Monday, February 27, 2012 8:00AM - 11:00AM –

Session A1 GIMS: Focus Session: Novel Instrumentation and measurements for Biomedical Research 203

8:00AM A1.00001 Instrumentation of Molecular Imaging on Site-Specific Targeting Fluorescent Peptide for Early Detection of Breast Cancer¹ PING YU, Department of Physics and Astronomy, University of Missouri, LIXIN MA, Department of Radiology and Biomolecular Imaging Center, University of Missouri — In this work we developed two biomedical imaging techniques for early detection of breast cancer. Both image modalities provide molecular imaging capability to probe site-specific targeting dyes. The first technique, heterodyne CCD fluorescence mediated tomography, is a non-invasive biomedical imaging that uses fluorescent photons from the targeted dye on the tumor cells inside human breast tissue. The technique detects a large volume of tissue (20 cm) with a moderate resolution (1 mm) and provides the high sensitivity. The second technique, dual-band spectral-domain optical coherence tomography, is a high-resolution tissue imaging modality. It uses a low coherence interferometer to detect coherent photons hidden in the incoherent background. Due to the coherence detection, a high resolution (20 microns) is possible. We have finished prototype imaging systems for the development of both image modalities and performed imaging experiments on tumor tissues. The spectroscopic/tomographic images show contrasts of dense tumor tissues and tumor necrotic regions. In order to correlate the findings from our results, a diffusion-weighted magnetic resonance imaging (MRI) of the tumors was performed using a small animal 7-Tesla MRI and demonstrated excellent agreement.

¹This work was supported by NSF grant CBET-0746871 and DOD grant PC081264.

8:12AM A1.00002 Digital Image Speckle Correlation for the Quantification of the Cosmetic Treatment with Botulinum Toxin Type A (BTX-A), DIVYA BHATNAGAR, Department of Materials Science and Engineering, SUNY Stony Brook, NICOLE CONKLING, Stony Brook University Medical Center, MIRIAM RAFAILOVICH, Department of Materials Science and Engineering, SUNY Stony Brook, ALEXANDER DAGUM, Division of Plastic Surgery, Stony Brook University Medical Center — The skin on the face is directly attached to the underlying muscles. Here, we successfully introduce a non-invasive, non-contact technique, Digital Image Speckle Correlation (DISC), to measure the precise magnitude and duration of facial muscle paralysis inflicted by BTX-A. Subjective evaluation by clinicians and patients fail to objectively quantify the direct effect and duration of BTX-A on the facial musculature. By using DISC, we can (a) Directly measure deformation field of the facial skin and determine the locus of facial muscular tension (b) Quantify and monitor muscular paralysis and subsequent re-innervation following injection; (c) Continuously correlate the appearance of wrinkles and muscular tension. Two sequential photographs of slight facial motion (frowning, raising eyebrows) are taken. DISC processes the images to produce a vector map of muscular displacement from which spatially resolved information is obtained regarding facial tension. DISC can track the ability of different muscle groups to contract and can be used to predict the site of injection, quantify muscle paralysis and the rate of recovery following BOTOX injection.

8:24AM A1.00003 Ultra-low field SQUID electron paramagnetic resonance for biomedical applications, P. BHUPATHI, B.H. EOM, Division of Physics, Mathematics and Astronomy, California Institute of Technology, K.I. PENANEN, P.K. DAY, I. HAHN, Jet Propulsion Laboratory, California Institute of Technology — We have constructed a SQUID-magnetometer system operating at 4K, for electron paramagnetic resonance (EPR) detection from room temperature samples in magnetic fields of the order of Earth's field. The magnetometer consists of a home-built gradiometer pick-up coil inductively coupled to the input of a commercially available 2-stage dc SQUID amplifier. Operation at low EPR excitation frequency of a few MHz has advantages of negligible sample heating and finite penetration depth effects in biological systems. The same system can be adapted to detect NMR signals at several kHz range. We describe our detection scheme and discuss the prospects for *in vivo* biomedical EPR imaging.

8:36AM A1.00004 Single cell microfluidics for systems oncology¹, RONG FAN, Department of Biomedical Engineering, Yale University — The singular term “cancer” is never one kind of disease, but deceptively encompasses a large number of heterogeneous disease states, which makes it impossible to completely treat cancer using a generic approach. Rather systems approaches are urgently required to assess cancer heterogeneity, stratify patients and enable the most effective, individualized treatment. The heterogeneity of tumors at the single cell level is reflected by the hierarchical complexity of the tumor microenvironment. To identify all the cellular components, including both tumor and infiltrating immune cells, and to delineate the associated cell-to-cell signaling network that dictates tumor initiation, progression and metastasis, we developed a single cell microfluidics chip that can analyze a panel of proteins that are potentially associated inter-cellular signaling network in tumor microenvironment from hundreds of single cells in parallel. This platform integrates two advanced technologies – microfluidic single cell handling and ultra-high density protein array. This device was first tested for highly multiplexed profiling of secreted proteins including tumor-immune signaling molecules from monocytic leukemia cells. We observed profound cellular heterogeneity with all functional phenotypes quantitatively identified. Correlation analysis further indicated the existence of an intercellular cytokine network in which TNF α -induced secondary signaling cascades further increased functional cellular diversity. It was also exploited to evaluate polyfunctionality of tumor antigen-specific T cells from melanoma patients being treated with adoptive T cell transfer immunotherapy. This platform could be further extended to analyze both solid tumor cells (e.g. human lung carcinoma cells) and infiltrating immune cells (e.g. macrophages) so as to enable systems analysis of the complex tumor microenvironment from small amounts of clinical specimens, e.g. skinny needle biopsies. Thus, it could potentially become a clinical tool for patient stratification based upon the inter-cellular signaling network and designing new anti-cancer therapy by targeting microenvironmental components.

¹We acknowledge the support from the NCI K99/R00 award (4R00 CA136759-02), the Bill & Melinda Gates Foundation GCE Award, the Alzheimer Association NIRG award and the NIH LINC Program Grant (1 U01 CA16425201).

9:12AM A1.00005 High resolution phase-sensitive optical coherence microscopy tracking of magnetic microbeads for cellular mechanics, VASILICA CRECEA, Department of Physics, University of Illinois at Urbana-Champaign, BENEDIKT GRAF, Department of Electrical Engineering, University of Illinois at Urbana-Champaign, QINGSHAN WEI, HYON-MIN SONG, ALEXANDER WEI, Department of Chemistry, Purdue University, STEPHEN BOPPART, Department of Electrical Engineering, University of Illinois at Urbana-Champaign — We present a real-time multi-modal near-infrared imaging technology that tracks externally induced axial motion of magnetic microbeads in mouse macrophages, human breast epithelial cells, and human breast primary ductal carcinoma cells. The imaging technique includes nanometer scale phase-sensitive magnetomotive integrated optical coherence (MM-OCM) and multiphoton (MPM) microscopy. MPM is used to visualize multifunctional microbeads based on their fluorescence, while MM-OCM detects sinusoidal displacements of the magnetic microbeads induced by a magnetic field. This methodology demonstrates imaging of cell dynamics and has the potential for measuring cell biomechanical properties, which are important in assessing cell health.

9:24AM A1.00006 Reagent-free ultrasensitive spectroscopic probes for long term diabetes monitoring¹, N.C. DINGARI, I. BARMAN, J.W. KANG, Laser Biomedical Research Center, G. R. Harrison Spectroscopy Laboratory, MIT, G. HOROWITZ, Division of Clinical Pathology, Beth Israel Deaconess Medical Center, Harvard Medical School, RAMACHANDRA RAO DASARI, Laser Biomedical Research Center, G. R. Harrison Spectroscopy Laboratory, MIT — Long-term glycemic control is essential in developing therapeutics for diabetics. Glycated hemoglobin (HbA1c) and glycated albumin have been increasingly accepted as a functional metric of glycemic control over the past two to three months and three weeks, respectively. In this talk, we present the first demonstration of non-enhanced Raman spectroscopy as a novel analytical method for quantitative detection of HbA1c and glycated albumin. Using the drop coating deposition Raman technique, we observe that the non-enzymatic glycosylation of these proteins results in subtle, but consistent, changes in vibrational features, which with the help of multivariate classification techniques can be used to discriminate the glycated proteins from their unglycated variants with 100%. Additionally, the developed multivariate calibration models show a high degree of prediction accuracy even at substantially lower concentrations than those typically encountered in clinical practice. The excellent accuracy and reproducibility achieved in this proof-of-concept study opens substantive avenues for basic investigations of glycated proteins as well as in high-throughput glycemic marker sensing in multi-component mixtures and potentially even in serum and whole blood samples.

¹The authors wish to thank the NIH National Center for Research Resources for their grant P41-RR02594, at the MIT Laser Biomedical Research Center.

9:36AM A1.00007 The measurand problem in infrared breath alcohol testing, TED VOSK, Of Counsel Cowan, Kirk, Gaston — Measurements are made to determine the value of a quantity known as a measurand. The measurand is not always the quantity subject to measurement, however. Often, a distinct quantity will be measured and related to the measurand through a measurement function. When the identities of the measurand and the quantity actually measured are not well defined or distinguished, it can lead to the misinterpretation of results. This is referred to as the measurand problem. The measurand problem can present significant difficulties when the law and not science determines the measurand. This arises when the law requires that a particular quantity be measured. Legal definitions are seldom as rigorous or complete as those utilized in science. Thus, legally defined measurands often fall prey to the measurand problem. An example is the measurement of breath alcohol concentration by infrared spectroscopy. All 50 states authorize such tests but the measurand differs by jurisdiction. This leads to misinterpretation of results in both the forensic and legal communities due to the measurand problem with the consequence that the innocent are convicted and guilty set free. Correct interpretation of breath test results requires that the measurand be properly understood and accounted for. I set forth the varying measurands defined by law, the impact these differing measurands have on the interpretation of breath test results and how the measurand problem can be avoided in the measurement of breath alcohol concentration.

9:48AM A1.00008 Nanoscale neuroelectronic interface based on open-ended nanocoax arrays, JEFFREY R. NAUGHTON, BINOD RIZAL, MICHAEL J. BURNS, JEE YEOM, SHANNON HEYSE, MICHELLE ARCHIBALD, STEPHEN SHEPARD, GREGORY MCMAHON, THOMAS C. CHILES, MICHAEL J. NAUGHTON, Boston College — We describe the development of a nanoscale neuroelectronic array with submicron pixelation for recording and stimulation with high spatial resolution. The device is composed of an array of nanoscale coaxial electrodes, either network- or individually-configured. As a neuroelectronic interface, it will employ noninvasive real-time capacitive coupling to the plasma membrane with potential for extracellular recording of intra- and interneuronal synaptic activity, with one target being precision measurement of electrical signals associated with induced and spontaneous synapse firing in pre- and post-synaptic somata. Subarrays or even individual pixels can also be actuated for precisely-localized stimulation. We report initial results from measurements using the rat adrenal pheochromocytoma PC12 cell line, which terminally differentiates in response to nerve growth factor, as well as SH-SY5Y neuroblastoma cells in response to retinoic acid, characterizing the basic performance of the fabricated device.

10:00AM A1.00009 Phosphorus-31 MRI of bones using quadratic echo line-narrowing, MERIDETH FREY, SEAN BARRETT, Yale University Physics Dept., KARL INSOGNA, JOSHUA VANHOUTEN, Yale University, School of Medicine Dept. of Internal Medicine — There is a great need to probe the internal composition of bone on the sub-0.1 mm length scale, both to study normal features and to look for signs of disease. Despite the obvious importance of the mineral fraction to the biomechanical properties of skeletal tissue, few non-destructive techniques are available to evaluate changes in its chemical structure and functional microarchitecture on the interior of bones. MRI would be an excellent candidate, but bone is a particularly challenging tissue to study given the relatively low water density and wider linewidths of its solid components. Recent fundamental research in quantum computing gave rise to a new NMR pulse sequence - the quadratic echo - that can be used to narrow the broad NMR spectrum of solids. This offers a new route to do high spatial resolution, 3D ³¹P MRI of bone that complements conventional MRI and x-ray based techniques to study bone physiology and structure. We have used our pulse sequence to do 3D ³¹P MRI of *ex vivo* bones with a spatial resolution of (sub-450 μ m)³, limited only by the specifications of a conventional 4 Tesla liquid-state MRI system. We will describe our plans to push this technique towards the factor of 1000 increase in spatial resolution imposed by fundamental limits.

10:12AM A1.00010 Phosphorus-31 MRI of cell membranes using quadratic echo line-narrowing, SEAN BARRETT, MERIDETH FREY, Yale University Physics Dept., JOSEPH MADRI, MICHAEL MICHAUD, Yale University, School of Medicine Dept. of Pathology — Soft biological tissues have phosphorus concentrated in the membranes, metabolites, RNA and DNA of cells. This leads to a complicated, multi-peak ³¹P nuclear magnetic resonance spectrum (including a broad membrane peak and narrow metabolite peaks), which precludes high-resolution ³¹P MRI of soft tissues. This long-standing barrier has been overcome by a novel pulse sequence - the quadratic echo - recently discovered in fundamental quantum computation research. Applying time-dependent gradients in synch with a repeating pulse block enables a new route to high spatial resolution, three-dimensional ³¹P MRI of the soft solid components of cells and tissues. This is a functionally different kind of MR image, since conventional ¹H MRI probes the intracellular and extracellular free water, whereas our ³¹P MRI signal is dominated by the cell membrane contribution, which in turn depends on the density of mitochondria. The unique aspects of the signal should provide new insights into cellular and tissue function that complement the information revealed by ¹H MRI. So far, various *ex vivo* soft tissue samples have been imaged with (sub-mm)³ voxels. We will describe plans to enhance the spatial resolution in future work, to open a new window into cells.

10:24AM A1.00011 Accelerating the magnetic resonance imaging of hard and soft solids, ZACHARY SETHNA, MERIDETH FREY, SEAN BARRETT, Yale University Physics Dept. — Recent fundamental research in quantum computing gave rise to a new NMR pulse sequence - the quadratic echo - that can be used to narrow the broad MR spectrum of solids by orders of magnitude. This advance enables high spatial resolution, 3D MRI of hard and soft solids (e.g., the ³¹P MRI of bone and soft tissues, which has recently been demonstrated in our group). While this is great progress, the next challenge to address is the slow imaging time in solids. The *T*₁ time of solids can be orders of magnitude larger than that of a liquid (e.g., for some of our samples the *T*₁ time can be >100 s). Since imaging sequences wait a repetition time (of order *T*₁) between scans, a three-dimensional image (requiring many scans) can take >24 hours. Here we discuss approaches under study that aim to decrease the total imaging time of our MRI of solids technique. One method is to implement a variant on the driven equilibrium approach. Another method is to take less data, namely, sparse MRI (i.e., under-sampling of k-space). This leads to artifacts in standard FFT image construction; more advanced alternatives, such as a difference map algorithm, may be used to produce an image closer to the ideal, which is a promising approach to reduce total imaging time.

10:36AM A1.00012 A Comparison of Raman Spectral Features of Frozen and Deparaffinized Tissues in Neuroblastoma and Ganglioneuroma¹ , SUNEETHA DEVPURA, JAGDISH S. THAKUR, Wayne State University, JANET M. POULIK, Children's Hospital of Michigan, RAJA RABAH, University of Michigan-Ann Arbor, VAMAN M. NAIK, University of Michigan-Dearborn, RATNA NAIK, Wayne State University — We have investigated the cellular regions in neuroblastoma and ganglioneuroma using Raman spectroscopy and compared their spectral characteristics with those of normal adrenal gland. Thin sections from both frozen and deparaffinized tissues, obtained from the same tissue specimen, were studied in conjunction with the pathological examination of the tissues. We found a significant difference in the spectral features of frozen sections of normal adrenal gland, neuroblastoma, and ganglioneuroma when compared to deparaffinized tissues. The quantitative analysis of the Raman data using chemometric methods of principal component analysis and discriminant function analysis obtained from the frozen tissues show a sensitivity and specificity of 100% each. The biochemical identification based on the spectral differences shows that the normal adrenal gland tissues have higher levels of carotenoids, lipids, and cholesterol compared to the neuroblastoma and ganglioneuroma frozen tissues. However, deparaffinized tissues show complete removal of these biochemicals in adrenal tissues. This study demonstrates that Raman spectroscopy combined with chemometric methods can successfully distinguish neuroblastoma and ganglioneuroma at cellular level.

10:48AM A1.00013 Expanding Cancer Detection Using Molecular Imprinting for a Novel Point-of-Care Diagnostic Device , YINGJIE YU, MIRIAM RAFAILOVICH, YANTIAN WANG, State University of New York- Stony Brook, ALINA RANJBARAN, Garden City High School, TOM WANG, The Wheatley School, DAVID NAM, Monta Vista High School — We propose the use of a potentiometric biosensor that incorporates the efficient and specific molecular imprinting (MI) method with a self-assembled monolayer (SAM). We first tested the biosensor using carcinoembryonic antigen, CEA, a biomarker associated with pancreatic cancer. No change in detection efficiency was observed when detection was performed in the presence of 100% serum albumin, indicating that the sensor is able to discriminate for the template analyte even in concentrated solution of similar substances. Computer simulations of the protein structure were performed in order to estimate the changes in morphology and determine the sensitivity of the biosensor to conformational changes in the proteins. We found that even small changes in PH can generate rotation of the surface functional groups, without significant change in the morphology. Yet, the results show that only when the detection and imprinting conditions are similar, robust signals occurs. Hence we concluded that both morphology and surface chemistry play a role in the recognition.

Monday, February 27, 2012 8:00AM - 11:00AM —
Session A2 GQI FEd: Invited Session: Teaching Quantum Information Science at Liberal Arts College 204AB

8:00AM A2.00001 Doing quantum theory at a liberal arts college , BENJAMIN SCHUMACHER, Kenyon College — An academic career at a liberal arts college poses some challenges for a researcher in quantum information and quantum foundations, most notably the lack of local collaborators and graduate students. Are there also complementary advantages and opportunities?

8:36AM A2.00002 Quantum Information in Non-physics Departments at Liberal Arts Colleges , MICHAEL WESTMORELAND, Denison University — Quantum information and quantum computing have changed our thinking about the basic concepts of quantum physics. These fields have also introduced exciting new applications of quantum mechanics such as quantum cryptography and non-interactive measurement. It is standard to teach such topics only to advanced physics majors who have completed coursework in quantum mechanics. Recent encounters with teaching quantum cryptography to non-majors and a bout of textbook-writing suggest strategies for teaching this interesting material to those without the standard quantum mechanics background. This talk will share some of those strategies.

9:12AM A2.00003 Theoretical Research Fostered by an Undergraduate Environment , WILLIAM WOOTTERS, Williams College — An undergraduate setting entails certain challenges for a faculty member doing research in theoretical physics, but it also offers particular opportunities. While it is possible to succeed in any area of theoretical research at an undergraduate institution, the experience of teaching at the undergraduate level and doing research with undergraduate students naturally leads one to think about problems that, though possibly very interesting, do not require a high level of technical expertise. Such problems tend to be “close to the trunk of the tree of physics,” as a colleague has suggested, meaning that they may be closer to the central ideas of physics than many highly specialized problems. In this talk I give examples of research projects in quantum information and quantum foundations that have been stimulated in part by undergraduate-level teaching and carried out with undergraduate collaborators.

9:48AM A2.00004 Is Theoretical Physics Locus-dependent? Quantum Information at Liberal Arts Colleges , HERBERT BERNSTEIN, Hampshire College — No abstract available.

10:24AM A2.00005 Fundamental Physics with Table-Top Optics , ENRIQUE GALVEZ, Colgate University — Experimental physics research at an undergraduate institution poses the challenge of requiring the production of publishable results while also being a suitable setting for mentoring undergraduates in research. It is tempting for young faculty to copy/adapt “big-machine” university research, but that is a tough enterprise that is hard to sustain. An option that suits the undergraduate setting better is a small, table-top, apparatus devoted to projects with promising potential. In optics I found such a setting, and a successful transition from big-machine to table-top setups. Optics is a fertile ground for student projects that does not involve heavy maintenance, can achieve substantial depth, and enables student independence. It also allows the creation of projects that match the abilities of the not-so-high achievers. At the conference I will present examples of recent projects involving the study of classical light beams that carry optical vortices and non-classical beams that encode qubits. This work has been funded by Research Corporation, NSF and Air Force.

Monday, February 27, 2012 8:00AM - 11:00AM —
Session A3 DCMP: Invited Session: Superconducting Fluctuations in Cuprates 205AB

8:00AM A3.00001 Decrease of pairing strength with underdoping in cuprate superconductors

, JOHAN CHANG, EPFL, Lausanne, Switzerland — The transition temperature T_c of cuprate superconductors decreases at low hole doping p , but it is still unclear whether the pairing strength decreases or increases. Different interpretations of the pseudogap lead to opposite conclusions. Different estimates of the upper critical field H_{c2} are in sharp contradiction. In this talk, we resolve the latter contradiction by showing that superconducting fluctuations in the underdoped cuprate Eu-LSCO, measured via the Nernst effect, obey the theory of Gaussian fluctuations, as in conventional superconductors [1, 2]. The extracted critical field H_{c2} is small, and it dips at $p = 0.11$, showing that pairing strength is weak where stripe order is strong. In the archetypal cuprate superconductor YBCO, H_{c2} extracted from other measurements [3] has the same doping dependence, also with a minimum at $p = 0.11$, again where stripe order is present [4, 5]. We conclude that competing states such as stripe order weaken the pairing strength and this, rather than phase fluctuations, is the predominant cause for the low T_c of underdoped cuprates. Work done in collaboration with N. Doiron-Leyraud, E. Hassinger, J.-Ph. Reid, O. Cyr-Choinière, F. Laliberté, R. Daou, S. Pyon, T. Takayama, H. Takagi, and Louis Taillefer.

8:36AM A3.00002 Pseudogap phase and superconducting fluctuation regime of the cuprate superconductors¹

, NEVEN BARIŠIĆ, School of Physics and Astronomy, University of Minnesota, Minneapolis, Minnesota 55455, USA — The pseudogap phenomenon in the cuprates is one of the most investigated topics in the field of correlated materials. A related question is the extent to which superconducting fluctuation persist between the pseudogap temperature (T^*) and superconducting transition temperature (T_c). We have addressed this question by combining several experimental probes: planar dc-resistivity [1], microwave conductivity [2,3], and torque magnetometry [4]. dc-resistivity measurements in the simple tetragonal model compound $\text{HgBa}_2\text{CuO}_{4+\delta}$ [5], which features the highest T_c (97 K) among all single-layer cuprates, reveal four characteristic temperatures: T^* , coincident with the onset of novel $\mathbf{q}=0$ magnetic order revealed by neutron diffraction [6]; a second, lower pseudogap temperature T^{**} associated with a further rearrangement of the states at the Fermi level; T' , which marks the onset of superconducting fluctuations; and finally T_c . Notably, T' lies only 10-20 K above T_c and closely tracks the superconducting dome with doping. The superconducting fluctuation regime is further investigated by microwave conductivity and torque magnetometry, and these results confirm the latter conclusion. The results for $\text{HgBa}_2\text{CuO}_{4+\delta}$ are complemented by a comprehensive investigation of other cuprates ($\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$, $\text{YBa}_2\text{Cu}_3\text{O}_{6+\delta}$, $\text{Bi}_2\text{Sr}_{2-z}\text{La}_z\text{CuO}_{6+\delta}$), which leads to new insights into the phase diagram of cuprate superconductors.

9:12AM A3.00003 Fluctuations of Superconductivity in $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$: A Terahertz Conductivity Study¹

, LUCAS BILBRO, The Institute for Quantum Matter, Department of Physics and Astronomy, Johns Hopkins University — In the underdoped pseudogap regime of the high-temperature superconductors, one expects that due to low superfluid densities and short correlation lengths, superconducting fluctuations will be significant for transport and thermodynamic properties. However, there has been disagreement about how high in temperature they may persist, their role in the phenomenology of the pseudogap regime, and their significance for understanding high-temperature superconductivity. We use THz time-domain spectroscopy (TTDS) to probe the temporal fluctuations of superconductivity above the critical temperature (T_c) in $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$ (LSCO) thin films over a doping range that spans almost the entire superconducting dome. Signatures of the fluctuations persist in the conductivity in a narrow temperature range above T_c . Our measurements show that superconducting correlations do not make an appreciable contribution to the charge transport anomalies of the pseudogap in LSCO at temperatures well above T_c .² I will compare our results for an underdoped ($x=0.095$) sample with measurements of diamagnetism in a similarly doped crystal of $\text{La}_{1.905}\text{Sr}_{0.095}\text{CuO}_4$. I will show, through a vortex-plasma model, that if the fluctuation diamagnetism originates solely in vortices, then these vortices must exhibit an anomalously large vortex diffusion constant, more than two orders of magnitude larger than the Bardeen-Stephen estimate.³ This points to either the extremely unusual properties of vortices in the underdoped d-wave Cuprates or a contribution to the diamagnetic response that is not superconducting in origin. Finally, I will introduce preliminary results of THz conductivity measurements of critically underdoped LSCO films, where superconductivity is fully suppressed.

9:48AM A3.00004 Distinct Ranges of Superconducting Fluctuations and Pseudogap in $\text{YBa}_2\text{Cu}_3\text{O}_{6+x}$

, FLORENCE RULLIER-ALBENQUE, Service de Physique de l'Etat Condense, IRAMIS, CEA Saclay, France — The contribution of superconducting fluctuations (SCF) to the ab-plane conductivity has been determined accurately in a series of $\text{YBa}_2\text{Cu}_3\text{O}_{6+x}$ single crystals using high magnetic fields to restore the normal state behavior [1]. This allows us to determine within the same set of transport measurements both the field $H'_c(T)$ and the temperature T'_c above which the SCFs are fully suppressed, and the pseudogap temperature T^* . A careful investigation near optimal doping shows that T^* becomes smaller than T'_c , which unambiguously evidences that the pseudogap cannot be assigned to preformed pairs [2]. In the nearly optimally doped samples, the SCF contribution to conductivity can be accounted for by Gaussian Aslamazov-Larkin fluctuations in the Ginzburg-Landau approach [3]. A phase fluctuation contribution might be invoked in the most underdoped sample in a T range which increases when controlled disorder is introduced by electron irradiation. The analysis of the fluctuation magnetoconductance allows us to determine the critical fields $H_{c2}(0)$ which are found to be very similar to $H'_c(0)$ and to increase with hole doping. These two depairing fields which are directly connected to the magnitude of the superconducting gap therefore follow the evolution of T_c , which is at odds with the sharp decrease of the pseudogap with increasing hole doping.

10:24AM A3.00005 Fluctuoscropy of Superconductors¹ , ANDREY VARLAMOV, Institute of Superconductivity and Innovative Materials SPIN- CNR — The study of superconducting fluctuations (SF) is a subject of fundamental and practical importance. Since the moment of discovery SF became a noticeable part of research in the field of superconductivity (SC) and a variety of fluctuation effects have been detected. The interest to SF in SC was regenerated by the discovery of HTS, where, due to extremely short coherence length and low effective dimensionality of the electron system, SF manifest themselves in a wide range of temperatures. The characteristic feature of SF is their strong dependence on temperature and magnetic field. This allows to separate SFs from other contributions and to use them as a tool for characterization of SC systems (“fluctuoscropy”) for example to extract the values of T_c , $H_{c2}(T)$ and phase-breaking time from experimental data. We present the complete results for fluctuation magneto-conductivity (FMC) and Nernst signal (FNS) of impure 2D superconductor in the whole phase diagram above the transition line $H_{c2}(T)$, including the domain of quantum fluctuations. Along some line $H_0(T)$, in agreement with experimental findings, FMC becomes zero and beyond it remains small and negative. The corresponding surface in coordinates (T, H) becomes in particular non-trivial at low temperatures and close to $H_{c2}(0)$, where it is trough-shaped. The observation of large FNS in HTS and conventional SC above $T_c(H)$, has attracted much attention recently. The idea to attribute it to the entropy transport by analogy to vortices was proposed. On the other hand this giant effect, close to $T_c(0)$, was explained in terms of SF. Our general results allow to successfully fit the available experimental data in a wide range of magnetic fields and temperatures, to extract the value of the “ghost” field and other parameters of SC. We offer also a qualitative consideration, which gives a natural explanation for the giant value of FNS attributing it to a strong dependence of the fluctuation Cooper pair (FCP) chemical potential on temperature. Close to zero temperature, when the magnetic field approaches $H_{c2}(0)$, a peculiar dynamic state consisting of clusters of coherently rotating FCP forms. We estimate the characteristic size and lifetime of such clusters and present the scenario of fluctuation nucleation of Abrikosov’s lattice.

Monday, February 27, 2012 8:00AM - 11:00AM – Session A4 DAMOP: Focus Session: Hybrid Systems and Quantum Information Science in Atomic, Molecular, and Optical Physics 205C

8:00AM A4.00001 A Light-Matter Interface with NV Centers , BRENDAN SHIELDS, NATHALIE DE LEON, Harvard University Department of Physics, BIRGIT HAUSMANN, Harvard University School of Engineering and Applied Sciences, YIWEN CHU, Harvard University Department of Physics, MICHAEL BUREK, Harvard University School of Engineering and Applied Sciences, PATRICK MALETINSKY, Institute of Quantum Electronics, ETH Zurich, QIMIN QUAN, Harvard University School of Engineering and Applied Sciences, ALEXANDER ZIBROV, Harvard University Department of Physics, HONGKUN PARK, Harvard University Department of Chemistry, MARKO LONCAR, Harvard University School of Engineering and Applied Sciences, MIKHAIL LUKIN, Harvard University Department of Physics — NV centers in diamond offer much promise as solid state qubits for scalable quantum communication and information processing. However, for bulk diamond systems the low collection efficiency and large phonon sideband emission represent substantial limitations for applications in quantum information science. In this talk we will describe the realization of nanoscale photonic cavities containing NV centers with desired optical properties. The experimental realization of spontaneous emission control and strong coupling regime of cavity QED will be discussed.

8:12AM A4.00002 Probing the motion of a mechanical resonator via coherent coupling to a single spin qubit¹ , SHIMON KOLKOWITZ, QUIRIN UNTERREITHMEIER, Department of Physics, Harvard University, ANIA BLESZYNSKI JAYICH, Department of Physics, UC Santa Barbara, STEVEN BENNETT, Department of Physics, Harvard University, PETER RABL, Austrian Academy of Science, Innsbruck, Austria, J.G.E. HARRIS, Departments of Physics and Applied Physics, Yale University, MIKHAIL LUKIN, Department of Physics, Harvard University — Mechanical systems can be influenced by a wide variety of extremely small forces, ranging from gravitational to optical, electrical, and magnetic. When mechanical resonators are scaled down to nanometer-scale dimensions, these forces can be harnessed to enable coupling to individual quantum systems. In this talk we will present results showing that the coherent evolution of a single electronic spin associated with a Nitrogen Vacancy (NV) center in diamond can be coupled to the motion of a magnetized mechanical resonator. Specifically we use coherent manipulation of the spin to sense the driven and Brownian motion of the resonator under ambient conditions at a picometer length scale. We will discuss potential applications of this technique including the detection of the zero-point fluctuations of a mechanical resonator, the realization of strong spin-phonon coupling at a single quantum level, and the implementation of quantum spin transducers.

8:24AM A4.00003 A nanoscale quantum interface for single atoms , TOBIAS TIECKE, Harvard University, Department of Physics and Research Laboratory of Electronics, MIT, JEFF THOMPSON, Harvard University, Department of Physics, JOHANNES FEIST, ITAMP, Harvard-Smithsonian center for Astrophysics, CHUN YU, Harvard University, Department of Chemistry, ALEXEY AKIMOV, Harvard University, Department of Physics, DARRICK CHANG, Caltech, ALEXANDER ZIBROV, Harvard University, Department of Physics, VLADAN VULETIC, Center for Ultracold Atoms, Department of Physics, MIT, HONGKUN PARK, Harvard University, Department of Chemistry, MIKHAIL LUKIN, Harvard University, Department of Physics — Neutral atoms are ideal quantum systems: they have long ground-state coherence times and strong optical cycling transitions that enable state detection and preparation. Building quantum networks of atoms interacting through photons is challenging, however, as many schemes for atom-photon interaction are inefficient or hard to scale. We propose a scheme to trap neutral atoms near silver nanowires, which are tightly confining waveguides for surface plasmons. The nanowire tip is used to generate a near-field optical trapping potential, and to enhance and efficiently collect spontaneous emission from the atom. We present experimental results on using the atom to sense the optical field at submicron distances from the wire and our current efforts towards loading the nanotrap.

8:36AM A4.00004 Estimating and characterizing electromechanical coupling of superfluid helium to a microwave resonator , YANG GE, BING LI, University of Chicago, ANDREAS FRAGNER, ROB SCHOELEKOPF, Yale University, DAVID SCHUSTER, University of Chicago — Electrons on helium is a unique two-dimensional electron gas system formed at the interface of a quantum liquid (superfluid helium) and vacuum. The motional state of single-electron quantum dots defined on such systems has been proposed as a good candidate for hybrid quantum computing and as a gateway to measuring the electron spin [1,2]. Incoherent fluctuations of the thickness or density of the helium film are potential sources of motional dephasing, hence require further experimental characterization. In addition, if these ripplons or phonons could be coherently coupled to an electromagnetic cavity one could realize a quantum electro-mechanical system. Here, I will present estimates and preliminary experimental characterization of the electromechanical couplings as well as progress with electrons on helium.

8:48AM A4.00005 Tunable High Q Superconducting Microwave Resonator for Hybrid System with ^{87}Rb atoms¹, ZAEILL KIM, K.D. VOIGT, JONGMIN LEE, J.E. HOFFMAN, J.A. GROVER, S. RAVETS, JQI/UMD, V. ZARETSKEY, UMD, B.S. PALMER, LPS, M. HAFEZI, J.M. TAYLOR, JQI/NIST/UMD, J.R. ANDERSON, A.J. DRAGT, C.J. LOBB, L.A. OROZCO, S.L. ROLSTON, F.C. WELLSTOOD, JQI/UMD — We have developed a frequency tuning system for a “lumped-element” thin-film superconducting Al microwave resonator [1] on sapphire intended for coupling to hyperfine ground states of cold trapped ^{87}Rb atoms, which are separated by about $f_{Rb} = 6.83$ GHz. At $T=12$ mK and on resonance at 6.81 GHz, the loaded quality factor was 120,000. By moving a carefully machined Al pin towards the inductor of the resonator using a piezo stage, we were able to tune the resonance frequency over a range of 35 MHz and within a few kHz of f_{Rb} . While measuring the power dependent response of the resonator at each tuned frequency, we observed anomalous decreases in the quality factor at several frequencies. These drops were more pronounced at lower power. We discuss our results, which suggest these resonances are attributable to discrete two-level systems.

9:00AM A4.00006 Coupling quantum microwave circuits to quantum optics via cavity electro-optic modulators¹, MANKEI TSANG, National University of Singapore — Experimental circuit quantum electrodynamics has made great strides in recent years, but it remains an open question how the quantum information stored in the microwave circuits can be transferred for long distances. Just as in classical information, the most promising solution is to convert the microwave fields to optical frequencies, where ultra-low-loss photonic devices such as optical fibers can be used. Here I propose the use of cavity electro-optic modulators for coherent coupling between microwave and optical fields. The electro-optic effect is the change in optical refractive index in certain materials, such as lithium niobate, under an applied voltage. Leveraging the fact that cavity electro-optics has the same physics as cavity optomechanics, a cavity electro-optic modulator can realize various joint quantum operations on the microwave and optical fields, including coherent frequency conversion, laser cooling of microwave resonance, hybrid entanglement, hybrid parametric amplification and oscillation, and optical quantum-nondemolition measurements of microwave quadrature and energy.

¹This material is based on work supported by the Singapore National Research Foundation under NRF Grant No. NRF-NRFF2011-07.

9:12AM A4.00007 Hybrid Quantum Systems with Circuit Quantum Electrodynamics¹, DAVID SCHUSTER, University of Chicago — Quantum Information Processing presents daunting challenges, with competing requirements of fast manipulation, long storage, and long distance transport of fragile quantum states. In aggregate, many of the challenges quantum computation have been met with nanosecond manipulations (quantum circuits), coherence times measured in seconds (atomic ions/nuclear spins), and entanglement transported over kilometers (linear optics), yet thus far no system has achieved all of the necessary components simultaneously. One promising direction is to leverage the best aspects of each system in a hybrid system, much as is done in a conventional computer, where transistors provide fast processing, magnetic memory provides massive long term storage, and information is transmitted via microwaves or fiber optics. A review of the constituent quantum systems, and the types of couplings between them will be presented. The coupling of a superconducting cavity/qubit system to electrons floating on helium will be discussed as an example of how to construct a hybrid system. Recent results on trapping and detection of electrons on helium using a superconducting cavity will be presented.

