ZHOU, MICHAEL LEFENFELD, COLIN NUCKOLLS, TONY F. HEINZ, GEORGE W. FLYNN, Columbia University, NY, MARK S. HYBERTSEN, Brookhaven National Laboratory, NY — We recently demonstrated the growth of epitaxial graphene flakes on Co(0001) surfaces [1]. Here we combine low-temperature scanning tunneling microscopy (STM) measurements and DFT calculations to study graphene edge stability and electronic properties, as resulting from the coupling with the substrate. Graphene edges display straight well-ordered structure with zigzag orientation. DFT calculations provide insights into their stability by comparing several edge morphologies with both armchair and zigzag orientation. Simulated images indicate that different edge structures can be clearly distinguished in topography at low bias. The calculated electronic properties for the low energy edge structures are consistent with the measured STS tunneling spectra, which show a prominent edge-localized peak at low bias. [1] D. Eom *et al.*, *Nano Lett.* **9**, 2844 (2009).

10:00AM V11.00009 Chemical versus Thermal Folding of Graphene Edges¹, NINGHAI SU, MIAO LIU, FENG LIU, Department of Materials Science and Engineering, University of Utah — Using molecular dynamics (MD) simulations, we have investigated the kinetics of the graphene edge folding process. The lower limit of the energy barrier is found to be ~ 380 meV/Å (or about 800 meV per edge atom) and ~ 50 meV/Å (or about 120 meV per edge atom) for folding the edges of intrinsic clean single-layer graphene (SLG) and double-layer graphene (DLG), respectively. However, the edge folding barriers can be substantially reduced by imbalanced chemical adsorption, such as of H atoms, on the two sides of graphene along the edges. Our studies indicate that thermal folding is not feasible at room temperature (RT) for clean SLG and DLG edges and is feasible at high temperature only for DLG edges, whereas chemical folding (with adsorbates) of both SLG and DLG edges can be spontaneous at RT. These findings suggest that the folded edge structures of suspended graphene observed in some experiments are possibly due to the presence of adsorbates at the edges.

¹This work was supported by DOE (#DE-FG02-03ER46027, DE-SC0001061); NSF-DMR (#0909212).

10:12AM V11.00010 Edge effects in Zigzag Graphene Nanoribbons¹, WEN YING RUAN, School of Physics, Georgia Institute of Technology, YIYANG SUN, SHENG BAI ZHANG, Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute, Troy, NY 12180, USA, MEI-YIN CHOU, School of Physics, Georgia Institute of Technology, Atlanta, GA 30332, USA, and Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan — Analytical and numerical results based on the tight binding model are presented for zigzag graphene nanoribbons with z1 and z12₁₂ edges. We show the crucial importance of the symmetry of the two edges in determining the electronic structures of the system. Examples of significant band gap narrowings due to symmetry breaking are illustrated.

¹Supported by US DOE grant No. DEFG02-97ER45632 and DE-SC0002623.

10:24AM V11.00011 Mapping edge-state wavefunctions in chiral graphene nanoribbons, YEN-CHIA CHEN, DIMAS G. DE OTEYZA, XIAOWEI ZHANG, DAVID STRUBBE, Department of Physics, University of California at Berkeley, LIYING JIAO, Department of Chemistry and Laboratory for Advanced Materials, Stanford University, ALEX ZETTL, Department of Physics, University of California at Berkeley, HONGJIE DAI, Department of Chemistry and Laboratory for Advanced Materials, Stanford University, STEVEN G. LOUIE, MICHAEL F. CROMMIE, Department of Physics, University of California at Berkeley — The electronic behavior of graphene is readily tunable through nanoscale patterning. A particularly important structural motif is the nanoribbon (GNR), a narrow strip of graphene defined by its width, length, and edge properties. GNRs, due to quantum confinement and edge effects, have been predicted to exhibit many novel behaviors, such as tunable energy gaps and the presence of magnetic edge states. Here we report measurement of the local electronic structure of GNRs with highly ordered edges obtained by unzipping carbon nanotubes. Due to variation in the precursor nanotubes, this synthesis method generally produces single- or multi-layered nanoribbons with varying widths, lengths and chiralities. We have combined scanning tunneling microscopy (STM) and spectroscopy (STS) to simultaneously characterize the structural and electronic properties of these GNRs at the atomic scale. In particular, we observe 1D edge states that exhibit an energy gap that is dependent on nanoribbon width and the chirality. We have further spatially mapped patterns in the electronic local density of states associated with different GNR spectroscopic resonances. These patterns are compared with theoretical simulations.

10:36AM V11.00012 Effects of edge-potential on armchair graphene open boundary and nanoribbon, CHI-HSUAN CHIU, CHON-SAAR CHU, ElectroPhysice department, National Chiao Tung University, Taiwan — The physics for the edge state formation and gap opening at an armchair graphene open boundary and nanoribbon due to an edge potential are investigated. At an open boundary, the edge-potential U_0 is shown to turn on pseudospin-flipped (intravalley) scattering even though U_0 does not post an apparent breaking of the AB site (basis atoms) symmetry. The interference between the pseudospin conserving (intervalley) and nonconserving (intravalley) processes in the scattering state leads to a finite out-of-plane pseudospin density. Similar two-waves feature in the evanescent regime leads to the formation of the edge state. This physical origin of the edge state is different from that for the Tamm states in semiconductors. For an armchair graphene nanoribbon with gapless energy spectrum, applying U_0 to both edges opens up an energy gap. In addition, dispersive edge state can be found inside the energy gap for the bulk-like states. The U_0 -induced out-of-plane pseudospin density vanishes for the armchair graphene nanoribbon, but we expect it to be finite, for more general cases, at an armchair graphene open boundary.

10:48AM V11.00013 Formation of unconventional standing waves at graphene edges, CHANG-WON PARK, Department of Physics and Astronomy, Seoul National University, HEEJUN YANG, Graphene Research Center, Samsung Advanced Institute of Technology, Samsung Electronics, JISOON IHM, Department of Physics and Astronomy, Seoul National University, GUNN KIM, Department of Physics and Graphene Research Institute, Sejong University — The electron scattering properties of graphene edge have been investigated by the interference images using the scanning tunneling microscopy (STM). A conventional metal with a terrace and a step can be modeled as a two-dimensional electron gas with a hard wall and this behavior was directly observed at the steps of Au(111) and Cu(111) surfaces by STM. Now, a question arises as to how two sublattices and two inequivalent valleys in graphene affect the scattering and the standing wave formation. We present how the contributions from two valleys vary in the scattering at different graphene edges. For the zigzag edge, only intravalley scattering is possible due to the different edge-direction crystal momentum of two valleys. For the armchair edge, in contrast, the wave is reflected mostly via intervalley scattering and as a result, an atomic-scale nodalike pattern and beats in the standing wave are generated near the edge. When the incident angle is small, this intervalley scattering process is quite robust in the presence of defects so that we can still observe nodal patterns even for edges of relatively high defect densities.

Thursday, March 1, 2012 8:00AM - 11:00AM –
Session V12 DMP DCMP: Graphene: Optical Properties and Responses 210C

8:00AM V12.00001 Temperature dependence of hot carrier-assisted photoresponse in graphene, QIONG MA, NATHANIEL GABOR, NITYAN NAIR, Department of Physics, Massachusetts Institute of Technology, Cambridge, MA 02139, USA, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Namiki 1-1, Tsukuba, Ibaraki 305-0044, Japan, PABLO JARILLO-HERRERO, Department of Physics, Massachusetts Institute of Technology, Cambridge, MA 02139, USA — We report on temperature dependent photocurrent measurements of high-quality dual-gated monolayer graphene p-n junction devices. Over temperatures ranging from 5 K to 300 K, we find that the photocurrent at the p-n interface peaks at an intermediate temperature, and decreases at higher and lower temperatures. Spatial photocurrent microscopy (at wavelength 850 nanometers) shows that the photocurrent measured as a function of distance away from the p-n interface also varies with temperature. We consider various electronic cooling processes in graphene to explain the photocurrent temperature dependence. Our measurements may reveal novel energy loss processes that reduce the electronic temperature of photoexcited charge carriers in graphene, and give additional insight into hot carrier photoresponse.

8:12AM V12.00002 Hot-Carrier cooling at Graphene-Metal Contact Interface¹, JASON ROSS, Department of Materials Science & Engineering, University of Washington, Seattle, GRANT AIVAZIAN, DONG SUN, AARON JONES, Department of Physics, University of Washington, Seattle, WANG YAO, Department of Physics and Center of Theoretical and Computational Physics, The University of Hong Kong, DAVID COBDEN, XIAODONG XU, Department of Physics, University of Washington, Seattle — There has been a recent surge of interest in using graphene as broadband and ultrafast optoelectronics, however the mechanisms of photodetection are not yet fully understood. Our previous measurements at a top gated graphene pn junction and at a monolayer-bilayer interface have found the dominating mechanism to be photothermoelectric (PTE) in nature, whereas most graphene-metal contact (GM) studies attribute photocurrent to the photovoltaic effect. By performing comprehensive ultrafast optical pump-probe measurements of photocurrent as a function of temperature, Fermi level, and laser power at various GM interfaces, the current work differentiates the contributions of PTE and photovoltaic effects to the photocurrent and identifies a hot-carrier relaxation time of ~ 2 ps at room temperature and ~ 7 ps at cryogenic temperatures. This work provides valuable insight to the design of new graphene based optoelectronic devices for sensing and communication.

¹We thank the support of DARPA YFA.

8:24AM V12.00003 Time Resolved Carrier Distributions in Graphene, STEVE GILBERTSON, GEORGI DAKOVSKI, TOMASZ DURAKIEWICZ, JIAN-XIN ZHU, KESHAV DANI, ADITYA MOHITE, ANDREW DATTELBAUM, GEORGE RODRIGUEZ, Los Alamos National Laboratory — Graphene, a recently discovered two-dimensional form of carbon, is a strong candidate for many future electronic devices. A question of central importance in optoelectronics, particularly high-speed applications, is how photoexcited carriers behave on ultrashort time scales. Even though time-resolved studies have provided a wealth of information, fundamental questions concerning the quantum descriptions of the transient electron-hole plasma remain. On one hand, conflicting views on the relaxation dynamics go as far as precluding the possibility of observing some predicted phenomena, such as THz lasing or tunable lasers while the observation of phenomena such as ultrafast photoluminescence and carrier multiplication are already established. Here, by employing the technique of time-resolved photoemission, we directly obtain the evolving Fermi-Dirac distributions of the electrons and holes: on an ultrashort 500 fs time scale the electron and hole populations can be described by two separate Fermi-Dirac distributions, while on longer time scales the populations coalesce to form a single Fermi-Dirac distribution at an elevated temperature. This unusual behavior is a consequence of graphene's unique band structure and has important implications for possible applications.

8:36AM V12.00004 Gate-tunable nanoplasmonic effects in single- and bi-layer graphene, ZHE FEI, GREGORY ANDREEV, University of California, San Diego, WENZHONG BAO, University of California, Riverside, ALEKSANDR RODIN, ALEXANDER MCLEOD, University of California, San Diego, LINGFENG ZHANG, Boston University, ZENG ZHAO, University of California, Riverside, GERARDO DOMINGUEZ, MARK THIEMENS, MICHAEL FOGLER, University of California, San Diego, ANTONIO CASTRO-NETO, National University of Singapore, CHUNNING LAU, University of California, Riverside, FRITZ KEILMANN, Max Plank Institute of Quantum Optics, DIMITRI BASOV, University of California, San Diego — We employed near-field infrared (IR) nanoscopy and nanoimaging to study mid-IR nanoplasmonic effects of both single-layer graphene (SLG) and bilayer graphene (BLG) on SiO₂/Si substrate. In our previous study, we found that SLG enhanced and blueshifted the surface phonon resonance of SiO₂ due to plasmon-phonon coupling [Z. Fei et al. Nano. Lett. 2011]. Here we report that both these effects are also observed in BLG. Using back-gate we were able to systematically change the carrier density in both SLG and BLG while monitoring the evolution of the hybrid plasmon-phonon resonance. New data are in accord with our point-dipole modeling results. IR imaging with nanoscale resolution revealed fringe patterns extending along the edges of both SLG and BLG. We ascribe these patterns to the interference of plasmon waves launched by the near-field probe with those reflected from the edges. Detailed analysis allowed us to observe gate-induced changes in the plasmon dispersion of both SLG and BLG, which are consistent with the notion of massless Dirac fermions in SLG and massive carriers in BLG.

8:48AM V12.00005 Atomically Localized Plasmon Enhancement in Monolayer Graphene, JUAN CARLOS IDROBO, Oak Ridge National Laboratory, WU ZHOU, JAEKWANG LEE, Vanderbilt University, JAGJIT NANDA, Oak Ridge National Laboratory, SOKRATES T. PANTELIDES, Vanderbilt University, STEPHEN J. PENNYCOOK, Oak Ridge National Laboratory — Graphene has attracted significant attention due to its exceptional properties and very promising applications, including optoelectronics and nanoplasmonics. All localized plasmon resonances observed so far in materials have been limited to the sub-10 nanometer scale, with a reported record of $\lambda/40$, where λ is the wavelength of the related plasmon excitation. In this talk, using aberration-corrected scanning transmission electron microscopy and total energy first-principles calculations, we show that single point defects can enhance the π and $\pi + \sigma$ plasmons of monolayer graphene at the atomic level. Our study shows that point defects in monolayer graphene represent a length scale smaller than $\lambda/200$, and suggest that the physical limit for the size of plasmonic and optoelectronic devices can be down to the single atom level. This research was supported by NSF grant No. DMR-0938330 (WZ, J-CI), DOE grant DE-F002-09ER46554 (STP), by the Shared Research Equipment (SHaRE) User Facility, Oak Ridge National Laboratory, which is sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences (J-CI), and by the Office of Basic Energy Sciences, Materials Sciences and Engineering Division, U.S. Department of Energy (JL, JN, SJP).

9:00AM V12.00006 Effect of nonhomogenous dielectric background on the plasmon modes in graphene double-layer structures¹, SAMVEL BADALYAN, PREDRAG KRSTAJIC, FRANCOIS PEETERS, Department of Physics, University of Antwerp, B-2020 Antwerpen, Belgium — We have calculated the plasmon modes in graphene double layer structures, taking into account the non-homogeneity of the system dielectric background. The effective dielectric function is obtained from the solution of the Poisson equation in three-layer dielectric medium with the graphene sheets located at the interfaces, separating different materials. Due to the momentum dispersion of the effective dielectric function, the intra- and inter-layer bare Coulomb interactions in graphene double layer systems acquire additional momentum dependence—an effect of the order of inter-layer interaction itself. It has been shown that in the long wavelength limit the energies of optical and acoustical plasmons, respectively, with the square root and linear dispersions are determined by different dielectric permittivities.

¹The work has been supported by the Flemish Science Foundation (FWO-VI), the Belgian Science Policy (IAP).

9:12AM V12.00007 Measurement of plasmon dispersion in graphene: tunable graphene plasmonics¹, BEN D. DAWSON, MIKE S. LODGE, Department of Physics and Nanoscience Technology Center, University of Central Florida, Orlando FL 32816, NIMA NADER ESFAHANI, R.E. PEALE, Department of Physics, University of Central Florida, Orlando FL 32816, M. ISHIGAMI, Department of Physics and Nanoscience Technology Center, University of Central Florida, Orlando FL 32816 — Graphene is an intriguing material for plasmonics. We have measured the transmission spectrum of large area graphene, grown using chemical vapor deposition, using Fourier transform infrared spectroscopy. By varying the Fermi level of graphene, we are able to explore the energy dispersion of plasmons in graphene. Our result lays the foundation for tunable plasmonic devices based on graphene.

¹This was supported by the Intelligence Community Postdoctoral Fellowship Program and by AFOSR grant FA95501010030, Program Manager Gernot Pomrenke.

9:24AM V12.00008 Scattering theory for graphene plasmons near edges and interfaces, ALEKSANDR RODIN, MICHAEL FOGLER, UCSD — Motivated by recent infrared nano-imaging experiments, we study eigenmodes of graphene plasmons near sample boundaries, corners, and interfaces. Such modes can be understood as standing-wave patterns formed by multiple scattering of elementary waves. We derive the rules of the corresponding scattering theory by analyzing the integro-differential equation for the plasmon dynamics. Our analytical results include the solution for the edge reflection problem in uniform graphene and a quasiclassical formalism for graphene of slowly varying density. Numerical simulations are employed for more complicated boundary geometries (wedge, constriction, etc.) and for singular density distributions that exist near the edge of a gated graphene.

9:36AM V12.00009 Edge Functionalization and Optical Excitations in Graphene Nanoflakes, CATERINA COCCHI, S3 CNR-Nano, IT and University of Modena, IT, DEBORAH PREZZI, S3 CNR-Nano, IT, ALICE RUINI, S3 CNR-Nano, IT and University of Modena, IT, MARILIA J. CALDAS, University of Sao Paulo, BR, ELISA MOLINARI, S3 CNR-Nano, IT and University of Modena, IT — We investigate the effects of edge covalent functionalization on the opto-electronic properties of finite elongated graphene nano-flakes (GNFs). Following our previous work on nanojunctions[1], we compute mean-field ground state electronic properties and configuration-interaction UV-vis optical excitations at varying size and functionalization by means of semi-empirical methods. The character of the lowest energy excitations and the influence exerted on them both by length/width modulation and by the specific chemical properties of the terminating groups are analyzed in details. The role of local distortions spontaneously arising upon geometrical optimization is inspected. Nanoplasmonic-like features related to the spectrum of these elongated finite graphene nanostructures are also discussed. [1] C. Cocchi et al. J. Phys. Chem. Lett. 2, 1315 (2011)

9:48AM V12.00010 Theory of double-resonant Raman spectra in graphene: intensity and line shape of defect-induced and two-phonon bands, PEDRO VENEZUELA, Universidade Federal Fluminense - Brazil, MICHELE LAZZERI, FRANCESCO MAURI, Université Pierre et Marie Curie - France — We calculate the double resonant Raman spectrum of graphene associated to both phonon-defect processes (such as the D and D' lines), and two-phonons ones (such as the $2D$, $2D'$ and $D + D''$ lines). For an excitation energy of 2.4 eV, the agreement with measurements is very good and calculations reproduce the relative intensities among phonon-defect or among two-phonon lines and the measured small widths of the D , D' , $2D$ and $2D'$ lines. We determine how the spectra depend on the excitation energy, on the light polarization, on the electronic linewidth, on the kind of defects and on their concentration. The intensity ratio between the D and D' lines depends on the kind of model defect, suggesting that this ratio could be used to identify actual defects. The present analysis reveals that, for both D and $2D$ lines, the dominant DR processes are those in which electrons and holes are both involved in the scattering. The most important phonons belong to the $\mathbf{K} \rightarrow \Gamma$ direction (*inner* phonons) and not to the $\mathbf{K} \rightarrow \mathbf{M}$ one (*outer* phonons), as usually assumed. The small $2D$ line width at $\epsilon_L = 2.4$ eV is a consequence of the interplay between the opposite trigonal warpings of the electron and phonon dispersions.

10:00AM V12.00011 A TD-DFT study on the Optical and dielectric properties of graphene nanoflakes, CARLOS RAMOS, EDUARDO CIFUENTES, ROMEO DE COSS, CINVESTAV Unidad Merida — Optical and dielectric properties of graphene nanostructures are of current interest because the potential applications in electronic and photonics devices. Recently, it has been reported important progress in the synthesis of graphene nanoflakes and their applications as quantum dots. In this work, the size and geometric shape effects on the optical spectrum and dielectric constant of graphene nanoflakes are studied by using an ab-initio approach. The calculations were performed using the Time-Dependent Density Functional Theory (TD-DFT) as implemented in the plane wave method and the results provide insights about controlling the optical properties of graphene using the size and shape of the nanostructure. This research was supported by Conacyt-México under Grant No. 83604.

10:12AM V12.00012 Two-photon absorption measurements in graphene fragments: Role of electron-electron interactions¹, A. SANDHU, Dept of Physics and OSC, Univ of Arizona, A. ROBERTS, OSC, Univ of Arizona, K. ARYANPOUR, Dept of Physics, Univ of Arizona, A. SHUKLA, Dept of Physics, IIT Bombay, S. MAZUMDAR, Dept of Physics, Univ of Arizona — Many-body interactions in graphene are an active field of research. There is a clear evidence of strong electron correlation effects in other carbon based materials which have the same sp^2 hybridization as graphene. For example, in linear-polyenes, the electron-electron interactions are considered responsible for the occurrence of lowest two-photon state below the optical one-photon state. The electronic correlation in these linear systems is a strong function of the chain length. Thus, it is pertinent to question if the two-dimensional graphene fragments also exhibit strong correlation effects and how these effects scale with fragment size. Using a white light super-continuum source, we perform z-scan measurements to extract frequency-dependent two-photon absorption coefficients in symmetric molecular fragments of graphene, e.g. coronene and hexabenzocoronene. A comparison of one-photon and two-photon absorption coefficients is then used to uncover the extent of correlation effects. In the smallest fragment, coronene, our results indicate a strong signature of the Coulomb interactions. We will discuss how the importance of electron-electron interaction varies with system size and its implication for the correlation effects in graphene.

¹Supported by the DoD SMART Fellowship.

10:24AM V12.00013 Pump-probe study of electron dynamics in bilayer graphene, LONG JU, TSUNG-TA TANG, FENG WANG, UC Berkeley, FENG WANG'S GROUP TEAM — Bilayer graphene exhibit many unusual physical properties, including a gate tunable electronic bandgap, and there is great interest in using it for novel electronic and optical devices. Understanding ultrafast dynamics in bilayer graphene is a prerequisite for many of its potential applications. We use ultrafast pump-probe spectroscopy to investigate such ultrafast electron relaxation behavior in bilayer graphene. In this talk, I will discuss the observed dynamic relaxations taking place in femto- and pico-second time scales..

10:36AM V12.00014 Theory of Two-Photon Absorptions in Graphene Fragments¹, K. ARYANPOUR, Dept of Physics, Univ of Arizona, A. SHUKLA, Dept of Physics, IIT Bombay, S. MAZUMDAR, Dept of Physics, Univ of Arizona, A. SANDHU, Dept of Physics and OSC, Univ of Arizona, A. ROBERTS, OSC, Univ of Arizona — Electron-electron correlations in graphene is currently an active field of research [1-3]. The carbon atoms in graphene have the same sp^2 hybridization as in strongly correlated π -conjugated polymer systems. The low energy behavior in graphene however appears to be reasonably described within the one-electron Dirac massless fermions model. Historically, the occurrence of the lowest two-photon state *below* the optical one-photon state provided the strongest proof for strong electron correlations in linear polyenes [4]. We systematically study the Coulomb interaction effects on the ground state and nonlinear absorptions in graphene fragments as a function of system size, beginning from the smallest stable fragment coronene. We report high order calculations of one- vs two-photon spin singlet and triplet states, in coronene, hexabenzocoronene and other molecular fragments that clearly indicate the strong role of electron-electron interactions. We will discuss the implications of our work on molecular systems for the thermodynamic limit of graphene.

10:48AM V12.00015 Floquet Spectrum and Transport Through an Irradiated Graphene Ribbon¹, H.A. FERTIG, ZHENGHAO GU, Indiana University, DANIEL AROVAS, University of California, San Diego, ASSA AUERBACH, Technion — Graphene subject to a spatially uniform, circularly-polarized electric field supports a Floquet spectrum with properties akin to those of a topological insulator, including non-vanishing Chern numbers associated with bulk bands and current-carrying edge states. Transport properties of this system however are complicated by the non-equilibrium occupations of the Floquet states. We address this by considering transport in a two-terminal ribbon geometry for which the leads have well-defined chemical potentials, with an irradiated central scattering region. We demonstrate the presence of edge states, which for infinite mass boundary conditions may be associated with only one of the two valleys. At low frequencies, the bulk DC conductivity near zero energy is shown to be dominated by a series of states with very narrow anticrossings, leading to super-diffusive behavior. For very long ribbons, a ballistic regime emerges in which edge state transport dominates.

Thursday, March 1, 2012 8:00AM - 11:00AM –
Session V13 DMP GMAG: Focus Session: Magnetic Nanostructures-Domain Walls 211

8:00AM V13.00001 Domain-wall dynamics in ferromagnetic nanowires¹ , OLEG TRETIKOV, Texas A&M University — Current-induced domain-wall (DW) dynamics is studied in a thin ferromagnetic nanowire. We derive effective equations of motion describing the dynamics of the DW soft modes with or without topological defects. Because the DWs are topological objects with a rigid spin structure, these equations are rather universal. The DW rigidity makes the microscopic details irrelevant, and it allows us to solve the DW dynamics for a very general class of spin Hamiltonians. We show that the DW dynamics is described by simple equations with only four parameters. Based on these equations, we study DW dynamics in a ferromagnetic wire with Dzyaloshinskii-Moriya interaction (DMI). We find spin spiral DW structure and how the critical current required to move the domain wall depends on DMI. We also investigate the DW dynamics driven by time-dependent currents. We find the most efficient (with the lowest Ohmic losses) way to move the DWs by resonant current pulses. In addition, we propose a procedure to unambiguously determine the DW dynamics parameters by all-electric measurements of the time-dependent voltage induced by moving DW. Furthermore, based on the derived DW dynamics equations for the translationally non-invariant nanowires, we show how to make potential magnetic memory nanodevices much more energy efficient.

8:36AM V13.00002 Reduction in critical current for domain wall injection by ion irradiation of perpendicular magnetic anisotropy nanowires , TIMOTHY PHUNG, IBM Almaden Research Center/Stanford University, LUC THOMAS, SEE-HUN YANG, CHARLES RETTNER, KWANG-SU RYU, JOHN BAGLIN, BRIAN HUGHES, STUART PARKIN, IBM Almaden Research Center — One of the key problems for realization of domain wall motion devices is the reliable and energy efficient injection of domain walls (DWs) into magnetic nanowires. In this work, we explore the injection of domain walls in perpendicular magnetic anisotropy nanowires (Co/Ni multilayers) which are locally softened by ion irradiation. We observe a minimum in the domain wall injection critical current, which occurs where the anisotropy of the irradiated region transitions from out of plane to in plane anisotropy. Furthermore, we find that the irradiated site acts as a pinning site for the DWs. At the irradiation site, we are able to create localized nanosecond long pulsed magnetic fields used to inject the DWs. By performing DC resistance measurements after each injection event, we are able to probe for the existence of the domain wall, and also find the strength of the ion irradiated pinning site. Using the above technique, we have demonstrated a five fold reduction in the domain wall injection current.

8:48AM V13.00003 360 Degree DW formation during vortex to vortex switching in thin ferromagnetic nanorings in an applied circular field¹ , YINENG SUN, ABBY GOLDMAN, ABIGAIL LICHT, YIHAN LI, NIHAR PRADHAN, Mount Holyoke College, MA, TIANYU YANG, MARK TUOMINEN, University of Massachusetts Amherst, MA, KATHERINE AIDALA , Mount Holyoke College, MA — We present simulations of the switching process between clockwise and counterclockwise vortex states in ferromagnetic nanorings in an applied circular field, relevant to potential data storage devices. This circular field can be experimentally generated by passing current through the solid metal tip of an atomic force microscope, which has achieved vortex-to-vortex switching in thicker asymmetric rings [1]. We find that in sufficiently thin rings, the vortex switching process occurs through the nucleation and annihilation of pairs of 360 degree domain walls (DW), with opposite topological indices. The DW with the same circulation as the vortex annihilates first. We can control which DW annihilates first by offsetting the center of our circular field to target a specific DW. Both exchange energy and demagnetization energy must be considered in predicting the energy barrier to DW annihilation. [1] T. Yang, N.R. Pradhan, A. Goldman, A.S. Licht, Y. Li, M. Kemei, M.T. Tuominen, K.E. Aidala. APL, 98, 242505 (2011).

¹NSF grant No. DMR-0906832, DMR-097201. NSF Center for Hierarchical Manufacturing (CMMI- 0531171). Simulations were performed with the facilities at the Center for Nanoscale Systems (CNS) (NSF award ECS-0335765)

9:00AM V13.00004 Individual domain wall manipulation in a local oersted circular field¹ , XIAOLIN HU, Mount Holyoke College, HUAJIE KE, NIHAR PRADHAN, University of Massachusetts, YINENG SUN, Mount Holyoke College, MARK TUOMINEN, University of Massachusetts, KATHERINE AIDALA, Mount Holyoke College — Understanding domain wall (DW) motion in nanoscale ferromagnetic structures reveals intriguing physics, with potential applications in nanoscale devices and DW data storage. One challenge is to create and move individual DWs in arbitrary locations. We developed a technique to generate localized circular magnetic field by applying a current through the tip of the atomic force microscope (AFM) and thereby manipulating the state of ferromagnetic rings [1]. Now we extend our ability to control domain walls in various structures, such as straight wires with notches and zigzag wires. By placing the tip near a 180 DW in a vertex of a zigzag wire, we can move the 180 DW along the wire and form a stable 360 DW in nearby vertex. We can also move 360 DWs with the local magnetic field around the AFM tip. We will discuss simulations and experimental implementations.

9:12AM V13.00005 Probing and manipulating magnetization at the nanoscale , NITIN SAMARTH, Dept. of Physics, Penn State University, University Park PA 16802 — Combining semiconductors with magnetism in hetero- and nano-structured geometries provides a powerful means of exploring the interplay between spin-dependent transport and nanoscale magnetism. We describe two recent studies in this context. First, we use spin-dependent transport in ferromagnetic semiconductor thin films to provide a new window into nanoscale magnetism [1]: here, we exploit the large anomalous Hall effect in a ferromagnetic semiconductor as a nanoscale probe of the reversible elastic behavior of magnetic domain walls and gain insight into regimes of domain wall behavior inaccessible to more conventional optical techniques. Next, we describe novel ways to create self-assembled hybrid semiconductor/ferromagnet core-shell nanowires [2] and show how magnetoresistance measurements in single nanowires, coupled with micromagnetic simulations, can provide detailed insights into the magnetization reversal process in nanoscale ferromagnets [3]. The work described here was carried out in collaboration with Andrew Balk, Jing Liang, Nicholas Deltas, Mark Nowakowski, David Rench, Mark Wilson, Roman Engel-Herbert, Suzanne Mohny, Peter Schiffer and David Awschalom. This work is supported by ONR, NSF and the NSF-MRSEC program.

9:48AM V13.00006 Beyond a compact magnetic domain wall, PHILIPP EIB, CARL ZINONI, ANTOINE VAN-HAVERBEKE, GIAN SALIS, RETO SCHLITTLER, ANDREAS BISCHOF, ROLF ALLENSPACH, IBM Research - Zurich, Säumerstr. 4, CH-8803 Rüschlikon, Switzerland — The generally accepted concept that limits magnetic domain wall velocity is the Walker breakdown. This is the magnetic field at which wall motion becomes oscillatory capping the performance of domain wall-based spintronic devices. To understand the limiting mechanisms, we study vortex walls in $\text{Ni}_{80}\text{Fe}_{20}$ wires with widths between 300 and 900 nm. We detect the walls by time-resolved magneto-optical Kerr effect in a pump-probe technique setup. The wires are fabricated by electron-beam lithography and by a nanostencil tool [1]. We find the dynamics of vortex walls to depart significantly from the current description of a compact entity evolving along the wire. Instead, the wall is composed of several substructures propagating in different dynamic regimes with very different velocities. Wire edges crucially affect this dynamics and can be influenced by variation of growth parameters. Extensive, parallelized micromagnetic simulations reveal the unusual wall structure and complement the experimental findings [2]. Possibilities how to overcome the limits imposed by the Walker breakdown will be discussed.

10:00AM V13.00007 Domain walls in ultrathin magnetic nanowires at finite temperatures, THOMAS MICHAELS, ALESSANDRO VINDIGNI, DANILO PESCIA, Laboratory for Solid State Physics, ETH Zurich, Switzerland — The possibility of inducing domain-wall (DW) motion in magnetic nanowires by means of electric currents has recently renewed theoretical interest in this field. The problem is usually modelled on a micromagnetic approach, but ignoring thermal fluctuations. However, some relevant experimental facts - like the correct order of magnitude of the critical current needed for DW motion - still lack satisfactory explanations. We thus developed a one-dimensional stochastic model for DW dynamics, which allowed us to take into account both thermal fluctuations and external drifts (magnetic field and electric spin-polarized current) simultaneously. We also provided a general theoretical framework, which highlights the crucial role played by thermal fluctuations at the centre of DWs. The latter, for example, qualitatively accounts for the shrinking of magnetic domains observed in Fe films on Cu(001) with increasing temperature and the renormalisation of the critical current for DW motion in magnetic nanowires at finite temperatures.

10:12AM V13.00008 Antiferromagnetic Domain Wall Engineering in Chromium Films, JONATHAN LOGAN, HYEKYUNG KIM, University of Chicago, ERIC ISAACS, Argonne National Laboratory, OLEG SHPYRKO, University of California, San Diego, DANIEL ROSENMAN, Center for Nanoscale Materials, Argonne National Laboratory, ZHONGHOU CAI, Advanced Photon Source, Argonne National Laboratory, RALU DIVAN, Center for Nanoscale Materials, Argonne National Laboratory — We have engineered an antiferromagnetic domain wall by utilizing a magnetic frustration effect of a thin iron cap layer deposited on a chromium film. Through lithography and wet etching we selectively removed areas of the Fe cap layer to form a patterned ferromagnetic mask over the Cr film. Removing the Fe locally removes magnetic frustration in user-defined regions of the Cr film. We present x-ray microdiffraction results confirming the formation of an antiferromagnetic spin-density wave propagation domain wall in Cr. This domain wall nucleates at the boundary defined by our Fe mask. We have characterized the region surrounding the domain wall using x-ray microdiffraction and microfluorescence with a resolution of 1 micron.

10:24AM V13.00009 Formation and structure of 360 and 540 degree domain walls in thin magnetic stripes¹, MARK MASCARO, YOUNGMAN JANG², Massachusetts Institute of Technology, S.R. BOWDEN, J. UNGURIS, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, C.A. ROSS, Massachusetts Institute of Technology — A method is presented for forming a 360° domain wall (DW) and more complex structures such as a 540° DW in a wire attached to an injection pad by applying an alternating in-plane field perpendicular to the wire. SEMPA, MFM measurements and OOMMF micromagnetic simulations give a consistent picture of the magnetic structure and stray field distribution of the 360° DW. Equilibrium 360° DWs in wires have a well-defined structure and size, persist over a wide field range, and can be distinguished from configurations consisting of two 180° DWs pinned near each other. The formation and stability of these complex walls has implications in memory and logic devices based on field- or current-induced DW motion, where impingement of adjacent 180° DWs can produce composite DWs whose behavior and stray field distribution differ significantly from that of a 180° DW, and these structures could also be used to examine intriguing resonant behavior as predicted by modeling. 10:36AM V13.00010 Polarization Dependent Switching of Asymmetric Nanorings with a Circular field¹, NIHAR PRADHAN, Mount Holyoke College and UMass Amherst, MARK TUOMINEN, UMass Amherst, MA 01003, KATHERINE AIDALA, Mount Holyoke College, South Hadley, MA 01075 — We present experimental switching from the onion to vortex states in asymmetric cobalt nanorings in an applied circular field. We initialize the onion state in two polarizations, along the symmetric or asymmetric axes. We apply a circular field by passing current through a solid metal AFM tip positioned at the center of the ring [1]. The asymmetry of the ring leads to different switching fields depending on the location of the domain walls (DWs) and direction of applied field. For polarization along the asymmetric axis, the field required to move the DWs to the narrow side of the ring is smaller than moving the DWs to the larger side of the ring. The direction of the DW motion is controlled by the circular field. When polarizing the ring along the symmetric axis, establishing one DW in the narrow side and one on the wide side, the field required to switch to the vortex state is an intermediate value. We will be presenting detail of the switching field of cobalt nanoring by circular field with two different direction of polarization.

10:48AM V13.00011 Non-volatile electric field tuning of magnetic domains in permalloy thin films coupled to ferroelastic PZT bilayers¹, ICHIRO TAKEUCHI, ANBUSATHAIAH VARATHARAJAN, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20424, SAMUEL BOWDEN, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, USA, SEAN FACKLER, TIEREN GAO, PARIS ALEXANDER, JOHN CUMINGS, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20424, DAN PIERCE, JOHN UNGURIS, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, USA, UNIVERSITY OF MARYLAND TEAM, NIST COLLABORATION — We are investigating electric field controlled magnetic domain motion in Py films on $\text{Pb}(\text{Zr}_{1-x}\text{Ti}_x)\text{O}_3$ (PZT) bilayers. Previously, we have shown that bilayered heterostructures consisting of a tetragonal $\text{PbZr}_{0.3}\text{Ti}_{0.7}\text{O}_3$ film (70 nm) above a rhombohedral $\text{PbZr}_{0.7}\text{Ti}_{0.3}\text{O}_3$ film (70 nm) display large ferroelastic domains in tetragonal PZT layer. The reversible non-volatile ferroelastic domain wall motion in this layer can serve as a basis for inducing controlled strain on magnetic thin films. This results in different ferroelastic domain configurations in the tetragonal PZT layer. This in turn leads to changes in magnetic domains of Py film. We find that a Py film on the ferroelastic PZT layer exhibits sharp magnetic domain patterns usually associated with out-of-plane magnetization by MFM. SEMPA imaging reveals that the magnetic domains are indeed in-plane magnetized as expected for Py films. OOMMF analysis indicates presence of unusual metastable in-plane anisotropy modulation in the Py film.

Session V14 DMP GMAG: Focus Session: Spins in Carbon - Spins and Magnetism in Carbon

212

8:00AM V14.00001 Inducing Magnetization by Flexing Graphene Nanoribbon, RENAT SABIRIANOV, NABIL AL-AQTASH, University of Nebraska at Omaha — Zigzag graphene nanoribbons (ZGNRs) are antiferromagnetic in the ground state with zero net magnetization due to the compensation of contributions from opposite edges. The uniform deformations (both shear and axial) do not produce magnetization due to the symmetry restrictions. However, we report the results of first-principles calculations that predict that the induction of net magnetization in the graphene nanoribbon upon non-uniform strain applied to the nanoribbon. Using density functional theory (DFT) method implemented in SIESTA code, we show that the bending or twisting of nanoribbon produces magnetization because in the presence of strain gradient the induced magnetization on opposite edges are not compensating each other. We estimate an average magnetization of $\sim 3.3\mu_B$ that produced from the bending of nanoribbon with the sinusoidal profile $\delta x = A \sin(2\pi z/L)$ with $A = 3\text{\AA}$ and $L = 87.4\text{\AA}$ ($z = 0..L/2$, i.e. the half of the period). Our study suggests that the induced magnetization can be used for the control of magnetic structure in graphene including the trap of the domain walls.

8:12AM V14.00002 Numerical studies of the magnetism in graphene nanoribbons and graphene dot, TIANXING MA, Department of Physics, Beijing Normal University, Beijing 100875, China, ZHONGBING HUANG, Faculty of Physics and Electronic Technology, Hubei University, Wuhan 430062, China, HAI-QING LIN, Beijing Computational Science Research Center, Beijing 100084, China — Within determinant quantum Monte Carlo simulation, the magnetic properties of graphene nanoribbons and graphene dot are studied. It is predicted that the armchair graphene nanoribbons show carrier mediated ferromagnetism as electron filling is lower than 0.8. The uniform magnetic susceptibility increase as the width of nanoribbons decrease, and it increases greatly as the next-nearest-neighbor hopping energy increases. It is also shown that strain may induce magnetism in doped square graphene dot having zigzag edge. The resultant ferromagnetism in graphene-based system may facilitate the development of spintronics.

8:24AM V14.00003 g-Tensor control in a bent carbon nanotube quantum dot, RUBY LAI, HUGH CHURCHILL, CHARLES MARCUS, Harvard University — We report low-temperature transport measurements of a carbon nanotube quantum dot containing a bend along its length. The bend occurred naturally in CVD growth, with a bend angle of 140 degrees and a radius of curvature of $\sim 1\mu\text{m}$. The device was contacted across the bend, with a global back gate and a top gate proximal to one arm of the bend. We measured the magnetic field angle dependence of conductance, tunneling rates, and bandgap in a 3-axis vector magnetic field. We characterize key signatures of carbon nanotube bends in the Kondo regime, comparing these dependencies in perpendicular and in-plane magnetic fields. We also demonstrate control of the electron spin g-tensor using gate voltages. Support from IBM, NSF-MWN, NSF-NRI through the INDEX Center, and Harvard University is acknowledged.

8:36AM V14.00004 Magnetic impurities and Kondo conductance anomalies in nanotubes: the importance of being “in”¹, ERIO TOSATTI, SISSA and ICTP, Trieste, PIERPAOLO BARUSELLI, SISSA Trieste, MICHELE FABRIZIO, SISSA and ICTP, Trieste — Transition metal impurities should yield zero bias anomalies in the conductance of well contacted metallic carbon nanotubes, but relevant temperatures and lineshapes cannot be anticipated without accurate ab initio calculations. Applying the density functional plus numerical renormalization group approach of Lucignano et al [1] to Co and Fe impurities in (4,4) and (8,8) nanotubes, we discover a huge difference of behaviour between outside versus inside impurity adsorption. The predicted Kondo temperatures and zero bias anomalies, tiny when the impurity is outside the nanotube [2] turn large and strongly radius dependent inside, owing to a change of symmetry of the magnetic orbital. These results foreshadow interesting field and temperature dependent nanotube electrical transport, to be addressed in future experiments.

8:48AM V14.00005 Spin-orbit coupling and electronic transport in carbon nanotubes in external fields¹, GINETOM DINIZ, S. E. ULLOA, Ohio University — We have investigated theoretically the role of spin-orbit coupling (SOC) on the conductance response of carbon nanotubes (CNT) in the presence of external electric and magnetic fields. We use an equilibrium Green's function formalism to calculate the spin resolved conductance by using a four-orbital orthogonal tight-binding representation in real space, taking into account curvature effects that induce orbital hybridization and are responsible for sizable SOC enhancements [1]. Different directions of external magnetic and electric fields (transverse and longitudinal to the CNTs), as well as length and chirality of the CNT, are shown to strongly affect the transport behavior of the systems. In particular, this results in stronger SOC effects for tubes with smaller radii. The interplay of electric and magnetic fields on the possible spin polarization of conductance will be discussed, as the sizable SOC effects result in effective control of the spin selective transport in these versatile nanoelectronic devices.

¹Supported by CAPES-Fulbright, NSF-PIRE and NSF-MWN/CIAM

9:00AM V14.00006 Spin-orbit induced strong coupling of a single spin to a nanomechanical resonator, PHILIPP STRUCK, University of Konstanz, ANDRAS PALYI, Eotvos University, Budapest, MARK RUDNER, Harvard University, Cambridge, KARSTEN FLENSBERG, Niels Bohr Institute, University of Copenhagen, GUIDO BURKARD, University of Konstanz — We theoretically investigate the coupling of an electron spin to vibrational motion due to curvature-induced spin-orbit coupling in suspended carbon nanotube quantum dots. Our estimates indicate that, with current capabilities, a quantum dot with an odd number of electrons can serve as a realization of the Jaynes-Cummings model of quantum electrodynamics in the strong-coupling regime. A quantized flexural mode of the suspended tube plays the role of the optical mode and we identify two distinct two-level subspaces, at small and large magnetic field, which can be used as qubits in this setup. The strong intrinsic spin-mechanical coupling allows for detection, as well as manipulation of the spin qubit, and may yield enhanced performance of nanotubes in sensing applications.

9:12AM V14.00007 Distinctive Magneto Conductance and Universal Scaling in One Dimensional Polymer Nanofibers, AJEONG CHOI, KYUNG HO KIM, SUNG JU HONG, Seoul National University, MUNJU GOH, KAZUO AKAGI, Kyoto University, RICHARD B. KANER, UCLA, YUNG WOO PARK, Seoul National University — The conducting polymers are one dimensional organic hydrocarbon systems where the non-linear local excitations such as solitons, polarons and bipolarons were predicted based on the electron-phonon interactions. The local excitations have different spin-charge relations in different kinds of polymers. In this work, the magneto conductance (MC) of polymer nanofibers is investigated in high magnetic field at low temperature to understand both spin (magneto) and charge (conductance) of the charge carriers simultaneously. We discovered the distinctive zero MC in polyacetylene nanofibers while the finite MC in polyaniline and polythiophene nanofibers. On the other hand, the charge transports of polymer nanofibers as a function of temperature and bias are observed to be scaled onto the universal curve. We conclude that the universal scaling and the zero MC (the finite MC) in polyacetylene (polyaniline and polythiophene) nanofibers are from the interacting spinless charged solitons (interacting polarons which have both spin and charge).

9:24AM V14.00008 Magneto-Photoinduced Absorption in Organic Polymer Films, BHOJ GAUTAM, THO NGUYEN, Department of Physics and Astronomy, University of Utah, Salt Lake City, UT 84112, EITAN EHRENFREUND, Physics Department, Technion-Israel Institute of Technology, Haifa, Israel, Z. VALY VARDENY, Department of Physics and Astronomy, University of Utah, Salt Lake City, UT 84112 — In order to elucidate the underlying mechanism of magneto-conductivity (MC) in OLEDs we studied magneto-photoinduced absorption (MPA) response in polymer films. The films were based on the MEH-PPV polymer in three different forms, namely: pristine film; film exposed to prolonged UV illumination; and MEH-PPV/PCBM blend having weight ratio 1:1. In pristine film we show that the MPA at low excitation intensity is due to sublevel spin mixing of triplet excitons; whereas at high excitation intensity the MPA is dominated by the triplet-triplet annihilation process. In UV illuminated MEH-PPV films that support photogenerated polarons we show that the MPA is due to sublevel spin-mixing of polaron-pairs via the hyperfine interaction with the closest hydrogen atoms to the chain. This mechanism also explains the MC response of OLED based on MEH-PPV, since its response is similar to that of MPA. Finally we found that the MPA in MEH-PPV/PCBM blend films is dominated by spin mixing of polaron-pair on the polymer and fullerene molecules, via the Δg mechanism. Supported by the NSF DMR-1104495, the NSF MRSEC at the UoU, and the BSF program.

9:36AM V14.00009 Tunnel magnetoresistance in Self-Assembled Monolayers Based Tunnel Junctions, RICHARD MATTANA, CLÉMENT BARRAUD, SERGIO TATAY, MARTA GALBIATI, PIERRE SENEOR, KARIM BOUZEHOUE, ERIC JACQUET, CYRILE DERANLOT, ALBERT FERT, FRÉDÉRIC PETROFF, Unité Mixte de Physique CNRS/Thales — Organic/molecular spintronics is a rising research field at the frontier between spintronics and organic chemistry. Organic molecule and semiconductors were first seen as promising for spintronics devices due to their expected long spin lifetime. But an exciting challenge has also been to find opportunities arising from chemistry to develop new spintronics functionalities. It was shown that the molecular structure and the ferromagnetic metal/molecule hybridization can strongly influence interfacial spin properties going from spin polarization enhancement to its sign control in spintronics devices. In this scenario, while scarcely studied, self-assembled monolayers (SAMs) are expected to become perfect toy barriers to further test these tailoring properties in molecular magnetic tunnel junctions (MTJs). Due to its very high spin polarization and air stability LSMO has positioned itself as the electrode of choice in most of the organic spintronics devices. We will present a missing building block for molecular spintronics tailoring: the grafting and film characterization of organic monofunctionalized long alkane chains over LSMO. We have obtained 35% of magnetoresistance in LSMO/SAMs/Co MTJs. We will discuss the unusual behaviour of the bias voltage dependence of the TMR.

9:48AM V14.00010 Electrical spin injection from an organic-based ferrimagnet in a hybrid organic/inorganic heterostructure¹, EZEKIEL JOHNSTON-HALPERIN, Department of Physics, The Ohio State University — The development of organic-based magnets with room temperature magnetic ordering and semiconducting functionality promises to broaden the field of semiconductor spintronics, providing a route to all-organic spintronic devices and hybrid organic/inorganic structures capable of exploiting the multifunctionality and ease of production in organic systems as well as the well established spintronic functionality of inorganic materials. Our work demonstrates the successful extraction of spin polarized current from the organic-based room temperature ferrimagnetic semiconductor $V[TCNE]_x$ ($x \sim 2$, TCNE: tetracyanoethylene; $T_C > 400$ K, $E_G \sim 0.5$ eV, $\sigma \sim 10^{-2}$ S/cm) and its subsequent injection into a GaAs/AlGaAs light-emitting diode (LED) [1]. The spin current is detected by monitoring the polarization state of the photons emitted from the LED structure and tracks the magnetization of $V[TCNE]_{x \sim 2}$, is weakly temperature dependent, and exhibits heavy hole / light hole asymmetry. This result opens the door to a new class of active, hybrid spintronic devices with multifunctional behavior defined by the optical, electronic and chemical sensitivity of the organic layer. In addition, spin transport in these hybrid structures provides the opportunity to leverage well-characterized inorganic materials as a probe of spin physics in organic and molecular systems and to explore the impact of the hybrid interface on spin injection efficiency. Initial studies exploring the impact of surface passivation of the inorganic layer with self-assembled monolayers of various chemistries will be presented, and additional experimental probes of the interfacial exchange interaction will be discussed.

10:24AM V14.00011 The effect on the properties of V(TCNE) grown on bare substrates and self assembled monolayers, MEGAN HARBERTS, HOWARD YU, MARK GUSEMAN, Department of Physics, The Ohio State University, YU LU, Department of Chemistry, The Ohio State University, EZEKIAL JOHNSTON-HALPERIN, Department of Physics, The Ohio State University, ARTHUR EPSTEIN, Departments of Chemistry and Physics, The Ohio State University — V(TCNE) is a room temperature T_C larger than 400K organic based magnetic semiconductor. It has been shown that this fully-spin polarized material can be used as a spin injector in hybrid organic inorganic spin-light emitting diode (spin-LED) as well as hybrid and all organic spin valves [1,2]. Attempts to improve the spin signal from a spin LED device are focusing on surface passivation of the III-V heterostructure surface by including a self-assembled monolayer (SAM). We present a comparison of the properties of V(TCNE) grown by chemical vapor deposition (CVD) on various SAM's and bare substrates. We find that the successful growth of uniform, thin films of CVD V(TCNE) requires careful purification of the SAM precursors. We observe bulk magnetic properties of V(TCNE) grown on SAM's to be consistent with or better than films grown on bare substrates. Therefore the presence of the SAM does not appear to adversely affect the desired properties of the V(TCNE) for use as a spin injector, dramatically expanding the range of potential hybrid device geometries.

10:36AM V14.00012 Spin multiplicity and symmetry breaking in vanadium-benzene complexes¹, IVAN STICH, LUCIA HORVATHOVA, MATUS DUBECKY, Institute of Physics, Slovak Academy of Sciences, LUBOS MITAS, Dept. of Physics, North Carolina State University — Despite use of vanadium-benzene complexes in spintronics applications [1], reliable theoretical and experimental knowledge of energetics, dissociation energy, spin multiplicity, etc. of these systems is missing. Fixed-node DMC calculations have been done with the quest to elucidate electronic and atomic structure of vanadium-benzene half-sandwiches. At variance with DFT results which favor either low- or high-spin state, depending on the functional used [2], DMC predicts degenerate energies for spin multiplicities 2, 4, and 6, irrespective of DFT functional used to fix the nodal hypersurfaces. Ultimately, we predict high-spin ground-state, based on comparison of experimental/theory ionization energy [3]. Based again on DMC, we predict vastly different gaps for spin-up/-down electrons. The DMC results indicate that both DFT [2] as well as experimental results [4] may be biased. [1] V. V. Maslyuk *et al.*, Phys. Rev. Lett. **97**, 097201 (2006) [2] R. Pandey, B. K. Rao, P. Jena, M. ¹Financial support from APVV projects APVV-0091-07, LPP-0392-09 is acknowledged. This research was supported in part also by ERDF OP R&D, Project CE meta-QUTE ITMS 26240120022, and via CE SAS QUTE.

10:48AM V14.00013 Total Scattering Study of Vanadium Tetracyanoethylene, D.M. PAJEROWSKI, NIST Center for Neutron Research, National Institute of Standards and Technology, J.L. ARTHUR, Dept. Chem., Univ. Utah, K. PAGE, LANSCE, Los Alamos National Laboratory, J.S. MILLER, Dept. Chem., Univ. Utah, J.W. LYNN, NIST Center for Neutron Research, National Institute of Standards and Technology — Vanadium tetracyanoethylene powder prepared in deuterated dichloromethane (henceforth V-TCNE) was studied using neutron and X-ray diffraction. V-TCNE is a molecule-based magnet that has been shown to display magnetic order above room temperature¹ as well as photocontrol of magnetism at cryogenic temperatures.² To date, all reported synthesis preparations of V-TCNE yield amorphous compounds that lack Bragg peaks in diffractograms. In the absence of long range structural order, diffraction experiments may still elucidate short range structural order. The experimental results, which display short range correlations, will be presented and compared to Monte Carlo simulations.

Thursday, March 1, 2012 8:00AM - 11:00AM — Session V16 DCMP: Heavy Fermions- 1-1-5 Systems and Others 251

8:00AM V16.00001 Fermi surface of Ce₂RhIn₈ studied by angle-resolved photoemission spectroscopy¹, RUI JIANG, R.S. DHAKA, CHANG LIU, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, Iowa, 50011, USA, C. PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, NY, 11973, USA, ADAM KAMINSKI, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, Iowa, 50011, USA — The superconductivity in heavy fermion compounds is one of most interesting, outstanding problems in condensed matter physics. In this family of materials, Ce₂RhIn₈ and related compounds is unique because its electronic properties are believed to be quasi 2D. Here, we use angle-resolved photoemission spectroscopy to measure its electronic properties. The lack of significant *k_z* dispersion confirms the quasi two dimensionality of the electronic structure. Fermi surface is quite complicated and consists of several hole and electron sheets. There are several extended segments of the Fermi surface which are likely nested. This provides clues to understanding of their unusual transport and thermodynamical properties.

¹The Ames Laboratory is operated for the US Department of Energy, Basic Energy Sciences, by Iowa State University under contract no. DE-AC02-07CH11358.

8:12AM V16.00002 Anomalous superfluid response in the layered heavy fermion compound Ce₂PdIn₈ near a magnetic quantum critical point, KENICHIRO HASHIMOTO, YUTA MIZUKAMI, RYO KATSUMATA, MINORU YAMASHITA, HIROAKI IKEDA, TAKASADA SHIBAUCHI, YUJI MATSUDA, Department of Physics, Kyoto University, DANIEL GNIDA, DARIUSZ KACZOROWSKI, Institute of Low Temperature and Structure Research, Polish Academy of Sciences, ANTONY CARRINGTON, H. H. Wills Physics Laboratory, University of Bristol — The recently discovered layered heavy fermion superconductor Ce₂PdIn₈ (*T_c* = 0.7 K) has attracted a great interest because of the appearance of unconventional superconductivity near a quantum critical point. Here we report high-precision measurements of magnetic penetration depth λ down to 60 mK ($\sim 0.1T_c/T_c$) by using a tunnel diode oscillator operating at ~ 13 MHz. A strong power-law temperature dependence of λ demonstrates low-energy excitations of quasiparticles, which is consistent with recent thermal conductivity measurements indicative of nodal superconductivity. The observed $T^{1.5}$ behavior at low temperatures, which is commonly seen in superconductors with line nodes near a magnetic quantum critical point such as CeCoIn₅ or organics, can be attributed to the enhancement of effective mass towards zero temperature due to quantum magnetic fluctuations even in the superconducting state.

8:24AM V16.00003 Magnetism in 2D Heavy Fermion Superconductor CePt₂In₇, NICHOLAS APROBERTS-WARREN, JOHN CROCKER, ADAM DIOGUARDI, PETER KLAIVINS, CHING LIN, KENT SHIRER, ABIGAIL SHOCKLEY, NICHOLAS CURRO, University of California at Davis — CePt₂In₇ was first synthesized in 2008, and it was discovered to be a superconductor under pressure shortly thereafter in 2009. It is closely related to the well-studied crystal class CeMIn₅ (*M* = Ir, Co, Rh), but CePt₂In₇ is considerably more anisotropic with a *c/a* ratio more than twice as large as the 115's. We present here nuclear quadrupole resonance results for the ¹¹⁵In nucleus, and follow it from the paramagnetic heavy fermion state into the anti-ferromagnetic state below *T_N* = 5.2 K. The NQR data will show a rich magnetic phase diagram, with a commensurate magnetic order parameter directly below *T_N*, and more complex magnetic states emerging as the material is further cooled. Additionally, we will present some additional results on how hydrostatic pressure affects the magnetic order in CePt₂In₇.

8:36AM V16.00004 Electric transport measurements on micro-structured CePt₂In₇ single crystals in a diamond anvil cell, J. KANTER, P. MOLL, Laboratory for Solid State Physics, ETH Zurich, Switzerland, F. RONNING, E. BAUER, P. TOBASH, J. THOMPSON, Los Alamos National Laboratory, Los Alamos, New Mexico, USA, B. BATLOGG, Laboratory for Solid State Physics, ETH Zurich, Switzerland — We report Shubnikov-de Haas and resistivity measurements of CePt₂In₇ samples under hydrostatic pressures using a diamond anvil cell. CePt₂In₇ belongs to the *C_{em}M_nIn_{3m+2n}* heavy fermion family. Compared to the CeMIn₅ members of this group, the structure of CePt₂In₇ has a more two dimensional character, but also exhibits an antiferromagnetically ordered and a superconducting phase. Upon increasing pressure the AFM order is suppressed with the Néel temperature extrapolating to a quantum critical point. The fluctuations associated with the QCP are thought to stabilize the unconventional superconducting phase. To investigate the weight of the different scattering channels the anisotropy of the resistivity above the Néel temperature was measured for various applied pressures. Shubnikov-de Haas measurements were conducted to deduce the changes in the effective electron masses in the AFM and superconducting phases under applied hydrostatic pressure. To this end we developed a method to conduct four terminal resistance measurements on micro-structured samples inside a diamond anvil cell.

8:48AM V16.00005 SmPt₄Ge₁₂ – a filled skutterudite with exotic heavy-fermion properties

ANDREAS LEITHE-JASPER, ROMAN GUMENIUK, WALTER SCHNELLE, HELGE ROSNER, MICHAEL NICKLAS, MICHAEL SCHÖNEICH, ULRICH SCHWARZ, YURI GRIN, Max-Planck-Institute for Chemical Physics of Solids — Ternary samarium-filled platinum-germanium skutterudite SmPt₄Ge₁₂ was prepared at a pressure of 5.0(0.5) GPa and a temperature of 1070(70) K. The compound crystallizes in the cubic space group $Im\bar{3}$ ($a = 8.6069(4)$ Å) and is isotopic with LaFe₄P₁₂. X-ray absorption spectroscopy measurements show that samarium in SmPt₄Ge₁₂ has a temperature-independent intermediate valence ($\nu = 2.90 \pm 0.03$). Magnetization data reveal van-Vleck paramagnetism above ~ 50 K. The low-temperature specific heat displays a broad anomaly centred at 2.9 K and a large linear coefficient $\gamma' = 450$ mJ mol⁻¹ K⁻² suggesting heavy-fermion behaviour. This state is remarkably field-independent and resembles the physics of SmOs₄Sb₁₂. [1] R. Gumeniuk et al. New J. Physics 12 (2010) 103035.

9:00AM V16.00006 Physical properties and Ce-valence of the filled skutterudite CePt₄Ge₁₂

WALTER SCHNELLE, ROMAN GUMENIUK, MICHAEL NICKLAS, HELGE ROSNER, ANDREAS LEITHE-JASPER, YURI GRIN, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, KRISTINA O. KVASHNINA, ESRF, Grenoble, France, YURI SKOURSKI, HLD, Helmholtz-Zentrum Dresden-Rossendorf, Germany — Filled skutterudite compounds MPt₄Ge₁₂ with a Pt-Ge framework structure show intriguing physical ground states (conventional ($M = \text{Sr, Ba}$) and unconventional superconductivity ($M = \text{Pr}$), heavy-fermion behavior ($M = \text{Sm}$), magnetic ordering), similar to the well-known transition-metal pnictogen skutterudites. Here, we report on the electronic, magnetic, and transport properties of CePt₄Ge₁₂ [1]. High-resolution X-ray absorption spectroscopy (XANES) measurements at the cerium L_{III} edge demonstrate that Ce in this compound has a temperature-independent valence close to three. However, magnetic susceptibility, thermopower, Hall effect, and electronic specific heat reveal broad maxima at $T_{\text{max}} = 65\text{--}80$ K, suggesting the presence of valence fluctuations. The Sommerfeld coefficient $\gamma = 105$ mJ mol⁻¹ K⁻² indicates moderately enhanced band masses for CePt₄Ge₁₂. We discuss these findings and conclude that CePt₄Ge₁₂ represents a system at the border between intermediate valence (IV) and Kondo lattice behavior.

[1] R. Gumeniuk et al. J. Phys.: Condensed Matter 23 (2011) 456601.

9:12AM V16.00007 Cu-NMR and magnetization in disordered nFL system UCu₄Ni¹, O.O. BERNAL,

A. VALDEZ, M. CHIANG, Department of Physics and Astronomy, California State University, Los Angeles, CA 90032, D.E. MACLAUGHLIN, Department of Physics and Astronomy, University of California, Riverside, CA 92125, G.R. STEWART, J.S. KIM, Department of Physics, University of Florida, Gainesville, FL 32611 — We present a study of the NMR spectra in a random powder of UCu₄Ni as a function of frequency (40–70 MHz) and temperature (5–300 K). Two types of spectral lines for each of the two isotopes of naturally abundant Cu in the material are clearly evident in the spectra. Their behavior is followed for temperature and field variations and compared/contrasted with the more studied case of UCu₄Pd, where only one type of Cu-NMR line has been observed clearly. Unlike in UCu₄Pd, the appearance of two types of signal from Cu nuclei in the Ni compound is unambiguous evidence of site disorder in UCu₄Ni. This alone is indication that the amount of site disorder in the Ni sample is larger than in the Pd system; however, the NMR line intensities reveal that the Ni ions do not seem to go completely randomly in the two available crystallographic sites of the underlying crystal structure as would be expected from ionic-size considerations alone. The NMR parameters for both types of spectral lines, together with complementary measurements of magnetic susceptibility performed on the same powder samples, will be discussed from the point of view of magnetic disorder and non-Fermi liquid behavior.

9:24AM V16.00008 Effect of pressure on CeGe_{2-x} single crystals, S.L. BUD'KO, Ames Laboratory US DOE and

Dept. of Physics and Astronomy, ISU, Ames, IA 50011, USA and SPSMS, UMR-E CEA/UJF-Grenoble 1, INAC, 38054 Grenoble, France, D. BRAITHWAITE, B. SALCE, SPSMS, UMR-E CEA/UJF-Grenoble 1, INAC, 38054 Grenoble, France, E. COLOMBIER, Ames Laboratory US DOE and Dept. of Physics and Astronomy, ISU, Ames, IA 50011, USA, M.S. TORIKACHVILI, Dept. of Physics and Astronomy, ISU, Ames, IA 50011, USA, and Dept. of Physics, SDSU, San Diego, CA 92182, USA, H. HODOVANETS, P.C. CANFIELD, Ames Laboratory US DOE and Dept. of Physics and Astronomy, ISU, Ames, IA 50011, USA — At ambient pressure CeGe_{2-x} has an antiferromagnetic (AFM) transition at $T_N \sim 7$ K and, on further cooling, a second transition, to a weak ferromagnetic (WFM) state, at $T_C \sim 4$ K. Under pressure the T_N goes through a broad maximum, and then is completely suppressed with a critical point at ~ 85 kbar, grossly following the Kondo-necklace picture. The WFM phase evolves into apparent AFM phase under moderate pressure of ~ 10 kbar, with T_N joining T_N at ~ 60 kbar. Resulting $P - T$ phase diagram and comparison with CeRu₂Ge₂ under pressure will be presented.

9:36AM V16.00009 A THz spectroscopy investigation of the heavy fermion state in CeCu₂Ge₂¹

GRACE BOSSE, L. BILBRO, R. VALDES AUGILAR, JHU Dept. of Physics and Astronomy, Y. LI, J. ECKSTEIN, Dept. of Physics, University of Illinois, N.P. ARMITAGE, JHU Dept. of Physics and Astronomy — We present time-domain THz spectroscopy data of a thin film of the heavy fermion compound CeCu₂Ge₂. Measurements to obtain the frequency dependent complex conductivity were taken as a function of temperature down to temperatures well below the onset of magnetic order. At low temperatures a narrow Drude-like peak forms, which is likely associated with the heavy fermion or spin density wave state. Using this data in conjunction with DC resistivity measurements, we obtain the frequency dependence of the scattering rate and the mass renormalization through an extended Drude model analysis.

9:48AM V16.00010 Influence of charge carrier doping on the T^* -scale in YbRh₂Si₂¹, PHILIPP

GEGENWART, H.S. JEEVAN, Y. TOKIWA, M. SCHUBERT, M. MCHALWAT, E. BLUMENROETHER, I. Physik. Institut, Goerg-August University Goettingen — YbRh₂Si₂ is a prototype heavy-fermion metal which displays a magnetic field-induced antiferromagnetic (AF) quantum critical point (QCP). It has attracted much attention due to an additional low-energy scale $T^*(B)$ merging at the QCP, whose origin is controversially discussed. Here, we report measurements of the electrical resistivity $\rho(T, B)$ on different single crystalline samples of charge-carrier doped Yb(Rh_{1-x}T_x)₂Si₂ (T=Fe, Ni) at temperatures down to 15 mK and in magnetic fields up to 7 T. The partial substitution of Rh by either Fe or Ni introduces holes or electrons, respectively. The evolution of the single-ion Kondo scale is similar as for isoelectronic Co substitution and in accordance with the chemical pressure effect. However, while chemical pressure has little influence on $T^*(B)$, we observe a drastic reduction or increase of $B^*(T = 0)$ by Fe- or Ni-doping, respectively. Most interestingly, $B^*(T = 0)$ is always pinned at the field-induced AF QCP, in contrast to chemical pressure results. As AF order is completely suppressed by Fe-doping, a heavy Fermi liquid ground (without $T^*(B)$ anomaly) is observed.

¹Work supported by the DFG through the research unit 960 (Quantum phase transitions).

10:00AM V16.00011 Quantum Criticality in the strongly correlated 3d electron system $\text{YFe}_2\text{Al}_{10}$, L.S. WU, Stony Brook University, K. PARK, Y. JANSSEN, M.S. KIM, C. MARQUES, Brookhaven National Lab, M.C. ARONSON, Stony Brook University, Brookhaven National Lab — $\text{YFe}_2\text{Al}_{10}$ has recently been identified as a strongly correlated 3d -electron system that is located very close to a quantum critical point (QCP). At low temperatures, divergences were found in the ac magnetic susceptibility ($\chi' \propto T^{-1.3}$) and magnetic specific heat ($C_M/T \propto T^{-0.47}$) based on the measurements carried out on single crystals. The magnetic Grüneisen ratio determined from these measurements ($\Gamma/H = -\frac{1}{T} \frac{\partial S/\partial B}{\partial S/\partial T} = -\frac{\partial M/\partial T}{C}$) also shows a strong divergence as $T \rightarrow 0$, which is suppressed in fields indicating a quantum critical point at $B=0$. When applying magnetic field, Fermi liquid like behavior with an enhanced magnetic susceptibility χ_0 and Sommerfeld coefficient C/T emerges at $T < T_{FL}$, and this enabled us to establish a field temperature (B - T) phase diagram with a crossover temperature $T_{FL}(B)$ coming out from the QCP at $B=0$. This is very similar to the quantum critical behavior observed in many f-electron based heavy fermion (HF) systems, and it makes $\text{YFe}_2\text{Al}_{10}$ an interesting 3d- electron candidate for studying quantum criticality.

10:12AM V16.00012 Small-angle neutron scattering study of the vortex lattice in $\text{PrOs}_4\text{Sb}_{12}$, ALEXANDRE DESILETS-BENOIT, ANDREA BIANCHI, University of Montreal, SIMON GERBER, NIKOLA EIGETENMEYER, JORGE GAVILANO, MICHEL KENZELMANN, Paul Scherrer Institut, CHRISTIAN PFLEIDERER, Technische Universität München, SEBASTIAN MUEHLBAUER, ETH Zürich, RYAN BAUMBACH, BRIAN MAPLE, University of California at San Diego — We carried out a small angle neutron scattering study of the vortex lattice in the Pr based heavy Fermion superconductor $\text{PrSb}_4\text{Os}_{12}$ with H applied along the c-axis. With a critical temperature T_c of 1.85 K and a H_{c2} of 2.5T, $\text{PrOs}_4\text{Sb}_{12}$ is the first Pr based heavy fermion superconductor (SC). Although $\text{PrOs}_4\text{Sb}_{12}$ crystallizes in a filled Skutterudite structure with a cubic lattice, this structure has a tetrahedral point group symmetry. In consequence, with the application of a magnetic field along the c-direction, the a and b-axis are no longer equivalent. Measurements of the angular dependence of the thermal conductivity in $\text{PrOs}_4\text{Sb}_{12}$ suggest a change of the superconducting order parameter deep inside the SC phase diagram from a two fold symmetry to a fourfold symmetry. Three ways of applying field were tested and wiggle field cooling was found to produce the highest intensity. We observed a twinned distorted hexagonal VL up to 1T of applied field which is consistent with s-wave superconductivity. We did not observe a field dependent phase transition associated with a change in symmetry of the VL. We found a rapidly decreasing form factor $-F^{-2}$ of the vortex lattice (VL) in $\text{PrOs}_4\text{Sb}_{12}$ with increasing field.

10:24AM V16.00013 In plane vortex lattice of the heavy Fermion superconductor CeCoIn_5 , A.D. BIANCHI, Université de Montréal, P. DAS, University of Notre Dame, J.S. WHITE, Paul Scherrer Institut, A.T. HOLMES, E.M. FORGAN, University of Birmingham, M. KENZELMANN, M. ZOLLIKER, S. GERBER, J.L. GAVILANO, Paul Scherrer Institut, E.D. BAUER, J.L. SARRAO, Los Alamos National Laboratory, C. PETROVIC, Brookhaven National Laboratory, M.R. ESKILDSEN, University of Notre Dame — We present a small angle neutron scattering study of the vortex lattice (VL) in the unconventional superconductor CeCoIn_5 for magnetic fields H applied in the crystallographic ab -plane. CeCoIn_5 is a $d_{x^2-y^2}$ superconductor with the lines nodes of the superconducting gap oriented along the $[110]$ direction. At low fields H applied parallel to $[100]$, and $[110]$, we observed a distorted hexagonal VL with an opening angle of about 80° . However, for $[110]$ we find a reorientation transition for fields above 9 T where the vortex lattice is rotated by 90° . The H -dependence of the form factor of the vortex lattice is similar to what we observed previously along the c-axis: The scattering intensity increases with increasing H due to Pauli paramagnetism. For fields where the transition into the SC state becomes first order, we observe a broadening of the VL.

10:36AM V16.00014 Low-energy magnetic excitations in single-crystalline CeCu_2Ge_2 in fields up to 10 T, MICHAEL LOEWENHAUPT, IFP/TU Dresden, ASTRID SCHNEIDEWIND, ENRICO FAULHABER, HZB/PANDA, OLIVER STOCKERT, MPI-CPFS — CeCu_2Ge_2 is a magnetically ordered ($T_N = 4.1$ K) Kondo lattice with a moderate enhanced Sommerfeld coefficient of 140 mJ/molK^2 . Calculations of the Fermi surface showed that the observed incommensurate antiferromagnetic order can only be explained by involving an itinerant component of the Ce 4f-moments in addition to their local character. We performed low-energy inelastic neutron scattering experiments on a 2 g single crystal of CeCu_2Ge_2 using the cold triple-axis spectrometer PANDA at FRM II. Data were taken at 1.5 K and in magnetic fields up to 10 T applied perpendicular to the (110/001) scattering plane. At zero field the magnetic excitations show an energy gap of 0.5 meV at all investigated Γ points in the (110/001) plane with similar intensities. Away from the Γ points the magnetic excitations become dispersive merging into a band of excitations around 1 meV. For increasing magnetic fields the gap energy decreases indicating opposite action of external and internal fields. The results will be discussed in the framework of local, crystal field related, and non-local, spin-wave-like, magnetic excitations.

10:48AM V16.00015 Universal Kondo effect in $\text{Ti}_{0.94}\text{M}_{0.06}\text{O}_2$ ($M = \text{Nb, Ta}$) Thin Films, KALON GOPINADHAN, NUSNNI-NanoCore, National University of Singapore, Singapore 117576, A. ROY BARMAN, A. ANNADI, T.P. SARKAR, Department of Physics, National University of Singapore, Singapore 117542, W.M. LU, NUSNNI-NanoCore, National University of Singapore, Singapore 117576, Z.Q. LIU, AMAR SRIVASTAVA, - ARIANDO, Department of Physics, National University of Singapore, Singapore 117542, SANKAR DHAR, T. VENKATESAN, NUSNNI-NanoCore, National University of Singapore, Singapore 117576 — We show that $\text{Ti}_{0.94}\text{M}_{0.06}\text{O}_2$ ($M = \text{Nb, Ta}$) thin films are Kondo systems by angle dependent magneto-resistance measurement. Surprisingly, the data fitted by both Goldhaber-Gordon and Hamann formula yield comparable carrier dependent Kondo temperatures (10 - 60 K). The Kondo temperature dependence on carrier density was different for Ta and Nb incorporated in TiO_2 but this result could be understood on the basis of the formation of compensating defects (Ti vacancies) which also act as localized magnetic scattering centers. Using the unitarity-limit resistivity and Kondo temperature estimated from these fits the normalized resistivity versus temperature for all these films collapse into a universal curve consistent with data observed in metallic systems. However, the size of the Kondo scattering is at least an order of magnitude larger than in metallic systems. Further, from the extrapolation of the Kondo temperature we are able to predict that Ta is a better candidate for observation of ferromagnetism versus Nb.

Thursday, March 1, 2012 8:00AM - 10:48AM –

Session V17 DMP: Focus Session: Electron, Ion, and Exciton Transport in Nanostructures - Junctions 252A

8:00AM V17.00001 Effects of electron-phonon coupling in the Kondo regime of a two-orbital single-molecule junction¹, EDSON VERNEK, GISELE IORIO, Universidade Federal de Uberlândia, LILI DENG, KEVIN INGERSENT, University of Florida - USA, ENRIQUE ANDA, Pontificia Universidade Católica do Rio de Janeiro - Brazil — Single-molecule junctions (SMJs) are electronic devices formed by a molecule bridging the gap between two metallic contacts. Despite their apparent simplicity, such systems have attracted much attention for the rich variety of experimentally accessible physics that they display. The spatial confinement of electrons in molecules can lead to collective phenomena such as Coulomb blockade and the Kondo effect, as well as to strong coupling of electrons to molecular vibrations. We explore the interesting interplay of electron-electron and electron-phonon interactions in a model of an SMJ in which the central molecule has two active orbitals. The nonperturbative numerical renormalization group method is used to treat the many-body Kondo physics and electron-phonon coupling on equal footing. Electron-phonon coupling renormalizes the energies and Coulomb interactions of the molecular orbitals. The effects are most pronounced in cases where both molecular orbitals lie close to the Fermi energy of the contacts. Here, a sufficiently strong phonon-assisted inter-orbital tunneling can suppress the Kondo effect and cause a crossover to a phonon-dominated regime having very different electrical transport properties.

¹We would like to thank FAPEMIG and CNPq for financial support.

8:12AM V17.00002 Rectification in Symmetric Conjugated Molecules with Asymmetric Linkers, ARUNABH BATRA, Dept. of Applied Physics and Applied Mathematics, Columbia University, JEFFREY S. MEISNER, Dept. of Chemistry, Columbia University, JONATHAN R. WIDAWSKY, EEK HUISMAN, Dept. of Applied Physics and Applied Mathematics, Columbia University, COLIN NUCKOLLS, Dept. of Chemistry, Columbia University, LATHA VENKATARAMAN, Dept. of Applied Physics and Applied Mathematics, Columbia University — Demonstrating single-molecule rectification is an important step towards the realization of molecule-based electronic devices. Most molecules put forward as potential rectifiers employ asymmetric molecular backbones. In contrast, we show that we can create rectifying junctions by designing asymmetry only into the linker groups used to bond the molecule to metal electrodes. Our molecules consist of a conjugated backbone terminated with methylsulfide on one end and methyl-trimethyltin on the other. These molecules couple to Au electrodes through an Au-SMe donor acceptor bond, which serves as the electronically weak link, and a Au-C covalent bond, which is created in-situ after the SnMe_3 cleaves off [1]. We create thousands of molecular junctions using a modified STM setup in a solution of molecules, measure their current-voltage (IV) characteristics and create averaged IV curves. We find that asymmetrically terminated molecules show non-linear IV curves with significant rectification, while molecules terminated symmetrically with either SMe or SnMe_3 do not show substantial rectification. We also find that the rectification direction is dependent on molecular orientation in the junction. [1] Chen, W., et al., J. Am. Chem. Soc., 2011. 133(43): p. 17160-17163

8:24AM V17.00003 Simultaneous Determination of Conductance and Thermopower of Single Molecule Junctions¹, JONATHAN WIDAWSKY, Department of Applied Physics and Applied Mathematics, Columbia University, PIERRE DARANCET, JEFFREY NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory, LATHA VENKATARAMAN, Department of Applied Physics and Applied Mathematics, Columbia University — We present a study of concurrent determination of conductance (G) and thermopower (S) of single-molecule junctions via direct measurement of electrical and thermoelectric currents. The junctions are created using the STM-based break-junction technique where a cold Au tip is repeatedly brought in and out of contact with a hot Au-on-mica substrate in an environment of the target molecule. We explore several amine-Au and pyridine-Au linked molecules that are predicted to conduct through either the highest occupied molecular orbital (HOMO) or the lowest unoccupied molecular orbital (LUMO), respectively. We find that the Seebeck coefficient is negative for pyridine-Au linked LUMO-conducting junctions and positive for amine-Au linked HOMO-conducting junctions. From histograms of thousands of junctions, we use the most probable Seebeck coefficient to determine a power factor, GS^2 , for each junction studied, and find that GS^2 generally increases with G .

¹Funded Primarily by the Energy Frontier Research Center of DOE under Award Number DE-SC0001085

8:36AM V17.00004 Theory of Solvent-Mediated Environmental Effects on Molecular-Scale Transport, MICHELE KOTIUGA, Department of Physics, UC Berkeley & Molecular Foundry, LBNL, PIERRE DARANCET, Molecular Foundry, LBNL, VALLA FATEMI, Department of Physics, MIT, BIRGER HENNINGS, MICHAEL FREI, LATHA VENKATARAMAN, Department of Applied Physics and Applied Mathematics, Columbia, JEFFREY NEATON, Molecular Foundry, LBNL — Single-molecule junctions, formed with well-defined and robust metal-molecule contacts, can provide an ideal model system to study mechanisms of charge transport at the molecular scale. However, the presence of solvent is often unavoidable, and recent experiments have shown that the junction conductance can be altered by a factor of two depending on the solvent present [1]. It has been proposed that the binding of the solvent to the gold electrodes changes their local work function, which in turn alters the conductance of the junction in a predictable manner. Here, we use a first-principles scattering-state approach, based on self-energy corrected density functional theory, to explore the transmission and conductance of bipyridine- and diaminestilbene-Au molecular junctions in the presence of solvent molecules, using an analytical model to compare with experimental results. We acknowledge DOE for support, and NERSC for computational resources.

8:48AM V17.00005 Tailoring IV Characteristics and Rectification in Single-Molecule Junctions¹, PIERRE DARANCET, Lawrence Berkeley National Laboratory, JONATHAN WIDAWSKY, Columbia University, HYOUNG JOON CHOI, Yonsei University, LATHA VENKATARAMAN, Columbia University, JEFFREY NEATON, Lawrence Berkeley National Laboratory — Asymmetry in the current-voltage characteristics, or current rectification, of nanoscale junctions is a critical property for many optoelectronic and energy conversion applications using nanostructured materials. Here, we compute the conductance, IV characteristics, and bias-dependent rectification of a class of molecular junctions, consisting of donor-acceptor molecules in contact with Au electrodes, using quantitative first-principles calculations [1]. We relate the rectification to the identities of the donor and acceptor moieties through the junction energy level alignment and dipole moments and find, surprisingly, that a large asymmetry in the contact coupling leads to weak rectification. We explain our results with an analytic coherent tunneling model, and suggest concrete strategies for obtaining high rectification in experimentally-achievable systems. [1] Darancet et al., submitted (2011).

¹We acknowledge DOE-BES for support and NERSC for computational resources.

9:00AM V17.00006 Electronic transport properties of functional single molecule junctions, E.S. TAM, H.D. ABRUNA, D.C. RALPH, Cornell University — We report experimental studies of single molecule conductance using two techniques: statistical measurements with repeatedly-formed breakjunctions in ambient conditions and low-temperature measurements with electromigrated breakjunctions. In each case, we chose molecules with specific functions. With statistical measurements, we measured the nonconducting open and conducting closed forms of dithienylethene, a photochromic (optically switchable) molecule. These molecules were synthesized with pyridine endgroups to achieve relatively well-defined and stable contacts to Au electrodes. For the closed isomer, we find a conductance of $(3.3 \pm 0.5) G_0$, while that of the open isomer is below the noise floor of our measurement. We can therefore set a lower limit of 30 for the on/off ratio of this molecule. We are currently investigating the use of electromigrated graphene nano-constrictions and breakjunctions for spin-polarized single molecule conductance measurements and plan to present initial results for this technique.

9:12AM V17.00007 Bias-Dependent Noise Measurements in Individual Electromigrated Nanoscale Junctions, PATRICK WHEELER, RUOYU CHEN, DOUGLAS NATELSON, Department of Physics Rice University — Shot noise provides insight into the correlated motion of electrons in nanostructures. Previous measurements have examined shot noise in mechanically controlled break junctions (MCBJs), looking at a large ensemble of junction configurations at room temperature. Electromigrated, lithographically created Au structures at liquid nitrogen and helium temperatures allow for noise measurements of individual junction configurations. High frequency excess noise is amplified by a RF amplifier chain and measured in combination with lock-in techniques simultaneously with the dc conductance. Noise measurements across bias and temperature are compared to previous experiments performed with MCBJs at room temperature, with an emphasis on the dependence of the noise on bias conditions. We find that measured noise in individual junctions can exhibit nonlinearities with bias as well as asymmetries as a function of the polarity of bias current. Individual junctions can also switch stochastically between different atomic configurations with nearly identical conductances but strikingly different noise properties. We discuss these observations in the context of “traditional” shot noise, bias-dependent noise processes, and $1/f$ contributions to the measured noise.

9:24AM V17.00008 Shot noise measurements as a function of bias in STM-style gold junctions¹

, RUOYU CHEN, PATRICK WHEELER, DOUGLAS NATELSON, Physics & Astronomy, Rice University — Shot noise measurements provide more detailed information regarding conductance channels than transport alone. Because of nearly fully transmitted modes, shot noise in nanoscale junctions is suppressed strongly near certain conductance values. In this experiment, we use a gold tip in a STM-style geometry to make nanoscale junctions, which function as the noise source when under bias. Peaks of conductance histograms and related mean square, radio frequency shot noise are successfully measured simultaneously at room temperature, at a series of voltage biases. Those peaks and related shot noise suppressions appear near integer multiples of the conductance quantum G_0 , especially the first three. We are able to measure shot noise at biases as low as tens of millivolts, and make use of even lower biases to estimate the systematical background existing in our measurements. Combined with a radio frequency reflection measurement, we convert the measured signal to current noise across the junction. The relevant noise processes and their evolution with bias across the junctions will be discussed.

9:36AM V17.00009 Testing the charge transport mechanism in molecule-nanoparticle networks by molecular exchange

, VENKATA KAMALAKAR, IPCMS CNRS-University of Strasbourg, EDWIN DEVID, Leiden University, JEAN-FRANCOIS DAYEN, BERNARD DOUDIN, IPCMS CNRS-University of Strasbourg, SENSE JAN VAN DER MOLEN, Leiden University — Nanoparticles molecular networks have recently emerged as useful toolbox for molecular electronics studies. Nanoparticles bridging the size gap between molecules and macroscopic electrical interconnects make possible the realization of large self-assemblies of particles interlinked by molecules, with unique advantage of high reproducibility and robustness. This results from averaging over ensembles of molecules and make possible applications ranging from electrical, optical, mechanical, to spintronics devices. Electronic properties of well-organized two-dimensional networks, where Coulomb blockade regime is expected to be predominant, make these materials of high interest as model systems. We present temperature-dependent transport properties of networks bridging high aspect ratio trenches, making possible measurements over a wide temperature range. We study how the charge transport is modified when reversible molecular exchange is performed, tailoring the intrinsic conductance of the molecule. Quantitative agreement with experiments is obtained using a model clarifying the role played by the intrinsic conduction properties of the molecules and the geometry of the network.

9:48AM V17.00010 Quantum phase transitions arising from competing electron-electron and electron-phonon interactions in a two-orbital single-molecule junction¹

, LILI DENG, KEVIN INGERSANT, U. Florida, GISELLE LUIZ, EDSON VERNEK, U. Fed. Uberlandia, Brazil, ENRIQUE ANDA, PUC-Rio, Brazil — Electron-electron and electron-phonon interactions both play important roles in determining the transport properties of nanostructures such as single-molecule junctions. We use the numerical renormalization group to study a molecule with two active electronic orbitals connecting a pair of metallic leads. We focus on quantum phase transitions (QPTs) that can be accessed by varying couplings to a local vibrational mode, particularly the strength of phonon-assisted tunneling between the two molecular orbitals. One type of QPT arises in situations where, in the absence of electron-phonon interactions, one of the molecular orbitals manifests the many-body Kondo effect with its characteristic zero-bias anomaly in the electrical conductance through the junction. At a critical coupling, the system undergoes a first-order QPT to a low-conductance phase in which the electron-phonon interaction overwhelms the strong bare electron-electron repulsion and Kondo physics is completely destroyed. A second type of first-order QPT is found in cases where there is also a Holstein coupling of local phonons to the molecular charge. We will explain the conditions that give rise to QPTs, as opposed to crossovers, between different ground states of this system.

¹Supported by the NSF and CNPq through the Inter-American Materials Collaboration.

10:00AM V17.00011 Motion and Photon Emission of Single Molecules in Space-Time¹

, JOONHEE LEE, SHAWN PERDUE, ALEJANDRO RODRIGUEZ PEREZ, V. ARA APKARIAN, University of California, Irvine, DEPARTMENT OF CHEMISTRY TEAM — We have visualized tunneling electron induced motion of single Zn-Etioporphyrin molecules adsorbed on the thin oxide film grown on NiAl(110) surface using scanning tunneling microscopy (STM). When tunneling electrons are injected resonantly to an unoccupied molecular orbital, nearly bistable switching in tunneling current occurs and the molecule starts exhibiting vibronic progression in its photon emission spectra. The switching behavior was spatially mapped by recording time traces on individual pixels of an STM image. We reconstruct the motion using the spatial distribution of amplitude, frequency, and on-time of the switching, and interpret it as the planar hindered rotation shuttling between two different adsorption configurations. The angle of rotation is close to 45 degrees, and the on-time reveals the nature of local potential barrier. Due to the two fold symmetry of the molecules under interrogation, the conductance switching shows different polarities. The electronic excitation of the molecule leads to vibronic transition in which the molecule emits photons and vibrates inside the local potential wells. Considering significant corrugation of oxide surfaces, rotation mediated by quantum tunneling of ethyl groups of the molecule will be discussed.

¹This research was made possible through NSF Center for Chemistry at the Space-Time Limit (Grant no. CHE-082913)

10:12AM V17.00012 Atomic-scale motor driven by the current-induced forces

, YU-CHANG CHEN, BAILEY C. HSU, ALLEN TSENG, Department of Electrophysics, National Chiao Tung University, 1001 University Road, Hsinchu 30010, Taiwan — From first-principles approaches, we investigate the current-induced forces in an asymmetric molecular junction using Hellmann-Feynman type theorem in the framework of density functional theory in scattering approaches. We observe that it is possible to construct atomic-scale systems where the current-induced forces can be used to rotate the atoms. As an example, we consider a junction formed by the benzene molecule which directly connected to the Pt electrodes, where the benzene molecule is highly tilted. The highly tilted benzene molecule causes the streamline flow of the current to curve considerably to one side of the benzene ring. This could cause a net torque due to the unbalanced current-induced forces, which tend to rotate the benzene molecule in a manner similar to a stream of water rotates a waterwheel. Thus, the highly asymmetric single molecule junctions offer the atomic-scale systems to explore the possibility of nano-motors driven by non-equilibrium electron transport. The authors thank National Science Council (Taiwan) for support under Grant NSC 100-2112-M-012-MY3

10:24AM V17.00013 Capacitance variations of a Nanocapacitor in the Field Emission Regime¹

, CARLOS UNTIEDT, Dep. Fisica Aplicada. Universidad de Alicante. Spain, GIOVANNI SAENZ-ARCE, Dep. Fisica Aplicada. Univ. Alicante. Spain, JOSE IGNACIO PASCUAL, Institut für Experimentalphysik. Freie Universität Berlin, Germany — The electronic transport properties and mechanical forces between two metallic electrodes separated by a nanometer-sized vacuum gap have been studied using a Scanning Tunneling Microscope combined with a Tuning Fork Force sensor. When applying a voltage difference to the electrodes above their work function energy, the Field Emission regime can be accessed at which Field Emission Resonances take place. Under these circumstances a decrease of the capacitance has been found to occur showing a new mechanism of capacitor leaking in the quantum regime.

10:36AM V17.00014 Probing Water Structures in Nanopores via Tunneling¹, PAUL BOYNTON, MASSIMILIANO DI VENTRA, University of California, San Diego — We study the effects of volumetric constraints on the structure and electronic transport properties of distilled water in a synthetic nanopore. Combining classical molecular dynamics simulations with the Landauer approach to scattering theory as originally done in the context of DNA sequencing [1], we develop a relationship between the electronic current and the structure the water assumes in the confining pore-electrode system. Prior research in the field shows a tendency for the tunneling current through water to fluctuate due to local cavities in the water's structure. We show a shift in the tunneling current's dependence on pore diameter at the transition from exclusion of water to a monolayer. Furthermore, we argue that the current with respect to pore diameter does not follow a simple exponential curve at this transition as one would expect from tunneling. This research develops our understanding of water as a complex medium and describes fundamental physics of aqueous solutions.

Session V18 DMP: Focus Session: Interfaces in Complex Oxides - Interface and Surface Conductivity in SrTiO₃ 252B

8:00AM V18.00001 Surface charges & adsorbates tune the electron gas at the LaAlO₃/SrTiO₃ interface, YANWU XIE, CHRISTOPHER BELL, YASUYUKI HIKITA, HAROLD Y. HWANG, Department of Applied Physics and Stanford Institute for Materials and Energy Science, Stanford University, Stanford, California 94305, USA — The physical properties of the LaAlO₃/SrTiO₃ heterointerface are substantially determined by the density and mobility of the electron gas at the buried interface. Here, we present two ways to tune the electron gas from the LaAlO₃ surface. First, the electron gas can be locally tuned by using biased atomic force microscope probe [1]. Our studies show that this is caused by the accumulation of charge on the LaAlO₃ surface [2], and can change the density by up to $3 \times 10^{13} \text{ cm}^{-2}$ [3], comparable to the maximum modulation achieved in normal field effect devices. Second, we found that the electron gas can be dramatically tuned by the surface adsorption of common polar solvents such as acetone, ethanol and water [4]. This strong surface-interface coupling provides a new technique for manipulating the interface-confined electrons. Most significantly, adsorbates induce an insulator to metal transition when the thickness of the LaAlO₃ is 3 unit cells, suggesting sensor applications with extremely large sensitivity.

8:12AM V18.00002 Unexpected Two Dimensional Electron Gas at the LaAlO₃/SrTiO₃ (110) Interface¹, A. ANNADI, X. WANG, K. GOPINADHAN, W.M. LV, Z.Q. LIU, A. ROY BARMAN, A. SRIVASTAVA, S. SAHA, S. DHAR, NUSNNI-Nanocore, National University of Singapore, Singapore, H. HILGENKAMP, University of Twente, The Netherlands, T. VENKATESAN, - ARIANDO, NUSNNI-Nanocore, National University of Singapore, Singapore — The observation of two dimensional electron gas (2DEG), superconductivity and magnetism at the interfaces of LaAlO₃/SrTiO₃ has further amplified the potential of complex oxides for novel electronics. These multifunctional properties are strongly believed to originate from the polarization discontinuity at the interface between the two oxides along (001) direction. In this scenario, the crystal orientation plays an important role and no conductivity would be expected for e.g., the interface between LaAlO₃ and (110)-oriented SrTiO₃, which should not have a polarization discontinuity. In this talk, we will show the observation of conductivity at the LaAlO₃/SrTiO₃ interface prepared on (110)-oriented SrTiO₃. The strong evidence for 2DEG at the interface of LaAlO₃/SrTiO₃ (110) is the observed thickness dependence of insulator-metal transition at 3-4 u.c. of LaAlO₃. Directional dependent electrical transport is observed in resistance versus temperature measurements. We propose some models for explaining the observed phenomena.

¹We thank National Research Foundation (NRF) Singapore under the Competitive Research Program (CRP) "Tailoring Oxide Electronics by Atomic Control" NRF2008NRF-CRP002-024 and Ministry of Education (MOE) FRC-ARF Grant No. R-144-000-278-112.

8:24AM V18.00003 Temperature Dependent Strain Relaxation in LaAlO₃ Thin Films on SrTiO₃ Substrates, GUOZHEN LIU, KE CHEN, QINGYU LEI, Department of Physics, Temple University, QUN LI, LONGQING CHEN, Department of Materials Science and Engineering, Penn State University, XIAOXING XI, Department of Physics, Temple University — LaAlO₃/SrTiO₃ interface has attracted great interest due to discoveries of rich interfacial properties. Strain and strain relaxation in LaAlO₃ films on SrTiO₃ substrates directly impact the lattice distortions and defects at the interface and therefore will influence the interfacial properties. Combining grazing incident x-ray diffraction and reciprocal space mapping, we directly measured the in-plane lattice constants of LaAlO₃ films on SrTiO₃ with thickness ranging from 4 u.c. to 250 u.c. We found a strong relationship between the strain relaxation behavior and the growth temperature of the LaAlO₃ films. Cracks were observed when the strain relaxed rapidly, consistent with the fracture theory. The processing temperature-dependent strain relaxation significantly affects the LaAlO₃/SrTiO₃ interface properties.

8:36AM V18.00004 The origin of the 2DEG at oxide polar-non polar interfaces: electron reconstruction versus defect doping¹, CLAUDIA CANTONI, Oak Ridge National Laboratory, FABIO MILETTO GRANOZIO, CARMELA ARUTA, Università di Napoli Federico II & CNR-SPIN, JAUME GAZQUEZ, MARK OXLEY, ANDREW LUPINI, MARIA VARELA, STEPHEN PENNYCOOK, Oak Ridge National Laboratory, UMBERTO SCOTTI DI UCCIO, PAOLO PERNA, Università di Napoli Federico II & CNR-SPIN, DANIELE MARRÈ, Università di Genova & CNR-SPIN — In spite of intense research efforts, the microscopic mechanism underlying the formation of a 2DEG at the LaAlO₃(LAO)/SrTiO₃(STO) interface is still controversial. In particular, there is no consensus on whether the interface charge stems from an electronic reconstruction or from mobile electrons introduced by oxygen vacancies and/or cation doping. We present direct, atomic-column-resolved scanning transmission electron microscopy and electron energy loss measurements in LAO/STO and LaGaO₃(LGO)/STO interfaces. We find that both the measured injected charge, the low concentration of point defects, and the lattice polarization are consistent with a model of electronic reconstruction in LAO/STO. On the other hand, LGO/STO interfaces grown in the same conditions show negligible polar lattice distortions and an injected charge incompatible with electronic reconstruction. Conductivity here is explained by the observed cation intermixing and the presence of oxygen vacancies.

¹ORNL research sponsored by US DOE Office of Science, Materials Science and Engineering Division.

8:48AM V18.00005 Computational study of oxygen vacancy defects in perovskite oxides, SrTiO₃ and LaAlO₃, CHANDRIMA MITRA, CHUNGWEI LIN, University of Texas at Austin, JOHN ROBERTSON, Cambridge University, ALEXANDER DEMKOV, University of Texas at Austin — Insulating perovskite oxides, SrTiO₃ (STO) and LaAlO₃ (LAO) have attracted a lot of attention due to the observed two dimensional electron gas at the interface of these two insulating oxides. Oxygen vacancies, which are easily incorporated in these oxide systems during various processes such as growth, annealing and redox reactions, form an n-type defect in these systems. Hence they are responsible for modifications of various physical properties such as conductivity and optical properties to name a few. As such, there is still a lack of comprehensive theoretical understanding of these important defects in these materials. In this work we present first principles calculations of neutral (V^0) and charged (V^+ , V^{++}) oxygen vacancies in STO and LAO. Density functional theory within the local density approximation proves insufficient in reliably predicting the defect levels due to their well known band gap problem. We therefore employ the Heyd, Scuseria, and Ernzerhof (HSE) hybrid functional to study these defects. Band gaps of 3.01 eV and 5.0 eV are obtained for bulk STO and LAO which are in excellent agreement to experimental values. In STO we find a localized V^0 defect state at 0.7 eV below the conduction band edge (CBE) while in LAO it is a deep lying level at 2.13 eV below the CBE. A band alignment of the defect levels in these two materials shows that upon stabilizing the singly ionized state, charge transfer could take place from the V^+ LAO state to the V^+ STO state which lies at 1.19 eV below the former.

9:00AM V18.00006 Oxygen vacancy shuttle across the LaAlO₃/SrTiO₃ interface, EVGENY Y. TSYMBAL, TULA R. PAUDEL, YONG WANG, J.D. BURTON, University of Nebraska, Lincoln — There have been several recent indications of a switchable piezo-response in oxide materials not associated with ferroelectric polarization. We explore a LaAlO₃/SrTiO₃ (LAO/STO) heterostructure as a model system to understand this behavior by considering oxygen vacancies as the origin. Using first-principles calculations based on a supercell approach and an adequate electrostatic model, we show that the oxygen vacancy formation energy has two local minima: one at the surface of LAO and another in STO few unit cell below the interface. Due to inbuilt electric field in the system, electrons forming the oxygen vacancies in LAO transfer to the interface leaving behind two holes at the vacancy site irrespective of their spatial position, whereas those in the STO exhibit such a behavior only when lying within a finite distance ~ 1 nm associated with the screening length of the electric field in STO. The two local minima may accommodate oxygen vacancies reversibly when the applied electric field changes its polarity producing a switchable piezo-response behavior in the LAO/STO system.

9:12AM V18.00007 Electronic phase separation at the LaAlO₃/SrTiO₃ interface¹, - ARIANDO, NUSNNI-Nanocore & Department of Physics, National University of Singapore, Singapore — In the last few years we have seen a number of new properties to emerge at the interface between two insulating oxides. However the origin of these properties remains unclear and needs further investigation. In this talk I will discuss our recent studies on oxide interfaces in which we vary various parameters such as oxygen content and crystal orientation, and use different polar layers and heterostructures. Surprisingly, at the LaAlO₃/SrTiO₃ interface a remarkable combination of strong diamagnetism (superconductor like), paramagnetism and ferromagnetism can coexist with the quasi two dimensional electron gas (Q2DEG) when prepared under a more oxidizing condition. The ferromagnetic phase is stable even above room temperature and the diamagnetism below a relatively high temperature of 60 K. Our measurements show that the free surface of SrTiO₃ may be responsible for all these fascinating phenomena. The phenomena are explained due to the selective occupancy of interface/surface sub-bands of the nearly degenerate Ti orbital in the SrTiO₃. On changing the interface orientation, we unexpectedly can also obtain conductivity at the LaAlO₃/SrTiO₃ interface prepared on (110)-oriented SrTiO₃. The conductivity is found to be highly anisotropic, which is a novel feature for these oxide Q2DEGs and of potential interest for applications. I will discuss various possible models that can explain this intriguing observation and also review various interfaces prepared using different polar layers coupled to other functional materials which result in new phenomena.

¹We thank National Research Foundation (NRF) Singapore under the Competitive Research Program (CRP) “Tailoring Oxide Electronics by Atomic Control” NRF2008NRF-CRP002-024 and Ministry of Education (MOE) FRC-ARF Grant No. R-144-000-278-112.

9:48AM V18.00008 Effect of cation-nonstoichiometry in the SrTiO₃ layer on the interfacial conductance of LaAlO₃/SrTiO₃ heterostructures, SUSANNE HOFFMANN-EIFERT, FELIX GUNKEL, SEBASTIAN WICKLEIN, FZ Juelich, PGI-7 and JARA-FIT, Juelich, Germany, PETER BRINKS, MARK HUIJBEN, JOSEE E. KLEIBEUKER, GERTJAN KOSTER, GUUS RIJNDERS, Mesa+ Institute for Nanotechnology, University of Twente, Enschede, The Netherlands, REGINA DITTMANN, RAINER WASER, FZ Juelich, PGI-7 and JARA-FIT, Juelich, Germany — A study of the interface conductivity in LaAlO₃/SrTiO₃ (LAO/STO) heterostructures will be presented with focus on the defect chemical state of the SrTiO₃ close to the interface. SrTiO₃ layers with a controlled deviation from cation stoichiometry ($Sr/Ti=1$) were grown to investigate the effect of cation-nonstoichiometry in the SrTiO₃ layer on the resulting interface conductance of the corresponding LAO/STO heterostructures. The study comprises structural information and electrical properties derived from Hall measurements and high-temperature conductance measurements performed under equilibrium oxygen atmospheres. According to the model of defect chemistry the results give further evidence for the importance of charge compensation through defects on cation lattice sites.

10:00AM V18.00009 Nature of localized states induced by an oxygen vacancy in SrTiO₃¹, CHUNGWEI LIN, CHANDRIMA MITRA, ALEXANDER DEMKOV, Department of Physics, University of Texas at Austin — Combining the density function theory and model analysis, we study the nature of localized states induced by an oxygen vacancy (OV) in SrTiO₃. The key effect caused by an OV is that it introduces a local mixing between $3z^2 - r^2$ and $4s$, $4p$ orbitals of Ti next to the vacancy. According to our analysis, the OV-induced localized state is highly one-dimensional and is mainly composed of Ti $3z^2 - r^2$ orbitals along the Ti-OV-Ti axis (defined as the z -axis) and Ti $4s$, $4p$ at the OV site. Ti t_{2g} based localized states are ruled out. We suggest the $4s$, $4p$ components of the OV induced localized state should be reflected in the x-ray adsorption spectroscopy when Ti $4s$, $4p$ are served as final states. Our analysis and conclusion apply to general transition metal perovskites.

10:12AM V18.00010 Oxygen deficiency on the p(1x1) structure of SrTiO₃ (001) surface¹, LINA CHEN, ZHAOLIANG LIAO, VON BRAUN NASCIMENTO, YI LI, A.C. ANTONY, E.W. PLUMMER, JIANDI ZHANG, Department of Physics and Astronomy, Louisiana State University, LA, 70810 USA — SrTiO₃(STO) is one of the most common substrates used for epitaxial film growth of oxide materials. However, the structure and stoichiometry of STO are still unclear even though they may dictate the interface properties. We have studied the STO(001) surface structure by Low Energy Electron Diffraction (LEED) and angle-resolved X-ray Photoelectron Spectroscopy (AR-XPS). The unreconstructed $p(1 \times 1)$ STO(001) surface terminated with TiO₂ layer is obtained by simple chemical etching which is always accompanied by oxygen deficiency. Both LEED and AR-XPS results suggest that the surface has a considerable oxygen deficiency, but LEED I(V) analysis indicates the existence of more oxygen vacancies than that from AP-XPS results. The structural analysis indicates a surface polarization due to a surface buckling combined with oxygen deficiency, which is consistent with recent surface x-ray scattering results [1] with important implications on surface ferroelectric phenomena in STO. The annealing effect of the as-etched surface in oxygen atmosphere on surface oxygen deficiency as well as reconstruction will also be discussed.

10:24AM V18.00011 Strain effects on the electron effective mass in SrTiO_3 ¹, ANDERSON JANOTTI, DANIEL STEIAUF, CHRIS G. VAN DE WALLE, Materials Department, University of California Santa Barbara — Strain can greatly affect the electronic properties of thin layers in epitaxial heterostructures, leading to improved transport properties. In SrTiO_3 -based heterostructures, strain can lift the degeneracy and modify the order of the states near the conduction-band minimum. Using density functional theory with the screened hybrid functional of Heyd, Scuseria, and Ernzerhof (HSE) we study the effects of strain on the energetic ordering and effective mass of the lowest-energy conduction-band states in SrTiO_3 . We predict that biaxial stress in the (001) or (110) planes results in the lowest-energy conduction-band state having significantly smaller electron mass in the in-plane directions compared to unstrained SrTiO_3 , thus suggesting that pseudomorphic growth is a promising route to increasing the electron mobility in epitaxial films. We propose possible substrates that may lead to SrTiO_3 films with enhanced electron mobilities, and report deformation potentials that allow accurate prediction of conduction-band splittings for arbitrary strain configurations.

¹Work supported by ARO and NSF.

10:36AM V18.00012 Electrical Transport in SrTiO_3 Under Biaxial Strain¹, ADAM KAJDOS, UC Santa Barbara - Materials, BHARAT JALAN, University of Minnesota - Chemical Engineering and Materials Science, JAMES ALLEN, UC Santa Barbara - Physics, SUSANNE STEMMER, UC Santa Barbara - Materials — Mobility engineering with strain is widely used for conventional semiconductors, but has only recently been proposed for complex oxides such as SrTiO_3 . The conduction band structure of SrTiO_3 is complicated with multiple degenerate bands derived from the Ti 3d orbitals. Strain is thus expected to have a significant effect by lifting this degeneracy and altering the occupancy and curvature of the bands. Indeed, a 300% increase in the electron mobility with values exceeding $128,000 \text{ cm}^2/\text{Vs}$ at 1.8 K was demonstrated in MBE-grown SrTiO_3 films subjected to *uniaxial* compressive strain [1]. For heterostructure engineering, the effect of *biaxial* strain is relevant. Here, the electron mobilities in SrTiO_3 subjected to biaxial strain are investigated through growth of coherent films on lattice-mismatched substrates. Lightly-doped (high-mobility) strained SrTiO_3 films below the critical thickness are insulating because of significant surface depletion, which increases with decreasing temperature due to the high dielectric constant of SrTiO_3 . We show that highly-doped, low-mobility capping layers address this problem, but require a multilayer model to analyze the Hall data in terms of the mobility in the lightly doped layer. [1] B. Jalan et al., Appl. Phys. Lett. **98**, 132102 (2011)

10:48AM V18.00013 The Influence of Oxygen in Transition Metal Oxides, P.L. BACH, V. LEBORAN, F. RIVADULLA, University of Santiago de Compostela — The existence of a 2D metallic state at the interface between LaAlO_3 and SrTiO_3 (LAO/STO) has generated much excitement. Its origin has been attributed to charge redistribution to avoid a dielectric catastrophe; however, oxygen vacancies in TiO_2 -terminated STO can play a significant role in the electronic properties of the interface. In order to determine the nature and origin of the metallic phase, we have induced vacancies in TiO_2 -terminated STO single crystal substrates by annealing under controlled vacuum conditions. We report resistivity, Hall effect, and thermopower measurements on these materials and discuss their implications for the nature of the 2D electron gas at the STO surface. We have explored the possibility of gate-tuning these systems in order to fabricate single-oxide based devices. This work was supported by the Ministerio de Ciencia e Innovación (Spain), grant MAT2010-16157, and the European Research Council, grant ERC-2010-StG 259082 2D THERMS.

Session V19 DCMP: Invited Session: Holography and Strongly Correlated Electron Matter
253AB

8:00AM V19.00001 Why black holes may be useful for condensed matter physics, SEAN HARTNOLL, Stanford University — I will give an overview of recent applications of black hole physics to strongly correlated electron systems, via the holographic correspondence. I will briefly review the thermodynamic nature of black hole horizons and explain how black holes exhibit quantum critical dissipation. I proceed to argue that black holes are associated with fractionalized phases of matter and provide a simple setting in which transport and other properties of such phases can be nonperturbatively studied. Black holes furthermore have natural instabilities to superconducting phases. The onset of superconductivity is described in a qualitatively different way than in BCS-derived theories of pairing. The superconductivity emerges from a non-Fermi liquid state of matter, without well-defined quasiparticles, and may suggest emphasis on different classes of observables.

8:36AM V19.00002 Holography and Mottness: A Discrete Marriage¹, PHILIP PHILLIPS, Dept. of Physics, University of Illinois, Urbana, IL 61801 — Gauge-gravity duality has allowed us to solve the physics of certain strongly coupled quantum mechanical systems using gravity. I will show how a space-time consisting of a charged black hole and a bulk Pauli coupling corresponds to a boundary theory with a dynamically generated gap (with no obvious symmetry breaking) and a massive rearrangement of the spectral weight as in classic Mott systems such as VO_2 . In this holographic set-up, the gap opens only when discrete scale invariance is present. This raises the possibility that the elusive symmetry that might be broken in Mott insulators, in general, might pertain to scale invariance. The relevance of this claim to recent theories of Mott systems that possess massless charged bosons is explored.

¹NSF DMR-0940992 and the Center for Emergent Superconductivity, a DOE Energy Frontier Research Center, Award Number DE-AC0298CH1088.

9:12AM V19.00003 Charge fractionalization and gauge-gravityduality¹, LIZA HUIJSE, Harvard University — We discuss zero temperature phases of compressible quantum matter, i.e. phases in which the expectation value of a globally conserved $U(1)$ density, Q , varies smoothly as a function of parameters. Provided the global $U(1)$ and translational symmetries are unbroken, such phases are expected to have Fermi surfaces, and the Luttinger theorem relates the volumes enclosed by these Fermi surfaces to $\langle Q \rangle$. We distinguish three compressible states: Landau's Fermi Liquid (FL), the fractionalized Fermi Liquid (FL*) and the non-Fermi Liquid (NFL). The motivation for this classification stems from the fact that compressible phases seem to be the rule rather than the exception in theories studied in the context of gauge-gravity duality. We argue that the three compressible phases we identify are indeed present in two paradigmatic supersymmetric gauge-theories underlying the duality. We then describe a gravity theory with an asymptotic electric flux dual to a zero temperature gauge theory at finite chemical potential. The flux can be sourced either by explicit charged matter in the bulk, by an extremal black hole horizon, or both. We argue that these three cases show important similarities with the three compressible states of matter. By tuning a relevant parameter we can study zero temperature phase transitions between the three phases in the dual description. The work I present was done in collaboration with S. Sachdev and S. Hartnoll.

¹The Netherlands Organization for Scientific Research (NWO)

9:48AM V19.00004 Emergent dimensions and quantum critical points¹, SUNG-SIK LEE, McMaster University / Perimeter Institute — When quantum many-body systems are strongly correlated, the underlying particles may dynamically organize themselves to show novel collective behaviors. Under certain conditions, collective fluctuations behave as if they are living in a space which has one more dimension than the space where the original particles are defined. In this talk, I will discuss about an example where an 'external' space emerges at a quantum critical point of a non-abelian gauge theory. A close analogy will be drawn between this phenomenon and fractionalization which can be viewed as an example of emergent 'internal' spaces. I will also discuss about non-trivial quantum orders associated with emergent dimensions.

¹This research was supported by NSERC, the Ontario Ministry of Research and Innovation and the Government of Canada.

10:24AM V19.00005 Embedding Fermi liquids in string theory, STEVEN GUBSER, Princeton University — Evidence of Fermi surfaces in strongly coupled gauge theories comes from calculations in the gauge-string duality based on the propagation of fermion fields in charged black hole backgrounds. Most of these calculations have been done without reference to explicitly known string theory constructions. When calculations based on the most universal sector of string theory constructions were at last done, no Fermi surface was found. In addition to reviewing the work just described, I will present new work showing that Fermi surfaces do exist in the next-to-simplest string theory constructions.

Thursday, March 1, 2012 8:00AM - 10:24AM —
Session V20 FIAP: Invited Session: High k Dielectrics for High Carrier Mobility Channel Applications 253C

8:00AM V20.00001 Materials and Device Aspects of III-V 3D Transistors, PEIDE YE, Purdue University — Recently, III-V MOSFETs with high drain currents ($I_{ds} > 1\text{mA}/\mu\text{m}$) and high transconductances ($g_m > 1\text{mS}/\mu\text{m}$) have been achieved at sub-micron channel lengths (L_{ch}), thanks to the better understanding and significant improvement in high-k/III-V interfaces. However, to realize a III-V FET at beyond 14nm technology node, one major challenge is how to effectively control the short channel effects (SCE). Due to the higher permittivity and lower bandgap of the channel materials, III-V MOSFETs are more susceptible to SCE than its Si counterpart. The scaling of planar devices stops at around 150nm L_{ch} . The dramatic increase in DIBL beyond 150nm indicates severe impact from 2D electrostatics. Therefore, the introduction of 3-dimensional (3D) structures to the fabrication of sub-100nm III-V FETs is necessary. In this talk, we will review the materials and device aspects of III-V 3D transistors developed very recently [1-3].

8:36AM V20.00002 Pushing the material limit and physics novelty in high κ 's/high carrier mobility semiconductors for post Si CMOS, MINGHWEI HONG, Department of Physics and Graduate Institute of Applied Physics, National Taiwan University, Taipei, Taiwan 10617 — The semiconductor industry is now facing unprecedented materials/physics challenges due to the scaling-limitation of Si CMOS transistor arising from non-scaling of matters, namely gate dielectrics and channel mobility. The new technology using high- κ plus metal gate on high carrier mobility semiconductors of InGaAs and Ge will lead to faster speed at lower power. The tasks for realizing the new devices equivalent oxide thickness (EOT) $< 1\text{ nm}$, interfacial density of state (D_{it}) $\leq 10^{11}\text{ eV}^{-1}\text{cm}^{-2}$, self-aligned process, low parasitic, and integration with Si, have been solved or are being feverishly studied. The key of achieving the above goals is to understand/tailor interfaces of the high κ 's/InGaAs (Ge). Tremendous progress has been made using molecular beam epitaxy (MBE) and atomic layer deposition (ALD) high κ 's of Ga_2O_3 (Gd_2O_3), Al_2O_3 , and HfO_2 , and the novel ALD/MBE dual dielectrics in attaining an EOT of 0.5 nm, D_{it} of low $10^{11}\text{ eV}^{-1}\text{cm}^{-2}$ (with a flat D_{it} distribution versus energy), and thermal stability at high temperatures higher than 800°C of the MOS structures. Electronic/electrical characteristics of the hetero-structures have been studied using in-situ synchrotron radiation photo-emission, cross-sectional scanning tunneling spectroscopy, capacitance (conductance)-voltage under various temperatures, and charge pumping methods. Device performance in world-record drain currents, transconductances, sub-threshold swings, etc. in self-aligned inversion-channel high κ 's/InGaAs and /Ge MOSFET's will also be presented. This work has been supported by Nano National Program (NSC 100-2120-M-007-010) of the NSC of Taiwan, and the AOARD of the US Air Force.

In collaboration with J. Kwo, W. C. Lee, M. L. Huang, T. D. Lin, Y. C. Chang, Y. H. Chang, C. A. Lin, Y. M. Chang (NTHU and NTU in Taiwan), T. W. Pi, C. H. Hsu (NSRRC in Taiwan), Y. P. Chiu (NSYSU in Taiwan), C. Merckling (IMEC in Belgium), J. I. Chyi (NCU, Taiwan), and G. J. Brown (AFRL, USA).

9:12AM V20.00003 Bonding principles of the Passivation Mechanism at III-V – oxide Interfaces, JOHN ROBERTSON, Cambridge University — It has always been much more difficult to make FETs from GaAs than Si, because of 'Fermi level pinning' and the difficulty of passivating its surfaces and interfaces. These issues have been discussed from the early days of PCSI by Spicer *et al* [1] with their "unified defect model." Hasegawa [2] introduced the idea of "Disorder Induced Gap states" (DIGS). Since 1997 it has been possible to make inverted MOSFETs on GaAs using the epitaxial Gadolinium gallium oxide [3], but the main impetuous has been since 2003 to use atomic layer dpeosition to make scalable FETs, as recently acheived by Intel [4]. The obvious question is why GaAs is so much more difficult to passivate than Si. The early answer was that the native oxide was poor. But since the advent of good deposited ALD oxides on Si such as HfO_2 or Al_2O_3 , this answer is no good, as they should also work on GaAs. They do to an extent, but the interfacial density of states is still too large and the CV p lots are distorted. The cause of the defects is cannot be due to stress. The reason must be some underlying chemical reason. I show that the reason is the polar nature of bonding in GaAa and other III-Vs, and the driving force to keep the Fermi level in a gap. The electron counting rule of Pashley [5] that describes surface reconstruction is shown to be a variant of auto-compensation, and it is proposed to work more generally, at each layer deposition or growth on GaAs [6]. This leads to a continuous generation of defects if it is not satisfied. So the answer is to deposit oxide layers that meet this rule, and also break up any surface reconstructions that would lead to As-As dimers [6].

9:48AM V20.00004 Exploring Ge and III-V devices to scale CMOS beyond the Si roadmap

, MARC HEYNS, imec — There is lots of interest in the use of germanium and III-V compounds as channel material in future CMOS generations. Direct growth of Ge and III-V in Si trenches allows to co-integrate these materials on bulk Si substrates. The formation of antiphase domain boundaries during epitaxy of III-V materials can be avoided by creating double atomic steps at the bottom of the trench through controlled Ge surface profiling. Much effort was dedicated to the electrical passivation of the interface between the high-k dielectric and these materials. Despite its relatively poor stability GeO₂-like passivation of Ge has been demonstrated for both pMOS and nMOS devices. Si capping layers of only a few monolayers were used to fabricate short channel Ge pMOS devices with high drive currents. Other successful Ge passivation methods are based on surface treatments such as in situ H₂S or wet (NH₄)₂S. Devices in III-V materials often suffer from Fermi level pinning associated with a high density of defect states near the high-k/III-V interface. These defects can be suppressed by optimized (in-situ) surface treatments and precise control of the oxidation states at the high-k/III-V interface. The Al₂O₃/InGaAs interface has been extensively investigated, often concentrating on the possibility to remove Ga and As oxides by exposure to trimethylaluminum (TMA) during atomic layer deposition (ALD), but good passivation has also been demonstrated with various other high-k materials. Since most III-V materials have a low conduction band density of states, the surface potential travels far into the conduction band before the necessary amount of mobile charge is accumulated at the interface. Therefore, the defect density at these energy levels must also be reduced, including border traps in the high-k layer that cause frequency dispersion in the capacitance-voltage behaviour. Finally, it is noteworthy to mention that the introduction of these advanced materials also allows the development of new device concepts, such as Implant-Free Quantum Well devices, heterojunction TunnelFETs and nanowire devices, that can fully exploit the properties of these new materials.

Thursday, March 1, 2012 8:00AM - 11:00AM –

Session V21 DCMP: Superconductivity: Mostly Cuprates 254A

8:00AM V21.00001 Evidence of strong correlations at the Van Hove singularity in the scanning-tunneling spectra of superconducting Bi₂Sr₂CaCu₂O_{8+δ} single crystals¹

, ARUN BANSIL, Northeastern University, JOUKO NIEMINEN, ILPO SUOMINEN, Tampere University of Technology, Finland, TANMOY DAS, ROBERT MARKIEWICZ, Northeastern University — We present realistic multiband calculations of scanning tunneling spectra in Bi₂Sr₂CaCu₂O_{8+δ} over a wide doping range. Our modeling incorporates effects of a competing pseudogap and pairing gap as well as effects of strong electronic correlations, which are included by introducing self-energy corrections in the one-particle propagators. The calculations provide a good description of the two-gap features seen in experiments at low energies. In particular, the Van Hove singularity (VHS) in the underlying electronic states is found to split into a prominent incoherent feature at high energies and a weaker coherent part near the Fermi level which is strongly involved in gap formation. The progressive hybridization of the localized VHS into the Fermi surface with increasing doping is suggestive of Kondo physics which has been proposed previously for cuprates and heavy fermion compounds.

¹Supported in part by the US DOE.

8:12AM V21.00002 Local correlations and deviations of energy scales from SI-STM in Bi-2212

, KYLE MCELROY, JACOB ALLDREDGE, University of Colorado Boulder, KAZUHIRO FUJITA, Cornell University, GENDA GU, Brookhaven National Laboratory, HIROSHI EISAKI, Institute of Advanced Industrial Science and Technology, S. UCHIDA, Department of Physics, University of Tokyo — One of the key difficulties in understanding the cuprate superconductors is reconciling the many probes that have been used to investigate them. In particular, in one of the most studied materials BSCCO-2212, this comparison is complicated by the striking atomic scale inhomogeneity that is seen in the electronic structure. We will present spectroscopic imaging scanning tunneling microscopy studies which show that the dominate energy scales are tied together not only as a function of doping but locally. This implies a single parameter that allows much of the low energy structure to be predicted. In addition, local structures which cause deviations in the ability of this single parameter to fit the data correspond to other phenomena previously described.

8:24AM V21.00003 Doping dependent study of non-equilibrium quasiparticle dynamics in the superconducting and normal state of La_{2-x}Sr_xCuO₄ thin films

, FAHAD MAHMOOD, DARIUS TORCHINSKY, Department of Physics, Massachusetts Institute of Technology, Cambridge MA 02139, A. BOLLINGER, I. BOZOVIC, Brookhaven National Laboratory, NUH GEDIK, Department of Physics, Massachusetts Institute of Technology, Cambridge MA 02139 — We report on measurements of non-equilibrium quasiparticle dynamics in La_{2-x}Sr_xCuO₄ thin films via ultrafast optical pump probe spectroscopy. Quasiparticles are excited into the thin films using ultrashort laser pulses. The transient change in the quasiparticle density causes a corresponding change in the reflectivity of the sample, allowing time resolved measurements of quasiparticle recombination. We describe the doping dependence of these measurements both above and below T_c and discuss their implications on the nature of the electron-boson coupling in the cuprates.

8:36AM V21.00004 Doping-dependence of Scattering Interference in Cuprates

, KAZUHIRO FUJITA, MOHAMMAD HAMIDIAN, INES FIRMO, SOURIN MUKHOPADHYAY, Cornell University, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology, SHIN-ICHI UCHIDA, University of Tokyo, J.C. DAVIS, Cornell University — Evolution of the k-space electronic structure from the strongly underdoped to overdoped regime upon doping is studied. At the doping level coincident with the disappearance of the pseudogap phenomenology a crossover in the scattering processes is identified [1]. We discuss the significance of such transition in conjunction with other experimental facts.

[1] K. Fujita, M. Hamidian, I. A. Firmo, S. Mukhopadhyay, H. Eisaki, S. Uchida, and J. C. Davis *Submitted* (2011).

8:48AM V21.00005 Time resolved reflectivity study of electron and hole doped cuprate superconductors

, JAMES HINTON, UC Berkeley, LBNL, JAKE KORALEK, LBNL, GUICHUAN YU, MUN CHAN, University of Minnesota, NEVEN BARISIC, University of Minnesota, University of Stuttgart, XUDONG ZHAO, Jilin University, MARTIN GREVEN, University of Minnesota, JOSEPH ORENSTEIN, UC Berkeley, LBNL — We study both the hole-doped cuprate HgBa₂CuO_{4+δ} (Hg1201) and the electron-doped cuprate Nd_{2-x}Ce_xCuO_{4+δ} (NCCO) using time-resolved optical reflectivity. In this technique, the sample is excited using an ultrashort 800 nm laser pulse, and the induced change in reflectivity is measured as a function of time after excitation. We focus on the temperature range above the superconducting transition; the fluctuating antiferromagnetic phase in NCCO and the pseudogap phase in Hg1201. In both cases we compare our results directly to neutron experiments, highlighting the relationship of the ultrafast optical response to magnetically ordered phases.

9:00AM V21.00006 Magnetic, Structural and Resistivity Characterization of New $R_3\text{Gd}_3\text{Ba}_2\text{Ca}_2\text{Cu}_7\text{O}_{10}:\text{Li}$ Compounds ($R=\text{rare earth}$), C. AGUILAR, Instituto de Investigaciones en Materiales, UNAM, Mexico, DF 04510, E.E. MARINERO, Hitachi San Jose Research Center, 3403 Yerba Buena Road, San Jose, CA 95135, E. CHAVIRA, Instituto de Investigaciones en Materiales, UNAM, Mexico, DF 04510, L. BUCIO, Instituto de Fisica, UNAM, Mexico, DF 04510, H. PFEIFFER, Instituto de Investigaciones en Materiales, UNAM, Mexico, DF 04510 — We report on the synthesis of $R_3\text{Gd}_3\text{Ba}_2\text{Ca}_2\text{Cu}_7\text{O}_{10}:\text{Li}$ compounds with different rare earth elements ($R=\text{Dy, Ho}$) by solid state reaction. Reaction products during the synthesis were identified by XRD and their thermal stability measured by Thermo-Gravimetric Analysis (TGA). Rietveld refinement of the XRD spectra enabled us to identify two coupled phases: a tetragonal one and an orthorhombic component. Magnetic measurements were conducted in the range of 5 to 300K to determine their Curie point and evidence for superconducting transitions. We find that in spite of the fact that both the Dy and Ho containing samples have the same crystalline structure, they exhibit different magnetic behavior over the temperature range studied. Evidence for a critical temperature at 15K for the Dy containing sample is observed exhibiting the characteristic M_s vs. T dependence ascribed to superconducting behavior. Detailed structural characterization results and measurements of R vs. T will be presented to confirm that the behavior observed at 15K is evidence for superconducting behavior.

9:12AM V21.00007 External vs. “internal” pressure effect on the anti-ferromagnetic super-exchange energy, J , in $\text{LnBa}_2\text{Cu}_3\text{O}_6$ ($\text{Ln}=\text{La, Nd, ..., Lu}$), BEN MALLETT, The MacDiarmid Institute, Victoria University of Wellington, JEFFERY TALLON, The MacDiarmid Institute, Industrial Research Limited, GRANT WILLIAMS, The MacDiarmid Institute, Victoria University of Wellington, THOMAS WOLF, Karlsruhe Institute of Technology, Institute of Solid State Physics — What causes the difference between the effect of “internal” pressure, as caused by ionic substitution, and external pressure on T_c^{max} in the cuprates [1]? Is it the density of states, the pairing boson energy scale (ω_B), condensation energy (which governs fluctuations), or ...? Many models of high temperature superconductivity put the energy scale of ω_B as the anti-ferromagnetic super-exchange energy, J , between adjacent Cu(2) ions in the CuO_2 plane. We therefore investigated Raman B_{1g} two-magnon scattering in high quality $\text{LnBa}_2\text{Cu}_3\text{O}_6$ ($\text{Ln}=\text{La, Nd, Sm, Eu, Gd, Dy, Yb, Lu}$), at ambient pressure to determine the effect of internal pressure on J . Comparing with measurements of J under external pressure reveals that internal and external pressure have *quantitatively* the same effect on J . However, and most surprisingly, we find an anticorrelation between J and T_c^{max} when ion size or internal pressure is the implicit variable. Given the opposite effects of internal and external pressure on T_c^{max} , this result suggests that some energy scale other than short range anti-ferromagnetic interactions has a more dominant effect on T_c^{max} .

9:24AM V21.00008 Anomalous High-Energy Spin Excitations in the High- T_c Superconductor Parent Antiferromagnet La_2CuO_4 , STEPHEN HAYDEN, NEIL HEADINGS, University of Bristol, RADU COLDEA, University of Oxford, TOBY PERRING, Rutherford Appleton Laboratory — Inelastic neutron scattering is used to investigate the collective magnetic excitations of the high-temperature superconductor parent antiferromagnet La_2CuO_4 . We find that while the lower energy excitations are well described by spin-wave theory, including one- and two-magnon scattering processes, the high-energy spin waves are strongly damped near the $(1/2, 0)$ position in reciprocal space and merge into a momentum dependent continuum. This anomalous damping indicates the decay of spin waves into other excitations, possibly unbound spinon pairs. The spinon dispersion that can explain the observed spin-wave damping in our experiments has the same form as the pseudogap dispersion observed in superconducting cuprates, with a minimum at $(1/4, 1/4)$.

9:36AM V21.00009 Charge transfer at the interface between ferromagnetic $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ and superconducting $\text{EuBa}_2\text{Cu}_3\text{O}_7$ probed by STM/STS, YINGHAO LIU, JIE XIONG, JASON HARALDSEN(2), LI YAN, ALEXANDER BALATSKY(2), QUANXI JIA, ANTOINETTE TAYLOR, DMITRY YAROTSKI, MPA-CINT and Theoretical Division(2), Los Alamos National Laboratory, NM 87545 — $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ (LSMO) is a ferromagnetic half-metallic compound with nearly 100% spin polarization at room temperature, making it an ideal candidate for applications in spintronic devices. However, this useful functionality disappears when the thickness of LSMO film grown on SrTiO_3 substrate is reduced to below 4 nm, limiting its application in nanoscale devices. Here, we show that metallic and ferromagnetic properties of ultrathin ($< 4\text{nm}$) LSMO film can be restored by interfacing it with a superconductor $\text{EuBa}_2\text{Cu}_3\text{O}_{7-\delta}$ (EBCO). We use scanning tunneling microscopy and spectroscopy to probe the evolution of the electronic structure of LSMO film grown on EBCO as functions of LSMO layer thickness and aging of bilayer LSMO/EBCO. Our results reveal that the charge (hole) transfer at LSMO/EBCO interface is responsible for driving LSMO film (of only five-unit-cell thickness) to metallic state. The conductive behavior of aged LSMO/EBCO bilayers varies systematically with the thickness of LSMO layer, allowing us to estimate the charge-transfer depth to be 4~5 nm on the LSMO side.

9:48AM V21.00010 Muon spin rotation investigation of the pressure effect on the magnetic penetration depth in $\text{YBa}_2\text{Cu}_3\text{O}_x$ ¹, ALEXANDER MAISURADZE, Paul Scherrer Institute, CH-5232 Villigen PSI, Switzerland, ALEXANDER SHENGELAYA, Tbilisi State University, GE-0128 Tbilisi, Georgia, ALEX AMATO, EKATERINA POMJAKUSHINA, Paul Scherrer Institute, CH-5232 Villigen PSI, Switzerland, HUGO KELLER, Physics Institute of University of Zurich, CH-8057 Zurich, Switzerland, UNIVERSITY OF ZURICH TEAM, PAUL SCHERRER INSTITUTE TEAM, TBILISI STATE UNIVERSITY TEAM — The pressure dependence of the magnetic penetration depth λ in polycrystalline samples of $\text{YBa}_2\text{Cu}_3\text{O}_x$ with different oxygen concentrations $x = 6.45, 6.6, 6.8$, and 6.98 was studied by muon spin rotation (μSR). The pressure dependence of the superfluid density $\rho_s \propto 1/\lambda^2$ as a function of the superconducting transition temperature T_c is found to deviate from the usual Uemura line. The ratio $(\partial T_c / \partial P) / (\partial \rho_s / \partial P)$ is factor of $\simeq 2$ smaller than that of the Uemura relation. In underdoped samples, the zero temperature superconducting gap Δ_0 and the BCS ratio $\Delta_0 / k_B T_c$ both increase with increasing external hydrostatic pressure, implying an increase of the coupling strength with pressure. The relation between the pressure effect and the oxygen isotope effect on λ is also discussed. In order to analyze reliably the μSR spectra of samples with strong magnetic moments in a pressure cell, a special model was developed and applied.

10:00AM V21.00011 Ultrafast spectroscopy of the stripe phase of underdoped $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$ thin films, DARIUS TORCHINSKY, FAHAD MAHMOOD, MIT, A. BOLLINGER, I. BOZOVIC, Brookhaven National Laboratory, NUH GEDIK, MIT — We have performed ultrafast measurements on high- T_c thin films of underdoped $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$. In these experiments, femtosecond pulses create photoexcitations derived from both the superconducting and striped phase fraction whose evolution and decay are probed as a function of time. We discuss the separate dynamics of these two electronic components as a function of temperature and excitation density.

10:12AM V21.00012 Nonlinear Response of the High-Temperature Superconductor $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$ to the Transmission of Intense Terahertz Pulses¹, IWA O KAWAYAMA, Osaka Univ. and PRESTO-JST, ANDREAS GLOSSNER, Osaka Univ. and Universität Erlangen-Nürnberg, CAIHONG ZHANG, SHINYA KIKUTA, HIRONARU MURAKAMI, Osaka Univ., PAUL MÜLLER, Universität Erlangen-Nürnberg, MASAYOSHI TONOUCHI, Osaka Univ. — High-Power Terahertz Time-Domain Spectroscopy (THz-TDS) was used to examine $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$ thin films when transmitted by intense single-cycle THz pulses. This allowed for an investigation of the nonlinear, time-resolved behavior of $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$ in the presence of strong THz electric fields for the first time. High field strengths of tens of kV cm^{-1} were achieved by improving the efficiency of optical rectification in LiNbO_3 through the tilted-pulse-front method and by ensuring a tight focusing of the THz beam. In the case of low field strengths, the behavior of the thin films agrees with previous examinations of $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$ by means of conventional, low-power THz-TDS. However, for strong THz electric fields, it was found by analysis with the two-fluid model that the superfluid population decreases dramatically, possibly due to Cooper pair breakup. This was accompanied by a drop in the imaginary part of the conductivity in the investigated frequency range of 0.2 to 0.8 THz. The results further suggest a decrease of the effective mass of the carriers for strong THz fields.

10:24AM V21.00013 Carrier mobility of insulating cuprates from time-resolved terahertz photoconductivity measurements, J. STEVEN DODGE, Dept. of Physics, Simon Fraser University, JESSE C. PETERSEN, Dept. of Physics, Oxford University, AMIR D. FARAHANI, Dept. of Physics, Simon Fraser University, RUIXING LIANG, Dept. of Physics and Astronomy, University of British Columbia, IVAN BOZOVIC, Brookhaven National Laboratory — We study the ultrafast transient photoconductivity of three insulating cuprates, $\text{Sr}_2\text{CuO}_2\text{Cl}_2$, $\text{YBa}_2\text{Cu}_3\text{O}_6$, and La_2CuO_4 . Terahertz spectroscopy reveals mobile dilute carriers, with a conductivity that appears promptly and decays non-exponentially in picoseconds. The peak photoconductivity is orders of magnitude larger than the static photoconductivity but smaller than that of chemically doped samples, with fast dynamics that depends weakly on material, concentration, and temperature. Decay dynamics indicate hopping transport with a low activation energy, suggesting weak to intermediate polaronic binding.

10:36AM V21.00014 Study of the radiation line width and shape from the Bi212 mesa structure¹, TAKANARI KASHIWAGI, TAKASHI YAMAMOTO, KAZUYA ISHIDA, MANABU TSUJIMOTO, KAVEH DELFANAZARI, RYO NAKAYAMA, TAKEO KITAMURA, MASASHI SAWAMURA, HIDEHIRO ASAI, HIDETOSHI MINAMI, KAZUO KADOWAKI, University of Tsukuba — Continuous electromagnetic waves in terahertz (THz) range have been observed from mesa structures of $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ (Bi212) single crystals¹. It has been established that the radiation frequency is determined by both the ac Josephson frequency and the resonance condition of the geometrical cavity². In order to understand the mechanism of the radiation from the intrinsic Josephson junctions (IJJs) in Bi212 , we studied the radiation line width and shape. These might depend upon the physical parameters of the Bi212 single crystal such as the number of IJJs the fluctuations of the quasiparticles and pairs, the non-linearity and non-equilibrium conditions, and the stability of the electrical circuit including the IJJs. However, technical difficulties have been delayed the line width measurements in the THz range. Recently, we succeeded in measuring the radiation line width using a frequency mixer. These results will be compared to those from a single junction 1) L. Ozyuzer *et al.*, Science **318** (2007) 1291., 2) K. Kadowaki *et al.*, J. Phys. Soc. Jpn. **79** (2010) 023703

10:48AM V21.00015 High resolution copper M-Edge resonant inelastic X-ray scattering at MERLIN, LEWIS WRAY, YI-DE CHUANG, Lawrence Berkeley National Laboratory — The Advanced Light Source MERLIN RIXS spectrometer (beamline 4.0.3) is a new user endstation for resonant inelastic X-ray scattering at the Advanced Light Source. I will discuss new scientific explorations that are expected to be possible with the system, including preliminary data obtained during the commissioning period on cuprate samples. Because very few previous studies have been performed at the M-Edge, the presentation will review how M-Edge scattering data at MERLIN resemble and differ from the more broadly studied transition metal K- and L-edges, including critical parameters of the excitation process such as fitted intermediate state lifetimes, X-ray penetration depth, spin-orbit coupling and scattering intensity for different types of excitation mode.

Thursday, March 1, 2012 8:00AM - 11:00AM –
Session V22 DMP DCOMP: Focus Session: Fe-based Superconductors - Magnetism and Anisotropy 254B

8:00AM V22.00001 In Plane Resistivity Anisotropy in iron Chalcogenides¹, JIUN-HAW CHU, CHRIS KUCHARCZYK, IAN FISHER, Stanford University — FeTe suffers a bicollinear antiferromagnetic ordering, with a $(\frac{1}{2} \ 0)$ ordering wave-vector, in contrast to the $(\frac{1}{2} \ \frac{1}{2})$ ordering wave-vector found in underdoped “122” and “1111” iron pnictides. At the optimal doping the static $(\frac{1}{2} \ 0)$ order disappears and a spin resonance at the $(\frac{1}{2} \ \frac{1}{2})$ wave-vector emerges. Here we report measurements of the in-plane resistivity anisotropy of single crystals of $\text{Fe}_{1+\delta}\text{Te}_{1-x}\text{Se}_x$ for underdoped and optimally doped compositions. The underdoped compounds were partially detwinned by applying uni-axial strain along the $(\frac{1}{2} \ 0)$, revealing a larger resistivity along the antiferromagnetic ordering direction. However, for optimal doping uni-axial strain induces the largest resistivity anisotropy along the $(\frac{1}{2} \ \frac{1}{2})$ direction, similar to the “122” family of compounds. This behaviour suggests that in addition to the presence of spin resonance, a divergent nematic susceptibility might be a key feature associated with optimal doping in iron based superconductors.

8:12AM V22.00002 The temperature dependence of the conductance anisotropy of the pnictides studied via Monte Carlo simulation of the Spin-Fermion model, SHUHUA LIANG, CENGIZ SEN, ADRIANA MOREO, ELBIO DAGOTTO, Department of Physics, University of Tennessee and Materials Science and Technology Division, ORNL, GONZALO ALVAREZ, Computer Science and Mathematics Division and Center for Nanophase Materials Sciences, ORNL — The undoped three-orbital (xz , yz , xy) spin-fermion model for the pnictides is studied via Monte Carlo (MC) simulations [1], using both the standard exact diagonalization of the fermionic sector (supplemented by cooling down procedures) developed in the manganite context [2], as well as the truncated polynomial expansion techniques [3]. The magnetic order is found to be the expected $(\pi, 0)$ wavevector and the angle-resolved photoemission signal is in good agreement with experiments. The low-temperature conductance reveals the experimentally observed anisotropy between the ferromagnetic and the antiferromagnetic (AFM) directions, with the largest conductance for the AFM case, similarly as observed in recent investigations using the Hartree-Fock approximation to the Hubbard model [4]. The finite temperature MC analysis also produces results in good agreement with transport experiments. [1] S. Liang, G. Alvarez, C. Sen, A. Moreo, and E. Dagotto, submitted for publication. [2] C. Sen, S. Liang, and E. Dagotto, arXiv: 1109.1797 ; and references therein. [3] C. Sen, G. Alvarez, Y. Motome, N. Furukawa, I. A. Sergienko, T. Schulthess, A. Moreo, and E. Dagotto. Phys. Rev. B 73, 224430 (2006). [4] X. Zhang and E. Dagotto, Phys. Rev. B 84 132505 (2011).

8:24AM V22.00003 Anisotropy in BaFe₂Se₃ single crystals with double chains of FeSe tetrahedra, HECHANG LEI, HYEJIN RYU, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, ANATOLY FRENKEL, Physics Department, Yeshiva University, CEDOMIR PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory — Since two-dimensional (2D) FePn or FeCh (Pn = pnictogens, Ch = chalcogens) tetrahedron layers are the common structural ingredient in all iron based superconductors, they are probably related to high temperature superconductivity. In order to fully understand the nature of iron-based superconductivity, study of materials containing similar FePn or FeCh tetrahedron as building blocks is of significant interest. BaFe₂Se₃ contains one-dimensional (1D) double chains of edge shared Fe-Se tetrahedra along the b-axis, in contrast to iron chalcogenide superconductors which feature two-dimensional (2D) Fe-Se planes. We report the anisotropic physical properties and local crystal structure of Ba_{1.00(4)}Fe_{1.9(1)}Se_{3.1(1)} single crystals. It shows that BaFe₂Se₃ is a semiconductor with a short-range AFM correlation at the room temperature and a long-range AFM order below 255 K. Composition analysis indicates that all crystallographic sites are fully occupied. X-ray absorption near edge structure (XANES) result shows that the valence of Fe is about 1.87+.

8:36AM V22.00004 Towards an understanding of magnetic interactions and anisotropies in iron superconductors, ELENA BASCONES, Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC) — The itinerant or strong coupling origin of magnetism in iron pnictides is still unsettled. The localized description generally assumes AF exchange constants satisfying $2J_2 > J_1$, with J_1 and J_2 referring to first and second nearest neighbors respectively. The itinerant picture relies on the nesting of the Fermi surface. Both descriptions reproduce the columnar ordering found experimentally. The role played by the Hund's coupling J_H and the orbital degree of freedom are also highly debated. Orbital ordering has been invoked to explain the anisotropic resistivity and optical conductivity. We make connection between these two pictures by studying the same five-orbital model within Heisenberg and mean field descriptions [1]. We have found that J_2/J_1 strongly depends on the charge and orbital filling what results in an unexpected sensitivity of the AF ordering to crystal field parameters. J_1 and J_2 can become ferromagnetic at large J_H . Consistent results are obtained in the mean field description. We also analyze the resistivity and optical conductivity anisotropies and show that they are a consequence of magnetism and not of orbital ordering [2].

9:12AM V22.00005 Nematic order and its implications to the iron pnictides: pseudogap behavior, orbital order, and magneto-structural phase diagram, R.M. FERNANDES, Columbia University and Los Alamos National Lab, A.V. CHUBUKOV, University of Wisconsin-Madison, J. KNOLLE, Max-Planck-Institut für Physik komplexer Systeme, Dresden, I. EREMIN, Institut für Theoretische Physik III, Ruhr-Universität Bochum, J. SCHMALIAN, Institut für Theorie der Kondensierten Materie, Karlsruher Institut für Technologie — We present an electronic model for the emergence of nematic order in the iron pnictides. In particular, we show that the degeneracy of the magnetic ground state, allied to spin fluctuations, gives rise to a state that spontaneously breaks the tetragonal symmetry of the system, but preserves its spin-rotational symmetry. The nematic state displays several anisotropic properties, inducing a weak orbital polarization as well as a small orthorhombic distortion of the lattice. Nematic order also enhances the magnetic fluctuations and facilitates the magnetic phase transition, leading to a joint magnetic and meta-nematic transition, as well as to a pseudogap behavior due to magnetic precursors. Finally, we discuss the characters of the magnetic and structural phase transitions, showing that electron doping tends to split both transitions, whereas pressure and lattice softness tend to make them simultaneous. Our model provides a simple framework to understand the interplay between the different degrees of freedom present in the iron pnictides, shedding light on the primary role played by magnetism in these materials.

9:24AM V22.00006 Impurity-Induced Electronic Nematic State in Iron-Pnictide Superconductors¹, YUICHI YAMAKAWA, YOSHIO INOUE, HIROSHI KONTANI, Nagoya University — We propose that impurity-induced electronic nematic state is realized above the orthorhombic structure transition temperature T_S in iron-pnictide superconductors [1]. In the presence of strong orbital fluctuations near T_S , it is theoretically revealed that a single impurity induces non-local orbital order with C_2 -symmetry, consistently with recent STM/STS measurements. Each impurity-induced C_2 orbital order aligns along a-axis by applying tiny uniaxial pressure along b-axis. In this impurity-induced nematic phase, the resistivity shows sizable in-plane anisotropy ($\rho_b/\rho_a \sim 2$) even above T_S , actually observed in various “detwinned” samples. The present study indicates the existence of strong orbital fluctuations in iron-pnictide superconductors. [1] Y. Inoue, Y. Yamakawa and H. Kontani, arXiv:1110.2401.

9:36AM V22.00007 Effect of uniaxial strain on the structural and magnetic phase transitions in BaFe₂As₂, CHETAN DHITAL, Boston College, Z. YAMANI, Canadian Neutron Beam center, Canada, WEI TIAN, Oak ridge National Laboratory, Oakridge, TN, J. ZERETSKY, Ames Laboratory, A.S. SEFAT, Oak ridge National Laboratory, Oakridge, TN, ZIQIANG WANG, Boston College, R.J. BIRGENEAU, University of California, Berkeley, STEPHEN WILSON, Boston College — We report neutron scattering experiments probing the influence of uniaxial strain on both the magnetic and structural order parameters in the parent bilayer iron pnictide compound BaFe₂As₂. Under the application of modest strain fields along the in-plane orthorhombic b-axis, we observe an upward shift in the onset of both the structural and magnetic phase transition temperatures. Our data show that modest strain fields can affect significant changes in phase behavior simultaneous to the removal of structural twinning effects. As a result, we demonstrate in BaFe₂As₂ samples detwinned via uniaxial strain that the in-plane C_4 symmetry is broken by both the structural lattice distortion and long-range spin ordering at temperatures far above the nominal, strain-free, phase transition temperatures. The relevance of our measurements to earlier transport measurements in detwinned crystals of BaFe₂As₂ is discussed.

9:48AM V22.00008 Anisotropic transport properties of the paramagnetic state of iron-based superconductors, JOERG SCHMALIAN, Institut für Theorie der Kondensierten Materie, Karlsruher Institut für Technologie, ELIHU ABRAHAMS, University of California Los Angeles, RAFAEL FERNANDES, Columbia University and Los Alamos National Lab — Recent experiments in detwinned iron-pnictide samples have revealed strong anisotropies in the in-plane transport properties of the paramagnetic state. Since these anisotropies cannot be attributed solely to the small orthorhombic distortion of the lattice, it has been proposed that an underlying anisotropic electronic order is at play. One of the candidates is the Ising-nematic order that emerges due to the degeneracy of the magnetic ground state. Here we present a microscopic model for the transport properties of this nematic phase, considering both the elastic scattering by impurities as well as the inelastic scattering by anisotropic spin fluctuations. We show that the interference between these two scattering channels give rise to anisotropic non-Fermi liquid transport properties. In particular, we explain the observed sign of the resistivity anisotropy in electron-doped samples and predict a sign-change for sufficiently hole-doped samples. We also address the suppression of the resistivity anisotropy with sample annealing, as well as its dependence on alkaline-earth substitution. Finally, we discuss the predictions of our model to the thermopower anisotropy.

10:00AM V22.00009 Anisotropic magnetoelastic coupling in iron arsenide superconductors: an x-ray diffraction study in high magnetic field, J.P.C. RUFF, R.K. DAS, Z. ISLAM, Advanced Photon Source, Argonne National Laboratory, J.-H. CHU, H.-H. KUO, I.R. FISHER, Stanford University, H. NOJIRI, Tohoku University — We report high-resolution single crystal x-ray diffraction measurements of underdoped $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$ in pulsed magnetic fields as high as 28 Tesla. Our direct measurements confirm earlier reports of strong and highly anisotropic magnetoelastic coupling in iron arsenides. We observe magnetic field induced de-twinning of orthorhombic samples, and characterize the magnitude of the effect as a function of temperature and field. We identify a range of field and temperature where samples can be 100% de-twinned by magnetic fields less than 30 Tesla. The effect shows a notable insensitivity to SDW ordering, but varies rapidly in the vicinity of the superconducting transition.

10:12AM V22.00010 In-plane structural and electronic anisotropy in de-twinned $(\text{Ba}_{1-x}\text{K}_x)\text{Fe}_2\text{As}_2$, ERICK BLOMBERG, M.A. TANATAR, W.E. STRASZHEIM, The Ames Laboratory, Ames, IA, USA., B. SHEN, H.H. WEN, Nanjin University, Nanjin, China., R. PROZOROV, The Ames Laboratory, Ames, IA, USA. — The iron-pnictides undergo a tetragonal to orthorhombic structural transition below a doping - dependent temperature T_s . In the absence of external stress or strain, the orthorhombic phase is divided into four degenerate, equally populated, “twin” structural domains, obscuring direct measurement of in-plane anisotropy. This degeneracy may be broken through mild mechanical stress or strain leaving the sample de-twinned. The properties of detwinned $(\text{Ba}_{1-x}\text{K}_x)\text{Fe}_2\text{As}_2$ with $x=0.1, 0.18$ (hole under-doped) were discussed previously [1]. Here we report polarized-light microscopy and AC transport measurements of strain-detwinned $(\text{Ba}_{1-x}\text{K}_x)\text{Fe}_2\text{As}_2$ with a doping range from $x=0.15$ to $x=0.35$. Our results provide new insight into a region of coexisting magnetic and superconducting order parameters.

[1] J. J. Ying, et al. Phys. Rev. Lett. **107** 067001 (2011).

10:24AM V22.00011 Nematic phase persisting above the superconducting dome of $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$, S. KASAHARA, H.J. SHI, K. HASHIMOTO, T. SHIBAUCHI, T. TERASHIMA, Y. MATSUDA, Kyoto University, T. FUKUDA, JAEA Spring-8, K. SUGIMOTO, JASRI Spring-8, A.H. NEVIDOMSKYY, Rice University — Strongly interacting electrons can exhibit novel collective phases, among which the electronic nematic phases are perhaps the most surprising as they spontaneously break rotational symmetry of the underlying crystal lattice. Here, we provide the first thermodynamic evidence in pure crystals of $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$ that the nematicity develops well above the structural transition and persists to the nonmagnetic superconducting regime, resulting in a new phase diagram strikingly similar to the pseudogap phase diagram in the cuprates. Our highly sensitive magnetic anisotropy measurements using microcantilever torque-magnetometry under in-plane field rotation reveal pronounced two-fold oscillations, which break the tetragonal symmetry. Combined with complementary high-resolution synchrotron X-ray and resistivity measurements, our results consistently identify two distinct temperatures—one at T^* , signifying a true nematic transition, and the other at $T_s (< T^*)$, which we show to be not a true phase transition, but rather what we refer to as a “meta-nematic transition”, in analogy to the well-known metamagnetic transition in the theory of magnetism.

10:36AM V22.00012 Unusual giant negative thermal expansion in La-doped CaFe_2As_2 superconducting single crystal¹, ALWYN REBELLO, JOHN J. NEUMEIER, Montana State University, ZHAOSHUN GAO, YANPENG QI, YANWEI MA, Chinese Academy of Sciences — Large negative thermal expansion (NTE), wherein a material substantially shrinks on heating, is a phenomenon that occurs only in very rare materials.^{2,3} Here we present results on anisotropic and unusually large NTE in single crystalline $\text{Ca}_{0.8}\text{La}_{0.2}\text{Fe}_2\text{As}_2$ (CLFA), a recently discovered high temperature superconducting material. The volume thermal expansion coefficient in CLFA remains negative over the entire measured temperature range and reaches a maximum of $\Omega = -90 \times 10^{-6} \text{ K}^{-1}$ near 65 K, which is remarkably large compared to the thermal expansion (TE) of most other materials. Furthermore, we do not observe signatures of any structural transition in the linear TE in the a , b and c axes. Our results on TE and heat capacity behavior in the vicinity of superconducting transition temperature ($T_C = 42.7 \text{ K}$) indicate non-bulk superconductivity in the sample. The observed large NTE in our sample is attributed to anomalous transverse modes which may vibrate in a quartic potential as in ScF_3 .⁴

10:48AM V22.00013 Lower critical field, anisotropy, and two-gap features of LiFeAs , KALYAN SASMAL, Department of Physics and TCSUH, University of Houston, Houston, Texas 77204-5002, USA, B. LV, Z. TANG, Department of Chemistry and TCSUH, University of Houston, Houston, Texas 77204-5003, USA, F. WEI, Y. XUE, Department of Physics and TCSUH, University of Houston, Houston, Texas 77204-5002, USA, A. GULOY, Department of Chemistry and TCSUH, University of Houston, Houston, Texas 77204-5003, USA, CHING-WU CHU, Department of Physics and TCSUH, University of Houston, Houston, Texas 77204-5002; Lawrence Berkeley National Laboratory, 1 Cyclotron Road, USA — The magnetic properties of LiFeAs , as single crystalline and polycrystalline samples, were investigated. The lower critical field deduced from the vortex penetration of two single crystals appears to be almost isotropic with a temperature dependence closer to that of two-gap superconductors. The parameters extracted from the reversible magnetizations of sintered polycrystalline samples are in good agreement with those from the single-crystal data.

8:00AM V23.00001 Thermal Conductivity Data Near T_c as a Probe of Unconventional Superconductivity, BRIAN SALES, Oak Ridge National Laboratory — In classical phonon-mediated superconductors, the thermal conductivity, κ , just below T_c decreases since electrons in the superfluid state carry no heat. A decrease in κ occurs just below T_c even for BCS superconductors with relatively high transition temperatures such as Nb_3Sn and MgB_2 . By contrast, in all of the unconventional superconductors, of which the author is aware, the thermal conductivity always increases just below T_c . It is hypothesized in these unconventional superconductors that magnetic or some other type of fluctuation that scatters phonons above T_c are frozen out below T_c , resulting in a larger κ . This suggests that a relatively simple thermal conductivity measurement may be a way of identifying superconductors with an unusual pairing mechanism. Although this phenomenology does not help identify new superconductors, it may help determine which materials have the potential for a much higher T_c . Several related examples of the effects of magnetic fluctuations or excitations on thermal transport also will be presented. This research was supported by the Materials Sciences and Engineering Division, Office of Science, U. S. Department of Energy.

8:12AM V23.00002 Critical currents in thin-film superconductors via two-coil mutual inductance measurements, JOHN DRASKOVIC, JIE YONG, MICHAEL HINTON, ADAM AHMED, Department of Physics, The Ohio State University, SONG WANG, Department of Physics, Stanford University, STANLEY STEERS, THOMAS LEMBERGER, Department of Physics, The Ohio State University — Following Claassen et al. (RSI 1991), we determine the critical current density, $J_c(T)$, in a superconducting thin film by measuring the inductive coupling between two coils located on opposite sides of the film as a function of temperature. For several values of the AC drive magnetic field, we record the temperature at which inductive coupling between the coils jumps dramatically. The peak current density in the film at such temperature is computed by numerical simulation. For thin niobium films, we obtain $J_c(0)$ values greater than 10 percent of the Ginzburg-Landau (GL) prediction with the correct temperature dependence. This suggests the possibility of practical measurement of the GL coherence length in thin films without need for the strong magnetic fields used to measure B_{c2} . Application of this technique to cuprates and pnictides will be discussed.

8:24AM V23.00003 Anomalous dependence of interface superconductivity on carrier density in metal-insulator bilayer, JIE WU, Brookhaven National Laboratory & National High Magnetic Field Laboratory, OSHRI PELLEG, GENNADY LOGVENOV, ANTHONY BOLLINGER, Brookhaven National Laboratory, GREG BOEBINGER, National High Magnetic Field Laboratory, IVAN BOZOVIC, Brookhaven National Laboratory — The interface superconductivity is of particular interest for its higher superconducting temperature (T_c) and close connection to the HTS study. However, despite of the experimental and theoretical progress, the answer to the following key question still remains ambiguous: can the underlying mechanism of the interface superconductivity be interpreted solely in terms of charge transfer and Sr interdiffusion? One experimental approach to answer this question is to study the dependence of T_c on the carrier density of $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4/\text{La}_2\text{CuO}_4$ (LSCO/LCO) bilayer by changing the doping level in the metallic LSCO layer. The charge transfer and cation interdiffusion at the interface is proportional to the carrier density in LSCO layer; therefore, T_c of the interface is expected to show a significant and non-monotonic dependence on the carrier density. To exam this prediction, we synthesized a series of $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4/\text{La}_2\text{CuO}_4$ bilayers with x ranging in 0.27 to 0.47 by atomic layer-by-layer molecular beam epitaxy (ALL-MBE). The uniqueness of these samples is a 4% Sr doping gradient of the central doping level across the 10mm width of the substrate. These combinatorial samples realize an extremely fine tuning of doping and enable us to construct a phase diagram that is 30 times denser than a normal method can achieve.

8:36AM V23.00004 Magnetotransport of $\text{La}_{(2-x)}\text{Sr}_x\text{CuO}_4$ with Nearly Continuous Doping, ZACHARY STEGEN, JIE WU, JONATHON KEMPER, GREG BOEBINGER, Florida State University, SCOTT RIGGS, Stanford University, FEDOR BALAKIREV, ALBERT MIGLIORI, Los Alamos National Laboratory, IVAN BOZOVIC, Brookhaven National Laboratory — Hall resistivity and longitudinal magnetoresistance were measured in fields up to 35 T. The samples were grown using Combinatorial Molecular Beam Epitaxy (COMBE) where the strontium doping changes continuously across the sample. Thirty simultaneous transport measurements were taken on a sample from a single growth, which allows for unprecedented resolution in doping ($\Delta p \approx 0.0002$). A series of these measurements were performed with the goal of examining the phase diagram of the hole-doped cuprates, particularly an increase in the Hall number around optimum doping.

8:48AM V23.00005 Decoupling of superconducting planes of $\text{La}_{1.905}\text{Ba}_{0.095}\text{CuO}_4$ in a transverse magnetic field¹, JOHN TRANQUADA, Brookhaven National Lab, Z. STEGEN, G.S. BOEBINGER, National High Magnetic Field Lab, SU JUNG HAN, JIE WU, ZHIJUN XU, GENDA GU, QIANG LI, Brookhaven National Lab — We have measured the resistivity parallel and perpendicular to the CuO_2 planes in single crystals of $\text{La}_{1.905}\text{Ba}_{0.095}\text{CuO}_4$ for magnetic fields up to 35 T applied along the c -axis. Below the zero-field superconducting transition temperature of 32 K, we observe that, above a threshold field, the c -axis resistivity grows with field, eventually reaching a maximum and then decreasing. At the resistivity maximum, interlayer pair tunneling becomes insignificant. Under the same field and temperature conditions, the in-plane resistivity remains quite low, reflecting robust superconductivity. We identify a regime in which the superconducting planes are effectively decoupled. At 20 K, a field much greater than 35 T would be required to destroy the in-plane pairing, despite the fact that the field also induces both charge and spin stripe order (J.S. Wen *et al.*, arXiv:1009.0031).

¹Work at BNL supported by Office of Basic Energy Sciences, US DOE, under Contract No. DE-AC02-98CH10886. NHMFL is supported by NSF under Cooperative Agreement No. DMR-084173.

9:00AM V23.00006 Spatial Inhomogeneity in Oxygen Modulated Potassium Tungsten Oxide Thin Films: implications for superconductivity and metal-insulator transitions¹, KO MUNAKATA, KATHERINE LUNA, Geballe Laboratory for Advanced Materials, Stanford University, AKIO TSUKADA, Department of Applied Physics, Tokyo University of Science, SUBHASH RISBUD, THEODORE GEBALLE, MALCOLM BEASLEY, Geballe Laboratory for Advanced Materials, Stanford University — High quality potassium tungsten oxide ($\text{K}_{0.33}\text{WO}_y$) films were synthesized by pulsed laser deposition followed by annealing in vacuum. Oxygen concentration modulated anomalous correlation of metal-insulator and superconductivity transitions were studied; a similar scenario was recently suggested in the literature [1] for polycrystalline rubidium tungsten oxide samples. Detailed studies of the transport properties below and above the superconducting transition temperature exhibit a diversity of unexpected behavior. Some of our results can be interpreted as a signature of reduced dimensionality in the ab -plane in oxygen-rich insulating samples, implying a formation of spatially inhomogeneous electronic structure. We compare such phenomenology to the behavior of other materials with strong electron-phonon interactions, and discuss its implication for the possible high temperature superconducting anomaly in sodium tungsten oxides reported in the literature [2]. [1] D. C. Ling et. al., J. Phys. Conf. Ser. 150, 052141 (2009). [2] S. Reich, and Y. Tsabba, Eur. Phys. J. B 9, 1 (1999).

9:12AM V23.00007 Thermal Hall effect in YBCO: Probing Fermi-surface reconstruction inside the superconducting state, OLIVIER CYR-CHOINIÈRE, FRANCIS LALIBERTÉ, SOPHIE DUFOUR-BEAUSÉJOUR, GAËL GRIS-SONNANCHE, RYAN T. GORDON, NICOLAS DOIRON-LEYRAUD, LOUIS TAILLEFER, Université de Sherbrooke, Canada, BRAD J. RAMSHAW, RUIXING LIANG, DOUG A. BONN, WALTER N. HARDY, University of British Columbia, Canada, CYRIL PROUST, LNCMI, France — The thermal Hall (Righi-Leduc) effect was measured in the cuprate superconductor YBCO at a doping $p = 0.11$, as a function of magnetic field H up to 29 T. At temperatures well below the zero-field superconducting T_c , the thermal Hall conductivity κ_{xy} is positive at low field and then turns over to become negative at fields above 15 T. The negative κ_{xy} is consistent with the negative Hall and Seebeck coefficients observed in the normal state above 25 T [1,2]. This further supports our interpretation: the Fermi surface of YBCO contains a small electron-like pocket [3] in that region of the phase diagram, the result of a Fermi-surface reconstruction attributed to stripe order [4]. In the $T = 0$ limit at $H = 29$ T, we find reasonable agreement with the Wiedemann-Franz law, $\kappa_{xy}/T = L_0\sigma_{xy}$. The fact that κ_{xy} changes sign at $H \approx 15$ T is consistent with a scenario of phase competition whereby stripe order emerges only at finite field, in agreement with recent NMR studies that detect the onset of charge-stripe order above 15 T [5].

9:24AM V23.00008 On the magnetic tricritical point in $\text{BaFe}_{2(1-x)}\text{Co}_{2x}\text{As}_2$, COSTEL ROTUNDU, Materials Science Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA, ROBERT BIRGENEAU, Department of Physics, Department of Materials Science and Engineering, University of California, Berkeley, CA 94720, USA — We present here high resolution magnetization measurements on high-quality $\text{BaFe}_{2(1-x)}\text{Co}_{2x}\text{As}_2$, $0 \leq x \leq 0.046$ as-grown single crystals. The results confirm the existence of a magnetic tricritical point in the (x, T) plane at $x_{tr}^m \approx 0.022$ [1,2]. We show that the extrapolated T_c onset doping could be close to the magnetic tricritical point x_{tr}^m . It has been speculated that the magnetic critical point is relevant to the superconductivity in this series [3]. Finally, we comment on the universality of the tricritical point in the superconducting 122s.

9:36AM V23.00009 $\text{Rb}_x\text{Fe}_2\text{Se}_2$: A study of superconductivity under high pressure, MELISSA GOOCH, BING LV, LIANGZI DENG, Dept. of Physics at the University of Houston and TcSUH, TAKAKI MURAMATSU, Geophysical Laboratory, Carnegie Institution of Washington, JIM MEEN, Dept. of Chemistry at the University of Houston and TcSUH, YUYI XUE, BERND LORENZ, Dept. of Physics at the University of Houston and TcSUH, CHING-WU CHU, Dept. of Physics at the University of Houston and TcSUH; Lawrence Berkeley National Laboratory — Superconductivity was reported in $\text{Rb}_x\text{Fe}_2\text{Se}_2$ in early 2011, after the discovery of similar Fe-based chalcogenides, $\text{K}_x\text{Fe}_2\text{Se}_2$ and $\text{Cs}_x\text{Fe}_2\text{Se}_2$ in December 2010. These Fe-based chalcogenides have similar structures to the iron pnictides, with a superconducting transition of approximately 30 K. Here we report the results of the physical characterization and the subsequent high-pressure study on two samples with slightly different compositions of $\text{Rb}_x\text{Fe}_2\text{Se}_2$. From resistivity measurements, $\text{Rb}_{0.93(2)}\text{Fe}_{1.70(2)}\text{Se}_2$ (sample A) was found to be superconducting and $\text{Rb}_{0.90(1)}\text{Fe}_{1.78(1)}\text{Se}_2$ (sample B) was found to be semiconducting. Further sample characterization was conducted through magnetic and thermoelectric power measurements, which support the initial resistivity findings. High pressure resistivity measurements were conducted with a BeCu clamp cell up to approximately 1.8 GPa. Initially, the T_c of sample A increases slightly until p reaches ~ 1 GPa. However, at further increasing pressure, T_c starts to decrease and superconductivity is completely suppressed at about 6 GPa. Sample B was not found to be superconducting up to 1.8 GPa.

9:48AM V23.00010 Unusual superconducting state in Pr-doped CaFe_2As_2 , LIANGZI DENG, BING LV, MELISSA GOOCH, FENGYAN WEI, YANYI SUN, Dept. of Physics at the University of Houston and TcSUH, JAMES MEEN, Dept. of Chemistry at the University of Houston and TcSUH, YUYI XUE, BERND LORENZ, Dept. of Physics at the University of Houston and TcSUH, CHING-WU CHU, Dept. of Physics at the University of Houston and TcSUH, Lawrence Berkeley National Laboratory — We report the detection of unusual superconductivity up to 49 K in Pr-doped single crystalline CaFe_2As_2 as evidenced from the resistive, magnetic and thermoelectric measurements. This superconducting transition observed suggests the possible existence of two phases: a field as low as 500 Oe can totally suppress the observed diamagnetic susceptibility above 21K. The 49 K part has a low critical field < 4 Oe, and the other at 21K, with a high upper critical field > 5 T. Our observations are in strong contrast to previous reports of doping or pressurizing layered compounds AeFe_2As_2 (Ae122), where Ae = Ca, Sr, or Ba. In Ae 122, hole-doping has been previously observed to generate superconductivity with a transition temperature (T_c) only up to 38 K and pressurization has been reported to produce superconductivity with a T_c up to 30 K. The experiment results of resistivity and inductance measurements of Pr-doped Ca122 under pressure up to 2.0 GPa will also be discussed.

10:00AM V23.00011 Fermi-liquid behavior of quasiparticle scattering in the normal state of $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$, YING JIA, LEI FANG, ULRICH WELP, ALEXEI KOSHELEV, GEORGE CRABTREE, WAI-KWONG KWOK, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439, USA — We present studies of the galvanomagnetic effects of compensated $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$ ($x=0.32\sim 0.6$) superconductors. The magnetoresistance follows the relaxed Kohler's scaling for all doping levels. Using a two-band model, we quantitatively extracted the scattering parameter m^*/τ and the carrier density of the electron and hole bands. The temperature dependence of the carrier concentration reveals the semimetal properties of $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$. The Fermi-liquid behavior, $m^*/\tau \sim T^2$, is observed from optimally doped $x=0.32$ to over-doped $x=0.6$ crystals, suggesting that the proximity of the SDW state does not play an important role in transport. Our analysis suggests that the normal state transport properties of $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$ can be well understood in the framework of a compensated two-band Fermi-liquid semimetal.

¹Crystal synthesis was supported by the Energy Frontier Research Center funded by the US DOE-BES (YJ, LF, WKK, GWC), materials characterization and theoretical support were provided by the DOE-BES (UW, AEK), under Contract No. DE-AC02-06CH11357.

10:12AM V23.00012 Pressure effect on the electronic transport properties of $\text{Fe}_{1+y}\text{Te}_{1-x}\text{Se}_x$, STEVAN ARSENIJEVIĆ, RICHARD GAÁL, HENRIK RØNNOW, Institute of Condensed Matter Physics, Swiss Federal Institute of Technology, EPFL, CH-1015 Lausanne, Switzerland, ROMAIN VIENNOIS, ENRICO GIANNINI, DIRK VAN DER MAREL, DPMC, University of Geneva, 24 Quai E.-Ansermet, 1211 Geneva, Switzerland, LÁSZLÓ FORRÓ, Institute of Condensed Matter Physics, Swiss Federal Institute of Technology, EPFL, CH-1015 Lausanne, Switzerland — We present a systematic study of electronic transport as function of pressure up to 25 kbar of $\text{Fe}_{1+y}\text{Te}_{1-x}\text{Se}_x$ single crystalline samples (with $y = 0.02, 0.05$, and $x = 0, 0.2$, and 0.3). Pressure is demonstrated to be a clean control parameter to drive the system with high Fe-excess through the metal-insulator (MIT) transition, in analogy with increasing the Se-doping or reducing the Fe-excess. The scaling of resistivity $\rho(T, p)$ below 50 K identified a critical pressure of $p_c = 8$ kbar which separates non-metallic and metallic temperature dependences. At the p_c the low-temperature sheet resistance is in the 6.5 k Ω /square range. The Seebeck coefficient (S) at p_c changes sign from negative to positive indicating a change in the electronic structure and in the balance between the electron and hole carriers. The S at the highest pressure exhibits low positive values similar to the metallic, superconducting cuprates. The critical MIT behavior, related to a quantum phase transition, indicates a universality of the Fe- and Cu-based high- T_c superconductors.

10:24AM V23.00013 DC transport properties of Fe(Se,Te) crystals: Effects of Se substitution into Te site, SEIKI KOMIYA, MASAFUMI HANAWA, ICHIRO TSUKADA, Central Research Institute of Electric Power Industry, JST-TRIP, ATSUTAKA MAEDA, University of Tokyo, JST-TRIP — FeTe is an antiferromagnetic semimetal and superconductivity shows up when Te is substituted with Se, but effects of Se substitution are still unclear. To elucidate this issue, we study the behavior of Hall resistance in detail using single crystalline $\text{FeSe}_x\text{Te}_{1-x}$ with $x = 0$ to 0.4. Single crystals are grown by Bridgman method, and Hall resistance is analyzed within the standard 2-carrier model. We find that the electron density n_e is larger than the hole density n_h for $x \leq 0.3$ samples, but n_h becomes greater than n_e for $x = 0.4$ crystal. We also find that electron mobility enhances especially at low temperatures with Se substitution.

10:36AM V23.00014 Ferroelectricity and magnetoelectric coupling in underdoped $\text{La}_2\text{CuO}_{4+x}$, Z. VISKADOURAKIS, I. RADULOV, IESL-FORTH, A.P. PETROVIC, Division of Physics and Applied Physics, Nanyang Technological University, Singapore, S. MUKHERJEE, B. ANDERSEN, Niels Bohr Institute, University of Copenhagen, Denmark, G. JELBERT, Cavendish Laboratory, University of Cambridge, U.K., N.S. HEADINGS, S.M. HAYDEN, H. H. Wills Physics Laboratory, University of Bristol, U.K., K. KIEFER, S. LANDSGESELL, Helmholtz-Zentrum-Berlin für Materialien und Energie, Germany, D.N. ARGYRIOU, European Spallation Source ESS AB, Sweden, C. PANAGOPOULOS, IESL-FORTH and Department of Physics, University of Crete, Greece — La_2CuO_4 is an archetypal antiferromagnetic Mott insulator. Upon oxygen doping, a wide range groundstates may be accessed, including glassy magnetic phases and high- T_c superconductivity. However, determining the nature of the charge correlations coexistent with magnetic order has remained elusive, particularly in the highly underdoped limit. In this study, we show that the first holes added to La_2CuO_4 drive the formation of a ferroelectric phase below 4.5K, with slow charge fluctuations developing below 40K. We invoke the formation of polar nanoregions – which are a natural consequence of non-stoichiometric oxygen doping – to explain the emergent ferroelectricity. An anisotropic magnetoelectric coupling is observed and attributed to the Dzyaloshinskii-Moriya interaction. Although this interaction is not responsible for the electronic ordering (unlike in other multiferroic perovskites), the presence of weak magnetoelectricity allows us to confirm charge carrier doping as the cause of ferroelectricity in $\text{La}_2\text{CuO}_{4+x}$.

10:48AM V23.00015 Surface pinning effects in Ag doped superconducting polycrystalline $\text{Y}_1\text{Ba}_2\text{Cu}_3\text{O}_{7-x}$, ATILGAN ALTINKOK, MURAT OLUTAS, KIVILCIM KILIC, ATILLA KILIC, Abant Izzet Baysal University — The current-voltage measurements (I - V curves) with different current sweep rates (dI/dt) were carried out to investigate the effects of silver on the flux dynamics in Ag doped superconducting polycrystalline $\text{Y}_1\text{Ba}_2\text{Cu}_3\text{O}_{7-x}$ sample (YBCO/Ag). Standard and reverse procedures were used in the measurements of I - V curves. In the standard procedure, the dc driving current is cycled up and down; whereas, in the reverse procedure, the current is first cycled down and, then, cycled up. The reverse procedure enables us to investigate the flux motion evolving from the outer surface of the sample to its interior. Upon cycling transport current, the I - V curves of the YBCO/Ag sample exhibit hysteresis effects for both procedures and are sensitive to the variation of dI/dt . The experimental data reveal that the irreversibilities in the I - V curves of undoped YBCO are more prominent than those of YBCO/Ag. One of the main observations in the I - V curves of YBCO/Ag is the peculiar voltage jumps and drops. It was found that these instabilities depend strongly on the magnitude of external parameters dI/dt and H . The instabilities and short and long lived plateau regions observed in I - V curves were explained in terms of plastic flow of flux lines along easy motion channels which are considered mainly as metallic silver paths in the YBCO/Ag sample. In order to understand better the flux dynamics evolving in YBCO/Ag, the results of present measurements were compared to our previous studies on polycrystalline samples of undoped YBCO and MgB_2 .

Thursday, March 1, 2012 8:00AM - 11:00AM – Session V24 FIAP: Low-Dimensional Semiconductors 256

8:00AM V24.00001 $1/f$ Noise in Delta Doped GaAs/AlGaAs Heterostructures¹, YUN SUK EO, STEVEN WOLGAST, CAGLIYAN KURDAK, University of Michigan Department of Physics, L. N. PFEIFFER, K. W. WEST, Princeton University Department of Electrical Engineering — We studied $1/f$ noise of a two-dimensional electron gases (2DEG) in δ -doped $\text{GaAs}/\text{Al}_x\text{Ga}_{1-x}\text{As}$ heterostructures. Three samples that we measured were identical except for the δ -doping concentration: $9.1 \times 10^{18}(\text{cm}^{-2})$ (high), $1.3 \times 10^{18}(\text{cm}^{-2})$ (medium), $0.3 \times 10^{18}(\text{cm}^{-2})$ (low). These δ -doping layers are located in the $\text{Al}_x\text{Ga}_{1-x}\text{As}$ region, 800Å above the GaAs and $\text{Al}_x\text{Ga}_{1-x}\text{As}$ interface. We fabricated Corbino and Hall bar structures with different sizes. Carrier density was varied by the persistent photoconductivity effect at low temperature (4.2K). Initially, the samples did not exhibit measurable $1/f$ noise. The high δ -doping concentration samples exhibited parallel conduction. As we increased the carrier concentration in the high and medium-doped samples, $1/f$ noised increased initially, but disappeared as the photo current was saturated. The low-doped samples did not exhibit $1/f$ noise as the carrier concentration was increased. We conclude that $1/f$ noise is caused by the remote ionized impurities in the δ -doped region. Also, changing the DX-center configuration changes the density of the ionized impurities, which then changes the magnitude of $1/f$ noise.

¹University of Michigan was funded by the NSF (DMR-1006500). Princeton University was funded by the Gordon and Betty Moore Foundation and the NSF MRSEC Program (DMR-0819860)

8:12AM V24.00002 Conductance noise in a strongly disordered 2D electron system in Si MOSFETs¹, PING V. LIN, XIAOYAN SHI, JAN JAROSZYŃSKI, DRAGANA POPOVIĆ, National High Magnetic Field Lab., Florida State Univ. — Studies have shown that the metal-insulator transition (MIT) in a 2DES in Si MOSFETs is closely related to the glassy freezing of electrons as temperature $T \rightarrow 0$. However, no glassy relaxations were seen after a T quench. Here we first study the effect of cooling in detail: the carrier density n_s is changed at a high $T \approx 20$ K, the system is then cooled to a desired T with a fixed n_s , and fluctuations of conductance G with time are measured. The analysis of the noise power spectra $S_G \propto 1/f^\alpha$ gives evidence for the onset of slow, glassy dynamics near the MIT as $T \rightarrow 0$, supporting conclusions obtained with a different protocol. While these noise measurements were done in the Ohmic regime, we have also explored the effect of high excitation voltages, deep into the nonlinear regime, on the noise statistics. The results will be discussed in detail. Finally, we show that sweeping n_s at low enough T results in a reproducible fluctuation pattern of $G(n_s)$. Such a pattern, which reflects a particular realization of disorder, does not change even after warming up to 30 K. This demonstrates that the disorder does not change at low T , and that the observed non-Gaussianity of the noise reflects the intrinsic glassiness of the 2DES.

¹Supported by NSF DMR-0905843, NHMFL via NSF DMR-0654118

8:24AM V24.00003 Extended States and Critical Behavior in 2D and 3D Amorphous Conductors, DONALD PRIOUR, Kansas City, Kansas Community College (KCKCC) — With a tight binding treatment for one, two and three dimensional systems, we calculate and analyze electronic states in a conductor with topological disorder, or no correlations among the positions of the hopping sites. The Inverse Participation Ratio (IPR) is used to characterize carrier wave functions with respect to localization. We consider an exponentially decaying hopping integral with range (or “Bohr radius”) l . Using two complementary finite size scaling techniques to extrapolate to the bulk limit (both methods exploit critical behavior in different ways to locate the energy marking the boundary between extended and localized wave functions) which nevertheless yield identical results, we obtain phase diagrams showing regions where states are extended and domains of localized states. We find exclusively localized wave functions for 1D geometries, irrespective of l . In the 2D case, states are localized below a threshold length scale $l_c \approx 1.0$, with a finite fraction of states extended for $l > l_c$. For 3D systems, the extended phase is flanked by regions of localized states and bounded by two mobility edges. The swath of extended states, broad for $l \sim 1$, becomes narrower with decreasing l , scaling asymptotically as $e^{-A/l}$ for $l \ll 1$.

8:36AM V24.00004 The disappearance of weak localization in a strongly correlated 2D hole system¹, RICHARD L.J. QIU, XUAN P.A. GAO², Dept of Physics, Case Western Reserve University, LOREN N. PFEIFFER, KEN W. WEST, Dept of Electrical Engineering, Princeton University — The origin of Metal-Insulator Transition (MIT) in strongly correlated two-dimensional (2D) electrons or holes in semiconductors has long been of great interest. We will present the low temperature (down to 0.05K) transport properties of 10nm GaAs quantum wells with metallic hole densities near the critical point of the 2D MIT (critical density $p_c \approx 0.8 \times 10^{10} \text{cm}^{-2}$). We found that 2D holes exhibit a negative magneto-resistance in small perpendicular magnetic fields, which has been attributed to weak localization in the literature. On the other hand, the magnitude of this negative magneto-resistance is much smaller than conventional 2D weak localization. What is more surprising is that the weak localization induced negative magneto-resistance peak around $B=0$ becomes weaker at lower temperature, suggesting there is a mechanism causing quasiparticles to lose coherence as temperature decreases.

8:48AM V24.00005 Strong negative magnetoresistance in high-mobility 2D electron systems, MICHAEL ZUDOV, ANTHONY HATKE, School of Physics and Astronomy, University of Minnesota, Minneapolis, MN 55455, USA, JOHN RENO, Sandia National Laboratories, Albuquerque, NM 87185, USA, LOREN PFEIFFER, KEN WEST, Princeton University, Department of Electrical Engineering, Princeton, NJ 08544, USA — This talk reports on a remarkably strong negative magnetoresistance effect in high mobility GaAs/AlGaAs heterostructures and quantum wells. The effect is the strongest at about 1 kG where a deep and strongly temperature dependent minimum is observed. At low temperature, the resistivity at this minimum is a small fraction of the zero field resistivity. The talk will discuss the effects of temperature and in-plane magnetic field on this negative magnetoresistance and compare experimental findings with existing theories. A portion of this work was performed at the National High Magnetic Field Laboratory, which is supported by NSF Cooperative Agreement No. DMR-0654118, by the State of Florida, and by the DOE and at the Center for Integrated Nanotechnologies, a U.S. Department of Energy, Office of Basic Energy Sciences user facility. The work at Minnesota was supported by the NSF Grant No. DMR-0548014 and by the DOE Grant No. DE-SC002567. The work at Princeton was partially funded by the Gordon and Betty Moore Foundation and the NSF MRSEC Program through the Princeton Center for Complex Materials (DMR-0819860) and the work at Sandia was supported by the Sandia Corporation under Contract No. DE-AC04-94AL85000. Sandia National Laboratories is a multi-program laboratory managed.

9:00AM V24.00006 Nonlinear response of magnetoplasmon resonance, ANTHONY HATKE, MICHAEL ZUDOV, School of Physics and Astronomy, University of Minnesota, Minneapolis, MN 55455, USA, MICHAEL MANFRA, Department of Physics, West Lafayette, IN 47907 — Magnetoplasmon resonances have been observed in microwave photoresistance of Hall bar-shaped two-dimensional electron systems more than two decades ago. This talk will report on such a resonance in a very high mobility two-dimensional electron gas where it appears as a distinct photoresistivity peak superimposed on a microwave-induced zero-resistance state. In particular, we will discuss the response of this peak to dc electric field. A portion of this work was performed at the National High Magnetic Field Laboratory which is supported by NSF Cooperative Agreement No. DMR-0654118, by the State of Florida, and the DOE. The work at Minnesota was supported by DOE Grant No. DE-SC002567 and NSF Grant No. DMR-0548014. The work at Purdue was supported by DOE grant de-sc0006671.

9:12AM V24.00007 Interference effect in magneto-oscillations in two-dimensional system under bichromatic irradiation, QIANHUI SHI, University of Minnesota, MAXIM KHODAS, University of Iowa, MICHAEL ZUDOV, University of Minnesota — We report on the studies of magneto-oscillations caused by bichromatic irradiation in perpendicular magnetic field. Using quantum kinetic method, we have studied the case of ω , 2ω , and the case of ω , 3ω frequencies. In the latter case the interference part is shown to produce a phase-sensitive contribution. Also, the final answer depends on the polarizations of the two waves.

9:24AM V24.00008 Quantum lifetime of 2D electron in magnetic field¹, SCOTT DIETRICH, SERGEY VITKALOV, City College of New York, DMITRY DMITRIEV, ALEXEY BYKOV, Institute of Semiconductor Physics, 630090 Novosibirsk, Russia — The lifetime of two dimensional electrons in GaAs quantum wells, placed in weak quantizing magnetic fields, is measured using a simple transport method in broad range of temperatures from 0.3 K to 20 K. The temperature variations of the electron lifetime are found to be in good agreement with conventional theory of electron-electron scattering in 2D systems.

¹Supported by NSF (DMR 1104503) and RFBR, project no. 11-02-00925

9:36AM V24.00009 Hall viscosity in lattice models, RUDRO BISWAS, TAYLOR HUGHES, University of Illinois at Urbana-Champaign — We present results from our investigations of the Hall viscosity in lattice models. We use the insight gained from these calculations to comment on using the Hall viscosity to characterize gapped quantum fluids.

9:48AM V24.00010 Rank Saturation in finite size Entanglement Spectrum for Quantum Hall states, BENOIT ESTIENNE, BOGDAN A. BERNEVIG, Princeton University, RAOUL SANTACHIARA, LPTMS Orsay — We investigate analytically in finite size the entanglement spectrum arising from real-space cuts for fractional quantum Hall states. We provide a proof that the rank of the reduced density matrix is saturated for the Laughlin state even on finite sizes.

10:00AM V24.00011 Magnetic field spectra and many-body correlations of spin 3/2 holes confined to GaAs quantum well, GEORGE SIMION, YULI LYANDA-GELLER, Purdue University — We consider two dimensional spin 3/2 hole liquid in the presence of a perpendicular magnetic field. Single particle states of Luttinger Hamiltonian are calculated. For the semiclassical limit, the Hamiltonian is separated into the time-symmetric part treated exactly and time-antisymmetric part treated perturbatively. The angular momentum (spin) 3/2 states are characterized by the Landau level index and parity with respect to reflection about the growth direction. The single-particle spectrum exhibits level-crossings as magnetic field is varied, with or without Rashba and Dresselhaus interactions. The numerical calculations were performed for infinite barrier well, finite size barrier, well doped on one side, symmetrically doped well and parabolic well. Cyclotron mass was calculated and its dependence of the type of structure, magnetic field and symmetry of states is discussed and compared with experimental values. Landé effective factor is defined and evaluated. Shubnikov-de Haas oscillations are calculated. Electron-electron interactions are accounted using (time-dependent) mean field theories. An interesting effect is a single-well non-homogeneous spin-texture state. Possible implications of shape of hole spectra for fractional quantum Hall states are explored.

10:12AM V24.00012 Tunneling spectroscopy of 5/2 fractional quantum Hall excitations in etch defined quantum point contacts, MADHU THALAKULAM, WEI PAN, Sandia National Labs, K.W. BALDWIN, K.W. WEST, L. PFEIFFER, Princeton University — Ever since its discovery the fractional quantum Hall (FQH) state at the even denominator filling fraction $\nu=5/2$ has generated immense interests among researchers. 5/2 FQH excitations are believed to obey non-Abelian statistics and possess topological properties making them an ideal candidate for the proposed fault tolerant topological quantum computation. Theoretical proposals to characterize the topological properties of the 5/2 state are usually based on confined geometries. In this work we report the characterization of the 5/2 state using quasiparticle tunneling experiments in quantum point contacts (QPC). We have successfully fabricated QPCs on high mobility GaAs/AlGaAs heterostructures using conventional photolithography followed by etching and evaporation of Cr/Au depletion gates. Our samples show very stable FQH plateaus at $\nu = 7/3, 5/2$ and $8/3$ filling fractions. Tunneling experiments are performed in the QPCs at various temperatures and also at various pinch-off voltages to characterize the effective charge and Coulomb interaction parameters of the quasiparticles. (Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000).

10:24AM V24.00013 Quasiparticles and excitons for the Pfaffian quantum Hall state, ANTOINE STERDYNIAK, Ecole Normale Supérieure Paris, IVAN RODRIGUEZ, National University of Ireland, Maynooth, Ireland, MARIA HERMANN, Princeton University, JOOST SLINGERLAND, National University of Ireland, Maynooth, Ireland, NICOLAS REGNAULT, Ecole Normale Supérieure Paris, CNRS — We propose trial wave functions for quasiparticle and exciton excitations of the Moore-Read Pfaffian fractional quantum Hall states, both for bosons and for fermions, and study these numerically. Our construction of trial wave functions employs a picture of the bosonic Moore-Read state as a symmetrized double layer composite fermion state. We obtain the number of independent angular momentum multiplets of quasiparticle and exciton trial states for systems of up to 20 electrons. We find that the counting for quasielectrons at large angular momentum on the sphere matches that expected from the CFT which describes the Moore-Read state's boundary theory. In particular, the counting for quasielectrons is the same as for quasiholes, in accordance with the idea that the CFT describing both sides of the FQH plateau should be the same. We also show that our trial wave functions have good overlaps with exact wave functions obtained using various interactions, including second Landau level Coulomb interactions and the 3-body delta interaction for which the Pfaffian states and their quasiholes are exact ground states.

10:36AM V24.00014 Exact results for a fermion chain with fractionalized excitations, MASAAKI NAKAMURA, ZHENG-YUAN WANG, Tokyo Institute of Technology, EMIL BERGHOLTZ, Freie Universität Berlin — We present a number of exact results for a fermion chain with center of mass conservation at $1/3$ filling. The ground state of our model, which is three-fold degenerate even in the case of site dependent interactions, show striking similarities with the superconducting BCS wave functions, the AKLT spin chain, and in particular, with the Laughlin state describing the fractional quantum Hall effect. This state supports exact zero modes with fractional charge slightly below $1/3$ filling, and it has a matrix product representation which enables us to analytically calculate correlation functions, excitation gaps, and the entanglement spectrum. Reference: M. Nakamura, Z.-Y. Wang and E. J. Bergholtz, arXiv:1110.5033

10:48AM V24.00015 Polaronic effects in a single modulation doped GaAs quantum well, GERARD MARTINEZ, CLEMENT FAUGERAS, MILAN ORLITA, Laboratoire National des Champs Magnétiques Intenses, Grenoble, A. RIEDEL, R. REY, KLAUS FRIEDLAND, Paul Drude Institute, Berlin — Absolute magneto-optical transmission measurements have been performed in the far-infrared range under magnetic fields up to 32 T and at a temperature of 1.8 K on a single modulation doped GaAs quantum well (QW) with a width $d_w = 13$ nm. This QW is sandwiched between two GaAs/AlAs superlattices, the whole epilayer being lift-off from the GaAs substrate and deposited on a wedged Si substrate. The carrier concentration $N_s = 3.8 \cdot 10^{11} \text{ cm}^{-2}$ and has a mobility exceeding $10^6 \text{ cm}^2/\text{V}/\text{sec}$ at low temperatures. Due to the absence of the GaAs substrate, the magneto-transmission of the sample, mainly governed by the cyclotron (CR) absorption line, can be followed continuously over the whole range of energies. It reveals a strong polaronic interaction with the LO GaAs-phonon: the results can be interpreted quantitatively using the FHIP model [1] and the related conductivity response [2].

Thursday, March 1, 2012 8:00AM - 11:00AM — Session V25 DCOMP DCMF: High Pressure: Experiment 257A

8:00AM V25.00001 Kinetics studies across the phase transition of metals using *dynamic*-DAC, JING-YIN CHEN, WILLIAM EVANS, LLNL — We utilize the time-resolved synchrotron x-ray diffraction and in-situ optical spectroscopy to study the dynamic properties of several metals across the phase transition under different compression rates. The dynamic properties of metals across the pressure-induced phase transition, for example the mechanism of solidification or solid-solid transitions, are lacking. Obtaining the time-resolved structural evolutions of metals under rapid compression is critical to understanding material stability or metastability, and transition mechanism. In addition, the dynamical pressure changes can dramatically influence the microstructure and even phase boundaries, further affecting the properties of metals, such as toughness and strength.

8:12AM V25.00002 Phase Transition Kinetics of GST at High Pressures, ADAM CADIEN, QING YANG HU, HOWARD SHENG, George Mason University — The phase change material Ge₂Sb₂Te₅ (GST) undergoes an amorphous to ordered phase transition in nanoseconds. This ultra-fast phase transition kinetics in conjunction with drastic electrical property changes makes GST an ideal candidate for next generation optical and digital storage media. The origins of this fast transition have thus far been traced back to the atomic configurations of both the amorphous and ordered phases. However the precise configurations of both the ordered and amorphous phases are still unknown with advances from simulations constantly altering our understanding of these structures. To discover the structural dependence of the phase transition kinetics of GST, we have performed in-situ synchrotron X-ray diffraction experiments on GST using a new Hydrothermal Diamond Anvil Cell under a range of pressures and observed new patterns of phase transition of GST at elevated temperatures. Ab initio simulations have been performed to interpret the structural evolutions of GST phases at different pressures, with an emphasis on the role of vacancies in the phase transition. Our results provide new insight into the mechanism of the fast phase transition kinetics of GST.

8:24AM V25.00003 ABSTRACT WITHDRAWN —

8:36AM V25.00004 Pressure-induced phase transitions in GeS under high pressures¹ , RANGA DIAS, Institute for Shock Physics, Department of Physics, Washington State University, Pullman, Washington 99164, CHOONG-SHIK YOO, Institute for Shock Physics, Department of Chemistry, Washington State University, Pullman, Washington 99164 — We have studied the pressure-induced structural and electronic phase transitions of layered GeS (*Pnma*) to 30 GPa, using micro-Raman spectroscopy and electrical resistivity measurements in diamond anvil cells. The result shows a steady decrease in resistivity to that of metal at around 18 GPa. The visual appearance of GeS supports the insulator-metal transition: initially black GeS becomes opaque and eventually reflective with increasing pressure. The Raman result indicates that the metallization is preceded by a structural phase transition, presumably to the previously predicted *Cmcm* structure.

8:48AM V25.00005 High pressure behavior of Cr₂O₃ to 62 GPa¹ , KRYSTLE CATALLI, HYUNCHAE CYNN, WILLIAM J. EVANS, Lawrence Livermore National Lab — Corundum-structured oxides are of interest for a broad range of reasons, including their mineralogical occurrences and technological uses. The high pressure behavior of Cr₂O₃ is of particular interest due to the widespread use of ruby, (Al,Cr)₂O₃, as a pressure standard in diamond anvil cells experiments. Although there have been a number of high pressure studies on Cr₂O₃, discrepancies still exist among the different data sets. Here we present synchrotron X-ray diffraction data on the structure and compressional behavior of Cr₂O₃ to 62 GPa. Although no change in crystal structure is detected within the resolution of the measurements, a change in compressional behavior occurs near 30 GPa where Cr₂O₃ changes color from red to orange.

¹Prepared by LLNL under Contract DE-AC52-07NA27344. Work performed at HPCAT, Advanced Photon Source (APS), Argonne National Lab. HPCAT is supported through funding from DOE-NNSA, DOE-BES and NSF. APS is supported by DOE-BES.

9:00AM V25.00006 Amorphous diamond – A high-pressure superhard carbon allotrope , YU LIN, Geological and Environmental Sciences, Stanford University, LI ZHANG, HO-KWANG MAO, Geophysical Laboratory, Carnegie Institution of Washington, PAUL CHOW, YUMING XIAO, High Pressure Collaborative Access Team, Geophysical Laboratory, MARIA BALDINI, High Pressure Synergetic Consortium, Geophysical Laboratory, JINFU SHU, Geophysical Laboratory, Carnegie Institution of Washington, WENDY MAO, Geological and Environmental Sciences, Stanford University — Compressing glassy carbon above 40 GPa, we have observed a new carbon allotrope with a fully *sp*³-bonded amorphous structure and diamond-like strength. Synchrotron x-ray Raman spectroscopy revealed a continuous pressure-induced *sp*²-to-*sp*³ bonding change, while x-ray diffraction confirmed the perseverance of non-crystallinity. The transition was reversible upon releasing pressure. Used as an indenter, the glassy carbon ball demonstrated exceptional strength by reaching 130 GPa with a confining pressure of 60 GPa. Such an extremely large stress difference of >70 GPa has never been observed in any material besides diamond, indicating the high hardness of this high-pressure carbon allotrope. The nanoscale transmission x-ray microscopy is being utilized for accurate pressure-volume determination of glassy carbon and its high-pressure phase.

9:12AM V25.00007 Comparison of the existing internally consistent pressure scales at high pressures and high temperatures¹ , HYUNCHAE CYNN, B.J. BAER, LLNL, Livermore, CA, S.G. MACLEOD, AWE, Aldermaston, UK, W.J. EVANS, M.J. LIPP, J.P. KLEPEIS, ZS. JENEI, J.Y. CHEN, K. CATALLI, LLNL, Livermore, CA, D. POPOV, C.Y. PARK, HP-CAT, APS — There have been several efforts to determine internally consistent pressure scales for static diamond anvil high pressure study. We decide to extend the choice of pressure scales to include W and Cu. A recent study of Cu claims that electronic theory can constrain cold curve and possibly room temperature isotherm (Greeff et al., 2006, JPCS). We will present our comparison of 6 different pressure scales in regards with the suggested Cu EOS. We have measured angle-dispersive x-ray diffraction of Au, Pt, W, Cu, Ne, and NaCl to directly compare with the current existing EOS. We will also discuss discrepancies in the precise determination of pressure of phase transformations.

¹This work performed under the auspices of the US DOE by LLNL under Contract DE-AC52-07NA27344. HPCAT use is supported by DOE-BES, DOE-NNSA, NSF, and the W.M. Keck Foundation. APS is supported by DOE-BES, under Contract No. DE-AC02-06CH11357.

9:24AM V25.00008 Simultaneous measurement of pressure evolution of crystal structure and superconductivity in Fese_{0.8} using designer diamonds , WALTER UHOYA, University of Alabama at Birmingham (UAB) Birmingham, AL 35294, USA, NATHANIEL WOLANYK, Illinois Wesleyan University (IWU), Bloomington, IL 61702-2900, USA, GEORGIY TSOI, University of Alabama at Birmingham (UAB) Birmingham, AL 35294, USA, YOGESH VOHRA, Department of Physics, University of Alabama at Birmingham (UAB) Birmingham, AL 35294, USA, SISTLA M RAO, MAU-KUEN WU, Institute of Physics, Academia Sinica, Nankang, Taipei 115, Taiwan, SAMUEL WEIR, Mail Stop L-041, Lawrence Livermore National Laboratory (LLNL) Livermore, CA 94550, USA — Simultaneous high pressure x-ray diffraction and electrical resistance measurements have been carried out on (P4/nmm) PbO type α -FeSe_{0.89} compound to a pressure of 44 GPa and at low temperatures down to 4 K using a synchrotron source and designer diamond anvils technique. At ambient temperature, a structural phase transition from the tetragonal (I4/nmm) phase to orthorhombic (Pbnm) is observed at 11 GPa and persist up to 75 GPa. The superconducting transition temperature increases rapidly with pressure in a parabolic manner reaching a maximum of ~40 K at ~11GPa. It then decreases at higher pressures. We also performed a complimentary pressure dependence x-ray diffraction simultaneously with resistance measurement at low temperatures and observe superconductivity only in the low pressure orthorhombic phase (Cmma) of α -FeSe_{0.89}. Upon increasing pressure at 10 K, structural phase change from a mixed phase of orthorhombic (Cmma) and hexagonal (P63/mmc) to a high pressure orthorhombic phase (Pbnm) is observed at around 12 GPa where T_c is maximum.

9:36AM V25.00009 Melting Studies of Metals in a Paris Edinbrough Cell via Radiography , MAGNUS LIPP, ZSOLT JENEI, DAVE RUDDLE, CHANTEL ARACNE-RUDDLE, HYUNCHAE CYNN, WILLIAM EVANS, Lawrence Livermore National Laboratory, YOSHIO KONO, CURTIS KENNEY-BENSON, CHANGYONG PARK, HPCAT, Advanced Photon Source, Argonne National Laboratory — Equation-of-state measurements of amorphous solids and liquids suffer from the lack of distinct X-ray diffraction patterns that can be indexed and used for a precise and accurate volume determination. For relatively high Z materials, however, a possible remedy might be found in the application of X-ray radiography. The presentation will describe current efforts with regard to cerium and alloys of noble metals in the liquid state. This work was performed under the auspices of the US DOE by LLNL under Contract DE-AC52-07NA27344. The X-ray studies were performed at HPCAT (Sector 16), APS/ANL. HPCAT is supported by CIW, CDAC, UNLV and LLNL through funding from DOE-NNSA, DOE-BES and NSF. APS is supported by DOE-BES, under Contract No. DE-AC02-06CH11357.

9:48AM V25.00010 Homoepitaxial Boron Doped Diamond Anvil as Heating Element in a Diamond Anvil Cell, JEFFREY MONTGOMERY, GOPI SAMUDRALA, YOGESH VOHRA, University of Alabama at Birmingham — Recent advances in designer-diamond technology have allowed for the use of electrically and thermally conducting homoepitaxially-grown layers of boron-doped diamond (grown at 1200 °C with a 2% mixture of CH₄ in H₂, resulting in extremely high doping levels $\sim 10^{20}/\text{cm}^3$) to be used as heating elements in a diamond anvil cell (DAC). These diamonds allow for precise control of the temperature inside of the diamond anvil itself, particularly when coupled with a cryostat. Furthermore, the unmatched thermally conducting nature of diamond ensures that no significant spatial gradient in temperature occurs across the culet area. Since a thermocouple can easily be attached anywhere on the diamond surface, we can also measure diamond temperatures directly. With two such heaters, one can raise sample temperatures uniformly, or with any desired gradient along the pressure axis while preserving optical access. In our initial experiments with these diamond anvils we report on the measurement of the thermal conductivity of copper-beryllium using a single diamond heater and two thermocouples. We augment these measurements with measurements of sample pressure via ruby fluorescence and electrical resistance of the sample and diamond heater.

10:00AM V25.00011 ABSTRACT WITHDRAWN —

10:12AM V25.00012 ABSTRACT WITHDRAWN —

10:24AM V25.00013 High pressure study of mixed valence compound CsAuI₃, SHIBING WANG, SHIGETO HIRAI, ALEXANDER KEMPER, Stanford University, MARIA BALDINI, Geophysical Laboratory, HONGWEI MA, Indiana University, SCOTT RIGGS, MAXWELL SHAPIRO, TOM DEVEREAUX, IAN FISHER, WENDY MAO, TED GEBALLE, Stanford University — CsAuI₃, chemically described as Cs₂Au^IAu^{III}I₆, is a mixed valence compound in the family of CsAuX₃ (X = Cl, Br, I), resembling the high T_c superconductor parent compound BaBiO₃. At ambient conditions it adopts a distorted perovskite structure with compressed Au^IX₆ octahedra and elongated Au^{III}X₆ octahedra along the crystallographic c-axis. The compound undergoes a pressure-induced transition into a new tetragonal phase comprising nearly equivalent AuX₆ octahedra around 5.3 GPa, which agrees with the valence transition previously reported using Mössbauer spectroscopy between 8-12 GPa. We present a thorough high pressure studies of CsAuI₃ through X-ray diffraction and Raman spectroscopy, confirming a pressure-induced band Jahn-Teller effect associated with the 5d⁹ Au^{III} ion. We will also report the reversible amorphization above 15 GPa.

10:36AM V25.00014 Pressure tuning of the thermal conductance of weak interfaces, WEN-PIN HSIEH, Stanford Institute for Materials and Energy Science, Stanford University and SLAC, AUSTIN LYONS, ERIC POP, Department of Electrical and Computer Engineering, University of Illinois, Urbana, PAWEL KEBLINSKI, Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, Troy, NY, DAVID CAHILL, Department of Materials Science and Engineering, University of Illinois, Urbana — We use high pressure to reveal the dependence of interfacial heat transport on the stiffness of interfacial bonds. The combination of time-domain thermoreflectance and SiC anvil techniques is used to measure the pressure-dependent thermal conductance $G(P)$ of clean and modified Al/SiC interfaces at pressures as high as $P=12$ GPa. We create low-stiffness, van der Waals bonded interfaces by transferring a monolayer of graphene onto the SiC surface before depositing the Al film. For such weak interfaces, $G(P)$ initially increases approximately linearly with P , consistent with results of molecular dynamics simulations. At high pressures, $P > 8$ GPa, the thermal conductance of weak interfaces approaches the high values characteristic of strongly-bonded, clean interfaces. The results provide new insight demonstrating that interface stiffness dominates thermal transport at weak interfaces, but plays a minor role for strong interfaces with stiffness similar to that in the bulk of the materials.

10:48AM V25.00015 Target tracking in a dusty plasma: phase transitions and equations of state¹, NEIL OXTOPY, JASON RALPH, CÉLINE DURNIAK, DMITRY SAMSONOV, University of Liverpool, United Kingdom — A dusty plasma is a low-density ionized gas containing micron-sized charged dust particles. Laboratory dusty plasmas can be used as kinematic simulators of condensed matter systems, displaying phenomena such as phase transitions. The motion of individual particles is resolvable using a high-speed video camera. We use recursive state estimation (target tracking) techniques to track the dust kinematics, from which we calculate an equation of state for the toy condensed matter system.

Thursday, March 1, 2012 8:00AM - 11:00AM —

Session V26 DCOMP: Focus Session: Computational Frontiers in Quantum Spin Systems III

257B

8:00AM V26.00001 A dynamical Marshall sign convention, KEVIN BEACH, University of Alberta — Monte Carlo sampling of quantum spin models is only practical when it is possible to gauge away simultaneously all negative signs in the coefficients of the ground state wavefunction. The existence of such a transformation is related to the possibility of establishing a bipartite pattern of magnetic order on the lattice and to the choice of a so-called Marshall sign convention. In practice, identifying the correct Marshall sign convention is the responsibility of the QMC practitioner, and the convention itself is generally hard coded. It turns out, however, that a locally optimal sign convention can be determined dynamically within the simulation—meaning that for nonfrustrated systems the simulation quickly establishes a Marshall sign convention that leads to sign-problem-free sampling and that for frustrated systems the Marshall sign convention continually evolves in Monte Carlo time so as to minimize the severity of the sign problem. For concreteness, we focus on a worm algorithm formulated in the basis of singlet product states.

8:12AM V26.00002 Monte Carlo Simulations of Quantum Spin Systems in the Valence Bond Basis, FABIAN ZSCHOCKE, University of Alberta — We propose a quantum Monte Carlo method for frustrated spin systems that partially alleviates the sign problem — thereby extending the range of frustrated couplings over which the system can be reliably sampled. The scheme is projective and takes advantage of the overcompleteness and nonorthogonality of the valence bond basis. It provides a framework for further semi-controlled approximations that are fully sign-problem-free in which the transition weights between bond configurations take on effective, renormalized values. We present results for the frustrated (J₁-J₂), spin-half Heisenberg model on the square lattice in the vicinity of its phase transition at $J_2/J_1 \approx 0.4$.

8:24AM V26.00003 Observing spinon excitations in quantum spin models¹, YING TANG, ANDERS SANDVIK, Boston University — We develop a technique to directly study spinons (emergent spin $S = 1/2$ particles) in quantum spin models in any number of dimensions [1]. Two characteristic lengths—the size of a spinon wave packet and the size of a bound pair (a triplon)—are defined in terms of wave-function overlaps that can be evaluated by quantum Monte Carlo simulations. We find that these two lengths are well distinguishable in one-dimensional models with valence-bond-solid (VBS) ground states and explicitly dimerized models, yet hardly separable in 2-leg ladder systems. We provide some physics insights for these phenomena. We also study spinons in two-dimensional resonating-valence-bond states and models with Néel-VBS transitions.

¹NSF Grant No. DMR-1104708.

8:36AM V26.00004 Lightcone renormalization and quantum quenches in one-dimensional Hubbard models, JESKO SIRKER, TU Kaiserslautern, TILMAN ENSS, TU Muenchen — The Lieb-Robinson bound implies that the unitary time evolution of an operator can be restricted to an effective light cone for any Hamiltonian with short-range interactions. Here we present a very efficient new renormalization group algorithm based on this light cone structure to study the time evolution of prepared initial states in the thermodynamic limit in one-dimensional quantum systems. The algorithm does not require translational invariance and allows for an easy implementation of local conservation laws. We use the algorithm to investigate the relaxation dynamics of a doublon lattice in fermionic Hubbard models as well as a possible thermalization. Furthermore, we present results for a doublon impurity in a Néel background. We find that the excess charge and spin spread at different velocities, providing an example of spin-charge separation in a highly excited state.

8:48AM V26.00005 Time Evolution within a Comoving Window¹, MARTIN GANAHL, VALENTIN ZAUNER, TU Graz, TOMOTOSHI NISHINO, Kobe University, HANS GERD EVERTZ, TU Graz — We present a modification of Matrix Product State time evolution to simulate the propagation of a signal front on an infinite system. The time evolution is calculated within a finite window that moves along with the signal front, in such a way that boundary effects do not occur. Signal fronts can then be studied unperturbed for much longer times than on truly finite systems, where boundary perturbations and reflections would interfere. The entanglement within in the comoving window remains small. Our approach avoids the large entanglement which develops around the location of the signal source and therefore requires significantly lower computational effort. We verify our approach against exact results and show examples of propagating signals for the XXZ model and the transverse Ising model.

9:00AM V26.00006 Emergence of prominent bound states in the spin-1/2 Heisenberg XXZ chain after a local quantum quench¹, HANS GERD EVERTZ, MARTIN GANAHL, ELIAS RABEL, Tu Graz, FABIAN ESSLER, University of Oxford — We calculate the non-equilibrium evolution in the spin-1/2 XXZ Heisenberg chain for fixed magnetization after a *local quantum quench*. Initially an infinite magnetic field is applied to n consecutive sites in the center of a large chain, and the ground state is determined. Then the field is switched off and the time evolution of observables such as the z-component of spin is computed using the Time Evolving Block Decimation (TEBD) algorithm. We find that the observables exhibit strong signatures of propagating spinon as well as bound state excitations. These persist even when integrability-breaking perturbations are included. Since bound states (“strings”) are notoriously difficult to observe using conventional probes such as inelastic neutron scattering we conclude that local quantum quenches are an ideal setting for studying their properties. We comment on implications of our results for cold atom experiments.

¹We acknowledge support by the Austrian Science Fund FWF (SFB F41 ViCoM), by EPSRC (grant EP/I032487/1) and by the NSF (KITP, PHY05-51164)

9:12AM V26.00007 Non-local order parameters in 1D symmetry protected topological phases, FRANK POLLMANN, Max Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany, ARI TURNER, University of Amsterdam, 1090 GL Amsterdam, The Netherlands, EREZ BERG, Department of Physics, Harvard University, Cambridge, MA 02138, USA — A topological phase is a phase of matter which cannot be characterized by a local order parameter. It has been shown that gapped phases in 1D systems can be completely characterized using tools related to projective representations of the symmetry groups. An example of a symmetry protected topological phase is the Haldane phase of $S = 1$ chains. Here the phase is protected by any of the following symmetries: dihedral group of π -rotations about two orthogonal axes, time-reversal symmetry, or bond centered inversion symmetry. We introduce non-local order parameters for each case which can be simply calculated using numerical methods such as Density-Matrix Renormalization Group (DMRG). These non-local order parameters provide a practical tool for numerically detecting these non-trivial phases.

9:24AM V26.00008 Projected Density of Transitions for Heisenberg Models¹, ROGER HAYDOCK, C.M.M. NEX, University of Oregon — The projected density of transitions (PDoT) is the interacting analogue of the projected or local density of states. The PDoT is proportional to the probability, averaged over all states of the system, that some disturbance (the projection) induces a transition with a specific energy. It is calculated in the same way as the density of states, but using Heisenberg’s equation instead of Schrödinger’s equation. As an example we have applied it to the Heisenberg model for spin interactions of electrons on linear, square, and cubic lattices. One surprise in these calculations is what seems to be a consequence of the spin’s rotational symmetry.

9:36AM V26.00009 Criticality in one-dimensional supersymmetric lattice fermions, MATTHIAS TROYER, Theoretische Physik, ETH Zurich, Switzerland, BELA BAUER, Station Q, Microsoft Research, Santa Barbara and Theoretische Physik, ETH Zurich, Switzerland, LIZA HUIJSE, EREZ BERG, Department of Physics, Harvard University, Cambridge, KARELJAN SCHOUTENS, Institute for Theoretical Physics, University of Amsterdam — A supersymmetric model for lattice fermions has been seen to host a plethora of interesting phenomena. On one-dimensional and quasi-one-dimensional lattices, the model naturally becomes critical and it has been conjectured that it is described by superconformal field theory. While this relation has been confirmed for the chain, establishing this link and exploring the phases adjacent to the critical point for the case of the square ladder has turned out to be a challenging problem for numerical simulations. In our work, we collect evidence in support of the conjecture and obtain insights into the adjacent phases using a variety of numerical techniques, including the density-matrix renormalization group and the multi-scale entanglement renormalization ansatz.

9:48AM V26.00010 Study of Kitaev-Heisenberg model with second-neighbor Heisenberg coupling by DMRG simulations and slave-particle theories, YI-FAN JIANG, Tsinghua University, HONG-CHEN JIANG, KITP, UCSB and Tsinghua University, HONG YAO, Stanford University and Tsinghua University — We study the effect of second-neighbor Heisenberg coupling J_2 to the first neighbor Kitaev-Heisenberg model on the honeycomb lattice by doing DMRG simulations and slave-particle theories. In the Kitaev limit, we find that the gapless spin liquid phase at $J_2 = 0$ survives up to a finite critical value J_{2c} . In an intermediate range, namely $J_{2c} < J_2 < J'_{2c}$, our results show that a new exotic (possibly a gapped chiral spin liquid) phase emerges. When J_2 is further increased beyond J'_{2c} , the ground state orders magnetically by spontaneously breaking spin-rotational and lattice translational symmetries. Possible implications of our results to the real materials Na_2IrO_3 and Li_2IrO_3 will also be discussed

10:00AM V26.00011 Thermodynamics and phase transitions of the pinwheel-distorted Kagome lattice Heisenberg model¹, EHSAN KHATAMI, Georgetown University, RAJIV R.P. SINGH, University of California, Davis, MARCOS RIGOL, Georgetown University — We study the Heisenberg model on the pinwheel-distorted Kagome lattice as observed in the material $Rb_2Cu_3SnF_{12}$. Experimentally relevant thermodynamic properties at finite temperatures are computed utilizing numerical linked-cluster expansions [1]. We introduce a Lanczos-based zero-temperature numerical linked-cluster expansion and study the approach of the pinwheel distorted lattice to the uniform Kagome lattice Heisenberg model. We find strong evidence for a phase transition before the uniform limit is reached, implying that the ground state of the Kagome lattice Heisenberg model is likely not pinwheel dimerized and is stable to finite pinwheel dimerizing perturbations [2].

10:12AM V26.00012 Numerical Schwinger boson approach to the Bethe lattice antiferromagnet at percolation¹, SHIVAM GHOSH, HITESH J. CHANGLANI, CHRISTOPHER L. HENLEY, Cornell University — What are the lowest energy excitations of a spin-1/2 Heisenberg antiferromagnet on a critical percolation cluster? On the square lattice, Wang et al.,² discovered anomalously low $S=1$ excitations, with energy scaling as $\Delta \sim 1/N^2$. Normally the “Anderson tower” would be the lowest, having energy $S(S+1)/2\chi N \sim 1/N$ (χ = transverse susceptibility). These anomalous excitations were attributed to “dangling spins” appearing in parts of the cluster where there was an imbalance of even and odd sites. Here, we look at the diluted $z=3$ Bethe lattice at the percolation threshold. Previous work confirmed the existence of emergent spin-1/2 degrees of freedom with an effective Heisenberg Hamiltonian but did not explain their origin. New results from DMRG (Density Matrix Renormalization Group) show strong dimerization tendency in the (singlet) ground state, yet there is long-range Neel order on the percolation cluster.³ To harmonize these results, we set up a numerical Schwinger Boson mean field calculation (with site dependent parameters); we find lowering of mean field energy and spin correlations which agree well with ED and DMRG.

10:24AM V26.00013 Spin Mott Glass Phase in the Disordered Spin Systems, DAO-XIN YAO, NV-SEN MA, State Key Laboratory of Optoelectronic Materials and Technologies, School of Physics and Engineering, Sun Yat-sen University, ANDERS SANDVIK, Department of Physics, Boston University, MA — We use quantum Monte Carlo simulations to study a glassy ground state of $S=1/2$ quantum spins by using a dimerized J1-J2-J3 Heisenberg model on the square lattice. J1 corresponds to weak bonds, and J2 and J3 are stronger bonds which are randomly distributed on columnar rungs forming coupled 2-leg ladders. By tuning the average value of J2 and J3, the system undergoes Neel-glass-paramagnetic quantum phase transition. The size of the glass region is affected by the value of the disorder strength. In the glass phase, we find that the uniform susceptibility decreases with T according to $\exp(-b/T^a)$ with $a < 1$; thus the state is incompressible at $T=0$ and classified as a Mott glass (MG). At the Neel-MG transition, the susceptibility behaves as $T^{2/z-1}$. The dynamical exponent z is found to be larger than 1.

10:36AM V26.00014 Tuning the disorder in a bosonic superglass¹, DEREK LARSON, YING-JER KAO, National Taiwan University — We study the phase transitions associated with tuning the disorder in a Bose-Hubbard model exhibiting a superglass phase. By shifting the distribution of a nearest neighbor $\pm J$ interaction between hard-core bosons on a three-dimensional lattice, we can produce anti-ferromagnetic, glassy, and ferromagnetic (diagonal) types of ordering, each of which interacts uniquely with the superfluid (off-diagonal) ordering. Quantum Monte Carlo simulation results using the worm algorithm show that the existence of superfluidity guards against the formation of large ferromagnetic clusters, presumably due to a lowering of the cost of interfaces. This leads to a strongly-temperature-dependent phase boundary between the glassy and ferromagnetic regions.

10:48AM V26.00015 Impact of spin-orbit coupling on the Holstein polaron, ZHOU LI, Department of Physics, University of Alberta, LUCIAN COVACI, Universiteit Antwerpen, MONA BERCIU, University of British Columbia, DEVIN BAILLIE, FRANK MARSIGLIO, University of Alberta — We utilize an exact variational numerical procedure to calculate the ground state properties of a polaron in the presence of a Rashba-like spin orbit interaction. Our results corroborate with previous work performed with the Momentum Average approximation and with weak coupling perturbation theory. We find that spin orbit coupling increases the effective mass in the regime with weak electron phonon coupling, and decreases the effective mass in the intermediate and strong electron phonon coupling regime. Analytical strong coupling perturbation theory results confirm our numerical results in the small polaron regime. A large amount of spin orbit coupling can lead to a significant lowering of the polaron effective mass

Session V27 DCMP FIAP: Invited Session: Flexible and Rolled Up Semiconductor Nanomembranes 258AB

8:00AM V27.00001 Making Novel Materials Using Strain in Nanomembranes¹, MAX G. LAGALLY, University of Wisconsin-Madison, Madison WI 53706 — The controlled introduction of strain in materials offers an important degree of freedom for fundamental studies of materials as well as advanced device engineering. Strain in a crystalline solid modifies the lattice constants and reduces the crystal symmetry. Because strain energy is proportional to thickness, a free-standing crystalline thin sheet, which we call a nanomembrane (NM), can be strained to a greater degree than a bulk material with the same surface area. I show the use of nanomembrane strain engineering to make defect-free single crystals that cannot be grown any other way, and materials with strain symmetries that they do not have naturally, in both cases alloys of Si and Ge. Strain in NMs causes significant shifts in energy band edges, splitting of degenerate states, and changes in effective masses. These effects can be used to produce a desired band offset between different materials, to increase carrier mobility, and to change relative energy positions of valleys. In the latter respect, through the use of NMs it has recently become possible, using tensile strain, to make Ge direct-bandgap and light emitting at room temperature. Periodic local stress can produce strain superlattices and thus single-element heterojunctions. Work performed with the Roberto Paiella, Mark Eriksson, Feng Liu, and Irena Knezevic research groups.

8:36AM V27.00002 Strain Superlattice: A Combination of Strain Induced Self-Assembly and Strain Engineered Band Structure¹, FENG LIU, University of Utah — Semiconductor nanomembrane affords a novel 2D platform for nanoscience and nanotechnology, especially for strain engineering of nanoelectronics. Strain is well known for band engineering to improve the performance of Si devices. The evidence that the band gap of Si changes significantly with strain suggests that by alternating regions of strained and unstrained Si one creates a single-element hetero-strain-junction electronic superlattice (SL), with the carrier confinement defined by strain rather than by the chemical differences in conventional SLs. Using first-principles calculations, we map out the electronic phase diagram of a 1D pure-silicon strain SL. It exhibits a high level of phase tunability, e.g., tuning from type I to type II. Our theory rationalizes a recent observation of a strain SL in a Si nanowire and provides general guidance for the fabrication of single-element strain SLs. The low-dimensional nanoscale strain SLs extend the concept of SL to a single element that exists in different structural states. It can be made in 1D nanowires or 2D nanomembranes by nanoscale self-assembly or by nanopatterning. It expands the application of strain engineering to new territories, by combining strain induced self-assembly with strain engineered band structure.

Thursday, March 1, 2012 8:00AM - 9:48AM — Session V28 DMP: Semiconductor Defects and Doping 258C

8:00AM V28.00001 Transition Metal Defects in Cubic and Hexagonal Polytypes of SiC: Site Selection and Electronic Structure from ab-initio Calculations¹, ADAM GALI, VIKTOR IVÁDY, Hungarian Academy of Sciences, ANDREAS GÄLLSTRÖM, NGUYEN SON, ERIK JANZÉN, Linköping University — Relatively little is known about point defects in different polytypes of a crystal. Silicon carbide is a prototype material for polytypism. There are unidentified photoluminescence centers in SiC that are presumably originated from transition metal defects, however, the number of detected centers does not follow the number of inequivalent substitutional sites in different polytypes. In this study we applied highly convergent and sophisticated density functional theory (DFT) based methods to investigate important transition metal impurities including titanium (Ti), vanadium (V), niobium (Nb), chromium (Cr), molybdenum (Mo) and tungsten (W) in cubic 3C and hexagonal 4H and 6H polytypes of SiC. We applied DFT with PBE functional in order to calculate the ground state of the defects. We calculated the electronic structure by a screened hybrid density functional (HSE06) which was very successful in the quantitative description of native defects in SiC. We found a special asymmetric split-vacancy configuration for a class of transition metal defects. The asymmetric split-vacancy configuration exclusively prefers the hexagonal-hexagonal sites in hexagonal polytypes, thus the probability of finding these defects in 3C polytype is much smaller than in hexagonal polytypes.

8:12AM V28.00002 Quantum Effects of Strain Influence on the Dopant Behavior in Semiconductors, DEYAN SUN, ZHENTANG WANG, East China Normal University, China, SHIYOU CHEN, East China Normal University, XIANGMEI DUAN, Ningbo University, China, SU-HUAI WEI, National Renewable Energy Laboratory, USA, XINGAO GONG, Fudan University, China — In most fields of physics, applying external strain (pressure) provides an important technique to investigate and tune the properties of materials. Quite often the theoretical treatment is based on the continuum elastic model, in which its validity is still under debate. In this talk, by using quantum mechanical theoretical analysis, we show that if the occupation change of different orbitals caused by the strain is negligible, the continuum elastic model is valid, otherwise it will fail. Our theory is confirmed by first-principles calculation of Mn-doped GaAs system. Moreover, we show that under compressive strain the hole density, thus the Curie temperature can increase in Mn-doped spintronic materials.

8:24AM V28.00003 First-principle Calculations of Donor and Acceptor Levels in PbI₂ for Ultra-fast Scintillation, GAIGONG ZHANG, Program in Applied Science, UC Davis, ANDREW CANNING¹, Computational Research Division, LBNL, NIELS GRONBECH-JENSEN², Program in Applied Science, UC Davis, LIN-WANG WANG, Materials Sciences Division, LBNL, STEPHEN DERENZO, Life Sciences Division, LBNL — In the past PbI₂ was studied as a candidate for semi-conductor gamma ray detectors as well as more recently as an ultra-fast scintillator for time-of-flight applications. The ultra-fast scintillation properties of this materials are believed to be related to donor-acceptor recombination in both the pure and doped system. This work presents first-principles electronic structure calculations of donor and acceptor levels for intrinsic defects and doped impurities in PbI₂. We performed density functional theory calculations within the generalized gradient approximation with U correction for the donor and acceptor modeling. For a more accurate description of band gaps and structures, we used more advanced methods, such as GW. Our study shows that intrinsic defects significantly affect the luminescence properties of bulk PbI₂. Moreover, the relative position of intrinsic defect levels to doped impurity levels can influence the luminosity. We will compare our theoretical work to known experimental work for this material.

¹Program in Applied Science, UC Davis

²Computational Research Division, LBNL

8:36AM V28.00004 Nonradiative lifetimes in intermediate band materials – absence of lifetime recovery¹, JACOB J. KRICH, Harvard University, Department of Chemistry and Chemical Biology, BERTRAND I. HALPERIN, Harvard University, Department of Physics, ALÁN ASPURU-GUZIĆ, Harvard University, Department of Chemistry and Chemical Biology — Intermediate band photovoltaics hold the promise of being highly efficient and cost effective photovoltaic cells. Intermediate states in the band gap, however, are known to facilitate nonradiative recombination. Much effort has been dedicated to producing metallic intermediate bands in hopes of producing *lifetime recovery* – an increase in carrier lifetime as doping levels increase. We show that lifetime recovery induced by the insulator-to-metal transition will not occur, because the metallic extended states will be localized by phonons during the recombination process. Only trivial forms of lifetime recovery, e.g., from an overall shift in intermediate levels, are possible. Future work in intermediate band photovoltaics must focus on optimizing subgap optical absorption and minimizing recombination, but not via lifetime recovery.

¹We acknowledge support from NSF Grant Nos. DMR-0934480 and DMR-0906475 and the Harvard University Center for the Environment.

8:48AM V28.00005 Imaging Defects in Semiconductors with a Snapshot Micro-Imaging Technique¹, KIRSTIN ALBERI, BRIAN FLUEGEL, DAN BEATON, ANGELO MASCARENHAS, National Renewable Energy Laboratory — Polycrystalline or metamorphically grown single crystalline thin films are ubiquitous in energy-related technologies, such as solar cells and light emitting diodes. A detailed understanding of the defects contained within these materials (i.e. dislocations, grain boundaries, inclusions) and the ability to control them play critical roles in their development. We will present the use of a novel “snapshot” micro-imaging technique to evaluate the presence and behavior of defects in a variety of materials and devices. Photoluminescence from a wide area of a sample is imaged onto a Si CCD in a single exposure, enabling real-time mapping with sub-micron resolution. A tunable liquid-crystal filter selects the exact wavelength that is imaged. Combined with a tunable excitation source, this technique is ideal for selectively investigating defects in thin films as well as individual layers in a device.

¹We acknowledge the financial support of the Department of Energy, Office of Science, Basic Energy Sciences

9:00AM V28.00006 Fluorescent nanodiamonds for biomedical thermal imaging, JUAN ENRIQUE RAMIREZ HERNANDEZ, JOSE GARCIA SOLE, MARTIN RAFAEL PEDROZA MONTERO, MARCELINO BARBOZA FLORES, DANIEL JAQUE, LAURA MARTINEZ MAESTRO, KARLA JOSEFINA SANTACRUZ GOMEZ, FRANCISCO SANZ RODRIGUEZ, NINGNING DONG, TOMAS CALDERON, None — The use of nanoparticles designed for a particular purpose in biological research has increased exponentially in the last ten years. Nanoscale particles have dimensions similar to those of most biological systems and present exceptional physical, chemical and optical properties. The optical absorption and emission of nanoparticles may be tuned by varying their shape, size and composition and recent advances in their synthesis and design suggest their potential use as probes in the detection and treatment of diseases such as cancer. One of these promising materials is nanodiamond which possesses excellent surface modification capacity and high biocompatibility. In addition to being compatible with the human body, nanodiamonds can be used as radiation sensors. In this report, the ability of nanodiamonds to be used as nanothermometers was studied by the obtention of a nanothermic scale (temperature dependence of nanodiamond's emission spectrum) to accurately measure temperature in small volumes.

9:12AM V28.00007 Laser induced local modification of material properties in a semiconductor alloy¹, YONG ZHANG, NAILI YUE, UNC-Charlotte — High energy (usually short pulse) lasers are routinely used for micromachining and surface modification of solid state materials. We demonstrate that a small power CW laser can be used to induce local modification of the electronic and optical properties of a semiconductor alloy at any desirable spatial location. The degree of modification can be precisely controlled by laser density and exposure time. The spatial resolution is determined currently by the beam size of a confocal optical system, but it can also be defined by the feature size of a lithographic method. The induced local changes in properties are measured by optical spectroscopy, and the results indicate the possibility of local structural modification.

¹Work partially supported by CRI

9:24AM V28.00008 Spatial Variation in Mobility-Lifetime Product in Bulk TlBr and CZT¹, DAVID PHILLIPS, NANCY HAEGEL, Naval Postgraduate School, KEVIN BLAINE, US Military Academy, HADONG KIM, GUIDO CIAMPI, LEN CIRIGNANO, Radiation Monitoring Devices (RMD) — The energy resolution of a semiconductor radiation detector depends on the charge transport properties of the semiconductor, and the mobility-lifetime ($\mu\tau$) product is a key figure of merit for charge transport. In this work, we investigate the effects of two impurities, Na and Cu, on the $\mu\tau$ product in bulk thallium bromide (TlBr) using cathodoluminescence (CL) and transport imaging. Transport imaging uses a scanning electron microscope to generate a line of charge carriers on the surface of a bulk sample, and the intensity and spatial distribution of the recombination luminescence are recorded. A Green's function approach is used to model the generation, diffusion, and recombination of charge carriers under steady-state conditions. The luminescence distribution is fit to the model to extract the ambipolar diffusion length and the $\mu\tau$ product, providing a high-resolution correlation between the luminescence variations due to dopants/defects and the quantitative transport behavior. The $\mu\tau$ product has been mapped across a 40 μm segment of TlBr at a resolution of 2 μm . Additionally, this approach has been used to locally map variations in ambipolar diffusion length and $\mu\tau$ product due to extended defects in cadmium zinc telluride (CZT).

9:36AM V28.00009 Quantum Stress: Density Functional Theory Formulation and Physical Manifestation¹, HAO HU, FENG LIU, Department of Materials Science and Engineering, University of Utah — The concept of “quantum stress (QS)” is introduced and formulated within density functional theory (DFT), to underlie extrinsic electronic effects on the stress state of solids and thin films in the absence of lattice strain. An explicit expression of QS (σ^Q) is derived in relation to the deformation potential of electronic states (Ξ) and the variation of electron density (Δn), $\sigma^Q = \Xi(\Delta n)$, as a quantum analog of classical Hook’s law. Two distinct QS manifestations are demonstrated quantitatively by DFT calculations: (1) in the form of bulk stress induced by charge carriers; and (2) in the form of surface stress induced by quantum confinement. QS has broad implications in physical phenomena and technological applications that are based on coupling of electronic structure with lattice strain.

¹The work was supported by DOE-BES (Grant # DE-FG02-04ER46148).

Thursday, March 1, 2012 8:00AM - 10:48AM –
Session V29 GQI: Focus Session: Superconducting Qubits: Epitaxial Junctions and Two-Level Systems 259A

8:00AM V29.00001 Coherence in a transmon qubit with epitaxial tunnel junctions, MARTIN WEIDES, JEFFREY KLINE, MICHAEL VISSERS, MARTIN SANDBERG, National Institute of Standards and Technology, DAVID WISBEY, Saint Louis University, DAVID PAPPAS, National Institute of Standards and Technology, BLAKE JOHNSON, TOM OHKI, Raytheon BBN Technologies — We developed transmon qubits based on epitaxial tunnel junctions and interdigitated capacitors. This multileveled qubit, patterned by use of all-optical lithography, is a step towards scalable qubits with a high integration density. The relaxation time T_1 is $.72 - .86 \mu\text{sec}$ and the ensemble dephasing time T_2^* is slightly larger than T_1 . The dephasing time T_2 ($1.36 \mu\text{sec}$) is nearly energy-relaxation-limited. Qubit spectroscopy yields weaker level splitting than observed in qubits with amorphous barriers in equivalent-size junctions. The qubit’s inferred microwave loss closely matches the weighted losses of the individual elements (junction, wiring dielectric, and interdigitated capacitor), determined by independent resonator measurements.

8:12AM V29.00002 Superconducting qubits consisting of epitaxially-grown NbN/AlN/NbN Josephson junctions¹, YASUNOBU NAKAMURA, RIKEN/NEC, HIROTAKA TERA, NICT, KUNIHIRO INOMATA, RIKEN, TSUYOSHI YAMAMOTO, RIKEN/NEC, WEI QIU, ZHEN WANG, NICT — We demonstrate superconducting qubits using epitaxially-grown Josephson junctions. A fully epitaxial NbN/AlN/NbN trilayer on MgO (100) substrate is processed by photolithography and dry-etching into transmon qubits with a large Josephson energy. The tunnel barrier made of cubic-phase AlN, rather than the ordinary hexagonal phase, is the key to avoid piezoelectric coupling to the phonon bath. The energy-relaxation time and the spin-echo decay time of ~ 500 ns are observed in the qubits that are coupled to a monolithically-made coplanar waveguide resonator.

¹This work is partly supported by FIRST, MEXT-KAKENHI, and NICT.

8:24AM V29.00003 Josephson phase qubits incorporating high-Q crystalline dielectrics, U. PATEL, Y. GAO, L. MAURER, S. SENDELBACH, D. HOVER, Department of Physics, University of Wisconsin, Madison, Wisconsin 53706, K.H. CHO, C.B. EOM, Department of Materials Science and Engineering, University of Wisconsin, Madison, Wisconsin 53706, R. MCDERMOTT, Department of Physics, University of Wisconsin, Madison, Wisconsin 53706 — The energy relaxation times of Josephson phase qubits are currently limited by spurious coupling of the qubit to unsaturated two level system (TLS) defects of the amorphous dielectrics. It is expected that incorporation of defect-free crystalline dielectrics into qubit circuits will dramatically improve coherence. Here, we describe the growth and characterization of novel crystalline dielectrics for superconducting qubit applications, including grown Al₂O₃ on epitaxial Re underlayers. We discuss the incorporation of epitaxial dielectrics into phase qubit circuits, and present data on qubit coherence.

8:36AM V29.00004 Growth of epitaxial Al/AlO_x/Re using a sputtering PLD hybrid system with *in-situ* RHEED, KWANG-HWAN CHO, JACOB PODKAMINER, Department of Materials Science and Engineering, University of Wisconsin-Madison, UMESHKUMAR PATEL, ROBERT MCDERMOTT, Department of Physics, University of Wisconsin-Madison, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison — Our objective is the growth of epitaxial dielectrics on crystalline superconducting underlayers to improve the performance of superconducting Qubits. We have grown epitaxial Re thin films on a c-plane sapphire substrate using RF magnetron sputtering, and then transferred *ex-situ* to a pulsed laser deposition (PLD) system where dielectrics thin film layer is deposited. One drawback of this fabrication approach is the necessity to expose the sample to air when the sample is transferred to different deposition chambers. In order to avoid these drawbacks, we have employed a hybrid PLD-sputtering deposition that will allow us to grow the oxide dielectric/Re heterostructures in an *in-situ* environment without breaking vacuum. The system is also equipped with reflection high energy electron diffraction (RHEED) which will allow us to perform *in-situ* characterization of the structure and growth dynamics. We will discuss our strategy of epitaxial growth of various single crystal dielectrics on superconducting thin films in this system and their structural and electrical properties of the heterostructures.

8:48AM V29.00005 Transport Characteristics of Self-Aligned Josephson Junctions Grown using co-Deposited Molecular Beam Epitaxy¹, GUSTAF OLSON, ALLISON DOVE, ZACHARY YOSCOVITS, CHRIS NUGROHO, VLADIMIR ORLYANCHIK, DALE VAN HARLINGEN, JAMES ECKSTEIN, University of Illinois Urbana Champaign — Low noise Josephson junctions are extremely desirable in SQUIDs and qubit circuits. Sources of flux noise and critical current noise can be reduced by using both clean, single crystal junctions to lower the density of fluctuators and by decreasing the size of the junctions to lower the absolute number of fluctuators. We report transport characteristics of small, single crystal Josephson junctions grown using a co-deposited aluminum-oxide barrier molecular beam epitaxy process. We also report a novel self-aligned fabrication process that allows us to produce sub-micron junctions from these single crystal films. We show that our co-deposited junctions have more ideal transport characteristics than those junctions grown with only a diffused barrier. -

¹Work supported by IARPA grant Army UCB-00006692

9:00AM V29.00006 Internal loss of superconducting resonators induced by interacting two level systems¹ , LARA FAORO, LPTHE, CNRS, LEV IOFFE, Rutgers University — In a number of recent experiments with microwave superconducting resonators the anomalously slow dependence of the quality factor on the power was observed. This observation implies that the monochromatic radiation does not saturate two level systems in the surrounding oxides as predicted by the standard model of two-level systems (TLS). We argue that these observations suggest the importance of interactions between TLS in these materials. We show that interactions between TLS lead to a drift of their energies that result in much slower, logarithmic dependence of their absorption on the radiation power in a reasonable agreement with the data.

9:12AM V29.00007 Two-level system dynamics in amorphous dielectrics probed with a dc electric field , MOE KHALIL, SERGIY GLADCHENKO, M.J.A. STOUTIMORE, University of Maryland and Laboratory for Physical Sciences, F.C. WELLSTOOD, University of Maryland, K.D. OSBORN, Laboratory for Physical Sciences — We report loss in a thin-film dc electric-field tunable LC resonator built with superconducting aluminum and silicon nitride dielectric. To measure the loss we continually apply microwave power on resonance and monitor the transmitted power. At milli-Kelvin temperatures, loss is limited by two-level systems in the dielectric which are saturated with high microwave excitation power. Measurements show that a sudden change of applied dc field causes the dielectric loss to increase to the intrinsic low power loss tangent of the dielectric. We study the subsequent relaxation of the loss tangent caused by two-level system saturation and interactions. We discuss how this arises from the dynamics of a distribution of two-level system defects and compare it with new theoretical work on interacting two-level systems.

9:24AM V29.00008 Studying two-level systems in Josephson junctions with a Josephson junction defect spectrometer , M.J.A. STOUTIMORE, M.S. KHALIL, SERGIY GLADCHENKO, Laboratory for Physical Sciences, University of Maryland, R.W. SIMMONDS, National Institute of Standards and Technology, C.J. LOBB, University of Maryland, K.D. OSBORN, Laboratory for Physical Sciences — We have fabricated and measured Josephson junction defect spectrometers (JJDSs), which are frequency-tunable, nearly-harmonic oscillators that probe two-level systems (TLSs) in the barrier of a Josephson junction (JJ). A JJDS consists of the JJ under study fabricated with a parallel capacitor and inductor such that it can accommodate a wide range of junction inductances, L_{J0} , while maintaining an operating frequency, f_{01} , in the range of 4-8 GHz. In this device, the parallel inductance helps the JJ maintain linearity over a wide range of frequencies. This architecture allows for the testing of JJs with a wide range of areas and barrier materials, and in the first devices we have tested Al/AIO_x/Al JJs. By applying a magnetic flux bias to tune f_{01} , we detect TLSs in the JJ barrier as splittings in the device spectrum. We will present our results toward identifying and quantifying these TLSs, which are known to cause decoherence in quantum devices that rely on JJs.

9:36AM V29.00009 Relaxation of a Cooper-Pair Box Coupled to Discrete Charge Fluctuators , B.S. PALMER, Laboratory for Physical Sciences, Z. KIM, F.C. WELLSTOOD, JQI, CNAM, Department of Physics, University of Maryland — Recently, Kim *et al.* have reported that the interaction of a Cooper-pair box (CPB) with discrete charge fluctuators can decrease the relaxation time (T_1) of the first excited state of a CPB when operating the CPB near the transition frequency of a charged two-level system (TLS).¹ Using a density matrix approach and a 4-level Hilbert space, we have simulated the T_1 of a CPB coupled to a TLS and a dissipative bath. We model the TLS with asymmetry and tunneling parameters which we obtain along with the CPB parameters from fits to microwave spectroscopic measurements.^{2,3} To model the bath, the CPB is coupled to a source of charge noise which causes relaxation and dephasing while the TLS is coupled to its own dissipative source of energy. Results of the simulation are presented and compared to the experimental measurements.

9:48AM V29.00010 Microwave Frequency Loss in Aluminum Nanobridge Josephson Junctions¹ , ELI LEVENSON-FALK, R. VIJAY, STEVEN WEBER, KATER MURCH, I. SIDDIQI, UC Berkeley, QNL — Dielectric loss is a major source of decoherence in many superconducting qubits. Weak link Josephson junctions have the potential advantage of eliminating any loss associated with the insulating barrier in conventional tunneling type devices. We present quality factor measurements of 6 GHz superconducting resonators realized from three dimensional aluminum nanobridges shunted by single crystal silicon overlap capacitors. We compare the measured Q values with those obtained from similar resonators with aluminum tunnel junctions, with critical currents also in the microamp range. We discuss potential relaxation mechanisms specific to weak link junctions, and describe nanobridge qubit designs.

¹ This research was supported by the DARPA YFA program.

10:00AM V29.00011 T_1 -echo sequence - Preserving the state of a qubit in the presence of coherent interaction , CLEMENS MÜLLER, Departement de Physique, Université de Sherbrooke, Quebec, Canada J1K 2R1, ALEXANDER SHNIRMAN, Institut fuer Kondensierten Materie, Karlsruhe Institute of Technology, D-76128 Karlsruhe, Germany, MARTIN WEIDES, National Institute of Standards and Technology, Boulder, CO 80309-044, USA — We propose a sequence of pulses intended to preserve the state of a qubit in the presence of strong, coherent coupling to another quantum system. The sequence can be understood as a generalized SWAP and works in formal analogy to the well-known spin echo. Since the resulting decoherence rate of the qubits state is strongly influenced by the additional system, this sequence might serve to protect its quantum state. A possible area of application would be in superconducting circuits, where often spurious two-level system interact strongly with the qubits and might thus provide the necessary resource.

10:12AM V29.00012 Circuit quantum electrodynamics with a scanning qubit , WILL SHANKS, DEVIN UNDERWOOD, JAMES RAFTERY, SRIKANTH SRINIVASAN, ANTHONY HOFFMAN, ANDREW HOUCK, Princeton University — We report measurements of the coupling between a superconducting microwave resonator and a transmon qubit fabricated on a separate chip and mounted to a three-dimensional cryogenic translation stage. The qubit-resonator system reached the strong coupling regime with a coupling strength in excess of 80 MHz. We use the translation stage to explore the position dependence of the coupling strength. With a scanning qubit stage, it is possible to measure many qubits in succession and study the statistics of the fabrication process. The system can also be used as a local probe of a large array of microwave cavities and superconducting qubits.

10:24AM V29.00013 Noise and microresonance of critical current in Josephson junction induced by Kondo trap states¹, MOHAMMAD ANSARI, University of Waterloo, FRANK WILHELM, Saarland University — We analyze the impact of trap states in the oxide layer of a superconducting tunnel junctions, on the fluctuation of the Josephson critical current, thus on coherence in superconducting qubits. We use second order perturbation theory which allows to obtain analytical formulae for the interacting bound states and spectral weights, limited to small and intermediate repulsions. Remarkably, it still reproduces the main features of the model as identified from the Numerical Renormalization Group. We present analytical formulations for the subgap bound state energies, the singlet-doublet phase boundary, and the spectral weights. We show that interactions can reverse the supercurrent across the trap. We finally work out the spectrum of junction resonators for qubits in the presence of on-site repulsive electrons and analyze its dependence on microscopic parameters that may be controlled by fabrication.

¹This research was partly funded by IARPA and ODNI

10:36AM V29.00014 Probing coupling mechanism between microscopic two-level system and superconducting qubits¹, YANG YU, ZHENTAO ZHANG, Nanjing University — We propose a scheme to clarify the microscopic nature of Josephson qubits interacting with the two-level systems, coming from microscopic defects located inside insulation layer. We found that the sensitivity of the generally used spectral method in phase qubit is not sufficient to evaluate the exact form of the coupling. On the contrary, our numerical calculation shows that the coupling strength changes remarkably with flux bias for a flux qubit, providing a useful tool to investigate the coupling mechanism between the two-level systems and qubits.

8:00AM V30.00001 Single-donor spin qubits in silicon¹, ANDREA MORELLO, University of New South Wales — The idea of using the spin of a single donor atom in silicon to encode quantum information goes back to the Kane proposal [1] in 1998. We have now resolved the technical challenges involved in the readout and control of the electron and nuclear spin of a single atom. The key breakthrough was the development of a device structure where the donor is tunnel-coupled to the island of an electrostatically-induced single-electron transistor [2]. This device allowed the single-shot readout of the electron spin with visibility $> 90\%$ and $3 \mu\text{s}$ readout time [3]. More recently we have integrated the single-shot readout device with a broadband microwave transmission line to coherently control the electron and nuclear spins. The resonance frequency of the electron is found by monitoring the excess spin-up counts while sweeping the microwave frequency. At any time, one of two possible frequencies is found to be in resonance with the electron spin, depending on the state of the nuclear spin. Alternately probing the two frequencies yields the (quantum nondemolition) single-shot readout of the nucleus, with fidelity $> 99.99\%$. Then we demonstrate the coherent control (Rabi oscillations) of both the electron and the nucleus, both detected in single-shot mode. The π -pulse fidelity is $\sim 70\%$ for the electron and $\sim 99\%$ for the nucleus. Hahn echo and multi-pulse dynamical decoupling sequences allow us to explore the true coherence of the qubits, yielding $T_{2e} \sim 200 \mu\text{s}$ for the electron, and $T_{2n} \sim 60 \text{ ms}$ for the nucleus. These results are fully consistent with the bulk values for donors in a natural Si sample. Further improvements in qubit coherence can be expected by moving to isotopically pure ^{28}Si substrates.

8:36AM V30.00002 Quantum read-out and fast initialization of nuclear spin qubits with electric currents¹, ROGERIO DE SOUSA, NOAH STEMEROFF, University of Victoria, BC — Nuclear spin qubits have the longest coherence times in the solid state, but their quantum read-out and initialization is a great challenge. We present a theory for the interaction of an electric current with the nuclear spins of donor impurities in semiconductors [1]. The theory yields a sensitivity criterion for quantum detection of nuclear spin states using electrically detected magnetic resonance, as well as an all electrical method for fast nuclear spin qubit initialization.

8:48AM V30.00003 Real-time readout and lifetime measurements of single-triplet states in a Si/SiGe double quantum dot, JONATHAN PRANCE, ZHAN SHI, University of Wisconsin-Madison, CHRISTIE SIMMONS, Massachusetts Institute of Technology, DON SAVAGE, MAX LAGALLY, University of Wisconsin-Madison, LARS SCHREIBER, LIEVEN VANDERSYPEN, Kavli Institute of Nanoscience, TU Delft, MARK FRIESEN, ROBERT JOYNT, SUE COPPERSMITH, MARK ERIKSSON, University of Wisconsin-Madison — The singlet and triplet states of a two-electron double quantum dot can be used as the basis for a logical qubit that combines fast gating and robust readout via Pauli spin blockade. We present measurements of the lifetimes of these states in a Si/SiGe double dot at magnetic fields between 1T and 0T [1]. The lifetimes are found by analyzing the statistics of repeated single-shot measurements of the spin state of the system. This technique allows multiple relaxation processes to be observed simultaneously. At zero magnetic field we find that all four spin states have lifetimes of approximately 10ms. With increasing magnetic field the lifetimes of the S and T0 states show no noticeable change, while the lifetime of the T- state rises, reaching 3 seconds at 1T. [1] J. R. Prance, et al., e-print: arxiv.org/abs/1110.6431

9:00AM V30.00004 Calibrated State Tomography in Singlet-Triplet Qubits¹, OLIVER DIAL, MICHAEL SHULMAN, SHANNON HARVEY, HENDRIK BLUHM², Harvard University, VLADIMIR UMANSKY, Weizmann Institute of Science, AMIR YACOBY, Harvard University — Quantitative and accurate state tomography is becoming increasingly necessary in spin qubits to establish gate fidelities, entanglement measures, and optimize the increasingly complex gate sequences needed to perform experiments. In spin-qubits, to perform state tomography single-qubit rotations are used to map different axes of the Bloch sphere to the singlet-triplet axis, followed by projective measurement onto the singlet-triplet axis. Two orthogonal rotations are provided by two physically distinct mechanisms: magnetic field gradients and exchange rotations. The complex interplay between these mechanisms, noise sources, and pulse distortions make it difficult to accurately predict the angle and axis of rotations from first principles, leading to a circular problem: how can one calibrate tomographic rotations without any calibrated tomographic rotations? We describe and demonstrate a method which, using minimal assumptions, makes it possible to detect and correct for both axis errors in tomography and losses during the rotations associated with state tomography. This allows state tomography with unprecedented precision in these systems.

9:12AM V30.00005 Readout and Control Technology for Spin Qubits, JAMES COLLESS, DAVID REILLY, The University of Sydney — Scale-up of spin qubits will require the development of new technological approaches that enable readout and control in multi-qubit device architectures. We report results demonstrating a fast readout method based on quantum capacitance that is well suited to detecting spin-states in qubit geometries beyond two quantum dots. Control protocols and device architectures for the selective rotation of single spins using on-chip transmission lines and ac-magnetic field gradients will be presented.

9:24AM V30.00006 Si/SiGe Quantum Dot Charge Sensing with Radio Frequency Single-Electron Transistor¹, MINGYUN YUAN, ZHEN YANG, A.J. RIMBERG, Dartmouth College, M.A. ERIKSSON, D.E. SAVAGE, University of Wisconsin — We report the operation of a radio frequency superconducting single-electron transistor (rf-SSET) as a charge sensor for single and double Si/SiGe quantum dots (QDs). The charge sensitivity is on the order of 10^{-5} to $10^{-6} e/\sqrt{Hz}$. In the reflectometry set-up, real-time electron tunneling events in a single QD are measured, which demonstrates a fast charge detection time of a few tens of microseconds. The stability diagram of a double QD is mapped out with the averaged reflected power of the rf-SSET. In addition, electron temperature is measured in a dilution refrigerator to be around 150 mK, allowing us to study spin blockade and Kondo effect.

¹This research is supported by the NSA, LPS and ARO.

9:36AM V30.00007 Study of the QPC Back-action to Electron Spin Based Qubits¹, MING XIAO, HAIYOU LI, GANG CAO, GUOPING GUO, GUANGCAN GUO, University of Science and Technology of China, HONGWEN JIANG, University of California at Los Angeles — The electron spin states in quantum dots (QD) are potential for implementing qubits. Quantum point contacts (QPC) are widely used to read-out these spin states. However, any read-out procedure inevitably causes back-action to the measured qubits. In this work we studied the back-action of a QPC to the electron spin states in a single GaAs QD. We found that the non-equilibrium effect in the QPC real-time charge counting statistics is a benchmark of the QPC back-action strength. The back-action driven excitations to higher energy levels contribute extra features which enabled us to study the QD's internal structures. The excitations between the two Zeeman states for odd number of electrons and between the spin singlet-triplet states for even number of electrons are respectively studied. This provides a way to quantitatively evaluate the influence of back-action on Zeeman or singlet-triplet based spin qubits. The dependence of the relaxation time of various spin excited states on the back-action strength was also studied.

9:48AM V30.00008 ABSTRACT WITHDRAWN —

10:00AM V30.00009 Fast charge sensing in InAs nanowire double quantum dot devices¹, MINKYUNG JUNG, MICHAEL SCHROER, KARL PETERSSON, JIRI STEHLIK, JASON PETTA, Princeton University, PRINCETON UNIVERSITY TEAM — Fast and sensitive charge and spin state readout is one of the most important requirements for quantum computing. Radio frequency (rf) reflectometry [1] provides a simple and fast charge detection scheme for charge and spin state readout in double quantum dot (DQD) devices without a separate charge detector [2]. Here, we demonstrate charge sensing measurements in InAs nanowire DQD devices using rf-reflectometry. The source electrode of the nanowire DQD is directly coupled to the tank circuit. We correlate standard dc transport measurements with the tank circuit response. We drive the resonator at its resonant frequency and detect the reflected signal via a cryogenic and room temperature amplifier. Using rf-reflectometry, we can observe charging transitions even when the device is tuned to a regime where current through the device is below the noise floor of the setup. The sensor enables the occupancy of the quantum dot to be probed down to a few electron regime. We present preliminary results of spin state readout using rf-reflectometry.

10:12AM V30.00010 Single charge sensing and transport in double quantum dots fabricated from commercially grown Si/SiGe heterostructures¹, K. WANG, C. PAYETTE, Y. DOVZHENKO, P. KOPPINEN, J.R. PETTA, Princeton University — We perform quantum Hall measurements on three types of commercially available modulation doped Si/SiGe heterostructures [1] to determine their suitability for depletion gate defined quantum dot devices. By adjusting the growth parameters, we are able to achieve two dimensional electron gases with low charge densities and high mobilities. We extract an electron temperature of 100 mK in the single quantum dot regime. Double quantum dots fabricated on these heterostructures show clear evidence of single charge transitions [2] as measured in dc transport and charge sensing.

10:24AM V30.00011 Charge sensing in a silicon MOS double quantum dot¹, M. LILLY, K. NGUYEN, R. YOUNG, E. NIELSEN, N. BISHOP, J. WENDT, R. GRUBBS, T. PLUYM, J. STEVENS, J. DOMINGUEZ, R. MULLER, M. CARROLL, Sandia National Laboratories — We report charge sensing measurements on a double quantum dot fabricated in a silicon / silicon dioxide double top gated structure. Depletion gates are used to laterally define a double quantum dot, and each dot has an adjacent quantum point contact (QPC) electrometer for remote detection of the dot occupation. For charge sensing, two techniques have been employed. In one, the direct conductance of the QPC measured with a low frequency ac voltage bias, and in the other the differential change in QPC conductance is measured as an ac voltage is applied to a dot plunger gate. Simultaneous direct and differential charge sense measurements are performed using an amplitude modulation technique. We characterize the double dot using honeycomb stability diagrams and non-linear transport. Results are compared to detailed modeling of our device structure.

¹Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE

10:36AM V30.00012 Dispersive readout of spin blockade in a carbon nanotube double quantum dot, HUGH CHURCHILL, RUBY LAI, CHARLES MARCUS, Harvard University — We probe the charge states of a carbon nanotube double quantum dot by coupling superconducting resonators to the leads and a gate of a device designed for operation as a spin-valley qubit. Multiplexed dispersive readout allows rapid reflectometry measurements of the device without the need for dedicated proximal charge sensors. In this way as-grown nanotubes may be used in a bottom-gated geometry to create low-disorder devices that are freely suspended and then insulated using atomic layer deposition. These techniques are demonstrated with measurements in the spin blockade regime. We acknowledge support from IBM, NSF-MWN, NSF-NRI through the INDEX Center, and Harvard University.

10:48AM V30.00013 Relaxation hotspots and fast reset of a single electron spin in a double quantum dot¹, KATJA NOWACK², MOHAMMAD SHAFIEI, Delft University of Technology, CHRISTIAN REICHL, WERNER WEGSCHEIDER, ETH Zurich, LIEVEN VANDERSYPEN, Delft University of Technology — We measure the relaxation time of a single electron spin in a double quantum dot as a function of the energy detuning between the two dots for Zeeman splitting larger than the tunnel coupling. Close to the charge degeneracy point at which the electron delocalizes over both dots we observe two "hot spots" at which relaxation times are enhanced by almost four orders of magnitude. We identify these hot spots to occur at degeneracies of orbital and spin excitations. The spin-orbit and hyperfine interaction in the GaAs host lattice efficiently mix degenerate spin states and in combination with fast orbital relaxation this can lead to a fast pumping of the electron spin to its ground state. The enhanced spin relaxation can be exploited to achieve a fast reset of the electron spin, which might prove useful in the context of spin based quantum information processing.

Session V31 DMP: Focus Session: Topological Insulators: Synthesis & Characterization - ARPES 260

8:00AM V31.00001 Topological Surface States in Ternary Spin-Orbit Insulators: An ARPES Viewpoint¹, MADHAB NEUPANE, S.-Y. XU, Department of Physics, Princeton University, L.A. WRAY, ALS, Lawrence Berkeley National Laboratory & Princeton University, A. PETERSEN, R. SHANKAR, Department of Physics, Princeton University, A. FEDOROV, ALS, Lawrence Berkeley National Laboratory, C. LIU, Department of Physics, Princeton University, Y.S. HOR, Department of Chemistry, Princeton University, J. XIONG, D.-X. QU, Department of Physics, Princeton University, H. LIN, Northeastern University, N.P. ONG, Department of Physics, Princeton University, A. BANSIL, Northeastern University, R.J. CAVA, Department of Chemistry, Princeton University, M.Z. HASAN, Department of Physics, Princeton University — Utilization of topological surface states is expected to lead to new vistas in electronics and fundamental physics. However, most of the known topological insulators either do not feature necessary band structure conditions (location of Dirac point with respect to the bulk band) or lack topological invariants essential for certain class of applications. Using angle-resolved photoemission spectroscopy (ARPES), we discuss the electronic band structure topology of a family of ternary spin-orbit insulators some of which feature functional electronic structure with in-gap Dirac point while others feature novel topological invariants (weak Z2 invariants) in crystalline form. We also present some of our recent results on ternary topological insulators.

¹This work is supported by DOE/BES.

8:12AM V31.00002 Rashba Spin-Splitting Control at the Surface of the Topological Insulator Bi₂Se₃, ZHIHUI ZHU, G. LEVY, B. LUDBROOK, C.N. VEENSTRA, J.A. ROSEN, R. COMIN, D. WONG, P. DOSANJH, Department of Physics and Astronomy, University of British Columbia, Vancouver, BC V6T 1Z1, Canada, A. UBALDINI, Department of Physics, University of Geneva, Switzerland, P. SYERS, N.P. BUTCH, J. PAGLIONE, CNAM, Department of Physics, University of Maryland, College Park, Maryland 20742, USA, I.S. ELFIMOV, A. DAMASCELLI, Department of Physics and Astronomy, Quantum Matter Institute, University of British Columbia, Vancouver, BC V6T 1Z1, Canada — The electronic structure of Bi₂Se₃ is studied by angle-resolved photoemission and density functional theory. We show that the instability of the surface electronic properties, observed even in ultra-high-vacuum conditions, can be overcome via *in situ* potassium deposition. In addition to accurately setting the carrier concentration, new Rashba-like spin-polarized states are induced, with a tunable, reversible, and highly stable spin splitting. *Ab initio* slab calculations reveal that these Rashba states are derived from the 5-quintuple-layer quantum-well states. While the K-induced potential gradient enhances the spin splitting, this may be present on pristine surfaces due to the symmetry breaking of the vacuum-solid interface. Phys.Rev.Lett. 107 186405 (2011)

8:24AM V31.00003 Recent Results on Topological Phase Transition and Texture Inversion in Tunable Topological Insulators¹, SU-YANG XU, YUQI XIA, Princeton University, LEWIS ANDREW WRAY, Lawrence Berkeley National Laboratory, SHUANG JIA, Princeton University, FABIAN MEIER, JAN HUGO DIL, Paul Scherrer Institute, JURG OSTERWALDER, University of Zurich, BARTOSZ SLOMSKI, Paul Scherrer Institute, ARON BANSIL, HSIN LIN, Northeastern University, ROBERT CAVA, M. ZAHID HASAN, Princeton University — The recently discovered three-dimensional or bulk topological insulators are expected to exhibit exotic quantum phenomena. It is believed that a trivial insulator can be twisted into a topological state by modulating the spin-orbit interaction or the crystal lattice, driving the system through a topological quantum phase transition. By directly measuring the topological quantum numbers, we report the observation of a phase transition in a tunable spin-orbit system, BiTi(S_{1-δ}Se_δ)₂, in which the topological state formation is visualized (S.-Y. Xu *et al.*, *Science* (2011)). In the topological state, vortex-like polarization states are observed to exhibit three-dimensional vectorial textures, which collectively feature a chirality transition as the spin momentum-locked electrons on the surface go through the zero carrier density point. Such phase transition and texture inversion can be the physical basis for observing fractional charge ($\pm e/2$) and other fractional topological phenomena. We also present some of our recent results that reveal further novel spin and electronic properties of the system close to the critical point of the topological phase transition.

¹We acknowledge support from DOE/BES.

8:36AM V31.00004 Surface Termination of Cleaved Bi_2Se_3 Investigated by Low Energy Ion Scattering, XIAOXIAO HE, ZHIYONG WANG, JING SHI, JORY YARMOFF, Department of Physics and Astronomy, University of California, Riverside — The 3D Topological Insulator, Bismuth Selenide (Bi_2Se_3), is investigated with low energy ion scattering (LEIS). Se vacancies are believed to be responsible for the metallic behavior in transport, and LEIS is uniquely sensitive to the outermost atomic layer composition. Bi_2Se_3 is comprised of Se-Bi-Se-Bi-Se quintuple layers (QLs). Since the van der Waals bonds between QLs is weaker than the covalent bonds within each QL, it has been assumed that it is Se-terminated when cleaved. This assumption has been used in previous surface studies, such as STM or ARPES, which do not provide the composition of the surface atoms. 3 keV Na^+ ions were scattered from single crystal Bi_2Se_3 cleaved in ultra-high vacuum. At room temperature, the spectra indicate a surface terminated with Bi, rather than Se, although some Se is still present. The samples display a sharp 1×1 LEED pattern, indicative of an ordered material. We conclude that Bi_2Se_3 cleaves between the QLs, but that the surface Se quickly desorbs, likely as Se_2 or Se_4 . To test this, the Se:Bi ratio was monitored by LEIS after a sample was cleaved at liquid nitrogen temperature. It was found that the ratio starts out high, but decreases over the course of hours until it reaches the same value as that of a room temperature cleave.

8:48AM V31.00005 Electronic Structure of Clean and Adsorbate-Covered Bi_2Se_3 , RICHARD HATCH, MARCO BIANCHI, TILO PLANKE, Department of Physics and Astronomy, Interdisciplinary Nanoscience Center, Aarhus University, JIANLI MI, BO BRUMMER-STEDT IVERSEN, Center for Materials Crystallography, Department of Chemistry, Interdisciplinary Nanoscience Center, Aarhus University, PHILIP HOFMANN, Department of Physics and Astronomy, Interdisciplinary Nanoscience Center, Aarhus University — The electronic structure of the topological insulator Bi_2Se_3 was probed using angle-resolved photoemission spectroscopy (ARPES). The electronic properties of clean and adsorbate-covered samples were studied for a combination of different bulk dopings and adsorbates. Due to contamination on the surface, the Dirac point of the topological surface states moves to higher binding energies, indicating an increasingly strong downward bending of the bands near the surface. This time-dependent band bending can be accelerated by intentionally exposing the surface to carbon monoxide, alkali atoms and other species. For a sufficiently strong band bending, new spectral features in the energy region of both the valence band and the conduction band are found. These changes are explained by a confinement of the states and the formation of quantum well states. This interpretation is supported by simple calculations of the band bending effects and by photon energy-dependent ARPES measurement that show how the band dispersion in the direction perpendicular to the surface is lost and non-dispersing, sharp states appear within the energy regions of the projected bulk bands. For a strong band bending, the conduction band quantum well states are strongly Rashba split.

9:00AM V31.00006 Sharp Dirac cone at a buried superconductor/topological insulator interface, JUSTIN WAUGH, YUE CAO, QIANG WANG, University of Colorado at Boulder, ALEXEI FEDOROV, Lawrence Berkeley National Laboratory, Z.J. XU, GENDA GU, Brookhaven National Laboratory, DANIEL DESSAU, University of Colorado at Boulder — We have studied the fully buried interface of a topological insulator, Bi_2Se_3 , with the conventional superconductor Nb. We characterized the chemical reactivity at the interface using core level photoemission spectroscopy. Using ARPES we are able to observe the sharp Dirac cone at the buried interface and characterize its details; including energy positions, band dispersion, and electronic scattering rates. All these measurements are carried out over a wide range of coverages, and set the stage for more advanced studies of this interface.

9:12AM V31.00007 Mapping the Orbital Texture of the Topological Insulator Bi_2Se_3 , YUE CAO, JUSTIN WAUGH, SEUNG RYONG PARK, QIANG WANG, THEODORE REBER, University of Colorado at Boulder, SUNG-KWAN MO, Advanced Light Source, Lawrence Berkeley National Laboratory, MATTHEW BRAHLEK, NAMRATA BANSAL, SEONGSHIK OH, Rutgers, the State University of New Jersey, GENDA GU, Brookhaven National Laboratory, DANIEL DESSAU, University of Colorado at Boulder — The orbital texture of the topological insulator Bi_2Se_3 was observed with ARPES using linearly polarized light. The topological state features a superposition of all three p orbitals. We compare the measured orbitals to the existing density functional theory calculations in the literature. This illustrates some of the unusual properties of this topological state and helps clarify the origin of the currently conflicting results from the spin resolved ARPES measurements.

9:24AM V31.00008 Spin resolved photoemission on surface doped topological insulator Bi_2Se_3 ¹, ZHIHUI PAN, ELIO VESCOVO, Brookhaven National Laboratory, ALEXEI FEDOROV, Lawrence Berkeley National Laboratory, D. GARDNER, S. CHU, YOUNG S. LEE, Massachusetts Institute of Technology, GENDA GU, TONICA VALLA, Brookhaven National Laboratory — Topological insulators (TI) have attracted much attention because of their exotic properties. Bi_2Se_3 is a model TI with a relative large bulk gap and a simple surface state structure. By depositing various impurities on the surface, we were able to fill the topological surface state and higher lying Rashba splitting surface states. The spin texture of the surface electronic structure was determined in spin resolved photoemission measurement.

9:36AM V31.00009 Controlling the Bulk-surface Spectroscopic Separation in 3D Topological “Metals” Exploiting Hybridization, YI-TING HSU, MARK FISCHER, Cornell University, TAYLOR HUGHES, University of Illinois at Urbana-Champaign, EUN-AH KIM, Cornell University — How to separately probe the surface state in 3D topological insulators (TI) with chemical potential crossing conduction bands, i.e. topological metals, is a key challenge in exploiting the topological nature of surface states. The advent of MBE grown thin films of TI's with varying thickness only adds to the importance of the issue. We study the effects of hybridization in the spirit of Fano model for the low-energy effective four-band model of Bi_2Se_3 on a slab. We find that the apparent bulk-surface spectroscopic separation in the ARPES data on 3D TI can be viewed as a *consequence of hybridization* rather than the evidence for the absence of hybridization. We describe how the separation depends on the film thickness and propose ways to control the separation using strain.

9:48AM V31.00010 Topological insulators in the quaternary chalcogenide compounds and ternary famatinite compounds, Y.J. WANG, H. LIN, Northeastern U. (NU), TANMOY DAS, LANL and NU, M.Z. HASAN, Princeton U., A. BANSIL, NU — We present first-principles calculations to predict several three-dimensional (3D) topological insulators in quaternary chalcogenide compounds of compositions $\text{I}_2\text{-II-IV-VI}_4$ and ternary famatinite compounds of compositions $\text{I}_3\text{-V-VI}_4$. Among the large number of members of these two families, we give examples of naturally occurring compounds that are mainly Cu-based chalcogenides. We show that these materials are candidates for 3D topological insulators or can be tuned to obtain topologically interesting phases by manipulating the atomic number of the various cations and anions. A band inversion can occur at a single point Γ with large inversion strength, in addition to the opening of a bulk bandgap throughout the Brillouin zone. We discuss how the two investigated families of compounds are related to each other by cross-substitution of cations in the underlying tetragonal structure. Work supported by the US DOE.

10:00AM V31.00011 Quasiparticle band structures of $\beta\text{-HgS}$, HgSe , and HgTe , NIELS E. CHRISTENSEN, AXEL SVANE, Aarhus University, Denmark, MANUEL CARDONA, Max Planck Institute FKF, Stuttgart, ATHANASIOS CHANTIS, American Physical Society, MARK VAN SCHILFGAARDE, Arizona State University, Tempe, TAKAO KOTANI, Tottori University, Japan — The electronic structures of mercury chalcogenides in the zinc-blende structure have been calculated by the LDA, GW (one-shot, G_0W_0) and quasi-particle self-consistent GW ($QSGW$) approximations including spin-orbit coupling (SO). The slight tendency to overestimation of the band gaps by $QSGW$ is avoided by using a *hybrid* scheme (20% LDA and 80 % $QSGW$). The results of G_0W_0 depend strongly starting wave functions and are thus quite different from those from $QSGW$. Within $QSGW$ HgS is found to be a semiconductor, with a Γ_6 s-like conduction-band minimum state above the valence-band top Γ_7 and Γ_8 (“negative” SO splitting). HgSe and HgTe have “negative” gaps (inverted band structure). In HgTe the Γ_7 state is below Γ_6 due to the large Te SO splitting, in contrast HgSe where Γ_6 is below Γ_7 .

10:12AM V31.00012 Exceptionally Weak Electron-Phonon Coupling on the Surface of the Topological Insulator Bi₂Se₃ - A Promise for Room Temperature Applications¹, TONICA VALLA, Z.-H. PAN, Brookhaven National Laboratory, A.V. FEDOROV, Lawrence Berkeley National Laboratory, D. GARDNER, Y.S. LEE, S. CHU, Massachusetts Institute of Technology — Gapless surface states on topological insulators are protected from elastic scattering on non-magnetic impurities which makes them promising candidates for low-power electronic applications. However, for wide-spread applications, these states should have to remain coherent at ambient temperatures. Here, we studied temperature dependence of the electronic structure and the scattering rates on the surface of a model topological insulator, Bi₂Se₃, by high resolution angle-resolved photoemission spectroscopy. We found an extremely weak broadening of the topological surface state with temperature and no anomalies in the state's dispersion, indicating exceptionally weak electron-phonon coupling. Our results demonstrate that the topological surface state is protected not only from elastic scattering on impurities, but also from scattering on low-energy phonons, suggesting that topological insulators could serve as a basis for room temperature electronic devices.

10:24AM V31.00013 Persistence of Topological Order and Formation of Quantum Well States in Topological Insulators B₂(Se,Te)₃ under Ambient Conditions¹, CHAOYU CHEN, XINGJIANG ZHOU², Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — We report high resolution angle-resolved photoemission measurements on the surface state of the prototypical topological insulators, Bi₂Se₃, Bi₂Te₃ and Bi₂Se_{0.4}Te_{2.6}, upon exposing to ambient conditions. We find that the topological order persists even when the surface is exposed to air at room temperature. However, the surface state is strongly modified after such an exposure. Particularly, we have observed the formation of two-dimensional quantum well states near the surface of the topological insulators after the exposure which depends sensitively on the original composition, x, in Bi₂Se_{3-x}Te_x. These rich information are crucial in utilizing the surface state and in probing its physical properties under ambient conditions.

SHIMADA, Hiroshima Synchrotron Radiation Center, Hiroshima University, Higashi-Hiroshima, Hiroshima 739-0046, Japan, J.H. HAN, Department of Physics, Sungkyunkwan University, Suwon, Korea, B.K. CHO, School of Physics and Department of materials science and engineering, GIST, Gwangju 500-712, Korea, C. KIM, Institute of Physics and Applied Physics, Yonsei University, Seoul, Korea — We performed angle resolved photoemission (ARPES) studies on Bi₂Te₃ with circularly polarized light. The alignment of OAM is found to have a strong binding energy dependence. OAM close to Dirac point has an ideal chiral structure ($\sin\theta$) without out-of-plane component. As the binding energy decreases, warping effect comes in and circular dichroism along the constant energy contour cannot be explained by a simple $\sin\theta$ function but requires a $\sin 3\theta$ term. When the warping effect becomes even stronger near the Fermi energy, circular dichroism has $\sin 6\theta$ symmetry. Such behavior is found to be compatible with the theoretically predicted spin structure.

10:48AM V31.00015 Three-Dimensional Massive Dirac Fermion in the Bulk Band Structure of Cubic Inverse Perovskite Ca₃PbO, TOSHIKAZE KARIYADO, MASAO OGATA, the University of Tokyo — The band structure of a cubic inverse perovskite Ca₃PbO, which has been proposed as a candidate for a topological insulator, is analyzed by means of the first-principles calculation. It turns out that Ca₃PbO is actually not a topological insulator, but a close observation of the calculated band structure near the Fermi energy reveals that there exist Dirac fermions in the bulk, instead of the surface, band structure. The Dirac fermion in this material is found on the Γ -X line in the momentum space and remarkably exactly at the Fermi energy in the energy space. It should also be noted that the discovered Dirac fermion is three-dimensional and massive with a very small mass of about 10^{-2} of the bare electron mass. The origin of the Dirac fermion in Ca₃PbO and the band structure of the materials related to Ca₃PbO will also be discussed.

Session V32 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides - Interfaces, Layered Materials, and Growth 261

8:00AM V32.00001 Electric-field control of magnetization in Co₄₀Fe₄₀B₂₀/Pb(Mg_{1/3}Nb_{2/3})_{0.7}Ti_{0.3}O₃ structure at room temperature¹, SEN ZHANG, Y.G. ZHAO, Department of Physics, Tsinghua University, Beijing 100084, China, S. RIZWAN, X.F. HAN, Beijing National Laboratory for Condensed Matter Physics, Chinese Academy of Sciences, Beijing 100190, China, J.X. ZHANG, R. RAMESH, Department of Materials Science and Engineering, University of California, Berkeley, California 94720, USA — Electric-field control of magnetization is important for new generation information storage technology with high integration density and low power consumption. A lot of work has been carried out on electric-field control of magnetization in artificial ferromagnetic-ferroelectric (FM-FE) two-phase systems via the piezo-strain effect. Beside strain, electric/elastic domains and phase structure also play important roles in the electric-field control of magnetization, especially in the case of amorphous FM film without magnetocrystalline anisotropy. We report a large magnetoelectric effect in a Co₄₀Fe₄₀B₂₀/Pb(Mg_{1/3}Nb_{2/3})_{0.7}Ti_{0.3}O₃ structure at room temperature. Investigations on the ferroelectric domains, phase structures, magnetic domains and strain with *in situ* electric fields reveal a new mechanism for electric-field control of magnetization. This work provides a new way to realize large magnetoelectric coupling and is significant for applications, especially in the field of CoFeB-based spin valves to achieve electric-controlled magnetic random access memories.

8:12AM V32.00002 Coherently Coupled ZnO and VO₂ Interface studied by Photoluminescence and electrical transport across a phase transition, AMAR SRIVASTAVA, S. SAHA, A. ANNADI, Y.L. ZHAO, K. GOPINADHAN, X. WANG, N. NAOMI, Z.Q. LIU, S. DHAR, NUSNNI-NanoCore, National University of Singapore, Singapore, T.S. HERNG, BAO NINA, Department of Mat. Sci. and Eng, National University of Singapore, Singapore, - ARIANDO, NUSNNI-NanoCore, National University of Singapore, Singapore, JUN DING, Department of Mat. Sci. and Eng, National University of Singapore, Singapore, T. VENKATESAN, NUSNNI-NanoCore, National University of Singapore, Singapore — In this work we report a study of a coherently coupled interface consisting of a ZnO layer grown on top of an oriented VO₂ layer on sapphire by photoluminescence and electrical transport measurements across the VO₂ metal insulator phase transition (MIT). The photoluminescence of the ZnO layer showed a broad hysteresis induced by the phase transition of VO₂ while the width of the electrical hysteresis was narrow and unaffected by the over layer. The enhanced width of the PL hysteresis was due to the formation of defects during the MIT as evidenced by a broad hysteresis in the opposite direction to that of the band edge PL in the defect luminescence. Unlike VO₂ the defects in ZnO did not fully recover across the phase transition. From the defect luminescence data, oxygen interstitials were found to be the predominant defects in ZnO mediated by the strain from the VO₂ phase transition. Such coherently coupled interfaces could be of use in characterizing the stability of a variety of interfaces and also for novel device application.

8:24AM V32.00003 Ferroelectricity and compositional inversion symmetry breaking in PbTiO₃/SrRuO₃ superlattices, S.J. CALLORI, J. GABEL, Department of Physics and Astronomy, Stony Brook University, D. SU, Center for Functional Nanomaterials, Brookhaven National Laboratory, J. SINSHEIMER, M.V. FERNANDEZ-SERRA, M. DAWBER, Department of Physics and Astronomy, Stony Brook University — Most work to date on artificially layered ferroelectric superlattices has utilized the insulating titanium perovskite oxides (e.g. PbTiO₃, BaTiO₃, CaTiO₃ and SrTiO₃) as “building blocks,” from which a layered structure is assembled by sequential deposition. However, the need for new functionalities, particularly related to magnetism, demands that we expand this set. The much-studied compound SrRuO₃ provides the proof of concept that metallic magnetic oxides can transform into thin-film dielectric components in certain heterostructures, in this case PbTiO₃/SrRuO₃ superlattices. Our high quality epitaxial PbTiO₃/SrRuO₃ superlattices, grown by RF magnetron sputtering on SrTiO₃ substrates (with SrRuO₃ bottom electrodes) show both ferroelectricity, and, as they have both A and B site variation, compositional breaking of inversion symmetry. We will present experimental measurements made on this system using x-ray diffraction, transmission electron microscopy, and electrical characterization, which together with first principles density functional theory simulations, demonstrate how, as the constituent layer thicknesses are varied, the metallicity of the superlattice changes and polarization evolves.

8:36AM V32.00004 Interface control of emergent ferroic order in Ruddlesden-Popper Sr_{n+1}Ti_nO_{3n+1}, TURAN BIROL, NICOLE A. BENEDEK, CRAIG J. FENNIE, School of Applied & Engineering Physics, Cornell University — We have discovered from first-principles an unusual polar state in the low n Sr_{n+1}Ti_nO_{3n+1} Ruddlesden-Popper (RP) layered perovskites in which ferroelectricity is nearly degenerate with antiferroelectricity, a relatively rare form of ferroic order. We show that epitaxial strain plays a key role in tuning the “perpendicular coherence length” of the ferroelectric mode, and does not induce ferroelectricity in these low dimensional RP materials as is well known to occur in SrTiO₃. These systems present an opportunity to manipulate the coherence length of a ferroic distortion in a controlled way, without disorder or a free surface. [T. Birol, N. A. Benedek, C. J. Fennie, Physical Review Letters, in press]

8:48AM V32.00005 Use of dimensionality to enhance tunable microwave dielectrics, D.G. SCHLOM, Cornell U., CHE-HUI LEE, R. HAISLMAIER, E. VLAHOS, V. GOPALAN, Pennsylvania State U., T. BIROL, Y. ZHU, L.F. KOURKOUTIS, N. BENEDEK, Y. KIM, J.D. BROCK, D.A. MULLER, C.J. FENNIE, Cornell U., N.D. ORLOFF, J.C. BOOTH, NIST, V. GOIAN, S. KAMBA, ASCR, M.D. BIEGALSKI, ORNL, M. BERNHAGEN, R. UECKER, Leibniz Institute for Crystal Growth, X.X. XI, Temple University, I. TAKEUCHI, U. Maryland — The miniaturization and integration of frequency-agile microwave circuits—*tunable* filters, resonators, phase shifters and more—with microelectronics offers tantalizing device possibilities, yet requires thin films whose dielectric constant at GHz frequencies can be tuned by applying a quasi-static electric field. Appropriate systems, e.g., Ba_xSr_{1-x}TiO₃, have a paraelectric-to-ferroelectric transition just below ambient temperature, providing high tunability. Unfortunately such films suffer significant losses arising from defects. Recognizing that progress is stymied by dielectric loss, we start with a system with exceptionally low loss—Sr_{n+1}Ti_nO_{3n+1} phases—where in-plane crystallographic shear (SrO)₂ faults provide an alternative to point defects for accommodating non-stoichiometry. In this talk we will establish both experimentally and theoretically the emergence of a ferroelectric and highly tunable ground state in biaxially strained Sr_{n+1}Ti_nO_{3n+1} phases with $n \geq 3$ at frequencies up to 40 GHz. With increasing n the (SrO)₂ faults are separated further than the ferroelectric coherence length perpendicular to the in-plane polarization, enabling tunability with a figure of merit at room temperature that rivals all known tunable microwave dielectrics.

9:00AM V32.00006 Ferroelectric-Antiferroelectric Phase Control: Interplay Between Octahedral Tilt, Polarization, and Chemistry at BFO-LSMO Interfaces¹, YOUNG-MIN KIM, Oak Ridge National Laboratory, PU YU, University of California Berkeley, YING-HAO CHU, National Chiao Tung University, STEPHEN PENNYCOOK, SERGEI KALININ, ALBINA BORISEVICH, Oak Ridge National Laboratory — Atomically-defined interfaces between complex oxides offer a paradigm of novel electronic and coupled functionalities. Here, we report the stabilization of the ferroelectric and antiferroelectric phases at the BFO-LSMO interface through termination control and reveal associated atomic-scale mechanisms with the help of aberration-corrected scanning transmission electron microscopy combined with Electron Energy Loss Spectroscopy. The BFO thin film grown on MnO₂-terminated surface of LSMO exhibits stabilized ferroelectric phase at the interface. The interfacial and bulk polarization are antiparallel, giving rise to head to head ferroelectric domain wall mostly parallel to the interface. In comparison, the film grown on (Sr,Li)O-terminated surface of LSMO exhibits antiferroelectric phase in the vicinity of the interface, with associated ferroelectric-antiferroelectric domain wall in the bulk. Details of tilt and polarization behavior, as well as electronic properties at the interfaces including charged domain walls and FE-AFE walls, will be presented. These results imply that the structural parameters such as octahedral tilt and ferroelectricity in BFO can be directly controlled by modifying the interface structure.

¹This research is sponsored by the MSE Division (YMK, SJP, SVK, AYB), Office of BES of the U.S. DOE.

9:12AM V32.00007 Interplay of couplings between antiferrodistortive, ferroelectric, and strain degrees of freedom in monodomain PbTiO₃/SrTiO₃ superlattices¹, PABLO AGUADO-PUENTE, PABLO GARCIA-FERNANDEZ, JAVIER JUNQUERA, DCITIMAC, Universidad de Cantabria, Avda. de los Castros s/n, 39005 Santander, Spain — We report first-principles calculations, within the density functional theory, on the coupling between epitaxial strain, polarization, and oxygen octahedra rotations in monodomain (PbTiO₃)_n/(SrTiO₃)_n superlattices. We show how the interplay between (i) the epitaxial strain and (ii) the electrostatic conditions at the interfaces can be used to control the orientation of the main axis of the system – defined by the direction of the polarization or the rotation axis of the oxygen octahedra. The electrostatic constraints at the interface facilitate the rotation of the polarization and, as a consequence, we predict large piezoelectric responses at epitaxial strains smaller than those that would be required considering only strain effects. In addition, ferroelectric (FE) and antiferrodistortive (AFD) modes are strongly coupled, with different rotation angles in the TiO₆ octahedra as a function of the polarization direction. The magnitude of the rotations cannot be explained by the usual steric arguments alone, and a covalent model is proposed to account for the large polarization-tilting coupling. The energy gain due to the FE-AFD coupling decreases with the periodicity of the superlattice, becoming negligible for $n \geq 3$.

¹Work accepted for publication in Phys. Rev. Lett. Financial support from grants FIS2009-12721-C04-02, and CP-FP 228989-2 OxIDES. Computational resources provided by the Red Española de Supercomputación.

9:24AM V32.00008 Engineered polarization rotation in $\text{PbTiO}_3/\text{CaTiO}_3$ superlattices, JOHN SINSHEIMER, SARA J. CALLORI, YUCEF BENKARA, BENJAMIN BEIN, JON DALEY, Dept of Physics and Astronomy, Stony Brook University, DONG SU, Center for Functional Nanomaterials, Brookhaven National Laboratory, MATTHEW DAWBER, Dept of Physics and Astronomy, Stony Brook University — Large piezoelectric responses, such as those seen in $\text{PbZr}_x\text{Ti}_{1-x}\text{O}_3$ in the vicinity of the compositional morphotropic phase boundary, can occur when the direction of the polarization in a ferroelectric material can rotate. Here we show experimentally that a similar enhancement of the piezoelectric response can be achieved in artificially layered epitaxial superlattices composed of alternating layers of PbTiO_3 and CaTiO_3 deposited on SrTiO_3 substrates by RF magnetron sputtering. The exceptional quality of our samples is demonstrated by x-ray diffraction and transmission electron microscopy. The structural and functional properties of the materials have been measured as a function of relative layer thickness. Electrically measured ferroelectric polarization and dielectric constants corroborate the enhancement of d_{33} we have measured experimentally using piezoforce microscopy. The structural changes, which allow polarization rotation, have been directly measured using grazing incidence in-plane x-ray diffraction (at NSLS X21 and X22C). Finally, the as-grown domain structure has been imaged with piezoforce microscopy, further confirming polarization rotation and explaining the unusual switching dynamics observed in our electrical characterization.

9:36AM V32.00009 In situ studies on ferroelectric BaTiO_3 interface¹, JUNSOO SHIN, VON BRAUN NASCIMENTO, WARD PLUMMER, JIANDI ZHANG, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, ALBINA BORISEVICH, VINCENT MEUNIER, SERGEI KALININ, ARTHUR BADDORF, Oak Ridge National Laboratory, Oak Ridge, TN 37831 — Ferroelectric phase stability in ferroelectric films is critically dependent on the surface and interface phenomena, especially governed by electrostatic depolarization energy. Predictions for the minimum critical film thickness for ferroelectricity have continuously decreased down to few unit cells. We have examined surface/interface atomic structures of ultrathin BaTiO_3 (BTO) films grown on conductive SrRuO_3 (SRO) and Nb-doped SrTiO_3 . The surface structure of BTO/SRO was refined using in-situ Low Energy Electron Diffraction (LEED) I-V, resulting to observation of polar distortion in ultrathin (≥ 4 ML) BTO films. The in-situ Scanning Tunneling Microscopy (STM) has been performed prior and after BTO deposition on SRO. However, the unusual 2×2 reconstruction is observed for 1-2 ML BTO films and bare SRO by STM. The surface reconstruction of SRO bottom electrode is shown to affect the interface of films deposited subsequently which could be reflected in ultrathin film properties. The in-situ LEED I-V structural studies on 1-2 ML BTO interface have been performed without SRO layer, which kept ultrathin BTO films from the preclusion of reconstructed SRO films.

9:48AM V32.00010 Ellipsometric study of SrTiO_3 thin film grown Si(100), YAO TIAN, University of Toronto, CAROLINA ADAMO, Cornell Center of Materials Research, KENNETH BURCH, University of Toronto — Recently, a new method to grow SrTiO_3 thin ferroelectric film directly on Si(100) has been demonstrated by *M. P. Warusawithana, et al.* We use ellipsometry to study the film and a model based on inhomogenous gap to oxide deficiency was made to interpret the data.

10:00AM V32.00011 Valence Fluctuation in Ultrathin $\text{Ti}_{1+x}\text{O}_2$ on Rutile TiO_2 , Q.Y. CHEN¹, P.V. WADEKAR, H.J. HUNAG, S.W. YEH, N.J. HO, National Sun-Yat Sen University, Kaohsiung, Taiwan, H.W. SEO, University of Arkansas, Little Rock, AR, USA, W.K. CHU, Texas Center for Superconductivity, University of Houston, TX, USA — The physical properties of metal oxides (TMO) can change drastically depending on the non-stoichiometry of oxygen, for which rutile TiO_2 single crystals were self-implanted with Ti to acquire a layers of ~ 6 nm populated with extra Ti found in +2, +3, and +4 charge states as revealed by X-ray photoelectron spectroscopy (XPS). The formations of the TiO and Ti_2O_3 crystalline phases were verified by high-resolution transmission electron microscopy (HRTEM). Variable-temperature electrical resistivity measurement suggests the occurrence of charge ordering at low temperatures, where weak localization of the charges take hold, commonly observed in heavily doped semiconductors. The magneto-transport behaviors follow mixed scenario of band conduction and fixed range hopping, albeit with different energy scales and weighting factors demarcated by a transition temperature of MR sign change, a signature of valence fluctuation in which the ordered low-temperature phase would melt into the high-temperature disordered phase, or by condensation in reverse. This work was supported by the National Science Council, the Ministry of Education, Taiwan, the National Science Foundation, and the State of Texas through Texas Center for Superconductivity.

¹Corresponding author, also with Texas Center for Superconductivity, University of Houston, TX, USA

10:12AM V32.00012 Atomic Layer-by-Layer Growth of Homoepitaxial SrTiO_3 Films by Laser MBE, QINGYU LEI, GUOZHEN LIU, KE CHEN, Department of Physics, Temple University, SUILIN SHI, FUQIANG HUANG, CAS Key Laboratory of Materials for Energy Conversion, Shanghai Institute of Ceramics, Chinese Academy of Sciences, XIAOXING XI, Department of Physics, Temple University — Two most effective techniques for oxides film growth are reactive MBE and laser MBE. With alternating monolayer growth, reactive MBE has shown the capacity of stoichiometry control and crystalline perfection in SrTiO_3 films on SrTiO_3 , while most works of laser MBE, using compound targets, often shows non-stoichiometry and lattice defects. In order to control layer-by-layer growth to atomic level, we carried out laser MBE from separate oxide targets, for example, growing SrTiO_3 from SrO and TiO_2 targets, such that the SrO and TiO_2 layers were deposited alternatively one atomic layer at a time. X-ray diffraction spectra showed that the stoichiometric SrTiO_3 film peak overlapped with and was indistinguishable from the SrTiO_3 substrate peak, while the off stoichiometric SrTiO_3 films, either Sr rich or poor, showed lattice expansion. We conclude that laser MBE from separate oxide targets can achieve the same stoichiometry control as reactive MBE.

10:24AM V32.00013 Preparation of Atomically Flat SrTiO_3 Surfaces Using Non-acid Etching and Thermal Annealing Process, JOHN CONNELL, AMBROSE SEO, The University of Kentucky — The growth of epitaxial thin films and heterostructures requires atomically flat surfaces of substrates. So far chemical etching processes by acidic etchant have been widely used for the surface preparation of oxide substrates. Here we show that atomically flat surfaces of single crystalline SrTiO_3 substrates of both the (100) and (111) orientations can be prepared using non-acidic etching and thermal annealing techniques. Atomic force microscopy confirms the evolution of the surface of the substrates from rough to a step-terrace structure. Scanning tunneling microscopy shows that SrO segregation on the surface is removed by our etching process. This new technique replaces the use of acidic oxide etchant as the primary method for etching SrTiO_3 substrates.

10:36AM V32.00014 Effect of Mg^{2+} on the structure of amorphous CaCO_3 – A molecular dynamics simulation, HIDEKAZU TOMONO, HIROKI NADA, National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, JAPAN — Molecular dynamics (MD) simulations of amorphous calcium carbonate (ACC) were carried out to investigate the effect of Mg^{2+} ions on the structure of CaCO_3 crystal nucleus formed from ACC. Our systems contained 432 CaCO_3 with several concentrations of MgCO_3 . In this study, our original ion model of Mg^{2+} was developed and combined with Raiteri model of Ca^{2+} and rigid CO_3^{2-} [1]. The simulations indicated that the fraction of vaterite-like ion arrangement was much larger than those of calcite-like and aragonite-like ion arrangements in pure ACC. However, as the Mg^{2+} concentration increased, the fraction of vaterite-like ion arrangements decreased, which suggests that Mg^{2+} ions play as inhibitors of vaterite nucleation. The result explains why calcite or aragonite is preferentially nucleated in the presence of Mg^{2+} , whereas vaterite is nucleated in the absence of them.[1] P. Raiteri, J. D. Gale, D. Quigley, and P. M. Rodger, J. Phys. Chem. C 114, 5997 (2010).

Thursday, March 1, 2012 8:00AM - 10:00AM —

Session V34 DCP: Focus Session: Impact of Ultrafast Lasers V: Applications II 107A

8:00AM V34.00001 Thermalization of photoexcited electrons in bismuth investigated by time-resolved THz spectroscopy and *ab initio* calculations¹, IURII TIMROV, Ecole Polytechnique, LSI, TOBIAS KAMPFRATH, Fachbereich Physik, Freie Universität, JEROME FAURE, NATHALIE VAST, Ecole Polytechnique, LSI, CHRISTIAN AST, Max-Planck-Institut für Festkörperforschung, CHRISTIAN FRISCHKORN, Fritz-Haber-Institut der Max-Planck-Gesellschaft, MARTIN WOLF, Fachbereich Physik, Freie Universität, PAOLA GAVA, LUCA PERFETTI, Ecole Polytechnique, LSI — The charge carrier dynamics of photoexcited bismuth generates a Drude response that evolves in time. In contrast to graphite, the plasma frequency of bismuth displays an initial increase and a subsequent decay. We have performed *ab initio* calculations of bulk bismuth within the density functional theory, and show that the non-monotonic behaviour of the plasma frequency is due to the presence of local minima in the conduction band: most of the photoexcited electrons first accumulate in these local minima, and reach the L point only 0.6 ps after photoexcitation.

¹Support from the ANR (project PNANO ACCATTONE) and from DGA are gratefully acknowledged. Computer time was granted by GENCI (project 2210).

8:12AM V34.00002 Spatio-temporal dynamics of plasmons on a metal cone, ALEJANDRO RODRIGUEZ PEREZ, JOONHEE LEE, SHAWN M. PERDUE, V. ARA APKARIAN, Department of Chemistry, University of California, Irvine — Localized surface plasmons (LSP) and propagating plasmon modes (PPM) field emit at the singularity of the metallic tip apex upon ultrafast optical excitation. Interferometric measurements, using frequency modulation-demodulation techniques, allow the characterization of the time profile of the optical field emission and the space-time profile of the propagating modes. A pump pulse launches a plasmon that oscillates on the cone and coherently interferes with a time-delayed probe pulse which is cross-polarized with respect to the pump. We present a simple model that accurately describes the experimental results. However, the observations of trapped propagating modes, their lifetime, and their polarization are not predicted by current theories, which describe tip-plasmons as strictly transverse magnetic modes.

8:24AM V34.00003 Time-Resolved ARPES Study of Ultrafast Dynamics in Cuprate Superconductor Bi2212¹, JIANQIAO MENG, Condensed Matter and Magnet Science, Materials Physics and Applications Division, Los Alamos National Laboratory, Los Alamos NM, 87545, USA, GEORGI L. DAKOVSKI, SLAC National Accelerator Laboratory, Menlo Park, CA 94025-7015, USA, JIAN-XIN ZHU, Physics of Condensed Matter and Complex Systems, Theoretical Division, Los Alamos National Laboratory, Los Alamos NM, 87545, USA, PETER S. RISEBOROUGH, Department of Physics, Temple University - Philadelphia, PA 19122, USA, GENDA GU, Condensed Matter Physics & Materials Science, Brookhaven National Laboratory, Upton, NY 11973, USA, STEVE M. GILBERTSON, GEORGE RODRIGUEZ, Center for Integrated Nanotechnologies, Materials Physics and Applications Division, Los Alamos National Laboratory, Los Alamos NM, 87545, USA, TOMASZ DURAKIEWICZ, Condensed Matter and Magnet Science, Materials Physics and Applications Division, Los Alamos National Laboratory, Los Alamos NM, 87545, USA — The momentum-dependent ultrafast dynamics in cuprate superconductor Bi2Sr2CaCu2O8 is investigated using ultra high resolution time-resolved angle-resolved photoemission spectroscopy (tr-ARPES). In this talk, we will present our observation and analysis of dynamics of the quasiparticle states in Bi2Sr2CaCu2O8 in nodal and antinodal direction as a function of doping. Work was performed with temporal resolution of 35fs. The consequences of our findings in terms of nodal-antinodal dichotomy will be discussed.

8:36AM V34.00004 SFG and SPR Study of Sodium Dodecyl Sulfate Film Assembly on Positively Charged Surfaces¹, SANGHUN SONG, TOBIAS WEIDNER, NESAC/BIO, Univ. of Washington, MATTHEW WAGNER, The Procter and Gamble Company, DAVID CASTNER, NESAC/BIO, Univ. of Washington, NESAC/BIO TEAM, PROCTER AND GAMBLE COLLABORATION — This study uses sum frequency generation (SFG) vibrational spectroscopy and surface plasmon resonance (SPR) sensing to investigate the structure of sodium dodecyl sulfate (SDS) films formed on positively charged and hydrophilic surfaces. The SPR signals show a good surface coverage suggesting that full monolayer coverage is reached at 1 mM. SFG spectra of SDS adsorbed exhibits well resolved CH₃ peaks and OH peaks. At both 0.2 mM and 1 mM SDS concentration the intensity of both the CH₃ and OH peaks decreased close to background levels. We found that the loss of SFG signal at 0.2 mM occurs at this concentration independent of surface charge density. It is more likely that the loss of signal is related to structural inhomogeneity induced by a striped phase - stand-up phase transition. This is supported by a distinct change of the relative SFG phase between CH₃/OH near 0.2 mM. The second intensity minimum might be related to charge compensation effects. We observed a substrate dependence for the high concentration transition. We also observed distinct SFG signal phase changes for water molecules associated with SDS layers at different SDS solution concentrations indicating that the orientation of bound water changed with SDS surface structure.

¹Procter and Gamble, Univ. of Washington, NTUF, and NNIN-UW

8:48AM V34.00005 Nanoscale sensing with surface-enhanced CARS spectroscopy, DMITRI VORONINE, ALEXANDER SINYUKOV, XIA HUA, GUOWAN ZHANG, WENLONG YANG, KAI WANG, PANKAJ JHA, GEORGE WELCH, ALEXEI SOKOLOV, MARLAN SCULLY, Texas A&M University, College Station, TX 77840 — Time-resolved coherent anti-Stokes Raman scattering (CARS) is extended to the nanoscale regime where nano-molar amounts of molecules may be investigated. We show that spectral resolution of CARS generated by ultrashort laser pulses may be improved by collecting a sequence of time-resolved spectra. This procedure provides additional linewidth information and allows detecting two species of pyridine molecules in a vicinity of aggregated gold nanoparticles. Surface-enhanced CARS (SE-CARS) signals of the adsorbed pyridine monolayer are detected in the presence of a bulk pyridine background CARS signal. Time-resolved SE-CARS signals are stronger than the conventional CARS, and more sensitive to the surface environment which makes them suitable for nano-surface characterization with high molecular specificity. This technique allows measuring the vibrational dephasing time of molecules on nano-surfaces and characterizing the effects of the surface local environment on the ultrafast molecular dynamics. This technique may be applied to a variety of artificial and biological systems and complex molecular mixtures and has a potential for nanophotonic sensing applications.

9:00AM V34.00006 ABSTRACT WITHDRAWN —

9:12AM V34.00007 Time-resolved photocurrent generation in graphene $p-n$ junctions; probing $e-h$ relaxation dynamics near the Fermi level, MATT GRAHAM, SU-FEI SHI, DANIEL RALPH, JIWOONG PARK, PAUL MCEUEN, Kavli Institute at Cornell for Nanoscale Science — In this contribution we probe the relevant timescales associated with photocurrent generation by optically exciting graphene at a $p-n$ junction defined by electrostatic gates. Time-resolution of the optical and electrical response are obtained by simultaneous collection of transient photocurrent and transient absorption using a two-pulse correlation approach with 160 fs resolution. The transient absorption signal decays biexponentially in the $p-n$ junction at 0.26 and 2.2 ps; timescales similar to those recently established for hot electron and hot optical phonon cooling in graphene sheets. By contrast, we find transient photocurrent decay signal is surprisingly slow, with tails extending for 100s of ps. At 10 K, the rate coefficient for transient photocurrent decay is $2.7 \pm 0.6 \text{ ps}^{-1} \text{ nA}^{-1}$, and it increases monotonically tenfold upon warming to room temperature. We attribute the stark difference in the transient photocurrent and absorption kinetics to a photocurrent response that is sensitive to recombination processes that are occurring well below optical excitation energies, near the Fermi level. Combining the measurements, transient photocurrent alongside the well-studied transient absorption allows us to construct a rough timeline of events associated with photocurrent production at a graphene $p-n$ junction.

9:24AM V34.00008 Standoff detection of trace compounds enabled by continuum pulse shaping and coherent Raman scattering, MARSHALL T. BREMER, ORIN YUE, VADIM V. LOZOVY, MARCOS DANTUS, Michigan State University — Raman spectroscopy has long been pursued as means to detect hazards from a safe distance. This approach promises high chemical specificity, but is limited in sensitivity because of the very small Raman cross-section. We recently demonstrated detection of trace quantities using a non-linear counterpart, coherent anti-Stokes Raman scattering (CARS), which offers large signal enhancement over spontaneous Raman due to coherent signal addition. Utilizing a pulse shaper and the bandwidth inherent in a 5fs laser pulse, CARS spectra were acquired from an explosive simulant dissolved within thin polymer films. Further, the pulse shaper offers total control of the non-linear process, including selective excitation of particular vibrational modes, enabling single channel detection and associated opportunities for rapid chemical imaging. We will present standoff chemical images and associated CARS spectra acquired in a standoff configuration, demonstrating the applicability of the new spectroscopy in a realistic environment.

9:36AM V34.00009 Transient Absorption Spectroscopy for the Detection of Multiexciton States in Semiconductor Quantum Dots¹, AMANDA NEUKIRCH, OLEG PREZHDO, University of Rochester — It has been shown that excitations of quantum dots at photon energies well above the band gap can produce a superposition of single exciton (SE) and multiple exciton (ME) states. The resulting electron hole dynamics can then be monitored using transient absorption (TA) spectroscopy. We have modeled the TA signal that can be expected when $\text{Pb}_{68}\text{Se}_{68}$ and $\text{Si}_{29}\text{H}_{24}$ are excited, and subsequently probed with attosecond laser pulses. In the proposed experiment a pump pulse serves to excite the sample. The energy of the probe pulse is chosen such that any detected absorption is attributable to the presence of a ME state. Oscillations in the absorption spectrum indicate the existence of a coherent superposition. The period of the oscillation depends on the energy difference between the superimposed states. We explore how dephasing of this signal is affected by the temperature of the system, as well as the number of states involved. We predict what can and cannot be measured experimentally and propose specific attosecond experimental scenarios.

9:48AM V34.00010 How much information do ultrafast spectra contain? The case for ultrafast quantum process tomography¹, ALAN ASPURU-GUZI, Department of Chemistry and Chemical Biology, Harvard University — In this talk, I will describe the concept of quantum process tomography (QPT). The QPT protocol is a novel way of thinking about ultrafast spectra that allows to design families of experiments for extracting the quantum dynamical map of any system addressable by ultrafast spectroscopy. I will explain how QPT works, and also will describe our progress towards an experimental realization in collaboration with the group of Keith Nelson (MIT).

Session V35 DCP: Focus Session: DFT VII: Time-Dependent Processes I: Driven Systems 107B

8:00AM V35.00001 Towards the ab-initio description of photo-induced processes, E.K.U. GROSS, Max Planck Institute of Microstructure Physics — Excitons are prominent features in the optical spectra of periodic solids and molecular aggregates. Time-dependent density functional theory should, in principle, be able to describe excitonic effects. However, with standard functionals for the exchange-correlation (xc) kernel f_{xc} , such as adiabatic LDA and adiabatic GGA, excitonic features are completely absent. The construction of improved functionals for f_{xc} yielding excitons has a long history. Here we propose a new parameter-free approximation for the xc kernel through an algorithm in which the exact Dyson equation for the response is solved self-consistently with an approximate expression for the kernel in terms of the dielectric function [PRL **107**, 186401 (2011)]. We apply this to the calculation of optical spectra for various small bandgap (Ge, Si, GaAs, AlN, TiO₂, SiC), large bandgap (C, LiF, Ar, Ne) and magnetic (NiO) insulators. The calculated spectra are in very good agreement with experiment for this diverse set of materials, highlighting the universal applicability of the new kernel. These optical spectra are calculated with clamped nuclei. However, in a variety of optical phenomena, the coupling between electronic and nuclear motion plays an important role. Prominent examples are the process of vision and photo-synthesis. Standard approximations such as Ehrenfest dynamics, surface hopping, or nuclear wave-packet dynamics only partially capture the occurring non-adiabatic effects. As a first step towards a full ab-initio treatment of the coupled electron-nuclear system, we deduce an exact factorization of the complete wavefunction into a purely nuclear part and a many-electron wavefunction which parametrically depends on the nuclear configuration. We derive formally exact equations of motion for the nuclear and electronic wavefunction [PRL **105**, 123002 (2010)]. These exact equations lead to a rigorous definition of time-dependent potential energy surfaces as well as time-dependent geometric phases.

8:36AM V35.00002 Exact factorization of the time-dependent electron-nuclear wavefunction: Time-dependent potential energy surface, ALI ABEDI, FEDERICA AGOSTINI, Max-Planck-Institut für Mikrostrukturphysik Weinberg 2, D-06120 Halle, Germany, NEEPA T. MAITRA, Department of Physics and Astronomy, Hunter College and the City University of New York, 695 Park Avenue, New York, New York 10065, USA, E.K.U. GROSS, Max-Planck-Institut für Mikrostrukturphysik Weinberg 2, D-06120 Halle, Germany — We have recently proved an exact decomposition of the electronic and nuclear degrees of freedom (Phys. Rev. Lett. **105** 123002 (2010)) and introduced a set of coupled equations of motion for the electrons and nuclei that describe the evolution of the complete electron-nuclear system. The nuclear equation is particularly appealing being a Schrödinger equation with a time-dependent potential energy surface (TD PES) and a time-dependent vector potential as rigorous concepts, mediating the coupling between the nuclear and the electronic degrees of freedom in a formally exact way. By studying physically different cases, we demonstrate that the TD PES is a powerful tool to investigate molecular processes.

8:48AM V35.00003 Exact factorization of the full electron-nuclear wavefunction: A quantum-classical study, FEDERICA AGOSTINI, ALI ABEDI, EBERHARD GROSS, Max-Planck-Institut für Mikrostrukturphysik — It was recently shown in [1] that the solution of the time-dependent Schrödinger equation for a molecular system can be exactly factorized to an electronic and a nuclear contribution. In [1], the authors derived exact equations of motion for the coupled evolution of the electronic and nuclear wavefunctions, which are a good starting point to develop approximations, systematically. Based on this exact decomposition of the electron and nuclear motion, we present a quantum-classical scheme for the coupled electron-nuclear dynamics. Nuclear degrees of freedom evolve along a classical trajectory, affecting electronic motion and inducing quantum transitions, which in turn alter nuclear dynamics. Applications of the proposed method to model systems will be presented.

9:00AM V35.00004 Time-dependent density functional theory for open quantum systems, DAVID TEMPEL, ALAN ASPURU-GUZI, Harvard University — We present the extension of time-dependent density functional theory (TDDFT) to the realm of open quantum systems (OQS). OQS-TDDFT allows a first principles description of electronic systems undergoing non-unitary dynamics due to coupling with a bath, such as that arising from molecular vibrations, solvent degrees of freedom or photon modes of the electromagnetic field. We first prove extensions of the Runge-Gross and van Leeuwen theorems to OQS-TDDFT, which rigorously establish it as a formally exact theory. We then discuss development of approximate OQS-TDDFT functionals, exact conditions on these functionals, as well as future challenges. Finally, we will discuss the application of OQS-TDDFT in obtaining broadened absorption spectra.

9:12AM V35.00005 Time-Dependent Electron Localization Functions, TDELFS, for Molecular Ionization and Harmonic Generation in Intense Laser Pulses¹, ANDRE D. BANDRAUK, EMMANUEL FOWE PENKA, Université de Sherbrooke — The nonlinear nonperturbative response of N₂, CO₂, OCS, CS₂ are studied numerically by solutions of Kohn-Sham (KS) orbital equations in the presence of few cycle intense $I > 10^{14}$ W/cm², 800nm laser pulses. It is found generally that ionization rates depend on different functionals and ionization also occurs from inner-shell KS orbitals. This is sensitive to laser-molecule orientation as predicted earlier [1]. Ionization rate maxima correspond to the alignment of maximum KS orbital densities with the laser polarization instead of orbital ionization potentials, I_p . These results are corroborated through time analysis of TDELFS where ionization occurs from lone pair or bond regions of the corresponding molecule at various times during the pulses. Time frequency analysis of Harmonic Generation spectra allow for identification of recollision times of ionized electrons with the parent ion.

9:24AM V35.00006 TDDFT for nonlinear phenomena of light-matter interactions, ANGEL RUBIO, NanoBio Spectroscopy Group and ETSF Scientific Development Centre, Faculty of Chemistry University of the Basque Country — Despite the success of linear-response schemes to describe excitations of many electron systems, many physical processes stemming from the interaction of light with matter are nonlinear in nature. In this talk we will address the problems and open questions related to the description of this phenomena with the goal of providing a sound description of laser-induced-population processes within TDDFT. Through the exact solution of a few electron system interacting with a monochromatic laser we highlight some common deficiencies of all adiabatic density functionals within time-dependent density-functional theory to handle photoinduced processes leading to population changes of many-body states. One prototype case is Rabi oscillations between the ground and an excited state when a monochromatic laser with a frequency close to the resonance is applied. All adiabatic functionals are not able to discern between resonant and nonresonant (detuned) Rabi oscillations. Only the inclusion of an appropriate memory dependence can correct the fictitious time-dependence of the resonant frequency. We extend this description to dynamical induced charge transfer processes and many body tunneling. Adiabatic functionals will fail similarly in the description of all processes involving a change in the population of states. We will show our recent advances in deriving a new memory-dependent functional. The description of photo-induced processes in chemistry, physics, and biology and the new field of attosecond electron dynamics and high-intense lasers all demand fundamental functional developments going beyond the adiabatic approximation.

10:00AM V35.00007 Performance of the exact adiabatic density functional to describe Rabi physics, JOHANNA ILDEMAR FUKS, Nano-Bio Spectroscopy group and ETSF Center, Dpto. Física de Materiales, Universidad del País Vasco, Av. Tolosa 72, E-20018 San Sebastian, Spain, NICOLE HELBIG, Forschungszentrum Jülich D-52425 Jülich Germany, HEIKO APPEL, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, D-14195 Berlin, Germany, ILYA TOKATLY¹, ANGEL RUBIO², Nano-Bio Spectroscopy group and ETSF Center, Dpto. Física de Materiales, Universidad del País Vasco, Av. Tolosa 72, E-20018 San Sebastian, Spain — Through the exact solution of few-electron systems interacting with a monochromatic laser we study the performance of adiabatic density functionals within time-dependent density-functional theory (TDDFT) to reproduce Rabi oscillations. The non-linear dynamics of the Kohn-Sham (KS) system shows the characteristic features of detuned Rabi oscillations even if the exact resonant frequency is used. We illustrate this effect by comparing the exact time-dependent many-body solution of a He-atom in one dimension and a few-site Hubbard model with the solution of TDDFT-KS equations for different adiabatic exchange-correlation functionals. Preventing the detuning introduces a new strong condition to be satisfied by approximate new xc-functionals.

10:12AM V35.00008 Curing pathologies of TDDFT with semiclassical electron correlation, PETER ELLIOTT, NEEPA MAITRA, Hunter College, City University of New York — Time-dependent density functional theory (TDDFT) has been identified as a prime candidate for describing the dynamics of atoms and molecules in strong laser fields. It would be especially useful in predicting the highly non-intuitive fields needed in the optimal control problem for photonic reagents. However TDDFT encounters a number of problems when simulating these systems, both in the functional approximation of the exchange and correlation potentials, but also for observables of interest, such as momentum distributions or ionization probabilities. Recently a method to overcome some of these problems was proposed[1], whereby an auxiliary semiclassical dynamics calculation produces a correlation potential, which is then used to drive a density-matrix propagation. This method incorporates memory, initial-state dependence, changing occupation numbers, all of which are known issues for TDDFT. In this talk we build on previous work[2] and examine this scheme for a number of model 1D systems including calculations for strong field dynamics, optimal control, non-sequential ionization, and double excitations [1] A.K. Rajam, I. Raczkowska, and N.T. Maitra, *Phys. Rev. Lett.* **105**, 113002 (2010). [2] P. Elliott and N.T. Maitra, *J. Chem. Phys.* **135**, 104110 (2011).

10:24AM V35.00009 Quantum dynamics integrators in a plane-wave implementation of time-dependent density functional theory, ANDRÉ SCHLEIFE, ALFREDO CORREA, Lawrence Livermore National Laboratory, YOSUKE KANAI, The University of North Carolina at Chapel Hill — In order to develop our understanding of various dynamical phenomena in materials at the electronic-structure level, computational methods based on first-principles theory are indispensable. Such approaches can make significant contributions to improving materials for a wide range of applications reaching from photovoltaic cells to nuclear reactors. Time-dependent density functional theory is an efficient approach for describing the real-time quantum dynamics of electronic systems. However, the numerical integration of the time-dependent Kohn-Sham equations, i.e., including a density-dependent effective Hamiltonian, is highly non-trivial. We studied various integrators for propagating the single-particle wave functions explicitly in time, in order to achieve a highly-scalable implementation based on plane-waves and pseudo-potentials. We show that the fourth-order Runge-Kutta scheme is conditionally stable and accurate within this framework. Moreover, the application of our scheme to a system consisting of several hundreds of electrons unveils its excellent scalability and, hence, its applicability for large-scale simulations.

10:36AM V35.00010 The effect of cusps in time-dependent quantum mechanics¹, ZENGHUI YANG, University of Missouri - Columbia, NEEPA MAITRA, Hunter College of the City University of New York, KIERON BURKE, University of California, Irvine — Spatial cusps in initial wavefunctions can lead to non-analytic behavior in time. We suggest a method for calculating the short-time behavior in such situations. For these cases, the density does not match its Taylor-expansion in time, but the Runge-Gross proof of time-dependent density functional theory still holds, as it requires only the potential to be time-analytic.

10:48AM V35.00011 Demonstration of the Gunnarsson-Lundqvist theorem and Lack of Hohenberg-Kohn Theorem for Excited States, XIAO-YIN PAN, YU-QI LI, BIAO LI, Ningbo University, VIRAH SAHNI, Brooklyn College CUNY — By considering two noninteracting fermions in a 1-D infinite square well we demonstrate the following: (a) The GL theorem is satisfied for the lowest excited triplet state. There exists only one potential for this density so that the HK theorem is satisfied for this lowest excited state configuration. (b) For the second excited triplet state, there exists no other potential with the original orbital configuration that reproduces the density. However, (c) for the second excited triplet state, there exist other potentials with orbital configurations different from the original that reproduce the density. Thus, there is no HK theorem for this and other excited states. The orbitals of the other set of potentials are related to the original orbitals by a rotation. The exact new eigenvalues, and solutions for the potentials and orbitals including near and at the boundaries are provided.

Thursday, March 1, 2012 8:00AM - 11:00AM – Session V36 DCP: General Chemical Physics 107C

8:00AM V36.00001 Measurement of kinetic and potential energy deposition in highly charged ion collisions with surfaces, R.E. LAKE, NIST and Clemson University, J.M. POMEROY, NIST, C.E. SOSOLIK, Clemson University — We measure craters in thin dielectric films formed by highly charged Xe^{Q+} ($26 \leq Q \leq 44$) projectiles [1]. Tunnel junction devices with ion-irradiated barriers were used to amplify the effect of charge-dependent cratering through the exponential dependence of tunneling conductance on barrier thickness. Electrical conductance of a crater $\sigma_c(Q)$ increased by 4 orders of magnitude ($7.9 \times 10^{-4} \mu\text{S}$ to $6.1 \mu\text{S}$) as Q increased, corresponding to crater depths ranging from 2 to 11 Å. By employing a heated spike model, we determine that the energy required to produce the craters spans from 8 to 25 keV over the investigated charge states where kinetic energies were $(8 \times Q)$ keV. We partition crater formation energy into potential and kinetic contributions to find that at least $(27 \pm 2)\%$ of the available ion potential energy is required. Decreasing projectile kinetic energy at constant Q , provides a new test for charge-dependent kinetic energy loss theory.

8:12AM V36.00002 Charge transport in single photochromic molecular junctions, YOUNGSANG KIM, T. PIETSCH, ELKE SCHEER, Department of Physics, University of Konstanz, Germany, T. HELLMUTH, F. PAULY, Institute for Theoretical Solid State Physics, Karlsruhe Institute of Technology, Germany, D. SYSOIEV, T. HUHN, T. EXNER, U. GROTH, U. STEINER, Department of Chemistry, University of Konstanz, Germany, A. ERBE, Helmholtz-Zentrum Dresden Rossendorf, Germany — Recently, photoswitchable molecules, i.e. diarylethene, gained significant interest due to their applicability in data storage media, as optical switches, and in novel logic circuits [1]. Diarylethene-derivative molecules are the most promising candidates to design electronic functional elements, because of their excellent thermal stability, high fatigue resistance, and negligible change upon switching [1]. Here, we present the preferential conductance of specifically designed sulfur-free diarylethene molecules [2] bridging the mechanically controlled break-junctions at low temperatures [3]. The molecular energy levels and electrode couplings are obtained by evaluating the current-voltage characteristics using the single-level model [4]. The charge transport mechanism of different types of diarylethene molecules is investigated, and the results are discussed within the framework of novel theoretical predictions.

8:24AM V36.00003 Length and temperature dependent crossover of charge transport across molecular junctions, YA-LIN LO, Department of Physics, National Taiwan University, SHIH-JYE SUN, Department of Applied Physics, National University of Kaohsiung, YING-JER KAO, Department of Physics, National Taiwan University — We study the electronic transport in a molecular junction, in which each unit is coupled to a local phonon bath, using the non-equilibrium Green's function method. We observe the conductance oscillates with the molecular chain length and the oscillation period in odd-numbered chains depends strongly on the applied bias. This oscillatory behavior is smeared out at the bias voltage near the phonon energy. For the phonon-free case, we find a crossover from tunneling to thermally activated transport as the length of the molecule increases. In the presence of electron-phonon interaction, the transport is thermally driven and a crossover from the thermally suppressed to assisted conduction is observed.

8:36AM V36.00004 Electrical properties of a layered manganese vanadate¹, VICTORIA SOGHOMONIAN, QIFAN YUAN, Virginia Tech, Physics, ELINOR SPENCER, NANCY ROSS, Virginia Tech, Geosciences — We present the electrical characteristics of a layered manganese vanadate. Octahedral Mn and tetrahedral V units form layers that in turn are connected to each other via weakly bonded strontium ions. The Mn sites are also connected to each other through bridging oxygen atoms that are partially protonated, allowing for possible proton conduction in the material. The conductivity is dependent on crystal direction. Variable temperature conductivity measurements, from 160 to 830 K, show semiconducting behavior with average activation energy of 0.35 eV. Around 670 K a dip in the conductivity is observed, correlated with loss of water from the structure inferred from thermogravimetric analysis. Above 760K, an increase in conductivity is observed. Single crystal x-ray analysis is performed on samples heated above 670 K, to probe temperature induced structural changes. Preliminary results show a contraction of one of the unit cell axes corresponding to the loss of the bridging oxygen and the ensuing movement of the two Mn sites closer to each other. Single crystal x-ray investigations of the material under hydrostatic pressure in a DAC are also performed, to probe the influence of structural changes on electronic transport properties.

¹We acknowledge support from NSF DMR-0943971

8:48AM V36.00005 Capturing Ion-Solid Interactions with MOS structures, R. SHYAM, Department of Physics and Astronomy, Clemson University, W.R. HARRELL, J.E. HARRISS, Holcombe Dept. of Electrical and Computer Engineering, Clemson University, C.E. SOSOLIK, Department of Physics and Astronomy, Clemson University — We have fabricated metal-oxide-semiconductor (MOS) devices for a study of implantation rates and damage resulting from low energy ion-solid impacts. Specifically, we seek to capture ion irradiation effects on oxides by exposing as-grown SiO₂ layers (50 nm to 200 nm) to incident beams of alkali ions with energies in the range of 100 eV to 10 keV. The oxide is analyzed post exposure by encapsulating the irradiated region under a top metallic contact or within a finished MOS device. Characterization of the resulting ion-modified MOS device involves the standard techniques of room temperature and bias-dependent capacitance-voltage (C-V) measurements. The C-V results reveal alkali ion-induced changes in the flatband voltage of irradiated devices which can be used to extract both the range and implantation probabilities of the ions. Biased C-V measurements are utilized to confirm the concentration or dosage of ions in the oxide. A triangular voltage sweep (TVS) measurement at elevated temperatures also reveals the total ionic space charge in the oxide and can be used to extract a mobility for the ions as they pass through the damaged oxide. Comparisons of these measurements to standard device models as well as to ion range calculations in the oxide are presented.

9:00AM V36.00006 Self-consistent full counting statistics of inelastic transport, TAE-HO PARK, MICHAEL GALPERIN, University of California at San Diego — The full counting statistics (FCS) of inelastic transport in molecular junctions is considered for the case of weak electron-vibration coupling. We introduce a self-consistent procedure for FCS within the non-equilibrium Green function (NEGF) method, and discuss its importance in two aspects. First, we show that in the case of FCS the self-consistent treatment provides a conserving approximation. Second, we discuss the importance of molecular vibration renormalization for the counting statistics of electron transport. We consider two-level bridge with diagonal and off-diagonal electron-vibration couplings. The latter model is shown to be especially sensitive to renormalization of the vibration. We show that heating the molecular vibration may lead to either an increase or a decrease in current through the junction depending on the strength of electron-vibration coupling in the bridge compared to molecule-contact coupling. We report an appearance of super-Poissonian noise induced by the non-equilibrium vibration at resonance, which is similar to the effect of the avalanche transport previously reported in the literature for a system with a strong electron-vibration interaction.