9:48AM A4.00008 Nonlinear optics quantum computing with circuit QED¹, PRABIN ADHIKARI, MOHAMMAD HAFEZI, Joint Quantum Institute at UMD, JACOB TAYLOR, Joint Quantum Institute at UMD and NIST — One approach to quantum information processing is to use photons as quantum bits and rely on linear optical elements for most operations. However, some optical non-linearity is necessary to enable universal quantum computing. We consider a circuit-QED approach to linear optics quantum computing in the microwave regime, including a deterministic two-photon phase gate. Our model is a hybrid quantum system comprising an LC resonator coupled to a flux or phase superconducting qubit, which will be used to implement a non-linear two photon phase shift operation. Using this model, we show how fast, low-noise two-qubit gates between photons are possible, and discuss limitations of these ideas based on current technology.

10:00AM A4.00009 Towards Hybrid Quantum Information Processing with Electrons on Helium, ANDREAS FRAGNER, Department of Applied Physics, Yale University, DAVID SCHUSTER, Department of Physics, University of Chicago, MARK DYKMAN, Department of Physics, Michigan State University, STEPHEN LYON, Department of Electrical Engineering, Princeton University, LUIGI FRUNZIO, Department of Applied Physics, Yale University, ROBERT SCHOELKOPF, Department of Physics and Applied Physics, Yale University — Electrons above the surface of superfluid helium form a two-dimensional electron gas in which single-electron quantum dots can be defined using electrostatic gates submerged under the helium film. The quantized motion and spin state of such a trapped electron on helium can be coupled to a high finesse superconducting cavity in a hybrid circuit QED architecture [1]. The cavity is used for nondestructive readout and as a quantum bus mediating interactions between distant electrons or an electron and a superconducting qubit. Coupling between motional states and individual photons in the cavity is estimated at a Rabi frequency of $g/2\pi \sim 20$ MHz with coherence times exceeding 20 μs for charge and 1 s for spin [1, 2]. Here I will discuss recent experiments in which we successfully trap and detect a two-dimensional electron gas on helium in a dc-biased superconducting cavity. Experimental progress towards the single-electron regime will also be presented.

10:12AM A4.00010 An ab-initio microscopic theory of anomalous heating in planar ion traps¹, H.R. SADEGHPOUR, ITAMP, Harvard-Smithsonian Center for Astrophysics, A. SAFAVI-NAINI, ITAMP/Dept of Physics MIT, P. RABL, IQOQI, Innsbruck, P.F. WECK, Advanced Systems Analysis, Sandia — Anomalous heating of trapped ions limits the scalability of the planar trap architecture for quantum computation. Measurements of the electric field noise present in ion traps indicate that the noise-induced heating scales as the inverse fourth power of the distance from the trap electrodes to the ion and its spectral density scales with the inverse of frequency [1]. These measurements also suggest that some thermally activated random process is at work. In this work, we present an ab-initio theory of this noise due to oscillating dipoles on the trap electrode surface [2]. The dipoles are formed when atoms are adsorbed on the trap surface, whose interaction with the surface is described with density functional theory (DFT). We present calculations for the spectral noise density and its distance, frequency and temperature dependencies. We consider both independent and correlated dipoles.

10:24AM A4.00011 Quantum logic for molecular quantum information processing, J. MUR-PETIT, J. PEREZ-RIOS, J. CAMPOS-MARTINEZ, M.I. HERNANDEZ, Instituto de Fisica Fundamental, IFF-CSIC, Spain, S. WILLITSCH, Department of Chemistry, University of Basel, Switzerland, J.J. GARCIA-RIPOLL, Instituto de Fisica Fundamental, IFF-CSIC, Spain — Very recently, molecular ions have been trapped and cooled to the mK regime in well defined internal states [1] opening a new window for precision spectroscopy of molecular species and quantum information with cold molecular ions. A first requirement for both applications is the ability to control and measure the state of molecular ions. I will present our proposal [2] of a fast, non-destructive and temperature independent spectroscopy method suitable to study electronic, vibrational, rotational and Zeeman transitions in complex ions that implements quantum logic schemes [3] between an atomic ion and the molecular ion of interest, using optical forces on the atom, and optical forces or magnetic field gradients on the molecule. This method sets a starting point for a hybrid quantum computation scheme with molecular and atomic ions, covering the measurement and entangling steps. Finally I will discuss the remarkable decoherence properties of two Zeeman states of the $^{16}\text{O}_2^+$ molecular ion that make it a promising system for QIPC purposes [4].

10:36AM A4.00012 Possibility of “magic” trapping of three-level system for Rydberg blockade implementation¹, MUIR J. MORRISON, ANDREI DEREVIANKO, University of Nevada, Reno — The Rydberg blockade mechanism has shown noteworthy promise for scalable quantum computation with neutral atoms. Both qubit states and gate-mediating Rydberg state belong to the same optically-trapped atom. The trapping fields, while being essential, induce detrimental decoherence. Here we theoretically demonstrate that this Stark-induced decoherence may be completely removed using powerful concepts of “magic” optical traps. We analyze “magic” trapping of a prototype three-level system: a Rydberg state along with two qubit states, which are hyperfine states attached to a $J = 1/2$ ground state. Our numerical results show that the group IIIB metals such as Al are suitable candidates. Such trapping may or may not be possible for the alkalis, as “magic” conditions depend sensitively on the the trap-Rydberg interaction. Calculations of these effects are ongoing, and the results will be presented.

10:48AM A4.00013 Cooling in the single-photon regime of optomechanics, ANDREAS NUNNENKAMP, Department of Physics, University of Basel, Klingelbergstrasse 82, CH-4056 Basel, Switzerland, KJETIL BORKJE, STEVEN GIRVIN, Departments of Physics and Applied Physics, Yale University, New Haven, Connecticut 06520, USA — Optomechanics experiments are rapidly approaching the regime where the radiation pressure of a single photon displaces the mechanical oscillator by more than its zero-point uncertainty. We show that in this limit the power spectrum has multiple sidebands and that the cavity response has several resonances in the resolved-sideband limit [Phys. Rev. Lett. **107**, 063602 (2011)]. We then discuss how red-sideband cooling is modified in this nonlinear regime. Using Fermi's Golden rule we calculate the transition rates induced by the optical drive. In the resolved-sideband limit we find multiple cooling resonances for strong single-photon coupling. They lead to non-thermal steady states and are accompanied by multiple mechanical sidebands in the optical output spectrum. Our study provides the tools to detect and take advantage of this novel regime of optomechanics.

Monday, February 27, 2012 8:00AM - 11:00AM –

Session A5 DCMP: Surfaces: Structure, Transitions and Morphological Evolution 206A

8:00AM A5.00001 The Relaxation of Vicinal (001) with ZigZag [110] Steps¹, MICAH HAWKINS, Department of Physics, University of Maryland, College Park, AJMI BH HAMOUDA, Faculte des Sciences de Monastir, Monastir, Tunisia, DIEGO LUIS GONZÁLEZ-CABRERA, THEODORE L. EINSTEIN, Department of Physics, University of Maryland, College Park — This talk presents a kinetic Monte Carlo study of the relaxation dynamics of [110] steps on a vicinal (001) simple cubic surface. This system is interesting because [110] steps have different elementary excitation energetics and favor step diffusion more than close-packed [100] steps. In this talk we show how this leads to relaxation dynamics showing greater fluctuations on a shorter time scale for [110] steps as well as 2-bond breaking processes being rate determining in contrast to 3-bond breaking processes for [100] steps. The existence of a steady state is shown via the convergence of terrace width distributions at times much longer than the relaxation time. In this time regime excellent fits to the modified generalized Wigner distribution (as well as to the Berry-Robnik model when steps can overlap) were obtained. Also, step-position correlation function data show diffusion-limited increase for small distances along the step as well as greater average step displacement for zigzag steps compared to straight steps for somewhat longer distances along the step. Work supported by NSF-MRSEC Grant DMR 05-20471 as well as a DOE-CMCSN Grant.

8:12AM A5.00002 Embedded Atom Method Potential for Ni-Cu Alloys and Its Applications for Ni, Cu growth on Cu(111)¹, BERK ONAT, Informatics Institute, Istanbul Technical University, Istanbul, Turkey, SONDAN DURUKANOGLU, Nanotechnology Research and Application Center, Faculty of Engineering and Natural Sciences, Sabanci University, Istanbul, Turkey — We developed a semi-empirical, many-body type model potential to investigate static and dynamic properties of Ni-Cu alloys. The formalism is based on the embedded atom method with improved optimization techniques. The Ni-Cu alloy potential was determined by fitting to data on lattice parameters, cohesive energies for L1₀, L1₁, L1₂, and L1₃ phases, together with vacancy formation energies, bulk modulus and elastic properties for L1₂, L1₃ phases. Our preliminary calculations for energy barriers for the diffusing Ni and Cu atoms on Cu(111) based on the nudged elastic band method are found to be consistent with the available experimental and other theoretical results. Our ultimate goal is to describe the varying characteristics in growing islands of pure Cu, Ni atoms and mixed Ni-Cu combinations on Cu(111) [S. Pons *et al.*, Surf. Sci., **511**, 449, (2002)].

¹This work was supported by TUBITAK under Grant No. 109T105. Computations were carried out through UYBHM at Istanbul Technical University, under Grant No. 20132007.

8:24AM A5.00003 Computational diffusion model of reconstructed regions in Ag/Si epitaxial growth, JOSEPH DRISCOLL, KELLY ROOS, Bradley University, D. WALL, M. HORN-VON HOEGEN, F.-J. MEYER ZU HERINGDORF, Department of Physics and Center for Nanointegration Duisburg-Essen (CeNIDE), Universität Duisburg-Essen, 47057 Duisburg, Germany — The thermal decay of Ag islands, grown epitaxially in a Stranski-Krastanov mode on Si(001) and Si(111) surfaces, has been studied experimentally with photoemission electron microscopy (PEEM). In a range of elevated temperatures the islands decay mainly by dissociation of Ag atoms from island edges, rather than by direct desorption into the gas phase. On the surrounding surface, the Ag atoms are subject to thermally-activated diffusion and desorption. The Ag surface concentration decreases with distance from the island edges. Where the local concentration is above a critical value, coverage-dependent reconstructed overlayers form surrounding the islands. The spread of the overlayers, relative to the position of the decaying island, depends on competition between diffusion and desorption. Previous quasi-static models [1] have shown that the observed reconstructed regions are related to the atomistic parameters describing surface diffusion, and have been applied to extract diffusion coefficients from the experimental data. Here we present results from a dynamic diffusion model that captures many of the qualitative and quantitative time- and temperature-dependent phenomena observed in the experiments.

[1] K.R. Roos et. al. PRL 100, 016103 (2008); D. Wall et. al. NJP 12 (2010) 103019

8:36AM A5.00004 Plasma-assisted molecular beam epitaxy growth of ZnSnN_2 , NATHANIEL FELDBERG, JAMES ALDOUS, YUAN YAO, IMTIAZ TANVEER, BENJAMIN KEEN, University at Buffalo, WOJCIECH LINHART, TIM VEAL, University of Warwick, YOUNG-WOOK SONG, ROGER REEVES, University of Canterbury, STEVE DURBIN, University at Buffalo, UNIVERSITY AT BUFFALO TEAM, UNIVERSITY OF WARWICK COLLABORATION, UNIVERSITY OF CANTERBURY COLLABORATION — The Zn-IV-nitrides are a promising series of “earth abundant element” semiconductors with a predicted band gap range of 0.6 eV to 5.4 eV, which, like the (Al,Ga,In)N family, spans the entire visible solar spectrum. Considering this alternative family has a number of advantages, including the avoidance of indium, the price of which has varied almost an order of magnitude over the past decade, and surface electron accumulation which is present in the In-rich alloys. Not all members of this family have yet been synthesized, in particular ZnSnN_2 , the most important member for PV with its predicted band gap of approximately 2 eV. We have successfully grown a series of these films using plasma-assisted molecular beam epitaxy using elemental Zn and Sn sources. In this report, we discuss the relationship between process parameters and microstructure, as well as stoichiometry as determined by Rutherford backscattering spectrometry. Additionally, we provide preliminary estimates for its bandgap energy based on photoluminescence and optical absorption.

8:48AM A5.00005 Transition between two patterns on an Au-deposited Si(111) surface¹, F.K. MEN, A.L. CHIN, C.P. CHANG, Department of Physics, National Chung Cheng University, Chia-Yi 621, Taiwan, — Two distinct patterns have been observed by depositing sub-monolayer Au onto a Si(111)-(7×7) surface with a small miscut angle. Upon depositing Au at 600 °C, we find that a stripe of (5×2) reconstruction forms at the upper step edge in every terrace. For 700 °C deposition, one entire terrace out of several terraces transforms into the (5×2) reconstruction while the other terraces are totally unaffected by the Au deposition. The relative population between the (5×2) and the (7×7) terrace is governed by the amount of deposited Au. After annealing at a temperature above 700 °C the striped (5×2) pattern transforms into the (5×2)-terrace pattern. The similarity between this coarsening of (5×2) reconstruction and the Ostwald ripening of clusters is striking and will be discussed. One application using the (5×2) pattern as a template to grow nanostructure in designated regions will be demonstrated.

¹Work supported by NSC of the Republic of China.

9:00AM A5.00006 Unusual Island Formations of Iridium on Ge(111) Studied by STM¹, MARSHALL VAN ZIJLL, CORY MULLETT, BRET STENGER, EMILIE HUFFMAN, DYLAN LOVINGER, WILLIAM MANN, SHIRLEY CHIANG, UC Davis — We have used scanning tunneling microscopy (STM) to characterize the growth of iridium onto Ge(111). Iridium was deposited onto the Ge(111) c(2×8) surface at different coverages less than 1ML, and the samples were annealed to temperatures between 550K and 750K. A new form of growth was observed, consisting of pathways connecting larger iridium islands. As the annealing temperature increased, the iridium growth first formed unusual shapes with finger-like protrusions. Next, these shapes broke apart into smaller islands, which ultimately formed into larger islands at higher temperatures. High resolution images have been obtained, which allow insight into the atomic arrangements.

¹Funding from NSF CHE-0719504 and NSF PHY-1004848

9:12AM A5.00007 Thickness-dependent Adatom-Adatom Binding Energy on Pb(111): The Effect of Quantum Size Effect on Critical Nucleus¹, MIAO LIU, FENG LIU, University of Utah — We perform first-principles calculations to investigate adatom-adatom binding energies on Pb(111) as a function of film thickness. An odd-even thickness-dependent oscillation is found in the adatom-adatom binding energies, in analogy to the similar behavior in adatom surface binding energies and diffusion barriers found previously. We will discuss these results in relation to the thickness-dependent island nucleation density and compactness, as observed in recent experiments.

¹The work was supported by NSF-DMR 0909212

9:24AM A5.00008 De-wetting of thin films: Analytic theory of cluster coarsening dynamics, ADI CONSTANTINESCU, Asia Pacific Center for Theoretical Physics, Pohang, South Korea, LEONARDO GOLUBOVIC, West Virginia University, ARTEM LEVANDOVSKY, University of California Riverside — Long range de-wetting forces acting across thin films, such as the fundamental van der Waals interactions, may drive the formation of large clusters (tall multi-layer islands) and pits, observed in thin films of soft materials (polymers), as well as in thin films of liquid and solid metals. These long range de-wetting interactions introduce a distinct long lasting early-time scaling behavior characterized by a slow growth of the cluster height/lateral size aspect ratio (i.e., a time-dependent Young angle), and by effective coarsening exponents that depend on cluster size. In this study, we develop an analytic theory capable to calculate these effective size-dependent coarsening exponents characterizing the cluster growth in the early-time cross-over regime. Such a pronounced cross-over behavior has been indeed seen in experiments; however its physical origin has remained elusive to this date. Our results attribute these observed phenomena to ubiquitous long range de-wetting interactions acting across thin films.

9:36AM A5.00009 Surface morphological stabilization of crystalline solids under the simultaneous action of electric, thermal, and mechanical fields, DWAI PAYAN DASGUPTA, GEORGIOS SFYRIS, RAUF GUNGOR, DIMITRIOS MAROUDAS, Department of Chemical Engineering, University of Massachusetts Amherst — We report a detailed analysis of the morphological stability of planar surfaces of electrically and thermally conducting stressed crystalline elastic solids under the simultaneous action of an electric field, an imposed temperature gradient, and uniaxial tension. Our analysis is based on linear stability theory and self-consistent dynamical numerical simulation according to a fully nonlinear model that accounts for curvature- and stress-driven surface diffusion, surface electromigration and thermomigration, as well as surface diffusional anisotropy. Our self-consistent dynamical simulations combine a front tracking method for monitoring surface morphological evolution with Galerkin boundary-integral computations of the displacement and temperature fields and the electrostatic potential. We determine the surface morphological stability domain boundaries and the critical values of the applied electric-field strength and temperature gradient required to stabilize the planar surface morphology. We explore the synergistic or competing effects on the surface morphological response of the simultaneously applied thermal and electric fields, aiming at optimization of the electric-field strength and temperature gradient requirements for planar surface stabilization.

9:48AM A5.00010 Electromigration-driven morphological evolution of monolayer-thick epitaxial islands on substrates, DIMITRIOS MAROUDAS, DWAIPAYAN DASGUPTA, GEORGIOS SFYRIS, Department of Chemical Engineering, University of Massachusetts Amherst — Electromigration-driven dynamics, with and without the simultaneous action of elastic strain, can lead to pattern formation of surface morphological features that may have significant impact on nanofabrication. An important example is epitaxial islands on substrates; for heteroepitaxial islands, misfit strain is induced due to lattice mismatch with the substrate. We develop a fully nonlinear model for the driven morphological evolution of monolayer-thick coherently strained islands on crystalline elastic substrates with diffusional mass transport limited to the island circumference. We carry out self-consistent dynamical simulations of such island dynamics, combining front tracking methods with solutions to the corresponding electrostatic and elastostatic boundary-value problems. We develop a universal scaling theory that explains the simulation results for the dependence of the island migration speed on the island size, electric field, and epitaxial system parameters for isolated, morphologically stable islands. We investigate systematically thermal, elastic, and size effects on the migration and morphological evolution of heteroepitaxial islands. We also find and characterize a variety of stable asymptotic states in the driven dynamical response of such heteroepitaxial islands.

10:00AM A5.00011 Electromigration-driven surface morphological stabilization of coherently strained thin films on elastically deformable substrates, GEORGIOS SFYRIS, RAUF GUNGOR, DIMITRIOS MAROUDAS, Department of Chemical Engineering, University of Massachusetts Amherst — We study the surface morphological stability of a coherently strained thin film grown epitaxially on a substrate and subjected to an external electric field; both infinitely thick and finite-thickness elastic substrates are examined. Due to its lattice mismatch with the substrate material, the film may undergo a Stranski-Krastanow (SK) instability, resulting in formation of islands on the film surface. To examine the morphological stability of the epitaxial film's planar surface state, we conduct a linear stability analysis based on a three-dimensional model of driven surface morphological evolution. We also consider the use of thin compliant substrates, which partly accommodate elastically the lattice-mismatch strain. We find that, regardless of the substrate type, the simultaneous action of a properly applied and sufficiently strong electric field is necessary to stabilize the planar morphology; in such cases, surface electromigration can inhibit SK-type instabilities and control the onset of island formation on the film surface. Our analysis shows that the critical electric-field strength required to stabilize the planar morphology of a thin film on a compliant substrate can be reduced by up to two orders of magnitude compared to that for a conventional thick substrate.

10:12AM A5.00012 Quantum Monte Carlo Study of Surface Energy, CHENG-RONG HSING, CHING-MING WEI, IAMS, Academia Sinica, Taipei 10617, Taiwan — The accuracy of Density Functional Theory (DFT) is based on the exchange-correlation approximation used and needs to be checked by highly accurate quantum many-body approaches. We have performed calculations of the surface energies using the state-of-the-art diffusion quantum Monte Carlo (QMC) method to examine the accuracy of LDA and GGA (PBE) functionals in the study of surface energy. The systems studied include NaCl(100), MgO(100), CaO(100), TiO₂(110), Si(100)-(2x2), C(100)-(2x2), and Ge(100)-(2x2) surfaces. Our results indicate that (i) the surface energy by DMC is always larger than the surface energy by LDA; and (ii) the surface energy by LDA is always larger than the surface energy by GGA. For the surface energies of NaCl(100) and MgO(100), the DMC results reproduce the experimental measured values accurately. To conclude, when compared the surface energies obtained by DFT and DMC, the results predicted by DFT using either LDA or GGA functional are underestimated.

10:24AM A5.00013 Reconstructions of the GaN(10 $\bar{1}\bar{1}$) surfaces: Density functional theory calculations¹, JUNG-MIN HYUN, Sookmyung Women's University, YONG-SUNG KIM, Korea Research Institute of Standards and Science, HANCHUL KIM, Sookmyung Women's University — GaN has been extensively studied for its potential applicability in optoelectronics as well as in spintronics. The functional performance in such applications depends on the surface characteristics of thin films. Thin films of GaN are typically grown along the polar [0001] direction, but their light-emission efficiency is reduced due to the electron-hole separation. A strategy to remedy such an undesired effect is to grow films along nonpolar or semipolar directions. In this presentation, we will address the reconstructions of the Ga-terminated semipolar (10 $\bar{1}\bar{1}$) surface. We performed the density functional theory calculations using the generalized gradient approximation, the projector augmented wave potentials, and the repeated slabs. From the calculated energetics of various reconstructions, we found that there exist a few structural motifs of GaN(10 $\bar{1}\bar{1}$). They are short Ga chains and Ga vacancies. For instance, a 4 × 2 reconstruction with a Ga tetramer and surface Ga vacancies is stable in the N-rich condition, which is significantly different from the previous results [Akiyama *et al.*, Jpn. J. Appl. Phys. 48, 100201 (2009)]. Our results would provide a comprehensive understanding on the Ga-terminated semipolar surfaces.

¹This work was supported by Nano R&D Program through the National Research Foundation of Korea (NRF) (No. 2009-0082490) and by the Strategic Supercomputing Support Program from KISTI (No. KSC-2008-S02-0010).

10:36AM A5.00014 Cross-sectional scanning tunneling microscopy at GaN (10-10), HOLGER EISELE, LENA IVANOVA, Technische Universität Berlin, SVETLANA BORISOVA, Forschungszentrum Juelich GmbH, MARIO DAEHNE, Technische Universität Berlin, PHILIPP EBERT, Forschungszentrum Juelich GmbH — Group-III nitrides are the materials of choice for optoelectronic devices in the green to ultraviolet wavelength range. Recently, the question arose, whether the growth of GaN based devices could be improved by switching from polar surfaces to the non-polar ones. For non-polar GaN surfaces only little is known about the exact energetic positions of surface states, and thus their possible influence on the Fermi level. Furthermore, GaN still suffers from high dislocation densities, far above that of zincblende type III-V semiconductor crystals, which are detrimental for optoelectronic applications of GaN. Therefore we investigated the GaN(10-10) cleavage surface by cross-sectional scanning tunneling microscopy and spectroscopy. We were able to identify the energetic positions of the intrinsic surface states and the Fermi level. We found that both, the filled N-derived and empty Ga-derived dangling bond states are outside the fundamental band gap, the latter one being 0.1–0.2 eV above the conduction band minimum. The observed band gap is 3.4±0.2 eV, in agreement with the nominal value from the bulk. The observed Fermi level pinning of about 1.0 eV below the conduction band edge is attributed to a high defect density at the surface, but not to intrinsic surface states.

10:48AM A5.00015 Geometrical and Electronic structures of Planar and Buckled Silicene on Ag(111), CHUN-LIANG LIN, Department of Advanced Materials Science, The University of Tokyo, RYUICHI ARAFUNE, International Center for Materials Nanoarchitectonics, National Institute for Materials Science, NORIYUKI TSUKAHARA, Department of Advanced Materials Science, The University of Tokyo, KAZUAKI KAWAHARA, Department of Applied Chemistry, The University of Tokyo, NORIAKI TAKAGI, MAKI KAWAI, Department of Advanced Materials Science, The University of Tokyo — Silicene grown on the Ag(111) surface was investigated by scanning tunneling microscopy / spectroscopy (STM / STS). Two atomic arrangements of honeycomb lattice, planar and buckled, were found. The planar silicene is consisted of Si atoms in the same height while the buckled one shows slightly twisted structure in the vertical direction. Compared to the planar silicene, the lateral distance between two neighboring atoms in the buckled silicene is reduced with about 7%. Assuming that there is no change in the length of Si-Si bond, the angle between the Si-Si bond and the axis normal to the surface is 110 degrees, which is close to the bond angle of 109 degrees in the sp³ hybridization. This might suggest that the Si-Si bonding in the buckled silicene is formed mainly by sp³ hybridization rather than sp². However, our STS observations certainly showed a Dirac cone feature at the Fermi level for both types of silicene. Thus, we conclude that the electronic configuration of buckled silicene partially remains in sp² hybridization and the charge carriers still behave as the massless Dirac fermions.

Session A6 DMP: Focus Session: van der Waals Bonding in Advanced Materials - Physisorption and Self Assembly on Metals 206B

8:00AM A6.00001 Application of vdW-DF Methods to Hydrogen Adsorptions and an Organic Ferroelectric¹, KYUHO LEE, Rutgers University — In recent years, several schemes have been proposed to include van der Waals (vdW) interactions into the framework of density functional theory (DFT). These offer the potential to extend the scope and usefulness of DFT, allowing applications to an entire new class of sparse materials. For finite systems, we validated our non-empirical van der Waals density functionals (vdW-DFs) with respect to very accurate quantum chemical calculations of the potential energy curves (PECs) for small molecular duplexes [1]. For extended systems, however, typical tests focus on comparisons with a few accessible observations, such as binding energy and bond length [1]. In this talk, we present a third approach in which full PECs from accurate experiments are used for the assessment of vdW methods for extended systems [2]. We calculate the PECs of the H₂ molecule and light atoms on the (100), (110), and (111) surfaces of Cu. The gas-surface-scattering experiments provide the rich data bank that covers results for the whole shape of the physisorption potentials. We also present an application of vdW-DF2 to an organic ferroelectric, phenazine-chloranilic acid [3]. In spite of extensive experimental efforts to characterize this rare organic material, the origin of the long-range order is unclear and even the ground state structure is not completely determined yet. We study its structure, energetics, ferroelectric properties, structural instability, and the proton-transfer process in it in comparison with PBE results and experiments wherever possible.

8:36AM A6.00002 Structure and Energetics of Benzene Adsorbed on Transition-Metal Surfaces: Density-Functional Theory with Screened van der Waals Interactions, WEI LIU, VICTOR G. RUIZ-LÓPEZ, GUO-XU ZHANG, XINGUO REN, MATTHIAS SCHEFFLER, ALEXANDRE TKATCHENKO, Fritz-Haber-Institut der MPG, Berlin, Germany — The adsorption of benzene on metal surfaces is an important benchmark system for more complex hybrid inorganic/organic interfaces. Here, the recently developed DFT+vdW^{surf} method (density-functional theory including screened van der Waals (vdW) interactions) [1] is used to study the structure and energetics of benzene on transition-metal surfaces (Cu, Ag, Au, Pd, Pt, Rh, and Ir). Benzene adsorbs in a planar configuration at coinage metal surfaces, with almost zero distortion and a flat potential-energy surface. In contrast, benzene is strongly bound to the (111) surface of Pd, Pt, Rh, and Ir, and located at the bridge-30° site. The vdW interactions significantly enhance the binding energy by more than 0.75 eV for all metals. The screening of the vdW energy plays a critical role in coinage metals, shortening the equilibrium distance by 0.2 Å, and lowering the binding energy by 0.25 eV. The validity of our results is confirmed by comparison with calculations using the random-phase approximation including renormalized single excitations (EX+cRPA+rSE scheme [2]), and the experimental data from temperature-programmed desorption and calorimetry measurements. [1] V. G. Ruiz-López et al., submitted. [2] X. Ren et al., *Phys. Rev. Lett.* **106**, 153003 (2011).

8:48AM A6.00003 Physisorption of three amine terminated molecules (TMBDA, BDA, TF-BDA) on the Au(111) Surface: The Role of van der Waals Interaction¹, MARAL AMINPOUR, DUY LE, TALAT S. RAHMAN, Department of Physics, University of Central Florida — Recently, the electronic properties and alignment of tetramethyl-1,4-benzenediamine (TMBDA), 1,4-benzenediamine (BDA) and tetrafluoro-1,4-benzenediamine (TFBDA) molecules were studied experimentally. Discrepancies were found for both the binding energy and the molecule tilt angle with respect to the surface, when results were compared with density functional theory calculations [1]. We have included the effect of vdW interactions both between the molecules and the Au(111) surface and find binding energies which are in very good agreement with experiments. We also find that at low coverages each of these molecules would adsorb almost parallel to the surface. N-Au bond lengths and charge redistribution on adsorption of the molecules are also analyzed. Our calculations are based on DFT using vdW-DF exchange correlation functionals. For BDA (since we are aware of experimental data), we show that for higher coverage, inclusion of intermolecular van der Waals interaction leads to tilting of the molecules with respect to the surface and formation of line structures. Our results demonstrate the central role played by intermolecular interaction in pattern formation on this surface.

9:00AM A6.00004 Effect of physisorbed molecules and an external external fields on the metallic Shockley surface state of Cu(111): A density functional theory study¹, KRISTIAN BERLAND, Chalmers University of Technology, T.L. EINSTEIN, University of Maryland, PER HYLDGAARD, Chalmers University of Technology — To manipulate the Cu(111) partially-filled Shockley surface state, we study its response to an external field² E and physisorbed PAHs and quinone molecules. We use density-functional theory calculations with periodic-boundary conditions. The van der Waals density functional version vdW-DF2 accounts for the molecular adsorption. The issue that the Kohn-Sham wave functions couple to both sides of the Cu slab is handled with a decoupling scheme based on a rotation in Hilbert space. A convergence study reveals that to obtain a proper Shockley surface state, 6 Cu layers is sufficient, while 15 is optimal. We use 6 layers for the response to the molecules and 15 to external field. We find that the surface state displays isotropic dispersion (up to order k^6), free-electron like until the Fermi wave vector but with a significant quartic component beyond. The shift in band minimum and effective mass depend linearly on E , with a smaller fractional change in the latter. Charge transfer occurs beyond the outermost copper atoms, and most of the screening is due to bulk electrons. We find that the molecular physisorption increases the band minimum, with the effect the of a quinone being much stronger than the corresponding PAH.

9:12AM A6.00005 Computational Study of Supramolecular Self-Assembly Using CH/ π Bonds

, C. HAN, CHIPS, NCSU, Q. LI, S. HORTON, M. FUENTES-CABRERA, B. SUMPTER, CNMS, ORNL, W. LU, J. BERNHOLC, CHIPS, NCSU, P. MAKSY-MOVYCH, M. PAN, CNMS, ORNL — Self assembly is an important research area in supramolecular engineering. We show that CH/ π bonds can be exploited as a vehicle to assemble clusters of well-defined sizes on metal surfaces. Specifically, we theoretically explain the observations of largely uniform distribution of phenylacetylene magic clusters, each consisting of six molecules, on Au(111) surfaces. Using density functional theory with a van der Waals functional, we discuss the reasons for the preference of the hexamer structure, the key effect of CH/ π bonding on the self-assembly, and the critical role of the metal surface. Our calculated STM images and electronic properties are in good agreement with experiment. The cooperative, multi-center CH/ π interactions offer an attractive tunability via chemical functionalization, and thus may provide a new avenue towards rationally designing a desired supramolecular shape and size.

9:24AM A6.00006 Noble Gases on Metal Surfaces: New Insights on Adsorption Site Preference

, DE-LI CHEN, WISSAM AL-SAIDI, KARL JOHNSON, University of Pittsburgh — Experiments have previously found that noble gases (Kr, Xe) adsorb on low-coordination atop sites on several different metal surfaces, rather than on high-coordination hollow sites. This unexpected preference for low-coordination sites has been previously ascribed to reduced Pauli repulsion mostly due to exchange energy at the atop site, based on density functional theory calculations within the local density approximation (LDA). In contrast, our calculations using non-local van der Waals (vdW-DF) density functional show that site preference is due to a delicate balance between the electrostatics which favor the hollow site and kinetic energy which favors the atop site; exchange-correlation energies has a very little role. Moreover, we find, using LDA, GGA, and vdW-DF functionals, that the hollow site is a saddle point of index 1 or 2 on the 2-dimensional potential energy surface, while the atop site is the only true minimum. Therefore, the reason that hollow site occupation is not observed is that it is a transition state and so has a very short life-time. Our results show that the inclusion of non-local vdW interactions is crucial for obtaining results in quantitative agreement with experiments for adsorption energies, equilibrium distances, and vibrational energies.

9:36AM A6.00007 Adsorption of polyvinylpyrrolidone on Ag surfaces: Insight into the workings of a structure-directing agent¹

, WISSAM AL-SAIDI, University of Pittsburgh, HAIJUN FENG, KRISTEN FICHTHORN, The Pennsylvania State University — We use density-functional theory to resolve the role of polyvinylpyrrolidone (PVP) as a structure-directing agent in the shape-selective synthesis of Ag nanostructures. We identify several different binding states for PVP segments on Ag(100) and Ag(111) and find an energetic preference for Ag(100), which arises from a surface-sensitive balance between direct binding and van der Waals attraction. At the chain level, correlated segment binding leads to a strong preference for PVP bind to Ag(100). Our study underscores differences between small-molecule and polymeric structure-directing agents.

9:48AM A6.00008 Adsorption of halogenated molecule on stepped metallic surfaces: the role of van der Waals interactions

, RENGIN PEKOZ, KAREN JOHNSTON, DAVIDE DONADIO, Max Planck Institute for Polymer Research — The deposition of halogenated aromatic molecules on metallic surfaces is the first step for the bottom-up fabrication of atomically precise graphene nanoribbons [1]. Interest in the binding properties in this type of systems and in general in organic/inorganic interfaces has stimulated the inclusion of van der Waals (vdw) interactions within density functional theory (DFT). Using a fully non-local Van der Waals density functional (vdW-DF) [2,3] we have studied the adsorption of dichlorobenzene on stepped Au(332) and Pt(332) surfaces and on flat (111) surfaces. For several different adsorption sites, the energies, and equilibrium geometries have been computed, and electron density analysis has been performed using both conventional generalized gradient approximation (GGA) and vdW-DF. The two approaches yield qualitatively different results, highlighting the importance of non-local dispersions in this class of systems. The non-trivial role of steps edges on adsorption energies and geometries is also elucidated. [1] J. Cai *et al.*, Nature 466, 470 (2010). [2] M. Dion *et al.*, Phys. Rev. Lett. 92, 246401 (2004). 10:00AM A6.00009 The Nature of Binding in the Phenalenyl Dimer and its Derivatives

, BRIAN KOLB, TIMO THONHAUSER, Wake Forest University, MIKLOS KERTESZ, Georgetown University — The biradical phenalenyl π -dimer and its derivatives have attracted interest recently because of their potentially useful electrical, optical, and magnetic properties. These properties can be tuned by adjusting the binding characteristics between the monomers within the dimer. Typically, this is done by substituting electron withdrawing or donating groups onto the α or β -site carbons. An understanding of this binding lies at the heart of useful application of these materials. In this work, the binding characteristics of phenalenyl dimers were investigated using density functional theory. In particular, the vdW-DF functional was used to explore the role of van der Waals interactions in the binding within this system. A comparison of the binding curves with those of the closed shell derivatives wherein the central carbons have been replaced by either nitrogen or boron sheds light into the nature of the interactions between the monomers.

10:12AM A6.00010 Binding nature of adenine and C60 on graphene: a van der Waals density functional analysis¹

, PER HYLDGAARD, KRISTIAN BERLAND, Chalmers University of Technology, VALENTINO COOPER, Oak Ridge National Laboratory, ANDERS BERGVALL, SERGEY KUBATKIN, TOMAS LÖFWANDER, ELSEBETH SCHRÖDER, Chalmers University of Technology — Based on van der Waals density functional theory (using vdW-DF1 and vdW-DF2), we study and analyze the adsorption of adenine² and C60³ on graphene. Understanding molecular binding on graphene helps development of functionals because the infinite graphene shifts the balance between short-range and long-range contributions to binding as compared dimers or molecular crystals. The potential of graphene as contacts in single-molecule electronics also motivates the study of the interaction between aromatic molecules and graphene; the binding separation affects the magnitude of hopping parameters. We present results on binding energy and separation, vibrational states, overlays, and charge transfer. We find that the hexagonal ring in C60 binds closer to the graphene sheet than what a flat molecule such as adenine does. The role played by the difference in geometry between the flat (adenine) and spherical (C60) shape is discussed.