9:12AM V36.00007 Measurement of the Spectral Distribution of Low Energy Electrons Emitted as a Result of M₃VV Auger Transitions in Cu(100)¹, SUMAN SATYAL, PRASAD JOGLEKAR, KARTHIK SASHTRY, ALEXANDER WEISS, University of Texas at Arlington, STEVEN HULBERT, Brookhaven National Lab, STEVEN HULBERT, BROOKHAVEN NATIONAL LAB COLLABORATION — Auger Photoelectron Coincidence Spectroscopy (APECS) was used to investigate the physics of the Low Energy Tail (LET) region of the Auger spectrum of a Cu(100) sample. A beam of 200eV photons was used to probe the sample. Two Cylindrical Mirror Analyzers (CMAs) were used to select the energy of electrons emitted from the sample. An APECS technique was used to obtain an Auger spectrum with one of the CMAs fixed at the core photoemission peak. The spectrum contains the extrinsic contributions from electrons excited by the M₃VV Auger transition plus a background due to true coincidence between photo-emitted valence band electrons that undergo inelastic scattering and other valence electrons. To remove the extrinsic contribution to the LET of the Auger Spectrum, Coincidence measurements were made with the fixed analyzer set at various energies (150eV, 165eV, 180eV, 190eV and 197eV) between the core and the valence band and obtain an estimate of the background due to the inelastic scattering of the valence band electrons. The extrinsic contribution to the LET was then subtracted to get the final spectrum consisting of the secondary electrons that are intrinsic to the M₃VV Auger transition only.

9:24AM V36.00008 Interaction of Water Layers on Calcite Surfaces¹, RASHID HAMDAN, HAI-PING CHENG, University of Florida — Calcite is a mineral of great interest because its abundance in both geological and biological systems. While the {10 $\bar{1}$ 4} surface largely dominates the calcite morphology, other surfaces consisting of {10 $\bar{1}$ 4} terraces and steps are important for the crystal dissolution or growth in aqueous environment. We use ab-initio calculations to study the interaction of single water molecule and one and two water layers with the flat {10 $\bar{1}$ 4} calcite surface and two step surfaces: {10 $\bar{1}$ 3} and {10 $\bar{1}$ 5} made of {10 $\bar{1}$ 4} terraces offset by one atomic layer along the {10 $\bar{1}$ 1} and the {0001} surface respectively. Preliminary results show that the first layer of water bond strongly to the calcite surface. However, dissociation of the water molecules is not favored on the surface.

¹NSF/DMR grant No. 0804407

9:36AM V36.00009 Tracking Amino Acids in Chiral Quantum Corrals¹, ESMERALDA YITAMBEN, REES RANKIN, ERIN ISKI, JEFFREY GREELEY, Center for Nanoscale Materials, Argonne National Laboratory, RICHARD ROSENBERG, Advanced Photon Source, Argonne National Laboratory, NATHAN GUISSINGER, Center for Nanoscale Materials, Argonne National Laboratory — Engineering molecular superstructures on metals opens great possibilities for the control and exploration of complex nanosystems for technological applications. Of particular interest is the use of chiral molecules, such as alanine, to build self-assembled nanoscale structures for the trapping of the two-dimensional free electron gas of a metal. In the present work, molecules of D- or L-alanine were deposited on Cu(111). Scanning tunneling microscopy, spectroscopy, and density functional theory (DFT) revealed the formation of a uniform network of hexagonal chiral pores of average diameter ~ 1.2 nm. Each pore acts as a quantum corral by confining the two-dimensional electron gas of the Cu(111) surface state. Furthermore, each hexagonal pore acts as nanoscale tracks when excess alanine molecules were trapped at the inner perimeter of the pore, and were observed as rotating spatial states periodically moving between the six vertices of the hexagon. This study demonstrates the engineering of one of the smallest quantum confined structure, and the dynamics of molecular motion within these chiral potentials wells.

9:48AM V36.00010 Influence of ligand and environment substitution on photo-triggered linkage isomerization of photochromic ruthenium sulfoxide complexes¹, KRISTIN SPRINGFELD, VOLKER DIECKMANN, SEBASTIAN EICKE, MIRCO IMLAU, Department of Physics, University of Osnabrueck, Osnabrueck, Germany — The group of ruthenium polypyridine sulfoxides features a pronounced photochromism in the UV/VIS spectral range based on an ultrafast photo-triggered linkage isomerization located at the SO-ligand. This isomerization exhibits a tremendous photosensitivity and a high thermal stability of the two metastable structural isomers. Here, we discuss the characteristic photochromic properties of the compounds in the frame of ligand substitution and the replacement of the dielectric environment. The complex [Ru(bpy)₂(ROSO)]·PF₆ [1] (with OSO: 2-methylsulfinylbenzoate) has been modified with the groups R = H, Bn, BnCl and BnMe [2] and studied in different solvents as well as in polydimethylsiloxane. The analysis is performed by cw-pump-probe technique as a function of temperature and exposure. Our results reveal a selective adjustability of the thermal stability in the compounds, while the photosensitivity and the characteristic absorption spectra remain unchanged. We discuss the impact of sulfoxide compounds with the desired features in view of application in molecular photonic devices.

10:00AM V36.00011 Classical models for electron capture by highly charged ions in the thin film regime, JOSH POMEROY, National Institute of Standards and Technology, RUSSELL LAKE, Clemson University — We present an extension of the classical over the barrier (COB) model[1] for highly charged ions (HCIs) that describes thin dielectric films on metal surfaces, bridging the bulk metal and bulk insulator regimes. Motivated by recent experiments [2,3], we detail the onset of charge transfer between a HCI and metal covered with a dielectric thin film. In this talk, capture distances as a function of C₆₀ film thickness on Au(111) will be presented. For ultrathin films, electron capture begins from filled levels in the metal and the C₆₀ film decreases the potential barrier for charge transfer and increases the critical distance compared to clean Au(111), increasing the time available for above-surface relaxation. This is consistent with the new observation of increasing HCI-induced electron emission yield as a function of film thickness [3]. As film thickness grows and reaches a critical value, the first captured electrons originate from the film at the distance expected for an insulator target.

10:12AM V36.00012 Coupling of Cobalt-Tetraphenylporphyrin Molecules in Copper Nitride Molecular Network, VINICIUS CLAUDIO ZOLDAN, Laboratório de Filmes Finos e Superfícies, Universidade Federal de Santa Catarina, CHUNLEI GAO, Max Planck Institute of Microstructure Physics, Halle, Germany, RICARDO FACCIO, Cryssmat-Lab and Centro NanoMat, Facultad de Química, Universidad de la República, Montevideo, Uruguay, ANDRÉ AVELINO PASA, Laboratório de Filmes Finos e Superfícies, Universidade Federal de Santa Catarina — We have used low temperature scanning tunneling microscopy to study the interaction between individual cobalt-tetraphenylporphyrin molecules and a molecular copper nitride network. We demonstrated that the molecular Cu₃N-Cu(110) network promotes the decoupling of the porphyrin, allowing to visualize the molecular orbitals and vibronic states of the molecule, while keeping a strong coupling of the Co atom in the center of macrocycle with the substrate. The reverse behavior was observed when the molecule was sitting on the Cu(110) metallic surface. First principle calculations confirm the assembled position of the molecule on top of N atoms and the decoupling from the surface.

10:24AM V36.00013 A New Series of Donor-Acceptor Substituted Small Organic Molecules With Large Third Order Molecular Polarizability, MARTEN BEELS, Lehigh University, IVAN BIAGGIO TEAM¹, FRANCOIS DIEDERICH COLLABORATION², MELANIE CHIU COLLABORATION³ — We report on the third-order nonlinear optical properties of a series of new small organic molecules with a non-planar structure. A large third-order molecular polarizability is achieved thanks to a lower excited state energy obtained due to donor-acceptor substitution. We determined the influence of variations in the donor-acceptor substitution pattern and relate them to the nonlinear response by modeling the molecular properties computationally, and by experimentally determining the rotational average of their third-order polarizability by degenerate four-wave mixing. We found that the best molecules are extremely efficient both in relation to their size and to the fundamental quantum limit. These molecules show great potential for applications where the molecules are combined into dense supramolecular solid state assemblies in the form of high optical quality thin films obtained by molecular beam deposition.

10:36AM V36.00014 Organic molecular crystals: materials with competing orders, GIANLUCA GIOVANNETTI, Scuola Internazionale Superiore di Studi Avanzati (SISSA), Via Bonomea 265, 34136 Trieste, Italy, SANJEEV KUMAR, Indian Institute of Science Education and Research Mohali, MGSIPAP Complex, Sector 26, Chandigarh 160 019, India, JEAN-PAUL POUGET, Laboratoire de Physique des Solides, Université Paris Sud, CNRS, UMR 8502, 91405 Orsay, France, MASSIMO CAPONE, Scuola Internazionale Superiore di Studi Avanzati (SISSA), Via Bonomea 265, 34136 Trieste, Italy — The search for multiferroics has become an important research topic in the last few years. Almost all newly discovered multiferroics are transition metal compounds where spin, lattice and charge degrees of freedom are strongly entangled. The possibility of finding organic multiferroics can open up a new area of research where new mechanisms, different from those active in standard transition metal oxide multiferroics, may have a role for the simultaneous occurrence of magnetic and ferroelectric order. By means of ab-initio and model calculations, we show an instability towards multiferroicity in the organic molecular crystal TMTTF₂-PF₆. Coexistence of charge ordering with a structural dimerization results in a ferroelectric phase with the tendency to the dimerization magnetically driven. The Multiferroicity is induced by competing orders: charge distribution and lattice distortions coupled with the magnetic state.

10:48AM V36.00015 Energy Transport in Quantum Systems with Discrete Spectrum¹, GEORGE LEVIN, WESLEY JONES, KAMIL WALCZAK, KIRK YERKES, Air Force Research laboratory, THERMAL MANAGEMENT TEAM — Energy transport in quantum system driven by stochastic perturbations is examined. One of the goals of this study is to determine how the Landauer channels can be defined in a system with discrete energy spectrum. A model describes a particle trapped in a confining potential and subjected to a stochastic perturbation localized off-center of the potential well. The perturbation pumps energy into the system which results in non-zero average energy flux between different regions of the confining potential. The energy flux can be defined in terms of quantum advection modes, where each mode is associated with an off-diagonal element of the density matrix and carries a finite, quantized amount of energy per unit of the probability flux. Statistical correlations between different modes and the net energy flux will be discussed.

Session V37 DCMF: Topological Insulators: Magnetoelectric Effect, Control, and Dynamics

108

8:00AM V37.00001 A thermodynamic measure of the Magento-electric coupling in the 3D topological insulator¹, DORON BERGMAN, GIL REFAEL, California Institute of Technology — We show that the magneto-electric coupling in 3D (strong) topological insulators is related to a second derivative of the bulk magnetization. The formula we derive is the non-linear response analog of the Streda formula for Hall conductivity (P. Streda, J. Phys. C: Solid State Physics, 15, 22 (1982)), which relates the Hall conductivity to the derivative of the magnetization with respect to chemical potential. Our finding allows one to extract the magneto-electric coefficient by measuring the magnetization, while varying the chemical potential and one more perturbing field. Such an experimental setup could circumvent many of the current difficulties with measuring the magneto-electric response in 3D topological insulators. The relation we find also makes transparent the effect of disorder, contained entirely in the density of states, and changing nothing as long as the system is gapped.

¹DLB is supported by the Sherman Fairchild foundation.

8:12AM V37.00002 Magnetoelectric response of a topological surface under the conditions of an imperfect quantum Hall effect¹, ALLAN MACDONALD, DMYTRO PESIN, The University of Texas at Austin, Austin, TX — An effective magnetic monopole is induced by an external charge in a topological insulator, and in an ordinary insulator covered by a graphene sheet or another two-dimensional electron system, when it has a perfect surface quantum Hall effect [X.-L. Qi, R. Li, J. Zang, and S.-C. Zhang, Science **323**, 1184 (2009)]. We discuss the observability of this magnetoelectric response under the realistic conditions of a quantum Hall effect that is imperfect because of finite temperature, disorder, or unintended doping. By generalizing the surface electrodynamics to allow for a finite longitudinal conductivity, we analyze the transient behavior which occurs as the potential from a suddenly introduced external charge is screened. Screening severely limits the experimental time scales on which observation of magnetic-monopole-related phenomena is possible. We estimate the longitudinal conductivity values that are necessary for the monopole to survive for an extended period of time and discuss implications of our findings for other transport properties of the surface.

8:24AM V37.00003 Magnetoelectric effect in topological insulator/magnetic layer nanostructure, YURIY SEMENOV, KI WOOK KIM, North Carolina State University — The topological insulator (TI) surface band structure can be modified by contacting ferromagnetic layers due to the proximity exchange interaction. When the magnetization $\mathbf{M}$ is in the in-plane direction, the proximate exchange interaction results in a shift of the Dirac cone in the momentum space, whereas an energy gap can be generated for out-of-plane orientation culminating the maximum value at perpendicular to plane direction. Such opening of energy gap lowers the valence electron energy that can be only partially compensated by increase of the conduction electron energies depending on chemical potential μ . Such correlation of electronic energy and magnetization direction open up a new way toward the electrical manipulation of $\mathbf{M}$. To quantitative estimation of this effect, we provide the thermodynamic potential calculation of the TI surface electrons interacted with proximate ferromagnetic insulator as a function of $\mathbf{M}$ rotation by angle θ about in-plane axis x . The result can be described as an additive magnetic energy $E = K_{eff}(\mu)\sin^2\theta$ in the form of uniaxial anisotropy, which is induced by interaction with TI surface electrons. In the case of TI Bi_2Se_3 , the numerical estimations predict the $K_{eff}(\mu)$ variation in the range of 1 meV/nm² if μ vary over 100 meV. The possible applications of the effect (memory and logic) are discussed.

8:36AM V37.00004 Magnetoelectric and thermoelectric transport in graphene and helical metal: Effect of applied electric field¹, SUNG-PO CHAO, HUAZHOU WEI, VIVEK AJI, University of California at Riverside — We report on the electrical and thermoelectric transport properties of the surface state of the 3D topological insulator (TI) and graphene in a quantizing magnetic field. An unique feature of these systems is the evolution of the Landau level spectrum as a function of applied in plane electric field. We bench mark out results at small fields by computing conductivity and thermopower within linear response. We find that the universal values of thermopower in the clean limit depend on the gyromagnetic ratio in TIs, providing a clear distinction from graphene. In large electric fields we find an oscillation of conductivity as a function of applied electric field for fixed chemical potential, but not for fixed particle density. Signatures of the Landau level dependence on electric fields are also found in thermopower. These results are suggested as possible probes, in transport measurements of topological surface states.

¹The authors' research is supported by University of California at Riverside under the initial complement for Vivek Aji.

8:48AM V37.00005 Noninvasive Probe of Charge Fractionalization in Quantum Spin-Hall Insulators, ION GARATE, KARYN LE HUR, Yale University — When an electron with well-defined momentum tunnels into a nonchiral Luttinger liquid, it breaks up into two separate wave packets that carry fractional charges and move in opposite directions. Observing this phenomenon has proven difficult, in part due to single-particle and plasmon backscattering caused by measurement probes. In this talk we propose a topological insulator RC circuit that might be ideally suited for detecting fractional charges directly and in a noninvasive fashion.

9:00AM V37.00006 Topological charge pumping effect by the magnetization dynamics on the Surface of Three-Dimensional Topological Insulators, HIROAKI UEDA, AKIHITO TAKEUCHI, GEN TATARA, Tokyo Metropolitan University, TAKEHITO YOKOYAMA, Tokyo Institute of Technology — We discuss a current dynamics on the surface of a 3-dimensional topological insulator induced by magnetization precession of a ferromagnet attached. It is found that the magnetization dynamics generates a direct charge current when the precession axis is within the surface plane. This rectification effect is due to a quantum anomaly (parity anomaly) and is topologically protected. The robustness of the rectification effect against first-varying exchange field is confirmed by the explicit calculation, where we adopt the dimensional regularization to remove the divergence which is inevitable in the study on the electromagnetic response of the Dirac system.

9:12AM V37.00007 ABSTRACT WITHDRAWN —

9:24AM V37.00008 Electric tuning of topological insulator states and their surface scattering, MICHAEL POVOLOTSKYI, TILLMANN KUBIS, GERHARD KLIMECK, Purdue University — Materials that show the topological insulating (TI) properties have been extensively studied both experimentally and theoretically in recent years, but an application of those materials for electronic devices is still a challenge. In this study we explored a possibility to switch electric conductance of a surface TI states in a Bi_2Te_3 thin film. In such films there are two surfaces that have TI states located at them. We have done a theoretical study of the surface states using atomistic description within an empirical tight binding approximation. It was found that applying electric field perpendicular to the surface one can affect spin polarization of the TI states. Analysis of the scattering rates for electrons that occupy TI states close to the Fermi level shows that: a) the surface states are spin polarized under an applied electric field; b) the electron scattering between two surface states depends on whether they occupy the same surface and have parallel spins; c) by varying strength of an applied electric field it is possible to modulate the scattering rate, because at small fields the states are not spin-polarized, while at higher fields the states become spin-polarized, and at very high fields the surface states are significantly coupled to the bulk states.

9:36AM V37.00009 Electrical control of the Kondo effect in a helical edge liquid, ERIK ERIKSSON, ANDERS STRÖM, University of Gothenburg, Sweden, GIRISH SHARMA, Ecole Polytechnique, France, HENRIK JOHANNESSON, University of Gothenburg, Sweden — Magnetic impurities affect the transport properties of the helical edge states of quantum spin Hall insulators by allowing single-electron backscattering. We study such a system in the presence of a Rashba spin-orbit interaction induced by an external electric field, showing that this can be used to control the Kondo temperature, as well as the correction to the electrical conductivity due to the impurity. In particular, the impurity contribution to the dc conductivity can be switched on and off by properly adjusting the strength of the Rashba coupling.

9:48AM V37.00010 Nonlinear spectroscopy of non-Abelian Berry curvature¹, FAN YANG, REN-BAO LIU, Department of Physics, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong, China — We propose a general scheme to measure the Berry curvatures of energy bands in insulators by standard nonlinear optical spectroscopy. Our method employs optical and terahertz lights to produce a signal. A general calculation shows that the third order response of the solid is directly related to the Berry curvatures of the energy bands. In particular, for a time-reversal invariant system, we get a nonzero effect compared with the linear response methods, which provides information about the underlying non-Abelian Berry curvature. For insulators with rotational symmetry, the response is proportional to the Berry curvature flux of the iso-energy surface, which enables people to determine the topological properties of the energy bands explicitly. The method is applied to the eight-band model of III-V compound semiconductors and gives a quantized susceptibility with some global coefficients.

10:00AM V37.00011 The Shockley-model description of the edge states in topological insulators, VICTOR YAKOVENKO, SERGEY PERSHOGUBA, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park, Maryland 20742-4111 — We show that the edge states in topological insulators can be understood based on the well-known Shockley model, a 1D tight-binding model with two atoms per elementary cell connected via alternating tunneling amplitudes. We generalize the model to a 3D Shockley-like model corresponding to the sequence of layers connected via the tunneling amplitudes dependent on the in-plane momentum $\mathbf{p} = (p_x, p_y)$. The Hamiltonian of the model is a 2×2 matrix with the complex off-diagonal matrix element $t(k, \mathbf{p})$ dependent on both $\mathbf{p}$ and the out-of-plane momentum k . The equation $t(k, \mathbf{p}) = 0$ defines vortex lines in the 3D momentum space. We show that the projection of the vortex lines on the 2D momentum space defines a boundary between the regions of $\mathbf{p}$ where the edge states exist or do not exist. The vorticity of the vortex lines determines the crystal sublattice on which the edge states are localized. We illustrate how our approach works for the well-established topological insulator model by Fu, Kane, and Mele. We find that different configurations of the vortex contours are responsible for the topological insulator phases with even or odd numbers of the surface Dirac cones. We discuss how real materials, such as Bi_2Se_3 , can be described by this model.

10:12AM V37.00012 Thermoelectric efficiency of holey topological insulators¹, ARTEM ABANOV, OLEG TRETIKOV, JAIRO SINOVA, Texas A&M University — We study the thermoelectric properties of three-dimensional topological insulators with many holes (or pores) in the bulk. We show that at high density of these holes the thermoelectric figure of merit, ZT , can be large due to the contribution of the conducting surfaces and the suppressed phonon thermal conductivity. The maximum efficiency can be tuned by an induced gap in the surface states dispersion through tunneling or external magnetic fields. The large values of ZT , much higher than unity for reasonable parameters, make this system a strong candidate for applications in heat management of nanodevices, especially at low temperatures.

10:24AM V37.00013 Spin-charge Dynamics On Surface States of Topological Insulators and 2DEG, XIN LIU, JAIRO SINOVA, Department of Physics, Texas A&M University — We study the spin-charge dynamics on the surface of a topological insulator and spin-orbit coupled two dimensional electron gas. A new approach is developed to study the spin-charge dynamics even valid in the very strong spin-orbit coupling regime where the spin splitting energy due to SOIs is at the same order to the Fermi energy. The effects of Coulomb interaction and external field are also considered. We predict the fast oscillation of spin polarization perpendicular and parallel to the surface. Based on our theory, we provide a scheme to measure the transport property of the surface state isolated from the bulk contribution.

10:36AM V37.00014 Ultrastrong coupling cavity QED of the magnetic cyclotron transition in a 2D electron gas: massive versus Dirac fermions, DAVID HAGENMÜLLER, SIMONE DE LIBERATO, CRISTIANO CIUTI, Laboratoire Matériaux et Phénomènes Quantiques, Université Paris Diderot-Paris 7 and CNRS, 75205 Paris Cedex 13, France — We show that the cyclotron transition of a two-dimensional electron gas can be ultrastrongly coupled to a cavity photon mode. The ratio between the vacuum Rabi frequency Ω_0 and the cyclotron frequency ω_0 can be much larger than 1 for large filling factor ν of the Landau levels (the normalized coupling Ω_0/ω_0 scales as $\sqrt{\alpha n_{QW} \nu}$, where α is the fine structure constant and n_{QW} is the number of quantum wells). We present a comprehensive cavity QED theory both for semiconductors with massive electrons[?, ?] and graphene with Dirac fermions[?]. We show the dramatic impact on the quantum ground state and excitation properties, drawing the comparison between the two different types of 2D electron gas.

10:48AM V37.00015 Topological Floquet Spectrum in Three Dimensions via a Two-Photon Resonance , NETANEL LINDNER, DORON BERGMAN, GIL REFAEL, California Institute of Technology, VICTOR GALITSKI, University of Maryland — A recent theoretical work [Nature Phys., 7, 490 (2011)] has demonstrated that external non-equilibrium perturbations may be used to convert a two-dimensional semiconductor, initially in a topologically trivial state, into a Floquet topological insulator. Here, we develop a non-trivial extension of these ideas to three-dimensional systems. In this case, we show that a two-photon resonance may provide the necessary twist needed to transform an initially unremarkable band structure into a topological Floquet spectrum. We provide both an intuitive, geometrical, picture of this phenomenon and also support it by an exact solution of a realistic lattice model that upon irradiation features single topological Dirac modes at the two-dimensional boundary of the system. It is shown that the surface spectrum can be controlled by choosing the polarization and frequency of the driving electromagnetic field. Specific experimental realizations of a three-dimensional Floquet topological insulator are proposed.

Thursday, March 1, 2012 8:00AM - 11:00AM –
Session V40 DBIO DPOLY DCOMP: Focus Session: Single Molecule Biological Physics - Proteins 156A

8:00AM V40.00001 From single molecule to single tubules , CHIN-LIN GUO, California Institute of Technology — Biological systems often make decisions upon conformational changes and assembly of single molecules. *In vivo*, epithelial cells (such as the mammary gland cells) can respond to extracellular matrix (ECM) molecules, type I collagen (COL), and switch their morphology from a lobular lumen (100-200 micron) to a tubular lumen (1mm-1cm). However, how cells make such a morphogenetic decision through interactions with each other and with COL is unclear. Using a temporal control of cell-ECM interaction, we find that epithelial cells, in response to a fine-tuned percentage of type I collagen (COL) in ECM, develop various linear patterns. Remarkably, these patterns allow cells to self-assemble into a tubule of length ~ 1 cm and diameter ~ 400 micron in the liquid phase (i.e., scaffold-free conditions). In contrast with conventional thought, the linear patterns arise through bi-directional transmission of traction force, but not through diffusible biochemical factors secreted by cells. In turn, the transmission of force evokes a long-range (~ 600 micron) intercellular mechanical interaction. A feedback effect is encountered when the mechanical interaction modifies cell positioning and COL alignment. Micro-patterning experiments further reveal that such a feedback is a novel cell-number-dependent, rich-get-richer process, which allows cells to integrate mechanical interactions into long-range (> 1 mm) linear coordination. Our results suggest a mechanism cells can use to form and coordinate long-range tubular patterns, independent of those controlled by diffusible biochemical factors, and provide a new strategy to engineer/regenerate epithelial organs using scaffold-free self-assembly methods.

8:36AM V40.00002 Studying spatial gradients of signaling proteins in mitotic spindles with time-integrated multipoint moment analysis , DOOGIE OH, DANIEL NEEDLEMAN, Harvard University — The organization of the mitotic spindle is orchestrated by the activities of multiple signaling proteins, such as the GTPase Ran. It has been proposed that the Ran pathway produces a cascade of events which gives rise to spatial gradients in the behavior of soluble proteins, which in turn produce spatial gradients in microtubule behaviors important for spindle assembly. Previous experiments have directly demonstrated the existence of gradients around the spindle in the upstream components of the Ran pathway, but it is still unclear if there are significant gradients in the downstream soluble components in this pathway. We recently developed a method, TIMMA, time-integrated multipoint moment analysis, a multipoint form of fluorescence fluctuation spectroscopy capable of quantitatively measuring the concentration, diffusion coefficient, and molecular brightness of soluble proteins throughout live cells. We are using TIMMA to characterize the behaviors of the upstream and downstream components of the Ran pathway in live mitotic cell to test the validity of the Ran gradient model.

8:48AM V40.00003 New chemical kinetics for description of chemical noise in small, heterogeneous biological systems: Beyond the paradigm of the rate constant concept¹ , JAEYOUNG SUNG, Chung-Ang University — We introduce a novel chemical kinetics for quantitative description of chemical fluctuations in a small, heterogeneous biological reaction system. At first, we discuss the recently proposed renewal chemical kinetics, and its application to quantitative interpretation of the randomness in fluctuating enzymatic turnover times of α -galactosidase. From the analysis of the randomness parameter data of the single enzyme reaction, one can extract valuable quantitative information about the enzyme reaction system, beyond the reach of the conventional Michaelis-Menten analysis. Next, we discuss a new universal behavior in the time dependence of the chemical fluctuation of product density for a small, heterogeneous reaction system, which is predicted from an exact analytic study for a general reaction model and confirmed by stochastic simulation results. We also discuss the dependence of the chemical noise on substrate concentrations for a heterogeneous enzyme reaction system, which turns out qualitatively different from that for a homogeneous enzyme reaction system.

¹Nation Research Foundation of Korea

9:00AM V40.00004 Generalized Michaelis-Menten equation for conformation-modulated monomeric enzyme catalysis¹ , JIANLAN WU, Physics Department, Zhejiang University, China, JIANSHU CAO, MIT — The conformational fluctuations induce complex enzymatic catalytic behaviors, which can be investigated by single-molecule experiments. We introduce a kinetic network model to describe conformation-modulated monomeric enzyme catalysis and formulate a generalized Michaelis-Menten (MM) rate equation for non-equilibrium steady-state turnover reactions. Using the flux balance method, we map the original kinetic network to a flux network with unbalanced population currents and derive the general substrate concentration dependence for the average turnover rate of non-equilibrium steady-state enzymatic reactions. In addition to the standard MM term, the generalized MM equation includes non-MM correction terms, which share the same functional form of substrate-dependence. Each non-MM correction term corresponds to a non-equilibrium unbalanced population current induced by conformational fluctuations. Under detailed balance conditions without population currents, non-MM terms vanish and the classical MM equation is recovered. With non-MM terms, the generalized MM equation provides a systematic approach to investigate non-MM behavior and predicts cooperativity, inhibition, and multiple-stability.

9:12AM V40.00005 Conformational-Modulated Enzyme Catalysis: Generalized Michaelis-Menten Equation and Single Molecule Measurements, JIANSHU CAO, Massachusetts Institute of Technology — The Michaelis-Menten (MM) equation is a basic rate equation to describe the substrate-dependence of enzymatic reactions; therefore, it is important to establish the validity of the MM-equation for complex enzymatic reactions and derive the correction terms when the MM equation fails. Indeed, single molecule experiments reveal complex catalytic behaviors induced by conformational dynamics and possible deviations from the MM rate equation. To model such complex catalytic reactions, we construct a generic kinetic network model characterized by multiple intermediates and multiple conformational sub-states and, by solving for the turnover rate of this network, we extend the MM equation into a general form. The generalized MM equation predicts that (i) the MM equation holds under detailed balance and (ii) the correction to the MM expression depends on the unbalanced conformational currents. Using these predictions, we can establish a relationship between the substrate-dependence of the turnover rate and the connectivity of the enzymatic network. To confirm these predictions, we propose several single molecule indicators to test the violations of detailed balance. However, these single molecule indicators may be difficult to resolve from noisy single molecule data. To address these issues, we propose information theory based data analysis methods to process single molecule time series, and apply the Bayesian technique to analyze a single protein fluctuation experiment.

9:48AM V40.00006 Probing short-lived protein ligand interactions with single-molecule force spectroscopy, OZGUR SAHIN, Columbia University, MINGDONG DONG, Interdisciplinary Nanoscience Center, iNano, Aarhus, Denmark — Hydrogen bonding plays an important role in stabilizing biomolecular complexes. Although life time of individual bonds can be extremely short, cooperativity among many interactions increase the overall life time of the complex. To probe short-lived individual interactions, we have employed a recently developed atomic force microscopy technique that can carry out single-molecule force spectroscopy experiments on the microsecond timescale. Our loading-rate dependent measurements provide experimental evidence for an additional energy barrier in the biotin-streptavidin complex. The width of this barrier, estimated from the measurements, is both close to theoretical predictions based on steered molecular dynamics simulations and to the characteristic width of individual hydrogen bonds. We will present our experimental methodology and analysis of the results on biotin-streptavidin complex.

10:00AM V40.00007 Using Surface Curvature to Control the Dimerization of a Surface-Active Protein, MARTIN KURYLOWICZ, MAXIMILIANO GIULIANI, JOHN DUTCHER, University of Guelph — Understanding the influence of surface geometry on adsorbed proteins promises new possibilities in biophysics, such as topographical catalysis, molecular recognition of geometric cues, and modulations of oligomerization or ligand binding. We have created nano-textured hydrophobic surfaces that are stable in buffer by spin coating polystyrene (PS) nanoparticles (NPs) to form patchy NP monolayers on a PS substrate, yielding flat and highly curved areas on the same sample. Moreover, we have separated surface chemistry from texture by floating a 10 nm thick film of monodisperse PS onto the NP-functionalized surface. Using Single Molecule Force Spectroscopy we have compared *in situ* the distribution of detachment lengths for proteins on curved surfaces to that measured on flat surfaces. We have shown that β -Lactoglobulin (β -LG), a surface-active protein which helps to stabilize oil droplets in milk, forms dimers on both flat PS surfaces and surfaces with a radius of curvature of 100 nm, whereas β -LG monomers exist for more highly curved surfaces with radii of curvature of 25 and 40 nm. It is surprising that rather large radii of curvature have such a strong influence on proteins whose radius is only ~ 2 nm. Furthermore, the transition from dimer to monomer with changes in surface curvature offers promising applications for proteins whose function can be modified by their oligomerization state.

10:12AM V40.00008 Ligand Binding Stability and Site Specific Chemical Potentials in the Anisotropic Network Model¹, RAHMI OZISIK, OSMAN BURAK OKAN, Rensselaer Polytechnic Institute, ARAVIND RAMMOHAN, Corning Research Center — Anisotropic network model (ANM) is a quadratic elastic model based on local force balance around each constituent material point. In ANM the potential energy functional is system specific and is built up from the connectivity and spatial distribution of elastic contacts (Atilgan et al., Biophysical J 2001, 80, 505). Because the potential energy functional is readily available in closed form, it becomes possible to derive exact expressions for energetics of the system. Recently, a simple analytical identity has been derived for free energy change associated with bond addition/removal for the Gaussian Network Model (GNM), which is one dimensional analog of ANM (Hamacher, Phys. Rev. E 2011, 84, 016703). In the current work, we generalize this formulation to ANM, and for an arbitrary potential functional which might have an acting force distribution on its constituents. Our formulation gives a complete characterization of site specific chemical potential under an arbitrary time independent force distribution. We correlate the chemical potentials with bond orientational order parameters evaluated at each site. Our results are validated on all-heavy atom networks for 15 ligand bound/unbound protein pairs, and show the decisive role of coordination geometry around each node. We show that local chemical potential is predominantly governed by changes in the bond orientational order.

10:24AM V40.00009 Watching Single Enzymes and Fluorescent Proteins in Action in Solution Using a Microfluidic Trap, RANDALL GOLDSMITH, University of Wisconsin, Madison — Observation of dynamics of single biomolecules over a prolonged time without altering the biomolecule via immobilization is achieved with a specialized microfluidic device. This device, the Anti-Brownian Electrokinetic (ABEL) Trap, uses real-time electrokinetic feedback to cancel Brownian motion of single objects in solution. First, we use the ABEL Trap to study Allophycocyanin (APC), a photosynthetic antenna-protein and popular fluorescent probe. A complex relationship between fluorescence intensity and lifetime is observed, suggesting light-induced conformational changes and radiative and non-radiative rate fluctuations. Second, we apply the ABEL Trap to single molecules of the multi-copper enzyme blue Nitrite Reductase where a fluorescent label reports on the oxidation state of the Type I Copper. Redox cycling is observed and kinetic analysis allows extraction of the microscopic rate constants in the kinetic scheme. Evidence of a substrate-induced shift of the intramolecular electron transfer rate is seen. Taken together, these observations provide windows of unprecedented detail into the dynamics of solution-phase biomolecules.

Thursday, March 1, 2012 8:00AM - 10:48AM —

Session V41 DBIO DPOLY: Focus Session: Physics of Proteins I: Dynamics and Function 156B

8:00AM V41.00001 Two tyrosyl radicals stabilize high oxidation states in cytochrome c oxidase for efficient energy conservation and proton translocation¹, DENIS ROUSSEAU, Albert Einstein College of Medicine — The reaction of hydrogen peroxide (H₂O₂) with oxidized bovine cytochrome c oxidase (bCcO) was studied by electron paramagnetic resonance (EPR) to determine the properties of radical intermediates. Two distinct radicals with widths of 12 and 46 G are directly observed by X-band CW-EPR in the reaction of bCcO with H₂O₂ at pH 6 and pH 8. High-frequency EPR (D-band) provides assignments to tyrosine for both radicals based on well-resolved *g*-tensors. The 46 G wide radical has extensive hyperfine structure and can be fit with parameters consistent with Y129. However, the 12 G wide radical has minimal hyperfine structure and can be fit using parameters unique to the post-translationally modified Y244 in CcO. The results are supported by mixed quantum mechanics and molecular mechanics calculations. This study reports spectroscopic evidence of a radical formed on the modified tyrosine in CcO and resolves the much debated controversy of whether the wide radical seen at low pH in the bovine system is a tyrosine or tryptophan. A model is presented showing how radical formation and migration may play an essential role in proton translocation. This work was done in collaboration with Michelle A. Yu, Tsuyoshi Egawa, Syun-Ru Yeh and Gary J. Gerfen from Albert Einstein College of Medicine; Kyoko Shinzawa-Itoh and Shinya Yoshikawa from the University of Hyogo; and Victor Guallar from the Barcelona Supercomputing Center.

8:36AM V41.00002 Structural and electronic properties of copper-containing nitrite reductase (CuNiR): elucidating the mechanism of nitrite reduction at the T₂Cu center, YAN LI, MIROSLAV HODAK, JERRY BERNHOLC, North Carolina State University — Copper-containing nitrite reductases (CuNiRs) play an important role in catalyzing the reduction of NO₂⁻ to NO during the bacterial denitrification process. Experimental studies have provided the structures of various states of CuNiR in the catalytic reaction, but many important aspects of the initial and intermediate attachments as well as the mechanism of the enzyme function remain unclear. We present a density-functional-theory-based study of the structural and electronic properties of different coordination forms at the T₂Cu center. The nudged elastic band (NEB) method is used to examine the activation energy barriers and to determine the minimum energy pathways (MEP) of the reaction processes. Our results reveal the role of the Asp⁹⁸ residue in the enzymatic function of CuNiR and also address the transformation from the initial O-coordinated binding of NO₂⁻ to the N-coordinated attachment of the NO during the enzymatic reaction.

8:48AM V41.00003 Nanometer Scale Distance Measurements for Biological Systems using Gd³⁺-based Spin Probes at High Magnetic Fields, DEVIN EDWARDS, Department of Physics, University of California, Santa Barbara, DANIELLA GOLDFARB, Department of Chemical Physics, Weizmann Institute of Science, Israel, SONGI HAN, Department of Chemistry, University of California, Santa Barbara, MARK SHERWIN, Department of Physics, University of California, Santa Barbara — Determination of nanometer-scale distances is critical for understanding structure and dynamics of proteins. Electron Paramagnetic Resonance (EPR), primarily below 1 T, is used to complement other structural techniques by quantifying sparse distances up to 8 nm in biomolecules labeled with nitroxide-based radicals. EPR becomes more powerful with increasing magnetic fields and frequencies. At 95 GHz (3.5 T), Gd³⁺ ions have shown clear advantages over nitroxide probes (Potapov, JACS 2010). We show that these advantages are even more dramatic at 240 GHz (8.5 T). The width of Gd³⁺'s central EPR transition narrows with increasing average distance between Gd³⁺ ions out to distances as long as 5 nm. This doubles the distances accessible with nitroxides in continuous wave measurements, which can be carried out above the 200K protein-glass transition and with broad distance distributions. Temperature-dependent measurements of the phase memory times at 8.5 T and low temperatures show distance dependence out to 10 nm. Measurements of Gd³⁺ labeled Proteorhodopsin confirm that phase memory times remain long enough to observe distance dependence in a spin-labeled protein. This work is supported by the National Science Foundation and the Binational Science Foundation.

9:00AM V41.00004 Metal-like transport in proteins: A new paradigm for biological electron transfer¹, NIKHIL MALVANKAR, MADELINE VARGAS, MARK TUOMINEN, DEREK LOVLEY, University of Massachusetts, Amherst — Electron flow in biologically proteins generally occurs via tunneling or hopping and the possibility of electron delocalization has long been discounted. Here we report metal-like transport in protein nanofilaments, pili, of bacteria *Geobacter sulfurreducens* that challenges this long-standing belief [1]. Pili exhibit conductivities comparable to synthetic organic metallic nanostructures. The temperature, magnetic field and gate-voltage dependence of pili conductivity is akin to that of quasi-1D disordered metals, suggesting a metal-insulator transition. Magnetoresistance (MR) data provide evidence for quantum interference and weak localization at room temperature, as well as a temperature and field-induced crossover from negative to positive MR. Furthermore, pili can be doped with protons. Structural studies suggest the possibility of molecular pi stacking in pili, causing electron delocalization. Reducing the disorder increases the metallic nature of pili. These electronically functional proteins are a new class of electrically conductive biological proteins that can be used to generate future generation of inexpensive and environmentally-sustainable nanomaterials and nanoelectronic devices such as transistors and supercapacitors. 9:12AM V41.00005 Behind the Scene Role of Conserved Threonine in Intein Splicing, ALBERT DEARDEN, Rensselaer Polytechnic Institute, BRIAN CALLAHAN, MARLENE BELFORT, University at Albany, SAROJ NAYAK, Rensselaer Polytechnic Institute — Protein splicing is an autocatalytic process where an "intein" self-cleaves from a precursor protein and catalyzes ligation of the flanking fragments. Inteins occur in all domains of life and have myriad uses in biotechnology. While reaction steps of intein splicing are known, mechanistic details remain incomplete. Here, we investigate the possible role of a highly conserved active-site Threonine residue in bringing about the initial step of splicing: peptide bond rearrangement at a conserved Glycine-Cysteine motif. We report that although not part of the active transition state in this reaction, Threonine plays an important role in reducing the energy barrier through charge screening of active residues in the transition state. Interestingly, Threonine-Glycine hydrogen bonding makes sulfur of the attacking Cysteine less nucleophilic, thereby minimizing Coulomb repulsion in the transition state. These non-intuitive results are obtained through a combination of crystal structure, quantum mechanical simulations, and mutagenesis data. Our results further predict that the sluggish reaction rates observed with intein mutants harboring Threonine-Alanine substitutions can be accelerated in the presence of non-aqueous solvents.

9:24AM V41.00006 Coherent Oscillations in Hemoglobin and Myoglobin Ligand Complexes and their Dynamical Connection to Global Protein Motion and Gas Discrimination, JACOB JANTZI, University of Pittsburgh, KRISTINA WOODS, Carnegie Mellon University — THz spectroscopy and Molecular Dynamics (MD) simulations are used to investigate the coherent oscillations in the heme group of two heme proteins (hemoglobin and myoglobin) and the affect of the heme dynamics on the collective fluctuations taking place in the proteins. Preliminary experiments have confirmed that the deoxy state (no gas in the active site) of both proteins do not possess a 40 cm^{-1} mode in their THz spectra. The 40 cm^{-1} mode has been observed in both experimental and theoretical investigations of myoglobin dynamics. The low-frequency mode at 40 cm^{-1} has been hypothesized to be connected with energy transport between the active site and the protein-solvent interface. Once a gas is introduced into the ligand, both proteins contain the 40 cm^{-1} mode in their experimental spectra. But both the shape and intensity of the myoglobin peak differs from that of hemoglobin. Additionally, we observe a number of collective protein fluctuations ($\leq 100 \text{ cm}^{-1}$) that are altered in the myoglobin spectrum but remain unchanged in the hemoglobin spectrum when a gas is introduced into the protein active site. We will present experimental data of both proteins that have been exposed to a number of different gases. The reaction of the protein collective motions in the gas is linked with the difference in the coupling of the coherent oscillations of the heme group with the protein global modes but also with the mechanism of protein relaxation that controls ligand migration.

9:36AM V41.00007 Vibrational Dynamics of Ferric MbCN-A Revisit by Resonance Raman and Vibrational Coherence Spectroscopy¹, WEIQIAO ZENG, YUHAN SUN, ABDELKRIM BENABBAS, PAUL M. CHAMPION, Department of Physics and Center for Interdisciplinary Research on Complex Systems, Northeastern University, Boston, MA 02115 — Ultrafast pump-probe spectroscopy has indicated that there exists a photoproduct state following the excitation of ferric MbCN^{[1][2]}. This excited state decays with a time constant of 3.6 ps^[1]. Previous studies on this system have suggested that in this photoproduct state, the heme is either (i) still six-coordinated but vibrationally hot in the electronic ground state^[1] or (ii) the proximal histidine residue (His93) is transiently dissociated, while CN⁻ is still bound^[2]. Recent resonance Raman measurements on ferric MbCN in static solution yield spectra that are very similar to ferric myoglobin, which has His93 and a water molecule as axial ligands. This indicates that a water molecule replaces CN⁻ in ferric MbCN under continuous laser excitation. Photolysis of CN⁻ from the heme iron is necessary to make this happen, which is not consistent with the above two suggestions. In this presentation we will revisit the dynamics of ferric MbCN with resonance Raman and vibrational coherence spectroscopy and try to explain how a water molecule competes with CN⁻ in binding to the heme under photo excitation^[3]. 9:48AM V41.00008 Effect of DNA binding on geminate CO recombination kinetics in CooA¹, ABDELKRIM BENABBAS, VENUGOPAL KARUNAKARAN, Northeastern University, HWAN YOUN, California State University, THOMAS POULOS, University of California, Irvine, PAUL CHAMPION, Northeastern University — CooA proteins are heme-based CO-sensing transcription factors. Here we study the ultrafast dynamics of geminate CO rebinding to RrCooA. The effects of DNA binding and the truncation of the DNA binding domain on the CO geminate recombination kinetics were investigated. The CO rebinding kinetics in these CooA complexes takes place on ultrafast timescales but remains non-exponential over many decades in time. We show that this non-exponential kinetic response is due to a quenched enthalpic barrier distribution resulting from a distribution of heme geometries that is frozen or slowly evolving on the timescale of CO rebinding. We also show that, upon CO binding, the distal pocket of the heme in RrCooA relaxes to form a very efficient hydrophobic trap for CO. DNA binding further tightens the narrow distal pocket and slightly weakens the iron-proximal histidine bond. Analysis of our data reveals that the uncomplexed and inherently flexible DNA binding domain adds additional structural heterogeneity to the heme doming coordinate. When CooA forms a complex with DNA, the flexibility of the DNA-binding domain decreases and the distribution of the conformations available in the heme domain becomes restricted.

10:00AM V41.00009 Physical control of carrier-mediated ion-transporters by entrainment of their turnover rate¹, WEI CHEN, CLAUSELL MATHIS, ZHIHUI FANG, JASON MAST, KARIM HAMIDI, PATRICK KELLY, University of South Florida, MAX EVE, Massachusetts College of Liberal Arts — In the past, tremendous efforts have been made to physically activate carrier-mediated ion-transporters, such as Na/K pumps. However, the outcome is not significant. Recently, we developed a new technique which can effectively and efficiently control the pumping rate by introducing a concept of an electronic synchrotron accelerator to the biological system. The approach consists of two steps. First, a specially designed oscillating electric field is used to force or synchronize individual pump molecules to run at the same turnover rate and phase as the field oscillation frequency. Then, by gradually changing the field frequency and carefully keeping the pump synchronization we can entrain the pump molecules so that their pumping rate can be progressively modulated, either decelerated or accelerated, following the field frequency to a defined value. Based on theoretical analysis of the underlying mechanisms involved in the technique, computer simulation of the entrainment process, and intensive experimental studies we have realized significant activation of the Na/K pumping rate up to ten-folds quickly in less than ten seconds.

10:12AM V41.00010 Molecular dynamics simulation studies of dielectric response and vibrational energy relaxation in photoactive yellow protein and green fluorescent protein, YAO XU, RAMACHANDRAN GNANASEKARAN, DAVID LEITNER, University of Nevada, Reno — The first step in the photocycle of many proteins involves conformational change of a chromophore or a charge transfer reaction following photoexcitation. To explore the response of the protein and solvent environment to photoexcitation of the chromophore in photoactive yellow protein (PYP) and green fluorescent protein (GFP) we carried out molecular dynamics simulations of the dielectric response and vibrational energy relaxation (VER) from the chromophore to the protein and solvent. In PYP the time scale of the protein response, mainly contributed by Tyr42 and Glu46, to photoexcitation appears prominently between 0.1 and 0.3 picoseconds. The frequency-dependent VER rate also reveals dynamic coupling between the chromophore and residues that hydrogen bond to it. Resonances in the VER rate appear at frequencies comparable to the oscillations observed in recent fluorescence decay studies. In GFP, which undergoes excited state proton transfer about 10 ps following photoexcitation that may be assisted by specific chromophore vibrations, both the protein and water molecules inside the β -barrel surrounding the chromophore mediate the dielectric response.

10:24AM V41.00011 Employing Solution X-Ray Scattering to Investigate Conformational Changes of Proteins, MUSTAFA TEKPINAR, WENJUN ZHENG, Department of Physics, University at Buffalo — Many proteins undergo global conformational changes to perform their functions. Small/Wide Angle Solution X-Ray Scattering (S/WAXS) is an increasingly used experimental technique to probe conformational changes of proteins in aqueous environment. We have developed a new modeling method to reconstruct coarse-grained and atomistic 3D models from S/WAXS data. The method has been applied to a variety of proteins including the R-T transition of hemoglobin.

10:36AM V41.00012 Near-Field Orientation Sensitive Terahertz Micro-Spectroscopy of Single Crystals, GHEORGHE ACBAS, ROHIT SINGH, Department of Physics, University at Buffalo, SUNY, Buffalo, NY, EDWARD SNELL, Department of Structural Biology, SUNY Buffalo, Buffalo, NY and Hauptman-Woodward Medical Research Institute, Buffalo, NY, ANDREA MARKELZ, Department of Physics, University at Buffalo, SUNY, Buffalo, NY — We present spectroscopic imaging studies of molecular crystals. These measurements examine the anisotropy of the intra and inter-molecular vibrational modes of single crystals at terahertz frequencies. The method is based on the technique developed in [1-2] for sub-wavelength resolution time domain terahertz spectroscopy (THz TDS), with added polarization orientation dependent measurements and hydration control. This method allows us to study the spectroscopic properties of small single crystals with sizes down to 20 micrometers. In addition, mapping the spectroscopic information at such small spatial scales allows us to reduce the water absorption and interference artifacts that usually affect protein THz TDS measurements. We show the polarization sensitive terahertz absorption spectra in the (0.3-3THz) range of sucrose, oxalic acid and lysozyme protein crystals.

Thursday, March 1, 2012 8:00AM - 11:00AM – Session V42 DBIO: Focus Session: Systems Biology - Stochastic Gene Expression 156C

8:00AM V42.00001 Mapping the environmental fitness landscape: Lessons from a noisy synthetic gene circuit¹, GABOR BALAZSI, The University of Texas MD Anderson Cancer Center — Gene expression actualizes the organismal phenotypes encoded within the genome in an environment-dependent manner. Among all encoded phenotypes, cell population growth rate (cell population fitness) is perhaps the most important, since it determines how well-adapted a genotype is in various environments. Currently it remains unclear how a cell population's growth rate and its subpopulation fractions in specific environments emerge from the stochastic molecular-level kinetics of gene networks and the division rates of single cells. To address this question we developed and quantitatively characterized synthetic a gene circuit controlling the expression of a bifunctional antibiotic resistance gene in *Saccharomyces cerevisiae*. We found that knowing the cell division rates and nongenetic (cellular) memory of gene expression states were necessary for predicting the overall fitness of cell populations in specific antibiotic- and inducer-containing environments. We validated these predictions experimentally and identified environmental conditions that determined a “sweet spot” of drug resistance.

8:36AM V42.00002 Stochastic description of birth and death processes governed by a mixture of exponential and non-exponential waiting times, STEPHAN EULE, Max Planck Institute for Dynamics and Self-Organization, Goettingen — The dynamics of complex systems is significantly influenced by fluctuations originating from intrinsic as well as extrinsic sources. In general, the discrete nature of individual events, such as the birth and death of an individual in a population or the production and degradation of a molecule in a chemical reaction, is the main source of intrinsic noise. The occurrence of such events is usually modeled by Poissonian statistics, implying that the probability per unit time for an event to happen is assumed to be constant. Many complex systems however exhibit deviations from elementary Poissonian statistics. Such deviations can arise for example in coarse-grained stochastic models of gene expression, where the waiting time distribution can be more general than the simple exponential distribution. In this contribution we consider birth and death processes which are governed by both, exponential as well as non-exponential waiting times. We derive the corresponding master equation and present methods to approach this equation analytically. As an example we consider a reaction where the production of molecules is governed by a non-exponential waiting time distribution and the degradation follows regular Poissonian statistics.

8:48AM V42.00003 Mechanistic basis for transcriptional bursting of ribosomal genes in E. coli, SANDEEP CHOUBEY, Graduate program in Physics, Brandeis University, ALVARO SANCHEZ, Graduate program in Biophysics, Brandeis University, JANE KONDEV, Professor of Physics, Brandeis University — Upon adding more ribosomal genes to the E. coli cell, it adjusts the overall transcription of these genes by reducing the average transcription rate per gene, so as to keep constant the level of ribosomal RNA in the cell. It was observed that this reduction in the average transcription level per gene is accompanied by the generation of transcriptional bursts. The biophysical mechanism responsible for this type of transcriptional control is not yet known. We consider three possible mechanisms suggested in the literature: proximal pausing by RNA polymerase, cooperative recruitment of RNA polymerase by DNA supercoiling, and competition between RNA polymerase and a transcription factor for binding to regulatory DNA. We compute the expected statistical properties of transcription initiation for each one of these models, and compare our predictions with published distributions of distances between the polymerases transcribing the ribosomal genes, obtained from electron micrographs. We use this data to estimate the rates of transcription initiation, which are found to be in good agreement with independent measurements. We also show that the three mechanisms considered here can be discriminated by comparing their predictions for the mean and the variance of interpolymerase distances.

9:00AM V42.00004 Decreasing the stochasticity of mammalian gene expression by a synthetic gene circuit¹, DMITRY NEVOZHAY, Department of Systems Biology, The University of Texas MD Anderson Cancer Center, TOMASZ ZAL, Department of Immunology, The University of Texas MD Anderson Cancer Center, GABOR BALAZSI, Department of Systems Biology, The University of Texas MD Anderson Cancer Center — Gene therapy and functional genetic studies usually require precisely controlled and uniform gene expression in a population of cells for reliable level of protein production. Due to this requirement, stochastic gene expression is perceived as undesirable in these fields and ideally has to be minimized. The number of approaches for decreasing gene expression stochasticity in mammalian cells is limited. This creates an unmet need to develop new gene expression systems for this purpose. Based on earlier synthetic constructs in yeast, we developed and assessed a negative feedback-based mammalian gene circuit, with uniform and low level of stochasticity in gene expression at different levels of induction. In addition, this new synthetic construct enables highly precise gene expression control in mammalian cells, due to the linear dependence of gene expression on the inducer concentration applied to the system. This mammalian gene expression circuit has potential applicability for the development of new treatment modalities in gene therapy and research tools in functional genetics. In addition, this work creates a roadmap for moving synthetic gene circuits from microbes into mammalian cells.

9:12AM V42.00005 Applications of queueing theory to stochastic models of gene expression¹

, RAHUL KULKARNI, Department of Physics, Virginia Tech — The intrinsic stochasticity of cellular processes implies that analysis of fluctuations ('noise') is often essential for quantitative modeling of gene expression. Recent single-cell experiments have carried out such analysis to characterize moments and entire probability distributions for quantities of interest, e.g. mRNA and protein levels across a population of cells. Correspondingly, there is a need to develop general analytical tools for modeling and interpretation of data obtained from such single-cell experiments. One such approach involves the mapping between models of stochastic gene expression and systems analyzed in queueing theory. The talk will provide an overview of this approach and discuss how theorems from queueing theory (e.g. Little's Law) can be used to derive exact results for general stochastic models of gene expression. In the limit that gene expression occurs in bursts, analytical results can be obtained which provide insight into the effects of different regulatory mechanisms on the noise in protein steady-state distributions. In particular, the approach can be used to analyze the effect of post-transcriptional regulation by non-coding RNAs leading to new insights and experimentally testable predictions.

¹Supported by NSF PHY-0957430

9:48AM V42.00006 Cross-talk and interference can enhance information capacity of a signaling pathway

, SAHAND HORMOZ, Kavli Institute for Theoretical Physics, University of California Santa Barbara — A recurring theme in gene regulatory networks is transcription factors (TFs) that regulate each other, and then bind to overlapping sites on DNA, where they interact and synergistically control transcription of a target gene. TF binding is inherently a noisy process due to thermal fluctuations and the small number of molecules involved. A consequence of multiple TFs interacting at the binding site through competition or cooperativity is that their binding noise becomes correlated. Using concepts from information theory, we show that a correlated-noise channel can enhance its capacity if the TFs are no longer independent but regulating each other. Essentially, the frequency of observing each TF at a given concentration is no longer separable, but "entangled." The form of this entanglement elucidates the upstream TF cross-regulation (cross-talk). We demonstrate these ideas using a cartoon model of two TFs competing for the same binding site. Surprisingly, competition can enhance the information transmission rate. We suggest that this mechanism explains the motif of a coherent feed-forward loop terminating in overlapping binding sites commonly found in developmental networks, and discuss specific examples.

10:00AM V42.00007 Exact results for integral thresholds in models of stochastic oscillatory gene expression

, SRIVIDYA IYER BISWAS, NORBERT SCHERER, AARON DINNER, James Franck Institute, University of Chicago — Oscillatory stochastic gene expression is often combined with threshold regulation to ensure periodic occurrence of some cellular activity, such as cell division. In this work we first demonstrate the virtue of implementing such regulation using an integral threshold, rather than a step threshold, in the fluctuating numbers of the regulator. We then develop a general theoretical framework using which we derive a model independent result that relates the stochastic distribution of the time oscillating regulator numbers to the distribution of event (cell division) times, regardless of the underlying mechanism that generates a specific form of oscillations in the regulator copy numbers. We then use this result in conjunction with a simple model of stochastically oscillating gene expression to show how the shape of the division time distribution can be used to make deductions about the underlying stochastic dynamics of the oscillating regulator. Specifically, we show that bimodal division time distributions can occur, even in the absence of any bistability in the underlying model, and connect that observation to general features of the underlying stochastic model. Finally, we discuss connections to ongoing single cell experimental studies of *Caulobacter* cell-cycle division times.

10:12AM V42.00008 Fitness Effects of Network Non-Linearity Induced by Gene Expression Noise¹

, CHRISTIAN RAY, The University of Texas M.D. Anderson Cancer Center, TIM COOPER, University of Houston, GABOR BALAZSI, The University of Texas M.D. Anderson Cancer Center — In the non-equilibrium dynamics of growing microbial cells, metabolic enzymes can create non-linearities in metabolite concentration because of non-linear degradation (utilization): an enzyme can saturate in the process of metabolite utilization. Increasing metabolite production past the saturation point then results in an ultrasensitive metabolite response. If the production rate of a metabolite depends on a second enzyme or other protein-mediated process, uncorrelated gene expression noise can thus cause transient metabolite concentration bursts. Such bursts are physiologically unnecessary and may represent a source of selection against the ultrasensitive switch, especially if the fluctuating metabolic intermediate is toxic. Selection may therefore favor correlated gene expression fluctuations for enzymes in the same pathway, such as by same-operon membership in bacteria. Using a modified experimental *lac* operon system, we are undertaking a combined theoretical-experimental approach to demonstrate that (i) the *lac* operon has an implicit ultrasensitive switch that we predict is avoided by gene expression correlations induced by same-operon membership; (ii) bacterial growth rates are sensitive to crossing the ultrasensitive threshold. Our results suggest that correlations in intrinsic gene expression noise are exploited by evolution to ameliorate the detrimental effects of nonlinearities in metabolite concentrations.

¹Supported by NSF grant BIO IOS 1021675 to TFC & GB.

10:24AM V42.00009 Stochastic Gene Expression in Networks of Post-transcriptional Regulators

, CHARLES BAKER, TAO JIA, HODJAT PENDAR, RAHUL KULKARNI, Virginia Polytechnic Institute and State University — Post-transcriptional regulators, such as small RNAs and microRNAs, are critical elements of diverse cellular pathways. It has been postulated that, in several important cases, the role of these regulators is to modulate the noise in gene expression for the regulated target. Correspondingly, general stochastic models have been developed, and results obtained, for the case in which a single sRNA regulates a single mRNA target. We generalize these results to networks containing a single mRNA regulated by multiple sRNAs and to networks containing multiple mRNAs regulated by a single sRNA. For these systems, we obtain exact expressions relating the mean levels of the sRNAs to the mean levels of the mRNAs. Additionally, we consider the convergence of the original model to an approximate model which considers sRNA concentrations to be high; for the latter model we derive an analytic form for the generating function of the protein distribution. Finally, we discuss potential experimental protocols which, in combination with the derived results, can be used to infer the underlying gene expression parameters.

10:36AM V42.00010 Accurate analytical distributions for stochastic gene expression

, HODJAT PENDAR, Engineering Science and Mechanics Department, Virginia Tech, RAHUL KULKARNI, Department of Physics, Virginia Tech — Gene expression is significantly stochastic process that can give rise to phenotypic heterogeneity across a population of genetically identical cells. Gene expression variability is generally characterized by the mean and variance of associated distributions, however the entire distributions are often not adequately characterized by the first two moments. For stochastic models of gene expression, exact analytic results for protein steady-state distributions have been obtained only for the simplest case. In this talk, we show how to obtain approximate but accurate representations of protein steady-state distributions for a broad class of models of stochastic gene expression. We first present a procedure to obtain analytical solutions in two limiting cases as the ratio of mRNA to protein lifetimes is varied. We then propose a general strategy for constructing an analytical distribution that interpolates these limits while reproducing the exact mean and variance. The corresponding analytical distributions show excellent agreement with results from stochastic simulations throughout parameter space.

10:48AM V42.00011 Stochastic Hopf bifurcation in transcription networks with delayed feedback, JOHN WENTWORTH, Harvey Mudd College, MATHIEU GAUDREAU, McGill University, JORGE VINALS, University of Minnesota — We study the oscillatory instabilities of two model systems that rely on delayed negative feedback to induce oscillation: a single gene auto repressor system, and a dimer negative autoregulation system. We focus on fluctuations of intrinsic origin in the range of low copy number. The bifurcation diagram is obtained for these stochastic models, and shown to differ significantly from that of a macroscopic description that neglects fluctuations. Bifurcation lines remain sharp under fluctuations, but their location is a function of the relative size of the fluctuations. Shifts in the stability threshold of the oscillators can be traced back to the interplay between statistical correlations and delayed feedback. We finally show that there results cannot be captured by weak noise approximations (the diffusion limit), but instead result from strong fluctuations associated with low copy numbers.

Thursday, March 1, 2012 8:00AM - 11:00AM —
Session V43 FEd FGSA: Invited Session: Entrepreneurship - The Quest for Start-Up Success Based on Research Advances 157AB

8:00AM V43.00001 Start-ups for Dummies, LAWRENCE BOCK, USA Science & Engineering Festival — I will present the best practices I have learned from founding, co-founding or seeding the early stage growth of 50 high technology and life sciences companies.

8:36AM V43.00002 Pushing a physics discovery towards commercial impact, ERIC MAZUR, Department of Physics, Harvard University — In 1997 my research group discovered that shining intense, ultrashort laser pulses on the surface of a crystalline silicon wafer drastically changes the optical, material and electronic properties of the wafer. The resulting textured surface is highly absorbing and looks black to the eye, making this 'black silicon' useful for a wide range of commercial devices, from highly-sensitive detectors to improved photovoltaics. Over the following ten years we investigated this material and developed a prototype detector. The prototype gave us the confidence to commercialize black silicon. Together with a graduate student, I founded SiOnyx. The company, based in Beverly, MA, is in the process of manufacturing the first commercial products based on black silicon.

9:12AM V43.00003 How a Venture Capitalist Approaches an Investment Decision, DANIEL COLBERT, Rockport Capital Partners —

9:48AM V43.00004 Having your cake and eating it too; effective engagement in start-ups from an academic seat, CHAD MIRKIN, Northwestern University — In order for scientific advances to have a positive impact on society, they must be successfully transitioned from conceptually fundamental endeavors in academic research laboratories to valuable enabling technologies at start-up companies. Nanosphere, Nanolnk, and AuraSense are three start-up companies that have been spun out of Northwestern based on research initiated in my laboratory. These companies are focused on commercializing nanotechnology-based applications in the life science and semiconductor industries and have turned discoveries from my lab into viable commercial products. For example, several of the systems developed at these start-ups are in the clinical trial phase, with one already approved by the FDA, and they are poised to have a positive world-wide impact. Herein, I discuss the challenges associated with identifying commercial value in academic research projects, securing intellectual property, forming a company as a legal entity, and locating sources of start-up funds. Further, I will discuss the rewards of venturing into such enterprises and the ways of ensuring a start-up company's long-term success, while juggling the numerous responsibilities of an academic seat. I argue that these two activities are done not in competition, but rather are integral for driving the type of high-level, synergistic scientific research that is being done today.

10:24AM V43.00005 An entrepreneurial physics method and its experimental test¹, ROBERT BROWN, Case Western Reserve University — As faculty in a master's program for entrepreneurial physics and in an applied physics PhD program, I have advised upwards of 40 master and doctoral theses in industrial physics. I have been closely involved with four robust start-up manufacturing companies focused on physics high-technology and I have spent 30 years collaborating with industrial physicists on research and development. Thus I am in a position to reflect on many articles and advice columns centered on entrepreneurship. What about the goals, strategies, resources, skills, and the 10,000 hours needed to be an entrepreneur? What about business plans, partners, financing, patents, networking, salesmanship and regulatory affairs? What about learning new technology, how to solve problems and, in fact, learning innovation itself? At this point, I have my own method to propose to physicists in academia for incorporating entrepreneurship into their research lives. With this method, we do not start with a major invention or discovery, or even with a search for one. The method is based on the training we have, and the teaching we do (even quantum electrodynamics!), as physicists. It is based on the networking we build by 1) providing courses of continuing education for people working in industry and 2) through our undergraduate as well as graduate students who have gone on to work in industry. In fact, if we were to be limited to two words to describe the method, they are "former students." Data from local and international medical imaging manufacturing industry are presented.

¹I am grateful for research support from more than a dozen high-tech industrial companies.

Thursday, March 1, 2012 8:00AM - 11:00AM —
Session V44 DPOLY: Focus Session: Interparticle Interactions in Polymer Nanocomposites - Surface Interactions 157C

8:00AM V44.00001 The synthesis of metal nanoparticulate catalysts within functional microgel particles¹, MARIA KALIVA, ELENI PAVLOPOULOU, KONSTANTINOS CHRISTODOULAKIS, MARIA VAMVAKAKI, SPIROS H. ANASTASIADIS, Foundation for Research and Technology-Hellas and Univ. of Crete, Heraklion Crete, Greece — Electrostatically and sterically stabilized polymer microgel particles have been prepared containing either amino (poly(2-(diethylamino)ethyl methacrylate), PDEA) or carboxylic acid (poly(acrylic acid), PAA; poly(methacrylic acid), PMMA) functional groups. The PDEA, PAA and PMAA particles can be used for the incorporation of a large variety of metal nanoparticulate catalysts due to their functional amine and carboxylic acid groups; Pd, Ru and Ni nanoparticles have been synthesized. The more polar PAA microgels were designed as the nanocatalyst carrier system in aqueous reaction media while the less polar PMAA particles were prepared as the metal nanoparticle template for use in catalytic reactions that take place in organic solvents. The sterically and electrostatically stabilized microgel particles possess surface functional groups that can potentially interact with the microchannel walls of microfluidic catalytic reactors.

¹Sponsored by the EU (POLYCAT; CP-IP 246095-2)

8:12AM V44.00002 The role of nanoparticle synergies in modifying the thermal properties of biodegradable polymer blends¹ , KAI YANG, SHAN HE, SUNY-Stony Brook, RACHEL DAVIS², Smithtown High School East, MIRIAM RAFAILOVICH, SUNY-Stony Brook, TAKASHI KASHIWAGI, National Institute of Standards and Technology — Most of thermoplastic polymers are brittle, when sufficient amounts are added to get flame retardant properties. Furthermore, melt-blending starch with other biodegradable polymers is difficult since very few polymers are compatible with starches. We have developed a new nanoparticles where resorcinol diphenyl phosphates (RDP) is used to modify the surface energy, allowing the particles to be dispersed within polymer. When multiple types of particles share the same coating, they can be melt blended simultaneously and synergies can be achieved, imparting properties to the nanocomposite, which cannot be achieved by any single additive. Here we show that RDP modified starch, can be extruded together with the biodegradable polymers, Ecoflex and polylactic acid, to produce flame retardant nanocomposites which can pass the UL-94-V0 test. TEM images of the blend show that the RDP-coated starch particles were well dispersed within the polymer matrix providing the flame retardant properties, while the RDP clays are reducing the interfacial tension and contributing to compatibilization. Nanomechanical measurements of the chars remaining after cone calorimetric measurements indicate that maintaining flexibility of the chars may be an additional factor in achieving good flame retardant properties.

8:24AM V44.00003 ABSTRACT WITHDRAWN —

8:36AM V44.00004 Supramolecular Assembly in a Polymer Nanocomposite , RICK BEYER, AARON JACKSON, SAMUEL PRICE, CHRISTOPHER GOLD, Army Research Laboratory, ANDREW DUNCAN, E. I. du Pont de Nemours and Company — Overcoming the inherent tendency of nanoparticles to aggregate is critical and has typically been the main focus of research on the fabrication of polymer nanocomposites. Developing specific or organized arrangements of nanoparticles is even more technically challenging, but also more appealing due to the possibility of creating nanocomposites with desired optical, electrical, or magnetic properties. Successful approaches in this area often rely on the polymer matrix to organize the nanoparticle additive, but are limited when one considers the high-throughput processing procedures used industrially. In this presentation, the preliminary findings of a research effort to use the strong, reversible, interparticle or intermolecular interactions found in supramolecular assembly to promote synergistic organization of the polymer matrix and dispersion of nanoparticles in a polymer nanocomposite will be described. Here, the effect of incorporating functionalized metal nanoparticles into a supramolecularly assembling metallopolymer based on reversible bonds formed between a metal atom (such as Zn^{2+}) and the “mebip” ligand (2,6-bis(19-methylbenzimidazolyl)pyridine) will be discussed.

8:48AM V44.00005 Stabilizing nanotube films with thin polymer layers: Mitigating van der Waals forces through excluded-volume interactions , MATTHEW R. SEMLER, JOHN M. HARRIS, ERIK K. HOBBIE, North Dakota State University — Thin membranes of single-wall carbon nanotubes (SWCNTs) on elastic polymer substrates show considerable promise for flexible electronics applications, but the modulus and conductivity of these films decrease dramatically in response to applied strains. This softening arises from the strong van der Waals interactions between contacted nanotubes, which favor the parallel coarsening of SWCNT bundles in response to even very small external forces. By capping the SWCNT membranes with a thin layer of glassy polymer, we demonstrate a dramatic improvement in the mechanical response of the strained films. We link this behavior to the stabilizing influence of excluded-volume interactions mediated by the glassy polymer layer.

9:00AM V44.00006 SANS Studies of DNA-Templated Silver Nanoclusters , HONGYU GUO, SUNIL SINHA, University of California, San Diego, JASWINDER SHARMA, JENNIFER MARTINEZ, ANDREW SHREVE, Los Alamos National Laboratory — DNA-templated silver nanoclusters have received significant attention due to their useful properties, including high molar absorptivities, good quantum yields and photostability, and small size. Their potential use may range from biology to nanoscience. For example, they are promising biological fluorescence probes due to their fluorescence properties dependence to DNA template sequence. However, some basic features, like the structure of the DNA/Ag complex, are still unclear. We have conducted Small Angle Neutron Scattering (SANS) experiments to investigate the formation of the Nanoclusters. By comparing the SANS data from conjugated samples, pure DNA and DNA/Ag complex, we can characterize the size and position of the Ag clusters along the DNA strand. The time evolution of the DNA/Ag complex can also be studied since such aging process is kind slow. We found that the formation and aging of the Ag Nanoclusters are also strongly dependent on the DNA template sequence.

9:12AM V44.00007 Theory of the Structure and Miscibility of Soft Filler Polymer Nanocomposites , JIAN YANG, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — A new hybrid theory for soft filler polymer nanocomposites is constructed based on combining integral equation methods and small scale Monte Carlo simulation. The consequences of nanoparticle softness (surface fluctuations) and corrugation (discrete roughness) on the equilibrium behavior is investigated in the dilute filler limit. Under athermal (entropic) conditions, the monomer-particle pair correlations exhibit qualitatively different features relative to hard smooth spheres. Polymer-mediated depletion attractions in the particle potential-of-mean-force (PMF) are qualitatively modified by surface corrugation and/or fluctuations. With increasing particle softness, monomer-scale PMF oscillations are destroyed, and the interparticle separation and effective maximum attraction strength depend sensitively on surface fluctuation amplitude and monomer-nanoparticle size ratio. Second virial coefficient calculations are performed to estimate how particle softness/roughness modifies miscibility, and a mechanism is identified for entropically stabilizing rough nanofillers in the absence of a cohesive interface. Surface corrugation and softness is also found to significantly modify the bridging and sterically stabilized states associated with adsorbing polymers.

9:24AM V44.00008 Self-assembly of Nano-rods in Photosensitive Phase Separation , YA LIU, OLGA KUKSENOK, EGOR MARESOV, ANNA BALAZS, University of Pittsburgh — Computer simulations reveal how photo-induced chemical reactions in polymeric mixtures can be exploited to create long-range order in materials whose features range from the sub-micron to the nanoscale. The process is initiated by shining a spatially uniform light on a photosensitive AB binary blend, which thereby undergoes both a reversible chemical reaction and phase separation. When a well-collimated, higher intensity light is rastered over the sample, the system forms defect-free, spatially periodic structures. We now build on this approach by introducing nanorods that have a preferential affinity for one the phases in a binary mixture. By rastering over the sample with the higher intensity light, we can create ordered arrays of rods within periodically ordered materials in essentially one processing step.

9:36AM V44.00009 Dynamic mechanical properties of hydroxyapatite/polyethylene oxide nanocomposites: characterizing isotropic and post-processing microstructures , MEISHA SHOFNER, JI HOON LEE, Georgia Institute of Technology — Compatible component interfaces in polymer nanocomposites can be used to facilitate a dispersed morphology and improved physical properties as has been shown extensively in experimental results concerning amorphous matrix nanocomposites. In this research, a block copolymer compatibilized interface is employed in a semi-crystalline matrix to prevent large scale nanoparticle clustering and enable microstructure construction with post-processing drawing. The specific materials used are hydroxyapatite nanoparticles coated with a polyethylene oxide-b-polymethacrylic acid block copolymer and a polyethylene oxide matrix. Two particle shapes are used: spherical and needle-shaped. Characterization of the dynamic mechanical properties indicated that the two nanoparticle systems provided similar levels of reinforcement to the matrix. For the needle-shaped nanoparticles, the post-processing step increased matrix crystallinity and changed the thermomechanical reinforcement trends. These results will be used to further refine the post-processing parameters to achieve a nanocomposite microstructure with triangulated arrays of nanoparticles.

9:48AM V44.00010 Thermodynamic Interactions in Polymer Nanocomposites towards Controlled Nanoparticle Dispersion, ALISYN NEDOMA, RAJEEV DATTANI, JOAO CABRAL, Imperial College London, CENTRE FOR PLASTIC ELECTRONICS TEAM — Thermodynamic interactions in polymer/nanoparticle blends can be used to control the dispersion of nanoparticles. Here we introduce the use of polymer blends comprising immiscible A and B homopolymers, an A-B diblock copolymer “surfactant,” and nanoparticles. Upon thermal annealing, the composites self-assemble into equilibrium morphologies with well-dispersed nanoparticles. Polystyrene (PS), polymethyl methacrylate (PMMA), and a PS-PMMA diblock were chosen as the model polymers; C₆₀ fullerene was the model nanoparticle. Blends were prepared for C₆₀ loadings from 0.1 to 2 mass% for blends with symmetric homopolymers and a symmetric diblock copolymer. The molecular weight of the matched homopolymers was varied as 2, 20, and 40 kDa whilst the same 60-60 kDa diblock copolymer was used. Samples were studied using small angle neutron scattering, and the resulting morphologies were found to be lamellar for all C₆₀ loadings. Ongoing work is exploring the effects of polymer asymmetry on the nanostructure of the composites.

10:00AM V44.00011 Effect of competing monomer-monomer and monomer-particle interactions on the assembly of copolymer grafted nanoparticles¹, TYLER MARTIN, ARTHI JAYARAMAN, University of Colorado at Boulder — Functionalizing nanoparticles with copolymer ligands is an attractive method to tailor the assembly of the nanoparticles. In this talk we present simulation results that show the effect of competing monomer-monomer and monomer-particle interactions on assembly of nanoparticles grafted with AB copolymers with diblock or alternating sequence. We vary strengths of like-monomer (A-A and/or B-B) attractive interactions in the presence of strong or negligible monomer A- particle (A-P) attraction or monomer B- particle (B-P) interaction. At a constant particle size and graft length, the competing interactions and copolymer sequence dictate the amount of inter-grafted particle monomer aggregation, inter- and intra-graft monomer aggregation within the same grafted particle. The resulting monomer aggregation on/near the particle surface imparts an effective patchiness to the particle. For e.g., in case of particles grafted with AB diblock copolymer (with A block closer to the surface) the presence of strong B-P and B-B attractions leads to smaller attractive patches that extend from the surface, and in turn lead to anisotropic assembly, while presence of strong A-P and A-A attractions lead to larger attractive patches closer to the particle surface and in turn isotropic assembly.

10:12AM V44.00012 Dielectric Breakdown in Filled Silicone Elastomers at the Particle/Matrix Interface¹, ROGER DIEBOLD, School of Engineering and Applied Sciences, Harvard University; Materials Department, University of California, Santa Barbara, MICHAEL GORDON, Chemical Engineering Department, University of California, Santa Barbara, DAVID CLARKE, School of Engineering and Applied Sciences, Harvard University — Silicone elastomers, widely used as electrical insulators and potting agents, are typically filled with large amounts of fumed silica nanoparticles to enhance their mechanical strength and toughness. It is well known that as the filler particle diameter decreases to the nanometer length scale, the interfacial surface area to volume ratio increases dramatically, consequently determining many of the physical properties of the macroscopic composite. Thus, to understand electrical breakdown in these materials, it is imperative to investigate the interface between the filler particle and the bulk elastomer. In order to eliminate some of the complexities of studying dielectric breakdown at the filler/matrix interface, it is necessary to remove particle-particle interactions. In this paper, the authors will present ‘creep’ (surface) and ‘strike’ (through-thickness) dielectric breakdown results at idealized oxide/polymer interfaces which closely emulate those found in filled elastomer systems. Weibull and I-V curve analysis will be used to describe the effects of silane coupling agent functionalization on dielectric breakdown, and in particular, how different chemical moieties play a role in high-field interfacial electronic transport.

10:24AM V44.00013 The Development of Filler Structure in Colloidal Silica – Polymer Nanocomposites, JEFFREY METH, E.I. Dupont de Nemours & Co., Inc. — The realization of the full potential for polymeric nanocomposites to manifest their entitled property improvements relies, for some properties, on the ability to achieve maximum particle-matrix interfacial area. Well-dispersed nanocomposites incorporating colloidal silica as the filler can be realized in both polystyrene and poly(methylmethacrylate) matrices by exploiting the charge stabilized nature of silica in nonaqueous solvents which act as Bronsted bases. We demonstrate that dispersions of colloidal silica in dimethylformamide are charge stabilized, regardless of organosilyl surface functionalization. When formulated with polymer solutions, the charge stabilized structure is maintained during drying until the charged double layer collapses. Although particles are free to diffuse and cluster after this neutralization, increased matrix viscosity retards the kinetics. We demonstrate how high molecular weight polymers assist in immobilizing the structure of the silica to produce well-dispersed composites. The glass transition temperatures of these composites do not vary, even at loadings up to 50 v%.

Thursday, March 1, 2012 8:00AM - 10:24AM –

Session V45 DPOLY DBIO: Soft Matter Physics of Heterogeneous Membranes - Experiments

159

8:00AM V45.00001 Structure and mechanics of biological fiber-laden membranes¹, YOGESH KUMAR MURUGESAN, ALEJANDRO REY, Department of Chemical Engineering, McGill University, DAMIANO PASINI, Department of Mechanical Engineering, McGill University — We present a mechanical model of the plant cell wall viewed as anisotropic 2D soft matter, where a dilute dispersion of cellulose fibrils of variable orientations is on a curved deformable viscoelastic membrane. The model integrates the elastic energy of the curved membrane, the nematic fiber orientation energy, and competing curvophilic and curvophobic interactions mediated by the membrane geometry and the fibrils' orientation. The selected membrane geometry is a straight cylinder, whose cross-sectional shape varies from a circle to a super-ellipse as in many plant species, and its size increases as in plant cell wall during growth. Model predictions indicate that due to curvature-orientation couplings, the fiber orientation displays three modes: axial (at large curvature), helical and transverse (at small curvature). The high curvature also promotes the order of the fibrils. The predicted fiber structure is validated with that in the cell wall of tracheids. To gain insight into the role of fiber structure on the elasticity of fiber-laden membranes, the effect of fiber orientation and order on the effective bending modulus of the fiber-laden membrane cross-section is investigated. The structure-property relations for super-elliptical membranes are established.

8:12AM V45.00002 From a single molecule to a membrane of structured ionic polymers: A molecular dynamic simulation study, DIPAK ARYAL, DVORA PERAHIA, Clemson University, GARY S. GREEST, Sandia National Laboratories — The association of an A-B-C-B-A co-polymer with an ionizable center and a bulky end block has been investigated using molecular dynamic simulations. The center block consists of a randomly sulfonated polystyrene connected to a flexible poly (ethylene-r-propylene) bridge and end capped with poly (t-butyl styrene). Tailoring the nature of individual segments within a block co-polymer is a potential design tool to form membranes with desired properties. The association mode and the dynamics of the segments control the overall characteristics. The membranes with three sulfonation level for the center block were made by evaporating a common solvent for all blocks. The local structure including size and distribution of the ionic blocks and the continuity of the styrene phase as well as long range correlations were identified at 300 and 500K. The initial membrane structure is affected by the structure in solution. Studies on changes that take place above the glass transition temperature for each of the blocks will also be presented.

8:24AM V45.00003 Investigation of the elastic properties of a lipid bilayer by fluorescence interferometry, DONG GUI, HSIANG-KU LIN, EHSAN NORUZIFAR, LEONID PRYADKO, ROYA ZANDI, UMAR MOHIDEEN, University of California, Riverside — Freestanding curved lipid bilayers were formed on micron diameter wells fabricated on a silicon chip. The height profile of the lipid bilayers was measured using fluorescence interference contrast microscopy. Dark and bright rings resulted from the interference of emission from the fluorophores in the lipid bilayers with the same light reflected from the bottom surface of the well. By changing the osmotic pressure difference across the bilayers, the relationship between the pressure and the membrane curvature was studied. By using Helfrich theory, the surface tension of the bilayer was extracted. The influence of detergents and antibiotics on the elastic property of lipid bilayers was also investigated.

8:36AM V45.00004 Regulating the Size and Stabilization of Lipid Raft-Like Domains and Using Calcium Ions as Their Probe, URI RAVIV, OR SZEKELY, The Hebrew University of Jerusalem — In this paper, we apply means to probe, stabilize and control the size of lipid raft-like domains in vitro. In biomembranes the size of lipid rafts is ca. 10 - 30 nm. In vitro, mixing saturated and unsaturated lipids results in micro-domains, which are unstable and coalesce. Using solution X-ray scattering, we studied the structure of binary and ternary lipid mixtures in the presence of calcium ions. Three lipids were used: saturated, unsaturated and a hybrid (1-saturated-2-unsaturated) lipid that is predominant in the phospholipids of cellular membranes. Only membranes composed of the saturated lipid can adsorb calcium ions, become charged and therefore considerably swell. The selective calcium affinity was used to show that binary mixtures, containing the saturated lipid, phase separated into large-scale domains. Our data suggests that by introducing the hybrid lipid to a mixture of the saturated and unsaturated lipids, the size of the domains decreased with the concentration of the hybrid lipid, until the three lipids could completely mix. We attribute this behavior to the tendency of the hybrid lipid to act as a line-active co-surfactant that can easily reside at the interface between the saturated and the unsaturated lipids and reduce the line-tension between them.

8:48AM V45.00005 Floret-shaped solid domains on giant fluid lipid vesicles induced by pH¹, STAVROULA SOFOU, AMEY BANDEKAR, Rutgers University — Lateral lipid phase separation and domain formation induced by changes in pH is significant in liposome-based drug delivery: environmentally responsive lipid heterogeneities can be tuned to alter collective membrane properties such as drug release and drug carrier reactivity impacting, therefore, the therapeutic outcomes. At the micron-meter scale, fluorescence microscopy on Giant Unilamellar fluid Vesicles (GUVs) shows that lowering pH (from 7.0 to 5.0) promotes the condensation of titratable PS or PA lipids into beautiful floret-shaped solid domains in which lipids are tightly packed via H-bonding and VdWs interactions. Solid domains phenomenologically comprise a circular “core” cap beyond which interfacial instabilities emerge resembling leaf-like stripes of almost vanishing Gaussian curvature independent of GUVs’ preparation path and in agreement with a general condensation mechanism. Increasing *incompressibility* of domains is strongly correlated with larger number of thinner stripes per domain, and increasing *relative rigidity* of domains with smaller core cap areas. Line tension drives domain ripening, however the final domain shape is a result of enhanced incompressibility and rigidity maximized by domain coupling across the bilayer. Introduction of a transmembrane osmotic gradient (hyperosmotic on the outer lipid leaflet) allows the domain condensation process to reach its maximum extent which, however, is limited by the minimal expansivity of the continuous fluid membrane.

9:00AM V45.00006 The influence of membrane stress on phase separation and domain shape in phospholipid vesicles, DONG CHEN, Physics Department of University of Massachusetts Amherst, MARIA SANTORE, Polymer Sci. & Eng. Department of University of Massachusetts Amherst — Phase separation of mixed phospholipid bilayers is of interest due to the potential role of phospholipid rafts in cell adhesion and signaling. Studies of membrane dynamics and the phase diagram itself typically neglect the role of tension, though it is expected that imposition of moderate membrane tensions might mildly shift the phase separation temperature, as anticipated by Clausius Clapeyron. We show here, using a simple binary system (DOPC/DPPC), a more dramatic effect: The tension imposed on giant unilamellar phospholipid vesicles can alter the phase and the domain shape, completely changing the composition of the liquid and solid phases, their proportions, and the transition temperature. The example in this talk demonstrates how striped or patchy hexagonal phases can develop, depending on thermal history and tension. Different incorporation of tracers into the ordered phases suggests fundamental differences in their structure at the molecular level. Rapid quenching and low tensions favor hexagonal patches while increased tension and slower quenching favors a striped phase. For this reason it is believed that the patches contain corrugations such that the structure of the ordered phase is metastable.

9:12AM V45.00007 Membrane fluctuations alter the fluidity of clathrin protein lattices¹, ANDREW SPAKOWITZ, NICHOLAS CORDELLA, Department of Chemical Engineering, Stanford University, SHAFIGH MEHRAEEN, School of Biochemistry and Chemistry, Georgia Tech — Clathrin is a protein that plays a major role in the creation of membrane-bound transport vesicles in cells. The pinwheel subunits of clathrin assemble into closed, nanoscale assemblies with various shapes and sizes. We develop a model for clathrin, facilitating the study of membrane, surface, and bulk assembly. The clathrin are modeled as pinwheels that form leg-leg associations and resist bending and stretching deformations. Invoking theories of dislocation-mediated melting in two dimensions, we discuss the phase behavior for clathrin. We demonstrate that the generation of defects resembles creation of two dislocations, and we use orientational- and translational-order correlation functions to predict the crystalline-hexatic and hexatic-liquid phase transitions. Accounting for membrane fluctuations, we address the phase behavior of clathrin on a membrane surface. Membrane fluctuations act to soften the elastic coupling between defects in the clathrin lattice, altering the conditions for the crystalline-hexatic phase transition. This effect offers a mechanism for altering the fluidity of protein or polymer films. Furthermore, these results illustrate the pivotal role that molecular elasticity plays in the physical behavior of self-assembling and self-healing materials.

9:24AM V45.00008 The structure of unsupported, self-assembled phospholipid bilayers on an artificially nano-patterned surface, GREGORY SMITH, SEUNG-YONG JUNG, JAMES BROWNING, JONG KEUM, NICKOLAY LAVRIK, PAT COLLIER, Oak Ridge National Laboratory — We present neutron reflectivity measurements of the in-situ microscopic architecture of phospholipid molecules at the interface between a regularly nano-patterned surface and an aqueous sub-phase using neutron reflectometry. 1,2-dilauroyl-sn-glycero-3-phosphocholine (DLPC) single bilayers were deposited on a patterned silicon substrate. The substrate was patterned with a rectangular array of nano-scaled holes using e-beam nano-lithographic techniques. The goal of these experiments is to produce a set of small freely-suspended bilayers spanning the nanostructured surface. We compare results for films deposited by vesicle adsorption or by the Langmuir–Shafer (L-S) technique. Initial data analysis shows that there are well formed bilayers on the surface. Detailed analysis of the reflectivity curves will be presented to confirm details of the architecture of these bilayer films. Bilayers prepared in this way may serve as model single bilayer systems with freely suspended areas for the study of membrane functionality in biological and biomimetic materials and systems.

9:36AM V45.00009 Peptide-induced Asymmetric Distribution of Charged Lipids in a Vesicle Bilayer Revealed by Small-Angle Neutron Scattering¹, WILLIAM HELLER, SHUO QIAN, Oak Ridge National Laboratory — Cellular membranes are complex mixtures of lipids, proteins and other small molecules that provide functional, dynamic barriers between the cell and its environment, as well as between environments within the cell. The lipid composition of the membrane is highly specific and controlled in terms of both content and lipid localization. Here, small-angle neutron scattering and selective deuterium labeling were used to probe the impact of the membrane-active peptides melittin and alamethicin on the structure of lipid bilayers composed of a mixture of the lipids dimyristoyl phosphatidylglycerol (DMPG) and chain-perdeuterated dimyristoyl phosphatidylcholine (DMPC). We found that both peptides enriched the outer leaflet of the bilayer with the negatively charged DMPG, creating an asymmetric distribution of lipids. The level of enrichment is peptide concentration-dependent and is stronger for melittin than alamethicin. The enrichment between the inner and outer bilayer leaflets occurs at very low peptide concentrations, and increases with peptide concentration, including when the peptide adopts a membrane-spanning, pore-forming state.

¹This research at Oak Ridge National Laboratory's Center for Structural Molecular Biology (DOE-BER project ERKP291) used facilities supported by the U.S. Department of Energy, managed by UT-Battelle, LLC under Contract DE-AC05-00OR22725.

9:48AM V45.00010 Cooperative assembly in targeted drug delivery, DEBRA AUGUSTE, Harvard University — Described as cell analogues, liposomes are self-assembled lipid bilayer spheres that encapsulate aqueous volumes. Liposomes offer several drug delivery advantages due to their structural versatility related to size, composition, bilayer fluidity, and ability to encapsulate a large variety of compounds non-covalently. However, liposomes lack the structural information embedded within cell membranes. Partitioning of unsaturated and saturated lipids into liquid crystalline ($L\alpha$) and gel phase ($L\beta$) domains, respectively, affects local molecular diffusion and elasticity. Liposome microdomains may be used to pattern molecules, such as antibodies, on the liposome surface to create concentrated, segregated binding regions. We have synthesized, characterized, and evaluated a series of homogeneous and heterogeneous liposomal vehicles that target inflamed endothelium. These drug delivery vehicles are designed to complement the heterogeneous presentation of lipids and receptors on endothelial cells (ECs). EC surfaces are dynamic; they segregate receptors within saturated lipid microdomains on the cell surface to regulate binding and signaling events. We have demonstrated that cooperative binding of two antibodies enhances targeting by multiple fold. Further, we have shown that organization of these antibodies on the surface can further enhance cell uptake. The data suggest that EC targeting may be enhanced by designing liposomes that mirror the segregated structure of lipid and receptor molecules involved in neutrophil-EC adhesion. This strategy is employed in an atherosclerotic mouse model in vivo.

10:00AM V45.00011 Polymer-Protein interaction at air/liquid interfaces: X-ray reflectivity and surface spectroscopy studies, WENJIE WANG, NATHANIEL ANDERSON, Ames laboratory, Iowa State University, SANJEEVA MURTHY, New Jersey Center for Biomaterials, Rutgers University, DAVID VAKNIN, Ames laboratory, Iowa State University — Adsorption of proteins onto a substrate is the first and a critical step that determines the cellular response of substrates. To understand the adsorption and distribution of proteins on surfaces, we employ surface sensitive X-ray scattering and spectroscopic techniques to monitor the adsorption of plasma proteins (fibrinogen) onto surfaces of polymers, poly(DTE carbonate), on aqueous surfaces. Our X-ray measurements provide the density profiles of the polymers-proteins systems on aqueous surfaces, with details on the interactions between the polymers and the protein, and distribution of the protein within and on the polymer surface. The hydrophobic and hydrophilic behaviors of these polymers are modified by incorporating poly(ethylene glycol) (PEG) and by iodinating the tyrosine rings. Our results confirm the inhibition of the adsorption of fibrinogen onto polymer surfaces by PEG, and the counteraction of this influence when the polymers are iodinated.

10:12AM V45.00012 Microporous device for local electric recordings on lipid bilayers, THERESA KAUFELD, CHRISTOPHER BATTLE, Drittes Physikalisches Institut, Georg August Universitaet Goettingen, CONRAD WEICHBRODT, CLAUDIA STEINEM, Fakultae fuer Chemie, Georg August Universitaet Goettingen, CHRISTOPH SCHMIDT, Drittes Physikalisches Institut, Georg August Universitaet Goettingen — Many methods for artificial membrane formation are available. We focus on the reconstitution of lipid bilayers on porous substrates combining the stability of solid supports and the accessibility of both sides of the bilayer of the classical BLM which is necessary for low noise electric experiments. Most commercially available porous substrates however are not suitable for electric experiments or a combination of several measuring techniques. Therefore, we designed a microporous substrate, which meets several demands: We wanted to have the possibility to perform multiple experiments in one, so we chose to divide the device into several individually addressable arrays of pores with separate electrolyte compartments and integrated electronic connections. Also, to perform electrical and fluorescence experiments at the same time, we designed a PDMS sample chamber so that the substrate is accessible to a microscope objective. By having separated electrolyte compartments, we are also able to exchange solutions or introduce chemicals throughout the experiment. Bilayer formation can be probed by impedance spectroscopy and fluorescence microscopy. The function of inserted ion channels can be measured by current recordings.

Session V46 DPOLY DBIO: Invited Session: Active Matter and Dynamical Systems 160AB

8:00AM V46.00001 From filamentous bundles to active random flows, ZVONIMIR DOGIC, Department of Physics, Brandeis University, Waltham MA, USA — The cytoskeleton has a number of highly unusual material properties which are essential for the reproduction and survival of the cell. However, the extraordinary structural complexity of the cytoskeleton, which contains hundreds of different proteins, presents a particular challenge to any study of its material properties. I will outline experiments whose goal is to reconstitute certain material properties of the cytoskeleton using a few well-defined biochemical components. The long term goal is to understand the behavior of the resulting materials at all levels of hierarchy. For this reason, I will first describe experiments that probe the behavior of equilibrium filamentous bundles and their dependence on the properties of the constituent filaments and their interactions. Subsequently, I will describe the emergent dynamical patterns that form when molecular motors drive an assembly of filamentous bundles to highly out of equilibrium steady states.

8:36AM V46.00002 Spindle Assembly and Architecture: From Laser Ablation to Microtubule

, DANIEL NEEDLEMAN, Applied Physics & Molecular and Cellular Biology, Harvard University — The spindle is a dynamic steady-state structure composed of microtubules and a wide range of factors which control microtubule nucleation, growth, and motion. While many of the individual components of the spindle have been studied in detail, it is still unclear how these molecular constituents self-organize into this structure. Crucially, the extent to which microtubule behaviors are spatially regulated is not known. Here I describe how we are using laser ablation experiments to obtain detailed structural information in spindles: the location of microtubule plus ends, microtubule minus ends, and the length distribution of microtubules in different regions. All of our data can be explained by a very simple model which provides surprising insight into how the regulation of microtubule nucleation and stability gives rise to spindle architecture.

9:12AM V46.00003 Synchronization of eukaryotic flagella *in vivo*: from two to thousands¹

, RAYMOND E. GOLDSTEIN, Department of Applied Mathematics and Theoretical Physics, University of Cambridge — From unicellular organisms as small as a few microns to the largest vertebrates on Earth, we find groups of beating flagella or cilia that exhibit striking spatiotemporal organization. This may take the form of precise frequency and phase locking, as frequently found in the swimming of green algae, or beating with long-wavelength phase modulations known as metachronal waves, seen in ciliates such as *Paramecium* and in our own respiratory systems. The remarkable similarity in the underlying molecular structure of flagella across the whole eukaryotic world leads naturally to the hypothesis that a similarly universal mechanism might be responsible for synchronization. Although this mechanism is poorly understood, one appealing hypothesis is that it results from hydrodynamic interactions between flagella. This talk will summarize recent work using the unicellular alga *Chlamydomonas reinhardtii* and its multicellular cousin *Volvox carteri* to study in detail the nature of flagellar synchronization and its possible hydrodynamic origins.

9:48AM V46.00004 Dynamic Patterns in Active Fluids

, FRANK JÜLICHER, Max Planck Institute for the Physics of Complex Systems, Noethnitzer Strasse 38, 01187 Dresden, Germany — Biological matter is inherently dynamic and exhibits active properties. A key example is the force generation by molecular motors in the cell cytoskeleton. Such active processes give rise to the generation of active mechanical stresses and spontaneous flows in gel-like cytoskeletal networks. Active material behaviors play a key role for the dynamics of cellular processes such as cell locomotion and cell division. We will discuss intracellular flow patterns that are created by active processes in the cell cortex. By combining theory with quantitative experiments we show that observed flow patterns result from profiles of active stress generation in the system. We will also consider the situation where active stress is regulated by a diffusing molecular species. In this case, spatial concentration patterns are generated by the interplay of stress regulation and self-generated flow fields.

10:24AM V46.00005 Order and instabilities in dense bacterial colonies¹

, LEV TSIMRING, University of California, San Diego — The structure of cell colonies is governed by the interplay of many physical and biological factors, ranging from properties of surrounding media to cell-cell communication and gene expression in individual cells. The biomechanical interactions arising from the growth and division of individual cells in confined environments are ubiquitous, yet little work has focused on this fundamental aspect of colony formation. By combining experimental observations of growing monolayers of non-motile strain of bacteria *Escherichia coli* in a shallow microfluidic chemostat with discrete-element simulations and continuous theory, we demonstrate that expansion of a dense colony leads to rapid orientational alignment of rod-like cells. However, in larger colonies, anisotropic compression may lead to buckling instability which breaks perfect nematic order. Furthermore, we found that in shallow cavities feedback between cell growth and mobility in a confined environment leads to a novel cell streaming instability. Joint work with W. Mather, D. Volfson, O. Mondragón-Palomino, T. Danino, S. Cookson, and J. Hasty (UCSD) and D. Boyer, S. Orozco-Fuentes (UNAM, Mexico).

Thursday, March 1, 2012 8:00AM - 11:00AM — Session V47 DPOLY: Focus Session: Heterogeneous Colloids II 160C

8:00AM V47.00001 Self Assembly of Soft Matter Quasicrystals and Their Approximants¹

, CHRISTOPHER IACOVELLA, AARON KEYS, SHARON GLOTZER, University of Michigan Chemical Engineering Dept — The discovery of soft-matter quasicrystals (QCs) and their approximants [1-4] hints at a unique thermodynamic mechanism underlying their stability. In the past, specific interaction potentials have been contrived to stabilize QCs and their approximants in computer simulations, but such interactions are difficult to achieve in colloidal systems. Here, we use molecular simulation to demonstrate an alternative approach for assembling dodecagonal QCs and their approximants based solely on particle functionalization and shape [5]. Our approach replaces complex energetic interactions with simpler-to-achieve bonded and excluded-volume interactions, encouraging the formation of structures with low surface contact area, including non-close-packed and polytetrahedral structures. We argue that this mechanism can be widely exploited to assemble QCs and approximants in colloidal systems, and may further elucidate the formation of soft matter QCs in experiment [1-4].

8:12AM V47.00002 ABSTRACT WITHDRAWN —

8:24AM V47.00003 Self-assembly of anisotropic colloidal particles under confinement

, CARLOS AVENDANO JIMENEZ, FERNANDO ESCOBEDO, Cornell University — We perform molecular simulations of two novel anisotropic colloidal particles under confinement. The first is an ensemble of hard-hemispheres (mimicking mushroom cap colloids [1]) confined between two parallel walls separated by a distance H. We simulated: a) Low values of H that restrict the rotation of the particles (in a monolayer) where three main dense crystal structures are found: buckled phase, square, and triangular structures. (b) Large values of H where the particles are able to fully rotate; here parallel (spheres-like) or anti-parallel (column-like) dimers are observed which form ordered structures with triangular and rectangular symmetries at high densities. The second system is a model of hard-square particles with rounded corners. Recently, Zhao et. al. have reported the phase behaviour of monolayers of polymeric squares platelets with rounded corners, assembled at the bottom of the container [2]. This system exhibits the formation of a hexagonal rotator phase and the rhombic crystal phase that were not observed in earlier simulations of squares [3] which found instead a tetratic and square crystal phases. By interpolating between hard discs and hard squares, we map out the phase diagram as a function of the roundness of the particles and resolve the discrepancies of the earlier studies. 8:36AM V47.00004 Towards Structural Complexity with Colloids¹ , MICHAEL ENGEL, University of Michigan

— Colloids rather easily assemble into simple crystal structures like the face-centered cubic lattice or the body-centered cubic lattice. More complex phases are harder to achieve, but have recently been reported using a number of approaches. Yet, assembling complex structures often results from trial-and-error and is not well understood. In this presentation, we show how novel crystals, quasicrystals, and liquid crystals can be achieved with colloidal building blocks by varying the interactions and the shapes of the building blocks. Using computer simulations, we demonstrate the formation of unusually ordered phases both with isotropic pair potentials, as well as with faceted shapes like polyhedra. We describe new tools we have developed to perform complex structural analysis on simulated systems and show how they may be used to analyze real space images from colloid experiments. We also compare the assembled structures with densest packings of the building blocks and show that good packings can often be distinct from what is observed to assemble from the disordered state. This suggests that dense packings may not be illustrative of what is achievable in colloid experiments.

9:12AM V47.00005 Novel Non-Close-Packed Structures Assembled by Spherical Colloids with Anisotropic Interactions under Electric Field , FUDUO MA, NING WU, Colorado School of Mines

— Spherical colloids with isotropic properties have been used as building blocks to assemble a variety of 2D and 3D structures in past, such as FCC, HCP, and BCT crystals. We recently, however, have observed new type of two-dimensional structures under the influence of electric field at the liquid-solid interface. This is primarily due to anisotropic interactions arising from electric field on both particles and aqueous solution. At low concentrations and low frequencies of the electric field, the isotropic spheres can form a series of colloidal clusters, ranging from 3 to 10. The analysis of cluster distributions shows non-trivial peaks for trimer, tetramer, hexamer, and nanomer. Those clusters can change bond angles freely while maintaining the overall structures intact. At high concentrations, those colloidal clusters with flexible bond angles can further assemble and connect themselves into a good variety of two-dimensional non-close-packed networks that have not been observed before. By precisely controlling the electric field strength, frequency, volume fraction of colloids, and ionic strength, we have made diversified non-close-packed structures that have potential applications in photonic crystal, catalysis, or filtration.

9:24AM V47.00006 Self-assembly of polydisperse nanoparticles into monodisperse supraparticles: a computer simulation study , TRUNG D. NGUYEN, University of Michigan, YUNSHENG XIA, National Center for Nanoscience and Technology, BYEONGDU LEE, Argonne National Laboratory, MING YANG, AARON SANTOS, University of Michigan, PAUL PODSIADLO, Argonne National Laboratory, ZHIYONG TANG, National Center for Nanoscience and Technology, SHARON C. GLOTZER, NICHOLAS A. KOTOV, University of Michigan

— Experiments have shown that polydisperse inorganic nanoparticles such as CdSe, CdS and PbS self-assemble into highly uniform supraparticles with a core-shell morphology[1]. The self-assembly process is believed to be self-limiting as indicated by the time evolution of the measured surface potential and supraparticle size distribution. We performed molecular dynamics simulations to demonstrate that the balance between van der Waals attraction and Coulombic repulsion leads to the self-limiting growth of the supraparticles[2-4]. That the uniform supraparticles are stable over a wide range of density indicates that they are thermodynamically stable, rather than consequences of limited diffusion. Our simulation results further reveal that the broad nanoparticle polydispersity leads to the core-shell morphology of the supraparticles. The generic nature of the governing interactions suggests great versatility in the composition, size and shape of the constituent building blocks, and allows for a large family of hierarchical self-assembled structures, including colloidal crystals. 9:36AM V47.00007 Particle dynamics in colloidal glasses with short-range attraction¹ , PIOTR

HABDAS, Department of Physics, Saint Joseph's University, KE CHEN, Department of Physics & Astronomy, University of Pennsylvania, MARTIN IWANICKI, DANIEL FLYNN, JOHN MICHAEL DEVANY, LISA MARIANI, Department of Physics, Saint Joseph's University, ARJUN G. YODH, Department of Physics & Astronomy, University of Pennsylvania — We study colloidal particle dynamics of a model glass system using confocal microscopy as the sample evolves from a repulsive glass towards an attractive glass. Short-range depletion forces induce the transition from a repulsive glass to the attractive glass. We identify particles which exhibit substantial motional events and characterize the transition using the properties of these motional events. It appears that number of particles that exhibit motional events doesn't change as the system is brought from a repulsive glass towards the attractive glass. Also, we investigate vibrational properties of these dense colloidal suspensions. Our preliminary results show that the boson peak for an attractive glass is lower than that for a repulsive system and it is shifted towards higher frequencies. To our knowledge, this is the first experimental investigation of the evolution of vibrational modes in colloidal glasses when particle interaction potential changes from repulsive to attractive.

9:48AM V47.00008 Self-assembly of colloidal surfactants , WILLEM KEGEL, Utrecht University, Utrecht

— We developed colloidal dumbbells with a rough and a smooth part, based on a method reported in Ref. [1]. Specific attraction between the smooth parts occurs upon addition of non-adsorbing polymers of appropriate size. We present the first results in terms of the assemblies that emerge in these systems.

10:24AM V47.00009 The Structure of Dipolar Colloidal Gels in the Dilute Regime , VERONICA

I. MARCONI, FaMAF and Ifeg-Conicet, National University of Cordoba, Argentina, MARCELO A. CARIGNANO, Department of Biomedical Engineering, Northwestern University and Chemistry of Life Processes Institute, Evanston, IL, USA. — Dipolar colloidal systems are one of the simpler material presenting anisotropic interactions and are highly relevant for designing new soft materials easy to control. Using stochastic dynamics simulations we investigate the gelation process in a high dilute system of dipolar colloidal particles immerse in an implicit dielectric solvent. This system self assembles in a rich variety of structures, from open percolated networks or gels to short chains of particles that self cross. We perform simulations using a "continues model" for the dipolar particles interactions and we present a phase diagram, density vs temperature. Each phase is characterized in detail as a function of the spatial correlation (clusters) and response. Interestingly at this low density regime, it is possible to find, characterize and follow the dynamics of a clear and huge variety of short strings configurations (cross loops, triple pointed chains, bundles), mainly at very low temperature. In addition, studying the dynamics of gelation in detail we observe an increasing gelation time while density is decreased in good agreement with previous simulations and experiments on colloidal systems with directional interactions.

10:36AM V47.00010 Two-Dimensional Crystals of Icosahedral Viruses at Liquid interfaces, MASAFUMI FUKUTO, LIN YANG, ANTONIO CHECCO, Brookhaven National Laboratory, IVAN KUZMENKO, Argonne National Laboratory, QUYEN NGUYEN, NICK MANK, QIAN WANG, University of South Carolina — Two-dimensional (2D) assembly of turnip yellow mosaic virus (TYMV) on cationic lipid monolayers is investigated at the air-water interface. TYMV, an icosahedral virus with a diameter of 28 nm, exhibits well-defined roughness, charge distribution, and hydrophilic/hydrophobic patches on its surface. The electrostatic attraction to the lipid-coated aqueous interface provides means to impose a specific virus orientation and hence reduce the number of possible inter-particle interactions. The 2D geometry is particularly advantageous in dissecting the role of anisotropy in aqueous-media assembly, which involves various types of similarly weak interactions. We show that the assembly approach used not only facilitates crystallization but also provides insights on how complex anisotropic interactions can be exploited to generate long-range order. Specifically, we report an *in situ* x-ray scattering observation of novel 2D crystal forms of TYMV that reflect the virus' icosahedral symmetry. The symmetry, shape, and surface heterogeneities of TYMV suggest a mechanism by which these crystals are stabilized by a combination of hydrophobic, electrostatic, and steric interactions.

10:48AM V47.00011 Active colloids at liquid-liquid interfaces: dynamic self-assembly and functionality, ALEXEY SNEZHKO, IGOR ARANSON, Argonne National Laboratory — Self-assembled materials must actively consume energy and remain out of equilibrium in order to support structural complexity and functional diversity. Colloids of interacting particles suspended at liquid-liquid interfaces and maintained out of equilibrium by external alternating electromagnetic fields develop nontrivial collective dynamics and self-assembly. We use ferromagnetic colloidal micro-particles (so the magnetic moment is fixed in each particle and interactions between colloids is highly anisotropic and directional) suspended over an interface of two immiscible liquids and energized by vertical alternating magnetic fields to demonstrate novel dynamic and active self-assembled structures ("asters") which are not accessible through thermodynamic assembly. Structures are attributed to the interplay between surface waves, generated at the liquid/liquid interface by the collective response of magnetic microparticles to the alternating magnetic field, and hydrodynamic fields induced in the boundary layers of *both* liquids forming the interface. Two types of magnetic order are reported. We demonstrate that asters develop self-propulsion in the presence of a small in-plane dc magnetic field. We show that asters can capture, transport, and position target microparticles.

Thursday, March 1, 2012 8:00AM - 10:48AM —
Session V48 DPOLY DBIO: Focus Session: Advanced Optical Probes of Soft Matter - Forces, Imaging, Excitons 161

8:00AM V48.00001 TBD —

8:36AM V48.00002 Brownian vortex circulation due to spin orbit conversion in a circularly polarized optical tweezer, DAVID RUFFNER, DAVID G. GRIER, New York University, DEPARTMENT OF PHYSICS AND CENTER FOR SOFT MATTER RESEARCH TEAM — Strong focusing of circularly polarized beams converts spin angular momentum into orbital angular momentum. We describe this process in terms of a generalized vector potential, involving the amplitude, phase, and polarization of the light. This gives a more general understanding of this force in terms of experimentally accessible parameters. In addition, this formalism provides a framework for understanding other polarization induced forces, which arise from the curl of the spin angular momentum density. Experimentally we demonstrate deterministic polarization-induced circulation with trapped clusters of $1\mu\text{m}$ polystyrene spheres, and Brownian vortex circulation for a single sphere trapped in elliptically polarized optical tweezers.

8:48AM V48.00003 Pulling Particles Backward Using a Forward Propagating Beam, JACK NG, The Hong Kong University of Science and Technology, JUN CHEN, ZHIFANG LIN, Fudan University, CHE TING CHAN, The Hong Kong University of Science and Technology, FUDAN UNIVERSITY COLLABORATION, THE HONG KONG UNIVERSITY OF SCIENCE AND TECHNOLOGY COLLABORATION — Can the scattering force of a forward propagating beam pull a particle backward? A photon carries a momentum of $\hbar k$, so one may expect light will push against any object standing in its path. However, light can indeed "attract" in some cases. For example, if light is focused to a spot, small particles will be attracted towards it due to the gradient force. But it is probably more appropriate to say that the gradient force "grabs" rather than "pulls", as the particle will remain stable in the trap after being drawn to the focus. Here, we discuss another possibility—a backward scattering force which is always opposite to the propagation direction of the beam so that the beam keeps on pulling an object towards the source without an equilibrium point. In the absence of intensity gradient, using a light beam to pull a particle backwards is counter intuitive. The underlining physics is the maximization of forward scattering via interference of the radiation multipoles. We show explicitly that the necessary condition to realize a pulling force is the simultaneous excitation of multipoles in the particle and if the projection of the total photon momentum along the propagation direction is small, attractive optical force is possible.

9:00AM V48.00004 Lateral optical binding forces between two colloidal Mie particles, MING-TZO WEI, Lehigh University, JACK NG, C.T. CHAN, Hong Kong University of Science and Technology, H. DANIEL OU-YANG, Lehigh University — Micro particles in an intense optical field can self-organize into an array with well defined structure. This phenomenon, first reported by Burns et al., as optical binding, was believed to be caused by the optical gradient force. In spite of many attempts to calculate the binding forces and the colloidal structures, there has been a lack of experiments directly measuring the forces between the particles. Positioning two micron-sized polystyrene particles, each held by a tightly focused laser beam from a single coherence laser source, we found the lateral optical binding force oscillates with the inter particle separation, as well as the relative phase between the beams due to retardation. By independently changing the polarization directions at each optical trap, we examined the periodicity and magnitude of the forces. Our research indicates the forces under such conditions require a model beyond dipole approximation. In addition, an accurate calculation based on Mie theory with consideration of high focusing compare well with our experimental findings.

9:12AM V48.00005 Super-Resolution Imaging Using Randomly Diffusing Probes, ANNA LABNO, HU CANG, CHRISTOPHER GLADDEN, XIANG ZHANG, University of California at Berkeley — Recent advances in super-resolution microscopy allow imaging of biological tissues labeled with fluorescent dyes with unprecedented resolution. These techniques often rely on the fact that single emitters can be localized with nm accuracy. When multiple emitters reside within a diffraction-limited spot they are serially photo-switched to ensure that they emit one at a time. This approach has not been applied to other imaging modalities, for example imaging local electromagnetic field enhancement, mainly because photo-switching would be infeasible. Here we present a super-resolution imaging technique which circumvents the requirement for serial photoswitching by using the random motion of single dye molecules to scan the surface in a stochastic manner. This technique allowed us to image electromagnetic field enhancement of a single spot formed on thin metallic film with 1.2nm accuracy and gain insight into the mechanism for generating field enhancement.

9:24AM V48.00006 Three-dimensional thermal noise images of single biopolymer filaments allows to determine their orientation and quantify their mechanical properties, MARTIN KOCHANZYK, TOBIAS BARTSCH, PINYU THRASHER, ERNST-LUDWIG FLORIN, The University of Texas at Austin — Intracellular biopolymer networks perform many essential functions for living cells. Most of these networks show a highly nonlinear mechanical response that is well-studied on the macroscopic scale. While much work has been done to connect the macroscopic responses of networks to specific network properties, such as filament persistence length, cross-linking geometry and pore size, there is a lack of experimental techniques that can simultaneously determine the structure and the mechanical properties of a network in situ on the single filament level. Thermal Noise Imaging is a scanning probe technique that utilizes the confined thermal motion of an optically trapped particle as a three-dimensional, noninvasive scanner for soft, biological material. It achieves nanometer precision in probe position detection at MHz bandwidth. Thermal noise imaging visualizes single biopolymer filaments as nanoscale tunnels and allows for the quantification of their mechanical properties from their transversal fluctuations. The experiments presented here pave the way for investigating force distributions inside biopolymer networks on the single filament level, as well as establish thermal noise imaging as a quantitative tool for studying biological material on the nanometer scale.

9:36AM V48.00007 Microscopy method for the characterization of structural color on a single wing scale of Morpho butterfly¹, BEOM-JIN YOON, MATIJA CRNE, JUNG OK PARK, MOHAN SRINIVASARAO, School of Materials Science and Engineering, Georgia Institute of Technology — The structural color and the iridescence of Morpho rhetenor were investigated using an optical microscope and a digital camera. Incoherent white light source was used for both spatial and spectral analysis. The scattering pattern from the micrometer sized single scale in the back focal plane of the objective lens was observed with Bertrand lens equipped in the optical microscope. We precisely controlled incident angle of the light using common components typically embedded in most optical microscope; aligning aperture stop at the center or off-center. Wide range of the angular scattering pattern from a single scale was measured and the iridescence of Morpho rhetenor was measured quantitatively. The single scale of Morpho rhetenor diffusively reflected the normally illuminated light, while blue band was more effectively reflected than green and red band. We retrieved the raw intensity data generated at the imaging sensor of the digital camera and quantitatively analyzed the spatial distribution of the scattered light. The reflectivity measured by the digital camera was comparable to the result from microspectrometer reported earlier.

¹This work was partially supported by NSF funding (DMR-0907529).

9:48AM V48.00008 High Fidelity Detection of Defects in Polymer Films using Surface-Modified Nanoparticles, CHAITANYA PRATIWADA, SINDHUJA CHARI, JOLANTA MARSZALEK, MATTHEW BECKER, ALAMGIR KARIM, University of Akron — Defects are ubiquitous to materials and material surfaces. As we push the thresholds of length scale producing defect free materials, surfaces and interfaces, it becomes increasingly difficult to detect their presence over multiple length scales. The ideal example is the semiconductor industry where the driving force is higher performance and lower cost devices with material interfaces. In this regard, Chemical mechanical planarization, CMP, emerged as the premier method for achieving ultra flat surfaces below the 0.35 micron technology node, enabling many of the advanced electronic devices currently in production. The interactions between numerous process settings and output metrics are difficult to predict and often lead to defects. Failure analysis (FA) is critical and the current methods involve advanced imaging methods such as SEM. We design a cost effective method to detect physico-chemical defects at multiple length scales through Polymer-Nanoparticles (NPs) interactions in relatively shorter period of time (time of imaging is reduced 50 fold). This method can be used in conjunction with the traditional imaging methods to pin point location of these defects, which can be further analyzed.

10:00AM V48.00009 A Study of the Polarizability of Single-Walled Carbon Nanotubes in an Optical Field, JINGYU WANG, H. DANIEL OU-YANG, Lehigh University — Whereas the behavior of single-walled carbon nanotubes (SWCNT) in an electric field has been extensively studied, the polarizability of SWCNTs at optical frequencies remains unclear due to the difficulty in direct detection. It was demonstrated by utilizing Raman spectroscopy as a characterization means, optical tweezers could selectively aggregate SWCNTs. While it was commonly believed that the trapping effect due to the large optical field gradient caused the strong response of tubes to the laser beam, we expect the aligning effect due to the optical polarization also has a considerable contribution. To quantify these two possible effects experienced by an ensemble of individual DNA-SWCNTs of different chiralities, and address the issue of tube-tube interaction, We design an experiment by applying optical tweezers with variable polarization states and inspecting resonance Raman excitation for sensitive detection. Specifically, we measure the radial breathing mode signal of SWCNTs as a function of laser power and the direction of polarization for different tube types and concentrations. The research may lead to a more complete understanding of sorting phenomenon of individual SWCNTs in an optical field at microscopic level.

10:12AM V48.00010 Dynamics of Aerial Tower Formation in Bacillus subtilis Biofilms, NAVEEN SINHA, AGNESE SEMINARA, JAMES WILKING, MICHAEL BRENNER, DAVE WEITZ, Harvard University — Biofilms are highly-organized colonies of bacteria that form on surfaces. These colonies form sophisticated structures which make them robust and difficult to remove from environments such as catheters, where they pose serious infection problems. Previous work has shown that sub-mm sized aerial towers form on the surface of Bacillus subtilis colony biofilms. Spore-formation is located preferentially at the tops of these towers, known as fruiting bodies, which aid in the dispersal and propagation of the colony to new sites. The formation of towers is strongly affected by the quorum-sensing molecule surfactin and the cannibalism pathway of the bacteria. In the present work, we use confocal fluorescence microscopy to study the development of individual fruiting bodies, allowing us to visualize the time-dependent spatial distribution of matrix-forming and sporulating bacteria within the towers. With this information, we investigate the physical mechanisms, such as surface tension and polymer concentration gradients, that drive the formation of these structures.

10:24AM V48.00011 The Orientation of Luminescent Excitons in Layered Organic Nanomaterials, JON SCHULLER, Columbia University, SINAN KARAVELLI, Brown University, KELIANG HE, Case Western Reserve University, SHYUAN YANG, Columbia University, JIE SHAN, Case Western Reserve University, JOHN KYMISSIS, Columbia University, RASHID ZIA, Brown University — A fundamental understanding of optoelectronics in organic semiconductors is complicated by the diversity of excitons which can exist within a single material system. Measurements that distinguish between different exciton types are crucial for a complete understanding of organic materials. By fitting experimental curves of angle-, polarization-, and energy-dependent PL to analytical Purcell calculations we quantify the relative dipole moments for in-plane and out-of-plane oriented excitons in organic and inorganic layered nanomaterials. In mono- and bi-layers of Molybdenum Disulfide (MoS₂) and Graphene Oxide the luminescence arises only from in-plane oriented excitons. In the perylene derivative PTCDA, however, we show that PL arises from both in-plane and out-of-plane excitons. We observe a difference in emission frequency between the dipole orientations which indicates the existence of two distinct exciton species: an in-plane oriented Frenkel exciton and an out-of-plane oriented Charge Transfer exciton. Based on these results we devise and implement a method for isolating luminescence from either exciton species. We observe different temporal dynamics for the two distinct excitons, highlighting the power of this technique for fundamental studies of organic materials.

10:36AM V48.00012 Accessing exciton transport in light-harvesting structures with plasmonic nanotip, SEMION K. SAIKIN, Department of Chemistry and Chemical Biology, Harvard University, JOHANNES FEIST, ITAMP, Harvard-Smithsonian Center for Astrophysics, Harvard University, M.T. HOMER REID, Research Laboratory of Electronics, Massachusetts Institute of Technology, MIKHAIL D. LUKIN, Department of Physics, Harvard University, ALAN ASPURU-GUZIK, Department of Chemistry and Chemical Biology, Harvard University — Natural light-harvesting complexes, such as that of plant cells or photosynthetic bacteria, are considered as possible prototypes for artificially designed solar cell materials. In these structures the energy of light absorbed by a peripheral antenna is transmitted very efficiently in a form of excitons to a reaction center. Usually, information about the exciton transport is obtained from time-resolved nonlinear optical experiments where the frequencies of a pump and a probe fields select particular electronic transitions in the light-harvesting complex. We explore a complimentary setup utilizing a plasmonic nanotip as a local sub-wavelength probe of excitation dynamics. As specific examples we consider an LHII complex involved in the light-harvesting process of purple bacteria and a Fenna-Matthews-Olson pigment-protein complex of green-sulphur bacteria.

Thursday, March 1, 2012 8:00AM - 11:00AM –
Session V49 DMP DPOLY: Focus Session: Organic Electronics and Photonics - Solar Cells and Light Emitting Devices 162A

8:00AM V49.00001 Frequency dependence of magnetoresistance in MEH-PPV, THADDEE KAMDEM DJIDJOU, THO NGUYEN, Z. VALY VARDENY, ANDREY ROGACHEV, University of Utah — The organic magnetoresistance (OMAR) in organic light emitting diodes (OLED) made of MEH-PPV was investigated by means of DC transport and the admittance spectroscopy in the range of 1 Hz to 10 MHz at room temperature. The measurements were carried out on unipolar and bipolar OLEDs made of pristine MEH-PPV as well as MEH-PPV with traps introduced by the UV light irradiation. We found that in bipolar, UV-exposed OLEDs, the magnitude of magnetoresistance effect in real part of admittance increases with DC bias, reaches very high value of 35 % (in the field 30mT) at bias 4.8 V and decreases at higher bias voltages. Also, we observed that the cutoff frequency of OMAR effect monotonically increases with DC bias voltage. The cutoff has extrinsic origin and is likely caused by a dissipative process related to the reorientation of permanent dipoles. At the highest tested bias voltage 6.7 V, we were able to detect the OMAR at the highest frequency of our system, 10 MHz. We have found that imaginary part of the admittance is also affected by magnetic field. The effect of magnetic field on dynamical capacitance of the device at low frequencies is very strong and opens up a possibility of using these devices as magnetic field sensors.

8:12AM V49.00002 Graphene-Based Polymer Bulk Heterojunction Solar Cells, FEI YU, VIKRAM KUPPA, University of Cincinnati — The requirement of exciton dissociation in organic photovoltaics necessitates the presence of a large-area interface accessible to the interior of the active layer. Traditionally, such bulk heterojunctions (BHJ) have been spin-coated from a blend of conjugated polymer and functionalized fullerene molecules. We propose and demonstrate BHJs that utilize chemically modified graphene nanoparticles in order to facilitate charge transfer in polymeric solar cells. Devices based on P3HT:PCBM:graphene were fabricated on patterned ITO glass, and the effect of graphene on performance was investigated. Various device parameters including short-circuit current density, open-circuit voltage, fill factor, power conversion efficiency, and external quantum efficiency are compared with traditional BHJs. Results are discussed in the context of the morphology of the active layer, and the distribution and orientation of graphene platelets, as characterized by SEM, AFM and TEM.

8:24AM V49.00003 Planar Organic Photovoltaics for more Opportunities of Efficiency Enhancement and Parameters Controlling¹, FERAS G. ALZUBI, Nanoscience Technology Center, Department of Physics, University of Central Florida, SAIFUL I. KHONDAKER, Nanoscience Technology Center, Department of Physics, School of Electrical Engineering and Computer Science, University of Central Florida — Organic photovoltaics have been intensively studied as a cheap, easy processed and reliable source of energy that will eventually substitute the inorganic photovoltaics. Commonly, PV devices are made in vertical geometry where the BHJ active material is sandwiched between two electrodes one of them must be transparent to shine the light through. This vertical geometry created some challenges such as requirement of transparent ITO electrode as well as tying up the active material film thickness and electrodes separation. As an approach to overcome these challenges, we utilize the planar geometry to fabricate PV device where the poly (3-hexylthiophene) and [6,6]-phenyl C61-butyric acid methylester (P3HT/PCBM) blend is deposited between two asymmetric metallic electrodes. We investigated the PV behavior for different metal electrodes which is an advantage provided by planar structure. Also, we discuss the behavior of the power conversion efficiency (PCE) with independently varying the active material film thickness and electrodes separation.

¹This work is supported by U.S. National Science Foundation under Grant No. ECCS 0801924.

8:36AM V49.00004 Low band gap polymer bulk heterojunction solar cell on a co-planar digitated electrodes structure, ABRAR QUADERY, FERAS ALZUBI, Nanoscience Technology Center, Department of Physics, University of Central Florida, SIMON TANG, ANDRE J. GESQUIERE, Nanoscience Technology Center, Department of Chemistry, University of Central Florida, SAIFUL KHONDAKER, Nanoscience Technology Center, Department of Physics, University of Central Florida — Usage of additive in a bulk heterojunction organic solar (BHJ) cell to enhance absorption of solar spectrum in the NIR range is attracting significant research interest. At present, the BHJ solar cells are fabricated in a vertical geometry where a transparent electrode is necessary limiting the choice to mostly ITO. This may create a significant challenge as the performance of organic solar cell is dependent on the work function matching of active materials and the electrode. In order to address this challenge, we fabricated solar cell by dropcasting a ternary blend of P3HT:PC₆₀BM: PCPDTBT on a simple structure comprising of co-planar digitated electrodes with different work functions. We will discuss the performance of our device and its implication.

8:48AM V49.00005 Charge Accumulation and Internal Photovoltaic Processes in Organic Solar Cells, HUIDONG ZANG, YU-CHE HSIAO, QING LIU, University of Tennessee, ILIA IVANOV, Oak Ridge National Laboratory, BIN HU, University of Tennessee — The accumulation of dissociated charge carriers plays an important role in reducing the loss occurring in open-circuit voltage (Voc), short-circuit photocurrent (Isc), fill factor (FF) in organic solar cells. We found from light-assisted capacitance measurements that the charge accumulation inevitably occurs at device interfaces in bulk-heterojunction ITO/PEDOT/P3HT:PCBM/Ca/Al solar cells. Our experimental studies have indicated that the charge accumulation can reduce the Voc through charge injection, Isc through charge collection, and FF through charge transport. Furthermore, our light-assisted capacitance measurements reveal that using a dielectric thin film of TiOx can decrease charge accumulation in the ITO/PEDOT/P3HT:PCBM/TiOx/Ca/Al solar cell. In particular, we find that decreasing the charge accumulation can reduce the loss occurring in Voc, Isc, and FF. Clearly, controlling charge accumulation presents a new mechanism to improve photovoltaic performance in organic solar cells.

9:00AM V49.00006 Photocurrent noise in organic bulk heterojunction solar cells, N.S. VIDHYADHIRAJA, MONOJIT BAG, K.S. NARAYAN, Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore, India — We report the first electrical noise measurements from illuminated bulk heterojunction polymer based solar cells. The dependence of photocurrent fluctuations on temperature, light intensity and device conditions was analyzed. We find flicker noise of the form $1/f^\alpha$ at low frequencies (<1 kHz). An unusual log-normal feature in the noise power spectrum is observed in the frequency regime > 5 kHz. We develop a theoretical description employing kinetic Monte-Carlo simulations that points to the importance of a mobility edge in the understanding of fluctuations in the low frequency regime, while also capturing the temperature dependence of the noise amplitude. We find that a Gaussian disorder model with uncorrelated traps is not sufficient to describe the log-normal feature, thus highlighting the significance of spatial and/or energetic correlations among the trap states.

9:12AM V49.00007 Relating charge transport and performance in single-layer graded-composition organic light-emitting devices, RUSSELL HOLMES, University of Minnesota — Organic light-emitting devices (OLEDs) continue to receive interest for application in displays and as solid-state lighting sources. While OLEDs can exhibit high external quantum and luminous power efficiencies, high performance often requires the use of complex, multilayer architectures. Consequently, there has been interest in the development of OLED architectures containing fewer device active layers or perhaps, a single active layer. Here, we describe an approach to realize efficient electroluminescence from a single active layer through the use of engineered composition gradients. Graded-emissive layer (G-EML) devices contain a single layer consisting of nearly 100% hole-transporting material (HTM) at the anode and nearly 100% electron-transport material (ETM) at the cathode, and having a continuously varying HTM:ETM composition across the active layer. Electroluminescence originates from a phosphorescent guest that is uniformly doped throughout the G-EML. For red-, green-, and blue-emitting phosphors, efficiencies are realized that rival those of more complex, multilayer structures. The G-EML balances electron and hole injection and transport leading to effective charge carrier confinement and exciton formation. This talk will examine how charge confinement in the G-EML is realized through a spatial variation in the carrier mobility across the active layer. In addition, separate measurements of the G-EML exciton recombination zone show that it is substantially broader than that of conventional, abrupt heterojunction OLEDs, a feature which may help to reduce bimolecular exciton quenching in these structures.

9:48AM V49.00008 Sources of high photo-current in inverted organic solar cells¹, ABAY GADISA, Department of Chemistry and Astronomy, UNC- Chapel Hill, YINGCHI LIU, RENE LOPEZ, Department of Physics and Astronomy, UNC- Chapel Hill, EDWARD SAMULSKI, Department of Chemistry, UNC- Chapel Hill, SOLAR UNC TEAM — Inverted organic solar cells have been proved to render exceptional environmental stability compared to the conventional solar cell architecture. On the other hand, polymer/fullerene based inverted solar cells produce more photo-current compared to conventional cells comprising the same active layer thickness. The origin of this current has never been clearly stated so far. We have investigated the photovoltaic properties of inverted solar cells comprising a bulk heterojunction layer of poly(3-hexylthiophene) (P3HT) and phenyl-C61-butyric acid methyl ester (PCBM). The blend layer was formed by spin casting the blend solution on ITO substrate, covered with an Al doped zinc-oxide layer (ZnO-Al) deposited through pulsed laser deposition technique. The inverted solar cells show over 15% increase in photo-current yield compared to conventional solar cells. We have discovered that the inverted solar cells produce additional photo-current through dissociation of excited electron-hole pairs near the polymer/ZnO-Al interfaces. Since ZnO-Al is a good electron conductor, the electrons generated at the polymer/ZnO-Al interface are more efficiently collected compared to photo-current produced in the bulk of the active film. External quantum efficiency exceeding 70% was recorded in the ZnO-Al based inverted solar cells. In general, ZnO-Al is not only characterized by its high electron conductivity, and transparency but also serves as electron acceptor.

¹This project is supported by the NSF-SOLAR program DMR-0934433.

10:00AM V49.00009 ABSTRACT WITHDRAWN —

10:12AM V49.00010 Near-Infrared Photodetector Consisting of J-Aggregating Cyanine Dye and Metal Oxide Thin Films, TIMOTHY OSEDACH, Harvard University, ANTONIO IACCHETTI, Politecnico di Milano, RICHARD LUNT, Michigan State University, TRISHA ANDREW, PATRICK BROWN, GLEB AKSELROD, VLADIMIR BULOVIC, MIT — We demonstrate a photodetector structure that employs metal-oxide charge transport layers and that is sensitized at near-infrared wavelengths by a thin film of a J-aggregating cyanine dye. The high absorption coefficient of the J-aggregate film, combined with the use of a reflective anode and optical spacer layer, enables an external quantum efficiency (EQE) of $16.1 \pm 0.1\%$ ($\lambda = 756$ nm) to be achieved at zero-bias in a device consisting of an 8.1 ± 0.3 nm-thick dye film. The specific detectivity (D^*) and response speed (f_{3dB}) of the fully-optimized device are measured to be $(4.3 \pm 0.1) \times 10^{11}$ cm Hz^{1/2} W⁻¹ and 91.5 kHz, respectively. Modeling of our structure reveals that the photocurrent is limited by the diffusion of photo-generated excitons to the metal oxide/J-aggregate hetero-interface and we determine the exciton diffusion length in the J-aggregate film to be $L_D = 2.0 \pm 0.4$ nm. This work provides insights relevant to the use of J-aggregating cyanine dyes in photodetector and photovoltaic applications and highlights the importance of engineering the optical field profile within such structures in order to maximize performance.

10:24AM V49.00011 Electrical Stability Tests of Polymer Light Emitting Devices¹, JACOB COX, ZAC BARCIKOWSKI, MARIAN TZOLOV, Lock Haven University of Pennsylvania — The degradation of polymer light emitting devices (PLEDs) is a main concern influencing the commercial production of functioning devices. There are various sources of degradation related to the polymer film, the interfaces, and the cathodes. The fundamental understanding of these processes helps to develop strategies for fabrication of devices with longer lifetimes. We are reporting on devices in which delamination of the metal cathode is the dominating degradation mechanism. We have performed stability tests at constant current and constant voltage accompanied by current-voltage characteristics. The results indicate initial improvement of functionality followed by degradation. The change in the current-voltage characteristics indicates modifications of the electron and hole transport through the polymer layer in addition to the delamination. The delamination appears only if the current is above a certain threshold value. We have studied the kinetics of the delamination which gradually increased with time. Several types of semitransparent anodes were used to clarify the origin of the observed delamination, e.g. gold, platinum, and ZnO:Al. The devices were also exposed to thermal stress tests to verify if the evolution of volatile molecules is involved in the observed degradation.

¹This work was partly supported by the NSF grant # 0923047.

10:36AM V49.00012 Rational design of charge transport molecules for blue organic light emitting devices, ASANGA PADMAPERUMA, LELIA COSIMBESCU, PHILLIP KOECH, EVGUENI POLIKARPOV, JAMES SWENSEN, DANIEL GASPAR, PNNL, PACIFIC NORTHWEST NATIONAL LABORATORY TEAM — The efficiency and stability of blue OLEDs continue to be the primary roadblock to developing organic solid-state white lighting as well as power efficient displays. It is generally accepted that such high quantum efficiency can be achieved with the use of organometallic phosphor doped OLEDs. The transport layers can be designed to increase the carrier density as a way to reduce the drive voltage. We have developed a comprehensive library of charge transporting molecules using combination of theoretical modeling and experimental evidence. Our work focuses on using chemical structure design and computational methods to develop host, transport, emitter, and blocking materials for high efficiency blue OLEDs, along with device architectures to take advantage of these new materials. Through chemical modification of materials we are able to influence both the charge balance and emission efficiency of OLEDs, and understand the influence of the location of photon emission in OLEDs as a function of minor chemical modifications of host and electron transport materials. Design rules, structure-property relationships and results from state of the art OLEDs will be presented.

10:48AM V49.00013 Transient Capacitance of Light-Emitting Electrochemical Cells¹, NANCY HAEGEL, YEVTTE DAVIS, PETER CROOKER, Naval Postgraduate School, J. DEVIN MACKENZIE, YUKA YOSHIOKA, Add-Vision, Inc. — Although the steady-state behavior of light-emitting electrochemical cells (LECs) has been addressed theoretically, the transient properties of LECs have yet to be studied in detail. We present time- and frequency-dependent measurements of the capacitance, current, and optical emission of LECs as a constant voltage bias is applied and removed. We find that the capacitance increases more rapidly than the light or current and, unlike the light and current behavior, can be oscillatory and even negative at lower frequencies. Variable temperature experiments were performed to enable observation of a range of transient phenomena that cannot be fully explored at room temperature. The transient behavior suggests that the capacitance is determined by a combination of ion distribution, free carrier screening, and junction width. We interpret our data by qualitatively extending the ideas of existing steady-state theory.

Thursday, March 1, 2012 8:00AM - 11:00AM – Session V50 DPOLY: Structure and Properties of Copolymers 162B

8:00AM V50.00001 Designing 100 K Glass Transition Breadths in Bulk Polymer Systems: Effects of Architecture in Homopolymers, Copolymers, and Copolymer Blends, STEPHEN MARROU, SEAN WUNDROW, JOHN TORKELOSON, Northwestern University — Gradient copolymers have attracted interest as vibration or acoustic damping materials due to their extremely broad, tunable glass transition temperature (T_g) responses, up to 100 K in breadth. This behavior is caused by large compositional heterogeneity resulting from sinusoidal composition profiles in nanophase-separated systems. We have also found that some homopolymers and random copolymers exhibit large T_g breadths caused by incompatible main- and side-chain interactions. For example, the T_g response broadens with increasing side-chain length in the poly(n-alkyl methacrylate) series by more than a factor of 2 in going from poly(methyl methacrylate) to poly(n-hexyl methacrylate). We have also blended weakly-segregating styrene/n-butyl acrylate random copolymers of different compositions to allow for tunable T_g breadths over a 100 K temperature range. Finally, we have shown that blending a selective plasticizer into a styrene/4-vinylpyridine gradient copolymer results in a dramatic shift in the T_g response of a single nanophase region, increasing the T_g breadth above 100 K.

8:12AM V50.00002 Structure and Mechanical Behavior of Elastomeric Multiblock Terpolymers Containing Glassy, Rubbery, and Semicrystalline Blocks, FENG ZUO, University of Minnesota, C. GUILLERMO ALFONZO, The Dow Chemical Company, FRANK BATES, University of Minnesota — Multiblock terpolymers containing poly(cyclohexylethylene) (C), poly(ethylene-*alt*-propylene) (P), and poly(ethylene) (E) were synthesized. The CECPEC (denoted XPX) and CECP (XP) each contain 50 v% P and equal amounts of C and E. These materials have been studied by DSC, DMS, TEM, SAXS, WAXS, and tensile deformation to characterize the morphology, phase behavior, and mechanical properties. Microphase separation is induced by crystallization of E and/or chemical incompatibility between the three blocks, leading to a morphology which contains continuous region of P and continuous region of microphase separated X, resulting in mechanically resilient materials. High M_w block copolymers microphase separate with two different length scales associated with segregation between C and E, and X and P. These structural features produce a non-classical scaling relationship for the C-E domain spacing, $d \sim N^{0.31}$. The role of semicrystalline E domains during uniaxial deformation has been exposed with WAXS experiments, which support a two-step mechanism involving recoverable and non-recoverable deformation to different extents. Strain hardening is observed in double-anchored XPX, but not in single-anchored XP, at large tensile strains.

8:24AM V50.00003 Energy Storage and Dissipation in Random Copolymers during Biaxial Loading, HANSOHL CHO, MARY BOYCE, Massachusetts Institute of Technology, MASSACHUSETTS INSTITUTE OF TECHNOLOGY TEAM — Random copolymers composed of hard and soft segments in a glassy and rubbery state at the ambient conditions exhibit phase-separated morphologies which can be tailored to provide hybrid mechanical behaviors of the constituents. Here, phase-separated copolymers with hard and soft contents which form co-continuous structures are explored through experiments and modeling. The mechanics of the highly dissipative yet resilient behavior of an exemplar polyurea are studied under biaxial loading. The hard phase governs the initially stiff response followed by a highly dissipative viscoplasticity where dissipation arises from viscous relaxation as well as structural breakdown in the network structure that still provides energy storage resulting in the shape recovery. The soft phase provides additional energy storage that drives the resilience in high strain rate events. Biaxial experiments reveal the anisotropy and loading history dependence of energy storage and dissipation, validating the three-dimensional predictive capabilities of the microstructurally-based constitutive model. The combination of a highly dissipative and resilient behavior provides a versatile material for a myriad of applications ranging from self-healing microcapsules to ballistic protective coatings.

8:36AM V50.00004 X-ray scattering studies of ordered block copolymer melts during uniaxial extensional flow, WESLEY BURGHARDT, RUINAN MAO, ERICA MCCREADY, Northwestern University — We present the design and implementation of a new apparatus for in situ x-ray scattering studies of polymer melts during homogenous uniaxial extensional flow. The instrument is based on the commercial SER extensional flow fixture, which employs counter-rotating drums to deform a strip of polymer melt, which is incorporated into a custom-built convection oven designed to facilitate x-ray access to the sample and operation in a synchrotron environment. Here we report measurements of extensional flow-induced structural changes in a cylindrically ordered styrene-ethylene butylene-styrene triblock copolymer melt. At early stages, SAXS data reveal that the ordered microstructure deforms affinely until Hencky strains of ~ 0.2 . A global re-orientation process leads to alignment of microdomains predominantly along the stretching direction after Hencky strains of ~ 1 . Further stretching does not lead to further qualitative changes in 2-D SAXS patterns. Relaxation of both microdomain orientation and d-spacing is observed following cessation of extensional flow, albeit with different characteristic time scales. In situ x-ray scattering data are compared with off-line measurements of transient extensional viscosity, performed using the SER fixture in a rotational rheometer.

8:48AM V50.00005 ABSTRACT WITHDRAWN —

9:00AM V50.00006 Understanding the Dynamics of Magnetic Field Alignment for Rod-Coil Block Copolymers, BRYAN MCCULLOCH, University of California - Berkeley, GIUSEPPE PORTALE, WIM BRAS, ESRF, DUBBLE CRG, ALEXANDER HEXEMER, Advanced Light Source, LBNL, RACHEL A. SEGALMAN, University of California - Berkeley — Alignment of semiconducting block copolymer nanostructures is crucial to optimize charge transport in these materials. Magnetic fields can act on the liquid crystalline conjugated polymers, inducing alignment in rod-coil block copolymers. By using a combination of small angle x-ray scattering (SAXS) and transmission electron microscopy (TEM) we have studied the magnetic field alignment of poly(alkoxy phenylene vinylene-*b*-isoprene) (PPV-PI) rod-coil block copolymers. In situ measurements have also shown the magnetic field leads to a stabilization of the ordered phase. Furthermore, there appear to be two distinct timescales for alignment: at short times the alignment of these materials is fast likely caused by preferential growth of aligned domains, and at long times alignment increases by the very slow process of defect annihilation. Further, there is an optimum temperature where the kinetics and thermodynamic driving forces for alignment are balanced, producing very highly aligned samples. Understanding the mechanisms by which alignment occurs has lead to knowledge helping to rationally optimize the magnetic alignment of rod-coil block copolymers.

9:12AM V50.00007 In-situ SAXS observation of magnetic field effects on block copolymer ordering and alignment¹, CHINEDUM OSUJI, MANESH GOPINADHAN, PAWEŁ MAJEVSKI, Dept. of Chemical and Environmental Engineering, Yale University — The use of external fields to direct block copolymer self-assembly is well documented. Magnetic fields offer particular promise due to their space-pervasive nature and the ability to produce arbitrary alignments over truly macroscopic length scales in appropriate systems. We present here the results of in-situ SAXS studies of side-chain liquid crystalline diblock copolymers ordering under high magnetic fields and ex-situ GISAXS data on thin films. Despite the coincidence of the block copolymer order-disorder transition (ODT) and the LC clearing temperature in these weakly segregated materials, there is no measurable effect of the field on the ODT of the system, up to 6 T. This is in line with rough estimates based simply on the magnitudes of the relevant energy scales - the free energy of field interaction and the enthalpy of the isotropic-LC transition. We show that the alignment of the system is critically limited by the viscosity of the mesophase such that alignment can only be advanced by residence in a small temperature window near T_{ODT} . This residence produces a weakly aligned system which thereafter transitions to a strongly aligned state on cooling even in the absence of the field.

¹NSF support under DMR-0847534 is gratefully acknowledged.

9:24AM V50.00008 Characterizing Mesoporous Block Copolymers by Resonant Soft X-ray Scattering¹, DAVID WONG, KEITH BEERS, UC Berkeley and Lawrence Berkeley National Lab, CHENG WANG, Advanced Light Source, Lawrence Berkeley National Lab, JEFFREY KORTRIGHT, Lawrence Berkeley National Lab, NITASH BALSARA, UC Berkeley and Lawrence Berkeley National Lab — Mesoporous block copolymers membranes can be used as water filtration membranes and battery separators. In these applications, it is often advantageous to generate a structure where one block serves as a structural component, and the second block lines the pores. The membrane thus has 3 components: the two blocks and vacuum (or air). Small Angle X-ray Scattering (SAXS), which relies on electron density for contrast, only distinguishes between vacuum and polymer. This is because the scattering contrast between the two blocks is much less than that between the polymer and vacuum. Resonant Soft X-ray Scattering (RSoXS) experiments can be used to adjust the contrast between block copolymer phases by tuning the energy of the incident x-ray beam. We have studied mesoporous poly(styrene-block-ethylene-block-polystyrene) (SES) films, where the semicrystalline polyethylene serves as a structural phase, and the polystyrene lines the pores. At a particular energy, the scattering contrast between PS and vacuum becomes negligible, while contrast between PS and PE is enhanced. We present RSoXS data at different x-ray energies to demonstrate this contrast enhancement.

9:36AM V50.00009 Self-assembly Morphology and Crystallinity Control of Di-block Copolymer Inspired by Spider Silk¹, WENWEN HUANG, SREEVIDHYA KRISHNAJI, DAVID KAPLAN, PEGGY CEBE, Tufts University — To obtain a fuller understanding of the origin of self-assembly behavior, and thus be able to control the morphology of biomaterials with well defined amino acid sequences for tissue regeneration and drug delivery, we created a family of synthetic silk-based block copolymers inspired by the genetic sequences found in spider dragline, HABn and HBAn ($n=1,2,3,6$), where B = hydrophilic block, A = hydrophobic block, and H is a histidine tag. We assessed the secondary structure of water cast films by Fourier transform infrared spectroscopy (FTIR). The crystallinity was determined by Fourier self-deconvolution of amide I spectra and confirmed by wide angle X-ray diffraction (WAXD). Results indicate that we can control the self-assembled morphology and the crystallinity by varying the block length, and a minimum of 3 A-blocks are required to form beta sheet crystalline regions in water-cast spider silk block copolymers. The morphology and crystallinity can also be tuned by annealing. Thermal properties of water cast films and films annealed at 120 C were determined by differential scanning calorimetry and thermogravimetry. The sample films were also treated with 1,1,1,3,3,3-Hexafluoro-2-propanol (HFIP) to obtain wholly amorphous samples, and crystallized by exposure to methanol. Using scanning and transmission electron microscopies, we observe that fibrillar networks and hollow micelles are formed in water cast and methanol cast samples, but not in samples cast from HFIP.

¹Support was provided from the NSF CBET-0828028 and the MRI Program under DMR-0520655 for thermal analysis instrumentation.

9:48AM V50.00010 The Effects of Blockiness on the Chemical Composition Distribution of Partially Functionalized Polystyrene, WAYNE POWERS, Rensselaer Polytechnic Institute, JAN GENZER, North Carolina State University, CHANG Y. RYU, Rensselaer Polytechnic Institute, RENSSELAER POLYTECHNIC INSTITUTE COLLABORATION, NORTH CAROLINA STATE UNIVERSITY COLLABORATION — Monodisperse polystyrene has been functionalized chemically to make random copolymers with controlled sequence distribution of the unmodified and modified styrene segments. The sequence blockiness of the resulting random copolymers can be controlled via the temperature of reaction, with a high temperature reaction resulting in a "truly random" copolymer, and a low temperature resulting in a "random blocky" copolymer. Interaction chromatography has been employed to estimate the chemical composition distribution of these partially functionalized polystyrenes. Two different chemical systems will be discussed; i.e., the brominated and borylated polystyrene systems. The results of our analysis reveal that the chemical composition distribution of "random blocky" copolymers is narrower than that of the corresponding "truly random" copolymers. The chemical composition of the two systems will be compared directly, and the influence of "chain conformation inversion" will be discussed.

10:00AM V50.00011 Large Scale Purification and Characterization of Model Poly(isopropyl methacrylate)-block-Poly(styrene) Diblock Copolymers, ASEM ABDULAHAD, Rensselaer Polytechnic Institute, DU YEOL RYU, Yonsei University, CHANG YEOL RYU, Rensselaer Polytechnic Institute — The development of purification techniques of block copolymers is vital for overcoming the synthetic difficulty of preparing well-defined block copolymers using various living polymerization techniques. A large scale separation technique would lead us to obtaining sufficient amounts of homopolymer-free block copolymers for subsequent physical characterization. This can potentially aid in the elucidation of the role of chemical heterogeneity on the thermodynamic transitions and viscoelastic properties of block copolymer materials. Employing an acute understanding of polymer adsorption/desorption onto nanoporous silica during solvent gradient interaction chromatography, we demonstrate the large scale purification of anionic polymerized poly(isopropyl methacrylate)-block-poly(styrene) diblock copolymers with narrow molecular weight distribution. Additionally, we address the impact of removing early-terminated poly(styrene) homopolymers on the viscoelasticity of these model diblock copolymers, as well as their impact on block copolymer assembly as analyzed by small-angle X-ray scattering.

10:12AM V50.00012 Quantifying Fluctuation Effects on the Order-Disorder Transition of Symmetric Diblock Copolymers, JING ZONG, QIANG (DAVID) WANG, Department of Chemical and Biological Engineering Colorado State University — How fluctuations change the order-disorder transition (ODT) of symmetric diblock copolymers is a classic yet unsolved problem in polymer physics.¹ Here we unambiguously quantify the fluctuation effects by direct comparisons between fast off-lattice Monte Carlo (FOMC) simulations² and mean-field theory using exactly the same model system (Hamiltonian), thus without any parameter-fitting. The symmetric diblock copolymers are modeled as discrete Gaussian chains with soft, finite-range repulsions as commonly used in dissipative-particle dynamics simulations. The effects of chain discretization and finite-range interactions on ODT are properly accounted for in our mean-field theory.³ Our FOMC simulations are performed in a canonical ensemble with variable box lengths to eliminate the adverse effects of fixed box sizes on ODT.⁴ Furthermore, with a new order parameter for the lamellar phase, we use replica exchange and multiple histogram reweighting to accurately locate ODT in our simulations.

10:24AM V50.00013 Simulation of micelle lattice ordering via nucleation from disorder in a diblock copolymer melt, RUSSELL SPENCER, ROBERT WICKHAM, University of Guelph — We examine the dynamics of the order-disorder transition (ODT) in diblock copolymer melts by simulating the nucleation of the BCC phase of spherical micelles out of the disordered phase, using the time-dependent Landau-Brazovskii model. Questions about the description of the disordered phase as a phase of disordered micelles, and the role of intermediate close-packed structures suggest a rich dynamics for this ordering transition. For a copolymer composition $f = 0.39$, we find that above a critical size, which diverges at the ODT, a spherical nucleus of the BCC micelle phase grows, forming the BCC phase directly. The growth rate varies linearly with undercooling. We also examine the growth of nuclei of the close-packed phases. For more asymmetric copolymers, $f = 0.35$ and $f = 0.3$, a region of disordered micelles surrounds a core of the BCC phase in the growing nucleus, suggesting that, for asymmetric copolymers, the ODT proceeds via a two-step mechanism.

10:36AM V50.00014 Order-to-order Transition in Closed-loop type Block Copolymer, HYUNGJU AHN, HOYEON LEE, SUNGMIN PARK, DU YEOL RYU, Yonsei University — Recently, the complex morphologies such as gyroid (GYR), hexagonally perforated layer (HPL) and non-cubic network phase (Fd $\bar{d}$) observed in block copolymer (BCP) melts. In this study, we investigated the unique and unusual OOT behavior of asymmetric deuterated polystyrene-block-poly(n-pentyl methacrylate) copolymers, denoted as dPS-b-PnPMA at narrow range of volume fraction. Scattering results and transmission electron microscopy show that dPS-b-PnPMA exhibits an unusual OOT phase behavior of GYR $\rightarrow$ HPL and GYR $\rightarrow$ HPL $\rightarrow$ GYR, whereas a general morphological transition occurs from HPL to GYR with increasing temperature. The OOT process found in this work provides a physical insight into a new type of morphological transition in diblock copolymer system.

10:48AM V50.00015 Self-assembly Behavior of Poly(3-alkylthiophene)-*block*-poly(methyl methacrylate) Block Copolymers Prepared by Anionic Coupling Reaction, JIN KON KIM, HONG CHUL MOON¹, Pohang University of Science and Technology — We synthesized rod-coil block copolymers composed of regioregular poly(3-alkylthiophene) (P3AT) and poly(methyl methacrylate) (PMMA) via anionic coupling reaction. For poly(3-hexylthiophene)-b-PMMA, the morphology was mainly determined by self-crystallization of P3HT moieties due to strong rod-rod interaction. On the other hand, poly(3-decylthiophene) (P3DDT)-b-PMMA, the self-crystallization was effectively suppressed. Detail phase behaviors were investigated at temperatures higher melting point (T_m) of P3DDT using small-angle x-ray scattering (SAXS), wide-angle x-ray scattering (WAXS) and transmission electron microscopy (TEM).

Session V52 GSNP DFD: Focus Session: Extreme Mechanics - Biological Systems and Structures 153C

8:00AM V52.00001 Micro-actuation through swelling and tissue engineering, NICHOLAS FANG, MIT
— No abstract available.

8:36AM V52.00002 Plant tendrils: Nature's hygroscopic springs, SHARON GERBODE, Harvey Mudd College, JOSHUA PUZEY, ANDREW MCCORMICK, L. MAHADEVAN, Harvard University — Plant tendrils are specialized climbing organs that have fascinated biologists and physicists alike for centuries. Initially straight tendrils attach at the tip to an elevated rigid support and then winch the plant upward by coiling into a helical morphology characterized by two helices of opposite handedness connected by a helical perversion. In his renowned treatise on twining and tendril-bearing plants, Charles Darwin surmised that coiled tendrils serve as soft, springy attachments for the climbing plant. Yet, the true effect of the perverted helical shape of a coiled plant tendril has not been fully revealed. Using a combination of experiments on Cucurbitaceae tendrils, physical models constructed from strained rubber sheets, and numerical models of helical perversions, we have uncovered that tendril coiling occurs via anisotropic shrinkage of a strip of specialized cells in the interior of the tendril. Furthermore, variations in the mechanical behavior of tendrils as they become drier and “woodier” adds a new twist to the story of tendril coiling.

8:48AM V52.00003 Radial force development during root growth measured by photoelasticity, EVELYNE KOLB, PMMH-UMR 7636 ESPCI, 10 rue Vauquelin, 75231 Paris Cedex 5, France; Université Pierre et Marie Curie - Paris 6, 75230 Paris cedex 05, France, CHRISTIAN HARTMANN, IRD-UMR 211 “BIOEMCO,” 46 rue d'Ulm, 75230 Paris cedex 05, France, PATRICIA GENET, CNRS-UMR 7618, 46 rue d'Ulm, 75230 Paris cedex 05, France; Université Paris Diderot - Paris 7, 75205 Paris cedex 13, France — The mechanical and topological properties of a soil like the global porosity and the distribution of void sizes greatly affect the development of a plant root, which in turn affects the shoot development. In particular, plant roots growing in heterogeneous medium like sandy soils or cracked substrates have to adapt their morphology and exert radial forces depending on the pore size in which they penetrate. We propose a model experiment in which a pivot root (chick-pea seeds) of millimetric diameter has to grow in a size-controlled gap δ (δ ranging 0.5-2.3 mm) between two photoelastic grains. By time-lapse imaging, we continuously monitored the root growth and the development of optical fringes in the photoelastic neighbouring grains when the root enters the gap. Thus we measured simultaneously and in situ the root morphological changes (length and diameter growth rates, circumnutation) as well as the radial forces the root exerts. Radial forces were increasing in relation with gap constriction and experiment duration but a levelling of the force was not observed, even after 5 days and for narrow gaps. The inferred mechanical stress was consistent with the turgor pressure of compressed cells. Therefore our set-up could be a basis for testing mechanical models of cellular growth.

9:00AM V52.00004 Digging Like Plants: Flexible Intruders in Granular Materials, DAWN WENDELL, KATHARINE LUGINBUHL, MIT, DIEGO SOLANO, Northeastern University, PEKO HOSOI, MIT — Inspired by plant root growth in granular media, we report on the effects of flexibility on the mechanical work required to dig through granular systems. In the case where the digger is significantly thinner than the grain diameter, increased flexibility in one-dimension leads to savings of nearly 50%. A simple numerical model based solely on the variability of forces in the granular substrate and the flexibility of the digger gives similar results to those observed in experiments.

9:12AM V52.00005 Helical Buckling of Plant Roots: Mechanics and Morphology, JESSE SILVERBERG, Department of Physics, Cornell University, ROSLYN NOAR, Department of Plant Pathology, North Carolina State University, MICHAEL PACKER, Department of Physics, Cornell University, MARIA HARRISON, Boyce Thompson Institute, Cornell University, CHRIS HENLEY, ITAI COHEN, Department of Physics, Cornell University, SHARON GERBODE, School of Engineering and Applied Sciences, Harvard University — How do plant roots respond to heterogeneities in their environment as they grow? Using a simple model system consisting of a layered hydrogel, we present a controlled mechanical barrier to the roots allowing us to perturb their growth. Interestingly, we find a localized helical root morphology which forms prior to the root passing through the gel layer interface. We interpret this geometry as a combination of a purely mechanical buckling caused by continued root elongation modified by the growth medium and a simultaneous twisting near the root tip. We study the morphology of the helical deformation as the modulus of the gel is varied using 3D time-lapse imaging and demonstrate that its shape scales with gel stiffness as expected by a simple model based on the theory of buckled rods. Our results demonstrate that mechanics is sufficient to account for the shape and its variations. In addition, we hypothesize that the twisted growth near the root tip arises from a touch-activated growth response that we call thigmotorsion.

9:24AM V52.00006 Dislocations and Grain Boundaries in Optimally-Packed, Twisted Filament Bundles, AMIR AZADI, Department of Physics, University of Massachusetts, Amherst, GREGORY GRASON, Department of Polymer Science and Engineering, University of Massachusetts, Amherst — From the collagen fiber to the parallel-actin bundle, twisted and rope-like assemblies of filamentous molecules are common and vital structural elements in cells and tissue of living organisms. We study the intrinsic frustration occurring in these materials between the two-dimensional organization of filaments in cross-section and out-of-plane interfilament twist in bundles based on the non-linear continuum elasticity theory of columnar materials. We find that interfilament twist generates in-plane stresses that couple favorably to the presence of topological defects, edge dislocations, in the cross-sectional packing, thereby restructuring the ground state filament packing of twisted bundles. The stability of dislocations increases with increases in both the degree of twist and lateral bundle size. We show that in ground states of large bundles, multiple dislocations pile up into linear arrays, radial grain boundaries, whose number and length grows with bundle twist. Remarkably, the “polycrystalline” texture of these optimal packings of twisted bundles show a striking similarity to models of the “almost crystalline” cross-section of collagen fibers.

9:36AM V52.00007 Mechanical Behavior of Bio-inspired Model Suture Joints, YANING LI, Department of Mechanical Engineering, ERICA LIN, CHRISTINE ORTIZ, Department of Materials Science and Engineering, MARY BOYCE, Department of Mechanical Engineering, BOYCE GROUP/MIT COLLABORATION, ORTIZ GROUP/MIT COLLABORATION — Suture joints of varying degrees of geometric complexity are prevalent throughout nature as a means of joining structural elements while providing locally tailored mechanical performance. Here, micromechanical models of general trapezoidal waveforms of varying hierarchy are formulated to reveal the role of geometric complexity in governing stiffness, strength, toughness and corresponding deformation and failure mechanisms. Physical constructs of model composite suture systems are fabricated via multi-material 3D printing (Object Connex500). Tensile tests are conducted on samples covering a range in geometry, thus providing quantitative measures of stiffness, strength, and failure. The experiments include direct visualization of the deformation and failure mechanisms and their progression, as well as their dependence on suture geometry, showing the interplay between shear and tension/compression of the interfacial layers and tension of the skeletal teeth and the transition in failure modes with geometry. The results provide quantitative guidelines for the design and tailoring of suture geometry to achieve the desired mechanical properties and also facilitate understanding of suture growth and fusion, and evolutionary phenotype.