Session A7 DMP DCOMP: Focus Session: Computational Design of Materials - Structure Prediction 207

8:00AM A7.00001 Crystal structure prediction: a novel approach based on minima hopping, MAXIMILIAN AMSLER, STEFAN GOEDECKER, University of Basel — With increasing computational resources the prediction of crystal structures from first principle calculations has become feasible, but still remains a demanding task. A reliable method to perform an efficient, systematic search for the ground state structure based solely on the system's composition is essential. Motivated by the promising results of the minima hopping method obtained on isolated systems, we have generalized the algorithm for crystal structure prediction. Optimized moves in the configurational space spanned by both atomic coordinates and simulation cell variables are performed to escape from local enthalpy minima, and revisiting known minima is avoided, thus allowing a fast exploration of the enthalpy surface. The predictive power of the novel method has been shown in several applications, of which the following will be presented. Superconducting phases in hydrogen rich materials were investigated, leading to the discovery of novel ground state structures. For the longstanding question of the crystal structure of cold compressed graphite a new candidate phase could be identified to perfectly match experimental results. And at last, new low energy structures for materials with possible applications in hydrogen storage are presented.

8:12AM A7.00002 Adaptive Genetic Algorithm method for Crystal Structure Prediction and Materials Discovery¹, CAI-ZHUANG WANG, MIN JI, SHUNQING WU, Ames Laboratory, Iowa State U, Ames, Iowa 50011, KOICHIRO UMEMOTO, U of Minnesota and Ames Laboratory, Iowa State U, RENATA WENTZCOVITCH, Univ of Minnesota, KAI-MING HO, Ames Laboratory, Iowa State U, Ames, Iowa 50011, AMES TEAM², MINNESOTA TEAM³ — We developed a fast and efficient method for crystal structure prediction and materials discovery. The method is based on the cut-and-paste genetic algorithm (GA) scheme introduced by Deaven and Ho [1]. In the evaluation of energies of target structures, first-principles calculations are accurate but time-consuming. Our method performs GA searches uses auxiliary model potentials to screen the energy of candidate structures, selecting only a few for more extensive first principles evaluation. Parameters of the auxiliary potentials are adaptively adjusted to reproduce the first-principles results during the course of the GA search. Our method combines the speed of empirical potential searches with the accuracy of first principles calculations. We will present results on applications to various systems including metallic alloys and ultrahigh pressure SiO₂, H₂O and Mg-Si-O systems.

8:24AM A7.00003 Periodic structure optimization via local heat pulse-quench cycles employing the GULP code, ARNULF MÖBIUS, Institute for Theoretical Solid State Physics, IFW, Dresden, Germany, J. CHRISTIAN SCHÖN, Max Planck Institute for Solid State Research, Stuttgart, Germany — We present an optimization algorithm for problems with many continuous degrees of freedom and a huge number of local minima. It is based on the thermal cycling approach, originally developed for combinatorial optimization tasks [1]. The main idea is to cyclically disturb a few randomly chosen degrees of freedom of the current best local minimum and to quench this state by a highly efficient local search code. As the optimization proceeds, the amplitude of the disturbance slowly decreases. This approach is applied to a lattice structure prediction problem. We use the general utility lattice program (GULP) by J.D. Gale and co-workers [2] for local search. As test, the hypothetical periodic Mg₁₀Al₄Ge₂Si₈O₃₆ compound is studied, where both the cell parameters and the atom positions are free to vary. The results demonstrate that the proposed procedure is robust and far more efficient than the previous approaches to this problem by means of multi-start local search, simulated annealing, and evolutionary algorithms in Ref. 3.

8:36AM A7.00004 Mapping the Materials Genome through Combinatorial Informatics, KRISHNA RAJAN, Iowa State University — The recently announced White House Materials Genome Initiative provides an exciting challenge to the materials science community. To meet that challenge one needs to address a critical question, namely *what* is the materials genome? Some guide on how to the answer this question can be gained by recognizing that a "gene" is a carrier of information. In the biological sciences, discovering how to manipulate these genes has generated exciting discoveries in fundamental molecular biology as well as significant advances in biotechnology. Scaling that up to molecular, cellular length scales and beyond, has spawned from genomics, fields such as proteomics, metabolomics and essentially systems biology. The "omics" approach requires that one needs to discover and track these "carriers of information" and then correlate that information to predict behavior. A similar challenge lies in materials science, where there is a diverse array of modalities of materials "discovery" ranging from new materials chemistries and molecular arrangements with novel properties, to the development and design of new micro- and mesoscale structures. Hence to meaningfully adapt the spirit of "genomics" style research in materials science, we need to first identify and map the "genes" across different materials science applications. On the experimental side, combinatorial experiments have opened a new approach to generate data in a high throughput manner, but without a clear way to link that to models, the full value of that data is not realized. Hence along with experimental and computational materials science, we need to add a "third leg" to our toolkit to make the "Materials Genome" a reality, the science of Materials Informatics. In this presentation we provide an overview of how information science coupled to materials science can in fact achieve the goal of mapping the "Materials Genome".

9:12AM A7.00005 Diamondlike carbo-boride C5B compound? Testing crystal structures and stability with Global Space Group Optimization (GSGO)¹, ARKADIY MIKHAYLUSHKIN, National Renewable Energy Laboratory, USA, XIUWEN ZHANG, Colorado School of Mines, Golden, USA, ALEX ZUNGER, University of Colorado, Boulder, USA — Diamond-like C5B has been alleged to be a new exciting material discovered at high pressures and temperatures. Using density-functional based evolutionary Global Space Group Optimization (GSGO) we established the likely structures of BC3 and BC5 phases and the known B4C compound. Examining the ground state line between solid Carbon and solid Boron we find only B4C is a ground state structure. C5B and C3B are high energy structure at high pressure. The reaction between BC3 and solid carbon producing C5B is found to have a positive reaction enthalpy that depends only weakly on pressure. In contrast to the previous reports, we argue that at 0 T the BC5 is less stable than BC3 in access of carbon. However, a small positive enthalpy of the reaction BC5 → BC3 + 2C cannot rule out formation of the BC5 from the BC3 precursor material as thermally stabilized due to vibrational entropy or/and disorder effects.

9:24AM A7.00006 Hands-free thermodynamic alloy modeling of ~700 binary alloys using a Bayesian approach: Part I, GUS HART, LANCE J. NELSON, Brigham Young University, STEFANO CURTAROLO, Duke University, C. SHANE REESE, Brigham Young University — Bayesian approaches have become useful in recent years as increasing computing power has made them practical. Bayes rule itself is nothing more than a simple statement of conditional probability but can be used to make strong inferences. We discuss the general idea behind Bayes rule and how to use it to build physical models. Using a database of about 150,000 first principle calculations, we are building models for ~700 binary alloys.

9:36AM A7.00007 Hands-free thermodynamic alloy modeling of ~700 binary alloys using a Bayesian approach: Part II, LANCE J. NELSON, Brigham Young University, STEFANO CURTAROLO, Duke University, C. SHANE REESE, GUS L.W. HART, Brigham Young University — In recent years, Bayesian statistics has become more popular as a scientific tool. This is mainly due to advances in computing power, which make the Bayesian formalism tractable. Baye's rule, which is a simple statement of conditional probability, is the foundation for Bayesian statistics. When used in conjunction with sampling algorithms, such as Metropolis-Hastings and Gibbs, Baye's rule provides a powerful framework for characterizing important parameters and for making inference. We demonstrate how the Bayesian framework can be applied to alloy modeling, providing the solution to several typical problem areas in this field. Together with our large database of first-principles data this Bayesian framework helps us quickly and accurately characterize hundreds of binary alloys.

9:48AM A7.00008 Sorting stable from unstable hypothetical compounds and determining the electronic structure of interesting candidates : The case of Half-Heusler Filled Tetrahedral ABX structures¹, XIUWEN ZHANG, Colorado School of Mines, Golden, CO 80401, LIPING YU, ANDRIY ZAKUTAYEV, DAVID GINLEY, National Renewable Energy Lab., Golden, CO 80401, ALEX ZUNGER, University of Colorado, Boulder, CO 80305 — Electronic structure theory has recently been used to propose hypothetical compounds, seeking new useful functional materials. In some cases, such hypothetical compounds in presumed crystal structures may be significantly higher in energy than (i) their lowest-energy structures or, than (ii) a combination of their constituents. We use the first-principles thermodynamics to sort (i) the lowest-energy structure and (ii) the thermodynamic stability with respect to disproportionation of the 488 unreported ABX octet compounds. We find that as many as 235 of the 488 are unstable with respect to decomposition, whereas other 235 of the unreported compounds are predicted to be thermodynamically stable. (18 materials are too close to call). The electronic structures of these predicted stable compounds are evaluated based on GW approximation for electron's self-energy. To support the theoretical predictions of new materials, thin film samples of AgYGe were synthesized using combinatorial Pulsed Laser Deposition. AgYSi-type ground state crystal structure and Y-rich composition stability range of AgYGe agree well with theory.

10:00AM A7.00009 Band-structure predictions for A2BX4 discovery compounds¹, STEPHAN LANY, V. STEVANOVIC, National Renewable Energy Lab., Golden, CO, A. ZUNGER, University of Colorado at Boulder, CO — The inverse design of materials requires to predict the existence and the properties of previously unknown materials. We have performed a computational search for thermodynamically stable materials within the family of A2BX4 compounds (A, B = main group and 3d cations; X = O, S, Se, Te) resulting in the theoretical discovery of about 100 previously unreported compounds. The challenge for the prediction of band-structures and optical spectra is to obtain accurate results for a wide range of materials within a single computational scheme, so that unknown materials can be predicted with confidence. Whereas the main group chalcogenides are rather accurately predicted by many-body GW calculations, large deviations from experiment are observed for many 3d oxides. In particular, we find that the 3d orbitals consistently occur at too high energies, independent on whether they are occupied (e.g., Cu2O) or unoccupied (e.g., TiO2). While the exact nature of these issues are under investigation, we pursue here a pragmatic approach, using attractive on-site potentials with a single parameter for each 3d element, which leads to good agreement with experiment for binary and ternary 3d oxides. We use this approach to predict the band-structures of the discovery compounds.

¹Supported by the US Department of Energy, Office of Basic Energy Sciences, as part of an Energy Frontier Research Center.

10:12AM A7.00010 New Crystal Structures Identified for PtO and PtO₂ using Density Functional Theory Calculations¹, JUAREZ L.F. DA SILVA, RICARDO K. NOMIYAMA, University of Sao Paulo, MAURICIO J. PIOTROWSKI, Federal University of Santa Maria — Platinum plays an important role in catalysis and electrochemistry, and it has been known that the direct interaction of oxygen with Pt surfaces can lead to the formation of platinum oxides (PtO_x), which can affects the reactivity. To contribute to the atomistic understanding of the atomic structure of PtO_x, we report a density functional theory study of the atomic structure of bulk PtO_x ($1 \leq x \leq 2$). From our calculations, we identified a lowest energy structure (GeS-type, space group *Pnma*) for PtO, which is 0.181 eV lower in energy than the structure suggested by Moore and Pauling (PtS-type). Furthermore, two atomic structures were identified for PtO₂, which are almost degenerate in energy with the lowest energy structure reported so far for PtO₂ (CaCl₂-type). Based on our results and analysis, we suggest that Pt and O atoms tends to form octahedron motifs in PtO_x even at lower O composition by the formation of Pt–Pt bonds.

¹We thank FAPESP (Sao Paulo Science Foundation) for support.

10:24AM A7.00011 Simulation of structural and electronic properties of amorphous tungsten oxycarbides, KALIAPPAN MUTHUKUMAR, HARALD O. JESCHKE, ROSER VALENTI, Institut fuer Theoretische Physik, Goethe-Universitaet Frankfurt, Max-von-Laue-Str. 1, 60438 Frankfurt, Germany — Electron beam induced deposition with tungsten hexacarbonyl W(CO)₆ as precursors leads to granular deposits with varying compositions of tungsten, carbon and oxygen. Depending on the deposition conditions, the deposits are insulating or metallic. We employ an evolutionary algorithm to predict the crystal structures starting from a series of chemical compositions that were determined experimentally. We show that this method leads to better structures than structural relaxation based on guessed initial structures. We approximate the expected amorphous structures by reasonably large unit cells that can accommodate local structural environments that resemble the true amorphous structure. Our predicted structures show an insulator to metal transition close to the experimental composition at which this transition is actually observed. Our predicted structures also allow comparison to experimental electron diffraction patterns.

10:36AM A7.00012 Predicting Two-Dimensional Boron-Carbon Compounds by the Global Optimization Method, XINYU LUO, JIHUI YANG, XINGAO GONG, HONGJUN XIANG, Fudan University, HANYU LIU, Jilin University, YANCHAO WANG, Jilin Univ, YANMING MA, Jilin University, CCMG, FUDAN UNIVERSITY TEAM, JILIN UNIVERSITY COLLABORATION — We adopt a global optimization method to predict two-dimensional (2D) nanostructures through the particle-swarm optimization (PSO) algorithm. By performing PSO simulations, we predict new stable structures of 2D boron-carbon (B-C) compounds for a wide range of boron concentrations. Our calculations show that: (1) All 2D B-C compounds are metallic except for BC₃ which is a magic case where the isolation of carbon six-membered ring by boron atoms results in a semi-conducting behavior. (2) For C-rich B-C compounds, the most stable 2D structures can be viewed as boron doped graphene structures, where boron atoms typically form 1D zigzag chains except for BC₃ in which boron atoms are uniformly distributed. (3) The most stable 2D structure of BC has alternative carbon and boron ribbons with strong in-between B-C bonds, which possesses a high thermal stability above 2000 K.

10:48AM A7.00013 Quantum confined Schottky barriers: Tuning the Schottky-Mott and Bardeen Limits, JAMES CHELIKOWSKY, TZU-LIANG CHAN, University of Texas at Austin, KAI-MING HO, Iowa State University and Ames Laboratory, CAI-ZHUANG WANG, Ames Laboratory, SHENGBAI ZHANG, Rensselaer Polytechnic Institute — Even though metal-semiconductor junctions are an essential component in electronic devices, an atomistic understanding of the electronic structure of such junctions has remained elusive. Hundreds, if not thousands, of atoms may be required to model such interfaces, owing to lattice mismatches at the interface. The absence of a detailed understanding of the interface structure has inhibited the application of electronic structure calculations to examine the evolution of Fermi level pinning. Here we capitalize on recent computational breakthroughs and apply them to a prototypical system: a Pb(111) film on a Si(111) substrate. We consider up to 1,500 atoms in our first principle calculations based on real space pseudopotentials, and explicitly model the atomistic details of the metal-semiconductor interface. We propose a pinning mechanism for the Fermi level that depends critically on the role of quantum confinement in the overlying metallic film. By changing the thickness of the overlying film, the pinning mechanism can be tuned from the abrupt interface description of Schottky and Mott to the metal induced gap state description of Bardeen.

Monday, February 27, 2012 8:00AM - 10:48AM — Session A8 DMP GMAG: Focus Session: Frustrated Magnetism - Triangular Lattice 208

8:00AM A8.00001 Spin Correlations in the quasi-triangular magnet, $\text{Cu}_2(\text{OH})_3\text{NO}_3$, JASON S. GARDNER, Indiana University, GEORG EHLERS, SNS, Oak Ridge National Laboratory, FLETCHER WERNER, S.A. SOLIN, Washington U in St. Louis — We have investigated the structural and magnetic properties of the spin $S = 1/2$ antiferromagnetic quasi-triangular lattice materials: $\text{Cu}_{2(1-x)}\text{Zn}_{2x}(\text{OH})_3\text{NO}_3$ ($0 < x < 0.65$) using a.c. susceptibility, heat capacity [1,2] and neutron scattering. After a brief introduction to the bulk properties of this family of materials, we will discuss recent inelastic neutron scattering results from the pure and doped materials. The temperature dependence of the quasielastic scattering reveals an abundance of slow spin dynamics at elevated temperatures. This scattering collapses as the system is cooled through its ordering temperature (11 K) and a Q-independent mode is observed at finite energy. These results will be compared to those seen in other triangular systems with a Kagome motif.

8:12AM A8.00002 Optical spectroscopy of the Triangular Lattice Antiferromagnets CuCrO_2 and $\alpha\text{-CaCr}_2\text{O}_4$, MICHAEL SCHMIDT, ZHE WANG, F. MAYR, Experimental Physics V, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, D-86135 Augsburg, Germany, S. TOTH, B. LAKE, A.T.M.N. ISLAM, Helmholtz-Zentrum Berlin fuer Materialien und Energie, D-14109 Berlin, Germany, V. TSURKAN, A. LOIDL, J. DEISENHOFER, Experimental Physics V, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, D-86135 Augsburg, Germany — We will compare and discuss our results obtained by optical spectroscopy on CuCrO_2 and $\alpha\text{-CaCr}_2\text{O}_4$. While CuCrO_2 is famous for its multiferroicity [1], in $\alpha\text{-CaCr}_2\text{O}_4$ a polarization can only be observed under the application of electric or magnetic field, despite having a closely related structure [2]. At near infrared and visible light frequencies we observe Cr^{3+} crystal field absorptions and below T_N excitons and exciton-magnon-transitions appear. The width of these exciton-magnon transitions is analyzed with respect to the existence of Z_2 vortices as proposed by Kojima et al. [3].

8:24AM A8.00003 Quantum Spin Fluctuations for an Incommensurate Spiral, RANDY FISHMAN, Oak Ridge National Laboratory, Oak Ridge, TN 37831 USA — Quantum spin fluctuations are investigated for the incommensurate spiral state of a geometrically-frustrated triangular-lattice antiferromagnet. With increasing anisotropy, the average spin amplitude becomes larger but the spiral becomes more distorted. Quantum fluctuations enhance both the wavevector of the distorted spiral and the critical anisotropy above which it undergoes a first-order transition into a collinear state. An experimental technique is proposed to isolate the effects of quantum fluctuations from the classical distortion of the spiral. Results of this work are used to estimate the change in spin amplitude and ellipticity in the multiferroic state of CuFeO_2 . Research sponsored by the Division of Materials Sciences and Engineering, U.S. Department of Energy under contract with UT-Battelle, LLC.

8:36AM A8.00004 Phase Diagram of the Spatially Anisotropic Heisenberg Model on a Triangular Lattice, SEDIGH GHAMARI, CATHERINE KALLIN, Dept. of Physics and Astronomy, McMaster University, SUNG-SIK LEE, Dept. of Physics and Astronomy, McMaster University and Perimeter Institute for Theoretical Physics, ERIK SORENSEN, Dept. of Physics and Astronomy, McMaster University — The spatially anisotropic spin-1/2 Heisenberg model on a triangular lattice is examined using a renormalization group (RG) analysis in the limit of weak interchain coupling ($J'/J \ll 1$ or large anisotropy). In agreement with a previous similar study, a collinear antiferromagnetic (CAF) state is found for large anisotropies. Retaining a marginal term that was not previously included, elucidates the strong competition between spiral and CAF order and suggests a direct transition at a fairly large anisotropy to incommensurate spiral order with a significantly renormalized wave vector that smoothly connects to the commensurate spiral state at the isotropic point. The significant renormalization of the ordering vector of this incommensurate spiral phase is argued to explain why many numerical studies found spin liquid behavior close to the isotropic point, (i.e. $J'/J \sim 0.85$). The agreement between the predictions of our RG analysis for the correlation function of the staggered magnetization on next-nearest-neighbor chains with DMRG results for small anisotropies further supports this picture. Finally, the effect on the phase diagram of Dzyaloshinskii-Moriya interactions, relevant to Cs_2CuCl_4 , will be discussed.

8:48AM A8.00005 Variational Monte Carlo study of quantum spin=1 liquid phases in the extended triangular-lattice Heisenberg model, SAMUEL BIERI, MAKSYM SERBYN, TODADRI SENTHIL, PATRICK LEE, Massachusetts Institute of Technology — Recent experiments in the compound $\text{Ba}_3\text{NiSb}_2\text{O}_9$ [PRL 107, 197204] indicated that quantum-spin liquid phases in a spin $S=1$ anti-ferromagnet may exist. Motivated by these experiments, we construct quantum spin=1 liquid states with three flavors of fermionic spinons. We use variational Monte Carlo calculations to investigate the phase diagram of a triangular-lattice quantum Heisenberg model with single-ion anisotropy, bi-quadratic, and ring-exchange terms. We compare the energies of the spin-liquid states with conventional magnetically ordered states. We find that in some parameter ranges, an exotic gapless $U(1)$ spin liquid is stabilized. In other parameter ranges, a BCS pairing instability with unconventional symmetry gaps out some of the spinons. We discuss our findings in relation with present and future experiments.

9:00AM A8.00006 Magnetic Structure and Spin Waves in $\text{Co}_2(\text{OD})_3\text{Cl}$, SACHITH DISSANAYAKE, S. JI, Department of Physics, University of Virginia, C. CHAN, T.K. NG, Department of Physics, Hong Kong University of Science and Technology, J. LEE, Department of Physics, University of Virginia, Y. QIU, NIST Center for Neutron Research, K.C. RULE, B. LAKE, Helmholtz Zentrum Berlin, M. GREEN, NIST Center for Neutron Research, X.G. ZHENG, Department of Physics, Saga University, S.-H. LEE, Department of Physics, University of Virginia — We have examined the magnetic structure of $\text{Co}_2(\text{OD})_3\text{Cl}$ with magnetic Co^{2+} ($3d^7$; $s=3/2$) ions using neutron powder diffraction data. Magnetic structure that yields the best refinement factor is an “umbrella”-type antiferromagnetic structure with ab-components of magnetic moments in the kagome plane forming a $q=0$ 120° structure and the moments are canted out of the plane by $\sim 40^\circ$. The magnetic moments in the triangular plane are aligned ferromagnetically along the c-axis. We have performed linear spin wave calculations considering the nearest neighbor interactions J within the kagome plane and J_F between the kagome and the triangular plane. The effects of J_F/J and the canting angle to the spin wave dispersion was studied thoroughly, to find out an effective spin hamiltonian that explains our inelastic neutron scattering data with two prominent excitation modes centered at 3 meV and 19 meV. Single ion-type anisotropy was also included in the spin hamiltonian to study its effect to the spin wave excitation.

9:12AM A8.00007 Partially disordered state and spin-lattice coupling in an $S=3/2$ triangular lattice antiferromagnet Ag_2CrO_2 , M. MATSUDA, Quantum Condensed Matter Division, Oak Ridge National Laboratory, H. YOSHIDA, M. ISOBE, National Institute for Materials Science (NIMS), Tsukuba, Japan, C. DE LA CRUZ, Quantum Condensed Matter Division, Oak Ridge National Laboratory, R.S. FISHMAN, Materials Science and Technology Division, Oak Ridge National Laboratory — Ag_2CrO_2 consists of triangular lattice planes of CrO_2 , which are well separated by the metallic Ag_2 layers. [1] This compound is an $S=3/2$ frustrated triangular lattice antiferromagnet without orbital degree of freedom. We performed neutron diffraction experiments on a powder sample of Ag_2CrO_2 on a neutron powder diffractometer HB-2A and a triple-axis neutron spectrometer HB-1, installed at HFIR in Oak Ridge National Laboratory. With decreasing temperature, a short-range 4-sublattice spin state develops. However, a long-range partially disordered state with 5 sublattices abruptly appears at $T_N=24$ K, accompanied by a structural distortion, and persists at least down to 2 K. The spin-lattice coupling stabilizes the anomalous state, which is expected to appear only in limited ranges of further-neighbor interactions and temperature. It was found that the spin-lattice coupling is a common feature in triangular lattice antiferromagnets with multiple-sublattice spin states, since the triangular lattice is elastic.

9:24AM A8.00008 Quantum Critical Magnetization Behaviors of the Kagome- and Triangular-Lattice Antiferromagnets, TORU SAKAI, JAEA, Spring-8, HIROKI NAKANO, University of Hyogo — Magnetization process of the $S=1/2$ isotropic Heisenberg antiferromagnets on the kagome and triangular lattices are studied. Data from numerical-diagonalization method up to 39-spin systems, are reexamined from the viewpoint of the derivative of the magnetization with respect to the magnetic field. We find that the behavior of the derivative around the $1/3$ height of the magnetization saturation is quite different from the cases of typical magnetization plateaus for the kagome-lattice antiferromagnet. This new phenomenon is called the “magnetization ramp” [1]. We also compare it with the $1/3$ magnetization plateau of the triangular antiferromagnet. The critical exponent analysis indicates a clear difference between the magnetization plateau and ramp [2]. In addition using the numerical diagonalization up to 42-spin systems we suggest that the kagome-lattice antiferromagnet has a gapless singlet-triplet excitation in the thermodynamic limit [3].

9:36AM A8.00009 Phase Diagram of Spin-1/2 Triangular Antiferromagnet in a Magnetic Field, RU CHEN, HYEJIN JU, Department of Physics, University of California, Santa Barbara, CA-93106-9530, HONGCHEN JIANG, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, CA-93106-9530, OLEG STARYKH, Department of Physics, University of Utah, Salt Lake City, Utah 84112, LEON BALENTS, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, CA-93106-9530 — We investigate the spin-1/2 quantum Heisenberg antiferromagnet on both two-dimensional triangular lattice and N-leg triangular ladder. The model describes isotropic Heisenberg chains (exchange constant J) coupled antiferromagnetically through interchain diagonal bonds (exchange constant J'). We study different regions using various controlled theoretical methods. Primarily we focus on the region slightly below saturation field. We show that the cone-coplanar state transition is absent, while commensurate-incommensurate transition emerges right below the saturation field for two-dimensional triangular lattice. We also determine the ground states in the limit $J' \ll J$, using one-dimensional bosonization, renormalization group methods and current algebra. Finally, we compare our theoretical result with DMRG result for N-leg ladder.

9:48AM A8.00010 Spin Correlations and Excitations in the Quasi-2D Triangular Bilayer Spin Glass LuCoGaO_4 , K. FRITSCH, McMaster University, Hamilton, G.E. GRANROTH, A.T. SAVICI, Neutron Scattering Sciences Division, ORNL, Oak Ridge, H.M.L. NOAD, McMaster University, Hamilton, H.A. DABKOWSKA, B.D. GAULIN, Brookhouse Institute for Materials Research, Hamilton — LuCoGaO_4 is a layered magnetic-bilayer material wherein Co^{2+} magnetic moments and nonmagnetic Ga^{3+} ions are randomly distributed on planar triangular bilayers. This makes it an ideal case to study the interplay between geometric frustration, site disorder and low dimensionality and its influence on the magnetic ground of the system. This novel material has been grown for the first time in single crystal form at McMaster University. We have performed magnetization measurements, revealing a previously identified spin glass transition near $T_f \sim 19$ K, and a Curie Weiss temperature of $T_{cw} \sim 96$ K, consistent with antiferromagnetic interactions[1]. We discuss time-of-flight neutron scattering measurements using SEQUOIA at SNS which elucidate the evolution of the static and dynamic spin correlations in LuCoGaO_4 over a range of temperatures from $T \ll T_f$ to $T > T_{cw}$. We observe quasielastic scattering at $(1/3, 1/3, L)$ positions in reciprocal space and rods of scattering along the c^* -direction, consistent with short range antiferromagnetic correlations within decoupled bilayers, and which confirm the 2-dimensional character of this system. Inelastic scattering measurements show a gapped ~ 12 meV spin excitation which softens and broadens in energy, filling in the gap on a temperature scale of $\sim T_{cw}/2$. [1] Cava et al., J. Solid State Chem. 140, 337 (1998).

10:00AM A8.00011 Emergence and lifting of frustration for dipolar molecules, SEBASTIAN HUBER, EHUD ALTMAN, The Weizmann Institute of Science, EUGENE DEMLER, Harvard University — Ising spins on a triangular lattice are like a “harmonic oscillator” of geometric frustration. We address the general question of how this frustration is lifted in a system of dipolar molecules confined to $2+\epsilon$ dimensions. When the confinement to two dimensions is strong, the dipoles arrange in a triangular lattice. Upon reduction of the confinement, the dipoles undergo a transition out of the two dimensional plane, leading to an Ising degree of freedom. Spin-lattice coupling gives rise to an effective model in terms of quantum dimers. We discuss the resulting phases and the implications to current experiments with hetero-nuclear molecules.

10:12AM A8.00012 Spin dynamics in Kagomé-staircase multiferroic $\text{Ni}_3\text{V}_2\text{O}_8$, ANDREY PODLESNYAK, G. EHLERS, M. FRONTZEK, Quantum Condensed Matter Division, NScD, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, R.S. FISHMAN, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, O. ZAHARKO, Laboratory for Neutron Scattering, Paul Scherrer Institut, CH-5232 Villigen PSI, Switzerland, M. KENZELMANN, Laboratory for Developments and Methods, Paul Scherrer Institut, CH-5232 Villigen PSI, Switzerland, S. BARILO, Institute of Solid State and Semiconductor Physics, Minsk 220072, Belarus — The coupling of magnetic and ferroelectric order has recently been drawing a lot of interest in condensed matter science given the fundamental interest and potential applications. $\text{Ni}_3\text{V}_2\text{O}_8$ (NVO) is a $S = 1$ magnet with Ni^{2+} ions arranged in a weakly coupled buckled Kagomé-staircase planes. Its complex magnetic phase diagram exhibits four different zero field incommensurate and commensurate magnetic phases below 10 K, with only one developing ferroelectric order. We present here a detailed study of low temperature magnetic dynamics in this geometrically frustrated spin system. Using single crystal inelastic neutron scattering technique we map the magnetic excitation spectra across all the magnetic phase transitions. We found that the spin-waves, well formed in the base temperature nonferroelectric phase at $T < 3$ K, are considerably damped when the system enters the low-temperature incommensurate phase with ferroelectric order ($3.9 < T < 6.3$ K). Finally, we discuss models that describe the coupling between magnetic and ferroelectric properties in the incommensurate magnets.

10:24AM A8.00013 Temperature-dependent Raman studies of the magnetodielectric vanadates: $\text{Ni}_3\text{V}_2\text{O}_8$, $\text{Co}_3\text{V}_2\text{O}_8$, and $\text{K}_2\text{V}_3\text{O}_8$ ¹, M. KIM, Y. GIM, S.L. COOPER, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois, Urbana, Illinois, 61801, USA, R.J. CAVA, Department of Chemistry, Princeton University, Princeton, New Jersey 08544 — The kagome staircase compounds, $\text{Ni}_3\text{V}_2\text{O}_8$ and $\text{Co}_3\text{V}_2\text{O}_8$, are known to exhibit dielectric anomalies at the magnetic transitions; and inhomogeneously mixed-valent $\text{K}_2\text{V}_3\text{O}_8$ has been shown to have a strong dependence of the dielectric constant on applied magnetic field. However, while strong spin-lattice coupling is generally associated with the complex phases and phenomena in these materials, there has been little microscopic information about this coupling. In this talk, we present temperature-dependent Raman scattering studies of $\text{Ni}_3\text{V}_2\text{O}_8$, $\text{Co}_3\text{V}_2\text{O}_8$, and $\text{K}_2\text{V}_3\text{O}_8$ that allow us to investigate the microscopic connection between the strong spin-lattice coupling and the magnetodielectric effects in these materials.

10:36AM A8.00014 Competing Interactions in the $S=3/2$ Kagome Staircase $\text{Co}_3\text{V}_2\text{O}_8$: Evolution of the Commensurate and Incommensurate Phases in a Magnetic Field, JOEL HELTON, YING CHEN, JEFFREY LYNN, National Institute of Standards and Technology, GEORGII BYCHKOV, SERGEI BARILO, Belarus Academy of Sciences, NYRISSA ROGADO, ROBERT CAVA, Princeton University — Single crystal neutron diffraction studies have been performed on the $S = 3/2$ kagome staircase compound $\text{Co}_3\text{V}_2\text{O}_8$ with a magnetic field applied along the magnetization easy-axis ($\vec{H} \parallel \vec{a}$). Previous zero-field measurements reported incommensurate, transversely polarized spin density wave (SDW) phases [with a temperature dependent propagation vector of $\vec{k} = (0 \delta 0)$] interspersed with multiple commensurate lock-in transitions at temperatures above the ferromagnetic ground state. For small applied fields along $\vec{a}$, $\mu_0 H \approx 0.05$ T, the commensurate lock-in phases are destabilized in favor of the incommensurate SDW, while slightly larger applied fields restore the commensurate lock-in phase with $\delta = 1/2$ and yield a new commensurate phase with $\delta = 2/5$. For measurements in an applied field, higher-order scattering is observed that corresponds to the second-harmonic.

Monday, February 27, 2012 8:00AM - 11:00AM –

Session A9 GMAG DMP: Focus Session: Magnetic Oxide Thin Films And Heterostructures - Cobaltite And Ferrite Thin Films 209

8:00AM A9.00001 Ferromagnetic insulating state in tensile-strained LaCoO_3 thin films¹, HAN HSU, University of Minnesota, PETER BLAHA, TU Vienna, RENATA WENTZCOVITCH, University of Minnesota — With local density approximation + Hubbard U (LDA+ U) calculations, we show that the ferromagnetic (FM) insulating state observed in tensile-strained LaCoO_3 epitaxial thin films is most likely a mixture of low-spin (LS) and high-spin (HS) Co, namely, a HS/LS mixture state. Compared with other FM states, including the intermediate-spin (IS) state (*metallic* within LDA+ U), which consists of IS Co only, and the insulating IS/LS mixture state, the HS/LS state is the most favorable one. The FM order in HS/LS state is stabilized via the superexchange interactions between adjacent LS and HS Co. We also show that Co spin state can be identified by measuring the electric field gradient (EFG) at Co nucleus via nuclear magnetic resonance (NMR) spectroscopy.

¹This work was primarily supported by the MRSEC Program of NSF grants DMR-0212302 and DMR-0819885, and partially by EAR-081272 and EAR-1047629. P.B. was supported by the Austrian Science Fund (SFB F41, “ViCoM”). Calculations were performed at the MSI.

8:12AM A9.00002 Aberration-corrected STEM-EELS studies of epitaxial $\text{La}_{0.5}\text{Sr}_{0.5}\text{CoO}_3$ thin films, MARIA VARELA, Oak Ridge National Laboratory, JAUME GAZQUEZ, NEVEN BISKUP, Universidad Complutense, Spain, STEPHEN PENNYCOOK, Oak Ridge National Laboratory, MARIA TORIJA, MANISH SHARMA, SHAMEEK BOSE, CHRIS LEIGHTON, University of Minnesota — Cobaltite thin films provide a unique opportunity to study magneto-electronic phase separation, which can be strong in this reduced dimensionality environment. Here we present an investigation of epitaxial $\text{La}_{0.5}\text{Sr}_{0.5}\text{CoO}_3$ thin films on SrTiO_3 and LaAlO_3 substrates by scanning transmission electron microscopy and electron energy loss spectroscopy. The different degrees of strain and also different orientations of the substrates (such as (001) vs. (110)) induce major changes of the crystal structure and the depth profile of the chemical composition, observed both in the La/Sr and O sub-lattices. These effects can lead to lower effective doping level at the interface, favoring interfacial magneto-electronic phase separation. Research Council Starting Investigator Award (JS, NB) and the U.S. Dept. of Energy, Office of Basic Energy Sciences, Materials Sciences and Engineering Div. (MV, SJP). Work at UMN supported by NSF and DOE (scattering).

8:24AM A9.00003 Atomic-Scale Imaging and Control of Interface Magnetic States in Vacancy Ordered Cobaltite Thin Films¹, ALBINA BORISEVICH, YOUNG-MIN KIM, MICHAEL BIEGALSKI, Oak Ridge National Laboratory, JUN HE, Vanderbilt University, HANS CHRISTEN, Oak Ridge National Laboratory, SOKRATES PANTELIDES, Vanderbilt University, STEPHEN PENNYCOOK, Oak Ridge National Laboratory — Magnetic properties of complex oxide thin films are strongly affected by strain, chemical composition, and octahedral tilt of the substrate. Here, we study lanthanum/strontium cobaltite ($\text{La}_{0.5}\text{Sr}_{0.5}\text{CoO}_{3-x}$, LSCO) thin films via quantitative aberration-corrected scanning transmission electron microscopy and Electron Energy Loss Spectroscopy (EELS) to explore the coupling between magnetic properties, ionic behavior, and oxygen octahedral tilts. LSCO films were grown by PLD in identical conditions on two different substrates, LSAT (cubic) and NGO (orthorhombic). These substrates have nearly identical lattice parameters, but different octahedral tilts. The film on NGO appears to be $\text{La}_{0.5}\text{Sr}_{0.5}\text{CoO}_{2.5}$, while the film on LSAT is less oxygen deficient. Comparison of measured lattice parameters with the first-principles calculations allows us to determine oxygen content in the film. In $\text{La}_{0.5}\text{Sr}_{0.5}\text{CoO}_{2.5}$ /NGO films, EELS reveals different valence states of Co at the interface depending on termination, resulting in different magnetic states. Therefore changes in octahedral tilts can induce changes in oxygen stoichiometry and interface magnetic states of the vacancy ordered structures.