9:48AM V52.00008 Morphogenesis of protrusions from confined lipid bilayers mediated by mechanics, MARINO ARROYO, Universitat Politècnica de Catalunya-BarcelonaTech, MARGARITA STAYKOVA, Princeton University, MOHAMMAD RAHIMI, Universitat Politècnica de Catalunya-BarcelonaTech, HOWARD A STONE, Princeton University — Biological membranes adopt a wide range of shapes that structure and give functionality to cells, compartmentalizing the cytosol, forming organelles, or regulating their area. The formation, stabilization, and remodeling of these structures is generally attributed to localized forces or to biochemical processes (insertion of proteins, active compositional regulation). Noting that in the crowded intra and extra-cellular environments membranes are highly constrained, we explore to what extent can mechanics explain the shape of protrusions out of confined membranes. For this purpose, we developed an in-vitro system coupling a lipid bilayer to the strain-controlled deformation of an elastic sheet (Staykova et al, PNAS 108, 2011). We show that upon contracting the elastic support, tubular or spherical protrusions grow out of the adhered membrane, which can be reversibly controlled with strain and osmolarity without resorting to localized forces or chemical alterations of the bilayer. The morphologies produced by our minimal system are ubiquitous in cells, suggesting mechanics may be a simple and generic organizing principle. We can understand most of our observations in terms of a phase diagram accounting for elasticity, adhesion, and the limited amount of area and volume available.

10:00AM V52.00009 Thin-shell model for faceting of multicomponent elastic vesicles, RASTKO SKNEPNEK, MONICA OLVERA DE LA CRUZ, Northwestern University — We use a discretized version of a thin elastic shell model to show that a two-component elastic vesicle can lower its energy by faceting into a wide variety of polyhedral shapes. The elastic shell model allows us to completely remove effects of the topological defects necessarily present in spherical topology. Therefore, we show that the faceting mechanism of multicomponent elastic vesicles is fundamentally different than the familiar defect-driven buckling into icosahedra. We present a detailed gallery of faceted shapes and discuss how the interplay between bending and stretching energies leads to faceting. Present work extends our recent study of the faceting of a two-component shell in the presence of topological defects [1]. [1] G. Vernizzi, R. Sknepnek, M. Olvera de la Cruz, Proc. Natl. Acad. Sci. USA 108, 4292 (2011).

10:12AM V52.00010 Charge Effects on Mechanical Properties of Elastomeric Proteins, RAVI KAPPIYOR, Department of Engineering Science and Mechanics, Virginia Tech, Blacksburg, VA 24061, USA, GANESH BALASUBRAMANIAN, Eduard-Zintl-Institute für Anorganische und Physikalische Chemie, Technische Universität Darmstadt, 64287 Darmstadt, Germany, DANIEL DUDEK, ISHWAR PURI, Department of Engineering Science and Mechanics, Virginia Tech, Blacksburg, VA 24061, USA — Several biological molecules of nanoscale dimensions, such as elastin and resilin, are capable of performing diverse tasks with minimal energy loss. These molecules are efficient in that the ratio of energy output to energy consumed is very close to unity. This is in stark contrast to some of the best synthetic materials that have been created. For example, it is known that resilin found in dragonflies has a hysteresis loss of only 0.8% of the energy input while the best synthetic rubber made to date, polybutadiene, has a loss of roughly 20%. We simulate tensile tests of naturally occurring motifs found in resilin (a highly hydrophilic protein), as well as similar simulations found in reduced-polarity counterparts (i.e. the same motif with the charge on each individual atom set to half the natural value, the same motif with the charge on each individual atom set to zero, and a motif in which all the polar amino acids have been replaced with nonpolar amino acids). The results show a strong correlation between charge and extensibility. In order to further understand the effect of properties such as charge on the system, we will run simulations of elastomeric proteins such as resilin in different solvents.

10:24AM V52.00011 Denaturation of Circular DNA: Supercoils, overtwist and condensation¹

, ALKAN KABAKCIOGLU, Koc University, AMIR BAR, DAVID MUKAMEL, Weizmann Institute of Science — The statistical mechanics of DNA denaturation under fixed linking number is qualitatively different from that of the unconstrained DNA. Past work suggests that the nature of this constrained melting transition is sensitive to the mechanism that relaxes the torsional stress induced on the bound portions by the loops. Quantitatively different melting scenarios are reached from two alternative assumptions, namely, that the denatured loops are formed in expense of 1) overtwist, 2) supercoils. Recent work has shown that the supercoiling mechanism results in a BEC-like picture where a macroscopic loop appears at T_c and grows steadily with temperature while no such phenomenon has been reported for the overtwisting case. By extending an earlier result, we show here that a macroscopic loop appears in the overtwisting scenario as well. We calculate its size as a function of temperature and show that the fraction of the total sum of microscopic loops decreases above T_c , with a cusp at the critical point.

10:36AM V52.00012 Mechanics of short rod-like molecules in tension , PRASHANT PUROHIT, University of

Pennsylvania — Rod like macromolecules such as actin, DNA etc., are most commonly stretched using optical tweezers or fluid flow. In this presentation we will describe the mechanics of short rod like molecules in tension. The mechanics is dominated by the competition between tensile forces (exerted by fluid flow, or by a device, such as, optical tweezers) and the thermal fluctuations of the molecule. For molecules whose contour length is comparable to the persistence length we show that the boundary conditions play major role in determining the mechanical behavior. We use the equipartition theorem of statistical mechanics to obtain expressions for the amplitude of the transverse fluctuations of the molecule and its force-extension relation for various boundary conditions. We then apply our theory to an experiment on short fluctuating actin filaments trapped by various means. We estimate the tension in these filaments by fitting our theory to the measured values of transverse fluctuations as a function of the position along the filament.

10:48AM V52.00013 Turning by buckling: a cheap evolutionary strategy for turning among

marine bacteria , KWANGMIN SON, JEFFREY GUASTO, ROMAN STOCKER, MIT — Marine bacteria have long been known to swim forward and backward ('run and reverse') by controlling the rotational direction of a 20 nm helical flagellum. Recent detailed observations have shown that these bacteria can also make sharp, $\sim 90^\circ$ turns, an astounding feature for a micron-scale organism with just one degree of freedom under its control. We demonstrate that a buckling instability originating from the flexible linkage ('hook') between the body and the flagellum is responsible for the reorientation. Using high-magnification (40~100X) observations based on high-speed video microscopy (420~1000 fps), we captured the extreme deformation of the flagellum and the hook involved in this process. The mechanical properties of the hook are finely tuned to the hydrodynamic loads experienced by the cell: the hook becomes unstable only when the compressive load during the onset of forward swimming exceeds the threshold for Euler buckling. Combining the data with a model of buckling of thin structures, we show that bacteria take advantage of the flexibility of the flagellum and the hook to generate a turn, which may represent the evolutionarily cheapest bacterial strategy to actively change direction.

Session V53 GSNP: Wet and Cohesive Granular Materials 153B

8:00AM V53.00001 An analytical framework for aeolian saltation , MEREDITH REITZ, DOUGLAS JEROLMACK,

University of Pennsylvania — We construct an analytical framework for steady state aeolian saltation, using experimentally-derived splash function relationships and the additional constraint of a threshold height, above which the wind velocity is strong enough to carry a grain from reptation into saltation. This threshold height rises as the wind profile magnitude is lowered by the increasing number of saltating grains being accelerated by the wind, until the number of grains being demoted below this threshold due to loss of energy to collisions with the bed equals the number being promoted. The balance of these populations at steady state determines both the flux of grains in saltation and the saturated wind velocity profile, while the approach to this balance describes the transient evolution to this state. We also formulate the difference between the critical impact Shields stress, defined as the stress below which transport ceases, and the higher critical fluid Shields stress, at which transport is initiated. Finally, we test the dependence of grain flux and trajectory lengths and speeds on the erodibility of the bed, and compare these results with observed differences in scaling. We also compare our results to findings for saltation under water.

8:12AM V53.00002 X-Ray Fluoroscopy of Sedimentation in Elastic Fluids , T.A. BRZINSKI, R. KARUNA-

MUNI, A.D.A. MAIDMENT, P.E. ARRATIA, D.J. DURIAN, University of Pennsylvania — Dispersions of spheres in a Newtonian fluid will sediment until all grains form a packing. While the system approaches its final configuration, the dispersion is roughly homogenous in space and time except at two well-defined interfaces: a dispersion-supernatant interface, and an interface below the dispersion at which grains stack to form a packing. In order to better understand this packing process we perturb the dynamics at the lower interface by adding a flexible, high molecular weight polymer that enhances fluid elasticity. The fluid strain-rate between spheres has an extensional component that is inversely proportional to grain separation, so elasticity dominates the fluid forces as the grain separation becomes small, thus frustrating the packing process. In order to observe the effect of this perturbation, we utilize x-ray fluoroscopy. In the case of a system without polymer we observe settling rates in accordance with a typical Stokes' model until all grains have settled into a random packing. In the polymeric case we see that, alongside the Newtonian-like settling, there's a time- and depth-dependent compression of the disperse phase, resulting in a smooth transition between dispersion and packing rather than the sharp interface observed in the Newtonian case.

8:24AM V53.00003 Three dimensional imaging of soft sphere packings under shear¹ , JOSHUA

DIJKSMAN, HU ZHENG, ROBERT BEHRINGER, Duke University — The (microscopic) flow of three dimensional disordered athermal granular packings remains poorly understood. However, experimentally studying flow and deformations in a three dimensional packing of grains is challenging due to the opacity of such packings. We use refractive index matched scanning with hydrogel spheres to image such flows. Hydrogel is soft and has low friction, which allows for the study of contact forces via contact deformations. We look at how force networks develop in sheared packings close to the onset of mechanical rigidity.

¹Support from NSF-DMR0906908 and ARO-W911NF-11-1-0110 is gratefully acknowledged

8:36AM V53.00004 Fluidization of wet granulates under hydrodynamic shear - experiments¹

, CHRISTOPH GÖGELEIN, ILENIA BATTIATO, MATTHIAS SCHRÖTER, STEPHAN HERMINGHAUS, JÜRGEN VOLLMER, Max-Planck-Institute for Dynamics and Self-Organization, Göttingen, Germany — Very recently, the fluidization threshold of a wet granular bed under hydrodynamic shear forces were predicted theoretically [1]. This theory described the flow through a wet granular bed by a continuum model and provides analytical expressions for the averaged drag force on a single particle. Moreover, the theory predicts the stability of the granular bed in dependence of the strength of the capillary and buoyancy forces. These theoretical predictions are tested in the present study by a newly designed flow channel. We will present our first experimental results for the fluidization onset of granular beds.

[1] I. Battiato, and J. Vollmer, "Fluidization of wet granulates under hydrodynamic shear," submitted for publication.

¹We all thank the BP Explore Program for generous funding.

8:48AM V53.00005 Building designed granular towers one drop at a time, JULIEN CHOPIN, ARSHAD KUDROLLI, Clark University — The impact of a drop on a surface leads to beautiful dynamical shapes that result from a subtle interplay between inertial effects, fluid properties and substrate characteristics. In this talk, we will present an experiment where the successive impacts of drops lead to surprisingly slender mechanically stable structures that we called granular towers. They are created by dripping a dense granular suspension on a liquid absorbing surface such as a blotter paper or a dry granular bed. These towers formed by rapid solidification of the drop upon impact are analogous to many natural structures found in nature including frozen lava flows, icicles and stalagmites. We find that the height can be determined by balancing the excess liquid flux and the drainage through the granular tower. The velocity impact, the free fall time and the density of the suspension are found to control the tower width and its detailed morphology. We show that these facts can be manipulated to obtain various symmetric, smooth, corrugated, zigzag, and chiral structures. Further, the shape of the tower can be used as a quick diagnostic tool to characterize the rheology of a granular suspension. [J. Chopin and A. Kudrolli, Phys. Rev. Lett. 107, 208304 (2011)]

9:00AM V53.00006 Dynamics of failure in cohesive granular packings¹, JENNIFER RIESER, University of Pennsylvania, WENBIN LI, JU LI, Massachusetts Institute of Technology, JERRY GOLLUB, University of Pennsylvania and Haverford College, DOUGLAS DURIAN, University of Pennsylvania — We explore the grain-scale interactions that precede large-scale deformations and mark the onset of mechanical failure in two-dimensional disordered granular packings. The two-dimensionality of the system allows for direct observation of all particle dynamics during the compression of a pillar. The grains are cohesive, with an attraction governed by tunable capillary forces induced through an interstitial fluid. For our analysis, we focus on the evolution of local rearrangements into shear bands within the pillar, quantifying the structural differences within the packing due to the presence of cohesion. We observe that cohesion results in greater spatial heterogeneity within the packing during compression. We also compare the compression of ordered and disordered packings.

¹DMR05-1120901

9:12AM V53.00007 Cohesive granular aggregates under punching: theory and experiments, ALEXEI PERELET, TAPAN SABUWALA, GUSTAVO GIOIA, Department of Mechanical Science and Engineering - University of Illinois, Urbana-Champaign — When poured into a container, cohesive granular materials form low-density, open granular aggregates. If put under compression, these aggregates densify by particle rearrangement. We seek experimental evidence that particle rearrangement occurs in the form of a phase transition between two configurational phases of the aggregate (G. Gioia, A. M. Cuitiño, S. Zheng, and T. Uribe, PRL 88, 204302, 2002). We use a simple model to show that when an open granular aggregate with two configurational phases is penetrated by a punch that lacks a characteristic length scale, the functional relation between the punching force and the penetration of the punch depends solely on the dimensionality of the punch: for a two-dimensional, wedge-shaped punch the force-penetration curve is linear whereas for a three-dimensional, conical punch the force-penetration curve is quadratic. To test these predictions we carry out experiments with open granular aggregates of a fine powder. The experimental measurements are in accord with the theoretical predictions.

9:24AM V53.00008 Discrete Particle Dynamics Simulations of Adhesive Systems with Thermostatting¹, FLINT PIERCE, JEREMY LECHMAN, JOHN HEWSON, Sandia National Laboratories — Aggregation/coagulation/flocculation processes are ubiquitous in modern industry from fields as diverse as waste water treatment, the food industry, algae biofuel production, and materials processing where control of the size and morphology of aggregates is paramount to the application of interest. Population balance models have historically been used with success in predicting aggregation kinetics and size distributions for these processes. However, even the most robust population balance schemes can lack an exact description of the underlying physical processes governing attractive or adhesive particulate matter suspended in a background medium, including finite aggregate strength and yield stress, restructuring length and time scales, and response to hydrodynamic forces. In order to elucidate these phenomena, We develop and use a JKR type model for simulating adhesive particulate matter in a background medium varying from dilute gas to liquid. We evaluate the time and length scales for restructuring/fragmentation that result from this model as a function of aggregate size and fractal dimension. We additionally introduce a method for pairwise thermostatting of the adhesive potential and discuss the applicability of this model to various adhesive systems.

¹Supported by LDRD program at Sandia National Laboratories

9:36AM V53.00009 Normal Mode Spectrum of Finite Sized Granular Systems: The Effects of Fluid Viscosity at the Grain Contacts, JOHN VALENZA, DAVID JOHNSON, Schlumberger-Doll Research — We investigate the effects of adsorbed films on the attenuative properties of loose granular media occupying a finite sized rigid container, which is open on the top. We measure the effective mass, $\bar{M}(\omega)$, of loose tungsten particles prepared under two different sets of conditions: 1) We lightly coat tungsten grains with a fixed volume fraction of silicone oil (PDMS), where the liquid viscosity is varied for individual realizations. 2) In the other set of experiments we vary the humidity. On a theoretical level we are able to decompose the effective mass into a sum over the contributions from each of the normal modes of the granular medium. Our results indicate that increasing either the PDMS viscosity or the humidity, as the case may be, does markedly increase the damping rate of each normal mode relevant to our measurements. However, there is appreciable damping even in the absence of any macroscopic film. With a notable exception in the case of the highest humidity in the humidity controlled experiments, all the relevant modes are weakly damped in the sense of a microscopic theory based on damped contact forces between rigid particles.

9:48AM V53.00010 Influence of liquid bridges on the macroscopic properties of granular assemblies, GEOFFROY LUMAY, University of Liege, JORGE FISCINA, Universität des Saarlandes, FRANCOIS LUDEWIG, NICOLAS VANDEWALLE, University of Liege — We present the results of two experimental studies concerning the compaction dynamics of cohesive granular materials. In the first study, the cohesion between neighboring grains is induced by capillary bridges in a wet granular material. The cohesiveness is tuned using different liquids having specific surface tension values. The second study concerns initially dry granular materials surrounded by a well controlled air humidity. Then, the cohesion inside the packing is controlled through the relative humidity which influence both triboelectric and capillary effects. For both cases, the evolution of the parameters extracted from the compaction curves (the compaction characteristic time τ , the initial and final packing fractions) have been analyzed as a function of the cohesiveness. A model, based on free volume kinetic equations and the presence of a capillary energy barrier, is able to reproduce quantitatively the experimental results (Phys. Rev. Lett. 105, 048001 (2010)).

10:00AM V53.00011 Wetting and packing effects on evaporation out of a porous medium, CESARE MIKHAIL CEJAS, BERTRAND SELVA, RAPHAEL BEAUFRET, LARRY HOUGH, CNRS UMI 3254 Complex Assemblies of Soft Matter COMPASS, CHRISTIAN FRETIGNY, CNRS UMR7615 Physico-chimie des Polymères et des Milieux Dispersés (PPMD) - ESPCI Paris, REMI DREYFUS, CNRS UMI 3254 Complex Assemblies of Soft Matter COMPASS, COMPASS TEAM — Evaporation through granular media involves complex fluid transport and exhibits two regimes: (1) a capillary-supported regime maintaining hydraulic continuity to the surface and vapor exchange with the atmosphere followed by (2) a diffusion-limited regime through the medium. A well-defined intermediate partially saturated zone (PSZ) has already been observed in the past. It is evidently seen from our experimental investigations using a 2D model soil of glass beads. The PSZ is the region identified above the interface formed by the drying front, which separates the PSZ from the fully-saturated wet region. This intermediate zone is filled with a dynamic mixture of vapor and liquid. The existence of this zone is of significant importance as it sets the kinetics of the evaporation process. Here we will present how wetting and packing effects influence the size of this partially saturated zone and we will show how a simple model based on geometrical considerations can explain our observations.

10:12AM V53.00012 A coupled deformation-diffusion theory for fluid-saturated porous solids, DAVID HENANN, KEN KAMRIN, LALLIT ANAND, Department of Mechanical Engineering, MIT — Fluid-saturated porous materials are important in several familiar applications, such as the response of soils in geomechanics, food processing, pharmaceuticals, and the biomechanics of living bone tissue. An appropriate constitutive theory describing the coupling of the mechanical behavior of the porous solid with the transport of the fluid is a crucial ingredient towards understanding the material behavior in these varied applications. In this work, we formulate and numerically implement in a finite-element framework a large-deformation theory for coupled deformation-diffusion in isotropic, fluid-saturated porous solids. The theory synthesizes the classical Biot theory of linear poroelasticity and the more-recent Coussy theory of poroplasticity in a large deformation framework. In this talk, we highlight several salient features of our theory and discuss representative examples of the application of our numerical simulation capability to problems of consolidation as well as deformation localization in granular materials.

10:24AM V53.00013 Water Retention of Sandy Soil with Hydrogel Particle Additives under Steady Rain, YULI WEI, 1. Department of Physics and Astronomy, University of Pennsylvania ; 2. Complex Assemblies of Soft Matter, CNRS-Rhodia-UPenn UMI 3254, DOUGLAS DURIAN, Department of Physics and Astronomy, University of Pennsylvania — We probe the water retention behavior of a dry model sandy soil with hydrogel particle additives under a steady rain using a self-built raindrop impingement set-up. The 0.4mm dry hydrogel particles are sent into a dry model sandy soil, 1mm glass beads, in different methods and a steady rain is created to irrigate the soil packing. The mass of the retained water in the packing is measured as a function of rain time. The influences of packing height, gel concentration, and gel location are examined respectively. For the model sandy soil alone, the packing height has little effect on the results. Rain water wets a shallow top region and flows out through a narrow path in the packing. With hydrogel particles uniformly mixed into the top region of a model sandy soil packing, the retained water increases as the gel number ratio increases or when the hydrogel particles are concentrated into the wet top region. A better way is to place hydrogel particles in a layer at certain depths under soil surface. The wet gel layers formed during the rain not only lock water inside but also clog the water path and force rain water to wet other dry soil regions. The clogging efficiency is determined by the wet gel layer number and the soil confinement.

10:36AM V53.00014 Period tripling causes rotating spirals in agitated wet granular matter, KAI HUANG, INGO REHBERG, Experimentalphysik V, Universitaet Bayreuth, 95440 Bayreuth, Germany — Pattern formation of a thin layer of vertically agitated wet granular matter is investigated experimentally. Due to the strong cohesion arising from the capillary bridges formed between adjacent particles, agitated wet granular matter exhibits a different scenario as its dry counter-part. Rotating spirals with three arms, which correspond to the kinks between regions with different colliding phases, are the dominating pattern. This preferred number of arms corresponds to period tripling of the agitated granular layer, unlike predominantly subharmonic Faraday crispations in dry granular matter. The chirality of the spatiotemporal pattern corresponds to the rotation direction of the spirals. Understanding this well traceable instability could pave a way for testifying elaborate theories on dense flow of wet granular matter.

10:48AM V53.00015 The melting of an ice blok assembly¹, STEPHANE DORBOLO, FRS-FNRS, Universite de Liege, NICOLAS VANDEWALLE, Universite de Liege, CLAUDE LAROCHE, Private Laboratory, GRASP TEAM, PRIVATE LABORATORY TEAM — The melting of an assembly of ice blocks under an unidirectional controlled load was investigated. The volume occupied by the ice blocks and the volume of ice were simultaneously measured. While the ice volume continuously decreases, sudden breakdown of the total volume was observed suggesting large reorganization of the whole assembly. The waiting-times between two successive collapses and the magnitudes of the collapse have been correlated. The pile structure was studied using a x-ray tomography before and after a collapse. The arch network re-organization is responsible for the melting dynamics as the pile becomes more and more ordered during the melting.

Session V54 DCMP: Superconductivity: Magnetic Field Effects Including Vortex Related Phenomena (Theory) 152

8:00AM V54.00001 Vortex Dynamics in Ferromagnetic Superconductors: Excitations of Domain Walls and Enhanced Viscosity, SHIZENG LIN, LEV BULAEVSKII, CRISTIAN BATISTA, Theoretical division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545 — As more and more superconductors with coexisting magnetic order are found in the last decades, understanding of the vortex dynamics in these superconductors becomes a relevant issue [1, 2]. We investigate vortex dynamics in ferromagnetic superconductors both numerically and analytically. Driven by the Lorentz force, the vortices perturb the magnetic moments and excite magnons. At some velocities, the motion of vortices is resonant with magnetic moments, and the amplitude of magnon excitation is enhanced. When the relaxation rate of magnon is smaller than the pumping rate, the magnon becomes unstable and domain walls are created. The domain walls interact strongly with vortices motion and greatly enhance the viscosity of vortices. Depending on the density of vortices, the vortex configuration may be modulated by the magnetic system. The underlying dynamics of the vortices and magnetic moments can be probed by transport measurement.

8:12AM V54.00002 The effect of impurities on the Superheating field of Type II superconductors¹, FAREH PEI-JEN LIN, ALEXANDER GUREVICH, Department of Physics, Old Dominion University — We calculate the superheating field $H_s(T)$, the maximum field at which the Meissner state exists, for a type-II, single band s-wave superconductor with nonmagnetic and magnetic impurities. $H_s(T)$ was calculated for the entire temperature region $0 < T < T_c$ and arbitrary impurity concentrations by solving the Eilenberger equations for the large Ginzburg-Landau parameter. We show that, although the effect of nonmagnetic impurities on H_s is relatively weak, they give rise to a maximum in $H_s(T, c)$ at a concentration c corresponding to a moderately clean limit. Impurities significantly affect the density of states at $H = H_s$: in the clean limit the superheating field corresponds to a gapless state, but above a critical concentration $c > c_g$, the quasiparticle gap $E_g(c)$ appears at $H = H_s$ so that $E_g \sim 0.410\Delta$ in the dirty limit. This feature can be important for the nonlinear surface resistance at strong rf fields $H \sim H_s$.

8:24AM V54.00003 Gap structure probed by field-angle resolved thermal oscillations in Ce-CoIn₅ superconductor¹, MATTHIAS J. GRAF, TANMOY DAS, Los Alamos National Laboratory, ANTON B. VORONTSOV, Montana State Univ., ILYA VEKHTER, Louisiana State Univ. — We calculate the angle-resolved oscillations of the specific heat and thermal conductivity in a rotating in-plane magnetic field in the multiband superconductor CeCoIn₅ using realistic tight-binding Fermi surfaces. We find that an electron pocket at the M point and a hole pocket at the Γ point of the Brillouin zone yield sufficiently large Fermi surface anisotropies to produce fourfold oscillations not only for d -wave pairing, but also for s -wave pairing in the regime where our approximations are valid for both nodal and isotropic gap, namely near the upper critical field H_{c2} and down to fields of order $H_{c2}/2$. More importantly, in this region we find a sign reversal in the oscillations as a function of temperature and fixed field for all gap symmetries investigated. We compare our results with available data on CeCoIn₅ and CeIrIn₅ and discuss how Fermi surface anisotropies affect the identification of gap structures and symmetries.

8:36AM V54.00004 Pnictide Half-Dirac Nodal Quasiparticle Scaling Properties in Vortex State, IMAM MAKHFUDZ, Johns Hopkins University — We investigate the scaling properties of quasiparticles of Pnictide with “half-Dirac” node under magnetic field in vortex state. By computing the density of states, we aim to find in vortex state the form of non-Simon-Lee scaling predicted for such system by several recent works in non-vortex state. We find by exact diagonalization of the BdG Hamiltonian and finite size scaling a $N(E) \sim \sqrt{E}$ power law in the case without magnetic field which agrees with analytical prediction. We consider the vortex state by first studying the hypothetical situation of uniform magnetic field without vortices and then we properly treat the magnetic field-induced vortex lattice by expressing the BdG Hamiltonian in terms of superfluid velocity and Berry's gauge field. The two calculations are shown to agree with each other. We then analyze quantitatively, the effects of anisotropic dispersion to the quasiparticles scaling properties in vortices. A very crucial prediction is also made on an upper bound to the value of “anomalous dimension” δ of density of states scaling with magnetic field, a quantity that can be measured experimentally.

8:48AM V54.00005 Vortex-assisted photon counts and their magnetic field dependence in superconducting nano-wire single-photon detectors, LEV BULAEVSKII¹, MATTHIAS GRAF, SHIZENG LIN, Los Alamos National Laboratory, VLADIMIR KOGAN², Ames National Laboratory — We argue that photon counts in a superconducting nano-wire single-photon detector (SNSPD) are caused by the transition from a current-biased metastable superconducting state into the normal state. Such a transition is triggered by photons with the frequency ω above the critical frequency ω_c or by photons with the frequency $\omega < \omega_c$ and subsequent vortex crossing from one edge of the superconducting strip to the other. The vortex is pushed across the strip due to the Lorentz force in the presence of the bias current I . We calculate the efficiency of photon counts as a function of ω , I , bath temperature, and the strip geometry. We derive the dependence of the rate of vortex-assisted photon counts on the bias current at given ω and strip geometry. The resulting photon count rate has a plateau at high currents, close to the critical current, and drops as a power-law with high exponent at lower currents. While a magnetic field applied perpendicular to the superconducting strip does not affect the formation of hot spots by photons, it increases the rate of vortex crossings (with and without photons). We show that by applying a magnetic field one may identify the origin of dark and photon-assisted counts.

9:00AM V54.00006 Type-1.5 superconductivity: effects of interband interactions and Semi-Meissner State¹, EGOR BABAEV, UMass Amherst and KTH Stockholm, JOHAN CARLSTROM, KTH Stockholm and UMass Amherst, JULIEN GARAUD, UMass Amherst — A conventional superconductor is described by a single complex order parameter field which has two fundamental length scales, the magnetic field penetration depth λ and the coherence length ξ . Their ratio κ determines the response of a superconductor to an external field, sorting them into two categories as follows; type-I when $\kappa < 1/\sqrt{2}$ and type-II when $\kappa > 1/\sqrt{2}$. Multicomponent systems can possess three or more fundamental length scales and allow a separate “type-1.5” superconducting state when $\xi_1 < \sqrt{2}\lambda < \xi_2$. In that state, as a consequence of the extra fundamental length scale vortices attract one another at long range but repel at shorter ranges. As a consequence the system should form an additional Semi-Meissner state. In that state vortices form clusters in low magnetic fields. In the vortex clusters the component with larger coherence length is depleted and consequently its current is mostly concentrated on the boundaries of the vortex cluster, thus resembling the screening currents in type-I superconductors. We discuss how the vortex clusters and type-1.5 regimes are affected by various interband couplings in multiband superconductors.

¹Supported by NSF CAREER Award No. DMR-0955902, Swedish Research Council, and by the Knut and Alice Wallenberg Foundation through the Royal Swedish Academy of Sciences fellowship.

9:12AM V54.00007 Length scales, collective modes, and type-1.5 regimes in three-band superconductors¹, JOHAN CARLSTROM, KTH Stockholm, UMass Amherst, JULIEN GARAUD, UMass Amherst, EGOR BABAEV, KTH Stockholm, UMass Amherst — The recent discovery of iron pnictide superconductors has resulted in a rapidly growing interest in multiband models with more than two bands. We derive normal modes and characteristic length scales in the conventional $U(1)$ three-band Ginzburg-Landau model as well as in its time-reversal symmetry-broken counterpart with $U(1) \times Z_2$ symmetry. We show that, in the latter case, the collective modes are associated with the mixed phase-density modes and thus are different from the Leggett modes in two band superconductors. Next we show that gradients of densities and phase differences can be inextricably intertwined in vortex excitations in three-band models. This can lead to very long-range attractive intervortex interactions and the appearance of type-1.5 regimes even when the intercomponent Josephson coupling is large. We next show that field-induced vortices can lead to a change of broken symmetry from $U(1)$ to $U(1) \times Z_2$ in the system. In the type-1.5 regime, it results in a semi-Meissner state where the system has a macroscopic phase separation in domains with broken $U(1)$ and $U(1) \times Z_2$ symmetries.

9:24AM V54.00008 Molecular Dynamics of Type-1.5 Superconductors, QINGZE WANG, CHRISTOPHER VARNEY, University of Massachusetts, Amherst, HANS FANGOHR, University of Southampton, EGOR BABAEV, University of Massachusetts, Amherst — In multi-component superconductors and structures of interlaced layered type-I type-II layers there exists a range of parameters where inter-vortex interaction is repulsive at short ranges and attractive at long range. Such regimes were termed “type-1.5 superconductivity” recently. This vortex interaction leads to a microscopic phase separation in Meissner and vortex droplets. In this talk, we utilize molecular dynamics to investigate the magnetic response of such superconductors in the type-1.5 regimes.

9:36AM V54.00009 Stabilization of a vortex-antivortex lattice created by a magnetic-field pulse, V.N. GLADILIN, TQC, University of Antwerp and INPAC-University of Leuven, Belgium, J. TEMPERE, J.T. DEVREESE, TQC, University of Antwerp, Belgium, V.V. MOSHCHALOV, INPAC-University of Leuven, Belgium — Using the time-dependent Ginzburg-Landau approach, we theoretically investigate the formation and evolution of vortex-antivortex patterns, which are created in a thin superconducting film by a single pulse of an inhomogeneous magnetic field. The field pulse is induced by a periodic square array of current loops, where the current direction is either the same for all the loops or changes from one loop to another in the checkerboard order. In an ideally homogeneous superconductor film, the vortices and antivortices, generated by an applied magnetic field pulse, fully recombine within a relatively short time interval after switching off the current in the loops. We demonstrate that in the presence of even relatively weak pinning centers the vortex-antivortex distributions, induced by a short magnetic-field pulse, can eventually evolve into vortex-antivortex lattices, which remain stable for an arbitrarily long time. This work was supported by the Methusalem Funding of the Flemish Government, the NES-ESF program, the Belgian IAP, the Fund for Scientific Research-Flanders (FWO- Vlaanderen).

9:48AM V54.00010 Topological solitons in three-band superconductors with broken time reversal symmetry, JULIEN GARAUD, UMass Amherst and KTH Stockholm, JOHAN CARLSTROM, KTH Stockholm and UMass Amherst, EGOR BABAEV, UMass Amherst and KTH Stockholm — We report that three-band superconductors with Broken Time Reversal Symmetry allow magnetic field-induced topological solitons. When time reversal symmetry is broken, ground state exhibits $U(1) \times Z_2$ symmetry. Domain-wall, are natural solutions when theories exhibit such a discrete symmetry. Closed domain-walls are unstable to collapse because of their line tension. We show that closed domain-walls can be stabilized by confining vortices. The resulting topological solitons are stable and can be induced by fluctuations or quenching the system through a phase transition. This new kind of solitons can provide an experimental signature of the Time Reversal Symmetry Breakdown. Based on: J. Garaud, J. Carlström, and E. Babaev, Phys. Rev. Lett. 107, 197001 (Nov 2011).

10:00AM V54.00011 Vortex dynamics in Superconducting Corbino Disks: Molecular Dynamics and Heat Transport Simulations¹, MASARU KATO, DAVID FUJIBAYASHI, Department of Mathematical Sciences, Osaka Prefecture University — Understanding vortex dynamics is important for application of superconductivity, because vortex motion causes resistive state of superconductors and controlling vortex motion is useful for superconducting devices. Also vortex dynamics shows much variety of phenomena. In a corbino disk geometry, where electric current is injected at the center of the disk and flows toward the perimeter of the disk, vortex moves circular by the Lorentz force from this current. But the Lorentz force depend on the distance from the center as $1/r$, and therefore the vortex velocity faster in the center region than those in the perimeter region. Then vortex motion generates heat and causes non-uniform temperature distribution. Non-uniform temperature distribution causes further vortex motion. Therefore in the superconducting corbino disk, vortex dynamics is not a simple problem. In order to investigate this vortex dynamics, we combine the molecular dynamics and the heat transport simulations. Our simulation results show that dynamical structure of vortices depends on the heat resistance between the superconductor and a substrate as well as the heat capacity and heat conductance of superconductors. Especially there is a transition from laminar flow to the spiral or non-uniform flow.

10:12AM V54.00012 Φ_0 as a smallest unit of the intermediate state of a type-I superconductor: Revelation through nonlinear dynamics, GOLIBJON BERDIYOROV, Departement Fysica, Universiteit Antwerpen, Groenenborgerlaan 171, B-2020 Antwerpen, Belgium, ALEXANDER HERNANDEZ-NIEVES, Centro Atómico Bariloche, 8400 San Carlos de Bariloche, Rio Negro, Argentina, FRANCOIS PEETERS, Departement Fysica, Universiteit Antwerpen, Groenenborgerlaan 171, B-2020 Antwerpen, Belgium, DANIEL DOMINGUEZ, Centro Atómico Bariloche, 8400 San Carlos de Bariloche, Rio Negro, Argentina, MILORAD MILOSEVIC, Departement Fysica, Universiteit Antwerpen, Groenenborgerlaan 171, B-2020 Antwerpen, Belgium — We study by time-dependent Ginzburg-Landau simulations the nonlinear dynamics of the intermediate state in a current-carrying type-I superconductor. The stray magnetic field of the current induces the intermediate state, where nucleation of flux domains is *discretized to a single fluxoid at a time*, while their final shape (tubular or laminar), size and nucleation rate depend on applied current and edge conditions. The current induces opposite flux domains on opposite sides of the sample, and subsequently drives them to annihilation – which is *also discretized*, as a sequence of vortex-antivortex pairs. Discretization of both nucleation and annihilation leave measurable traces in the voltage signal across the sample. These dynamic phenomena provide an unambiguous proof of a flux quantum being the smallest building block of the intermediate state in type-I superconductors.

10:24AM V54.00013 Nucleation and development of dendritic flux avalanches in superconducting films, JØRN INGE VESTGÅRDEN, DANIIL SHANTSEV, YURI GALPERIN, TOM HENNING JOHANSEN, Department of Physics, University of Oslo, Norway — The stability of superconducting films is threatened by thermomagnetic runaways commonly observed as abrupt dendritic flux avalanches. We report numerical simulations of the electrodynamics and thermal behavior of superconducting films, where the gradual flux penetration is interrupted by such avalanches. The simulation formalism is based on an efficient method for treating the nonlinear and nonlocal electrodynamics, and it handles both the slow flux creep dynamics prior to the avalanches and the transition to the many orders of magnitude faster instability regime. Then the temperature rises quickly above the critical temperature, and the avalanche develops fully in less than 100 nanoseconds, with an initial velocity of approximately 100 km/s. Both the morphology and speed of the avalanches are in excellent agreement with results from magneto-optical imaging experiments. The sample is seeded with randomly distributed disorder, which results in a significantly reduced threshold for onset of avalanches. Interaction with the material disorder also contributes to branching and irreproducibility of the flux structures. However, disorder is not the main mechanism behind branching and dendritic structures are also found to develop in completely uniform samples.

10:36AM V54.00014 Josephson and pancake vortices in Bi-2212 with anti-dots array, KAZUTO HIRATA, SHUICHI OOI, TAKASHI MOCHIKU, National Institute for Materials Science — Josephson and pancake vortices in Bi-2212 with anti-dots (holes) array have been studied with measuring the flow-resistance and the c-axis resistance. The samples for the measurements were prepared by a focused ion-beam milling with a diameter of 200 nm and 1000 nm pitch hole-array and in the in-line structure. Angular dependence of the flow-resistance does not show lock-in phenomenon as usually observed in the behaviors of Josephson vortices in Bi-2212. Instead, there are several peaks observed in the flow-resistance. A couple of peak can be explained with the matching field effect of pancake vortices to the array, but the others not. The c-axis transport measurements show characteristic transitions near the matching fields and between them in the c-axis resistance with the perpendicular field to the superconducting layers. This is related to the accommodation rate of pancake vortices into the holes and to the interaction between/among the vortices outside the holes and the trapped vortices.

10:48AM V54.00015 Effect of pinning force on critical current using molecular dynamic simulation, ABDALLA OBEIDAT, HADEEL ABU LAHIM, Jordan University of Science and Technology — Molecular dynamics have been used to study the effect of pinning force on the critical current at different temperatures. Our simulation is built on assuming a two dimensional periodic arrays of vortices and pins at different sites. The critical current density has been studied at different temperatures by solving the over damped equation of vortex motion taking into account the vortex-vortex interaction, the thermal force, the vortex-pinning interaction as well as the driving Lorentz force. The results show a second phase transition at specific low temperature at all pinning forces with a definite pinning size.

Thursday, March 1, 2012 11:15AM - 1:51PM – Session W1 DAMOP: Photonic Systems and Entanglement Generation 203

11:15AM W1.00001 Efficient quantum computing using coherent photon conversion, NATHAN K. LANGFORD, University of Vienna, Austrian Academy of Sciences, University of Oxford, SVEN RAMELOW, University of Vienna, Austrian Academy of Sciences, ROBERT PREVEDEL, University of Vienna, University of Waterloo, WILLIAM J. MUNRO, NII and NTT Basic Research Laboratories, GERARD J. MILBURN, University of Queensland, University of Vienna, ANTON ZEILINGER, University of Vienna, Austrian Academy of Sciences — Single photons make very good quantum information carriers, but current schemes for photonic quantum information processing (QIP) are inefficient. We describe a new scheme, *coherent photon conversion (CPC)*, using classically pumped nonlinearities to generate and process complex multiqumata states¹. One example based on four-wave mixing provides a full suite of QIP tools for scalable quantum computing from a single, versatile process, including: deterministic multiqubit entanglement gates based on a novel photon-photon interaction, high-quality heralded multiphoton states without higher-order imperfections, and robust, high-efficiency detection. Using photonic crystal fibres, we present observations of quantum correlations from a four-colour nonlinear process suitable for CPC and study the feasibility of reaching the deterministic regime with current technology. The scheme could also be implemented in optomechanical, electromechanical and superconducting systems.

¹Published in Nature **478**, 360 (2011)

11:27AM W1.00002 Dephasing of multiparticle Rydberg excitations for fast entanglement generation¹, F. BARIANI, Y.O. DUDIN, T.A.B KENNEDY, A. KUZMICH, School of Physics, Georgia Institute of Technology, Atlanta, GA, 30332-0430, USA — We propose an approach to fast entanglement generation based on Rydberg dephasing of collective excitations (spin waves) in large, optically thick atomic ensembles. Rather than trying to prevent multiple excitations via the Rydberg blockade mechanism, our idea is to allow multiple Rydberg level excitations to self-interact and dephase. The strong interaction required to dephase multiple excitations is induced by mixing adjacent, opposite-parity Rydberg levels with a microwave field. These levels experience resonant $1/r^3$ dipole-dipole interactions ($ns + n'p \rightarrow n'p + ns$) that extend over the whole ensemble in contrast to the weaker, short range $1/r^6$ Van der Waals coupling due to non-resonant processes ($ns + ns \rightarrow np + (n-1)p$). The interaction-induced phase shifts suppress the contribution of multiply excited states in phase matched optical retrieval. The dephasing mechanism therefore permits isolation and manipulation of individual spin wave excitations. High quality single photons can be created with $1/e$ maximum efficiency in few microseconds. The dephasing mechanism is shown to have favorable, approximately exponential, scaling. Required long coherence times are achieved via four-photon excitation and read-out of long wavelength spin waves.

¹We acknowledge financial support from NSF and AFOSR.

11:39AM W1.00003 Unconventional ultra-efficient photon blockade and single-photon emitters from weakly nonlinear systems based on coupled cavities, MOTOAKI BAMBA, CRISTIANO CIUTI, Laboratory MPQ, University Paris Diderot - Paris 7 and CNRS — Single photons are usually generated by non-resonant excitation of single (artificial) atoms or by resonant excitation of Kerr systems with a giant nonlinear interaction much larger than the losses of the system (standard photon blockade). Here, we present a general class of destructive quantum interference effects [1,2], which provide a robust protocol to achieve strong photon antibunching and single-photon emission in a double cavity system, where one resonantly driven cavity is coupled to an auxiliary nonlinear cavity. An original scheme [2] shows the single-photon emission can be also produced by the auxiliary cavity with orthogonal polarization with respect to the pump beam, hence providing a direct way to get spatial and polarization selection.

11:51AM W1.00004 Anomalous Stokes scattering by an atomic ensemble: detection of entanglement and vector metrology of field gradient¹, WANG YAO, HONGYI YU, Department of Physics and Center for Theoretical and Computational Physics, The University of Hong Kong — We investigate the collective Stokes scattering by a typical atomic cloud, i.e. with size much larger than the light wavelength and with density much lower than that required for Dicke superradiance. We show that the diffraction pattern of the Stokes photon can be used to detect entanglement in the atomic ensemble. When the atomic cloud is placed in a static magnetic field or electric field, the change of diffraction pattern by the evolution in the field can also provide sensitive vector metrology of the spatial gradient of the field.

¹The work was supported by the Research Grant Council of Hong Kong under Grant No. HKU 706711P.

12:03PM W1.00005 Unique Properties and Prospects: Quantum Theory of the Orbital Angular Momentum of Ince-Gauss Beams¹, WILLIAM PLICK, MARIO KRENN, ROBERT FICKLER, SVEN RAMELOW, ANTON ZEILINGER, Institute for Quantum Optics and Quantum Information — The Ince-Gauss modes represent a new addition to the standard solutions to the paraxial wave equation. Parametrized by the ellipticity of the beam, they span the solution space between the Hermite-Gauss and the Laguerre-Gauss modes. These beams may be decomposed in either basis, and single photons in the Ince-Gauss modes exist naturally as superpositions of either Laguerre-Gauss or Hermite-Gauss modes. We present the fully quantum theory of the orbital angular momentum of these beams. Interesting features that arise are: stable beams with fractional orbital angular momentum, non-monotonic behavior of the OAM with respect to ellipticity, and the possibility of orthogonal modes possessing the same OAM. We believe that these modes may open up a fully new parameter space for quantum informatics and communication, and thus are worthy of thorough study.

¹Austrian Academy of Sciences

12:15PM W1.00006 Entanglement of Ince-Gauss Modes of Photons¹, MARIO KRENN, ROBERT FICKLER, WILLIAM PLICK, RADEK LAPKIEWICZ, SVEN RAMELOW, ANTON ZEILINGER, University of Vienna, Faculty of Physics, IQOQI Vienna, Austrian Academy of Sciences, Austria — Ince-Gauss modes are solutions of the paraxial wave equation in elliptical coordinates [1]. They are natural generalizations both of Laguerre-Gauss and of Hermite-Gauss modes, which have been used extensively in quantum optics and quantum information processing over the last decade [2]. Ince-Gauss modes are described by one additional real parameter – ellipticity. For each value of ellipticity, a discrete infinite-dimensional Hilbert space exists. This conceptually new degree of freedom could open up exciting possibilities for higher-dimensional quantum optical experiments. We present the first entanglement of non-trivial Ince-Gauss Modes. In our setup, we take advantage of a spontaneous parametric down-conversion process in a non-linear crystal to create entangled photon pairs. Spatial light modulators (SLMs) are used as analyzers. 12:27PM W1.00007 Entangling two spatially separated qubits via interaction with nonclassical radiation¹, EYOB SETE, Department of Physics and Astronomy, Texas A&M University, SUMANTA DAS, Max-Planck-Institute fur Kernphysik — We propose a scheme for entangling two spatially separated noninteracting qubits using two-mode squeezed light in a cavity. Unlike other methods that typically require dipolar coupling for creating entanglement, our proposal relies solely on the interaction of the qubits with the squeezed cavity field. The squeezed field induces exchange of correlated photons which leads to transfer of entanglement from the field to discrete entanglement between qubits. Our scheme exhibits substantial steady-state entanglement which is robust against decoherence under the strong squeezing condition. In addition, we find that the entanglement generated between two asymmetric qubits is stronger than that generated by identical ones and crucially depends on the degree of squeezing.

¹E. A. S. is supported by the Herman F. Heep and Minnie Belle Heep Texas A&M University Endowed Fund held and administered by the Texas A&M Foundation.

12:39PM W1.00008 Generating coherent states of entangled spins¹, HONGYI YU, YU LUO, WANG YAO, Department of Physics and Center of Theoretical and Computational Physics, The University of Hong Kong, Hong Kong, China — A coherent state of many spins contains quantum entanglement, which increases with the decrease of the collective spin value. We present a scheme to engineer this class of pure state based on incoherent spin pumping with several collective raising and lowering operators. In a pumping scenario aimed for maximum entanglement, the N -qubit steady state realizes the ideal resource for the $1 \rightarrow N/2$ quantum telecloning. We show how the scheme can be implemented in the cold atomic system in an optical lattice. Error analysis shows that high-fidelity state engineering is possible for $N \sim O(100)$ spins in the presence of decoherence. The scheme can also prepare the large-scale Affleck-Kennedy-Lieb-Tasaki state.

¹The work was supported by the Research Grant Council of Hong Kong under Grant No. HKU 706711P.

12:51PM W1.00009 Non-destructively probing matter-photon correlations described by the Dicke-Hubbard Lattice model¹, SARA RAJARAM, NANDINI TRIVEDI, The Ohio State University — The Dicke-Hubbard Lattice (DHL) Hamiltonian is a prototypical system to study photon matter entanglement across a symmetry breaking quantum phase transition in the matter subsystem. The model describes a cavity containing a periodic lattice, with a single mode photon field delocalized across the cavity. Like the Bose-Hubbard model, the Hamiltonian includes on-site repulsion between atoms and nearest neighbor hopping of an atom from one site to another. In addition, matter-light coupling in the DHL model can excite an atom to a higher band by absorbing a photon and the reverse process. We focus on the DHL model in a region of parameter space in which light is “superradiant” and matter is either a Mott-insulator or superfluid of both bands. Through mean field, exact diagonalization, and quantum Monte Carlo calculations we examine photon statistics across the matter quantum phase transition in order to elucidate how the photon statistics reflect the matter correlations. Doing so provides a novel technique to non-destructively probe the Mott-insulator to superfluid phase transition.

¹We acknowledge support from ARO W911NF-08-1-0338 (SR) and NSF DMR-0907275 (NT).

1:03PM W1.00010 The Impact of Geometry on the TM PBGs of Photonic Crystals and Quasicrystals, LIN JIA, MIT, ION BITA, Qualcomm MEMS Technologies, EDWIN THOMAS, Rice University — Here we demonstrate a novel quantitative procedure to pursue statistical studies on the geometric properties of photonic crystals and photonic quasicrystals (PQCs) which consist of separate dielectric particles. The geometric properties are quantified and correlated to the size of the photonic band gap (PBG) for wide permittivity range using three characteristic parameters: shape anisotropy, size distribution, and feature-feature distribution. Our concept brings statistical analysis to the photonic crystal research and offers the possibility to predict the PBG from a morphological analysis.

1:15PM W1.00011 A low-dimensional population-competition model for analyzing transverse optical patterns¹, Y.C. TSE, M.H. LUK, Physics Department, Chinese University of Hong Kong, N.H. KWONG, College of Optical Sciences, University of Arizona, P.T. LEUNG, Physics Department, Chinese University of Hong Kong, S. SCHUMACHER, Physics Department and Center for Optoelectronics and Photonics Paderborn, University of Paderborn, R. BINDER, College of Optical Sciences and Department of Physics, University of Arizona — Under favorable conditions, laser beams passing through a nonlinear medium (e.g. atomic vapors) can undergo directional instabilities, generating transverse optical patterns in the far field. In particular, a low intensity all-optical switching scheme using these transverse patterns in semiconductor quantum well microcavities was numerically demonstrated. Trying to understand the switching mechanism through the simulation results has turned out to be a complicated task. In this Contribution, we present a low-dimensional “population-competition” model that (i) exhibits nearly all the pattern selection and switching behaviors and (ii) is simple enough to allow a comprehensive analysis of its solution structure in the relevant region of parameter space. We will explain the relation between this simple model and the realistic theory. Using elementary methods in Catastrophe Theory, we analyze the “phase diagrams” of our model’s steady state solutions in parameter space, with the help of which we construct an organized picture of the behaviors of the realistic simulation results.

1:27PM W1.00012 Phonon effects on analog quantum simulation with ultracold ions in a linear Paul trap, C.-C. JOSEPH WANG, JAMES FREERICKS, Georgetown University — Linear Paul traps have been used to simulate the transverse field Ising model with long-range spin couplings. Here, we study the effects of phonon creation on the spin state probability and spin entanglement. The effective spin models are created by applying a spin-dependent force with a laser that couples the spin state to the phonons of the ion crystal. Adiabatically removing the phonons creates an action described by a static spin Hamiltonian plus additional quantum time-dependent phases. In appropriate limits, the system is described predominantly by the static spin Hamiltonian. Here, we solve for the evolution of the coupled spin-phonon system exactly using exact diagonalization and examine the effect of phonon creation during the simulation on the probabilities of different spin states and on their entanglement. In particular, we examine phonon effects on the possibility for seeing the kink transition when the laser is detuned between the two phonon modes that lie below the COM mode.

1:39PM W1.00013 Entanglement Effects in Highly Dense Systems, SAMINA MASOOD, University of Houston-Clear Lake — We study the effect of entanglement in Jaynes-Cummings model using Neumann Entropy in the highly dense systems. We study a highly dense system such as neutron star as a good application of our results.

Session W2 GIMS GERA: Invited Session: Instrumentation and Measurement Science for Energy Research: PV and Batteries 204AB

11:15AM W2.00001 Using Deep Level Transient Spectroscopy (DLTS) to characterize defects in semiconductor devices, DAVID LANG, Materials Physics Consultant — Deep Level Transient Spectroscopy (DLTS) is a member of the class of instrumentation methods that utilizes the detection of trapped electronic charge to characterize defects in solids. Such methods detect this charge either directly, e.g. via capacitance measurements, or indirectly, e.g. via the current associated with the release of trapped charge. These types of instrumentation have been widely used since the dawn of solid-state physics, particularly for nonradiative defects in semiconductors and insulators. In the case of semiconductor devices, the highly sensitive capacitive detection of trapped charge in the junction depletion layer makes these methods particularly powerful. The DLTS method introduced the concept of time-domain filtering (the so-called “rate window”) to create a defect spectrum from the transient response of the device versus temperature. This talk will give an overview of DLTS, with particular emphasis on the correlation between defects and device performance.

11:51AM W2.00002 Role of Defects and Their Analysis in Photovoltaics, ROBERT OPILA, University of Delaware — Defects are intrinsically related to the performance of solar cells. In solar cells the generation and collection of charge carriers determines their efficiency. Effective transport of charge carriers across interfaces and minimization of their recombination in the bulk or at surfaces and interfaces is of utmost importance. In this talk we will discuss the role of surface and bulk defects. First, the role of surface passivation is very important in limiting the rate of carrier of recombination. Here we will combine spectroscopic evaluation of the surface of a Si device with electrical lifetime measurements to ascertain what factors determine the quality of a solar cell passivation. We have also utilized time-resolved photoluminescence (TRPL) to assess the quality of materials grown under varying conditions. TRPL decay is best fit by a biexponential model that includes both the minority carrier lifetime and the rate of trap filling. At low laser powers the trap state recombination dominates and decay times are very short. At higher laser powers the trap states become saturated and we can extract the minority carrier lifetime. By evaluating the relative contributions of the trap-filling and minority carrier lifetimes we can assess the density of traps (defects) as a function of the growth conditions and guide refinement of growth recipes to improve material quality.

12:27PM W2.00003 The Integration of Scanning Electron Microscopy, Scanning Probe Microscopy, and Luminescence Spectroscopy in one Platform: New Opportunities and Applications in Photovoltaics, MANUEL ROMERO, National Renewable Energy Laboratory — We have recently integrated scanning tunneling microscopy (STM), atomic force microscopy (AFM), and near-field scanning optical microscopy (NSOM) onto the mechanical stage of a scanning electron microscope compatible with operation under high vacuum and the use of cryogenics. This instrument is unique in the sense that is not just the assembly of different microscopes but an integrated platform in which both the electron beam and the ultrasharp tip of the AFM/STM/NSOM can be controlled simultaneously and independently as excitation or sensing elements, providing innovative modes of operation and access to optoelectronic properties in the micro and nanoscale not accessible before. Furthermore, this instrument is equipped with focused laser illumination of the tip and detection of luminescence and can be used to measure cathodoluminescence, scanning tunneling luminescence, photoluminescence, and electroluminescence, all with high resolution. In this contribution, we review the application of these techniques to the development of second- and third-generation photovoltaics (PV) beyond those commercially available today. Among these applications, we present the luminescence and electron transport across single grain boundaries in chalcopyrite and kesterite compounds, the detection of single molecule species using plasmonics, the nanoscale imaging of the exciton transport in organic semiconductors, and the *in situ* manipulation and measurement of nanowires.

1:03PM W2.00004 Li ion nanowire batteries and their *in situ* characterization in the TEM, DMITRY RUZMETOV, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Gaithersburg, MD, USA — The ability to measure the morphological, chemical, and transport characteristics with nanoscale resolution in electrochemical energy storage devices is critical for understanding the complex interfacial reactions and phase transformation that accompany cycling of secondary batteries. In this talk I will describe the use of an all-nanowire Li ion battery for *in situ* characterization of charge and discharge reactions. The nanowire batteries (NWBs) consist of a metalized core, a LiCoO₂ cathode, LiPON solid electrolyte, and a thin film Si anode. Measuring several micrometers in length and several hundred nanometers in diameter, the NWBs can be readily imaged and analyzed in transmission electron microscopes (TEM, STEM). We use focused ion beam milling and electron beam induced deposition to separate the cathode and anode and fabricate Pt contacts to a NWB. *In situ* electrical cycling of NWBs in TEM reveals that the most of the structural changes due to cycling happens in the electrolyte layer especially near the cathode/electrolyte interface. Electrical response from a single NWB was measured in the sub-pA range. For NWBs with the thinnest electrolyte, approximately 100 nm, we observe rapid self-discharge, along with void formation at the electrode/electrolyte interface, indicating electrical and chemical breakdown. The analysis of the NWB's electrical characteristics reveals space-charge limited electronic conduction, which effectively shorts the anode and cathode electrodes. When the electrolyte thickness is increased, the self-discharge rate is reduced substantially and the NWBs maintain a potential above 2 V. Our study illustrates that at reduced dimensions the increase in the electric field can lead to large electronic current in the electrolyte effectively shorting the battery even when the electrolyte layer is uniform and pinhole free. The scaling of this phenomenon provides useful guidelines for design of 3D Li ion batteries.

1:39PM W2.00005 In-Situ TEM Electrochemistry of Individual Nanowire and Nanoparticle Electrodes in a Li-Ion Cell, JIANYU HUANG, Sandia National Lab. — Recently, we created the first Li-ion electrochemical cell inside a transmission electron microscope (TEM) and observed, in real time with atomic scale resolution, the lithiation/delithiation processes. This experiment opened the door for a suite of experimental studies involving in-situ TEM characterization of Li-ion battery materials. In this presentation, I'll first review our latest progress of using the in-situ electrochemical cell setup inside the TEM to reveal the intrinsic electrochemistry of several high energy density anode materials such as SnO₂, ZnO, Si, Ge, Al nanowires, Si nanoparticles, carbon nanotubes, and graphene. Several electrochemical mechanisms were observed and characterized in real-time, including lithiation induced stress, volume changes, phase transformations, pulverization, cracking, embrittlement, and mechanical failure in anode materials. These results indicate the strong material, size and crystallographic orientation dependent electrochemical behavior and degradation mechanisms that occur in Li-ion battery anodes. In the future, we will need further advancements in in-situ characterization for understanding important processes in Li-ion batteries. For example, liquid cells are required in order to examine the electrochemical reactions between battery materials and the standard battery electrolytes, which are ethylene carbonate-based. Furthermore, in-situ studies need to be correlated with electrochemical studies performed on bulk electrodes. I will present a comparison between our in-situ results and electrochemical studies on conventional battery electrodes and highlight how in-situ studies can have important impact on the design of Li-ion batteries. Finally I will discuss outstanding challenging issues and opportunities in the field of Li-ion battery research.

Thursday, March 1, 2012 11:15AM - 2:15PM – Session W3 DCMF: Invited Session: Fractional Topological Insulators 205AB

11:15AM W3.00001 Fractional Topological Insulators in 2 and 3 dimensions, F.J. BURNELL, Oxford University — I will present a family of exactly solvable models whose low energy physics is that of a 3D topological band insulator of fractionally charged fermions. When time reversal is broken at the surface, these insulators display a fractional magnetoelectric effect, leading to fractional quantum Hall surface states. Further, some – but not all – of them can be shown to be genuine topological insulators, whose gapless surface states are protected by time reversal. This gives an explicit construction of fractional topological insulators in 3D. This work has been done in collaboration with Michael Levin (University of Maryland), Maciej Koch-Janusz (Weizmann Institute), and Ady Stern (Weizmann Institute).

11:51AM W3.00002 Composite fermions for fractionally filled Chern bands¹, R. SHANKAR², Yale Physics — We consider fractionally filled bands with a non-zero Chern index that exhibit the Fractional Quantum Hall Effect in zero external field³ a possibility supported by numerical work.⁴ Analytic treatments are complicated by a non-constant Berry flux and the absence of Composite Fermions (CF), which would not only single out preferred fractions, but also allow us compute numerous response functions at nonzero frequencies, wavelengths and temperature using either Chern-Simons field theory or our Hamiltonian formalism.⁵ We describe a way to introduce CF's by embedding the Chern band in an auxiliary problem involving Landau levels. The embedded band can be designed to approximate a prescribed Chern density in k space which determines the commutation relations of the charge densities and hence preserve all dynamical and algebraic aspects of the original problem. We find some states for which the filling fraction and dimensionless Hall conductance are not equal. The approach extends to two-dimensional time-reversal invariant topological insulators and to composite bosons.

12:27PM W3.00003 Fractional Topological Insulators¹, CLAUDIO CHAMON, Boston University — The prediction and experimental discovery of topological band insulators and topological superconductors are recent examples of how topology can characterize phases of matter. In these examples, electronic interactions do not play a fundamental role. In this talk I shall discuss cases where interactions lead to new phases of matter of topological character. Specifically, I shall discuss fractional topological states in lattice models which occur when interacting electrons propagate on flattened Bloch bands with non-zero Chern number. Topologically ordered many-particle states can emerge when these bands are partially filled, including a possible realization of the fractional quantum Hall effect without external magnetic fields. I shall also ponder on the possible practical applications, beyond metrology, that the quantized charge Hall effect might have if it could be realized at high temperatures and without external magnetic fields in strongly correlated materials.

1:03PM W3.00004 Generic Wavefunction Description of Fractional Quantum Anomalous Hall States and Fractional Topological Insulators, XIAO-LIANG QI, Stanford University — No abstract available.

1:39PM W3.00005 Correlated topological insulators and the fractional magnetoelectric effect¹, BRIAN SWINGLE, Harvard University — I will describe the recent theoretical construction of electronic phases in 3d that combine the physics of electron fractionalization with that of topological insulators. Called fractional topological insulators, these states of matter host protected surface states and fractionally charged quasiparticle excitations. I will then discuss the emergent gauge theory description of these phases with an emphasis on the crucial role of deconfinement at low energies. I will also describe a wide variety of experimental signatures of fractional topological insulators as well as suggesting directions for experimental searches.

Thursday, March 1, 2012 11:15AM - 1:51PM – Session W4 DAMOP: Strongly Interacting Fermi Gases 205C

11:15AM W4.00001 Revealing the Superfluid Lambda Transition in the Universal Thermodynamics of a Unitary Fermi Gas¹, MARK KU, ARIEL SOMMER, LAWRENCE CHEUK, MARTIN ZWIERLEIN, Department of Physics, MIT-Harvard Center for Ultracold Atoms, and Research Laboratory of Electronics, MIT, Cambridge, Massachusetts 02139, USA — We have observed the superfluid phase transition in a strongly interacting Fermi gas via high-precision measurements of the local compressibility, density and pressure down to near-zero entropy. We perform the measurements by in-situ imaging of ultracold ⁶Li at a Feshbach resonance. Our data completely determine the universal thermodynamics of strongly interacting fermions without any fit or external thermometer. The onset of superfluidity is observed in the compressibility, the chemical potential, the entropy, and the heat capacity. In particular, the heat capacity displays a characteristic lambda-like feature at the critical temperature of $T_c/T_F = 0.167(13)$. This is the first clear thermodynamic signature of the superfluid transition in a spin-balanced atomic Fermi gas. We provide a new value of the Bertsch parameter ξ_S . The experimental results are compared to recent Monte-Carlo calculations. Our measurements provide a benchmark for many-body theories on strongly interacting fermions, relevant for problems ranging from high-temperature superconductivity to the equation of state of neutron stars.

11:27AM W4.00002 Probing upper branch physics in strongly interacting Fermi gases¹, SHIZHONG ZHANG, The Ohio State University, EDWARD TAYLOR, McMaster University, WILLIAM SCHNEIDER, MOHIT RANDERIA, The Ohio State University — Motivated by a recent experiment at MIT, we consider the collision of two clouds of spin-polarized atomic Fermi gases close to a Feshbach resonance. We explain why two dilute gas clouds, with attractive interactions between its constituents, bounce off each other as if they were billiard balls. Our hydrodynamic analysis, in excellent agreement with experiment, gives strong evidence for a novel metastable many-body state, the so-called upper branch, with repulsive effective interactions. We also propose another experiment, measuring spin decoherence rates, to study the physics of the upper branch.

11:39AM W4.00003 Strongly interacting atomic Fermi gases in a trap with mass and population imbalances at finite temperature¹, JIBIAO WANG, Zhejiang University, HAO GUO, Hong Kong University, QIJIN CHEN, Zhejiang University — A great advantage of studying atomic Fermi gases is the easy tunability of multiple physical parameters, including interaction strength, mass and population imbalances, as well as species dependent trapping potential. Indeed, the mixture of ⁶Li and ⁴⁰K gases has been of great interest, with and without population imbalance. In this talk, we will address the finite temperature phase diagrams of two component atomic Fermi gases with both mass and population imbalances in a trap, using a pairing fluctuation theory. We show that in certain parameter ranges, there exist intermediate temperature superfluids as well as phase separation with exotic sandwich-like shell structure with superfluid or pseudogapped normal state in the middle. We consider pairing strength over the entire range of BCS-BEC crossover. Our result is relevant to future experiment on mixtures of ⁶Li and ⁴⁰K and possibly other Fermi atoms. References: H. 11:51AM W4.00004 Two-particle current from Superfluid Fermi Gases in the BCS-BEC Crossover, EMIKO ARAHATA, Department of Basic Science, The University of Tokyo, TETSURO NIKUNI, Department of Physics, Faculty of Science, Tokyo University of Science — In recent years, the crossover from the BCS-type superfluid to the Bose-Einstein condensation (BEC) of tightly-bound molecules has been realized in ultracold atomic Fermi gases using a tunable pairing interaction associated with a Feshbach resonance. In the BCS-BEC crossover it will be important to reveal the nature of fermion pairs. In this paper, we propose that two-particle (double photoemission) current (DPE current) is a powerful technique to provide direct insight into the pair-correlations. The DPE from superconductors has been studied both theoretically and experimentally, where a pair of electrons is emitted from the system upon the absorption of one photon. In this study, we consider an analogous situation in ultracold atomic gases, and derive a general expression for DPE current from superfluid Fermi gases in the BCS-BEC crossover. We show DPE current as a function of energy and momentum transfers, and identify the contributions of the condensed pair components and uncorrelated pair states, and discuss the possibility of distinguishing between weakly-bound Cooper pairs and tightly-bound molecules.

12:03PM W4.00005 Feshbach resonances and BCS-BEC crossover in optical lattices, ZHAOCHUAN SHEN, LEO RADZIHOVSKY, VICTOR GURARIE, Department of Physics, University of Colorado — In this talk we study Feshbach resonances of fermionic atoms placed in a periodic potential. We investigate the criteria when such a system can be described by a Hubbard model with variable interaction strength in case of broad resonance, or by a tight binding model of atoms and molecules which can convert into each other on sites of the lattice in case of narrow resonances. Assuming the applicability of these models, we first study the BCS-BEC crossover for broad resonance. We find that while below half filling the system undergoes the conventional crossover from a BCS superconductor to a Bose condensate of molecules, above half filling the nature of the BEC phase changes to that of a condensate of molecules made of holes. Switching our attention to the case of narrow resonance, we find that the crossover takes the system from a BCS to hole-BEC regime, then back to BCS, and finally to a conventional BEC of atomic molecules. In the latter crossover, we find that the size of Cooper pairs/molecules changes non-monotonously, being larger in the BCS and smaller in the BEC regimes. Finally, at a unity filling we find a quantum phase transition from a band insulator to a BCS-BEC superfluid replacing the crossover.

12:15PM W4.00006 Resonant enhancement of the FFLO state in 3D by an optical potential¹, JEROEN DEVREESE, SERGHEI KLIMIN, MICHEL WOUTERS, JACQUES TEMPERE, Universiteit Antwerpen, TQC (THEORIE VAN KWANTUMSYSTEMEN EN COMPLEXE SYSTEMEN) TEAM — In a two component Fermi gas, spin-imbalance leads to a competition between Cooper-pairing with zero momentum and with nonzero momentum. The latter gives rise to the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state. Hitherto this state has not been observed in a 3D Fermi gas. We propose a new way to enhance the presence of the FFLO state, by adding a 1D periodic potential. To investigate the effect of this potential, we study the ground state properties of the system, starting from the partition sum of an imbalanced Fermi gas in path-integral representation. To describe the FFLO state, a saddle point is chosen in which the pairs can have nonzero momentum. Minimizing the resulting free energy leads to the phase diagram of the system. The stability region of the FFLO state is found to be greatly enlarged due to the presence of the periodic potential, compared to the ordinary 3D case. We find that the FFLO state can exist at higher spin imbalance if the wavelength of the optical potential becomes smaller. We propose that this concept can be used experimentally to enhance the FFLO state.

12:27PM W4.00007 Single magnetic impurity in a spin-imbalanced superfluid Fermi gas¹, JIAN LI, CHIN-SEN TING, Texas Center for Superconductivity and Department of Physics, University of Houston, TEXAS CENTER FOR SUPERCONDUCTIVITY AND DEPARTMENT OF PHYSICS, UNIVERSITY OF HOUSTON TEAM — A spin-imbalanced superfluid Fermi gas harmonically trapped in a two-dimensional optical lattice with a single classical magnetic impurity is investigated by Bogoliubov-de Gennes equations. In spin-balanced and weak spin-imbalanced case, we show that a strong magnetic impurity can change sign of the pairing order parameter. The amplitude of the sign-changed order parameter caused by impurity is affected by the strength of impurity potential, temperature and particle density. Compared to spin-balanced case, we find that an additional in-gap bound state can be induced by a strong magnetic impurity in weak spin-imbalanced case. In strong spin-imbalanced case where the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state is established as the ground state, the impurity induces wide spatial oscillations of pairing order parameters and can enhance the order parameters by suppressing the local spin-imbalance. Our results can be used to create and manipulate the FFLO state with magnetic impurities in spin-imbalanced Fermi gases.

12:39PM W4.00008 Proposal for interferometric detection of the topological character of modulated superfluidity in ultracold Fermi gases¹, MASON SWANSON, The Ohio State University, YEN LEE LOH, The University of North Dakota, NANDINI TRIVEDI, The Ohio State University — A system with unequal populations of up and down fermions may exhibit a Larkin-Ovchinnikov (LO) phase characterized by periodic domain walls across which the order parameter changes sign and the excess polarization is localized. Despite fifty years of theoretical and experimental work, there has so far been no unambiguous observation of an LO phase. We propose an experiment in which two fermion clouds, prepared with unequal population imbalances, are allowed to expand and interfere. We show that a pattern of staggered fringes in the interference is unequivocal evidence of LO physics. The resilience of these interference signatures against thermal and quantum fluctuations is also discussed, and our results are supported with time-of-flight simulations of the experiment. Y.-L. Loh and N. Trivedi, Phys. Rev. Lett. 104, 165302 (2010). M. Swanson et al., arXiv:1106.3908

12:51PM W4.00009 A single impurity atom in a two-dimensional Fermi gas, JESPER LEVINSEN, University of Cambridge, MEERA PARISH, University College London — We consider a single impurity atom immersed in a Fermi gas in two dimensions and interacting via an attractive, short-range potential. Using variational wave functions for polarons, molecules, trimers, and quadruplets, we arrive at the ground state phase diagram as a function of mass ratio and interaction strength. We show that the phase diagram includes a Fulde-Ferrell-Larkin-Ovchinnikov phase for experimentally relevant mass ratios.

1:03PM W4.00010 Realization of a Resonant Fermi Gas with a Large Effective Range, ERIC HAZLETT, YI ZHANG, RON STITES, KEN O'HARA, The Pennsylvania State University — We have measured the interaction energy and three-body recombination rate for a two-component Fermi gas near a narrow Feshbach resonance and found both to be strongly energy dependent. Even for deBroglie wavelengths greatly exceeding the van der Waals length scale, the behavior of the interaction energy as a function of temperature cannot be described by atoms interacting via a contact potential. Rather, energy-dependent corrections beyond the scattering length approximation are required, indicating a resonance with an anomalously large effective range. For fields where the molecular state is above threshold, the rate of three-body recombination is enhanced by a sharp, two-body resonance arising from the closed-channel molecular state which can be magnetically tuned through the continuum. This narrow resonance can be used to study strongly correlated Fermi gases that simultaneously have a sizeable effective range and a large scattering length.

1:15PM W4.00011 Anomalous Dimers in Quantum Mixtures near Broad Resonances:Pauli Blocking, Fermi Surface Dynamics and Implications¹, JUNLIANG SONG, Institute of Quantum Optics and Quantum Information of Austrian Academy of Sciences, FEI ZHOU, University of British Columbia — We study the energetics and dispersion of anomalous dimers that are induced by the Pauli blocking effect in a quantum Fermi gas of majority atoms near interspecies resonances. Unlike in vacuum, we find that both the sign and magnitude of the dimer masses are tunable via Feshbach resonances. We also investigate the effects of particle-hole fluctuations on the dispersion of dimers and demonstrate that the particle-hole fluctuations near a Fermi surface (with Fermi momentum $\hbar k_F$) generally reduce the effective two-body interactions and the binding energy of dimers. Furthermore, in the limit of light minority atoms the particle-hole fluctuations disfavor the formation of dimers with a total momentum $\hbar k_F$, because near $\hbar k_F$ the modes where the dominating particle-hole fluctuations appear are the softest. Our calculation suggests that near broad interspecies resonances when the minority-majority mass ratio m_B/m_F is smaller than a critical value (estimated to be 0.136), dimers in a finite-momentum channel are energetically favored over dimers in the zero-momentum channel. We apply our theory to quantum gases of $^6\text{Li}^{40}\text{K}$, $^6\text{Li}^{87}\text{Rb}$, $^{40}\text{K}^{87}\text{Rb}$ and $^6\text{Li}^{23}\text{Na}$ near broad interspecies resonances, and discuss the implications.

1:27PM W4.00012 Unpolarized Fermi gas in squeezed anisotropic harmonic trap by Quantum Monte Carlo methods, XIN LI, LUBOS MITAS, Physics Department, North Carolina State University — Using diffusion Monte Carlo (DMC) method, we calculate the ground state properties of unpolarized Fermi gas at unitarity regime in both isotropic and anisotropic harmonic potentials. We study the effects of anisotropy by increasing the frequency in z direction ω_z of the harmonic potential while keeping the frequency in x and y direction unchanged. The true unitarity regime is obtained by extrapolating the interaction range to zero and the calculations are done using the fixed-node diffusion Monte Carlo method. The trial function is of the BCS form with the pairing function expanded in appropriate linear combinations of the anisotropic oscillator eigenstates. We evaluate the binding energies for varying particle numbers and we estimate its behavior in the limit of large number of atoms. We estimate dependence of projected density profile and momentum distribution on the X-Y plane with respect to ω_z . Our results can be readily used as a benchmark for the cold atom experiment with similar experimental set-up. Supported by ARO and NSF.

1:39PM W4.00013 A Theory for Normal Fermi Gases at Unitarity, ERIK WEILER, THEJA DE SILVA, Binghamton University — In this study, we will develop a simple, yet accurate, mean-field-like theory for the normal phase of a unitarity Fermi gas. First, we derive a self-consistent equation for the self-energy using a momentum-dependent coupling constant. Using zero temperature Monte Carlo results as a starting point, we then derive an analytical expression for the momentum-dependent self-energy within one-step iteration. Lastly, we determine the validity of our analytical self-energy by comparing it to fully numerical calculations. Our theory shows excellent agreement with pressure measurements made by Nascimbene, *et al.* in a recent experiment performed by the ENS group.

Thursday, March 1, 2012 11:15AM - 2:03PM —
Session W5 DCMP: Thin Film Growth and Processing 206A

11:15AM W5.00001 Etch induced losses in high Q-value superconducting resonators, MARTIN SANDBERG, MICHAEL VISSERS, JEFF KLINE, MARTIN WEIDES, JIANSONG GAO, National Institute of Standards and Technology, Boulder, CO 80305, DAVID WISEBEY, Saint Louis University, St. Louis, Missouri 63103, DAVID PAPPAS, National Institute of Standards and Technology, Boulder, CO 80305 — We have investigated how the microwave loss in coplanar wave-guide titanium nitride resonators fabricated on Si wafers is affected by the choice of etch method used to pattern the resonators. Three different etches has been investigated, one fluorine based reactive etch, one chlorine based reactive ion etch, and one argon ion mill. At high microwave probe powers, the two different reactive etches show low internal loss whereas the milled samples show dramatically higher loss. At single photon powers we observe that the fluorine etch resonators exhibit substantially lower loss than the chlorine etched resonators. In the single photon limit we observe loss tangents of $1 \cdot 10^{-6}$ for the fluorine etched, $4 \cdot 10^{-6}$ to $5.5 \cdot 10^{-6}$ for the chlorine etch and $1.4 \cdot 10^{-4}$ for the argon ion mill. We compare these results to numerically calculated filling factors and find that the chlorine etch Si surface has a higher loss tangent than the fluorine etched surface. We also find that re-deposition of Silicon onto the titanium nitride surfaces is the probable cause of the high loss observed for argon ion milled resonators.

, AMY MARQUARDT, Department of Materials Science and Engineering, University of Maryland, College Park, MD, 20742, ERIC BREITUNG, Library of Congress, Washington D.C., TERRY DRAYMAN-WEISSER, GLENN GATES, Walters Art Museum, Baltimore, MD, GARY W. RUBLOFF, RAY J. PHANEUF, Department of Materials Science and Engineering, University of Maryland, College Park, MD, 20742 — Atomic layer deposition (ALD) was investigated as a means to create transparent oxide diffusion barrier coatings to reduce the rate of tarnishing for silver objects in museum collections. Accelerated aging by heating various thicknesses (5 to 100nm) of ALD alumina (Al_2O_3) thin films on sterling and fine silver was used to determine the effectiveness of alumina as a barrier to silver oxidation. The effect of aging temperature on the thickness of the tarnish layer (Ag_2S) created at the interface of the ALD coating and the bulk silver substrate was determined by reflectance spectroscopy and X-Ray Photoelectric Spectroscopy (XPS). Reflectance spectroscopy was an effective rapid screening tool to determine tarnishing rates and the coating's visual impact. X-Ray Photoelectric Spectroscopy (XPS), and Time of Flight Secondary Ion Mass Spectroscopy (ToF-SIMS) analysis showed a phase transformation in the Ag_2S tarnish layer at 177 °C and saturation in the thickness of the silver sulfide layer, indicating possible self-passivation of the tarnish layer.

11:51AM W5.00004 ABSTRACT WITHDRAWN —

12:03PM W5.00005 Normal versus anomalous roughening of electrodeposited Prussian Blue layers, ANDRE PASA, MARILIA ALAMINI, RENE DA SILVA, VINICIUS ZOLDAN, EDUARDO ISOPPO, Laboratorio de Filmes Finos e Superfícies, Departamento de Física, Universidade Federal de Santa Catarina, 88.040-900 Florianópolis, SC, Brazil, UBIRAJARA RODRIGUES-FILHO, Instituto de Química de São Carlos, USP, 13.564-970 São Carlos, SP, Brazil, FABIO AARAO REIS, Instituto de Física, Universidade Federal Fluminense, Av. Litorânea s/n, Niterói, RJ, 24210-340, Brazil, ALOISIO KLEIN, Laboratorio de Materiais, UFSC, C.P. 476, Florianópolis, SC, Brazil. — Electrochemically deposited Prussian Blue films on gold over silicon substrates are studied by various microscopy methods. Film surface features and roughness scaling suggest faceted anomalous roughening. However, accounting for the time increase of adsorption rate, which reduces surface diffusion lengths as the film grows, a scenario of diffusion-dominated growth (Mullins-Herring class) emerges. A significant effect of the diffusion-to-deposition ratio on the roughness scaling is found, consistently with the close packed surface morphology and formation of a film with single crystalline grains. That effect also explains the striking difference of exponents obtained from the anomalous and normal scaling interpretations.

12:27PM W5.00007 ABSTRACT HAS BEEN MOVED TO X50.00007 —

12:39PM W5.00008 Continuum Description of Atomistics for Nanomechanics of Grain Boundary Embrittlement in FCC Metals, K.-S. KIM, C.-K. WANG, M.-H. CHA, H. B. CHEW, School of Engineering, Brown University — A nonlinear field projection method has been developed to study nanometer scale mechanical properties of grain boundaries in nanocrystalline FCC metals [1]. The nonlinear field projection is based on the principle of virtual work, for virtual variations of atomic positions in equilibrium through nonlocal interatomic interactions such as EAM potential interaction, to get field-projected subatomic-resolution traction distributions on various grain boundaries. The analyses show that the field projected traction produces periodic concentrated compression sites on the grain boundary, which act as crack trapping or dislocation nucleation sites. The field projection was also used to assess the nanometer scale failure processes of Cu $\Sigma 5$ and $\Sigma 9$ grain boundaries doped with Pb. It was revealed that the most significant atomic rearrangement is dislocation emission which requires local GB slip, and some Pb locks the local GB slip and in turn, embrittles the GB. 12:51PM W5.00009 Coherent Surface X-ray Scattering: Observation of Pt (001) Step-Flow Motion, MICHAEL PIERCE, Department of Physics, Rochester Institute of Technology, DANIEL HENNESSY, KEE-CHUL CHANG, Materials Science Division, Argonne National Laboratory, VLADIMIR KOMANICKY, Faculty of Science, Safarik University, JOSEPH STRZALKA, ALEC SANDY, Advanced Photon Source, Argonne National Laboratory, ANDI BARBOUR, HOYDOO YOU, Materials Science Division, Argonne National Laboratory — We recently [1] observed oscillations of speckle intensities from the Pt (001) surface at high temperatures ($T > 1620\text{K}$), persisting for tens of minutes. Using a model of hex-reconstructed terraces we showed that the observed oscillations come from surface dynamics due to sublimation induced step-flow motion. Our results demonstrate the possibility that coherent surface x-ray scattering (CSXS) can be applied to monitor the real-time evolution of surfaces. Hopefully CSXS can be extended further to in-situ “real-world” environments. 1:03PM W5.00010 Study of Electrode Surface Dynamics Using Coherent Surface X-ray Scattering¹, HOYDOO YOU, Argonne National Laboratory, MICHAEL PIERCE, Rochester Institute of Technology, VLADIMIR KOMANICKY, Safarik University — We present successful efforts to develop a new surface x-ray scattering technique that allows in-situ measurements of surface dynamics in electrochemical systems. The technique, sensitive to the microstates of the system, can measure the transient dynamics of phase relaxation from one phase to another upon changing electrochemical conditions, as well as the equilibrium dynamics of microstates even if the electrode macroscopic state appears static. We will discuss the underlying physics of surface x-ray speckle correlation spectroscopy and present our recent study of Au (100) surface in vacuum, water, and electrolytes.

1:15PM W5.00011 Effect of tensile misfit dislocation on diffusion of Ni adatom on Ni/Cu(111): a Molecular Dynamics study¹, OLEG TRUSHIN, Yaroslavl Branch of the Institute of Physics and Technology of RAS, Yaroslavl, Russia, MARAL AMINPOUR, TALAT S. RAHMAN, Physics Department, University of Central Florida — We apply molecular dynamics and molecular static methods to calculate the effect of tensile misfit dislocation on Ni adatom diffusion for Ni/Cu(111) system and compare the results with those calculated previously for Cu adatom on the Cu/Ni(111) system [1] which has compressive dislocation. Our Ni/Cu(111) substrate model system consists of 5 layers of Ni on top of a 7-layer Cu(111) slab which after energy minimization displays an isolated misfit dislocation buried at the Cu-Ni interface, causing the Ni film to be under tensile stress. In contrast to the isotropic trajectory that emerges on a defect-free surface, in this tensile stressed system we find that presence of the defect under the surface strongly affects the adatom trajectory, introducing anisotropy in atomic diffusion similar to compressive system, but with the difference: tensile misfit dislocation enhances diffusion in the direction perpendicular to the misfit dislocation line and decreases it in the direction parallel to it, whereas compressive dislocation induces the opposite behavior. We present the calculated energy barriers for the adatom and compare them with adatom diffusion on defect – free and on the surface containing compressive dislocation.

1:27PM W5.00012 Enhancement of Ag Cluster Mobility on Ag(111) Surface by clustering with Chlorine¹, YU-NING WU, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida, USA, NOUARI KEBAILI, ALBERT MASSON, CATHERINE BRÉCHIGNAC, Laboratoire Aimé Cotton, CNRS-Université Paris Sud 11, France — Chlorine is observed to accelerate the fragmentation of Ag nanostructures deposited on graphite. To understand the role of chlorine in the stability of Ag nanostructures, we have studied the formation and diffusion of Ag_n and Ag_nCl_m (n = 1 to 4) clusters on Ag(111) surface, using density functional theory (DFT) with generalized gradient approximations (GGA) and the projector-augmented wave method. Our calculation shows that the formation energies and diffusion barriers of Ag_n clusters are both lowered by clustering with chlorine when n=1, 3 and 4, indicating the enhancement of mass transport on Ag(111) surface. (AgCl)_n clusters (n=1, 3 and 4) are good candidates for surface mass transport units. We have also studied a chloridized Ag₅₅ cluster and an Ag₅₅-Ag₅₅ neck structure. Chlorine is found to loosen the Ag₅₅ structure and weaken the binding between the Ag₅₅ bulbs in the neck structure.

1:39PM W5.00013 Growth and Characterization of Metal Oxides Layers on CVD Graphene, A. MATSUBAYASHI, J. ABEL, D.P. SINHA, J.U. LEE, V.P. LABELLA, College of Nanoscale Science and Engineering, University at Albany, State University of New York — Thin metal oxide layers deposited on graphene can be utilized as dielectric barriers between ferromagnetic metals and graphene to help overcome conductivity mismatch between the metal and graphene. Furthermore, these layers have been shown to increase the spin relaxation time measured utilizing non local detection and spin precession measurements. However, simply depositing metal oxide layers such as aluminum oxide on graphene results in non uniform film lowering the quality of the interface barrier. This presentation will show our work growing uniform aluminum oxide layers on graphene under ultra high vacuum conditions utilizing a Ti seed layer. The surface roughness of the films was measured with atomic force microscopy with and without titanium seed layers. The results show titanium seed layers reduced the surface roughness by a factor of 4 indicating a more uniform film. In addition, X-ray photoelectron spectroscopy results will be presented to confirm the stoichiometry of the films.

1:51PM W5.00014 Ab-initio study on stabilized ZnO (0001) polar surface with graphene substrate, GUO-HONG CHEN, HONG-JUN XIANG, XIN-GAO GONG, Fudan University — First-principles calculations have been performed on interfaces between zinc oxide (0001) surfaces and graphene layer. By modifying the initial interface configurations we have found the energetically stable interface structure. Results indicate that the unstable polar ZnO (0001) surface could be stabilized by the graphene layer. Further analyses show that the structure stabilization could be well understood by the charge transfer between the carbon atoms and oxygen atoms. This suggests that polar ZnO (0001) surfaces can be obtained in experiments by growing them on graphene substrates.

Session W6 DMP: Focus Session: Carbon Nanotube Synthesis, Structure and Defects 206B

11:15AM W6.00001 Chirality selective growth of carbon nanotubes from one-dimensional fusion of aromatic compounds, HONG EN LIM, YASUMITSU MIYATA, RYO KITAURA, Nagoya University, HIROMICHI KATAURA, AIST, JST-CREST, HISANORI SHINOHARA, Nagoya University — We have investigated the formation of carbon nanotubes (CNTs) from one-dimensional coalescence of various polyaromatic compounds with different edge structures within an outer tube template. Transformation of the filled precursors into an inner tube was confirmed upon high-temperature thermal annealing. These newly formed inner tubes were then extracted through ultrasonication, as reported in our previous study [1]. High resolution transmission electron microscope observations of the samples together with the photoluminescence analyses of the extracted dispersions reveal that the chirality of the inner tubes generated were greatly affected not only by the edge structures but also by the intermediates formed. In particular, graphene nanoribbon-like intermediates obtained from perylene-derivative can be preferentially converted into near-zigzag CNTs with (8,1) chirality. The present method may provide the controlled growth of chiral-specific CNTs, which has been difficult to achieve using ordinary synthesis approaches.

11:27AM W6.00002 Hierarchical 3D microstructures from pyrolysis of epoxy resin, MICHAEL DE VOLDER, DOMINIEK REYNAERTS, KULeuven, CHRIS VAN HOOFF, IMEC, A. JOHN HART, University of Michigan — Nature is replete with examples of microscale dendrites connected to tree-like backbones ranging from the overall structures of trees to vascular networks. These branched structures have emerged as a result of an optimization between the maximization of a surface area and the minimization of transport losses. Elucidating these sophisticated designs proposed by nature is of paramount importance for the creation of higher-efficiency materials. The fabrication of such structures is however particularly challenging at small scale. In this paper, we focus on amorphous carbon microstructures, which provide a wide electrochemical stability window, excellent bio-compatibility, and cost-effective fabrication. However, relatively few methods have been developed for the fabrication of hierarchical amorphous carbon microstructures. Here we show that novel anisotropic microarchitectures comprising vertically aligned amorphous carbon nanowires CNWs can be made by oxygen plasma treatment of epoxy resins, followed by pyrolysis. Interestingly, these structures can also be shaped into deterministic three-dimensional (3D) hierarchical structures where nanowires are anchored to a micro-sized solid carbon core. These structures could play a key role in the development of new electrodes for micro-sensors, bioprobes, batteries, and fuel cells.

11:39AM W6.00003 Semiconducting nanotube dominant chemical vapor deposition synthesis of isopropanol carbon feedstock, YUCHI CHE, CHUAN WANG, JIA LIU, XUE LIN, University of Southern California, H.-S. PHILIP WONG, Stanford University, CHONGWU ZHOU, University of Southern California — The development of guided chemical vapor deposition (CVD) growth of single wall carbon nanotubes provides great platform for wafer-scale integration of aligned nanotube into circuits and systems. However, the co-existence of the metallic and semiconducting nanotubes is still a major problem for the development of carbon nanotube based nanoelectronics. To address this limitation, we developed a method to get semiconducting dominant nanotube by using isopropanol carbon feedstock. We achieved a purity of 87% of semiconducting nanotube growth, which was verified by measuring single nanotube transistors fabricated from aligned nanotube arrays. Besides, Raman spectrum was characterized to confirm the enhanced fraction of semiconducting nanotube as well. To further understand chemical mechanism of synthesis at atomic level, we performed the mass spectrum study and compared the measurement results from different carbon source. Furthermore, to discuss the future application of this synthesis method, we fabricated thin-film transistor from as-grown nanotube network. Transistor with on/off ratio over 104 and mobility up to 116 cm²/v•s was achieved, which shows great potential for thin-film transistor applications.

11:51AM W6.00004 Synthesis and Characterization of Carbon Nanotubes Produced From Thermal Decomposition of Nickelocene, HERBERT VINSON, BALEESWARAIAH MUCHHARLA, X. ZHANG, Southern Illinois University, Carbondale, AMÉLIA CHURCH, Rice University, Houston, VAIVA KRUNGLEVICIUTE, Southern Illinois University, Carbondale, S. KAR, Northeastern University, Boston, ALDO MIGONE, SAIKAT TALAPATRA, Southern Illinois University, Carbondale, SOUTHERN ILLINOIS UNIVERSITY, CARBONDALE COLLABORATION, NORTHEASTERN UNIVERSITY, BOSTON COLLABORATION — We have employed a direct thermal deposition technique, which used Nickelocene both as the catalyst as well as the carbon source, to grow films of carbon nanotubes (CNT). The CNT films obtained using this procedure were characterized using Transmission Electron Microscopy which indicated the presence of thin diameter carbon nanotubes as well as single walled CNT ropes. Volumetric adsorption measurements were performed to determine the porosity and specific surface areas of these samples. Electrical transport measurements performed on long ropes of CNTs extracted from these bulk films will be presented and will be discussed in the framework of transport theories of quasi-one dimensional systems.

12:03PM W6.00005 Covalently Functionalized Carbon Nanotubes for Electronics¹, DELPHINE BOUILLY, JANIE CABANA, FRANÇOIS MEUNIER, FRANÇOIS LAPOINTE, FRANCIS L. LAROCHE, MATTHIEU PAILLET, RICHARD MARTEL, Université de Montréal, MAXIME DESJARDINS-CARRIÈRE, PHILIPPE GAGNON, ELYSE ADAM, Ecole Polytechnique de Montréal, REGROUPEMENT QUÉBÉCOIS SUR LES MATÉRIAUX DE POINTE (RQMP) TEAM — Covalent chemistry on carbon nanotubes generates useful and stable functionalities, but it also generally damages their electronic properties, which is a critical drawback for device applications. Here we present two approaches to achieve covalent functionalization of carbon nanotubes without compromising on their electronic properties. For each case, we demonstrate the fabrication of functional carbon nanotube devices. First, double-walled carbon nanotubes (DWNTs) are functionalized using a monovalent reaction with aryldiazonium salts. Absorption and Raman spectroscopy along with electrical measurements show that the functionalization occurs strictly on the outer wall and preserves the optical and transport properties of the inner wall. Functionalized-DWNT devices are operated with similar characteristics as pristine single-walled carbon nanotube (SWNT) devices [1]. Second, SWNTs are functionalized with different addends using a divalent carbene reaction. For both metallic and semiconducting species, electrical measurements of numerous functionalized and unfunctionalized SWNT devices show identical characteristics. Ref: [1] Bouilly D. et al. ACS Nano, 5 (6), 4927 (2011)

12:15PM W6.00006 Mechanocapillary forming of carbon nanotube microstructures, A. JOHN HART, University of Michigan — The hierarchical structure and organization of filaments within both natural and synthetic materials can determine a wide variety of collective chemical and physical functionalities. Carbon nanotubes (CNTs) are known for their record properties, and densely packed CNTs are therefore expected to enable new materials having outstanding multifunctional performance. However, it remains a significant challenge to build highly ordered assemblies of CNTs, and this challenge has largely limited the design and properties of macroscale CNT yarns and sheets, and CNT-based surfaces and interfaces. We have created a versatile technique called *capillary forming* to manipulate patterned vertically aligned (VA-) CNTs into diverse 3D microarchitectures, and to enable their integration in applications ranging from microsystems to macroscale functional films. Capillary forming relies on shape-directed capillary rise during solvent condensation, followed by evaporation-induced shrinkage. Three-dimensional transformations result from shrinkage of the vapor-liquid-solid interface and the resulting heterogeneous strain distribution in the microstructures. A portfolio of microscale CNT assemblies with highly ordered internal structure and freeform geometries including straight, bent, folded and helical profiles, are fabricated using capillary forming. The mechanical stiffness and electrical conductivity of capillary formed CNT micropillars are 5 GPa and 10⁴ S/m respectively. These values are at least hundred-fold higher than as-grown CNT forests and exceed the properties of typical microfabrication polymers. Finally, the potential applications of these structures are demonstrated as vertical microsprings with geometrically tunable compliance, and hydrogel-driven microtransducers.

12:51PM W6.00007 *Ab initio* studies of defects in carbon nanofoam structures¹, DAVID TOMANEK, ZHEN ZHU, Michigan State University, ARKADY KRASHENINNIKOV, University of Helsinki — We combine *ab initio* density functional and GW calculations to study the stability, electronic and elastic properties of hypothetical cellular foam-like carbon nanostructures. These systems with a mixed sp²/sp³ bonding character are structurally related to bundles of carbon nanotubes. The cross-sectional honeycomb structure may accommodate the same type of structural defects as the honeycomb lattice of graphene. The infinite 3D foam structure is a narrow-gap semiconductor, with the binding energy of atoms nearly 0.5 eV lower than graphene. Quasi-2D layered foam structures of finite thickness may be stabilized by terminating caps. When exposed to hydrostatic pressure, the unit cells of the foam deform significantly from their initially hexagonal shape.

¹Supported by the National Science Foundation Cooperative Agreement #EEC-0832785, titled “NSEC: Center for High-rate Nanomanufacturing”.

1:03PM W6.00008 Energetical Stability of Near-Armchair Carbon Nanotubes: A Systematic First-Principles Study, KOICHIRO KATO, TAKASHI KORETSUNE, SUSUMU SAITO, Department of Physics, Tokyo Institute of Technology — We perform the systematic first-principles study of 57 kinds of carbon nanotubes (CNTs) and investigate the energetical stability of so-called “near-armchair” CNTs. The density functional theory computational code which utilizes the helical symmetry and has been developed in our group is extensively used in the present work. Because the computational effort can be drastically reduced by using the helical symmetry of CNTs, the systematic study of fully-optimized CNTs including the experimentally abundant CNTs was finally achieved in this work. As a result, it is found that “near-armchair” CNTs including (6,5) and (7,5) CNTs are energetically more stable than other CNTs. This result corresponds well with the high abundance of these near-armchair CNTs experimentally reported so far. In addition, by performing the systematic analysis of CNT bond-lengths and angles, the presence of the geometrical family pattern after their structural optimizations has been revealed for the first time. It is also confirmed that the geometrical optimization plays a very important role in predicting electronic structures of chiral CNTs as well as achiral CNTs. The fundamental gap corrections associated with the geometrical optimizations are sizable even in one nm diameter CNTs.

1:15PM W6.00009 Diameter and Chiral Selective Purification of SWNT and DWNT Using CO₂, PHILIPPE GAGNON, MAXIME BIRON, MAXIME DESJARDINS-CARRIERE, Ecole Polytechnique de Montreal, EMMANUEL FLAHAUT, Université Paul Sabatier, PATRICK DESJARDINS, Ecole Polytechnique de Montreal, RICHARD MARTEL, Université de Montreal — Oxidation of carbon nanotubes in air is a well known method to eliminate carbonaceous impurities from raw material. Recently, it has also been used to selectively remove single-wall carbon nanotubes (SWNT) present in double-walled carbon nanotubes (DWNT) soot[1]. Here, we propose a more efficient purification process for both SWNT and DWNT based on a high temperature oxidation in a pure CO₂ gas flow. This treatment, combined with a standard reflux in nitric acid, provides fast oxidation of amorphous carbon and removal of other impurities without affecting the structure of the carbon nanotubes. Parameterization of the treatment allowed us to observe both diameter and chirality dependence of the nanotubes reaction rate with CO₂. This selective character was applied to produce thin films of clean and highly enriched DWNT and of semiconducting SWNT. Microscopy and spectroscopy analyses will be shown and reveal that those films are composed of very high quality carbon nanotubes (micrometers long, very low impurity and catalyst concentration, low Raman I_D/I_G ratios). Also, no significant nanotube shortening is observed following the different diameter or chirality enrichment treatments.

[1] K. Iakoubovskii et al., J. Phys. Chem. C, 112, 30 (2008)

1:27PM W6.00010 Radial Elasticity Measurement of Single-walled Carbon Nanotubes by Atomic Force Microscopy¹, YUEHAI YANG, WENZHI LI, Department of Physics, Florida International University, CONDENSED MATTER PHYSICS TEAM — By applying well-calibrated tapping mode and contact mode AFM upon horizontally aligned SWCNTs grown directly on quartz substrates, we have obtained effective radial modulus (E_{radial}) of SWCNTs with diameters less than 2 nm. The measured E_{radial} decreases from 57 to 9 GPa with the increase of the SWCNT diameter from 0.92 to 1.91 nm. Our experimental result is consistent with the computational data obtained using the modified molecular structure mechanics model. We have also compared our measurements with the reported experimental results obtained on SWCNTs with diameters from 2 to 3 nm. Our measurements of large diameter SWCNTs (diameter close to 2nm) are in agreement with the reported data and modeling. However, our measurements of SWCNTs with smaller diameters deviate from this previous study. This has been explained by the compressibility of the substrate and the AFM tip. By employing Hertzian theory, we specifically exploit the components of deformation of the AFM tip-SWCNT-substrate system. Further calculation using our measured E_{radial} indicates that under the same normal force the deformation of our quartz-SWCNT-silicon tip system can be as much as 96% more than the deformation of the SWCNT compressed between a rigid substrate and an AFM tip.

1:39PM W6.00011 ABSTRACT WITHDRAWN —

1:51PM W6.00012 Synthesis and high temperature stability of amorphous Si(B)CN-MWCNT composite nanowires, ROMIL BHANDAVAT, GURPREET SINGH, Kansas State University — We demonstrate synthesis of a hybrid nanowire structure consisting of an amorphous polymer-derived silicon boron-carbonitride (Si-B-C-N) shell with a multiwalled carbon nanotube core. This was achieved through a novel process involving preparation of a boron-modified liquid polymeric precursor through a reaction of trimethyl borate and polyureasilazane under atmospheric conditions; followed by conversion of polymer to glass-ceramic on carbon nanotube surfaces through controlled heating. Chemical structure of the polymer was studied by liquid-NMR while evolution of various ceramic phases was studied by Raman spectroscopy, solid-NMR, Fourier transform infrared and X-ray photoelectron spectroscopy. Electron microscopy and X-ray diffraction confirms presence of amorphous Si(B)CN coating on individual nanotubes for all specimen processed below 1400 degree C. Thermogravimetric analysis, followed by TEM revealed high temperature stability of the carbon nanotube core in flowing air up to 1300 degree C.

Thursday, March 1, 2012 11:15AM - 2:15PM —

Session W7 DMP: Focus Session: Graphene Devices - Mechanical Effects 207

11:15AM W7.00001 Nanomechanical Field-Effect Magnetometry in Graphene¹, JAMES HONE, Columbia University — This presentation will describe our studies of graphene nanomechanical resonators in the quantum Hall (QH) regime. We observe strong magneto-mechanical coupling to de Haas-van Alphen oscillations of magnetization, resulting in oscillatory frequency shifts of up to 1 MHz. This response is over two orders of magnitude larger than the expected response in a “standard” torque magnetometry framework. Instead, we find that the electric field-effect modulation of the magnetic energy provides a gradient force without a magnetic field gradient. Modeling of the effect produces excellent agreement with experiment, using only the disorder as a free parameter. We further use this novel mechanism to quantify the many-body exchange interaction of broken-symmetry QH states. This new mechanism may prove to be a useful tool for magnetic studies across low-dimensional materials and in sensing applications.

11:51AM W7.00002 High frequency graphene resonators¹, KEVIN FISCHER, BRITT BAUGHER, TCHEFOR NDUKUM, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — We study mechanical resonance properties of suspended graphene devices through radio frequency electromechanical downmixing techniques. Taking advantage of graphene's atomically thin nature, unusually large transconductance, and extremely high Young's Modulus, we have fabricated high-frequency suspended graphene resonators. Our global-gate devices have resonated at over 500MHz in a low temperature environment with reasonable quality factors. This research will pave the way for high-quality resonators in the GHz regime which will be used in high frequency applications such as ultra high sensitive mass, chemical and charge detectors.

12:03PM W7.00003 Optical Detection of Vibrations and Mass Loading of Graphene Mechanical Resonators Compatible with TEM and AFM, BENJAMIN ALEMAN, MICHAEL ROUSSEAS, YISHENG YANG, WILL REGAN, FENG WANG, ALEX ZETTL, University of California, Berkeley — We produce arrays of exceptionally clean, suspended graphene mechanical resonators in high-yield using a simple, polymer-free procedure by transferring CVD-graphene to a flexible perforated substrate. The lack of a backing substrate facilitates Transmission Electron Microscopy (TEM) characterization, yet the membranes are still compatible with Atomic Force Microscopy (AFM) studies. We detect mechanical vibrations of resonators through optical interferometry and find excellent agreement with a theoretical model based on the 2D wave equation. We find quality factors of 1.25 μm diameter circular membranes to be as high as $Q \sim 800\text{--}1000$ at room temperature, and observe lifting of mode degeneracies in square membranes. TEM and AFM studies reveal graphene folding, nanoparticle contamination, holes, tears, and other defects that can lead to the observed degeneracy splitting in square membranes. Controlled mass loading is also explored to suppress certain vibrational modes and tune vibrational frequencies for possible high density archival memory applications. The graphene membrane devices reported here open up a host of new possibilities for correlating TEM and AFM studies of an individual graphene membrane to its performance and properties as a mechanical resonator.

12:15PM W7.00004 Graphene xylophone: Mechanical properties of graphene based nano resonators¹, SANG WOOK LEE, HAKSEONG KIM, HOYEOL YUN, JEONG-AH LEE, Konkuk University, YOUNGWOOK KIM, JUN SUNG KIM, POSTECH — Mechanical properties of graphene xylophone structure were investigated. The arrays of the graphene ribbon patterns were prepared using nano lithography and suspended graphene structure was realized on the pre-patterned trench by the micro contact transfer printing method. Xylophone like structure was prepared for studying length and thickness dependence of mechanical properties of graphene resonator. The various mechanical behaviors, such as frequency tuning, non-linearity and bistability of single, bi and multi layer graphene structure will be discussed in this presentation. The potential application of our graphene xylophone structure for RF component will be suggested in the end of this presentation.

12:27PM W7.00005 Cavity Optomechanics with Graphene Resonators, ROBERT BARTON, ISAAC STORCH, VIVEKANANDA ADIGA, Cornell University, REYU SAKAKIBARA, University of California Berkeley, SI PING WANG, PEIJIE ONG, B. ILIC, Cornell University, PAUL MCEUEN, Kavli Institute, Cornell University, JEEVAK PARPIA, HAROLD CRAIGHEAD, Cornell University — Optical manipulation of micromechanical and nanomechanical resonators promises control of quantum states of macroscopic systems, among other applications. Because the spring constant of a resonator scales with its mass, there are advantages associated with using the lightest possible membranes as the mechanical elements. Here, we demonstrate that graphene, a one-atom-thick membrane, can be used as the mechanically active part of an optomechanical system. We show that a laser coupled to a Fabry-Perot cavity between a graphene resonator and a reflective backplane can both enhance and damp graphene motion. The enhancement of resonator motion is sufficient to induce self-oscillation, which is useful for applications in sensing and signal processing. These experiments demonstrate that graphene resonators are useful for optomechanical applications and show promise for resonator cooling toward the quantum ground state.

12:39PM W7.00006 Ultrathin circular membranes with high quality factors, VIVEKANANDA ADIGA, School of Applied and Engineering Physics, Cornell University, ROB ILIC, Cornell Nanofabrication Facility, ROB BARTON, School of Applied and Engineering Physics, Cornell University, JEEVAK PARPIA, Physics Department, Cornell University, HAROLD CRAIGHEAD, School of Applied and Engineering Physics, Cornell University — We have fabricated large ultrathin circular drum resonators from monolayer graphene (up to 90 μm in diameter) and silicon nitride ($\sim 15\text{ nm}$, up to 1mm in diameter). Resonant frequency, quality factor (Q) of different modes of these self tensioned graphene drums and high tensile stress ($\sim 1\text{ GPa}$) silicon nitride were measured using optical interferometric detection technique. We measured extremely high quality factors (up to 5,000 for graphene and up to 4,000,000 for ultrathin silicon nitride membranes) at room temperature. High quality factors observed in these resonators indicate dissipation mechanisms which differ from the conventional high surface to volume ratio resonators that show very low quality factors. The measured mechanical dissipation (Q^{-1}) shows a strong size and modal dependence, possibly indicating the influence of clamping losses in these tensioned membranes. These findings pave the way for identifying optimum size and modes for achieving high Q oscillators for applications in mass sensing and optomechanical coupling experiments which are underway.

12:51PM W7.00007 Novel Fabrication Techniques for Wafer-Scale Graphene Drum Nano-ElectroMechanical Resonators, SUNWOO LEE, CHANGYAO CHEN, VIKRAM V. DESHPANDE, GWAN HYOUNG LEE, Columbia University, ISAAC STORCH, Cornell University, CONGCHUN ZHANG, YOUNG-JUN YU, PHILIP KIM, Columbia University, PAUL MCEUEN, Cornell University, JAMES HONE, Columbia University — Graphene NanoElectroMechanical Systems (NEMS) have shown excellent mass sensitivity as well as resonant and oscillatory behaviors that are desirable in mass sensors and active elements in Radio Frequency Integrated Circuit (RFIC) design. Out of many structures proposed for graphene NEMS, it has been recently shown that a drum resonator exhibits higher Q-factor than other structures such as a bar resonator. However, fabricating a large array of drum graphene resonator has been problematic because liquid or gas can be trapped inside the drum. Such issues led to designs with a hole in the center of a drum or with a drainage trench, either at the cost of additional lithography step or lowered Q-factor. Here, we demonstrate two novel fabrication methods that are free of the trapping without any compromise in additional lithography step or Q-factor degradation. In one method, wafer scale graphene is dry-stamped on prefabricated leads, holes and local gates. In the other method, an resist strip with a circular hole at the center holds graphene underneath. I will discuss direct electrical readout and characterization of devices using these two methods. These drum structures may provide a practical way to achieve wafer scale high Q graphene NEMS.

1:03PM W7.00008 Graphene NanoElectroMechanical Oscillator, CHANGYAO CHEN, VIKRAM DESHPANDE, SUNWOO LEE, PHILIP KIM, JAMES HONE, Columbia University — Graphene based NanoElectroMechanical Systems (NEMS) working in Radio Frequency (RF) regime possess considerable advantages own to the remarkable electrical and mechanical properties of this atomic thin material. Here we demonstrated self-sustained nanoelectromechanical oscillator made from graphene. Our recent developed transduction scheme enables the direct conversion from mechanical motion to electrical domain, then subsequently being fed back to the system as excitation. The absence of extra RF actuation and the stable performance shows the possibility of practical application of graphene oscillator, for example, as signal filters, mass sensors or timing devices.

1:15PM W7.00009 Uniaxially Strained Graphene Resonators, HIRAM CONLEY, KIRILL BOLOTIN, Vanderbilt University — Strained graphene allows one to explore the connection between the mechanical and electrical properties of graphene. Exploring this interplay between the mechanical and electrical properties in graphene may enable tuning graphene's mechanical and electrical properties as well as opening up new exotic electronic states. We have developed a technique to fabricate uniaxial strained graphene transistors and mechanical resonators with strains as high as 0.5%. We demonstrate how strain perturbs both the mechanical and electrical properties of graphene, highlighted by the strain quenching of flexural phonons.

1:27PM W7.00010 Local Optical Probe of Motion and Stress in a NEMS, ANTOINE RESERBAT-PLANTEY, LAËTITIA MARTY, OLIVIER ARCIZET, NEDJMA BENDIAB, VINCENT BOUCHIAT, Institut Néel CNRS, DEP NANO TEAM — Nanoelectromechanical systems (NEMSs) are emerging nanoscale elements at the crossroads between mechanics, optics and electronics, with significant potential for actuation and sensing applications. The reduction of dimensions compared to their micronic counterparts brings new effects including sensitivity to very low mass, resonant frequencies in the radiofrequency range, mechanical non-linearities and observation of quantum mechanical effects. An important issue of NEMS is the understanding of fundamental physical properties conditioning dissipation mechanisms, known to limit mechanical quality factors and to induce aging due to material degradation. There is a need for detection methods tailored for these systems which allow probing motion and stress at the nanometer scale. Here, we show a non-invasive local optical probe for the quantitative measurement of motion and stress within a multilayer graphene NEMS provided by a combination of Fizeau interferences, Raman spectroscopy and electrostatically actuated mirror. Interferometry provides a calibrated measurement of the motion, resulting from an actuation ranging from a quasi-static load up to the mechanical resonance while Raman spectroscopy allows a purely spectral detection of mechanical resonance at the nanoscale. Such spectroscopic detection reveals the coupling between a strained nano-resonator and the energy of an inelastically scattered photon, and thus offers a new approach for optomechanics.

1:39PM W7.00011 Nonlinear Damping Mechanism in Mechanical Graphene Resonators. , ALEXANDER CROY, DANIEL MIDTVEDT, ANDREAS ISACSSON, JARI M. KINARET, Chalmers University of Technology — Based on a continuum mechanical model for single-layer graphene¹ we propose and analyze a microscopic mechanism for dissipation in nano-electromechanical graphene resonators. We find that coupling between flexural modes and in-plane phonons leads to linear and nonlinear damping of out-of-plane vibrations. By tuning external parameters, such as static gate voltage, one can cross over from a linear to a nonlinear-damping dominated regime. We discuss how the effective quality factor depends on parameters such as temperature, and compare our results with recent experiments.

¹J. Atalaya, A. Isacsson, and J. M. Kinaret, Nano Letters 8, 4196 (2008).

1:51PM W7.00012 Graphene Nanoelectromechanical Systems are Unique¹ , TCHEFOR NDUKUM, BRITT BAUGHER, KEVIN FISCHER, PABLO JARILLO-HERRERO, MIT — Graphene Nanoelectromechanical systems (GNEMS) with their light mass show a lot of interesting novel physics effects compared to conventional Nanoelectromechanical systems (NEMS). Superior gate tunability of the order of $>10\text{MHz/V}$ at room temperature as well as high quality factors of $\sim 10^5$ at mK temperatures for the fundamental mode have already been obtained. Studying their high frequency modes, we have observed for the first time avoided crossing between graphene modes as well as between graphene modes and their suspended contacts. In addition we have studied the atypical variation of the mode dispersion versus gating resulting from tensioning and electrostatic coupling to the gate. In particular, we measure an additional frequency shift near 0Vg which could be due to a strong electromechanical coupling near the Dirac Point.

¹NSF, ONR, CMSE

2:03PM W7.00013 Current-induced forces in graphene-based nanoelectromechanical systems , SILVIA VIOLA KUSMINSKIY, Dahlem Center for Complex Quantum Systems - Freie Universität Berlin — Transport currents have distinct effects on the vibrational dynamics of nanoelectromechanical systems. Recently, we have developed a comprehensive scattering-matrix approach to treat out-of-equilibrium current-induced forces [c.f. Phys. Rev. Lett. 107, 036804 (2011)]. We apply our method to the vibrational dynamics of a suspended graphene membrane, paying special attention to the different coupling mechanisms between Dirac fermions and flexural modes in graphene.

Thursday, March 1, 2012 11:15AM - 2:15PM – Session W8 DMP GMAG: Focus Session: Frustrated Magnetism - Pyrochlore lattice 208

11:15AM W8.00001 Topological phases in $\text{R}_2\text{Ir}_2\text{O}_7$, GANG CHEN, MICHAEL HERMELE, CU Boulder — We construct and analyze a theoretical model for the pyrochlore iridates $\text{R}_2\text{Ir}_2\text{O}_7$ with R ($= \text{Pr}, \text{Nd}, \text{Sm}, \text{Gd}, \text{Tb}, \text{Dy}, \text{Ho}, \text{Yb}$) magnetic. The electrons on trivalent rare earth ions R^{3+} form local Ising doublets due to the local crystal field. Based on a space group symmetry analysis, we write down the generic Kondo coupling between the Ising spin at R sites and the effective spin at Ir sites. Besides this interaction, we also include direct electron tunneling between Ir sites and indirect electron tunneling via intermediate oxygens for Ir-Ir coupling. This simple minimal model gives a rich phase diagram with broad regions of topological semi-metal and axion insulator phases. Based on these findings, we propose $\text{R}_2\text{Ir}_2\text{O}_7$ to be one of the most promising candidates to realize the topological semi-metal and axion insulator phases. Implications for existing and future experiments are discussed.

11:27AM W8.00002 Muon Spin Relaxation Studies of Pyrochlore Iridates $\text{R}_2\text{Ir}_2\text{O}_7$, ($\text{R} = \text{Y}, \text{Yb}$, and Nd) , STEVEN DISSELER, CHETAN DHITAL, STEPHEN WILSON, Boston College, SEAN GIBLIN, ISIS-RAL, ALEX AMATO, CHRIS BAINES, Paul Scherrer Institute, MICHAEL GRAF, Boston College — We report results for zero field muon spin relaxation measurements over the range $2\text{ K} < T < 220\text{ K}$ taken at the ISIS facility for three members of the pyrochlore iridate family, $\text{R}_2\text{Ir}_2\text{O}_7$, comprised of both magnetic ($\text{R} = \text{Yb}, \text{Nd}$) and non-magnetic ($\text{R} = \text{Y}$) species. The formation of a static internal field is detected via a loss of asymmetry below the bifurcation temperature observed in magnetic susceptibility for all three compounds. We will present results describing the nature of this internal field based on short time muon depolarization data taken at PSI. Longitudinal field measurements reveal the internal field is of order 1000 G for all three materials, and the existence of dynamic fluctuations at 2 K for $\text{R} = \text{Yb}, \text{Nd}$; the depolarization is quasistatic near 2 K for $\text{R} = \text{Y}$. We discuss these results as applied to understanding the unusual magnetic and transport properties observed in the iridate family, and the implications regarding long range magnetic order and the low temperature ground state.

11:39AM W8.00003 Chiral RKKY interaction in $\text{Pr}_2\text{Ir}_2\text{O}_7$, REBECCA FLINT, T. SENTHIL, Massachusetts Institute of Technology — $\text{Pr}_2\text{Ir}_2\text{O}_7$ experimentally realizes a chiral spin liquid selected out of a degenerate quantum spin-ice manifold. We propose that such a chiral state is selected by an analogue of the magnetic RKKY effect, whereby the chiral fluctuations of conducting Ir electrons close to a Mott transition promote correlations between the chirality of the local Pr moments. $\text{Pr}_2\text{Ir}_2\text{O}_7$ provides the perfect setting for such a *chiral RKKY* effect, as its spin ice manifold naturally contains chiral states, and chiral fluctuations in the Ir are enhanced by the proximity to the metal insulator transition between $\text{Pr}_2\text{Ir}_2\text{O}_7$ and $\text{Nd}_2\text{Ir}_2\text{O}_7$. We calculate the chiral susceptibility within a simplified model, showing that this chiral RKKY coupling can be ferro-chiral and estimating the magnitude.

11:51AM W8.00004 Emergent spin superstructures and degeneracy in models of itinerant magnets , SANJEEV KUMAR, Indian Institute of Science Education and Research (IISER) Mohali, Knowledge City, Sector 81, Mohali 140306 India, JOERN VENDERBOS, MARIA DAGHOFER, JEROEN VAN DEN BRINK, Institute for Theoretical Solid State Physics, IFW Dresden, 01171 Dresden, Germany — In recent years, there has been immense research interest in frustrated magnets with metallic character, such as the pyrochlores $\text{R}_2\text{Mo}_2\text{O}_7$, where R denotes a rare-earth element (Science **291**, 2573 (2001)). The frustration in magnetic sector in such systems can have interesting consequences for the electronic properties. More interestingly, the electronic degree of freedom can aid the system in selecting unconventional magnetic states. Motivated by these possibilities we investigate the double-exchange model with competing super-exchange interactions on various lattices. On a triangular lattice we find a novel chiral spin state to be the ground state at half filling (PRL **105**, 216405 (2010)). On checkerboard and Kagome lattices, the itinerant electrons play a crucial role in lifting the degeneracy of the magnetic sector and select specific ground states with intriguing superstructures. A very interesting effect takes place on a honeycomb lattice, where a Yafet-Kittel type magnetic structure emerges from the interplay between the super-exchange and double-exchange interactions (PRL **107**, 076405 (2011)). Some of these emergent spin states have a macroscopic degeneracy related to a symmetry which is intermediate between local and global.

12:03PM W8.00005 Resolving magnetic frustration in a Laves lattice , JIYANG WANG, University of Chicago, YEJUN FENG, Argonne National Laboratory, RAFAEL JARAMILLO, Harvard University, JASPER VAN WEZEL, Argonne National Laboratory, PAUL CANFIELD, Ames Laboratory, THOMAS ROSENBAUM, University of Chicago — CeFe_2 is a ferromagnet that exhibits antiferromagnetic fluctuations in its ground state. We use x-ray diffraction and diamond-anvil-cell techniques to directly measure the transition to antiferromagnetism in pure CeFe_2 at high pressure which couples to the change in the lattice symmetry. Numerical simulations are adopted to identify the magnetic structure of the ground states and to quantitatively illustrate effects of competing magnetic energy scales and geometrical frustration on the magnetic phase diagram. Comparison of phase transitions under both chemical substitution and applied pressure suggests a general solution to the physics of Laves phase magnets.

12:15PM W8.00006 Neutron Diffraction Investigation of Magnetic and Orbital Order in FeV_2O_4 , G.J. MACDOUGALL, A.A. ACZEL, V.O. GARLEA, Oak Ridge National Laboratory, Oak Ridge, TN, H.D. ZHOU, National High Magnetic Field Laboratory, Tallahassee, FL, S.E. NAGLER, Oak Ridge National Laboratory, Oak Ridge, TN — The vanadium spinels, AV_2O_4 , with divalent cations on the diamond sublattice are model magnetic systems for the study of interacting orbital, lattice and spin degrees of freedom. Studies of both systems with diamagnetic (e.g. Zn^{2+} , Cd^{2+} , Mg^{2+}) and spin-only (e.g. Mn^{2+}) cations on the A-site sublattice have revealed multiple phase transitions and ground state properties heavily influenced by V^{3+} orbital degrees-of-freedom. I will report on neutron powder diffraction measurements of another spinel system, FeV_2O_4 , which additionally has two-fold orbitally degenerate Fe^{2+} cations on the A-site sublattice. Previous x-ray and Mossbauer studies have reported four structural phase transitions in this material and at least one magnetic transition. Our data confirm the existence of three structural transitions and reveal distortions of local polyhedra with important implications for orbital order. We confirm the existence of hypothesized collinear antiferromagnetism below a temperature $T_{N1}=110\text{K}$ and further identify a second magnetic transition at $T_{N2}=60\text{K}$ where V^{3+} moments cant away from the Fe^{2+} spin direction to form a 2-in-2-out spin structure on the pyrochlore sublattice. I will discuss these observations in the context of recent predictions for orbital order in vanadate spinels.

12:27PM W8.00007 Universal exchange-driven phonon splitting, JOACHIM DEISENHOFER, Augsburg University, CHRISTIAN KANT, Technical University of Vienna, MICHAEL SCHMIDT, ZHE WANG, FRANZ MAYR, VLADIMIR TSURKAN, ALOIS LOIDL, Augsburg University — We report on a linear dependence of the phonon splitting on the non-dominant exchange coupling J_{nd} in the antiferromagnetic monoxides MnO , $\text{Fe}_{0.92}\text{O}$, CoO and NiO , and in the highly frustrated antiferromagnetic spinels CdCr_2O_4 , MgCr_2O_4 and ZnCr_2O_4 . For the monoxides our results directly confirm the theoretical prediction of a predominantly exchange induced splitting of the zone-centre optical phonon [1,2]. We find the linear relation $\hbar\Delta\omega = \beta J_{nd} S^2$ with slope $\beta = 3.7$. This relation also holds for a very different class of systems, namely the highly frustrated chromium spinels. Our finding suggests a universal dependence of the exchange-induced phonon splitting at the antiferromagnetic transition on the non-dominant exchange coupling [3].

12:39PM W8.00008 First-principles study of the structural and magnetic phase transition in CdCr_2O_4 , ANIL KUMAR, KARIN RABE, Rutgers University — We use first-principles calculations to investigate the mechanism for the paramagnetic (PM) cubic to an antiferromagnetic (AFM) tetragonal structural phase transition at 7.8 K in the spinel oxide compound CdCr_2O_4 . Because of the magnetic frustration associated with AFM interactions on the pyrochlore lattice formed by the Cr ions, we focus on the spin-lattice coupling, specifically (a) the forces on the atoms and resulting atomic displacements induced by the spin configuration and (b) the spin-phonon coupling. Using the linear response method, we determine the full phonon dispersion relations for the PM, FM and AFM orderings in cubic and tetragonal structures. We determine the strength of spin-phonon couplings using IFCs for various magnetic orderings and show that the spin-phonon couplings are large but do not lead to any unstable modes that could alone drive the structural transition at low temperatures. Instead, we find that it is the symmetry-lowering forces and stresses induced by AFM ordering that drive the cubic to tetragonal phase transition at low temperature. The results are compared with a recent experimental determination of the phonon dispersion in the cubic and tetragonal phases of CdCr_2O_4 and the implications for related compounds discussed.

12:51PM W8.00009 Frustration and Jahn-Teller ordering in magnetic spinel oxides, MOUREEN KEMEL, STEPHANIE MOFFITT, University of California, Santa Barbara, MATTHEW SUCHOMEL, DANIEL SHOEMAKER, Argonne National Laboratory, RAM SESHADRI, University of California, Santa Barbara — Geometrically frustrated magnetic systems have become extremely important for the study of novel phenomena often present in highly degenerate magnetic ground states. Extensive study of the canonically frustrated ZnCr_2O_4 and MgCr_2O_4 has increased the understanding of frustration in three-dimensional systems, however little is known about the structural effect of dilute magnetism on the A site. We present the effects on magneto-structural coupling of dilute magnetic cations on the diamagnetic A site of ZnCr_2O_4 and MgCr_2O_4 . In ZnCr_2O_4 and MgCr_2O_4 , a spin-driven structural distortion concomitant with the onset of long-range magnetic order resolves the large ground state degeneracy at temperatures far below the theoretical Curie-Weiss temperature. Employing variable temperature high-resolution synchrotron powder diffraction studies and magnetic susceptibility measurements, we show the changes in spin-lattice coupling in the solid solutions $\text{Zn}_{1-x}\text{Co}_x\text{Cr}_2\text{O}_4$, $\text{Zn}_{1-x}\text{Cu}_x\text{Cr}_2\text{O}_4$ and $\text{Mg}_{1-x}\text{Cu}_x\text{Cr}_2\text{O}_4$ for $x \leq 0.2$. These results highlight the effect of dilute A site magnetism on magnetic frustration as well as the role of dilute Jahn-Teller active Cu^{2+} on spin-lattice coupling in these frustrated systems.

1:03PM W8.00010 Ultrasound Velocity Measurements in the Geometrically Frustrated Spinel MgCr_2O_4 , TADATAKA WATANABE, Department of Physics, College of Science and Technology (CST), Nihon University, Chiyoda, Tokyo 101-8308, Japan, YUSUKE KOUSAKA, Department of Physics and Mathematics, Aoyama-Gakuin University, Sagami-hara, Kanagawa 229-8558, Japan, KEISUKE TOMIYASU, Department of Physics, Tohoku University, Aoba, Sendai 980-8578, Japan — Magnesium chromite spinel MgCr_2O_4 is a geometrically frustrated magnet with the Néel temperature $T_N \simeq 13\text{ K}$, and the Weiss temperature $\theta_W = -390\text{ K}$. Recent inelastic neutron scattering experiments provided a compelling evidence for the spin molecular ground states in not only the paramagnetic phase but also the antiferromagnetic phase. We performed ultrasound velocity measurements of MgCr_2O_4 in all the symmetrically independent elastic moduli of C_{11} , $(C_{11} - C_{12})/2$, and C_{44} . Temperature dependence of all of these elastic moduli exhibits a remarkable softening in the paramagnetic phase. Taking into account the absence of orbital degrees of freedom in Cr^{3+} ($3d^3$) in MgCr_2O_4 , the spin degrees of freedom should play a significant role for the elastic softening. The most probable origin for the elastic softening in the paramagnetic phase is the strong coupling of the acoustic phonons to the molecular spin fluctuations.

1:15PM W8.00011 Magnetic correlations and magnetic order in the pyrochlore $\text{Er}_2\text{Ti}_2\text{O}_7$, S.H. CURNOE, Memorial University of Newfoundland, P. DALMAS DE RÉOTIER, A. YAOUANC, Y. CHAPUIS, B. GRENIER, E. RESSOUCHE, C. MARIN, Institut Nanosciences et Cryogénie, SPMS, CEA and University Joseph Fourier, C. LAGO, Universidade del País Vasco, C. BAINES, Paul Scherrer Institute, S.R. GIBLIN, ISIS Facility, Rutherford Appleton Laboratory — We analyse short-range magnetic correlations in the pyrochlore magnet $\text{Er}_2\text{Ti}_2\text{O}_7$. Four unique nearest-neighbour exchange interactions are permitted by the space group symmetry of the pyrochlore lattice; the four corresponding nearest-neighbour exchange constants for $\text{Er}_2\text{Ti}_2\text{O}_7$ are extracted from diffuse neutron scattering maps. Low-temperature magnetic order in $\text{Er}_2\text{Ti}_2\text{O}_7$ is discussed in light of these results. The results are compared to recently published values for the sister compound $\text{Yb}_2\text{Ti}_2\text{O}_7$, which has similar features.

1:27PM W8.00012 Low Temperature Spin Structure of Gadolinium Titanate, BEHNAM JAVANPARAST, PAUL MCCLARTY, MICHEL GINGRAS, University of Waterloo — Many rare earth pyrochlore oxides exhibit exotic spin configurations at low temperatures due to frustration. The nearest neighbor coupling between spins on the corner-sharing tetrahedral network generate geometrical magnetic frustration. Among these materials, gadolinium titanate ($\text{Gd}_2\text{Ti}_2\text{O}_7$) is of particular interest. Its low temperature ordered phases are not yet understood theoretically. Bulk thermal measurements such as specific heat and magnetic susceptibility measurements find two phase transitions in zero external field, in agreement with simple mean field calculations. However, recent neutron scattering experiments suggest a so-called 4-k spin structure for intermediate phase and a so called canted 4-k structure for lower temperature phase that does not agree with either mean-field theory or Monte Carlo simulation which find the 1-k state and Palmer-Chalker state respectively as the lowest free energy configuration for those phases. In our work, we study the 4-k structure in detail and present a new phase diagram for dipolar Heisenberg spins on a pyrochlore lattice, certain portions of which describe gadolinium titanate.

1:39PM W8.00013 Elastic properties of the titanate pyrochlore $\text{Tb}_2\text{Ti}_2\text{O}_7$ ¹, V. KEPPENS, Y. LUAN, Department of Materials Science and Engineering, The University of Tennessee, Knoxville, TN, A. MIGLIORI, J. BETTS, National High Magnetic Field Laboratory, Los Alamos, NM, H.D. ZHOU, National High Magnetic Field Laboratory, Tallahassee, FL, H.A. DABKOWSKA, B.D. GAULIN, Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON — The presence of geometric frustration inhibits the formation of long-range spin ordering in $\text{Tb}_2\text{Ti}_2\text{O}_7$ even at very low temperatures, making this compound the prototype of a “spin liquid.” We have initiated a study of the elastic properties of $\text{Tb}_2\text{Ti}_2\text{O}_7$ as a function of temperature (0.5-300 K) and magnetic field (0-15T) using Resonant Ultrasound Spectroscopy (RUS). All three elastic constants show a pronounced softening below 50 K, indicative of a possible structural transition at very low temperatures. Application of a magnetic field partially suppresses the elastic softening in this compound, suggesting that the magnetoelastic coupling plays a significant role in the spin liquid physics of $\text{Tb}_2\text{Ti}_2\text{O}_7$ at low temperatures.

¹Work supported by NSF-DMR-0804719.

1:51PM W8.00014 Imaging Magnetic Order in Magnetostructural Phases of Mn_3O_4 ¹, XU WANG, MINJUNG KIM, S.L. COOPER, RAFFI BUDAKIAN, Department of Physics and Frederick Seitz Materials Research Laboratory University of Illinois at Urbana-Champaign, Urbana, IL 61801 — Frustration in A-site spinels due to the competition between complex structure and strong interactions has been the focus of many theoretical and experimental studies recently. Mn_3O_4 is one such material with a three way interplay between complex lattice geometry, strong spin-lattice coupling and magnetic interactions. Mn_3O_4 is known to have two distinct phases below the Neel temperature that differ in both structure and magnetic order, including a tetragonal phase with disordered spins, and at lower temperatures, an orthorhombic phase exhibiting long-range commensurate magnetic order. In this talk, we present a nanometer-scale imaging investigation of the transition between these two phases. With cryogenic magnetic force microscopy (MFM), we observe novel magnetic stripe patterns accompanying this phase transition. Complementary electron backscatter diffraction (EBSD) measurements indicate that the magnetic patterns are closely related to local crystalline orientation. The onset and spatial periodicity of the magnetic patterns show variations with temperature and external magnetic field. We will also discuss possible causes of this phenomenon and their implications.

¹Work supported by the U.S. Department of Energy under Award No. DE-FG02-07ER46453

2:03PM W8.00015 Spin state of Mn_3O_4 investigated by ^{55}Mn NMR, EUNA JO, KYONGMO AN, JEONGHYUN SHIM¹, CHANGSOO KIM, SOONCHIL LEE, Department of physics, KAIST, Daejeon 305-701, Korea, KAIST TEAM — The ^{55}Mn nuclear magnetic resonance spectrum for spinel oxide Mn_3O_4 was measured in the temperature range of 6 K - 30 K to investigate the spin structure in the ground state. The spectrum consists of three peaks in the frequency range of 250 - 265 MHz, which corresponds to the hyperfine field range of 24 - 25 T. The temperature dependence of the spectrum and the rf enhancement factor show that Mn^{3+} ions have two different magnetic moments, one of which is strongly related with the commensurate-incommensurate phase transition. This is consistent with the picture of two magnetic moments, R and S, claimed from the result of a neutron experiment. The dipolar hyperfine field was calculated to explain the splitting of two peaks coming from R and S and to estimate the magnetic moments. The spin-spin relaxation time has a frequency dependence that induces spectrum broadening and further splitting of the peak coming from S, indicating that the Suhl-Nakamura interaction is the major relaxation mechanism in Mn_3O_4 .

¹current address : Fakultät Physik, Technische Universität Dortmund, Dortmund, Germany

Thursday, March 1, 2012 11:15AM - 2:15PM – Session W9 DMP GMAG: Focus Session: Complex Bulk Oxides: Multiferroics 209

11:15AM W9.00001 Evolution of spin wave excitations in $\text{Sr}_2\text{FeSi}_2\text{O}_7$ under an external magnetic field, KAZUKI IIDA, JOOSEOP LEE, NAOYUKI KATAYAMA, SUNGDAE JI, ISRAEL KLICH, SEUNGHUN LEE, University of Virginia, DUC LE, Helmholtz Zentrum, SUNG CHANG, NIST Center for Neutron Research, TAEHWAN JANG, YOONHEE JEONG, Pohang University of Science and Technology, SANGWOOK CHEONG, Rutgers University, UNIVERSITY OF VIRGINIA TEAM, HELMHOLTZ ZENTRUM COLLABORATION, NIST CENTER FOR NEUTRON RESEARCH COLLABORATION, POHANG UNIVERSITY OF SCIENCE AND TECHNOLOGY COLLABORATION, RUTGERS UNIVERSITY COLLABORATION — Evolution of static and dynamic spin correlations in a new multiferroic material $\text{Sr}_2\text{FeSi}_2\text{O}_7$ under an external magnetic field was investigated by elastic and inelastic neutron scattering techniques. An external magnetic field up to $B = 14$ Tesla induces four different magnetic and ferroelectric phases in $\text{Sr}_2\text{FeSi}_2\text{O}_7$. The static magneto-electric coupling can be understood as the spin-dependent metal-ligand hybridization proposed for a related material $\text{Ba}_2\text{CoGe}_2\text{O}_7$. By analyzing the inelastic neutron scattering data obtained from a single crystal of $\text{Sr}_2\text{FeSi}_2\text{O}_7$ without field, we have determined the effective spin Hamiltonian in this material that includes isotropic nearest neighbor exchange interaction in the two-dimensional Fe square plane and easy plane single ionic anisotropies. The spin wave excitations show interesting changes as upon ramping up the system enters the field-induced phases for $B > 6.5$ Tesla, which will also be discussed.

11:27AM W9.00002 THz spectroscopy of spin waves in multiferroic $\text{Ba}_2\text{CoGe}_2\text{O}_7$ in high magnetic fields¹, URMAS NAGEL, T. RÕÕM, NICPB, Tallinn, Estonia, S. BORDÁCS, D. SZALLER, I. KÉZSMÁRKI, Department of Physics, BUTE, Budapest, Hungary, H. ENGELKAMP, HFML, Radboud University Nijmegen, The Netherlands, J. ROMHÁNYI, K. PENC, MTA SzFKI, Budapest, Hungary, L. DEMKÓ, N. KIDA, H. MURAKAWA, Y. ONOSE, R. SHIMANO, S. MIYAHARA, N. FURUKAWA, Y. TOKURA, Multiferroics Project, ERATO, University of Tokyo, Japan — By applying external magnetic field the square-lattice antiferromagnet $\text{Ba}_2\text{CoGe}_2\text{O}_7$ can be transformed to a chiral form, evidenced by large optical activity when the light is in resonance with spin excitations at sub-terahertz frequencies. We found that the magnetochiral effect, the absorption difference for the light beams propagating parallel and anti-parallel to the applied magnetic field, has an exceptionally large amplitude close to 100% and persists to fields up to 30 T. All these features are ascribed to the magnetoelectric nature of spin excitations as they interact both with the electric and magnetic components of light. We observe a spin flop at 15 T, that is consistent with our theoretical calculations.

11:39AM W9.00003 Ground State Properties and Magnetodielectric Coupling in $\text{Sm}_{0.5}\text{Nd}_{0.5}\text{Fe}_3(\text{BO}_3)_4$ ¹, C.S. NELSON, Brookhaven National Laboratory, Upton, NY, USA, R.P.S.M. LOBO, LPEM, ESPCI, CNRS, UPMC, Paris, France, L.N. BEZMATERNYKH, Kirensky Institute of Physics, Siberian Branch of RAS, Russia — We report x-ray scattering and polarized infrared reflectivity measurements of the substituted ferroborate $\text{Sm}_{0.5}\text{Nd}_{0.5}\text{Fe}_3(\text{BO}_3)_4$. Below $T_N = 33$ K, a new set of commensurate peaks with resonant enhancements at the rare earth L edges indicates a doubling of the magnetic structure along the c-axis and simultaneous ordering of the rare earth and iron ions. Rare earth spin polarizations decrease rapidly with increasing temperature, in contrast to that of the iron ions. Shell-specific measurements of the rare earth spin polarizations indicate similar behaviors of the Sm and Nd 5d states, while the Sm 4f and 5d states have different temperature dependences. Along the c-axis we observe negative thermal expansion below ~ 75 K and a strong phonon softening from room temperature down to T_N , at which it freezes in frequency. Also at T_N we observe the appearance of an electromagnon in the ab-plane that gets its spectral weight from the lowest frequency phonon. These results indicate a lattice instability linked to magnetism with a strong coupling between magnetic and elastic properties.

11:51AM W9.00004 Spin-driven ferroelectricity in ferroaxial crystals, LAURENT CHAPON, Institut Laue-Langevin, France — Spin-driven ferroelectricity in most non-collinear magnets, such as TbMnO_3 , is induced by the so-called inverse Dzyaloshinskii-Moriya mechanism and requires a cycloidal magnetic structure, an ordered magnetic state that is not truly chiral (or lacks helicity). Conversely, in a truly chiral magnetic state (proper helix), the pseudo-scalar helicity can not couple directly to the electric polarization, and therefore can't induce ferroelectric order. However, in systems of specific crystal symmetry, named here “ferroaxials,” the presence of collective structural rotations mediates an indirect coupling between magnetic helicity and ferroelectricity. I will review our recent experimental results for new compounds of this class, obtained by magnetic X-ray and neutron diffraction techniques, including a clear demonstration that the magnetic helicity can be controlled by an electric field.

12:27PM W9.00005 Multiferroic behavior in trimerized Mott insulators, YOSHITOMO KAMIYA, CRISTIAN BATISTA, Theoretical Division, Los Alamos National Laboratory — We demonstrate multiferroic behavior in trimerized Mott insulators through the interplay between spins and electric dipole moments resulting from electronic charge fluctuations in frustrated units [L. N. Bulaevskii, C. D. Batista, M. V. Mostovoy, and D. I. Khomskii, Phys. Rev. B 78, 024402 (2008)]. The model consists of stacked triangular layers of trimers with small inter-trimer exchange interactions J' and J'' . We construct a phase diagram using a semi-classical approach. Ferroelectric states coexist with ferro- or antiferromagnetic orderings depending on the value of the magnetic field H and the sign of the inter-layer exchange J'' . The electric polarization undergoes abrupt changes as a function of H .

12:39PM W9.00006 Electric field control of magnetic chiralities in ferroaxial multiferroic $\text{RbFe}(\text{MoO}_4)_2$ ¹, ALEXANDER J. HEARMON, FEDERICA FABRIZI, Clarendon Laboratory, Department of Physics, Oxford University, UK, LAURENT C. CHAPON, Institut Laue Langevin, Grenoble, France, ROGER JOHNSON, Clarendon Laboratory, Department of Physics, Oxford University, UK, P. JANE BROWN, Institut Laue Langevin, Grenoble, France, PAOLO G. RADAELLI, Clarendon Laboratory, Department of Physics, Oxford University — The onset of ferroelectric polarisation in high symmetry, proper-screw type multiferroic materials cannot be explained in terms of conventional microscopic mechanisms or symmetry analysis since the direction of the magnetic propagation vector is orthogonal to the plane of the spins. $\text{RbFe}(\text{MoO}_4)_2$ undergoes a structural distortion at $T_c = 190$ K in which the oxygen tetrahedra rotate, imposing an “axiality” to the crystal structure. We show that a simple symmetric-exchange driven coupling of this axiality with the magnetic chiralities below $T_N = 4$ K explains the appearance of a ferroelectric polarisation parallel to both the axial vector and direction of magnetic propagation. We present spherical neutron polarimetry data that are sensitive to both helical and triangular chiral domains of the magnetic structure. We are able to distinguish the magnetic order in the two axial domains that are present in equal proportions, and to demonstrate direct control of the magnetic structure by an applied electric field. The above formalism may be readily generalised to other ‘ferroaxial’ systems in which the magnetic ordering breaks the inversion symmetry in a point group supporting an axial vector.

12:51PM W9.00007 Electric field control of nonvolatile four-state magnetization at room temperature, SAE HWAN CHUN*, YI SHENG CHAI*, BYUNG-GU JEON, HYUNG JOON KIM, YOON SEOK OH, INGYU KIM, HANBIT KIM, BYEONG JO JEON, SO YOUNG HAAM, JU-YOUNG PARK, SUK HO LEE, KEE HOON KIM, CeNSCMR, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea, JAE-HO CHUNG, Department of Physics, Korea University, Seoul 136-713, Korea, JAE-HOON PARK, Department of Physics and Division of Advanced Materials Science, POSTECH, Pohang 790-784, Korea — We find the realization of large converse magnetoelectric (ME) effects at room temperature in a multiferroic hexaferrite $\text{Ba}_{0.52}\text{Sr}_{2.48}\text{Co}_2\text{Fe}_{24}\text{O}_{41}$ single crystal, in which rapid change of electric polarization in low magnetic fields (about 5 mT) is coined to a large ME susceptibility of 3200 ps/m. The modulation of magnetization then reaches up to $0.62 \mu_B/\text{f.u.}$ in an electric field of 1.14 MV/m. We find further that four ME states induced by different ME poling exhibit unique, nonvolatile magnetization versus electric field curves, which can be described by an effective free energy with a distinct set of ME coefficients. *These authors contributed equally to this work.

1:03PM W9.00008 Magnetoelectric Effects and Related Phenomena in Spin-spiral Hexaferrites, TSUYOSHI KIMURA, Division of Materials Physics, Graduate School of Engineering Science, Osaka University — Among various multiferroics, extensive studies of ferroelectrics originating from magnetic orders, i.e., *magnetically-induced ferroelectrics* in which the inversion symmetry breaking and resultant ferroelectricity are induced by complex magnetic orders, have been triggered almost a decade ago by the discovery of multiferroic nature in a perovskite-type rare-earth manganites TbMnO_3 . The magnetically-induced ferroelectrics often show giant magnetoelectric effects, remarkable changes in electric polarization in response to a magnetic field, since the origin of their ferroelectricity is driven by magnetism which sensitively responds to an applied magnetic field. Though a large number of new magnetically-induced ferroelectrics have been reported in the past decade, so far there has been no practical application employing the magnetoelectric effect of the magnetically-induced ferroelectrics. This is partly because none of the existing magnetically-induced ferroelectrics have combined large and robust electric and magnetic polarizations at room temperature until quite recently. The situation is changed by the discoveries of magnetoelectricity in hexagonal ferrites (*hexaferrites*) with spin-spiral structures.^{1,2,3} In this presentation, I show our recent studies on magnetoelectric effects and related phenomena in the new series of magnetically-induced ferroelectrics which are promising candidates for multiferroics operating at room temperature and low fields. This work has been done in collaboration with Y. Hiraoka, T. Ishikura, K. Okumura, Y. Kitagawa, H. Nakamura, Y. Wakabayashi, M. Soda, T. Asaka, and Y. Tanaka.

1:39PM W9.00009 Pressure-induced Polarization Reversal in Z-type Hexaferrite Single Crystal, BYUNG-GU JEON, SAE HWAN CHUN, KEE HOON KIM, CeNSCMR, Seoul National University — Multiferroic materials with a gigantic magnetoelectric (ME) coupling at room temperature have been searched for applications to novel devices. Recently, large direct and converse ME effects were realized at room temperature in the so-called Z-type hexaferrite ($\text{Ba,Sr}_3\text{Co}_2\text{Fe}_{24}\text{O}_{41}$) single crystals [1,2]. To obtain a new control parameter for realizing a sensitive ME tuning, we studied ME properties of the crystals under uniaxial pressure. Upon applying a tiny uniaxial pressure of about 0.6 GPa, magnetic field-driven electric polarization reversal and anomaly in a $M-H$ loop start to appear at 10 K and gradually disappear at higher temperature above 130 K. By comparing those results with longitudinal magnetostriction at ambient pressure, we propose the pressure-dependent variations of transverse conical spin configuration as well as its domain structure under small magnetic field bias, and point out the possibility of having two different physical origins of the ME coupling in this system. [1] Y. Kitagawa *et al.*, Nat. Mater. **9**, 797 (2010) [2] S. H. Chun *et al.*, submitted.

1:51PM W9.00010 The complex multiferroic phase diagram of $\text{Mn}_{1-x}\text{Co}_x\text{WO}_4$ ¹, B. LORENZ, K.-C. LIANG, TCSUH and Dept. of Physics, University of Houston, Y. Q. WANG, Y.Y. SUN, TCSUH, University of Houston, F. YE, J.A. FERNANDEZ-BACA², H.A. MOOK, Neutron Scattering Science Division, Oak Ridge National Laboratory, C.W. CHU³, TCSUH and Dept. of Physics, University of Houston — MnWO_4 is a classical multiferroic where ferroelectricity is induced by an inversion symmetry breaking helical spin order. The origin of the helical order is found in competing magnetic exchange interactions with strong uniaxial anisotropy, resulting in magnetic frustration. The microscopic parameters can be tuned by chemical substitution of Fe, Zn, or Co for Mn. The effects of Co substitution up to 30% on the magnetic structure and the ferroelectric (FE) phase are investigated. The multiferroic phase diagram of $\text{Mn}_{1-x}\text{Co}_x\text{WO}_4$ is completely resolved. At low Co content, the FE polarization is oriented along the b-axis and decreases with increasing x. At doping levels between 7.5% and 12% Co, the polarization points along the a-axis and it reaches a maximum value of 90 $\mu\text{C}/\text{m}^2$ at x=10%. With further increasing x, the FE polarization rotates back to the b-axis. Its magnitude decreases continuously and vanishes above 30% Co content. This complex behavior comes along with a delicate sequence of different magnetic phases which are explored by magnetization, heat capacity, and neutron scattering experiments.

2:03PM W9.00011 Spin flop transition in the multiferroic $\text{Mn}_{1-x}\text{Co}_x\text{WO}_4$ studied by neutron diffraction, FENG YE, SONGXUE CHI, HUIBO CAO, JAIME FERNANDEZ-BACA, Oak Ridge National Laboratory, BERND LORENZ, YAQI WANG, P.W. CHU, University of Houston — Elastic neutron diffraction is employed to investigate the ground state magnetic structure of the multiferroic $\text{Mn}_{1-x}\text{Co}_x\text{WO}_4$. Unlike the undoped MnWO_4 that has low- T collinear spin structure, the doped MnWO_4 exhibits complex evolution of magnetic structure. Samples at lower concentration ($x < 0.10$) have similar elliptical spiral structure as MnWO_4 in the multiferroic phase. With increasing x , the magnetic structure undergoes a sudden spin-flop transition which switches electric polarization from crystalline b -axis to a -axis. Polarized neutron scattering is also used to study the correlation between the bulk electricity and magnetic helicity.

Session W10 DAMOP: Invited Session: Novel Bose-Einstein Condensates: Photons, Excitons, Magnons, Rydberg Atoms, and Polar Molecules 210A

11:15AM W10.00001 Bose-Einstein condensation of photons, MARTIN WEITZ, University of Bonn — Bose-Einstein condensation, the macroscopic ground state accumulation of particles with integer spin (bosons) at low temperature and high density, has been observed in several physical systems, including cold atomic gases and solid state physics quasiparticles. However, the most omnipresent Bose gas, blackbody radiation (radiation in thermal equilibrium with the cavity walls) does not show this phase transition. The photon number is not conserved when the temperature of the photon gas is varied (vanishing chemical potential), and at low temperatures photons disappear in the cavity walls instead of occupying the cavity ground state. Here I will describe an experiment observing a Bose-Einstein condensation of photons in a dye-filled optical microcavity [1]. The cavity mirrors provide both a confining potential and a non-vanishing effective photon mass, making the system formally equivalent to a two-dimensional gas of trapped, massive bosons. By multiple scattering of the dye molecules, the photons thermalize to the temperature of the dye solution. In my talk, I will begin with a general introduction and give an account of current work and future plans of the Bonn photon gas experiment.

11:51AM W10.00002 Superfluid Phase Transition of Long-Lifetime Polaritons¹, DAVID SNOKE, University of Pittsburgh — Exciton-polaritons are quanta of electronic excitation which can have their properties tailored in semiconductor structures to have extremely light mass, about four orders of magnitude less than a free electron. One can think of them as photons dressed with an effective mass and an atom-like interaction. Because of their very light mass, exciton-polaritons show Bose quantum effects even at moderate densities and temperatures from tens of Kelvin up to room temperature. In the past five years, multiple experiments have shown effects of polaritons analogous to Bose condensation of cold atoms, such as a bimodal momentum distribution, quantized vortices, a Bogoliubov excitation spectrum, spatial condensation in a trap, and Josephson junction oscillations. In these experiments, though, the lifetime of the polaritons has been just a little longer than their thermalization time, which means that nonequilibrium effects play an important role; in particular, the transition to superfluidity has been smeared out rather than a sharp transition. In this talk I report new results with polaritons that have very long lifetime compared to their thermalization time. We see a discontinuous jump in the properties of the polariton gas indicative of a true phase transition, and we see ballistic transport over hundreds of microns. We also now have a way to use a laser to create a potential barrier for the polaritons.

Session W11 DMP: Focus Session: Graphene Structure, Stacking, Interactions: Local Probes and Microscopy 210B

11:15AM W11.00001 Direct Imaging of a Two-Dimensional Silica Glass on Graphene, P.Y. HUANG, Cornell University, S. KURASCH, University of Ulm, A. SRIVASTAVA, V. SKAKALOVA, Max Planck Institute for Solid State Research, J. KOTAKOSKI, A.V. KRASHENINNIKOV, University of Helsinki, R.M. HOVDEN, Q. MAO, Cornell University, J.C. MEYER, University of Vienna, J. SMET, Max Planck Institute for Solid State Research, D.A. MULLER, Cornell University, U. KAISER, University of Ulm — Large-area graphene substrates [1] are a promising lab bench for synthesizing and characterizing novel low-dimensional materials such as two-dimensional (2D) glasses. Unlike 2D crystals such as graphene, 2D glasses are almost entirely unexplored—yet they have enormous applicability for understanding amorphous structures, which are difficult to probe in 3D. We report direct observations of the structure of an amorphous 2D silica supported on graphene. To our knowledge, these results represent the first discovery of an extended 2D glass. The 2D glass enables aberration-corrected scanning transmission electron microscopy and spectroscopy, producing the first atomically-resolved experimental images of a glass. The images strikingly resemble Zachariasen's seminal 1932 cartoons of a 2D continuous random network glass [2] and allow direct structural analyses not possible in 3D glassy materials. DFT calculations indicate that van der Waals interactions with graphene energetically favor the 2D structure over bulk SiO₂, suggesting that graphene can be instrumental in stabilizing new 2D materials. [1] J. C. Meyer et al., *Nature* **454**, 319–322 (2008). [2] W. H. Zachariasen, *J. Am. Chem. Soc.* **54**, 3841–3851 (1932).

11:27AM W11.00002 Imaging defects on epitaxial graphene/SiC(0001) using non-contact AFM with a Q-plus sensor¹, Y. LIU, L. LI, University of Wisconsin, Milwaukee — STM has been commonly used to study the atomic structures of resonant scatters such as vacancies and adsorbates on graphene, which are leading factors limiting its mobility. However, since STM probes primarily the local density of states, complex patterns are often observed when imaging defects on graphene, making it challenging to determine their atomic structures using STM alone. In this work, we carried out an integrated study of defects on epitaxial graphene/SiC(0001) using non-contact AFM with Q-plus sensors in addition to STM. With atomic resolution AFM imaging, straight forward identifications of single- and di-vacancy defects can be made. These results and their implications for understanding electron scattering in epitaxial graphene on SiC(0001) will be presented at the meeting.

11:39AM W11.00003 Direct Imaging of Charged Impurities in Substrates used for Graphene Devices, K.M. BURSON, Center for Nanophysics and Adv. Mat. (CNAM), U. of Maryland, College Park, C.R. DEAN, Dept. of Mech. Eng. and Dept. of Elec. Eng., Columbia U., New York, P. KIM, Dept. of Phys., Columbia U., New York, K. WATANABE, T. TANIGUCHI, Adv. Mat. Laboratory, Nat. Inst. for Materials Science, Tsukuba, Japan, S. ADAM, Center for Nanoscale Science and Tech., NIST, Gaithersburg, A.E. CURTIN, W.G. CULLEN, M.S. FUHRER, CNAM, U. of Maryland, College Park — The use of hexagonal boron nitride (h-BN) as a substrate for graphene led to approximately an order of magnitude improvement in electron mobility compared to graphene on SiO₂. One hypothesis for the improvement is a reduction in trapped charge density on the surface of h-BN compared to SiO₂. We address this directly by mapping local potential fluctuations above the bare substrates h-BN and SiO₂ using Kelvin probe microscopy in ultra-high vacuum. We compare the results to a model of randomly distributed charges in a 2D plane at the surface of an insulating substrate. For SiO₂, the results are well modeled by a 2D charge density of $\sim 2.5 \times 10^{11} \text{ cm}^{-2}$. Previous measurements of charged impurity scattering in graphene indicates that this density of substrate charges would limit graphene mobility to 20,000 cm²/Vs, in good agreement with the maximum values reported for graphene on SiO₂. h-BN displays potential fluctuations that are approximately an order of magnitude lower than SiO₂, consistent with an order of magnitude improvement in mobility in graphene/h-BN devices. This work was supported by the US ONR MURI program, and the U. of MD NSF-MRSEC under Grant No. DMR 05-20471.

11:51AM W11.00004 Self-Organized Graphene Nanoribbons on SiC(0001) Studied with Scanning Tunneling Microscopy¹, DAVID TORRANCE, BAIQIAN ZHANG, TIEN HOANG, PHILLIP FIRST, Georgia Institute of Technology — Graphene nanoribbons grown directly on nanofacets of SiC(0001) offer an attractive union of top-down and bottom-up fabrication techniques. Nanoribbons have been shown to form on the $\langle 1\bar{1}0n \rangle$ facets of templated silicon carbide substrates,² but also appear spontaneously along step-bunches on vicinal SiC(0001) miscut slightly towards $\langle 1\bar{1}00 \rangle$. These self-organized graphene nanoribbons were characterized with low-energy electron diffraction (LEED) and Auger electron spectroscopy (AES) in ultra-high vacuum. Our measurements indicate that the graphene forms a continuous “buffer layer” across the SiC(0001) terraces during nanoribbon formation, with the zigzag edge of the buffer layer aligned parallel to the step-bunched nanofacets. Scanning tunneling microscopy/spectroscopy (STM/STS) was used to characterize the topography and electrical characteristics of the graphene nanoribbons. These measurements indicate that the graphene nanoribbons are highly-crystalline with predominantly zigzag edges.

12:03PM W11.00005 Imaging epitaxial graphene on SiC(0001) using STM with functionalized W tips¹, S.H. RHIM², Y. QI, G.F. SUN, Y. LIU, M. WEINERT, L. LI, U. Wisconsin-Milwaukee — Epitaxial graphene on SiC(0001) is studied using scanning tunneling microscopy with W tips functionalized by transition-metal (Cr, Fe) coatings, enabling the imaging of states within a few meV of the Fermi level that are not accessible with conventional W tips. First-principles modeling of these tips as pyramidal structures on W(110) indicates that an apex atom is stable for the Cr/W(110) tip but not for the Fe/W(110) or W/W(110) tips. Further calculations of the tunneling current show that the Cr- and Fe-coated tips can get significantly closer to the substrate than a bare W tip at a given current, and that the Cr (Fe) tip states contributing to the tunneling at low bias are spatially more localized than the W tip states. These characteristics lead to increased resolution, making possible the selective imaging of the complex electronic properties of the epitaxial graphene on SiC(0001)^{1,2}.

¹DOE (DE-FG02-05ER46228)

²present: Northwestern University

12:15PM W11.00006 Scanned probe studies of dielectric screening and charge puddles in epitaxial graphene on SiC(0001) , A.E. CURTIN, A. IMTIAZ, T.M. WALLIS, P. KABOS, National Institute of Standards and Technology, Boulder, CO, R.L. MYERS-WARD, C.R. EDDY, JR., L.O. NYAKITI, V.D. WHEELER, D.K. GASKILL, U.S. Naval Research Laboratory, Code 6880, Washington, DC 20375 — Epitaxial growth of graphene on SiC(0001) produces wafer-scale monolayer films suitable for large scale device applications. However, the presence of the buffer layer beneath the graphene produces n-doping of 10^{12} - 10^{13} cm⁻² and limits mobility to $\sim 10^3$ cm²/Vs. Recently H intercalation has produced p-doped samples with similar carrier density and improved mobility. Transport measurements on processed devices show evidence of charge impurity scattering, but these measurements cannot show whether the transport behavior is due to top gate dielectrics or intrinsic to the as-grown graphene. Here we use scanning microwave microscopy to look at graphene samples and bare SiC substrates to extract information about the screening role of the buffer layer. This data is complemented by earlier results suggesting charge puddles due to random impurities to not exist in epitaxial samples.

12:27PM W11.00007 Scanning Tunneling Microscopy Study of Mechanically-Stacked Double Layer Graphene , HONGWOO BAEK, Seoul National University, JEONGHOON HA, National Institute for Standards and Technology, BEOMYONG HWANG, JEONGHOON KWON, Seoul National University, JOSEPH STROSCIO, National Institute for Standards and Technology, YOUNG KUK, Seoul National University — Bilayer graphene has drawn considerable attention due to deviation from Dirac Fermion picture such as anomalous quantum hall effect and a tunable band gap in their spectrum. While a pristine Bernal (AB) stacked bilayer graphene can be synthesized by mechanical exfoliation, growth on a SiC single crystal and epitaxial growth on metal substrates, separate control of the top and the bottom layers has seldom been performed. In this study, artificially modified 2D layers were demonstrated with individually stacked double layer graphene. Large-area graphene was grown on a Cu foil by chemical vapor deposition (CVD). CVD-grown graphene layers were transferred successively onto several insulating substrates with minimum chemical process for realizing bilayer graphene. Mechanically-stacked double layer graphene was mainly investigated using scanning tunneling microscopy and spectroscopy. The artificial bilayer graphene showed Moire patterns as determined by misalignment angle. In spatially resolved spectrums of local density of states, dependence on separation distance between two graphene layers and their corrugation was measured. In addition, we confirmed less charging effects of graphene on BN thin film than on SiO₂ or SiN.

12:39PM W11.00008 Scanning Tunneling Spectroscopy of Potassium on Graphene , DANIEL COR-MODE, BRIAN LEROY, MATTHEW YANKOWITZ, University of Arizona — We investigate the effect of charged impurities on the electronic properties of large single crystal CVD grown graphene using scanning tunneling microscopy. Mono- and multilayer crystals were prepared by transferring graphene from copper onto exfoliated boron nitride flakes on 300 nm SiO₂ substrates. The boron nitride provides an ultra flat surface for the graphene. Potassium atoms are controllably deposited on the graphene at low temperature by heating a nearby getter source. Scanning tunneling spectroscopy and transport measurements were performed in ultra high vacuum at 4.5 K. Transport measurements demonstrate the shifting of the Dirac point as the samples are doped, while STM measurements demonstrate the size, arrangement and local electronic influence of the potassium atoms.

12:51PM W11.00009 Nanoscale electronic and optical investigations of functionalized graphene¹ , OZGUN SUZER, JONGWEON CHO, JOSEPH SMERDON, LI GAO, NATHAN GUISINGER, JEFFREY GUEST, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL 60439, USA — A rigorous understanding of light-matter interactions at the nanometer scale is pivotal in the development of nanoscale device applications. Graphene and its functionalized derivatives, due to their unique properties, promise unexpected capabilities as a platform for such devices, which has led to significant interest in graphene-based nano-optical, optoelectronic, and photovoltaic applications. Here, we will describe our efforts to resolve and understand the structural, electronic and optical properties of these systems. We will present a UHV STM study of the structural and electronic properties of C60 molecules deposited on graphene that was grown epitaxially on SiC(0001), which serves as a model system for the study of molecule-surface interactions. Our results indicate reduced coupling of the molecules to the graphene and underlying substrate, compared to those on metallic substrates, suggesting a path for developing molecular-scale electronic and optically active “devices” that are not dominated by the substrate. We will also discuss our efforts to correlate these STM studies with the optical properties of the system using a UHV STM that incorporates confocal optical microscopy and spectroscopy at the tip-sample junction with integrated high-numerical aperture optics.

¹This work was supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Contract No. DE-AC02-06CH11357 and “SISGR” Contract No. DE-FG02-09ER16109.

1:03PM W11.00010 Three Different Translations Can Each Convert the Top Plane of Graphite to Graphene¹ , D. QI, P. XU, Y. YANG, M.L. ACKERMAN, S.D. BARBER, J.K. SCHOELZ, L. BELLAICHE, SALVADOR BARRAZA-LOPEZ, P.M. THIBADO, Department of Physics, University of Arkansas, IGOR A. KORNEV, Propriétés et Modélisation des Solides, France — The discovery of graphene, a unique two-dimensional electron system with extraordinary physical properties, has ignited tremendous research activity in both science and technology. Graphene can be obtained from graphite by moving its top layer until it becomes locally decoupled from the bulk. However, a detailed microscopic understanding of this process has yet to be completed. Here we present STM images of the top plane of graphite, which has been transformed into graphene. In addition, we also present STM images which reveal several intermediate stages in between pure graphene and pure graphite. Density functional theory was used to simulate STM images from a six-layer slab of graphite. We also moved the top layer of graphite incrementally in three different directions. Vertical movement of the top layer by about 0.1 nm created graphene. A continuous transition from pure graphite to pure graphene was observed with the simulations. Horizontal movement of the top layer can also create graphene in two ways. In one configuration, the carbon atoms perfectly align with the layer below, while in the second the carbon atoms have no vertical alignment with the layer below. Other significant details found between graphite and graphene will be discussed.

¹Support provided by ONR N00014-10-1-0181, N00014-08-1-0915, NSF 0855358, 0701558, DoE 46612

1:15PM W11.00011 Graphene on Ru(0001): The four hills in the 25 on 23 structure , THOMAS GREBER, Physik-Institut, University of Zurich, Switzerland, MARCELLA IANNUZZI, Physical Chemistry, University of Zurich, HAIFENG MA, Physik-Institut, University of Zurich, IRAKLI KALICHAHA, Swiss Light Source, Paul Scherrer Institut, HAITAO ZHOU, GENG LI, YI ZHAO, Institute of Physics, Chinese Academy of Sciences, Beijing, 100190, China, STEVEN LEAKE, OLIVER BUNK, Swiss Light Source, Paul Scherrer Institut, HONJUN GAO, Institute of Physics, Chinese Academy of Sciences, Beijing, JÜRIG HUTTER, Physik-Institut, University of Zurich, PHIL WILLMOTT, Swiss Light Source, Paul Scherrer Institut — A single layer of sp² hybridized carbon on Ru(0001) accommodates in a 23 on 25 superstructure with 625 carbon honeycombs as found by surface x-ray diffraction (SXRD) [1]. In a significant computational effort 25x25 unit cells of graphene were relaxed on 23x23 Ru(0001) unit cells with up to 6 substrate layers. The density functional theory calculations that take van der Waals interactions into account predict 4 protrusions, quantum dots [2] or “hills” in the unit cell with two kinds of hills: 3 Ω -type hills with a honeycomb around the summits, and one T-type hill with a single carbon atom on the summit. This prediction is confirmed by state of the art low temperature scanning tunneling microscopy and is in line with the SXRD data in Ref.[1].

1:39PM W11.00013 High resolution transmission electron microscopy of lattice dynamics of graphene, JIAN-HAO CHEN, NASIM ALEM, Department of Physics, University of California at Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory, ABHAY GAUTAM, MARTIN LINCK, CHRISTIAN KISIELOWSKI, Nation Center for Electron Microscopy, Lawrence Berkeley National Laboratory, ALEX ZETTL, Department of Physics, University of California at Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory — Lattice dynamics of carbon atoms in graphene was investigated by aberration corrected ultra-high resolution transmission electron microscopy near the holes and the grain boundaries. We studied in-situ formation of various unusual defect structures in graphene under various conditions. In this presentation we will show the stability and dynamics of the atoms at the holes, grain boundaries and the defects and discuss their formation mechanism. This work will also elaborate on the electronic properties of the defects in light of recent experimental and theoretical progress.

1:51PM W11.00014 High resolution transmission electron microscope Imaging and first-principles simulations of atomic-scale features in graphene membrane, WEI WANG, SAGAR BHANDARI, WEI YI, DAVID BELL, ROBERT WESTERVELT, EFTHIMIOS KAXIRAS, Harvard University, KAXIRAS TEAM, WESTERVELT TEAM — Ultra-thin membranes such as graphene[1] are of great importance for basic science and technology applications. Graphene sets the ultimate limit of thinness, demonstrating that a free-standing single atomic layer not only exists but can be extremely stable and strong [2–4]. However, both theory [5, 6] and experiments [3, 7] suggest that the existence of graphene relies on intrinsic ripples that suppress the long-wavelength thermal fluctuations which otherwise spontaneously destroy long range order in a two dimensional system. Here we show direct imaging of the atomic features in graphene including the ripples resolved using monochromatic aberration-corrected transmission electron microscopy (TEM). We compare the images observed in TEM with simulated images based on an accurate first-principles total potential. We show that these atomic scale features can be mapped through accurate first-principles simulations into high resolution TEM contrast. [1] Geim, A. K. & Novoselov, K. S. *Nat. 2:03PM W11.00015 Interference effects in electronic transport in mesoscopic graphene, LINGLI WANG, University of California, Riverside, VICTOR A. GOPAR, Universidad de Zaragoza, Spain, SHAN-WEN TSAI, University of California, Riverside — Graphene consists of a monolayer of carbon atoms arranged in a honeycomb lattice and has been intensively studied due to its fascinating physical properties. We study transport in mesoscopic graphene systems, in particular, conductance oscillations due to interference of the Dirac electrons in phase-coherent transport. Green's functions are calculated in the tight-binding model via *T*-matrix formalism, and the conductance is then obtained using the Landauer-Büttiker formalism. We consider a measurement set-up consisting of two STM tips, as well as transport from a contact and a STM tip. Regular Bloch oscillations are obtained, as well as richer structures when different types of isolated impurities are considered.

Session W12 DMP: Focus Session: Graphene: Growth, Mechanical Exfoliation, and Properties - Exfoliation and Doping 210C

11:15AM W12.00001 Graphene Carrier Control and Band Gap Formation through Stacked Graphene Sheets, GLENN JERNIGAN¹, US Naval Research Laboratory — Graphene's use in RF transistors and frequency doublers is attractive since its high mobility and high saturation velocity translate into operation at high frequencies while utilizing little power. However, further graphene development for device applications is hindered by high metal contact resistance, poor control of channel conductivity, and the absence of a band gap. In this talk, I will present our efforts at NRL to address these challenges using two strategies: 1) substitutional insertion of group III-V atoms into graphene's lattice to control the carriers and 2) through a synthetic means to create bilayer graphene with a band gap. Substitutional incorporation of atoms into graphene can result in doping, if their concentration does not drastically affect the π -network. Using selective oxidation to remove C atoms from the graphene lattice, we are able to backfill the C vacancies using molecular beam deposition of dopants with controllable ultra-low fluxes. We will show that boron and phosphorus dopants can provide extra holes and electrons to the graphene π -network, respectively, modifying the carrier concentration in transport measurements. Bernal-stacked graphene bilayers have a relatively small band gap ($\sim$ few meV). However, if the symmetry of the system is broken by the application of a large applied electric field, the band gap can be increased ($\sim$ 250 meV). Alternatively, we find it is possible to obtain such large built-in electric fields when graphene sheets of opposite doping are stacked. By bonding a p-type, CVD-grown graphene monolayer transferred from Cu to an n-type, epitaxially grown graphene monolayer on SiC, we formed a p-n graphene bilayer. Transport measurements and modeling of the resulting electric field generated by opposite doping of the graphene sheets indicate the creation of a 100-300 meV band gap in the synthetic bilayer.

¹Electronics Science and Technology Division, Solid State Devices Branch Code 6812

11:51AM W12.00002 Atomic characterization of monolayer doped graphene sheets synthesized by chemical vapor deposition, R.T. LU, Department of Physics, The Pennsylvania State University, USA, Q. LI, Center for Nanophase Materials Sciences Division, Oak Ridge National Laboratory, USA, A. BOTELLO-MÉNDEZ, Institute of Condensed Matter and Nanosciences, Université Catholique de Louvain, Belgium, J.C. CHARLIER, Institute of Condensed Matter and Nanosciences, Université Catholique de Louvain, Belgium, B. WANG, A. BERKDEMIR, H.R. GUTIÉRREZ, J. ZHU, H. TERRONES, Department of Physics, The Pennsylvania State University, USA, M.H. PAN, Center for Nanophase Materials Sciences Division, Oak Ridge National Laboratory, USA, M. TERRONES, Department of Physics, The Pennsylvania State University, USA; Research Center for Exotic Nanocarbons, Shinshu University, Japan — Large-area, high-quality monolayer nitrogen (or boron)-doped graphene sheets were synthesized on copper foils by a modified chemical vapor deposition (CVD) apparatus. As-grown graphene sheets could be easily transferred from copper foils onto different substrates (e.g. silicon/silicon dioxide wafers). Compared with pristine graphene, nitrogen (or boron)-doped graphene shows strong D-band caused by doping and structural defects formed within the lattice. Scanning tunneling microscopy (STM) and spectroscopy (STS) reveal that the defects in the doped graphene samples arrange in different geometrical configurations. The localized states in the valence and conduction bands are in accordance with the type of dopant and bonding type. These experimental results are in agreement with first principles calculations of LDOS of doped graphene and STM image simulations.

12:03PM W12.00003 Graphene melting by molecular dynamics simulations, BRAD STEELE, ROMAIN PERRIOT, VASILY ZHAKHOVSKY, IVAN OLEYNIK, University of South Florida — Mechanisms of melting of graphene were studied by molecular dynamics (MD) using two different interatomic potentials: the Reactive Empirical Bond Order (REBO) and recently developed Screened Environment Dependent (SED)-REBO potentials. Melting was investigated in two-dimensional (2-D) and three-dimensional (3-D) coordinate space. It was shown that the loss of long-range order and melting proceeds through generation and in-plane aggregation of Stone-Wales (S-W) defects in REBO-graphene, followed by the formation of a complex 3D network of carbon chains. Although S-W defects are also formed in the SED-REBO-graphene, they do not cluster. Instead, the melting proceeds through the formation of dangling bonds and vacancies. The melting temperature of graphene using REBO was found to be 5,200 K, whereas for SED-REBO it is lower by ~800K. The melting in 2-D occurs at higher temperatures compared to 3-D because of in-plane geometrical constraints.

12:15PM W12.00004 Unexpected Structures for Intercalation of Sodium in Epitaxial SiC-Graphene Interfaces¹, ANDREAS SANDIN, North Carolina State University, THUSHARI JAYASEKERA, Southern Illinois University-Carbondale, J. E. (JACK) ROWE, KI-WOOK K, MARCO BUONGIORNO-NARDELLI, DANIEL B. DOUGHERTY, North Carolina State University — We show using scanning tunneling microscopy and spectroscopy and calculations from first principles that several different intercalation structures exist for Na in epitaxial graphene on SiC(0001). Intercalation takes place rapidly at room temperature and tunneling spectroscopy shows that it significantly electron dopes the graphene. Upon annealing above room temperature a quite different intercalation structure is formed which removes the carbon-rich interface layer and transforms this into a second graphene layer. In addition, we find that direct deposition of Na onto the carbon rich buffer layer graphene precursor decouples it from the SiC substrate leading to formation of a new sheet of graphene. This interface-layer decoupling is unambiguously demonstrated by transforming bare buffer layer to a graphene layer. Our observations show that intercalation in graphene is fundamentally different than in graphite and provides a very versatile approach to metal-graphene functionality and electronic-property control.

12:27PM W12.00005 Electron phonon renormalization in N-doped graphene, RAMAKRISHNA PODILA, Department of Physics, Clemson University, PAOLA AYALA, University of Vienna, JOHN SPEAR, Department of Physics, Clemson University, THOMAS PICHLER, University of Vienna, APPARAO RAO, Department of Physics, Clemson University, CLEMSON UNIVERSITY TEAM, UNIVERSITY OF VIENNA COLLABORATION — Current research efforts are aimed at controlling the electronic properties graphene sheets using electron (or hole) doping for successful device fabrication. The presence of strong coupling between electronic and vibrational properties in graphene greatly assists Raman spectroscopy in probing the dopant-induced electronic energy changes. Previously, Raman spectroscopy was employed as a tool to probe the electron and phonon renormalization in doped single-walled carbon nanotubes (SWNT). It was found that the increase in electron velocity influences lattice vibrations locally near a negatively charged defect. These local renormalization effects were observed to result in a new effectively downshifted (up-shifted) Raman peak below the G' peak for n-doped (p-doped) SWNTs. In case of graphene, we find that the several Raman features for CVD grown N-doped graphene vary depending upon local dopant bonding environment. For instance, non-graphitic dopants (pyridinic, pyrrolic) were observed to result in highly intense D & D'-band unlike the graphitic dopants. We explain these results in terms of the zig-zag (armchair) edges formed by graphitic (non-graphitic) bonding environment of the dopant.

12:39PM W12.00006 Transport properties of pristine and doped graphene, POOJA PUNEET, RAMAKRISHNA PODILA, Department of Physics and Astronomy, Clemson University, Clemson SC 29634, LUCIANA OLIVEIRA, Department of Materials Science and Engineering, Clemson University, Clemson SC 29634, TERRY TRITT, APPARAO RAO, Department of Physics and Astronomy, Clemson University, Clemson SC 29634 — Graphene has attracted a lot of attention for various applications recently. Chemically exfoliated graphene is one of the best methods to prepare good quality and large amount of few-layer graphene sheets. We prepared pristine and doped graphene using chemical exfoliation through high energy tip sonication technique. The exfoliated graphene was later sintered for studying thermoelectric properties. The thermopower of these samples exhibits valleys, tentatively assigned to phonon drag, which shift towards higher temperature upon vacuum annealing and electron doping. Such a similar behavior was previously observed in doped carbon nanotubes. The effects of vacuum annealing and doping upon the fundamental behavior of thermoelectric power and thermal conduction of graphene will be presented.

12:51PM W12.00007 Experimental investigation of carrier quantum confinement in graphene quantum dots and nanoribbons, KIRAN LINGAM, RAMAKRISHNA PODILA, APPARAO RAO, Department of Physics and Astronomy, Clemson University, CLEMSON UNIVERSITY TEAM — Recently, Zhu *et al.* (Chem. Comm., 2011. 47(24), 6858) and Pan *et al.* (Adv. Mat., 2010. 22(6), 734) have successfully synthesized graphene quantum dots (width <10 nm). They probed the carrier quantum confinement in such GQDs using photoluminescence spectroscopy (PL). However, a self-consistent explanation for the observed PL spectra is lacking. Interestingly, we find that the organic reducing agents used for synthesizing GQDs have PL signature similar to the GQDs themselves. Thus, deconvoluting solvent effects is extremely important to achieve further progress in synthesis and application of GQDs. We studied the PL behavior of hydrothermally synthesized graphene nanoribbons (GNRs) and GQDs to understand the solvent effects and the underlying mechanism for the observed PL. We will discuss the effects of size, shape and morphology on the PL behavior of GQDs and GNRs.

1:03PM W12.00008 Scanned Probe Measurements of Graphene on Ferroelectrics, SCOTT SCHARFENBERG, RUIJUAN XU, CHRISTOPH BAEUMER, MOONSUB SHIM, LANE MARTIN, NADYA MASON, University of Illinois at Urbana-Champaign — We present results on scanned probe measurements of graphene and few-layer graphite (FLG) on ferroelectric thin films. The graphene was mechanically exfoliated onto the PbZr_{0.2}Ti_{0.8}O₃ and other ferroelectric films, and its topography and polarization were characterized using atomic force microscopy, Kelvin Probe (surface potential) Force Microscopy, and Piezoresponse Force Microscopy. We discuss how graphene can be used as a top electrode for ferroelectric materials, as changing the potential of the graphene can cause the ferroelectric region beneath it to switch polarization. We demonstrate that the change in polarization is reversible. We also show how the surface potential of FLG on PZT depends on the number of layers of graphene. *The authors acknowledge Grant DMR-1124696, Sub-Award 235743-3668.

1:15PM W12.00009 Can Structured Mixed Solvents be Used for Graphene Exfoliation?, ANDREW OYER, CHETAN HIRE, JAN-MICHAEL CARRILLO, ALEXANDRU ASANDEI, DOUGLAS ADAMSON, ANDREY DOBRYNIN, University of Connecticut — Using a combination of computational and experimental techniques we investigate graphene exfoliation and suspension in C₆H₆, C₆F₆ and their mixtures. Our MD simulations show that an equimolar mixture of C₆H₆/C₆F₆ has the highest affinity for graphene. This is manifested in the formation of translational and orientational order normal to the graphene surface, with no translational ordering parallel to the graphene surface. The solvent structure is driven by quadrupolar interactions and consists of stacks of alternating C₆H₆/C₆F₆ molecules rising from the surface of the graphene. These stacks give rise to density oscillations in registry with the graphene surface. The period of the density oscillations is on the order of 3.4 Å, corresponding to the van der Waals diameter of carbon and this ordered structure extends 30 Å from each side of the graphene sheet. To experimentally verify the results of the molecular dynamics simulations we use dynamic contact angle measurements. These measurements demonstrate an increase in solvent affinity for HOPG in the case of 1:1 mixtures in comparison with pure components. The quality of the exfoliated material and flakes after sonication is verified by AFM, SEM, and TEM techniques. The graphene sheets produced in the equimolar mixture can be freeze-dried at room temperature, (T=300K) producing sponge-like graphene structures held together entirely by graphene sheet interactions and reflecting the structure of the graphene sheets in solution.

1:27PM W12.00010 Fabrication and Characterization of folded Graphene on Graphite, DAVID COSTA MILAN, GIOVANNI SAENZ ARCE, University of Alicante, MOHAMMED MOAIED, University Autonoma of Madrid, MARIA JOSE CATURLA, University of Alicante, JUAN JOSE PALACIOS, University Autonoma of Madrid, CARLOS UNTIEDT, University of Alicante, LT-NANOLAB TEAM, COND. MATTER DEPT TEAM — Graphene is one of the most studied carbon compounds due to its electronic properties. Applying an electric pulse between a Graphite surface and STM tip the upper layer of a Graphite surface could be folded due to mechanical and electrostatic forces forming voids, bend, move, and decouple or transfer part of the tip to the surface. Ab-initio electrostatic calculations and MD thermal simulations support our experimental method. Due to the different new discovered and studies physical-effects in Graphene edges, which can significantly influence the overall electronic and magnetic properties of Graphene nanostructures, this results may be exploited as an method to obtain different structures. Here we study Graphene flakes obtained with this Method. Folded Graphene's structure and electronic properties are studied to determine its degree of coupling to the graphite substrate. Cross-sectional analysis of the fold shown reveals that it consists of a single sheet of graphite folded. Graphene edges and folded line reveals new electronic and magnetic properties. Among others the possibility of a multi folded Graphene sheet system gains importance due to the opportunity of getting a Semi-Carbon-Nanotube-Graphene device.

1:39PM W12.00011 Controlling desorption of H, O, atoms and OH group from graphene by pulse laser, YOSHIYUKI MIYAMOTO, Nanosystem Res. Ins., AIST, HONG ZHANG, College of Physical Science and Technology, Sichuan University — Possibilities of reduction of graphene oxide and one-side dehydrogenation of graphane (H-terminated graphene) with using ultra-short pulse (~ 2 fs) laser are discussed. We have performed molecular dynamics (MD) simulation of O-, H-, and OH-adsorbed graphene sheets induced by electronic excitation upon irradiation with laser pulse. The time-dependent density functional theory treating real-time propagation of electron wave functions combined with the Ehrenfest approximation for the MD was employed and FPSEID [1] code was used to check the energy conservation rule under dynamical external field [2]. We found asymmetric pulse shape as a function of time causes an efficient desorption of O atoms and OH groups from graphene which can be applicable for reduction of graphene oxide alternative to chemical and thermal treatment. Meanwhile, such asymmetric pulse shape is beneficial for one-side H-desorption from graphane that will trigger further structural changes such as spontaneous shrink/rippling or heterogeneous termination on side-by-side.

1:51PM W12.00012 Graphene on Au-coated SiO_x substrate: Its visibility and intrinsic core-level photoemission, CHUNG-LIN WU, JHIH-WEI CHEN, CHIANG-LUN WANG, Department of Physics, National Cheng-Kung University, CHIA-HAO CHEN, National Synchrotron Radiation Research Center, YI-CHUN CHEN, Department of Physics, National Cheng-Kung University — With the motivation of precisely and intrinsically characterizing a exfoliated graphene using photoelectron spectroscopy, a conducting substrate having high optical contrast is greatly desired. Here, we demonstrate that exfoliated graphene can be optically visible on a thin 9-nm Au-coated SiO_x substrate, and can be easily conducted into scanning photoelectron microscopy/spectroscopy (SPEM/S) studies. Because of the elimination of charging effect, precisely core-level characterization of exfoliated graphene is presented with different numbers of layers. Consequently, the usage of Au-coated SiO_x substrate serves a simple but effective method to study pristine graphene by photoelectron spectroscopy and other electron-detection techniques.

2:03PM W12.00013 Stage-1 intercalation compounds of few graphene layers by anhydrous ferric chloride, PINGHENG TAN, WEIJIE ZHAO, JIAN LIU, SKLSM, Institute of Semiconductors, Chinese Academy of Sciences, Beijing 100083, PR China, ANDREA FERRARI, Engineering Department, University of Cambridge, Cambridge CB3 0FA, UK — Anhydrous ferric chloride (FeCl_3) was used to intercalate few graphene layers into stage-1 intercalation compounds. The intercalant, staging, stability, and doping of the resulting intercalation compounds are characterized by Raman scattering. The G peak of pure stage-1 compounds upshifts to $\sim 1626 \text{ cm}^{-1}$, which is similar to that of heavily-doped monolayer graphenes by 18M sulfuric acid. A single Lorentzian line shape for the 2D band of stage-1 compounds were observed, which indicates that each layer behaves as a decoupled heavily doped monolayer. By performing Raman measurements at different excitation energies, we show that, for a given doping level, the variation of the 2D intensity relative to the G peak with excitation energy allows one to assess the Fermi energy. This allows us to estimate a Fermi level shift of up to $\sim 0.85 \text{ eV}$, which agrees well with that estimated from the 2D/G intensity ratio and is close to $\sim 0.9 \text{ eV}$ measured in stage-1 GICs by electron energy loss spectroscopy. The stage-1 intercalation compound of few graphene layers is thus ideal test-beds for the physical and chemical properties of heavily doped graphenes.

**Session W13 DMP GMAG: Focus Session: Low-Dimensional and Molecular Magnetism - Met-
allorganics and Spincrossover Molecular Magnets 211**

11:15AM W13.00001 Magnetic properties of selected Prussian Blue Analogs (PBAs), MANJITA SHRESTHA, SOURAV ADAK, HEINZ NAKOTTE, New Mexico State University, LUKE L. DAEMEN, MONIKA HARLT, VIVIEN ZAPF, Los Alamos National Laboratory — Prussian Blue Analogs consists of MC_6 and AN_6 octahedra connected by cyanide ligands (M, A= metals). They typically crystallize in cubic structures. We have studied temperature and field dependence of the magnetization and the susceptibility of selected Prussian Blue Analogs such as hexacyanocobaltates, -ferrates and -chromates. All compounds exhibit modified Curie –Weiss behavior in the paramagnetic region. The observed effective moments of those compounds were compared with the ones of the respective free-ion values. Furthermore, we find evidence that a few of the compounds exhibit a transition to long-range magnetic order at low temperatures.

11:27AM W13.00002 Persistent Photocontrolled Magnetism in Core-Shell Prussian Blue Analogues¹, ELISABETH S. KNOWLES, MATTHIEU F. DUMONT, MARCUS K. PEPRAH, MARK W. MEISEL, Dept. Phys. and NHMFL, Univ. Florida, CARISSA H. LI, DANIEL R. TALHAM, Dept. Chem., Univ. Florida — Cubic heterostructured (BA) particles of Prussian blue analogues, composed of shells of ferromagnetic $\text{K}_7\text{Ni}_6[\text{Cr}(\text{CN})_6]_4 \cdot n\text{H}_2\text{O}$ (A), $T_c \sim 70 \text{ K}$, surrounding bulk cores ($\sim 350 \text{ nm}$) of photoactive ferrimagnetic $\text{Rb}_6\text{Co}_6[\text{Fe}(\text{CN})_6]_4 \cdot m\text{H}_2\text{O}$ (B), $T_c \sim 20 \text{ K}$, have been studied. Below $T_c \sim 70 \text{ K}$, these samples exhibit a persistent photoinduced decrease in low-field magnetization, resembling results from previous core-shell particles² and analogous ABA films.³ This net decrease suggests that the photoinduced lattice expansion in the B layer generates a strain-induced decrease in the magnetization of the A layer, similar to a pressure-induced decrease observed by others in a pure A material⁴ and by us in the BA cubes. To quantify the length scale over which the photoinduced strain dissipates into the A layer, a series of B and BA cubes of varying shell thickness have been characterized.

11:39AM W13.00003 Pressure-induced local lattice distortions in Co(dca)₂¹, J.L. MUSFELDT, University of Tennessee, Z. LIU, Carnegie Institute of Washington, A. LITVINCHUK, University of Houston, T.V. BRINZARI, University of Tennessee, G.L. CARR, Brookhaven National Laboratory, J.A. SCHLUETER, Argonne National Laboratory, J.L. MANSON, Eastern Washington University, M.-H. WHANGBO, North Carolina State University — We employed vibrational spectroscopy along with complementary lattice dynamics and spin density calculations to investigate local structure and magnetism through the series of pressure-induced transitions in Co(dca)₂. Analysis of several ligand bending modes reveals compression and distortion of molecular linkages and a major change in the crystal lattice through the 1 GPa transition, whereas a modified local structure (due to a change in molecular symmetry) but similar crystal lattice is anticipated above 3 GPa. We discuss our findings in terms of the competition between antiferromagnetic and ferromagnetic exchange interactions.

¹We thank the NSF for support of this work.

11:51AM W13.00004 Magnetotransport Properties of Switchable Valence Tautomer Films¹, WILLIAM RICE, FRANK TSUI, Physics, University of North Carolina at Chapel Hill, DANIEL STASIW, ROBERT SCHMIDT, DAVID SHULTZ, Chemistry, North Carolina State University, ROBERT BRUCE, WEI YOU, Chemistry, University of North Carolina at Chapel Hill — We report tunneling magnetoresistance (TMR) and spectroscopy results in trilayer stacks of spincoated molecular films sandwiched between two metallic thin film electrodes. The molecules, cobalt dioxolene complexes, exhibit switchable bistable paramagnetic states as a result of intramolecular electron transfer accompanied by a spin-crossover of the Co ion, the so-called valence tautomerism (VT). Temperature dependent differential conductance measurements show changes in the density of states that correspond to the temperature dependent VT transition. The observed electronic transition is shown to be switchable by light exposure, which correlates the counterpart in the magnetic susceptibility. In trilayers with two ferromagnetic electrodes, e.g. Permalloy and Co, spin valve effects have been observed above and below the VT transition, including room temperature. The dependence of the TMR effect on bias voltage, light exposure, and molecular film thickness has been examined systematically as a function of temperature, aimed at exploring the effects of spin dependent states in the VT molecules.

12:03PM W13.00005 Computational studies of the Fe(II) spin crossover compound Fe[H₂B(pz)₂]₂(bpy)¹, YIFENG CHEN, MARCO BUONGIORNO NARDELLI, Department of Physics, North Carolina State University — Using calculations from first principles, we studied the electronic and transport properties of the Fe(II) spin crossover (SCO) compound Fe[H₂B(pz)₂]₂(bpy). The magnetic transition has been imposed by constrained magnetization calculations and the computed electronic structure agrees with available experimental data. Besides the characterization of the single molecule, we constructed a π -stacking molecular chain of the compound and evaluated electronic transport in the direction of the chain for both the low-spin and the high-spin configurations. We found the high-spin configuration to be more conductive than the low-spin case, in agreement with experimental measurements of corresponding currents through disordered thin films. Molecule-molecule interactions are taken into account by the London dispersion forces. The spin-switchable electronic transport properties of this kind of Fe(II) SCO compound systems provide viable proofs for future switchable molecular spintronic devices and applications.

12:15PM W13.00006 ABSTRACT WITHDRAWN —

12:27PM W13.00007 Highly Unquenched Orbital Moment In Fe Phthalocyanine¹, JUAN BAR-TOLOME, Consejo Superior de Investigaciones Científicas — Metal-Phthalocyanine molecules (MPc) form a family of compounds with a wide range of commercial application such as catalysts or dyes, and more recently in thin film technology. In an early work we found that in the α -phase of FePc, where the FePc molecules are stacked in a herringbone structure, the Fe atoms are strongly magnetically coupled into ferromagnetic Ising chains with very weak antiferromagnetic interchain coupling. The chains achieve 3D long range ordering at $T_N=10$ K, and strong irreversibility (slow relaxation) below 5K. The Fe(II) is in a S=1 state and the hyperfine field in the ordered phase reaches a record value in Fe(II) of $B_{hf}=66.2$ T. This result is consistent with a large, unquenched orbital moment. It has been measured directly in a X-ray Magnetic Circular Dichroism (XMCD) spectroscopic study on FePc thin films deposited parallel on a Au surface predeposited on a Si substrate. The XMCD spectra at the L₃ and L₂ edges were measured as a function of incident angle γ . The orbital moment is $|m_L| = 0.53 \pm 0.04 \mu_B$ and the isotropic spin component is $m_S = 0.64 \pm 0.05 \mu_B$. The origin of this unusually high orbital moment is the incompletely filled e_g level lying close to the Fermi energy. The ferromagnetically coupled Fe moments show strong, in-plane anisotropy [1]. Angular dependent measurements at the Fe K-edge also show strong quadrupolar excitations associated to a strong orbital moment, confirming the above result of the existence of a large, unquenched orbital moment in this molecule. Submonolayer FePc thin films deposited on Au, recently studied my XAS and XMCD have shown that there is charge transfer from the substrate to the Fe atom, modifying the electronic structure and magnetic properties [2]

1:03PM W13.00008 Theoretical modelling of exchange interactions in metal-phthalocyanines, WEI WU, Department of Materials, Imperial College London, ANDREW FISHER, Department of physics and astronomy, University College London, NIC HARRISON, Department of Chemistry, Imperial College London, MICHELE SERRI, ZHENLIN WU, SANDRINE HEUTZ, Department of Materials, Imperial College London, TIM JONES, Department of Chemistry, Warwick University, UK, GABRIEL AEPPLI, Department of physics and astronomy, University College London, ORGANIC SPINTRONICS TEAM — The theoretical understanding of exchange interactions in organics provides a key foundation for quantum molecular magnetism. Recent SQUID magnetometry of a well know organic semiconductor, copper-phthalocyanine [1,2] (CuPc) shows that it forms quasi-one-dimensional spin chains. Green's function perturbation theory calculation [3] is used to find the dominant exchange mechanism. Hybrid density functional theory simulations [4] give a quantitative insight to exchange interactions and electronic structures. Both calculations are performed for different stacking and sliding angles for lithium-Pc, cobalt-Pc, chromium-Pc, and copper-Pc. The exchange interactions depend strongly on stacking angles, but weakly on sliding angles. Our results qualitatively agree with the experiments, and remarkably α -cobalt-Pc has a very large exchange above liquid-Nitrogen temperature. Our theoretical predictions on the exchange interactions can guide experimentalists to design novel organic semiconductors.

1:15PM W13.00009 Magneto-optical spectroscopic studies of solid and solution-phase tetraphenyl porphyrin¹, JACOB WAHLEN-STROTHMAN, ZHEN WEN PAN, CODY LAMARCHE, LANE MANNING, NAVEEN RAWAT, University of Vermont, TAKAHISA TOKUMOTO, STEPHEN MCGILL, National High Magnetic Field Lab, MADALINA FURIS, KELVIN CHU, University of Vermont — Tetraphenylporphyrin (TPP) is a heterocyclic model system for porphyrins found in heme proteins, cytochromes and photosynthetic cofactors. TPP can accommodate a metal ion in the center; D-shell ion porphyrin complexes with a crystalline solid phase are of interest for magnetic studies because of the possibility of macroscopic long-range magnetic order of the ion spins. We have investigated the 5K magnetic properties of poly-crystalline thin films of TPP complexed with Zn, Mn and Cu and deposited through a room temperature capillary pen technique that produces grain size in the 100 micron to 1mm range. Our novel setup measures the UV/VIS, linear dichroism and MCD simultaneously and incorporates a photoelastic modulator and a microscopy superconducting magnet for high-field (5T) measurements. In addition, we present 25T data on samples from the new split magnet at NHMFL. We present solution and crystalline data on metal-complexed TPP; data are analyzed in terms of A and B-type MCD using a perimeter model. We find good agreement with previous solution data, and novel crystalline phase spectra that are correlated to the long range ordering of the solid state.

1:27PM W13.00010 Spin exchange interaction in quasi-1D Cu-phthalocyanine crystalline thin film measured by Magnetic Circular Dichroism (MCD) spectroscopy, ZHENWEN PAN, NAVEEN RAWAT, CODY LAMARCHE, Material Science and Physics Dept., University of Vermont, TAKAHISA TOKUMOTO, National High Magnetic Field Laboratory, ANTHONY WETHERBY, RORY WATERMAN, Chemistry Dept., University of Vermont, RANDY HEADRICK, Material Science and Physics Dept., University of Vermont, STEVE MCGILL, National High Magnetic Field Laboratory, MADALINA FURIS, Material Science and Physics Dept., University of Vermont — Highly-oriented Cu-phthalocyanine (PC) pen-written crystalline thin films can be viewed as quasi-1D spin 1/2 magnetic chains. In order to reveal the nature of spin exchange between localized S=1/2 Cu spins, MCD spectroscopy was performed on films with millimeter-sized grains fabricated from a soluble CuPc derivative in magnetic fields up to 10 Tesla at temperatures ranging from 0.4 K to 77K. At T<2K and B<4T the MCD associated with transitions between Q-band π electron states exhibits a non-linear temperature-dependent Brillouin-like increase with magnetic field. For B>4T the MCD evolves linearly with magnetic field, as expected from diamagnetic carbon-based systems. Theoretical modeling¹ of electronic structure and exchange interactions in this system predicts an indirect exchange mechanism mediated by delocalized ligand states. Our MCD measurements identified the states responsible for this exchange.

1:39PM W13.00011 Introducing copper phthalocyanine as a qubit¹, MARC WARNER, London Centre for Nanotechnology, SALAHUD DIN, Imperial College London, London, UK, JULES GARDENER, Harvard University, GAVIN W. MORLEY, University of Warwick, UK, WEI WU, Imperial College London, UK, MARSHALL STONEHAM, ANDREW J. FISHER, University College London, UK, SANDRINE HEUTZ, Imperial College London, London, UK, CHRISTOPHER W. M. KAY, GABRIEL AEPPLI, University College London, UK — Quantum information processing (QIP) has been shown to solve certain useful problems faster than its classical counterpart. However finding a physical system upon which to execute these algorithms is a challenging task. One promising implementation is to use an electron spin in a magnetic field as the information bearing quantum system. Numerous options have been proposed along these lines. Here I discuss a new candidate qubit, copper phthalocyanine. The copper atom at the centre of the molecule carries an unpaired electron. Pulsed electron paramagnetic resonance measurements of relaxation times reveal that it has potential for QIP. We measure the spin-lattice and spin-spin relaxation times of this electron and demonstrate single qubit manipulations. Solid-state electronic devices can be built with this low cost material, which is optically active, and offers great opportunities for chemical and physical modification, leading to significant control of magnetic and other properties.

1:51PM W13.00012 Structure-Controlled Coercivity of Low-Dimensional Metallo-Organic Thin Films¹, THOMAS GREDIG, MATTHEW BYRNE, BRIAN CACHA, JACOB KALMANIR, MATHEW WERBER, California State University Long Beach, CA — Metallo-organic thin films based on iron phthalocyanine were prepared to form self-assembled structures. Based on the substrate, the metal-ion chains can be grown perpendicular or parallel to the substrate. Individual iron chains are separated by 1.3 nm and interact weakly at low temperatures. The magnetic response of these structurally templated thin films is studied for a fixed film thickness and varied deposition temperatures. The magnetic hysteresis loops are wasp-shaped and mark long-range ferromagnetic interaction below a temperature of 4.5 K. The hysteresis loop coercivity can be correlated with the grain size of the iron phthalocyanine thin film. The enhanced coercivity is attributed to longer iron chains that are formed in larger grains.

2:03PM W13.00013 The Otto thermodynamic cycle using the magnetic molecule Ni₂, WOLFGANG HÜBNER, CHUANDING DONG, GEORGIOS LEFKIDIS, Dept. of Physics and Research Center OPTIMAS, University of Kaiserslautern — In order to design realistic molecular heat engines, the study of quantum thermodynamics is essential since classical thermodynamics does not apply in this extreme miniaturization limit [1,2]. Realizing a thermodynamic cycle on an existing magnetic molecule embodies a novel and unique approach to understand and exploit the thermodynamic properties of spin at the molecular level.

Here we propose an Otto cycle in the Ni₂ dimer based on a fully ab-initio calculation of the electronic states and the perturbative inclusion of spin-orbit coupling. A laser pulse, described by the time-dependent Schrödinger equation, is used to heat the Ni₂ dimer. The pulse not only excites the electrons to higher, many-body electronic states, but also influences the spin of the system due to spin-orbit coupling. Using a low-temperature thermal bath the system is cooled back to the ground state. The adiabatic work exchange between the Ni₂ and the environment is described by the quasi-static expansion or compression of the bond length of the dimer. The calculated efficiency of the cycle is up to 34%.

11:15AM W14.00001 Spin Dynamics in Bi₂Se₃ / GaAs Heterostructures, ANDREW L. YEATS, PAUL V. KLIMOV, BOB B. BUCKLEY, Center for Spintronics and Quantum Computation, University of California, Santa Barbara CA 93106, ANTHONY RICHARDELLA, DUMING M. ZHANG, NITIN SAMARTH, Center for Nanoscale Science & Dept. of Physics, Penn State University, University Park PA 16802, MICHAEL E. FLATTE, Dept. of Physics, University of Iowa, Iowa City IA 52242, DAVID D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara CA 93106 — The narrow band gap semiconductor Bi₂Se₃ has been characterized as a topological insulator (TI), wherein strong spin-orbit coupling and time-reversal symmetry give rise to spin-polarized surface conduction states. Molecular beam epitaxy (MBE) of Bi₂Se₃ thin films onto conventional semiconductors such as GaAs [1] provides an attractive pathway for the creation of hybrid devices, coupling the exotic spin physics of TIs with the well-understood properties of spin coherence in semiconductors. We employ spatio-temporally resolved optoelectronic techniques to probe the carrier spin dynamics at the heterointerface between a TI and GaAs. Results are compared with interface band structure calculations.

This work is supported by ONR and NSF.

11:27AM W14.00002 Optical Aharonov-Bohm Effect in Al_{0.08}Ga_{0.92}As/Al_{0.25}Ga_{0.75}As Quantum Wells¹, ANDREAS RUSS, LARS SCHWEIDENBACK, JOSEPH MURPHY, ALEXANDER CARTWRIGHT, ATHOS PETROU, SUNY at Buffalo, Buffalo, NY, GEORGE KIOSEOGLOU, University of Crete, Heraklion, Greece, ALEXANDER GOVOROV, Ohio University, Athens, OH, AUBREY HANBICKI, BEREND JONKER, Naval Research Laboratory, Washington DC — The photoluminescence (PL) from Al_{0.08}Ga_{0.92}As/Al_{0.25}Ga_{0.75}As quantum wells (QW) was studied as function of magnetic field applied along the normal to the QW planes. The PL intensity exhibits two maxima at 2.3 and 4.9 tesla. The time-resolved PL from the same sample has a decay time which is one order of magnitude longer than the PL from a GaAs/AlGaAs QW, indicating that the recombination in the AlGaAs QW is spatially indirect. The PL intensity oscillations are attributed to the optical Aharonov-Bohm effect associated with spatially quasi-indirect excitons, which are located in the vicinity of islands with lower Al composition. The holes are localized by the islands, while the electrons move around them in a ring-like geometry. This model is in agreement with the interpretation of earlier results from Al_xGa_{1-x}As/Al_yGa_{1-y}As Fe spin-LEDs.

11:39AM W14.00003 Optical response of relativistic electrons in the polar BiTeI semiconductor, J.S. LEE, Graduate program of Photonics and Applied Physics, Gwangju Institute of Science and Technology (GIST), Gwangju 500-712, Korea, G.A.H. SCHOBER, Department of Applied Physics, University of Tokyo, Tokyo 113-8656, Japan, M.S. BAHRAMY, Correlated Electron Research Group (CERG) and Cross-Correlated Materials Research Group (CMRG), ASI, RIKEN, Wako 351-0198, Japan, H. MURAKAWA, Multiferroics Project, ERATO, Japan Science and Technology Agency (JST), Tokyo 113-8656, Japan, Y. ONOSE, R. ARITA, N. NAGAOSA, Department of Applied Physics, University of Tokyo, Tokyo 113-8656, Japan, Y. TOKURA, Department of Applied Physics and Quantum Phase Electronics Center (QPEC), University of Tokyo, Tokyo 113-8656, Japan — The transitions between the spin-split bands by spin-orbit interaction are relevant to many novel phenomena such as the resonant dynamical magneto-electric effect and spin Hall effect. Here, we present a combined experimental and theoretical study of the dynamics of relativistic electrons in the recently discovered giant bulk Rashba spin splitting system BiTeI. Several novel features are observed in the optical spectra including sharp edge singularity due to the reduced-dimensionality of joint density of states and a systematic doping dependence of the intraband transitions between the Rashba-split branches. These confirm the bulk nature of the Rashba-type splitting in BiTeI and manifest relativistic nature of the electron dynamics in a solid.

11:51AM W14.00004 Room temperature ferromagnetism in transparent conducting Fe-doped In₂O₃ films, MICHAEL OSOFSKY, HEUNGSOO KIM, MICHAEL MILLER, SEYED QADRI, RAYMOND AUYEUNG, ALBERTO PIQUE, Naval Research Laboratory — Oxide semiconductors have been widely studied as a host compound for spintronic devices since they can be doped with transition metals to realize a higher Curie temperature and can produce high n-type carriers by either doping with Group IV elements or introducing oxygen vacancies. Among various oxide semiconductors, Fe-doped In₂O₃ is a promising ferromagnetic semiconductor due to the high solubility of Fe-ions into the In₂O₃ lattice. Recently, at NRL, In_{2-x}Fe_xO₃ thin films have been deposited on MgO, sapphire, and YSZ substrates by pulsed laser deposition. The lattice constant decreases linearly with increasing Fe-doping concentration suggesting the incorporation of Fe ions into the In₂O₃ lattice matrix. Magneto-transport characteristics including anomalous Hall effect along with structural analysis demonstrate that an intrinsic ferromagnetism is observed for some films grown under optimized conditions. In this presentation, we will discuss our work to date on the growth of In_{2-x}Fe_xO₃ thin films grown by pulsed laser deposition with various deposition conditions and present the structural, optical, magnetic, and transport properties along with spin-polarization measurements.

12:03PM W14.00005 Selective optical excitation of in-plane and out-of-plane spin polarizations with linearly polarized light in InGaAs¹, STEFAN GOEBBELS, FREDERIK KLEIN, PHILIPP SCHAEFERS, MARKUS HAGEDORN, KLAUS SCHMALBUCH, GERNOT GUENTHERODT, II. Physikalisches Institut, RWTH Aachen University, Germany, MIHAIL LEPSA, THOMAS SCHAEPEPERS, Peter Gruenberg Institut (PGI-9), Forschungszentrum Juelich GmbH, Germany, BERND BESCHOTEN, II. Physikalisches Institut, RWTH Aachen University, Germany — Excitation with circularly polarized light is a standard technique for optical spin orientation in semiconductors. This method is based on the transfer of angular momentum from the photons to the electrons and yields a polar spin polarization directed along the propagation direction of the exciting laser beam. Here we present linearly polarized all-optical pump-probe experiments to excite and detect coherent electron spins in InGaAs [1]. We find the magnitude and the orientation of the spin polarization strongly depend on the polarization axes of the exciting light. While in general the excited spin ensemble is composed of both polar and transverse spin components, the polarization axis of the exciting light can be chosen such that polar and transverse spin components can be excited separately. Thus, selective excitation of in-plane and out-of-plane spin polarizations is feasible with linearly polarized light.

12:15PM W14.00006 Carrier Dynamics in Narrow Gap Ferromagnetic Semiconductors¹, D. SAHA, X. PAN, G.D. SANDERS, C.J. STANTON, University of Florida, M. BHOWMICK, T. MERRITT, G.A. KHODAPARAST, Virginia Tech, C. FEESER, B.W. WESSELS, Northwestern University, S. MCGILL, NHMFL — Narrow gap ferromagnetic semiconductors are promising materials for spin photonic and spin transport devices because of their small effective masses, small energy gap, and high carrier mobility. We use time resolved differential transmission (TRDT) experiments to study carrier dynamics in ferromagnetic InMnAs and InMnSb. Electronic structure for InMnAs and InMnSb is calculated using an 8-band Pidgeon-Brown model generalized to include the effects of an external magnetic field. Our model includes the effects of the ferromagnetic Mn ions and their coupling to electrons and holes with or without an external magnetic field. Optical transitions are calculated from Fermi's Golden rule and interband transitions at a given pump or probe laser energy are identified. This allows us to understand a sign change seen in the TRDT. Our results show that 1) Phase-Space Filling, 2) Band Gap Renormalization and 3) Free Carrier Absorption all contribute to the TRDT and that the relative importance of these effects depends on the laser probe energy.

12:27PM W14.00007 Ferromagnetism in cobalt-doped SrTiO₃ on Si grown by molecular beam epitaxy, AGHAM POSADAS, CHANDRIMA MITRA, ALEXANDER DEMKOV, University of Texas at Austin — We report the epitaxial growth of ferromagnetic cobalt-doped SrTiO₃ directly on silicon without the use of any buffer by molecular beam epitaxy (MBE). Magnetization as a function of magnetic field was performed for samples with varying doping concentration at room temperature and at 10 K. Room-temperature ferromagnetism is confirmed in single phase samples with composition 20-30% cobalt. We also performed x-ray photoelectron spectroscopy of the Co and Ti 2p levels to determine stoichiometry and cobalt oxidation state. In order to elucidate the origin of ferromagnetism, we also performed first-principles calculations of cobalt-doped SrTiO₃ with different doping concentrations and dopant configurations. The calculations show that intrinsic ferromagnetism can be stabilized beyond a critical concentration in SrTiO₃ under particular conditions. The ability to directly integrate a ferromagnet on silicon in epitaxial form may potentially overcome the problems of impedance mismatch and interface losses in applications involving spin injection in silicon.

12:39PM W14.00008 Two-dimensional MnGa_N Layer formed by Nitridation of Mn $\sqrt{3} \times \sqrt{3}$ -R30 structure on Wurtzite GaN (0001)¹, MENG SHI, ABHIJIT CHINCHORE, Department of Physics and Astronomy, Nanoscale and Quantum Phenomena Institute, Ohio University, Athens, Ohio - 45701, YINHAO LIU, Los Alamos National Lab, Los Alamos, NM 87545, ARTHUR SMITH, Department of Physics and Astronomy, Nanoscale and Quantum Phenomena Institute, Ohio University, Athens, Ohio - 45701 — There has been much interest in dilute Mn-doped GaN as a spintronic material. Recently, it has become of interest to consider the possible advantages of delta-doped magnetic layers, rather than a bulk alloy. Here we investigate experimentally the growth of single Mn-containing layers on top of wurtzite GaN as well as the overgrowth of GaN onto the Mn-containing layer, using a combination of N-plasma molecular beam epitaxy and reflection high energy electron diffraction. Sub-monolayer Mn deposition on GaN(0001) results in a novel $\sqrt{3} \times \sqrt{3}$ -R30 structure [1]. Upon nitrogen plasma exposure, this periodicity is removed; whereas, Mn is found remaining on the surface as measured by Auger electron spectroscopy. Unexpectedly, and in dramatic comparison to tiny lattice constant changes seen for bulk films, we find a huge -3.3 percent surface lattice contraction in both [1010] and [1120] azimuthal directions. This suggests the possible formation of a Mn_{0.25}Ga_{0.75}N 2-D alloy. Furthermore, subsequent overgrowth of GaN layers does not show significant lattice constant change compared to the nitridation process, up to a thickness of 20 ML or more.

¹ Authors gratefully acknowledge DOE & NSF.

12:51PM W14.00009 Structural transition and giant spintronic response of two dimensional Manganese-Gallium $\sqrt{3} \times \sqrt{3}$ R30° surface structure¹, ABHIJIT CHINCHORE, MENG SHI, WENZHI LIN, KANGKANG WANG, Ohio University Nanoscale and Quantum Phenomena Institute, YIANGHAO LIU, Los Alamos National Laboratory, ARTHUR SMITH, Ohio University Nanoscale and Quantum Phenomena Institute, VALERIA FERRARI, ANDREA BARRAL, ANA MARIA LLOIS, Universidad de Buenos Aires and Comision Nacional de Energia Atomica — In recent experiments, we have found that gallium nitride surface when exposed to transition metal atoms, results in novel well-ordered two dimensional spintronic structure, with tunable spintronic properties. A 2000 Å N-polar *w*-gallium nitride (0001) layer is grown on a sapphire substrate, by molecular beam epitaxy. The growth is monitored using reflection high energy electron diffraction system. Post growth, the standard 1×1 gallium nitride surface, is exposed to sub monolayer doses of manganese. At low deposition temperature the diffraction patterns show manganese atoms forming a metastable 3×3 structure, on supplying little heat to the manganese 3×3 structure, it undergoes an irreversible transition to form a stable $\sqrt{3} \times \sqrt{3}$ R30° structure. Both the structures are studied using a scanning tunneling microscope. The $\sqrt{3} \times \sqrt{3}$ R30° structure shows a giant change in spectroscopic response on application of a very small out-of-plane magnetic field. The new findings suggest that the two dimensional magnetic nitride systems have excellent potential for both fundamental investigations and for use in future spintronic devices.

¹ Authors gratefully acknowledge the funding from NSF and DOE.

1:03PM W14.00010 Spinglass Dynamics of Amorphous Ferromagnetic Ge:Mn¹, SAMARESH GUCHAHAIT, SANJAY BANERJEE, RAYMOND ORBACH, The University of Texas at Austin — Ge_{0.84}Mn_{0.16} is an amorphous ferromagnetic semiconductor with a Curie temperature of about 160 K (measured at 1000 Oe). Magnetic field-cooled and zero-field-cooled experiments show existence of a spinglass phase well below the Curie temperature. The spinglass temperature is about 23 K at a 50 Oe field. The spinglass temperature scales monotonically with applied magnetic field. Magnetic hysteresis experiments show a non-zero coercive field below the spinglass temperature, and a very small coercive field or a superparamagnetic phase above it. Under a rapid quench, thermoremanent magnetization (TRM) decay experiments (at 14 K) exhibit a very large effective waiting time. This is associated with a slow rate of cooling, allowing communication between phase space states before the measuring temperature is reached, leading to an effective reduction in the attempt frequency. This is consistent with experiments on other more typical spin glass systems.

1:15PM W14.00011 Magnetism in Iron-Titanium Oxide Nanostructures¹, PEGAH HOSSEINPOUR, Chemical Engineering Department, Northeastern University, EUGEN PANAITESCU, Physics Department, Northeastern University, LAURA H. LEWIS, Chemical Engineering Department, Northeastern University, LATIKA MENON, DON HEIMAN, Physics Department, Northeastern University — Modification of the titania nanotubes with magnetic transition metal additions is anticipated to provide the opportunity of creating a novel multifunctional nanostructured material with magnetic, semiconducting and catalytic properties. Incorporation of Fe into titania to produce ordered arrays of amorphous (Fe+Ti)₂O₃ nanotubes was achieved by electrochemical anodization. As-made nanotubes were subjected to a systematic thermal treatment in a variety of atmospheres for crystallization; their associated morphological, structural and magnetic character was examined. Preliminary results indicate that the Fe-modified nanotubes possess a unit cell volume that is slightly larger than that of titania (137 vs 136 Å³) confirming Fe incorporation into the lattice. The temperature-dependent magnetic susceptibility data obtained from the samples may be decomposed into a Curie-Weiss component that represents the localized magnetic character of titania nanotubes and a Pauli paramagnetic component that represents the semiconducting behavior of the nanotubes. It is noted that Fe incorporation causes an increase in both components of the magnetic signal, suggesting modification of the electronic structure of the crystalline titania phase with iron incorporation.

1:27PM W14.00012 Magnetoluminescence Studies of Mn-doped PbS Quantum Dots¹, BIPLOB BARMAN, YUTSUNG TSAI, GEN LONG, SAVAS DELIKANLI, ATHOS PETROU, HAO ZENG, SUNY at Buffalo, Buffalo, NY — Diluted magnetic semiconductor quantum dots are interesting model systems for the investigation of carrier dopant exchange interactions. In this work, we report the carrier spin polarization studies in narrow band gap Mn-doped PbS quantum dots, a much less studied system compared to their II-VI counterparts. The PbMnS quantum dots were synthesized by hot colloidal solution technique. They are single crystalline with cubic structure. The doping concentration is 3-4% as measured by energy dispersive X-ray spectroscopy. The system is paramagnetic down to 2 K, as measured by VSM. We have recorded the PL spectra in the Faraday geometry for magnetic fields of up to 7 tesla in the 0-50 K temperature range. The PL was excited at 780 nm and the emission is centered at 940 meV with a FWHM of 100 meV. In the presence of a magnetic field the emission becomes strongly σ^+ polarized ($P = 35\%$ at 4 tesla), suggesting carrier spin polarization. The polarization is temperature sensitive and decreasing sharply with increasing temperature. The polarization vanishes at around $T = 40$ K. The degree of spin polarization can be tuned by quantum confinement.

¹This work is supported by NSF

1:39PM W14.00013 All-Optical observation of Nuclear Magnetic Resonance in a 2D electron system, YANG JI, XUAN QIAN, SKLSM, Institute of Semiconductors, Chinese Academy of Sciences, Beijing 100083, PR China, VLADIMIR UMANSKY, Braun Center for Submicron Research, Department of Condensed Matter Physics, Weizmann Institute of Science, Rehovot 76100, Israel — Electron-nuclear spin interaction may be utilized to manipulate nuclear states coherently in quantum computation. Here we report on an all-optical observation of nuclear magnetic resonance (NMR) in a 2D electron system embedded in a GaAs/AlGaAs heterostructure. In analogy to radio-frequency fields used in traditional NMR, circularly polarized light creates electron spins in semiconductors whose hyperfine coupling with nuclei could tip nuclear moments. At a fixed time-delay ~ 12.5 ns, time-resolved Kerr-rotation (TRKR) signals were measured as a function of the modulation frequency (from 1 KHz to 100 kHz) of the pump laser. Spin-polarized carriers generated by the pump laser pulse train acts on the nuclear spins as an effective rf magnetic field synchronized at the pulse repetition frequency, which resonates nuclear spins at suitable frequencies in an external magnetic field in Voigt geometry. Several dips were observed in a TRKR trace at, which shift linearly with increasing magnetic field. They are ascribed to be NMR signals of elements As-75, Ga-69, Al-27 and Ga-71.

1:51PM W14.00014 Confinement and Diffusion Effects in Dynamical Nuclear Polarization in Low Dimensional Nanostructures, DAN HENRIKSEN, IONEL TIFREA, California State University, Fullerton — We investigate the dynamic nuclear polarization as it results from the hyperfine coupling between nonequilibrium electronic spins and nuclear spins in semiconductor nanostructures. The natural confinement provided by low dimensional nanostructures is responsible for an efficient nuclear spin - electron spin hyperfine coupling [1] and for a reduced value of the nuclear spin diffusion constant [2]. In the case of optical pumping, the induced nuclear spin polarization is position dependent even in the presence of nuclear spin diffusion. This effect should be measurable via optically induced nuclear magnetic resonance or time-resolved Faraday rotation experiments. We discuss the implications of our calculations for the case of GaAs quantum well structures.

2:03PM W14.00015 ABSTRACT WITHDRAWN —

Thursday, March 1, 2012 11:15AM - 2:03PM —

Session W15 DMP FIAP GMAG: Focus Session: Spins in Metals - Domain Wall, Vortex, Magnonic Based Devices 213

11:15AM W15.00001 High speed domain wall motion in MgO-based magnetic tunnel junctions driven by perpendicular current injection¹, P.J. METAXAS, A. CHANTHBOUALA, R. MATSUMOTO, V. CROS, A. ANANE, J. GROLLIER, A. FERT, Unite Mixte de Physique CNRS/Thales, France, K.A. ZVEZDIN, Istituto P.M. s.r.l., Italy, A. FUKUSHIMA, S. YUASA, National Institute of Advanced Industrial Science and Technology (AIST), Japan — The ability to efficiently drive fast domain wall (DW) motion will pave the way for revolutionary new electronic devices ranging from DW-MRAMs to spintronic memristors. The majority of domain wall devices use a lateral, current-in-plane configuration in which critical current densities for domain wall motion remain quite high, typically being on the order of 100 MA/cm^2 with velocities generally limited to about 100 m/s . In this contribution we show that critical current densities can be decreased by up to two orders of magnitude using the current-perpendicular-to-plane geometry. Indeed, we demonstrate that a DW can be propagated back and forth along the free layer of a MgO-based magnetic tunnel junction (MTJ) in the absence of an external magnetic field using current densities that are on the order of 5 MA/cm^2 . More notably however, we obtain high domain wall velocities for these low current densities: the MTJ's large resistance variations allow us to carry out time-resolved measurements of the wall motion from which we evidence DW velocities exceeding 500 m/s .

11:27AM W15.00002 Thermal activation energy for domain wall motion in out-of-plane magnetized submicron strips, SATORU EMORI, GEOFFREY BEACH, Massachusetts Institute of Technology — We have experimentally studied micrometer-scale domain wall (DW) motion driven by magnetic field and electric current in 500-nm wide out-of-plane magnetized Co/Pt multilayer strips with Co layer thicknesses $0.5\text{-}0.7 \text{ nm}$. The scaling of thermal activation energy for DW motion with driving field and current has been extracted directly from the temperature dependence of the DW velocity. For DWs driven by field, the activation energy follows creep and depinning dynamics below a critical field and collapses to zero above the critical field. DW motion assisted by current shows velocity enhancement independent of current polarity, but causes no measurable change in the activation energy barrier. Through this analysis, the observed current-induced DW velocity enhancement in these Co/Pt multilayer strips can be entirely and unambiguously attributed to Joule heating.

11:39AM W15.00003 Intrinsic domain wall flexing from current-induced spin torque , ELIZABETH

GOLOVATSKI, Dept. of Physics, Luther College, MICHAEL FLATTÉ, OSTC and Dept. of Physics and Astronomy, University of Iowa — Spin torque generated by coherent carrier transport in domain walls [1] is a major component in the development of spintronic devices [2]. We model spin torque in Néel walls [3] using a piecewise linear transfer-matrix method [4] to calculate spin torque on interior wall segments. For a π wall with a total positive torque (current left-to-right), we find the largest positive and negative spin torques left of the central region, 4-5 orders of magnitude larger than the center. The wall's rightward push comes from the back of the wall; all other significant regions pull to the left. Adding a second wall (both walls with positive total torque) changes the first wall little, but produces spin torques in the second wall with large canceling torques on the left, and the push rightward from a smaller torque on the right. The gradient of torque across the wall generates an intrinsic domain wall flexing (distinct from extrinsic wall flexing from pinning centers [5]). Work supported by an ARO MURI.

11:51AM W15.00004 Spinmotive force due to domain wall motion in high field regime , JUN'ICHI

IEDA, Advanced Science Research Center, JAEA; CREST, JST, YUTA YAMANE, Institute for Materials Research, Tohoku University, SADAMICHI MAEKAWA, Advanced Science Research Center, JAEA; CREST, JST — Spinmotive force associated with a moving vortex domain wall is investigated numerically. Dynamics of magnetization textures such as a domain wall exerts a non-conservative spin-force on conduction electrons [1], offering a new concept of magnetic devices [2]. This spinmotive force in permalloy nanowires has been detected by voltage measurement [3] where magnitude of the signal is limited less than 500 nV. Theoretically it is suggested that the spinmotive force signal increases as a function of external magnetic fields. At higher magnetic fields, however, the wall propagation mode becomes rather chaotic involving transformations of the wall structure and it remains to be seen how the spinmotive force appears. Numerical simulations show that the spinmotive force scales with the field even in a field range where the wall motion is no longer associated coherent precession. This feature has been tested in a recent experiment [4]. Further enhancement of the spinmotive force is explored by designing ferromagnetic nanostructures [5] and materials. [1] S. Barnes and S. Maekawa, PRL (2007). [2] S. Barnes, J. Ieda, and S. Maekawa, APL (2006). [3] S. A. Yang et al., PRL (2009). [4] M. Hayashi, J. Ieda et al., submitted. [5] Y. Yamane, J. Ieda et al., APEX (2011).

12:03PM W15.00005 All-magnonic spin-transfer torque and domain wall propagation¹ , X.R. WANG,

P. YAN, X.S. WANG, The Hong Kong University of Science and Technology — In this talk, we will discuss the spin-transfer torque (STT) between magnons and magnetic domain wall (DW). It is found that a spin wave passes through a transverse magnetic DW in a magnetic nanowire without reflection. A magnon, the quantum of the spin wave, carries opposite spins on the two sides of the DW. As a result, there is a spin angular momentum transfer from the propagating magnons to the DW. This magnonic STT can efficiently drive a DW to propagate in the opposite direction to that of the spin wave. In comparison with the electronic STT, the energy consumption is much lower when the magnonic STT is used to drive a DW propagating at a useful velocity. Since this STT does not require any itinerant electrons, it opens a door of using magnetic insulators like YIG in spintronics devices. One extra benefit of using magnetic insulators is the low damping coefficient so that it should further lower the energy consumption and increase operation efficiency.

12:15PM W15.00006 Disentangling the physical contributions to the anomalous Hall effect and domain wall resistance in isoelectronic L1₀-FePd and L1₀-FePt alloys , KLAUS SEEMANN, FELIPE GARCIA-SANCHEZ, ATTILA KAKAY, CLAUS SCHNEIDER, Peter Gruenberg Institut, Research Centre Juelich, Germany, FRANK FREIMUTH, YURIY MOKROUSOV, STEFAN BLUEGEL, Institute for Advanced Simulation, Research Centre Juelich, Germany, RICCARDO HERTEL, Institut de Physique et Chimie des Matériaux de Strasbourg, Université de Strasbourg, CNRS UMR 7504, Strasbourg, France — We analyze the origin of the electrical resistance arising in domain walls of perpendicularly magnetized materials by considering a superposition of anisotropic magnetoresistance and the resistance implied by the magnetization chirality. The domain wall profiles of L1₀-FePd and L1₀-FePt are determined by micromagnetic simulations based on which we perform first principles calculations to quantify electron transport through the core and closure region of the walls. The wall resistance, being twice as high in L1₀-FePd than in L1₀-FePt, is found to be clearly dominated in both cases by a high gradient of magnetization rotation, and not by the spin-orbit interaction driven anisotropic magnetoresistance effect. Concerning the anomalous Hall effect on the other hand, we show that difference in spin-orbit interaction strength of Pt and Pd atoms leads to a pronounced cross-over from an extrinsic side jump mechanism in L1₀-FePd to an intrinsic Berry-phase anomalous Hall effect in L1₀-FePt.

12:27PM W15.00007 Stochastic dynamics of vortex cores in a pinning potential observed via torsional magnetometry¹ , ALASTAIR FRASER, JACOB BURGESS, JOSEPH LOSBY, FATEMEH FANISANI, University of Alberta, DOUG VICK, WAYNE HIEBERT, National Institute for Nanotechnology, JOHN DAVIS, University of Alberta, MARK FREEMAN, National Institute for Nanotechnology — Measurements of a single 1 micrometer diameter permalloy disk fabricated on a silicon nitride torsional resonator are presented. Sensitivity of this device is sufficiently high to allow study of the vortex core interaction with very weak pinning sites. Low speed stochastic dynamics are revealed and attributed to the vortex core hopping between bistable states around pinning sites. The temperature and field dependence of this noise around the pinning site was investigated. Analysis employing an analytical description of the vortex in a thin disk and an Arrhenius model allows determination of the pinning potential.

12:39PM W15.00008 Dimensionality crossover in magnetic vortex dynamics¹ , TE-YU CHEN, MICHAEL ERICKSON, ANDREW GALKIEWICZ, CHRIS LEIGHTON, PAUL CROWELL, University of Minnesota — The ground state of a micron diameter ferromagnetic disk is often a single magnetic vortex, in which the gyrotropic mode of the vortex core is the lowest frequency excitation. In thin disks (thickness $L \ll$ diameter D), the vortex can be treated two-dimensionally (2D), and the gyrotropic frequency f_G is determined by L/D . We have observed a crossover from 2D to 3D dynamics as the thickness increases. Using time-resolved Kerr microscopy, we have investigated the gyrotropic mode in 1 μm diameter Ni₈₀Fe₂₀ disks as a function of L , which was varied from 20 nm to 200 nm. In thin disks ($L < 80$ nm), f_G is approximately proportional to L . For $L > 100$ nm, f_G increases less rapidly than predicted by the 2D model, and an additional gyrotropic mode appears at higher frequencies. We have explored the thickness dependences of both modes. In the ordinary gyrotropic mode, which is magnetostatic in character, the core oscillates uniformly through the thickness of the disk. The second gyrotropic mode is exchange-dominated, and the core oscillates with larger amplitude at the surfaces and a node in the equatorial plane of the disk. In the thickest disks, the exchange-dominated mode is the lowest in frequency.

12:51PM W15.00009 Magnonic band gaps in films with periodically modified surfaces¹, RODRIGO ARIAS, CLAUDIO JARUFE, Universidad de Chile — It is of current interest to understand the electromagnetic response of different nano-structures. In this study we focus on the role of geometry in ferromagnetic modes and response. Specifically we consider a ferromagnetic thin film with periodically perturbed surfaces, in the magnetostatic limit. We focus on the changing behavior of surface modes of the unperturbed film. Our film shows a behavior of interest since magnons propagate in it with band gaps associated to the geometry, i.e. they may be controlled by design. A reduced Brillouin zone scheme is introduced to describe the modes, which are of the Bloch type. Different bands are identified, and they are calculated numerically. For small geometric perturbations we develop a perturbation theory that agrees with our numerical results, and we obtain analytic expressions for the band gaps at the edges of the Brillouin zone. The underlying theory used to calculate the modes was previously developed, and relies on solving integral equations along the edges of the sample for the magnetostatic potential. We also calculate the response to magnetic field waves of a given wavevector that travel along the modulation direction, finding effective line width increments at the edge of the Brillouin zone, where the bands strongly couple.

1:03PM W15.00010 Manipulation of propagating spin waves in straight and curved magnetic microstrips¹, ARABINDA HALDAR, HAU-JIAN LIU, Colorado State University, HELMUT SCHULTHEISS, Argonne National Laboratory, KATRIN VOGT, Technische Universität Kaiserslautern, AXEL HOFFMANN, Argonne National Laboratory, KRISTEN BUCHANAN, Colorado State University — The main challenges in realizing magnonics devices are the generation, manipulation and detection of spin waves, especially in metallic magnetic materials where the length scales are of interest for applications. We have studied the propagation of spin waves in transversely magnetized Permalloy (Py) microstrips of different shapes using micro-Brillouin light scattering. The Py stripe was 30-nm thick, several micrometers wide and $>50\text{ }\mu\text{m}$ long. Spin waves were excited in the Py strip using a $2\text{-}\mu\text{m}$ wide antenna. We compare the spin wave propagation along a straight wire to the propagation along a magnetic microstrip with a smooth bend. We will also discuss the use of a current through a gold wire under the Permalloy to provide a local magnetic field to maintain a transverse magnetization around the bend.

¹This work was supported by NIST and NSF.

1:15PM W15.00011 Dynamics of wavepacket of magnetostatic spin wave in magnet, RYO MATSUMOTO, SHUICHI MURAKAMI, Tokyo Institute of Technology — A semiclassical equation of motion of a wave packet of the magnetostatic spin wave is theoretically constructed. There appears the Berry curvature as an anomalous velocity term in the equation of motion, which causes characteristic orbital motions of the wave packet such as a self-rotational motion and a motion along the edge of the system. Due to the symmetry, the Berry curvature in the case of a thin film of an insulating ferromagnet appears when the magnetization is perpendicular to the film. We show a numerical calculation of the Berry curvature for this mode, i.e., the magnetostatic forward volume wave mode. Around the degeneracy point, the Berry curvature from the highest energy band enhances and that from other bands decreases. We also propose experimental settings to observe this effect.

1:27PM W15.00012 Nonlinear Behavior for the Uniform Mode and Horizontal Standing Spin Wave Modes in Metallic Ferromagnetic Microstrips: Experiment and Theory¹, B.W. SOUTHERN, M.P. WISMAYER, X.L. FAN, Y.S. GUI, C.-M. HU, University of Manitoba, R.E. CAMLEY, University of Colorado at Colorado Springs — Micron sized rectangular ferromagnetic bars have a variety of spin excitations, including a quasi-uniform mode, horizontal and vertical standing spin wave modes, and edge and corner modes. When driven by a strong microwave field, these modes differ from those found in the linear regime. For example, the resonance field or frequency becomes amplitude dependent. We study the nonlinear spin dynamics in such microstrips both experimentally and theoretically for a geometry where the static magnetic field is perpendicular to the plane of the sample. Experimentally it is found that, at a fixed microwave frequency, the resonance field for the uniform mode is significantly reduced as the microwave power is increased. In contrast, the resonance fields for the standing horizontal spin wave modes are only slightly reduced. This behavior is confirmed theoretically using micromagnetic calculations, and an intuitive explanation for this behavior is developed.

1:39PM W15.00013 Efficient computation of Magnon dispersions within Time Dependent Density Functional Theory Using Maximally Localized Wannier Functions, BRUNO ROUSSEAU, CSIC - Centro de Física de Materiales, ASIER EIGUREN, AITOR BERGARA, Condensed Matter Physics Department, University of the Basque Country — An efficient scheme is presented to compute the transverse magnetic susceptibility within time dependent density functional theory from which magnon dispersions can be extracted. The scheme makes use of maximally localized Wannier functions in order to interpolate the band structure onto a fine k-mesh in order to converge sums on the first Brillouin zone. An optimal real space basis set containing few basis functions is shown to be sufficient to extract the magnon dispersion, making computations very efficient. The gap error in the magnon dispersion at Γ , numerically violating Goldstone's theorem, is analysed and a correction scheme is devised which can be generalized to systems where Goldstone's theorem does not apply. The method is applied to the computation of the magnon dispersion of bulk bcc iron and fcc nickel.

1:51PM W15.00014 Electron Paramagnetic Resonance of Transition Metal Ions: New Relativistic Effects at High Magnetic Fields, AYODEJI AWOBODE, University of Ibadan, Ibadan, Nigeria — We calculate the shift in the Electron Spin Resonance (ESR) frequency due to an inhomogeneous term in the equation of motion describing the precession of the angular momenta of relativistic electrons coupled to a static magnetic field. It is proposed that the calculated frequency shift may be observed in transition metal complexes in which the contributions from the ligand field are completely and precisely known. Furthermore, it is shown that a measurable transient oscillation of the dipole moment occurs after the external magnetic field is suddenly switched off.

Thursday, March 1, 2012 11:15AM - 2:15PM –
Session W16 DCMP: Quantum Criticality 251

11:15AM W16.00001 Pairing of critical Fermi-surface states, MAX METLITSKI, KITP, DAVID MROSS, MIT, SUBIR SACHDEV, Harvard University, TODADRI SENTHIL, MIT — States of matter with a sharp Fermi-surface but no well-defined Landau quasiparticles are expected to arise in a number of physical systems. Examples include i) quantum critical points associated with the onset of order in metals, ii) the spinon Fermi-surface (U(1) spin-liquid) state of a Mott insulator and iii) the Halperin-Lee-Read composite fermion charge liquid state of a half-filled Landau level. In this work, we use renormalization group techniques to investigate possible instabilities of such non-Fermi-liquids to pairing. We show that for a large class of phase transitions in metals, the attractive interaction mediated by order parameter fluctuations always leads to a superconducting instability, which preempts the non-Fermi-liquid effects. On the other hand, the spinon Fermi-surface and the Halperin-Lee-Read states are stable against pairing for a sufficiently weak attractive short-range interaction. However, once the strength of attraction exceeds a critical value, pairing sets in. We describe the ensuing quantum phase transition between i) the U(1) and the Z_2 spin-liquid states, and ii) the Halperin-Lee-Read and Moore-Read states.

11:27AM W16.00002 Fractionalized Fermi liquids as ground states of single band tJ models, MATTHIAS PUNK, SUBIR SACHDEV, Harvard University — Recently it has been argued that the normal state of underdoped cuprates might realize a fractionalized Fermi liquid (FL*), where electron-like quasiparticles couple to fractionalized excitations of a fluctuating antiferromagnetic background. The corresponding Fermi surface consists of pockets, the area of which is determined by the density of doped charge carriers alone as opposed to the total density of electrons, thereby violating Luttinger's theorem. Most previous studies of the FL* phase were based either on two-band models such as the Kondo lattice model, or on phenomenological models where Fermions are coupled to a fluctuating unit vector field representing the local Neel order. In this talk I will show that the FL* phase can indeed arise as the ground-state of a single band tJ model and discuss its implications.

11:39AM W16.00003 Doping the Kane-Mele-Hubbard model: A Slave-Boson Approach¹, JUN WEN, MEHDI KARGARIAN, University of Texas at Austin, ABOLHASSAN VAEZI, Institute for Research in Fundamental Sciences, IPM, 19395-5531, Iran; Department of Physics, Sharif University of Technology, Tehran 11155-9161, Iran, GREGORY FIETE, University of Texas at Austin — We study the Kane-Mele-Hubbard model both at half-filling and away from half-filling using a slave-boson mean-field approach at zero temperature. We obtain a phase diagram at half-filling and discuss its connection to recent results from quantum Monte Carlo, cellular dynamical mean field, slave-rotor, and Z_2 mean-field studies. In particular, we find a small window in parameter space where a spin liquid phase with gapped spin and charge excitations reside. Upon doping, we show the spin liquid state becomes a superconducting state by explicitly calculating the singlet pairing order parameters. Interestingly, we find an "optimal" doping for such superconductivity. Our work reveals some of the phenomenology associated with doping an interacting system with strong spin-orbit coupling and intermediate strength electron-electron interactions.

11:51AM W16.00004 Stripe melting and quantum criticality in correlated metals, DAVID MROSS, SENTHIL TODADRI, Massachusetts Institute of Technology — In the last several years evidence for the occurrence of stripe and related orders has accumulated in many underdoped cuprates. With increasing doping the stripe ordering tendency disappears. This has given rise to the idea that a stripe melting quantum phase transition in the "underlying normal state" may play a role in some of the physics of the optimally doped strange metal. However there is currently no controlled understanding of a stripe-disordering phase transition in the presence of a Fermi-surface of electrons. We obtain a controlled critical theory of a continuous melting transition of charge stripes in a metal by proliferating pairs of dislocations in the stripe-order parameter, without proliferating single dislocations. At such a (deconfined) quantum critical point (QCP) the fluctuations of the stripe order parameter are strongly coupled, yet tractable. They also decouple dynamically from the Fermi-surface. We find that the full Fermi-surface and the associated Landau quasiparticles remain sharply defined at the QCP. On the stripe ordered side the reconstruction of the Fermi surface occurs at an energy scale that is parametrically different from that associated with the onset of stripe order.

12:03PM W16.00005 Quantum Criticality for Extended Nodes on the Bethe Lattice¹, JAMES MURRAY, Johns Hopkins University, ADRIAN DEL MAESTRO, University of Vermont, ZLATKO TESANOVIC, Johns Hopkins University — Theoretical description of anisotropic systems, such as layered superconductors and coupled spin chains, is often a challenge due to the different natures of interactions along different directions. As a model of such a system, we present an analytical study (1) of d -dimensional "nodes" arranged as the vertices of a Bethe lattice, where each node has nonzero spatial dimension and is described by an $O(N)$ quantum rotor model, and there is hopping between neighboring nodes. In the limit of large connectivity on the Bethe lattice, the hopping can be treated by constructing a self-consistent effective action for a single node. This procedure is akin to dynamical mean field theory, but generalized so that spatial as well as quantum fluctuations are taken into account on each node. The quantum phase transition is studied using this effective action for both infinite and finite N . The importance of the Perron-Frobenius uniform mode on the Bethe lattice is discussed, and its elimination via an "infinite range hopping" term shifts the transition, leading to nontrivial critical behavior. We calculate critical exponents and find that the internode hopping reduces the upper and lower critical dimensions each by one.

12:15PM W16.00006 Quantum Criticality on Graphs¹, ADRIAN DEL MAESTRO, University of Vermont, JAMES MURRAY, ZLATKO TESANOVIC, Johns Hopkins University — One of the tenets of our understanding of strongly correlated systems is that their macroscopic critical behavior is often universal and independent of any microscopic details. Continuous phase transitions driven by either thermal or quantum fluctuations can be placed in universality classes defined by the spatial dimension and the symmetry of a Landau-like order parameter. In an attempt to further understand the role of the spatial dimension in universality, we imagine a system whose symmetries and connectivities are controlled by the low-lying spectrum of degrees of freedom on a graph. As an elucidating example, we study a quantum phase transition on large random regular graphs, with coupled vertices described by d -dimensional $O(N)$ quantum rotor models.

¹This work was supported by the Johns Hopkins-Princeton Institute for Quantum Matter, under No. DE-FG02-08ER46544 by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering.

12:27PM W16.00007 Entropic Signatures of Quantum Criticality in Itinerant Ferromagnets and Metamagnetic Systems, JIANDA WU, Rice University, LIJUN ZHU, LANL, QIMIAO SI, Rice University, ANDREAS ROST, ANDY MACKENZIE, University of St. Andrews — We investigate the thermodynamic properties of itinerant ferromagnets near quantum critical points described by a quantum Landau-Ginzburg ϕ^4 theory. We show that the quartic coupling in this theory, which is dangerously irrelevant, has a singular contribution to the renormalized Gaussian free energy. We trace this singularity to some ultraviolet contributions, thereby demonstrating its unphysical nature. We introduce a procedure to regularize this singularity, and apply the prescription to calculate thermodynamic quantities across ferromagnetic quantum critical points in both two and three dimensions. Our calculation illustrates various thermodynamic signatures of quantum criticality, including the entropy accumulation at the quantum critical point which was first proposed on scaling grounds [1]. We systematically compare our theoretical results with the experimental data on entropy and specific heat as a function of magnetic field in Sr3Ru2O7 [2]. We demonstrate that the thermodynamic data are compatible with a quantum critical scenario, but the critical behavior does not agree well with the conventional itinerant ferromagnetic quantum criticality picture. 12:39PM W16.00008 Quantum criticality in a dissipative (2+1)-dimensional XY model of circulating currents in high- T_c cuprates¹, IVER B. SPERSTAD, EINAR B. STIANSEN, ASLE SUDBO, Norwegian University of Science and Technology — We present large-scale Monte Carlo results for the dynamical critical exponent z and the spatio-temporal two-point correlation function of a (2+1)-dimensional quantum XY model with bond dissipation, proposed to describe a quantum critical point in high- T_c cuprates near optimal doping. The phase variables of the model, originating with a parametrization of circulating currents within the CuO₂ unit cells in cuprates, are compact, $\{\theta_{vv\tau,\tau}\} \in [-\pi, \pi)$. The dynamical critical exponent is found to be $z \approx 1$, and the spatio-temporal correlation functions are explicitly demonstrated to be isotropic in space-imaginary time. The model thus has a fluctuation spectrum where momentum and frequency enter on equal footing, rather than having the essentially momentum-independent marginal Fermi liquid-like fluctuation spectrum previously reported for the same model.

12:51PM W16.00009 Strong Electron Correlation by Virtual Phonon Exchange in Jahn-Teller Crystals, MICHAEL KAPLAN, Simmons College, GEORGE ZIMMERMAN, Boston University, KAPLAN/ZIMMERMAN COLLABORATION — In Jahn-Teller crystals - crystals with at least one sublattice of ions with orbitally degenerate electronic states - virtual phonon exchange is a major source of strong electron correlation. This type of electron correlation leads to different structural and magnetic transitions the interplay of which is especially interesting in case of the triple degeneracy of the electronic ground states. The interest to these systems lately has increased as it is related to some unusual situations in perovskite and spinel structure compounds that are of big practical interest (multiferroicity, piezomagnetism, and others). Mutual influence of the antiferrodistortive XY-type and ferroelastic ZZ-type orderings mediated by magnetic external or internal interactions in such a type of crystals is under discussion. It is found that even in case of stronger interactions leading to the ferroelastic ordering the presence of magnetic interaction causes new type of structural phase transition from the ZZ- type of ordering to the XY-type. These structural transformations are accompanied by specific anomalies in the temperature and external magnetic field dependences. The thermodynamics of the systems with strong electron correlation leading to such a phase transitions is analyzed.

1:03PM W16.00010 Features of Fermi Systems near $\ell=0$ Pomeranchuk Instabilities: A Crossing Symmetric Approach, KELLY REIDY, KHANDKER QUADER, Kent State University, KEVIN BEDELL, Boston College — In Fermi systems, interactions can cause symmetry-breaking deformations of the Fermi surface, called Pomeranchuk instabilities. In Fermi liquid (FL) language, this occurs when one of the Landau harmonics $F_{\ell}^{a,s} \rightarrow -(2\ell + 1)$; e.g. $F_0^{a,s} = -1$ are related to ferromagnetic (a), and density instabilities (s) respectively. The corresponding point in parameter space may be viewed as a quantum critical point (QCP). Using graphical and numerical methods to solve coupled non-linear integral equations of a crossing symmetric equation (TSCE) scheme, we study the behavior of spin/density excitations; effective mass; ferromagnetic, spin density wave, phase separation, and pairing transitions near $\ell=0$ Pomeranchuk instabilities in a 3D Fermi system. Considering momentum dependence of the renormalized FL interactions, we find a number of results for repulsive and attractive couplings of arbitrary strengths; viz. attraction in both singlet and triplet pairing amplitudes (though singlet pairing is primarily favored); possibility of a second ferromagnetic transition due to spin waves, and possibility of phase separation with and without ferromagnetic transition. Some of our results may apply to ferromagnetic superconductors, such as UGe₂ and UIr.

1:15PM W16.00011 Phase reconstruction near to the two-dimensional ferromagnetic quantum critical point, CHRIS PEDDER, London Centre for Nanotechnology & UCL, UNA KARAHASANOVIC, FRANK KRUGER, University of St. Andrews, ANDREW GREEN, London Centre for Nanotechnology & UCL — We study the formation of new phases in two dimensions near to the putative quantum critical point of the itinerant ferromagnet to paramagnet phase transition. In addition to the first order and helimagnetic behaviour found in non-analytic extensions to Hertz-Millis theory [1] and in the quantum order-by-disorder approach [2], we find a small region of spin nematic order. Our approach also admits a concurrent formation of superconducting order. We further study the effect of small deformations from quadratic electron dispersion – as previously found in three dimensions, these enlarge the region of spin nematic order at the expense of spiral order.

1:27PM W16.00012 Divergence of the effective mass in a strongly-interacting 2D electron system¹, SHIQI LI, City College of New York, New York, NY 10031; Graduate Center of CUNY, New York, NY 10016, ANISH MOKASHI, Northeastern University, Boston, MA 02115, BO WEN, City College of New York, New York, NY 10031, S.V. KRAVCHENKO, Northeastern University, Boston, MA 02115, A.A. SHASHKIN, V.T. DOLGOPOLOV, Institute of Solid State Physics, Chernogolovka, Moscow District 142432, M.P. SARACHIK, City College of New York, New York, NY 10031 — The diffusion thermopower in a low-disorder, strongly-interacting 2D electron system in silicon increases with decreasing electron density and tends to infinity at a finite density n_t . Comparison with earlier data for a high-disorder silicon system indicates that the critical density n_t does not depend on the degree of disorder. The increase of the thermopower is associated with a diverging electron mass in the close vicinity of an interaction-induced phase transition.

1:39PM W16.00013 A New View of the Mott-Hubbard Transition: Renormalization of the Fermi-Surface Topology, LUCA FAUSTO TOCCHIO, Goethe University Frankfurt, FEDERICO BECCA, SISSA Trieste, CLAUDIUS GROS, Goethe University Frankfurt — We present the renormalization of the (underlying) Fermi-surface topology in the Hubbard model on a square lattice with frustrating hopping, that is relevant for the physics of high-temperature superconductors. With the help of novel high precision variational tools, including Jastrow factors and backflow correlations, we show that the Fermi surface renormalizes to perfect nesting at the interaction-driven Mott-Hubbard transition and in the large interaction limit. Moreover, we present new results for the density-driven Mott-Hubbard transition, investigating the Fermi-surface renormalization flow as a function of doping, where the renormalization occurs only when the half-filled case is insulating. We associate the flow to the appearance of a van Hove singularity at the Fermi level at small doping, that is interpreted as an instability to magnetic order. Finally, we show also that Fermi surface renormalization is associated to a strong crossover at finite doping for the critical U corresponding to the Mott-Hubbard transition.

1:51PM W16.00014 Detecting Quantum Phase Transitions using Classical Noises, YAN CHEN, YINCHEN HE, Fudan University — We theoretically propose that the classical noise spectra provide an efficient and straightforward way to detect the quantum phase transition points in low-dimensional quantum spin systems. By using Ornstein-Uhlenbeck noise, we employ both a quadratic response theory and time-dependent density matrix renormalization group method to study the quantum system. In the non-Markovian region, the time evolutions of physical observables exhibit distinct behaviors for different quantum phases. In addition, we have the freedom to choose various noises to detect peculiar quantum phases. This method can be used to measure the three body correlation function directly. We demonstrate that the method can determine faithfully the quantum transition points of the transverse Ising model as well as spin-1 bilinear-biquadratic Heisenberg model. The possible experimental realizations of noise detection are discussed.

2:03PM W16.00015 Topological non-Fermi liquids and continuous transitions to Fermi liquids in fractional Chern states, JOHN MCGREEVY, MIT, MAISSAM BARKESHLI, Stanford University — We develop a slave-particle formulation of the Halperin-Lee-Read (HLR) non-Fermi liquid state and extend it to situations without an external magnetic field. We use this formulation to develop a theory of a continuous transition to a Fermi liquid, producing an example in which we can understand how a Fermi surface is continuously destroyed to obtain a fractionalized Fermi liquid. We discuss senses in which the HLR state should be viewed as a topological non-Fermi liquid, and finally we discuss experimental possibilities for inducing such transitions by tuning the bandwidth of a topologically non-trivial bandstructure.

Session W17 FIAP: Optics of Semiconductor Nanowires 252A

11:15AM W17.00001 Scalable Synthesis of Vertically Aligned, Catalyst-Free Gallium Arsenide Nanowire Arrays – Towards Optimized Optical Absorption and Reflection.¹, MAOQING YAO, ANUJ MADARIA, CHUNYUNG CHI, CHENXI LIN, NINGFENG HUANG, University of Southern California, RUIJUAN LI, None, MICHELLE POVINELLI, DANIEL DAPKUS, CHONGWU ZHOU, University of Southern California, USC NANOLAB TEAM, USC COMPOUND SEMICONDUCTOR LABORATORY TEAM, USC NANOPHOTONICS LABORATORY TEAM — Vertically aligned, catalyst-free nanowires hold great potential for photovoltaic applications, where scalable synthesis and optimized optical absorption are critical. Here, we report using nanosphere lithography, scalable synthesis of vertical gallium arsenide nanowires grown by selected area MOCVD. A comparative study was done between regular nanowires arrays using electron beam lithography and slightly more defective nanowire arrays using nanosphere lithography. Reflection of light by the nanowire array has been used as a measure to study the effects of defects in the patterned structures using NSL both experimentally and by simulation. Both studies show similar reflection behavior between nanowire prepared by EBL and NSL. GaAs nanowires as short as 130 nm show reflection of <10% over the visible range of solar spectrum. Optimized nanowire configuration to maximize the absorption has also been discussed.

11:27AM W17.00002 Theory of photoluminescence polarization reversal in GaAs nanowires, W.R.L. LAMBRECHT, T. CHEIWCHANHAMNANGIJ, T. BIRKEL, CWRU, AL. L. EFROS, NRL — The polarization of photoluminescence (PL) in wurtzite (WZ) GaAs nanowires (NW) of diameter 100 nm has been observed to reverse as a function of temperature from perpendicular to parallel to the NW axis. We use the weak confinement limit for excitons and the envelope function approximation to study this phenomenon. The WZ GaAs crystal field and spin-orbit splittings were determined using GW calculations and agree well with resonant Raman spectra on WZ NWs. In contrast to zincblende (ZB) NWs, the crystal field splitting in WZ NWs leads to a perpendicularly polarized exciton ground state. The first excited state, however, has a parallel component and can be mixed in at slightly elevated temperature, leading to a polarization reversal. We find that a reversal can only take place for much smaller crystal field splittings than the one obtained in pure WZ. Strain induced reduction of the crystal field splitting would require an unrealistically large strain. On the other hand, multiple twinning, can lead to a substantially lower crystal field splitting as obtained from our GW calculations for lower hexagonality polytypes, such as 4H GaAs, and can thus explain the observed polarization reversals.

11:39AM W17.00003 Phonon Spectrum and Thermal Properties of free standing <100> and <111> InGaAs alloy nanowires, MEHDI SALMANI JELODAR, ABHIJEET PAUL, Purdue University, TIMOTHY BOYKIN, University of Alabama in Huntsville, GERHARD KLIMECK, Purdue University — The phonon spectra in zinc blende InAs, GaAs and their ternary alloy nanowires (NWs) are computed using an enhanced valence force field (EVFF) model. The physical and thermal properties of these nanowires such as sound velocity, elastic constant, specific heat (Cv), phonon density of states, phonon modes, and the ballistic thermal conductance are explored. The calculated transverse and longitudinal sound velocities along <100> direction in these NWs are ~25% and 20% smaller compared to the bulk velocities, respectively. These velocities along <111> direction are about twice smaller than bulk values. The Cv for NWs are about twice as large as the bulk values due to higher surface to volume ratio (SVR) and strong phonon confinement in the nanostructures. The temperature dependent Cv for InAs and GaAs nanowires show a cross-over at 180K and 155K along <100> and <111> directions respectively. It happens due to higher phonon density in InAs nanowires at lower temperatures. With the phonon spectra and Landauer's model the ballistic thermal conductance is reported for these III-V NWs. The results in this work demonstrate the potential to engineer the thermal behavior of III-V NWs.

11:51AM W17.00004 How and why a magnetized quantum wire can act as an optical amplifier, MANVIR KUSHWAHA, Rice University — The fundamental issues associated with the magnetoplasmon excitations are investigated in a quantum wire characterized by a confining harmonic potential and subjected to a perpendicular magnetic field. Essentially, we embark on the device aspects of the intersubband collective (magnetoroton) excitations which observe a negative group velocity between the maxon and the roton. The computation of the gain coefficient suggests an interesting and important application: the electronic device based on such magnetoroton modes can act as an optical amplifier.¹

12:03PM W17.00005 Electronic band structure calculations of bismuth-antimony nanowires, ANDREI LEVIN, Harvard University, MILDRED DRESSELHAUS, Massachusetts Institute of Technology — Alloys of bismuth and antimony received initial interest due to their unmatched low-temperature thermoelectric performance, and have drawn more recent attention as the first 3D topological insulators. One-dimensional bismuth-antimony (BiSb) nanowires display interesting quantum confinement effects, and are expected to exhibit even better thermoelectric properties than bulk BiSb. Due to the small, anisotropic carrier effective masses, the electronic properties of BiSb nanowires show great sensitivity to nanowire diameter, crystalline orientation, and alloy composition. We develop a theoretical model for calculating the band structure of BiSb nanowires. For a given crystalline orientation, BiSb nanowires can be in the semimetallic, direct semiconducting, or indirect semiconducting phase, depending on nanowire diameter and alloy composition. These “phase diagrams” turn out to be remarkably similar among the different orientations, which is surprising in light of the anisotropy of the bulk BiSb Fermi surface. We predict a novel direct semiconducting phase for nanowires with diameter less than ~15 nm, over a narrow composition range. We also find that, in contrast to the bulk and thin film BiSb cases, a gapless state with Dirac dispersion cannot be realized in BiSb nanowires.

12:15PM W17.00006 Gas phase interactions with bare and gold nanoparticle decorated gallium nitride nanowires by ultraviolet photoelectron spectroscopy¹, ISHWAR NIRLAULA, BLAISE-ALEXIS KENGNE, DAVID MCILROY, University of Idaho — Ultraviolet photoelectron spectroscopy (UPS) has been used to characterize the interaction of CO and H₂O with the surface of bare and gold nanoparticle (Au NP) decorated gallium nitride nanowires at 298 K, 77 K and 20 K. The average diameter of the Au NPs is 4.5 ± 0.5 nm and the average nanowire diameter is 105 ± 75 nm. CO and H₂O do not bond to the surface of the bare GaN nanowires at 298K, 77K, or 20K. Temperature dependent UPS analysis reveals that CO and H₂O weakly physisorbed to the Au NP decorated GaN nanowires with heats of adsorption of 4.37 ± 0.03 meV and 1.25 ± 0.04 meV, respectively. The adsorption at 298K of 50 Langmuir of CO followed by 50 Langmuir of H₂O showed that CO adsorption promotes H₂O adsorption, while 50 Langmuir of H₂O followed by 50 Langmuir of CO showed that H₂O inhibits CO adsorption. The findings of this study that the adsorption of H₂O inhibits CO adsorption onto the Au NP-GaN nanowires explains previous studies of the gas sensing properties of mats of Au NP- GaN nanowires.

12:27PM W17.00007 Genomic design of strong direct-gap optical transition in Si/Ge core/multishell nanowires¹, LIJUN ZHANG, MAYEUL D'AVEZAC, JUN-WEI LUO, National Renewable Energy Laboratory, ALEX ZUNGER, University of Colorado — Converting the electronically superior but optically impractical indirect-gap Si and Ge semiconductors into a strongly light-absorbing system has been a long-standing challenge, given that the phonon-assisted optical transition of the indirect gap has weak intensity, requiring thick absorbers. One of main strategies has been the use of two-dimensional (2D) layer-by-layer growth of Si/Ge superlattices (SLs). However, the maximum thickness of SLs that can be grown coherently on a substrate is limited by the lattice-mismatch-induced strain. This limitation can be greatly relaxed by changing from 2D SLs to one-dimensional quantum nanowire (NW), where much higher strain can be accommodated. With developed Vapor-Liquid-Solid based technique, experimental growth of Si/Ge core-multishell NWs has recently demonstrated a significant level of synthetic control. However, the number of possible core/multishell sequences and thicknesses might easily reach an astronomical value. We will present here a genomic search for targeted core/multishell NW geometries that give both a direct gap and a significantly enhanced dipole-allowed optical transition in the Si/Ge system, by using a combination of genetic algorithm with atomistic pseudopotential electronic-structure calculations.

12:39PM W17.00008 Axially-Resolved Luminescence of Individual ZnSe Nanowires¹, S.K. HARK, JUNPING ZHUANG, The Chinese University of Hong Kong, WAI-NING MEI, University of Nebraska at Omaha — Axially resolved distributions of luminescence intensity and lifetimes along individual ZnSe nanowires were studied using two-photon excited luminescence imaging and time-correlated single photon counting techniques. The nanowires were grown on GaAs substrates via the self-catalyzed VLS mode. An intense tip, to which a gallium particle is attached, is found for the deep level (DL) emissions via luminescence imaging, while the intensity for the near band edge (NBE) emissions is more uniform. The luminescence decays at all locations of the nanowires are dominated by a fast process at early times, followed by a slow one. In addition, the shape of distribution of the lifetimes along the length of nanowire resembles a flattened letter "U" for the NBE emissions, but it resembles a long tailed letter "L" for the DL emissions. Possible explanations of these results will be discussed.

12:51PM W17.00009 ABSTRACT WITHDRAWN —

1:03PM W17.00010 Studies of electronic excitations of rectangular ZnO nanorods by electron energy-loss spectroscopy, CHIEN-TING WU, National Nano Device Laboratories, National Applied Research Laboratories, Taiwan, MING-WEN CHU, Center for Condensed Matter Sciences, National Taiwan University, Taiwan, CHUAN-PU LIU, Dept. of Materials Science and Engineering, National Cheng Kung University, Taiwan, KUEI-HSIEN CHEN, Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan, LI-CHYONG CHEN, Center for Condensed Matter Sciences, NTU, Taiwan, CHUN-WEI CHEN, Dept. of Materials Science and Engineering, NTU, Taiwan, CHENG-HSUAN CHEN, Center for Condensed Matter Sciences, NTU, Taiwan — Electronic excitations of single ZnO rectangular nanorod have been investigated by electron energy-loss spectroscopy in conjunction with scanning transmission electron microscopy (STEM-EELS). We focus primarily on the surface excitations greatly enhanced at the grazing incidence parallel to the surfaces of ZnO nanorods. An uncommon kind of surface excitation known as surface exciton polaritons occurring near interband transitions is found to dominate in the spectral range between the band gap at 3.4 eV and the surface plasmon peak at 15.8 eV. In addition, the dielectric function of ZnO up to 25 eV has also been derived from the bulk excitation spectra using the Kramers-Kronig analysis on a single nanorod. Theoretical EELS simulations are also compared with the experimental results and good agreements are obtained.

1:15PM W17.00011 Precise investigation of optical/electronic fine structures of nanostructures via cathodoluminescence spectroscopy, DAPENG YU, XINLI ZHU, JIASSEN ZHANG, ZHIMIN LIAO, XIAOBING HAN, QIANG FU, State Key Laboratory for Mesoscopic Physics, and Electron Microscopy Laboratory, Department of Physics, Peking University, Beijing 100871, P.R.China, WANLIN GUO, Institute of Nano Science, Nanjing University of Aeronautics and Astronautics, Nanjing 210016, P.R.China, XUEWEN FU, JUN XU, State Key Laboratory for Mesoscopic Physics, and Electron Microscopy Laboratory, Department of Physics, Peking University, Beijing 100871, P.R.China, PEKING UNIVERSITY COLLABORATION, NANJING UNIVERSITY OF AERONAUTICS AND ASTRONAUTICS COLLABORATION — High special/energy resolution cathodoluminescence (CL) spectroscopy enables us to make precise investigation on the optical/electronic fine structures in nanostructures. The linear distribution of strain gradient from tensile to compression in bent ZnO nano/microwires provides ideal conditions to address the modification of the electronic structures by strain in semiconductor materials. Radial line scan of the CL spectroscopy along bent ZnO wires at liquid helium temperature shows very fine excitonic emission structures, which demonstrates systematic red shift towards the increase of tensile strain, and blue shift as well as excitonic peak splitting towards the increase of compressive strain. First-principle simulations reveal an electronic band structure evolution under continuously tuned strain.

1:27PM W17.00012 Raman scattering study of mixed metal oxide Ir_xRu_{1-x}O₂ nanowires grown by chemical vapor deposition, HAE-YOUNG SHIN, Department of Physics, Ewha Womans University, Seoul, 120-750, Korea, YUMIN LEE, SUNG HEE CHUN, JAEYEON LEE, MYUNG HWA KIM, Department of Chemistry and Nano Sciences, Ewha Womans University, Seoul, 120-750, Korea, SEOKHYUN YOON, Department of Physics and Department of Chemistry and Nano Sciences, Ewha Womans University, Seoul, 120-750, Korea — We present Raman scattering results of mixed metal oxide Ir_xRu_{1-x}O₂ nanowires that have been studied for their stability and for activity as electrocatalysts. For our study, 1-dimensional metallic mixed oxide single crystalline Ir_xRu_{1-x}O₂ nanowires were synthesized, for the first time, via a simple physical vapor transport process by controlling relative ratios of two precursors, RuO₂ and IrO₂, respectively. We measured Raman spectra of Ir_xRu_{1-x}O₂ nanowires using excitation laser sources with wavelengths of 488 nm and 632.8 nm. We observed that an E_g phonon mode of an Ir_xRu_{1-x}O₂ nanowire is being blue-shifted linearly with respect to the Ir contents. We could use our observation of frequency shift of the E_g phonon to determine stoichiometry information of nanowires which we also measured and confirmed by using EDS. From the shape of the phonon modes we measured, we could get information regarding crystalline quality that was also measured by HRTEM. We show that Raman scattering spectroscopy can provide a simple, prompt, and effective mean to measure the stoichiometry and crystalline quality of mixed metal oxide nanowires.

1:39PM W17.00013 Strain effects in polytypical wurtzite/zinc-blend nanowhiskers¹, GUILHERME SIPAHI, PAULO FARIA, Instituto de Física de Sao Carlos - Universidade de Sao Paulo — The recent interest on III-V nanowhiskers has led to the growth of high quality samples of systems with two different crystalline structures [1]. The crystals grown in [111]-direction for the zinc-blend (ZB) phase and [0001]-direction for the wurtzite (WZ) phase are very similar and can both be described as stacked hexagonal layers. The effect of two different structural phases coexisting in the same nanostructure is known as polytypism and creates confinement profiles similar to a heterostructure. One can notice band offsets at the interface and the formation of electronic minibands that can be explored to design systems for device applications. Although some of the III-V compounds do not present WZ structure in bulk form, recent calculations [2] presented a theoretical prediction of their band structure. However, as they considered that ZB and WZ to have the same lattice parameters no strain effects should appear on a first approach. Our theoretical approach introduces strain effects in our previous model [3] by using group theory arguments. It allows the analysis of the biaxial strain effects for both structures in a single matrix. [1] P. Caroff et al. Nature Nanotech. 4, 50, 2009. [2] A. De and C. E. Pryor, Phys. Rev. 1:51PM W17.00014 Quantum Zigzag Phase Transition in Quantum Wires¹, ABHIJIT C. MEHTA, Duke University, CYRUS J. UMRIGAR, Cornell University, HAROLD U. BARANGER, Duke University — We use Quantum Monte Carlo (QMC) techniques to study the quantum phase transition of interacting electrons in quantum wires to a quasi-one dimensional zigzag phase. The phase diagram of particles with Coulomb interaction that undergo a linear to zigzag transition is relevant to electrons in quantum wires [Meyer et al, PRL 2007] and ions in linear traps [Simshoni et al., PRL 2011]. Interacting electrons confined to a wire by a transverse harmonic potential form a Wigner crystal at low densities; as density increases, symmetry about the axis of the wire is broken and the electrons undergo a transition to a quasi-one-dimensional zigzag phase. Using QMC, we characterize this phase transition by measuring the power spectrum and addition energies.

2:03PM W17.00015 Raman Spectroscopy and Strain Mapping in Individual Ge- Si_xGe_{1-x} Core-Shell Nanowires¹, DAVID DILLEN, KAMRAN VARAHRAMYAN, EMANUEL TUTUC, University of Texas at Austin — Core-shell Ge-Si_xGe_{1-x} nanowires (NWs) are expected to contain large strain fields due to the lattice-mismatch at the core/shell interface. Here we report measurement of the core strain in such NW heterostructures by Raman Spectroscopy. We measure the diameter dependence of Raman spectra in individual Ge NWs, as well as Ge-Si_xGe_{1-x} core-shell NW heterostructures. We find that the bare Ge NWs show no diameter-dependence of the Ge-Ge peak at 300.5 cm^{-1} . On the other hand, the Ge-Ge peak of the Ge-Si_xGe_{1-x} core-shell NW shows a blue shift by comparison to the bare Ge NWs. This blue shift increases with reducing the NW diameter as a result of larger compressive strain in the Ge core. While the elastic strain is expected to split the triply degenerate Ge-Ge mode into separate singlet and doublet peaks, only the singlet mode was observed in experiment, a finding explained by the NW absorption and emission anisotropy. Using lattice dynamical theory and the Raman spectroscopy results we determine the strain in Ge-Si_xGe_{1-x} core-shell NWs as a function of the NW diameter. We compare the experimental results with the strain values calculated using a continuum elasticity model.

252B

11:15AM W18.00001 Mesoscopic transport properties of LaAlO₃/SrTiO₃ devices, DANIELA STORNAIUOLO, STEFANO GARIGLIO, ALEXANDRE FETE, NUNO COUTO GUIMARÃES, DANFENG LI, ANDREA CAVIGLIA, CLAUDIA CANCELLIERI, ALBERTO MORPURGO, JEAN-MARC TRISCONE, DPMC - University of Geneva — The conducting interface between the two band insulators LaAlO₃ and SrTiO₃ [1], with its unique electronic properties, stands as a prominent example of an oxide heterostructure for the realization of multifunctional devices. Using the electric field effect the ground state of this system can be tuned from insulating to superconducting [2]. Recently we demonstrated also the possibility to tune the carriers mobility by changing the deposition conditions of the LaAlO₃ film [3] and measured Shubnikov-de Haas oscillations, whose analyses demonstrate the 2D nature of the electronic states at the interface [3,4]. We are currently focusing on the realization of devices where the 2D quantum nature of the electronic states can be fully exploited. We show the feasibility of structures with lateral dimensions down to few hundreds nanometers, using an electron beam lithography based process. The lateral confinement of the electron gas in these devices is demonstrated by a phase coherent transport regime, which can be tuned by electric field.

11:27AM W18.00002 Sketched Oxide Single-Electron Transistor¹, JEREMY LEVY, GUANGLEI CHENG, JOSH VEAZEY, PATRICK IRVIN, MENGCHEN HUANG, Department of Physics and Astronomy, University of Pittsburgh, CHUNG-WUNG BARK, SANGWOO RYU, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison — Devices that confine and process single electrons represent an important scaling limit of electronics. Such devices have been realized in a variety of materials and exhibit remarkable electronic, optical and spintronic properties. Here, we use an atomic force microscope tip to reversibly “sketch” single-electron transistors by controlling a metal-insulator transition at the interface of two oxides.² In these devices, single electrons tunnel resonantly between source and drain electrodes through a conducting oxide island with a diameter of ~ 1.5 nm. We demonstrate control over the number of electrons on the island using bottom- and side-gate electrodes, and observe hysteresis in electron occupation that is attributed to ferroelectricity within the oxide heterostructure. These single-electron devices may find use as ultradense non-volatile memories, nanoscale hybrid piezoelectric and charge sensors, as well as building blocks in quantum information processing and simulation platforms.

11:39AM W18.00003 Unexpected magnetic Exchange Interaction between Epitaxial $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$ film and a two Dimensional Electron Gas at an $\text{LaAlO}_3/\text{SrTiO}_3$ Interface¹, W.M. LU, X. WANG, Z.Q. LIU, K. GOPINADHAN, A. ANNADI, S.W. ZENG, Z. HUANG, S. DHAR, - ARIANDO, T. VENKATESAN, NUSNNI-Nanocore, University of Singapore, Singapore — We have examined the electrical and magnetic properties of LSMO films epitaxially grown on STO, LAO and LAO/STO substrates. Compared to LAO and STO the LSMO films on LAO/STO shows a higher metal-insulator transition temperature and also an order of magnitude larger magnetization. The magnetic hysteresis loops measured in pinning fields show a large exchange coupling for the case of the LAO/STO substrate and the sign of the coupling supports a ferromagnet to a ferromagnet exchange. The magnetization measured arises from a combination of substrate magnetism and that of the film and the enhanced conductivity, metal-insulator transition temperature and magnetization can be accounted for by the exchange coupling between the magnetic phase observed in the LAO/STO interfaces and the LSMO layer. The decay length of this interaction in LSMO is 90 nm which is surprisingly much longer than has been observed in ferromagnetic metals. Furthermore, the discovery of a long range oscillatory magnetic exchange coupling with LAO thickness suggests a role for the LAO layer beyond a simple insulator in this magnetic heterostructure.

11:51AM W18.00004 Quantum spin hall effect in $\text{LaAlO}_3/\text{SrTiO}_3$ nanostructures¹, GUANGLEI CHENG, University of Pittsburgh — $\text{LaAlO}_3/\text{SrTiO}_3$ heterostructures are known to exhibit strong spin-orbit coupling. We investigate local and non-local transport behavior of nanoscale Hall crosses created by conductive AFM lithography. The four-terminal resistance of these structures is consistently found to be $\sim h/e^2$, independent of the length of the channel. We also observe large (1-10 k Ω) non-local resistances and zero-field Hall resistance that are attributed to quantum spin Hall phase with a spin-orbit derived pseudo-magnetic fields $B_{\text{eff}} \sim 15$ T. The pure spin current is blocked by Cooper pairs that form below T_c 200 mK, leading to a collapse of the non-local and zero-field Hall resistances.

12:27PM W18.00005 Nonvolatile Ferroelectric Manipulation of Electronic Structure at LAO/STO Heterointerface, JHIH-WEI CHEN, Department of Physics, National Cheng Kung University, Tainan, Taiwan, TRA-VU THANH, JIUNN-YUAN LIN, Institute of Physics, National Chiao-Tung University, Hsinchu, Taiwan, YING-HAO CHU, Department of Material Science and Engineering, National Chiao-Tung University, Hsinchu, Taiwan, YI-CHUN CHEN, CHUNG-LIN WU, Department of Physics, National Cheng Kung University, Tainan, Taiwan — Hetero-interfaces between different oxide insulators have attracted a lot of interests. One of the most important system is the 2D electron gas at LaAlO_3 (LAO) and SrTiO_3 (STO), which had been reported to possess metallic conduction and superconductivity. In this study, the top-patterned $\text{Pb}(\text{Zr}_{0.2}\text{Ti}_{0.8})\text{O}_3$ ferroelectric layer epitaxially grown on LAO/STO was proposed as a nonvolatile electronic modulation, and the interface band deformation was investigated using photoelectron spectroscopy (PES). Result showed different thickness and polarization state of top PZT significantly affected the band structure and its corresponding valence band offset at the LAO/STO hetero-interface. The transport data indicated that the as-grown PZT would deplete the conducting interface of LAO/STO, while switching the polarization of PZT would enhance the interface conduction.

12:39PM W18.00006 Non-local piezoresponse in 3 u.c. $\text{LaAlO}_3/\text{SrTiO}_3$, MENGCHEN HUANG, FENG BI, University of Pittsburgh, CHUNGWUNG BARK, SANGWOO RYU, CHANGBEOM EOM, University of Wisconsin, JEREMY LEVY, University of Pittsburgh — Nanoscale control of the metal-insulator transition in 3 unit cell (u.c.) $\text{LaAlO}_3/\text{SrTiO}_3$ heterostructures can be achieved by the conducting AFM lithography,¹ however the mechanism behind this transition is still not well understood. One proposed mechanism invokes ionic transport through the LaAlO_3 layer.² We have performed a variety of local and non-local piezoforce measurements on 3 u.c. $\text{LaAlO}_3/\text{SrTiO}_3$ heterostructures. The existence and nature of the non-local piezoelectric effect places strong constraints on the origin of the piezoelectric response. This work is supported by NSF DMR-1104191.

12:51PM W18.00007 Piezoresponse Force Microscopy of Gated $\text{LaAlO}_3/\text{SrTiO}_3$ Heterostructures¹, FENG BI, MENGCHEN HUANG, Department of Physics and Astronomy, University of Pittsburgh, CHUNGWUNG BARK, SANGWOO RYU, CHANG-BEOM EOM, Department of Materials Science, University of Wisconsin, Madison, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — The quasi-two-dimensional (q-2DEG) electron liquid at the $\text{LaAlO}_3/\text{SrTiO}_3$ (LAO/STO) interface can be tuned through the metal-insulator transition using a metallic top gate. At low carrier densities, the capacitance between the top gate and q-2DEG is significantly enhanced beyond the geometric capacitance.² In order to understand the origins of this enhancement in capacitance, we have performed spatially resolved piezo-force microscopy (PFM) on a top-gated 5u.c. LAO/STO structure. A large enhancement in piezoresponse is observed as the interface is switched to the conducting phase. Within the transition region, spatial structures or domains are observed. We propose that such measurement can provide new insights into the metal-insulator transition of the interface, and the associated capacitance enhancement.

¹This work is supported by NSF DMR-1104191.

1:03PM W18.00008 Ferroelectric control of two dimensional electron gas in oxide heterointerface¹, TRA VU THANH, Institute of Physics, National Chiao-Tung University, Hsinchu, Taiwan, JHIH-WEI CHEN, Department of Physics, National Cheng-Kung University, Tainan, Taiwan, CHAO-HUI YEH, Department of Electrical Engineering, National Tsing Hua University, Hsinchu, Taiwan, YI-CHUN CHEN, CHUNG-LIN WU, Department of Physics, National Cheng-Kung University, Tainan, Taiwan, JIUNN YUAN LIN, Institute of Physics, National Chiao-Tung University, Hsinchu, Taiwan, YING-HAO CHU, Department of Material Science and Engineering, National Chiao-Tung University, Hsinchu, Taiwan — Oxide heterointerfaces are emerging as one of the most exciting materials systems in condensed-matter science. One remarkable example is the $\text{LaAlO}_3/\text{SrTiO}_3$ (LAO/STO) interface, a model system in which a highly mobile electron gas forms between two band insulators. Our study to manipulate the conductivity at this interface by using ferroelectricity of $\text{Pb}(\text{Zr,Ti})\text{O}_3$. Our transport data strongly suggests that down polarization direction depletes the conducting interface of LAO/STO. After switching the polarization direction (up), it becomes accumulation. In addition, our experiments show there is obvious the band structure changed by cross-sectional scanning tunneling microscopy and combining with X-ray photoelectron spectroscopy (XPS) measurements. The transport properties are measured to build up the connection between macroscopic properties and local electronic structures that have been applied to study this structure. Controlling the conductivity of this oxide interface suggests that this technique may not only extend more generally to other oxide systems but also open much potential to ferroelectric field effect transistors.

1:15PM W18.00009 Anomalous High Mobility in $\text{LaAlO}_3/\text{SrTiO}_3$ Nanowires¹, PATRICK IRVIN, JOSHUA VEAZEY, GUANGLEI CHENG, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA 15260, C.W. BARK, S. RYU, C.B. EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, Madison, WI 53706 — Nanoscale control over the $\text{LaAlO}_3/\text{SrTiO}_3$ interface² provides a possible pathway for reconfigurable oxide-based nanoelectronics at densities that exceed conventional silicon electronics. One of the central challenges in replacing silicon relates to energy dissipation, which in turn depends on the carrier mobility. We have performed four-terminal transport measurements of $\text{LaAlO}_3/\text{SrTiO}_3$ nanowires at room temperature (300 K) and at low temperature (~ 500 mK). We find that the equivalent 2D mobility of nanowires greatly exceeds that of bulk SrTiO_3 ($\mu_{\text{STO}} = 6 \text{ cm}^2/\text{Vs}$), and approaches that of optimally doped Si at room temperature. Low-temperature mobilities can exceed $30,000 \text{ cm}^2/\text{Vs}$. We discuss possible physical mechanisms to explain the anomalously high mobility and the implications for future device technologies.

¹This work is supported by NSF NEB-1124131.

1:27PM W18.00010 First-principles modeling of $\text{Pt}/\text{LaAlO}_3/\text{SrTiO}_3$ nanocapacitors under an external bias potential, CLAUDIO CAZORLA, MASSIMILIANO STENGEL, Institute of Materials Science of Barcelona — We study the electronic, structural and electrical properties of $\text{Pt}/\text{LaAlO}_3/\text{SrTiO}_3$ nanocapacitors under the action of an external applied bias, using first-principles calculations performed at fixed electric displacement D . In particular, we deduce a complete set of *ab initio* band diagrams and a simple analytical expression for the electric field within the LaAlO_3 (LAO) film as a function of thickness and applied potential. In addition, we investigate the capacitance of the metal-oxide heterostructure in a field-effect transistor setup. We find that the electric field within LAO is a non-intrinsic quantity that monotonically decreases with increasing LAO thickness. The occurrence of spontaneous Zener tunneling in this system, therefore, is ruled out. We discuss the implications of our results in the light of recent experimental observations involving biased LAO/STO junctions and metallic top electrodes.

1:39PM W18.00011 THz rectified optical response of $\text{LaAlO}_3/\text{SrTiO}_3$ nanojunctions, YANJUN MA, Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA 15260, USA, CHUNG WUNG BARK, SANGWOO RYU, CHANG-BEOM EOM, Department of Materials Science, University of Wisconsin, Madison, WI 53706, USA, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA 15260, USA — Conducting AFM lithography can be used to create a variety of nanoscale devices at the $\text{LaAlO}_3/\text{SrTiO}_3$ interface^{1,2}. Nanoscale junctions have been shown to exhibit strongly localized photoconductivity over a range of wavelengths spanning the visible and near-infrared regime³. Power-dependent and interferometric measurements of these nanostructures with ultrafast laser pulses reveal a nonlinear photoconductive response attributed to second-order nonlinear susceptibility of SrTiO_3 . The breaking of inversion symmetry comes from the strong local electric field that extends across the junction. The ultrafast response of these nanojunctions make them attractive candidates for generation and detection of THz radiation at molecular scales. This work is supported by NSF DMR-1104191.

1:51PM W18.00012 Tuning the two-dimensional electron gas at the $\text{LaAlO}_3/\text{SrTiO}_3(001)$ interface by metallic contacts¹, ROSSITZA PENTCHEVA, REMI ARRAS, VICTOR G. RUIZ LOPEZ, Ludwig Maximilians University Munich, Germany, WARREN E. PICKETT, University of California, Davis — Density functional theory calculations reveal that adding a metallic overlayer on $\text{LaAlO}_3/\text{SrTiO}_3(001)$ reduces/eliminates the electric field within the polar LaAlO_3 film and thus suppresses the thickness-dependent insulator-to-metal transition observed in uncovered films. Independent of the LaAlO_3 thickness both the surface and the interface are metallic, with an enhanced interface carrier density relative to $\text{LaAlO}_3/\text{SrTiO}_3(001)$ after the metallization transition. Moreover, a monolayer thick metallic Ti-contact exhibits a finite magnetic moment and for a thin SrTiO_3 -substrate induces a spin-polarized 2D electron gas at the *n*-type interface due to confinement effects. The height of the Schottky barrier formed between the metal contact and LaAlO_3 depends strongly on the choice of the overlayer and allows to tune the carrier density at the interface [1].

2:03PM W18.00013 Spatial Analogue of Quantum Spin Dynamics via Spin-Orbit Interaction¹, VANITA SRINIVASA, JEREMY LEVY, University of Pittsburgh — We theoretically demonstrate the mapping of electron spin dynamics from time to space in quantum wires with built-in spatially uniform and oscillating Rashba spin-orbit coupling in orthogonal directions. The presence of the spin-orbit interaction introduces pseudo-Zeeman couplings of the electron spins to effective magnetic fields. By periodically modulating the spin-orbit coupling along the quantum wire axis, it is possible to create the spatial analogue of spin resonance, without the need for real magnetic fields. The mapping of time-dependent operations onto a spatial axis suggests a new mode for quantum information processing in which gate operations are encoded into the band structure of the material. We describe a potential realization of such a material within nanowires at the interface of $\text{LaAlO}_3/\text{SrTiO}_3$ heterostructures.

Thursday, March 1, 2012 11:15AM - 2:15PM —
Session W19 DCMP: Invited Session: Spin Coupling and Kondo Screening in Individual Magnetic Spins 253AB

11:15AM W19.00001 The Impact of the Local Environment on the Kondo Screening of a High-Spin Atom, CYRUS F. HIRJIBEHDIN, London Centre for Nanotechnology, Dept. of Physics & Astronomy, Dept. of Chemistry, UCL, London, UK — Spin 1/2 Kondo systems have been investigated extensively in theory and in a variety of experimental geometries. However the magnetic atoms that give rise to the Kondo effect in metals often have a larger spin, which makes the properties of the system more complex. Using low-temperature scanning tunneling microscopy and spectroscopy, we explore the Kondo effect of individual high-spin magnetic atoms on small islands of the thin insulator copper nitride (Cu_2N) in $\text{Cu}(100)$ surfaces. Using a combination of elastic spectroscopy to probe the local density of states features arising from the Kondo screening and inelastic tunneling spectroscopy to study the higher energy spin excitations, we determined the spin of the atom and explore its impact on the Kondo resonance [1]. We find that the local magnetic anisotropy plays a decisive role in the physics of Kondo screening. In addition, we find that the splitting of the Kondo peak matches the splitting of the underlying unscreened spin levels, and surprisingly does not show any evidence of a renormalization of energy scales even though large renormalizations have been predicted for lower spin system. In addition, we find remarkably large variations in the strength of both the Kondo screening and magnetic anisotropy for Co atoms on both small and large Cu_2N islands. In both cases, the anisotropy and Kondo screening are inversely related: the Kondo resonance weakens as the anisotropy increases. For small islands, the Kondo screening is strongest near the center of the island, while for large island this trend is reversed. We examine the possible origins of this phenomenon, including variations in the physical and electronic structure of the Cu_2N surface.

11:51AM W19.00002 Mechanical Control of Spin States in Spin-1 Molecules and the Under-screened Kondo Effect¹, DANIEL RALPH, Cornell University — The ability to make electrical contact to single molecules creates opportunities to examine fundamental processes governing electron flow on the smallest possible length scales. We report experiments in which we controllably stretched individual molecules with spin $S = 1/2$ and $S = 1$ while simultaneously measuring Kondo-assisted current flow through the molecule as a probe of its spin states. For molecules with $S = 1/2$, the temperature dependence of the Kondo signal is in excellent agreement with the predicted universal scaling curves for the $S = 1/2$ Kondo effect and the molecular spin states exhibit no energy splitting with stretching, consistent with Kramers' theorem. However, for cobalt complexes we observe temperature scaling curves that are very different from the $S = 1/2$ Kondo predictions, and instead are in quantitative agreement with the predictions of the underscreened Kondo model for $S = 1$, in which conduction electrons only partially compensate the molecular spin. This allows us to identify the spin state as $S = 1$. As a function of stretching, the $S = 1$ molecules exhibit energy splittings of the spin states in the absence of magnetic field due to magnetic anisotropy arising from modification of the molecular symmetry. These findings demonstrate a mechanism of spin control in single-molecule devices and establish that they can serve as model systems for making precision tests of correlated-electron theories.

¹This research was performed primarily by Joshua J. Parks, in collaboration with A. R. Champagne, T. A. Costi, W. W. Shum, A. N. Pasupathy, E. Neuscamman, S. Flores-Torres, P. S. Cornaglia, A. A. Aligia, C. A. Balseiro, G. K.-L. Chan, and H. D. Abruña.

12:27PM W19.00003 STEM in Kondo Lattices: a new window on correlated electron materials¹, PIERS COLEMAN, Physics and Astronomy, Rutgers University — The tremendous developments in scanning tunneling electron spectroscopy over the past decade, applied with tremendous success to the cuprate superconductors, are now beginning to be applied to other strongly correlated electron systems. One area where they offer tremendous potential, is in the context of heavy fermion materials. In the last few years, it has become possible to start probing the physics of the Kondo lattice using STEM methods. In this talk I will review this field, discussing the physics of tunneling into the Kondo lattice, showing how tunneling involves a co-operative process of electron transfer and spin-flip, called "cotunnelling" [1,2]. I will provide an overview of latest results in this field, especially URu_2Si_2 [3,4], YbRh_2Si_2 [5] and CeCoIn_5 [6], discussing how STEM can be used to probe various new theoretical proposals [7,8] for the exotic order and critical behavior.

1:03PM W19.00004 Pseudo-spin Resolved Transport Spectroscopy of the Double Dot Kondo Effect, SAMI AMASHA, Stanford University — The Kondo effect is a paradigmatic example of a highly correlated many-body state, describing how conduction electrons screen a localized spin via spin-flip scattering. Experimentally probing the spin physics of the Kondo effect is challenging, as spin-resolved measurements require either large magnetic fields that break the spin degeneracy of the localized site or ferromagnetic contacts that give the spin states different tunnel rates to the localized site. We demonstrate how the desired spin resolution can be achieved for arbitrary tunnel rates and fields in a double quantum dot system. A quantum dot consists of a confined droplet of electrons connected by tunnel barriers to conducting leads. We study two dots that are capacitively coupled with negligible inter-dot tunneling. In this system, one can have a degeneracy associated with an electron being in either dot 1 or dot 2, and this degeneracy acts as a pseudo-spin degree of freedom that gives rise to Kondo screening. We present transport spectroscopy measurements that show the zero-bias peak that is the hallmark of the Kondo effect. We use gate voltages to break the degeneracy between the pseudo-spin states, creating a pseudo-magnetic field. We show that spectroscopy measurements in this regime are analogous to measurements of the spin Kondo effect in a magnetic field. Finally, we demonstrate how measuring transport through each dot individually as a function of the bias voltage on the measured dot gives us the ability to perform pseudo-spin resolved measurements that are difficult to achieve in spin systems.

1:39PM W19.00005 Evolution of Kondo Resonance from a Single Impurity Molecule to the Two-Dimensional Kondo Lattice, NORIAKI TAKAGI, The University of Tokyo — We investigated the Kondo resonance formed by the adsorption of magnetic molecule, iron(II) phthalocyanine (denoted as FePc), on $\text{Au}(111)$ from a single impurity regime to the two-dimensional Kondo lattice by using scanning tunneling microscopy, the density functional theory (DFT) and numerical renormalization group (NRG). In the single molecule regime, FePc takes on-top and bridge configurations. These species show characteristic Kondo signatures in their one-particle energy spectra depending on the adsorption site. The on-top species shows a broad peak accompanied by a sharp dip, while the bridge species only a broad peak. The origin of these features comes from the difference in the local symmetry around the Fe ion. The two-stage Kondo screening occurs for two localized electrons in the different 3d orbitals characterized by low and high Kondo temperatures, reflecting the different coupling strength of these orbitals with $\text{Au}(111)$. For the on-top species, highly-symmetric $\text{SU}(4)$ Kondo effect is realized, leading to the sharp dip. The dip observed for the on-top species is also evolved from the single impurity regime to the two-dimensional lattice. The spectral evolution and the quantum phase of the lattice are discussed by the competition of the Kondo effect with antiferromagnetic RKKY coupling between the molecular spins.

11:15AM W20.00001 The Accident at TEPCO's Fukushima-Daiichi Nuclear Power Plant: Technical Description of What Happened and Lessons Learned for the Future, AKIRA OMOTO, The University of Tokyo — Tsunami that followed M9.0 earthquake on March 11th left the Fukushima-Daiichi Nuclear Power Plants without power and heat sink. While water makeup continued by AC-independent systems to keep the fuel core covered by coolant, operating team tried to depressurize and enable low pressure injection to the reactor to avoid overheating but was not successful enough primarily due to limited available resources. This resulted in core melt, hydrogen explosion and release of radioactivity to the environment. Key lessons learned are; 1) safety regulation and safety culture, 2) workable/executable severe accident management procedure, 3) crisis management and 4) design. Implications on security include revealed vulnerability and the nexus of safety and security. Given the scale of damage to the environmental, attention must be paid to defense against it and to societal safety goal of nuclear power by considering offsite remedial costs, compensation to damage, energy replacement cost etc. A sort of root cause analysis first by asking "Why nuclear community failed to prevent this accident?" was initiated by the University of Tokyo.

11:51AM W20.00002 The U.S. nuclear industry following the Fukushima event, STEPHEN KUCZYNSKI, Southern Nuclear Operating Co. — The nuclear industry is executing a coordinated, comprehensive and safety focused strategic plan in response to the accident in Japan. This beyond design basis external hazard driven event resulted in loss of core cooling due to a loss of offsite power as a result of the significant earthquake which was followed by a loss of on-site power due to the tsunami. Site response actions were impacted due to difficulty accessing the site. The current US fleet of operating reactors has over the last decades implemented numerous reviews assessing external hazards with post 911 actions being the most current. The industry took immediate actions following the March accident to verify existing capabilities to address events driven from external hazards and is now implementing a "Way Forward" plan that has as a priority the continued safe operation of the existing US fleet while examining both the technical and organizational root causes of the Fukushima Dai-ichi accident. Industry focus is to provide additional defense in depth through a "Flex" approach that adds the most significant safety benefit in the most efficient time frame. From a topical perspective, the industry is in agreement with the tier 1 recommendations from the NRC near term task force report. Southern Nuclear Operating Company operates 6 reactors and is building Vogtle 3&4 which is expected to be granted a COL in the near term. This generation III+ reactor design has passive safety features that would have mitigated an event similar to the Fukushima accident.

12:27PM W20.00003 Lessons from Fukushima for Improving the Safety of Nuclear Reactors, EDWIN LYMAN, Union of Concerned Scientists — The March 2011 accident at the Fukushima Daiichi nuclear power plant has revealed serious vulnerabilities in the design, operation and regulation of nuclear power plants. While some aspects of the accident were plant- and site-specific, others have implications that are broadly applicable to the current generation of nuclear plants in operation around the world. Although many of the details of the accident progression and public health consequences are still unclear, there are a number of lessons that can already be drawn. The accident demonstrated the need at nuclear plants for robust, highly reliable backup power sources capable of functioning for many days in the event of a complete loss of primary off-site and on-site electrical power. It highlighted the importance of detailed planning for severe accident management that realistically evaluates the capabilities of personnel to carry out mitigation operations under extremely hazardous conditions. It showed how emergency plans rooted in the assumption that only one reactor at a multi-unit site would be likely to experience a crisis fail miserably in the event of an accident affecting multiple reactor units simultaneously. It revealed that alternate water injection following a severe accident could be needed for weeks or months, generating large volumes of contaminated water that must be contained. And it reinforced the grim lesson of Chernobyl: that a nuclear reactor accident could lead to widespread radioactive contamination with profound implications for public health, the economy and the environment. While many nations have re-examined their policies regarding nuclear power safety in the months following the accident, it remains to be seen to what extent the world will take the lessons of Fukushima seriously and make meaningful changes in time to avert another, and potentially even worse, nuclear catastrophe.

1:03PM W20.00004 Nuclear Power in China, YUN ZHOU, Harvard University — In response to the Fukushima accident, China is strengthening its nuclear safety at reactors in operation, under construction and in preparation, including efforts to improve nuclear safety regulations and guidelines based on lessons learned from the accident. Although China is one of the major contributors in the global nuclear expansion, China's nuclear power industry is relatively young. Its nuclear safety regulators are less experienced compared to those in other major nuclear power countries. To realize China's resolute commitment to rapid growth of safe nuclear energy, detailed analyses of its nuclear safety regulatory system are required. This talk explains China's nuclear energy program and policy at first. It also explores China's governmental activities and future nuclear development after Fukushima accidents. At last, an overview of China's nuclear safety regulations and practices are provided. Issues and challenges are also identified for policy makers, regulators, and industry professionals.

1:39PM W20.00005 Nuclear Power in India, M.V. RAMANA, Program on Science and Global Security, Princeton University — India has ambitious plans for expanding nuclear power over the next few decades. A major accident in a densely populated country like India can be catastrophic and thus of concern. There are both technical and organizational requirements for safety of nuclear facilities. This talk will describe some of the organizational factors that safety theorists have identified and examine, from the publicly available information about incidents and failures at India's nuclear facilities to see if these requirements are met. It will also describe some of the reactions to the Fukushima accident from officials associated with nuclear energy in India.

Thursday, March 1, 2012 11:15AM - 2:15PM —
Session W21 DMP: Focus Session: Search for New Superconductors- Electron-Phonon Coupling 254A

11:15AM W21.00001 Correlation-enhanced electron-phonon coupling produces high-temperature superconductors, ZHIPING YIN, ANDREY KUTEPOV, GABRIEL KOTLIAR, Department of Physics and Astronomy, Rutgers University — The microscopic origin of superconductivity has been established in numerous classes of materials. In elemental metals it results from the exchange of phonons whereas in copper oxides and iron pnictides it is intimately connected to magnetism. On the other hand, the cause of superconductivity in a large third class of isotropic high temperature superconductors is still mysterious and subject of debate. In this talk, we will demonstrate that dynamical correlations among electrons enhance their coupling to phonons in a large number of superconductors, raising significantly the previously underestimated theoretical superconducting critical temperature T_c of up to a few Kelvin to their experimental values of tens of Kelvin. The mechanism we propose is quite general, explains the magnitude and the doping dependence of superconductivity in many materials such as the celebrated $\text{Ba}_{1-x}\text{K}_x\text{BiO}_3$ ($T_C=32$ K) compounds and the electron-doped $\beta\text{-HfNiCl}$ compounds ($T_c = 25.5$ K) and can be used to design other high temperature superconductors which have not yet been synthesized. We will also propose a few novel materials which are good superconductors in our theory and can be easily synthesized and tested by experiments.

11:27AM W21.00002 Spectral properties of correlated systems with electron-phonon coupling, ELIZABETH NOWADNICK, Stanford University and SLAC, STEVEN JOHNSTON, IFW Dresden, ANDREY MISHCHENKO, RIKEN and RRC Kurchatov Institute, BRIAN MORITZ, Stanford University and SLAC, NAOTO NAGAOSA, RIKEN and University of Tokyo, THOMAS DEVEREAUX, Stanford University and SLAC — Results from a variety of experiments, including single particle probes such as ARPES and STM, and multi-particle spectroscopies such as optical and Raman responses, have revealed the importance of the electron-phonon interaction in strongly correlated electron materials. We present a determinant quantum Monte Carlo study of the single-band Hubbard-Holstein model, which treats electron-electron and electron-phonon interactions on an equal footing. We focus on the behavior of the single- and multi-particle dynamical properties of the model, such as the spectral function and optical conductivity, as a function of electron-phonon coupling and Hubbard U.

11:39AM W21.00003 Vibrational spectrum and electron-phonon coupling of doped solid picene from first principles, LILIA BOERI, ALASKA SUBEDI, Max Planck Institute for Solid State Physics, Stuttgart — The search for new intercalated hydrocarbon superconductors was initiated by the report of a superconducting critical temperature (T_c) of 18 K in K- and Rb- doped picene ($C_{22}H_{14}$), followed by phenanthrene, coronene and di-benz-picene (27 K). These compounds, formed by just approx benzene rings, bear a strong resemblance both to fullerenes and intercalated graphites. Using first-principles linear response calculations have performed calculations of the phonon spectrum and electron-phonon (ep) interaction, we have shown that the coupling of the high-energy C bond-stretching phonons to the π molecular orbitals for a doping of 3 electrons per picene molecule is sufficiently strong to reproduce the experimental T_c of 18 K within Migdal-Eliashberg theory. For hole doping, we predicted a similar coupling leading to a maximum T_c of 6 K. However, we argue that, due to its molecular nature, picene may belong to the same class of strongly correlated *ep* superconductors as fullerides [1]. Our results are in agreement with estimates based on molecular orbital models; we also discuss possible reasons and implications of the discrepancy with linear response calculations that include explicitly the dopant.

11:51AM W21.00004 Strong Correlation Physics in Aromatic Hydrocarbon Superconductors¹, MASSIMO CAPONE, GIANLUCA GIOVANNETTI, CNR-IOM and International School for Advanced Studies (SISSA) — We show, by means of ab-initio calculations, that electron-electron correlations play an important role in doped aromatic hydrocarbon superconductors, including potassium doped picene with $T_c = 18K$ [1], coronene and phenanthrene [2]. For the case of picene the inclusion of exchange interactions by means of hybrid functionals reproduces the correct gap for the undoped compound and predicts an antiferromagnetic state for $x = 3$, where superconductivity has been observed [3]. The latter finding is compatible with a sizable value of the correlation strength. The differences between the different compounds are analyzed and results of Dynamical Mean-Field Theory including both correlation effects and electron-phonon interactions are presented. Finally we discuss the consequences of strong correlations in an organic superconductor in relation to the properties of Cs_3C_{60} , in which electron correlations drive an antiferromagnetic state [4] but also lead to an enhancement of superconductivity [5].

12:03PM W21.00005 Transport Anomalies and Possible High T_c Superconductivity in interconnected multiwall carbon nanotube sheets doped by ion implantation¹, ANVAR ZAKHIDOV, AUSTIN HOWARD, NICHOLAS CORNELL, ULAS GOSKUN, MYRON SALAMON, RAY BAUGHMAN, JULIA BYKOVA, NATHANAEAL MAYO, University of Texas at Dallas, XUEMEI WANG, EDUARD GALSTYAN, HERBERT FREYHARDT, WEI KAN CHU, University of Houston, UTD-UH TEAM COLLABORATION, UTD TEAM — Ion implantation offers an alternative doping method. In searching for superconductivity, we describe here the ion-implantation doping of MW-CNT interconnected networks by boron and other dopants (phosphorous, sulfur, arsenic) and report transport anomalies in oriented networks of ion implanted MWCNT sheets as compared to cross coated (non-oriented multilayer MWCNT sheets). The strong drop of resistance $R(T)$ with temperature decrease starting at $T_{c1} = 50-60$ K and even at higher T is reminiscent of inhomogeneous superconducting islands appearing in the non-SC matrix. An unusual anomaly of the 4-terminal resistance is observed in many samples, $R(T)$ becoming negative at lower $T < T_{c2} \sim 10-20$ K. This negative resistance is found to be associated with unusual I-V curves with s-shape at low $T < T_{c2}$ and $R(T)$ shows nonlinear dependence on excitation current and other features that are studied carefully in MWCNTs with different lengths and densities. This negative-resistance behavior gives a hint for the possible incorporation of superconducting areas and can be explained in terms of an imbalanced resistance bridge.

¹AFOSR grant FA 9550-09-10384

12:15PM W21.00006 Large Magnetoresistance and low temperature Transport anomalies in Ion implanted HOPG¹, NICHOLAS CORNELL, ANVAR ZAKHIDOV, MYRON SALAMON, YURI GARTSTEIN, University of Texas at Dallas, XUEMEI WANG, HERBERT FREYHARDT, WEI KAN CHU, University of Houston, UTD NANOTECH INST. TEAM, U. HOUSTON TEAM — Strong positive magnetoresistance (MR) was found in highly oriented pyrolytic graphite (HOPG) upon ion implantation by boron and phosphorous. Similar effects, but with smaller amplitude, are induced by carbon ion implantation, but due to structural disorder and defect formation without carrier concentration increase. The magnetic field dependence of the MR is linear at high fields with no sign of saturation, but different contact geometries result in a wide range of parameters. Two possible explanations of strong MR are suggested and analyzed. While the MR remains large at all temperatures, plots of $R(T)$ in constant field show a drop at lower T . Future experiments will clarify the origin of the $R(T)$ drop, in particular, whether this might be interpreted as the onset of inhomogeneous superconductivity, as proposed in some previous work, or could be explained in the context of strong linear MR effects seen in high-mobility, disordered materials.

¹NanoTech team supported by AFOSR grant FA 9550-09-10384

12:27PM W21.00007 Quantitative reliability of the Migdal-Eliashberg theory for strong coupling superconductors, JOHANNES BAUER, Max-Planck Institute for Solid State Research, Heisenbergstr.1, 70569 Stuttgart, Germany, JONG HAN, Department of Physics, SUNY at Buffalo, Buffalo, New York 14260, USA, OLLE GUNNARSSON, Max-Planck Institute for Solid State Research, Heisenbergstr.1, 70569 Stuttgart, Germany — The Migdal-Eliashberg (ME) theory for strong electron-phonon coupling and retardation effects of the Morel-Anderson type form the basis for the quantitative understanding of conventional superconductors. The validity of the ME theory for values of the electron-phonon coupling strength $\lambda > 1$ has been questioned by model studies. By distinguishing bare and effective parameters, and by comparing the ME theory with the dynamical mean field theory (DMFT), we clarify the range of applicability of the ME theory. Specifically, we show that ME theory is very accurate as long as the product of effective parameters, $\lambda\omega_{ph}/D$, where ω_{ph} is an appropriate phonon scale and D an electronic scale, is small enough [1]. The effectiveness of retardation effects is usually considered based on the lowest order diagram in the perturbation theory. We analyze these effects to higher order and find modifications to the usual result for the Coulomb pseudo-potential μ^* . Retardation effects are weakened due to a reduced effective bandwidth. Comparison with the non-perturbative DMFT corroborates our findings [2].

12:39PM W21.00008 Influence of Surface Termination of Boron-Doped Diamond on Superconducting Property, KEISUKE NATSUI, TAKASHI YAMAMOTO, TAKESHI WATANABE, YASUAKI EINAGA, Keio University, JST-CREST TEAM — In 2004, a heavily boron-doped diamond was found to be a superconductor. Since then, a superconducting diamond has attracted considerable attention, mainly explored for fundamental properties and a theoretical basis. Meanwhile, it is known that the surface of diamond is easily modified by a chemical treatment, and the physical properties, such as surface conductivity, could be modulated through the surface modification. Here, we report modulation of superconducting properties of a heavily boron-doped diamond by tuning the surface electronic state. A heavily boron-doped diamond was prepared onto a silicon wafer substrate by a microwave plasma-assisted chemical vapor deposition method. The surface of a boron-doped diamond was changed between hydrogen- and oxygen-termination by thermal and electrochemical reactions, respectively. As a result, the critical current and the diamagnetic magnetization value could be modulated in a reversible manner between the hydrogen- and oxygen-terminated diamonds with maintenance of the superconducting transition temperature. It is assumed that the carrier density at grain boundaries would change due to the induced dipole moment via surface modification, resulting in modulation of the magnetic flux pinning effect at grain boundaries.

12:51PM W21.00009 Energy landscape of fullerene materials: A comparison of boron to boron nitride and carbon¹, SANDIP DE, University of Basel, Basel, Switzerland — After the discovery of the C₆₀ fullerene some 25 years ago, many more hollow and endohedrally doped structures made out of various elements have been proposed theoretically. However, since no other fullerenes have been synthesized up to date, the question arises whether experimentalists have just not yet found a way to synthesize these theoretically predicted fullerenes, or whether they do not exist at all in nature. Following the theoretical discovery of the B₈₀ fullerene by Szwacki et al, various other fullerene and stuffed fullerene structures were proposed but none of them could be synthesized in the laboratory yet. Using the minima hopping global geometry optimization method on the density functional potential energy surface we show that the energy landscape of boron clusters is glass like. Medium size boron clusters exhibit many structures which are lower in energy than the cages. This is in contrast to carbon and boron nitride systems which can be clearly identified as structure seekers. The differences in the potential energy landscape explain why carbon and boron nitride systems are found in nature whereas pure boron fullerenes have not been found. We thus present a methodology which can make predictions on the feasibility of the synthesis of new nano structures.

¹Indi-swiss research grant., Swiss national foundation, cscs swiss national super computer

1:03PM W21.00010 Light element ternary compounds – searching for new superconductors in the “upper left corner”¹, ANDREAS HERMANN, NEIL W. ASHCROFT, ROALD HOFFMANN, Cornell University — We propose here a new class of ternary compounds, composed entirely of light elements drawn from the upper left corner of the Periodic Table, as a new family of superconductors with the promise of high transition temperatures (T_c). In this explorative computational study, we have investigated stoichiometric 1:1:1 compounds of lithium, beryllium, and boron. We find layered metallic phases that are thermodynamically stable at P=1 atm, with still others stabilized at relatively low pressures and hence in principle accessible to synthesis and experimental characterization. At high pressures, close packed structures are again stabilized and a metal-to-insulator transition is predicted. Superconducting transition temperatures for the most structurally attractive metallic phases are estimated using BCS theory. An outlook on other stoichiometries, as well as the incorporation of different constituents, Mg instead of Be in particular, is given.

1:15PM W21.00011 Progress on Determining the alpha-beta Phase Boundary of Elemental Boron¹, TADASHI OGITSU, ERIC SCHWEGLER, LLNL — Recently, it was reported that the phase boundary between alpha-boron and beta-boron has been directly determined using high-pressure and temperature experiments down to P~4GPa and T~1400K [Scientific Reports 1, 96 (2011)]. Based on linear extrapolation of their results to lower pressure and temperature, these authors proposed that at P=0GPa alpha-boron is the stable form below about T~933(20)K, in conflict with the recent theoretical works based on DFT total energy calculations [JACS 129, 2458 (2007); PRB 77, 064113 (2008); JACS 131, 1903 (2009)], where it was concluded that beta-boron is the most stable at all temperature below melting temperature and down to zero Kelvin. At the talk, we show that the theoretical alpha-beta boundary obtained with a few approximations agrees well with the aforementioned experimental results within the error bars except for the lowest P, T point, and in this case, the ground state is still beta-boron [submitted]. We will also discuss on the recent experimental efforts in measuring the specific heat of boron allotropes that lead to a tentative conclusion supporting the aforementioned DFT results.

1:27PM W21.00012 Calculation of electron-phonon coupling in Arsenic under pressure¹, KEVIN T. CHAN, MARVIN L. COHEN, Dept. of Physics, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory — Elemental As undergoes a structural transformation from a rhombohedral A7 phase to a simple cubic (sc) phase at around 25 GPa as pressure is increased. At pressures near this phase transformation, As is superconducting, with a maximum superconducting transition temperature T_c of about 2.5 K. Experiments indicate that this maximum T_c occurs at the transition pressure for structural transformation, and the increase in T_c as the transition pressure is approached has been attributed to phonon softening. In this work, we calculate from first principles the electronic structure, phonon dispersions, and electron-phonon coupling constant λ for As in the A7 and sc phases at various pressures near the A7 to sc transition. Using these detailed quantitative calculations, we explain the trends in T_c as function of pressure in terms of phonon softening, electronic density of states, and electron-phonon matrix elements. We discuss the implications of these results for finding new superconducting materials.

1:39PM W21.00013 Physical properties of heavily boron doped silicon, AUDREY GROCKOWIAK, Institut Néel, CNRS and UJF, CHRISTOPHE MARCENAT, INAC, CEA, THIERRY KLEIN, Institut Néel, CNRS and UJF, GILLES PRUDON, CHRISTIANE DUBOIS, Institut des Nanotechnologies de Lyon, CNRS and INSA, France, THIERRY KOCINIEWSKI, DOMINIQUE DEBARRE, Institut d'Electronique Fondamentale, Université Paris Sud, Orsay, France — The discovery of superconductivity (SC) in heavily boron doped silicon in 2006 by [1] occurred shortly after diamond in 2004 by [2]. However, the SC in these 2 materials occurs differently. For diamond, the SC is obtained for a boron concentration close to the metal-insulator transition (MIT), while for silicon, the onset of superconductivity is obtained well above the MIT threshold. The aim of this study is to determine the influence of different parameters that impact the SC, such as the doping concentration nB, or the thickness of the layer. Interpolation between resistivity measurements of $T_c(nB)$ and ab initio calculations of the electron phonon coupling $\lambda(nB)$ showed a complete mismatch of the dependency of $\lambda(T_c)$ with the BSC MacMillan exponential law. The results obtained suggest rather a power law dependence such as $\lambda \propto T_c^2$. This dependency suggests a fractal dimension of the superconducting wave function as reported by Feigel'man et al. [3].

1:51PM W21.00014 Eliashberg-McMillan Parameters of Polysulfur Nitride, (SN)_x, PAUL GRANT, W2AGZ Technologies, Jet Propulsion Laboratory, California Institute of Technology, Pasadena, CA — Thirty-seven years following the discovery of superconductivity in polysulfur nitride, (SN)_x remains the lone conducting polymer exhibiting this phenomenon. The transition temperature is only 0.3 – 0.4 K, and details of its origin remain largely unknown, although it very likely arises from conventional phonon-mediated BCS pairing of normal state carriers. In pursuit of such a possible mechanism, we have performed density functional theory (DFT) investigations of the phonon and electron-phonon dispersion relationships in (SN)_x, and will present values for the coupling strength of the latter along with an estimate of T_c.

2:03PM W21.00015 Probing electronic order via coupling to phonons in Bi2Sr2CuO6 (Bi2201)¹, CRAIG BONNOIT, DILLON GARDNER, ROBIN CHISNELL, Massachusetts Institute of Technology, AYMAN SAID, Advanced Photon Source, Argonne National Laboratory, YOSHI OKADA, Nagoya University, TAKESHI KONDO, University of Tokyo, TSUNEHIRO TAKEUCHI, HIROSHI IKUTA, Nagoya University, DAVID MONCTON, YOUNG LEE, Massachusetts Institute of Technology — Recent work on several members of the cuprate family of high-temperature superconductors has revealed the occurrence of broken lattice translational, rotational, and time reversal symmetries in various materials at low temperatures. We report on measurements of acoustic phonons on Bi₂(La,Sr)₂CuO_{6+δ}, which reveal a coupling to an underlying electronic density-wave state. Longitudinal acoustic phonons are found to be anomalously broadened at a wavevector of q ≈ 1/4 rlu along the Cu-O direction. At low temperatures a disparity between the scattered intensity at positive and negative energy transfer is seen. These measurements indicates a breaking of time reversal and inversion symmetry in the bulk.

Session W22 DMP DCOMP: Focus Session: Fe-based Superconductivity - Magnetism in AxFe(1-y)Se2 254B

11:15AM W22.00001 NMR Study of Superconductivity and Spin Fluctuations in Intercalated Iron Selenides A_yFe_{2-x}Se₂¹, WEIQIANG YU, Department of Physics, Renmin University of China, Beijing 100872, China — The role of spin fluctuations in superconductivity is an essential topic in both cuprate and Fe-based superconductors. NMR works in several Fe-based superconductors proposed that the low-energy antiferromagnetic spin fluctuations (AFSF) is a possible pairing glue for superconductivity. However, studies on other systems such as KFe₂As₂ and Li_{1-x}FeAs does not support a strong correlation between low-energy spin fluctuations and superconductivity. In the newly discovered A_yFe_{2-x}Se₂ superconductors with T_c ~ 32 K, our NMR study identifies unambiguously a paramagnetic superconducting phase, which is phase separated from the block antiferromagnetic state. The low-energy AFSF is not seen at all, even though the T_c is high. The A_yFe_{2-x}Se₂ are singlet superconductors evidenced from the NMR Knight shift K; However, the absence of the coherence peak in the spin-lattice relaxation rate 1/T₁ suggests an unconventional behavior of superconductivity. In fact, we found that both the K and the 1/T₁T increase dramatically with temperature and follow a a + bT² form from T_c up to 300 K. Such behavior is strong evidence for spin fluctuations with a high-energy, local nature in 3D systems, and inconsistent with a band-gap effect. Furthermore, K and 1/T₁T saturate above 400 K, indicating an energy scale of 35 meV, which is distinct from the low-energy spin fluctuations. The above temperature enhanced spin fluctuations seem to be universal in Fe-based superconductors.

11:51AM W22.00002 Spin Waves and magnetic exchange interactions in insulating Rb_{0.89}Fe_{1.58}Se₂, MIAOYIN WANG, Dept. Phys., University of Tennessee, Knoxville, CHEN FANG, Dept. of Phys., Purdue University, DAOXIN YAO, State Key Laboratory of Optoelectronic Materials and Technologies, Sun Yat-sen University, GUOTAI TAN, College of Nuclear Science and Technology, Beijing Normal University, LELAND HARRIGER, YU SONG, TUCKER NETHERTON, CHENGLIN ZHANG, Dept. Phys., University of Tennessee, Knoxville, MENG WANG, IOP, Chinese Academy of Sciences, MATTHEW STONE, Neutron Scattering Science Division, ORNL, WEI TIAN, Ames Lab and Dept. Phys., Iowa State University, JIANGPING HU, Dept. of Phys., Purdue University, PENGCHENG DAI, Dept. Phys., University of Tennessee, Knoxville — Superconductivity in alkaline iron selenide AFe_{1.6+x}Se₂ (A = K, Rb, Cs) may have a different origin from the sign reversed s-wave electron pairing mechanism, because they are insulators near x = 0 and form a blocked AF structure that is completely different from the iron pnictides. We use neutron scattering to map out spin waves in the AF insulating Rb_{0.89}Fe_{1.58}Se₂. A comparison of the fitted effective exchange couplings using a local moment Heisenberg Hamiltonian in Rb_{0.89}Fe_{1.58}Se₂, (Ba,Ca,Sr)Fe₂As₂, and iron chalcogenide Fe_{1.05}Te reveals that their next nearest neighbor (NNN) exchange couplings are similar. Therefore, superconductivity in all Fe-based materials may have a common magnetic origin that is intimately associated with the NNN magnetic exchange interactions, even though they have metallic or insulating ground states, different AF orders and electronic band structures.

12:03PM W22.00003 77Se NMR Study of K_xFe_{2-y}Se_{2-z}S_z, DAVID TORCHETTI, MINGXUAN FU, TAKASHI IMAI, Department of Physics and Astronomy, McMaster University, H.C. LEI, C. PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory — We will present a ⁷⁷Se NMR study of the superconducting properties of the recently discovered K_xFe_{2-y}Se₂ (T_c ~ 33 K), in a temperature range of 4 to 250 K [1]. Our Knight shift data reflect the progressive decrease in uniform spin susceptibility with temperature, in analogy with FeSe and iron-arsenide systems. Nuclear spin-lattice relaxation rate data shows no Hebel-Slichter coherence peak, nor any enhancement of antiferromagnetic spin fluctuations (AFSF) toward T_c. We have also conducted ⁷⁷Se NMR measurements on K_xFe_{2-y}Se_{0.4}S_{1.6} (non-superconducting) and K_xFe_{2-y}Se_{1.2}S_{0.8} (T_c ~ 21 K) to study the effect of sulphur substitution in this superconductor [2]. Sulphur applies a chemical pressure on the lattice, because it has the same valence as Selenium but less than half the ionic radius. We again measure NMR Knight shift and nuclear spin-lattice relaxation rate 1/T₁, and find that both are suppressed with S substitution. We will discuss these results in comparison with K_xFe_{2-y}Se₂.

12:15PM W22.00004 Magnetic state of $K_{0.8}Fe_{1.6}Se_2$ from a five-orbital Hubbard model in the Hartree-Fock approximation¹, QINLONG LUO, ANDREW NICHOLSON, ADRIANA MOREO, ELBIO DAGOTTO, Univ. of Tennessee/ORNL, JOSÉ RIERA, Universidad Nacional de Rosario, DAO-XIN YAO, Sun Yat-Sen Univ. — The five-orbital Hubbard model (without lattice distortions) is investigated to study theoretically the recently discovered Fe-based superconductors $K_{0.8}Fe_{1.6}Se_2$, by using the real-space Hartree-Fock approximation and employing a 10×10 Fe cluster with Fe vacancies in a $\sqrt{5} \times \sqrt{5}$ pattern[1]. The phase diagram contains an insulating state with the same spin pattern as observed experimentally, involving 2×2 ferromagnetic plaquettes coupled with one another antiferromagnetically. The magnetic moment $\sim 3\mu_B/Fe$ is in good agreement with experiments. Several other competing phases are also stabilized in the phase diagram, in agreement with recent calculations using phenomenological models. [1] Qinlong Luo *et al.*, Phys. Rev. B **84**, 140506(R) (2011), and references therein.

12:27PM W22.00005 Electronic structure and magnetic excitations in iron selenides, MARK VAN SCHILFGAARDE, King's College, London, UK, LIQIN KE, VLADIMIR ANTROPOV, Ames Laboratory — We calculate the electronic structure and magnetic excitations in the $K_4Fe_{4+x}Se_5$ alloy, with x between 0 and 1, within the local-density approximation. Analysis of the electronic structure with varying x leads to a prediction of the coexistence of two phases: one, strongly magnetic and another, weakly or nonmagnetic. Using linear response techniques we calculate spin wave spectra in $K_4Fe_{4+x}Se_5$, and find it is in excellent agreement with a recent experiment. The spectrum can be described rather well by an anisotropic J_1 - J_2 model. We confirm that exchange coupling between NN Fe magnetic moments is strongly anisotropic, and show directly that in the ideal system this anisotropy can be associated with higher order terms in spin Hamiltonian (biquadratic coupling). Structural relaxation provides an additional source of the exchange anisotropy of approximately the same strength. The dependence of spin wave spectra on filling of Fe vacancy sites is discussed.

12:39PM W22.00006 Novel Magnetism in $K_{0.8}Fe_{1.6}Se_2$ Explained in the Unified Picture, WEI-GUO YIN, CHIA-HUI LIN, WEI KU, Brookhaven National Laboratory — The novel block checkerboard antiferromagnetism in Fe-vacancy-ordered insulating $K_{0.8}Fe_{1.6}Se_2$ is investigated theoretically [1]. Neither of the Fermi surface nesting and the Mott insulator scenarios, which were widely employed to model previous Fe-vacancy-free iron-based superconductors, is supported by our first-principles analysis of its electronic structure including unfolded Fermi surface, band gap, and orbital polarization. Instead, the orbital-degenerate double-exchange model, previously proposed to unify the metallic collinear and bicollinear antiferromagnetism of iron-based superconductors, is found sufficient to explain this insulating spin order as well as associated quantum magnetic transition induced by tetramer lattice distortion. Our findings demonstrate that the iron-based superconductors be universally described in the framework of coexisting itinerant and localized electronic states, which are coupled by Hund's rule coupling on the Fe atoms. Work supported by DOE DE-AC02-98CH10886.

12:51PM W22.00007 Vacancy-driven orbital and magnetic order in $(K,Tl,Cs)_yFe_{2-x}Se_2$ ¹, WEI-CHENG LV, WEI-CHENG LEE, PHILIP PHILLIPS, Department of Physics, University of Illinois — We investigate the effects of the $\sqrt{5} \times \sqrt{5}$ Fe vacancy ordering on the orbital and magnetic order in $(K,Tl,Cs)_yFe_{2-x}Se_2$ using a three-orbital (t_{2g}) tight-binding Hamiltonian with generalized Hubbard interactions. We find that vacancy order enhances electron correlations, resulting in the onset of a block antiferromagnetic phase with large moments at smaller interaction strengths. In addition, vacancy ordering modulates the kinetic energy differently for the three t_{2g} orbitals. This results in a breaking of the degeneracy between the d_{xz} and d_{yz} orbitals on each Fe site, and the onset of orbital order. Consequently, we obtain a novel inverse relation between orbital polarization and the magnetic moment. We predict that a transition from high-spin to low-spin states accompanied by a crossover from orbitally-disordered to orbitally-ordered states will be driven by doping the parent compound with electrons, which can be verified by neutron scattering and soft X-ray measurements.

¹support by NSF DMR-0940992 and the Center for Emergent Superconductivity, a DOE Energy Frontier Research Center, Grant No. DE-AC0298CH1088

1:03PM W22.00008 Phase separation and magnetic order in K-doped iron selenide superconductor, XI CHEN, WEI LI, HAO DING, PENG DENG, KAI CHANG, CANLI SONG, Tsinghua University, KE HE, LILI WANG, XUCUN MA, Chinese Academy of Sciences, JIANG-PING HU, Purdue University, QI-KUN XUE, Tsinghua University — The newly discovered alkali-doped iron selenide superconductors exhibit unique characters that are absent in other iron-based superconductors, such as anti-ferromagnetically ordered insulating phases, extremely high Neel transition temperatures, and the presence of Fe vacancies and ordering. We have grown high-quality $K_xFe_{2-y}Se_2$ thin films on graphene by molecular beam epitaxy and measured their atomic and electronic structures by low-temperature scanning tunneling microscopy. We demonstrate that a typical $K_xFe_{2-y}Se_2$ sample contains two distinct phases: an insulating phase with well-defined $\sqrt{5} \times \sqrt{5}$ order of Fe vacancies, and a superconducting KFe_2Se_2 phase containing no Fe vacancies. An individual Fe vacancy can locally destroy superconductivity in a similar way as a magnetic impurity in conventional superconductors. The measurement of magnetic field dependence of the Fe-vacancy-induced bound states reveals a magnetically-related bipartite order in the tetragonal iron lattice. These findings elucidate the existing controversies on this new superconductor and provide atomistic information on the interplay between magnetism and superconductivity in iron-based superconductors.