¹This research is sponsored by the MSE Division (YMK, JH, SJP, AYB) and SUF Division (MDB, HMC), Office of BES of the U.S. DOE.

8:36AM A9.00004 Stress and magnetism in LaCoO₃ films¹, ALEX DEMKOV, The University of Texas at Austin — Cobaltates exhibit a wide variety of exciting electronic properties resulting from strong electron correlations; these include superconductivity, giant magnetoresistance, metal-insulator transition, and strong thermoelectric effects. This makes them an excellent platform to study correlated electron physics, as well as being useful for various applications in electronics and sensors. In the ground state in the bulk, the prototypical complex cobalt oxide LaCoO₃ is in a spin-compensated low-spin state (t_{2g}^6), which results in the ground state being nonmagnetic. In a recent experiment, Fuchs *et al.* (*Phys. Rev. B* **75**, 144402 (2007)) have demonstrated that a ferromagnetic ground state could be stabilized by epitaxial tensile strain resulting in a Curie temperature (T_C) of ~ 90 K when LaCoO₃ (LCO) is grown on SrTiO₃ (STO) using pulsed laser deposition. In this talk I will discuss our recent successful attempt to integrate a LCO/STO heterostructure with Si (001) using molecular beam epitaxy. We have grown strained, epitaxial LaCoO₃ on (100)-oriented silicon using a single crystal STO buffer (Appl. Phys. Lett. **98**, 053104 (2011)). SQUID magnetization measurements confirm that the ground state of the strained LaCoO₃ is ferromagnetic with a T_C of 85 K. Our first-principles calculations of strained LaCoO₃ using the LSDA+ U method show that beyond biaxial tensile strain of 2.5% local magnetic moments, originating from the high spin state of Co³⁺, emerge in a low spin Co³⁺ matrix. Ferromagnetism found in tensile-strained LaCoO₃ is tightly coupled to the material's orbital and structural response to applied strain. Theoretical calculations show how LaCoO₃ accommodates tensile strain *via* spin state disproportionation, resulting in an unusual sublattice structure.

¹This work is supported by the National Science Foundation under grant DMR-0548182

9:12AM A9.00005 Ordering of defects induced by epitaxy in LaCoO₃ films¹, VIRAT MEHTA, University of California-Berkeley, NEVEN BISKUP, Universidad Complutense, Madrid 2840, Spain, FRANKLIN WONG, University of California-Berkeley, ELKE ARENHOLZ, Lawrence Berkeley National Laboratory-Advanced Light Source Division, MARIA VARELA, Oak Ridge National Laboratory, YURI SUZUKI, University of California-Berkeley — In the bulk, LaCoO₃ (LCO) undergoes a spin state transition from a diamagnet to a paramagnet with increasing temperature. Recent studies of epitaxial LCO thin films have resulted in the stabilization of a higher spin state and ferromagnetic ordering at low temperatures. Here, we explore the effects of epitaxy on the electronic structure of LCO films with X-ray absorption spectroscopy (XAS) and scanning transmission electron microscopy (STEM). We find differences in XAS spectra in coherently strained thinner films compared to the thicker partially relaxed films which may be due to differences in Co valence and bonding. STEM and electron energy loss spectroscopy of thinner LCO films reveal ordered defect planes that appear to be associated with a change in the O and Co bonding environments. In films on LaAlO₃ strained in compression periodic planes occur parallel to the substrate-film interface, while films on SrTiO₃ strained in tension have perpendicular defect planes. Correlation with magnetic data suggests that defect rich regions may exhibit greater ferromagnetism.

9:24AM A9.00006 Spin state disproportionation and ferromagnetism in strained LaCoO₃: Ab-initio study, SEO HOSUNG, ALEXANDER DEMKOV, Department of Physics, The University of Texas at Austin — Strain engineering of artificial oxide heterostructures opens up routes for the creation of novel electronic phases that do not exist in the bulk. To fully exploit the functionalities of the oxide, understanding its electronic and structural response to epitaxial strain is crucial. One example is the recent demonstration of biaxial tensile strain stabilizing an insulating ferromagnetic ground state in normally non-magnetic LaCoO₃. However, theoretical understanding is incomplete. In this talk, using the LSDA+ U method we discuss the origin of strain induced transition to insulating ferromagnetic ground state in LaCoO₃. We show that beyond biaxial tensile strain of 2.5% local magnetic moments, originating from high spin state of Co³⁺, emerge in low spin Co³⁺ matrix. We further show that these local moments are ferromagnetically coupled via superexchange interaction. In contrast, we find that compressive strain by itself is not able to stabilize a magnetic state, that agrees with recent experiment. Ferromagnetism found in tensile-strained LaCoO₃ is tightly coupled to the material's orbital and structural response to applied strain. We discuss how LaCoO₃ accommodates tensile strain *via* spin state disproportionation, resulting in an unusual sublattice structure.

9:36AM A9.00007 Percolation-Type Ferromagnetic Order in Epitaxial Strained LaCoO₃ Thin Films, GEORGE STERBINSKY, National Institute of Standards and Technology, PHILIP RYAN, JONG-WOO KIM, EVGUENIA KARAPETROVA, Advanced Photon Source, Argonne National Laboratory, J. MA, JING SHI, Department of Physics, University of California, Riverside, JOSEPH WOICK, National Institute of Standards and Technology — Support for percolation-type ferromagnetic order in LaCoO₃ thin films is provided by x-ray diffraction and Co K -edge x-ray absorption fine structure (XAFS) spectroscopy. X-ray diffraction shows considerable changes in structure with respect to bulk LaCoO₃, and extended XAFS (EXAFS) demonstrates a large Jahn-Teller like distortion of the oxygen octahedra in highly strained films. Structural distortions of the oxygen octahedra are strongly coupled to the hybridization between orbitals of Co and O atoms, as shown by x-ray absorption near edge spectroscopy (XANES). Our results indicate that increased Co-O hybridization, and therefore increased magnetic exchange energy, does not cause ferromagnetism to occur in LaCoO₃ thin films. Instead, we suggest that the strain-induced distortions of the oxygen octahedra increase the population of e_g electrons and concurrently depopulate t_{2g} electrons beyond a stabilization threshold for ferromagnetic order.

9:48AM A9.00008 Imaging Local Magnetic Domain Rearrangement in Strained LaCoO₃ Thin Films Using Magnetic Force Microscopy¹, MORGANN BERG, NELIZA LEON, AGHAM POSADAS, ALFRED LEE, University of Texas at Austin, JEEHOON KIM, Los Alamos National Laboratory, ALEX DE LOZANNE, ALEX DEMKOV, University of Texas at Austin — Previous studies we have conducted on thin films of lanthanum cobaltate (LCO) under tensile strain have revealed a tendency toward local magnetic domain rearrangement into streak-like configurations near the ferromagnetic to paramagnetic phase transition. Moreover, the persistence of these streak-like characteristics to lower temperatures after field-cooling appears to be linked to the strength of the applied magnetic field in which these films are field-cooled. This tendency has not yet been verified for thin films of LCO under compressive strain which could indicate whether this magnetic domain rearrangement is intrinsic to thin film samples of LCO or is merely an effect of tensile strain. Using magnetic force microscopy, we investigate the microscale magnetic properties of a thin film of LCO under compressive strain, prepared by molecular beam epitaxy and deposited on a lanthanum aluminate substrate. We observe these properties across a wide temperature range and compare our results to global magnetic characteristics of this film as measured by a SQUID magnetometer.

¹I'd like to acknowledge the IGERT (DGE-0549417) and NSF (DMR-0923231) grants which supported this work and contributions from collaborators which made this research possible.

10:00AM A9.00009 Origin of ferromagnetic ordering in LaCoO₃ epitaxial thin films¹, WOO SEOK CHOI, Oak Ridge National Laboratory, J.-H. KWON, Seoul National University, HYUNGJEEN JEEN, Oak Ridge National Laboratory, VLADIMIR HINKOV, University of British Columbia, M. KIM, Seoul National University, HO NYUNG LEE, Oak Ridge National Laboratory — LaCoO₃ (LCO) film has received attention due to its unexpected ferromagnetic (FM) ordering, which is distinctly different from the bulk counterpart. Although the exact origin has not been understood, previous studies have suggested that the epitaxial strain should play an important role. In this work, we show that the FM ordering could be related to a locally-ordered microstructure. We used PLD to deposit epitaxial LCO thin films on various substrates in order to impose different degree of strain. XRD and XAS studies showed that the films are of high quality, without any secondary phases or changes in the Co valence. In addition, all the films were coherently-strained. From the STEM investigation, however, we noticed that some of the films had an unexpected stripe-like superstructure along the <100> direction. While the microstructure resembles that of oxygen-vacancy or charge ordering, typically found in doped transition metal oxides, we could rule out such possibilities and interpret it as a nanoscale twin boundary. The strain induced structural change seems to originate the FM ordering.

¹The work was supported by the U.S. Department of Energy, Basic Energy Sciences, Materials Sciences and Engineering Division.

10:12AM A9.00010 Magnetic properties of LuFeO₃ thin films¹, XIAOSHAN XU², Oak Ridge National Lab, WENBIN WANG, University of Tennessee, ZHENG GAI, Oak Ridge National Lab, XUEMEI CHENG, Bryn Mawr College, LEYI ZHU, DAVID KEAVNEY, Argonne National Laboratory, PAUL SNIJDER, THOMAS WARD, Oak Ridge National Lab, JIAN SHEN, University of Tennessee — In order to extract their intrinsic magnetic properties, we have grown LuFeO₃ thin films epitaxially on Al₂O₃ (0001), a substrate with minimum magnetic impurities, using pulsed laser deposition. The magnetization measurements reveal strong anisotropy between in-plane and out-of-plane, not only in terms of coercivity and remanence, but also obvious in the zero field cool and field cool splitting. Further experiment using X-ray magnetic linear dichroism suggest magnetic ordering higher than 290 K and a spin reorientation at lower temperature. Over all, the films appear weak-ferromagnetic.

¹Research supported by US DOE, Office of Basic Energy Science, Materials Science and Engineering Division.

²Research performed as a Eugene P. Wigner Fellow and staff member at the Oak Ridge National Laboratory, managed by UT-Battelle, LLC, for the U.S. Department of Energy under Contract DE-AC05-00OR22725.

10:24AM A9.00011 Fabrication and properties of LuFeO₃ thin film¹, WENBIN WANG, University of Tennessee & Oak Ridge National Lab, XIAOSHAN XU, ZHENG GAI, NINA BALKE, MIAOFANG CHI, THOMAS Z. WARD, PAUL C. SNIJDER, Oak Ridge National Lab, JIAN SHEN, University of Tennessee & Fudan University, UNIVERSITY OF TENNESSEE TEAM, OAK RIDGE NATIONAL LAB TEAM, FUDAN UNIVERSITY COLLABORATION — We have succeeded in growing the hexagonal LuFeO₃ single crystalline thin films on Al₂O₃(0001) substrates using Pulsed Laser Deposition (PLD). The structures, epitaxial relation between film and substrate, ferroelectric and magnetic properties of the samples were characterized by RHEED, LEED, XRD, AFM, TEM, PFM and SQUID magnetometry. The structure of our hexagonal LuFeO₃ films is consistent with that of YMnO₃, and the samples exhibit a piezoelectric effect at room temperature. RHEED data are consistent with a structural change from a polar P6₃cm (185) to non-polar P6₃/mmc (194) at 1050 K. SQUID measurements reveal strong magnetic order in the thin film. All the data suggests a coexistence of ferroelectricity and magnetic order in hexagonal LuFeO₃ films.

10:36AM A9.00012 Enhancement of the Magnetic Moment in Ultrathin Fe-doped CoFe₂O₄¹, JARRETT MOYER, CARLOS VAZ, DIVINE KUMAR, Department of Applied Physics and CRISP, Yale University, DARIO ARENA, National Synchrotron Light Source, Brookhaven National Laboratory, VICTOR HENRICH, Department of Applied Physics and CRISP, Yale University — The magnetic properties of magnetic oxides can be drastically altered through a reduction in film thickness. It has previously been demonstrated that the magnetic moments of CoFe₂O₄ and NiFe₂O₄ are enhanced for ultrathin films; however, the physical mechanisms for this enhancement are still unknown. To determine the physical cause of this increased magnetic moment and to examine the effect of Fe doping, thin films of Co_{1-x}Fe_{2+x}O₄ (0 ≤ x ≤ 0.8) are grown epitaxially on MgO (001) substrates by MBE at thicknesses ranging from 3 – 20 nm. SQUID magnetometry measures the bulk magnetic properties of the samples and confirms that there is an increase in the magnetic moment for all stoichiometries as the film thickness is reduced. XAS, XMLD and XMCD measurements examine the cation-specific magnetic moments and spin directions to explain the physical mechanisms that lead to an enhanced magnetic moment in ultrathin Fe-doped CoFe₂O₄ films.

10:48AM A9.00013 Electronic states and magnetic structure at the Co₃O₄ (110) surface: a first principles study, JIA CHEN, ANNABELLA SELLONI, Princeton University — Tricobalt tetraoxide (Co₃O₄) is an important catalyst and Co₃O₄(110) is a frequently exposed surface in Co₃O₄ nanomaterials. We employed Density-functional theory with on-site Coulomb repulsion U term to study the atomic structures, energetics, magnetic and electronic properties of the two possible terminations, A and B, of this surface. These calculations predict A as the stable termination in a wide range of oxygen chemical potentials, consistent with recent experimental observations. The Co³⁺ ions do not have a magnetic moment in the bulk, but become magnetic at the surface, which leads to surface magnetic orderings different from the one in the bulk. Surface electronic states are present in the lower half of the bulk band gap and cause partial metallization of both surface terminations. These states are responsible for the charge compensation mechanism stabilizing both polar terminations. Furthermore, our calculations predict that the critical thickness for polarity compensation is 4 layers.

Monday, February 27, 2012 8:00AM - 11:00AM –
Session A10 DCOMP: Invited Session: Computational Assessment of a Sustainable Energy Future: The Earth-abundant Materials Approach 210A

8:00AM A10.00001 Computational Design of Solar Energy Harvesting Materials Made of Earth-Abundant Elements¹, YIYANG SUN, Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute — Very large-scale deployment of photovoltaic (PV) technology based on both the first and second generation solar cells poses serious questions on the materials supply as they rely on either high-purity and high-quality silicon crystals or rare elements such as indium and tellurium. “Ancient” PV materials made of earth-abundant elements, such as oxides and sulfides of copper and iron, have attracted resurgent interests. There is also intensive research devoted to the search for “modern” earth-abundant PV materials, with a recent promising example being $\text{Cu}_2\text{ZnSnSe}_4$. Computational approaches play a key role in this endeavor by guiding the screening and optimization of the materials toward high device performance. In this paper, I will focus on two aspects of computational design of earth-abundant PV materials. First, I will discuss the methods for accurately predicting band gaps of semiconductor materials. The emphasis will be on the performance of hybrid functional method on different classes of materials. Based on these understandings, I will discuss how to tune the band gap of a material to match the solar spectrum. For example, one could reduce the band gap of anatase to 1.5 eV by the chemical codoping approach. Second, I will discuss the methods for accurate computation of defect properties, which is important as the defectiveness is intrinsic to the low-cost synthesized materials. I will introduce a method for calculation of defect formation energies by minimizing the error due to the “band-gap problem” of the density functional theory. I will also discuss approaches to mitigating the effects of defects, e.g., by passivation.

¹The author acknowledges the support by NSF under Award No. DMR-1104994 and DOE under Award No. DE-SC0002623.

8:36AM A10.00002 Computational approaches to finding earth-abundant thermoelectric materials¹, VIDVUDS OZOLINS², Dept of Materials Science and Engineering, University of California, Los Angeles — Good thermoelectric materials should possess a combination of seemingly incompatible properties, such as high electronic mobility and low lattice thermal conductivity. Therefore, search for crystalline materials with glass-like thermal conductivity has been an active field of research. Several cubic I-V-VI₂ semiconductors, the paradigm for which is AgSbTe_2 , have been shown to exhibit minimal values of lattice thermal conductivity at ambient temperatures when the phonon mean free path equals the interatomic distance. These modes are due to the existence of highly polarizable lone s^2 electron pairs on the group V cations. Electrostatic repulsion between the lone s^2 pairs and the valence charge on group VI anions tends to favor locally distorted bonding configurations and may lead to unstable phonons. We present the results of first-principles density functional theory (DFT) calculations of phonon dispersion and electron-phonon interactions in cubic I-V-VI₂ semiconductors, where the group I elements are Cu, Ag, Au or alkali metals, the group V elements are P, As, or Bi, and the group VI elements are S, Se, or Te. Compounds that have only marginally stable phonons have extremely large Grüneisen parameters that result in a thermal conductivity limited by Umklapp processes to values at the amorphous limit above 200 K. Following the *ab initio* calculation, we synthesized AgSbTe_2 , AgSbSe_2 , AgBiTe_2 , NaSbTe_2 , NaSbSe_2 , and NaBiTe_2 and report their thermal conductivity and specific heat: in all cases, the experiments confirm the theory.

9:12AM A10.00003 Solar energy into fuels - the importance of interface catalysis¹, FRANK ABILD-PEDERSEN, SUNCAT Center for Interface Science and Catalysis Photon Science, SLAC National Accelerator Laboratory — Finding sustainable energy solutions for the future will rely heavily on the energy influx from the sun. One convenient way of storing solar energy is by transforming that energy into a chemical form - like a fuel. The efficiency of such a transformation will require catalysts that are optimized for specific reactions, and we will need to find new catalysts for a number of processes, if we are to successfully synthesize fuels from sunlight. A fundamental insight into the way the catalysts work at the molecular level is an essential ingredient if one wants to speed up the discovery process. In this presentation I will discuss some of the challenges in catalyst discovery. In particular, I will focus on the conversion of syngas to methanol, an important sub-reaction in the biomass to fuels process.

¹U.S. Dept. of Energy, Office of Basic Energy Sciences

9:48AM A10.00004 Key electronic processes in organic solar cells: a theoretical perspective, VEACESLAV COROPCEANU, Center for Organic Photonics and Electronics and School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA 30332-0400, USA — In this contribution, we discuss state-of-the-art quantum-chemical approaches used to derive the microscopic parameters and model the key electronic processes in organic solar cells. We illustrate the application of recently developed computational methods by computing the electronic couplings and the rates of exciton dissociation and charge recombination in several model donor-acceptor complexes. The contributions of both intra-molecular and inter-molecular vibrations to the electron-vibrational interaction will be discussed in detail. The impact on the charge-transport characteristics of the interplay between electron-vibration coupling and electronic coupling is investigated in the framework of band, disorder, and semi-classical models.

10:24AM A10.00005 Harvesting the energy from the sun: insights from ab initio materials modeling, GIULIA GALLI, University of California, Davis — Can quantum and atomistic simulations make valuable contributions to the search of materials for sustainable energy sources? We will address this question by discussing some specific examples where quantum simulations have been used to predict optical properties of nanostructured semiconductors and of complex oxides in contact with water. We will also discuss issues related to the comparisons with increasingly complex experiment.

Monday, February 27, 2012 8:00AM - 11:00AM — Session A11 DCMP: Graphene: Transport in Devices and Structures 210B

8:00AM A11.00001 Transport in Graphene: Ballistic, Anomalous, or Diffusive?, MARIO BORUNDA, HOLGER HENNIG, ERIC HELLER, Harvard University — The discovery of graphene, consisting of a layer of carbon atoms arranged in a honeycomb lattice, represents a conceptually new class of materials that are only one atom layer thick. Recent experiments achieved extremely high mobilities in suspended graphene leading to ballistic transport. In this talk, we study implications of diffusive and ballistic transport in graphene devices and ask what could be possible signatures of “anomalous” (or superdiffusive) transport. Experimental setups to differentiate between these stochastic processes are discussed.

8:12AM A11.00002 Transport in high-mobility mesoscale graphitic devices¹, ANDREI GARCIA, FRANCOIS AMET, Applied Physics Department, Stanford University, JAMES WILLIAMS, DAVID GOLDBABER-GORDON, Physics Department, Stanford University — Recent advances in graphene fabrication have allowed for high-mobility structures to be created. We report on the fabrication and measurement of mesoscale devices of graphene on boron-nitride. We present the details by which graphene is transferred on to boron-nitride substrates, where we observed enhanced mobility over similar devices fabricated on silicon dioxide substrates. Transport measurements at low temperature are described with focus given to reconfigurable, mesoscale devices in graphene.

¹This work is supported by FENA, an FCRP center based at UCLA, and the Center for Probing the Nanoscale at Stanford University, an NSF NSEC.

8:24AM A11.00003 Gate defined quantum confinement in suspended bilayer graphene, MONICA ALLEN, Harvard University, JENS MARTIN, University of Exeter, AMIR YACOBY, Harvard University — Devices that confine electrons in graphene have sparked substantial interest due to applications ranging from spin-based quantum computation to valley filters. However, the absence of an intrinsic bandgap in graphene has limited such devices to on-chip nanopatterned structures to date. Here we present high quality quantum dots in suspended bilayer graphene with tunnel barriers defined by external electric fields that break layer inversion symmetry, thereby eliminating both edge and substrate disorder. We demonstrate clean electron confinement in two regimes: at zero magnetic field B using the single particle energy gap induced by a perpendicular electric field and at $B > 0$ using the quantum Hall ferromagnet $\nu=0$ gap. Our devices exhibit clean quantum transport behavior at magnetic fields ranging from zero to seven Tesla, including a highly resistive $\nu=0$ quantum Hall state and over forty consecutive Coulomb blockade oscillations with symmetric source-drain coupling. The data indicate that the dots are defined by local top gating and are not disorder formed. Geometric control over oscillation periodicity is confirmed by electrostatic simulations based on lithographic gate geometry.

8:36AM A11.00004 Quantum Transport in Double-gated Trilayer Graphene *pnp* Junctions, YONGJIN LEE, JAIRO VELASCO JR., LEI JING, WENZHONG BAO, DAVID TRAN, MARC BOCKRATH, CHUN NING (JEANIE) LAU, Department of Physics and Astronomy, University of California, Riverside — Using trilayer graphene *pnp* junctions with suspended top gates, we perform transport measurements. At a magnetic field $B=0$, by an applied perpendicular electric field, the conductance is increased that it is suggestive of a semi-metallic band overlap. At $B=8T$ we observe quantum Hall conductance with fractional values, which can be explained equilibration of edge state between differentially-doped regions, and the presence of an insulating state at filling factor $\nu=0$.

8:48AM A11.00005 Superconducting proximity effect in graphene: Injecting Cooper pairs in quantum Hall edge states, KATSUYOSHI KOMATSU, CHUAN LI, SANDRINE AUTIER-LAURENT, ALIK KASUMOV, HELENE BOUCHIAT, SOPHIE GUERON, Laboratoire de Physique des Solides, Université Paris Sud, 91405 Orsay, France — A superconductor-graphene(SG) hybrid system, such as an SGS junction or an SG interface, provides an ideal platform to investigate the relativistic nature of Dirac fermions combined with superconductivity. Instead of the retro-reflection of carriers in an ordinary superconductor-normal metal interface, an SG interface is theoretically predicted to show the specular reflection of quasiparticle carriers. We show that a supercurrent flows through a SGS junction with Nb electrodes even through a very long graphene distance of $1.2\mu m$, more than 3 times the length previously reported. This supercurrent disappears in the vicinity of the Dirac point, indicating a strong sensitivity of the transmission of Andreev pairs to the formation of charge puddles with size greater than the superconducting coherence length. We also present data on similar size graphene samples with superconducting electrodes with a high critical field (more than 7 Tesla) for which the properties of the normal state are dominated by quantum Hall physics. Whereas the behavior of the supercurrent is similar to the Nb/Graphene/Nb system in zero field, new features are observed in the high field quantum Hall regime.

9:00AM A11.00006 Gate-Tunable Superconducting-Insulating Transition in Tin-Decorated Graphene, VINCENT BOUCHIAT, ZHENG HAN, ADRIEN ALLAIN, Neel Institute, CNRS-Grenoble — We report the measurement of electrostatically tuned superconducting-insulating transition in macroscopic, CVD-Grown samples of graphene which decorated with tin nanoparticles. The self assembled network of Tin islands generates superconducting correlations locally in the Graphene by means of proximity effect. Correlations eventually leads to percolation of a supercurrent. This system exhibits features related to granular superconductivity, a giant magnetoresistance peak, as well as an intermediate metallic behavior. We emphasize outstanding dynamics of the transition, which exhibit a change in resistance of more than 7 orders of magnitude within 40V of gate voltage, thus realizing a real electrostatically driven superconducting-insulating transition. The intense positive magnetoresistance observed for fields below the critical field of Tin nanoparticles is a signature of the localization of Cooper pairs. This hybrid superconductor provides a model system to better understand the physics of inhomogeneous superconductivity, as crossing the transition by adjusting the carrier density is conceptually simpler than using a magnetic field. It also allows to cross the transition continuously and under constant disorder.

9:12AM A11.00007 Transport through Andreev Bound States in a Graphene-base Quantum Dot¹, YANJING LI, NADYA MASON, University of Illinois at Urbana-Champaign — We perform tunneling spectroscopy on a graphene-quantum dot (QD)-superconductor junction, a system in which sharp, gate-tunable Andreev bound states (ABS) in the spectra have been observed [1]. Here we extend previous results, particularly regarding the origins of the QD. In particular, we discuss how a discontinuous layer of AlO_x between the superconductor and the graphene plays a role in the formation of the QD. We also discuss additional spectroscopic features that may be due to multiple QDs and energy levels. Finally, we show that a robust superconducting tunneling junction can be created in a lead-graphene structure, without the explicit deposition of a tunneling barrier.

9:24AM A11.00008 Direct Measurement of the Fermi Energy in Graphene Using a Double Layer Structure¹, SEYOUNG KIM, INSUN JO, DAVID DILLEN, DOMINGO FERRER, BABAK FALLAHZAD, ZHEN YAO, SANJAY BANERJEE, EMANUEL TUTUC, The University of Texas at Austin — The Fermi energy is a fundamental property of an electron system. Here we introduce a direct measurement technique of the relative Fermi energy as a function of carrier density, using transport measurement in a double layer structure where one of the layers is graphene. The principle of this method is that the Fermi energy in the target material is equal to the applied inter-layer bias required to bring the graphene layer to charge neutrality point. Using a double layer graphene structure, we illustrate the technique by measuring the Fermi energy in one of the graphene layers. By mapping the top graphene layer zero density line as a function of bottom and inter-layer bias, we measure the Fermi energy as a function of carrier density at zero and in high magnetic fields. We extract the Fermi velocity, Landau level spacing and Landau level broadening.

¹We thank C. P. Morath and M. P. Lilly for discussions. This work was supported by NRI, ONR, and Intel. Part of this work was performed at the National High Magnetic Field Laboratory, which is supported by NSF (DMR-0654118), the State of Florida, and DOE.

9:36AM A11.00009 Magnetic field dependence of the carrier's effective mass and the g-factor in graphene¹, ANDRII IUROV, Hunter College and Graduate Center, City University of New York, GODFREY GUMBS, OLEKSIY ROSLYAK, Hunter College, City University of New York, DANHONG HUANG, USAF Research Lab (AFRL/RVSS) — It has been established that the intrinsic Zeeman energy is one half of the cyclotron energy for “bare” electrons in graphene. Consequently, there could be Landau-level mixing between the energy bands. We investigate how the band mixing is affected by the Coulomb interaction. Pairing of the electrons and holes in the presence of a circularly polarized light is also considered for several filling factors. We calculate the quasiparticle effective mass and effective g -factor for dressed electrons and holes in monolayer graphene. As an intermediate step of these calculations, we obtain the dielectric function for the case of electron dressed states and investigate how the magnetoplasmons modes are affected by the electron-photon interaction.

¹This research was supported by contract # FA 9453-11-01-0263 of AFRL. DH would like to thank the Air Force Office of Scientific Research (AFOSR) for its support.

9:48AM A11.00010 Magnetic-field tunable electron-phonon coupling in graphite, LI-CHUN TUNG, Dept. of Phys. and Astrophys., University of North Dakota, W. YU, School of Physics, Georgia Institute of Technology, P. CADDEN-ZIMANSKY, Department of Physics, Columbia University, M. KINDERMANN, School of Physics, Georgia Institute of Technology, D. SMIRNOV, National High Magnetic Field Laboratory, Z. JIANG, School of Physics, Georgia Institute of Technology — Electron-phonon coupling (EPC) plays a pivotal role in condensed matter physics, governing intriguing phenomena such as superconductivity, ballistic transport, and excited-state dynamics. In graphitic systems, EPC is found to be strongly related to the quasiparticle excitations, electronic states and optical properties. Thus, the EPC may be manipulated via external parameters, such as electric field or magnetic field, and provide alternative access to adjust the characteristics of carbon-based devices. Here, we explore the EPC in graphite via magnetophonon resonance using cyclotron resonance (CR) spectroscopy. A marked avoided-level-crossing splitting of the CR and a Fano resonance-like behavior are observed, when the CR energies intersect the specific phonon energies via tuning the magnitude of the magnetic field. We attribute these results to the resonance between the CR excitations and the large momentum zone-edge, and the long-wavelength zone-center phonons, respectively. This work suggests that rich interacting physics exists in graphitic materials, which may have profound implications in future optoelectronics.

10:00AM A11.00011 High frequency high magnetic field response of graphene monolayers, IVANA PETKOVIC, Laboratoire National de Métrologie et d'Essais, Trappes, France, FRANCIS WILLIAMS, FABIEN PORTIER, PATRICE ROCHE, KEYAN BENNACEUR, CHRISTIAN GLATTLI, Commissariat à l'Energie Atomique, Saclay, France — We study the electronic magnetotransport in graphene at rf frequencies (5-50GHz). Our aim is to investigate the dynamics of charge carriers in the quantum Hall regime. The graphene sample is placed in a break made in a coplanar waveguide and the transmitted power is measured. In order to isolate the response of the sample from the direct transmission between the input and output waveguides, the graphene electron density distribution is modulated with a side gate and the resulting modulation in the transmitted power detected via a standard lock-in technique. The fixed frequency graphene response as a function of magnetic field reveals two different components. One is symmetric in B and dominates under large side gate voltage, and the other shows reproducible fluctuations revealed only at low gate voltage modulation amplitude. The first part is thought to be related to the bulk conductivity and the fluctuations to the carrier dynamics close to the edge. The amplitude of the fluctuations depends on the trajectory of the carriers, since the parity with respect to magnetic field reversal is not conserved. We thus demonstrate the chiral nature of the transport. We assume that the fluctuations of impedance originate in the scattering from localized states close to the sample edge.

10:12AM A11.00012 Impurity-limited carrier transport in graphene nanoribbons¹, C.W. SMITH, MASAHIRO ISHIGAMI, Department of Physics and Nanoscience Technology Center, University of Central Florida, Orlando, FL 32816 — We have measured the transport property of graphene nanoribbons as a function of impurity density in ultra high vacuum. Specifically, the impact of Coulomb and van der Waals impurities on the transport and source-drain gap of nanoribbons is investigated. Our results have direct consequences on fundamental science using graphene constrictions and graphene-based devices.

¹This work is based upon research supported by the National Science Foundation under Grant No. 0955625.

10:24AM A11.00013 Electrical Transport Study of Suspended Graphene Nanoribbons, MING-WEI LIN, KULWINDER DHINDSA, LEZHANG LIU, QING LAN, Department of Physics and Astronomy, Wayne State University, MARK MING-CHENG CHENG, Wayne State University, LUIS AGAPITO, NICHOLAS KIOUSSIS, California State University, ZHIXIAN ZHOU, Department of Physics and Astronomy, Wayne State University — Suspended graphene nanoribbon field effect transistors from unzipped multiwall carbon nanotubes have been fabricated. Electrical transport measurements show that current-annealing effectively removes the adsorbed impurities on the suspended graphene nanoribbons. Further increasing the annealing current creates a narrow constriction in the ribbons with non-negligible disorder, leading to the formation of a large band-gap and subsequent high on/off ratio. On the other hand, uniform suspended graphene nanoribbons with ultra-low-disorder reveal a high mobility exceeding 3000 cm² V⁻¹ s⁻¹ and an intrinsic band gap. The width and length dependence of the electrical transport properties of ultra-low-disorder graphene nanoribbons with nearly atomically smooth edges will also be discussed.

10:36AM A11.00014 Quantum Transport in Graphene Nanoribbon Networks, ANDRÉS RAFAEL BOTELLO-MÉNDEZ, Institute of Condensed Matter and Nanosciences(IMCN), Université Catholique de Louvain (UCL), Belgium, EDUARDO CRUZ-SILVA, Oak Ridge National Laboratory (ORNL), USA, JOSÉ MANUEL ROMO-HERRERA, Departamento de Química Física, Universidad de Vigo, Spain, FLORENTINO LÓPEZ-URÍAS, IPICYT, Mexico, MAURICIO TERRONES, Materials Research Institute, The Pennsylvania State University, USA, BOBBY G. SUMPTER, ORNL, USA, HUMBERTO TERRONES, JEAN-CHRISTOPHE CHARLIER, IMCN, UCL, Belgium, VINCENT MEUNIER, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, USA — Focusing on systems that can be realized experimentally, both in-plane conductance of inter-connected graphene nanoribbons and tunneling conductance in out-of-plane nanoribbon intersections are investigated. The quantum transport properties of such networks are computed using first-principles calculations based on the density functional theory formalism. The electronic transport through in-plane nanoribbon cross-points is found to be significantly affected by scattering at the intersections with the exception of all zigzag nanoribbon terminals arranged at a 60 degree angle. This result demonstrates the possibility of designing graphene nanoribbon networks capable of guiding electron along desired and predetermined paths. In addition, the electron transport properties of out-of-plane nanoribbons cross-points with realistic size are described within a simple tight-binding approach. The stacking angle is predicted to play a key role on the electronic transmission through nanoribbon networks.

10:48AM A11.00015 Current Quantization in Corrugated Graphene Nanoribbons, UPALI APARAJITA, OLEKSIY ROSLYAK, GODFREY GUMBS, Physics & Astronomy Department, Hunter College, CUNY, DANHONG HUANG, USAF Research lab, Kirtland AFB, NM — Corrugated graphene provides such a phenomenon as curvature induced $p-n$ junction band gap opening and decoherence. We report yet another effect of current quantization in graphene nanoribbons via energy minigaps induced by the corrugation. Effects of edge roughness and long range charged scatterers on the quantization are investigated. Comparison is drawn with acoustically induced minigaps in carbon nanotubes [Talyanskii et al., PRL 87,276082(2001)].

Monday, February 27, 2012 8:00AM - 11:00AM —

Session A12 DCMP: Graphene: Electronic Structure and Interactions - Adsorbates, Doping and Defects 210C

8:00AM A12.00001 Transport study of electrochemically decorated and intercalated graphene, DMITRI K. EFETOV, KIN FAI MAK, YINSHENG GUO, TONY F. HEINZ, LOUIS BRUS, PHILIP KIM, Columbia University in the City of New York — Due to the surface-only properties of graphene, the decoration and/or intercalation of single, bi- and multi-layer graphene with foreign atoms can severely modify its electronic interactions, similar to those observed in its 3D counterpart the graphite intercalation compounds. Supported by a highly increased density of state due to a strong charge transfer above 10¹⁴ cm⁻² into the graphene π -bands, certain adatoms are expected to induce strong electronic interactions to the graphenes own Dirac fermions, where theoretical predictions reach from the Kondo-effect and magnetism to as far as superconductivity in graphene. In this study we will present evidence of specific adsorption and intercalation of diverse atomic species by electrochemical means. We will present a detailed transport study, including resistivity-, Hall- and magneto-resistivity measurements of single-, bi- and multi-layer graphene devices which were subjected to electrochemical doping by a variety of electrolytes and ionic species such as Li⁺, ClO₄⁻, Cs⁺, Ca²⁺, etc.

8:12AM A12.00002 Electronic detection of phase transition of adsorbed water on graphene, SHUDONG XIAO, MICHAEL FUHRER, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742-4111 — Graphene is sensitive to overlayers on its surface through charge transfer and also through changes in dielectric constant, which can alter the scattering by static disorder in graphene. We performed transport measurement on graphene devices *in situ* in ultra-high vacuum at low temperature. Water vapor is introduced to the chamber and is adsorbed on graphene at low temperature. After deposition of a few monolayers of water, the resistivity of graphene at fixed gate voltages is measured as the temperature is raised from 40K to room temperature. Sharp features in the temperature-dependent resistivity mark reproducible, irreversible (upon re-cooling) changes in the sample which we interpret as phase transitions in the adsorbed water overlayer, likely corresponding to dewetting and desorption. This work has been supported by the University of Maryland NSF-MRSEC under Grant No. DMR 05-20471 with supplemental funding from NRI.

8:24AM A12.00003 *GW* study of the effect of various defects on the band gap of fluorographene, YOUNG-MOO BYUN, JORGE SOFO, VINCENT CRESPI, Penn State University — Recently synthesized fluorographene, fully fluorinated graphene in a chair configuration, is a wide band-gap (E_g) semiconductor with an experimental optical band gap of ~ 3 eV. However, first-principles calculations have shown that pristine fluorographene should have E_g of 5.4 to 7.5 eV. To explain this discrepancy, we have studied the effect of F vacancies, a Stone-Wales (SW) defect, C single vacancies and C double vacancies on E_g of fluorographene using density functional theory and the *GW* approximation. F vacancies and a SW defect are not likely to affect E_g of fluorographene, whereas a C single vacancy with a doubly fluorinated C atom, a C double vacancy, and a C double vacancy with two doubly fluorinated C atoms lead to a *GW* band gap of ~ 4 eV, which is consistent with the optically measured E_g , and they are energetically more favorable than other C vacancies at a wide range of chemical potential of F (μ_F).

8:36AM A12.00004 Controlled electrochemical functionalization of epitaxial graphene¹, CALVIN CHAN, THOMAS BEECHEM, TAISUKE OHTA, DAVID WHEELER, Sandia National Laboratories, KEITH STEVENSON, University of Texas, Austin — Chemical functionalization is a promising means of modifying graphene for applications ranging from nanoelectronics to transparent electrodes. Various schemes have been demonstrated, but control over functionalization density with well-specified molecules is still a challenge. We report on the controlled electrochemical functionalization of epitaxial graphene with trifluoromethylphenylene (CF₃Ph), where the functionalization density was controlled by the electron injection rate. CF₃Ph peaks were observed in x-ray photoemission spectroscopy, along with binding energy shifts consistent with bonding between CF₃Ph and graphene. A maximum functionalization density of one molecule per six graphene carbons was inferred from the peak intensities. Spectroscopic Raman mapping revealed increasing graphene D:G peak intensity ratios that scaled with increasing functionalization-induced localized defects. While a minimal shift in the π orbital structure and the emergence of CF₃Ph related features were observed in ultraviolet photoemission spectroscopy, a work function increase by 0.5 eV in CF₃Ph-graphene suggests a shift of the electron distribution towards the CF₃ moieties on the surface. This work has positive implications for transparent electrode applications.

¹This work was supported by the Early Career LDRD program at SNL, and the DOE EFRC in Charge Separation and Transfer (DE-SC0001091). SNL is operated by Sandia Corp., a Lockheed Martin Co., for the US DOE-NNSA (DE-AC04-94AL85000).

8:48AM A12.00005 Adsorption of NH₂ on Graphene in the Presence of Primary Defects, CHAD JUNKERMEIER, NRC Post-Doctoral Associate, U.S. Naval Research Laboratory, STEFAN BADESCU, U.S. Air Force Research Laboratory, THOMAS REINECKE, U.S. Naval Research Laboratory — The primary amine, NH₂, is of interest as a linker between graphene and organic molecules in novel biotechnologies using graphene platforms. We are using *ab initio* electronic structure calculations to study NH₂ adsorption on graphene. We find that the adsorption energy on pristine graphene is on the order of 0.778 eV, a relatively weak bond. We are interested in situations in which the bonding of NH₂ is stronger and are studying systems in which NH₂ adsorbs near defects. We find the adsorption energy of a NH₂ molecule near a second NH₂ molecule is as high as 1.037 eV and that the adsorption near a substitutional N atom is 1.063 eV. We find that there is a RKKY-like interaction between the adsorbate molecules in the case of two NH₂. We will also give results for NH₂ adsorption near other defects.

9:00AM A12.00006 Influence of subsurface hydrogen on the properties of single layer graphene grown on Ru(0001)¹, BOGDAN DIACONESCU, Los Alamos National Laboratory, FRANK HAGELBERG, East Tennessee State University, MAXWELL GRADY, KARSTEN POHL, University of New Hampshire — Graphene has aroused tremendous interest due to its remarkable electronic and mechanical properties. The lack of a band-gap, however, causes a serious challenge for implementing graphene as a material for electrical switches and therefore creative ways of inducing this band-gap are needed. We will present a STM/LEED/DFT study of the single layer graphene on Ru(0001) system in the presence of hydrogen. Structural studies show arrays of Moire superlattices with sizes ranging from 0.9 to 3.0 nm in the presence of hydrogen on the compact surface of ruthenium. First principle calculations help explain the appearance of these arrays of graphene reconstructions driven by the H presence at the Ru(0001) interface, and furthermore, predict the appearance of a bandgap with values correlated with the Moire superstructure sizes in the presence of hydrogen.

¹This work was supported by the Nanoscale Science and Engineering Center for High-rate Nanomanufacturing (NSF NSEC-425826) and NSF DMR-1006863.

9:12AM A12.00007 Graphene symmetry-breaking with molecular adsorbates: modeling and experiment¹, M.A. GROCE, M.K. HAWKINS, Y.L. WANG, W.G. CULLEN, T.L. EINSTEIN, U. of Maryland — Graphene's structure and electronic properties provide a framework for understanding molecule-substrate interactions and developing techniques for band gap engineering. Controlled deposition of molecular adsorbates can create superlattices which break the degeneracy of graphene's two-atom unit cell, opening a band gap. We simulate scanning tunneling microscopy and spectroscopy measurements for a variety of organic molecule/graphene systems, including pyridine, trimesic acid, and isonicotinic acid, based on density functional theory calculations using VASP. We also compare our simulations to ultra-high vacuum STM and STS results.

¹Supported by U. of Maryland NSF-MRSEC under Grant No. DMR 05-20471.

9:24AM A12.00008 Overcoming Doping Difficulty in Graphene via Substrate¹, SU-HUAI WEI, BING HUANG, HONGJUN XIANG, National Renewable Energy Laboratory — Controlling the type and density of charge carriers by doping is the key step for developing graphene electronics. However, direct doping of graphene is rather challenge. Using first-principles method we find that doping could be strongly enhanced in epitaxial graphene grown on silicon carbide substrate. Compared to free-standing graphene, the formation energies of the dopants can decrease by as much as 8 eV. The type and density of the charge carriers of epitaxial graphene layer can be effectively manipulated by suitable dopants and surface passivation. More importantly, contrasting to the direct doping of graphene, the charge carriers in epitaxial graphene layer are weakly scattered by dopants due to the spatial separation between dopants and conducting channel.

¹Work is supported by DOE/BES and NREL LDRD Program

9:36AM A12.00009 Calculations of double-sided coverage of transition metals on graphene, TIMOTHY HECHT, BRET HESS, Brigham Young University — We study the properties of transition metal atoms adsorbed in high coverage on graphene using first principles density functional theory. While there have been many studies on single-sided coverage of adatoms on graphene, we focus on coverage of both sides of graphene. We have observed systems with significantly stronger binding with double-sided coverage than systems with only single-sided coverage. We discuss the effect of double-sided coverage on the electronic structure of these systems.

9:48AM A12.00010 Excited Carriers Relaxation and Hydrogen Dissociation on Hydrogenated Graphene: A Theory, JUNHYEOK BANG, Y.Y. SUN, D. WEST, S.B. ZHANG, Department of Physics, RPI, Troy, New York 12180, USA, S. MENG, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, Z.G. WANG, F. GAO, PNNL, Richland, Washington 99352, USA — Using *ab initio* molecular dynamics coupled with time-dependent density functional theory (TDDFT), we show that the energy transfer of photo-excited carriers into atomic kinetic energy on hydrogenated graphene depends sensitively on the surface H coverage. Here, the energy transfer rate plays a crucial role in the determination of the H dissociation dynamics from graphene. In the low density “isolated” hydrogen atom limit, the energy transfer is significantly suppressed 80 fs after the excitation. Thus, it is difficult to dissociate hydrogen due to the faster energy dissipation from H into carbon backbone, despite that initially the H kinetic energy had increased to around 1.5 eV and the C-H bondlength had stretched to 2.4 Å. In sharp contrast, at the high-density graphene limit, an efficient energy transfer channel is established when the C-H bondlength exceeds 1.4 Å. A fraction of the H readily dissociates within 15 fs. This is because ionized H forms a charged layer that expels, and as such accelerates the H ions with higher initial thermal velocities flying away. Our study thus reveals the importance of performing TDDFT calculations for excited carrier dynamics as from the widely adopted ground-state or constrained DFT dynamics one would expect the C-H bonds in graphene to be significantly stronger, due to full surface passivation, than that of isolated H.

10:00AM A12.00011 Theory of hydrogen induced giant spin-orbit coupling in graphene¹, MARTIN GMITRA, DENIS KOCHAN, JAROSLAV FABIAN, University of Regensburg — Adatoms seem for now the most perspective way of increasing and controlling spin-orbit coupling in graphene. Hydrogen in particular is a role representative, as it gives both lattice deformation and covalent bonding, both contributing towards sigma-pi hybridization needed for the increase of the spin-orbit coupling around K. To establish the relevant physics of the H induced spin-orbit coupling in graphene, we have performed systematic calculations of hydrogenated graphene. We found that the magnitude of the coupling is of the order of meVs, exactly what is needed to explain the experimental data on spin relaxation. Doing both first-principal calculations and tight-binding modeling we calculate the spin-orbit splittings and introduce an effective hopping model that can be used in realistic investigations.

¹The work is supported by the DFG SFB 689.

10:12AM A12.00012 Understanding electron-phonon interactions in doped graphene: the case of Li-intercalated graphite, ANDREW WALTERS, MPI for Solid State Research, Germany, MARK DEAN, Brookhaven National Lab, USA, CHRISTOPHER HOWARD, MARK ELLERBY, JONATHAN PAYNE, University College London, UK, MICHAEL KRISCH, ALEXEI BOSAK, European Synchrotron Radiation Facility, France, GIANNI PROFETA, University of L'Aquila, Italy, MATTEO CALANDRA, FRANCESCO MAURI, University Paris 6, France — The recent explosion of research on doped graphene systems together with the discovery of superconductivity in CaC₆ has reignited the interest in graphite intercalation compounds (GICs). While it is generally agreed that the superconductivity observed in GICs is BCS-like, there is still much controversy over which electrons and which phonons are primarily involved in the electron-phonon (e-ph) coupling leading to superconductivity. Moreover, thanks to the close similarity between the electronic structure of GICs and doped graphene, the study of e-ph interactions in GICs provides a unique approach to help elucidate the complex e-ph interactions in doped graphitic systems. We present inelastic x-ray scattering measurements of the high energy (~ 200 meV) graphitic phonons in LiC₆ across the Brillouin zone. The LiC₆ phonons are much softer than in pure graphite, as the electron doping destabilizes the C-C bonds. We observe large phonon broadening for all phonons at the graphite Brillouin zone center, suggestive of unusual e-ph interaction phenomena. We discuss our results in the light of the e-ph coupling reported from angle-resolved photoemission spectroscopy and in relation to strong non-adiabatic effects observed using Raman scattering.

10:24AM A12.00013 p-n codoping induced improvement of adsorption, magnetism, and electronic structure in 3d transition metal adatoms on graphene¹, SHIFEI QI, Shanxi Normal Univ. and Univ. of Science & Technology of China, ZHENYU ZHANG, Univ. of Science & Technology of China and Harvard Univ., XIAOHONG XU, Shanxi Normal Univ. — Generating ferromagnetism and preserving its unique properties in graphene are crucial to the development of graphene-based spintronics. Using first-principles calculations, we investigate the effects of p-n codoping method on absorption, magnetic properties, and of electronic structures 3d transition metal adatoms (TMs, i.e., Fe, Co, and Ni) on graphene. It is found that p-n codoping can strengthen the adsorption of TMs on graphene, and enhance the magnetic moments of Fe and Co adatoms on graphene. It can also cause Ni to transition from nonmagnetic to magnetic states. Furthermore, magnetic coupling between two p-n pairs is also explored. Electronic structure analysis indicates that p-type dopant turns graphene into an electron-deficient system, and compensates for the shift in Fermi level caused by adsorption of TMs. Therefore, p-n codoping can bring about increases in the magnetic moment and adsorption of TM-adsorbed graphene systems while preserving the unique properties of graphene.

¹Supported by NNSF of China, USNSF, and DMSE/BES of USDOE.

10:36AM A12.00014 Directed Assembly of Molecules on Graphene/Ru(0001)¹, L.Z. ZHANG, H.G. ZHANG, J.T. SUN, Y. PAN, Q. LIU, J.H. MAO, H.T. ZHOU, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, T. LOW, IBM Thomas J. Watson Research Center, New York 10598, USA, H.M. GUO, S.X. DU, H.-J. GAO, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES TEAM, IBM THOMAS J. WATSON RESEARCH CENTER COLLABORATION — Recently, the graphene monolayers have been seen to adopt a superstructure - moiré pattern - on Ru(0001). By using low temperature scanning tunneling spectroscopy, we identified the laterally localized electronic states on this system. The individual states are separated by 3 nm and comprise regions of about 90 carbon atoms. This constitutes a highly regular quantum dot-array with molecular precision. It is evidenced by quantum well resonances with energies that relate to the corrugation of the graphene layer. By using scanning tunneling microscopy/spectroscopy, we demonstrate the selective adsorption and formation of ordered molecular arrays of FePc and pentacene molecules on the graphene/Ru(0001) templates. With in-depth investigations of the molecular adsorption and assembly processes we reveal the existence lateral electric dipoles in the epitaxial graphene monolayers and the capability of the dipoles in directing and driving the molecular adsorption and assembly. When increasing the molecular coverage, we observed the formation of regular Kagome lattices that duplicate the lattice of the moiré pattern of monolayer graphene.

¹Supported by MOST (2009CB929103, 2011CB932700) of China

10:48AM A12.00015 Study on the Adsorption of Small Gas Molecules on graphene by the Density Functional Theory Calculations, YIMING MI, Graduate Department, Shanghai University of Engineering Science, 333 Longteng Rd., Shanghai 201620, PR CHINA, XINXIN ZHAO, School of Fundamental Studies, Shanghai University of Engineering Science, 333 Longteng Rd., Shanghai 201620, PR CHINA, SHUICHI IWATA, Graduate School of Frontier Sciences, The University of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo 113-8654, JAPAN — The absorption of different small gas molecules on graphene is investigated based on the pseudopotential method within the density functional theory formalism. The preferred adsorption site (among the top, bridge, and hollow positions) and orientations of these molecules on the graphene surface are analyzed and the related adsorption energies are calculated. The charge transfer between the adsorbed molecules and the graphene is discussed as well.

Monday, February 27, 2012 8:00AM - 10:48AM –
Session A13 DMP GMAG: Focus Session: Magnetic Nanostructures-Patterned Nanostructures and Nanowires 211

8:00AM A13.00001 High Frequency Excitation of Nanometer-Scale, Strongly Coupled FM / NM / FM Disks¹, JAVIER PULECIO, PETER WARNICKE, SHAWN POLLARD, DARIO ARENA, YIMEI ZHU, Brookhaven National Laboratory — There is great interest in the manipulation of magnetic domains in nanostructures from both a fundamental and applications perspective. In particular, the use of resonant frequency excitations permits a power reduction of the driving forces necessary to induce detectable motion in magnetic vortex structures. Here we present an experimental and numerical study of patterned tri-layered disk stacks which are composed of 25nm Permalloy|1nm Copper|15nm Permalloy, excited at resonance, ranging from 250-500nm in radii. In-situ Lorentz microscopy was used to acquire time averaged real space images of the vortices' gyrotropic motion and micromagnetic simulations were implemented to further understand the coupled dynamics between the ferromagnetic layers across the thin non-magnetic spacer layer. We discuss the effects of interlayer coupling on the vortex trajectories and resonant frequencies for the individual ferromagnetic layers.

¹Work supported by Department of Energy, Office of Basic Energy Science, under contract No. DE-AC02-98CH10886

8:12AM A13.00002 Controlling the formation process of vortex states in magnetic nanodots with asymmetric geometry¹, MI-YOUNG IM, PETER FISCHER, CXRO/LBNL, ANDREAS VOGEL, GUIDO MEIER, IAP/U Hamburg — Magnetic vortex structures in nanoscale elements are currently highly attractive, since they offer exciting topological spin configurations to study on a fundamental level nanoscale spin behavior and they show great potential for applications in data storage and memory technologies. One of the primary questions is to tailor the nucleation process of vortex structures, which would open the opportunity for the control of magnetic/spin phenomena in magnetic vortices such as the resonant motion of a magnetic vortex core, etc. We have investigated the stochastic character of the formation process of vortex states in permalloy (Ni₈₀Fe₂₀) nanodots with different geometries by direct imaging of vortex structures with high resolution magnetic transmission soft X-ray microscopy (MTXM). We observe that the formation process of vortex state sensitively depends on the geometry of nanodots. Based on our experimental result, we will discuss the possibility to control the generation process of magnetic vortex states by directed modifications of the geometry of nanodots.

8:24AM A13.00003 Quantum depinning of the magnetic vortex core in micron-size permalloy disks, RICARDO ZARZUELA, SAÜL VÉLEZ, JOAN MANEL HERNANDEZ, JAVIER TEJADA, Departament de Física Fonamental, Universitat de Barcelona, VALENTYN NOVOSAD, Materials Sciences Division, Argonne National Laboratory, GRUP DE MAGNETISME TEAM, MATERIALS SCIENCES DIVISION TEAM — The vortex state being characterised by an in-plane closed flux domain structure and an out-of-plane magnetization at its centre (known as the vortex core) is one of the magnetic equilibria of thin soft ferromagnetic micron-size dots. The vortex core is a mesoscopic object and so it is a suitable candidate to observe quantum tunneling of its magnetic moment between classically stable magnetic configurations. For the first time, we report experimental evidence of quantum dynamics of the vortex core of micron-size Permalloy (Fe₁₉Ni₈₁) disks induced by the application of an in-plane magnetic field. It is attributed to the quantum tunneling of the vortex core through pinning barriers, which are associated to structural defects in the dots, towards its equilibrium position. The crossover temperature from the thermal to the quantum regime is obtained within the framework given by the Caldeira-Leggett theory. Comparison between experiments and theory points to tunneling of the vortex core by steps of the order of 0.3 nm and gives estimates to the parameters characterising the pinning barriers.

8:36AM A13.00004 Energy barriers for vortex nucleation and annihilation in sub-100 nm magnetic dots¹, ANDREW T. KING, IGOR V. ROSHCHIN, Texas A&M University — Understanding energy barriers involved in nucleating and annihilating magnetic vortices in nanodots is important for magnetic memories and nano-oscillators. We used a "rigid-vortex approximation" and micromagnetic approach to calculate the total magnetic energy of a nanodot for various magnetic configurations. This was done for 20 nm-thick iron nanodots with different diameters (30, 40, 65, and 80 nm) as a function of applied magnetic field. By analyzing the energy landscape for different magnetic configurations, we calculated the energy barrier for switching from the vortex to the single-domain state (vortex annihilation) and the converse (vortex nucleation). The applied fields required to overcome these two barriers are compared to those obtained from the simulations directly and to the experimental values.² The role of the thermal fluctuations in the temperature dependence of these critical fields will be discussed by comparison of the energy barriers with the thermal energy, kT.

¹Work is supported by Texas A&M University, TAMU-CONACYT Collaborative Research Program.

²R. K. Dumas, et al., *Appl. Phys. Lett.* **91**, 202501 (2007).

8:48AM A13.00005 A Novel Non-lift-off Block Copolymer Nanolithography Technique for Etch-damage Susceptible Magnetic Materials, A. BARUTH, A. SHANKAR, K. WALSTER, M.D. RODWOGIN, M.J. ERICKSON, M.A. HILLMYER, C. LEIGHTON, University of Minnesota - Twin Cities — Nanolithographic techniques based on self-assembled block copolymer templates offer exceptional potential for fabrication of large-area nanostructure arrays from a wide variety of functional materials. Despite significant progress with control of the template ordering and development of pattern transfer schemes, significant issues exist with common techniques such as lift-off and etching. Here, we demonstrate successful execution of a nanolithographic process based on climate-controlled solvent annealing of easily degradable cylinder-forming poly(styrene-*b*-lactide) block copolymer films that avoids both lift-off, and some of the most challenging aspects of etching. In particular, our overfill/planarize/etch-back scheme leads to retention of robust ferromagnetism even in 24 nm diameter dots of a material ($\text{Ni}_{80}\text{Fe}_{20}$) that is both magnetically soft and susceptible to etch damage. The result is a large-area array of 24 ± 1.6 nm diameter magnetic nanodots with exceptional hexagonally-close-packed long range order that retain their crystallinity and $\sim 70\%$ of the bulk magnetization. Extensive diffraction, microscopy, magnetometry, and electrical measurements provide detailed characterization of the pattern formation and fidelity. Funded by NSF MRSEC.

9:00AM A13.00006 Quenching of the initial ac Susceptibility in Single Domain Ni Nanobars, ZHENG GAI, XIAOGUANG ZHANG, IVAN I. KRAVCHENKO, SCOTT T. RETTERER, J. WENDELKEN, Oak Ridge National Laboratory — The ac susceptibility measurement probes the dynamic properties of a magnetic material, which is believed to consist of magnetization rotation and domain wall motion contributions. Here we report the observation of a complete quenching of the initial ac susceptibility for a single domain Ni nanobar array, when the ac field is aligned with the long axis of the bars. The vanishing of the susceptibility in one direction is a unique nanoscale phenomena, allowing an unambiguous determination of the magnetic state of the nanostructure and a clean separation of different contributions to its dynamic properties. For example, an unambiguous determination of the temperature dependent surface anisotropy energy is obtained when the field is applied perpendicular to the long axis. This research was conducted at the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Office of Basic Energy Sciences, U.S. Department of Energy.

9:12AM A13.00007 Microwave assisted magnetization reversal in cylindrical antidot arrays with in-plane and perpendicular anisotropy, MEHMET YUMAK, KERIM TURE, GULEN AKTAS, Bogazici University Department of Physics, VICTOR VEGA, VICTOR PRIDA, Dpto. Física, Universidad de Oviedo, Calvo Sotelo, CARLOS GARCIA, Bogazici University Department of Physics — Porous anodic alumina is a particularly attractive self-ordered system used as template to fabricate nanostructures. The anodic film contains a self-ordered hexagonal array of parallel pores with tunable pore size and interpore distance, and whose pore locations can be templated. Deposition of magnetic films onto porous alumina leads to the formation of porous magnetic films, whose properties differ significantly from those of unpatterned films. The study of antidot arrays has both technological and fundamental importance. Although porous alumina films are typically synthesized in a planar geometry, in this work we deposited NiFe and Ti/CoCrPt magnetic films with in-plane and out-of-plane anisotropy onto cylindrical-geometry porous anodic alumina substrates to achieve cylindrical antidot arrays. The effect of both, the magnitude of the AC current and the circular magnetic field on the magnetization reversal has been studied for in-plane and perpendicular anisotropies. The level of reduction in the switching field was found to be dependent on the power, the frequency of the microwave pulses and the circular applied magnetic field. Such a reduction is associated with the competition between pumping and damping processes.

9:24AM A13.00008 DC and High-frequency Magnetic Properties of Patterned Ferromagnetic Nanostructures¹, HUAJIE KE, YITZI CALM, MARK TUOMINEN, Department of Physics, Center for Hierarchical Manufacturing, University of Massachusetts Amherst — Magnetic mesoscopic and nanostructures have promising applications such as high-density data storage, magnetic field sensors, and microwave devices. Patterned magnetic structures are especially interesting because their constitutive material, sizes and geometry are easily adjustable in fabrication. This work aims to study dc and radio frequency magnetic properties of Co and permalloy patterned structures and the effect of magnetic coupling. We use electron-beam lithography and complementary techniques to ferromagnetic nanostructures with various separations to control the strength of magnetic interaction. SQUID and complementary MFM characterization are performed to observe the dc magnetic properties. AC susceptibility is used to investigate the low frequency response. Microstrip transmission lines are then incorporated to measure the scattering parameters between 300kHz and 6GHz. The equivalent RLCG circuit elements can be extracted to obtain the effective magnetic permeability for different ferromagnetic structures.

¹This research is supported by NSF grants CMMI-1025020 and DMR-0907201.

9:36AM A13.00009 Precise control of vortex chirality and polarity in “Pac-Man”-like magnetic nanodots by in-plane magnetic field¹, VLADIMIR CAMEL, JAROSLAV TÓBIK, Institute of Electrical Engineering, Slovak Academy of Sciences, Slovakia, GORAN KARAPETROV, Department of Physics, Drexel University and Institute of Electrical Engineering, Slovak Academy of Sciences — Here we explore size-dependent magnetic states of sub-100 nm Permalloy nanomagnets of specific geometry. The geometry is suitable for independent setting and readout of vortex polarity and chirality by applying *in-plane magnetic fields* only. Micromagnetic calculations show that in “Pac-Man”-like magnetic nanodots the relaxation channels to specific chirality and polarity states from uniform magnetization state are deterministic and are not influenced by the presence of moderate out-of-plane fields. The particular geometry opens straight channel for magnetization relaxation towards stable closure-domain vortex state with specific chirality and polarity. We explore a wide geometrical phase space in search for stable and predictable remanent vortex configurations. We find that in these nanomagnets the write process is simple and the signal is easily readable.

9:48AM A13.00010 Direct imaging of complex domain walls and chirality sensors in magnetic nanostripes, S.R. BOWDEN, J. UNGURIS, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Gaithersburg, MD 20899, Y. JANG¹, M. MASCARO, C.A. ROSS, Department of Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge MA 02139 — Domain walls (DWs) in patterned ferromagnetic nanostripes are increasingly being considered for non-volatile and radiation hard data storage and logic applications. We use scanning electron microscopy with polarization analysis (SEMPA) to image the formation of complex domain walls in nanostripes and local patterned structures used for sensing DW chirality. The DWs studied have a transverse orientation, where the in-plane spin direction of a 180° DW is perpendicular to the nanostripe axis. We demonstrate a technique where two 180° DWs of alternating chirality may interact to form a stable DW with 360° rotation as opposed to DW annihilation. Higher order DWs with $n\pi$ rotation are demonstrated, where n is an integer number of interacting 180° DWs. The detection of moving 180° DWs via external fields is studied by placing patterned magnetic triangular elements above and below the nanostripe in-plane. As the DW propagates across the wire, the stray field interacts and switches the magnetization of the triangles. The chirality of the DW may be sensed by designing the triangles to respond to the inherent asymmetry of the DW's stray field.

¹Present Address: Samsung Advanced Institute of Technology, Gyeonggi-Do 446-712, Republic of Korea

10:00AM A13.00011 A high-spin atomic 1-D system with a spin-induced CDW instability¹, NADER ZAKI, CHRIS MARIANETTI, Columbia University, PETER JOHNSON, Brookhaven National Lab, RICHARD OSGOOD, Columbia University — We report on low-temperature STM measurements of a Co atomic-wire system that has been realized by the technique of self-assembly on a vicinal Cu(111) substrate [1,2]. We show that for this bimetallic case, the Co-wire system undergoes a CDW instability leading to a 1-D high-spin system. This type of instability does not appear to have been previously reported for a bi-metallic system, particularly for a chain of Co atoms. Using ab initio theoretical calculations, it is deduced that the CDW instability is spin-induced by way of symmetry breaking in the spin population. This result presents a fundamental electronic-structure mechanism for CDW instability that is distinct from previously reported metal-semiconducting systems [3], in that spin clearly plays an essential role in lowering the energy of the system. Furthermore, the calculations indicate that the high-spin correlated state of the constituent Co atoms is a necessary consequence of this CDW instability. Finally, the ferromagnetic nature of this realized system raises questions with regard to substrate spin mediation, such as the possible role of Kondo and RKKY interaction. [1] N. Zaki et al, Phys. Rev. B 80, 155419 (2009) [2] N. Zaki et al, Phys. Rev. B 83, 205420 (2011) [3] P. C. Snijders and H. H. Weitering, Rev. Mod. Phys. 82, 307 (2010)

10:12AM A13.00012 Spin resonance in Luttinger liquid with spin-orbit interaction, OLEG TRETIKOV, K.S. TIKHONOV, V.L. POKROVSKY, Texas A&M University — The spin-orbit interaction leads to a narrow spin resonance at low temperatures, even in the absence of an external magnetic field [1]. We study the effect of electron-electron correlations on the resonance. These correlations are strong in quantum wires and cannot be neglected. We show that the electron correlations change the shape and width of the resonance and produce an additional weak resonance at the plasmon frequency.

[1] Ar. Abanov, V. L. Pokrovsky, W. M. Saslow, and P. Zhou, arXiv:1008.1225.

10:24AM A13.00013 Telegraph Noise in LSMO Nanowires¹, NICHOLAS BRONN, XIAOQIAN CHEN, University of Illinois at Urbana-Champaign, Department of Physics, Materials Research Laboratory, JASON HOFFMAN, ANAND BHATTACHARYA, Argonne National Laboratory, Center for Nanoscale Materials, PETER ABBAMONTE, NADYA MASON, University of Illinois at Urbana-Champaign, Department of Physics, Materials Research Laboratory — Hole-doped manganites with the perovskite structure exhibit a variety of superlative properties because of close competition among ferromagnetic metallic, paramagnetic insulating, as well as various charge, spin, and orbitally ordered phases. We have recently observed random telegraph noise (RTN) in low-temperature conductance measurements of epitaxially-grown $\text{La}_{2/3}\text{Sr}_{1/3}\text{MnO}_3$ nanowires patterned by electron-beam lithography and ion milling to widths of $\sim 80\text{nm}$. The RTN is apparent at temperatures less than 30K. It is thought that the RTN is the result of domain fluctuations, which are more clearly observable in such narrow wires.

10:36AM A13.00014 Direct Imaging of Non-Adiabatic Spin Torque Effects on Vortex Core Orbits, SHAWN POLLARD, LEI HUANG, Department of Condensed Matter Physics, Brookhaven National Laboratory, NY 11973, KRISTEN BUCHANAN, Department of Physics, Colorado State University, Fort Collins, CO 80523, DARIO ARENA, National Synchrotron Source, Brookhaven National Laboratory, NY 11973, YIMEI ZHU, Department of Condensed Matter Physics, Brookhaven National Laboratory, NY 11973 — Recently high frequency, current induced vortex motion has received a great deal of interest from a spintronic perspective, as it suggests a possible low power, high speed writing process. However, understanding the processes that govern this motion, specifically the relative contributions of adiabatic and non-adiabatic spin torque effects, has been difficult due to experimental constraints. We developed a novel TEM sample stage in which we apply high frequency currents in-situ to excite resonant motion in Permalloy disc structures ($2000 \times 2000 \times 50\text{nm}$) with high spatial resolution ($< 5\text{nm}$ for dynamic measurements). We have imaged the time-averaged vortex trajectory through resonance. We find that the orbital amplitudes are drastically different for clockwise and counterclockwise chiralities, indicating the presence of both Oersted fields and non-adiabatic spin torque effects, and that the orbital size scales linearly with current density varied between $(7.1-10.0) \times 10^{10} \text{ A/m}^2$. These results allow us to extract a value for the non-adiabatic spin torque with unprecedented precision. Additionally, we report on off-resonance effects, such as tilting and variations in the ellipticity of the orbit as it is swept through resonance, with first of their kind experimental observations.

Session A14 GMAG DMP FIAP: Focus Session: Spins in Semiconductors - Magnetic Semiconductors I 212

8:00AM A14.00001 Oxygen Annealing Studies of $\text{SnO}_2\text{:Co}$ Thin Films Deposited by RF Sputtering¹, GRATIELA STOIAN, Florida State University, P.A. STAMPE, R.J. KENNEDY, Florida A&M University, Y. XIN, National High Magnetic Field Laboratory, Tallahassee, S. VON MOLNAR, Florida State University — We report on post-deposition oxygen annealing studies of $\text{SnO}_2\text{:Co}$ thin films to examine the origin of the room temperature ferromagnetism (RTFM) observed in such materials. Materials are deposited on r-cut sapphire substrates by RF sputtering from a doped target with 5 at.% Co nominal concentration. Magnetization measurements reveal that as-grown samples in Ar atmosphere are non-magnetic at RT. However, by annealing them in low O_2 pressure (10^{-4} - 2×10^{-4} Torr), the saturation moment increases to $\sim 0.78 \mu_B/\text{Co}$ at RT, somewhat lower than the expected value for Co^{2+} ions. This verifies that the Co ions are incorporated in the matrix. X-ray diffraction data show a decrease in crystallinity for the most magnetic samples annealed in O_2 at 2×10^{-4} Torr. To confirm this, further structural and temperature-dependent magnetic measurements for various annealing protocols are underway to determine the nature of magnetism in $\text{SnO}_2\text{:Co}$ sputtered thin films.

8:12AM A14.00002 Embedded Ferromagnetic GdN Nano-Islands in GaN by Molecular Beam Epitaxy¹, T.F. KENT, J. YANG, L. YANG, M.J. MILLS, R.C. MYERS, Department of Materials Science and Engineering, The Ohio State University, Columbus, OH — Nano-islands of GdN are embedded into a GaN matrix by plasma-assisted molecular beam epitaxy. X-ray diffractometry shows that the cubic rocksalt islands are (111) oriented to the c-axis of the hexagonal wurtzite GaN matrix. Cross-sectional scanning transmission electron microscopy allows for the study of island formation, which occurs after 1.2 monolayers of GdN coverage, forming discrete particles, which the GaN matrix grows epitaxially around. Magnetometry reveals two ferromagnetic phases, one due to the GdN particles with Curie temperature of 70K and an anomalous phase with ferromagnetism persistent to room temperature. This room temperature ferromagnetic phase is strongly anisotropic, with out of plane magnetization nearly 300% larger than in-plane at fields less than 1T. Optical characterization reveals that GdN, when strained to GaN, is a semiconductor with direct and indirect bandgaps at 1.2eV and 0.75eV, respectively.

8:24AM A14.00003 Synthesis and Characterization of Co-doped ZnO Dilute Magnetic Semiconducting Nanorods¹, N. DAS, S. KHANRA, S. BHAMIDIPATI, K. MANIVANNAN, P. KAHOL, K. GHOSH, Missouri State University, DEPARTMENT OF PHYSICS ASTRONOMY AND MATERIALS SCIENCE TEAM — Transition-metal doped ZnO dilute magnetic semiconducting nanomaterials are considered as ideal systems for carrying out research in the field of spintronics as they can successfully combine magnetism and electronics in a single substance. ZnO is a wurtzite-type wide-bandgap semiconductor of the II-VI semiconductor group with band gap energy of 3.37 eV. Hydrothermal synthesis of undoped ZnO and Co-doped ZnO nanorods is carried out using aqueous solutions of $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, $\text{Co}(\text{C}_2\text{H}_3\text{OO})_2 \cdot 4\text{H}_2\text{O}$, and using NH_4OH as hydrolytic catalyst. Nanomaterials of different sizes and shapes were synthesized by varying the process parameters such as molarity (0.15M, 0.3M, 0.5M) and pH (8-11) of the precursors, growth temperature (130°C), and annealing time during the hydrothermal Process. Structural, morphological, optical and magnetic properties are studied using various techniques such as XRD, SEM, UV-vis spectroscopy, and SQUID magnetometer. XRD and SEM studies reveal nanorods with hexagonal wurtzite structure with length in the range of 200 to 500 nm, and cross section in the range of 30 to 60 nm. Detailed structural, optical, and magnetic properties will be discussed in this presentation.