1:15PM W22.00009 Magnetism and Superconductivity in $Rb_{1-x}Fe_{2-y}Se_2$, VLADIMIR TSURKAN, Academy of Sciences of Moldova, JOACHIM DEISENHOFER, AXEL GÜNTHER, JONAS FISCHER, ZHE WANG, MICHAEL SCHMIDT, HANS-ALBRECHT KRUG VON NIDDA, SEBASTIAN WIDMANN, ALOIS LOIDL, Augsburg University — We report on the structural, magnetic, and superconducting properties of $Rb_{1-x}Fe_{2-y}Se_2$ single crystals. The system exhibits a strongly anisotropic antiferromagnetic behavior below 400 K. For $1.53 < 2 - y < 1.6$ superconductivity is found, whereas for Fe concentrations $2 - y < 1.5$ and $2 - y > 1.6$ insulating and semiconducting behavior is observed, respectively. The sharpest transition to the superconducting state and the highest transition temperature T_c of 32.4 K is found for compositions close to $Rb_2Fe_4Se_5$. Comparison of the magnetic behavior of non-superconducting and superconducting samples provides evidence for the coexistence of superconductivity and static antiferromagnetic order [1]. THz time-domain transmission spectroscopy in superconducting samples evidences a metallic response and the superconducting transition of the system [2].

1:27PM W22.00010 Defect formation, magnetic interaction and electron phonon coupling in iron selenides $M_{1-x}Fe_{2-y}Se_2$, XUHUI LUO, University of Illinois at Chicago & National Institute of Standard and Technology, SERDAR OGUT, University of Illinois at Chicago, TANER YILDIRIM, National Institute of Standard and Technology & University of Pennsylvania — We perform a systematic study to explore the electronic and magnetic structures in iron selenide superconductors $M_{1-x}Fe_{2-y}Se_2$ using first principles calculations. We show that there is an intimate relationship between Se-height and the underneath Fe-spin square in $M_{1-x}Fe_{2-y}Se_2$. A displacement of the Se atom by as small as $0.2\text{\AA}$ is enough to change the amount of charge in the Fe-plane as much as 0.7 e per Fe. The Se-height increases as the number of ferromagnetic Fe-Fe bonds increases, yielding an expansion of $2\text{\AA}$ expansion in the c-axis for fully ferromagnetic spin configuration, which indicates a giant magneto-elastic coupling in these systems. Our calculations also explain why the formation of Fe vacancies is favorable in iron selenides, but not in iron pnictides. Finally, we calculate the spin-resolved electron-phonon coupling in MFe_2Se_2 and $M_{1-x}Fe_{2-y}Se_2$ to shed light on the mechanism of superconductivity in these materials.

1:39PM W22.00011 Phononic, magnetic, and inter-band Raman scattering in $K_{0.75}Fe_{1.75}Se_2$ superconductor¹, ALEXANDER IGNATOV, PHIL LUBIK, Department of Physics & Astronomy, Rutgers University, Piscataway, NJ 08854, USA, R.H. YUAN, W.T. GUO, NAN-LIN WANG, Beijing Natl Lab for Condensed Matter Physics, CAS, Beijing 100190, China, GIRSH BLUMBERG, Department of Physics & Astronomy, Rutgers University, Piscataway, NJ 08854, USA — We have analyzed collective excitations in $K_{0.75}Fe_{1.75}Se_2$ single crystal ($T_c \sim 32$ K) by polarized Raman scattering in the energy shift range of 20-8000 cm^{-1} , the temperature range of 10-300 K, and laser excitation energies from 1.8 to 3.0 eV. Seven B_g and nine A_g phonon modes are observed at 300K. Below ~ 150 K an extra A_g mode appears at 165 cm^{-1} . The amplitudes of the A_g modes at ~ 67 , 112, and 124 cm^{-1} are reduced, while the amplitude of 183 cm^{-1} A_g mode is enhanced by factor of five as temperature decreases from 300 to 40 K. Magnetic scattering bands at 1000-2000 cm^{-1} consist of at least three distinct peaks each, implying different Fe-Fe AFM exchange coupling constants for underlying structure. Inter-band transitions are observed at ~ 3700 and 4600 cm^{-1} at 300 K in the A_g and B_g channels, respectively. Below 140 K these excitations are hardened to ~ 4040 and 4820 cm^{-1} .

¹Research at Rutgers was supported by the U.S. DOE, office of BES, Division of Materials Science and Engineering under award DE-SC0005463.

1:51PM W22.00012 Electronic structure and magnetism of doped $A_xFe_{2-y}Se_2$, YUAN-YEN TAI, Dept. of Physics, Univ. of Houston, Houston, Texas 77054, USA, JIAN-XIN ZHU, MATTHIAS J. GRAF, Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, C.S. TING, Dept. of Physics, Univ. of Houston, Houston, Texas 77054, USA — We develop a new multiorbital t-J Hamiltonian with realistic tight-binding and Heisenberg parameters to study the electronic and magnetic structure of $A_xFe_{2-y}Se_2$ superconductors for $0 < y < 0.4$. The ARPES experiments are fitted by a tight-binding lattice model with random vacancy order. We find that the vacancy order greatly affects the electronic band structure. For intermediate doping levels $0 < y < 0.4$, the stable electronic structure is a compromise between the solution for $y=0$ and $y=0.4$. Based on this model, we study the paramagnetic and antiferromagnetic (AFM) phases of $A_{0.8}Fe_{1.6}Se_2$. In the AFM phase the calculated spin susceptibility for the bare band structure agrees with a block-spin structure. This theoretical result is in good agreement with neutron scattering experiments of the spin structure. Furthermore, we show the results on the evolution of low-energy quasiparticle states with electron filling factor in the vacancy-ordered magnetic state.

2:03PM W22.00013 Nodeless d-wave Superconductivity and spin resonance in iron-selenide superconductors, A.V. BALATSKY, TANMOY DAS, LANL — Iron-selenide based layered compounds have been realized to be high-transition temperature superconductor in December, 2010. The superconductivity is tuned by varying number of iron vacancies in the crystal. This unique tunability of the high-temperature superconducting properties has reinforced the debate of universal properties in Fe based superconductors. Experiments and band structure calculations have shown that the electronic and magnetic structures of these compounds are significantly different from other iron-based superconductors. This fact leads us to propose that the superconducting state is nodeless d-wave pairing which is still driven by magnetic interactions. Nodeless gap leads to the fully gapped quasiparticle spectrum. Sign-changing gap lends itself naturally to the sharp feature in neutron scattering spectrum, the so called spin resonance. We predict the upward “horseshoe” dispersion of the spin resonance, in a sharp contrast with the “hourglass” dispersion in high- T_c oxides where similar spin resonance is ubiquitously seen. In conclusion, despite iron-selenide systems exhibit very different observables, we show that the underlying pairing mechanism is driven by similar spin-fluctuation instabilities as in other high-temperature superconductors.

Thursday, March 1, 2012 11:15AM - 2:15PM —

Session W23 DMP DCOMP: Focus Session: Fe-based Superconductors - AFeAs and RFeAsO Families 255

11:15AM W23.00001 Quantum oscillations in LiFeAs, AMALIA COLDEA, MATTHEW WATSON, Oxford University, ANTONY CARRINGTON, CARSTEN PUTZKE, ISABEL I. GUILLAMON, University of Bristol, ALIX MCCOLLAM, HMFL, Nijmegen, DAVID VIGNOLLES, DAVID LEBOEUF, LNCMI, Toulouse, IGOR MAZIN, Naval Research Laboratory, USA, SHIGERU KASAHARA, T. TERASHIMA, T. SHIBAUCHI, Y. MATSUDA, Kyoto University — Quantum oscillations are a powerful technique to establish with accuracy the three-dimensional topology of the Fermi surface and it has been successfully used in the study of iron-based superconductors. Here we report quantum oscillations in the 111 pnictide superconductor, LiFeAs, with $T \sim 18$ K, by using highly sensitive torque magnetometry in high magnetic fields (up to 58T) and at very low temperatures (0.3-4.2K). We observe clearly three different orbits around 1.5kT, 2.4kT and 2.9kT. By comparing the angular dependence of the measured frequencies with the predictions given by the first principle band calculations we conclude that the observed orbits belong to the electronic bands. The values of the quasiparticle masses for these orbits are significantly enhanced as compared with the band masses (a factor 4-5) suggesting that either that electron-electron and/or electron-phonon correlations are significant. We will compare our data with available APRES data on the same material and discuss the effect of the spin-orbit coupling. The details of the Fermi surface of LiFeAs will be compared with other iron-based superconductors. This work was supported by EPSRC (UK), EuroMagNET II, KAKENHI from JSPS and National Science Foundation, State of Florida and the U.S. Department of Energy.

11:27AM W23.00002 Effects of correlations in LiFeAs and LiFeP, JOHANNES FERBER, KATERYNA FOYEVTSOVA, HARALD O. JESCHKE, ROSER VALENTI, Institut fuer Theoretische Physik, Goethe-Universitaet Frankfurt, 60438 Frankfurt, Germany — We will discuss the role of electronic correlations in the iron-based superconductors LiFeAs and LiFeP by considering the effects on band structure, mass enhancements, and Fermi surface in the framework of density functional theory combined with dynamical mean field theory calculations. We show that LiFeAs shows characteristics of a moderately correlated metal and that the strength of correlations is mainly controlled by the value of the Hund's rule coupling J . The hole pockets of the Fermi surface show a distinctive change in form and size with implications for the nesting properties. We discuss our results in view of recent angle-resolved photoemission spectroscopy and de Haas-van Alphen experiments.

11:39AM W23.00003 Anisotropic Energy-Gaps of Iron-based Superconductivity from Intra-band Quasiparticle Interference in LiFeAs, Part I, M.P. ALLAN, Brookhaven National Laboratory, University of St Andrews, Cornell University, A.W. ROST, Cornell University, University of St Andrews, A.P. MACKENZIE, University of St Andrews, YANG XIE, Cornell University, J.C. DAVIS, Brookhaven National Laboratory, Cornell University, University of St Andrews, Kavli Institute at Cornell for Nanoscale Science, K. KIHOU, C.-H. LEE, A. IYO, H. EISAKI, Institute of Advanced Industrial Science and Technology, Tsukuba, Japan, T.-M. CHUANG, Academia Sinica, Taipei, Taiwan — Cooper pairing in the iron-based high- T_c superconductors is thought to occur due to the projection of the antiferromagnetic interactions between neighboring iron atoms onto the complex momentum-space electronic structure. It is thus pivotal to have an exact measurement of the electronic structure in these materials. In this talk, I will introduce intra-band Bogoliubov quasiparticle scattering interference (QPI) to iron-based superconductor studies. We report a precise determination of the low energy band structure of LiFeAs using QPI. We observe three hole-like bands, in qualitative agreement with dHvA and ARPES studies (“ γ ”, α_2 & α_1). The quantitative determination of the bandstructure is the foundation that we later use to measure the superconducting gap structure with QPI.

11:51AM W23.00004 Non-magnetic impurity effects in LiFeAs studied by STM/STS, T. HANAGURI, RIKEN, SEUNG HYUN KHIM, BUMSUNG LEE, KEE HOON KIM, Seoul National Univ., K. KITAGAWA, K. MATSUBAYASHI, Y. MAZAKI, Y. UWATOKO, M. TAKIGAWA, ISSP, Univ. Tokyo, H. TAKAGI, RIKEN/Univ. Tokyo — Detecting the possible sign reversal of the superconducting gap in iron-based superconductors is highly non-trivial. Here we use non-magnetic impurity as a sign indicator. If the sign of the superconducting gap is positive everywhere in momentum space, in-gap bound state should not be observed near the impurity site unless it is magnetic. On the other hand, if there is a sign-reversal in the gap, even non-magnetic impurity may create in-gap bound state [1]. We performed STM/STS experiments on self-flux and Sn-flux grown LiFeAs crystals and examined the effects of Sn impurity. In STM images of Sn-flux grown samples, we found a ring-like object which may represent Sn. Tunneling spectrum taken at this defect site exhibits in-gap bound state. Together with flat-bottom superconducting gap observed far from the defects, sign-reversing *s*-wave gap is the most plausible gap structure in LiFeAs. [1] T. Kariyado and M. Ogata, JPSJ **79**, 083704 (2010).

12:03PM W23.00005 Bogoliubov Electronic Structure at Individual Impurity Atoms in LiFeAs, YANG XIE, Laboratory of Solid State Physics, Department of Physics, Cornell University, Ithaca, NY 14853, USA, MILAN ALLAN, CMPMS Department, Brookhaven National Laboratory, Upton, NY 11973, USA, ANDREAS ROST, Laboratory of Solid State Physics, Department of Physics, Cornell University, Ithaca, NY 14853, USA, ANDY MACKENZIE, SUPA, School of Physics and Astronomy, University of St. Andrews, St. Andrews, Fife KY16 9SS, UK, KUNIHITO KIHOU, HIROSHI EISAKI, Institute of Advanced Industrial Science and Technology, Tsukuba, Ibaraki 305-8568, Japan, TIEN-MING CHUANG, JAMES DAVIS, CMPMS Department, Brookhaven National Laboratory, Upton, NY 11973, USA — Individual impurity atoms in a superconductor can strongly perturb the surrounding electronic environment and can therefore be used to probe high-temperature superconductivity at the atomic scale. Spectroscopic imaging scanning tunneling microscopy (SI-STM) is an ideal technique for the study of such effects. This has provided the motivation for several theoretical studies predicting the spatial and energetic structure of Bogoliubov electronic states at single impurity atoms in Fe-based superconductors. Here we report on a type of impurity atom that forms a strong in-gap quasi-particles interference (QPI) pattern nearby in the Fe-based superconductor LiFeAs. Our result puts a number of restrictions on theoretical studies of Fe-based superconducting mechanism.

12:15PM W23.00006 Theory of quasiparticle vortex bound states in Fe-based superconductors: application to LiFeAs, YAN WANG, PETER HIRSCHFELD, Department of Physics, University of Florida, Gainesville, Florida 32611, USA, ILYA VEKHTER, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, Louisiana 70803-4001, USA — Spectroscopy of vortex bound states can provide valuable information on the structure of the superconducting order parameter. Quasiparticle wavefunctions are expected to leak out in the directions of gap minima or nodes, if they exist, and scanning tunneling spectroscopy (STS) on these low-energy states should probe the momentum dependence of the gap. Anisotropy can also arise from band structure effects, however. We perform a quasiclassical calculation of the density of states of a single vortex in an anisotropic superconductor, and show that if the gap itself is not highly anisotropic, the Fermi surface anisotropy dominates, preventing direct observation of superconducting gap features. This serves as a cautionary message for the analysis of STS data on the vortex state on Fe-based superconductors, in particular LiFeAs, which we treat explicitly. YW and PJH were supported by the DOE under DE-FG02-05ER46236, and I. V. under DE-FG02-08ER46492.

12:27PM W23.00007 Local electronic structure near a vortex in LiFeAs within self-consistent BdG, KYUNGMIN LEE, MARK FISCHER, EUN-AH KIM, Cornell University — A major question in Fe-based superconductors is whether the pairing is of an unconventional nature with a sign change. The electronic structure in the presence of vortices can serve as a platform for phase sensitive measurements to answer this question. However as Fe-based superconductors are in the intermediate regime of correlation strength, a delicate balance between band structure effects and interaction effects may challenge a simple guess. We perform a microscopic self-consistent BdG calculation for LiFeAs in the presence of a perpendicular magnetic field and calculate the energy-dependent local electronic structure near a vortex. We use a band structure in agreement with recent experiments and compare different gap-symmetry possibilities. We find the low-energy local density of states to be dominated by the geometry of the Fermi surface, with tails along the directions perpendicular to the flat portions of the Fermi surface. These are the directions of the gap *maxima* on the square-like hole pocket around the Γ point according to recent observations. We discuss how the gap symmetry affects high-energy local density of states.

12:39PM W23.00008 Elastic neutron scattering on Co-doped NaFeAs superconductors, CHENGLIN ZHANG, GUOTAI TAN, YU SONG, TUCKER NETHERTON, SCOTT CARR, Univ of Tennessee, Physics dept, WEI TIAN, Oak Ridge National Lab, PENGCHENG DAI, Univ of Tennessee, Physics dept, UTK TEAM, ORNL COLLABORATION — NaFeAs and LiFeAs are the only two members in the Pnictide superconductors 111 family. Without doping, NaFeAs shows filamentary superconductivity coexisting with static antiferromagnetic (AF) order. In addition to the superconducting transition at 9 K, structural and AF transitions appear at ~ 50 K and ~ 40 K, respectively. By gradually doping Co on Fe sites, the AF order is suppressed and bulk superconductivity occurs. Although the electronic phase diagram of Co-doped NaFeAs is similar to the phase diagram of Co-doped 122 family, the NaFeAs system is much simpler because it does not have strong *c*-axis magnetic coupling and therefore a detailed investigation of this system will shed new light to our understanding on the common features amongst different classes of Fe-based superconductors. We will report our elastic neutron scattering results about this system.

12:51PM W23.00009 Temperature-dependent resistivity in single crystals $\text{Na}_{1-\delta}\text{Fe}_{1-x}\text{Co}_x$, M. A. TANATAR, Ames Laboratory US DOE, Ames, Iowa, N. SPYRISON, K. CHO, Ames Laboratory US DOE, Ames Iowa, G.T. TAN, J.Q. YAN, P.C. DAI, C.L. ZHANG, Oak Ridge National Laboratory, Knoxville, TN, R. PROZOROV, Ames Laboratory US DOE, Ames Iowa — Stoichiometric NaFeAs superconductor is representative of the slightly underdoped part of the doping phase diagram, with a sequence of tetragonal-to-orthorhombic, $T_s \approx 60$ K, magnetic, $T_m = 45$ K, and superconducting, $T_c = 12$ K transitions. Doping level in the compound can be tuned with Co substitution of Fe, acting as electron donor. This doping suppresses structural and magnetic instabilities and induces superconductivity with T_c up to 25 K. Doping with Co allows for studying complete doping phase diagram. We performed systematic measurements of the temperature-dependent in-plane, $\rho_a(T)$, and inter-plane, $\rho_c(T)$, electrical resistivities in the compounds. At optimal doping, both $\rho_a(T)$ and $\rho_c(T)$ show close to T -linear temperature dependence above the superconducting T_c . With doping this dependence gradually evolves towards T^2 . At much higher temperatures a slope-change is observed in $\rho_a(T)$, which we relate with onset of carrier activation over a pseudogap.

¹The work at Ames was supported by the U.S. DOE, under contract No. DE-AC02-07CH11358. The single crystal growth is supported by U.S. DOE BES U.S. DOE BES under Grant No. DE-FG02-05ER46202.

1:03PM W23.00010 Oxidative deintercalation of single crystal $\text{Na}_{1-\delta}\text{FeAs}$ upon Interaction with the environment, NICHOLAS SPYRISON, M.A. TANATAR, K. CHO, E. BLOMBERG, The Ames Laboratory, Ames, IA, G. TAN, J. YAN, P. DAI, C. ZHANG, Oak Ridge National Laboratory, Knoxville, TN, R. PROZOROV, The Ames Laboratory, Ames, IA — Due to high mobility of Na ions, NaFeAs superconductor exhibits pronounced reaction with the environment, leading to a bulk change in stoichiometry. We study the doping evolution of the same single crystals as a function of time of the environmental exposure. In NaFeAs, a controlled reaction with air increases the superconducting transition temperature, T_c , from the initial value of 12 K to 27 K as probed by transport and magnetic measurements. Temperature dependent resistivity, $\rho_a(T)$, shows a dramatic change with the exposure time. In freshly prepared samples, $\rho_a(T)$ reveals clear features at the structural, $T_s \approx 60$ K, and magnetic, $T_m = 45$ K, transitions and superconductivity with onset $T_{c,ons} \approx 16$ K and offset $T_{c,off} \approx 12$ K. The exposed samples show T -linear variation of $\rho_a(T)$ above $T_{c,ons} \approx 30$ K ($T_{c,off} \approx 26$ K). This suggests bulk doping and implies the existence of a quantum critical point at the optimal doping. The resistivity for different doping levels is affected below ~ 200 K suggesting the existence of a characteristic energy scale that caps the T -linear regime, which could be identified with a pseudogap.

1:15PM W23.00011 Some magnetic and electronic properties of Vanadium (hole) doped NaFeAs, SCOTT CARR, University of Tennessee, Knoxville — We examine the magnetic properties of the hole doped system $V_x\text{Na}_{1-x}\text{FeAs}$. It's known that the Na111 system exhibits structural, magnetic, and superconducting phase transitions. As opposed to the better studied electron doped systems, we successfully grew homogeneous single crystals with holes doped into the iron sites. Preliminary results show a total suppression of the superconducting phase and partial suppression of the AF order with doping as low as 1%. I will present a range of susceptibility measurements to examine the effect of Vanadium doping on T_c and the Neel Temperature.

1:27PM W23.00012 Cerium-Iron Magnetic Coupling in Single Crystal CeFeAsO at Low Temperatures¹, QIANG ZHANG, WEI TIAN, H.-F. LI, J.-Q. YAN, T.A. LOGRASSO, Ames Laboratory, U.S. DOE, R.W. MCCALLUM, Ames Laboratory; Department of Materials Science and Engineering, Iowa State University, J.L. ZARESTKY, DAVID VAKNIN, Ames Laboratory; Department of Physics and Astronomy, Iowa State University, J.W. KIM, Argonne National Laboratory, H. CAO, Oak Ridge National Laboratory — Neutron and synchrotron resonant X-ray scattering techniques have been used to determine the intricate magnetic structure of single crystal CeFeAsO at low temperatures, way below the spin-density wave (SDW) transition around 130 K associated with Fe moments ordering. Our synchrotron X-ray scattering results at the Ce L_{II} -edge clearly show a magnetic transition that is specific to the Ce ordering at $T_{Ce} = 4$ K, whereas neutron diffraction data indicate a transition at $T^* = 12$ K with unusual order parameter. Detailed order parameter measurements on the (100) & (101) magnetic reflections by neutrons show an anomaly at $T = 4$ K which we associate with the Ce ordering. The successive transitions at T_{Ce} and T^* can also be clearly identified by two anomalies in heat capacity measurements. We argue that the higher transition temperature observed in neutron measurements reflects Fe-Ce combined rearrangement prior to the complete ordering of the Ce. The effect of the weak Ce-Fe coupling on the rearrangement of Fe ordering is yet another example of the vulnerability of the Fe-SDW as influenced by minute doping or by relatively low applied pressures.

¹Supported by U.S. DOE Office of Basic Energy Sciences, Cont. No. DE-AC02-07CH11358

1:39PM W23.00013 FT-IR evaluation of SmFeAsO_{1-x}F_x (x = 0, 0.069), HAJIME SHINOHARA, YOICHI KAMIHARA, Department of Applied Physics and Physico-Informatics, Keio University — Optical properties of superconducting SmFeAsO_{1-x}F_x (x=0, 0.069) were demonstrated by reflection measurement with FT-IR method. Polycrystalline SmFeAsO_{1-x}F_x samples were synthesized using two-step solid state reaction described elsewhere [New J. Phys. **12**, 033005 (2010)]. Purity of samples was checked by X-ray diffraction patterns using Cu K- α radiation. The reflection measurement was performed at the range from 9000 cm^{-1} to 18000 cm^{-1} that was corresponded to an energy region from 1.12 eV to 2.25 eV. A photoconductivity of SmFeAsO_{1-x}F_x was determined by Kramer-Kronig (KK) relation. Reflectivity and photoconductivity measurements, as well as by FT-IR, at various areas were performed to define an energy level of materials [EPL, **84** 67013 (2008), and J. Phys. Soc. Jpn. **80** 013707 (2011)]. Obtained photoconductivity and reflection spectra were similar to those of LaFeAsO_{1-x}F_x that was a basic compound of LnFeAsO_{1-x}F_x (Ln=La, Ce, Sm), reported by Z. G. Chen et al [Phys. Rev. B **81**, 100502 (2010)]. Our result suggests that the energy band structure of SmFeAsO was affected by F-doping even in visible area. Details and temperature dependence of the reflection and photoconductivity spectra will be presented at the conference.

1:51PM W23.00014 Superconducting and normal state properties of single crystalline RFeAsO-based materials¹, J.J. HAMLIN, C.A. MCELROY, B.D. WHITE, D.Y. TUTUN, N. KANCHANAVATEE, Y. HEO, A.N. ELLINGTON, M.B. MAPLE, Department of Physics, University of California, San Diego, La Jolla, CA 92093, USA — We report electrical resistivity, Hall effect, magnetoresistance, magnetization, and specific heat measurements on single crystals of several RFeAsO-based materials (R = rare-earth). We also discuss the effects of lattice compression on the magnetic and superconducting transition temperatures. These single crystal studies benefit from significantly sharper signatures of the transitions, compared to earlier studies on polycrystalline samples.

¹Synthesis and superconductivity screening supported by AFOSR-MURI, Grant FA9550-09-1-0603. Physical properties characterization supported DOE, Grant DE-FG02-04-ER46105. High pressure measurements supported by DOE grant DE-FG52-06NA26205.

2:03PM W23.00015 Growth conditions of oxypnictide compounds LaFePnO Pn={P,As,Sb}, JASON VIELMA, SEAN MUIR, M.A. SUBRAMANIAN, A.W. SLEIGHT, GUENTER SCHNEIDER, Oregon State University — The discovery of superconductivity in layered ferro-oxypnictides LaFePO ($T_c \sim 4$ K) and LaFeAsO_{1-x}F_x ($T_c \sim 26$ K) lead to an intense search for other iron based superconducting materials. For the hypothetical compound LaFeSbO, ab initio density functional theory (DFT) calculations predict an enhanced density of states at the Fermi level together with increased nesting between the electron and hole sheets in the tetragonal structure (isostructural to LaFeAsO) and an enhanced spin-density wave ground state in a closely related orthorhombic structure; indicating the potential for superconductivity with a higher transition temperature [1]. We report ab initio DFT calculations of the phase stability of the oxypnictides LaFePnO Pn={P,As,Sb} and find growth conditions where LaFePO and LaFeAsO are thermodynamically stable, but LaFeSbO is unstable with respect to the formation of La₂SbO₂. Indeed, our attempt to synthesize LaFeSbO led to the synthesis and characterization of La₂SbO₂. The phonon spectrum of hypothetical LaFeSbO shows no soft modes, indicating that LaFeSbO is potentially metastable and leaving open the possibility of a nonequilibrium synthesis route.

Thursday, March 1, 2012 11:15AM - 2:15PM – Session W24 FIAP: Integer Quantum Hall Effect 256

11:15AM W24.00001 A quantitative examination of the collapse of spin splitting in the quantum Hall regime¹, W. PAN, Sandia National Labs, K.W. BALDWIN, K.W. WEST, L.N. PFEIFFER, D.C. TSUI, Princeton University — There is a great deal of current interest in understanding electron spin physics in semiconductors for potential quantum computation applications. The quantum Hall effect in the two-dimensional electron system (2DES) has proved to be a unique system in this avenue due to a tunability in the difference of spin population and thus the strength of exchange interaction provided by the formation of Landau levels. In this talk, we want to present our experimental results to *quantitatively* examine the theoretical model of spin splitting collapse in the quantum Hall regime [by Fogler and Shklovskii, Phys. Rev. B **52**, 17366 (1995)] at fixed magnetic fields as a function of electron density in a high quality heterojunction insulated-gate field effect transistor. In the density range between $n = 2 \times 10^{10}$ and $2 \times 10^{11} \text{ cm}^{-2}$, the Landau level number N follows a power-law dependence on the critical electron density n_c , where the spin splitting collapses, and $N = 11.47 \times n_c^{0.64 \pm 0.01}$. This power law dependence is in good agreement with the theoretical prediction in the low density regime.

¹SNL is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

11:27AM W24.00002 Single electron wave packets probed by Hanbury-Brown and Twiss interferometry, GWENDAL FEVE, ERWANN BOCQUILLON, FRANCOIS PARMENTIER, Ecole Normale Supérieure, Paris, CHARLES GRENIER, Ecole Normale Supérieure, Lyon, JEAN-MARC BERROIR, Ecole Normale Supérieure, Paris, PASCAL DEGIOVANNI, Ecole Normale Supérieure, Lyon, CHRISTIAN GLATTLI, BERNARD PLACAIS, Ecole Normale Supérieure, Paris, ANTONELLA CAVANNA, YONG JIN, Laboratoire de Photonique et Nanostructures — The ballistic propagation of electronic waves in the quantum Hall edge channels of a 2DEG bears strong analogies with photon optics which inspired a whole set of experiments, including the realization of electronic Mach-Zehnder [1] and Hanbury-Brown and Twiss [2] interferometers. So far, these experiments have been performed with continuous sources, but the recent realization of on-demand single electron emitters [3] has risen the hope to reach, in these experiments, the single charge control. We report here on the first realization of a Hanbury-Brown and Twiss experiment on a single electron beam generated by the single electron emitter recently developed by our group [3]. Using the chiral edge channels of the quantum Hall effect, single electron emitted by the source are directed towards an electronic beam-splitter. From the low frequency current correlations at the output of the beam splitter, we are able to count and characterize the elementary excitations produced by the source. By analyzing their antibunching with thermal excitations, we show that we are able to shape single particle states in a tuneable way. [1] Ji et al., Nature 422, 415 (2003) [2] Henny et al., Science 284 296 (1999) [3] Fève et al., Science 316, 1169 (2007)

11:39AM W24.00003 Hall Viscosity I: Linear Response Theory for Viscosity, BARRY BRADLYN, MOSHE GOLDSTEIN, NICHOLAS READ, Yale University — In two dimensional systems with broken time-reversal symmetry, there can exist a non-dissipative viscosity coefficient [1,2,3]. This Hall viscosity is similar in nature to the non-dissipative Hall conductivity. In order to investigate this phenomenon further, we develop a linear response formalism for viscosity. We derive a Kubo formula for the frequency dependent viscosity tensor in the long wavelength limit. We compute the viscosity tensor for the free electron gas, integer quantum Hall systems, and two-dimensional paired superfluids. In the zero frequency limit, we show how the known results [3,4] for the Hall viscosity are recovered.

11:51AM W24.00004 Hall Viscosity II: Extracting Viscosity from Conductivity, MOSHE GOLDSTEIN, BARRY BRADLYN, NICHOLAS READ, Yale University — When time reversal symmetry is broken, the viscosity tensor of a fluid can have non-dissipative components, similarly to the non-dissipative off-diagonal Hall conductivity. This "Hall viscosity" was recently shown to be half the particle density times the orbital angular momentum per particle. Its observation can thus help elucidate the nature of the more exotic quantum Hall states and related systems (e.g., p+ip superconductors). However, no concrete measurement scheme has hitherto been proposed. Motivated by this question we use linear response theory to derive a general relation between the viscosity tensor and the wave-vector dependent conductivity tensor for a Galilean-invariant quantum fluid. This relation enables one to extract the Hall viscosity, as well as other viscosity coefficients (shear and bulk) when relevant, from electromagnetic response measurements. We also discuss the connection between this result and a similar one recently derived by C. Hoyos and D. T. Son [arXiv:1109.2651].

12:03PM W24.00005 Four-point characterization using capacitive and ohmic contacts, WANG ZHOU, BRIAN KIM, YASH SHAH, CHUANLE ZHOU, MATTHEW GRAYSON, Dept. of Electrical Engineering and Computer Science, Northwestern University, NEBILE İŞIK, Walter Schottky Institut, Technische Universität München — A four-point characterization method is developed for semiconductor samples that have either capacitive or ohmic contacts. When capacitive contacts are used, capacitive current- and voltage-dividers result in a capacitive scaling factor which is not present in four-point measurements with only ohmic contacts. Both lock-in amplifier and pre-amplifier are used to measure low-noise response over a wide frequency range from 1 Hz – 100 kHz. From a circuit equivalent of the complete measurement system after carefully being modeled, both the measurement frequency band and capacitive scaling factor can be determined for various four-point characterization configurations. This technique is first demonstrated with a discrete element four-point test device and then with a capacitively and ohmically contacted Hall bar sample using lock-in measurement techniques. In all cases, data fit well to a circuit simulation of the entire measurement system over the whole frequency range of interest, and best results are achieved with large area capacitive contacts and a high input-impedance preamplifier stage. Results of samples (substrates grown by Max Bichler Dieter Schuh, and Frank Fischer of the WSI) measured in the QHE regime in magnetic fields up to 15 T at temperatures down to 1.5 K will also be shown.

12:15PM W24.00006 Growth and magnetotransport measurements of triple-valley high mobility, miscut (111) AlAs quantum wells, SUNANDA PRABHU-GAUNKAR, M. GRAYSON, Dept. of Electrical Engineering and Computer Science, Northwestern University, F. HERZOG, G. KOBLMUELLER, Walter Schottky Institut, Tech. Univ. Munchen — We optimize growth of AlAs on (111)B GaAs substrates and perform magnetotransport measurements on vicinal (111)AlAs quantum wells (QWs). Previous literature reports that MBE growth on exactly oriented GaAs (111)B substrates is difficult, and the grown epi-layers are obscured by pyramid-like surface faceting and twin defect formation; slight substrate miscut results in stable step-flow growth. We perform a combined structural analysis with AFM, TEM and XRD to correlate MBE growth conditions with defect density scaling. We find that a high growth temperature of 690° C and low As beam fluxes reduce micro-twin formation for exactly oriented substrates and eliminate them for miscut substrates. A slight miscut of 2°, at which slip-step growth is known to occur, lead to AlAs QWs with record electron mobility $\mu = 13000 \text{ cm}^2/\text{Vs}$ at a sheet density $n_{2D} = 2.17 \times 10^{11} \text{ cm}^{-2}$. Numerical calculations reveal that valley splitting is about 1 meV per degree of miscut, which compares to typical Fermi energies of 2DEGs in AlAs QWs. Signatures in the transport data indicate that not only miscut but also exchange splitting between valleys can play an important role. Magnetotransport data at 15 mK in magnetic fields up to 15 T will also be presented.

12:27PM W24.00007 Chiral heat transport in driven quantum Hall and spin Hall edge states, LILIANA ARRACHEA, Universidad de Buenos Aires, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — We consider a model for an edge state of electronic systems in the quantum Hall regime with filling $\nu = 1$ as well as in the quantum spin Hall regime. In both cases the system is in contact with two reservoirs by tunneling at point contacts. Both systems are locally driven by applying an ac voltage in one of the contacts. By weakly coupling them to a third reservoir, the transport of the generated heat is studied in two different ways: i) when the third reservoir acts as a thermometer the local temperature is sensed, and ii) when the third reservoir acts as a voltage probe the time-dependent local voltage is sensed. Our results indicate a chiral propagation of the heat along the edge in the quantum Hall case and in the quantum spin Hall case (if the injected electrons are spin polarized). The temperature profile shows that electrons along the edge thermalize with the closest upstream reservoir.

12:39PM W24.00008 Wigner path integral solution for the integer quantum Hall effect, DRIES SELS, FONS BROSENS, WIM MAGNUS, BART SÖREE, Universiteit Antwerpen — The real time propagator of the Wigner distribution function can be constructed from the Wigner-Liouville equation as a phase space path integral. By analogy with the Feynman path integral one can define a new effective Lagrangian of the system in the Wigner-Weyl representation. The effects of gauge transformations and geometric constraints on the action are discussed. In particular we discuss the dynamics of a non-interacting 2DEG on a Hall strip.

12:51PM W24.00009 Microwave reflection study of GaAs/AlGaAs devices in the regime of the radiation-induced magnetoresistance oscillations¹, TIANYU YE, A.N. RAMANAYAKA, R.G. MANI, Georgia State University, W. WEGSCHEIDER, ETH-Zurich, ETH-ZURICH COLLABORATION — The microwave-induced magnetoresistance oscillations are revealed in the GaAs/AlGaAs two dimensional electron system (2DES) under microwave and terahertz photo-excitation at liquid helium temperatures. Such oscillations are understood in terms of the displacement and inelastic models for photo-excited transport in this system. In order to identify the relative physical contributions, we have concurrently examined magnetotransport and microwave reflection from the 2DES. For the reflection measurements, a sensitive microwave detector was assimilated into the standard experimental setup. Here, we report on the observed magnetic field induced changes in the microwave reflection, and correlate the observations with concurrent transport response of the photo-excited 2DES.

¹Work has been supported by the ARO under W911NF-07-01-0158, and by the DOE under DE-SC0001762.

1:03PM W24.00010 Observation of linear-polarization-sensitivity in the microwave-radiation-induced magneto-resistance oscillations¹, RAMESH MANI, ARUNA RAMANAYAKA, Georgia State University, WERNER WEGSCHEIDER, ETH Zurich — In the quasi two-dimensional GaAs/AlGaAs system, we investigate the effect of rotating *in-situ* the electric field of linearly polarized microwaves relative to the current, on the microwave-radiation-induced magneto-resistance oscillations. We find that the frequency and the phase of the photo-excited magneto-resistance oscillations are insensitive to the polarization. On the other hand, the amplitude of the resistance oscillations are remarkably responsive to the relative orientation between the microwave antenna and the current-axis in the specimen. The results suggest a striking linear polarization sensitivity in the radiation-induced magnetoresistance oscillations.

¹DOE: DE-SC0001762, ARO: W911NF-07-01-015

1:15PM W24.00011 Non-equilibrium bosonization and its applications to quantum Hall systems, IVAN LEVKIVSKYI, EUGENE SUKHORUKOV, University of Geneva — Bosonization is a powerful theoretical method allowing one to treat interactions in 1D systems non-perturbatively. This technique in its original formulation applies to equilibrium states. In order to describe recent experiments on 1D systems far from equilibrium, we introduce a new bosonization method: A non-equilibrium state is described by imposing non-trivial boundary conditions for collective boson fields. This method allows to reduce the problem of finding correlation functions in an interacting 1D system to the calculation of full counting statistics of a process, which creates a non-equilibrium state. The full counting statistics has been extensively studied, and it is well known in several important situations. We apply the non-equilibrium bosonization technique to explain recent experiments on noise-induced dephasing in quantum Hall interferometers and to the energy equilibration at quantum Hall edge states.

1:27PM W24.00012 Single-electron quantum tomography in quantum Hall edge channels¹, PASCAL DEGIOVANNI, CNRS / ENS Lyon, CHARLES GRENIER, CPHT - Ecole Polytechnique Paris, RÉMY HERVÉ, INSA Lyon, ERWANN BOCQUILLON, Laboratoire Pierre Aigrain ENS Paris, FRANÇOIS D PARMENTIER, CNRS - Laboratoire de Photonique et Nanostructures, JEAN-MARC BERROIR, GWENDAL FÈVE, BERNARD PLAÇAIS, Laboratoire Pierre Aigrain ENS Paris — The recent demonstration of an on demand single electron source [1,2] has opened the way to a new generation of "electron quantum optics" experiments aimed at preparing, manipulating and measuring coherent single electron excitations propagating in ballistic conductors such as the edge channels of a 2DEG in the integer quantum Hall regime. In this talk, I will describe a proposal [3] for measuring single electron coherence using an Hanbury Brown and Twiss interferometer. This quantum tomography protocol could be used to characterize single electron sources and to perform quantitative studies of decoherence.

¹ANR GRant 1shot (ANR-2010-BLANC-0412)

1:39PM W24.00013 Linear polarization rotation study of the radiation-induced magnetoresistance oscillations¹, A.N. RAMANAYAKA, R.G. MANI, Georgia State University, Atlanta, GA, J. INARREA, Universidad Carlos III, Madrid, Spain, W. WEGSCHEIDER, ETH Zurich, Zurich, Switzerland — The polarization sensitivity of microwave-radiation-induced magneto-resistance oscillations is investigated by rotating, by an angle θ , the polarization of linearly polarized microwaves with respect to the long-axis of GaAs/AlGaAs Hall-bar electron devices. At low microwave power, P , experiments show a strong sinusoidal variation in the diagonal resistance R_{xx} vs. θ at the oscillatory extrema, indicating linear polarization sensitivity in the microwave radiation-induced magneto-resistance oscillations. Surprisingly, the phase shift θ_0 for maximal oscillatory R_{xx} response under photo-excitation appears dependent upon the radiation-frequency f , the extremum in question, and the magnetic field orientation or $\text{sgn}(B)$.

1:51PM W24.00014 Wave function multifractality and dephasing at quantum Hall transitions: A numerical investigation, S. BERA, Institut Neel, CNRS, Grenoble., I.S. BURMISTROV, L. D. Landau Institute for Theoretical Physics, Moscow, Russia, F. EVERS, Karlsruhe Institut für Technologie, Germany, I. GORNYI, Karlsruhe Institut für Technologie, Germany and A. F. Ioffe Physico Technical Institute, St. Petersburg, Russia, A.D. MIRLIN, Karlsruhe Institut für Technologie, Germany and Petersburg Nuclear Physics Institute, St. Petersburg, Russia — To understand the effect of the Coulomb interaction is one of the most challenging problems in the context of Anderson localization and the quantum Hall effect. In our study we address this question by following a perturbation theory in the interaction near the non-interacting fixed point. In each order diagrams appear which contain correlation functions characterizing the fluctuation properties of wavefunctions at the (non-interacting) critical fixed point. It turns out that the correlators relevant for dephasing combine in a way such that the *leading* multifractal powerlaws cancel; the subleading terms govern the interaction corrections. We present a numerical study based on the Chalker-Coddington network, in which we determine quantitatively the subleading multifractal exponents of the salient wavefunction correlators.

2:03PM W24.00015 Corrections to scaling near the quantum Hall transition, FERDINAND EVERS, HIDEAKI OBUSE, SOUMYA BERA, Institute of Nanotechnology, Karlsruhe Institute of Technology, ILYA GRUZBERG, James Franck Institute, University of Chicago — Corrections to scaling near critical points are important to understand, because they superimpose and often obscure the true asymptotics of critical scaling laws. This is true, in particular, for studies near the quantum Hall transition where recent numerical work by Slevin and Ohtsuki (Phys. Rev. B **80**, 041304 (2009)) reports a very small value for the leading irrelevant scaling index $|y| \approx 0.17$. We here report a numerical study of two-point conductances and two-terminal conductances at the integer quantum Hall transition within the Chalker-Coddington network. The scaling of these observables will be analyzed in the two-dimensional and the quasi-one-dimensional geometries. We confirm the relation between the conductance exponents X_q and the anomalous dimensions Δ_q known from the multifractal wavefunction analysis: $X_q = 2\Delta_q$. For a consistent picture it is essential to carefully account for corrections to scaling due to subleading power laws and irrelevant scaling operators.

Session W25 DCOMP: Focus Session: Modeling of Rare Events: Methods and Applications I

257A

11:15AM W25.00001 Pathways to forming glass¹, DAVID CHANDLER, University of California, Berkeley — Upon super-cooling at a finite rate, many liquids transform to glass. It is a non-equilibrium transition that depends upon both the material and the cooling protocols. We have used methods of transition path sampling to study this phenomenon in models of glass forming liquids. For the models considered, we establish the order of the transition and the nature of excitations that distinguish a melt from a glass.

¹This research has been supported in the past by grants from NSF and currently by BES-DOE.

11:51AM W25.00002 The kinetic activation-relaxation technique: an off-lattice, self-learning kinetic Monte Carlo algorithm with on-the-fly event search¹, NOMAND MOUSSEAU, Université de Montréal — While kinetic Monte Carlo algorithm has been proposed almost 40 years ago, its application in materials science has been mostly limited to lattice-based motion due to the difficulties associated with identifying new events and building usable catalogs when atoms moved into off-lattice position. Here, I present the kinetic activation-relaxation technique (kinetic ART) is an off-lattice, self-learning kinetic Monte Carlo algorithm with on-the-fly event search [1]. It combines ART nouveau [2], a very efficient unbiased open-ended activated method for finding transition states, with a topological classification [3] that allows a discrete cataloging of local environments in complex systems, including disordered materials. In kinetic ART, local topologies are first identified for all atoms in a system. ART nouveau event searches are then launched for new topologies, building an extensive catalog of barriers and events. Next, all low energy events are fully reconstructed and relaxed, allowing to take complete account of elastic effects in the system's kinetics. Using standard kinetic Monte Carlo, the clock is brought forward and an event is then selected and applied before a new search for topologies is launched. In addition to presenting the various elements of the algorithm, I will discuss three recent applications to ion-bombarded silicon, defect diffusion in Fe and structural relaxation in amorphous silicon.

This work was done in collaboration with Laurent Karim Béland, Peter Brommer, Fedwa El-Mellouhi, Jean-François Joly and Laurent Lewis.

12:27PM W25.00003 An improved Activation-Relaxation Technique method for finding transition pathways¹, FREDERIC LEGOLL, Ecole Nationale des Ponts et Chaussées — The Activation-Relaxation Technique nouveau (ARTn) is an eigenvector following method for systematic search of saddle points and transition pathways on a given potential energy surface. We propose a variation of this method aiming at improving the efficiency of the local convergence close to the saddle point. The efficiency of the method is demonstrated in the case of point defects in body centered cubic iron. We also prove the convergence and robustness of a simplified version of this new algorithm. Joint work with E. Cancès, M.-C. Marinica, K. Minoukadeh and F. Willaime.

12:39PM W25.00004 ABSTRACT WITHDRAWN –

12:51PM W25.00005 Entropic stabilization of nanoscale voids in materials under tension, DANNY PEREZ, ARTHUR F. VOTER, TIMOTHY C. GERMAN, Theoretical Division T-1, Los Alamos National Laboratory, Los Alamos, NM — While preexisting defects are known to act as nucleation sites for plastic deformation in strained materials, the kinetics of the early stages of plastic yield are still poorly understood. We use a wide range of atomistic simulation techniques (molecular dynamics, accelerated molecular dynamics, umbrella sampling, etc) to investigate the kinetics of plastic yield around small nanoscale voids in copper under uniaxial tensile strain. We demonstrate that, at finite temperatures, these voids are stabilized by strong entropic effects and show that their lifetime is significant even when the static mechanical instability limit is exceeded. This stabilization phenomenon dramatically affects the yield kinetics: the lifetime of the voids is seen to increase with increasing temperature, in contrast with the usual thermally-activated behavior. Even accounting for thermal activation, very small voids prove to be extremely inefficient nucleation sites for plasticity.

1:03PM W25.00006 Estimate Exponential Large Mean Exit Time for Diffusion Process, XIANG ZHOU, HUI WANG, Brown University — We propose an efficient numerical method to estimate the mean exit time of a high dimensional diffusion process associated with an Ito SDE with a gradient drift and small ϵ diffusion coefficient, starting from a stable equilibrium of the drift. It is well-known that the mean exit time is exponential large in ϵ and thus the direct simulation of the SDE requires long time integration. Our method only requires the simulation time $O(1/\epsilon)$ and is based on the Ornstein-Uhlenbeck diffusion in each dimension.

1:15PM W25.00007 K-ART study of defect evolution on experimental time scales in bcc iron and Cu–Zr interfaces, PETER BROMMER, NORMAND MOUSSEAU, Département de physique, Université de Montréal, Québec, Canada — Defects in metals are challenging to study in linear simulation schemes like molecular dynamics (MD), as diffusive activation barriers are typically high compared to $k_B T$, and most resources are devoted to integrating out thermal vibration. Simultaneously, low-energy non-diffusive rearrangements (so-called basins) are serious obstacles for methods that use state-to-state trajectories like kinetic Monte Carlo (KMC). We combined the kinetic Activation-Relaxation technique (k-ART, [1]), an off-lattice, self-learning KMC method which correctly reproduces long-range interactions, with an autonomous basin identification scheme that averages over all in-basin transitions. This allows us to study defect evolution on much longer time scales than MD. In this talk, we present results on the vacancy cluster formation in bcc iron and interface diffusion in the Cu–Zr system.

1:27PM W25.00008 Accelerated Molecular Dynamics of GaAs(001) Homoepitaxy: Effects of Long-Range Disorder¹, YANGZHENG LIN, KRISTEN FICHTHORN, Penn State University — GaAs homoepitaxy and heteroepitaxy are both fundamentally and technologically significant. From a fundamental perspective, recent experimental work has shown that the GaAs(001) $\beta 2(2\times 4)$ substrate can transform and play an active role in diffusion and the morphologies that form during thin-film growth. Structural transformations lead to a substrate with local (2×4) domains that exhibit long-range disorder characteristic of $c(2\times 8)$. At experimentally relevant temperatures, these transformations are mediated by rare events that occur over time scales ranging from ns to ms, which makes it difficult to probe the kinetics with conventional rare-event techniques. We develop an accelerated molecular dynamics (MD) protocol to deal with this challenge and we apply it to describe the temperature-dependent long-range structure of the surface. Our results are in agreement with experiment. Adatom diffusion occurs over longer time scales than those associated with transformations of the surface. Our accelerated MD studies indicate that adatom diffusion on this surface occurs via different mechanisms than those suggested by previous theoretical studies based on first-principles density-functional theory.

1:39PM W25.00009 Ultimate self-learning metabasin escape algorithm for supercooled liquids and glasses, PENGHUI CAO, HAROLD S. PARK, XI LIN, Department of Mechanical Engineering, Boston University — A generic history-penalized metabasin escape algorithm is presented in this work without any predetermined parameters. The configuration space location and volume of imposed penalty functions are determined in self-learning processes as the complete 3N-dimensional potential energy surface is sampled. The computational efficiency is demonstrated using the binary Lennard-Jones liquid supercooled to the glass transition temperature, which shows an exponential enhancement over previous algorithm implementations.

1:51PM W25.00010 Modeling Correlation and Defect Effects on Mixed Polaronic and Ionic Transport in Rare-Earth Phosphates, NICOLE ADELSTEIN, University of California at Berkeley — Rare-earth phosphates are promising candidates for intermediate-temperature proton-conducting fuel cell membranes, with Sr-doped CePO_4 showing particularly high conductivity in oxidizing conditions. Since this high conductivity is likely due to hole-polarons rather than protons, the defect chemistry of incorporating charge carriers (protons versus holes versus oxygen vacancies) is currently being investigated with experiments and calculations. In this work, the dominant charge carrier and its transport in CePO_4 is calculated with density functional theory and compared to conductivity and photon beam experiments. In particular, we present ab-initio calculations on the thermodynamics of the dopants and defects and proton and hole-polaron mobilities. For the case of hole-polaron mobilities, the strength of the coupling with the lattice and the electronic coupling between sites will be investigated.

Session W26 DCOMP: Focus Session: What is Computational Physics? New Technologies and Their Application 257B

11:15AM W26.00001 The Future of Scientific Computing, THOM DUNNING, National Center for Supercomputing Applications, University of Illinois at Urbana-Champaign — Computing technologies are undergoing a dramatic transition. Multicore chips with up to eight cores are now available from many vendors. This trend will continue, with the number of cores on a chip continuing to increase. In fact, many-core chips, e.g., NVIDIA GPUs, are now being seriously explored in many areas of scientific computing. This technology shift presents a challenge for computational science and engineering—the only significant performance increases in the future will be through the increased exploitation of parallelism. At the same time, petascale computers based on these technologies are being deployed at sites across the world. The opportunities arising from petascale computing are enormous—predicting the behavior of complex biological systems, understanding the production of heavy elements in supernovae, designing catalysts at the atomic level, predicting changes in the earth's climate and ecosystems, and designing complex engineered systems. But, petascale computers are very complex systems, built from multi-core and many-core chips with 100,000s to millions of cores, 100s of terabytes to petabytes of memory, and 10,000s of disk drives. The architecture of petascale computers has significant implications for the design of the next generation of science and engineering applications. In this presentation, we will provide an overview of the directions in computing technologies as well as describe the petascale computing systems being deployed in the U.S. and elsewhere.

11:51AM W26.00002 GPU Acceleration of the Qbox First-Principles Molecular Dynamics Code¹, WILLIAM DAWSON, FRANCOIS GYGI, Department of Computer Science, University of California Davis, Davis CA 95616 — The availability of double precision graphics cards provides an opportunity to speed up electronic structure computations. We modify the Qbox [1] code to utilize Fermi GPUs on the Keeneland [2] platform. We use the CUFFT library to speed up Fourier transforms and perform asynchronous communication to cut down the cost of data transfers. The modified code is used in simulations of a 64-molecule water system with an 85 Ry plane wave energy cut off. Preliminary results show a 2-3 times speedup in the calculation of the charge density and in the application of the Hamiltonian operator to the wave function. We present these findings as well as further speedups measured in other parts of the code.

12:03PM W26.00003 Quantum Monte Carlo in the era of petascale computers, JEONGNIM KIM, University of Illinois at Urbana-Champaign and Oak Ridge National Laboratory, KENNETH ESLER, Stone Ridge Technology, JEREMY MCMINIS, University of Illinois at Urbana-Champaign, MIGUEL MORALES, Lawrence Livermore National Laboratory, BRYAN CLARK, Princeton University, LUKE SHULENBURGER, Sandia National Laboratories, DAVID CEPERLEY, University of Illinois at Urbana-Champaign — Continuum quantum Monte Carlo (QMC) methods are a leading contender for high accuracy calculations for the electronic structure of realistic systems, especially on massively parallel high-performance computers (HPC). The performance gain on recent HPC systems is largely driven by increasing parallelism: the number of compute cores of a SMP and the number of SMPs have been going up, as the Top500 list attests. However, the available memory as well as the communication and memory bandwidth per element has not kept pace with the increasing parallelism. This severely limits the applicability of QMC and the problem size it can handle. (OpenMP,CUDA)/MPI hybrid programming provides applications with simple but effective solutions to overcome efficiency and scalability bottlenecks on large-scale clusters based on multi/many-core SMPs. We discuss the design and implementation of hybrid methods in QMCPACK and analyze its performance on multi-petaflop platforms characterized by various memory and communication hierarchies. Also presented are QMC calculations of bulk systems, including defects in semiconductors.

12:15PM W26.00004 GPU accelerated replica-exchange simulations of polymers, JONATHAN GROSS, MICHAEL BACHMANN, Center for Simulational Physics, University of Georgia, Athens, Georgia 30602, USA — Precise estimation of physical quantities using Monte Carlo computer simulations strongly depends on the amount of statistical data gathered during the simulation. Being able to increase the performance of the sampling process will allow more accurate results in a shorter time period. To employ the parallel tempering replica-exchange algorithm on parallel hardware such as multicore CPUs and GPUs turns out to be very suitable for the task. We achieve rapid speedups in our investigation of an exemplified bead-spring polymer model. Identification and classification of phase-like transitions were done by analyzing the microcanonical entropy.

12:27PM W26.00005 Graphics Processing Unit Accelerated Hirsch-Fye Quantum Monte Carlo, CONRAD MOORE, SAMEER ABU ASAL, KAUSHIK RAJAGOPLAN, DAVID POLIAKOFF, JOSEPH CAPRINO, Louisiana State University, KAREN TOMKO, Ohio State University, BHUPENDER THAKUR, SHUXIANG YANG, JUANA MORENO, MARK JARRELL, Louisiana State University — In Dynamical Mean Field Theory and its cluster extensions, such as the Dynamic Cluster Algorithm, the bottleneck of the algorithm is solving the self-consistency equations with an impurity solver. Hirsch-Fye Quantum Monte Carlo is one of the most commonly used impurity and cluster solvers. This work implements optimizations of the algorithm, such as enabling large data re-use, suitable for the Graphics Processing Unit (GPU) architecture. The GPU's sheer number of concurrent parallel computations and large bandwidth to many shared memories takes advantage of the inherent parallelism in the Green function update and measurement routines, and can substantially improve the efficiency of the Hirsch-Fye impurity solver.

1:27PM W26.00010 Mantid, A high performance framework for reduction and analysis of neutron scattering data, JON TAYLOR, ISIS STFC, O. ARNOLD, Tessella PLC, J. BILHEAUX, ORNL, A. BUTS, ISIS STFC, S. CAMPBELL, M. DOUCET, ORNL, N. DRAPER, Tessella PLC, R. FOWLER, STFC, M. GIGG, Tessella PLC, V. LYNCH, ORNL, A. MARKVARDSEN, K. PALMEN, P. PARKER, ISIS STFC, P. PETERSON, S. REN, M. REUTER, A. SAVICI, ORNL, R. TAYLOR, R. TOLCHENOV, Tessella PLC, R. WHITLEY, ISIS STFC, W. ZHOU, J. ZIKOVSKY, ORNL — The use of large scale facilities by researchers in the field of condensed matter, soft matter and the life sciences is becoming ever more prevalent in the modern research landscape. Facilities such as SNS and HiFNR at ORNL and ISIS at RAL have ever increasing user demand and produce ever increasing volumes of data. One of the single most important barriers between experiment and publication is the complex and time consuming effort that individual researchers apply to data reduction and analysis. The objective of the Manipulation and Analysis Toolkit for Instrument Data or MANTID [1] framework is to bridge this gap with a common interface for data reduction and analysis that is seamless between the user experience at the time of the experiment and at their home institute when performing the final analysis and fitting of the data.

1:39PM W26.00011 SU(N) Clebsch-Gordan coefficients and non-Abelian symmetries, ARNE ALEX, LUKAS EVERDING, Arnold Sommerfeld Center, LMU Munich, PETER LITTELMANN, University of Cologne, JAN VON DELFT, Arnold Sommerfeld Center, LMU Munich — The numerical treatment of models with SU(N) benefits greatly from the Wigner-Eckart theorem. Its application requires the explicit knowledge of the Clebsch-Gordan coefficients (CGCs) of the group SU(N). We present an algorithm for the explicit numerical calculation of SU(N) CGCs based on the *Gelfand-Tsetlin pattern* calculus. Further exploitation of the Weyl symmetry of SU(N) irreducible representations (irreps) leads to a significant speed-up compared to our previous algorithm (J. Math. Phys. 52, 023507, 2011). Our algorithm works for arbitrary N and tensor products of two arbitrary SU(N) irreps. It is well-suited for numerical implementation; we provide a well-tested computer code for download and online use. Possible applications of our code include numerical treatments of quantum many-body systems using the numerical renormalization group (NRG), the density matrix renormalization group (DMRG), and general tensor network methods.

1:51PM W26.00012 Efficient interacting many body simulations using GPUs, TOBIAS KRAMER, Universität Regensburg — Graphics Processing Units (GPUs) provide an ideal tool to study interacting systems using classical mechanics with huge speedups for example in molecular dynamics. The quantum-mechanical calculations of many-body systems require additional work, but are feasible using additional degrees of freedom to incorporate quantum-mechanical effects [1]. As an example of the method I show the self-consistent solution to the current transport in a magnetic field can be obtained from a microscopic model with thousands of Coulomb interacting electrons. This yields a microscopic model of the Hall effect [2]. For few electron systems I compare the electronic density evolution based on the GPU classical-quantum model to TD-DFT calculations and discuss prospects of GPUs for solving the Schrodinger equation for many-particles.

Session W27 DCMP: Invited Session: Electrons, Spins, and Collective Modes in Nanofilms

11:15AM W27.00001 Plasmons under extreme dimensional confinement, HANNO WEITERING, Department of Physics and Astronomy, The University of Tennessee — In our studies, we explore how surface and bulk plasmons emerge under extreme dimensional confinement, i.e., dimensions that are orders of magnitude smaller than those employed in ‘nanoplasmonics’. Atomically-smooth ultrathin Mg films were epitaxially grown on Si(111), allowing for atomically-precise tuning of the plasmon response.¹ While the single-particle states in these 3-12 monolayer (ML) thick films consist of a series of two-dimensional subbands, the bulk-plasmon response is like that of a thin slice carved from bulk Mg subject to quantum-mechanical boundary conditions. Remarkably, this bulk-like behavior persists all the way down to 3 ML. In the 3-12 ML thickness range, bulk loss spectra are dominated by the $n=1$ and $n=2$ normal modes, consistent with the excitation of plasmons involving quantized electronic subbands. The collective response of the thinnest films is furthermore characterized by a thickness-dependent spectral weight transfer from the high-energy collective modes to the low-energy single-particle excitations, until the bulk plasmon ceases to exist below 3 ML. Surface- and multipole plasmon modes even persist down to 2 ML. These results are striking manifestations of the role of quantum confinement on plasmon resonances in precisely controlled nanostructures. They furthermore suggest the intriguing possibility of tuning resonant plasmon frequencies via precise dimensional control.

11:51AM W27.00002 Radial band structure of a ultrathin liquid metal film¹, HAN WOONG YEOM, Department of Physics, POSTECH — Understanding the properties of strongly disordered materials has been one of the long standing and most challenging problems in condensed matter physics. One major difficulty lies in the failure of the band structure concept to describe electronic properties due to the lack of the periodicity, as notorious for electrons in liquid metals without any well-established and well-tested alternative until now. In this work, we experimentally, using angle-resolved photoelectron spectroscopy, establish the formation of an intriguing “double radial band structure” in a strongly disordered electronic system of a liquid metal Pb. A monolayer Pb film was formed on Si(111) with an unusually low melting temperature and its detailed band dispersions and Fermi contours were mapped throughout the melting process. Furthermore, we introduce the way to understand this characteristic band structure based on an old theoretical idea proposed in 1962 invoking the coherent radial scattering of electrons, which can be widely encountered in wave scatterings within disordered media. In conclusion, liquid metals, or possibly other strongly disordered electronic systems, have well defined radial bandstructures through the coherent radial scattering of electrons and the radial correlation of atoms.

¹This work was supported by National Research Foundation of Korea through the CRi program.

12:27PM W27.00003 Ultrafast mass transport during decay of gigantic Pb mesas on Ni(111), BENE POELSEMA, Physics of Interfaces and Nanomaterials, MESA+ Institute for Nanotechnology, University of Twente — We have studied the initial growth of Pb films on Ni(111) at elevated temperatures of 424 K and 474 K. Quantum Well States (QWS's) have been found to be responsible for the morphology of these Pb films on Ni(111). The delicate balance between surface energies, elastic energies and QWS's is initially tilted towards QWS's, as discrete layer heights are observed. First, a strong preference for 5 and 7 layers high, flat topped Pb islands is observed, showing several striking similarities with Pb films on Si(111) and on Cu(111). Key examples of these will be discussed. When the character of the rough film gradually changes from 2D to 3D, the balance between these forces becomes more and more dominated by interfacial energies. A tipping point is reached by very slowly heating the surface to about 520 K. As the energetic balance is tipped for good in favor of the interface free energy, the electronically stabilized, extended, about 40 layers high mesas suddenly decay towards compact hemispheric structures. The spectacular speed at which the transition takes place (billions of atoms move over several microns during a few milliseconds!) is many orders of magnitude larger than what is expected, based on arguments involving thermally activated behavior on atomic scales. I will discuss peculiarities of the wetting layer and its changes, which appear to coincide with the ultrafast transition of the film morphology. With a widespread interest in nanostructures in general, our results illustrate the generic need to characterize all aspects of nanostructures, both structural and electronic, since small excursions away from equilibrium can have dramatic consequences. Phys. **13**, 103025 (2011).

1:03PM W27.00004 Regulating spin and Fermi surface topology of a quantum metal film by the surface (interface) monatomic layer, IWAO MATSUDA, the Institute for Solid State Physics, the University of Tokyo — Spin and current controls in solids have been one of the central issues in researches of electron and spin transport. Nowadays, electronics/spintronics deals with nanometer- or atomic-scale structures and miniaturization of these systems implies emergence of various quantum phenomena, intimately linked to the formation of electronic states different from those of the corresponding bulk materials. For example, valence electrons of films with the thickness comparable to the electron wavelength form discrete quantum-well states (QWSs) under opportune conditions of confinement (quantum size effect). Furthermore, the size reduction also increases the surface/volume ratio and a film possibly changes its electronic (spin) properties by the surface effect. Concerning metal films, the quantum size effect requires the thickness in a range of nanometers and the length corresponds to several tens of atoms, indicating the very large ratio of a surface (interface) monatomic layer to film atomic layers. Thus, we have been interested in combining the quantum size effects and the surface effect on the metal films to induce new physical phenomena. In the present talk, two research cases are shown. 1) Instead of isotropic two-dimensional in-plane states expected for an isolated metal film, quasi-one-dimensional quantized states were measured by photoemission spectroscopy in an epitaxial Ag(111) ultra thin film, prepared on an array of atomic chains [1]. 2) High-resolution spin-resolved photoemission and magneto-transport experiments of ultrathin Ag(111) films, covered with a $\sqrt{3}\times\sqrt{3}$ -Bi/Ag surface ordered alloy, were performed. The surface state (SS) bands, spin-split by the Rashba interaction, selectively couple to the originally spin-degenerate QWS bands in the metal film, making the spin-dependent hybridization [2,3]. Magnetoconductance of the films, measured in situ by the micro-four-point probe method as a function of the applied magnetic field [4], has shown that the formation of the Rashba-type surface alloy reduces the spin-relaxation time in the ultrathin film significantly [5]. These results demonstrate that spin and Fermi surface topology of a quantum metal film can be regulated by the surface (interface) monatomic layer.

1:39PM W27.00005 Quantum Oscillations of Surface Electronic Structure: Inter-relation Between Quantum Well States, Work Functions and Surface Energies, CHIH-KANG SHIH, The University of Texas at Austin — Quantum size effects (QSE) in ultra-thin metallic film has been a topic of intense investigations. Of particular interests are the inter-relationship between the quantum well states (QWS), work function (W) and surface energy (E_s). In ultrathin Pb films on semiconductors, quantum oscillations of E_s as a function of layer thickness (L) have been investigated by various experimental methods which have all yielded identical results. Experimental studies of work function, however, took a longer journey. Photoemission can probe the work function for a uniform film but in this case uniform film only exists for certain thicknesses. Scanning tunneling microscopy, can probe “local” properties for all thicknesses, but the very existence of QWS in these films profoundly affects the measured tunneling decay constant κ . Consequently, L-dependence of κ also depends on the bias voltage. It was then discovered that at a very low sample bias ($|V_s| < 0.03$ V) the measured κ vs. L accurately reflects the quantum size effect on the work function [1]. With this last obstacle removed, we are able to simultaneously measure the W vs. L, E_s vs. L and to correlate these quantities with the measured QWS locations, yielding the quantitative phase relationship between the quantum oscillations of work function and surface energy. To our surprise, instead of a predicted $1/4$ wavelength phase shift, we find that the quantum oscillations of these two quantities are exactly in-phase. A new model is proposed.

Thursday, March 1, 2012 11:15AM - 1:51PM —

Session W29 GQI: Focus Session: Superconducting Qubits: Resonators and Loss Mechanisms

259A

11:15AM W29.00001 Microwave Loss in Josephson Junction Embedded Superconducting Resonators¹, STEVEN WEBER, KATER MURCH, I. SIDDIQI, UC Berkeley, QNL — We report on progress to identify and mitigate sources of microwave frequency loss in Josephson junction resonant circuits at low temperature and power—the operating regime of superconducting qubits. Large critical current junctions (>500nA) were embedded in lumped element 4–8 GHz superconducting resonators based on single crystal silicon dielectric overlap capacitors. Small critical current junctions (25-100nA) were characterized by measuring the T_1 relaxation time of transmon qubits. For both sets of measurements, the critical current density was varied from 20-800 A/cm². We present the dependence of junction loss on junction area and environmental factors such as shielding and filtering.

¹This research was supported by the IARPA CSQ program.

11:27AM W29.00002 Superconducting Microwave Resonators, CHARLES NEILL, ANTHONY MEGRANT, MIKE LENANDER, RAMI BARENDs, JIM WENNER, TED WHITE, DANIEL SANK, YU CHEN, YI YIN, BEN CHIARO, JULIAN KELLY, PETER O'MALLEY, PEDRAM ROUSHAN, ERIK LUCERO, AMIT VAINSENER, JOERG BOCHMANN, MATTEO MARIANTONI, CHRIS AXLINE, JOHN MARTINIS, ANDREW CLELAND, UCSB — High quality factor superconducting microwave resonators play a key role in applications to quantum computation and single photon detection schemes. We have optimized our aluminum quarter wavelength coplanar waveguide resonators in an effort to improve energy decay times. As the characteristic decay times in our samples begin to approach the requirements set out by fault tolerant error correction algorithms, reproducibility becomes a growing focus. Consistent reproduction of high quality factor resonators requires reliable determination of device parameters independent of experimental imperfections and environmental influences. These measurements permit an improved understanding of the variations between nominally identical resonators as well as variations in an individual sample over time. Recent experimental results will be discussed.

11:39AM W29.00003 Improving the Quality Factor of Superconducting Resonators¹, ANTHONY MEGRANT, CHARLES NEILL, RAMI BARENDs, BEN CHIARO, MIKE LENANDER, CHRIS PALMSTROM, JOHN MARTINIS, ANDREW CLELAND, UC Santa Barbara, UCSB SUPERCONDUCTING QUANTUM INFORMATION GROUP TEAM — Superconducting resonators hold great promise for quantum information storage in quantum computing. Improving the coherence lifetimes is therefore of central interest. We have focused on improving the interface between the resonator's underlying dielectric and superconducting metallization, as simulations have shown this interface to be a major source of loss, possibly associated with two-level states. After mitigating for stray light and magnetic fields, we have achieved low power intrinsic quality factors in excess of one million at single photon energies, with high power Q's in excess of ten million. Attaining such high quality factors is dependent on substrate preparation before depositing the superconductor, as well as the deposition method. We will describe the fabrication method and characterization of resonators that consistently achieve quality factors above one million.

¹IARPA\ARO Grant : W911NF-09-1-0375

11:51AM W29.00004 Investigation of superconducting resonator designs for measuring the microwave response of vortices, I. NSANZINEZA, H. CHEN, C. SONG, B.L.T PLOURDE, Syracuse University — The microwave response of superconductors can be influenced by the presence of vortices and the dynamics they exhibit at high frequencies. We present measurements of vortices trapped in superconducting resonators fabricated from thin aluminum films, a common material for superconducting qubit circuits. In particular, we are studying the dependence of the threshold magnetic field for trapping vortices on the resonator geometry. We perform field-cooled measurements of various configurations of coplanar waveguide resonators to study the magnetic field, frequency, and temperature dependence of the microwave vortex response. The addition of vortices results in a downward shift in resonant frequency and a reduction in the resonator quality factor. We discuss the optimization of the resonator layout for detecting the response from only a few vortices trapped in the superconducting film.

12:03PM W29.00005 Anomalous magnetic field effects in high Q superconducting resonators, M. LENANDER, R. BARENDs, YU CHEN, J. KELLY, ERIK LUCERO, MATTEO MARIANTONI, A. MEGRANT, P.J.J. O'MALLEY, C. NEILL, D. SANK, A. VAINSENER, H. WANG, J. WENNER, T.C. WHITE, Y. YIN, J. ZHAO, C. PALMSTROM, A.N. CLELAND, JOHN M. MARTINIS, UCSB — Superconducting coplanar wave guide resonators are an important tool in quantum computing for use as memory elements. Recent process improvements have allowed for quality factors in excess of 1.5 million at single photon excitations. While allowing for more sensitive experiments, the most recent group of resonators exhibit very high sensitivity to magnetic fields. Ordinarily Abrikosov vortex physics is expected to govern the magnetic response of the resonators. During field cooling, vortices begin to form at a threshold field, B_{th} , that depends quadratically on the width of the resonator. However these resonators show an observed B_{th} two orders of magnitude lower than predicted by theory and without any scaling with resonator width. We explore increased sensitivity to frequency fluctuations at nonzero field as a possible explanation for reduced quality factor long before vortices are expected to form.

12:15PM W29.00006 Quality Factor Measurements with Improved Superconducting Stripline Resonators¹, ERIC HOLLAND, LUYAN SUN, MATTHEW REAGOR, KEVIN CHOU, LUIGI FRUNZIO, ROBERT SCHOELKOPF, Yale University — Superconducting microwave resonators can be coupled to a superconducting qubit to manipulate, read out and protect the qubit from the environment. Improvements in resonator quality factors, Q, offer a variety of benefits. One benefit of higher Qs is the possibility for longer coherence times. Alternatively, higher Q resonators could be implemented as a quantum memory. We fabricated and tested superconducting stripline resonators which are designed to minimize sensitivity to surface dielectric losses. These devices allow the possibility of sensitive testing of superconducting film quality and/or losses in the bulk substrate dielectric. By measuring these losses we can better understand possible mechanisms of decoherence in superconducting qubits. Preliminary quality factor results, taken at milliKelvin temperatures, will be given.

¹Funded by IARPA

12:27PM W29.00007 Dielectric loss analysis using linear resonators with different impedances, BAHMAN SARABI, M.S. KHALIL, M.A. KHASAWNEH, M.J.A. STOUTIMORE, SERGIY GLADCHENKO, University of Maryland and Laboratory for Physical Sciences, F.C. WELLSTOOD, C.J. LOBB, University of Maryland, K.D. OSBORN, Laboratory for Physical Sciences — It is known that amorphous dielectrics are a major source of decoherence in superconducting qubits due to energy absorption by two-level systems coupled to the electric fields. Linear resonators have been applied extensively to study loss in different dielectrics used in qubit circuits due to their versatility and relative simplicity in design, fabrication and measurement. We have designed linear resonators with multi-turn inductors and parallel-plate capacitors with resonance frequencies of 4.8-6.4 GHz. We achieve substantially different L/C values and capacitor volumes by varying the number of inductance turns and the area of the capacitors. We will present results of continuous wave measurements with SiN_x capacitors and show how loss tangent and phase noise are related to impedance and capacitor volume.

12:39PM W29.00008 ABSTRACT WITHDRAWN —

12:51PM W29.00009 Reduction of Microwave Loss in Titanium Nitride CPW Resonators, MICHAEL VISSERS, National Institute of Standards and Technology, Boulder, CO, DAVID WISBEY, St Louis University, St Louis, MO, JIANGSONG GAO, JEFFREY KLINE, MARTIN SANDBERG, MARTIN WEIDES, DAVID PAPPAS, National Institute of Standards and Technology, Boulder, CO — Titanium Nitride (TiN) thin films, when optimally grown and processed, exhibit very low microwave loss at high and low power. We investigate reducing the loss by systematically removing Si substrate material from the gap region in TiN coplanar waveguides (CPWs) fabricated on intrinsic Si substrates. By exploiting the radial dependence of the etch rate in a parallel plate reactive ion etcher, otherwise identical CPWs with only the gaps etched to varying depth, i.e. trenched, were created in a single TiN film within a single processing step. The high power loss is similar for all resonators, $< 2 \times 10^{-7}$. However, when comparing the loss from all trench depths in the single photon regime at 50 mK we find that loss was reduced for the deeper trenches with the deepest reduced by a factor of 2. Predictions from finite-element analysis, with a reduced participation of lossy surface oxides in the deeper trenched CPW gaps, fit well to the measured reduction.

1:03PM W29.00010 Cooper Pair Transistor Embedded in a dc-Biased High-Q Microwave Cavity¹, JULIANG LI, FEI CHEN, JOEL STETTENHEIM, Dartmouth College, A.J. SIROIS, University of Colorado, Boulder, R.W. SIMMONDS, National Institute of Standards and Technology, Boulder, M.P. BLENCOWE, A.J. RIMBERG, Dartmouth College — A high-Q microwave cavity design based on the circuit quantum electrodynamics architecture has been developed to introduce a dc bias to the center conductor of the cavity without significantly degrading the Q at high frequencies [1]. Here we directly couple Cooper pair transistors (CPTs) to such a cavity. In the subgap region of the CPT, the dc bias generates a tunable oscillating current through the CPT via the ac Josephson effect. Evidence of such self-oscillations has been observed as current peaks in our dc measurements, which are in good agreement with calculated cavity modes, and indicate the strong coupling between the CPT and the cavity. Recent experimental results will be discussed.

1:15PM W29.00011 Photon Emission from a Self-oscillating Cavity-Embedded-Cooper Pair Transistor¹, FEI CHEN, JOEL STETTENHEIM, JULIANG LI, Dartmouth College, A.J. SIROIS, University of Colorado, Boulder, R.W. SIMMONDS, National Institute of Standards and Technology, Boulder, M.P. BLENCOWE, A.J. RIMBERG, Dartmouth College — A strongly non-linear superconducting device consisting of a Cooper pair transistor embedded in a dc voltage biased microwave cavity is investigated. The cavity-embedded-Cooper pair transistor (CECPT) is driven via the ac Josephson effect by an applied dc bias and exhibits self-oscillation without an external ac drive. Tunneling Cooper pairs can both emit photons into and absorb photons from microwave cavity modes. Photons emitted into the cavity are directly probed and are in good agreement with dc measurements. Photon emission arising from both sequential tunneling and cotunnelling processes has been observed. The CECPT offers an interesting system for studying nonlinear quantum dynamics and the quantum-to-classical transition. Recent experimental results will be discussed.

¹This work is supported by the NSF, AFOSR and DARPA.

1:27PM W29.00012 Superconducting microstrip resonators for circuit QED experiments¹, M. HAEBERLEIN, M. KRAWCZYK, A. BAUST, J. GOETZ, E. HOFFMANN, E. P. MENZEL, M. SCHWARZ, F. WULSCHNER, L. ZHONG, F. DEPPE, A. MARX, R. GROSS, Walther-Meissner-Institut — Superconducting microstrip resonators have several advantages when designing scalable circuit QED systems. Their simple geometry facilitates the implementation of additional circuit elements and control lines, and, most importantly, their spectrum tends to exhibit nearly no parasitic modes up to 20 GHz even for more complicated geometries. However, due to their specific field configuration they are not expected to yield high Q-factors at very low temperatures. We analyzed such resonators at Millikelvin temperatures and find experimentally useful quality factors of approximately 1500 even in the low temperature low power limit. Our analysis indicates that even ten times higher quality factors can be achieved straightforwardly by choosing substrates with better dielectric properties. Supported by the DFG via SFB 631 and by the German Excellence Initiative via NIM

1:39PM W29.00013 Superconducting Resonators with Parasitic Electromagnetic Environments, JOHN HORNIBROOK, School of Physics, University of Sydney, 2006, Australia, EMMA MITCHELL, CSIRO Materials Science and Engineering, Lindfield 2070 Australia, DAVID REILLY, School of Physics, University of Sydney, 2006, Australia — Microwave losses in niobium superconducting resonators are investigated at milli-Kelvin temperatures and with low drive power. In addition to the well-known suppression of Q-factor that arises from coupling between the resonator and two-level defects in the dielectric substrate [1-4], we report strong dependence of the loaded Q-factor and resonance line-shape on the electromagnetic environment. Methods to suppress parasitic coupling between the resonator and its environment are demonstrated.

Thursday, March 1, 2012 11:15AM - 2:15PM – Session W30 GQI: Quantum Entanglement 259B

11:15AM W30.00001 Entanglement, Fluctuations, and Quantum Critical Points, STEPHAN RACHEL, Department of Physics, Yale University, New Haven, CT 06520, USA, NICOLAS LAFLORENCIÉ, Laboratoire de Physique Theorique, Universite de Toulouse, UPS, (IRSAMC), F-31062 Toulouse, France, H. FRANCIS SONG, Department of Physics, Yale University, New Haven, CT 06520, USA, KARYN LE HUR, Center for Theoretical Physics, Ecole Polytechnique, 91128 Palaiseau Cedex, France and Department of Physics, Yale University, New Haven, CT 06520 — We show that bipartite fluctuations F can be considered an entanglement measure. We further demonstrate that the concept of bipartite fluctuations F provides a very efficient tool to detect quantum phase transitions in strongly correlated systems. We investigate paradigmatic examples for both quantum spins and bosons in one and two dimensions. As compared to the von Neumann entanglement entropy, we observe that F allows to find quantum critical points with a much better accuracy in one dimension. We further demonstrate that F can be successfully applied to the detection of quantum criticality in higher dimensions with no prior knowledge of the universality class of the transition. Promising approaches to experimentally access fluctuations are discussed for quantum antiferromagnets and cold gases.

11:27AM W30.00002 A statistical portrait of the entanglement decay of two-qubit memories¹, KAREN FONSECA-ROMERO, JULIAN MARTINEZ-RINCON², Universidad Nacional de Colombia — We present a novel approach to the study of entanglement decay, which focuses on collective properties. As an example, we investigate the entanglement decay of a two-qubit memory, produced by local identical reservoirs acting on the qubits, for three experimentally and theoretically relevant cases: depolarizing, dephasing and amplitude-damping channels. We study the probability distributions of disentanglement times, a quantity independent of the measure used to quantify entanglement, and the time-dependent probability distribution of concurrence. Uniformly distributed pure states are assumed for the two-qubit system. The calculation of these probability distributions gives a clearer insight on how different decoherence channels affect the entanglement initially contained in the set of two-qubit pure states. The entanglement evolution of mixed states, under the Hilbert-Schmidt metric, is also considered.

11:39AM W30.00003 Quantum Mutual Information Capacity for High Dimensional Entangled States¹, P. BENJAMIN DIXON, Research Laboratory of Electronics, MIT, GREGORY A. HOWLAND, JAMES SCHNEELOCH, JOHN C. HOWELL, University of Rochester — High dimensional Hilbert spaces used for quantum communication channels offer the possibility of large data transmission capabilities and improved security. We propose a method of characterizing the channel capacity of an entangled photonic state in high dimensional position and momentum bases. We use this method to measure the channel capacity of a parametric downconversion state, achieving a channel capacity over 7 bits/photon in either the position or momentum basis, by measuring in up to 576 dimensions per detector. The channel strongly violated an entropic separability bound, indicating the performance cannot be replicated classically.

11:51AM W30.00004 Entangling Qubits in a One-Dimensional Harmonic Oscillator, EDMUND OWEN, MATTHEW DEAN, CRISPIN BARNES, University of Cambridge — We present a method for generating entanglement between qubits associated with a pair of particles interacting in a one-dimensional harmonic potential. By considering the effect of the interaction on the energy spectrum of the system, we show that, under certain approximations, a “power-of-SWAP” operation is performed on the initial two-qubit quantum state without requiring any time-dependent control. Initialization errors and deviations from our approximation are shown to have a negligible effect on the final state. Using a GPU-accelerated iteration scheme to find numerical solutions to the two-particle time-dependent Schrödinger equation, we demonstrate that it is possible to generate maximally entangled Bell states between the two qubits with high fidelity for a range of possible interaction potentials.

12:03PM W30.00005 Entanglement entropy for arbitrary quantum lattice models from quantum Monte Carlo, TOMMASO ROSCILDE, Ecole Normale Supérieure de Lyon (France), STEPHAN HUMENIUK, Ecole Normale Supérieure de Lyon (France) and Ludwig-Maximilians-Universität, Munich (Germany) — We present a general scheme to numerically calculate the Renyi entropy for the reduced density matrix of a subsystem in a quantum lattice model at finite and (physically) zero temperature. This scheme is based on an extended-ensemble formulation of quantum Monte Carlo, which can be applied in principle to any quantum Monte Carlo algorithm. It improves on the existing approach of R. G. Melko et al., Phys. Rev. B 82, 100409(R) (2010) and of M. B. Hastings et al., Phys. Rev. Lett. 104, 157201 (2010) in that it allows to probe the ground-state properties of lattice models regardless of their symmetry – as long as they admit an efficient quantum Monte Carlo algorithm. We test the entanglement entropy scaling of fundamental quantum spin models, showing e.g. that the two-dimensional XX model, describing lattice hardcore bosons, exhibits an area law despite lacking an intrinsic length scale for the decay of correlations.

12:15PM W30.00006 Different Measures of Entanglement in Spin Chains, VLADIMIR KOREPIN, Yang Institute for Theoretical Physics in Stony Brook — Different measures of entanglement in spin chains are considered. Main example is VBS state, it is important because of measurement based quantum computation. Entanglement spectrum and negativity are considered in the lecture. These measures are calculated analytically in one dimension. In 2D we have only estimates. Lecture follows the papers: <http://arxiv.org/abs/1109.4971> and <http://arxiv.org/abs/1110.3300>

12:27PM W30.00007 Rényi entropy of d -wave Bose metal phases on multi-leg ladders, JAMES R. GARRISON, RYAN V. MISHMASH, MATTHEW P.A. FISHER, University of California, Santa Barbara — In recent years, much progress has been made toward understanding 2D Bose metal-type phases by accessing them through a series of controlled quasi-1D ladder studies [1]. Crucially, such quasi-1D descendants of these exotic phases are expected to have a number of gapless Luttinger modes, c , that grows with the width of the ladder. Therefore, characterizing scaling of the entanglement entropy has become an essential tool for establishing the existence of these phases, as it provides a direct measure of c . With density-matrix renormalization group (DMRG) methods, it is easy to calculate the entanglement entropy but the results converge prohibitively slowly as the ladder becomes wider. Here, we present results where we have calculated, using Variational Monte Carlo (VMC), the Rényi entropy S_2 for Gutzwiller-projected d -wave Bose metal (DBM) [2] trial wave functions on ladders, following the method employed in [3]. We compare with DMRG results (where they are available), and comment on what our findings mean for the ability of our trial wave functions to faithfully represent the DBM phase.

12:39PM W30.00008 Rényi Entanglement Entropies and the Entanglement Spectrum, FRANCIS SONG, STEPHAN RACHEL, KARYN LE HUR, Yale University — We describe a simple method for computing the full entanglement spectrum of any finite density matrix from the Rényi entropies of integer order. This has important implications for non-interacting fermionic systems where the Rényi entropies are directly related to the cumulants of charge number fluctuations, and for quantum Monte Carlo simulations where it is now becoming possible to compute the Rényi entropies but not the von Neumann entropy or the full entanglement spectrum.

12:51PM W30.00009 Entanglement Entropy of Fermi Liquids via Multi-dimensional Bosonization¹, WENXIN DING, National High Magnetic Field Laboratory & Florida State University, ALEXANDER SEIDEL, Washington University in St. Louis, KUN YANG, National High Magnetic Field Laboratory & Florida State University — The logarithmic violations of the area law, i.e. an “area law” with logarithmic correction of the form $S \sim L^{d-1} \log L$, for entanglement entropy are found in both 1D gapless system and for high dimensional free fermions. The purpose of this work is to show that both violations are of the same origin, and in the presence of Fermi liquid interactions such behavior persists for 2D fermion systems. In this paper we first consider the entanglement entropy of a toy model, namely a set of decoupled 1D chains of free spinless fermions, to relate both violations in an intuitive way. We then use multi-dimensional bosonization to re-derive the formula by Gioev and Klich [Phys. Rev. Lett. **96**, 100503 (2006)] for free fermions through a low-energy effective Hamiltonian, and explicitly show the logarithmic corrections to the area law in both cases share the same origin: the discontinuity at the Fermi surface (points). In the presence of Fermi liquid (forward scattering) interactions, the bosonized theory remains quadratic in terms of the original local degrees of freedom, and after regularizing the theory with a mass term we are able to calculate the entanglement entropy perturbatively up to second order in powers of the coupling parameter for a special geometry via the replica trick.

1:03PM W30.00010 Multipartite Entanglement classes via Negativity Fonts¹, SANTOSH SHELLEY SHARMA, Depto. de Física, Universidade Estadual de Londrina, Londrina PR, Brazil, NARESH KUMAR SHARMA, Depto. de Matemática, Universidade Estadual de Londrina, Londrina — The number and types of K-way negativity fonts in canonical form of an N-qubit state depends on the nature and amount of quantum coherences in the state. Non zero determinants of negativity fonts, characterizing a given state, are easily written down and reflect the entanglement microstructure of the superposition. A classification criterion for multipartite entangled states, based on negativity fonts in canonical state and decomposition of global partial transpose in terms of K-way partially transposed operators, is proposed. Inequivalent sub-classes are labelled by N-qubit local unitary invariants. A complete classification of four qubit states is obtained. The number of major families for $N > 3$ is found to be $2^N - 2N$. Classification of four qubit states indicates that a small number of relevant polynomial invariants is enough to classify N-qubit states.

1:15PM W30.00011 Entanglement Spectrum Classification of Disordered Class AII Symplectic Systems¹, MATTHEW GILBERT, TAYLOR HUGHES, University of Illinois at Urbana-Champaign, ANDREI BERNEVIG, Princeton University — Of the available classes of random matrices which have been shown to contain topologically non-trivial properties², one of the most intriguing is class AII, which characterizes a system that possesses time-reversal symmetry. This class of random matrices has been the subject of significant attention as it encompasses Z_2 topological systems of which the quantum spin Hall (QSH) state is a member³. We calculate the entanglement spectrum for disordered class AII symplectic systems in two-dimensions as a function of disorder strength, chemical potential, and bulk inversion asymmetry. We show that there is a one to one correspondence between the full system Hamiltonian and that of the entanglement spectrum not only in terms of level statistics but also in terms of the scaling of the inverse participation ratios. We also use the properties of the entanglement spectrum to illustrate the nature of the symplectic metal phase which appears when inversion symmetry is broken.

1:27PM W30.00012 Experimental entanglement estimation for a general unknown input state of a multiqubit system, ELIZABETH BEHRMAN, Department of Mathematics and Physics, Wichita State University, JAMES STECK, Department of Aerospace Engineering, Wichita State University — Measurement of entanglement remains an important problem for quantum information. We present the design and simulation of an experimental method for entanglement estimation for a general, unknown, state of a multiqubit system. The state can be in pure or mixed, and it need not be “close” to any particular state. Our method, based on dynamic learning, does not require prior state reconstruction or lengthy optimization. Results for three-qubit systems compare favorably with known entanglement measures. The method is then extended to four- and five-qubit systems, with relative ease. As the size of the system grows the amount of training necessary diminishes, raising hopes for applicability to large computational systems.

1:39PM W30.00013 Entanglement Spectrum of the Kugel-Khomskii Model, REX LUNDGREN, VICTOR CHUA, GREGORY A. FIETE, Department of Physics, University of Texas at Austin — We study the entanglement spectrum of the Kugel-Khomskii model in one dimension. The Kugel-Khomskii Hamiltonian describes transition metal oxides with orbital degeneracy, and is rich with both gapless and gapped phases with interesting symmetries. The entanglement spectrum reveals much more information than the commonly studied entanglement entropy. In this work, we investigate the entanglement spectrum for different phases and different partitions. We also make comparisons with previous field theoretic and numerical studies.

1:51PM W30.00014 Entanglement Spectrum In Topological Phases¹, B. ANDREI BERNEVIG, Princeton University — I will review the information that entanglement spectra give for a wide range of systems in condensed matter physics, such as fractional quantum hall effect, quantum spin chains, topological insulators, and disordered systems. I will also show how the entanglement spectrum is a unique tool to examine previously unknown many-body wavefunctions such as the ground-states of Fractional Chern Insulators (the results are based on a series of works performed in collaboration with N. Regnault, M. Hermanns, B. Estienne, Yangle Wu, Aris Alexandradinata, R. Thomale, A. Sterdyniak, Z. Papić, T.L. Hughes, E. Prodan, D.P. Arovas, P. Bonderson)

2:03PM W30.00015 Topological Order in Three Dimensions and Entanglement Entropy of Gapped Phases, TARUN GROVER, UC Berkeley, ARI TURNER, University of Amsterdam, ASHVIN VISHWANATH, UC Berkeley — In this talk, I will present two very general, yet easy to understand results in the entanglement entropy of the ground states corresponding to the gapped phases of matter. In particular, I will focus on the following two results: 1) In contrast to the familiar result in two dimensions, a size independent constant contribution to the entanglement entropy can appear for non-topological phases in any odd spatial dimension. 2) The “topological entanglement entropy” corresponding to discrete gauge theories in any given spatial dimension D (and in particular, $D = 3$) has an interesting dependence on the Betti numbers of the boundary manifold defined by the entanglement cut.

Thursday, March 1, 2012 11:15AM - 2:15PM –
Session W31 DMP: Focus Session: Topological Insulators: Synthesis & Characterization - Quantum Transport & Nanostructures 260

11:15AM W31.00001 Evidence for a Dirac Spectrum in the Topological Insulator $\text{Bi}_2\text{Te}_2\text{Se}$ from High-Field Shubnikov-de Haas Oscillations, JUN XIONG, Princeton University, YONGKANG LUO, Zhejiang University, YUEHAW KHOO, SHUANG JIA, ROBERT CAVA, NAI PHUAN ONG, Princeton University — The transport properties of surface states in the 3D topological insulators based on bismuth have been observed in a number of experiments. However, there is still no direct evidence for the Dirac dispersion predicted for these states. We have measured the Shubnikov-de Haas (SdH) oscillations in $\text{Bi}_2\text{Te}_2\text{Se}$ in intense dc fields. At $B > 40$ T, we can reach the $n=1$ surface Landau Level. In the index plot (of $1/B$ versus n), the relatively large oscillation amplitudes in our crystals (as large as 17% of the total conductance) enables us to resolve, in the high-field limit, the $\frac{1}{2}$ -shift predicted from the Berry phase in the Dirac spectrum. In addition, the linearity of the index plot shows that the surface Lande g-factor is quite small (less than 5) in $\text{Bi}_2\text{Te}_2\text{Se}$, in contrast with recent inferences based on low-B SdH experiments. Supported by NSF DMR 0819860

11:27AM W31.00002 Thin films of topological insulators in a parallel or tilted magnetic field, SERGEY PERSHOGUBA, VICTOR YAKOVENKO, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park, Maryland 20742-4111 — In thin films of topological insulators, the surface states on the opposite edges are coupled by a tunneling coupling t . We discuss the energy spectrum and the transport properties of the system in a magnetic field. When an electron tunnels between the edges, the Lorentz force due to the in-plane magnetic field $\mathbf{B} = (0, B_y, 0)$ changes the in-plane electron momentum by $\Delta p_x \propto B_y$. As a result, the Fermi circles on the opposite edges shift by Δp_x in the momentum space. We propose that this effect can be detected by measuring the tunneling conductance $\sigma_{zz}(B_y)$ between the edges of the system. We show that $\sigma_{zz}(B_y)$ has special signatures due to the helical spin configuration of the surface Dirac cones. In case of a tilted field $\mathbf{B} = (0, B_y, B_z)$, the perpendicular component B_z quantizes the in-plane motion to the Landau levels, while the in-plane component B_y spatially shifts the wave functions on the different edges. As the overlap between the wave functions changes, the tunneling amplitude t is renormalized and acquires dependence on both B_y and B_z . This effect can be observed as the dependence of the interlayer conductance and in-plane conductivity on the tilt angle θ of the magnetic field $\tan\theta = B_y/B_z$.

11:39AM W31.00003 Clear Revelation of Topological Surface States in Bi_2Se_3 Thin Films by *in situ* Al Passivation, MURONG LANG, LIANG HE, XINXIN YU, JIANSHI TANG, XUFENG KOU, KANG L. WANG, UCLA Electrical Engineering, ALEXEI V. FEDOROV, Lawrence Berkeley National Laboratory — We report that *in situ* aluminum (Al) passivation of Bi_2Se_3 can inhibit the degradation process and clearly reveal the massless, Dirac-like topological surface states. In this work, an 8 quintuple layers Bi_2Se_3 film was passivated with 2 nm Al, immediately after the MBE growth, which prevents native oxide (BiO_x) formation, isolates the film from ambient n -type doping or contaminations in the subsequent fabrication process. Dual evidences from both Shubnikov-de Haas (SdH) oscillations and weak antilocalization (WAL) effect, originated from the π Berry phase of the nontrivial surface states, were clearly revealed in the sample with *in situ* Al passivation. In contrast, we show that the two dimensional carrier density was increased 39.2% for the un-passivated control samples. Also, the SdH oscillations were completely absent and a large deviation from the WAL was observed

11:51AM W31.00004 High Field Magnetoresistance in ultra pure Bi_2Se_3 , PAUL SYERS, University of Maryland, NICHOLAS BUTCH, Lawrence Livermore National Laboratory, CYRIL PROUST, BAPTISTE VIGNOLLE, LNCMI-Toulouse, JOHNPIERRE PAGLIONE, University of Maryland — The longitudinal and transverse components of magnetoresistance were measured in bulk crystals of undoped, high purity Bismuth Selenide in pulsed magnetic fields of up to 60 Tesla. Data is presented from samples with a range of carrier concentrations extending into the quantum limit. Measurements were also performed at multiple angles along the plane containing the current direction to investigate the angular dependence of the linear behavior of the magnetoresistance in this material.

12:03PM W31.00005 Surface-dominated conduction in a 6nm-thick Bi_2Se_3 thin, LIANG HE, XINXIN YU, XUFENG KOU, MURONG LANG, KANG L. WANG, UCLA Electrical Engineering, FAXIAN XIU, Iowa State University, Department of Electrical and Computer Engineering, MARCUS TEAGUE, NAI-CHANG YEH, CalTech, department of Physics — We report a direct observation of surface dominated conduction in an intrinsic Bi_2Se_3 thin film with a thickness of 6 quintuple layers (QLs) grown on lattice-matched CdS (0001) substrates by molecular beam epitaxy (MBE). Shubnikov-de Haas (SdH) oscillations from the topological surface states suggest that the Fermi level falls inside the bulk band gap and is 53 $\pm$ 5 meV above the Dirac point, in agreement with 70 $\pm$ 20 meV obtained from scanning tunneling spectroscopies (STS). Our results demonstrate a great potential of producing genuine topological insulator devices using Dirac Fermions of the surface states.

12:15PM W31.00006 Magnetoconductance in high-mobility topological insulator Bi_2Se_3 devices, HADAR STEINBERG, VALLA FATEMI, JAVIER SANCHEZ-YAMAGISHI, LUCAS ORONA, PABLO JARILLO-HERRERO, MIT — We report the fabrication and measurement of gate-tunable high mobility exfoliated ($<100\text{nm}$ thick) Bi_2Se_3 devices. We measure electronic transport of these devices in magnetic fields up to 35T, and find a complex pattern of quantum oscillations consistent with both the surface and the bulk channels. We study the dependence of the oscillations on the magnetic field angle and gate voltage and discuss models for coexistence of surface and bulk oscillations.

12:27PM W31.00007 Magnetic Field Signatures of Topological States in 3D Time-Reversal Invariant Insulators, BRIAN DELLABETTA, Department of Electrical and Computer Engineering, University of Illinois at Urbana-Champaign, TAYLOR HUGHES, Department of Physics, University of Illinois at Urbana-Champaign, BENJAMIN LEV, Department of Applied Physics, Stanford University, MATTHEW GILBERT, Department of Electrical and Computer Engineering, University of Illinois at Urbana-Champaign — While the topological behavior of Bi_2Se_3 has been identified experimentally^{1, 2}, characterization by electron transport has been difficult due to high bulk transport caused by inadvertent doping of the crystal.³ We perform self-consistent quantum transport calculations to show that patterned surfaces offer a unique environment in which the system may be characterized by resultant magnetic field distributions. We compare doped and undoped Bi_2Se_3 samples with normal metals to show a qualitative difference in current flow around the patterned surface. We find that the surface to bulk conductance ratio can be inferred from the magnetic field in patterned systems due to the spatial separation of bulk and surface currents created by the corrugation, which applies even in heavily doped systems. The magnetic field is sufficiently large so as to be observed using ultracold atom microscopy.

12:39PM W31.00008 Quantum Hall effect from Dirac fermions of the 3D topological insulator HgTe , A.V. STIER, R. VALDÉS AGUILAR, S. HUANG, T. MCQUEEN, N.P. ARMITAGE, Department of Physics & Astronomy, Johns Hopkins University, Baltimore, MD 21218, B. UELAND, F. RONNING, Los Alamos National Laboratory, Los Alamos NM 87545 — Three dimensional (3D) topological insulators (TI) exhibit two dimensional (2D) topologically protected conducting surface states created by strong spin-orbit coupling. Time reversal invariance (TRI) of those states manifest itself in spin-momentum locking and a dispersion relation of massless Dirac fermions. We present our results of magneto-transport of the 3D TI HgTe [1]. Our samples are 70 nm HgTe films strained on slightly Zn doped CdTe substrates. Tensile strain due to the lattice mismatch between the HgTe film and the substrate lifts the heavy hole - light hole degeneracy, which results in TI states at the Brillouin zone center. We observe evidence for a quantized Hall (QH) resistance developing at temperatures below $T=50\text{K}$. The observed effect is confirmed to derive from Dirac fermions of the two TI surfaces as shown through a non-zero Berry's phase by an extrapolation of the filling factors of the QH plateaus to the large magnetic field limit. We have also confirmed the 2D character of the probed states through tilted magnetic field measurements. If time allows, we will discuss our results for very high magnetic fields and dilution refrigeration temperatures experiments. Work supported by the Gordon and Betty Moore Foundation. [1] C. Brüne et.al., PRL 106, 126803 (2011)

12:51PM W31.00009 Topological insulator Bi_2Te_3 nanowire field effect devices, LUIS A. JAUREGUI, GENQIANG ZHANG, YUE WU, YONG P. CHEN, Purdue University — Bismuth telluride (Bi_2Te_3) has been studied extensively as one of the best thermoelectric materials and recently shown to be a prototype topological insulator with nontrivial conducting surface states. We have grown Bi_2Te_3 nanowires by a two-step solution phase reaction and characterized their material and structural properties by XRD, TEM, XPS and EDS. We fabricate both backgated (on SiO_2/Si) and top-gated (with ALD high-k gate dielectric such as Al_2O_3 or HfO_2) field effect devices on such nanowires with diameters $\sim 50\text{nm}$. Ambipolar field effect and a resistance modulation of up to 600% at low temperatures have been observed. The 4-terminal resistance shows insulating behavior (increasing with decreasing temperature) from 300 K to 50K, then saturates in a plateau for temperatures below 50K, consistent with the presence of metallic surface state. Aharonov-Bohm (AB) oscillations are observed in the magneto-resistance with a magnetic field parallel to the nanowire, providing further evidence of the presence of surface state conduction. Finally, a prominent weak anti-localization (WAL) feature that weakens with increasing magnetic field and/or temperature is observed in the magneto-resistance with a magnetic field perpendicular to the nanowire.

1:03PM W31.00010 Analysis of quantum interference in mesoscopic channels of epitaxial Bi_2Se_3 , ABHINAV KANDALA, DUMING ZHANG, ANTHONY RICHARDELLA, NITIN SAMARTH, Penn State University, University Park PA 16802 — Predictions of topologically protected surface states lead to expectations of longer scattering lengths from the surface channel in candidate topological insulators such as Bi_2Se_3 . In this context, we probe coherent transport in mesoscopic channels of MBE-grown Bi_2Se_3 at temperatures down to 0.5K and magnetic fields up to 6T. The magnetoresistance reveals two types of quantum corrections superimposed upon a classical background: low-field weak antilocalization and an aperiodic, reproducible fingerprint. Analysis and comparison of the quantum corrections data are used to extract important length scales and provide insights into the origin of these corrections. The channel length and temperature dependence of the magnetofingerprint is consistent with the theory of universal conductance fluctuations for diffusive systems that are two dimensional in phase coherent phenomena. Periodic oscillations in the autocorrelation of the fingerprint, persistent to high fields and high temperatures, point towards the presence of dominant scattering centers. Work supported by NSF-MRSEC and ONR.

1:15PM W31.00011 Synthesis and Transport Measurements of Catalyst-Free Topological Insulator Bi_2Se_3 Nanostructures, JEROME T. MLACK, ATIKUR RAHMAN, GARY L. JOHNS, NINA MARKOVIC, Johns Hopkins University — The semiconductor bismuth selenide (Bi_2Se_3) was predicted to be a topological insulator (TI) with a single Dirac cone, which was observed using Angle-Resolved-Photo-Emission-Spectroscopy in 2008. TI's are materials which exhibit electrically insulating properties in the bulk, but they have metallic surface states. The surface states are topologically protected from perturbations, defects, and impurities. Nano-sized structures might be well suited for the study of surface states because the surface effects are likely to dominate over bulk properties due to the high surface-to-volume ratio. So far, nanowires and nanoribbons of TI's have been synthesized using metal catalysts, such as gold, iron, or nickel. However, it has been found that these catalysts dope the nanostructures, which has the potential to modify their properties. We show catalyst-free growth of nanowires and nanoribbons of Bi_2Se_3 using the Vapor-Liquid-Solid method. Analysis by EDAX and TEM imaging suggest high purity samples. We have fabricated devices from these nanostructures and present electron transport measurements.

1:27PM W31.00012 Topological Insulator Nanoribbon Synthesis by Metal-Organic Chemical Vapor Deposition¹, LOREN ALEGRIA, MICHAEL SCHROER, GERALD POIRIER, MICHAEL PRETKO, ANASUA CHATTERJEE, Princeton University, SHIVANG PATEL, None, JASON PETTA, Princeton University — We report a method for metal-organic chemical vapor deposition (MOCVD) synthesis of Bi_2Se_3 topological insulator nanoribbons. We use gold nanoparticles to catalyze nanoribbon growth on silicon substrates. Trimethyl Bismuth and Diethyl Selenium are used as the metal-organic precursors. The growth parameters can be varied to control the morphology from narrow nanoribbons to wide platelets. Resulting nanostructures are characterized by electron diffraction, energy dispersive X-ray spectroscopy, and low-temperature transport measurements. We also investigate the synthesis of ternary compounds using this growth method.

¹Funded by the Sloan and Packard Foundations, and the NSF supported Princeton Center for Complex Materials.

1:39PM W31.00013 Electrical, Thermal, and Thermoelectric Characterizations of Vapor Solid Bi₂Te₃ Nanoplates, MICHAEL PETTES, LI SHI, The University of Texas at Austin — Single-crystal nanoplates of Bi₂Te₃ synthesized by the vapor solid method are characterized by electrical, thermal, and thermoelectrical measurements. The Bi₂Te₃ domains investigated are less than 12 nm thick and are suspended to remove substrate doping effects. A room temperature thermal conductivity of 1.5 Wm⁻¹K⁻¹ was measured, lower than the 1.8–3.3 Wm⁻¹K⁻¹ range reported for bulk crystals with different carrier types and concentrations. The room temperature electrical conductivity was measured at 1.5×10⁵ Sm⁻¹. Applying the Wiedemann-Franz Law, the electron contribution to the total thermal conductivity is nearly 40 % at room temperature. The electrical conductivity is similar to that reported for bulk single crystals at an electron concentration of 3.5×10¹⁹ cm⁻³. However, the room-temperature Seebeck coefficient of -66 μVK⁻¹ indicates *n*-type doping and is lower than that reported for *n*-type Bi₂Te₃ single crystals at an electron concentration as high as 14.6×10¹⁹ cm⁻³. Consequently, the figure of merit is only 0.11 at room temperature, a factor of 7.9 lower than the highest ZT reported for *n*-type single crystals at the optimized doping level.

1:51PM W31.00014 Hybrid Bismuth Selenide Nanostructures Synthesized by Chemical Vapor Deposition, EUGEN PANAITESCU, FANGZE LIU, SWASTIK KAR, LATIKA MENON, Physics Department, Northeastern University — The recent demonstration of theoretically predicted topologically ordered states in real bismuth based chemical compounds such as bismuth antimony, bismuth selenide, bismuth telluride etc opened the field of topological insulators (materials exhibiting insulator properties in bulk, but metallic behavior on the surface) for a plethora of possible applications. Topological insulator nanostructures in particular are of great interest due to their large surface to volume ratio. We will report on the CVD synthesis of various hybrid 1D and 2D nanostructures of the bismuth-selenium complex, and their morphological and structural properties (investigated by SEM and TEM imaging coupled with EDAX and XRD spectroscopy). Optical and transport properties will be also presented and related to possible spintronics and no dissipation electronics applications.

2:03PM W31.00015 Electronic transport of Sb-doped Bi₂Se₃ topological insulator nanoribbons, SEUNG SAE HONG, JUDY CHA, DESHENG KONG, YI CUI, Stanford University — Vapor-liquid-solid (VLS) grown nanoribbons, having large surface / volume ratio and high crystal quality, provide a unique opportunity to study topological insulator materials by electronic transport. However, clear observation of the surface states is often hindered due to materials' imperfections. Bulk impurities and environmental doping effects are known to contribute to dominant background transport signal, so that appropriate doping and surface protection are necessary to reduce the excess carriers. We report that Antimony (Sb), known to be an effective compensational dopant for bulk crystals, can be incorporated into Bi₂Se₃ nanoribbons and it reduces the bulk electron contribution significantly. With a Zinc Oxide protective layer, the carrier density of thin ribbons reaches below 10¹²cm⁻². This talk will include magnetotransport studies and temperature dependant transport of nanoribbons as well.

Thursday, March 1, 2012 11:15AM - 2:15PM –

Session W32 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides - Bandgaps, Surfaces, Oxides on Semiconductors 261

11:15AM W32.00001 Band Gap and Edge Engineering of SrTiO₃ and Related Compounds via Ferroic Distortion and Anisotropic Strain, ROBERT BERGER, The Molecular Foundry, Lawrence Berkeley National Laboratory — Due to its electronic band edge energies and its stability in water, the perovskite strontium titanate (SrTiO₃) is a promising water splitting photocatalyst. However, its ability to use solar photons to split water into hydrogen and oxygen would be more efficient if its wide optical band gap (3.2 eV) better matched the solar spectrum. Therefore, there is interest in modifying the crystal structure of SrTiO₃ (e.g., via chemical doping or epitaxial strain) to tune its electronic and optical properties. We use density functional theory (DFT) and many-body perturbation theory within the GW approximation to calculate the effects of structural and chemical modifications of SrTiO₃ on its band gap and edges. Much of our work (Berger, Fennie, and Neaton, Phys. Rev. Lett. 107, 146804 [2011]) focuses on the effects of epitaxial strain and the associated ferroic distortions. Anisotropic strains are shown to reduce the SrTiO₃ gap by breaking degeneracies at the band edges. Ferroic distortions are shown to widen the gap by allowing new band edge orbital mixings. To reduce the SrTiO₃ gap, one must lower the symmetry from cubic while suppressing ferroic distortions. Our calculations indicate that for engineered orientation of the growth direction along [111], the SrTiO₃ gap can be controllably and considerably reduced at room temperature. Chemical doping and substitution can, in combination with strain and distortion, further tune the band gap and edges. Our results and their favorable qualitative agreement with experiment suggest achievable paths toward engineering efficient solar water splitting catalysts, and more generally provide fundamental insight into the relationships between crystal and electronic structure in the property-rich perovskite family.

11:51AM W32.00002 Epitaxial strain tuning of polarization and band gap in perovskite SnTiO₃¹, WILLIAM PARKER, SERGE NAKHMANSON, Argonne National Laboratory, JAMES RONDINELLI, Drexel University — Lead toxicity has motivated theoretical studies of a tin-based perovskite ferroelectric material. Density-functional calculations predict a polar perovskite ground state for SnTiO₃. Simulated epitaxial strain up to ±2% tunes both the magnitude of the polar distortion, its direction, and the electronic band gap — compressive bi-axial strain creates the largest polar distortions, which occur entirely in the growth direction, while tensile strain reorients the polar displacements, enlarging the band gap. Projected densities of states indicate that the broken four-fold symmetry of the non-growth-oriented distortion allows Ti *d_{xy}* bands to mix with O *p_x* bands, further separating the valence band maximum and conduction band minimum. Comparing Sn and Pb in the perovskite titanate phases shows similar trends and suggests that SnTiO₃ ferroelectrics may be viable thin-film alternatives to Pb-based oxides.

12:03PM W32.00003 Ferroelectric Properties of TiO₂ Rutile Bulk and Surfaces Investigated by Ab Initio Calculations¹, ANNA GRÜNEBOHM, PETER ENTEL, Department of Physics, University Duisburg-Essen and CeNIDE, CLAUDE EDERER, School of Physics, Trinity College, Dublin — TiO₂ rutile is an incipient ferroelectric material [Lee et al., Phys. Rev. B **50**, 13379 (1994)] and theoretical studies have shown that a ferroelectric transition can be enforced [Montanari et al., J. Phys. Condens. Matter **16**, 273 (2004)]. The experimental realization of ferroelectric TiO₂ (110) surfaces would have great technical impact and already the tuning of the electric permittivity would be of interest, e.g., for optical coating. In order to get an insight into the ferroelectric trends, we have studied the atomic and electronic structure, as well as phonon spectra, dipolar interactions and the polarization, using density functional theory (VASP and PWscf). Accordingly, ferroelectric states polarized along (110) and (001) can be stabilized within bulk. We demonstrate the different strain dependencies of the corresponding polar modes, which opens up the possibility of strain engineering the polarization direction, and the resulting dielectric response [Grünebohm et al., Phys. Rev. B **84**, 132105 (2011) and Grünebohm et al. arxiv:1111.2575]. Although the dipolar interaction and the short range repulsion are both modified at the (110) surface, stable local dipoles are obtained within the surface planes, which increase with increasing strain.

¹Computational time was granted by the Jülich Supercomputing Center (JSC) and the Center for Computational Sciences and Simulation (CCSS) of the University of Duisburg-Essen

12:15PM W32.00004 XPS measurements of interface dipole switching at the a-Al₂O₃/Si interface, STEPHANIE FERNANDEZ-PENA, Geneva University, D.P. KUMAR, Yale University, Z. ZHANG, Argonne National Laboratory, A.M. KOLPAK, MIT, S. ISMAIL-BEIGI, C.H. AHN, F.J. WALKER, Yale University — In this work, we describe work on polarization switching at a high-*k* oxide-silicon interface. The procedure involves inserting a monolayer (ML) of ZrO₂ in-between an amorphous-Al₂O₃ and Si. Theoretical calculations using density functional theory (DFT) predict that the ZrO₂ should display two stable configurations of the polarization. Deposition of the ZrO₂ in UHV is used to avoid SiO₂ formation. The device is transferred in vacuum and the interface chemistry analyzed using x-ray photoelectron spectroscopy (XPS) to determine the oxidation state of the Si. When the ZrO₂ is in direct contact with the Si, chemical shifts as large as 0.58 [eV] are observed, implying a polar interface. In addition, XPS measurements on devices under applied voltage, along with electron transport measurements, show a switching of the interface dipole of 0.25 [eV]. These voltage dependent XPS results are consistent with the magnitude and direction of hysteresis loops observed in Capacitance-Voltage measurements. Finally, the microscopic structure has been investigated using extended x-ray absorption fine structure (EXAFS) at the Zr K-edge. The results are compared to DFT-calculated atomic positions.

12:27PM W32.00005 Macroscopic electrostatics at the nanoscale: From ferroelectric capacitors to confined electron gases, MASSIMILIANO STENGEL, ICREA - Institució Catalana de Recerca i Estudis Avançats, 08010 Barcelona — Complex oxides are characterized by a multitude of coupled electronic and lattice degrees of freedom, and therefore constitute an unusually rich playground for experimentalists and theoreticians alike. These microscopic variables manifest themselves in macroscopically measurable quantities such as polarization, magnetization and strain, whose mutual coupling is sought after for applications in multifunctional electronic devices. To understand the interplay of these many factors, density functional theory (DFT) has proven an invaluable tool. However, the treatment of the macroscopic electrical variables (electric fields and polarization), which are a crucial ingredient in describing the experimentally observed response properties, has traditionally been difficult within first-principles calculations. In this talk I will first review a number of recent methodological developments that removed this limitation, thus extending the scopes of first-principles theory to the simulation of realistic devices within arbitrary electrical boundary conditions. Next, I will discuss the evolution of the band offset at a metal/ferroelectric interface as a function of polarization, and its implications for the electrical properties of nanocapacitors. Finally, I will show that, depending on the polarization of the film, a problematic regime might occur where the metallic carriers populate the energy bands of the insulator, making it metallic. As the most common approximations of density functional theory are affected by a systematic underestimation of the fundamental band gap of insulators, this scenario is likely to be an artifact of the simulation. I will discuss a number of criteria to systematically identify this situation in simulations, and effective modeling strategies to describe this peculiar charge compensation mechanism.

1:03PM W32.00006 Band Alignment of Plasma-Enhanced ALD High-*k* Dielectrics on Gallium Nitride, JIALING YANG, BRIANNA ELLER, CHIYU ZHU, ROBERT NEMANICH, Arizona State University — GaN-based transistors have shown immense promise because of their high saturation velocity and breakdown field, but their performance is limited by the high gate leakage. This limitation is mitigated with the use of metal/high-*k* oxide/III-N structures. This experiment investigates three promising high-*k* dielectrics deposited by plasma enhanced ALD: Al₂O₃, HfO₂, and La₂O₃. The band gaps of these materials are 6.5eV, 5.8eV, and 4.3eV, while the dielectric constants are 9, 20, and 27, respectively. The large band gap associated with Al₂O₃ reduces the leakage current; however, the lower dielectric constant increases the equivalent oxide thickness. The band alignment of the high-*k* oxide/GaN interface plays a critical role in determining the confinement properties of semiconductor carriers and ultimately device performance. In situ photoemission gave valence band offsets for Al₂O₃, HfO₂, and La₂O₃ with GaN as 1.8eV, 1.3eV, and 0.9eV. The results are described by the charge neutrality level and interface dipole models. We also investigated the use of Al₂O₃ as an interfacial passivation layer between HfO₂ and GaN. This research is supported by the Office of Naval Research.

1:15PM W32.00007 High-*k* dielectrics on n-Al_{0.25}Ga_{0.75}N via atomic layer deposition, N. NEPAL, N.Y. GARCES, D. MEYER, T.J. ANDERSON, J.K. HITE, M.A. MASTRO, C.R. EDDY, JR., U.S. Naval Research Laboratory, Washington, DC 20375, USA — AlGaIn/GaN and AlInN/GaN high-electron-mobility transistors (HEMTs) are promising devices for high-temperature and high-power electronics applications. A key issue with these devices is the high gate leakage current, particularly for enhancement-mode HEMTs. There has been an increased interest in developing high quality gate insulators to reduce gate leakage current. Al₂O₃ and HfO₂ layers (21nm thick) were deposited via atomic layer deposition on n-Al_{0.25}Ga_{0.75}N pretreated with one of two different surface preparations, H₂O₂:H₂SO₄ (1:5) (piranha) or HF:H₂O (1:3). Dielectrics were characterized using spectroscopic ellipsometry, X-ray photoelectron spectroscopy, atomic force microscopy (AFM), and capacitance-voltage (C-V) measurements. AFM shows that Al₂O₃ and HfO₂ layers are continuous and uniform in thickness on both HF and piranha pretreated surfaces. However, C-V measurement shows smaller (15%) hysteresis for HF pretreated samples. The estimated dielectric constants (ϵ) are 9 and 18 for Al₂O₃ and HfO₂ on HF pretreated surfaces, respectively, in general agreement with theoretical values of 9 and 25. Al₂O₃ layers on Al_{0.25}Ga_{0.75}N exhibited a lower leakage (7×10^{-8} A/cm² at 5 V) current and higher forward breakdown voltage of 7.5 MV/cm compared to that of HfO₂ layer. The higher breakdown voltage and lower leakage current for Al₂O₃ is due to larger conduction band offset with Al_{0.25}Ga_{0.75}N.

1:27PM W32.00008 The growth of c-axis oriented BaTiO₃ films on Si and Ge for a non-volatile field-effect transistor¹, J.H. NGAI, D. KUMAR, M. MARSHALL, Y. SEGAL, C.H. AHN, F.J. WALKER, Dept. of Applied Physics, Yale University — The reorientable polarization of a ferroelectric material can be utilized in a variety of applications, including the development of novel memory devices. Of particular interest is the use of a ferroelectric's spontaneous polarization to maintain "on" and "off" conductivity states in a field effect transistor. BaTiO₃ has been proposed as a Pb-free ferroelectric for such an application. Direct coupling of the ferroelectric polarization with the channel of a field effect transistor requires c-axis oriented BaTiO₃ films to be grown on Si or Ge. However, due to the small thermal expansion coefficients of Si and Ge, BaTiO₃ films tend to be a-axis oriented, having the polarization lying in the plane of the film. In order to achieve c-axis oriented BaTiO₃ films, we have developed a graded buffer layer that imparts in-plane compressive strain to overcome the incompatibility in thermal expansion. Ferroelectric, c-axis oriented, BaTiO₃ films with thicknesses exceeding 120 nm have been achieved. We will discuss the growth and characterization of these films in the development of a non-volatile, ferroelectric transistor.

1:39PM W32.00009 First principles analysis of the capacitance density of high-k nanocapacitors utilizing the orbital separation approach, SHUSUKE KASAMATSU, Department of Materials Engineering, the University of Tokyo, SEUNGWU HAN, Department of Materials Science and Engineering, Seoul National University, SATOSHI WATANABE, Department of Materials Engineering, the University of Tokyo — In order to realize further scaling of electronic devices, capacitors and transistors with higher capacitance density are necessary. To this end, higher-k films of nanometer thickness are being considered for next-generation devices. However, high-k/metal interfaces often suffer from degraded dielectric properties due to, e.g., contamination, defects, and the intrinsic dead layer effect [1]. In this work, we developed a new first principles approach based on the Kohn-Sham formalism that we call orbital separation approach [2] to calculate the capacitance of nano-sized capacitors and examine the limit in capacitance density. In this method, the Kohn-Sham orbitals around the Fermi level of a metal/insulator/metal slab are separated into left and right electrode. The separated orbitals are occupied according to different Fermi levels to simulate the effect of bias voltage. We applied this approach to Au/MgO/Au and SrRuO₃/SrTiO₃/SrRuO₃ systems to examine the effect of the interface on the dielectric response. We confirmed that this method gives reasonable results. The impact of the intrinsic dead layer and that of defects on the capacitance are also examined.

1:51PM W32.00010 Properties of Ultrathin Al₂O₃-TiO₂ Nanolaminate Films for Gate Dielectric Applications Deposited by Plasma-Assisted Atomic Layer Deposition, NELSON GARCES, DAVID MEYER, NEERAJ NEPAL, VIRGINIA WHEELER, CHARLES EDDY, U.S. Naval Research Laboratory — High permittivity dielectrics such as Al₂O₃, HfO₂, Ta₂O₅, TiO₂, etc., are an essential component of aggressively-scaled III-V and graphene field effect transistors (FETs) where insulators are necessary to reduce gate leakage current while maintaining high gate capacitance and charge control of the channel. Atomic layer deposition (ALD) has the capability to deposit hybrid films, or nanolaminates, of two or more dielectrics that have unique properties. Thin [Al₂O₃+TiO₂] nanolaminates with varying TiO₂ and Al₂O₃ content were deposited on *n*-Si substrates at ~225-300 °C using ALD. A nanolaminate is composed of bilayers, defined as the sum of (x)Al₂O₃ and (y)TiO₂, where x, and y indicate the number of times a component monolayer is repeated. While the overall thickness of the dielectric was held at ~ 17-20 nm, the relative ratio of Al₂O₃ to TiO₂ in the bilayer stack was varied to evaluate changes in the material properties and electrical performance of the oxides. C-V and I-V measurements on various [(x)TiO₂+(y)Al₂O₃] MOS capacitors were taken. The high-TiO₂-content films show limited evidence of oxide charge trapping and relatively large dielectric constants ($\kappa \sim 15$), whereas the high-Al₂O₃-content films offer a larger optical bandgap and improved suppression of leakage current. We will discuss the properties of very thin nanolaminates and their possible use as gate oxides. Morphological, electrical, and XPS composition assessments will be presented.

2:03PM W32.00011 Ferroelectric Surface Chemistry: First-principle study of NO_x Decomposition¹, ARVIN KAKEKHANI, SOHRAB ISMAIL-BEIGI, Yale University, SOHRAB ISMAIL-BEIGI'S TEAM — NO_x molecules are critical and regulated air pollutants produced during automotive combustion. As part of a long-term effort to design viable catalysts for NO_x decomposition that operate at higher temperatures and thus would allow for greater fuel efficiency, we are studying NO_x chemistry on ferroelectric perovskite surfaces. Changing the direction of the ferroelectric polarization can modify surface properties and thus can lead to switchable surface chemistry. We will discuss our results for NO and NO₂ on the polar (001) surfaces of PbTiO₃ as function of ferroelectric polarization, surface stoichiometry, and various molecular or dissociated binding modes.

Thursday, March 1, 2012 11:15AM - 2:15PM –
Session W33 GERA: Physics of Hydrogen Production, Storage, Delivery 106

11:15AM W33.00001 Boron Doping Carbon Structures Using Decaborane? A Theoretical Study¹, CARLOS WEXLER, MATTHEW CONNOLLY, MATTHEW BECKNER, PETER PFEIFER, University of Missouri Physics Department, ALLIANCE FOR COLLABORATIVE RESEARCH IN ALTERNATIVE FUEL TECHNOLOGY COLLABORATION — Boron-doped carbon materials have been shown to improve hydrogen storage. Boron-doped activated carbons have been produced using a novel process involving the pyrolysis of a boron containing compound and subsequent high-temperature annealing. A model for the boron doping process based on a Langmuir isotherm is presented. A theoretical study of the interaction of the boron containing compound with the undoped carbon precursor will be presented. Ab-initio calculations of the potential energy surface and the Langmuir isotherm parameters derived from them are also presented. The theoretical study outlines the unique capabilities and limits of this doping procedure.

¹This material is based on work supported by the US Department of Defense under Awards No. N00164-07-P-1306 and N00164-08-C-GS37 and the US Department of Energy under Awards No. DE-FG02-07ER46411 and DE-FG36-08GO18142.

11:27AM W33.00002 Mass Transport in the Dehydrogenation Reaction of B₂₀H₁₆, KYLE MICHEL, CHRISTOPHER WOLVERTON, Northwestern University — The compound B₂₀H₁₆ has been predicted to decompose directly into 20B and 8H₂ with favorable hydrogen release (6.9 wt. %) and equilibrium temperature ($T = 20$ °C at a pressure of 1 bar H₂) [W.Q. Sun, et. al. *Phys. Rev. B*, **83**, 064112, 2011]. The segregation of B and H during this reaction is investigated using density functional theory assuming that this process is mediated by the diffusion of native point defects in solid B₂₀H₁₆. Using the calculated formation energies under relevant chemical conditions, those defects that form in the largest concentrations, and thus those that facilitate mass segregation, are identified. These results are used to gain insight into the possible kinetic limitations of this hydrogen storage reaction.

11:39AM W33.00003 Theoretical prediction of intermediates in the decomposition of Mg(BH₄)₂, ERIC MAJZOUB, Center for Nanoscience, and Department of Physics and Astronomy, University of Missouri, YONGSHENG ZHANG, Materials Science and Engineering, Northwestern University, VIDVUDS OZOLINS, Materials Science and Engineering, University of California, Los Angeles, CHRISTOPHER WOLVERTON, Materials Science and Engineering, Northwestern University — We have studied the decomposition pathway of Mg-borohydride using density-functional theory (DFT) calculations of the free energy (including vibrational contributions) in conjunction with a Monte Carlo-based crystal structure prediction method, the prototype electrostatic ground state (PEGS) method. We find that a recently proposed Mg(B₃H₈)₂ intermediate [Chong, et al., *Chem. Commun.* **47**, 1330, (2011)] is energetically highly unfavorable with respect to decomposition into MgB₁₂H₁₂. We systematically search for low-energy structures of Mg-triboranes [Mg(B₃H₈)₂, MgB₃H₇, and Mg₃(B₃H₆)₂], closo-borane MgB_nH_n (n=6,7,8,9,10,11), and Mg(B₁₁H₁₄)₂ compounds using PEGS+DFT simulations. We find that only the reaction enthalpy to Mg₃(B₃H₆)₂ is close to the stable MgB₁₂H₁₂ pathway, and falls within the thermodynamic conditions for reversibility [e.g., $\Delta H = 20 \sim 50$ kJ/(mol H₂)]. Careful control over experimental conditions might allow for Mg₃(B₃H₆)₂ as a possible intermediate in the decomposition of Mg(BH₄)₂, and might allow Mg₃(B₃H₆)₂ to be rehydrided back to Mg(BH₄)₂ under modest H₂(*T, p*) conditions.

11:51AM W33.00004 Industrial Scale Measurements of Hydrogen Uptake and Delivery in KOH Activated Carbons¹, TYLER RASH, DAVE STALLA, MATT BECKNER, JIMMY ROMANOS, G. SUPPES, A TEKEEI, University of Missouri, P. BUCKLEY, P. DOYNOV, MRIGlobal, PETER PFEIFER, University of Missouri, ALL-CRAFT TEAM — The Alliance for Collaborative Research in Alternative Fuel Technologies (ALL-CRAFT) has been producing high surface area activated carbons. Here we will investigate the hydrogen adsorption characteristics of these activated carbons using a custom built 10 liter hydrogen adsorption apparatus filled with 4 kg of activated carbon. We will discuss problems and solutions specific to filling and delivering hydrogen from industrial scale systems. Results show that activated carbons can produce a significant but surmountable, amount of impedance to hydrogen flow. The 10 liter hydrogen storage system measures adsorption at temperatures between -78 Celsius and 100 Celsius and at pressures between zero and 100 bar. The 10 liter hydrogen adsorption uptakes are compared against results obtained with the Hiden Isochema HTP1 volumetric gas analyzer.

¹This material is based on work supported by the US Department of Energy under Award Number DE-FG36-08GO18142 and the US NAVY under Awards Number N00164-07-P-1306 and N00164-08-C-GS37.

12:03PM W33.00005 Reversible Storage of Hydrogen and Natural Gas in Nanospace-Engineered Activated Carbons¹, JIMMY ROMANOS, MATT BECKNER, TYLER RASH, PING YU, GALEN SUPPES, PETER PFEIFER, Department of Physics, University of Missouri — An overview is given of the development of advanced nanoporous carbons as storage materials for natural gas (methane) and molecular hydrogen in on-board fuel tanks for next-generation clean automobiles. High specific surface areas, porosities, and sub-nm/supra-nm pore volumes are quantitatively selected by controlling the degree of carbon consumption and metallic potassium intercalation into the carbon lattice during the activation process. Tunable bimodal pore-size distributions of sub-nm and supra-nm pores are established by subcritical nitrogen adsorption. Optimal pore structures for gravimetric and volumetric gas storage, respectively, are presented. Methane and hydrogen adsorption isotherms up to 250 bar on monolithic and powdered activated carbons are reported and validated, using several gravimetric and volumetric instruments. Current best gravimetric and volumetric storage capacities are: 256 g CH₄/kg carbon and 132 g CH₄/liter carbon at 293 K and 35 bar; 26, 44, and 107 g H₂/kg carbon at 303, 194, and 77 K respectively and 100 bar. Adsorbed film density, specific surface area, and binding energy are analyzed separately using the Clausius-Clapeyron equation, Langmuir model, and lattice gas models.

¹ This material is based upon work supported by the U.S. Department of Energy under Award No. DE-FG36-08GO18142 and the California Energy Commission under Contract No. 500-08-022.

12:15PM W33.00006 The Stationary States of Adsorbed Hydrogen, RAINA OLSEN, EERE Postdoctoral Fellow, Oak Ridge National Laboratory, HASKELL TAUB, CARLOS WEXLER, University of Missouri Columbia — In order to investigate the impact of quantum effects on hydrogen adsorption, it is important to understand the stationary states occupied by adsorbed hydrogen molecules. We present experimental inelastic neutron scattering spectra which provide evidence for significant mixing of degrees of freedom which are normally decoupled in free space. Results suggest that simultaneous treatment of translational and rotational degrees of freedom and consideration of the potential corrugation are necessary for improved theoretical understanding of the problem. Numerical calculations of the full five dimensional single body potential are used to understand the origins of the experimentally observed stationary states. In addition, we briefly discuss how our results may be used to understand the shape of hydrogen adsorption isotherms.

12:27PM W33.00007 Measured Enthalpies of Adsorption of Boron-Doped Activated Carbons¹, M. BECKNER, J. ROMANOS, E. DOHNKE, A. SINGH, J. SCHAEFERKOETTER, D. STALLA, J. BURRESS, S. JALISATGI, G. SUPPES, M.F. HAWTHORNE, P. YU, C. WEXLER, P. PFEIFER, University of Missouri — There is significant interest in the properties of boron-doped activated carbons for their potential to improve hydrogen storage.² Boron-doped activated carbons have been produced using a process involving the pyrolysis of decaborane (B₁₀H₁₄) and subsequent high-temperature annealing. In this talk, we will present a systematic study of the effect of different boron doping processes on the samples' structure, hydrogen sorption, and surface chemistry. Initial room temperature experiments show a 20% increase in the hydrogen excess adsorption per surface area compared to the undoped material. Experimental enthalpies of adsorption will be presented for comparison to theoretical predictions for boron-doped carbon materials. Additionally, results from a modified version of the doping process will be presented.

²Multiply Surface-Functionalized Nanoporous Carbon for Vehicular Hydrogen Storage, P. Pfeifer et al. DOE Hydrogen Program 2011 Annual Progress Report, IV.C.3, 444-449 (2011).

12:39PM W33.00008 Performance of Carbon Hydrogen Storage Materials as a Function of Post-Production Thermal Treatment¹, E. DOHNKE, J. ROMANOS, M. BECKNER, J.W. BURRESS, P. YU, P. PFEIFER, University of Missouri — High-surface-area activated carbons for hydrogen storage were investigated as a function of post-synthesis surface treatment. Thermal treatment of the initial carbon in high vacuum at temperatures 200-1000 °C leads to materials with significantly different surface chemistries and hydrogen storage capacities. Results from nitrogen pore-structure analyses, FT-IR spectroscopy before and after the treatment, and thermogravimetric analysis and mass spectroscopy of volatile reaction products during treatment, are reported. For treatment at 600 °C, excess hydrogen adsorption at 80 K and 303 K is found to be 20-30% higher than for the untreated sample. At temperatures below 450 °C, volatiles are mostly water and air; volatiles above 450 °C are mostly carbon dioxide and carbon monoxide. The results are interpreted as that high-temperature treatment produces materials with a large fraction of high-binding-energy sites.

¹This material is based on work supported by the US Department of Energy under Award No. DE-FG36-08GO18142.

12:51PM W33.00009 Size-scaling behavior of hydriding phase transformations in nanocrystals, LESTER HEDGES, RIZIA BARDHAN, Lawrence Berkeley National Laboratory, CARY PINT, ALI JAVEY, University of California, Berkeley, STEPHEN WHITELAM, JEFFREY URBAN, Lawrence Berkeley National Laboratory — By partnering data obtained from a novel in-situ luminescence-based probe with a statistical mechanical model we derive size-scaling laws for hydriding phase transformations relevant for hydrogen storage. We conclude that the observed experimental trends are consistent with thermally-driven nucleation, and derive scaling relations that reveal the fundamental size-dependence of nucleation barriers in nanocrystals for first-order phase transformations: near the critical point, the barrier to nucleation is controlled directly by the size of the nanocrystal. Consequently, phase transformation can occur in a nanocrystal even at the critical point, in stark contrast to the classical bulk scenario. Our results provide a detailed framework for understanding how nanoscale interfaces impact broad classes of thermally-driven solid-state phase transformations of relevance for hydrogen storage, catalysis, batteries, and fuel cells.

1:03PM W33.00010 Hydrogen affinity and structural stability of Mg-films on substrates¹, MINA YOON, Oak Ridge National Laboratory, Oak Ridge, MURAT OZER, HANNO WEITERING, University of Tennessee, Knoxville — Using first-principles density functional theory we investigated the binding mechanism of hydrogen to thin Mg films and alloyed films. In ultrathin Mg films the stability of hydrides is much lower than in the corresponding bulk systems and it can be modified by metal alloying. We calculated the chemical potential of hydrogen in Mg films for different dopant species and film thicknesses while including all vibrational degrees of freedom. By comparing the chemical potential with that of free hydrogen gas at finite temperature and pressure, we construct a hydrogenation phase diagram and identify the conditions for hydrogen absorption/desorption. Experimentally those films were synthesized on the Si substrate using MBE technique, where we observed the formation of both Mg and Mg silicides. We studied the competing mechanism of Mg/Mg₂Si formation and their structural stabilities on the substrate.

1:15PM W33.00011 Hydrogen storage through spillover at sub-2nm Pt nanoparticle - support interfaces, SOMIK MUKHERJEE, BALAVINAYAGAM RAMALINGAM, SHUBHRA GANGOPADHYAY, University of Missouri — Hydrogen generation and storage are essential components in the increasingly important field of energy storage. Electrochemical generation of Hydrogen atoms at the surface of Pt like metals at select potentials is a widely studied phenomenon. However, moving these adsorbed Hydrogen atoms to high surface area support systems (primarily Carbon) for storage is an issue. We show spillover of these adsorbed Hydrogen atoms to the conducting transition-metal oxide support for sub-2 nm Pt nanoparticles sputtered on fluorine doped tin oxide (FTO) using cyclic voltammetry. The sub-2 nm Pt nanoparticles are deposited on oxide and carbon support systems using a unique tilted target sputtering (TTS) system developed by our lab. The resultant Pt nanoparticles are highly homogeneous, have high number density and are crystalline in nature. We propose integrating this sub-2 nm Pt nanoparticle-FTO system with different carbon structures to see if the spilled over hydrogen can be stored reversibly on adjacent carbon support systems and study the involved hydrogen spillover and storage mechanisms.

1:27PM W33.00012 Activated carbon monoliths for methane storage, NAGARAJU CHADA, JIMMY ROMANOS, RAMSEY HILTON, GALEN SUPPES, JACOB BURRESS, PETER PFEIFER, University of Missouri — The use of adsorbent storage media for natural gas (methane) vehicles allows for the use of non-cylindrical tanks due to the decreased pressure at which the natural gas is stored. The use of carbon powder as a storage material allows for a high mass of methane stored for mass of sample, but at the cost of the tank volume. Densified carbon monoliths, however, allow for the mass of methane for volume of tank to be optimized. In this work, different activated carbon monoliths have been produced using a polymeric binder, with various synthesis parameters. The methane storage was studied using a home-built, dosing-type instrument. A monolith with optimal parameters has been fabricated. The gravimetric excess adsorption for the optimized monolith was found to be 161 g methane for kg carbon.

1:39PM W33.00013 A DFT Study of Atomic Hydrogen and Oxygen Chemisorption on the γ -U Surface¹, DAYLA MORRISON, ASOK RAY, Physics Department, University of Texas at Arlington — Generalized gradient approximation to density functional theory has been used to compute O and H atomic adsorption properties on the (100) surface of γ -U. The computational method used is the all-electron full-potential linearized augmented plane wave plus local orbitals basis method as implemented in the WIEN2k code. The adatom was allowed to approach the five-layer slab surface at the top, center and bridge sites. The bridge site was found to be most stable with chemisorption energies of 8.43 and 3.76 eV for O and H, respectively, spin-orbit coupling (SOC) included. The optimized distances to the surface for the O atom was 1.98 Å at the top, 0.75 Å at center and 1.32 Å and at the bridge sites. For H, these distances were found to be 2.07, 0.57, and 1.40 Å at the corresponding sites, respectively. Inclusion of SOC has significant effects on the energies, changing the chemisorption energy by as much as 0.63 eV for O and 0.43 eV for H. Possible changes in work function, magnetic moment, and charge density distributions have been investigated and will be presented. We will also present results on interstitial sites, by incorporation of O and H atoms inside the slab. Different properties were observed for the O adatom as compared to the H atom.

¹This work is partially supported by a GAANN fellowship and a grant from the Welch foundation.

1:51PM W33.00014 Effect of Nitrogen Doping on the Electronic and Optical Properties of TaON, NABIL AL-AQTASH, FLORIN APOSTOL, RENAT SABIRIANOV, University of Nebraska at Omaha — TaON is considered as a potential candidate as a visible-light responsive photocatalyst. We report the results of ab initio studies of electronic structure of TaON in monoclinic and hypothetical cubic phases using VASP code. Specifically, we show that the position of conduction and valence band can be modified by varying the nitrogen (N) concentration in TaO_{1+x}N_{1-x}. The bandgap decreases monotonically with the increase of N concentration from near 2.7eV to just over 1.1eV (i.e. by 230%) when N concentration is reduced from x=0.5 to 1.5. The bandgap reduction is mostly associated with the change in the position of the valence band, while the conduction band is not sensitive to nitrogen content. We calculated the optical absorption spectra and discuss the effect of nitrogen doping on the photocatalytic activity of oxinitrides.

2:03PM W33.00015 Determination of crystal structure and the study of electronic properties of AgBiW₂O₈ by density functional theory¹, PRANAB SARKER, MUHAMMAD N. HUDA, Physics Department, University of Texas at Arlington, Texas 76019 — AgBiW₂O₈ shows promising features in solar energy to hydrogen conversion through photoelectrochemical (PEC) approach because of moderate band gap, stability in the liquid solution, suitable band edge positions and low production cost. However, there is not much study available to determine its crystal structure. Using mineral database of relevant oxides and density functional theory (DFT) total energy calculation, we have determined the crystal structures of AgBiW₂O₈ to be a wolframite structure, which contradicts a previous report. Our theoretical electronic structure and optical properties calculation agrees well with the recent experimental result.

Session W34 DCP: Focus Session: Nano V: Nanoscale Materials and Properties II 107A

11:15AM W34.00001 In Quest of a Systematic Framework for Unifying and Defining Nanoscience¹, DONALD TOMALIA, NanoSynthons LLC — A *central paradigm driven, Mendeleev-like nano-periodic system* has been cited as a critical missing link in the transformation of nanotechnology from an empirical to a highly predictive science. A systematic framework is proposed based on the same first principles underpinning “central paradigms” for chemistry/physics.² As such, a **Nanomaterials Classification Roadmap** considers *structure controlled* nanoparticles defined by **Critical Nanoscale Design Parameters (CNDPs)**; namely, **size, shape, surface chemistry, flexibility, architecture and elemental composition**. Classified as either **hard (H)** (inorganic) or **soft (S)** (organic) **nano-element categories**, these nanoparticles (e.g., nano-clusters) generally manifest pervasive **atom mimicry** features.³ Many literature examples demonstrate chemical bonding/assembly of these nano-element categories to produce extensive libraries of **hard-hard [H_n:H_n], soft-soft [S_n-S_n] or hard-soft [H_n-S_n]** nano-element combinations, referred to as **nano-compounds**. Due to their quantized CNDP features, these nano-element/compounds exhibit many well-defined **nano-periodic property patterns**. These property patterns are observed in their intrinsic physico-chemical properties (i.e., melting points, reactivity/self-assembly, sterics), as well as important functional/ performance properties (i.e., magnetic, photonic, and electronic behavior). The importance of these CNDP directed property patterns was recently demonstrated by publication of **first Mendeleev-like nano-periodic tables** by Percec, et al.⁴ Similarly, Mirkin, et al.⁵ recently reported six CNDP dependent nano-periodic rules for predicting hard-soft nano-element assemblies. These two independent reports appear to fulfill/validate this proposed nano-periodic concept. This lecture will overview this unifying **nano-periodic system** suitable for tuning optimal nanostructure/application properties, as well as predicting important risk/benefit/performance boundaries in the nanoscience field.

11:51AM W34.00002 DFT-based Modeling of Field-Dependent Control and Response of Nano-magnetic Molecules¹, MARK PEDERSON, Chemical Sciences, Biosciences, and Geosciences Division, Office of Basic Energy Sciences, Department of Energy — Regardless of whether one is interested in characterizing, utilizing or controlling molecular-scale systems [1], one requisite to their understanding, design, and improvement is the ability to realistically model their response to electromagnetic fields. Since such responses are often collective their description requires an understanding of the interplay between bonding, spin, spin-orbit, vibrations, and electromagnetic fields. Inclusion of spin and magnetism influences the behaviors significantly. I provide an overview of a density-functional-based method (NRLMOL) for determining resonant tunneling of magnetization and Berry's phase oscillations in molecular magnets (primarily Mn₁₂-Acetate and derivatives) [2] and spin-electric effects in frustrated spin systems [Na₁₂Cu₃(AsW₉O₃₃)₂·3H₂O] [3]. The complexities related to spin- and magnetically dependent transport are compared to those of a nonmagnetic case [4]. Direct comparisons to experiments will be made. Challenges and recent progress associated with incorporating these effects into a realistic description of the frequency and amplitude dependent field driven response of many-electron/spin nanosystems will be discussed.

12:27PM W34.00003 On the mechanism of enhanced photocatalytic activity of composite TiO₂/carbon nanofilms¹, DINKO CHAKAROV, RAJA SELLAPPAN, Department of Applied Physics, Chalmers University of Technology — We fabricated and analyzed well-defined model samples consisting of anatase and graphitic carbon films with and without modifying the interface between them by a thin SiO₂ space layer. The study was performed in the search for the origin of the enhanced photocatalytic activity of composite TiO₂-carbon systems observed previously by us, but also reported in number of publications. We found that the films with a TiO₂/C interface show noticeably lower photoluminescence intensity and shorter carrier life times compared to single TiO₂ films with the same thickness and composition. The stronger non-radiative recombination was mainly assigned to charge carrier leakage (transfer) at the interface between TiO₂ nanocrystallites and the carbon film.

¹The study is performed with financial support from N-INNER, project Solar Hydrogen (P30938-1).

12:39PM W34.00004 Light-sensitive gold nanoparticles designed for solar energy use, SUNGSOOK AHN, SUNG YONG JUNG, SEUNGGOON KIM, SANG JOON LEE, POSTECH, POSTECH TEAM — Light-sensitive organic ligands are incorporated with gold nanoparticles (AuNPs) to utilize solar energy. The physical properties of the ligand-AuNP systems are mainly modulated by the ligand/AuNP ratio. Hydrodynamic size measurement, laser Doppler electrophoresis and transmission electron microscopy are used for physical characterization. The interconnectivity of the AuNPs by dual-functional ligands also has a great impact on the physical properties. In addition, fs-THz spectroscopy is applied to evaluate electron activation of the designed AuNPs. Electron beams of different energy levels are applied to change the surface energy of AuNPs, which strongly affects the absorption energy band. This study contributes to the basic understanding on the nanoparticle technology for solar energy use.

12:51PM W34.00005 Factors controlling thermodynamic properties at the nanoscale: Ab initio study of Pt nanoparticles¹, GHAZAL SHAFI, MARISOL ALCANTARA ORTIGOZA, TALAT S. RAHMAN, University of Central Florida — We analyze via density-functional-theory calculations how factors such as size, shape, and hydrogen passivation influence the bond lengths, vibrational density of states (VDOS), and thermodynamic quantities of 0.8-1.7 nm diameter Pt nanoparticles (NPs), whose shape was previously characterized via extended X-ray absorption fine structure spectroscopy (EXAFS) [1]. For a given shape, unsupported NPs display increasingly broader bond-length distributions with decreasing size. Since the VDOS is remarkably non-Debye-like (even for the largest NPs), the VDOS and the thermal properties are not correlated as they are in the bulk. Generally, the fundamental vibrational frequency of a NP is associated with the shape and decreases with increasing size, as in macroscopic systems. Not surprisingly, we find that the frequency of this fundamental mode largely characterizes the thermal properties. We demonstrate that the qualitative difference between the atomic mean-square-displacement and the corresponding mean bond-projected bond-length fluctuations should be taken into account when interpreting the Debye-Waller factor of NPs measured by X-ray (or neutron) scattering or EXAFS. We find that in H-passivated Pt NPs, H desorption with increasing temperature explains the appearance of negative thermal expansion.

1:03PM W34.00006 Nucleation in the Anatase-to-Rutile Transformation of Nanocrystalline Anatase¹, YA ZHOU, KRISTEN FICHTHORN, Penn State University — We use molecular dynamics (MD) simulations to investigate the anatase-to-rutile transformation of titania nanocrystals in vacuum. By comparing energies of various Wulff-shaped nanocrystals, we find that rutile becomes favored over anatase past a critical size that is significantly smaller than that predicted by thermodynamic models based on surface energies, indicating that edges play a profound role in the energetics of nanocrystals. We develop a local order parameter to distinguish anatase from rutile and intermediate anatase (112) twins at the resolution of a single TiO₂ unit and we apply it in direct MD simulations of spherical and Wulff-shaped anatase nanocrystals, as well as nanocrystal aggregates. To further characterize the transformation, we simulate X-ray diffraction of the nanoparticles. The anatase-to-rutile transformation originates at surfaces and interfaces, where alternating anatase (112) twin planes form. Rutile nuclei form via transformation of anatase (112) twins and they grow rapidly when they reach a critical size that can be as small as 10 TiO₂ units. Rutile nuclei tend to have planar structures bounded by (101) surfaces and the ease with which they form is dependent on the structure of the nanocrystal.

1:15PM W34.00007 Local Ionic Environment around Polyvalent Nucleic-Acid Functionalized Gold Nanoparticles¹, MONICA OLVERA DE LA CRUZ, JOS ZWANIKKEN, Department of Materials Science and Engineering, Northwestern University, CHAD MIRKIN, Department of Chemistry, Northwestern University — Polyvalent oligonucleotide-functionalized gold nanoparticles (DNA-AuNPs) are remarkably stable in a cellular environment against degradation by nucleases, a property that was recently attributed to the local high concentration of mono- and divalent ions (Ref 1). In order to evaluate this hypothesis, we investigated the composition of the ion cloud around spherical nanoparticles that are functionalized by stiff, highly charged polyelectrolyte chains by means of classical density functional theory and molecular dynamics simulations. We developed a cell model that includes ligands explicitly and both applies over the entire relevant parameter space and is in excellent quantitative agreement with simulations (Ref 2). The ion distribution around the DNA-AuNPs as a function of DNA grafting densities and bulk ionic concentrations, as well as different sizes of nanoparticles and chains, is studied. For small particles with high DNA surface densities, we find strongly enhanced local salt concentrations, a pronounced localization of divalent ions near the surface of the nanoparticle, and a large radial component of the electric field between the ligands. Therefore, we conclude that enzyme activity in general may be heavily influenced by the local environment around DNA-AuNPs.

1:27PM W34.00008 Mechanical properties of Ge nanowire, ALEX LEE, MINJUNG KIM, JAMES CHELIKOWSKY, The University of Texas at Austin — Nanowires possess unique properties owing to their low dimensionality and high surface-to-volume ratio. Although numerous calculations exist for the electronic properties of nanowires, the mechanical properties have not been addressed to the same extent. Here, we present real-space pseudopotential calculations for the mechanical properties of Ge nanowires. In particular, we examine three different orientations of Ge nanowires, with the axis along the [111], [110], and [100] directions. We present calculations for the elastic properties as a function of wire diameter. We find that Young's modulus is decreased as the surface-to-volume ratio increases, except for the [110] orientation, which shows the opposite trend. In addition, we will discuss the band structure under strain for each nanowire system.

1:39PM W34.00009 Chemisorption on Palladium and Silver Clusters, AJIT HIRA, CHRISTELLA LOVATO, Northern New Mexico College — We continue our interest on the chemisorption of different atomic and molecular species on small clusters of metallic elements, by examining the interactions of H, O and F atoms with Pd_n and Ag_n clusters (n = 6 thru 12). The hybrid ab initio methods of quantum chemistry (particularly the DFT-B3LYP model) are used to derive optimal geometries for the clusters of interest. We compare calculated binding energies, bond-lengths, ionization potentials, electron affinities and HOMO-LUMO gaps for the clusters of the two different metals. Of particular interest are the comparisons of binding strengths at the three important types of sites: edge (E) sites, hollow sites (H) site and on-top (T) sites. Effects of crystal symmetries corresponding to the bulk structures for the two metals will also be investigated. Our theoretical results will be compared with the experimental studies where they are available. Implications for the molecular dissociation of the H₂ and O₂ species will be considered.

1:51PM W34.00010 Blinking in nanoscale systems: a universal theoretical framework, SANDOR VOLKAN-KACSO, California Institute of Technology, PAVEL FRANTSUZOV, BOLDIZSAR JANKO, University of Notre Dame — Fluctuations of fluorescence intensity (blinking) is observed in many different kinds of optically active nanoscale objects. These fluctuations with extremely long-term correlations manifest on timescales longer than seconds and were observed in the emission of colloidal and self-assembled quantum dots, nanorods, nanowires, and some organic dyes. We suggest the idea of a universal physical mechanism underlying the blinking phenomenon. Here we show that the features of this universal mechanism can be captured phenomenologically by the multiple recombination center model (MRC) we proposed in a recent work to explaining single colloidal QD intermittency. Within the framework of the MRC model we qualitatively explain all the important features of fluorescence intensity fluctuations for a broad spectrum of nanoscale emitters.

Thursday, March 1, 2012 11:15AM - 2:15PM –

Session W35 DCP: Focus Session: DFT VIII: Time-Dependent Processes II: Excitations 107B

11:15AM W35.00001 Watching excitons move: the time-dependent transition density matrix¹, CARSTEN ULLRICH, University of Missouri — Time-dependent density-functional theory allows one to calculate excitation energies and the associated transition densities in principle exactly. The transition density matrix (TDM) provides additional information on electron-hole localization and coherence of specific excitations of the many-body system. We have extended the TDM concept into the real-time domain in order to visualize the excited-state dynamics in conjugated molecules. The time-dependent TDM is defined as an implicit density functional, and can be approximately obtained from the time-dependent Kohn-Sham orbitals. The quality of this approximation is assessed in simple model systems. A computational scheme for real molecular systems is presented: the time-dependent Kohn-Sham equations are solved with the OCTOPUS code and the time-dependent Kohn-Sham TDM is calculated using a spatial partitioning scheme. The method is applied to show in real time how locally created electron-hole pairs spread out over neighboring conjugated molecular chains. The coupling mechanism, electron-hole coherence, and the possibility of charge separation are discussed.

11:51AM W35.00002 A minimal TDDFT model for excitons¹, YONGHUI LI, ZENGHUI YANG, CARSTEN ULLRICH, University of Missouri — Optical processes in insulators and semiconductors, including excitonic effects, can be accurately described with linear-response TDDFT, provided one uses suitable exchange-correlation kernels. We have developed a conceptually and computationally simple formalism for calculating exciton binding energies with TDDFT, based on a two-band approximation. This formalism is implemented in a one-dimensional Kronig-Penney model, and we discuss the requirements for excitonic binding in this model. The performance of different types of exchange-correlation kernels (long- versus short-ranged, adiabatic versus nonadiabatic) is analyzed, with a particular emphasis on the excitonic Rydberg series.

¹This work is supported by NSF Grant DMR-1005651.

12:03PM W35.00003 Nonlinear ultrafast optical response in organic molecular crystals¹, TALAT S. RAHMAN, VOLODYMYR TURKOWSKI, MICHAEL N. LEUENBERGER, Physics Department and NSTC, University of Central Florida — We analyze possible nonlinear excitonic effects in the organic molecule crystals by using a combined time-dependent DFT and many-body approach. In particular, we analyze possible effects of the time-dependent (retarded) interaction between different types of excitations, Frenkel excitons, charge transfer excitons and excimers, on the electric and the optical response of the system. We pay special attention to the case of constant electric field and ultrafast pulses, including that of four-wave mixing experiments. As a specific application we examine the optical excitations of pentacene nanocrystals and compare the results with available experimental data.[1] Our results demonstrate that the nonlinear effects can play an important role in the optical response of these systems. 12:15PM W35.00004 Electronic and dielectric properties of organic photovoltaic compounds from first principles, ISMAILA DABO, CERMICS, Université Paris-Est, ANDREA FERRETTI, Istituto Nanoscienze, CNR, CHEOL-HWAN PARK, Department of Materials, Oxford University, NICOLAS POILVERT, Rowland Institute, Harvard University, MATTEO COCCIONI, CEMS, University of Minnesota, NICOLA MARZARI, Department of Materials, Oxford University — The initial step towards the design of organic photovoltaic (OPV) devices from first principles is to predict the electronic spectra and dielectric responses of molecular and polymer OPV compounds to quantitative accuracy [*Phys. Rev. B* **71**, 041306 (2005)]. To date, determining the frontier levels and dielectric properties of materials within conventional density-functional theory approximations has been elusive. To address current limitations, orbital-dependent density-functional methods, namely, hybrid density-functional theory (hybrid-DFT) and self-interaction-corrected density-functional theory (SIC-DFT) approximations, represent promising alternatives. In this presentation, we provide a critical comparison of hybrid-DFT and SIC-DFT functionals in determining electronic energies for families of OPV materials. We demonstrate that SIC-DFT based upon Koopmans' condition [*Phys. Rev. B* **82**, 115121 (2010)] is apt at describing donor and acceptor levels within 0.1-0.4 eV and 0.2-0.6 eV relative to experiment. Furthermore, SIC-DFT dielectric responses for semiconducting polymers are predicted in close agreement with more expensive wave-function methods, thereby allowing the accurate and computationally tractable description of donor-acceptor molecular complexes.

12:27PM W35.00005 Discontinuities of the exchange-correlation kernel and charge-transfer excitations in time-dependent density functional theory, MARIA HELLGREN, Max-Planck-Institute, Weinberg 2, Halle(Saale), Germany, E.K.U. GROSS, Max-Planck-Institute, Weinberg 2, Halle (Saale), Germany — We identify the key property that the exchange-correlation (XC) kernel of time-dependent density functional theory (TDDFT) must have in order to describe long-range charge-transfer excitations. We show that the discontinuity of the XC potential as a function of particle number induces a frequency-dependent discontinuity of the XC kernel which diverges in the dissociation limit. This divergency compensates for the exponentially small overlap between the acceptor and donor orbitals, thereby yielding a finite correction to the Kohn-Sham eigenvalue differences. This mechanism is illustrated to first order in the Coulomb interaction.

12:39PM W35.00006 Density Functional Resonance Theory: The Complex Density Function, Orbital Energies and Lifetimes, and Results for Simple Systems¹, DANIEL WHITENACK, Purdue University Department of Physics, ADAM WASSERMAN, Purdue University Department of Chemistry and Department of Physics — Density Functional Resonance Theory (DFRT) is a recently developed complex-scaled version of ground-state Density Functional Theory (DFT) for metastable systems. This work is a detailed study of the formalism itself, its consequences and its application. The meaning of the complex "density" function, which is used as the primary variable, is discussed along with its possible application to study the reactivity of metastable systems. In addition, orbital energies and lifetimes are defined and related to physical quantities. Finally, results for energies and lifetimes are presented for simple systems.

¹Acknowledgment is made to the Donors of the American Chemical Society Petroleum Research Fund for support of this research under grant No. PRF # 49599-DN16.

12:51PM W35.00007 Meta-GGA-based adiabatic time-dependent density-functional theory¹, VLADIMIR NAZAROV, Research Center for Applied Sciences, Academia Sinica, GIOVANNI VIGNALE, University of Missouri-Columbia — The local-density approximation (LDA) to the ground-state density functional theory (DFT) is well known to allow for a generalization to the time-dependent case [1]. The assumption of the adiabaticity of the process greatly simplifies the theory. The further extension of the time-dependent DFT (TDDFT) to the generalized gradient approximation (GGA) is trivial. Here we address lifting the adiabatic TDDFT to the third rung of the "Jacobs ladder" [2]: We work out the kinetic energy density dependent (meta-GGA) TDDFT formalism. The new theory possesses remarkable properties not present in LDA and GGA: (i) It is non-local with respect to the particle density; (ii) In the case of bulk semiconductors, it supports the $1/q^2$ singularity of the exchange-correlation kernel, where q is the wave-vector, the latter being important to reproduce the excitonic effect. We also present illustrative calculations of the optical absorption in semiconductors [3].

1:03PM W35.00008 Describing electronic excitations using electron-hole density functional theory (eh-DFT), ARINDAM CHAKRABORTY, Syracuse University — The electron-hole interaction play a crucial role in calculating optical properties of atoms, molecules, clusters and solids. In this talk, the density functional treatment of electron-hole quasiparticle interaction will be presented in the framework of electron-hole density functional theory (eh-DFT). The electron-hole correlation functional plays a central role in accuracy of any eh-DFT calculations. In the present work, the development of eh-correlation functional using the eh-reduced density matrix will be presented. Benchmark calculation using the developed functional will be compared with HF, full CI, R12-full CI, and explicitly correlated Hartree-Fock calculations. Exciton binding energies in CdSe quantum dots have been calculated and the eh-DFT results will be compared with experimental and pseudopotential+CI results. Discussion on construction of electron-hole adiabatic connection curve (ACC) using density-constrained minimization will be presented and the results from the ACC will be compared with eh-DFT calculations. Finally, similarity and difference between the GW+Bethe-Salpeter method and eh-DFT approach for treating electron-hole interaction will be presented.

1:15PM W35.00009 Applying state-of-the-art signal processing to time-dependent density functional theory, JACOB SANDERS, XAVIER ANDRADE, ALAN ASPURU-GUZI, Harvard University Department of Chemistry and Chemical Biology — Real-time time-dependent density functional theory (TDDFT) is a computationally efficient method that can be used to calculate optical absorption spectra, circular dichroism spectra, and other properties including non-linear ones. These properties are often obtained via time-propagation methods, and a discrete Fourier transform is used to convert from the time domain to the frequency domain. However, a Fourier transform requires long time propagations to resolve spectra, especially if they contain closely-spaced frequencies. Instead, we apply a state-of-the-art signal processing technique known as compressed sensing to the spectral analysis of electron dynamics. Compared to a Fourier transform, compressed sensing provides higher-resolution absorption spectra with shorter propagation times. In the systems we study, the method requires about 80% less time series data to obtain comparable frequency resolution, thus reducing total computational cost by approximately a factor of five. By combining the computational efficiency and parallelizability of real-time TDDFT for large systems with the dramatic reduction in simulation time enabled by compressed sensing, we increase the feasibility of studying electron dynamics in large biological molecules and organic photovoltaics.