8:36AM A14.00004 Defect-Induced High- T_C Ferromagnetism and Spinodal Nanodecomposition in MgO, MASAYOSHI SEIKE, Grad. School of Eng. Sci., Osaka Univ. and Cent. Research Labs., Sysmex Corp., TETSUYA FUKUSHIMA, KAZUNORI SATO, HIROSHI KATAYAMA-YOSHIDA, Grad. School of Eng. Sci., Osaka Univ. — Based on a first-principles study of the magnetic properties of MgO with Mg vacancies [1,2], we calculated the electronic structures and exchange coupling constants for Monte Carlo Simulation (MCS) of the Curie temperature (T_C). We also performed MCS of the spinodal nanodecomposition based on the calculated chemical pair interactions between the vacancies. In this study, it was found that hole-doping by Mg vacancies leads to a ferromagnetic ground state, invoking long-range magnetic interaction, and that T_C can reach room temperature at sufficient vacancy concentrations of 15 at.% under a homogeneously distributed condition. However, it was also found that the chemical pair interactions between vacancies are significantly attractive and that the system can form super-paramagnetic clusters of vacancies with strong ferromagnetic coupling in the clusters. These results suggest that, by the spinodal nanodecomposition, the T_C or blocking temperature (T_B) can be enhanced and reach room temperature at smaller vacancy concentrations compared with those estimated for room-temperature ferromagnetism under the homogeneous distribution condition.

8:48AM A14.00005 Gd in GaN: the role of magnetic vacancy clusters¹, ALEXANDER THIESS, PETER H. DEDERICH, STEFAN BLÜGEL, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, 52425 Jülich, Germany, WALTER R.L. LAMBRECHT, Department of Physics, Case Western Reserve University, Cleveland, Ohio 44106-7079, USA — Five years after the experimental discovery of colossal magnetic moments and ferromagnetic ordering above room temperature in gadolinium doped gallium nitride the identification of its microscopic origin is still not accomplished. Here, we are proposing a new model explaining the origin: the clustering of magnetic gallium vacancies. First, we show that such clustered gallium vacancies indeed can preferentially occur by utilizing a simplified growth model, for which we provide the input by large-scale first-principles Green function calculations. The same calculations reveal that the dangling bond nitrogen states around gallium vacancies become significantly spin-polarized. Moreover, we are able to extract a rich set of information on the magnetic exchange interactions between those spin-polarized atoms. These exchange interactions are the basis for our study on the thermal behavior of magnetic vacancy clusters by means of Monte-Carlo simulations. We present the resulting magnetic properties of our simulations and highlight important similarities to the experiment that all point at gallium vacancy clusters as the origin of the experimentally observed magnetic properties in GaN:Gd.

9:00AM A14.00006 Photoluminescence studies of various magnetic phases in (Zn,Mn)Te/ZnSe QDs¹, JOSEPH MURPHY, LARS SCHWEIDENBACK, BIPLOB BARMAN, RAFAL OSZWALDOWSKI, ALEXANDER CARTWRIGHT, BRUCE MC-COMBE, ATHOS PETROU, IGOR ZUTIC, SUNY at Buffalo, Buffalo, NY, IAN SELLERS, University of Oklahoma, Norman, OK, WEN CHUNG CHOU, WU-CHING FAN, National Chiao Tung University, Hsinchu, Taiwan — We have carried out a magneto-PL study of a single layer of (Zn,Mn)Te/ZnSe quantum dots. The CW PL from a previously studied 5 layer sample exhibits high circular polarization but very small Zeeman splitting. Time-resolved PL exhibited a temperature independent temporal red shift, associated with the magnetic polaron formation. These data have been interpreted as due to the presence of an antiferromagnetic phase for the Mn ions. In the present study, the CW magneto-PL spectra exhibit high circular polarization, but significantly larger Zeeman splittings. Furthermore the Zeeman splitting depends strongly on temperature and vanishes at 50 K. These results indicate the presence of a different magnetic phase for the Mn ions in the single layer QD sample. Time-resolved PL experiments suggest the formation of magnetic polarons in this sample.

9:12AM A14.00007 Controlling Curie Temperature of (GaMn)As Through Location of the Fermi Level Within the Impurity Band¹, MARGARET DOBROWOLSKA, University of Notre Dame — This talk will address the unresolved issue of ferromagnetism in the ferromagnetic semiconductor GaMnAs, a material whose understanding is of central importance to semiconductor-based spintronics. The above unresolved issue concerns the question of whether the ferromagnetic order in GaMnAs is mediated by valence band holes or by holes residing in the impurity band. The results to be presented are based on the investigation of a wide range of GaMnAs samples using a comprehensive set of experiments that include magnetization, electrical transport and magneto-optics, along with studies of microscopic composition by channeling Rutherford back-scattering and particle-induced x-ray emission. These experiments show unambiguously that the holes underlying ferromagnetic order in GaMnAs reside in the impurity band; and that it is not only the concentration of Mn and of holes, but also the specific location of the Fermi level in the impurity band that establishes the Curie temperature of this material. Specifically, we show that having the Fermi level near the middle of the impurity band, where the states are most extended, is more important for raising T_c than increases in the effective Mn or hole concentrations. Since the location of the Fermi level can be controlled by a variety of means both during and after growth, this new understanding automatically provides practical guidelines for increasing the critical temperature.

9:48AM A14.00008 Interstitial Cu Codoping Method for High Curie Temperature (Ga,Mn)As, HITOSHI FUJII, KAZUNORI SATO, HIROSHI KATAYAMA-YOSHIDA, Department of Materials Engineering Science, Graduate School of Engineering Science, Osaka University, Japan, LARS BERGQVIST, Retired Department of Materials Science and Engineering, KTH Royal Institute of Technology, SE-100 44 Stockholm, Sweden, PETER H. DEDERICH, Peter Gruenberg Institut, Forschungszentrum Juelich, D-52425 Juelich, Germany — Based on first principles calculations, we propose a solubility control method of magnetic impurities in dilute magnetic semiconductors (DMSs). We show that donor atoms, such as Cu, introduced at the interstitial sites in GaAs enhance the solubility of Mn. As a result, Mn can be doped to more than 20 percent in GaAs in the thermal equilibrium condition [1]. Due to the carrier-induced nature of the ferromagnetism in DMSs, the ferromagnetism is suppressed because of the compensation of hole from Mn acceptors by the codoped interstitial Li or Cu. In order to recover the ferromagnetism, we propose low temperature annealing after crystal growth to remove only the interstitials. Our NEB (Nudged Elastic Band method) calculation results show that the effective migration barrier of Cu in GaMnAs is about 0.2eV. This value is small compared with the migration barrier of Li in GaMnAs (about 0.5eV). Even if Li, it is possible to diffuse Li in (Ga_{0.7}Mn_{0.3})As at 0.12 micron in 24 hours [2]. In case of Cu, therefore, we can expect further annealing distance than Li case because of the low migration barrier.

10:00AM A14.00009 Tight binding study of single ion magnetic anisotropy of Mn²⁺ in Ga(Mn)As¹, HEMACHANDER SUBRAMANIAN, JONG HAN, University at Buffalo, State University of New York — Bulk uni-axial magnetic anisotropy of Ga(Mn)As observed in experiments has not been well understood as much as cubic magnetic anisotropy in the same material. We propose that the uni-axial anisotropy arises due to the coupling of local lattice distortions around Mn²⁺ impurity ion to its spin state through spin-orbit coupling of holes bound to the impurity ion. We model the coupling using nearest-neighbor tight-binding and many-body perturbation theory. The model includes intra-atomic Coulomb interaction inside Mn²⁺ ion, spin-orbit interaction of holes at the Γ point, $p-d$ hopping interaction between Mn²⁺ ion d orbitals and As ion p orbitals, and strain due to local lattice distortions. We observe breaking of tetrahedral symmetry around the Mn²⁺ ion when the system is paramagnetic. We explore the effect of this broken symmetry in stabilizing certain magnetization directions through spin-orbit coupling in the ferromagnetic regime.

10:12AM A14.00010 Infrared to visible magneto-optical effects in (Ga,Mn)As, N. TESAROVA, C.T. ELLIS, G. ACBAS, A. MUKHERJEE, K. VYBORNÝ, J. CERNE, Physics Dept., University at Buffalo, SUNY, J. SUBRT, T. OSTATNICKY, P. NEMEC, Faculty of Mathematics and Physics, Charles University in Prague, Czech Rep., V. NOVAK, Institute of Physics ASCR, v.v.i., Prague, Czech Rep., J. SINOVA, Dept. of Physics, Texas A&M Univ., College Station, TX — (Ga,Mn)As is perceived as a model material for future low-power spintronics devices due to its carrier mediated ferromagnetic properties. Despite the extensive theoretical and experimental studies, the energy band structure and the mechanism of ferromagnetic order (of Mn spins) still remains a matter of controversy [Ohya, Nature Physics 2011; Jungwirth, PRL 2010]. In our study, we employ magneto-optical Faraday and Kerr measurements to probe the character of the states near the Fermi energy, which is expected to be responsible for Mn-ordering. We also study the spectral dependence of magnetic linear dichroism that is mainly sensitive to the states mediating the Mn-Mn interaction [Kimel, PRL 2005]. The measurements are performed from the infrared to visible range (100 – 2600 meV) on high quality samples with different Mn concentration (1.5 – 14 %) with Curie temperatures up to 190 K. The results are compared with the predictions of $k \cdot p$ theory with antiferromagnetic $p-d$ exchange. We acknowledge the financial support provided by NSF-DMR1006078 and Faculty of Mathematics and Physics, Charles University in Prague.

10:24AM A14.00011 Spin-Transfer-Torque Driven Domain Wall Motion in (Ga,Mn)(As,P), E.K. VEHSTEDT, Dept of Physics & Astronomy, Texas A&M Univ; Inst of Physics, ASCR vvi, L.P. ZARBO, Inst of Physics, ASCR vvi, K. VYBORNÝ, Dept of Physics, SUNY Buffalo; Inst of Physics, ASCR vvi, E. DE RANIERI, Hitatch-Cambridge Laboratory, Uni of Cambridge, H.G. KATZGRABER, Dept of Physics & Astronomy, Texas A&M Univ; ETH Zurich, J. WUNDERLICH, Hitatch-Cambridge Laboratory, Uni of Cambridge; Inst of Physics, ASCR vvi, T. JUNGWIRTH, Inst of Physics, ASCR vvi; School of Physics & Astronomy, Uni of Nottingham, J. SINOVA, Dept of Physics & Astronomy, Texas A&M Univ; Inst of Physics, ASCR vvi — Precise control of domain wall (DW) motion in magnetic materials is a prerequisite for the realization of novel non-volatile and down-scalable logic/memory devices which promise to overcome the limitations of current technologies. While magnetic fields are the obvious choice for DW manipulation, in spin-orbit (SO) coupled materials, electric fields provide an additional means of control via current-induced spin torque. We extend the existing theoretical framework used to describe magnetization dynamics in uniform ferromagnets (FM) to dilute FM semiconductors. Analogous to the study of homogeneous systems, we compute the current-induced internal fields (CIF) corresponding to the spin torques and perform a quantitative analysis of the effect of CIFs on DW motion by solving the phenomenological Landau-Lifshitz-Gilbert equations. Microscopic calculations based on an accurate description of the SO coupling effects are used to estimate the observed anisotropies. Our theoretical efforts are complemented by experimental studies in the SO coupled FM (Ga,Mn)(As,P).

10:36AM A14.00012 Magnetic properties of Ga_{1-x}Mn_xAs/Ge heterojunctions, JONATHAN LEINER, XINYU LIU, JACEK FURDYNA, MARGARET DOBROWOLSKA, University of Notre Dame — It has been shown that the incorporation of Mn in substitutional and interstitial positions of GaAs is linked to the Fermi level of GaMnAs during the growth [1]. Additionally, experiments with samples that are doped with either Be or Si reveal the role of the Fermi level in determining T_c [2]. To further investigate this effect, we deposited Ge in varying thicknesses on top of GaMnAs layers. Germanium is very nearly lattice matched to GaMnAs, and the valence band offset of the two materials (~0.54 eV) places the top of the valence band as well as the Mn acceptor level of GaMnAs significantly below the top of the valence band of Ge. Thus, when Ge is grown on GaMnAs, the incorporation of Mn has already been fixed during its growth, but the holes are drained off into Ge. SQUID measurements on these samples show that the T_c of the GaMnAs drops very rapidly when layers of Ge are deposited over it, the decrease in T_c scaling roughly with the thickness of the Ge layers. This behavior is consistent with the expected “draining away” of holes from the GaMnAs layer into the Ge. Results of our efforts to fine-tune the amount of holes removed from GaMnAs by Ge will be presented.

10:48AM A14.00013 Spin-dependent Transport in GaAs/MnAs Core/shell Nanowires, JING LIANG, JIAN WANG, A. PAUL, B.J. COOLEY, D.W. RENCH, N.S. DELLAS, S.E. MOHNEY, R. ENGEL-HERBERT, N. SAMARTH, Center for Nanoscale Science and Materials Research Institute, Penn State University, University Park PA 16802 — Hybrid GaAs/MnAs core/shell nanowires synthesized by molecular beam epitaxy [APL 97, 072505 (2010)] are of potential interest for proof-of-concept room temperature nanospintronics applications. Magnetic order in these nanostructures is directly influenced by a unique competition between the magnetocrystalline and shape anisotropies in MnAs. We report four probe measurements of the temperature dependence of the resistivity and the anisotropic magnetoresistance (AMR) in single nanowires over a temperature range 1 K - 300 K and in magnetic fields ranging up to 80 kOe, applied both parallel and perpendicular to the nanowire axis. We used the measured AMR in conjunction with micromagnetic simulations to reveal the detailed magnetization reversal process in the MnAs nanoshell. The micromagnetic simulations also provide insights into interesting structures for spin engineering at the nanoscale. Supported by NSF-MRSEC and ONR.

Monday, February 27, 2012 8:00AM - 11:00AM — **Session A15 DMP FIAP GMAG: Focus Session: Spins in Metals - Thermal Effects on Magnons and Spin Currents** 213

8:00AM A15.00001 Theory of phonon-driven spin Seebeck effect, HIROTO ADACHI, Japan Atomic Energy Agency, JUN-ICHIRO OHE, Toho University, SABURO TAKAHASHI, Tohoku University, SADAMICHI MAEKAWA, Japan Atomic Energy Agency — Spin Seebeck effect refers to a thermal spin injection occurring over millimeter scales from a ferromagnet into an attached nonmagnetic metal [Uchida et al., Nature 455, 778 (2008)]. We discuss the importance of the phonon-drag process in the spin Seebeck effect. Our theory of phonon-drag spin Seebeck effect [Adachi et al., Appl. Phys. Lett. 97, 252506 (2010)] explains simultaneously the local nature of the spin Seebeck effect [Jaworski et al., Nature Materials 9, 898 (2010); Uchida et al., Nature Materials 10, 737 (2011)] and the signal enhancement at low temperatures [Jaworski et al., Phys. Rev. Lett. 106, 186601 (2011)]. We also discuss the difference between our approach and that developed in Xiao et al., Phys. Rev. B 81, 214418 (2010).

8:12AM A15.00002 Spin Seebeck Effect Measurements on Ferromagnetic Thin Films Using Micromachined Thermal Isolation Platforms, AZURE D. AVERY, DAIN BASSETT, University of Denver, MATT R. PUFALL, NIST, Boulder, CO, BARRY L. ZINK, University of Denver — The newly discovered thermoelectric effect, called the spin Seebeck effect (SSE), refers to a spin imbalance generated by a thermal gradient. This spin imbalance, capable of driving a pure spin current into a contact, is detected by measuring the conversion of the spin current into a transverse voltage (V_T) via the inverse spin Hall effect. A robust theoretical treatment of the SSE has so far eluded the community at large, and more experimental data are needed to understand the underlying physics. In this talk we present V_T measurements associated with the SSE and AMR measurements for Ni, Fe, and Ni-Fe alloy thin films, along with Au as a control, made using our micromachined thermal isolation platforms. The sensitive thermal transport measurements we make using these platforms offer several advantages including concurrent measurements at hot and cold ends of the sample, equal heating of the sample ends to isolate traditional thermoelectric effects, and a large reversible thermal gradient. Additionally, the substrate thickness results in a virtually 2-D thermal platform that dramatically reduces the likelihood of thermal gradients perpendicular to the sample.

8:24AM A15.00003 Search For Spin Seebeck effect in in situ grown thin films¹, PRIYANGA JAY-ATHILAKA, DUSTIN BELYEA, HILLARY KIRBY, CASEY W. MILLER, Department of Physics, University of South Florida, SPINLAB TEAM — The Spin Seebeck Effect (SSE) is a phenomenon in which the application of a temperature gradient across a ferromagnet causes a measurable electric potential difference transverse to the gradient when a normal metal is grown onto the ferromagnet. The spin current diffusing into the normal metal is transduced to a voltage via the Inverse Spin Hall Effect. Measuring the SSE accurately is challenging due to presence of other effects, possibly including regular Seebeck effect and anomalous thermo-magnetic phenomena. Here we report on our efforts to measure the SSE in thin films of NiFe and Co, using Au and Ta as the electrodes. All samples were grown on Si/SiO_x substrates by magnetron sputtering through contact masks. The mask exchange was done in situ in a chamber where the base pressure was 2.0x10⁻⁷ Torr in order to limit contamination of the interfaces. The samples were measured using a rig with a reversible temperature gradient of 15K/cm and the resultant voltage was measured at the hot and cold ends of the sample using nanovoltmeters. The voltage signal we observe is strongly correlated with the magnetic hysteresis loops measured by Magneto-Optical Kerr Effect magnetometer.

¹Supported by NSF

8:36AM A15.00004 Intrinsic spin-dependent thermal transport¹, C.L. CHIEN, Department of Physics and Astronomy, The Johns Hopkins University — Spin caloritronic effect, such as spin Seebeck effect, has attracted a great deal of attention recently. In most cases such studies have been made on patterned ferromagnetic thin films on substrates. The mechanism of spin Seebeck effect has evolved from intrinsic difference in the spin chemical potentials to magnon-phonon interaction through the substrate. We use patterned ferromagnetic thin film to demonstrate the profound effect of a substrate on the spin-dependent thermal transport. With different sample patterns and on varying the direction of temperature gradient, both longitudinal and transverse thermal voltages exhibit asymmetric instead of symmetric spin dependence. This unexpected behavior is due to an out-of-plane temperature gradient imposed by the thermal conduction through the substrate and the mixture of the anomalous Nernst effects. Only with substrate-free samples have we determined the intrinsic spin-dependent thermal transport with characteristics and field sensitivity similar to those of anisotropic magnetoresistance effect.

¹In collaboration with S. Y. Huang (JHU), W. G. Wang (JHU), S. F. Lee (IoP, Academia Sinica in Taiwan), and J. Kwo (NTHU and NTU in Taiwan). This work has been supported by the US NSF grant DMR 05-20491 and the Taiwan NSC grant 99-2911-I-007-510.

9:12AM A15.00005 Thermoelectric coating based on the spin Seebeck effect, AKIHIRO KIRIHARA, NEC Corporation, KEN-ICHI UCHIDA, YOSUKE KAJIWARA, Tohoku University, MASAHICO ISHIDA, YASUNOBU NAKAMURA, TAKASHI MANAKO, SHIGERU KOHMOTO, NEC Corporation, EIJI SAITOH, Tohoku University, SHINICHI YOROZU, NEC Corporation — Thermoelectric (TE) technologies have been drawing great interest, since they can directly generate electricity from thermal energy that is available in various places. However, their complicated module structure, which is based on a number of thermocouples, still makes it difficult to fabricate large-area TE devices at low cost. In this work, we show a novel concept based on the spin Seebeck effect (SSE) called TE coating, which is characterized by a simple film structure, convenient scaling capability, and easy fabrication. We fabricated a TE-coating film with a bismuth-substituted yttrium iron garnet (Bi:YIG) by a highly productive spin-coating-based process on a nonmagnetic substrate, and demonstrated the SSE-induced TE conversion. The TE-coating layer amounts to only 0.01 % of the total sample thickness, suggesting that such an ultrathin magnetic film can work as a useful thermal-energy collector. This new concept may enable us to implement low-cost and large-area TE functions on various objects, opening opportunities for innovative energy harvesting applications.

9:24AM A15.00006 Linear response theory for magnon transport in ferromagnetic insulators, SHUICHI MURAKAMI, RYO MATSUMOTO, Tokyo Institute of Technology — We study transverse response of magnons in ferromagnetic insulators within linear response theory. In analogy with the corresponding theory for electrons [1], magnon transverse response is described, including the Hall effect, Nernst effect, and thermal Hall effect. As is also the case for electrons [1], the response functions for magnons consist of the Kubo-formula term, and the term corresponding to the orbital angular momentum. We can rewrite the response functions in terms of the Berry curvature in momentum space [2]. We apply this theory to the (quantum-mechanical) magnons and to the classical magnetostatic waves. For the magnetostatic waves, the eigenmodes are given by a generalized eigenvalue problem, giving rise to the special form of the Berry curvature [2]. We explain various properties of this Berry curvature for the generalized eigenvalue problem, and discuss its implications for the physical properties of magnetostatic modes. [1] L. Smrcka and P. Streda, J. Phys. C, 10, 2153 (1977); H. Oji, P. Streda, Phys. Rev. B 31, 7291 (1985); [2] R. Matsumoto and S. Murakami, Phys. Rev. Lett. 106, 197202 (2011); Phys. Rev. B 84, 184406 (2011).

9:36AM A15.00007 Thermally-assisted magnetization reversal in nanomagnets with spin-transfer torque: a GPU approach, DANIELE PINNA, ANDREW KENT, ADITI MITRA, DANIEL STEIN, New York University — Spin transfer magnetization reversal has a direct impact on magnetic information storage technologies. The probability that a nanomagnet switches under an applied magnetic field is expected to follow a simple thermally activated LLG model¹. However, a direct current applied to a nanomagnet produces a spin-transfer torque that drives the magnetization out of equilibrium². Such dynamics have been studied in limits where both the low and high current regimes allow analytical treatment³. Nonetheless, the inability to study numerically the long time behavior has hampered with theoretical verification and comparison to current experimental data⁴. In this talk, we present results obtained by employing modern GPU computational techniques to massively parallelize the Langevin equations of the model. We test the numerics by considering a simplified uniaxial case. The full current spectrum is reviewed, verified and compared to the present literature. We then proceed to break the symmetries in the problem and explore the general macrospin model.

9:48AM A15.00008 Can heat flow induced spin currents move a magnetic domain wall?, AAKASH PUSHUP, TIMOTHY PHUNG, LUC THOMAS, KONSTANTINOS ALEXANDROU, XIN JIANG, SEE-HUN YANG, BRIAN HUGHES, CHARLES RETTNER, STUART PARKIN, IBM Almaden Research Center — It has been established in the past few years that heat flow within a ferromagnet can induce a spin current and an associated voltage. This Spin Seebeck effect, initially reported in ferromagnetic metals, has also been observed in magnetic semiconductors as well as magnetic insulators. An open question has been whether heat flow induced spin currents can also move magnetic domain walls in 'racetrack' magnetic nanowires. In order to answer this question, we investigate the interaction of a magnetic domain wall with spin currents induced by sharp temperature gradients in magnetic nanowire spin valves. We use optical as well as electrical techniques to create sharp temperature gradients on the order of 1-10 K/nm on nanosecond timescales. We will describe our experimental setup and present data that show the various roles that temperature plays on the saturation magnetization of the material as well as on the induced spin currents that influence magnetic domain wall motion.

10:00AM A15.00009 Observation of spin-wave cooling effect in magnets, TOSHU AN, KEN-ICHI UCHIDA, KAZUYA HARI, YOSUKE KAJIWARA, KAZUYA YAMAGICHI, M.B. JUNGFLISCH, The Institute for Materials Research, Tohoku University, A.V. CHUMAK, V.I. VASYUCHKA, BURKARD HILLEBRANDS, Technische Universität Kaiserslautern, Germany, EIJI SAITOH, The Institute for Materials Research, Tohoku University — We focused on utilizing a surface spin wave (Damon-Eshbach mode); traveling on top and bottom surfaces in a non reciprocal manner, as a good carrier of heat. As a sample, Yttrium iron garnet (YIG) was chosen because the spin waves excited in the YIG is known to have a long coherence length propagating distances even a few millimeters. By exciting the surface spin wave of only one side, heat transportation was successfully observed by measuring sample temperature with an infrared thermocamera. More interestingly, the temperature where the spin wave is initially excited shows cooling effect to drop its temperature just after the excitation of the surface spin wave. Here we call this effect as microwave cooling effect which is introducing a new cooling principle.

10:12AM A15.00010 Thermodynamics of magnetic systems from first principles, MARKUS EISENBACH, Oak Ridge National Laboratory, GREGORY BROWN, Florida State University, AURELIAN RUSANU, University of Tennessee, DON M. NICHOLSON, Oak Ridge National Laboratory — Density functional calculations have proven to be a useful tool in the study of ground state properties of many materials. The investigation of finite temperature magnetism on the other hand has to rely usually on the usage of empirical models that allow the large number of evaluations of the system's Hamiltonian that are required to obtain the phase space sampling needed to obtain the free energy, specific heat, magnetization, susceptibility, and other quantities as function of temperature. We have demonstrated a solution to this problem that harnesses the computational power of today's large massively parallel computers by combining a classical Monte-Carlo calculations with our first principles multiple scattering electronic structure code (LSMS) for constrained magnetic states. Here we will present recent advances in our method that improve the convergence as well as applications to 3d element based ferromagnets. This research was performed at Oak Ridge National Lab and sponsored in parts by the Center for Nanophase Material Sciences, Scientific User Facilities Division, the Center for Defect Physics, an Energy Frontier Research Center funded by the US DOE Office of Basic Energy Sciences and the Division of Materials Science and Engineering, Office of Basic Energy Science of

10:24AM A15.00011 Effect of Temperature and Spin Torque on the Stoner-Wohlfarth Astroid of a Nanomagnet, YU-JIN CHEN, University of California, Irvine, JORDAN KATINE, Hitachi Global Storage Technologies, JUERGEN LANGER, Singulus Technologies, MARK LEWIS, University of California, Los Angeles, GRAHAM ROWLANDS, JIAN ZHU, University of California, Irvine, PEDRAM KHALILI AMIRI, KANG WANG, University of California, Los Angeles, ILYA KRIVOROTOV, University of California, Irvine — We report measurements of the Stoner-Wohlfarth switching astroid curves of the free layer nanomagnet in CoFeB/MgO/CoFeB/Ru/CoFe/PtMn elliptical nanoscale magnetic tunnel junctions made as a function of applied voltage and temperature. Measurements of the astroid area as a function of temperature allow us to determine the magnetic anisotropy energy barrier of the free layer and thereby quantify its thermal stability - an important performance parameter of spin torque nonvolatile magnetic memory. Measurements of the astroid as a function of voltage (V) applied to the junction at the bath temperature of 4 K reveal significant voltage-induced deformations of the astroid curve. We observe a decrease of the hard-axis length of the astroid, which arises from ohmic heating of the junction. Comparison of the hard-axis astroid length measured at $T = 4$ K and $-V \rightarrow 0$ to the hard-axis astroid length measured at $T \rightarrow 4$ K and $V = 0$ allows us to quantify ohmic heating of nanoscale tunnel junctions by the applied voltage. The applied voltage reduces the easy-axis length of the astroid as well, but the reduction is asymmetric for positive and negative easy-axis directions. This easy-axis asymmetry reverses upon the applied voltage sign reversal and thus it can be attributed to spin transfer torque.

10:36AM A15.00012 Magnetization dynamics at elevated temperatures¹, LEI XU, SHUFENG ZHANG, The University of Arizona — The conventional Landau-Lifshitz (LL) equation is the basis for simulation of magnetic structure and dynamics as long as the temperature is not too close to Curie temperature. In order to model the magnetization dynamics at elevated temperatures, one needs to extend the LL equation by including a finite longitudinal relaxation. Here within the self-consistent mean-field treatment of ferromagnetism, we propose an effective equation which is capable of addressing magnetization dynamics for a wide range of temperatures. At low temperatures, the equation reduces to the Landau-Lifshitz equation, namely, the transverse relaxation governs the dynamics. At high temperatures, it reduces to paramagnetic Bloch equation. Near the Curie temperature, the longitudinal relaxations play a more important role on the magnetization reversal. We present numerical calculations to simulate a heat-assisted-magnetic-recording process when the temperature is heated and cooled through the Curie temperature.

10:48AM A15.00013 Temperature dependence of magnetic losses in GMR and TMR devices¹, KEVIN HAUGHEY, RYAN STEARRETT, ARIF OZBAY, EDMUND NOWAK, University of Delaware — Thermally induced magnetization fluctuations in the free and reference magnetic layers of giant and tunneling magnetoresistance (GMR and TMR) spin valves (SV) devices typically give rise to a low-frequency 1/f power spectral density that has been related to local dissipative processes [1]. Understanding the origin of these magnetic losses is essential for increasing the magnetic field sensitivity of GMR and TMR sensors. The low-frequency magnetic losses can be parameterized through a loss angle, $\varepsilon(T, H)$. $\varepsilon(T)$ for the reference layer in our GMR SV is non-monotonic: first decreasing with increasing T, then exhibiting a minimum near 50K and what may be the onset of a plateau or peak near 300K. The peak and minimum shift to lower temperatures when the applied field is oriented perpendicular to the exchange pinning direction. Data for TMR devices show similar trends. The measurements will be described in the context of a model involving thermally activated kinetics and a field-dependent distribution of activation energies for the nanoscale magnetic fluctuators.

Monday, February 27, 2012 8:00AM - 11:00AM – Session A16 DCMP: Liquid and Solid Helium 251

8:00AM A16.00001 Solid helium in rigid torsional oscillators¹, D.Y. KIM, M.H.W. CHAN, Department of Physics, The Pennsylvania State University, University Park, PA 16802, USA — In torsional oscillator experiments on solid helium, separating out the effect of shear modulus stiffening is important to measure true non-classical rotational inertia (NCRI). An increase in the shear modulus of solid helium stiffens the oscillator and causes the resonant period to drop thus mimicking NCRI. This effect can be multiplied in a torsional oscillator that is not completely rigid. We have carried out measurements in torsional oscillators specially designed to minimize the shear modulus effect. These oscillators are different from conventional ones in two aspects. Annulus sample spaces are located in the outermost part from rotational axes and all other parts consist of rigid metal. In this design, the resonant period change by loading solid helium is maximized and the effect of shear modulus change is minimized. We found a NCRI fraction on the order of 3×10^{-5} in these torsional oscillators.

¹Support for this experiment was provided by NSF Grants No. DMR 1103159.

8:12AM A16.00002 Thermal Conductivity of Solid ⁴He in Vycor¹, ZHIGANG CHENG, SAMHITA BANAVAR, STEFAN T. OMELCHENKO, MOSES H.W. CHAN, The Pennsylvania State University — In addition to non-classical rotational inertia (NCRI) observed in torsional oscillator (TO), we have carried out thermal conductivity measurement of solid ⁴He embedded in porous Vycor glass to search for possible anomaly related to the onset of NCRI. Because of the high thermal conductivity of bulk solid ⁴He, it is difficult to resolve any small 'extra' thermal conductivity signal due to the onset of supersolidity. However, when it is confined in porous Vycor, the thermal conductivity of solid ⁴He is significantly reduced. This makes it easier to single out possible anomaly. Preliminary measurements show a rounded peak in the thermal conductivity near 0.1 K.

¹This work is supported by NSF Grants No. DMR 1103159

8:24AM A16.00003 NMR studies of very dilute concentrations of ³He in solid ⁴He, SUNG SU KIM, C. HUAN, L. YIN, J. XIA, Department of Physics and National High Magnetic Field Laboratory, University of Florida, D. CANDELA, Department of Physics, University of Massachusetts, N. S. SULLIVAN, Department of Physics and National High Magnetic Field Laboratory, University of Florida — We compare the results of recent measurements of the nuclear spin-lattice relaxation time (T_1) and nuclear spin-spin relaxation time (T_2) for very dilute concentrations of ³He ($16 \leq x_3 \leq 2000$ ppm) in solid ⁴He with results from previous studies in the temperature range where the relaxation is attributed to the quantum tunneling of ³He atoms in the ⁴He lattice. The comparison shows that the results cannot be explained in terms of a unique correlation time and the effects of ⁴He lattice are important.

8:36AM A16.00004 Observation of superfluid components in solid ^4He ¹, HANS LAUTER, SNS-ORNL, ECKHARD KROTSCHKE, University at Buffalo SUNY Buffalo, EFIM KATS, Institut Laue Langevin France, ALEXANDER PUCHKOV, IPPE Obninsk Russia, VALERIA LAUTER, SNS-ORNL, VESA APAJA, University of Jyväskylä Finland, IVAN KALININ, IPPE Obninsk Russia, MAREK KOZA, Institut Laue Langevin France — Neutron scattering demonstrated that localized superfluid components exist at high pressure within solid helium in aerogel [1]. Two sharp phonon-roton spectra are clearly distinguishable from modes in bulk superfluid helium. These roton excitations exhibit different roton gap parameters than the roton observed in the bulk fluid at freezing pressure. One of the roton modes disappears after annealing. Comparison with theoretical calculations suggests that the model that reproduces the observed data best is that of superfluid double layers within the solid and at the helium-substrate interface. The elastic scattering evidenced in addition to the hcp phase also the bcc-phase. both consisting of a small crystallites as a consequence of the confinement. The structural aspect of coexisting hcp and bcc phases in the aerogel matrix seems to be important for the creation of the localized superfluid components.

8:48AM A16.00005 Evidence for a BCC to HCP Phase Transition for Solid Helium in Porous Vycor Glass at 100 bar and 800 mK¹, LAURENCE LURIO, SAMBUNATH BERA, JONATHAN MALONEY, Department of Physics Northern Illinois University, NORBERT MULDER, Department of Physics, University of Delaware, ZHIGANG CHENG, MOSES CHAN, Department of Physics, Pennsylvania State University, CLEMENT BURNS, Department of Physics, Western Michigan University, ZHAN ZHANG, Argonne National Laboratory — In 2004, Kim and Chan² found evidence that solid helium grown in porous vycor glass exhibited changes in rotational inertia at millikelvin temperatures similar to that observed for superfluids. The nature of this putative supersolid phase is a question of current debate. Subsequent experiments have shown that supersolid behavior depends strongly on crystal quality. For the case of solid helium in vycor, little is known about the crystal quality, or even the crystal phase. In the present work we have performed transmission x-ray diffraction experiments on solid helium in porous vycor glass, over a range of pressures from 1 bar to 162 bar. At pressures up through 96 bar a single peak is observed in the diffraction pattern. At 114 bar and above this peak is observed to split into three peaks. We tentatively identify the low pressure phase as BCC and the high pressure phase as coexistence between BCC and HCP. We interpret the absence of higher order peaks as due to a combination of zero-point motion and defects.

9:00AM A16.00006 Simultaneous observation of 10 MHz ultra sound in solid ^4He contained in torsional oscillator¹, BETTINA HEIN, University of Wuerzburg, JOHN GOODKIND, UCSD, HARRY KOJIMA, Rutgers University — Kim and Chan[1] were motivated in part by an anomalous ultra sound propagation observed by Ho et al.[2] in solid ^4He near 200 mK to carry out torsional oscillator(TO) experiments which led to the discovery of supersolid phenomena. We constructed a 270 Hz TO oscillator which incorporated quartz transducers for simultaneously observing 10 MHz longitudinal ultra sound and torsional oscillation of solid ^4He samples. We are searching for correlation between behaviors in ultra sound propagation and TO response. The length and density of dislocations extracted from ultra sound and the frequency shifts of TO measured in some half a dozen solid ^4He samples have not shown clear correlation.

9:12AM A16.00007 More on the shear modulus of solid helium¹, NORBERT MULDER², University of Delaware — In experiments on solid ^4He one finds a striking similarity between the response of torsional oscillators and the shear modulus. It has been suggested that in fact the observed increase in the torsional oscillator frequency at low temperature is just a reflection of the stiffening of the solid helium, and thus that of the oscillator as a whole. In some cases this may indeed be the case, but a recent experiment by Keiya Shirahama and Eunseong Kim's groups in which a measurement of the shear modulus was incorporated in a torsional oscillator cell seemed to indicate that the response of the solid to shear is decoupled from that of the oscillator. However, one may object that a) the shear was not applied at a frequency different from that of the oscillator, and that b) the direction of the applied shear was orthogonal to the stress imposed by the motion of the oscillator. In a series of experiments using two stacks of piezoelectric transducers that can be excited, and are able to detect, in orthogonal shear directions, we show that shearing the solid at one frequency affects the shear modulus at different frequencies, and similarly, that shearing in one direction affects the modulus as measured at the orthogonal direction. We conclude that quite generally shear and torsional oscillator responses are decoupled. And while they may both reflect the same underlying physics, it is unlikely that one causes the other.

9:24AM A16.00008 Simultaneous Measurement of Non-Classical Rotational Inertia and Shear Modulus of Solid ^4He , WONSUK CHOI, JAEHO SHIN, Center for Supersolid & Quantum Matter Research and Department of Physics, KAIST, Daejeon 305-701, R. O. K., HYOUNG CHAN KIM, National Fusion Research Institute(NFRI), Daejeon 305-333, R. O. K., KEIYA SHIRAHAMA, Department of Physics, Keio University, Yokohama, Japan, EUNSEONG KIM, Center for Supersolid & Quantum Matter Research and Department of Physics, KAIST, Daejeon 305-701, R. O. K. — A failure to rotate or oscillate is the essential nature of low temperature superfluid helium, and more technically known as non-classical rotational inertia (NCRI). It is counter-intuitive, but NCRI is also found in solid helium-4 below ~200 mK [1,2]. Recently, shear modulus showed unusual increase with striking resemblance to those of NCRI [3]. Extended measurements show the NCRI occurs only in a stiffened Bose solid, but it is not understood how they are related. Here we report the first simultaneous measurement of shear modulus and NCRI in solid helium to elucidate the fundamental connection between them. Both emerge at remarkably similar temperatures, whereas no quantitative agreement between the increase of the shear modulus and the magnitude of NCRI is found. The increase of shear modulus seems to be the necessary condition for the onset of NCRI.

9:36AM A16.00009 Interplay of Aerogel Anisotropy and Superfluid ^3He Textures, JIA LI, J. POLLANEN, C.A. COLLETT, W.J. GANNON, W.P. HALPERIN, Department of Physics and Astronomy, Northwestern University, Evanston, IL 60208, USA — The effect of aerogel anisotropy on the ^3He superfluid order parameter and the relative stability of A and B -phases has been investigated. We have performed pulsed NMR on ^3He in high porosity aerogel samples that have different types of anisotropy, characterized with an optical, cross-polarization technique. One aerogel sample has 14.3% growth-induced axial stretching. Its superfluid phase diagram is occupied by the A -phase. Linewidth analysis gives the distribution of the orbital angular momentum, $\vec{l}$. The orientation of $\vec{l}$ is consistent with an easy plane distribution that is perpendicular to the strain axis. A second aerogel sample is axially compressed mechanically by 22.5%. The major part of the zero magnetic field phase diagram is occupied by the B -phase. Additionally, our results show that aerogel anisotropy introduced by compressing and stretching have different orienting effects on the ^3He superfluid order parameters. This work was supported by the National Science Foundation, DMR-1103625.

9:48AM A16.00010 Experiments with ^3He in 10% uniaxially compressed aerogel: the superfluid phase diagram, NIKOLAY ZHELEV, ROBERT BENNETT, ERIC SMITH, Cornell University, JOHANNES POLLANEN, WILLIAM HALPERIN, Northwestern University, JEEVAK PARPIA, Cornell University — Entraining ^3He in aerogel provides a way to introduce disorder in the otherwise ideal quantum fluid. Motivated by the recent prediction that uniaxially compressed aerogel can stabilize the anisotropic A phase over the isotropic B phase, we use a torsional oscillator technique to measure the superfluid phase diagram of ^3He entrained in 10% axially compressed, 98% porous aerogel. We observe that a broad region of the temperature-pressure phase diagram is occupied by the metastable A phase. The reappearance of the A phase on warming from the B phase, before superfluidity is extinguished at T_c , is in contrast to its absence in uncompressed aerogel. We also find that the anticipated alignment of the angular momentum vector by compression is not observed.

10:00AM A16.00011 Application of MEMS Devices to the Study of Liquid ^3He ¹, MIGUEL GONZALEZ, PAN ZHENG, ERIK GARCELL, Department of Physics, University of Florida, Gainesville, FL 32611, USA, HO BUN CHAN, Department of Physics, The Hong Kong University of Science and Technology, Hong Kong, China, YOONSEOK LEE, Department of Physics, University of Florida, Gainesville, FL 32611, USA — We report measurements on the mechanical properties of a micro-electro-mechanical (MEMS) resonator submerged in liquid ^3He at millikelvin temperatures and at pressures 3, 21 and 29 bar. The device consists of a pair of parallel plates with a well-defined gap of $0.75\text{ }\mu\text{m}$. The sub-micron gap size and geometry of the device gives access to physics in the high Knudsen regime and allows the investigation of surface scattering effects in thin films of quantum fluids. Details of design, fabrication, and operation will be presented along with a study of the damping characteristics of the submerged resonator through a wide range of temperatures spanning from classical fluid to degenerate Fermi liquid. The device shows potential for the use in low temperature experiments and to investigate novel phenomena in quantum fluids at the micro/nano scale such as superfluid ^3He films.

10:12AM A16.00012 Partial depinning of dislocation in ^4He from ^3He impurities induced by thermal roughening¹, DARYA ALEINIKAVA, ANATOLY KUKLOV, College of Staten Island, CUNY — The mechanism of the roughening induced partial depinning of gliding dislocations from ^3He impurities is proposed [1] as an alternative to the standard “boiling off” scenario [2]. We give a strong argument that ^3He remains bound to dislocations even at large temperatures due to very long equilibration times. This conjecture is based on two observations: First, the experimental data [2] for shear modulus temperature dependence obtained at very different ^3He concentrations (1 ppb and 300 ppb) can be, practically, collapsed on each other by a simple rescaling of temperature; Second, both moduli can be fit by the Monte-Carlo simulations data within the assumption that the impurities remain confined to the spatial region occupied by dislocation. Conversely, impurities evaporation violates strongly the data collapse and is absolutely inconsistent with the simulations. We propose that such long equilibration time is due to the very narrow band of ^3He impuritons [3].

10:24AM A16.00013 Microscopic Dynamics of Liquid Helium Confined in 1D Nanopores, TIMOTHY PRISK, PAUL SOKOL, NARAYAN DAS, Indiana University, SOULEYMANE DIALLO, Oak Ridge National Laboratory, NOBUO WADA, Nagoya University, SHINJI INAGAKI, Toyota Central R and D Laboratories — Recently, Toda et al. performed torsional oscillator and heat capacity measurements on liquid He^4 confined within FSM-16. This porous silica glass has 1D pores with a very narrow diameter of $d = 2.8\text{ nm}$. This system is an example of a 1D quantum fluid in the sense that the thermal wavelength λ is longer than the pore diameter d . Because neutron time-of-flight (ToF) spectroscopy probes elementary excitations, it can be used to study the microscopic dynamics underlying the thermodynamic properties of this 1D quantum liquid. Using the Cold Neutron Chopper Spectrometer (CNCS) at the Spallation Neutron Source (SNS), we performed the first direct measurements of the elementary excitation spectrum of liquid He^4 confined in FSM-16. Measurements were performed at full pore at temperatures $T = 33, 80, 800$, and 1500 mK with an elastic energy resolution of approximately $80\text{ }\mu\text{eV}$. We will discuss the temperature T dependence of the static structure factor $S(Q)$, the energies $\hbar\omega$ and line widths Γ of the phonon-roton spectrum, and the evidence for 2D layer modes in this system. This research was supported by NIST and employed facilities sponsored by the Scientific User Facilities Division of the US Department of Energy.

10:36AM A16.00014 Path-Integral Monte Carlo Simulations of the Ideal Strength of HCP Helium ⁴, MAURICE DE KONING, EDGAR JOSUÉ LANDINEZ BORDA, Universidade Estadual de Campinas — Using path-integral Monte Carlo simulations we assess the ideal strength of solid He-4 in its HCP phase. This fundamental material parameter is defined as the stress necessary to produce irreversible deformation in a defect-free crystal. For this purpose we impose slowly increasing homogeneous deformations to defect-free He-4 crystals and measure the corresponding internal stress state. In this manner, we determine the ideal shear strength in the basal plane as a function of the shear orientation, as well as the tensile and compressive strength perpendicular to this plane. Our results establish upper bounds to the strength of real HCP He-4 crystals.

10:48AM A16.00015 Fitting of m^*/m with Divergence Curve for He_3 Fluid Monolayer using Hole-driven Mott Transition, HYUN-TAK KIM, MIT Creative Research Center in ETRI — The electron-electron interaction for strongly correlated systems plays an important role in formation of an energy gap in solid. The breakdown of the energy gap is called the Mott metal-insulator transition (MIT) which is different from the Peierls MIT induced by breakdown of electron-phonon interaction generated by change of a periodic lattice. It has been known that the correlated systems are inhomogeneous. In particular, He_3 fluid monolayer [1] and $\text{La}_{1-x}\text{Sr}_x\text{TiO}_3$ [2] are representative strongly correlated systems. Their doping dependence of the effective mass of carrier in metal, m^*/m , indicating the magnitude of correlation (Coulomb interaction) between electrons has a divergence behavior. However, the fitting remains unfitted to be explained by a Mott-transition theory with divergence. In the case of He_3 regarded as the Fermi system with one positive charge (2 electrons + 3 protons), the interaction between He_3 atoms is regarded as the correlation in strongly correlated system. In this presentation, we introduce a Hole-driven MIT with a divergence near the Mott transition [3] and fit the m^*/m curve in He_3 [1] and $\text{La}_{1-x}\text{Sr}_x\text{TiO}_3$ systems with the Hole-driven MIT with $m^*/m=1/(1-\rho^4)$ where ρ is band filling. Moreover, it is shown that the physical meaning of the effective mass with the divergence is percolation in which m^*/m increases with increasing doping concentration, and that the magnitude of m^*/m is constant.

Monday, February 27, 2012 8:00AM - 11:00AM —
Session A17 DMP GERA FIAP: Focus Session: Thermoelectrics - Nanostructured and Oxide TE 252A

8:00AM A17.00001 Thermoelectric properties of filling-controlled zinc-antimonides with layer structure, T. SUZUKI, M.S. BAHRAMY, CMRG and CERG, RIKEN ASI, Japan, R. ARITA, Dept. of Appl. Phys., Univ. of Tokyo, CMRG and CERG, RIKEN ASI, Japan, Y. TAGUCHI, CMRG and CERG, RIKEN ASI, Japan, Y. TOKURA, Dept. of Appl. Phys., Univ. of Tokyo, CMRG and CERG, RIKEN ASI, ERATO MF, JST, Japan — Thermoelectric properties have been investigated for polycrystalline samples of layer-structured $R_{1-x}A_x\text{ZnSbO}$ ($R=\text{La, Ce}$; $A=\text{Ca, Sr}$) as two-dimensional analogues of a conventional thermoelectric semiconductor ZnSb [1]. By substituting A^{2+} for R^{3+} in the charge-reservoir layers, carrier concentration can be successfully controlled without lowering the carrier mobility. The hole doped materials showed low thermal conductivity and moderately high thermopower, whose temperature- and doping-dependence were well explained by theoretical calculation. The values of dimensionless figure of merit ZT were found to increase without showing any sign of saturation up to 390 K, and even higher values can be expected along the conducting ZnSb layers for a single crystal. These results indicate the potential of the hole-doped $R\text{ZnSbO}$ as a good thermoelectric material. This work was in part supported by FIRST program on "Quantum Science on Strong Correlation" from JSPS.

8:12AM A17.00002 Enhancing thermoelectric properties of FeSb_2 by altering stoichiometry and nanostructure, MANI POKHAREL, HUAIZHAU ZHAO, KEVIN LUKAS, ZHIFENG REN, CYRIL OPEIL, Boston College, BC TEAM — FeSb_2 is a strongly correlated semiconductor that has been shown to have an extraordinarily large Seebeck coefficient in single crystal samples. Bienten *et al.* report a Seebeck Coefficient of -45000 $\mu\text{V/K}$ at 10K. The peak value of the dimensionless figure of merit (ZT_{max}) for single crystal samples is calculated to be approximately 0.005 at 10 K and is constrained by its relatively high thermal conductivity. In our previous studies, we find that nanocomposites (NC) tend to decrease thermal conductivity substantially by introducing phonon mismatches between crystal grains. Given that the Seebeck coefficient on the FeSb_2 system is quite sensitive to carrier concentration, we focus on the effects of stoichiometric changes that heighten thermoelectric properties of FeSb_x where $x=2.04, 2.00, 1.96, 1.92$. By tuning the stoichiometry and using the nanocomposite method, the peak value of ZT_{max} was found to be 0.0123 at 43K. Carrier concentration and Hall-mobility measurements will also be discussed.

8:24AM A17.00003 Local Structure of Thermoelectric Clathrates¹, SCOTT MEDLING, FRANK BRIDGES, University of California, Santa Cruz, TOSHIRO TAKABATAKE, Hiroshima University — We present local structure results from extended X-ray absorption fine structure (EXAFS) analysis of two new kinds of clathrates: type I clathrates with a light 'rattler' atom and type VIII clathrates. The rattler atom is extremely important for the thermoelectric properties as it is what strongly scatters phonons and lowers the thermal conductivity without affecting the electrical conductivity. In most thermoelectric clathrates, the rattler atom is a heavy atom, typically Ba or Eu, and such type I clathrates have been discussed extensively in the literature; a smaller rattler atom such as K results in more free space inside the cage. Type VIII clathrates have the same chemical formula as type I clathrates, but have a different, more distorted, cage structure resulting in differing electronic properties. Recent studies indicate a thermoelectric figure of merit at least as high as 1.2 at 400 K is attainable. For both kinds of clathrates, we collect and analyze temperature-dependent data over the range 10-300 K and compare the results with our models.

¹NSF Grant DMR-1005568

8:36AM A17.00004 Nanostructured Thermoelectrics and the New Paradigm¹, MERCOURI KANATZIDIS, Northwestern University — A comprehensive and stable energy strategy would require proportionate attention to all three legs of the "energy stool"; supply (sources), demand (efficiency) and storage/transport (delivery). Thermoelectric materials, that convert waste thermal energy into useful electrical energy, have an important role to play in any and all these three legs. The efficacy and efficiency of thermoelectrics is reflected in the figure of merit ZT , which is directly proportional to the power factor (comprising electrical conductivity and Seebeck coefficient) and inversely proportional to thermal conductivity (comprising carrier and lattice contributions). The recent emergence of nanostructured thermoelectrics has ushered in a new era for bulk thermoelectrics, which show considerable promise to enhance the "contra-indicating" parameters of high electrical conductivity and low thermal conductivity. This is achieved by introducing nanostructures in bulk thermoelectric host materials to significantly reduce lattice thermal conductivity via effective scattering of heat carrying phonon through hierarchical architecture of nanostructured thermoelectrics. The presentation will cover recent developments, current research in our EFRC and future prospects for high performance bulk materials. Systems based on lead chalcogenides (e.g., PbTe , PbSe , PbS) present key science challenges with promising properties and are given particular emphasis. We have achieved excellent control of synthesis and crystal growth of such materials resulting in record enhancements in the figure of merit. These enhancements derive from very large reductions in lattice thermal conductivity possible with nanostructuring. We have experimentally realized concurrent synergistic effect of phonon blocking and charge transmission via the endotaxial placement of nanocrystals in thermoelectric material host. In particular, we have shown that the enhanced performance is due to nanostructuring of thermoelectric host matrix, with a compelling influence of hierarchy of length-scales associated with these systems. The presentation will outline possible future strategies for enhancing the thermoelectric figure of merit of bulk thermoelectric materials.

9:12AM A17.00005 Assessing the thermoelectric properties of sintered compounds via high-throughput *ab initio* calculations, SHIDONG WANG, Department of Mechanical Engineering and Materials Science, Duke University, ZHAO WANG, LITEN, CEA-Grenoble, 17 rue des Martyrs, 38054 Grenoble Cedex 9, France, WAHYU SETYAWAN, Department of Mechanical Engineering and Materials Science, Duke University, NATALIO MINGO, LITEN, CEA-Grenoble, 17 rue des Martyrs, 38054 Grenoble Cedex 9, France, STEFANO CURTAROLO, Department of Mechanical Engineering and Materials Science and Department of Physics, Duke University — In order to identify promising thermoelectric materials, we study several thousand compounds from the ICSD database. In particular, we consider nano-grained sintered power thermoelectric compounds with the high-throughput *ab initio* AFLOW framework (<http://afwlib.org> and <http://materials.duke.edu/aflow.html>). By regression analysis, we find that the power factor is positively correlated to electronic band gap, carrier effective mass, and the number of atoms per unit cell. This work illustrates the important role that experimental and theoretical databases can play in the development of novel materials.

9:24AM A17.00006 Enhancement of the figure-of-merit in strongly correlated multilayers¹, VELJKO ZLATIĆ, Institute of Physics, Zagreb, JIM FREERICKS, Physics Department, Georgetown University, Washington, D.C. — A theory of charge and heat transport in inhomogeneous multilayers (ML) with correlated electrons is presented. We consider the device which consists of several strongly correlated metallic planes (channel) sandwiched between two semi-infinite Mott insulators (barriers). A driving field is applied parallel to the ML planes and the gate voltage perpendicular to the ML planes. The device is described by the Falicov-Kimball model and transport coefficients are calculated by the linear response theory using the DMFT. The device is tuned by i) increasing the correlation strength so as to enhance the slope of the local density of states in the channel-planes at the chemical potential and ii) changing the gate voltage so as to shift the position of the chemical potential with respect to the band-edge. Both effects have a large impact on the thermoelectric properties and are used to optimize the figure-of-merit, ZT, of the device. The effect of the number of planes is discussed as well. The results for the electrical conductivity, the Seebeck coefficient, the power factor, the Lorenz number and ZT are presented. Optimal tuning gives $ZT \gg 1$.

9:36AM A17.00007 Thermoelectric and Structural Properties of the Chemically Doped $\text{Ca}_3\text{Co}_4\text{O}_9$ System, JIANMING BAI, Oak Ridge National Laboratory, TAO WU, TREVOR A. TYSON, HAIYAN CHEN, New Jersey Institute of Technology — The Cu and Y doped thermoelectric oxide system $[\text{Ca}_2\text{CoO}_3][\text{CoO}_2]_{1.61}$, also referred to as $\text{Ca}_3\text{Co}_4\text{O}_9$, was prepared by solid state reaction followed by annealing under oxygen. The temperature dependent thermoelectric properties, including resistivity (ρ), Seebeck coefficient (S) and thermal conductivity (κ), were measured on Cu doped $[\text{Ca}_2\text{Co}_{1-x}\text{Cu}_x\text{O}_3][\text{CoO}_2]_{1.61}$ and Y doped $[\text{Ca}_{2-x}\text{Y}_x\text{CoO}_3][\text{CoO}_2]_{1.61}$. In order to understand the origin of the changes in ZT with doping, local (XAS) and long range (XRD) structural measurements as a function of doping were conducted. Identification of the locations of the doping sites and the impact on ZT will be discussed. This work is supported by DOE Grant DE-FG02-07ER46402. The Physical Properties Measurements System was acquired under NSF MRI Grant DMR-0923032 (ARRA award).

9:48AM A17.00008 The effects of increased Co-ion spin states on the Seebeck coefficient in thermoelectric $\text{Ca}_3\text{Co}_4\text{O}_9$ ¹, ROBERT KLIE, TADAS PAULAUŠKAS, QIAO QIAO, ALEJANDRO REBOLA, SERDAR OGUT, University of Illinois at Chicago, DIPANJAN MAZUMDAR, ARUN GUPTA, Center of Materials for Information Technology, University of Alabama, STANISLAW KOLESNIK, Northern Illinois University, JUAN-CARLOS IDROBO, Materials Science and Technology Division, Oak Ridge National Laboratory — Thermoelectric oxides have attracted increasing attention due to their high thermal power and temperature stability. In particular, $\text{Ca}_3\text{Co}_4\text{O}_9$ (CCO), a misfit layered structure consisting of single layer hole-doped CoO_2 sandwiched between insulating Ca_2CoO_3 rocksalt layers, exhibits a high Seebeck coefficient at 1,000 K. It was previously suggested that the Seebeck-coefficient can be further improved by stabilizing an increased Co-ion spin state in the CoO_2 layers. Here we report a significant increase in the room-temperature in-plane Seebeck coefficient of 40 nm thick CCO films grown by pulsed laser deposition on SrTiO_3 substrates. We combine aberration-corrected Z-contrast imaging, atomic-column resolved electron energy-loss spectroscopy, and density-functional calculations to show that the increase is caused by CoO_2 stacking faults with Co^{4+} -ions in a higher spin state compared to that of bulk CCO. The higher Seebeck coefficient makes the CCO system suitable for many high-temperature waste-heat-recovery applications. The role of dopants, such as Bi and Ti will also be explored.

10:00AM A17.00009 Anisotropic thermopower and magnetothermopower in a misfit-layered calcium cobaltite¹, HUAHONG GUO, TENG YANG, ZHIDONG ZHANG, Institute of Metal Research, Chinese Academy of Sciences — An unusual anisotropy of thermopower and magnetothermopower has been observed in the powerful thermoelectric $\text{Ca}_3\text{Co}_4\text{O}_{9+\delta}$ single crystal. The in-plane thermopower is about twice as big as the out-of-plane thermopower. Combining *ab initio* band structure calculation with semi-classical model analysis, we understand this anisotropy with band structure effects and especially with anisotropic Fermi surface. We find that a strong anisotropy in the topology of Fermi surface leads to the anisotropy of (magneto)thermopower. This study may also shed light on anisotropic properties of other layered cobalt oxides.

10:12AM A17.00010 The Origin of Enhanced High Temperature Electron Transport in Thermoelectric $\text{Ca}_3\text{Co}_4\text{O}_9$, TAO WU, TREVOR A. TYSON, HAIYAN CHEN, New Jersey Institute of Technology, JIANMING BAI, Oak Ridge National Laboratory, CHERNO JAYE, National Institute of Standards and Technology — Temperature dependent measurements of resistivity, crystal structure and heat capacity reveal significant hysteresis occurring near 400 K in $\text{Ca}_3\text{Co}_4\text{O}_9$. The largest changes in structure occur in the CoO_2 layer associated with electron transport: manifested mainly by b_2 axis changes. Application of magnetic fields up to 8 T reduces the area of the resistivity hysteresis loop with saturation at ~ 4 T. Reduced resistivity associated with this first order phase transition from metallic to semiconducting behavior enhances the thermoelectric properties at high temperatures and points to the metal-insulator transition as a mechanism for improved ZT in high temperature thermoelectric oxide. This work is supported by DOE Grant DE-FG02-07ER46402. The Physical Properties Measurements System was acquired under NSF MRI Grant DMR-0923032 (ARRA award).

10:24AM A17.00011 Electrical and Thermal Transport Properties of $\text{Bi}_2\text{Sr}_2\text{Co}_2\text{O}_{9-\delta}$ Single Crystals and Thin Films, ZHENYU DIAO, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, H.N. LEE, M. CHISHOLM, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, RONGYING JIN, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803 — Layered $\text{Bi}_2\text{Sr}_2\text{Co}_2\text{O}_{9-\delta}$ possesses rich physical properties, promising for thermoelectric applications. We have successfully synthesized $\text{Bi}_2\text{Sr}_2\text{Co}_2\text{O}_{9-\delta}$ in both single crystal and epitaxial thin film forms by applying various oxygen pressures. We found that their electrical and thermal transport properties are sensitive to the oxygen content, suggesting that the oxidation state of Co plays an important role in thermoelectric properties. Comparison of power factor between single crystals and thin films will be presented.

10:36AM A17.00012 Transport Properties of La- doped SrTiO₃ Ceramics Prepared Using Spark Plasma Sintering¹, ARASH MEHDIZADEH DEHKORDI, Department of Materials Science and Engineering, Clemson University, Clemson, South Carolina, SRIPARNA BHATTACHARYA, TERRY M. TRITT, Department of Physics and Astronomy, Clemson University, Clemson, South Carolina, HUSAM N. ALSHAREEF, Materials Science and Engineering, King Abdullah University of Science and Technology (KAUST), Thuwal, Saudi Arabia — In this work, thermoelectric transport properties of La-doped SrTiO₃ ceramics prepared using conventional solid state reaction and spark plasma sintering have been investigated. Room temperature power factor of single crystal strontium titanate (SrTiO₃), comparable to that of Bi₂Te₃, has brought new attention to this perovskite-type transition metal-oxide as a potential n-type thermoelectric for high temperature applications. Electronic properties of this model complex oxide, SrTiO₃ (ABO₃), can be tuned in a wide range through different doping mechanisms. In addition to A site (La-doped) or B site (Nb-doped) substitutional doping, introducing oxygen vacancies plays an important role in electrical and thermal properties of these structures. Having multiple doping mechanisms makes the transport properties of these perovskites more dependent on preparation parameters. The effect of these synthesis parameters and consolidation conditions on the transport properties of these materials has been studied.

10:48AM A17.00013 Transition-metal-based perovskite oxides for enhanced thermopower, STANISLAW KOLESNIK, BOGDAN DABROWSKI, Department of Physics, Northern Illinois University, DeKalb, IL and Materials Science Division, Argonne National Laboratory, Argonne, IL, KRZYSZTOF WOJCIECHOWSKI, Faculty of Materials Science and Ceramics, AGH-UST, Cracow, Poland, KONRAD SWIERCZEK, Faculty of Energy and Fuels, AGH-UST, Cracow, Poland — Due to the enhancement of thermopower by spin and orbital degrees of freedom, transition-metal-based perovskite oxides are good candidates for stable and nontoxic materials with a large thermoelectric figure of merit ZT. We have investigated the most promising Mn-, Co- and Ti-based perovskite oxides. Electron doping of SrMnO₃ materials on either Mn or Sr sites induces a rapid decrease in both electrical resistivity and thermopower with the doping level due to the introduction of itinerant charge carriers. The thermopower of electron-doped SrTiO₃ materials satisfy the basic Heikes description, however, no additional enhancement is observed. The hole-doped RCoO₃ perovskites exhibit limited solubility of alkaline earth's for small rare earth ion sizes. The dependence of thermopower on charge doping and temperature appears to follow the extended Heikes formulation only at low doping and below 300 K, which indicates that Co³⁺ and Co⁴⁺ exist in several spin states beyond that range. Among all investigated compounds the largest ZT~0.3 values were observed for 3-8% Nb-substituted SrTiO₃ materials at about 700 K. Supported by the U.S. DOE-BES DE-AC02-06CH11357.

Monday, February 27, 2012 8:00AM - 11:00AM – Session A18 DCMP: Dynamics in II-VI Nanocrystals 252B

8:00AM A18.00001 Blinking and spectral diffusion of CdSe/ZnS nanoparticles, AXEL LORKE, DANIEL BRAAM, ANDREAS MÖLLEKEN, MATTHIAS OFFER, GÜNTHER PRINZ, MARTIN GELLER, Fakultät für Physik und CeNIDE, Universität Duisburg-Essen, 47048 Duisburg — Even though the tunable optical properties of colloidal nanoparticles have been studied extensively, their luminescent behaviour is still not fully understood. The random emission intermittency and the power-law of on- and off-times as well as shifts in the emission wavelength still lack a comprehensive understanding [1]. We investigate the excitonic structure of CdSe/ZnS core/shell nanoparticles using a micro-photoluminescence (PL) setup with confocal as well as imaging optics. The nanoparticles are dispersed in toluene with 1% PMMA and deposited by spin-coating on different substrates (bare Si/SiO₂ as well as Si/SiO₂ covered with different rough metallic layers). Depending on the substrate, we observe emission intermittency or nearly blinking-free emission with spectral jumps of 25 meV in the emission energy. Both can be assigned to excitonic transitions affected by additional charge inside or outside the nanoparticle [2]. Furthermore, we observe a phonon replica of 25 meV and smaller (<10 meV) energetic shifts of the emission lines, which are likely caused random charge variations in the environment of the nanoparticle.

8:12AM A18.00002 Photoluminescence blinking and carrier dynamics in giant nanocrystals with different electron confinement, SID SAMPAT, University of Texas at Dallas, YIJUN GUO, JAVIER VELA, Iowa State University, ANTON MALKO, University of Texas at Dallas — Quantum dots have shown great promise as high quantum yield photon sources for applications in bioimaging, LEDs, lasers, etc. However, their photoluminescence (PL) intermittency (blinking) often complicates practical implementations. Recently, a new breed of giant nanocrystal quantum dots (gNQDs) with a large number of shell monolayers (ML) has been developed that show strongly suppressed blinking¹ and existence of multiexcitons.^{2,3} So far, their PL emission has been limited to around 630nm. In this work, we broadened this approach and extended gNQD emission to shorter wavelength in the visible spectrum. We investigated photostable CdSe/CdS gNQDs with small (480nm emission) core and compared them to large (625nm emission) core non-blinking gNQDs with similar shell thickness (14-17 ML). The small core dots show increased blinking behavior and shorter PL decay times in comparison to large core dots. The observed difference in blinking behavior is suggestive of different carrier confinement regimes leading to enhanced electron trapping at the dot's surface as well as modifications to non-radiative Auger recombination rates.

8:24AM A18.00003 Lifetime Blinking in Non Blinking Quantum Dots¹, VICTOR KLIMOV, YAGNASENI GHOSH, ANDREA STEINBRUECK, JENNIFER HOLLINGSWORTH, HAN HTOON, CHRISTOPHE GALLAND, Los Alamos National Laboratory — Photoluminescence (PL) blinking is a common property of nanoscale light emitters. Nanocrystal quantum dots have often been used as model systems in studies of this intriguing phenomenon. Here, we use recently developed thick-shell CdSe/CdS NQDs to demonstrate a new regime of blinking where discrete fluctuations in the PL lifetime ("lifetime blinking") occur without appreciable changes in the PL intensity. Single-dot measurements under controlled electrochemical charge injection [1] yield the PL lifetimes of neutral and charged excitons. We show that the observed "lifetime blinking" are due to random charging/discharging of the nanocrystal [2]. Indeed, the injection of electrons does not appreciably modify the PL quantum yield, which explains the coexistence of a nonblinking intensity with a "blinking" lifetime. At higher excitation power, charged excitons dominate the PL emission. We build a quantitative model showing that nanocrystal charging is caused by Auger-assisted ejection of a hole, producing negatively charged species. Importantly, Auger recombination that involves excitation of an electron is suppressed while hole-based processes remain efficient.

8:36AM A18.00004 Two types of luminescence blinking revealed by spectroelectrochemistry of single quantum dots¹, CHRISTOPHE GALLAND, YAGNASENI GHOSH, ANDREA STEINBRUECK, MILAN SYKORA, JENNIFER HOLLINGSWORTH, VICTOR KLIMOV, HAN HTOON, Los Alamos National Laboratory — The phenomenon of fluorescence intermittency (blinking between ON/OFF states) has been observed for both naturally occurring fluorophores and artificial nanostructures. This study aims to resolve the long-standing controversy surrounding the origin of photoluminescence blinking in core/shell nanocrystal quantum dots. Researchers usually evoke the Auger, or A-type, mechanism in which photo-ionization of the dot leads to the OFF state, but recent observations have raised doubts about this explanation. Here we report time-resolved photoluminescence studies of individual nanocrystal quantum dots performed while electrochemically controlling the degree of their charging [1]. We find that a second mechanism (called B-type) is the dominant cause for blinking. During B-type blinking, a photo-excited, “hot” electron is trapped in a surface state before being released to the core; the luminescence is quenched without any Auger process. By controlling the applied potential and the shell thickness, we can control the frequency and type of blinking, or suppress it completely.

8:48AM A18.00005 Ultrafast Cathodoluminescence Studies of Colloidal Nanocrystals, LAZARO PADILHA, WAN KI BAE, VICTOR KLIMOV, JEFFREY PIETRYGA, Los Alamos National Laboratory, RICHARD SCHALLER, Argonne National Laboratory, Northwestern University — Despite possessing numerous desirable properties, including excellent photostability, high stopping-power, and fast, efficient fluorescence, semiconductor nanocrystal quantum dots are only mediocre gamma-ray scintillator materials. Efforts to improve performance are forestalled by a lack of understanding of how those materials respond to high energy radiation, which in turn comes from a lack of appropriate ultrafast tools for examining the relaxation of gamma-excited quantum dots. To this end, we have developed a 20keV as a surrogate for spontaneous gamma irradiation. We apply this technique to study the time-resolved response of thin films of CdSe/ZnS core/shell quantum dots. Energetic excitation produces a variety of excited states that can be separately resolved by consideration of their established energies and relaxation dynamics. We analyze the relative branching ratios of single excitonic, multi-excitonic and charged excitonic states to derive surprising conclusions regarding the physics of highly-excited quantum dots, as well as the probable source of poor gamma-scintillating performance.

9:00AM A18.00006 Dynamic fluctuations in ultrasmall nanocrystals induce white light emission, TIMOTHY J. PENNYCOOK, JAMES R. MCBRIDE, SANDRA J. ROSENTHAL, Vanderbilt University, STEPHEN J. PENNYCOOK, Oak Ridge National Laboratory, SOKRATES T. PANTELIDES, Vanderbilt University — Nanocrystals typically emit monochromatically at their size-dependent energy gaps. Recently, it was found that by pushing the size of a nanocrystal to its lower limits, absorption occurs at increasingly larger energies, but the expected blue to ultraviolet emission does not occur. Instead, ultrasmall nanocrystals begin to emit a broader spectrum. For instance, ultrasmall CdSe nanocrystals emit white light [1]. We have investigated small to ultrasmall CdSe nanocrystals using a combination of state-of-the-art scanning transmission electron microscopy and finite-temperature quantum molecular dynamics simulations. Our findings indicate that following excitation, partial thermalization sets the ultrasmall nanocrystals into a fluxional state, with a continuously varying energy gap, which results in white light emission when averaged over time. Furthermore, although the larger monochromatic emitting nanocrystals we have observed possess stable crystal cores, their surfaces are fluxional. Dynamic fluxionality should be taken into consideration when optimizing nanocrystals for applications. This work is supported by DOE grant DE-FG02-09ER46554 and Basic Energy Sciences Materials Sciences and Engineering Division.

9:12AM A18.00007 Dynamics of charge separation and multicarrier recombination in CdS/CdTe heterodimer nanocrystals, SEIJI TAGUCHI, Institute for Chemical Research, Kyoto University, MASAKI SARUYAMA, University of Tsukuba, TOSHIHARU TERANISHI, YOSHIHIKO KANEMITSU, Institute for Chemical Research, Kyoto University — Heterostructured semiconductor nanocrystals provide new ways to manipulate electronic wave functions and carrier recombination pathways. Recently, we developed a novel anion exchange reaction and synthesized anisotropically phase-segregated CdS/CdTe heterodimers with staggered band-edge alignment [1]. Here we report the ultrafast carrier dynamics in the heterodimers measured by transient absorption spectroscopy. While pump laser energy was tuned to create excitons only in the CdTe phase, we observed the bleaching of the CdS excitonic transition. The bleaching of CdS exciton states should be induced by electron injection from the CdTe phase to the CdS phase. Very rapid electron transfer time was evaluated to be about 400 fs. Moreover we found that temporal evolutions of CdS excitonic bleaching are almost independent of excitation intensity over a wide range, implying the suppression of Auger recombination. Our results indicate that charge separation efficiency of the heterodimers is enhanced due to their centrosymmetry-broken structures, and the designed nanocrystals are useful for next generation solar cells. [1] Saruyama *et al.*, *J. Am. Chem. Soc.* **133**, 17598 (2011).

9:24AM A18.00008 Transient Photoluminescence in Ligand-Exchanged Quantum Dot Assemblies¹, MICHAEL E. TURK, PATRICK M. VORA, AARON T. FAFARMAN, BENJAMIN T. DIROLL, CHRISTOPHER B. MURRAY, CHERIE R. KAGAN, JAMES M. KIKKAWA, University of Pennsylvania — Improving electronic contact between nanocrystals (NCs) within self-assembled NC solids is a long standing goal, and recent work on ligand exchange using ammonium thiocyanate has demonstrated marked improvements in the charge mobility of NC films over longer, more insulating ligands [1]. Here, we use transient photoluminescence (PL) to study changes in radiative lifetime caused by ligand exchange. Our work begins by examining differences in lifetime and radiative efficiency between liquid dispersions and solid films of CdSe semiconductor NCs, and moves on to study additional changes in both types of samples correlated with ligand substitution. We use a combination of time-correlated single photon counting and non-linear optical Kerr gating to study PL on nanosecond and sub-picosecond time frames, respectively. We discuss the relationship between nanosecond and picosecond dynamics, and examine temperature dependence from 300 to 5 Kelvin. Initial data indicate a decrease in PL lifetime with ligand exchange, which we discuss in the context of increased transport mobilities and decreased interparticle separations, as well as changes in the steady-state optical spectra of these systems. [1] A.T. Fafarman, *et al.*, *J. Am. Chem. Soc.*, **133**, 15753 (2011).