1:27PM W35.00010 Density Functional Theory Investigation of Tunable Surface Composition of CdS Quantum Dots¹, OLEG PREZHDO, AMANDA NEUKIRCH, JEREMY YOUNG, HELEN WEI, CHRISTOPHER EVENS, TODD KRAUSS, University of Rochester — It has recently been observed that surface composition of CdS QDs greatly affects photoluminescence. Band edge emission is quenched in sulfur terminated CdS QDs and recovered when QDs were cadmium terminated. However, in all cases the absorption spectra remained relatively unchanged. To understand the origin of this phenomenon, the density of states in a stoichiometric, Cd rich, and S rich dots was investigated using density functional theory (DFT). It was found that in the S rich system states within the band gap were introduced, providing a channel for non-radiative electronic relaxation. Gap states were also introduced in the Cd rich system compared to the stoichiometric system, but a significant band gap remained in even the most Cd rich systems. Finally, time dependent (TD)DFT was used to calculate the spectra of the various systems. It was found that created gap states were largely optically inactive. Therefore the new states would not participate in optical absorption or emission, but could participate in electron phonon relaxation. This study clarifies the role of surface defects in QD optical properties and provides a route for tuning those optical properties by controlling surface composition.

1:39PM W35.00011 First-Principles Approach to Chemical Raman Enhancement of Organic Adsorbates on Metal Surfaces¹, ALEXEY ZAYAK, Molecular Foundry, LBNL, HYUCK CHOO, California Institute of Technology, YING S. HU, Rice University, DANIEL GARGAS, STEFANO CABRINI, JEFFREY BOKOR, P. JAMES SCHUCK, JEFFREY B. NEATON, Molecular Foundry, LBNL — A first-principles density functional theory (DFT)-based approach is developed [1] to determine chemical contributions to surface-enhanced Raman spectroscopy (SERS) for molecular adsorbates on metal surfaces. While SERS applications are often directed at sensing trace amounts of chemical species, quantitative calculations of how Raman spectra of molecules are altered on chemisorption [1], coupled to experiments, can contribute significantly to our understanding of the electronic structure of the metal-adsorbate interface. For two adsorbates on Au – benzene thiol and trans-1,2-bis(4-pyridyl) ethylene (BPE) – DFT calculations of the static Raman tensor demonstrate a strong mode-dependent modification of Raman spectra by Au substrates. Raman active modes with the largest enhancements result from stronger contributions from Au to their electron-vibron coupling, as quantified through a deformation potential. Based on our calculations, we introduce a straightforward analysis to extract “chemical enhancement” from measurements, and demonstrate how SERS spectra of BPE change as a function of the relative fraction of BPE molecules chemisorbed to the substrate.

1:51PM W35.00012 Electron-Hole Pairs during Adsorption Dynamics of O₂ on Pd(100) – Exciting or not?, JOERG MEYER, KARSTEN REUTER, TU Muenchen — *Ab initio* modeling can provide important atomistic insights into the dynamics of elementary reaction steps in heterogeneous catalysis. But already an apparently simple example like the adsorption of O₂ on a frozen Pd(100) surface brings up several fundamental challenges: The corresponding six-dimensional potential energy surface (PES) is required, and excitations of electron-hole (eh) pairs as well as the transition from the ³Σ_g⁻ spin-triplet in the gas phase to a singlet-like state of adsorbed oxygen might require to go beyond the Born-Oppenheimer approximation. We tackle the PES by neural network interpolation, based on a coordinate transformation that correctly includes and exploits the underlying symmetry. Classical molecular dynamics thereon yields the initial sticking coefficient in good agreement with experimental data. Scrutinizing this result, we calculate spin-resolved eh pair spectra for several trajectories of different statistical relevance using a computationally appealing perturbative approach building on time-dependent DFT.¹ Although non-adiabatic energy losses do not exceed 5% of the chemisorption energy, their importance for the spin transition is finally discussed.

2:03PM W35.00013 Self-consistent GW calculations with basis of dominant products, PETER KOVAL, Centro de Fisica de Materiales, DIETRICH FOERSTER, University of Bordeaux 1, DANIEL SANCHEZ PORTAL, Centro de Fisica de Materiales — Hedin's GW approximation (GWA) is a well known method to study charged excitations in electronic systems with a moderate computational cost [1]. Already one-shot GWA delivers a considerable improvement if compared with Green's functions from density-functional theory (DFT). However, the one-shot results are dependent on the used starting point. This unphysical dependence can be eliminated by iterating a GW calculation to self-consistency. We implemented self-consistent GWA for molecules [2], within our original framework of dominant products basis. We use the DFT calculation by SIESTA code as starting point. The framework allowed to calculate Green's functions on a fine frequency mesh for such small molecules as benzene. We demonstrate the level of independence on starting point achievable within pseudo-potential framework, validating the implementation. Effects of the self-consistency on the interacting Green's function will be discussed along with different levels of self-consistency and mixing schemes. Finally, we compare the self-consistency with so-called quasi-particle self-consistent GW [3].

Thursday, March 1, 2012 11:15AM - 2:15PM – Session W37 DMP: Topological Insulators: Fractionalization 108

11:15AM W37.00001 Zoology of Fractional Chern Insulators, YANG-LE WU, B. ANDREI BERNEVIG, Princeton University, N. REGNAULT, Ecole Normale Supérieure, CNRS — We study four different models of Chern insulators in the presence of strong electronic repulsion at partial fillings. We observe that all cases exhibit a Laughlin-like phase at filling fraction $1/3$. We provide evidence of such a strongly correlated topological phase by studying both the energy and the entanglement spectra. In order to identify the key ingredients of the emergence of Laughlin physics in these systems, we show how they are affected when tuning the band structure. We also address the question of the relevance of the Berry curvature flatness in this problem. Using three-body interactions, we show that some models can also host a topological phase reminiscent of the $\nu = 1/2$ Pfaffian Moore-Read state. Additionally, we identify the structures indicating cluster correlations in the entanglement spectra.

11:27AM W37.00002 Time-reversal symmetric hierarchy of fractional incompressible liquids, LUIZ SANTOS, Harvard University, TITUS NEUPERT, Paul Scherrer Institute, SHINSEI RYU, University of Illinois at Urbana-Champaign, CLAUDIO CHAMON, Boston University, CHRISTOPHER MUDRY, Paul Scherrer Institute — In this talk I shall establish a hierarchical construction for a class of BF theories and present it as a candidate topological field theory to describe fractional topological insulators in 2D. The structure of the K matrix and the universal properties that it describes will be discussed, and the properties of the time-reversal symmetric edge theory will be derived via the bulk-edge correspondence.

11:39AM W37.00003 Fractional Chern Insulator, NICOLAS REGNAULT, Ecole Normale Supérieure Paris, CNRS, BOGDAN ANDREI BERNEVIG, Princeton University — Chern insulators are band insulators exhibiting a nonzero Hall conductance but preserving the lattice translation symmetry. We conclusively show that a partially filled Chern insulator at $1/3$ filling exhibits a fractional quantum Hall effect and rule out charge-density wave states that have not been ruled out by previous studies. By diagonalizing the Hubbard interaction in the flat-band limit of these insulators, we show the following: the system is incompressible and has a 3-fold degenerate groundstate whose momenta can be computed by postulating an generalized Pauli principle with no more than 1 particle in 3 consecutive orbitals. The groundstate density is constant, and equal to $1/3$ in momentum space. Excitations of the system are fractional statistics particles whose total counting matches that of quasiholes in the Laughlin state based on the same generalized Pauli principle. The entanglement spectrum of the state has a clear entanglement gap which seems to remain finite in the thermodynamic limit. The levels below the gap exhibit the identical counting of Laughlin $1/3$ quasiholes. The 3 groundstates and excited states exhibit spectral flow upon flux insertion. All the properties above disappear in the trivial state of the insulator.

11:51AM W37.00004 Fractional Chern Insulators from the n th Root of Bandstructure¹, BRIAN SWINGLE, Harvard University, KY-ANH TRAN, JOHN MCGREEVY, MIT — I will describe some recent theoretical results pertaining to fractional Chern insulators. These are interacting lattice models of partially filled Chern bands which have been numerically shown to realize some universal aspects of fractional quantum Hall physics. We use parton/slave-particle techniques to provide model wavefunctions for these phases. We also provide a strong coupling expansion that gives new insights into the foundations of the parton approach. I will conclude by describing some of the practical uses of our results, including suggesting candidate models to realize non-Abelian fractional Chern insulators.

¹This work partially supported by a Simons Fellowship.

12:03PM W37.00005 Wannier states and pseudopotential Hamiltonians for fractional Chern insulators, CHING HUA LEE, Department of Physics, Stanford University, DONG-NING SHENG, Department of Physics and Astronomy, California State University, RONNY THOMALE, XIAO-LIANG QI, Department of Physics, Stanford University — Fractional Chern insulators are fractional quantum Hall states realized in lattice models with full lattice translational symmetry in the absence of an external magnetic field. In fractional quantum Hall systems, pseudopotential Hamiltonians have been constructed for which the ideal ground states such as Laughlin states are exact ground states. In this work, we constructed pseudopotential Hamiltonians for the fractional Chern insulators by making use of the Wannier function representation. The physical interaction Hamiltonians can be expanded in pseudopotentials, from which one can analyze the preferred fractional quantum Hall states in the corresponding systems. The results of this analysis are compared with exact diagonalization. Our approach may be generalized to studying nonabelian fractional Chern insulator states and time-reversal invariant fractional topological insulators.

12:15PM W37.00006 Topological insulators and fractional quantum Hall effect on the ruby lattice¹, XIANG HU, MEHDI KARGARIAN, GREGORY A. FIETE, The University of Texas at Austin — We study a tight-binding model on the two-dimensional ruby lattice. This lattice supports several types of first and second neighbor spin-dependent hopping parameters in an s -band model that preserves time-reversal symmetry. We discuss the phase diagram of this model for various values of the hopping parameters and filling fractions, and note an interesting competition between spin-orbit terms that individually would drive the system to a $\mathbb{Z}_2$ topological insulating phase. We also discuss a closely related spin-polarized model with only first and second neighbor hoppings and show that extremely flat bands with finite Chern numbers result, with a ratio of the band gap to the band width approximately 70. Such flat bands are an ideal platform to realize a fractional quantum Hall effect at appropriate filling fractions. The ruby lattice can be possibly engineered in optical lattices, and may open the door to studies of transitions between quantum spin liquids, topological insulators, and integer and fractional quantum Hall states.

¹We acknowledge support from ARO Grant W911NF-09-1-0527 and NSF Grant DMR-0955778, and the Texas Advanced Computing Center (TACC) for providing computing resources.

12:27PM W37.00007 Charge and spin fractionalization in strongly correlated topological insulators¹, PREDRAG NIKOLIC, George Mason University, TANJA DURIC, Max Planck Institute, Dresden — The recently discovered two-dimensional topological insulators (TI) with time-reversal symmetry are closely related to integer quantum Hall states in which electron spin plays the role of charge. The appearance of protected edge states in these systems can be understood by describing the spin-orbit coupling as the source of an SU(2) (spin-dependent) magnetic flux. However, the absence of spin conservation cripples the quantum spin-Hall effect. In this talk we will explore the possibility of obtaining strongly correlated TIs with fractional quasiparticles. Such states are the SU(2) analogues of fractional quantum Hall states, but with modified topological orders due to the spin non-conservation. We will discuss two heterostructure designs featuring a “conventional” TI quantum well that could host a fractional TI state of Cooper pairs or excitons. These devices exploit a quantum critical point for electron localization to provide a fragile spectrum that can be dramatically reshaped by the strong spin-orbit coupling. Then, we will present a topological spinor-field theory of fractional TIs and explain how the spin-orbit coupling can produce a combined charge and spin fractionalization despite the spin non-conservation.

¹Supported by ONR, NIST and DOE (IQM at Johns Hopkins University)

12:39PM W37.00008 Symmetry protected fractional Chern insulators and fractional topological insulators, YUAN-MING LU, Department of Physics, University of California at Berkeley, Berkeley, CA 94720, USA, YING RAN, Department of Physics, Boston College, Chestnut Hill, Massachusetts 02467, USA — We construct fully symmetric wavefunctions for the spin-polarized fractional Chern insulators (FCI) and time-reversal-invariant fractional topological insulators (FTI) using the parton approach. We show that the lattice symmetry gives rise to many different FCI and FTI phases even with the same filling fraction ν (and the same quantized Hall conductance σ_{xy} in FCI case). They have different symmetry-protected topological orders, which are characterized by different projective symmetry groups. We mainly focus on FCI phases with which are realized in a partially filled band with Chern number one and filling fraction $\nu = 1/m$. Examples of FCI/FTI wavefunctions on honeycomb lattice and checkerboard lattice are explicitly given. Possible non-Abelian FCI phases which may be realized in a partially filled band with Chern number two are discussed. Generic FTI wavefunctions preserving all lattice symmetries in the absence of spin conservation are also presented for filling fraction $\nu = 2/m$.

12:51PM W37.00009 High-temperature fractional quantum Hall states, EVELYN TANG, XIAO-GANG WEN, Massachusetts Institute of Technology — Using a suitable combination of geometric frustration, ferromagnetism, and spin-orbit coupling in a hopping model on the kagome lattice, we obtain a flat band with nonzero Chern number. Partial filling of this band could give rise to the fractional quantum Hall effect in this system which, when considering realistic parameters, would persist at room temperature. Possible material realizations that indicate new directions for exploration and synthesis are discussed.

1:03PM W37.00010 Fractional Quantum Hall states in strongly correlated multi-orbital systems¹, MARIA DAGHOFER, JÖRN W.F. VENDERBOS, STEFANOS KOURTIS, JEROEN VAN DEN BRINK, IFW Dresden — For topologically nontrivial and very narrow bands, Coulomb repulsion between electrons has been predicted to give rise to a spontaneous fractional quantum-Hall (FQH) state in absence of magnetic fields. We will discuss how orbital degrees of freedom in frustrated lattice systems lead to a narrowing of topologically nontrivial bands [1]. This robust effect does not rely on fine-tuned long-range hopping parameters and is directly relevant to a wide class of transition metal compounds. In addition, we will show that strongly correlated electrons in a t_{2g} -orbital system on a triangular lattice self-organize into a spin-chiral magnetic ordering pattern that induces precisely the required topologically nontrivial and flat bands [2]. On top of a self-consistent mean-field approach, we use exact diagonalization to study an effective one-band model for the emerging flat band in the presence of longer-range interactions and establish the signatures of a spontaneous $\nu = \frac{1}{3}$ FQH state.

1:15PM W37.00011 Hall Crystal States in Fractionally Filled Chern Bands, GANPATHY MURTHY¹, University of Kentucky, RAMAMURTI SHANKAR², Yale University — Two-dimensional time-reversal-invariant topological insulators can be thought of as a time-reversed pair of Chern bands. Numerical evidence shows the existence of states at fractional filling which are analogous to FQH states[1]. In [2] it was noted that at small momenta, the algebra of the density operators projected to the Chern band resembles the magnetic translation algebra. The authors have constructed a mapping[3] between Chern bands and a Landau level in a periodic potential which works at all momenta. This mapping is dynamically faithful, and reproduces the commutators of the projected density operator. There turn out to be Hall Crystal states, characterized by a Hall conductance, and another integer which described the charged dragged when the potential is adiabatically moved by a lattice unit. Using the Hamiltonian formalism developed by the authors some time ago for the FQHE[4], we calculate gaps and collective mode dispersions for such states. 1. D. N. Sheng et al, arxiv:1102.2568, N. 1:27PM W37.00012 Chiral Topological Phases and Fractional Domain Wall Excitations in One-Dimensional Chains and Wires¹, JUKKA VAYRYNEN, Yale University, TEEMU OJANEN, Harvard University — According to the general classification of topological insulators, there exist one-dimensional chirally (sublattice) symmetric systems that can support any number of topological phases. We introduce a zigzag fermion chain with spin-orbit coupling in magnetic field and identify three distinct topological phases. Zero-mode excitations, localized at the phase boundaries, are fractionalized: two of the phase boundaries support $\pm e/2$ charge states while one of the boundaries support $\pm e$ and neutral excitations. In addition, a finite chain exhibits $\pm e/2$ edge states for two of the three phases. We explain how the studied system generalizes the Peierls-distorted polyacetylene model and discuss possible realizations in atomic chains and quantum spin Hall wires.

1:39PM W37.00013 Quantum Hall Effect and Bound Fractional Charge in Topological Insulator Magnetic Tunnel Junctions, TAYLOR HUGHES, QINGLEI MENG, SMITHA VISHVESHWARA, University of Illinois at Urbana Champaign — Proximity coupling 2D and 3D time-reversal invariant topological insulators to ferromagnetic domain walls is known to lead to bound fractional charge and an integer quantum Hall effect respectively. Here we show that by correctly engineering the sample geometry these effects can appear in the presence of only a single magnet with no domain walls, thus reducing the experimental complexity. We will prove that a magnetic layer sandwiched between 3D topological insulator films will exhibit the quantum Hall effect, possibly leading to a room-temperature realization of the quantum Hall effect.

1:51PM W37.00014 Phase Diagram of a Simple Model for Fractional Topological Insulator, HUA CHEN, Zhejiang Institute of Modern Physics and Department of Physics, Zhejiang University, Hangzhou 310027, China, KUN YANG, National High Magnetic Field Laboratory and Department of Physics, Florida State University, Tallahassee, FL 32306, USA — We study a simple model of two species of (or spin-1/2) fermions with short-range intra-species repulsion in the presence of opposite (effective) magnetic field, each at filling factor 1/3. In the absence of inter-species interaction, the ground state is simply two copies of the 1/3 Laughlin state, with opposite chirality. Due to the overall time-reversal symmetry, this is a fractional topological insulator. We show this phase is stable against moderate inter-species interactions. However strong enough inter-species repulsion leads to phase separation, while strong enough inter-species attraction drives the system into a superfluid phase. We obtain the phase diagram through exact diagonalization calculations. Nature of the fractional topological insulator-superfluid phase transition is discussed using an appropriate Chern-Simons-Ginsburg-Landau effective field theory.

2:03PM W37.00015 Fractional Chern Insulators and the W_∞ Algebra, RAHUL ROY, Rudolf Peierls Centre for Theoretical Physics, Oxford University, SIDDHARTH PARAMESWARAN, University of California, Berkeley, SHIVAJI SONDHI, Princeton University — A set of recent results indicates that fractionally filled bands of Chern insulators in two dimensions support fractional quantum Hall states analogous to those found in fractionally filled Landau levels. We provide an understanding of these results by examining the algebra of Chern band projected density operators. We find that this algebra closes at long wavelengths and for constant Berry curvature, whereupon it is isomorphic to the W_∞ algebra of lowest Landau level projected densities first identified by Girvin, MacDonald and Platzman [Phys. Rev. B 33, 2481 (1986).] For Hamiltonians projected to the Chern band this provides a route to replicating lowest Landau level physics on the lattice.

Thursday, March 1, 2012 11:15AM - 2:15PM –
Session W39 DMP DBIO DPOLY: Focus Session: Materials and Functional Structures for Biological Interfaces: Cells 109B

11:15AM W39.00001 Controlling Cell Function with Geometry, MILAN MRKSICH, Northwestern University — This presentation will describe the use of patterned substrates to control cell shape with examples that illustrate the ways in which cell shape can regulate cell function. Most cells are adherent and must attach to and spread on a surface in order to survive, proliferate and function. In tissue, this surface is the extracellular matrix (ECM), an insoluble scaffold formed by the assembly of several large proteins—including fibronectin, the laminins and collagens and others—but in the laboratory, the surface is prepared by adsorbing protein to glass slides. To pattern cells, gold-coated slides are patterned with microcontact printing to create geometric features that promote cell attachment and that are surrounded by inert regions. Cells attach to these substrates and spread to adopt the shape defined by the underlying pattern and remain stable in culture for several days. Examples will be described that used a series of shapes to reveal the relationship between the shape of the cell and the structure of its cytoskeleton. These geometric cues were used to control cell polarity and the tension, or contractility, present in the cytoskeleton. These rules were further used to control the shapes of mesenchymal stem cells and in turn to control the differentiation of these cells into specialized cell types. For example, stem cells that were patterned into a “star” shape preferentially differentiated into bone cells whereas those that were patterned into a “flower” shape preferred a fat cell fate. These influences of shape on differentiation depend on the mechanical properties of the cytoskeleton. These examples, and others, reveal that shape is an important cue that informs cell function and that can be combined with the more common soluble cues to direct and study cell function.

11:51AM W39.00002 Role of fiber functionality and angle on cell migration.¹, SISI QIN, RICHARD CLARK, MIRIAM RAFILOVICH, Stony Brook University, DEPARTMENT OF MATERIALS SCIENCES AND ENGINEERING, STONY BROOK UNIVERSITY TEAM, DEPARTMENT OF BIOMEDICAL ENGINEERING, STONY BROOK UNIVERSITY TEAM — In order to determine the role of surface interactions on cell migration we compared the cell velocity on electrospun PMMA fibers which were either etched with UV/ozone plasma, had pre-adsorbed Fibronectin or both. It shows that dermal fibroblasts (CF-29, ATCC) did not adhere to the fibers without treatment, and the migration of cells was fastest on with both etching and pre-coat FN fibers. Vinculin was used to stain for the focal adhesion points and the largest number per cell were found on the FN pre-incubated samples, and nearly none on the plasma etched surface, despite good proliferation and migration. The results indicate that the migration velocity need not directly correlate to the cell adhesion. Using FN coated fibers we also studied the effect of angle on crossed fibers. We found that there was a clear preference by the cells for crossing a matrix where the fibers were oriented at 30 degrees. At this angle the migration velocity was slowest. Movies of the migrating cells indicate that the residence time of the cells at junctions with this angle is the longest cut to the interactions of the motion between fibers. The largest speed was observed for fibers placed at 90 degree.

¹NSF-DMR-MRSEC Program

12:03PM W39.00003 Anomalous cell migration properties on electrospun fibers¹, RICHARD CLARK, SISI QIN, MIRIAM RAFILOVICH, Stony Brook University, DEPARTMENT OF MATERIALS SCIENCES AND ENGINEERING, STONY BROOK UNIVERSITY TEAM, DEPARTMENT OF BIOMEDICAL ENGINEERING, STONY BROOK UNIVERSITY TEAM — We have studied the influence of substrate morphology on the en-mass cell migration from an agarose droplet. On flat surfaces, the cell velocity decreases asymptotically towards the single cell value as the radial distance increases, and remains constant thereafter. On fibers, the velocity remains constant at the single cell limit for the first 24 hours and then begins to increase continuously for the next four days. On flat surfaces we have shown that migration was triggered by nuclear deformation [Pan Z. et al, 2009], whereas on fibers the nucleus is constantly deformed as the cell assumes the shape of the fiber and hence does not seem to play as major a role. Vinculin and paxillin immunofluorescent staining were performed to determine the role of traction forces. We found that whereas polarization remains constant on flat surfaces with time, it increases on the fiber surfaces after the first 24 hours, and may explain the increased migration speed.

¹NSF-DMR-MRSEC Program

12:15PM W39.00004 Control cell adhesion with dynamic bilayer films, ANDREAS KOUROUKLIS, Department of Chemical Engineering, Umass Amherst, RONALD LERUM, Department of Polymer Science & Engineering, Umass Amherst, HARRY BERMUDEZ, Department of Polymer Science & Engineering and Department of Chemical Engineering, Umass Amherst — Interfacially-directed assembly of amphiphilic block copolymers was employed to create ultrathin films having the potential to correlate the dynamics of ECM cues with cell adhesion and cytoskeletally-generated forces. The mobility of the polymeric bilayer films were tuned by the incorporation of hydrophobic homopolymer chains, which are thought to reduce interlayer friction. Labeling of the block copolymer chains with an adhesive peptide ligand (RGD) provided a specific means to study integrin-mediated cellular processes and the corresponding mechanotransduction. By seeding anchorage-dependent cells on “dynamic” (laterally mobile) and “static” films that display the same amount of RGD, we have found that cells recognize the difference in RGD diffusivity and develop distinct responses over time. We intend to examine changes in cell response by controlling the extent of cytoskeletally-generated forces and the assembly dynamics of focal adhesion complexes. Such films provide a unique platform to unveil the biomechanical signals related with ECM dynamics, and may ultimately facilitate a deeper understanding of cellular processes.

12:27PM W39.00005 Diblock Copolymer Foams with Adhesive Nano-domains Promote Stem Cell Differentiation¹, ADAM ENGLER, UC San Diego — Adhesions play an important role in cell behavior, including differentiation. Substrates are typically modified with homogeneous protein coatings; extracellular matrices *in vivo* provide heterogeneous adhesive sites. To mimic adhesive heterogeneity, internal phase emulsion foams were polymerized with polystyrene-polyacrylic acid (PAA) and polystyrene-polyethylene oxide (PEO) to determine if interface de-mixing would form patch-like surfaces. PEO/PAA mole ratios were confirmed by XPS and water contact angle while spatial distribution was measured by chemical force spectroscopy. This method confirmed the presence of patch-like PAA domains. Protein differentially adsorbs on PEO and PAA, so adsorption on foam mixtures was copolymer ratio dependent. Bone marrow-derived mesenchymal stem cell (BMSC) adhesion was ratio dependent, but the highest density and vinculin expression was observed for 75PEO/25PAA. BMSCs appeared to change lineage expression the most on this composition, suggesting that this foam, which exhibits small adhesive PAA domains, may be more biomimetic than uniformly adhesive scaffolds, e.g. 0PEO/100PAA.

1:03PM W39.00006 Dental Pulp Stem Cell Differentiation on Poly-4-vinyl-pyridine surfaces¹, GIULIA SUARATO, Department of Materials Science and Engineering, SUNY at Stony Brook, ANEEL BHERWANI, Oral Biology and Pathology, SUNY at Stony Brook, CHUNG-CHUEH CHANG, MIRIAM RAFAILOVICH, Department of Materials Science and Engineering, SUNY at Stony Brook, MARCIA SIMON, Oral Biology and Pathology, SUNY at Stony Brook — In the regeneration of a natural tissue, the mechanics and the chemical properties of the artificial substrate play a critical role. In this study, the influence of poly-4-vinyl-pyridine scaffold morphology on dental pulp stem cell differentiation was analyzed. Cells were plated on spun cast films and electrospun fibers with diameters ranging from nano to micrometers. Confocal microscopy showed the presence of various cell morphologies: on microfibers cells conform precisely to the main axis of elongation, while on nanometric scaffolds they result spread and in contact with several fibers. Even if the surface chemistry was identical, a great variation in the curvature was present. From day 9 of incubation, spontaneous biomineralization in the absence of induction agents occurred only on the fibrous structures. The SEM revealed template deposits directly on the microfibers, while on the nanofibers large spherical islands were also present. EDAX determined hydroxyl apatite nature of the deposits. RT-PCR indicated upregulation of osteogenic markers, confirming differentiation. SEM also revealed the presence of ECM fibers covering the polymer structure, which may enhance the expression of focal adhesion sites on the cell membrane.

¹NSF-DMR-MREC program and the DMR-CBET program

1:15PM W39.00007 Spontaneous Differentiation of Dental Pulp stem cells on Dental polymers, ANEEL BHERWANI, Oral Biology and Pathology, Stony Brook University, GIULIA SUARATO, SISI QIN, CHUNG-CHUEH CHANG, Materials Science, Stony Brook University, AARON AKHAVAN, Ramban Mesizta High School, JOSEPH SPIEGEL, VLADIMIR JURUKOVSKI, MIRIAM RAFAILOVICH, Materials Science, Stony Brook University, MARCIA SIMON, Oral Biology and Pathology, Stony Brook University — Dental pulp stem cells were plated on two dentally relevant materials i.e. PMMA commonly used for denture and Titanium used for implants. In both cases, we probed for the role of surface interaction and substrate morphology. Different films of PMMA were spun cast directly onto Si wafers; PMMA fibers of different diameters were electro spun onto some of these substrates. Titanium metal was evaporated onto Si surfaces using an electron beam evaporator. In addition, on some surfaces, P4VP nanofibers were spun cast. DPSC were grown in alpha-MEM supplemented with 10% fetal bovine serum, 0.2mM L-ascorbic acid 2-phosphate, 2mM glutamine and 10mM beta-glycerol phosphate either with or without 10nM dexamethasone. After 21 days samples were examined using confocal microscopy of cells and by scanning electron microscopy (SEM) and Energy dispersive X-ray Analysis (EDAX). In the case of Titanium biomineralization was observed independent of dexamethasone, where the deposits were templated along the fibers. Minimal biomineralization was observed on flat Titanium and PMMA samples. Markers of osteogenesis and specific signaling pathways are being evaluated by RT-PCR, which are up regulated on each surface, to understand the fundamental manner in which surfaces interact with cell differentiation.

1:27PM W39.00008 Interaction of Substrate Mechanics with Dental Pulp Stem Cells (DPSCs) differentiation to generate a scaffold for Bone regeneration, MIRIAM RAFAILOVICH, DIVYA BHATNAGAR, Department of Materials Science and Engineering, SUNY Stony Brook, ANEEL BHERWANI, MARCIA SIMON, School of Dental Medicine, SUNY Stony Brook — This work investigates the interaction of the substrate mechanics with the differentiation in the absence of chemical induction and only resulting from the stimuli of the substrate mechanics and chemistry. We chose enzymatically cross-linked gelatin hydrogels substrates of different stiffness varying from 8KPa to 100Pa. DPSCs were cultured and differentiated on the substrates for 7, 14 and 21 days with and without dexamethasone induction media. SEM and EDX analysis after 21 days indicate that cells produced a sheet of biomineralized deposits, several tenths of mm thick on the hard substrate irrespective of chemical induction. Moduli of the cells was independent of the induction and stiffness of the hydrogels. RT-PCR assays indicated that cells expressed more osteocalcin when cultured in non-induction media and harder substrate. The shape of the deposits was more uniform and in close packing on the harder substrate with a higher Ca:P ratio. On soft substrate the deposits were more flat with less Ca:P ratio. Further experiments indicated that conformational change due to the crosslinking of gelatin could be the reason for biomineralization.

1:39PM W39.00009 Neuron Growth on Carbon Nanotube Thread Bio-Scaffolds for Repair of Central Nervous System Damage, DAVID MAST, SARAH PIXLEY, MARK SCHULZ, VESSILIN SHANOV, University of Cincinnati — Approximately 11,000 new spinal cord injuries occur each year. Repairing such central nervous system (CNS) damage has proven to be very difficult. We report on *in vitro* experiments using carbon nanotube (CNT) threads as a bio-scaffold for promoting CNS repair via directed neuron regrowth along the CNT material. Mouse brain neurospheres, containing neuronal stem cells, neurons and support glia, were observed to attach to and grow along laminin-coated CNT threads *in vitro*. However, due to their limited mobility, only neurospheres close to the threads attach. To increase cellular attachment to the threads, we exploit the fact that these cells can exhibit enhanced, directed migration along an externally applied electric field. Recent *in vitro* cell growth was carried out in chambers containing several parallel CNT threads with electrical connections extending out of the incubator so that a voltage applied across adjacent threads established an appropriate electric field. Electrochemical Impedance Spectroscopy, Cyclic Voltammetry and dc and ac IV measurements were used to monitor cell growth and attachment as a function of applied electric field and time. Cell migration and attachment were also investigated using time lapse photography in a separate growth chamber mounted on the stage of an optical microscope.

1:51PM W39.00010 Stiffness nanotomography of human epithelial cancer cells, JACK R. STAUNTON, BRYANT L. DOSS, C. MICHAEL GILBERT, Arizona State University, SANDOR KASAS, EPFL, ROBERT ROS, Arizona State University — The mechanical stiffness of individual cells is important in both cancer initiation and metastasis. We present atomic force microscopy (AFM) based nanoindentation experiments on various human mammary and esophagus cell lines covering the spectrum from normal immortalized cells to highly metastatic ones. The combination of an AFM with a confocal fluorescence lifetime imaging microscope (FLIM) in conjunction with the ability to move the sample and objective independently allow for precise alignment of AFM probe and laser focus with an accuracy down to a few nanometers. This enables us to correlate the mechanical properties with the point of indentation in the FLIM image. We are using force-volume measurements as well as force indentation curves on distinct points on the cells to compare the elastic moduli of the nuclei, nucleoli, and the cytoplasm, and how they vary within and between individual cells and cell lines. Further, a detailed analysis of the force-indentation curves allows study of the cells' mechanical properties at different indentation depths and to generate 3D elasticity maps.

2:03PM W39.00011 Snakeskin tribology: How snakes generate large frictional anisotropy , HAMIDREZA MARVI, JEFFREY STREATOR, DAVID HU, Georgia Institute of Technology — The limbless locomotion of snakes relies fundamentally upon friction. Snakes can adjust their spatial and temporal frictional properties in order to get friction anisotropies of around 2. Ventral scales play a major role in friction adjustment. In this combined experimental and theoretical study we measure the mechanical and frictional properties of snakeskin. We report the effect of substrate roughness and compliance on snake frictional anisotropy. We numerically model a snake scale interacting with an elastic rough substrate using contact mechanics. The scale is modeled as an isotropic rigid material attached to the body using a torsional spring. We find that the combined effect of the scales geometry and angle of attack leads to the scale high frictional anisotropy. Our results suggest that fabricating engineering surfaces such as artificial snakeskin with optimized geometry and orientation of scales will improve the efficiency of snake-like robots.

Session W40 DBIO DPOLY DCOMP: Focus Session: Single Molecule Biological Physics - Nucleic acids and Proteins 156A

11:15AM W40.00001 Single-molecule Imaging Reveals Molecular Mechanisms of A DNA Strippase , ERIC GREENE, Columbia University and HHMI — No abstract available.

11:51AM W40.00002 ABSTRACT WITHDRAWN –

12:03PM W40.00003 Sequence-dependent sliding kinetics of p53 , JASON LEITH, ANAHITA TAFVIZI, Harvard University, Massachusetts Institute of Technology, FANG HUANG, Cambridge University, WILLIAM USPAL, PATRICK DOYLE, Massachusetts Institute of Technology, ALAN FERSHT, Cambridge University, LEONID MIRNY, Massachusetts Institute of Technology, ANTOINE VAN OIJEN, Rijksuniversiteit Groningen — Theoretical work has long proposed that one-dimensional sliding along DNA while simultaneously reading its sequence can accelerate transcription factors' (TFs) search for their target sites. More recently, functional sliding has been shown to require TFs to possess at least two DNA-binding modes. The tumor suppressor p53 has been directly observed to slide on DNA, and structural and single-molecule studies have provided evidence for a two-mode model for the protein. If the model is in fact applicable to p53, then the requirement that TFs read while they slide implies that p53's mobility on DNA should be affected by non-cognate sites and thus that its diffusivity should be generally sequence-dependent. Here we confirm this prediction with single-molecule microscopy measurements of p53's local diffusivity on non-cognate DNA. We show how a two-mode model accurately predicts the variation in local diffusivity while a single-mode model does not. Our work provides evidence that p53's sliding is indeed functional and suggests that the timing and efficiency of its activating and repressing transcription can depend on its non-cognate binding properties and its ability to change between multiple modes of binding, in addition to the much better-studied effects of cognate-site binding.

12:15PM W40.00004 Single-molecule study of protein-DNA target search mechanisms for dimer-active protein complexes¹ , MARKITA LANDRY, Dept of Chemistry, University of Illinois at Urbana-Champaign, WAI MUN HUANG, Dept of Pathology, University of Utah Health Sciences Center, YANN CHEMLA, Dept of Physics, University of Illinois at Urbana-Champaign — Protein-DNA interactions are essential to cellular processes, many of which require proteins to recognize a specific DNA target-site. This search process is well-documented for monomeric proteins, but not as well understood for systems that require dimerization at the target site for activity. We present a single-molecule study of the target-search mechanism of Protelomerase TelK, a recombinase-like protein that is only active as a dimer. We observe that TelK undergoes 1D diffusion on non-target DNA as a monomer, as expected, but becomes immobile on DNA as a dimer or oligomer despite the absence of its target site. We further show that TelK condenses non-target DNA upon dimerization, forming a tightly bound nucleo-protein complex. Together with simulations, our results suggest a search model whereby monomers diffuse along DNA, and subsequently dimerize to form an active complex on target DNA. These results show that target-finding occurs faster than nonspecific dimerization at biologically relevant protein concentrations. This model may provide insights into the search mechanisms of proteins that are active as multimeric complexes for a more accurate and comprehensive model for the target-search process by sequence specific proteins.

12:27PM W40.00005 Single-Molecule Encoders for Tracking Motor Proteins on DNA , EVERETT A. LIPMAN, Department of Physics, University of California, Santa Barbara — Devices such as inkjet printers and disk drives track position and velocity using optical encoders, which produce periodic signals precisely synchronized with linear or rotational motion. We have implemented this technique at the nanometer scale by labeling DNA with regularly spaced fluorescent dyes. The resulting molecular encoders can be used in several ways for high-resolution continuous tracking of individual motor proteins. These measurements do not require mechanical coupling to macroscopic instrumentation, are automatically calibrated by the underlying structure of DNA, and depend on signal periodicity rather than absolute level. I will describe the synthesis of single-molecule encoders, data from and modeling of experiments on a helicase and a DNA polymerase, and some ideas for future work.

1:03PM W40.00006 Tuning Cargo Travel via Single Motor Velocity , JING XU, University of California, Merced, ZHANYONG SHU, University of California, Irvine, STEPHEN KING, University of Central Florida, STEVEN GROSS, University of California, Irvine — Active intracellular transport is crucial for cell function, and defects are linked to diseases including neurodegeneration. Single molecule biophysical studies have revealed a great deal about the function of individual motors in vitro. However, it remains challenging to use single molecule properties of molecular motors to explain the complex range of cargo motions observed in vivo, in particular how motors work together in small ensembles. Recent reports have highlighted the sensitivity of ensemble transport to the single motor properties of processivity and force production. Here we investigate the previously unexplored role of motor velocity, and report a combined experimental and theoretical demonstration that single motor velocity crucially controls the ensemble function of two-motor transport.

1:15PM W40.00007 Study of Large Multimeric Biomolecules by Single-Molecule Manipulation and Imaging , KAI LOU, SITARA S. WIJERATNE, Department of Physics and Astronomy, Rice University, JERAHME MARTINEZ, Department of Biochemistry and Cell biology, Rice University, HUI-CHUN YEH, Puget Sound Blood Center and Division of Hematology, Department of Medicine, University of Washington, JOEL MOAKE, Department of Bioengineering, Rice University, JING-FEI DONG, Puget Sound Blood Center and Division of Hematology, Department of Medicine, University of Washington, MARY C. FARACH-CARSON, Department of Biochemistry and Cell biology, Rice University, CHING-HWA KIANG, Department of Physics and Astronomy, Rice University — Single-molecule manipulation enables us to study the properties of long chain, multimeric biomolecules. Perlecan, a giant secreted heparin sulfate proteoglycan, is a major component of basement membrane, bone stroma and blood vessels. It is involved in processes such as cell adhesion, migration and modulation of apoptosis. The changes in its synthesis and function are closely associated with many diseases, including cancer. Von Willebrand factor is a large multimeric protein circulating in blood, and is crucial for initiation of blood coagulation. We use atomic force microscope to obtain force curves and images of these proteins. We characterized the mechanical property of perlecan as well as the domain conformational changes of von Willebrand factor. The results demonstrate that single-molecule manipulation can probe directly the dynamics of large biomolecules that are usually not accessible with other methods.

1:27PM W40.00008 Uncovering the microscopic mechanism of strand exchange during RecA mediated homologous recombination using all-atom molecular dynamics simulations¹, MANISH SHANKLA, JEJOONG YOO, ALEKSEI AKSIMENTIEV, University of Illinois at Urbana-Champaign — Homologous recombination (HR) is a key step during the repair process of double-stranded DNA (dsDNA) breakage. RecA is a protein that mediates HR in bacteria. RecA monomers polymerize on a single-stranded DNA (ssDNA) separated from the broken dsDNA to form a helical filament, thus allowing strand exchange to occur. Recent crystal structures depict each RecA monomer in contact with three contiguous nucleotides called DNA triplets. Surprisingly, the conformation of each triplet is similar to that of a triplet in B-form DNA. However, in the filament the neighboring triplets are separated by loops of the RecA proteins. Single molecule experiments demonstrated that strand exchange propagation occurs in 3 base-pair increments. However, the temporal resolution of the experiments was insufficient to determine the exact molecular mechanism of the triplet propagation. Using all-atom molecular dynamics simulations, we investigated the effect of both the RecA protein and the conformation of the bound ssDNA fragment on the stability of the duplex DNA intermediate formed during the strand-exchange process. Specifically, we report simulations of force-induced unzipping of duplex DNA in the presence and absence of the RecA filament that explored the effect of the triplet ladder conformation.

¹This work was supported by the Center for the Physics of Living Cells through a grant from the National Science Foundation (PHY0822613).

1:39PM W40.00009 Transduction of Glycan-Lectin Binding using Near Infrared Fluorescent Single Walled Carbon Nanotubes for Glycan Profiling, NIGEL REUEL, JIN-HO AHN, MIT - Chemical Engineering, JONG-HO KIM, Hanyang University, Ansan, Republic of Korea, JINGQING ZHANG, ARDEMIS BOGHOSSIAN, MIT - Chemical Engineering, LARA MAHAL, NYU - Chemistry, MICHAEL STRANO¹, MIT - Chemical Engineering — In this work, we demonstrate a sensor array employing recombinant lectins as glycan recognition sites tethered via Histidine tags to Ni²⁺ complexes that act as fluorescent quenchers for semi-conducting single walled carbon nanotubes embedded in a chitosan to measure binding kinetics of model glycans. Two higher-affined glycan-lectin pairs are explored: fucose (Fuc) to PA-IIL and N-acetylglucosamine (GlcNAc) to GafD. The dissociation constants (KD) for these pairs as free glycans (106 and 19 μ M respectively) and streptavidin-tethered (142 and 50 μ M respectively) were found. The absolute detection limit for the current platform was found to be 2 μ g of glycosylated protein or 100 ng of free glycan to 20 μ g of lectin. Glycan detection is demonstrated at the single nanotube level (GlcNAc to GafD). Over a population of 1000 nanotubes, 289 of the SWNT sensors had signals strong enough to yield kinetic information (KD of $250 \pm 10 \mu$ M). We are also able to identify the locations of "strong-transducers" on the basis of dissociation constant (4 sensors with KD < 10 μ M) or overall signal modulation (8 sensors with > 5% quench response). The ability to pinpoint strong-binding, single sensors is promising to build a nanoarray of glycan-lectin transducers as a method to profile glycans without protein labeling or glycan liberation pretreatment steps.

1:51PM W40.00010 Comprehensive single molecule dynamics and functions of lysozyme upon linear and cross-linked substrate using a carbon nanotube circuit, YONGKI CHOI, PATRICK C. SIMS, BRAD L. CORSO, Department of Physics and Astronomy, University of California, Irvine, ISSA S. MOODY, Department of Molecular Biology, University of California, Irvine, DAVID SEITZ, LARRY BLASZCAZK, Muroplex Therapeutics, Inc., GREGORY A. WEISS, Department of Molecular Biology, University of California, Irvine, PHILIP G. COLLINS, Department of Physics and Astronomy, University of California, Irvine — The dynamic processivity of individual lysozyme molecules was monitored in the presence of either linear or cross-linked peptidoglycan substrates using a single-walled carbon nanotube transistor. The substrate-driven, hinge bending motions of lysozyme induce dynamic electronic signals in the underlying transistor to allow long-term monitoring of the same molecule, all without the limitations of fluorophore quenching or bleaching. For both types of substrates, lysozyme exhibits slow, processive turnover at 20 Hz and also rapid, nonproductive motions at 300 Hz. However, the latter type of motion nearly vanishes with the linear substrate, which lacks cross-links. Specifically, the nonproductive binding fills 43% of the enzyme's total activity when the substrate has cross-links, but only 7% with the cross-links are absent. The continuous, uninterrupted processing indicates that lysozyme can catalytically hydrolyze glycosidic bonds all the way to the end of a linear substrate, and that the motion attributed to nonproductive binding may be the lysozyme sidestepping the peptide cross-links.

2:03PM W40.00011 A hierarchical coarse-grained (all-atom to all residue) approach to peptides (P1, P2) binding with a graphene sheet¹, RAS PANDEY, University of Southern Mississippi, ZHIFENG KUANG, BARRY FARMER, SANG KIM, RAJESH NAIK, Air Force Research Laboratory — Recently, Kim et al. [1] have found that peptides P1: HSSYWAFNNKT and P2: EPLQLKM bind selectively to graphene surfaces and edges respectively which are critical in modulating both the mechanical as well as electronic transport properties of graphene. Such distinctions in binding sites (edge versus surface) observed in electron micrographs were verified by computer simulation by an all-atomic model that captures the pi-pi bonding. We propose a hierarchical approach that involves input from the all-atom Molecular Dynamics (MD) study (with atomistic detail) into a coarse-grained Monte Carlo simulation to extend this study further to a larger scale. The binding energy of a free amino acid with the graphene sheet from all-atom simulation is used in the interaction parameter for the coarse-grained approach. Peptide chain executes its stochastic motion with the Metropolis algorithm. We investigate a number of local and global physical quantities and find that peptide P1 is likely to bind more strongly to graphene sheet than P2 and that it is anchored by three residues ⁴Y⁵W⁶Y. [1] S.N. Kim et al J. Am. Chem. Soc. 133, 14480 (2011).

Thursday, March 1, 2012 11:15AM - 2:03PM –
Session W41 DBIO: Focus Session: Quantum Coherence in Biological Systems 156B

11:15AM W41.00001 Quantum Coherence in Biology, BIRGITTA WHALEY, University of California, Berkeley — Discussion of quantum mechanical effects in biology is generally restricted to molecular energetics, stability, and kinetics as determined by potential energy barriers. In recent years however, an increasing number of experiments have shown evidence for the existence of dynamical phenomena in biological systems that involve coherent quantum motion. One prominent instance is electronic quantum coherence in photosynthesis. I shall present theoretical studies that analyze the nature of this coherence, its relation to the non-local quantum correlations characteristic of entanglement, implications for relevance of quantum information processing in natural systems and address the question of whether and how such quantum coherence might result in a biological advantage.

11:51AM W41.00002 Absence of quantum oscillations in electronic excitation transfer in the Fenna-Matthews-Olson complex¹, ALEXANDER EISFELD, Harvard University, GERHARD RITSCH, JAN RODEN, Max-Planck-Institute for the Physics of Complex Systems, WALTER STRUNZ, TU Dresden, ALAN ASPURU-GUZIK, Harvard University — Energy transfer in the photosynthetic Fenna-Matthews-Olson (FMO) complex of the Green Sulfur Bacteria is studied theoretically taking all three subunits (monomers) of the FMO trimer and the recently found eighth bacteriochlorophyll (BChl) molecule into account. For the calculations we use the efficient Non-Markovian Quantum State diffusion approach. Since it is believed that the eighth BChl is located near the main light harvesting antenna we look at the differences in transfer between the situation when BChl 8 is initially excited and the usually considered case when BChl 1 or 6 is initially excited. We find strong differences in the transfer dynamics, both qualitatively and quantitatively. When the excited state dynamics is initialized at site eight of the FMO complex, we see a slow exponential-like decay of the excitation. This is in contrast to the oscillations and a relatively fast transfer that occurs when only seven sites or initialization at sites 1 and 6 is considered. Additionally we show that differences in the values of the electronic transition energies found in the literature lead to a large difference in the transfer dynamics.

12:03PM W41.00003 Progress Towards Room-Temperature Electron Spin Detection in Biological Systems, NICHOLAS CHISHOLM, IGOR LOVCHINSKY, ALEX SUSHKOV, Harvard University, DAVID HUNGER, Ludwig-Maximilians-Universität (LMU) Munich, ALEXEY AKIMOV, Lebedev Physics Institute, PEGGY LO, AMY SUTTON, JACOB ROBINSON, NORMAN YAO, STEVEN BENNETT, HONGKUN PARK, MIKHAIL LUKIN, Harvard University — We report on recent progress of room-temperature electron spin sensing for biological applications using nitrogen-vacancy (NV) centers in diamond. Our approach involves room-temperature detection of a small number of electron spins, situated outside the measurement substrate. Potential applications will be discussed, including detection of magnetic resonance signals from individual electron or nuclear spins of complex biological molecules, measurement of concentrations of radicals in living cells, and monitoring the ion channel function across cell membranes (important for exploring drug delivery mechanisms).

12:15PM W41.00004 Coherent transfer in biological systems: a study of the role of environmental noise, NAYELI ZUNIGA-HANSEN, MARK S. BYRD, Southern Illinois University Carbondale — We study the effects of environmental noise on quantum mechanical systems, we focus mainly on biological systems in which noise is believed to assist coherent transport of energy. We use error correction methods aimed at avoiding decoherence and dissipation due to coupling to a reservoir, with the purpose of investigating if modifying the coupling to a noisy bath can provide further insight on its effects on transport mechanisms, and propose that this work is carried out experimentally.

12:27PM W41.00005 Noise induced quantum effects in photosynthetic complexes, KONSTANTIN DORFMAN, DMITRI VORONINE, Texas A&M University, College Station, Texas 77843, SHAUL MUKAMEL, University of California, Irvine, California 92697, MARLAN SCULLY, Texas A&M University, College Station, Texas 77843 — Recent progress in coherent multidimensional optical spectroscopy revealed effects of quantum coherence coupled to population leading to population oscillations as evidence of quantum transport. Their description requires reevaluation of the currently used methods and approximations. We identify couplings between coherences and populations as the noise-induced cross-terms in the master equation generated via Agarwal-Fano interference that have been shown earlier to enhance the quantum yield in a photocell. We investigated a broad range of typical parameter regimes, which may be applied to a variety of photosynthetic complexes. We demonstrate that quantum coherence may be induced in photosynthetic complexes under natural conditions of incoherent light from the sun. This demonstrates that a photosynthetic reaction center may be viewed as a biological quantum heat engine that transforms high-energy thermal photon radiation into low entropy electron flux.

12:39PM W41.00006 FMO complex: exciton transfer and interaction with vibronic modes, LEV MOUROKH, Physics Department, Queens College of CUNY, ANATOLY SMIRNOV, FRANCO NORI, Frontier Research System, RIKEN, Japan and Physics Department, The University of Michigan — We examine transport of excitons through Fenna-Matthews-Olson (FMO) complex from a receiving antenna to a reaction center, using methods of condensed matter and statistical physics. Writing equation of motion for creation/annihilation operators, we are able to describe the exciton dynamics in the regime when the reorganization energy is of the order of the intra-system couplings. Well-known quantum oscillations of the site populations are obtained, in particular. We determine the exciton transfer efficiency and its dependencies of the system parameters. While the majority of vibronic modes are treated as a heat bath, we address the situation when specific modes are strongly coupled to excitons and examine the effects of these modes on the quantum oscillations and the energy transfer efficiency.

12:51PM W41.00007 Non-Markovian harmonic bath model for molecular systems: Influence of the bath spectral density, JAN RODEN, Department of Chemistry, University of California, Berkeley, California 94720, USA, ALEXANDER EISFELD, Department of Chemistry and Chemical Biology, Harvard University, 12 Oxford Street, Cambridge, MA 02138, K. BIRGITTA WHALEY, Department of Chemistry, University of California, Berkeley, California 94720, USA — In quantum mechanical simulations of the electronic excitation dynamics in molecular complexes, like natural or artificial light-harvesting complexes, often open quantum system descriptions are applied, to treat a large number of degrees of freedom involved. A popular approach is then, to include only the electronic degrees of freedom into the system part and to couple them to a non-Markovian bath of harmonic vibrational modes. The coupling to the bath, representing intra-molecular as well as external vibrations, is usually described via the bath spectral density, which therefore is an important ingredient in this approach. Here, we discuss different aspects of the influence of the bath spectral density on dynamics and optical spectra. In particular, we consider structured spectral densities, consisting of multiple broadened peaks. It is often assumed that the strong coupling to an intra-molecular vibrational mode, which is damped by coupling to other vibrational modes, is described reasonably by such a broadened peak in the spectral density. Here we demonstrate that this interpretation should be used with caution, because the damping of the mode differs from the model for an intra-molecular mode that one would usually apply when including the mode directly in the system part.

1:03PM W41.00008 Curvature, torsion and temperature in energy transfer, YASSER OMAR, ISEG, Technical University of Lisbon & Instituto de Telecomunicações — Curvature and torsion can play a role in energy transfer in alpha-helical proteins [New J. Phys. 12, 055003 (2010)]. The phenomenon is specific to alpha-helices and not to beta-sheets in proteins due to the three strands of hydrogen bonds constituting the alpha-helical backbone. In this work we analyse and discuss how temperature can affect the role of geometry in the energy transfer.

1:15PM W41.00009 Quantum Process Tomography for Energy Transfer Systems via Ultrafast Spectroscopy, JOEL YUEN-ZHOU, Harvard University, Chemistry and Chemical Biology — The description of excited state dynamics in energy transfer systems constitutes a theoretical and experimental challenge in modern chemical physics. A spectroscopic protocol that systematically characterizes both coherent and dissipative processes of the probed chromophores is desired [1,2]. In this talk, I show that a set of two-color photon-echo experiments performs quantum state tomography (QST) of the one-exciton manifold of a dimer by reconstructing its density matrix in real time. This possibility in turn allows for a complete description of excited state dynamics via quantum process tomography (QPT). Simulations of a noisy QPT experiment for an inhomogeneously broadened ensemble of model excitonic dimers show that the protocol distills rich information about dissipative excitonic dynamics, which appears nontrivially hidden in the signal monitored in single realizations of four-wave mixing experiments. Progress on the experimental side will be discussed, as well as new insights that QPT has offered on the understanding of 2D electronic and vibrational spectroscopy. [1] J. Yuen-Zhou, J. J. Krich, A. Aspuru-Guzik, Quantum state and process tomography of energy transfer systems via ultrafast spectroscopy Joel Yuen-Zhou, Jacob J. Krich, Masoud Mohseni and Alán Aspuru-Guzik Proc. Nat. Acad. Sci. USA, Early Edition (2011). [2] J. Yuen-Zhou, A. Aspuru-Guzik, Quantum process tomography of molecular dimers from two-dimensional electronic spectroscopy I: General theory and application to homodimers Joel Yuen-Zhou and Alán Aspuru-Guzik. Chem. Phys. 134, 134505 (2011).

1:27PM W41.00010 Coherent vs. dissipative nonequilibrium dynamics in spectroscopy of molecular aggregates¹, DARIUS ABRAMAVICIUS, ANDRIUS GELZINIS, VYTAUTAS BUTKUS, LEONAS VALKUNAS, Physics Faculty, Vilnius University, Sauletekio al. 9, 10222 Vilnius, Lithuania — Molecular aggregates embedded in a protein environment are the core elements in photosynthetic antennae units. Photoexcitations in these systems experience multistep relaxation, which could be traced using various time-resolved spectroscopy techniques. Initiated coherent processes turn into dissipative. Understanding of these processes is still a major theoretical task. We study theoretically spectroscopic properties of simple molecular aggregates coupled to a bath, which contains main ingredients of protein environment: high-energy vibrations, long-range correlations, and smooth spectrum of frequencies. At short times after the optical excitation high-energy coherent vibrational resonances can be observed in two-dimensional repumping spectroscopy. Their beats overlap with electronic quantum coherences, responsible for the quantum transport. We show the way to discriminate between them. At the long times we find that the conventional excitonic picture of eigenstates is valid only in the Markovian regime. In the non-Markovian regime the exciton concept breaks down and renormalized system parameters must be introduced: effective intermolecular coupling, widely used in polaron theories, can be used to account for the effects of the bath.

1:39PM W41.00011 New quantum state of protons and electrons in nano-confined water¹, GEORGE REITER, University of Houston, ALEXANDER KOLESNIKOV, ORNL, STEPHEN PADDISON, University of Tennessee, Knoxville, JERRY MAYERS, ISIS, PHIL PLATZMAN, University of Houston — Neutron Compton Scattering provides a means of directly and accurately measuring the momentum distribution of protons in water, which is determined primarily by the protons ground state wavefunction. We find that in water confined on scales of $\sim 20\text{\AA}$, this wave function responds to the details of the confinement, corresponds to a strongly anharmonic local potential, shows evidence in some cases of coherent delocalization in double wells, and involves differences in zero point kinetic energy of the protons from that of bulk water at room temperature of -40 to $+120$ meV. This behavior is a generic feature of nanoscale confinement, and in particular, this state should be that which is present in water confined in biological cells. It is exhibited here in $16\text{\AA}$ inner diameter carbon nanotubes, two different hydrated proton exchange membranes (PEMs), Nafion 1120 and Dow 858, and has been seen earlier in xerogel and $14\text{\AA}$ diameter carbon nanotubes. The existence of this state is confirmed by x-ray Compton scattering measurements of the electron momentum distribution.

1:51PM W41.00012 Spectroscopic Characterization of the Water Oxidation Intermediates in the Blue Dimer Ru-Based Catalyst for Artificial Photosynthesis¹, DOOSHAYE MOONSHIRAM, YULIA PUSHKAR, Purdue University, JONAH JURSS, JAVIER CONCEPCION, THOMAS MEYER, University of North Carolina at Chapel Hill, TAI SIYA ZAKHAROVA, IGOR ALPEROVICH, Purdue University — Utilization of sunlight requires solar capture, light-to-energy conversion and storage. One effective way to store energy is to convert it into chemical energy by fuel-forming reactions, such as water splitting into hydrogen and oxygen. Ruthenium complexes are among few molecular-defined catalysts capable of water splitting. Mechanistic insights about such catalysts can be acquired by spectroscopic analysis of short-lived intermediates of catalytic water oxidation. Use of techniques such as EPR and X-ray absorption spectroscopy (XAS) are used to determine electronic requirements of catalytic water oxidation. About 30 years ago Meyer and coworkers reported first ruthenium-based catalyst for water oxidation, the "blue dimer". We performed EPR studies and characterized structures and electronic configurations of intermediates of water oxidation by the "blue dimer". Intermediates were prepared chemically by oxidation of Ru-complexes with defined number of Ce (IV) equivalents and freeze-quenched at controlled times. Changes in oxidation state of Ru atom were detected by XANES at Ru K-edges. K-edges are sensitive to changes in Ru oxidation state for Blue Dimer $[3,3]^{4+}$, $[3,4]^{4+}$, $[3,4]^{4+}$ and $[4,5]^{3+}$ allowing a clear assignment of Ru oxidation state in intermediates. EXAFS demonstrated structural changes.

Session W42 DBIO DPOLY: Focus Session: The Physics of Genome Folding I: Fractal Globules and Condensed Polymer States 156C

11:15AM W42.00001 How the genome folds¹, EREZ LIEBERMAN AIDEN, Harvard Society of Fellows — I describe Hi-C, a novel technology for probing the three-dimensional architecture of whole genomes by coupling proximity-based ligation with massively parallel sequencing. Working with collaborators at the Broad Institute and UMass Medical School, we used Hi-C to construct spatial proximity maps of the human genome at a resolution of 1Mb. These maps confirm the presence of chromosome territories and the spatial proximity of small, gene-rich chromosomes. We identified an additional level of genome organization that is characterized by the spatial segregation of open and closed chromatin to form two genome-wide compartments. At the megabase scale, the chromatin conformation is consistent with a fractal globule, a knot-free conformation that enables maximally dense packing while preserving the ability to easily fold and unfold any genomic locus. The fractal globule is distinct from the more commonly used globular equilibrium model. Our results demonstrate the power of Hi-C to map the dynamic conformations of whole genomes.

11:51AM W42.00002 Contact probability scaling of the Hilbert curve¹ , ADRIAN SANBORN, JIAN LI, Harvard College, EREZ L. AIDEN, Harvard Society of Fellows — Using Hi-C experiments, it has become possible to measure contact probability scalings for genomic polymers. However, the theoretical analysis of such scalings remains in its infancy. Here, we prove that contact probability scales with linear distance for lattice approximations of the Hilbert curve. These results point to the potential for new theoretical approaches to the study of contact probability, and shed light on the analysis behind the fractal globule, a recent model for the three-dimensional structure of the human genome.

¹This work is supported by NIH Grants 1P50HG006193-01 (Center for Cell Circuits) and 1DP2OD008540-01 (NIH New Innovator Award).

12:03PM W42.00003 Territorial Polymers and Large Scale Genome Organization , ALEXANDER GROSBERG, New York University, Center for Soft Matter Research and Department of Physics — Chromatin fiber in interphase nucleus represents effectively a very long polymer packed in a restricted volume. Although polymer models of chromatin organization were considered, most of them disregard the fact that DNA has to stay not too entangled in order to function properly. One polymer model with no entanglements is the melt of unknotted unconcatenated rings. Extensive simulations indicate that rings in the melt at large length (monomer numbers) N approach the compact state, with gyration radius scaling as $N^{1/3}$, suggesting every ring being compact and segregated from the surrounding rings. The segregation is consistent with the known phenomenon of chromosome territories. Surface exponent β (describing the number of contacts between neighboring rings scaling as N^β) appears only slightly below unity, $\beta \approx 0.95$. This suggests that the loop factor (probability to meet for two monomers linear distance s apart) should decay as $s^{-\gamma}$, where $\gamma = 2 - \beta$ is slightly above one. The later result is consistent with HiC data on real human interphase chromosomes, and does not contradict to the older FISH data. The dynamics of rings in the melt indicates that the motion of one ring remains subdiffusive on the time scale well above the stress relaxation time.

12:39PM W42.00004 Diffusion of Particles in the Melt of Polymeric Rings and Diffusion of Proteins in the Cell Nucleus¹ , KURT KREMER, Max Planck Institute for Polymer Research, Mainz, Germany, JONATHAN HALVERSON, Center for Functional Nanomaterials, Brookhaven National Laboratory, Upton, NY, GARY GREEST, Center for Integrated Nanotechnologies, Sandia National Laboratories, Albuquerque, NM, ALEXANDER GROSBERG, Department of Physics, New York University, New York, NY — Ring polymers in the melt are partially collapsed and partially segregated as revealed by both simulation and experiment. This behavior is qualitatively consistent with the arrangement of chromosomes in the cell nucleus which are found in distinct territories. Working under the hypothesis that a melt of nonconcatenated rings serves as a simple model for the packing of chromatin fibers in the nucleus of higher eukaryotes, we have investigated the dynamic behavior of a non-sticky spherical particle in polymer melts composed of rings using molecular dynamics simulation. Linear chains are also studied for comparison. In the case of rings such systems are thought to represent protein diffusion in the cell nucleus. The sub-diffusive motion of the particle is found to be independent of the polymer architecture and chain length but depends strongly on particle size. The long-time behavior suggests that these particles diffuse faster in the rings. We compare our results to existing models of protein diffusion.

¹Research carried out in part at the Center for Functional Nanomaterials, Brookhaven National Laboratory, which is supported by the U.S. Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-98CH10886.

12:51PM W42.00005 Spatial autocorrelation in fractal and knotted globules , MIRIAM HUNTLEY, EREZ LIEBERMAN AIDEN, Harvard University — The unknotted fractal globule is a model for the state of nuclear chromatin, and has properties that are distinct from those of knotted globules. One crucial property is a stronger correspondence between one-dimensional position along the polymer contour and three-dimensional position in the bulk. Here we introduce measures of spatial autocorrelation, such as Moran's I and Geary's C, and investigate spatial autocorrelation in both fractal and knotted globules. We show that fractal globules exhibit higher levels of spatial autocorrelation at both small and intermediate length scales. This autocorrelation may be relevant to the study of how proteins find their DNA targets inside the nucleus.

1:03PM W42.00006 Simulation of Interphase DNA , RALF EVERAERS, Ecole Normale Supérieure de Lyon — No abstract available.

1:39PM W42.00007 In silico simulations of polymer condensation: the fractal globule as a metastable state¹ , LEON FURCHTGOTT*, ASHOK CUTKOSKY*, NAJEEB TARAZI, Harvard University, EREZ LIEBERMAN AIDEN, Harvard Society of Fellows — The fractal globule is a model for the metastable conformation of a long polymer after initial immersion in a poor solvent. Recent experimental findings describing the conformation of the human genome at the megabase scale are consistent with a fractal globule conformation. Here, we simulate the collapse of a polymer in a poor solvent using both molecular dynamics and Monte-Carlo simulations. We show that the statistics of the resulting configuration, such as radius of gyration, end-to-end distance, and contact probability, are independent of the approach used to simulate the condensation process. (* contributed equally).

1:51PM W42.00008 Fractal Globule as a model of DNA folding in eukaryotes , MAKSIM IMAKAEV, LEONID MIRNY, Massachusetts Institute of Technology — A recent study (Lieberman-Aiden et al., Science, 2009) observed that the structure of the genome, on the scale of a few megabases, is consistent with a fractal globule. The fractal globule is a quasi-equilibrium state of a polymer after a rapid collapse. First proposed theoretically in 1988, this structure had never been simulated. Fractal globule was seen as a state, in which each subchain is compact, and doesn't mix with other subchains due to their mutual unentanglement (topological constraints). We use GPU-assisted dynamics to create fractal globules of different sizes and observe their dynamics. Our simulations confirm that a polymer after rapid collapse has compact subchains. We measure the scaling of looping probability of a subchain with its length, and observe the remarkably robust inverse proportionality. Dynamic simulation of the equilibration of this state show that it exhibits Rose type subdiffusion. Due to diffusion, fractal globule quickly degrades to a quasi-equilibrium state, in which subchains of a polymer are mixed, but topologically unentangled. We propose that separation of spatial and topological equilibration of a polymer chain might have implications in different fields of physics.

2:03PM W42.00009 High-order chromatin architecture shapes the landscape of chromosomal alterations in cancer¹ , GEOFFREY FUDENBERG, Harvard, GAD GETZ, MATTHEW MEYERSON, Broad Institute, LEONID MIRNY, MIT — The rapid growth of cancer genome structural information provides an opportunity for a better understanding of the mutational mechanisms of genomic alterations in cancer and the forces of selection that act upon them. Here we test the evidence for two major forces, spatial chromosome structure and purifying (or negative) selection, that shape the landscape of somatic copy-number alterations (SCNAs) in cancer (Beroukhi et al, 2010). Using a maximum likelihood framework we compare SCNA maps and three-dimensional genome architecture as determined by genome-wide chromosome conformation capture (HiC) and described by the proposed fractal-globule (FG) model (Lieberman-Aiden and Van Berkum et al, 2009). This analysis provides evidence that the distribution of chromosomal alterations in cancer is spatially related to three-dimensional genomic architecture and additionally suggests that purifying selection as well as positive selection shapes the landscape of SCNAs during somatic evolution of cancer cells.

Session W43 DBIO DPOLY: Invited Session: Physical Mechanisms of Collective Microbial Dynamics 157AB

11:15AM W43.00001 Chiral patterning in *Paenibacillus* colonies under stress, HERBERT LEVINE, University of California, San Diego — One of the most striking examples of bacterial colony patterning occurs in the C-morphotype of *Paenibacillus* strains. Here, macroscopic chirality results from the interaction of local liquid-crystal ordering of the long bacterial cells with the self-propelled motility driven by the non-reflection-symmetric flagella. This talk will review some of the original experimental data from the Ben-Jacob lab as well as recent insight obtained via genomics. I will then discuss attempts to model and simulate the chiral patterns via solving reaction-diffusion equations on random lattices. At the end, I will introduce the challenges still to be faced in understanding transitions between these patterns and more common branching structures

11:51AM W43.00002 The effects of self-induced noise on the onset of collective behavior in suspensions of swimming bacteria¹, IGOR ARONSON, Argonne National Laboratory, 9700 South Cass Av, Argonne, IL60439 — Collective dynamics of self-locomoting micro-organisms, such as bacteria and algae have attracted enormous attention, with a large number of experimental and theoretical works published in the last few years. A plethora of nontrivial properties have been predicted and consequently studied, including dynamic instabilities, anomalous density fluctuations, nontrivial stress-strain relations, rectification of chaotic motion, and viscosity reduction. Here we investigate the viscosity of a suspension of swimming bacteria analytically and numerically. We propose a simple model that takes into account excluded volume constraints and allows for efficient computation for a large number of bacteria. Our calculations show that long-range hydrodynamic interactions, intrinsic to self-locomoting objects in a viscous fluid, result in a dramatic reduction of the effective viscosity. In agreement with experiments on suspensions of *Bacillus subtilis*, we show that the viscosity reduction is related to the onset of large-scale collective motion due to interactions between the swimmers. The simulations reveal that the viscosity reduction occurs only for relatively low concentrations of swimmers: further increases of the concentration yield an increase of the viscosity. We derive an explicit asymptotic formula for the effective viscosity in terms of known physical parameters and show that hydrodynamic interactions are manifested as self-induced noise in the absence of any explicit stochasticity in the system. We also explain the increase in the viscosity for pullers by analysis of the deviations from the mean field approximation

¹The work was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Science and Engineering, under Contract DE-AC02-06CH11357.

12:27PM W43.00003 Synchronization of flagella, THOMAS R. POWERS, Brown University — Motivated by the observed coordination of nearby beating flagella, we use highly controlled simple model experiments with rotating paddles to study how hydrodynamic interactions can lead to phase-locking. The agreement between our numerical models and experimental results confirms that hydrodynamic interactions can lead to synchronization or phase-locking if the system has sufficient flexibility. We also present a simple theory, valid for weakly interacting paddles, for both viscous and viscoelastic fluids.

1:03PM W43.00004 Formation and propagation of high density waves during swarming of *P. aeruginosa*¹, MARK ALBER, Department of Applied and Computational Mathematics and Statistics, University of Notre Dame — We will describe in this talk how the bacterium *P. aeruginosa* alters its local physical environment by propagating high density waves of cells into branched tendrils during surface motility described as swarming. Biologically justified model simulations will be used to suggest a mechanism of wave propagation and branched tendril formation that depend upon competition between the changing viscosity of the bacterial liquid suspension and the liquid film boundary expansion caused by Marangoni forces. Thus, *P. aeruginosa* controls physical forces responsible for liquid film expansion to efficiently colonize surfaces.

¹This research was partially supported by NIH grant 1R01GM100470-01

1:39PM W43.00005 Alignment vs noise in self-propelled particles: minimal models for collective motion and their continuous descriptions, HUGUES CHATE, CEA - Saclay — Two important 1995 papers have marked the birth of collective motion studies in physics: Vicsek et al introduced what could now be described as the "Ising model" of this new subfield. This prompted Toner and Tu to propose a continuum theory of flocks which they showed to give rise to long-range orientational order even in two space dimensions. In this setting, the complexity of most natural instances of collective motion is reduced to the competition between local alignment and noise in interacting self-propelled particles. As I will show, this nevertheless gives rise to important and new physics. In this talk, I will give an update of our current knowledge about the Vicsek model, the Toner-Tu theory, and their relationship. I will also present the emerging picture of universality classes brought about by recent progress in the study of Vicsek-like models together with their continuous descriptions.

Thursday, March 1, 2012 11:15AM - 2:15PM –

Session W44 DPOLY: Focus Session: Interparticle Interactions in Polymer Nanocomposites - Mechanical, Electrical, and Optical Properties 157C

11:15AM W44.00001 Bio-inspired Fillers for Mechanical Enhancement, LASHANDA KORLEY, Case Western Reserve University — An examination of natural materials has offered a new perspective on the development of multi-functional materials with enhanced mechanical properties. One important lesson from nature is the utilization of composite structures to impart improved mechanical behavior and enhanced functionality using nanofillers. A relatively unexplored expansion of this bio-inspired, nanoscale filler approach to high performance materials is the incorporation of responsive, multi-functional reinforcing elements in polymeric composites with the goal of combining superior mechanical behavior that can be tuned with additional functionality, such as sensing and bioactivity. One approach is the use of self-assembling small molecules that form uniform, one-dimensional nanostructures as an emerging class of filler components. Another pathway toward mechanical enhancement is the incorporation of stimuli-responsive and high-modulus electrospun nanofibers. We have probed the utilization of high-aspect ratio, self-assembled small molecules and responsive electrospun nanofibers as all-organic nanofillers to achieve significant modulus changes within elastomeric matrices. The influence of matrix-filler interactions and the role of hierarchical organization in these nature-inspired composites will be discussed. Potential applications in barrier technology and drug delivery have also been explored.

11:51AM W44.00002 Temperature sensitive mechanical properties of Graphene-epoxy nanocomposites¹, ARDAVAN ZANDIATASHBAR, CATALIN PICU, NIKHIL KORATKAR, Rensselaer Polytechnic Institute — Carbon-based polymeric nanocomposites have potential applications including structural parts in aerospace vehicles and civil infrastructure. In this work various aspects of mechanical properties of Graphene-epoxy nanocomposites are studied at different scales. The quasi-static tensile yield stress and stiffness of the nanocomposite are larger than those of neat epoxy. While the creep response of the nanocomposite is similar to that of neat epoxy at lower stress and room temperature, a significant discrepancy is observed at high temperature and/or large stress, the nanocomposite creeping less. The fracture toughness for the nanocomposite with the optimum filler fraction is larger than the toughness of unfilled epoxy at room temperature. This difference decreases at higher temperatures. Local mechanical properties were investigated using nanoindentation and similar trends are observed.

¹We gratefully acknowledge support from the NSF under grant CMMI 0900188 and from the ONR under grant N00014-09-1-0928.

12:03PM W44.00003 Mechanical Properties of Polymer Nanocomposites under Large Amplitude Deformation, ERKAN SENSES, PINAR AKCORA, Stevens Institute of Technology — Bare silica nanoparticle dispersion in polystyrene and poly(methyl methacrylate) homopolymers are found to be controlled upon changing the evaporation condition. In this study, we deformed the polymer nanocomposites at different states of particle dispersion under large amplitude oscillatory shearing (LAOS). As the structure evolved during LAOS, the TEM images and small-angle X-ray scattering results obtained for different states of deformation together with the measured moduli allowed us to relate the mechanical reinforcement and nonlinearities such as strain stiffening/softening or shear thinning/thickening to the particle-polymer and particle-particle interactions effective at nanometer dimensions. Our results show that well-dispersed system with attractive interactions between particle and polymer becomes more elastic under large shear and behaves as attractive gels.

12:15PM W44.00004 Polymer Nanocomposite Mechanical Properties as a Function of Nanoparticle Dispersion¹, JOSEPH MOLL, Columbia University, SHUSHAN GONG, RALPH COLBY, Pennsylvania State University, DIMITRIS VLASSOPOULOS, IESL-FORTH, SANAT KUMAR, Columbia University — Nanoparticle (NP) dispersion critically affects the properties of polymer nanocomposites (PNCs), especially mechanical properties. Previous work by our group and others has shown optimal material properties occur when particles form a percolated network. Particle dispersion is a function of the interaction between the polymer and nanoparticle surface, and as such is difficult to control as an independent variable. In our previous work, dispersion was controlled via polymer grafts. Thus in order to vary the particle dispersion states the length and density of the grafted chains were necessarily simultaneously varied. Here we consider bare silica nanoparticles, 14nm in diameter, in 97kg/mol poly(2-vinyl pyridine). Although the particles are bare, the dispersion can still be controlled by proper solvent casting of the material; we use varying amounts of pyridine to charge stabilize the particles in solution and thus vary the dispersion state. We use TEM to probe PNP structure and NP dispersion state, and rheology is used to quantify mechanical properties. We look at the recovery of the storage modulus after large amplitude oscillatory shear and use this to probe the mechanism of particle reinforcement. Because the dispersion is an independently controlled variable, we are able to more accurately quantify its effect on nanocomposites.

12:27PM W44.00005 Elastic Moduli of Polymeric Thin Films of Nanocomposites and Blends via Buckling on Elastomeric Substrates, HONGYI YUAN, JOLANTA MARSZALEK-KEMPKE, Department of Polymer Engineering, The University of Akron, Akron, OH 44325, PRATEEK VERMA, School of Materials Science and Engineering, Georgia Institute of Technology, Atlanta, GA 30332, ALAMGIR KARIM, Department of Polymer Engineering, The University of Akron, Akron, OH 44325, THE UNIVERSITY OF AKRON TEAM, GEORGIA INSTITUTE OF TECHNOLOGY TEAM — Mechanical properties are important for the long term durability of polymeric thin films. Unfortunately, there are very few methods for mechanical characterization of sub-micron thin films with high accuracy and repeatability. The technique of Strain-Induced Elastic Buckling Instability for Mechanical Measurements (SIEBIMM) was employed to determine the elastic moduli of nanocomposite and blend films, which were calculated from the buckling patterns generated by applying compressive stresses. In this study, polylactic acid (PLA) / Cloisite 30B nanocomposite thin films and polycaprolactone (PCL) / PLA blend thin films were prepared via spin-coating and then transferred to crosslinked polydimethylsiloxane (PDMS) flexible substrates. Results showed the strengthening effect of Cloisite 30B on PLA systems. The effect of nanoparticle concentrations and the influences of crystallinity and phase separation of blends will be presented.

12:39PM W44.00006 Electrical Conductivity in Transparent Silver Nanowire Networks: Simulations and Experiments, MICHELLE SHERROTT, ROSE MUTISO, University of Pennsylvania, AARON RATHMELL, BENJAMIN WILEY, Duke University, KAREN WINEY, University of Pennsylvania — We model and experimentally measure the electrical conductivity of two-dimensional networks containing finite, conductive cylinders with aspect ratio ranging from 33 to 333. We have previously used our simulations to explore the effects of cylinder orientation and aspect ratio in three-dimensional composites, and now extend the simulation to consider two-dimensional silver nanowire networks. Preliminary results suggest that increasing the aspect ratio and area fraction of these rods significantly decreases the sheet resistance of the film. For all simulated aspect ratios, this sheet resistance approaches a constant value for high area fractions of rods. This implies that regardless of aspect ratio, there is a limiting minimum sheet resistance that is characteristic of the properties of the nanowires. Experimental data from silver nanowire networks will be incorporated into the simulations to define the contact resistance and corroborate experimentally measured sheet resistances of transparent thin films.

12:51PM W44.00007 Effect of Nanowire Size Dispersity and Orientation on Electrical Conductivity in Polymer Nanocomposites, ROSE MUTISO, MICHELLE SHERROTT, University of Pennsylvania, JU LI, Massachusetts Institute of Technology, KAREN WINEY, University of Pennsylvania — We model the percolation threshold (ϕ_c) and electrical conductivity of isotropic and oriented three-dimensional networks containing finite, conductive cylinders with experimentally typical (Gaussian) and engineered (bidisperse) distributions in their length and/or diameter. Our results show that narrow Gaussian distributions do not affect the threshold concentration or electrical conductivity significantly in either isotropic or oriented networks. In contrast, the addition of a small fraction of longer rods in a bidisperse system can improve the electrical properties considerably. We have also successfully extended the excluded volume percolation theory to predict ϕ_c of polydisperse networks of soft-core rods with finite-L/D by generalizing the monodisperse case and applying an empirical calibration factor from our simulations. Our analytical expression finds the critical concentration in nanocomposites with arbitrary distributions in L and/or D.

1:03PM W44.00008 Finite-size effects in nanocomposites: experimental and computational studies, L.I. CLARKE, M.P. ROMAN, E.W. SKAU, D.R. STEVENS, L.N. DOWNEN, T.J. HOFFMAN, J.R. BOCHINSKI, Department of Physics, NC State University — Many proposed applications for electrically-conducting composite materials (smart textiles, e-m shielding coatings, tissue scaffolds) are nanostructured - that is, characteristic sample length scales may be similar to at least one dimension of the embedded particle. This is particularly true for long aspect-ratio particles such as nanotubes where the length of the particle can approach or exceed the thickness of a thin nanocomposite film or a nanofiber diameter. In these cases, the formation of a particle network and thus the electrical conductivity enhancement is affected by finite size effects, that is, percolation thresholds and the width of the transition to percolation differ with sample size [Stevens et al., *Phys. Rev. E* **84**, 021126 (2011)]. We present experimental electrical conductivity and 3-D continuum Monte-Carlo simulation results on such finite-sized percolation effects for particles with aspect ratios of 1 to 1000 and discuss proposed scaling laws and techniques to improve conductance in the finite-size regime.

1:15PM W44.00009 Spectral and polarization modulation of quantum dot emission in a one-dimensional liquid crystal photonic cavity¹, ANDREA RODARTE, C. GRAY, L.S. HIRST, S. GHOSH, University of California, Merced — We demonstrate spectral and polarization modulation of chemically synthesized core shell CdSe/ZnS quantum dots (QDs) embedded in a one-dimensional photonic cavity formed by a cholesteric liquid crystal (CLC) matrix. A Cano-wedge cell varies the pitch of the CLC leading to the formation of Grandjean steps. This spatially tunes the photonic stop band, changing the resonance condition and continuously altering both the emission wavelength and polarization state of the QD ensemble. Using high resolution spatially- and spectrally-resolved photoluminescence measurements we find that the emission is elliptically polarized and that the tilt of the ellipse, while dependent on the emission wavelength, additionally varies with distance across the Grandjean steps. This work opens up the possibility of designing new QD based optical devices, such as tunable single photon sources, where spatial control of wavelength and polarization of the embedded QDs would allow great flexibility and added functionalities.

¹This work is funded by NSF, UC MEXUS and UC MERI

1:27PM W44.00010 Self-assembly of silicon quantum dot clusters in polymer nanocomposites, AUSTIN R. VAN SICKLE, JOSEPH B. MILLER, North Dakota State University, REBECCA R. ANTHONY, UWE R. KORTSHAGEN, University of Minnesota, DANIEL M. KROLL, ERIK K. HOBBIE, North Dakota State University — We measure the influence of polymer-driven silicon nanocrystal (SiNC) self-assembly on the photoluminescent stability of SiNC clusters. Coexisting phases of varying nanoparticle density are identified in annealed SiNC-polymer nanocomposites, and the local photobleaching kinetics are measured under varied exposure to atmospheric oxygen. Increased particle packing and decreased oxygen exposure both contribute to improvements in cluster photostability, with Monte Carlo simulations of ensemble photobleaching clarifying the critical role of nanoparticle packing. The simulations further demonstrate the potential importance of nanoparticle interactions in dictating the photo-response of the self-assembled SiNC clusters.

1:39PM W44.00011 Utilizing photothermal heating by metal nanoparticles within polymer composites, SOMSUBHRA MAITY, JASON BOCHINSKI, LAURA CLARKE, NC State University — Photothermal heating by metal nanoparticles have been extensively researched in solution environments for applications such as cancer treatment and drug delivery, but very few have explored photothermal heating in solids, such as metal nanoparticle-polymer composites. When metal nanoparticles are excited by light resonant with the particle's surface plasmon, non-radiative relaxation efficiently generates heat. Thus, this photothermal effect facilitates *in situ* thermal processing of polymeric materials via externally-controllable light excitation. By embedding fluorophores in the composite, a sensitive relative fluorescence approach can be utilized to dynamically monitor the average temperature within the sample as it is thermally processed. With modest light intensities and dilute nanoparticle concentrations, controllable temperature changes of several hundred degrees Celsius have been achieved. We discuss various cooling mechanisms and their respective effect on the heating process. The spatial specificity and temperatures achieved can potentially be used for triggering phase transitions, cross-linking, or enabling region-specific chemical reactions within a polymeric material.

1:51PM W44.00012 What determines photoluminescence and quenching when fluorophores in a polymer matrix?, HYUNSOOK JANG, University of Connecticut, Institute of Materials Science, YING WANG, YU LEI, University of Connecticut, Chemical, Materials & Biomolecular Engineering, MU-PING NIEH, University of Connecticut, Institute of Materials Science, Chemical, Materials & Biomolecular Engineering — A model system composed of fluorophore (pyrene), dispersed in a polymer matrix (polystyrene, PS) is investigated in order to find the relation between the structure of pyrene assembly in the PS matrix and its fluorescence/quenching. It has been shown that the pyrene disperses differently in the polymer matrix as it is prepared by different processes (namely, electrospin, solution cast and spincoat) with same composition. The difference can result in drastically variation of fluorescence response and quenching efficiency in presence of DNT. Our preliminary data indicate that the salt (tetrabutylammonium hexafluorophosphate, TBAP) applied to electrospinning process plays a crucial role in excimer fluorescence in the emission spectra, while various polymer matrices (e.g., PS and poly-methyl methacrylate, PMMA) yield similar fluorescence without TBAP. X-ray diffraction data suggests that strong dimer fluorescence of the sample may relate to the alignment of pyrene crystal structure, with a lattice length of 8.4 Å. Moreover, a C^{13} solid-state NMR result seems to indicate that the mobility of pyrene in the PS matrix of electrospin system is lower for samples with higher quenching efficiency.

2:03PM W44.00013 Microtextured Omniphobic Surfaces by Solution Spraying of Fluorodecyl POSS/PMMA Blends, SIDDARTH SRINIVASAN, GARETH MCKINLEY, ROBERT COHEN, Massachusetts Institute of Technology — We present a simple technique to prepare various micro-structured surfaces by spray coating a polymer blend of poly(methyl methacrylate) (PMMA) and the low surface energy molecule 1H,1H,2H,2H-heptadecafluorodecyl polyhedral oligomeric silsesquioxane (fluorodecyl POSS) using an air brush with a pressurized nitrogen stream. The sprayed surface morphology can be systematically tuned from a spherical or corpuscular microstructure to beads-on-string and a fibrous non-woven mesh, nearly identical to structures obtained by electrospinning similar PMMA/fluorodecyl POSS solutions. A semi-empirical framework is used to develop an operating diagram to predict the surface morphology produced during the simple spraying technique based on the polymer solution concentration and molecular weight. The presence of the low-surface-energy POSS molecules at the surface combined with the re-entrant microtextured features confers super-liquid-repellent properties to the spray-coated substrate, which are characterized by advancing and receding contact angle measurements with liquids of a range of surface tensions.

- Theory and Simulation 159

11:15AM W45.00001 Hybrid Lipids as Line Active Molecules, TETSUYA YAMAMOTO, Weizmann Institute of Science — The lipid raft hypothesis suggests that stable nanoscopic domains in cellular membranes play an important role in several biological processes. Model membranes composed of saturated lipids, unsaturated lipids, and cholesterol (SUC membranes) exhibit coexisting chain-ordered and -disordered domains. However, these domains are unstable and the positive line tension at the interfaces between these domains drives coarsening until their size reaches of the order of the system size. This motivates the search for physical mechanisms that may reduce the line tension to zero and thus stabilize nanoscopic domains in biological membranes. There is a theoretical suggestion that the positive line tension at the interfaces between domains in SUC membranes results from the chain packing incompatibility between the ordered chains of saturated lipids and the disordered chains of unsaturated lipids. Hybrid lipids that have one saturated and one unsaturated chains may reconcile this chain packing incompatibility. We have used a phenomenological model to predict that a small concentration of hybrid lipids added to SUC membranes can reduce the line tension between coexisting domains to zero. However, this tends to occur only at low temperatures that may not be experimentally accessible, because localizing the hybrid lipids to the interfaces costs mixing entropy and this strongly suppresses the reduction of the line tension. Indeed, hybrid lipids are major components of biological membranes; unsaturated lipids are rather minor and uncommon. We have used a liquid crystal model to analyze the phase separation and line tension between domains in model membranes composed of saturated lipids, hybrid lipids, and cholesterol (SHC membranes). This model predicts that the line tension is reduced to zero at relatively higher in SHC membranes because the hybrid lipids are already at the interface and the mixing entropy of localization is no longer relevant.

11:51AM W45.00002 Turing Patterns on Curved Surfaces¹ , JOHN FRANK, MIT, JEMAL GUVEN, Instituto de Ciencias Nucleares, Universidad Nacional Autonoma de Mexico, MEHRAN KARDAR, MIT — Surface curvature modifies the emergence of Turing patterns in reaction-diffusion systems on two-dimensional interfaces. We adapt operator perturbation theory, familiar in quantum mechanics, to determine how curvature affects diffusion. When these modifications are taken into account in Turing's stability analysis, we observe new phenomena that may be relevant to patterning on cell membranes, neuron synapses, and fluid interfaces with reactive surfactants. A cylinder with longitudinal ripples illustrates how Turing patterns can lock into phase with the ripples when the most unstable mode is nearly commensurate with the ripples. The framework we introduce also sheds light on diffusion constrained to a rippled sphere, a Gaussian bump, and other shapes. More generally, it is relevant to any model that involves the Laplacian on a curved manifold.

12:03PM W45.00003 2D Ising Model correlation function: Precise functional forms for comparison to membrane experiments , NATALIE PAQUETTE, BENJAMIN MACHTA, YAN-JIUN CHEN, JAMES SETHNA, LASSP, Cornell University — We find a precise form for the 2D Ising correlation function in the entire scaling regime as a function of external field H and temperature T . It is surprising that there is no functional form available, perhaps explained by the surprising complexity of the universal scaling function compared to other statistical mechanics models (e.g. 2D free energy or 3D Ising correlation function). We can use these results to test the hypothesis that heterogeneities found in a wide variety of membrane systems are manifestations of an underlying Ising critical point. We fit Monte Carlo lattice simulations in the (H, T) -plane with a functional form in parametric coordinates, while matching analytical results at $H = 0$ and $T = T_c$ to high accuracy. This functional form allows us to interpret FRET, NMR, or ESR data from membranes, where we can map experimentally controllable variables of composition and temperature onto the Ising axes of reduced temperature and magnetization.

12:15PM W45.00004 Fluctuating Lipid Bilayer Membranes With Diffusing Protein Inclusions: Hybrid Continuum-Particle Model , JON K. SIGURDSSON, Department of Mathematics, UC Santa Barbara, FRANK L.H. BROWN, Department of Chemistry, UC Santa Barbara, PAUL J. ATZBERGER, Department of Mathematics, UC Santa Barbara — Many proteins through their geometry and specific interactions with lipids induce changes in local membrane material properties. This can manifest in local stiffness variations and locally induced curvatures that track protein location. To study such phenomena we introduce a new hybrid continuum-particle description for the membrane-protein system that incorporates protein interactions, hydrodynamic coupling, and thermal fluctuations. We investigate how protein curvature and membrane stiffness influences protein diffusion. We discuss how collective protein effects influence membrane mechanical properties, such as the spectrum of membrane bending fluctuations and the effective elastic bending modulus of the heterogeneous protein-lipid membrane. Finally, we discuss possible roles of the membrane fluctuations influencing the distribution of proteins within the membrane.

12:27PM W45.00005 Influence of chain rigidity on the conformation of model lipid membranes in the presence of cylindrical nanoparticle inclusions , CHRIS DILORETO, ROBERT WICKHAM, Department of Physics, University of Guelph — We employ real-space self-consistent field theory to study the conformation of model lipid membranes in the presence of solvent and cylindrical nanoparticle inclusions ("peptides"). Whereas it is common to employ a polymeric Gaussian chain model for the lipids, here we model the lipids as persistent, worm-like chains. Our motivation is to develop a more realistic field theory to describe the action of pore-forming anti-microbial peptides that disrupt the bacterial cell membrane. We employ operator-splitting and a pseudo-spectral algorithm, using SpharmonicKit for the chain tangent degrees of freedom, to solve for the worm-like chain propagator. The peptides, modelled using a mask function, have a surface patterned with hydrophobic and hydrophilic patches, but no charge. We examine the role chain rigidity plays in the hydrophobic mismatch, the membrane-mediated interaction between two peptides, the size and structure of pores formed by peptide aggregates, and the free-energy barrier for peptide insertion into the membrane. Our results suggest that chain rigidity influences both the pore structure and the mechanism of pore formation.

12:39PM W45.00006 Mechanics, morphology, and mobility in stratum corneum membranes¹ , PETER OLMSTED, CHINMAY DAS, University of Leeds, School of Physics & Astronomy, MASSIMO NORO, Unilever Discover Port Sunlight — The stratum corneum is the outermost layer of skin, and serves as a protective barrier against external agents, and to control moisture. It comprises keratin bodies (corneocytes) embedded in a matrix of lipid bilayers. Unlike the more widely studied phospholipid bilayers, the SC bilayers are typically in a gel-like state. Moreover, the SC membrane composition is radically different from more fluid counterparts: it comprises single tailed fatty acids, ceramides, and cholesterol; with many distinct ceramides possessing different lengths of tails, and always with two tails of different lengths. I will present insight from computer simulations into the morphology, mechanical properties, and diffusion (barrier) properties of these highly heterogeneous membranes. Our results provide some clue as to the design principles for the SC membrane, and is an excellent example of the use of wide polydispersity by natural systems.

¹This work was funded by Yorkshire Forward and the European Regional Development Fund.

12:51PM W45.00007 Curvature-driven domain formation in ternary lipid membranes , MATTHEW DEMERS, RASTKO SKNEPNEK, MONICA OLVERA DE LA CRUZ, Northwestern University — We model vesicles formed by three-component fluid membranes whose components have differing spontaneous curvatures. We use Monte Carlo simulated annealing to find low energy configurations for a range of component characteristics. A wide variety of ordered structures are found, including highly symmetric structures with elongated domains resembling faceted edges. We also observe an effective attraction between components of highest and lowest spontaneous curvature. We relate these effects to the interplay of spontaneous curvature and underlying geometric constraints. Our results suggest that the composition-shape coupling can be an important mechanism in the formation of highly ordered structures in many-component membranes.

1:03PM W45.00008 Entropy driven aggregation of adhesion sites of supported membranes , ODED FARAGO, Ben Gurion Univ Beer Sheva — Supported lipid membranes are useful and important model systems for studying cell membrane properties and membrane mediated processes. One attractive application of supported membranes is the design of phantom cells exhibiting well defined adhesive properties and receptor densities. Adhesion of membranes may be achieved by specific and non-specific interactions, and typically requires the clustering of many adhesion bonds into "adhesion zones". One potential mediator of the early stages of the aggregation process is the Casimir-type forces between adhesion sites induced by the membrane thermal fluctuations. In the talk, I will present a theoretical analysis of fluctuation induced aggregation of adhesion sites in supported membranes. I will first discuss the influence of a single attachment point on the spectrum of membrane thermal fluctuations, from which the free energy cost of the attachment point will be deduced. I will then analyze the problem of a supported membrane with two adhesion points. Using scaling arguments and Monte Carlo simulations I will demonstrate that two adhesion points attract each other via an infinitely long range effective potential that grows logarithmically with the pair distance. Finally, I will discuss the many-body nature of the fluctuation induced interactions. I will show that while these interactions alone are not sufficient to allow the formation of aggregation clusters, they greatly reduce the strength of the residual interactions required to facilitate cluster formation. Specifically, for adhesion molecules interacting via a short range attractive potential, the strength of the direct interactions required for aggregation is reduced by about a factor of two to below the thermal energy kT .

1:39PM W45.00009 Membrane lateral structure: How immobilized particles can stabilize small domains¹, RICHARD VINK, TIMO FISCHER, Institute of Theoretical Physics, University of Goettingen, Germany — Membranes are two-dimensional fluid environments, consisting of lipids and proteins. In model membranes, macroscopic phase separation is routinely observed, but not so in biological membranes. Instead, the lateral structure of a biological membrane is characterized by small domains. This poses an interesting puzzle because a structure of small domains inevitably implies a large amount of interface, which is unfavorable because of line tension. In this contribution, it is shown that immobilized protein obstacles provide a mechanism to compensate the cost of line tension. The presence of such obstacles in biological membranes is known to occur (arising for instance from interactions with the underlying cytoskeleton). We present results from computer simulation, which indeed show that a structure of small domains becomes stable, already at a low concentrations of quenched obstacles. In addition, these results confirm a fundamental conjecture of de Gennes, stating that a fluid with quenched obstacles belongs to the universality class of the random-field Ising model.

1:51PM W45.00010 In-Plane Dynamics of Membranes with Immobile Inclusions, NAOMI OPPENHEIMER, HAIM DIAMANT, School of chemistry, Tel Aviv University — Cell membranes are anchored to the cytoskeleton via immobile inclusions. We investigate the effect of such anchors on the in-plane dynamics of a fluid membrane and mobile inclusions embedded in it. The immobile particles lead to a decreased diffusion coefficient of mobile ones and suppress the correlated diffusion of particle pairs. Due to the long-range, quasi-two-dimensional nature of membrane flows, these effects become significant at a low area fraction (below one percent) of immobile inclusions.

2:03PM W45.00011 Charge correlations in multicomponent ionic crystalline membranes, CREIGHTON THOMAS, MONICA OLVERA DE LA CRUZ, Northwestern University — We investigate the dissociation state of a polyelectrolyte membrane with charged head groups in solution. This state depends on the salt concentration and pH of the solution, but spatial correlations also highly influence it. Spatial correlations are typically neglected in these systems, as they are difficult to treat analytically, but they can qualitatively alter the results. We numerically incorporate charge correlations on both flat and curved membranes by simulating a multicomponent system on a fluctuating network with electrostatic interactions, using the replica exchange Monte Carlo approach. The salt-induced screening effects are modeled within the Debye-Huckel theory. For weak enough screening, we find a strong suppression of dissociation regardless of pH, and the membrane may exhibit a reentrant structural phase transition as pH is varied.

Session W46 DCMP GQI: Invited Session: Silicon Spin Qubits: Relaxation and Decoherence

160AB

11:15AM W46.00001 Single-shot readout of spin qubits in Si/SiGe quantum dots¹, CHRISTIE SIMMONS, University of Wisconsin - Madison / Currently: Massachusetts Institute of Technology — Si/SiGe quantum dots are an attractive option for spin qubit development, because of the long coherence times for electron spins in silicon, arising from weak hyperfine interaction and low spin orbit coupling. I will present measurements of gate-defined single and double quantum dots formed in Si/SiGe semiconductor heterostructures. Control of the gate voltages on these dots enables tuning of the tunnel coupling to the leads and to other dots. Careful tuning of these tunnel rates, in combination with fast, pulsed-gate manipulation and spin-to-charge conversion, allow spin state measurement using an integrated quantum point contact as a local charge detector. Single spin qubit readout relies on the Zeeman energy splitting from an external magnetic field for spin-to-charge conversion. Two-electron singlet-triplet qubits, on the other hand, can be measured by using Pauli spin blockade of tunneling between the dots to readout the qubit even at zero magnetic field. I will present real-time, single-shot readout measurements of both individual spin [1] and singlet-triplet qubits [2] in gated Si/SiGe quantum dots. Work performed in collaboration with J. R. Prance, Zhan Shi, B. J. Van Bael, Teck Seng Koh, D. E. Savage, M. G. Lagally, R. Joynt, L. R. Schreiber, L. M. K. Vandersypen, M. Friesen, S. N. Coppersmith, and M. A. Eriksson.

11:51AM W46.00002 Coherent manipulation of a Si/SiGe-based singlet-triplet qubit¹, MARK GYURE, HRL Laboratories, LLC — Electrically defined silicon-based qubits are expected to show improved quantum memory characteristics in comparison to GaAs-based devices due to reduced hyperfine interactions with nuclear spins. Silicon-based qubit devices have proved more challenging to build than their GaAs-based counterparts, but recently several groups have reported substantial progress in single-qubit initialization, measurement, and coherent operation. We report [1] coherent control of electron spins in two coupled quantum dots in an undoped Si/SiGe heterostructure, forming two levels of a singlet-triplet qubit. We measure a nuclei-induced T_2^* of 360 ns, an increase over similar measurements in GaAs-based quantum dots by nearly two orders of magnitude. We also describe the results from detailed modeling of our materials and devices that show this value for T_2^* is consistent with theoretical expectations for our estimated dot sizes and a natural abundance of ²⁹Si. The views and conclusions contained in this document are those of the authors and should not be interpreted as representing the official policies, either expressly or implied, of the United States Department of Defense or the U.S. Government. 12:27PM W46.00003 Measurement and control of single electron spins in silicon MOS-based quantum dots, HONGWEN JIANG, UCLA — No abstract available.

1:03PM W46.00004 Simulating a solid state spin qubit in a spin bath, WAYNE WITZEL, Sandia National Laboratories, NM — Powerful computational methods have been developed in recent years for understanding decoherence induced by environmental spins. Specifically, the cluster correlation expansion [Phys. Rev. B 78, 085315 (2008)] and adaptations [Phys. Rev. Lett. 105, 187602 (2010)] provide successive approximations that approach the solution to the full quantum mechanical problem for small and large spin baths with good efficiency. With these methods, we are able to study the nature of spin-bath decoherence in various regimes, for different types of qubits (e.g., donors or quantum dots) and for different types of spin baths (e.g., nuclei or electrons). Our quantitative analyses have implications for solid state spin qubit prospects and materials choices. Sandia National Laboratories is a multiprogram laboratory operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

1:39PM W46.00005 Two-Spin Decoherence and Disentanglement in Semiconductor Nanostructures¹, XUEDONG HU, University at Buffalo, The State University of New York — A crucial issue in spin-based quantum information processing is spin coherence. Decoherence of a single electron spin confined in a quantum dot or to a donor ion has been studied extensively, with hyperfine interaction to the environmental nuclear spins being identified as the most important channel of spin decoherence [1]. Decoherence of two-spin-qubit states is inevitably affected by single-spin decoherence. Moreover, for exchange-coupled spin qubits, there are new decoherence channels beyond those for single spins because of the Coulombic nature of the exchange interaction. Here we discuss a series of studies of two-spin decoherence mechanisms [2-6], including both known single-spin decoherence and relaxation channels due to nuclear spins and new channels based on electrostatic coupling. More specifically, we examine two-spin relaxation due to hyperfine interaction and phonon emission [2], spin-orbit interaction and phonon emission [3], nuclear spin dynamics mediated by electrons, charge noise [4,5], and electron-phonon interaction [6]. We also analyze the associated disentanglement of the two spins as the decoherence processes go on. Our results show that while nuclear spins affect two-spin states in a qualitatively similar manner as for single spin states, there are interesting new twists because of the weaker hyperfine interaction due to the electron orbital symmetry. On the other hand, the charge noise and phonon induced dephasing depends strongly on the electrical features of the nanostructure, and could pose a significant constraint on two-qubit gates and quantum computing schemes based on two-spin encoding.

Thursday, March 1, 2012 11:15AM - 2:15PM –
Session W47 DPOLY DMP: Focus Session: Polymers for Energy Storage and Conversion -
Fundamentals of Ion Transport 160C

11:15AM W47.00001 Decoupling of Ionic Transport from Segmental Relaxation in Polymer Electrolytes, YANGYANG WANG, Oak Ridge National Lab, ALEXANDER AGAPOV, University of Akron, FEI FAN, University of Tennessee-Knoxville, KUNLUN HONG, XIANG YU, Oak Ridge National Lab, JIMMY MAYS, University of Tennessee-Knoxville, ALEXEI SOKOLOV, Oak Ridge National Lab — Polymer electrolytes provide elegant solutions to many difficulties in battery technology. However, their relatively low ionic conductivity has become the bottleneck for developing batteries with higher power density, shorter charging time, and better operations at low temperatures. In this work, we present detailed studies of the relationship between ionic conductivity and segmental relaxation in a set of specially-designed polymer electrolytes with systematic variation in chain rigidity. Our analysis shows that the ionic conductivity indeed can be decoupled from segmental dynamics in rigid polymers and the strength of the decoupling correlates with the fragility, but not with the glass transition temperature. These results call for a revision of the current picture of ionic transport in polymer electrolytes. We relate the observed decoupling phenomenon to frustration in packing of rigid polymers, which also affects their fragility. The principles demonstrated in this study may provide an alternative approach to design of highly conductive materials: by incorporating relatively rigid chain structures, it is possible to develop a new class of solid polymer electrolytes with strongly decoupled ionic conductivity.

11:27AM W47.00002 Ion Dynamics in Solid-State Polymer Electrolyte Electrochemical Cells using *in situ* Time-Resolved Infrared Spectroscopy, FRANCIS RICHEY, YOSSEF ELABD, Drexel University — Understanding ion transport in solid-state polymer electrochemical cells is of great interest for the advancement of cell efficacy. However, currently there is limited experimental knowledge of ion transport on a molecular level. In this study, we report a new spectroelectrochemical experimental technique that provides *in situ* molecular level detail about cation and anion transport of an ionic liquid in solid-state polymer electrolyte electrochemical cells. *In situ* time-resolved Fourier transform infrared attenuated total reflectance (FTIR-ATR) spectroscopy was utilized to measure the time dependent accumulation of ions at the cathode and anode interface under an applied potential. The results show that the cation and anion of the ionic liquid both transport and accumulate at the cathode under dry conditions, but only the cation accumulates at the cathode under humid conditions. This experiment was coupled with electrochemical impedance spectroscopy to simultaneously measure overall charge transport and cyclic voltammograms.

11:39AM W47.00003 Ion Transport in Polymerized Ionic Liquid Block and Random Copolymers, YOSSEF ELABD, YUESHENG YE, Drexel University, JAE-HONG CHOI, KAREN WINEY, University of Pennsylvania — Polymerized ionic liquid (PIL) block copolymers, a new type of solid-state polymer electrolyte, are of interest for energy conversion and storage devices, such as fuel cells, batteries, supercapacitors, and solar cells. In this study, a series of PIL diblock and random copolymers with various PIL compositions were synthesized. These consisted of an IL monomer and a non-ionic monomer, 1-[(2-methacryloyloxy)ethyl]-3-butylimidazolium bis(trifluoromethanesulfonyl)imide (MEBIm-TFSI) and methyl methacrylate (MMA), and 1-[(2-acryloyloxy)ethyl]-3-butylimidazolium bis(trifluoromethanesulfonyl)imide (AEBIm-TFSI) and styrene (S), respectively, were synthesized. The anion conductivity (ion transport) and morphology were measured in all of the polymers with EIS, SAXS/WAXS, and TEM. Ion transport in block copolymers are significantly higher than random copolymers at the same PIL composition and are highly dependent on the block copolymer nanostructure. The relationship between ion transport mechanisms and the phase behavior of these materials will be discussed.

11:51AM W47.00004 Ion conduction in phosphonium-polysiloxane ionomers, SIWEI LIANG, U. HYEOK CHOI, JAMES RUNT, RALPH COLBY, Penn State University — Low T_g ionomers with phosphonium cations covalently attached as side chains have potential application in energy conversion and storage devices. For example, alkaline fuel cells rely on membranes that transport hydroxide anions and some advanced batteries rely on membranes transporting fluoride anions. To better understand ion conduction in phosphonium-polysiloxane ionomers, allyl tributyl phosphonium bromide monomer was synthesized and, along with a vinyl ethylene oxide monomer, attached to polymethylhydrosiloxane by hydrosilylation. These ionomers maintain low T_g ≈ -74 °C with up to 10 mol% phosphonium and are fully water soluble, allowing easy anion exchange and purification. We report dielectric spectroscopy results for these ionomers with a variety of counter-anions. Electrode polarization at low frequencies is analyzed to determine the number density of simultaneously conducting counter ions and their mobility. This analysis reveals higher mobility and lower activation energy for conducting anions that are larger and more diffuse, such as bis(trifluoromethane sulfonyl)imide, contributing to better performance as anion-conducting membranes.

12:03PM W47.00005 Ion Conduction in Polymerized Ionic Liquid Thin Films, JAE-HONG CHOI, Department of Materials Science and Engineering, University of Pennsylvania, YUESHENG YE, Department of Chemical and Biological Engineering, Drexel University, MATTHEW D. GREEN, Department of Chemical Engineering, Macromolecules and Interfaces Institute, Virginia Tech, YOSSEF A. ELABD, Department of Chemical and Biological Engineering, Drexel University, TIMOTHY E. LONG, Department of Chemistry, Macromolecules and Interfaces Institute, Virginia Tech, KAREN I. WINEY, Department of Materials Science and Engineering, University of Pennsylvania — The ion conductivity in thin films is typically assumed to be isotropic. We have developed methods to measure in-plane and through-plane ionic conductivity in thin homopolymer and block copolymers. Specifically, we are studying the conductivity in imidazolium-containing polymerized ionic liquids as a function of film thickness. These data will be compared to conductivity measurements in a triblock copolymer with a polymerized ionic liquid midblock.

12:15PM W47.00006 Cross-linking of Ordered Pluronic/Ionic Liquid Blends for Solid Polymer Electrolytes, DANIEL MIRANDA, CRAIG VERSEK, MARK TUOMINEN, JAMES WATKINS, THOMAS RUSSELL, University of Massachusetts, Amherst — Ion gels were fabricated by cross-linking PPO-PEO-PPO triblock copolymers swollen in a room temperature ionic liquid (IL). The copolymers are modified by esterification to replace the terminal hydroxyl endgroups with methacrylate endgroups. This allows the copolymer/IL blends to be cross-linked by a UV cure, forming a gel. The strong interaction of the IL with the PEO block suppresses PEO crystallization which is necessary for good ion conduction. In addition, the interaction between the IL and PEO is strongly selective for PEO, strengthening microphase separation. Despite this, the low molecular weight copolymers remain disordered in the melt even when blended with the IL. However, high molecular weight copolymers are capable of microphase separating into highly ordered block copolymer morphologies. This difference allows the effect of microphase separation on ion transport to be studied. The effect of block copolymer composition is also studied, by varying the PEO fraction of the copolymer. The resultant gels show high ionic conductivity and solid-like behavior, indicating that these materials may be effective as solid polymer electrolytes.

12:27PM W47.00007 Ionomer Design Principles for Single Ion-Conducting Energy Materials¹, RALPH COLBY, SIWEI LIANG, WENJUAN LIU, U. HYEOK CHOI, JAMES RUNT, HUAI-SUEN SHIAU, MICHAEL JANIK, Penn State University — Single-ion conducting ionomers with low glass transition temperature, high dielectric constant and containing bulky ions with diffuse charge, are needed for polymer membranes that transport small counterions. Overarching design principles emerging from quantum chemistry calculations suggest that diffuse charge can be attained from simple considerations of atomic electronegativity. For lithium or sodium batteries, perfluorinated tetraphenyl borate ionomers with solvating polar comonomers are proposed. For fluoride or hydroxide batteries and for iodide transporting solar cells, tetra-alkyl phosphonium ionomers with anion receptors are proposed. First attempts to construct such ionomers to test these ideas will be discussed, with results from dielectric spectroscopy to measure conductivity, dielectric constant and number density of simultaneously conducting ions.

¹support from DOE-BES DE-FG02-07ER46409

12:39PM W47.00008 Ion Dynamics in Model Ionomer Melts as a Function of Polymer Architecture, LISA M. HALL, MARK J. STEVENS, AMALIE L. FRISCHKNECHT, Sandia National Laboratories — Ionomers, polymers with a small fraction of covalently bound ionic groups, have potential advantages as solid, single ion conducting electrolytes in future batteries. However, the strong electrostatic interactions in these materials can make counterion diffusion unacceptably slow. Understanding how controllable molecular properties affect ionomer dynamics could spur design of improved materials. With this goal, we perform molecular dynamics simulations of ionomers of various architectures and evaluate their dynamic behavior. Our model of coarse-grained polymers with explicit counterions captures the fundamental physics while allowing access to the long time and length scales relevant to ionomer melts. The simulated structure factors reproduce the trends found in experimental scattering of recently synthesized ionomers with controlled precise or pseudorandom spacing of charged groups along the chain. We calculate counterion diffusion constants and other dynamic properties, which can change significantly depending on the location and spacing of charges along the chain. Randomly spaced materials can have slower or faster dynamics than periodically spaced materials, depending on whether the sequence is completely random or pseudorandom, which will be discussed.

12:51PM W47.00009 Ion Conduction and Dielectric Response of Imidazolium-based Single-ion Conductors¹, U. HYEOK CHOI, Penn State University, MINJAE LEE, ANUJ MITTAL, Virginia Polytechnic Institute & State University, YUESHENG YE, YOSSEF ELABD, Drexel University, HARRY GIBSON, Virginia Polytechnic Institute & State University, JAMES RUNT, RALPH COLBY, Penn State University — We synthesized ionomers with imidazolium cations covalently attached as side groups with various ionic liquid counter-anions. Since these ionic polymers are single-ion conductors that are potentially useful for ionic actuators, it is of great interest to understand structure-property relations, such as the effect of different counterions and different imidazolium pendant structures, including tail and side chain lengths. Conductivities and dielectric properties of a range of monomers and polymers containing ionic liquid moieties are compared. The effects of counterions and side chain length are clearly observed in the T_g and ionic conductivity: larger anions and/or longer side chains lead to lower T_g and higher conductivity than smaller anions and/or shorter side chains. However, if the tail becomes too long (12 carbons) it facilitates - ion aggregation with a significantly lower dielectric constant and lower mobility for the conducting ions. Our study of counter-anions and polymer structural variations leads to insight regarding optimal design of imidazolium single-ion conductors for facile ion transport.

¹This work is supported in part by the U.S. Army Research Office under Grant No. W911NF-07-1-0452 Ionic Liquids in Electro-Active Devices (ILEAD) MURI.

1:03PM W47.00010 Effect of matrix crystallinity on the ionic conductivity in microstructured block copolymer solid electrolytes, NICHOLAS YOUNG, NITASH BALSARA, University of California, Berkeley — Polyethylene oxide (PEO)-based block copolymers have been studied extensively for use as solid electrolytes for rechargeable lithium metal batteries. Previous work has concentrated on block copolymers containing an amorphous second block, such as polystyrene, for which the modulus is sufficiently high to resist growth of dendrites that would lead to short circuiting. In this work, we instead focus on using semicrystalline polyethylene as the mechanically robust component. Polyethylene-polyethylene oxide (EEO) block copolymers doped with lithium bis(trifluoromethanesulfone) imide (LiTFSI) were characterized using AC impedance spectroscopy over a range of temperature, molecular weight, and composition values in order to determine the effect of crystallinity in the structural microphase on the conductivity of this material.

1:15PM W47.00011 Solvation Effects on Counterion Transport in Single-Ion Conducting Ionomers, JING-HAN HELEN WANG, Chemical Engineering, The Pennsylvania State University, University Park PA 16802, RALPH COLBY, Chemical Engineering and Materials Science and Engineering, The Pennsylvania State University, University Park PA 16802 — Ionomers with short ethylene oxide side chains are synthesized by free radical polymerization, to systematically test effects of solvating anion and cation, including directly substituting the ion attached to the polymer with its counterion. Dielectric relaxation spectroscopy is used to measure the conductivity, dielectric constant and segmental relaxations in these ionomers and the electrode polarization at very low frequencies is used to assess the number density of simultaneously conducting ions and their mobility. Conductivity and conducting ion content are larger for polyanions than their corresponding polycation because the counterion can be more effectively solvated by the ether oxygens. Changing ester linkages to amide linkages in polycations boosts conductivity and conducting ion content by solvating the anionic counterion. Such findings point a clear path toward design of superior single-ion conductors.

1:27PM W47.00012 Correlation between superionic behavior and ion aggregation in PEO-based single-ion conductors¹, KAN-JU LIN, JANNA MARANAS, Pennsylvania State University — PEO-based ionomers as solid polymer electrolytes offer the advantage of preventing reverse polarization in batteries by covalently bonding the anion to the PEO backbone. These ionomers form ion aggregates, which reduces the polymer mobility. Since ion transport is coupled to polymer dynamics, these systems have low conductivity. We therefore need a mechanism that decouples ion conduction and PEO dynamics to improve conductivity. We investigate these conduction mechanisms using different models in MD simulations of PEO based benzene sulfonate ionomers. The study shows that these ionomers are capable of showing superionic behavior. The geometry of benzene rings helps aligning the anions, assisting in the formation of chain-like aggregates. The simulations show that the chain-like aggregates result in ionomer conductivity greater than its self-diffusion limits. The superionic behavior is attributed to a charge transfer between two chain ends (conduction sites): a cation hopping to one chain end and the cation at the other end hopping to a nearby site. This allows long range positive charge transfer while the cations only move locally. The results suggest that the superionic behavior depends on the length and lifetime of the chain aggregates. While a long chain reduces the overall number of conduction sites, a short chain prevents long range charge transfer. If the lifetime of an aggregate is shorter than the hopping time for cations, the hopping will not occur and the self-diffusion dominates conductivity.

1:39PM W47.00013 Simulation of Ionic Aggregation and Ion Dynamics in Model Ionomers, AMALIE L. FRISCHKNECHT, Sandia National Laboratories — Ionomers, polymers containing a small fraction of covalently bound ionic groups, are of interest as possible electrolytes in batteries. A single-ion conducting polymer electrolyte would be safer and have higher efficiency than the currently-used liquid electrolytes. However, to date ionomeric materials do not have sufficiently high conductivities for practical application. This is most likely because the ions tend to form aggregates, leading to slow ion transport. A key question is therefore how molecular structure affects the ionic aggregation and ion dynamics. To probe these structure-property relationships, we have performed molecular simulations of a set of recently synthesized poly(ethylene-co-acrylic acid) copolymers and ionomers, with a focus on the morphology of the ionic aggregates. The ionomers have a precise, constant spacing of charged groups, making them ideal for direct comparisons with simulations. *Ab initio* calculations give insight into the expected coordination of cations with fragments of the ionomers. All-atom molecular dynamics (MD) simulations of the ionomer melt show aggregation of the ionic groups into extended string-like clusters. An extensive set of coarse-grained molecular dynamics simulations extend the results to longer times and larger length scales. The structure factors calculated from the MD simulations compare favorably with x-ray scattering data. Furthermore, the simulations give a detailed picture of the sizes, shapes, and composition of the ionic aggregates, and how they depend on polymer architecture. Implications for ion transport will be discussed. Thursday, March 1, 2012 11:15AM - 2:15PM –
Session W48 DPOLY: New Experimental, Theoretical, and Computational Methods in Polymer and Soft Matter Physics 161

11:15AM W48.00001 Coherent States Formulation of Polymer Field Theory¹, XINGKUN MAN, Department of Chemical Engineering and the Materials Research Laboratory, University of California, Santa Barbara, KRIS DELANEY, Department of the Materials Research Laboratory, University of California, Santa Barbara, GLENN FREDRICKSON, Department of Chemical Engineering and the Materials Research Laboratory, University of California, Santa Barbara, HENRI ORLAND, Institut de Physique Theorique, CEA-Saclay, France — We developed a coherent-states formulation of equilibrium polymer field theory. Compared with the traditional Edwards' auxiliary field framework that underpins both field-theoretic simulation (FTS) and self-consistent field theory (SCFT) methods, this formulation has a number of attractive features, including much more local operators and a finite order polynomial action. The formalism is developed in the grand canonical ensemble for the Edwards model of polymers in an implicit solvent, and we show how to derive a numerically tractable scheme. We explore the efficiency and stability of the method in mean-field and fully fluctuating simulations for a polymer solution confined to a slit in one dimension.

¹This work made use of MRL Central Facilities supported by the MRSEC Program of the National Science Foundation under Award DMR-0520415.

11:27AM W48.00002 How Reliable Are Soft Potentials? Ensuring Thermodynamic Consistency Between Hierarchical Models of Polymer Melts, JAMES MCCARTY, MARINA GUENZA, University of Oregon — The use of soft effective potentials to represent macromolecular systems has become widespread in the areas of biophysics and materials science. A survey of the field reveals a vast array of various phenomenological potentials whose ability to provide quantitative information about several different properties of the same system is not evident. This talk will present a formally sound approach to obtain soft potentials for realistic models of simple linear polymer melts which reproduce the correct center of mass distribution of particles as well as the correct equation of state of the underlying system of interest. Furthermore, an analytical potential allows us to rigorously address the implications of coarse-graining on the entropy and free energies of the system and to account for the reduced degrees of freedom and smoothed energy landscape implicit to coarse-grained models. Finally, the transferability of the method to other systems and potential applications will be discussed.

11:39AM W48.00003 Simulation of Stress Induced Polymer-Polymer Interfacial Slip, ANDREW GUSTAFSON, DAVID MORSE, University of Minnesota — The phenomena of stress-induced tangential slip at polymer-polymer interfaces is studied via a slip-link simulation technique. Simulations combine a slip-link model of entanglement with a self-consistent field description of the chemical potential landscape near an interface. We consider how the slip velocity depends upon shear stress, interfacial entanglement density, and polymer chain length. Our model is based on the idea that the strongly non-linear shear thinning of the interface observed in experiment is a result of stress-induced convective release (pulling-out) of entanglements across the interface.

11:51AM W48.00004 Tumbling dynamics of isolated polymer chains in strong shear flows and the effects of chain resolution, RONALD LARSON, INDRANIL SAHA DALAL, ALEX ALBAUGH, University of Michigan, NAZISH HODA, ExxonMobil Upstream Research — Using Brownian dynamics simulations, without hydrodynamic and excluded volume interactions, on polymer chain models encompassing a wide range of resolutions, we present a detailed investigation on the behavior of isolated chains in shear flow. We find a highly non-monotonic behavior for all models, with chain compression occurring at ultra-high shear rates that is consistent with the recent simulation studies. However, results obtained using highly refined models, with resolutions lower than a Kuhn step, reveal that this transition is an artifact of the level of chain discretization. Also, our results clearly indicate that, at high shear rates, the chain thickness in the shear-gradient direction is independent of the chain length, which differ from previously reported scaling law. We show that the chain thickness is fixed by the distance a sub-section of the chain can diffuse in the shear-gradient direction before convection stretches it out and suppresses further diffusion. Simple physical arguments are then used to derive the correct scaling laws for the coil width and the tumbling time at high shear rates. We believe that our findings presented here will provide the foundation for a better understanding of this basic problem in polymer dynamics.

12:03PM W48.00005 ABSTRACT WITHDRAWN —

12:15PM W48.00006 A Mesoscale Simulation Method for High Salt Concentrations, STEFAN MEDINA¹, Caltech, USA / University of Mainz, Germany, FRIEDERIKE SCHMID, University of Mainz, Germany — In mesoscale simulations of electrolyte solutions the interplay between electrostatics and hydrodynamics plays the critical role for computational efficiency and accuracy. In the past it became apparent that high salt concentrations are too costly, if every salt ion is treated explicitly as a separate particle. On the other hand, charges are highly screened at high salt concentrations and ion-ion correlations are less important than in the low-salt limit. Therefore, we have developed a dynamic mean-field treatment of charges which is expected to be perfectly sufficient in many cases leading to applications in controlled manipulation of polyelectrolytes and charged colloids by external electric fields.

12:27PM W48.00007 Molten Salt Eutectics from Atomistic Alchemical Simulations, SAIVENKATARAMAN JAYARAMAN, AIDAN THOMPSON, Advanced Device Technologies department, Sandia National Laboratories, Albuquerque, NM, O. ANATOLE VON LILIENFELD, Leadership Computing Facility, Argonne National Laboratory, Argonne, IL — Molten salt mixtures are gaining importance in solar thermal power applications. Unfortunately, their phase diagrams cannot be easily computed from first principles calculations. The eutectic mixture composition and temperature are located using the liquid mixture free energy and the pure component solid-liquid free energy differences. The liquid mixture free energy is obtained using thermodynamic integration of alchemical transformations of one atom to another. Numerical results for binary and ternary mixtures of alkali nitrates agree well with experimental measurements [1]. Some results involving mixtures of monovalent and divalent cations will also be presented.

12:39PM W48.00008 ABSTRACT WITHDRAWN —

12:51PM W48.00009 An $[N]PT$ Ensemble for Studying the Intricate Thermodynamics of Cluster Crystals, KAI ZHANG, PATRICK CHARBONNEAU, Duke University — Exotic soft matter systems such as certain dendrimers can overlap with only a finite energy penalty. Systems governed by steep, bounded repulsive interactions, such as the penetrable sphere model (PSM), indeed form cluster crystals with multiple particles per lattice site under compression. Standard simulation approaches that keep NVT , NPT , or μVT constant cannot directly equilibrate cluster crystals, because either N or lattice constant is not free to relax. It is tempting to allow all fields to fluctuate by keeping " μPT " constant, but basic thermodynamics indicates that infinite fluctuations then result. We avoid this caveat by using a $[N]PT$ ensemble, in which P and T are fixed but N is allowed to fluctuate within bounds $[N_{\min}, N_{\max}]$ under a conjugate field analogous to μ . The approach provides the equilibrium properties of neighboring state points through histogram reweighting. We solve the phase diagram of the PSM, and confirm that the FCC crystal lattice occupancy linearly increases with ρ at high T . At low T the occupancy plateaus at integer values, but the transitions remain continuous and the crystal does not phase separate. We also examine the critical behavior of another related model.

1:03PM W48.00010 From nucleus to phase: Growing dynamics of critical nucleus in polymer blends¹, DADONG YAN, XINGHUA ZHANG, Department of Physics, Beijing Normal University, Beijing 100875 — In metastable system, nonclassical critical nucleus is not a drop of stable bulk in core wrapped with a sharp interface, but a diffuse structure depending on the metastability. Thus, forming a critical nucleus does not mean the birth of a new phase. Also, the dynamics of nucleus' growing before the phase is born is still unknown. In present work, the nonclassical growing dynamics of the critical nucleus is addressed in the metastable polymer blends by incorporating self-consistent field theory and external potential dynamics theory, and leads to an intuitionistic description for the results of scattering experiments. Our results suggest that the growth of nonclassical critical nucleus is not self-similarly, but forms shell structure, which gives the scattering peak at nonzero wavenumber in the experiments. This phenomenon comes from the spinodal-decomposition-like behaviors constrained within the critical nucleus. The growing dynamics of the critical nucleus can be considered as a spinodal-assistant nucleation process.

1:15PM W48.00011 An Interactive 3D Interface to Model Complex Surfaces and Simulate Grazing Incidence X-ray Scatter Patterns, ELIOT GANN, North Carolina State University, Jema Science Inc., SLIM CHOUROU, ABHINAV SARJE, Lawrence Berkeley National Laboratory, HARALD ADE, North Carolina State University, CHENG WANG, ELAINE CHAN, Lawrence Berkeley National Laboratory, XIAODONG DING, Jema Science Inc., ALEXANDER HEXEMER, Lawrence Berkeley National Laboratory — Grazing Incidence Scattering is becoming critical in characterization of the ensemble statistical properties of complex layered and nano structured thin films systems over length scales of centimeters. A major bottleneck in the widespread implementation of these techniques is the quantitative interpretation of the complicated grazing incidence scatter. To fill this gap, we present the development of a new interactive program to model complex nano-structured and layered systems for efficient grazing incidence scattering calculation.

1:27PM W48.00012 Numerical Computation of Diffusion Properties in Molecular Systems on a Topology-Conforming Grid¹, IVAN TEO, KLAUS SCHULTEN, Department of Physics, University of Illinois at Urbana-Champaign, Beckman Institute for Advanced Science and Technology — Multiscale problems involving diffusion in molecular systems are a mainstay of computational biophysics. Given a molecular system, the local diffusion coefficient $D(\mathbf{r})$ as well as the equilibrium distribution function $P(\mathbf{r})$ that characterizes the local free energy are computed to describe the kinetics of diffusing particles at each point in space through the Smoluchowski equation (SE). An irregular grid of space-varying fineness conforming to $P(\mathbf{r})$ is generated via the method of topology-representing networks and a subsequent Voronoi tessellation. The discretized SE produces a rate matrix which describes the probabilities of particles hopping from point to point on the grid. We demonstrate the calculation of the rate matrix for ions diffusing through the balloon-like structure of the mechanosensitive channel of small conductance (MscS) and thence the determination of mean first-passage times that characterize conduction of ions through balloon and channel.

1:39PM W48.00013 Fluorescent excitation transfer as a tool for the phase transition studies ,

ALEXEI GOUN, Postdoctoral researcher — The use of the fluorescent resonant excitation transfer technique (FRET) to study the phase transition kinetics is demonstrated. The laser temperature jump is applied to the water/2,6-lutidine mixture and causes the demixing. Coumarin 480 and hydroxypyrene laser dyes form excitation transfer that interrogates the spatial structure of the system. Due to the differential solubility of these dyes in the components of the mixture, the excitation transfer ceases once the phase separation occurs. The spatial resolution of the method is determined by the Forster distance of the excitation transfer pair, and in this case is equal to 3 nm. The phase separation is completed within 1 microsecond. The rising edge of the fluorescence is consistent with polynomial growth of the phase separated domains, and not with Cahn-Hilliard fixed length instability. The theoretical model for the excitation transfer in a variety of systems such as separation of binary mixture, phase reorganization of membranes, formation of lamellar structure is developed.

1:51PM W48.00014 The Physics of Phase-Separation Fronts ,

ALEXANDER WAGNER, ERIC FOARD, Department of Physics, North Dakota State University, Fargo, ND 58108 — When phase separation does occur in a sequential manner, e.g. due to the diffusion of a control parameter into the system, the resulting phase-separation structures have a markedly different appearance than homogeneous phase-separation patterns. The reason lies in the influence the already phase-separated material and the recent phase-separation dynamics exert on the newly phase-separating material. We call the region where phase-separation first occurs the phase-separation front. In this talk we will consider the simplest possible phase-separation front, i.e. a sharp transition in the control parameter moving through the system with a prescribed velocity inducing phase-separation. We show numerical and analytical solutions for the structures that are formed by such a front as a function of the front speed and the composition of the overtaken material.

2:03PM W48.00015 Protected TERS Probes for the Study of Polymer Surfaces ,

REBECCA AGAPOV, The University of Akron, Dept. of Polymer Science, Akron, OH, ALEXEI SOKOLOV, Chemical Sciences Division, ORNL and Department of Chemistry, University of Tennessee, Knoxville, TN, MARK FOSTER, The University of Akron, Dept. of Polymer Science, Akron, OH — The chemistry of polymer surfaces can potentially be imaged with high (~20nm) lateral resolution using Tip Enhanced Raman Spectroscopy (TERS). The method's applicability can be tremendously broadened if the metallized tips central to the technique can be made more robust. Protecting the TERS probes with alumina coatings reduces chemical, mechanical, and thermal degradation, prolonging the use lifetime. Most recently we have focused on the detailed effect of the protective coating for cases in which the enhancement is particularly strong. "Blinking", which is characteristic of extreme enhancement, has been observed with TERS on polymer films for the first time. An alumina coating prolongs the duration of blinking from 20 min to 30 h, greatly extending the experimental window of extreme enhancement. The protective coating is also helpful for illuminating the mechanism behind blinking. Our results are consistent with thermal diffusion of molecules as the major mechanism facilitating blinking.

Session W49 DMP DPOLY: Focus Session: Organic Electronics and Photonics - Thin Film Transistors 162A

11:15AM W49.00001 Pressure effect on organic field-effect transistors ,

YUGO OKADA, KEN-ICHI SAKAI, SHIN KITAOKA, TAKAFUMI UEMURA, JUN TAKEYA, ISIR, Osaka University — Macroscopic transport in organic semiconductors is governed by intermolecular charge transfer, necessarily resulting in its sensitivity to molecular arrangement. The effect of external pressure in such soft materials is fundamentally important because of vulnerability in molecular displacement against relatively small force. Here, we introduce a method of measuring the effect of hydrostatic pressure on the conductivity in organic semiconductor crystals inducing high-mobility charge with the application of electric field. We performed four-terminal conductivity measurement to exclude extrinsic influence of the metal/semiconductor contact resistance. In addition, Hall coefficients are simultaneously measured to deduce the pressure coefficient properly. Using rubrene single-crystal transistors, variation of mobility under pressure turned out to be about 7 times larger than in the typical experiments reported for silicon and other inorganic semiconductors. Interestingly, the mobility starts to decrease with further increasing pressure above 600 MPa. The anomalous negative pressure effect indicate that the application of pressure not only diminishes distance between centers of adjacent molecules but relative positions of equivalent atoms in the two molecules.

11:27AM W49.00002 Determining the elastic constants of rubrene single-crystals¹ ,

MARCOS REYES-MARTINEZ, Polymer Science & Engineering, University of Massachusetts Amherst, ASHWIN RAMASUBRAMANIAM, Mechanical & Industrial Engineering, University of Massachusetts Amherst, ALEJANDRO BRISENO, ALFRED CROSBY, Polymer Science & Engineering, University of Massachusetts Amherst — Organic single crystals have opened the doors to a new generation of high-performance organic electronic devices. Exceptional charge-transport properties combined with the advent of large-area patterning techniques make organic single crystals excellent candidates for flexible electronics applications. However, in order to effectively employ organic single crystals on mechanically flexible architectures, their mechanical properties need to be understood and characterized. In this presentation, the mechanical properties of rubrene single-crystals are investigated. Given the limited dimensions of as-grown crystals and associated handling difficulty, the elastic buckling instability is chosen as a metrology tool for determining the in-plane elastic constants. Our results show that ultrathin (200nm - 1000nm) rubrene crystals exhibit anisotropic wrinkling wavelengths as a function of crystallographic direction, which can be correlated to the anisotropic nature of its molecular packing. An adaptive intermolecular reactive bond order potential (AIREBO) is employed to calculate the nine elastic constants corresponding to orthorhombic rubrene.

¹US Department of Energy, Office of Basic Energy Sciences as part of Polymer-Based Materials for Harvesting Solar Energy, an Energy Frontier Research Center (EFRC)

11:39AM W49.00003 Tuning contorted hexabenzocoronene crystal structure and texture for organic field-effect transistors ,

ANNA HISZPANSKI, Chemical and Biological Engineering Department, Princeton University, ARTHUR WOLL, Cornell High Energy Synchrotron Source, Cornell University, YUEH-LIN LOO, Chemical and Biological Engineering Department, Princeton University — Crystallography conducted on single crystals reveals contorted hexabenzocoronene (HBC) can adopt either herringbone (Pbcn) or slip-stack (P21/c) packing motifs. By adjusting the molecule-solvent interactions during solvent-vapor annealing (SVA), we can controllably crystallize thin films of HBC and access both packing motifs. In HBC films annealed with dichloromethane (DCM) vapor, molecule-solvent interactions are strong and yield highly oriented Pbcn crystals. However, in films annealed with hexanes vapor, molecule-solvent interactions are weaker and randomly oriented P21/c crystals form. In addition to tuning the molecule-solvent interactions via solvent choice, the interactions may also be modulated by selectively fluorinating the peripheral aromatic rings of HBC. With increased fluorination, we decrease molecule-solvent interactions during SVA. As such, we can coax these HBC derivatives to adopt the P21/c crystal structure even with DCM SVA. Further, more fluorinated HBCs form more oriented crystals when exposed to DCM vapors. Transistors fabricated with crystalline HBC active layers suggest that the mobilities of these devices are, to first order, determined by the extent of crystal orientation and less so by the crystal structure. The ability to independently access both crystal structures with varying degrees of orientation has allowed us to decouple their relative contributions to device performance.

11:51AM W49.00004 Quantitative assessments of the effect of microstructure on transport in organic semiconductors, ALBERTO SALLEO, Stanford University — From the fundamental standpoint, organic semiconductors are fascinating as they are neither crystalline nor amorphous and their microstructure plays a central role in governing charge transport. I will show that understanding disorder is the key to determining charge transport mechanism. We are particularly interested in cumulative disorder (paracrystallinity), where the lattice parameter takes on a Gaussian distribution about its mean value. The disorder parameter g allows us to rank materials quantitatively on a continuous scale, from a perfectly crystalline material ($g < 1\%$) to an amorphous one ($g > 10\%$). Surprisingly, even the polymers that are considered to have the highest crystallinity (PBTBT) have a g in the π -stacking direction close to that of an amorphous material ($\sim 7\%$). Furthermore, comparison of X-ray diffraction data and optical absorption data provides insight into the nature of the disordered phase as well. Using first principle calculations and tight binding methods, I will show that paracrystallinity in the π -stacking direction provides a fundamental mechanism for the existence of an exponential distribution of localized tail states in the gap. The larger the degree of disorder the higher the trap density and the deeper their energy. Using disorder as a ranking parameter, I will discuss the differences in transport between small molecule and polymer films as well as their respective inherent limitations and bottlenecks.

12:27PM W49.00005 Air-Stable Solution-Processed Thin-Film Transistors with Hole Mobilities of $3.5 \text{ cm}^2/\text{Vs}$, YAOCHUAN MEI, KATELYN GOETZ, Department of Physics, Wake Forest University, Winston-Salem, NC, MARSHA LOTH, JOHN ANTHONY, Department of Chemistry, University of Kentucky, Lexington, KY, OANA JURCHESCU, Department of Physics, Wake Forest University, Winston-Salem, NC — We report on organic thin-film transistors fabricated on a novel soluble small molecule organic semiconductor difluoro bis(triethylgermyl) anthradithiophene. Fabrication techniques are all applicable at room temperature and ambient pressure, and include drop-casting, spin-coating, and spray deposition. Devices exhibit remarkable electronic properties, including charge carrier mobilities as high as $3.5 \text{ cm}^2/\text{Vs}$, on/off current ratios of 10^5 , and good environmental and operational stability. Chemical treatment of the contact surface with self-assembled monolayers allows us great control of the crystalline order within the organic semiconductor layer. Because thin-film microstructure defects such as grain boundaries reduce the charge transport capabilities of the active layer, high quality single crystals are grown by physical vapor transport for comparison. By correlating the electrical properties with the structural data obtained from X-ray diffraction, we find that a good $\pi - \pi$ overlap is responsible for this superior electronic behavior.

12:39PM W49.00006 Variable-range hopping transport and Hall effect measurements in electrolyte-gated P3HT, SHUN WANG, MINGJING HA, MICHAEL MANNO, C. DANIEL FRISBIE, C. LEIGHTON, Department of Chemical Engineering and Material Science, University of Minnesota — Extensive charge transport measurements ($1.5 - 250 \text{ K}$) at gate-tuned hole concentrations between 1×10^{20} and $9 \times 10^{20} \text{ cm}^{-3}$ have been made on a single ion-gel gated poly-(3-hexylthiophene) (P3HT) thin film transistor. We report observation of a robust Hall effect, having rational trends with magnetic field, gate voltage, and temperature, and yielding hole concentrations close to those measured via the charging current. At high doping we observe transitions from apparent band transport, to 3D Mott variable range hopping (VRH), to Efros-Shklovskii (ES) VRH on cooling. At lower doping ES VRH is observed at all temperatures. A detailed analysis of the temperature and field-dependence of the VRH resistivity provides information on the localization length and dielectric constant as a function of doping, providing significant insights into the approach to the insulator-metal transition in this system and the nature of the Coulomb-gapped density of states. Work at UMN supported by NSF MRSEC

12:51PM W49.00007 Charge Density Dependent Hole Mobility and Density of States Throughout the Entire Finite Potential Window of Conductivity in Ionic Liquid Gated Poly(3-hexylthiophene), BRYAN D. PAULSEN, C. DANIEL FRISBIE, Department of Chemical Engineering & Materials Science, University of Minnesota — Ionic liquids, used in place of traditional gate dielectric materials, allow for the accumulation of very high 2D and 3D charge densities ($>10^{14} \text{ \#}/\text{cm}^2$ and $>10^{21} \text{ \#}/\text{cm}^3$ respectively) at low voltage ($<5 \text{ V}$). Here we study the electrochemical gating of the benchmark semiconducting polymer poly(3-hexylthiophene) (P3HT) with the ionic liquid 1-ethyl-3-methylimidazolium tris(pentafluoroethyl)trifluorophosphate ([EMI][FAP]). The electrochemical stability of [EMI][FAP] allowed the reproducible accumulation of $2 \times 10^{21} \text{ hole}/\text{cm}^3$, or one hole (and stabilizing anion dopant) per every two thiophene rings. A finite potential/charge density window of high electrical conductivity was observed with hole mobility reaching a maximum of $0.86 \text{ cm}^2/\text{V s}$ at $0.12 \text{ holes per thiophene ring}$. Displacement current measurements, collected versus a calibrated reference electrode, allowed the mapping of the highly structured and extremely broad density of states of the P3HT/[EMI][FAP] doped composite. Variable temperature and charge density hole transport measurements revealed hole transport to be thermally activated and non-monotonic, displaying an activation energy minimum of $\sim 20 \text{ meV}$ in the region of maximum conductivity and hole mobility. To show the generality of this result, the study was extended to an additional four ionic liquids and three semiconducting polymers.

1:03PM W49.00008 Conductivity Maxima on the Surface of Organic Semiconductor Crystals at High Charge Densities¹, WEI XIE, C. DANIEL FRISBIE, Department of Chemical Engineering and Materials Science, University of Minnesota — We have previously achieved effective carrier mobility up to $3.2 \text{ cm}^2\text{V}^{-1}\text{s}^{-1}$ at charge densities larger than 10^{13} cm^{-2} in rubrene electrical double layer transistors (EDLTs) gated with ionic liquids (ILs). At lower temperatures when a larger gate bias can be applied, the maximum attainable charge density reaches $6.5 \times 10^{13} \text{ cm}^{-2}$ ($0.34 \text{ holes per rubrene molecule}$), and more remarkably, two pronounced maxima in channel conductivity have been reproducibly and stably observed. This feature, which has not been reported for any EDLTs gated with electrolytes, is independent of ionic liquid composition, current-voltage sweep rate, and crystallographic directions of rubrene crystals. We have identified that the first and second conductivity peaks occur at charge densities of $2.0 \times 10^{13} \text{ cm}^{-2}$ and $5.2 \times 10^{13} \text{ cm}^{-2}$, respectively. Capacitance-voltage (C-V) measurements at different frequencies have also revealed two maxima at the same gate voltages as in current-voltage measurements. Collectively, these observations imply that the conductivity maxima at high charge densities are very likely related to the electronic band structure on the surface of rubrene crystals.

¹This work is funded by NSF MRSEC at the University of Minnesota

1:15PM W49.00009 Solvent-Resistant Organic Transistors and Thermally-Stable Organic Photovoltaics Based on Crosslinkable Conjugated Polymers, H.J. KIM, C.-H. CHO, B.J. KIM, KAIST, A.-R. HAN, J.H. OH, UNIST, J.M.J. FRECHET, UC Berkeley — Conjugated polymers in general are unstable when exposed to air, solvent, or thermal treatment, and these challenges limit their practical applications. Herein we have developed a simple, but powerful approach to achieve solvent-resistant and thermally stable organic electronic devices with improved air-stability, by introducing a crosslinkable group into a conjugated polymer. To demonstrate this concept, we have synthesized polythiophene with crosslinkable groups attached to the end of alkyl chain. Photo-crosslinking of crosslinkable P3HT dramatically improves the solvent resistance of the active layer without disrupting the molecular ordering and charge transport. This is the first demonstration of solvent-resistant organic transistors. Furthermore, the bulk-heterojunction organic photovoltaics (BHJ OPVs) containing crosslinkable P3HT show an average efficiency higher than 3.3% after 40 h annealing at an elevated temperature of 150°C , which represents one of the most thermally-stable OPV devices reported to date. This enhanced stability is due to an in-situ compatibilizer that forms at the P3HT/PCBM interface and suppresses macrophase separation.

1:27PM W49.00010 Surface enhanced Raman spectroscopic studies of the metal-semiconductor interface in organic field effect transistors¹, DANISH ADIL, SUCHI GUHA, Departemnt of Physics and Astronomy, University of Missouri, Columbia, MO 65211 — The performance of organic field-effect transistors (FETs) largely depends on the nature of interfaces of dissimilar materials. Metal-semiconductor interfaces, in particular, play a critical role in the charge injection process. Here, Raman spectroscopy is used to investigate the nature of the Au-semiconductor interface in pentacene based FETs. A large enhancement in the Raman intensity (SERS) is observed from the pentacene film under the Au layer. The enhancement is evidence of a nano-scale roughness in the morphology of the interface, which is further confirmed by electron microscopy images. The morphology of the interface is investigated by SERS as a function of the pentacene layer thickness and the Au layer thickness. The Raman spectra are found to be extremely sensitive in detecting small changes in the morphology of the interface in the sub-nanometer range. Changes in the Raman spectra are further tracked after biasing and ageing the devices. Evolution of these Raman spectra is correlated with degradation in device performance. Finally, FETs based on other donor-acceptor semiconductors are probed by Raman scattering and contrasted with those of the pentacene-based devices.

1:39PM W49.00011 Ultra-thin body poly(3-hexylthiophene) transistors with improved short-channel performance, CHENCHEN WANG, Applied Physics, Stanford University, JONATHAN RIVNAY, SCOTT HIMMELBERGER, Department of Materials Science and Engineering, Stanford Univerity, KIARASH VAKHSOURI, ENRIQUE D. GOMEZ, Department of Chemical Engineering, The Pennsylvania State University, ALBERTO SALLEO, Department of Materials Science and Engineering, Stanford Univerity — The microstructure and charge transport properties of binary blend of regioregular (rr) and regiorandom(RRa) poly(3-hexylthiophene) (P3HT) are investigated. X-ray diffraction study shows vertical phase separation in the blend films, with rr-P3HT crystallized at the semiconductor/dielectric interface. These thin film transistors with layered structure preserve high field effect mobility when rr-P3HT contents are reduced to as low as 5.6% where the channel thickness is only a few nanometers. As a result of this ultra-thin active layer at interface, short channel effects due to bulk currents are eliminated, suggesting a new route to fabricate high performance, small size and reliable electronic devices.

1:51PM W49.00012 Physical Characterization of Functionalized Silk Material for Electronic Application and Devices¹, EDEN STEVEN, National High Magnetic Field Laboratory, USA, ERIC JOBILIONG, University of Pelita Harapan, Indonesia, JIN GYU PARK, ANANT PARAVASTU, MICHAEL DAVIDSON, MICHELLE BAIRD, RUFINA ALAMO, PAPATYA KANER, JAMES BROOKS, THEO SIEGRIST, National High Magnetic Field Laboratory, USA — Naturally harvested spider silk fibers are investigated for their physical properties under ambient, humidified, iodine-doped, pyrolyzed, sputtered gold and carbon nanotube coated conditions. The functional properties include: humidity activated conductivity; enhanced flexibility and carbon yield of pyrolyzed iodized silk fibers; full metallic conductivity and flexibility of micron-sized gold-sputtered silk fibers; and high strain sensitivity of carbon nanotube coated silk fibers. Magic angle spinning nuclear magnetic resonance (MAS-NMR) and Fourier transform infrared spectroscopy (FTIR) are used to explore the nature of ambient and functionalized spider silk fiber, and significant changes in amino acid-protein backbone signature are correlated with gold sputtering, and iodine-doped conditions. The application of gold-sputtered neat spider silk fibers for making four terminal flexible, clean, ohmic contacts to organic superconductor samples and carbon nanotube coated silk fibers for heart pulse monitoring sensor are demonstrated. The role of silk thin film in organic thin film transistor will be briefly discussed.

2:03PM W49.00013 Spectroscopic signatures of ambipolar injection in narrow gap donor-acceptor polymer transistors, OMAR KHATIB, UCSB, JONATHAN D. YUEN, UCSB, JIM WILSON, UCSB, RAJEEV KUMAR, Nanoterra, FRED WUDL, UCSB, MASSIMILIANO DI VENTRA, UCSB, ALAN J. HEEGER, UCSB, DIMITRI N. BASOV, UCSB — Donor-Acceptor (D-A) copolymers have recently emerged as versatile materials for use in a large variety of device applications. Specifically, these systems possess extremely narrow bandgaps, enabling ambipolar charge transport when integrated in solution-processed field-effect transistors (OFETs). However, the fundamentals of electronic transport in this class of materials remain unexplored. We present a systematic investigation of ambipolar charge injection in D-A conjugated polymers polybenzobisthiadiazole-dithienopyrrole (PBBTPD) and polybenzobisthiadiazole-dithienocyclopentane (PBBTCD) using infrared spectroscopy. We observed a significant modification of the absorption edge in both PBBTPD- and PBBTCD-based OFETs under the applied electric field. The absorption edge reveals hardening under electron injection and softening under hole injection. The most straightforward interpretation of the observed band edge modification is in terms of the linear Stark effect, implying the existence of a built-in electrical dipole moment in these polymers. Additionally, we carried out microscopic IR measurements to characterize the ambipolar injection profile between electrodes.

11:15AM W50.00001 Self-Sorting of Deformable Particles in a Microfluidic Circuit¹, MARCO A. CARTAS-AYALA, MOHAMMED RAAFAT, ROHIT KARNIK, MIT — Sorting of cells, droplets, and particles based on physical characteristics including size and deformability is important for bioseparation, diagnostics, and two-phase microfluidics. While several methods have been developed to sort particles based on size, few techniques exist for sorting of particles based on deformability. Here, we present a microfluidic circuit that enables self-sorting of deformable particles based on the hydraulic resistance that the particle induces in a microchannel, which directly relates to the particle deformability. The present method employs a feed-forward circuit that biases a microfluidic Y-junction based on the hydraulic resistance induced by the particle as it enters a sensing channel. Since particles encountering a symmetric junction follow the branch with the higher flow rate, the resulting modulation of fluid flow at the junction switches the particle into one of two output channels depending on the resistance induced by the particle. Since hydraulic resistance can be influenced by particle-wall interactions, it also opens possibilities for functionalizing the sensing channel for sorting based on specific interactions. This technique may find use in cell sorting and analysis and in two-phase microfluidics.

11:27AM W50.00002 Accelerating Yeast Prion Biology using Droplet Microfluidics¹, LLOYD UNG, ASSAF ROTEM, Harvard School of Engineering and Applied Sciences, DANIEL JAROSZ, Whitehead Institute for Biomedical Research, MANOSHI DATTA, Whitehead Institute for Biomedical Research, MIT Computational and Systems Biology, SUSAN LINDQUIST, Whitehead Institute for Biomedical Research, Howard Hughes Medical Institute, MIT Department of Biology, DAVID WEITZ, Harvard School of Engineering and Applied Sciences, Department of Physics — Prions are infectious proteins in a misfolded form, that can induce normal proteins to take the misfolded state. Yeast prions are relevant, as a model of human prion diseases, and interesting from an evolutionary standpoint. Prions may also be a form of epigenetic inheritance, which allow yeast to adapt to stressful conditions at rates exceeding those of random mutations and propagate that adaptation to their offspring. Encapsulation of yeast in droplet microfluidic devices enables high-throughput measurements with single cell resolution, which would not be feasible using bulk methods. Millions of populations of yeast can be screened to obtain reliable measurements of prion induction and loss rates. The population dynamics of clonal yeast, when a fraction of the cells are prion expressing, can be elucidated. Furthermore, the mechanism by which certain strains of bacteria induce yeast to express prions in the wild can be deduced. Integrating the disparate fields of prion biology and droplet microfluidics reveals a more complete picture of how prions may be more than just diseases and play a functional role in yeast.

11:39AM W50.00003 Microfluidic devices for droplet injection, DONALD AUBRECHT, ILKE AKARTUNA, DAVID WEITZ, Harvard University — As picoliter-scale reaction vessels, microfluidic water-in-oil emulsions have found application for high-throughput, large-sample number analyses. Often, the biological or chemical system under investigation needs to be encapsulated into droplets to prevent cross contamination prior to the introduction of reaction reagents. Previous techniques of picoinjection or droplet synchronization and merging enable the addition of reagents to individual droplets, but present limitations on what can be added to each droplet. We present microfluidic devices that couple the strengths of picoinjection and droplet merging, allowing us to selectively add precise volume to our droplet reactions.

11:51AM W50.00004 Microfluidic devices for label-free separation of cells through transient interaction with asymmetric receptor patterns¹, S. BOSE, R. SINGH, M.H. HOLLATZ², C.-H. LEE, MIT, J. KARP, Brigham & Women's Hospital, R. KARNIK, MIT — Cell sorting serves an important role in clinical diagnosis and biological research. Most of the existing microscale sorting techniques are either non-specific to antigen type or rely on capturing cells making sample recovery difficult. We demonstrate a simple; yet effective technique for isolating cells in an antigen specific manner by using transient interactions of the cell surface antigens with asymmetric receptor patterned surface. Using microfluidic devices incorporating P-selectin patterns we demonstrate separation of HL60 cells from K562 cells. We achieved a sorting purity above 90% and efficiency greater than 85% with this system. We also present a mathematical model incorporating flow mediated and adhesion mediated transport of cells in the microchannel that can be used to predict the performance of these devices. Lastly, we demonstrate the clinical significance of the method by demonstrating single step separation of neutrophils from whole blood. When whole blood is introduced in the device, the granulocyte population gets separated exclusively yielding neutrophils of high purity (<10% RBC contamination). To our knowledge, this is the first ever demonstration of continuous label free sorting of neutrophils from whole blood. We believe this technology will be useful in developing point-of-care diagnostic devices and also for a host of cell sorting applications.

12:03PM W50.00005 Role of Structural Asymmetry in Controlling Drop Spacing in Microfluidic Ladder Networks, WILLIAM WANG, JEEVAN MADDALA, SIVA VANAPALLI, RAGHUNATHAN RENGASAMY, Texas Tech University — Manipulation of drop spacing is crucial to many processes in microfluidic devices including drop coalescence, detection and storage. Microfluidic ladder networks —where two droplet-carrying parallel channels are connected by narrow bypass channels through which the motion of drops is forbidden—have been proposed as a means to control relative separation between pairs of drops. Prior studies in microfluidic ladder networks with vertical bypasses, which possess fore-aft structural symmetry, have revealed that pairs of drops can only undergo reduction in drop spacing at the ladder exit. We investigate the dynamics of drops in microfluidic ladder networks with both vertical and slanted bypasses. Our analytical results indicate that unlike symmetric ladder networks, structural asymmetry introduced by a single slanted bypass can be used to modulate the relative spacing between drops, enabling them to contract, synchronize, expand or even flip at the ladder exit. Our experiments confirm all the behaviors predicted by theory. Numerical analysis further shows that ladders containing several identical bypasses can only linearly transform the input drop spacing. Finally, we find that ladders with specific combinations of vertical and slanted bypasses can generate non-linear transformation of input drop spacing, despite the absence of drop decision-making events at the bypass junctions.

12:15PM W50.00006 Synchronized Reinjection and Coalescence of Droplets in Microfluidics, MANHEE LEE, Department of Physics, Harvard University, JESSE COLLINS, DONALD AUBRECHT, SHINHYUN KIM, TINA LIN, ASSAF ROTEM, School of Engineering and Applied Sciences, Harvard University, LAURA SOLOMON, College of Engineering, Temple University, DAVID WEITZ, School of Engineering and Applied Sciences, Harvard University, VINOTHAN MANOHARAN, Department of Physics & School of Engineering and Applied Sciences, Harvard University, DAVID A. WEITZ COLLABORATION — In droplet-based microfluidics, one of the essential techniques is controlled addition of desired materials into the droplets. This is best achieved through the coalescence of pairs of droplets, and therefore various methods of coalescence have been developed over the last decade. However, the coalescence of two different droplets made independently in different devices still remains a challenging problem, primarily because it is difficult to synchronize the reinjection of the different droplets before their coalescence. In addition, typical coalescers require some specific conditions such as uniform droplet-droplet distances and constant flow rate, which hinders the flexible use of coalescers in practical applications. Here we present a straightforward method for synchronizing reinjection of two kinds of droplets and coalescing them. We employ a home-made emulsion collector operated by hydrostatic pressure to reinject droplets into a device, where two kinds of droplets are driven into two opposing T-junction alternatively and then pairs of droplets are merged at the new coalescer proposed here. We use the technique to create droplets with a controlled number of colloidal particles inside, so that we can observe their self-assembly into a cluster.

12:27PM W50.00007 Probing cell mechanical properties with microfluidic devices, AMY ROWAT, University of California, Los Angeles — Exploiting flow on the micron-scale is emerging as a method to probe cell mechanical properties with 10-1000x advances in throughput over existing technologies. The mechanical properties of cells and the cell nucleus are implicated in a wide range of biological contexts: for example, the ability of white blood cells to deform is central to immune response; and malignant cells show decreased stiffness compared to benign cells. We recently developed a microfluidic device to probe cell and nucleus mechanical properties: cells are forced to deform through a narrow constrictions in response to an applied pressure; flowing cells through a series of constrictions enables us to probe the ability of hundreds of cells to deform and relax during flow. By tuning the constriction width so it is narrower than the width of the cell nucleus, we can specifically probe the effects of nuclear physical properties on whole cell deformability. We show that the nucleus is the rate-limiting step in cell passage: inducing a change in its shape to a multilobed structure results in cells that transit more quickly; increased levels of lamin A, a nuclear protein that is key for nuclear shape and mechanical stability, impairs the passage of cells through constrictions. We are currently developing a new class of microfluidic devices to simultaneously probe the deformability of hundreds of cell samples in parallel. Using the same soft lithography techniques, membranes are fabricated to have well-defined pore distribution, width, length, and tortuosity. We design the membranes to interface with a multiwell plate, enabling simultaneous measurement of hundreds of different samples. Given the wide spectrum of diseases where altered cell and nucleus mechanical properties are implicated, such a platform has great potential, for example, to screen cells based on their mechanical phenotype against a library of drugs.

1:03PM W50.00008 Droplet Microfluidics for Virus Discovery , ASSAF ROTEM, Department of Physics and SEAS Harvard University, SHELLEY COCKRELL, Department of Biological Sciences University of Pittsburgh, MIRA GUO, Department of Physics and SEAS Harvard University, JAMES PIPAS, Department of Biological Sciences University of Pittsburgh, DAVID WEITZ, Department of Physics and SEAS Harvard University, WEITZ LAB TEAM, PIPAS LAB TEAM — The ability to detect, isolate, and characterize an infectious agent is important for diagnosing and curing infectious diseases. Detecting new viral diseases is a challenge because the number of virus particles is often low and/or localized to a small subset of cells. Even if a new virus is detected, it is difficult to isolate it from clinical or environmental samples where multiple viruses are present each with very different properties. Isolation is crucial for whole genome sequencing because reconstructing a genome from fragments of many different genomes is practically impossible. We present a Droplet Microfluidics platform that can detect, isolate and sequence single viral genomes from complex samples containing mixtures of many viruses. We use metagenomic information about the sample of mixed viruses to select a short genomic sequence whose genome we are interested in characterizing. We then encapsulate single virions from the same sample in picoliter volume droplets and screen for successful PCR amplification of the sequence of interest. The selected drops are pooled and their contents sequenced to reconstruct the genome of interest. This method provides a general tool for detecting, isolating and sequencing genetic elements in clinical and environmental samples.

1:15PM W50.00009 Creating 3D chemical gradients with self-folding microfluidic networks , MUSTAPHA JAMAL, YEVGENIY KALININ, AASIYEH ZARAFSHAR, DAVID GRACIAS, Chemical and Biomolecular Engineering, Johns Hopkins University — We describe the reversible self-folding of polymeric films into intricate three-dimensional (3D) microfluidic networks and investigate their utility as bio-inspired synthetic vasculature for in vitro tissue culture models. Our fabrication methodology relies on patterning of channels inside the films at the planar microfabrication stage followed by programmable self-folding of the two-dimensional patterned structures. Here self-folding action is enabled by stress gradients which develop in the films due to differential ultraviolet cross-linking and subsequent solvent conditioning. We achieved wafer-scale assembly of micropatterned geometries including helices, polyhedra and corrugated sheets. To demonstrate utility of such self-folded microfluidic devices we present localized chemical delivery of biochemicals in 3D to discrete regions of cells cultured on the curved self-assembled surfaces and in a thick, surrounding hydrogel. We believe that the devices can be used to mimic such natural self-assembled systems as leaves and tissues. Reference: M. Jamal et al., Nature Communications (2011; in press).

1:27PM W50.00010 Control of Mass Transport and Chemical Reaction Kinetics in Ultrasmall Volumes , CHARLES COLLIER, ORNL — This talk will describe means for triggering chemical reactions for studying reaction kinetics under extreme confinement with sub-millisecond temporal resolution, including on-demand generation and fusion of femtoliter (10^{-15} L) volume water-in-oil droplets, and triggering reactions in femtoliter chambers microfabricated in poly(dimethylsiloxane) (PDMS). We demonstrated a reversible chemical toggle switch, which lays the groundwork for exploring more complex chemical and biochemical reaction sequences triggered and monitored in real time in discrete ultrasmall reactors, such as sequential and coupled enzymatic reactions. We are also developing methods to vary confinement and macromolecular crowding in ultrasmall, water-in-oil droplets and chambers micromolded in PDMS as biomimetic reaction vessels containing minimal synthetic gene circuits, in order to better understand how confinement, reduced dimensionality and macromolecular crowding affect molecular mechanisms involved in the operation and regulation of genetic circuits in living cells.

1:39PM W50.00011 Thin Polymer Films as Microvalves in Microfluidic Devices , CLEMENCE VERGNE, FABRICE MONTI, PATRICK TABELING, UMR 7083 CNRS ESPCI, YVETTE TRAN, LUCIE DEVYS, UMR 7615 CNRS ESPCI, MMN TEAM, PPMD TEAM — We report on a novel technology allowing the integration of microvalves and micropumps in lab-on-a-chips made of either soft or hard materials. The approach is based on the grafting of responsive hydrogels onto the microchannel walls. These gels undergo large volume variations by absorbing or expelling water when subjected to external stimuli (here, temperature is used as the stimulus). The hydrogel thin films we study here are chemical polymer networks that are covalently bound to the surface. The first step of the elaboration of that valves is the development of the surface-attached hydrogel thin films. The objective is to obtain hydrogel films with a wide range of thicknesses. The second step is the completion of the microfluidic system by bonding a channel on the active surface. The polymer used is thermoresponsive, at room temperature the swollen gel forms a thick layer, measuring typically several micrometers. When the system is heated above the LCST (Low Critical Solution Temperature), the gel collapses, forming a submicrometric film. In this work we introduce two different applications. In the first situation, the gel layer constitutes a variable resistance. In the second situation the polymer entirely closes the channel after swelling, thus forming a valve.

1:51PM W50.00012 Nanofluidic Transistor Circuits¹ , HSUEH-CHIA CHANG, LI-JING CHENG, YU YAN, ZDENEK SLOUKA, SATYAJYOTI SENAPATI, University of Notre Dame — Non-equilibrium ion/fluid transport physics across on-chip membranes/nanopores is used to construct rectifying, hysteretic, oscillatory, excitatory and inhibitory nanofluidic elements. Analogs to linear resistors, capacitors, inductors and constant-phase elements were reported earlier (Chang and Yossifon, BMF 2009). Nonlinear rectifier is designed by introducing intra-membrane conductivity gradient and by asymmetric external depletion with a reverse rectification (Yossifon and Chang, PRL, PRE, Europhys Lett 2009-2011). Gating phenomenon is introduced by functionalizing polyelectrolytes whose conformation is field/pH sensitive (Wang, Chang and Zhu, Macromolecules 2010). Surface ion depletion can drive Rubinstein's microvortex instability (Chang, Yossifon and Demekhin, Annual Rev of Fluid Mech, 2012) or Onsager-Wien's water dissociation phenomenon, leading to two distinct overlimiting I-V features. Bipolar membranes exhibit an S-hysteresis due to water dissociation (Cheng and Chang, BMF 2011). Coupling the hysteretic diode with some linear elements result in autonomous ion current oscillations, which undergo classical transitions to chaos. Our integrated nanofluidic circuits are used for molecular sensing, protein separation/concentration, electrospray etc.

2:03PM W50.00013 The Lab-on-a-Disc: Miniature Counterpart to the Lab-on-a-CD for Driving Chip-Based Microcentrifugation , LESLIE YEO, NICK GLASS, RICHARD SHILTON, PEGGY CHAN, JAMES FRIEND, Micro/Nanophysics Research Laboratory, RMIT University — The Lab-on-a-CD concept has opened up the powerful possibility of carrying out a range of microfluidic operations simply by using a compact disc (CD) player to spin a disc on which microchannels are fabricated. Nevertheless, the bulk rotation of the entire CD structure is cumbersome, expensive and unreliable - the antithesis of microfluidic philosophy. Fluid transfer on and off the chip can also be difficult. We have instead developed a miniaturized centrifugal microfluidic platform for lab-on-a-chip applications that employs surface acoustic waves to drive the rotation of a 10 mm SU-8 disc on which microfluidic structures are patterned. Unlike its macroscopic Lab-on-a-CD counterpart, the Lab-on-a-Disc does not require moving parts, and is inexpensive, disposable, and significantly smaller both in terms of the disc itself and the portable palmtop battery-operated circuit used to power the chip-sized device. In the first proof of concept, we show the capability of the Lab-on-a-Disc platform to drive capillary-based valving, mixing and size-based concentration/separation of aqueous particle suspensions in microchannels on the disc. To the best of our knowledge, the miniature Lab-on-a-Disc concept is the first microcentrifugation platform small enough to comprise a handheld device.

11:15AM W52.00001 Capillary rise between exible walls¹ , JOSÉ BICO, THOMAS CAMBAU, ETIENNE REYSSAT, PMMH-ESPCI — We report experimental work on capillary rise of a liquid in a cell formed by parallel plates, one of which is flexible. We show that above a critical width, the cell collapses under the negative capillary pressure in the liquid. This collapse allows the liquid to rise virtually without limit between the plates. The height of the rising front is found to increase with time as $t^{1/3}$, a characteristic of capillary imbibition in a wedge.

¹funding: ANR MecaWet-Paris 7 University-CNRS-ESPCI

11:27AM W52.00002 Motion of a rigid sphere through an elastic tube , THOMAS CAMBAU, JOSE BICO, ETIENNE REYSSAT, PMMH ESPCI PARISTECH — The transport of soft objects through small rigid channels is a common problem in the biological world : red blood cells are deformed when passing through small capillaries and polymer coils can make their way through minute pores. We study the opposite model problem of a rigid sphere moving in a narrower elastic tube. Geometry, mechanical properties of the tube and friction or lubrication conditions determine the dynamics of the entrapped sphere. We present experimental results on this problem, together with scaling law analysis.

11:39AM W52.00003 Equilibrium and stability of an elastic meniscus¹ , MARCO RIVETTI, ARNAUD ANTKOWIAK, Institut Jean le Rond d'Alembert, UPMC & CNRS — A liquid-air interface touching a solid wall gives rise to a liquid meniscus, whose shape has been well known for two centuries and results from the balance between capillarity and gravity. We investigate the case in which a portion of the liquid interface has been replaced by a soft strip, adding the elastic ingredient to this physical problem. We experimentally study the equilibrium configurations, from small to high non-linear deformations, and we compare to a 2D theoretical model. Stability of the system involving 3D corrections is also addressed.

11:51AM W52.00004 Capillary-Induced Self-Organization of Soft Pillar Arrays into Moiré Patterns by Dynamic Feedback Process , SUNG KANG, NING WU, ALISON GRINTHAL, JOANNA AIZENBERG, School of Engineering and Applied Sciences, Harvard University — We report a self-organized pattern formation of polymer nanopillar arrays by dynamic feedback: two nanopillar arrays collectively structure a sandwiched liquid and pattern the menisci, which bend the pillars into Moiré patterns as it evaporates. Like the conventional Moiré phenomenon, the patterns are deterministic and tunable by mismatch angle, yet additional behaviors—chirality from achiral starting motifs and preservation of the patterns after the surfaces are separated—appear from the feedback process. Patterning menisci based on this mechanism provides a simple, scalable approach for making a series of complex, long-range-ordered structures. Reference: Sung H. Kang, Ning Wu, Alison Grinthal, and Joanna Aizenberg, Phys. Rev. Lett., **107**, 177802 (2011).

12:03PM W52.00005 Study of waving of grass using a soap film model , RAVI SINGH, Brown University, MAHESH BANDI, Okinawa Institute of Science and Technology, L. MAHADEVAN, Harvard University, AMALA MAHADEVAN, Woods Hole Oceanographic Institution, SHREYAS MANDRE, Brown University — Wind blowing over a grass field incites synchronized response from the grass blades, which appear as waves. This effect is called Mo-nami in a terrestrial setting, while in an aquatic setting it is termed as Ho-nami. We use a combination of experimental observations, numerical simulations and theoretical analysis to understand this effect. The experiment is conducted in two-dimensional realization of these phenomena in a gravity driven soap film tunnel. Nylon filaments attached to the boundaries of the soap film play the role of the grass. We provide a preliminary characterization of this analog model for the synchronized oscillations of grass.

12:15PM W52.00006 Direct measurements of flow and deformation of a free reed , PETER BUCHAK, University of Massachusetts Amherst, JOHN BUSH, Massachusetts Institute of Technology — The free reed, responsible for producing sound in a family of air-driven musical instruments, is an example of a coupled fluid-structure system engineered to vibrate efficiently at a controllable frequency. In Western free reed instruments, a flexible metal plate is clamped at one end above a slot cut into a rigid support plate. This geometry allows a constant driving pressure to produce and sustain large-amplitude vibrations. The mechanism behind this has been discussed by several investigators. However, it has yet to be verified experimentally with direct measurements of the flow speed. We present simultaneous measurements of the reed motion and the flow speed in the downstream jet, which enable characterization of the relationship between the finite-amplitude deformation of the reed and the flow.

12:27PM W52.00007 Control and Manipulation of Fluid Flow Using Elastic Deformations , BEHROUZ TAVAKOL, DOUGLAS HOLMES, Virginia Tech, GUILLAUME FROELICHER, HOWARD STONE, Princeton University — In this work, we utilize elastic deformations within a flexible microfluidic device via mechanical actuation to control and direct fluid flow. The device consists of a microchannel with a flexible arch prepared by buckling a thin elastic film. The deflection of the arch can be predicted and controlled using the classical theory of Euler buckling. We controlled the fluid flow rate by coupling the elastic deformation of the arch to the gap within the microchannel, and matched these experimental results analytically with a perturbation of lubrication theory and with computational simulations. These results illustrate an experimental design paradigm for the preparation of portable microchannels for chemical mixing, self-healing, and in situ diagnostics.

12:39PM W52.00008 Curling paper , ETIENNE REYSSAT, PMMH-ESPCI, L. MAHADEVAN, Harvard University — As many soft materials, paper is mechanically sensitive to humidity. Owing to its hygroscopic cellulose-based structure, it is known to wrinkle when subject to humidity fluctuations. Here, we present experimental results on the more extreme deformations observed when a sheet of tracing paper is put on a bath of water. After contact with the liquid surface, water diffuses into the hygroscopic material from below and induces differential swelling, resulting in the curling of the paper. Within seconds, a spectacular roll-up motion follows. We explain the observed shapes and curling dynamics.

12:51PM W52.00009 Walking and jumping spores , PHILIPPE MARMOTTANT, University of Grenoble and CNRS, Lab. Interdisciplinaire de Physique, France — The Equisetum plants, more commonly called “horsetail,” emit 50-microns spores that are spherical in shape and present four hygroscopic arms. Under high humidity, the arms are retracted. But under lower humidity, less than 70%, the four arms deploy beautifully. With time-lapse image recordings, we show that under repeated cycles of dry and high humidity, the spores behave as random walkers, since they move by about their size in a different direction at every cycle. The process is apparently stochastic because of the complex shape of the arms and hysteretic friction of the arms on the ground. For some spores, a decrease in humidity level results in very fast jumps, the spores taking off at a typical velocity of a meter per second, as recorded on high-speed camera. With these jumps, they reach centimetric elevations, much larger than their size. The physical mechanism at the root of these “Levy-flight” jumps is still under investigation. The walking and jumping phenomena thus provide motility, which we believe is helpful for the understanding of the biological dispersion of the spores. It could also bring biomimetic inspiration to engineer new motile elastic structures.

1:03PM W52.00010 Mechanic instabilities of swelling gels , MARTINE BEN AMAR, JULIEN DERVAUX, Ecole Normale Supérieure — While the study of gels takes undoubtedly its roots within the field of physico-chemistry, the interest for gels has flourished and they progressively became an important object in the study of the mechanics of polymeric materials and volumetric growth, rising some fascinating problems, some of them remaining unsolved. Because gels are multiphase objects, their study represents an important step in the understanding of the mechanics of complex soft matter as well as for the process of shape generation in biological bodies. I will present here experiments and models of swelling gels mainly in the cylindrical geometry which mimic various growth instabilities from tumors up to the morphogenesis of tubular organs.

1:15PM W52.00011 Patterns formed by swelling-induced folding of films¹, SACHIN VELANKAR, VICTORIA LAI, University of Pittsburgh, RICHARD VAIA, Wright Patterson Air Force Base — The solvent swelling of a thin polymer film attached to a rigid substrate is known to induce a creasing pattern on the free surface of the film. Here we show that if the film is weakly attached to the substrate, the swelling-induced compressive stress nucleates buckle delamination of the film from the substrate. Surprisingly, the buckles do not have a sinusoidal profile, instead, the film near the delamination buckles slides towards the buckles causing growth of sharp folds of high aspect ratio. The folds persist even after the solvent evaporates. Such fold formation depends on the size of the region of the film exposed to solvent. A very small region of exposure (realized by placing a small drop of solvent on the film) does not induce delamination. Remarkably, with moderate sized drops, the delamination and folding occurs around the perimeter of the drop, thus culminating in a corral with tall walls. We quantify the parameters (drop volume, film thickness) which demarcate the transitions between no fold formation, corral formation, and multiple fold formation.

1:27PM W52.00012 Swelling-Driven Shaping of Thermally Responsive Photo-Patterned Gel Sheets, MYUNGHWAN BYUN, JUNGWOOK KIM, RYAN HAYWARD, Polymer Science and Engineering Department, University of Massachusetts Amherst, JAMES HANNA, CHRISTIAN SANTANGELO, Physics Department, University of Massachusetts Amherst — Swelling-mediated shaping of patterned non-Euclidean plates offers a powerful route to design and engineer complex 3-D structures, with possible applications in biomedicine, robotics, and tunable micro-optics. We have studied the behavior of poly(N-isopropyl acrylamide) (PNIPAm) copolymers containing pendent benzophenone units that allow the degree of crosslinking to be tuned by varying the dose of ultraviolet light. A halftone (gray) gel lithography approach, wherein two photomasks enable patterning of highly-crosslinked domains within a lightly-crosslinked matrix, is shown to provide effectively continuous variations in swelling in truly two-dimensional patterns. We show how this technique can be harnessed to form complex, reversibly actuating, 3-D structures through patterned growth.

1:39PM W52.00013 Dynamical Actuation and Pattern Formation with Local Swelling in Microgels¹, HOWON LEE, KIN HUNG FUNG, NICHOLAS FANG, MIT — In this invited talk, we present a set of study on swelling-induced actuation and pattern formation in hydrogels of three dimensional microstructures. For example, rapid actuation of a micro hydrogel device is observed by exploiting swelling-induced snap-buckling. Utilizing its fast actuation speed, the device can even jump by itself upon wetting. It is demonstrated that elastic energy is effectively stored and quickly released from the device by incorporating elastic instability. In our experiment, the micro device could generate a snapping motion within 12 milliseconds, releasing power at a rate of 34 mW/g. We also captured the evolution circumferential buckling of tubular shaped microgels. Inhomogeneous stress develops as gel swells under mechanical constraints, which gives rise to buckling instability. A simple analytical model is developed using elastic energy to predict stability and post-buckling patterns upon swelling. Our experiment demonstrates that circumferential buckling of desired mode can be created in a prescribed manner. Our study on the mechanics of three-dimensionally microstructured gels might provide new insights for in morphogenesis in tissue engineering, and provide new gateways in many emerging fields such as soft robotics and tunable matamaterials.

1:51PM W52.00014 Separating Viscoelasticity and Poroelasticity of Gels with Different Length and Time Scales, ANIRUDH MOHAN, XUANHE ZHAO, Soft Active Materials Laboratory, Duke University, SOFT ACTIVE MATERIALS LABORATORY, DUKE UNIVERSITY TEAM — Viscoelasticity and poroelasticity commonly coexist in polymer gels. We propose a method capable of separating the viscoelasticity and poroelasticity of gels in various mechanical tests. The viscoelastic characteristic times and the poroelastic diffusivities of a gel can define intrinsic material length scales of the gel. The experimental setup can give sample length scales, over which the solvent migrates in the gel. By setting the sample lengths to be much larger or smaller than the material lengths, the viscoelasticity and poroelasticity of the gel will manifest at different time scales in a test. Therefore, the viscoelastic and poroelastic properties of the gel can be probed separately at different time scales of the test.

2:03PM W52.00015 A constitutive theory for visco-hyperelastic gels, SHAWN CHESTER, Lawrence Livermore National Laboratory — Many gels operate in chemically saturated environments in a variety of applications. Most constitutive theories for gels are formulated using large deformation hyperelasticity coupled with fluid transport. However, in most cases the mechanical response of such gels show hysteresis and other dissipative effects which are not accounted for in present constitutive theories. We have recently developed a three dimensional continuum level theory to describe the coupled fluid permeation and large deformation response of visco-hyperelastic materials. In this work, we apply our theory and numerical simulation capability to study the indentation response among others of visco-hyperelastic gels.

Session W53 GSNP: Focus Session: Common Features of Soft Materials: Polymers, Colloids and Granular Media I 153B

11:15AM W53.00001 Athermal Jamming Vs Thermalized Glassiness in a Simple Model of Soft-Core Interacting Particles¹, STEPHEN TEITEL, University of Rochester, PETER OLSSON, Umeå University — Numerical simulations of soft-core frictionless disks in two dimensions are carried out to study shear viscosity η and pressure p of a simple model liquid, as a function of thermal temperature T , packing fraction ϕ , and uniform applied shear strain rate $\dot{\gamma}$. We find that viscosity in the athermal hard-core limit, $\lim_{\dot{\gamma} \rightarrow 0} [\lim_{T \rightarrow 0} \eta]$, is singularly disconnected from viscosity in the hard-core thermal limit, $\lim_{T \rightarrow 0} [\lim_{\dot{\gamma} \rightarrow 0} \eta]$, demonstrating that thermal glassy behavior is not governed by the athermal jamming critical point, “point J”.

¹Work supported by Department of Energy Grant No. DE-FG02-06ER46298 and Swedish Research Council Grant No. 2010-3725. Simulations were performed on resources provided by the Swedish National Infrastructure for Computing (SNIC) at PDC and HPC2N.

11:27AM W53.00002 Spontaneous formation of permanent shear bands in a mesoscopic model of flowing disordered matter¹, KIRSTEN MARTENS, LYDÉRIC BOCQUET, LPMCn, Université Lyon 1, JEAN-LOUIS BARRAT, LiPhy, Université Joseph Fourier, Grenoble — In this presentation we propose a coherent scenario of the formation of permanent shear bands in the flow of yield stress materials. Within a minimalistic mesoscopic model we investigate the spatial organisation of plasticity. The most important parameter is the typical time needed to regain the original structure after a local rearrangement. In agreement with a recent mean field study [Coussot *et al.*, *Eur. Phys. J. E*, 2010, **33**, 183] we observe a spontaneous formation of permanent shear bands, when this restructuring time is large compared to the typical stress release time in a rearrangement. This heterogeneous flow behaviour is different in nature from the transient dynamical heterogeneities that one observes in the small shear rate limit in flow without shear-banding [Martens *et al.*, *Phys. Rev. Lett.*, 2011, **106**, 156001]. We analyse the dependence of the shear bands on system size, shear rate and restructuring time. Further we rationalise the scenario within a mean field version of the model, that explains the instability of the homogeneous flow below a critical shear rate. Our study therefore strongly supports the idea that the characteristic time scales involved in the local dynamics are at the physical origin of permanent shear bands.

¹ANR - SYSCOMM, Marie Curie FP7-PEOPLE-2009-IEF

11:39AM W53.00003 Creep and critical scaling in random spring networks¹, BRIAN TIGHE, Delft University of Technology — Random networks of springs are a minimal model for physical, biological, and engineered materials ranging from foams and emulsions to biopolymer and bar-joint networks. Near the central force isostatic point, the creep response of damped networks is intimately tied to the presence or absence of floppy motions in the long time limit. We show that nearly isostatic networks display dynamical critical scaling, and that this scaling connects viscous flow and elastic deformation via a critical creep regime. We give scaling arguments for the critical exponents and confirm our predictions with numerics.

¹Supported by the Dutch Organization for Scientific Research (NWO).

11:51AM W53.00004 Rheology of particle assemblies close to a jamming transition, CLAUD HEUSSINGER, University of Goettingen, Germany — The jamming paradigm aims at providing a unified view for the elastic and rheological properties of materials as different as foams, emulsions, suspensions or granular media. Structurally, these systems can all be viewed as dense assemblies of particles, and the particle volume fraction ϕ plays the role of the coupling constant that tunes the distance to the jamming transition. Enhanced experimental techniques allow to visualize the dynamics of these systems on the level of the individual particles, generating huge amount of information. Several interesting, and partially conflicting, results have emerged. It therefore seems necessary to ask in how far the experimental results reveal genuine aspects of a universal jamming transition, or just system-specific properties that depend on microscopic details, the driving mechanism or the preparation protocol. By comparing different computational models we will discuss the question of universality on the macroscopic level of rheological observables as well as on the microscopic level of single particle trajectories and collective particle motion.

12:03PM W53.00005 Inhomogeneous structure and position-dependent dynamics in complex fluids, JAMES CARMER, Department of Chemical Engineering, University of Texas at Austin, GAURAV GOEL, Department of Chemical Engineering, Indian Institute of Technology, Delhi, JEFFREY ERRINGTON, Department of Chemical and Biological Engineering, University at Buffalo, THOMAS TRUSKETT, Department of Chemical Engineering, University of Texas at Austin — We present computer simulation results of model complex fluids, quantifying how inhomogeneous structuring and dynamics of particles can be tuned through interactions. We first illustrate how a tracer particle's interactions can be tuned to significantly modify its long-time diffusivity. We use a recently proposed propagator-based formalism to address how this enhancement can be understood in terms of the local dynamics of neighboring particles. We then discuss how these results compare to related behaviors of model confined colloidal and molecular fluids.

12:15PM W53.00006 Demonstration of Secondary Currents in the Pressure-Driven Flow of a Concentrated Suspension Through a Square Conduit, ARUN RAMCHANDRAN, ADAM ZREHEN, University of Toronto — It has been known for several decades now that the pressure-driven flow of polymer melts in non-axisymmetric conduits is not unidirectional; the main flow through the channel is accompanied by secondary currents, whose origin can be attributed to second normal stress differences. However, only recently was it realized [Ramachandran and Leighton, *J. Fluid Mech.* (2008)] that the same may be true for concentrated suspensions, which, upon shearing, exhibit strong second normal stress differences. This work confirms the existence of these secondary flows by carrying out pressure-driven suspension flow experiments through a square (non-axisymmetric) duct. By tracking the motion of a thin stream of a contrastingly-dyed suspension introduced into the bulk flow of another, it is demonstrated that the suspension flows out of the sidewalls of the geometry towards the corners of the square cross-section, and then flows towards the center. This is found to be qualitatively consistent with calculations based on the suspension balance model of Nott and Brady [*J. Fluid Mech.* (1994)]. Secondary currents have been predicted to be the dominant mechanism determining particle distribution in suspension flows, and this work lends support to that idea.

12:27PM W53.00007 Understanding entangled polymers: What we can learn from athermal chain packings¹, NIKOS KARAYIANNIS, Institute of Optoelectronics and Microsystems (ISOM) and ETSII, Universidad Politécnica de Madrid (UPM) — The study of random and ordered packings (from atoms and colloidal particles to sand grains) has been the focus of extensive research. This is not surprising since an understanding of the mechanisms that control morphology and packing is the key to the design and synthesis of novel “smart” materials and functionalities. In particular, the study of packings of chain molecules presents challenges but also insights which are absent in monatomic systems and further allows for a direction comparison with them. In this contribution we give an overview of our work on very dense and nearly jammed packings of athermal polymers. We show that chain molecules can be as efficiently and as densely packed as monatomic analogs up to the same maximally random jammed state. We also show that an exact correspondence can be established between the statistical-mechanical ensembles of packings of monatomic, and chain systems, which yields insights on the universality of jamming. By studying the effect of concentration on polymer size and on the underlying network of topological hindrances we precisely identify the distinct universal scaling regimes and the corresponding exponents. An unsuspected connection, valid from dilute up to very dense assemblies, is established between knots (of intermolecular origin) and entanglements (intermolecular constraints). We finally show that, against expectations, entropy-driven crystallization can occur in dense systems of athermal polymers once a critical volume fraction is reached. Such phase transition is driven by the increase in translational entropy: ordered sites exhibit enhanced mobility as their local free volume becomes more spherical and symmetric. Incipient nuclei develop well defined, stack-faulted layered crystal morphologies with a single stacking direction. The ordering transition and the resulting complex morphologies are analyzed, highlighting similarities and differences with respect to monatomic crystallization.

1:03PM W53.00008 Sudden Chain Energy Transfer Events in Vibrated Granular Media , NICOLÁS

RIVAS, University of Twente, SUOMI PONCE, RODRIGO SOTO, PATRICIO CORDERO, NICOLÁS MUJICA, Departamento de Física, FCFM, Universidad de Chile, Santiago, Chile, DINO RISSO, Departamento de Física, Universidad del Bío-Bío, Concepción, Chile, BASILLE GALLET, Laboratoire de Physique Statistique, CNRS, Ecole Normale Supérieure, Paris, France — In a mixture of two species of grains of equal size but different mass, placed in a vertically vibrated shallow box, there is spontaneous segregation. Once the system is at least partly segregated and clusters of the heavy particles have formed, there are sudden peaks of the horizontal kinetic energy of the heavy particles, that is otherwise small. Together with the energy peaks the clusters rapidly expand and the segregation is partially lost. The process repeats once segregation has taken place again, either randomly or with some regularity in time depending on the experimental or numerical parameters. An explanation for these events is provided based on the existence of a fixed point for an isolated particle bouncing with only vertical motion. The horizontal energy peaks occur when the energy stored in the vertical motion is partly transferred into horizontal energy through a chain reaction of collisions between heavy particles.

1:15PM W53.00009 Equation of state and jamming density for equivalent bi-, tri- and poly-disperse, smooth, elastic sphere systems¹ , VITALIY OGARKO, STEFAN LUDING, University of Twente — We study binary, ternary and polydisperse mixtures of hard particle fluids as models for granular matter, colloids and other soft matter. Size ratios between 1 and 100 are studied for different size distributions. Simulation results are compared with previously found analytical equations of state by looking at the compressibility factor, Z , and agreement is found with much better than 1% deviation in the fluid regime. A slightly improved empirical correction to Z is proposed. When the density is further increased, the behavior of Z changes and there is a close relationship between many-component mixtures and their two- and three-component equivalents (where our contribution is to define the term “equivalent”). We determine the size ratios for which the liquid-solid transition exhibits crystalline, amorphous or mixed system structure. Near the jamming density, Z is independent of the size distribution and follows a -1 power law as function of the difference from the jamming density. In this limit, Z depends only on one free parameter, the jamming density itself, as reported for several different size distributions with a wide range of widths.

1:27PM W53.00010 Recovery of polymer glasses from mechanical perturbation , ANTON SMESSAERT, JÖRG RÖTTLER, The University of British Columbia — There is a longstanding debate about the nature and extent of mechanical rejuvenation in aging glasses and most related studies have concentrated on the impact of aging during plastic deformation. Here we study the time period after nonlinear creep where the glass recovers, using molecular dynamics simulations of a bead-spring model for a wide range of stress amplitudes and glass ages. We compute α -relaxation times as well as several quantities that characterize structural changes. From an analysis of the recovery paths we find a transition from memory effects to mechanical rejuvenation that is controlled by the total strain and not the stress amplitude. Although strong mechanical perturbation can make the dynamics appear very similar to that of a freshly quenched glass, various measures of short range order as well as inherent structure energies reveal systematic differences in the underlying thermodynamic state.

1:39PM W53.00011 Spatiotemporal stress/strain correlations in a quasi-2D jammed emulsion , KENNETH DESMOND, ERIC R. WEEKS, Emory University — We flow quasi-2D emulsions in a flow geometry analogous to pure shear to better understand the microscopic events within jammed materials during the straining process. Our quasi-2D system serves as an experimental model system of jamming and consists of oil-in-water emulsion droplets confined between two parallel plates. Using a technique we have developed, we can determine the forces between pairs of droplets in contact based on each droplet's deformation. By imaging the motion and deformation of the droplets during the flowing process, we quantify the microscopic events using spatiotemporal correlations in strain and stress. We study these spatiotemporal correlations at various droplet concentrations to understand how the microscopic events change as we approach the jamming point.

1:51PM W53.00012 Low- k behavior in Structure Factor and Compressibility Factor for Monodisperse and Bidisperse Packings of Frictionless Spheres , JAIME BOHORQUEZ-BALLEN, LEONARDO SILBERT, Southern Illinois University - Carbondale — One particular structural signature of jamming transition has emerged in studies of large systems: *hyperuniformity*, which is the suppression of the long wavelength density fluctuations. Also, it has been observed an unusual linear dependence ($S(k) \sim k$) of the structure factor in the low k limit, in monodisperse systems. The small wavenumber region of the static structure factor $S(k)$ for monodisperse systems and the compressibility factor $\theta(k)$ for bidisperse mixtures, are investigated for jammed packings of frictionless spheres with Hooke and Hertz force model, using a high precision data analysis. We have found that the zero-wavenumber intercept $S(k=0)$ and $\theta(k=0)$, as a function of the pressure, are non-zero constant, revealing a finite compressibility. This behavior is relatively insensitive to the force model but shows a dependence on the bidispersity. We have studied also zero-temperature Lennard-Jones glasses which exhibit a finite compressibility that depend weakly on the density of the glass.

2:03PM W53.00013 Jamming and Unjamming of the Rigid Amorphous Fraction , PEGGY CEBE, QIAN MA, Tufts University, GEORGI GEORGIEV, Assumption College — Semicrystalline polymers obey a three-phase model comprising crystalline, mobile amorphous (MAF), and rigid amorphous fractions (RAF) as an interphase. Using quasi-isothermal temperature modulated differential scanning calorimetry (QI-TMDSC), we investigate the formation behavior of these fractions in poly(trimethylene terephthalate), PTT. PTT was quasi-isothermally cooled step-wise from the melt which causes its crystalline fraction to be fixed below 451K, and RAF is determined as a function of temperature. For PTT, most of the RAF vitrifies between 451K and T_g step-by-step during QI cooling. With lamellar crystals acting as topological constraints, a model is proposed in which the vitrification and devitrification of RAF are interpreted using the concepts of “jamming” and “unjamming.” Constraints of the crystal surfaces reduce the mobility of the highly entangled polymer chains attached to the lamellae, and the layers which constitute RAF are formed one after another in the manner of successive jamming. In this way, several features of the RAF temperature dependence are explained for the first time, with implications in other research areas, such as topological constraints exerted on the polymer melt through effects of inclusions in polymer-based nanocomposites.

For support of this research, the authors thank the NSF, Polymers Program of the Division of Materials Research through DMR-0602473, and the MRI Program under DMR-0520655 for thermal analysis instrumentation. A portion of this work was conducted at the BNL, National Synchrotron Light Source, supported by the DoE. G. Georgiev thanks Assumption College for continuous research support.

Thursday, March 1, 2012 2:30PM - 5:42PM –

Session X1 GIMS: Focus Session: Advances in Scanned Probe Microscopy IV: New Instrumentation & Techniques 203

2:30PM X1.00001 ezAFM: A low cost Atomic Force Microscope(AFM) , UMIT CELIK, KUBRA CELIK, Department of Material Science and Engineering, Istanbul Technical University, HUSNU ASLAN, IHSAN KEHRIBAR, Faculty of Engineering & Natural Sciences, Sabanci University, MUNIR DEDE, NanoMagnetics Instruments Ltd., H. OZGUR OZER, Department of Physics Engineering, Istanbul Technical University, AHMET ORAL, Faculty of Engineering & Natural Sciences, Sabanci University — A low cost AFM, ezAFM is developed for educational purposes as well as research. Optical beam deflection method is used to measure the deflection of cantilever. ezAFM scanner is built using voice coil motors (VCM) with $\sim 50 \times 50 \times 6 \mu\text{m}$ scan area. The microscope uses alignment free cantilevers, which minimizes setup times. FPGA based AFM feedback Control electronics is developed. FPGA technology allows us to drive all peripherals in parallel. ezAFM Controller is connected to PC by USB 2.0 interface as well as Wi-Fi. We have achieved $< 5\text{nm}$ lateral and $\sim 0.01\text{nm}$ vertical resolution. ezAFM can image single atomic steps in HOPG and mica. An optical microscope with $< 3 \mu\text{m}$ resolution is also integrated into the system. ezAFM supports different AFM operation modes such as dynamic mode, contact mode, lateral force microscopy. Advanced modes like magnetic force microscopy and electric force microscopy will be implemented later on. The new ezAFM system provides, short learning times for student labs, quick setup and easy to transport for portable applications with the best price/performance ratio. The cost of the system starts from \$15,000, with system performance comparable with the traditional AFM systems.

2:42PM X1.00002 Compact Scanning Tunneling Microscope for Spin Polarization Measurements¹ , SEONG HEON KIM, LEUJEN CHEN, ALEX DE LOZANNE, Department of Physics, The University of Texas at Austin — We have built a low temperature scanning tunneling microscope for spin-polarized studies. An important aspect of our design philosophy is to keep everything small, starting with a one-inch STM body that fits in the UHV bore of a small superconducting solenoid that provides up to 8 Tesla parallel to the tip. This, in turn, makes the liquid helium and liquid nitrogen dewars smaller and leads to a compact UHV chamber. The largest flange in the system is 10 inches in outer diameter. The benefits of a smaller system include lower consumption of cryogenics and a reduced footprint. The STM has been tested from 300K to 77K and has achieved atomic resolution. A test at 4.2K will be done soon. We have imaged cobalt clusters deposited in situ using a simple and compact design for an electron-beam evaporator. We have developed new electronics for z-approach and a novel magnetically-coupled manipulator with an actuated grabber for tip and sample exchange.

¹Supported by NSF DMR-0923231

2:54PM X1.00003 Development of Molecular Beam Epitaxy/Pulsed Laser Deposition/Low Temperature Spin-Polarized Scanning Tunneling Microscopy System¹ , JEONGIHM PAK, WENZHI LIN, KANGKANG WANG, ANDREW FOLEY, TIANJIAO CHEN, YINGHAO LIU, ABHIJIT CHINCHORE, DANIEL BERGMAN, MENG SHI, ARTHUR R. SMITH, Ohio University Nanoscale and Quantum Phenomena Institute — Spin-polarized scanning tunneling microscopy and spectroscopy have shown tremendous abilities to obtain detailed spin information about surfaces down to the atomic scale. In order to take full advantage of this method for studying pristine, as-prepared sample surfaces, we couple an SP-STM system to a sophisticated ultra-high-vacuum growth facility. The hybrid molecular beam epitaxy/pulsed laser deposition/spin-polarized STM system is home-designed and constructed with many unique features. A wide variety of engineered spintronic materials can be grown in the 8 source growth chamber, or using the 9 source laser deposition system. Samples may be heated during growth to as high as 1300 K or cooled using LN₂ to temperatures below 195 K, while being simultaneously probed using reflection high energy electron diffraction. The system is currently configured for nitride systems as well as transition metal or rare earth ultra-thin films. Prepared samples are transferred through a central distribution chamber to the LHe-cooled, spin-polarized STM operating inside an integral superconducting magnet (0-4.5 T). The system is outfitted with magnetic tip preparation. The magnetic field allows us to manipulate the magnetic structure of samples during SP-STM experiments.

3:06PM X1.00004 ABSTRACT WITHDRAWN —

3:18PM X1.00005 A Dual Tip STM for Imaging the Superconducting Phase Difference¹ , ANITA ROYCHOWDHURY, Laboratory for Physical Sciences and Physics Dept., University of Maryland, College Park, M.A. GUBRUD, Department of Physics and Astronomy, University of North Carolina, Chapel Hill, D. SULLIVAN, NASA - Goddard, MICHAEL DREYER, Laboratory for Physical Sciences and Physics Dept., University of Maryland, College Park, J. R. ANDERSON, C.J. LOBB, F.C. WELLSTOOD, Physics Dept., University of Maryland, College Park — We have built a dual tipped millikelvin STM with each tip capable of independently scanning a sample. We will use the STM to measure spatial variations of the gauge-invariant phase difference at the atomic scale. The two tips along with the superconducting sample constitute a SQUID. This configuration is designed to minimize fluctuations in the superconducting phase of one of the tips as it scans the sample, hence inhibiting supercurrent suppression. We are currently developing a technique to fabricate superconducting Niobium tips for use with this system.

¹This project was funded in part by NSF and the Laboratory for Physical Sciences

3:30PM X1.00006 mK-Scanning Probe Microscope(mK-SPM) operating in a Cryogen-Free Dilution Refrigerator at 20mK , MUNIR DEDE, Nanomagnetics Instruments Ltd. Suite 290 266 Banbury Road OX2 7DL. Oxford, UK, OZGUR KARCI, Hacettepe University, Dept. of Nanotechnology and Nanomedicine, Beytepe, 06800, Ankara, Turkey, CHRIS SNELLING, Oxford Instruments plc Tubney Woods, Abingdon, Oxon OX13 5QX, UK, AHMET ORAL, Sabanci University, Faculty of Science and Engineering, Orhanli - Tuzla, 34956, Istanbul, Turkey — Dramatic increase in liquid helium price limits the usage of cryogenic equipment. Dry cryogen-free dilution refrigerators(DR) systems are promising platforms to run mK-Scanning Probe Microscopes(mK-SPM) systems with a number of operating modes: STM, AFM, MFM, EFM, SSRM, PFM, etc. We present the design of a mK-Scanning Probe Microscope (mK-SPM) operating in a cryogen-free DR. An Oxford Instrument cryogen-free DR(Triton DR200) with 200uW cooling power and 7mK base temperature is used for the experiments. A 1W Pulse Tube cryocooler is integrated into the DR. After wiring and attaching the microscope we achieved 20mK base temperature. Piezo driven Stick slip coarse approach mechanism is used to bring the sample in to close proximity of the sample. In these initial results we deliberately did not take any precautions to isolate the pumping lines, attached to the DR and the DR itself. The turbomolecular pump was attached directly to the top plate of the DR. We first tested our mK-SPM in Scanning Tunnelling Microscope (STM) mode as it is the most sensitive of the SPM techniques. An image, using a gold coated $6 \mu\text{m}$ period calibration grating at 20mK, obtained under these rudimentary conditions.

3:42PM X1.00007 Atom-Specific Interaction Quantification and Identification by 3D-SPM

TODD C. SCHWENDEMANN, Southern Connecticut State University, MEHMET Z. BAYKARA, HARRY MONIG, Dept. of Mech. Eng & Mat. Sci., Yale University, MILICA TODOROVIC, Dept. de Física Teórica de la Materia Condensada, JAN GOTZEN, OZHAN UNVERDI, Dept. of Mech. Eng & Mat. Sci., Yale University, RUBEN PEREZ, Dept. de Física Teórica de la Materia Condensada, ERIC I. ALTMAN, Dept. of Chem. & Env. Eng., Yale University, UDO D. SCHWARZ, Dept. of Mech. Eng & Mat. Sci., Yale University — Entire scientific disciplines such as mechanics and chemistry are governed by the interactions between atoms and molecules. On surfaces, forces extending into the vacuum direct the behavior of phenomena such as thin film growth, nanotribology, and surface catalysis. To advance our knowledge of the fundamentals governing these topics, it is desirable to simultaneously map electron densities and quantify force interactions between the surface of interest and a probe with atomic resolution. Using the oxygen-reconstructed copper (100) surface as a model system, we demonstrate that much of this information can be derived from combining three-dimensional atomic force microscopy (3D-AFM) with simultaneous STM. The three-dimensional scanning probe microscopy (3D-SPM) variant resulting from this combination provides complementary information in the various interaction channels recorded. The surface oxide layer of copper (100) features defects and a distinct structure of the Cu and O sublattices that is ideally suited for such model investigations. The analysis of our experimental results allows for the identification of atomic species and defects on the sample surface through the comparison of simultaneously recorded force and current data.

3:54PM X1.00008 Laser Scanning Microscopy for Quantitative Measurement of the Local Microwave-Photonic Properties of Advanced Materials and Devices¹

BEHNOOD GHAMSARI, JACOB TOSADO, MAHITO YAMAMOTO, JINGLEI PING, DANIEL LENSKE, MICHAEL FUHRER, STEVEN ANLAGE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park — We present laser scanning microscopy (LSM) as a non-contact and non-invasive instrumentation technique for quantitative measurement of the local microwave, optoelectronic, and optical properties of advanced materials including superconductors and graphene. Since an LSM setup may be configured in different modes of operation, we will focus on the photoresponse and reflectivity imaging modes. It will be discussed how an LSM, in the photoresponse measurement mode, may be used to image the distribution of rf/microwave currents at the surface of a superconducting device, such as a resonator. In addition, relevant techniques for distinguishing the kinetic and resistive parts of the superconductor's photoresponse as well as imaging its possible anisotropic microwave properties are addressed. With regard to the reflectivity mode, we will present how this method enables precise measurement of the topological features and optical properties of non-opaque samples. As an example, we will show how the thickness of few-layer graphene flakes may be measured by this method.

¹B.G.G and S.M.A would like to acknowledge technical help from Dr. Alexander Zhuravel. This work is, in part, supported by the DOE grant number DESC0004950 and ONR/AppEl, Task D10, through grant number N000140911190.

4:06PM X1.00009 Torsional tapping atomic force microscopy for molecular resolution imaging of soft matter

JAMIE HOBBS, NIC MULLIN, University of Sheffield — Despite considerable advances in image resolution on challenging, soft systems, a method for obtaining molecular resolution on 'real' samples with significant surface roughness has remained elusive. Here we will show that a relatively new technique, torsional tapping AFM (TTAFM), is capable of imaging with resolution down to 3.7 Angstrom on the surface of 'bulk' polymer films [1]. In TTAFM T-shaped cantilevers are driven into torsional oscillation. As the tip is offset from the rotation axis this provides a tapping motion. Due to the high frequency and Q of the oscillation and relatively small increase in spring constant, improved cantilever dynamics and force sensitivity are obtained. As the tip offset from the torsional axis is relatively small (typically 25 microns), the optical lever sensitivity is considerably improved compared to flexural oscillation. Combined these give a reduction in noise floor by a factor of 12 just by changing the cantilever geometry. The ensuing low noise allows the use of ultra-sharp 'whisker' tips with minimal blunting. As the cantilevers remain soft in the flexural axis, the force when imaging with error is also reduced, further protecting the tip. We will show that this combination allows routine imaging of the molecular structure of semicrystalline polymer films, including chain folds, loose loops and tie-chains in polyethylene, and the helical conformation of polypropylene within the crystal, using a standard, commercial AFM.

[1] N Mullin, JK Hobbs, PRL 107, 197801 (2011)

4:18PM X1.00010 Reference system for scanning probe tip fingerprinting¹

ROBERT TURANSKY, Institute of Physics, Slovak Academy of Sciences, JOSEPH BAMIDELE, Dept. of Physics, King's College London, YASUHIRO SUGAWARA, Dept. of Applied Physics, Osaka University, LEV KANTOROVICH, Dept. of Physics, King's College London, IVAN STICH, Institute of Physics, Slovak Academy of Sciences — Knowledge of the chemical structure of the tip asperity in Non-Contact Atomic Force Microscopy (NC-AFM) is crucial as controlled manipulation of atoms and/or molecules on surfaces can only be performed if this information is available. However, a simple and robust protocol for ensuring a specific tip termination has not yet been developed. We propose a procedure for chemical tip fingerprinting and an example of a reference system, the oxygen-terminated Cu(110) surface, that enables one to ensure a specific tip termination with Si, Cu, or O atoms. To follow this up and unambiguously determine tip types, we performed a theoretical DFT study of the line scans with the tip models in question and found that the tip characterization method based on experimental results (Cu/O-terminated tip imaging Cu/O atoms) is in fact incorrect and the opposite is true (Cu/O-terminated tip imaging O/Cu atoms). This protocol allows the tip asperity's chemical structure to be verified and established both before as well as at any stage of the manipulation experiment when numerous tip changes may take place.

4:30PM X1.00011 Micromolding fabrication of "T" cross section SiC SPM probes

CHIAYUN WU, Physics U. Mass Lowell, SHIHANG WANG, DANIEL SCHMIDT, Plastics Eng U. Mass Lowell, JOEL THERRIEN, ECE U. Mass Lowell — Micromolding techniques using pre-ceramic polymers have been demonstrated for the creating silicon carbide based AFM cantilevers. In an attempt to reach higher resonance frequencies without significantly increasing the spring constant of the cantilevers, a "T" cross section cantilever was fabricated. The resonant frequency and spring constant have been compared to the standard rectangular cross section cantilevers of both SiC and commercially available silicon cantilevers.

4:42PM X1.00012 Single molecule and single atom sensors for atomic resolution imaging of chemically complex surfaces

F. STEFAN TAUTZ, GEORGY KICHIN, CHRISTIAN WEISS, CHRISTIAN WAGNER, RUSLAN TEMIROV, Peter Gruenberg Institute (PGI-3), Forschungszentrum Juelich, Germany — To resolve single atoms has always been a major goal of surface science. Mapping forces with a dynamic AFM, it is possible to reconstruct atomic resolution of various surfaces and of large organic molecules [1]. At the same time scanning tunneling hydrogen microscopy (STHM) reaches atomic scale resolution and reveals intermolecular interactions with much less technical effort [2]. Besides H₂ and D₂, also individual Xe atoms, single CO and CH₄ molecules adsorbed at the tip apex of an STM function as microscopic force sensors that change the tunneling current in response to the forces acting from the surface. An STM equipped with any of these sensors is able to image the Pauli repulsion and thus resolve the inner structure of organic adsorbates. The more rigidly bounded CO yields the strongest, least distorted contrast. Thus, the sensor functionality can be tailored by tuning the interaction between sensor particle and STM tip. Hence, STHM belongs to a wider family of atomic-sensor microscopy techniques.

4:54PM X1.00013 Detection of cantilever thermal motion and feedback cooling using a quantum point contact, MICHELE MONTINARO, University of Basel, Switzerland, SARAH HELLMÜLLER, KLAUS ENSSLIN, ETH Zuerich, Switzerland, MARTINO POGGIO, University of Basel, Switzerland — Nanomechanical oscillators enable ultrasensitive detection of force, mass and displacement. In particular, recent measurements of oscillator displacement have achieved an imprecision below that at the standard quantum limit (SQL), using optical [1] or microwave techniques [2]. A quantum point contact (QPC) has been employed as a transducer of nanomechanical motion, thanks to the sensitive dependence of its conductance on electrostatic fields. Such an approach has been demonstrated in combination with an off-board micromechanical cantilever in a versatile design compatible with nanoscale oscillators and, in principle, with a variety of force-sensing applications, including magnetic resonance force microscopy [3]. The aim of the research we present here is to improve this technique and to approach the SQL by accessing a regime in which, due to the one-dimensional electron transport, quantum mechanical back-action effects emerge on the mechanical resonator. We demonstrate the use of different types of QPCs as sensitive detectors of the low-temperature thermal motion of an off-board cantilever and their ability to cool the cantilever oscillation mode through feedback.

5:06PM X1.00014 Design of a Self-Aligned, High Sensitivity Fiber Fabry-Perot Interferometer for Low Temperature Atomic Force Microscope/Magnetic Force Microscope, OZGUR KARCI, Hacettepe University, MUNIR DEDE, NanoMagnetics Instruments Ltd., AHMET ORAL, Sabanci University — We describe the design of a high sensitivity fiber Fabry-Perot interferometer for low temperature atomic force microscope/magnetic force microscope. This is a self-aligned system utilizing an alignment chip and eliminating all tedious alignment procedures. Our interferometer cavity is composed of a cleaved fiber, which is coated using dielectric to increase the reflectivity of laser from fiber-air interface, and a cantilever. 50 percent of the incident laser beam is reflected at the end of the fiber. The transmitted light propagates from the fiber end and hits the cantilever. Multiple reflections occur between cantilever and the fiber then the beams go into the fiber again. These two beams interfere and generate a photocurrent at the PD which is used for deflection measurement. We designed a special stick-slip coarse approach mechanism using piezoelectric tube scanner of the microscope. We have measured 8fm per square root Hz noise level at 300K, while the shot noise limit was 2fm per square root Hz. Our previous Michelson interferometer design had 20 fm per square root Hz noise level and gave better than 10nm MFM resolution on hard disk. Our goal is to further enhance the noise levels and achieve 6 nm resolution for LT-MFM with this new interferometer.

5:18PM X1.00015 Next Generation SPM Control System with ppm precision, ALESSANDRO PIODA, SPECS Surface Nano Analysis GmbH — Novel scanning probe microscopy techniques, modes of operation, and advances in microscope hardware are pushing the boundary for signal resolution and flexibility in SPM measurements. Here we present a new state of the art SPM control system, which improves signal precision, resolution, bandwidth and noise performance by about one order of magnitude compared to current generation controllers. The controller incorporates the performance of expensive dedicated instruments in a compact modular multichannel package. In combination with the well proven and flexible Nanonis SPM control software, this next generation controller is the ideal platform for the most demanding microscopy, spectroscopy and transport measurements tasks, opening the door to a larger range of applications compared to current systems. Furthermore, the flexible and easily configurable user interface of the controller and the large number of measurement channels allows its operation as a high performance DC and AC source and measurement interface with ppm precision and multiple lock-in amplifiers, opening new perspectives for materials research.

5:30PM X1.00016 Conical spin-spiral ground state of a Mn double layer on W(110) driven by higher-order exchange interactions, YASUO YOSHIDA, University of Hamburg / The University of Tokyo, SILKE SCHROEDER, PÁOLO FERRIANI, University of Kiel, DAVID SERRATE, Universidad de Zaragoza, KIRSTEN VON BERGMANN, ANDRE KUBETZKA, University of Hamburg, STEFAN HEINZE, University of Kiel, ROLAND WIESENDANGER, University of Hamburg — The magnetic properties of transition-metal nanostructures are commonly explained based on the interplay of Heisenberg exchange, Dzyaloshinskii-Moriya (DM) interaction and magnetocrystalline anisotropy while higher order terms such as the biquadratic exchange and the four-spin interaction are typically neglected due to their small strength. Here, we demonstrate that higher-order terms can play a crucial role for the magnetic ground state and report as an example a transverse conical spin-spiral state in an ultra-thin film composed of two atomic layers of Mn on W(110). This spin structure is characterized by magnetic moments rotating on a cone that is perpendicular to the [001] propagation direction of the spin-spiral with a periodicity of 2.4 nm. The cones of nearest-neighbor Mn atoms point into opposite directions which results in nearly antiferromagnetic alignment. This intriguing spin structure has been resolved on the atomic-scale using spin-polarized scanning tunneling microscopy and confirmed to be the ground state by first-principles calculations based on DFT. Our calculations also reveal that the canting of the spins is induced by higher-order exchange interactions while the spiraling along the [001]-direction is due to frustrated Heisenberg exchange and DM interaction.

Session X2 FHP: Invited Session: History of Metrology and Today's Frontiers of Measurement
204AB

2:30PM X2.00001 Dreams of a Final System: Origins of the Quest for an Absolute Standard, ROBERT CREASE, Stony Brook University — The first attempts to find unchanging phenomena that could be used to evaluate the accuracy of standards and recreate them if lost predated the metric system. As early as the seventeenth century, members of the French Academy and British Royal Society sought to use the seconds pendulum and the Earth's meridian as tethers for length standards. These efforts ultimately failed. The vision of an absolute standard was revived in the 1870s, when C. S. Peirce was the first to experimentally tie a unit, the meter, to a natural standard, the wavelength of a spectral line, using a diffraction grating. This work inspired A. Michelson and E. Morley, in the 1880s, to apply the interferometer with which they were attempting to detect ether drift to this purpose. Michelson further pursued this work at the BIPM in 1892, which set the stage for the later redefinition, in 1960, of the meter in terms of the wavelength of a spectral line.

3:06PM X2.00002 Beller Lectureship: From Artefacts to Atoms: The Origins and Early Years of the International Bureau of Weights and Measures (BIPM), TERRY QUINN¹, Retired — The BIPM was founded by the Metre Convention in 1875. Its main task was to maintain and disseminate the units of length and mass using the new International Prototypes of the Metre and Kilogram. My talk will be based on the opening chapters of my book "From Artefacts to Atoms" which recount the story of the Metre Convention and the creation of the BIPM at the Pavillon de Breteuil in Sèvres on the outskirts of Paris, as the first international scientific institute. I shall include a brief outline of the sometimes acrimonious discussions at the Diplomatic Conference of the Metre, which opened on 1 March 1875 and concluded with the signing of the Convention on 20 May, of the construction of a new laboratory building, recruitment of staff, purchase of instruments and equipment and the beginning of scientific work. There was no precedent for any of this, success was due to the wisdom and foresight of those who drafted the Convention and to the founder Members of the International Committee for Weights and Measures overseeing the BIPM and to the high quality of the original scientific staff. However, success came at a price, the decision to define the Metre at 0 °C, for example, led to much ill health in the early years among the staff from working in cold damp laboratories, an aspect of metrology that is easy to forget these days.

¹The author is Emeritus Director of the BIPM

3:42PM X2.00003 Measurement of the gravitational quantities g and G : How ideas for precision measurement experiments come about, JAMES FALLER, JILA (CU and NIST), University of Colorado, and University of Glasgow — I will talk about g and G whose determinations go back to some of the earliest measurements in the history of metrology. Although today's measurement accuracy for g , the free-fall acceleration due to the Earth's gravity, has improved by nearly nine orders of magnitude, the measurement accuracy of G , the Newtonian Constant of Gravitation, has improved by only two orders of magnitude over its 300 year measurement history. I will discuss what has driven (and impeded) this progress, and how ideas for improvements in these measurements have helped advance the frontiers of measurement science. Finally, I will point out the interconnectedness of all precision measurement experiments.

4:18PM X2.00004 The Odyssey of the Frequency Measurements of Visible Light at NBS/NIST, HOWARD LAYER, National Institute of Standards and Technology — The long term goal of defining the length standard based on a constant of nature rather than an artifact was pursued at the National Bureau of Standards/National Institute of Standards and Technology during the period of 1968 to 1983. With the invention of the laser it became possible to measure the frequency of lasers, stabilized on atoms or molecules, with the cesium atomic clock as the time standard. Using lasers, high speed MIM (metal insulator metal) diodes, and summing the radiation from three lasers in a He-Ne plasma the frequency of the iodine stabilized HeNe laser at 633 nm was measured by direct frequency counting to an accuracy of 1.6 parts in 10^{10} . The major consequences of this accomplishment were the adoption of a fixed value for the speed of light and the redefinition of the SI meter based on the speed of light. After a brief historical review, the milestones of the research will be outlined and the principle researches indicated.

4:54PM X2.00005 Evolving Planck Constant Measurements into the SI Kilogram Standard, RICHARD STEINER, National Institute of Standards and Technology — This is a very brief 100 year history of measuring $2e/h$ (pre-and post-Josephson), with a little on e^2/h (quantum Hall Effect, QHE), and then on to a direct measure of Planck constant h , where the watt balance technique combines four basic standards, i.e., physical constants of time, length, voltage, and resistance into a mass redefinition. There are parallels between old and new controversies. In the 1970's and 80's the controversy was in the changeover from standard cells to the Josephson effect as voltage reference. A slightly similar and briefer one concerned the ohm and QHE. Today's discussion is about changing definitions from an artifact mass standard to the Planck constant (or Avogadro constant) using the different methods as realization. The mass redefinition concerns are two orders of magnitude down from those of voltage, and the discrepancies between h are probably more systemic rather than artifact related (or not) as compared to the Josephson effect testing. This shows how far electronic metrology has progressed but also that it is not completed research. The conclusion summarizes the latest efforts on the watt balances.

Thursday, March 1, 2012 2:30PM - 5:30PM –
Session X3 DCMF: Invited Session: Full Counting Statistics, Fluctuation Theorems, and Many-Body Entanglement 205AB

2:30PM X3.00001 Towards Measuring the Many-Body Entanglement from Fluctuations¹, KARYN LE HUR, CNRS and Center For Theoretical Physics, Ecole Polytechnique, 91128 Palaiseau France; Yale University, Physics Department, New Haven CT 06520 USA — The degree of entanglement in a many-body quantum system is often characterized using the bipartite entanglement entropy. We propose that bipartite fluctuations are also an effective tool for studying many-body physics [1] particularly its entanglement properties, in the same way that noise and full counting statistics have been used in mesoscopic transport and cold atoms. We apply some concepts underlying the field of full counting statistics to the study of the ground states of many-body Hamiltonians, with the boundary introduced by the bipartition playing the role of the scattering or interacting region. For systems that are equivalent to non-interacting fermions, we show that fluctuations and higher-order cumulants fully encode the information needed to determine the entanglement entropy [1-3]. In the context of quantum point contacts, measurement of the second charge cumulant showing a logarithmic dependence on time [2] then would constitute a strong indication of many-body entanglement [1]. Here, the measurability of the entanglement entropy, while suggestive, is particular to the nature of non-interacting particles [4,5].

3:06PM X3.00002 Charge sensing and real-time electron counting in quantum dots, THOMAS IHN, ETH Zurich — The charge state of a Coulomb blockaded quantum dot can be sensed at the single-electron level using charge sensors integrated on-chip [1]. Quantum point contacts or quantum dots have proven to work as reliable charge sensors. Coupling between the quantum dot's charge state and the sensor is provided by Coulomb interactions between electrons in the two systems. The technique is therefore independent of the material of quantum dot and sensor, and works for diverse systems such as GaAs [1] and graphene [2]. Different materials, such as InAs and GaAs have even been combined. Time-resolved charge sensing is of fundamental interest for studying the statistical properties of charge flow, like the full counting statistics. Single-shot charge and spin read-out schemes are also needed for the measurement of qubits. Some of our recent work has focused on the exploration and optimization of the read-out bandwidth limits. Towards this goal, we learned how to influence the dot-detector coupling [3], and how to employ high-frequency techniques in the range of a few hundred megahertz [4], or even up to a few gigahertz for improved performance. New experiments using the slower conventional sensing schemes have allowed us to explore non-equilibrium statistics and the fluctuation theorem. In our measurements, rare events can be detected, where electrons flow against the applied source-drain bias direction thereby consuming entropy in agreement with theoretical predictions.

3:42PM X3.00003 High-order counting statistics and interactions , CHRISTIAN FLINDT, University of Geneva

— Full counting statistics concerns the stochastic transport of electrons in mesoscopic structures [1]. Recently it has been shown that the charge transport statistics for noninteracting electrons in a two-terminal system is always generalized binomial: it can be decomposed into independent single-particle events, and the zeros of the generating function are real and negative [2]. In this talk I show how the zeros of the generating function move into the complex plane due to interactions and demonstrate how the positions of the zeros can be detected using high-order factorial cumulants [3]. As an illustrative example I discuss electron transport through a Coulomb blockade quantum dot for which the interactions on the quantum dot are clearly visible in the high-order factorial cumulants. These findings are important for understanding the influence of interactions on counting statistics, and the characterization in terms of zeros of the generating function provides a simple interpretation of recent experiments, where high-order statistics have been measured [4].

4:18PM X3.00004 Hidden correlations in the zero-point motion of electrons revealed by non-Gaussian quantum noise , BERTRAND REULET, Université de Sherbrooke

— We have performed the measurement of the correlation between the low frequency voltage fluctuations and the power fluctuations of the high frequency electromagnetic field generated by a tunnel junction at very low temperature. Our experiment provides the first observation of the correlation between the electron transport at low frequency and the photon field at high frequency, both when real photons are emitted ($eV > hf$, with V the dc voltage and f the frequency) and when the electromagnetic field is solely due to vacuum fluctuations. In terms of electrons only, our observations indicate that the intrinsic current fluctuations in a tunnel junction are given by $S_3(0, f) = e^2 I$, regardless of the frequency f . Despite its classical look, this result expresses that the high frequency current fluctuations, caused by the zero-point motion of electrons, are correlated with their low frequency counterpart, associated with "real" motion of electrons. In terms of photons only, we observe that the electromagnetic field exhibits a discontinuity at $eV = hf$, not in the amplitude of the fluctuations but in their relative phases.

4:54PM X3.00005 Noise and fluctuation statistics in mesoscopic heat transport , DMITRI AVERIN, Department of Physics and Astronomy, Stony Brook University, SUNY

— Fluctuations play important role in thermodynamics of small systems. In the talk, I will discuss two recent results on fluctuations in mesoscopic heat transport. One is the demonstration [1] that the fluctuation-dissipation theorem for thermal conductance of a mesoscopic junction is not valid at non-zero frequencies ω . Finite relaxation energy creates fluctuations of the energy flux in the junction even at vanishing temperature, $T=0$, when the conductance vanishes. This suggests that in contrast to electrical conductance, there is no "Kubo-Green formula" for equilibrium thermal conductance at $\omega \neq 0$. Non-equilibrium heat transfer satisfies general "fluctuation relations" of non-equilibrium thermodynamics. Recently, we have established the conditions of applicability of these relations to single-electron tunneling (SET), and calculated explicitly the statistics of dissipated energy in driven SET transitions [2], which gives an example of general statistics of energy dissipation in reversible information processing. An interesting consequence of this statistics is the possibility of implementing the electronic version of Maxwell's demon in the SET structures [3].

Session X4 DAMOP: Focus Session: Quantum Quench Dynamics in Cold Atom Systems 205C

2:30PM X4.00001 Integrability versus Thermalizability in Isolated Quantum Systems¹ , MAXIM OLSHANII, University of Massachusetts Boston

— The purpose of this presentation is to assess the status of our understanding of the transition from integrability to thermalizability in isolated quantum systems. In Classical Mechanics, the boundary stripe between the two is relatively sharp: its integrability edge is marked by the appearance of finite Lyapunov's exponents that further converge to a unique value when the ergodicity edge is reached. Classical ergodicity is a universal property: if a system is ergodic, then every observable attains its microcanonical value in the infinite time average over the trajectory. On the contrary, in Quantum Mechanics, Lyapunov's exponents are always zero. Furthermore, since quantum dynamics necessarily invokes coherent superpositions of eigenstates of different energy, projectors to the eigenstates become more relevant; those in turn never thermalize. All of the above indicates that in quantum many-body systems, (a) the integrability-thermalizability transition is smooth, and (b) the degree of thermalizability is not absolute like in classical mechanics, but it is relative to the class of observables of interest. In accordance with these observations, we propose a concrete measure of the degree of quantum thermalizability, consistent with the expected empirical manifestations of it. As a practical application of this measure, we devise a unified recipe for choosing an optimal set of conserved quantities to govern the after-relaxation values of observables, in both integrable quantum systems and in quantum systems in between integrable and thermalizable.

3:06PM X4.00002 Chaos and statistical relaxation in quantum systems of interacting particles , LEA SANTOS, Yeshiva University, USA, FAUSTO BORGONOV, Università Cattolica, FELIX IZRAILEV, Universidad Autónoma de Puebla, Mexico

— Recent experimental progresses in the studies of quantum systems of interacting particles with optical lattices have triggered the interest in basic problems of many-body physics. One of the issues that has been widely discussed in the literature is the onset of thermalization in an isolated quantum system caused by interparticle interactions. A prerequisite for thermalization is the statistical relaxation of the system to some kind of equilibrium and its viability has been associated with the onset of quantum chaos. We propose a method to study the transition to chaos in isolated quantum many-body systems, which is based on the concept of delocalization of eigenstates in the energy shell. We show that although the fluctuations of energy levels and delocalization measures in integrable and non-integrable systems differ, global properties of the eigenstates may be quite similar, provided the interaction between particles exceeds some critical value. In this case the quench dynamics can be described analytically, demonstrating the universal statistical relaxation of the systems irrespectively of whether they are chaotic or not.

3:18PM X4.00003 Non-adiabatic ramps in quantum many-particle systems , MASUD HAQUE, Max Planck Institute (PKS), Dresden

— A change of system parameter can be neither truly instantaneous nor truly adiabatic in real life. For several quantum many-particle systems, I will consider non-equilibrium dynamics induced by finite-rate ramps. The ramp rate extrapolates between an instantaneous quench and an adiabatic sweep. I will characterize the deviation from adiabaticity through the excess energy or "heating" of the system. For cold-atom systems in a harmonic trapping potential, I will show that the non-adiabatic heating in finite-time ramps has universal features common to a wide range of systems.

3:30PM X4.00004 Entropy of Isolated Quantum Systems after a Quench¹ , MARCOS RIGOL, Georgetown University, LEA SANTOS, Yeshiva University, ANATOLI POLKOVNIKOV, Boston University — A diagonal entropy, which depends only on the diagonal elements of the system's density matrix in the energy representation, has been argued to be the proper definition of thermodynamic entropy in out-of-equilibrium quantum systems. We study this quantity after an interaction quench in lattice hardcore bosons and spinless fermions, and after a local chemical potential quench in a system of hard-core bosons in a superlattice potential. The former systems have a chaotic regime, where the diagonal entropy approaches the equilibrium microcanonical entropy, coinciding with the onset of thermalization. The latter system is integrable. We show that its diagonal entropy is additive and different from the entropy of a generalized Gibbs ensemble, which has been introduced to account for the effects of conserved quantities at integrability [1].

3:42PM X4.00005 Mode coupling induced dissipative and thermal effects at long times after a quantum quench¹ , ADITI MITRA, New York University, THIERRY GIAMARCHI, University of Geneva — An interaction quench in a Luttinger liquid can drive it into an athermal steady state. We analyze the effects on such an out of equilibrium state of a mode coupling term due to a periodic potential. Employing a perturbative renormalization group approach we show that even when the periodic potential is an irrelevant perturbation in equilibrium, it has important consequences on the athermal steady state as it generates a temperature as well as a dissipation and hence a finite life-time for the bosonic modes.

[1] Supported by NSF DMR 1004589

3:54PM X4.00006 Random phase approximation study of one-dimensional fermions after a quantum quench¹ , JARRETT LANCASTER, New York University, THIERRY GIAMARCHI, DPMC-MaNEP, University of Geneva, ADITI MITRA, New York University — The effect of interactions on a system of fermions that are in a nonequilibrium steady state due to a quantum quench is studied employing the random phase approximation. As a result of the quench, the distribution function of the fermions is greatly broadened. This gives rise to an enhanced particle-hole spectrum and overdamped collective modes for attractive interactions between fermions. On the other hand, for repulsive interactions, an undamped mode above the particle-hole continuum survives. The sensitivity of the result to the nature of the nonequilibrium steady state is explored by also considering a quench that produces a current-carrying steady state.

[1] Supported by NSF-DMR1004589

4:06PM X4.00007 Ballistic expansion of interacting fermions in one-dimensional optical lattices , FABIAN HEIDRICH-MEISNER, STEPHAN LANGER, LMU Munich, MARTIN J.A. SCHUETZ, MPQ Garching and LMU Munich, IAN MCCULLOCH, U Queensland, Brisbane, Australia, ULRICH SCHOLLWOECK, LMU Munich — In most quantum quenches, no net particle currents arise. Access to studying transport properties can be gained by letting a two-component Fermi gas that is originally confined by the presence of a trapping potential expand into an empty optical lattice. In recent experiments, this situation was addressed in 2D and 3D optical lattices [1]. We focus on the 1D case in which an exact numerical simulation of the time-evolution is possible by means of the DMRG method. Concretely, we study the expansion in the 1D Hubbard model with repulsive interactions, driven by quenching the trapping potential to zero, and we concentrate on the most direct experimental observable, namely density profiles [2]. In the strict 1D case, we identify conditions for which the expansion is ballistic, characterized by an increase of the cloud's radius that is linear in time. This behavior is found whenever initial densities are smaller or equal to one, both for the expansion from box and harmonic traps. We make quantitative predictions for the expansion velocity as a function of onsite repulsion and initial density that can be probed in experiments.

4:18PM X4.00008 Quenching across a quantum critical point: dependence of scaling laws on spatial periodicity , SMITHA VISHVESHVARA, University of Illinois at Urbana-Champaign, MANISHA THAKURATHI, Indian Institute of Science, Bangalore, India, WADE DEGOTTARDI, University of Illinois at Urbana-Champaign, DIPTIMAN SEN, Indian Institute of Science, Bangalore, India — We study the quenching dynamics of a quantum many-body system in one dimension described by a Hamiltonian having spatial periodicity. Specifically, we consider a spin-1/2 XX chain subject to a periodically varying magnetic field in the $\hat{z}$ direction or, equivalently, a tight-binding model of spinless fermions having a periodic local chemical potential. If the strength of the magnetic field (or chemical potential) is varied slowly in time at a rate $1/\tau$ so as to take the system across a quantum critical point, we find that the density of excitations thereby produced scales as a power of $1/\tau$. Remarkably, the power depends on the spatial periodicity of the field and deviates from the $1/\sqrt{\tau}$ scaling that is ubiquitous to a range of systems. This behavior is analyzed by mapping the slow quenching problem to a collection of fermionic two-level systems, labeled by the lattice momentum k , for which the effective Hamiltonians vary as a power of the time close to the quantum critical point. For a magnetic field described by multiple periodicities, the power depends on the smallest period for very large values of τ . Finally, we find that if there are interactions between the fermions, the power varies continuously with the interaction strength.

4:30PM X4.00009 Kibble-Zurek Scaling: Universality and scaling , ANUSHYA CHANDRAN, Princeton University, AMIR EREZ¹, Ben-Gurion University, SHIVAJI L. SONDHI, STEVEN S. GUBSER, Princeton University — Near a critical point, the equilibrium relaxation time of a system diverges and any change of control/thermodynamic parameters leads to non-equilibrium behavior. The Kibble-Zurek (KZ) problem is to determine the dynamical evolution of the system parametrically close to its critical point when the change is parametrically slow. We formulate the KZ problem as a scaling limit and compute its universal content analytically (critical exponents+scaling functions) in a few classical and quantum models. We also use gauge-gravity duality to compute KZ response functions in more exotic critical theories.

[1] Equal contribution

4:42PM X4.00010 Universal Quantum Dynamics of the Transverse-Field Ising Model , MICHAEL KOLODRUBETZ, BRYAN CLARK, DAVID HUSE, Princeton University — The one-dimensional transverse field Ising model is a prototypical example of a quantum phase transition. While its equilibrium scaling has been known for more than half a century, we discuss the non-equilibrium quantum dynamics as the system is swept slowly through the critical point (a Kibble-Zurek ramp). Scaling is well understood for Kibble-Zurek ramps that end at the quantum critical point or deep in the ferromagnetic regime. We solve for the full finite-size scaling forms of excess heat and spin-spin correlation function for an arbitrary point along the ramp. We also confirm the postulated universality of the dynamic scaling forms by numerically simulating Mott insulating bosons in a tilted potential, an experimentally realizable model in the same universality class [Simon et. al., Nature 472, 372 (2011)]. Our numerics indicate that the time-scales necessary to see non-equilibrium scaling should already be within the reach of experiment.

4:54PM X4.00011 Self-consistent theory of instabilities in the spin-1 Bose gas, AUSTEN LAMACRAFT, University of Virginia, RYAN BARNETT, University of Maryland — We discuss instabilities of a spin-1 Bose condensate using a Hartree-Fock-Bogoliubov approximation to account for the interactions between the unstable modes. There is a close analogy to the “S-theory” that describes parametric excitation of magnons in solid state systems. We particularly emphasize the pair-breaking effect of phase fluctuations in the parent condensate and their role in inhibiting the instability.

5:06PM X4.00012 Decay of classical quasiperiodic state and emergence of prethermalization in quenched Fermi-Pasta-Ulam system, RAFAEL HIPOLITO, City University of New York, College of Staten Island, IPPEI DANSHITA, Computational Condensed Matter Physics Laboratory, RIKEN, VADIM OGANESYAN, City University of New York, College of Staten Island, ANATOLI POLKOVNIKOV, Boston University — We will discuss the relaxation of the Fermi Pasta Ulam system in the presence of quantum fluctuations. In order to make comparisons with the classical relaxation, we strongly excite a single normal mode, while the rest of the modes are initially in the quantum ground state. We confine ourselves to the quasiperiodic regime where the classical system never thermalizes. We show that the short time dynamics of the quantum problem are very different from classical evolution, with the quantum zero point energy playing a key role. The short time dynamics can be viewed as an enhancement of zero point energy, parametrically driven by the classical degrees of freedom. This introduces nontrivial off-diagonal correlations in the low momentum sector and dampens the classical oscillations eventually leading to both dephasing and decay, and we identify the time scales associated with these processes. Eventually the system reaches a nontrivial very long lived quasistationary regime where off-diagonal correlations disappear and the energy remains mostly localized in the low q sector while the high q sector relaxes to a uniform effective temperature. In this regime, correlations are very well described by a generalized Gibbs ensemble.

5:18PM X4.00013 Fisher zeroes and non-analytic real time evolution for quenches in the transverse field Ising model, STEFAN KEHREIN, University of Goettingen, MARKUS HEYL, University of Munich, ANATOLI POLKOVNIKOV, Boston University — We study quenches of the magnetic field in the transverse field Ising model. For quenches across the quantum critical point, the boundary partition function in the complex temperature-time-plane shows lines of Fisher zeroes that intersect the time axis, indicating non-analytic real time evolution in the thermodynamic limit (analogous to well-known thermodynamic phase transitions). We obtain exact analytical results for these dynamic transitions and show that the dynamic behavior cannot be obtained from a naive analytic continuation of the thermal equilibrium partition function: Real time evolution across this quantum critical point generates a new non-equilibrium energy scale. We argue that this behavior is expected to be generic for interaction quenches across quantum critical points in other models as well.

Thursday, March 1, 2012 2:30PM - 5:30PM – Session X5 DCMP: Structure and Formation of Oxide Surfaces and Interfaces 206A

2:30PM X5.00001 Quasi-long range ordered hole-adatoms pairs on SrTiO₃(110)-(4×1) surface¹, JIANDONG GUO, FENGMAO LI, ZHIMING WANG, SHENG MENG, ZHIQIANG ZHANG, Institute of Physics, Chinese Academy of Sciences — The surface structure of transition metal oxides (TMOs) has been an important issue for chemistry and photocatalysis. We studied the surface of SrTiO₃, which is a wide-gap semiconductor and has been believed useful for photo-induced water splitting. Specifically we focused on the (110) surface that bears intrinsic instability of reconstruction due to the surface polarity. The monophased (4×1)-reconstructed surface was obtained with the treatment of argon ion sputtering followed by annealing in ultra high vacuum. More interestingly, we observed a (4×10) quasi-long range ordered hole-adatom structure. The atomic configuration was identified by both experimentally adsorbing additional Sr atoms and density functional calculations. The ordering of the hole-adatom pairs was robust since its formation effectively released the stress on (4×1)-reconstructed SrTiO₃(110) surface. Such a surface with ordered defects served as a good template for the guided growth of noble metal nanoclusters with controlled size and density.

¹This work was supported by CMOST.

2:42PM X5.00002 Growth modes of multiferroic BiFeO₃ (001) thin films on SrTiO₃ – Real time X-ray synchrotron study, PRIYA V. CHINTA, RANDALL HEADRICK, ASHRAFI ALMAMUN, Dept. of Physics & Materials Science, University of Vermont, SARA CALLORI, MATTHEW DAWBER, Dept. of Physics, Stony Brook University — Real time X-ray scattering measurements during heteroepitaxial film deposition provide details of initial nucleation and growth, thus giving insight into atomic-scale processes and growth mechanisms. In this work the growth of pulsed laser deposited (PLD), and RF-magnetron sputter deposited multiferroic BiFeO₃ (001) thin films on SrTiO₃ substrates are studied using *in-situ* X-ray specular and diffuse scattering. Both the out-of-plane (height distribution) and lateral (surface mounds and correlations) information is obtained from these measurements. Specular X-ray intensity monitored at (00 1/2) shows unit-cell growth oscillations during the first few monolayers, while both diffuse scattering width and intensity oscillate out-of-phase with specular, characteristic of 2D layer-by-layer growth for PLD deposited films. The coarsening process is consistent with growth and coalescence of islands - identified as key fundamental processes in epitaxial growth. Beyond several monolayers oscillations decay and the diffuse intensity increases indicating rapid growth of mounds. However, the mounds themselves subsequently merge after a few more deposited layers, leaving arrays of mesas with some holes due to incomplete coalescence. This behavior was corroborated with ex-situ Atomic Force Microscopy (AFM) at each stage. Results for sputter deposited films showed unusually strong specular and diffuse oscillations; implications for interface structure and formation will be discussed.

2:54PM X5.00003 Polarization Dependent Reconstructions of Ferroelectric Surfaces¹, JOHN MARK MARTIREZ, The Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania, WISSAM AL-SAIDI, Department of Chemical and Petroleum Engineering, University of Pittsburgh, ANDREW RAPPE, The Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania — We present an *ab initio* density-functional study of the surface structures and the thermodynamic stability of ferroelectric tetragonal (001)-oriented slabs of BaTiO₃ and PbTiO₃, including both cases where the bulk polarization is directed towards (positive) and away (negative) from the surface. We analyzed systematically the total energies of surfaces with different reconstruction symmetries and stoichiometries. The thermodynamic stability diagrams show that the stable surface compositions for the positive and negative surfaces are different, which are in turn different from those of the paraelectric phase. We show that the prevalence of certain surface reconstructions can be understood in the light of the ability of ions to passivate ferroelectric surface charges.

3:06PM X5.00004 STM study of the Mn-dopants on the surface of $\text{Sr}_3(\text{Ru}_{1-x}\text{Mn}_x)_2\text{O}_7$ ($x=6\%$, 16%)¹, WARD PLUMMER, GUORONG LI, Louisiana State University, QING LI, MINGHU PAN, Oak Ridge National Laboratory, BIAO HU, VON BRAUN NASCIMENTO, JIANDI ZHANG, RONGYING JIN, Louisiana State University — The double-layered $\text{Sr}_3\text{Ru}_2\text{O}_7$ is a paramagnetic metal, but the substitution of Mn for Ru ($\text{Sr}_3(\text{Ru}_{1-x}\text{Mn}_x)_2\text{O}_7$) results in a metal-to-insulator transition at T_{MIT} and antiferromagnetic (AF) ordering at T_M (the two transitions are closely coupled for $x < 6\%$). STM measurements at 4.2 K and 100 K on the surface of $\text{Sr}_3(\text{Ru}_{1-x}\text{Mn}_x)_2\text{O}_7$ ($x = 6\%$, 16%) reveal a $(\sqrt{2} \times \sqrt{2})R45^\circ$ unit cell, consistent with the orthorhombic bulk structure. The Mn dopant has been identified through bias-dependent STM topography and dI/dV mapping. The Mn dopant equally occupies two sites which are anti-phase - one sitting at the center and the other on the corner of the $(\sqrt{2} \times \sqrt{2})R45^\circ$ unit cell. We have directly imaged the chirality of MnO_6 rotation at the anti-phase sites. In contrast to the bulk measurements, the surface is always metallic for $x=16\%$ and insulating only for 4.2K measurements on the $x = 6\%$ sample. The surface apparently suppresses the Mn-induced insulating (AF) phase observed in the bulk.

3:18PM X5.00005 Morphology and Magnetism of Atomically Thin Layers of Chromia – An STM Investigation, XUMIN CHEN, DONNA KENKEL, GEOFFREY ROJAS, XI HE, CHRISTIAN BINEK, AXEL ENDERS, University of Nebraska-Lincoln, MSREC COLLABORATION — A low temperature scanning tunneling microscopy (LT-STM) study of ultrathin chromium oxide films on Cu(111) is presented. The (0001) surface of Cr_2O_3 (chromia) exhibits long-range antiferromagnetic ordering, and its usefulness for electric field control of exchange bias has been recently established [Xi He, Ch. Binek, et al., *Nature Materials* 9, 579 – 585 (2010)]. We deposited ultrathin chromium layers on Cu(111), followed by post-annealing in oxygen partial pressures to promote oxidation of the chromium films. We find that chromium grows on Cu(111) in the Volmer-Weber mode, resulting in small 3D islands. During annealing, the small islands coalesce to form large, flat terraces and the most stable oxide of chromium, Cr_2O_3 , is formed at 630°C . Spin-polarized scanning tunneling microscopy has been performed to image the layer-wise antiferromagnetism in different structural layers of the chromia films. Thin layers of cobalt have been deposited on the chromia so that the magnetism of the Co couples to that of the chromia. Imaging the magnetism of the Co islands on the Cr_2O_3 terraces with spin-polarized STM helped us distinguishing between magnetic and electronic contrast in the complex dI/dV maps of the chromia surface.

3:30PM X5.00006 Structures of Stoichiometric and Oxygen Deficient Sapphire Surfaces, HA-WOONG HONG, Argonne National Laboratory, AARON GRAY, T.-C. CHIANG, Department of Physics, University of Illinois at Urbana-Champaign, SHAWN HAYDN, MICHAEL GRAMLICH, YIYAO CHEN, PAUL MICELI, Department of Physics, University of Missouri — Sapphire, $\alpha\text{-Al}_2\text{O}_3$ is one of widely used oxide substrates. Its (0001) surface is presumed quite stable. However, when it is heat-treated under vacuum, the surface shows the variety of different surface structures, mostly due to oxygen deficiency. The initial surface structure could be also modified by covering the substrate with another sapphire substrate during air annealing above 1500°C . During the course of the heat-treatment under UHV condition, the x-ray reflectivity and crystal truncation rods were measured in addition to observing reflection high energy electron diffraction patterns. Metal films such as Pb, Ag, and Pd were deposited onto these various sapphire surfaces. Contrary to common belief that metal films would not grow well on insulating oxide substrates, metal films could be formed on some of the sapphire surfaces. The influence of the sapphire surface structure to the morphology of the metal films will be discussed.

3:42PM X5.00007 Crystallographic Orientation(s) of Vanadium Dioxide Nano-Grains on Various Single-Crystal Sapphire Substrates, FELIPE RIVERA, Brigham Young University, JOYEETA NAG, RICHARD HAGLUND, Vanderbilt University, ROBERT DAVIS, RICHARD VANFLEET, Brigham Young University — Vanadium dioxide (VO_2) is a material of particular interest due to its reversible structural semiconductor to metal phase transition near room temperature (68°C) and its accompanied hysteresis. Electron Back-Scattered Diffraction (EBSD) was used to study the orientation of the crystalline VO_2 grains deposited on three cuts of sapphire (a-, c-, and r-cuts) by pulsed laser deposition. EBSD showed a predominant family of crystallographic relationships present in all cuts of sapphire wherein the rutile VO_2 {001} planes tend to lie parallel to the substrate's {10-10} and the rutile VO_2 {100} planes lie parallel to the substrate's {1-210} and {0001}. This family of relationships accounts for the majority of the VO_2 grains observed on all the studied sapphire substrates. However, due to the symmetry of the substrate, there were variations of these same relationships that prevent a single epitaxy from taking place in these cuts as the VO_2 grains did orient themselves with equivalent out-of plane directions in the substrate.

3:54PM X5.00008 Growth of Vanadium Dioxide Thin Films Using Magnetron Sputtering, FANGFANG SONG, B.E. WHITE JR., Binghamton University — In this work, we present our experimental investigation of vanadium oxide thin film deposition. RF and DC magnetron sputtering are used for thin film deposition. Post deposition anneal are introduced to stabilize the vanadium dioxide phase. The impact of deposition conditions and anneal conditions on the structural and morphological properties of the thin films, as determined by x-ray diffraction and scanning electron microscopy, will be discussed. Results indicate that on the technologically relevant silicon dioxide surface, the transitional phase of vanadium dioxide can be stabilized by post deposition anneal at 550°C and oxygen partial pressures between 3.6×10^{-4} torr and 10^{-2} torr. The films obtained show a resistivity change of a factor of 200 at 350K. The shift in transition temperature is attributed to thin film stress.

4:06PM X5.00009 Studies of high coverage oxidation of the Cu(100) surface using low energy positrons, N.G. FAZLEE, W.B. MADDOX, A.H. WEISS, Department of Physics, University of Texas at Arlington — The study of oxidation of single crystal metal surfaces is important in understanding the corrosive and catalytic processes associated with thin film metal oxides. The structures formed on oxidized transition metal surfaces vary from simple adlayers of chemisorbed oxygen to more complex structures which result from the diffusion of oxygen into subsurface regions. In this work we present the results of theoretical studies of positron surface and bulk states and annihilation probabilities of surface-trapped positrons with relevant core electrons at the oxidized Cu(100) surface under conditions of high oxygen coverage. Calculations are performed for various high coverage missing row structures ranging between 0.50 and 1.50 ML oxygen coverage. The results of calculations of positron binding energy, positron work function, and annihilation characteristics of surface trapped positrons with relevant core electrons as function of oxygen coverage are compared with experimental data obtained from studies of oxidation of the Cu(100) surface using positron annihilation induced Auger electron spectroscopy (PAES).

4:18PM X5.00010 *In situ* TEM Studies of the Initial Oxidation stage of Cu and Cu Alloy Thin Films, JUDITH YANG, YIHONG KANG, University of Pittsburgh, LANGLI LUO, State University of New York at Binghamton, JAMES CISTON, Lawrence Berkeley National Laboratory, ERIC STACH, Brookhaven National Laboratory, GUANGWEN ZHOU, State University of New York at Binghamton — The fundamental understanding of oxidation at the nanoscale is important for the environmental stability of coating materials as well as processing of oxide nanostructures. Our previous studies show the epitaxial growth of Cu_2O islands during the initial stages of oxidation of Cu thin films, where surface diffusion and strain impact the oxide development and morphologies. The addition of secondary elements changes the oxidation mechanism. If the secondary element is non-oxidizing, such as Au, it will limit the Cu_2O island growth due to the depletion of Cu near the oxide islands. When the secondary element is oxidizing, for example Ni, the alloy will show more complex behaviour, where duplex oxide islands were observed. Nucleation density and growth rate of oxide islands are observed under various temperatures and oxygen partial pressures ($p\text{O}_2$) as a function of time by *in situ* ultra high vacuum (UHV)-transmission electron microscopy (TEM). Our initial results of Cu-Ni(001) oxidation is that the oxide epitaxy and morphologies change as function of Ni concentration. For higher spatial resolution, we are examining the atomic scale oxidation by aberration-corrected ETEM with $1\text{\AA}$ resolution.

4:30PM X5.00011 Quantum-Mechanical Investigations for the Oxidation Mechanism of Ti_3Al , WENHUA XUE, The University of Tulsa, SHI-YU LIU, Tianjin Normal University, SHIYANG LIU, Zhejiang Normal University, DEJUN LI, Tianjin Normal University, TARA DRWENSKI, SHUXIA YIN, SANWU WANG, The University of Tulsa — First-principles density-functional theory and thermodynamics calculations are combined to establish a microscopic mechanism for the oxidation of the $\alpha_2\text{-Ti}_3\text{Al}(0001)$ surface. The surface energies as functions of the chemical potentials, as well as structural relaxations and electronic densities of states, are determined. The surface phase diagram (SPD) of the $\alpha_2\text{-Ti}_3\text{Al}(0001)$ systems with different defects and at various oxygen coverages is constructed. It is found that the Al antisite defect prefers to segregate on the $\alpha_2\text{-Ti}_3\text{Al}(0001)$ surface and oxygen adsorption enhances the segregation with the formation of the surface with three Al antisites per unit surface cell (i.e., the top surface layer is full of Al atoms) at the initial stage of oxidation, accounting for the aluminum selective oxidation observed experimentally. After the initial stage of oxidation, the $\text{O}/\alpha_2\text{-Ti}_3\text{Al}(0001)$ system manifests itself with a non-uniform double-phase SPD, suggesting the competition between oxidations of the Al and Ti elements in the oxidation process. This result explains the experimentally observed second regime of oxidation in which both metal elements are oxidized.

4:42PM X5.00012 Site Specific Molecular Chemisorption of O_2 on $\text{TiO}_2(110)$: A Scanning Tunneling Microscopy Study, ZHITAO WANG, YINGGE DU, ZDENEK DOHNÁLEK, IGOR LYUBINETSKY, Pacific Northwest National Laboratory — The investigation of O_2 adsorption on TiO_2 is critical since it can help us to better understand the photooxidation mechanism of TiO_2 . In our work, molecularly chemisorbed O_2 were directly imaged on reduced $\text{TiO}_2(110)$ at 50 K with scanning tunneling microscopy (STM). Two O_2 adsorption channels, one at bridging oxygen vacancies (V_O) and another at five-fold coordinated Ti atoms (Ti_{5c}), have been identified. While O_2 at Ti_{5c} appears as a single protrusion, the O_2 at V_O manifests itself by a disappearance of the V_O feature. It is found that STM tip can easily dissociate O_2 and the dissociation details strongly depend on the tunneling conditions and the type of the O_2 adsorption site. The chemisorbed O_2 at these two distinctive sites are the most likely precursors for the two previously established O_2 dissociation channels, observed at temperatures above 150 and 230 K at the V_O and Ti_{5c} sites, respectively

4:54PM X5.00013 Hard x-ray photoemission studied and band alignment in $\text{TiO}_2/\text{HfO}_2/\text{Ge}$ heterojunctions, ABDUL RUMAIZ, NSLS, Brookhaven National Laboratory, JOSEPH WOICK, NIST, QI XIE, University of Ghent, PETER SIDONS, NSLS, Brookhaven National Laboratory, CONAN WEILAND, NIST, CHRISTOPHE DETAVERNIER, University of Ghent — Novel high K oxides such as hafnium oxide and zirconium oxide have replaced silicon dioxide as gate oxide. Although titanium oxide has a high dielectric constant, the poor conduction band offset between titanium oxide and Si/Ge makes it a poor choice for gate oxide. One way to address this issue is to have a thin intermediate layer with appropriate band alignment between titanium oxide and the semiconductor. Here we present hard x-ray photoelectron spectroscopy (HAXPES) study on the band alignment between atomic layer deposited (ALD) $\text{TiO}_2/\text{HfO}_2/\text{Ge}$ heterojunctions. The exact position of the valence band maximum was determined by convoluting theoretical calculated density of states from first-principles calculations and comparing with experimental valence band data. We will also discuss the dependence of the band alignment on the thickness of the intermediate layer.

5:06PM X5.00014 Synchrotron Photoemission Characterization of Process Dependent Oxidation Control in InGaAs/High-k Film Systems, CONAN WEILAND, JOSEPH WOICK, National Institute of Standards and Technology, JIMMY PRICE, PAT LYSAGHT, JEFF HUANG, SEMATECH — To continue CMOS scaling, higher mobility substrates, such as III-V semiconductors, are being investigated. However, certain technological barriers must be overcome before high-mobility devices can be employed; notably, defects at the semiconductor/high-k interface need to be well controlled. Here, we investigate the role of an AlN interlayer between InGaAs and ALD ozone deposited ZrO_2 using synchrotron source X-ray photoemission spectroscopy (XPS). XPS is able to quantify the relative levels of oxidation from the In, Ga and As signals. Also, by comparing the relative As 3d_{3/2}: As 3d_{5/2} peak intensities, it is possible to quantify the level of As-As bond formation, which is common to coarse As-O reduction processing and consistent with mobility degradation. To elucidate the role of the AlN interlayer, XPS spectra of InGaAs/AlN/ ZrO_2 , InGaAs/ ZrO_2 and InGaAs/AlN films will be presented and compared. We will demonstrate that an AlN interlayer is effective in reducing In, Ga and As interfacial oxides, as well as As-As bonding, yet is not sufficient to passivate the interface against further oxidation from ozone based ALD processing.

5:18PM X5.00015 Engineering an epitaxial dielectric/metal/dielectric trilayer system¹, JISUN KIM, Department of Physics, The University of Texas at Austin, YANG MENG, Z.Q. QIU, Department of Physics, University of California at Berkeley, CHIH-KANG SHIH, Department of Physics, The University of Texas at Austin — Ag is a favorable material platform for plasmonic applications. Most plasmonic devices to date have been based on granular polycrystalline metal films, which suffer from scattering due to surface roughness. Recently, superior plasmonic properties have been demonstrated by using atomically smooth epitaxial Ag(111) films grown on Si(111), illustrating the advantages of an epitaxial approach. For further device applications of the above example, it is desirable to create epitaxially grown dielectric/metal/dielectric multi-layer systems. Here we report successful epitaxial growth of a $\text{MgO}(001)/\text{Ag}(001)/\text{MgO}(001)$ trilayer system which can be used as a material platform for creating multi-layered (dielectric/metal)_N heterostructures with any desired number, N. This type of new structure can be utilized for plasmonic devices with a wider wavelength range due to the transparency of MgO substrates in visible light. Moreover, it can open a door to new integrated devices with high quality atomically smooth films.

Thursday, March 1, 2012 2:30PM - 5:30PM – Session X6 DMP: Carbon Nanotube Optics II: Absorption and Raman Spectroscopy 206B

2:30PM X6.00001 Measurement of Absolute Absorption Cross-section of Individual Carbon Nanotubes on a Substrate, LIHONG HERMAN, ADAM TSEN, JIWOONG TSEN, Cornell University — The absorption cross-section is one of the central parameters that determine the efficiency of most optical and optoelectronics processes in single-walled carbon nanotubes (SWNT), including photoluminescence, photodetection, and photovoltaic energy conversion. While absorption measurements on SWNT ensembles in solution provide a reliable estimate, the absolute absorption cross-sections of individual carbon nanotubes on and off resonance have not been reported. Here, we measure the absorption cross-section of SWNTs on chip with spatial resolution using lock-in technique with a spatial modulation of a focused laser spot near SWNTs. We measure the absorption cross-section of SWNTs near resonance to be on the order of 10^{-17} cm^2 per carbon atom, which is consistent with on-chip Rayleigh measurements as well as recent time-resolved photoluminescence measurements. Since our measurement is performed on SWNTs on chip, it can be directly applied to various optoelectronic devices made with SWNTs, thus allowing quantitative analysis of the fundamental performance limits of SWNT photovoltaic devices.

2:42PM X6.00002 Measurement of Absorption Cross-section for Single-walled Carbon Nanotubes, XIAOPING HONG, KAIHUI LIU, FENG WANG, University of California Berkeley — Optical absorption is the most fundamental optical property. Quantitative knowledge of absorption cross-section provides valuable information on the material electronic structure, and is necessary for evaluating quantum efficiency of other important optical processes, such as photoluminescence and photocurrent generation. However, absorption measurement of individual single-walled carbon nanotubes (SWCNTs) is quite challenging. Here we used an efficient interferometric method to obtain the absorption cross-section of individual chirality-defined SWCNTs. We will discuss how the absorption cross-section varies in different carbon nanotubes.

2:54PM X6.00003 Enhancement of photoluminescence from single-walled carbon nanotubes by photonic crystal microcavities¹, R. WATAHIKI, T. SHIMADA, P. ZHAO, S. CHIASHI, S. IWAMOTO, Y. ARAKAWA, S. MARUYAMA, Y.K. KATO, The University of Tokyo — Single-walled carbon nanotubes are bright nanoscale emitters, while photonic crystal microcavities offer the possibility for efficient optical coupling at the nanoscale because of their small mode volumes and high quality factors. Here we report on the enhancement of photoluminescence from single-walled carbon nanotubes by L3 cavities in hexagonal lattice photonic crystals. Free-standing photonic-crystal membranes are fabricated from silicon-on-insulator substrates, and micelle-encapsulated carbon nanotubes are dispersed on the devices. We observe sharp peaks with a typical spectral width of 0.4 nm which corresponds to a quality factor of ~3000. As the peaks appear at wavelengths longer than those of Si photoluminescence, they are attributed to carbon nanotube emission coupled to the microcavity modes. We find that the photoluminescence intensity is enhanced by more than a factor of four compared to luminescence from an unpatterned area.

¹This work is supported by SCOPE, Casio Science Promotion Foundation, Global COE and Photon Frontier Network Programs of MEXT, Japan.

3:06PM X6.00004 Can we look into carbon nanotubes by infrared light?¹, KATALIN KAMARAS, ARON PEKKER, ZSOLT SZEKRENYES, Research Institute for Solid State Physics and Optics, Hungarian Academy of Sciences, Budapest, FERENC SIMON, Budapest University of Technology and Economics, BEA BOTKA, RUDI HACKL, Walther-Meissner-Institute, Garching, AKOS BOTOS, ANDREI KHLOBYSTOV, University of Nottingham — Individual molecules filled into carbon nanotubes exhibit Raman activity but very weak, if any, infrared absorption. We will present infrared (transmission and ATR), Raman and transmission electron microscopy data of various filled nanotubes (sorted by diameter and metallicity; encapsulating organometallic, aromatic and fullerene-based molecules) to illustrate this puzzling behavior. In the infrared spectra of double-walled carbon nanotubes, however, vibrational signatures of the inner and outer tubes are clearly discernible. A strong proof for this assignment is the shift of the inner-tube modes with ¹³C isotope content in samples where the inner tube is enriched with ¹³C.

¹Supported by OTKA Grant No. 75813 and ERC-259374-Sylo grant

3:18PM X6.00005 ABSTRACT WITHDRAWN —

3:30PM X6.00006 Intersubband Edge Singularity in Metallic Nanotubes, EUGENE MISHCHENKO, OLEG STARYKH, University of Utah — Tunneling density of states of both the massless and massive (gapped) particles in metallic carbon nanotubes is known to have anomalous energy dependence. This is the result of coupling to multiple low-energy bosonic excitation (plasmons). For both kinds of particles the ensuing effect is the suppression of the density of states by electron-electron interactions. We demonstrate that the optical absorption between gapless and gapped states is affected by the many-body effects in the opposite way. The absorption probability is enhanced compared with the non-interacting value and develops a power-law frequency dependence, with the -0.2 exponent for typical nanotubes.

3:42PM X6.00007 Indication of Long Lived States in Decay Associated Spectra of Single-Walled Carbon Nanotubes¹, VASUDEV LAL, ROSEANNE SENSION, DUNCAN STEEL, University of Michigan, Ann Arbor — The direct bandgap nature of Single-Walled Carbon Nanotubes(SWCNTs) along with the quantized energy level structure due to reduced dimensionality makes them useful elements in chip-based photonic devices for sensing and communications. However, their fundamental linear and nonlinear optical properties remain poorly understood. Using various nonlinear optical spectroscopy techniques with micelle encapsulated SWCNTs, we have measured carrier dynamics at both the picosecond, and tens of nanosecond timescale. We measure a fast 20ps timescale decay that agrees well with the lifetime of the lowest excited state measured before for such samples but surprisingly we also obtain an optical double-resonance signal on the slow timescale (10nsec). Such slow timescale signals due to artifacts such as thermal effects have been ruled out. Decay associated spectra shows striking differences between the spectral lineshapes arising from the fast and slow components of the nonlinear optical signal which might indicate the creation of a long-lived state by the pump pulse that changes the subsequent probe spectra. This indicates the possibility of the presence of either a trap state or possibly a more complex energy level structure for the SWCNT involving the presence of a metastable state.

3:54PM X6.00008 Asymmetric resonance Raman excitation profiles and violation of the Condon approximation in single-wall carbon nanotubes, STEPHEN DOORN, JUAN DUQUE, HAGEN TELG, Los Alamos National Laboratory, HANG CHEN, ANNA SWAN, Boston University, ERIK HAROZ, JUNICHIRO KONO, Rice University, XIAOMIN TU, MING ZHENG, NIST — DNA wrapping-based ion exchange chromatography and density gradient ultracentrifugation provide nanotube samples highly enriched in single chiralities. We present resonance Raman excitation profiles for the G-band of several single chirality semiconducting and metallic species. The expected incoming and outgoing resonance peaks are observed in the profiles, but contrary to long-held assumptions, the outgoing resonance is always significantly weaker than the ingoing resonance peak. This strong asymmetry in the profiles arises from a violation of the Condon approximation [1]. Results will be discussed in the context of theoretical models that suggest significant coordinate dependence in the transition dipole (non-Condon effects). The generality of the behavior across semiconducting and metallic types, nanotube family, phonon mode, and Eii will be demonstrated.

4:06PM X6.00009 Raman Spectroscopy characterization of individual triple-walled carbon nanotubes, THOMAS HIRSCHMANN, PAULO ARAUJO, MILDRED DRESSELHAUS, Massachusetts Institute of Technology, USA, KORNELIUS NIELSCH, University of Hamburg, Germany — The characterization of individual triple-walled carbon nanotubes (TWCNT) was studied in detail by using Raman spectroscopy resonant signals taken with various laser excitation energies. TWCNTs are in fact an assembly of three concentric weakly coupled single-walled carbon nanotubes (SWCNTs) or, equivalently, a double-walled carbon nanotube (DWCNT) concentric to an external SWCNT. An isolated TWCNT consists of an inner, middle and outer tube, each of which can be either metallic or semiconducting. All of the eight possible combinations provide a multitude of information about the electrical and optical properties. Among numerous applications, TWCNTs offer an ideal structure to study and understand how an interacting medium influences the properties of both, SWCNTs and DWCNTs structures. The measured spectra show exceptionally distinctive radial breathing modes, G-, G'-band and further modes of the three concentric tubes. All of the Raman three bands described above are very sensitive to changes in the structure of each tube. By following the spectral changes of these frequency modes, we can extract important information about, for example, the respective tube distances, inter-tube interaction in TWCNTs systems and its consequences on their related SWCNTs and DWCNTs counterparts.

4:18PM X6.00010 Resonance Raman Spectroscopy of Separated Single-Wall Carbon Nanotube¹, J.R. SIMPSON², Towson University, J.A. FAGAN, X. TU, M. ZHENG, A.R. HIGHT WALKER, National Institute of Standards and Technology, J.G. DUQUE, J. CROCHET, S.K. DOORN, Los Alamos National Laboratory — The heterogeneity of single-wall carbon nanotubes (SWCNTs) produced by typical techniques complicates characterization and presents a barrier for technological applications. Improvements in separation and purification techniques enable detailed studies of specific nanotube properties by providing samples of unique chirality, length, metallicity, bundling, and interior filling. We report resonant Raman spectroscopy (RRS) measurements on these samples over a wide range of excitation wavelengths using a series of discrete and continuously tunable laser sources coupled to a triple-grating spectrometer. RRS of these homogeneous samples reveals unique spectral features and affords interpretation of intrinsic nanotube optical properties. Of particular interest are the G-band of chirally-pure armchair metallic SWCNTs and shifts of the radial breathing mode and excitation energy with water filling. Additionally, we will compare Raman results with other optical characterization techniques.

4:30PM X6.00011 Optical properties of single-walled carbon nanotube aerogels¹, GORDANA OSTOJIC, Northwestern University — A network of connected single-walled carbon nanotubes (SWNT) is created by a novel DNA-protein complex directed assembly. Due to a point-like nature of connectors, the SWNT aerogel represents a network of self-suspended nanotubes with a record ultra-low density of less 0.75 mg/cm³. The assembly method and low density enables a direct comparison of optical properties of nanotubes in solvent and air to surfactant solubilized nanotubes. Optical properties of SWNT gels are investigated using optical absorption, photoluminescence and Raman spectroscopy. Gelled nanotubes in water and in the low population regime behave similar to solubilized nanotubes. In contrast, photoluminescence of SWNT aerogels exhibit nonlinear effects and a phonon-induced broadening. In addition, aerogels show a previously unobserved photoluminescence peak at 1.3 eV that corresponds to a phonon-assisted recombination of photoexcited charges. Raman spectra of carbon nanotube aerogels display narrow peaks due to the phonon decoupling of suspended SWNTs in air and a redistribution of G phonon population due to nonlinear effects.

4:42PM X6.00012 ABSTRACT WITHDRAWN —

4:54PM X6.00013 Coupled Radial Breathing Oscillation in Double-Walled Carbon Nanotubes, KAIHUI LIU, XIAOPING HONG, UC Berkeley, ENGE WANG, Peking University, China, FENG WANG, UC Berkeley, UC BERKELEY COLLABORATION, PEKING UNIVERSITY, CHINA COLLABORATION — Double-walled carbon nanotubes (DWNTs) provide a model system for quantitative study of electronic and vibrational couplings in the nanoscale. Here we investigate coupled radial breathing mode (RBM) oscillations in structurally defined DWNTs by combining electron diffraction, Rayleigh scattering, and Raman scattering spectroscopy on the same individual nanotubes. We find that the two RBM oscillations in DWNTs are strongly coupled, with vibration energies significantly higher than those of constituent inner- and outer-wall nanotubes. In addition, the oscillation strength of these two coupled modes shows an interesting quantum interference behavior between the inner- and outer-wall electronic resonance channels.

5:06PM X6.00014 Observation of Optical Phonon Emission Threshold in the Current-Voltage Characteristics of Suspended Carbon Nanotubes, MOH AMER, University of southern california, ADAM BUSHMAKER, The Aerospace Corporation, IKAI HSU, STEVE CRONIN, University of southern california — Electrically-heated suspended, nearly defect-free, carbon nanotubes (CNTs) exhibiting negative differential conductance in the high bias regime experience a sudden drop in current (or “kink”). The bias voltage at the kink (V_{kink}) is found to depend strongly on the applied gate voltage, substrate temperature, pressure, and gas environment. After subtracting the voltage drop across the contacts, however, the kink bias voltages converge around 0.2V, independent of gate voltage and gas environment. Due to the ballistic nature of these defect free carbon nanotubes, this bias voltage of 0.2V corresponds to the threshold energy of optical phonon emission. This phenomenon is corroborated by simultaneously monitoring the Raman spectra of these nanotubes as a function of bias voltage. At the kink bias voltage, the Gband Raman modes experience a sudden downshift, further indicating threshold optical phonon emission. A Landauer model is used to fit these kinks in various gas environments where the kink is modeled as a sudden change in the optical phonon lifetime, which corresponds to a change in the non-equilibrium factor that describes the existence of hot phonons in the system.

5:18PM X6.00015 The Electronic and Vibrational Properties of Carbon Nanorings, HANG CHEN, ANNA SWAN, Electrical and Computer Engineering Department and Photonics Center, Boston University — [n]-Cycloparaphenylenes ([n]-CPPs), carbon nanorings with n benzene units reminiscent of a single unit of a (n, n) armchair carbon nanotubes, show unusual optical behaviors: the absorption maximum is almost size independent at 340 nm, while the lower energy fluorescence exhibits multiple peaks with strong size dependence, opposite of quantum confinement behavior [1]. The energy levels for CPPs with various sizes are calculated using time-dependent density functional theory (TDDFT) and compared to the experimental results. Moreover, we calculate the Raman modes of various [n]-CPPs and propose that the multiple peaks observed in the fluorescence spectra could be due to the electron-phonon coupling effects. We also consider possible excitonic effects in these carbon nanorings, and discuss their similarities as well as differences to carbon nanotubes. [1] T. Iwamoto, Y. Watanabe, Y. Sakamoto, T. Suzuki, S. Yamago. *J. Am. Chem. Soc.*, 133, 2011;

Session X7 DCMP: Electronic, Structural and Chemical Properties of Non-Carbon Nanotubes and Nanowires 207

2:30PM X7.00001 Electronic properties of fluorine passivated silicon nanowires: density functional calculations, KEENAN ZHUO, MEI-YIN CHOU, Georgia institute of technology — Arrays of silicon nanowire (SiNWs) have recently gained attention as a promising new photovoltaic technology. Previous studies show that halogen passivated SiNWs have good chemical stability and also form a critical pathway towards organic group functionalization. Yet, surface halogens are known to alter the SiNW electronic structure, most notably by reducing the band gap. We explore the fundamental physics behind this effect through first principles calculations on hydrogen and fluorine passivated (110) SiNWs. Electronic structure analysis reveals that the highly electronegative fluorine passivation modifies the quantum confinement potential and induces changes in the energy level ordering. Furthermore, we show how a modified cylindrical potential well model can demonstrate a link between this quantum confinement modification and the shift in energy levels responsible for the band gap reduction.

2:42PM X7.00002 Molecular Hydrogen and Oxygen Interactions with Armchair Si Nanotubes¹

, HAOLIANG CHEN, ASOK RAY, Physics Department, University of Texas at Arlington, Arlington, Texas 76019 — First principles calculations based on hybrid density functional theory have been used to study the electronic structure properties of armchair silicon nanotubes from (3, 3) to (12, 12). Full geometry and spin optimizations have been performed without any symmetry constraints with an all electron 3-21G* basis set and the B3LYP functional. The largest silicon nanotube studied has a cohesive energy of 3.47eV/atom. Molecular hydrogen and oxygen adsorptions on a (6, 6) tube have been studied by optimizing the distances of the ad molecules from both inside and outside the tube. The molecule is originally placed perpendicular or parallel to the tube axis. The on-top external site is the most preferred site for the hydrogen molecule with adsorption energy of 3.71eV and an optimized distance of 3.31 Å when it is perpendicular to the tube axis. For oxygen, the molecule dissociates into two atoms with adsorption energy of 7.45eV, the optimized distances being 1.65/1.68Å. The buckling of the nanotubes increased significantly indicating structural deformation and an increase of sp³ structure. The band gap increases from 0.98eV of bare nanotube to 1.26eV after adsorption of hydrogen molecule. For oxygen molecule, the band gap slightly increases from 0.98eV to 1.01eV.

2:54PM X7.00003 Modeling Earle-Stage Kinking during VLS Ge Nanowire Growth , SEUNGHWA

RYU, Mechanical Engineering, Stanford University, Stanford, CA, United States, YANYING LI, Applied Physics, Stanford University, Stanford, CA, United State, ANN F. MARSHALL, Geballe Laboratory for Advanced Materials, Stanford University, Stanford, CA, United State, WEI CAI, Mechanical Engineering, Stanford University, Stanford, CA, United State, PAUL C. MCINTYRE, Materials Science Engineering, Stanford University, Stanford, CA, United State — The catalyzed growth of Ge nanowires from gold nanoparticles via the vapor-liquid-solid (VLS) mechanism has been the subject of intense research worldwide, due to their potential applications in nanotechnology. Understanding the fundamental mechanisms underlying kinking during Ge nanowire growth, especially at the early-stage, is helpful for better control of Ge nanowire growth for technological applications. We report an investigation of wire morphology before and during Ge nanowire kinking in early stage growth under typical nucleation conditions. The Ge nanowires grew either along the vertical [111] direction or kinked away onto inclined <111> axes early on during their growth. We found that most kinked Ge nanowire deposited under these conditions kinked at similar height, and had similar sidewall facet structure in the kinked region. High-resolution transmission and scanning electron microscopy investigations also showed that the typical kinking-structure was bounded by (111) and other relatively stable Ge surface facets. We construct 3D phase field model of the nanowire based on the transmission and scanning electron microscopy and compare the evolution of the droplet and nanowire with experimental observations.

3:06PM X7.00004 Detection of bio-molecules of different polarities by Boron Nitride Nan-

otube , SAIKAT MUKHOPADHYAY, Michigan Technological University, RALPH SCHEICHER, Department of Physics and Astronomy, Uppsala University, RAVINDRA PANDEY, Michigan Technological University, SHASHI KARNA, U.S. Army Research Laboratory, Weapons and Materials Research Directorate, DEPARTMENT OF PHYSICS, MICHIGAN TECHNOLOGICAL UNIVERSITY COLLABORATION, DEPARTMENT OF PHYSICS AND ASTRONOMY, UPPSALA UNIVERSITY COLLABORATION, U.S. ARMY RESEARCH LABORATORY, WEAPONS AND MATERIALS RESEARCH DIRECTORATE COLLABORATION — The effect of molecular polarity on the interaction between a boron nitride nanotube (BNNT) and amino acids is investigated with density functional theory. Three representative amino acids, namely, tryptophane (Trp), a nonpolar aromatic amino acid, and aspartic acid (Asp) and arginine (Arg), both polar amino acids are considered for their interactions with BNNT. The polar molecules, Asp and Arg, exhibit relatively stronger binding with the tubular surface of BNNT. The binding between the polar amino acid molecules and BNNT is accompanied by a charge transfer, suggesting that stabilization of the bioconjugated complex is mainly governed by electrostatic interactions. The results show modulation of the BNNT band gap by Trp. Interestingly, no change in band gap of BNNT is seen for the polar molecules Asp and Arg. The predicted higher sensitivity of BNNTs compared to carbon nanotubes (CNTs) toward amino acid polarity suggests BNNTs to be a better substrate for protein immobilization than CNTs.

3:18PM X7.00005 Quantum Confinement and Surface Relaxation Effects in Rutile TiO₂

Nanowires¹ , ABRAHAM HMIEL, YONGQIANG XUE, College of Nanoscale Science and Engineering, State University of New York at Albany — Recent developments in synthesis of TiO₂ nanowires with diameters on the atomic scale have opened up new grounds for studying structure-property relationships in the regime where quantum confinement effects are important. In the sub-nanometer range, the properties of nanowires can be sensitive to atomic-level control of surface morphology, functionalization, and nanowire stoichiometry during the growth and fabrication processes, thereby opening the way for new applications. First-principles density functional theory calculations have been applied to investigate the size- and shape-dependent properties of [001]-oriented rutile TiO₂ nanowires of rectangular cross section. We find that the pronounced oscillation in the formation energy and band structure of the nanowires as a function of the number of TiO₂ trilayers is largely connected to the presence or absence of a mirror Ti-O plane along each confinement direction. We demonstrate that the relative stability and the indirect or direct character of the band structure of the rutile TiO₂ nanowires arise from the interplay between surface relaxation and quantum confinement effects that depend on the even-odd parity of the number of TiO₂ trilayers.

3:30PM X7.00006 Simulation of Nanowires on Metal Vicinal Surfaces: Effect of Growth Parameters and Energetic Barriers , AJMI B.H. HAMOUDA, University of Maryland & Univ. of Monastir, SONIA BLEL, Univ. of Monastir,

T.L. EINSTEIN, University of Maryland, MRSEC, MARYLAND TEAM, LAB. OF QUANTUM PHYSICS OF MONASTIR TEAM — Growing one-dimensional metal structures is an important task in the investigation of the electronic and magnetic properties of new devices. We used kinetic Monte-Carlo (kMC) method to simulate the formation of nanowires of several metallic and non-metallic adatoms on Cu and Pt vicinal surfaces. We found that mono-atomic chains form on step-edges due to energetic barriers (the so-called Ehrlich-shwoebel and exchange barriers) on step-edge. Creation of perfect wires is found to depend on growth parameters and binding energies. We measure the filling ratio of nanowires for different chemical species in a wide range of temperature and flux. Perfect wires were obtained at lower deposition rate for all tested adatoms, however we notice different temperature ranges. Our results were compared with experimental ones [Gambardella et al., Surf. Sci. 449, 93-103 (2000), PRB 61, 2254-2262, (2000)]. We review the role of impurities in nanostructuring of surfaces [Hamouda et al., Phys. Rev. B 83, 035423, (2011)] and discuss the effect of their energetic barriers on the obtained quality of nanowires. Our work provides experimentalists with optimum growth parameters for the creation of a uniform distribution of wires on surfaces.

3:42PM X7.00007 Escape of an axial dislocation from a thin rod , ZHAOXUAN WU, YONG-WEI ZHANG, MARK

JHON, DAVID SROLOVITZ, Institute of High Performance Computing — Whiskers, nanowires and nanorods have been supposed to grow by preferential attachment to the atomic step formed from a screw dislocation intersecting the surface. This is expected to leave behind an axial screw dislocation, as has been observed in ionic nanowires such as NaCl, PbS and PbSe. However, we are not aware of any studies that have directly observed axial dislocations in pure FCC metal nanowires. To explain this, we speculate that thermal vibrations will be enough to kick out dislocations due to their high mobility. We consider two models of how a dislocation might escape from a nanowire. The first model is that the dislocation vibrates inside the nanowire. The second is that the nanowire itself vibrates, causing deformations of the nanowire that push the dislocation out. Analysis of these models imply that dislocations in thin nanowires are remarkably thermally stable. We test this prediction with molecular dynamics calculations on Cu nanowires, and find that the preparation of these systems is critical to the dislocation stability. Preparing the sample by simply raising the MD temperature will cause the dislocation to run out.

3:54PM X7.00008 Ensemble Measurements of Temperature Dependence in High-Q GaN Nanowire Mechanical Resonators¹, JOSHUA MONTAGUE, University of Colorado, KRIS BERTNESS, NORMAN SANFORD, NIST Quantum Electronics and Photonics Division, VICTOR BRIGHT, CHARLES ROGERS, University of Colorado — We report on measurements of c-axis oriented, single crystal, gallium nitride nanowire (GaN NW) mechanical resonators. Our measurements use a capacitively-coupled, microwave homodyne reflectometer that allows for simultaneous detection of large ensembles of the as-grown, GaN NW resonators. The NWs - grown via molecular beam epitaxy - behave as singly clamped beams, have lengths near 15 microns, and radii near 100 nm. We observe, respectively, typical resonance frequencies and mechanical quality factors (defined as the ratio of resonance frequency to full width at half maximum power), Q, near 1 MHz and above 10,000, near room temperature [1]. At lower temperatures, we observe increases in resonance frequencies consistent with temperature-dependent elastic moduli. Measured Q factors demonstrate a minimum near 150 K and typically increase an order of magnitude - to above 100,000 - below 100 K.

4:06PM X7.00009 ABSTRACT WITHDRAWN —

4:18PM X7.00010 Low-frequency noise in gallium nitride nanowire mechanical resonators, JASON GRAY, University of Colorado, KRIS BERTNESS, NORMAN SANFORD, National Institute of Standards and Technology, CHARLES ROGERS, University of Colorado — We report on the low-frequency 1/f (flicker) parameter noise displayed by the resonance frequency and resistance of doubly clamped c-axis gallium nitride nanowire (NW) mechanical resonators. The resonators are electrostatically driven and their mechanical response is electronically detected via NW piezoresistance. With an applied dc voltage bias, an NW driven near its mechanical resonance generates a dc and Lorentzian rf current that both display 1/f noise. The rf current noise is proportional to the square of the derivative of the Lorentzian lineshape with a magnitude highly dependent on NW dc bias voltage conditions, consistent with noise in the NW's resistance leading to temperature noise from local Joule heating, which in turn generates resonance frequency noise. An example device with a 27.8 MHz resonance frequency and 220 k Ω resistance experiences an approximate resonance frequency shift of -5.8 Hz/nW. In terms of NW resistance change, this corresponds with shifts of 0.1 Hz/ Ω and 2.6 Hz/ Ω at 1 V bias and 4 V bias, respectively, with an average resistance fluctuation of 1 k Ω in a 1-second bandwidth.

4:30PM X7.00011 Unusual Germanium Nanowire Crystal Structures Formed During Low Temperature Catalytic Growth¹, ANDREW GAMALSKI, Dep. of Engineering, University of Cambridge, JERRY TERSOFF, IBM T. J. Watson Research Center, CATERINA DUCATI, Dep. of Materials Science and Metallurgy, University of Cambridge, RENU SHARMA, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, STEPHAN HOFMANN, Dep. of Engineering, University of Cambridge — Implementing bottom-up grown semiconductor nanowires (NW) in technological applications will require a detailed understanding of the electronic/physical properties of the NWs, which are closely related to their crystal structure. We present environmental transmission electron microscopy video data of Au catalyzed Ge NW growth under digermane exposure at 240 – 320 °C. The catalyst particles are initially liquid after gas exposure [1], and Ge NWs temporarily grow by step flow from the liquid AuGe alloy [2] before the liquid catalyst crystallizes into a metastable solid phase. Nucleating solid Ge at low temperatures requires a considerable supersaturation in the liquid catalyst, which drives the formation of a NW with a non-equilibrium crystal structure [3]. We explore how nanoscale systems with high supersaturations lead to the formation of metastable phases whose properties can be dramatically different from those of the common bulk phases. [1] A. D. Gamalski et al., Nano Lett., 10, 2972 (2010) [2] A. D. Gamalski et al., J. Phys. Chem. C, 115, 4413 (2011) [3] A. D. Gamalski et al., in preparation

4:42PM X7.00012 Strong Spin-Orbit Interaction and Helical Hole States in Ge/Si Nanowires, CHRISTOPH KLOEFFEL, University of Basel, MIRCEA TRIF, University of California, Los Angeles, DANIEL LOSS, University of Basel — We study theoretically the low-energy hole states of Ge/Si core/shell nanowires. The low-energy valence band is quasidegenerate, formed by two doublets of different orbital angular momenta, and can be controlled via the relative shell thickness and via external fields. We find that direct (dipolar) coupling to a moderate electric field leads to an unusually large spin-orbit interaction of Rashba type on the order of meV which gives rise to pronounced helical states enabling electrical spin control. The system allows for quantum dots and spin qubits with energy levels that can vary from nearly zero to several meV, depending on the relative shell thickness [1].

4:54PM X7.00013 Spontaneous Formation of A Nanotube From A Square Ag Nanowire: An Atomistic View¹, MINE KONUK ONAT, Department of Physics, Istanbul Technical University, Istanbul, Turkey, SONDAN DURUKANOGLU, Nanotechnology Research and Application Center, and Faculty of Engineering and Natural Sciences, Sabanci University, Istanbul, Turkey — We have performed molecular static calculations to investigate the recently observed phenomenon of the spontaneous formation of a nanotube from a regular, square Ag nanowire[1]. In the simulations, atoms are allowed to interact via the model potential obtained from the modified embedded atom method. Our simulations predict that this particular type of structural phase transformation is controlled by the nature of applied strain, length of the wire and initial cross-sectional shape. For such a perfect structural transformation, the <100> axially oriented fcc nanowire needs (1) to be formed by stacking A and B layers of an fcc crystal, both possessing the geometry of two interpenetrating one-lattice-parameter-wide squares, containing four atoms each, (2) to have an optimum length of eight layers, and (3) to be exposed to a combination of low and high stress along the length direction. The results further offer insights into atomistic nature of this specific structural transformation into a nanotube with the smallest possible cross-section. [1] M.J. Lagos et al., Nature Nanotech. 4, 149 (2009).

5:06PM X7.00014 Crossed Andreev Reflection in Quantum Wires with Strong Spin-Orbit Interaction, KOJI SATO, University of California, Los Angeles, DANIEL LOSS, University of Basel, YAROSLAV TSERKOVNYAK, University of California, Los Angeles — We theoretically study tunneling of Cooper pairs from an s-wave superconductor into two semiconductor quantum wires with strong spin-orbit interaction under magnetic field, which approximate helical Luttinger liquids. The entanglement of the two electrons within a Cooper pair can be detected by the electric current cross correlations in the wires. By controlling the relative orientation of the wires, either lithographically or mechanically, on the substrate, the ensuing current correlations can be tuned, as dictated by the initial spin entanglement. This proposal of a spin-to-charge readout of quantum correlations is alternative to a recently proposed utilization of the quantum spin Hall insulator.

5:18PM X7.00015 A Microscopic View of Repeated Polytypism in Self-organization of Hierarchical Nanostructures¹, MU WANG, MING LIU, GUO-BIN MA, ZHAO-WU WANG, RU-WEN PENG, Natl. Lab. Solid State Microstructures, Nanjing University, China — We demonstrate that the stacking-fault-induced repeated polytypism of wurtzite (WZ) and zinc-blend (ZB) phases may lead to a hierarchical nanostructure of ZnO possessing a hexagonal central trunk decorated with thin blades. Each blade keeps a fixed angle to the central trunk, resembling propellers with seemingly six-fold symmetry. The blades epitaxially nucleate on the ZB stripe assisted by the defect-induced reentrant corners at the interface of ZB-WZ phases. Our experiments reveal a unique approach to assemble hierarchical nanostructures, and the mechanism could be general to many materials.

2:42PM X8.00002 Lifetime of gapped excitations in antiferromagnets¹, SASHA CHERNYSHEV, UC Irvine, MICHAEL ZHITOMIRSKY, CEA Grenoble — We show that local modulations of magnetic couplings may have a profound effect on the temperature-dependence of the relaxation rate of gapped excitations in a class of antiferromagnets in which gapless modes are also present. Considering a prototypical 2D XY antiferromagnet with random disorder we find that the disorder-induced relaxation rate of the gapped mode should greatly exceed the effect of conventional magnon-magnon scattering, which becomes negligible at low temperatures. Our results compare favorably with the available experimental data. Generalizations to the other systems are discussed.

¹Supported by the DoE.

2:54PM X8.00003 Effect of Interlayer Coupling on Field-Induced Magnon Decays in Square-Lattice Antiferromagnet¹, WESLEY FUHRMAN, UC Irvine, MARTIN MOURIGAL, Johns Hopkins, MICHAEL ZHITOMIRSKY, CEA Grenoble, SASHA CHERNYSHEV, UC Irvine — We study the high-field magnon dynamics in the quasi-2D tetragonal Heisenberg antiferromagnet. Within spin-wave theory, we show that non-zero interlayer coupling mitigates singular corrections to the excitation spectrum occurring above the threshold field that would otherwise require a self-consistent approach beyond the Born approximation. Increasing field yields widening two-magnon sidebands with significant shifting of the spectral weight away from the quasi-particle peak. We examine the dynamic structure factor with interlayer coupling corresponding to realistic materials.

¹Supported by DoE

3:06PM X8.00004 Detecting non-magnetic excitations in quantum magnets¹, ZHIHAO HAO, Department of Physics and Astronomy, University of Waterloo — Many unconventional quantum phases host special non-magnetic excitations such as photons and visons. We discuss two possible ways to detect these excitations experimentally. Firstly, spin-lattice coupling mixes the excitations with phonons. The phonon spectral function acquires new features that can be detected by neutron or X-ray scattering. Secondly, valence-bond fluctuations translate into charge density fluctuations on non-bipartite lattices. Such charge fluctuations can be characterized by conventional spectroscopies such as Terahertz spectroscopy. Observation of exotic singlet excitations would provide positive identification of unconventional quantum phases in frustrated antiferromagnets.

3:18PM X8.00005 Finite temperature phase diagram of quantum compass model¹, FEI LIN, VITO SCAROLA, Virginia Tech — The quantum compass model has been proposed as a simplified model to study Mott insulators with orbital degeneracy and, more recently, as a candidate model to study protected non-local qubits. In this talk we will show that in addition to well known bond-directional ordering, there is additional ordering associated with long range string operators. We will discuss quantum Monte Carlo results that explore the thermodynamics of non-local order in the quantum compass model.

¹This work is supported by AFOSR (FA9550-11-1-0313) and DARPA-YFA (N66001-1-1-4122).

3:30PM X8.00006 Order by geometrical disorder in a 2D quantum antiferromagnet, ANURADHA JAGANNATHAN, Universite Paris-Sud, Orsay, BENOIT DOUCOT, Universite Pierre et Marie Curie, Paris 6, ATTILA SZALLAS, S3 nanoscience Institute- CNR, Modena, Italy, STEFAN WESSEL, Institute for Theoretical Solid State Physics, RWTH Aachen University — We consider the effects of random fluctuations in the local geometry on the ground state properties of a two-dimensional quantum antiferromagnet. We analyse the behavior of spins described by the Heisenberg model as a function of what we call “phason flip disorder,” following a terminology used for aperiodic systems. The calculations were carried out both within linear spin wave theory and using quantum Monte Carlo simulations. An “order by disorder” phenomenon is observed in this model, wherein antiferromagnetism is found to be enhanced by phason disorder. The value of the staggered order parameter increases with the number of defects, accompanied by an increase in the ground state energy of the system. We furthermore find a long-ranged attractive Casimir-like force between two domain walls of defects separated by a finite distance.

3:42PM X8.00007 From Popov-Fedotov case to universal fermionization¹, BORIS SVISTUNOV, NIKOLAY PROKOF'EV, University of Massachusetts, Amherst — We show that Popov-Fedotov trick of mapping spin-1/2 lattice systems on two-component fermions with imaginary chemical potential readily generalizes to bosons with a fixed (but not limited) maximal site occupation number, as well as to fermionic Hamiltonians with various constraints on the site Fock states. In a general case, the mapping—fermionization—is on multi-component fermions with many-body non-Hermitian interactions. Additionally, the fermionization approach allows one to convert large many-body couplings into single-particle energies, rendering the diagrammatic series free of large expansion parameters; the latter is essential for the efficiency and convergence of the diagrammatic Monte Carlo method.

3:54PM X8.00008 Universality of modulation length exponents, SAURISH CHAKRABARTY, ALEXANDER SEIDEL, ZOHAR NUSSINOV, Department of Physics, Washington University in St Louis — We study systems (classical or quantum) with general pairwise interactions. Our prime interest is in frustrated spin systems. First, we focus on systems with a crossover temperature T^* across which the correlation function changes from exhibiting commensurate to incommensurate modulations. We report on a *new exponent*, ν_L , characterizing the universal nature of this crossover. Near the crossover, the characteristic wave-vector k on the incommensurate side differs from that on the commensurate side, q by $|k - q| \propto |T - T^*|^{\nu_L}$. We find, in general, that $\nu_L = 1/2$, or in some special cases, other rational numbers. We discuss applications to the axial next nearest neighbor Ising model, Fermi systems (with application to the metal to band insulator transition) and Bose systems. Second, we obtain a universal form of the high temperature correlation function in general systems. From this, we show the existence of a diverging correlation length in the presence of long range interactions. Such a correlation length tends to the screening length in the presence of screening. We also find a way of obtaining the pairwise interaction potentials in the high temperature phase from the correlation functions.

4:06PM X8.00009 Restricted Spin Set Lattice Models: A Route to Topological Order¹, R. ZACHARY LAMBERTY, Cornell University, STEFANOS PAPANIKOLAOU, Yale University, C.L. HENLEY, Cornell University — A typical lattice gauge model configuration consists of elements of a finite symmetry group G placed on directed edges of a two-dimensional lattice. We consider generalized models² which are defined by instead only allowing elements from a subset $S \subset G$ consisting of certain classes of group elements. The subset restriction can be regarded as a new (but discrete) tunable model parameter, providing a novel pathway to topologically ordered phases. Taking a small allowed set S , we can realize well understood critical models (e.g. the square lattice ice model or dimer covering); in contrast, for large enough S the configuration ensemble realizes a form of topological order. Using a sequence of sets $S_1 \subset S_2 \subset \dots$, we can “interpolate” from one kind of state to the other. This is confirmed by Monte Carlo simulations, measuring two characteristic properties: (1) the distribution of separations between two (possibly deconfined) topological defects, and (2) the relative probabilities of different sectors (sub-ensembles with inequivalent products of the group elements around the periodic boundary conditions). We also discuss how to construct quantum-mechanical extensions of these models.

¹Supported by the National Science Foundation through a Graduate Research Fellowship to R. Zach Lamberty, as well as grant DMR-0552461.

4:18PM X8.00010 Stability of the quantum Lifshitz model in 2+1 Dimensions, BENJAMIN HSU, Princeton University, EDUARDO FRADKIN, University of Illinois, Urbana Champaign — Magnetic and electric perturbations to the quantum Lifshitz model in 2+1 dimensions are examined in this paper. The quantum Lifshitz model is an effective field theory for quantum critical systems that include generalized 2D quantum dimer models in bipartite lattices. Magnetic perturbations break the dimer conservation law. Electric excitations have been studied extensively both in the classical 3D model and in the quantum 2D model, but magnetic vortex excitations have been ignored. While they are forbidden in classical 3D statistical mechanics, they are allowed in the quantum version. To study the interplay of both excitations, we perform a perturbative renormalization group study to one loop order. This is done by generalizing the operator product expansion to anisotropic models. The relation with recent classical Monte Carlo simulations will be discussed.

4:30PM X8.00011 Supersymmetry in strongly correlated fermion models, DIMITRIOS GALANAKIS, Nanyang Technological University, STEFANOS PAPANIKOLAOU, Yale University, CHRIS HENLEY, Cornell University — We investigate the Fendley and Schoutens¹ model of hard core fermions on a lattice which have hopping elements t , and potential terms V which include a second-neighbor repulsion with some multi-particle terms. At the special point $t = V$, the Hamiltonian is $H = \{Q^\dagger(r), Q\}$ with $Q = \sum_r q(r) = \sum_r c(r)P(r)$, where $c(r)$ is an annihilation operator and $P(r)$ enforces the hard core. That means the system acquires an exact non-relativistic supersymmetry, and for a range of fillings has a large number of zero-energy ground states¹. To better understand the nature of the zero-energy states and excitations, we perform exact diagonalizations on finite clusters for the square and triangular lattice, different fillings and center of mass momenta. In momentum sectors with unique zero energy ground states we find a menagerie of symmetry breaking patterns in the density-density correlation functions and we investigate them further by evaluating the entanglement spectrum. In momentum sectors with degenerate ground states we search for topological ground states using the numerical Berry matrix method².

4:42PM X8.00012 First-principles study on electronic properties of the pyrochlore oxide Cd₂Os₂O₇¹, HIROSHI SHINAOKA, NRI, AIST, TAKASHI MIYAKE, SHOJI ISHIBASHI, NRI, AIST — The pyrochlore oxide Cd₂Os₂O₇ is one of 5d pyrochlore oxides in which the interplay of geometrical frustration, electron correlation, and spin-orbit coupling is expected. This compound exhibits a metal-insulator transition at 227 K, below which the emergence of a magnetic order has been suggested by experiments. Despite extensive studies for over thirty years, however, the nature of the low-temperature phase remains to be clarified. We depict the ground-state phase diagram based on the LSDA+ U method (LSDA denotes local spin density approximation). We find that the all-in/all-out non-collinear magnetic order is stable in a wide range of U . We show that the easy-axis anisotropy arising from the spin-orbit coupling plays a significant role in stabilizing the all-in/all-out magnetic order. A pseudo gap extending up to high energy is found to appear near a continuous metal-insulator transition between an antiferromagnetic metallic phase and an antiferromagnetic insulating phase. Based on the computed results, we discuss possible origins of peculiar low-temperature properties observed in experiments.

¹This study has been funded by JST-CREST.

4:54PM X8.00013 Exchange and Magnetic Anisotropic Interactions of Magnetic Ions in Antiferromagnetic Materials, ALEXANDER BAZHAN, P.L. Kapitza Institute for Physical Problems, RAS, Kosygin str, 2, Moscow, Russia — Investigations of exchange and magnetic anisotropic interactions, based on materials crystallographic and magnetic symmetry, introducing quadratic forms of thermodynamic potentials, invariant with respect to operations of magnetic symmetry groups and presented in irreducible representations of interacting ions magnetic moments, are in discussions in connection with considerations of symmetric, Anderson exchange interactions, based on Hubbard Hamiltonians, that indicates dependencies of symmetric exchange on electrons transferings between magnetic, nonmagnetic ions, electrons kinetic energy, Coulomb interactions and, determined by crystal fields, energy levels. As example, according to symmetry for some rhombohedral structures, spin Hamiltonians of symmetric, Anderson and antisymmetric, Dzyaloshinskii-Moria exchange, $H_{ex} = \sum_{ij} J_{ij}(\mathbf{S}_i \mathbf{S}_j) - \sum_{ij} D_{ij,z}(\mathbf{S}_{ix} \mathbf{S}_{jy} - \mathbf{S}_{iy} \mathbf{S}_{jx})$, with $D_{ij,z}$ in abs values. Magnetic field dependencies of separate, three components of samples magnetic moments of vector v.s. magnetometer, indicating magnetic moments orientations, present direct information about interactions of magnetic ions, especially with high spin orbit interactions.

2:30PM X9.00001 Temperature and pressure induced Cu-Fe intermetallic charge transfer in $\text{LaCu}_3\text{Fe}_4\text{O}_{12}$ ¹, YOUWEN LONG, ICR, Kyoto Univ., Kyoto 611-0011, Japan; IOP, CAS, Beijing 100190, China, T. KAWAKAMI, IQS, Nihon Univ., Tokyo 101-8308, Japan, Y. SHIMAKAWA, ICR, Kyoto Univ., Kyoto 611-0011, Japan — An A-site ordered double perovskite $\text{LaCu}_3\text{Fe}_4\text{O}_{12}$ was prepared at high pressure and high temperature. At ambient condition, the charge combination was proved to be $\text{LaCu}_3^{3+}\text{Fe}_4^{3+}\text{O}_{12}$. When the temperature was increased to 393 K, however, an intermetallic charge transfer was found to occur between the A-site Cu and the B-site Fe ions, giving rising to the change of charge combination from the low-temperature $\text{LaCu}_3^{3+}\text{Fe}_4^{3+}\text{O}_{12}$ to the high-temperature $\text{LaCu}_3^{2+}\text{Fe}_4^{3.75+}\text{O}_{12}$. [1,2] Similarly, at room temperature, if high pressure was applied, the Cu-Fe intermetallic charge transfer could also be induced. This charge transfer led to a first-order isostructural phase transition with sharp reduction in unit cell, negative thermal expansion and unusual softening (decreased bulk modulus). Moreover, the material experienced antiferromagnetism-to-paramagnetism and insulator-to-metal transitions accompanying with the charge-transfer transition.

2:42PM X9.00002 Spin-phonon coupling effect in AMnO_3 ($A=\text{Ca, Sr, Ba}$) and LaMO_3 ($M=\text{Cr, Fe, Cr/Fe}$) from DFT+ U and hybrid functional methods, JIAWANG HONG, Rutgers University, ALESSANDRO STROPPA, CNR-SPIN, Italy, JORGE INIGUEZ, ICMA-B-CSIC, Spain, SILVIA PICOZZI, CNR-SPIN, Italy, DAVID VANDERBILT, Rutgers University — Spin-phonon coupling effects, as reflected in phonon frequency shifts between ferromagnetic (FM) and G-type antiferromagnetic (AFM) configurations in cubic CaMnO_3 , SrMnO_3 , BaMnO_3 , LaCrO_3 , LaFeO_3 and $\text{La}_2(\text{CrFe})\text{O}_6$, are investigated using density-functional methods. The calculations are carried out using the DFT+ U method with a U that has been extracted by comparing with hybrid-functional (HSE) calculations. The phonon frequency shifts $\Delta\omega = \omega_{\text{AFM}} - \omega_{\text{FM}}$ obtained in this way agree well with those computed directly from the more accurate HSE approach, but are obtained with much less computational effort. We find that in the AMnO_3 materials class with ($A=\text{Ca, Sr, Ba}$), the Γ (R) phonon frequency shift $\Delta\omega$ decreases (increases) as the A^{2+} size increases. In LaMO_3 ($M=\text{Cr, Fe, Cr/Fe}$), the phonon frequencies at Γ decrease as spin order changes from AFM to FM for LaCrO_3 and LaFeO_3 , but they increase for double perovskite $\text{La}_2(\text{CrFe})\text{O}_6$. We discuss the prospects for bulk and superlattice forms of these materials to be useful as multiferroics.

2:54PM X9.00003 Nd magnetic order in $\text{NdFe}_x\text{Ga}_{1-x}\text{O}_3$, FERNANDO BARTOLOME, ICMA - CSIC, MARIA PARRA-BORDERIAS, Centro de Astrobiologia - CSIC, JOSE ALBERTO RODRIGUEZ-VELAMAZAN, JUAN BARTOLOME, BURZURI ENRIQUE, FERNANDO LUIS, MARCO EVANGELISTI, ICMA - CSIC — The Nd magnetic order in $\text{NdFe}_x\text{Ga}_{1-x}\text{O}_3$ has been studied as a function of Fe content along the whole $0 < x < 1$ range, both experimental and theoretically. In NdGaO_3 , where Nd-Nd exchange interaction is in isolation, Nd sublattice orders antiferromagnetically at $T_N = 1$ K. In NdFeO_3 , the Nd sublattice is polarized at low temperatures by Fe-Nd exchange, and a competition between Nd-Nd and Nd-Fe interactions is established, but Nd still orders cooperatively at $T_N = 0.95$ K. The evolution of the magnetic ordering of Nd with the Fe content is studied by low-temperature specific-heat, ac susceptibility and neutron scattering measurements. In the Fe-rich side of the phase diagram, Nd order is inhibited by Fe-Nd internal field at very low Ga content, while in the Fe-poor side, Nd order is more robust, reaching the Fe magnetic percolation concentration ($x_c = 0.33$). We have used a mean field model as well as MonteCarlo simulations to clarify the interpretation of the results. The introduction of Ga ions induces discompensation of the ordered ferromagnetic Fe sublattice which strongly inhibits Nd order. However, this is only effective at every temperature if the Fe sublattice is long range ordered, while below Fe percolation, Nd is able to orders at sufficiently low T.

3:06PM X9.00004 Magnetic phase transitions in single crystalline $\text{Mn}_{0.68}\text{Ni}_{0.32}\text{TiO}_3$ ¹, SONGXUE CHI, HUIBO CAO, FENG YE, JAIME A. FERNANDEZ-BACA, Oak Ridge National laboratory, HAIDONG ZHOU, National High Magnetic Field Laboratory, Florida State University — The magnetoelectric MnTiO_3 has the ilmenite structure and order antiferromagnetically with neighboring Mn^{2+} spins antiparallel to each other both within the ab-plane and along the c-axis. We have observed a magnetic field induced electric polarization in the 32%Ni-doped MnTiO_3 . To understand the origin of this magnetoelectric effect, we have carried out neutron diffraction study on single crystalline $\text{Mn}_{0.68}\text{Ni}_{0.32}\text{TiO}_3$. The Mn^{2+} spins order below 27 K and arrange in the same antiparallel manner as the parent compound, but with different spin direction. On cooling the magnetic phase goes through a second transition at 15 K, below which the spins lock into a new direction. We have also determined the spin structure under a magnetic field applied along the c-axis.

3:18PM X9.00005 Electron energy loss spectroscopy study of $\text{Sr}_{2-x}\text{Gd}_x\text{TiMnO}_6$ ¹, NEVENKO BISKUP, INMACULADA ALVAREZ-SERRANO, MARIA LUISA VEIGA, Universidad Complutense Madrid, Spain, MAR GARCIA-HERNANDEZ, ICMM, CSIC, Spain, MARIA LUISA LOPEZ, Universidad Complutense Madrid, Spain, MARIA VARELA, Oak Ridge National Laboratory — The newly synthesized double perovskite family $\text{Sr}_{2-x}\text{Gd}_x\text{TiMnO}_6$ ($0 < x < 1$) is magnetically frustrated system that orders magnetically at $T=40\text{K}$. In spite of the probable double exchange interaction around $x=0.5$, no metallic state is established and the magnetoresistance is weak in the whole family. The most interesting feature in this material is the giant electroresistance that persists even at room temperature. We have studied the microscopic composition of these polycrystals by the electron energy loss spectroscopy. We find that, in spite of some precipitations of Mn and Ti rich regions that exist in $0.25 \leq x \leq 0.75$, the manganese and titanium ions are generally well intermixed in both interior of the grains and on the grain boundaries. We discuss these results in the frame of highly non-linear electrical conductivity found in these materials.

3:30PM X9.00006 Density functional modeling for a perovskite $\text{SrTi}_{1-x}\text{Co}_x\text{O}_3$ system: Beyond GGA+U functional¹, JUAN MANUEL FLOREZ, Massachusetts Institute of Technology and Universidad Técnica Federico Santa María, SHYUE PING ONG, GERBRAND CEDER, GERALD F. DIONNE, Massachusetts Institute of Technology, PATRICIO VARGAS, Universidad Técnica Federico Santa María, CAROLINE A. ROSS, Massachusetts Institute of Technology — Understanding the exact mechanisms of spin-stabilization according to the oxygen stoichiometry and substituting metal-transition ions is essential to finding new perovskites-based technologies to augment silicon-based devices with room-temperature spintronic materials. We perform ab-initio modeling for the $\text{SrTi}_{1-x}\text{Co}_x\text{O}_3$ system with $x = 0.0, 0.25, 1.0$, and by using a HSE06 hybrid functional. Electronic structure for $x=(0.0,1.0)$ predicts 3.1 eV band gap and a metallic behavior, respectively, predicting lattice parameters in agreement with experiments. Different positions for the cobalt ions are taken into account for $x=0.25$, and predicted ground states and Co energy-correlations suggest the structurally stabilized Co-site positions as fingerprints of whether possible intrinsic magnetic ordering or other phenomena is giving rise to the macroscopic magnetism. Passing from Stoichiometric $\text{SrTi}_{0.75}\text{Co}_{0.25}\text{O}_3$ to 1-O-vacancy $\text{SrTi}_{0.75}\text{Co}_{0.25}\text{O}_{3-\delta}$ produces a lattice parameter expansion due to the valence state distribution of the substituting B (ABO_3) ions, which is turn lead us to a band gap expansion. The stabilized valence spin states of the magnetic ions are discussed in comparison with the ligand-field theory.

3:42PM X9.00007 Role of cooperative structural distortions in the metal–insulator transitions of perovskite ferrates¹, ANTONIO CAMMARATA, JAMES RONDINELLI, Drexel University — Transition-metal oxides within the perovskite crystal family exhibit strong electron–electron correlation effects that coexist with complex structural distortions, leading to metal-insulator (MI) transitions. Using first-principles density functional calculations, we investigate the effects of cooperative octahedral rotations and dilations/contractions on the charge-ordering MI-transition in CaFeO_3 . By calculating the evolution in the lattice phonons, which describe the different octahedral distortions present in the low-symmetry monoclinic phase of CaFeO_3 with increasing electron correlation, we show that the MI-transition results from a complex interplay between these modes and correlation effects. We combine this study with group theoretical tools to disentangle the electron–lattice interactions by computing the evolution in the low-energy electronic band structure with the lattice phonons, demonstrating the MI-transition in CaFeO_3 proceeds through a symmetry-lowering transition driven by a cooperative three-dimensional octahedral dilation/contraction pattern. Finally, we suggest a possible route by which to control the charge ordering by fine-tuning the electron–lattice coupling.

3:54PM X9.00008 Far infrared spectroscopy of magnons and phonons in TbFeO_3 single crystal¹, T.N. STANISLAVCHUK, E.C. STANDARD, A.A. SIRENKO, Department of Physics, New Jersey Institute of Technology, Newark, NJ, USA, G.L. CARR, National Synchrotron Light Source, Brookhaven National Laboratory, Upton, NY, USA, A.A. MUKHIN, Prokhorov General Physics Institute, Moscow, Russia, M.V. MOSTOVOY, Zernike Institute for Advanced Materials, University of Groningen, The Netherlands, N. LEE, S-W. CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, USA — Far-infrared spectra of TbFeO_3 single crystals have been studied in the temperature range between 1.6 K and 300 K using transmission in high magnetic field and rotating analyzer ellipsometry. The symmetry of the IR optical phonons and their oscillator strengths were determined. Polarization and frequencies of two AFM resonances at around 18 and 23 cm^{-1} were analyzed around the spin reorientation (SR) transition at $\sim 8\text{K}$ and magnetic fields up to 9 T. Intensity of the AFM resonances exhibit an unusual oscillator dependence on both temperature and magnetic field. The observed effects are analyzed taking into account main magnetic interactions in the system including exchange of the Fe^{3+} spins with Tb^{3+} paramagnetic moments as well as the geometry of the measurements.

4:06PM X9.00009 Optical properties of iron oxides¹, JANICE MUSFELDT, University of Tennessee — Magnetoelectric coupling in materials like multiferroics, dilute magnetic semiconductors, and topological insulators has attracted a great deal of attention, although most work has been done in the static limit. Optical spectroscopy offers a way to investigate the dynamics of charge-spin coupling, an area where there has been much less effort. Using these techniques, we discovered that charge fluctuation in LuFe_2O_4 , the prototypical charge ordered multiferroic, has an onset well below the charge ordering transition, supporting the “order by fluctuation” mechanism for the development of charge order superstructure. Bragg splitting and large magneto-optical contrast suggest a low temperature monoclinic distortion that can be driven by both temperature and magnetic field. At the same time, dramatic splitting of the LuO_2 layer phonon mode is attributed to charge-rich/poor proximity effects, and its temperature dependence reveals the antipolar nature of the W layer pattern. Using optical techniques, we also discovered that $\alpha\text{-Fe}_2\text{O}_3$, a chemically-similar parent compound and one of the world's oldest and most iconic antiferromagnetic materials, appears more red in applied magnetic field than in zero field conditions. This effect is driven by a field-induced reorientation of magnetic order. The oscillator strength lost in the color band is partially transferred to the magnon side band, a process that also reveals a new exciton pattern induced by the modified exchange coupling. Analysis of the exciton pattern exposes $C2/c$ monoclinic symmetry in the high field phase of hematite. Taken together, these findings advance our understanding of iron-based materials under extreme conditions.

4:42PM X9.00010 Theory of Spectroscopy and Transport in Half-metallic Double Perovskites¹

JULIA JANCZAK, OINAM NGANBA MEETEI, MOHIT RANDERIA, NANDINI TRIVEDI, The Ohio State University — Half-metallic double perovskites hold great promise in spintronics applications, hence we are motivated to understand the spectroscopy and charge transport in these materials. We present theoretical calculations of the temperature and disorder dependence of the spin-resolved density of states of the conduction electrons, the optical conductivity $\sigma(\omega)$, and the anomalous Hall conductivity for $\text{Sr}_2\text{FeMoO}_6$ (SFMO), a half-metal with 100% spin-down polarized charge carriers at $T = 0$. We build on the recent progress [1] in modeling magnetic properties of SFMO by using an exact diagonalization plus Monte Carlo scheme. We obtain $\sigma(\omega)$ as a function of disorder as well as temperature using the Kubo formula for linear response in the exact eigenstate basis. In agreement with experiment, we find a secondary peak in $\sigma(\omega)$ at $\omega \sim 0.5 \text{ eV}$, and attribute it to a spin-up density of states at the chemical potential induced by disorder and/or thermal fluctuations. We propose that the size of the secondary peak can be used to determine the polarization of conduction electrons at the chemical potential, facilitating experimental measurements. [1] O. Erten et al, arXiv:1107.0983; Phys. Rev. Lett. (to appear)

4:54PM X9.00011 High T_c Ferrimagnetism, Multiband Mott Transition and Spin-Orbit Coupling in Double Perovskites¹

ONUR ERTEN, O. NGANBA MEETEI, The Ohio State University, ANAMITRA MUKHERJEE, University of British Columbia, MOHIT RANDERIA, NANDINI TRIVEDI, PATRICK M. WOODWARD, The Ohio State University — The ferrimagnetic insulator $\text{Sr}_2\text{CrOsO}_6$ (SCOO), which has the highest $T_c = 725\text{K}$ among all double perovskites, raises several questions. Why is this material an insulator? What sets the scale for the high T_c ? Why is there a net moment given that both Cr and Os have d^3 configurations? What is the role of spin-orbit coupling in Os? Finally, why does SCOO show a highly unusual, non-monotonic magnetization $M(T)$ as a function of temperature? We address all of these questions. First, we describe the charge sector using slave-rotor mean field theory and obtain an analytic Mott criterion $\sqrt{U_{Cr}U_{Os}} > 2.5W$ relating the Hubbard U 's to the bandwidth W . We argue that SCOO is a multiband Mott insulator. Next, we argue that the orbital moment on Os is quenched in SCOO and spin-orbit coupling does not play a major role in this material. Finally, we show that the effective spin Hamiltonian for SCOO has both Cr-Os and Os-Os superexchange interactions that are frustrated. This leads to a canted ground state with a net moment at $T = 0$ and a nonmonotonic magnetization $M(T)$. Our results are in excellent agreement with available data and we make predictions to test our theory.

¹Supported by the NSF-MRSEC grant DMR-0820414.

5:06PM X9.00012 Magnetically driven metal-insulator transition in NaOsO_3 ¹

STUART CALDER, VASILE GARLEA, ORNL, DESMOND MCMORROW, UCL, MARK LUMSDEN, MATHEW STONE, ORNL, JONATHAN LANG, JONG-WOO KIM, JOHN SCHLUETER, ANL, YOUGUO SHI, CAS, YING SUN, YOSHIRA TSUJIMOTO, KAZUNARIA YAMAURA, NIMS, ANDREW CHRISTIANSON, ORNL — The metal-insulator transition (MIT) is one of the most dramatic manifestations of electron correlations in materials, enjoying interest both for its fundamental nature and technological application. Various mechanisms producing MITs have been extensively considered over the years associated with the names of their originators, including most especially Mott (electron localization through Coulomb repulsion) and Anderson (localization through disorder). An alternative route due to Slater dating back to 1951, in which long-range magnetic order in a three dimensional system drives the MIT, has received relatively little attention, particularly from an experimental viewpoint. Using neutron and X-ray scattering we have shown that the MIT in NaOsO_3 is coincident with the onset of long-range commensurate three dimensional magnetic order at 410 K. NaOsO_3 thus encompasses all of the expected features of the long predicted Slater transition. Our results are the first definitive experimental example of a Slater MIT and we discuss them in the light of recent reports of a Mott spin-orbit insulating state in other 5d oxides.

3:06PM X10.00002 Phonon Raman scattering from first principles

CLAUDIA AMBROSCH-DRAXL, University of Leoben — Light propagating through a crystal can be inelastically scattered by lattice vibrations. Thereby the exciting light beam experiences a frequency shift which is detected in the Raman experiment. This *Raman shift* is caused by the modulation of the material's polarizability upon time-dependent ionic displacements. Experimental Raman data thus contain a wealth of information about phonons, electronic structure, as well as their interplay. For instance, temperature-dependent lineshapes and overtone spectra can be related to the extent of anharmonic effects, and strong electron-phonon interaction is expressed in terms of large scattering intensities. The assignment of frequencies to specific vibrations typically relies on comparison with reference systems by considering atomic masses and the symmetry of the crystal. For an in-depth understanding of the measured features and an unambiguous assignment of modes, *ab initio* theory can provide valuable insight. In the Raman spectra, the peak positions correspond to the phonon frequencies and thus can be solely determined from frozen-phonon or linear-response calculations. The scattering intensities, however, involve the change of the frequency-dependent complex dielectric tensor with atomic displacements along the phonon eigenvector. All these quantities can be obtained from density-functional theory (DFT) in combination with time-dependent DFT or many-body perturbation theory. In this talk, I will review how to compute Raman spectra from first principles. Selected examples will demonstrate the effects of isotope substitution, anharmonicity, temperature, and excitation energy, as well as the role of symmetry. They reveal that Raman scattering is a beautiful technique as it reflects basic principles of quantum mechanics as much as complex excitations of complex matter.

3:42PM X10.00003 Pushing the limits of first-principles electron-phonon calculations: from photoemission kinks to band gaps, FELICIANO GIUSTINO, Department of Materials, University of Oxford — The electron-phonon interaction is key to some of the most intriguing and technologically important phenomena in condensed matter physics, ranging from superconductivity to charge density waves, electrical resistivity, and thermoelectricity. Starting from the late nineties first-principles calculations of electron-phonon interactions in metals have become increasingly popular, mainly in connection with the study of conventional superconductors and with the interpretation of angle-resolved photoemission experiments. In contrast, progress on first-principles calculations of electron-phonon interactions in insulators has been comparatively slower. This delay is arguably due to the conventional wisdom that the signatures of electron-phonon interactions in semiconductor band structures are so small that they fall within the error bar of the most accurate electronic structure calculations. In order to fill this gap we developed, within the context of state-of-the-art density-functional techniques, a theory proposed by Allen and Heine for calculating the temperature dependence of band gaps in semiconductors [P. B. Allen, V. Heine, J. Phys. C: Solid State Phys. 69, 2305 (1976)]. This methodology allows us to calculate both the temperature dependence of the quasiparticle energies and the renormalization due to zero-point quantum fluctuations. In order to demonstrate this technique an application to the intriguing case of diamond will be discussed [F. Giustino, S. G. Louie, M. L. Cohen, Phys. Rev. Lett. 105, 265501 (2010)]. In this case the calculated temperature dependence of the direct band gap agrees well with spectroscopic ellipsometry data, and the renormalization due to the electron-phonon interaction is found to be spectacularly large (>0.6 eV). This unexpected finding might be only the tip of the iceberg in a research area which remains largely unexplored and which, from a first glimpse, appears rich of surprises.

4:18PM X10.00004 Phonon-assisted Auger recombination and optical absorption in semiconductors, EMMANOUIL KIOUPAKIS, University of Michigan — The coupling of charge carriers to lattice vibrations is an important process in materials that enables higher-order electronic transitions. We employed first-principles methods based on density functional theory to study various phonon-assisted electronic processes in semiconductors, such as Auger recombination and optical absorption. Auger recombination is a three-particle non-radiative recombination process that affects optoelectronic devices at high carrier densities. Phonon-assisted Auger recombination, in particular, is expected to be important in wide-band-gap materials. We describe the computational formalism to study phonon-assisted Auger recombination in semiconductors. We show that these indirect Auger processes are strong in the group-III nitrides and affect the high-power performance of visible light-emitting diodes. Moreover, the electron-phonon interaction facilitates the absorption of light by free carriers in doped semiconductors and transparent conducting oxides, which limits the output power of optoelectronic devices. We describe how first-principles techniques can be used to calculate the phonon-assisted free-carrier absorption coefficient in semiconductors and discuss our results for the group-III nitrides. In addition, the electron-phonon coupling enables indirect interband optical transitions in indirect-gap materials such as silicon. These processes are instrumental for the absorption of visible light and the operation of silicon solar cells. We present our first-principles formalism and calculated results for the phonon-assisted absorption of visible light in silicon. Our calculated results are in very good agreement with experiment. Our work highlights the significance of first-principles methods in understanding key microscopic quantum phenomena in technologically important materials and devices. Work done in collaboration with C. G. Van de Walle, P. Rinke, K. Delaney, A. Schleife, F. Bechstedt, D. Steiauf, H. Peelaers, J. Noffsinger, S. G. Louie, and M. L. Cohen. 4:54PM X10.00005 Large scale atomistic approaches to thermal transport and phonon scattering in nanostructured materials¹, IVANA SAVIC, Department of Chemistry, University of California at Davis, Davis, California, USA — Decreasing the thermal conductivity of bulk materials by nanostructuring and dimensionality reduction, or by introducing some amount of disorder represents a promising strategy in the search for efficient thermoelectric materials [1]. For example, considerable improvements of the thermoelectric efficiency in nanowires with surface roughness [2], superlattices [3] and nanocomposites [4] have been attributed to a significantly reduced thermal conductivity. In order to accurately describe thermal transport processes in complex nanostructured materials and directly compare with experiments, the development of theoretical and computational approaches that can account for both anharmonic and disorder effects in large samples is highly desirable. We will first summarize the strengths and weaknesses of the standard atomistic approaches to thermal transport (molecular dynamics [5], Boltzmann transport equation [6] and Green's function approach [7]). We will then focus on the methods based on the solution of the Boltzmann transport equation, that are computationally too demanding, at present, to treat large scale systems and thus to investigate realistic materials. We will present a Monte Carlo method [8] to solve the Boltzmann transport equation in the relaxation time approximation [9], that enables computation of the thermal conductivity of ordered and disordered systems with a number of atoms up to an order of magnitude larger than feasible with straightforward integration. We will present a comparison between exact and Monte Carlo Boltzmann transport results for small SiGe nanostructures and then use the Monte Carlo method to analyze the thermal properties of realistic SiGe nanostructured materials. This work is done in collaboration with Davide Donadio, Francois Gygi, and Giulia Galli from UC Davis.

Thursday, March 1, 2012 2:30PM - 5:30PM –
Session X11 DMP: Focus Session: Graphene Structure, Stacking, Interactions: Twisting, Stretching, Folding, Wrinkling 210B

2:30PM X11.00001 Graphene Origami, MELINA BLEES, Department of Physics, Cornell University, ARTHUR BARNARD, School of Applied and Engineering Physics, Cornell University, SAMANTHA ROBERTS, Department of Physics, Cornell University, PEIJIE ONG, Materials Science and Engineering, Cornell University, ALIAKSANDR ZARETSKI, Florida International University, SI PING WANG, School of Electrical and Computer Engineering, Cornell University, PAUL MCEUEN, Department of Physics, Kavli Institute at Cornell for Nanoscale Science, Cornell University — Graphene, which features unparalleled in-plane strength and low out-of-plane bending energy, is an ideal material with which to tackle the challenge of building three-dimensional structures and moving parts at the nanoscale. Here we demonstrate laser-induced folding and scrolling of large-area monolayer graphene in solution. Monolayer graphene is typically well-adhered to its substrate, but we have achieved control of the adhesion using a combination of an aluminum sacrificial layer and surfactants. Once the graphene can move, local heating with an infrared laser and the interfacial tension of laser-nucleated bubbles allow us to lift, fold, and scroll the graphene. We have also formed a regular array of polymer dots on the graphene surface which can be easily imaged in three dimensions, allowing us to optically track the shape of the graphene as it moves. And finally, we establish graphene's viability as a strong but flexible sheet hinge by building and manipulating structures of rigid metallic panels connected by strips of graphene.

2:42PM X11.00002 Twisting Graphene into Carbon Nanotubes¹ , OLEG O. KIT, University of Jyväskylä, Finland, TUOMAS TALLINEN, L. MAHADEVAN, Harvard University, JUSSI TIMONEN, PEKKA KOSKINEN, University of Jyväskylä, Finland — Carbon nanotubes are usually described as being rolled up from graphene sheets; this process, however, have never been realized experimentally. We showed that graphene can indeed be transformed into nanotube by twisting [1]. Further, we showed that tube formation can be well-explained within classical theory of elasticity—in fact the very mechanism of tube formation can be observed by twisting a strap from one's backpack (try now!). Furthermore, we showed that nanotube chirality may not only be predicted, but can also be controlled externally. The quantum molecular dynamic simulations at T=300K were achieved thanks to the revised periodic boundary conditions (RPBC) approach [2-3]. The structures similar to simulated have been recently observed experimentally [4]. This novel route for nanotube formation opens new opportunities in nanomaterial manipulation not restricted to carbon alone. In the presentation, I will describe tube formation, as well as outline the easy and efficient technique for distorted nanostructures simulation, the RPBC approach.