9:36AM A18.00009 Optically Excited Exciton Transfer of Spherical Quantum Dots via Optical Near-Field Interactions, TOGAY AMIRAHMADOV, Bilkent University, PEDRO LUDWIG HERNANDEZ MARTINEZ, HILMI VOLKAN DEMIR, Bilkent University, Nanyang Technological University — We study a system composed of a mixture of different-sized spherical quantum dots (QDs) involving optical near-field (ONF) interactions to induce effective optical excitation transfer. Here energy transfer was explained by resonant energy transfer via the optical near-field interaction between the first excited state of small QDs and the second excited state of large QDs. The energy transfer in a film of different-sized QDs made of CdTe and CdSe were experimentally demonstrated. An analysis between the optical near field transfer rate [1] and Förster type transfer rate was made. The proper understanding of the exciton transfer between these QDs is important for the design and implementation of near-field photonic devices employing them. [1] M. Ohtsu, *et al.*, *Principles of Nanophotonics*, CRC Press (2008).

9:48AM A18.00010 Efficient Exciton Transfer from an Epitaxial Quantum Well to an Energy Gradient Structure Composed of Layer-by-Layer Assembled Colloidal Quantum Dots, SEDAT NIZAMOGLU¹, Bilkent University, PEDRO LUDWIG HERNANDEZ MARTINEZ, Bilkent University, Nanyang Technological University, EVREN MUTLUGUN, Bilkent University, HILMI VOLKAN DEMIR, Bilkent University, Nanyang Technological University — In this work, we study exciton migration from a violet-emitting epitaxial quantum well (QW) to an energy gradient structure that consists of layer-by-layer assembled, green- and red-emitting quantum dot (QD) bilayer. In the experimental study, the energy gradient of these green and red QDs provides an increase of 64.2% in the exciton transfer efficiency with respect to the bilayer of only red-emitting QDs. These results suggest that the energy difference between the QD layers significantly boosts the QW-QD exciton transfer rate compared to the mono-dispersed case. To support this experimental observation, we propose a theoretical model based on optical near field and density matrix to investigate the effects of energy difference between the QD layers. The strong exciton transfer from the epitaxial QWs to the colloidal QDs is essential to the energy efficiency of hybrid optoelectronic devices [1-3].

10:00AM A18.00011 Anomalous photo-induced spectral changes in CdSe/ZnS quantum dots¹, GEORGIY SHCHERBATYUK, University of California, Merced, RICHARD INMAN, University of California, San Diego, PATRICK TALBOT, SAYANTANI GHOSH, University of California, Merced — We study photo-induced static and dynamic spectral changes in self-assembled CdSe/ZnS quantum dot (QD) thin films with varying QD concentrations under ambient conditions. Using spatially resolved scanning photoluminescence microscopy in conjunction with spectrally resolved time-correlated photon counting, we measure the variations in spectral intensity, emission wavelength, and recombination lifetimes as functions of photo-exposure time. We find that at low concentrations photo-darkening and photo-oxidation rates slow down with increasing QD density, but in the high concentration limit these rates are strongly enhanced. Our measurements lead us to conclude that the interplay of photo-induced surface trap discharging with preferential photo-oxidation of smaller QDs is further modulated by resonant energy transfer driven by strong inter-dot interactions in highly concentrated samples. Finally, we extend our studies to thin films with two different QD diameters to vary the ratio of donors to acceptors and modify the energy transfer efficiency

10:24AM A18.00013 Waveguide Integrated Colloidal Quantum Dot Emitters, MINGMING JIANG, DONGFANG LI, RASHID ZIA, Brown University — High-yield II-VI colloidal quantum dots (QDs) have received considerable attention as quantum emitters for photonic device applications. Given their scalable synthesis and self-assembly, these QDs could serve as the basis for large arrays of single photon sources. Here, we present preliminary results on the integration of CdSe-based QDs into dielectric waveguides. Specifically, we will show how the local optical environment can be used to direct and enhance QD emission into specific spatial and spectral modes. First, we will present fabrication techniques to safely embed QDs into thin film dielectric waveguides. Then, we will present experimental back-focal-plane (BFP) measurements that demonstrate how thin-film interference effects can be used to control the QD angular emission patterns. Experimental BFP data will be discussed and analyzed in terms of theoretical predictions based on the local density of optical states (LDOS), thus demonstrating how interference effects can be used to effectively direct emission from randomly oriented QDs. If time permits, we will also show how the extension of these techniques to individual QD emitters in ridge waveguides.

10:36AM A18.00014 Comparison of carrier multiplication yields in the PbX salts¹, JAYSON STEWART, LAZARO PADILHA, JEFFREY PIETRYGA, Los Alamos National Laboratory, AARON MIDGETT, JOSEPH LUTHER, MATTHEW BEARD, ARTHUR NOZIK, National Renewable Energy Laboratory, VICTOR KLIMOV, Los Alamos National Laboratory — In this talk I will present recent results of a collaborative effort investigating the quantum efficiency of carrier multiplication (CM) of the lead salt nanocrystals: PbS, PbSe and PbTe. These materials are promising candidates for exploring generation-III photovoltaic concepts that rely on carrier multiplication, the process in which a single photon generates more than one electron-hole pair. Despite the many apparent similarities of these materials in their bulk form, we find that these compounds exhibit strikingly different CM yields in their nanocrystalline form. We suggest that the difference in CM yields in these nanomaterials is the consequence of different competing relaxation rates, such as phonon emission. Indeed, we estimate the rate of energy dissipation due to phonon emission mediated by a polar Frohlich-type interaction for these three materials and find excellent qualitative agreement with the data. This approach could prove useful for predicting future materials to investigate for increasingly high CM yields.

8:00AM A19.00001 Local Kondo screening and spatial coherence in YbRh_2Si_2 ¹, STEFFEN WIRTH,

Max-Planck-Institute for Chemical Physics of Solids Dresden — Heavy fermion metals are often characterized by a variety of relevant energy scales and competing interactions which may result in such fascinating phenomena as quantum criticality and unconventional superconductivity. Therefore, these materials have advanced to suitable model systems by means of which electronic interactions can be studied in detail. This will be discussed for the interplay of localized and itinerant electronic states in Kondo lattice systems in which heavy charge carriers are generated. We investigate the generic Kondo lattice system YbRh_2Si_2 , one of the heaviest heavy fermion metals, by utilizing atomically resolved Scanning Tunneling Spectroscopy (STS) [1]. An analysis of the topography allows for a determination of the terminating surface as well as a comparison to results from chemical analysis. Importantly, the crystal field excitations are unambiguously reflected by our STS measurements, clearly relating STS to bulk properties. The hybridization of conduction and $4f$ electrons results in a gap-like feature in the tunneling conductance. In addition, a strongly temperature dependent peak in the tunneling conductance is attributed to a resonance resulting from the Kondo lattice. The experimental data are discussed in relation to results obtained within the non-crossing approximation (NCA) and renormalized band structure calculation. In a brief outlook we discuss further investigations by STS, e.g. with respect to the quantum critical phenomena observed in YbRh_2Si_2 [2], to substitutions-induced changes of the relevant energy scales [3], or on heavy fermion superconductors.

8:36AM A19.00002 Correlated Spin Phenomena in Molecular Systems, WILSON HO, University of California,

Irvine — While a great deal of work has been carried out on molecular magnets, the spatial distribution of the spin wave function and the many body interactions between the delocalized molecular spin and its surrounding electrons can now be obtained with atomic scale resolution with the scanning tunneling microscope (STM). The combination of surface science, self-assembly, and STM enables correlated spin phenomena, such as the Kondo state, to be probed in a wide range of well characterized systems from single molecules to a two-dimensional lattice of interacting spins. Nonlocality, Kondo gap, and the Kondo lattice in correlated electron physics are revealed by the atomic-scale spatial resolution and high energy resolution spectroscopy and imaging with the STM from oxygen to porphyrins and phthalocyanine molecules adsorbed on metal and oxide surfaces.

9:12AM A19.00003 Long-range Kondo signature of a single magnetic impurity¹, MARTIN WEN-

DEROTH, 4. Physikalisches Institut, University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany — Scanning tunneling spectroscopy (STS) has provided an approach to study the Kondo effect - one of the oldest many particle phenomena known in condensed matter physics - in real space. In spite of the high spatial resolution of scanning tunneling spectroscopy, experiments performed on single magnetic atoms on metal surfaces, have shown that the fingerprint of the Kondo effect is only visible if the tip is placed directly above the impurity (e.g. [1]). In the present work we follow a novel route and investigate single isolated Co and Fe impurities not on top but buried below a Cu(100) surface. It has been shown recently [2] that the anisotropy of the copper Fermi surface leads to a strongly directional propagation of quasi particles called electron focusing which gives access to individual bulk impurities in a metal. We have studied the energy-dependent scattering characteristics for single isolated atoms of Ag, Co and Fe buried under a Cu(100) surface using low temperature scanning tunnelling spectroscopy (STS). For the case of a non-magnetic Ag impurity a Friedel oscillation in the local density of states is observed. For both magnetic impurity atoms we observe, in contrast to previous works, a long range Kondo signature which is periodic with the distance to the impurity [3]. The comparison of Co and Fe atoms demonstrates that both impurity species show similar behavior on completely different energy scales, which is determined by the Kondo temperature. We investigate the scattering amplitude as well as the phase. A theoretical interpretation based on a combined approach of band structure and many-body numerical renormalization group calculations is able to describe the rich spatially and spectroscopically resolved experimental data.

9:48AM A19.00004 Defects in Heavy-Fermion Materials: Unveiling Strong Correlations in Real Space¹, DIRK MORR, University of Illinois at Chicago — Heavy-fermion materials exhibit a plethora of puzzling phenomena which are believed

to arise from the competition between Kondo screening and antiferromagnetic ordering. The microscopic origin of these phenomena, such as the non-Fermi-liquid properties observed in the quantum critical region, is still a topic of debate. Recent groundbreaking scanning tunneling spectroscopy (STS) experiments [1-4] have shed new light on this debate by providing important insight into the electronic and magnetic structure of heavy fermion materials. In this talk, I review some recent progress made in our theoretical understanding of the differential conductance, dI/dV and the resulting quasi-particle interference (QPI) patterns [5-7], observed in these experiments. In particular, I will demonstrate that defects in heavy-fermion materials provide an unprecedented opportunity to disentangle electronic correlations arising from Kondo screening, and antiferromagnetic correlations between the magnetic moments by inducing perturbations in the electronic and magnetic structure that exhibit characteristically different spatial patterns. The spatial extent of these perturbations grows with the strength of the magnetic interactions, and thus directly reflects the degree of correlations [5]. In addition, I show that non-magnetic defects (Kondo holes) in heavy fermion materials can give rise to the formation of an impurity bound. Our prediction of spatial hybridization oscillations and the formation of an impurity bound state were recently confirmed by STS experiments [4]. Moreover, I will demonstrate that QPI spectroscopy, utilizing spatial oscillations in the LDOS induced by defects, does not only provide important insight into the electronic structure of heavy fermion materials, but also in the entanglement of electronic and magnetic states [6,7]. Finally, the strongly correlated nature of heavy-fermion materials leads to a highly non-linear quantum interference between defects, and the creation of order from disorder. These results provide unique insight into the spatial complexity of heavy fermion materials.

10:24AM A19.00005 Tunable Kondo Effect in SrTiO_3 ¹, JAMES WILLIAMS, Stanford University — Correlated, low-dimensional systems offer the possibility of tuning complex physical phenomena. Using strong electric fields applied with an electrolytic gate, we continuously tune through three regimes of transport in SrTiO_3 : an insulator, a metal and a Kondo metal. Two of these regimes – the metallic and Kondo metal state – are investigated as a function of temperature and magnetic field, where clear signatures of each regime are evident and discussed. This diverse system not only displays behavior distinct from conventional two-dimensional electron gases, but also show similarities to the $\text{LaAlO}_3/\text{SrTiO}_3$ interface, elucidating on some of the phenomena observed in this heterostructure of debated origin.

8:00AM A20.00001 Graphene-based Electronics and Optoelectronics¹, PHAEDON AVOURIS, IBM, T.J. Watson Research Center, Yorktown Heights, NY 10598 — Graphene has rather unique electrical and properties and there is currently strong interest in taking advantage of these properties for technological applications. In my talk I will review some of the key properties of free graphene, how these properties are affected by environmental interactions and under technologically relevant conditions, and how they can be utilized in electronics and optoelectronics. In electronics, I will focus on high frequency (≥ 300 GHz) graphene transistors and simple IC circuits, as well as related device physics problems, such as the role of electrical contacts, scattering effects, graphene topology, device size scaling, energy dissipation, etc. I will then review the key optical properties of graphene and their use in optoelectronics. Specifically, I will focus on the far-infrared and THz range of the spectrum, on ways of controlling graphene's absorption in this spectral range and provide examples of corresponding applications. I will also discuss photocurrent generation in graphene and its use in ultrafast graphene photodetectors.

8:36AM A20.00002 Visualizing Helical Metals on Topological Insulators¹, ALI YAZDANI, Princeton University — During the last few years, it has become apparent that there can be a distinct type of insulator, which can occur because of the topology of electronic wavefunctions in materials comprised of heavier elements. Strong interaction between the spin and the orbital angular momentum of electrons in these compounds alters the sequence in energy of their electronic states. The key consequence of this topological characteristic (and the way to distinguish a topological insulator from an ordinary one) is the presence of metallic electrons with helical spin texture at their surfaces. I will describe experiments that directly visualize these novel quantum states of matter and demonstrate their unusual properties through spectroscopic mapping with the scanning tunneling microscope (STM). These experiments show that the spin texture of these states protects them against backscattering and localization. These states appear to penetrate through barriers that stop other electronic states. I will also describe more ongoing efforts focused on unraveling the physics of topological surface states and their potential for device-like applications.

9:12AM A20.00003 Quantum information processing with defect spins in diamond and silicon carbide¹, WILLIAM KOEHL², Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 USA — Many proposals for quantum information technologies require quantum systems that can be easily manipulated by an outside observer, while remaining largely unaffected by destructive interactions with the surrounding environment. One system that matches this description is a defect in the crystal lattice of diamond known as the nitrogen-vacancy (NV) center. Electrons trapped at this defect form an atomic scale spin state that can be used as an individually addressable, solid state quantum bit (qubit) even at room temperature. The exceptional quantum properties of the diamond NV have motivated recent efforts to search for similar defects in other semiconductors, as these would expand the technological opportunities available to defect-based quantum systems [1]. We discuss these efforts, which make use of techniques from both computational materials science and experimental quantum physics, focusing on explorations of the 4H polytype of silicon carbide (4H-SiC). In particular, we present recent experimental results that identify several defect spin states in 4H-SiC that function as analogs to the diamond NV. Using optical and microwave techniques similar to those used with diamond NV qubits, the spins of these defects can be optically addressed and coherently controlled in the time domain at temperatures ranging from 20 – 300 K. Additionally, these defects are optically active near telecom wavelengths, inhabit a host material for which there already exist industrial scale crystal growth and advanced microfabrication techniques, and possess desirable spin coherence properties comparable to those of the diamond NV. This makes them promising candidates for various photonic, spintronic, and quantum information applications that merge quantum degrees of freedom with classical electronic and optical technologies [2].

9:48AM A20.00004 Quantum Transport in Dirac Materials, PABLO JARILLO-HERRERO, MIT — Over the past few years, the physics of low dimensional electronic systems has been revolutionized by the discovery of materials with very unusual electronic structures. Among these, graphene and topological insulators have taken center stage due to their relativistic-like electron dynamics and their potential applications in nanotechnology. In this talk I will briefly review the properties of graphene and topological insulators and discuss some of our recent quantum electronic transport experiments in these systems.

10:24AM A20.00005 GHz - THz plasmonic circuits using low dimensional electronic systems¹, DONHEE HAM, Harvard University — Nature offers a broad variety of plasma systems consisting of electrons unbound from atoms, e.g.; astrophysical plasmas in intergalactic, interstellar, and stellar media; the Earth's ionosphere; and solid-state plasma, the free electrons in metals and semiconductors, only to name a few. A key feature of many plasma systems is collective motions of electrons; as the electron density profile is perturbed from equilibrium, Coulomb restoring forces (and sometimes quantum pressure in dense plasma) arise to power these collective motions, usually in the form of bulk electron density oscillations or electron density waves. Solid-state plasmas are particularly interesting, as the fabrication technologies available for solid-state materials allow us to alter the boundaries and interfaces of the plasma media in various ways to engineer the collective motion. A notable example is the surface plasmons, which have been a source of many breakthroughs in photonics. I will talk about a set of our recent developments where the plasmons are brought down to the electronics-regime (GHz~THz) and manipulated to produce a range of functionalities, while offering unique advantages to electronics over their purely electromagnetic counterparts. (Co-workers) William Andress (Harvard), Hosang Yoon (Harvard), Kitty Yeung (Harvard), Ling Qin (Harvard), Ken West (Princeton), and Loren Pfeiffer (Princeton).

Monday, February 27, 2012 8:00AM - 11:00AM – Session A21 DCMP: Superconductivity: Josephson, Tunneling and Proximity Effects 254A

8:00AM A21.00001 Equal-spin Andreev reflection from quasiparticle interference effects in high- T_C /half metallic ferromagnet junctions¹, C. VISANI, R. BERNARD, J. BRIATICO, M. BIBES, A. BARTHÉLÉMY, J.E. VILLEGAS, Unité Mixte de Physique CNRS/Thales, J. TORNOS, Z. SEFRIOUI, J. SANTAMARIA, GFMC, Universidad Complutense de Madrid — We report evidence for long-range superconducting correlations in the half-metallic ferromagnet (F) $\text{La}_{0.7}\text{Ca}_{0.3}\text{MnO}_3$, obtained from conductance measurements along the c-axis in SFS and SF junctions (with S the high- T_C superconductor $\text{YBa}_2\text{Cu}_3\text{O}_7$). Well below the superconducting T_C , we observed oscillations in the differential conductance as a function of the voltage bias, in which we identified two sets of resonances: i) quasiparticle interferences in the S (top) layer (Tomasch resonances) and ii) in the half-metallic F layer (McMillan-Rowell resonances). Both of them imply Andreev-like reflections at the SF interface and the coherent propagation of the resulting phase-conjugated quasiparticles through the entire S and F layers thickness (up to 30 nm for the F layer). Because conventional Andreev reflection and the coherent long-range propagation of the outcoming opposite-spin electron/hole pairs are heavily suppressed in strongly polarized ferromagnets, the observation of the above effect implies the occurrence of equal-spin Andreev reflection at the studied SF interfaces.

8:12AM A21.00002 Proximity Effect in Mesoscopic Superconductor-Normal-Superconductor Arrays¹, SERENA ELEY, SARANG GOPALAKRISHNAN, University of Illinois Urbana-Champaign, PAUL GOLDBART, Georgia Institute of Technology, NADYA MASON, University of Illinois Urbana-Champaign — Systems of superconducting islands on normal metal films provide a tunable medium with which to study the superconducting proximity effect, phase transitions, and vortex dynamics. Such systems are predicted to exhibit 2D zero-temperature metallic states. Although there has been experimental evidence of such states, they cannot be explained by conventional transport theory. Here, we report transport measurements on triangular arrays of mesoscopic, proximity-coupled Nb islands placed on normal metal Au films. The arrays undergo a two-step transition to a superconducting state; we characterize the superconducting transitions in these systems as a function of island thickness and spacing. The temperature of the first step of the transition linearly decreases with increasing island spacing, and the spacing-dependence of the second step deviates from conventional theories. Moreover, the trends of both steps suggest that the system is approaching zero-temperature metallic states. Through a phenomenological model, we resolve these transitions as a consequence of intra- and inter-island coupling between superconducting phases of individual Nb grains.

8:24AM A21.00003 Coherent Two Photon Production in Superconductor-Semiconductor Heterostructures¹, PAUL BAIREUTHER, Karlsruhe Institute of Technology, Karlsruhe, Germany, ILYA VEKHTER, Louisiana State University, Baton Rouge, LA, USA, JÖRG SCHMALIAN, Karlsruhe Institute of Technology, Karlsruhe, Germany — Connecting a thin (direct band gap) p-n junction to a superconductor allows Cooper pairs to tunnel into the junction. This leads to an enhancement of the luminescence at the junction via Cooper pair based radiative recombination[1,2], an effect that has recently been observed experimentally[3]. Due to the proximity-induced Cooper pairs in the junction, anomalous photon production related to coherent two photon processes becomes allowed. Using a simple model for direct band gap luminescence we study a superconductor-p-n-superconductor heterostructure where the two photon state depends on the relative phase between the two superconductors. We investigate to what extent the production rate of entangled photons is controlled by the phase difference between the attached superconductors.

8:36AM A21.00004 Field-Dependent Effects in Superconductors Coupled to Semiconducting Heterostructures¹, STEPHANIE LAW, Department of Physics and Materials Research Lab, University of Illinois at Urbana-Champaign, WADE DEGOTTARDI, SMITHA VISHVESHWARA, NADYA MASON, JAMES ECKSTEIN, University of Illinois at Urbana-Champaign — We report transport measurements between superconducting leads separated by a small InAs gap. The NbTi superconducting layer is grown in-situ on top of the InAs to allow good contact. The samples are then fabricated into Hall bars with narrow gaps between the superconducting leads. Differential resistance and IV characteristics are measured in two and four terminal setups at 300mK both on and off quantum Hall plateaus. Multiple Andreev reflection peaks are observed (up to $n=4$ in some cases) and their field dependence measured. As the field increases, the MAR peaks shift to lower voltages and follow a general scaling law which holds across devices with different gap lengths. One device shows a supercurrent at all fields and in this device, MAR peaks corresponding both to the superconducting gap as well as a proximity-induced normal gap are seen. Explanations for the field-dependence of the MAR peaks will be discussed.

¹This material is based upon work supported by the U.S. Department of Energy, Division of Materials Sciences under Award No. DE-FG02 07ER46453, through the Frederick Seitz Materials Research Laboratory at the University of Illinois at Urbana-Champaign

8:48AM A21.00005 Transport Properties Characterized by Magnetic Domain-Wall Motion in Josephson Junction¹, MICHYASU MORI, Japan Atomic Energy Agency, SIN-ICHI HIKINO, WATARU KOSHIBAE, RIKEN, Japan, SADAMICHI MAEKAWA, Japan Atomic Energy Agency — Nano-scale magnetic materials for spintronics devices are extensively studied due to many advantages. Non-volatile memory using a magnetic domain wall (DW) is one example of such devices, and the oscillatory DW is examined toward several applications. Once such devices are realized in a microscopic circuit, one needs to measure the DW motion more precisely. In this talk, we discuss the transport properties characterized by a magnetic domain wall (DW) motion in a ferromagnetic Josephson junction, which is composed of a ferromagnetic wire with DW and two superconducting electrodes. Our previous theory [1] is developed to include the DW motion into the Josephson current. By supposing a simplified DW structure, we find that the current-voltage curve exhibits stepwise structures, when DW oscillates in the ferromagnetic wire. The mechanism behind this result is common to the electric field generated by the vortex motion in the superconductor.

9:00AM A21.00006 Dramatic suppression of the Josephson effect in floating superconductors, MARIA JOSE MARTINEZ-PEREZ, FABIO TADDEI, FRANCESCO GIAZZOTTO, NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, Piazza S. Silvestro 12, I-56127 Pisa, Italy — A number of devices exploiting the Josephson effect consist of floating superconducting islands. A well-known example are SISIS junctions (where S and I stand for superconductor and insulating barrier, respectively) present in many applications such as SQUIDS. The Josephson effect relies on the macroscopic phase describing the wave function of the electrons in the superconducting electrodes. This phase is fixed by the electrochemical potential of the superconductor that is settled experimentally. An intriguing situation arises then when dealing with floating superconducting islands that have no well-defined reference potential. Here we present an experimental characterization of Al/AlO_x/Al/AlO_x/Al junctions. We focus, on the one hand, on genuine SISIS junctions in which the central aluminium island remains floating and, on the other, on virtually grounded samples in which the central aluminium island is referred to a fixed potential through a metallic contact. We observe that, under identical circumstances, floating junctions exhibit a dramatic suppression of their Josephson current compared to their grounded counterparts. Possible reasons such as the overheating of the central island or quasiparticle fluctuations are addressed.

9:24AM A21.00008 Dominant second harmonic in the Josephson current–phase relation: Manifestation of the long-range spin-triplet proximity effect in SFF’S junctions, ZORAN RADOVIC, University of Belgrade, Serbia, LUKA TRIFUNOVIC, University of Basel, Switzerland, MILOŠ KNEZEVIC, University of Cambridge, UK — We present theoretical study of the Josephson effect and pairing correlations in planar SFF’S junctions that consist of conventional superconductors connected through two metallic monodomain ferromagnets. Both singlet and triplet pair amplitudes, the Josephson current-phase relations, and density of states for arbitrary orientation of magnetizations are calculated from the self-consistent solutions of Eilenberger equations in the clean limit and for moderate disorder in ferromagnets. We find that in highly asymmetric SFF’S junctions the long-range spin-triplet proximity effect manifests itself as a dominant second harmonic in the Josephson current-phase relation [1] and gives distinctive tunneling conductance spectra [2]. Unambiguous detection of the long-range spin-triplet proximity effect by tunneling spectroscopy and experimental realization of the Josephson junctions ground state degeneracy (like at 0- π transitions) is accessible for small interface roughness and moderate disorder in ferromagnets at low temperatures.

9:36AM A21.00009 Andreev bound states in proximitized InAs nanowires¹, WILLY CHANG, VLADIMIR MANUCHARYAN, MERRITT MOORE, FERDINAND KUEMMETH, CHARLES MARCUS, Harvard University, THOMAS SAND JESPERSEN, JESPER NYGARD, University of Copenhagen — We present measurements of individual Andreev bound states (ABS) in semiconducting InAs nanowires contacted by a superconductor. The two ends of a U-shaped Al lead are deposited on the nanowire to form low-resistance contacts, between which a normal lead is then deposited to form a high-resistance tunnel contact to the nanowire. A tunneling current through the nanowire is formed by grounding the Al leads and by applying a voltage bias to the tunnel contact. Measurements of the differential conductance of the device as a function of voltage bias, magnetic field, and backgate show resonances that are associated with the density of states in the proximitized nanowire. This sub-gap structure depends periodically on magnetic flux, with a period of $\phi_0 = h/2e$. At voltages and magnetic fields exceeding the gap and the critical field of the Al leads, this structure disappears completely. Further control is achieved via a global backgate, with the tunneling current completely switched off at sufficiently low gate voltages. We interpret this structure as ABS arising from the normal electronic properties of the nanowires.

9:48AM A21.00010 A Superconductor in the Presence of an Exchange Field and Spin-orbit Interaction¹, MARIUS EICH, FBML, MIT, JOHANNES C. LEUTENANTSMEYER, FBML, MIT and I. Phys. Inst., Georg-August-Universitaet Goettingen, PENG WEI, FBML, MIT, MARKUS MUENZENBERG, I. Phys. Inst., Georg-August-Universitaet Goettingen, JAGADEESH S. MOODERA, FBML and Physics Dept., MIT — A superconductor (SC) in contact with a magnetic semiconductor experiences a large internal exchange field (IEF) that acts on the spins [1,2]. The quasi particle density of states (*q-DOS*) in the SC splits by the Zeeman energy, $2\mu H_{EX}$ where μ is the electron magnetic moment and H_{EX} is the IEF [1,2]. Here we combine IEF and spin-orbit (S-O) interaction to investigate the properties of Al by superconductive (SIS) tunneling spectroscopy [1]. Thin film sandwich junction 4EuS/4.5Al/(*d*-Au)/Al₂O₃/8Al (film thickness in nm and *d* from 0 to 0.06nm) was studied: ferromagnetic EuS layer provides the IEF whereas the Au layer creates the S-O scattering in Al. Tunnel conductance measured at 0.4K showed a large Zeeman splitting of *q-DOS* in Al film due to the IEF, even at $H_{appl} = 0$. In zero H the large asymmetry in the conductance peaks and reduction in the Zeeman splitting were observed due to S-O scattering when compared to control junctions (no Au). The sharp features in the SIS tunnel conductance allowed these studies even at the lowest level of S-O scattering.

10:00AM A21.00011 Quantum tunneling of Normal-Superconducting interfaces in a type-I superconductor, SAUL VELEZ, ANTONI GARCIA-SANTIAGO, RICARDO ZARZUELA, JOAN MANEL HERNANDEZ, JAVIER TEJADA, Universitat de Barcelona, Spain, EUGENE CHUDNOVSKY, The City University of New York, New York, USA — The magnetic irreversibility in the intermediate state in various disks of pure type-I superconducting lead (Pb) with structural defects of diverse nature is presented. The results are discussed in terms of the contributions of the shape-dependent geometrical barrier (which is the origin of the so-called topological hysteresis) and the energy barriers associated to stress defects that act as pinning centers on normal-superconductor interfaces (NSI). The effect of the defects is to enhance the capability of the system to trap magnetic flux along the descending branch of the hysteresis cycle driving the system in a set of metastable states that would originate the occurrence of time-dependent phenomena. Magnetic relaxation studies reveal that the dynamics of the intermediate state of a type-I superconductor with defects is ruled by nonthermal processes for low enough temperatures. It is attributed to quantum tunneling of NSI mediated by the formation/flattening of bumps at the defects of the sample. The average value of the tunneling barriers is estimated and the temperature of crossover from the thermal to the quantum regime is obtained from the Caldeira-Leggett theory. Comparison between theory and experiment points to tunneling of interface segments of a size comparable to the coherence length, by steps of the order of 1 nm. Finally, the effect of an applied magnetic field on the quantum dynamics of the system is also explored.

10:12AM A21.00012 Josephson superjunction: an SIS junction with a correlated insulator¹, DAVID STROUD, CHRIS PORTER, Ohio State University, KWANGMOO KIM, Korea Institute of Advanced Study — We consider the properties of an SIS Josephson junction, in which the insulating region is itself a superconductor, but below its superconducting-insulating transition. The junction could, for example, be made of a superconducting film, in which the central region is much thinner than the two regions on either side. To treat quantum fluctuations in both the insulating and the superconducting region, we model the insulator as itself an SIS Josephson array below its S/I transition and the superconductor as an array above that transition. We calculate the coupling energy of the junction as a function of insulator thickness using two methods. The first is a mean-field approach, generalized to allow for spatial variation of the order parameter. The second approach is to use quantum Monte Carlo simulation, which we use to calculate the phase stiffness as a function of insulator thickness. In both cases, the properties of the junction can be tuned by varying the thickness of the insulating region, and the properties of both superconducting and insulating materials.

¹Supported in part by NSF MRSEC, Grant No. DMR 08-20414 and the Ohio Supercomputer Center.

10:24AM A21.00013 Neural dynamics in superconducting networks, KENNETH SEGALL¹, Colgate University, DAN SCHULT², Colgate University, PATRICK CROTTY³, MAX MILLER⁴, Colgate University — We discuss the use of Josephson junction networks as analog models for simulating neuron behaviors. A single unit called a “Josephson Junction neuron” composed of two Josephson junctions [1] displays behavior that shows characteristics of single neurons such as action potentials, thresholds and refractory periods. Synapses can be modeled as passive filters and can be used to connect neurons together. The sign of the bias current to the Josephson neuron can be used to determine if the neuron is excitatory or inhibitory. Due to the intrinsic speed of Josephson junctions and their scaling properties as analog models, a large network of Josephson neurons measured over typical lab times contains dynamics which would essentially be impossible to calculate on a computer. We discuss the operating principle of the Josephson neuron, coupling Josephson neurons together to make large networks, and the Kuramoto-like synchronization of a system of disordered junctions.

10:36AM A21.00014 Half-metallic *d*-wave Josephson junctions, HENRIK ENOKSEN, JACOB LINDER, ASLE SUDBØ, Department of Physics, Norwegian University of Science and Technology, N-7491 Trondheim, Norway — We examine the dc Josephson effect in a ballistic superconductor/half-metal/superconductor junction by means of the Bogoliubov-de Gennes equations. We study the role of spin-active interfaces and compare how different superconductor symmetries affect the Josephson effect. We analyze critical current as a function of junction width, spin-flip strength and direction, and temperature. We show that the temperature-dependence of the supercurrent in the d_{xy} -symmetry case differs qualitatively from the *s*- and $d_{x^2-y^2}$ -symmetries. Finally, we have found a general analytical expression for the Andreev Bound State-energies which shows how we can either induce $0 - \pi$ -transitions, or continuously change the ground state phase of the junction by controlling the magnetic misalignment at the interfaces.

10:48AM A21.00015 A Microfabricated Phonon Spectrometer to Spectrally Resolve Phonon Transport, OBAFEMI OTELAJA, JARED HERTZBERG, RICHARD ROBINSON, Cornell University, Department of Materials Science and Engineering — In this work we show how frequency-dependent phonon transport can be probed with non-equilibrium phonons. We demonstrate a method of generating and detecting non-equilibrium phonons in micron- and nanoscale structures [1]. Our scalable method of fabricating phonon generators and detectors involves formation of Al-AlxOy-Al superconducting tunnel junctions on the sidewalls of a silicon mesa. In the line-of-sight path in these mesas, we generate and detect non-equilibrium, ballistically propagating phonons with a frequency ~ 100 GHz. Phonons are generated through the decay of quasiparticles injected into one superconducting film of the generator. This process excites phonons in a tunable, non-thermal spectral distribution. The phonons radiate into the mesa and are observed by the detector after passing through the mesa. By utilizing electron-beam lithography and plasma etching, we demonstrate the fabrication of high aspect ratio nanostructures along the ballistic path in order to observe surface scattering effects. This work is supported by DOE (DE-SC0001086).

Session A22 DMP DCOMP: Focus Session: Fe-based Superconductors - Gap Structure 254B

8:00AM A22.00001 Anisotropic Energy-Gaps of Iron-based Superconductivity from Intra-band Quasiparticle Interference in LiFeAs, ANDREAS W. ROST, University of St Andrews / Cornell University, MILAN P. ALLAN, CMPMS Department, Brookhaven National Laboratory, ANDREW P. MACKENZIE, University of St Andrews, YANG XIE, J.C. DAVIS, Cornell University, K. KIHOU, C.-H. LEE, A. IYO, H. EISAKI, Institute of Advanced Industrial Science and Technology, Tsukuba, T.-M. CHUANG, Institute of Physics, Academia Sinica, Nankang, Taipei — Cooper pairing in the iron-based high- T_C superconductors is thought to occur due to the projection of the antiferromagnetic interactions between neighboring iron atoms onto the complex momentum-space electronic structure. A key consequence is that distinct anisotropic energy gaps $\Delta_i(k)$ with specific relative orientations should occur on the different electronic bands i . However, the high-precision spectroscopy required to demonstrate anisotropy of the energy gaps, and to determine the relationship between the $\Delta_i(k)$ on different bands, has not been achieved. Here we introduce intra-band Bogoliubov quasiparticle scattering interference (QPI) to iron-based superconductor studies, focusing specifically on LiFeAs. This approach provides direct spectroscopic confirmation of multiple anisotropic energy gaps on different bands. We identify the QPI signatures of the three hole-like bands assigned by photoemission studies to be γ , α_2 and α_1 . Then, by introducing a new QPI technique, we determine the magnitude and relative orientations of the anisotropic $\Delta_i(k)$. Intra-band Bogoliubov QPI therefore yields the spectroscopic information required to identify the mechanism of superconductivity in iron-based superconductors.

8:12AM A22.00002 Low temperature specific heat of the codoped iron-arsenic superconductor $\text{Ba}_{0.55}\text{K}_{0.45}\text{Fe}_{1.95}\text{Co}_{0.05}\text{As}_2$ ¹, K. GOFRYK, J. LASHLEY, Los Alamos National Laboratory, A. LEITHE-JASPER, W. SCHNELLE, Max-Planck Institute for Chemical Physics of Solids, Dresden, F. RONNING, Los Alamos National Laboratory, M. NICKLAS, Max-Planck Institute for Chemical Physics of Solids, Dresden, F. WEICKERT, Los Alamos National Laboratory, H. ROSNER, Max-Planck Institute for Chemical Physics of Solids, Dresden, J.L. SMITH, Los Alamos National Laboratory — Despite large experimental and theoretical efforts the structure of the superconducting gap and the origin of the pairing mechanism in iron-based superconductors is still unresolved. Measurements of the low temperature specific heat and its magnetic response inside the superconducting state give important information about the symmetry of the gap. Here, we present results of our studies of codoped $\text{Ba}_{0.55}\text{K}_{0.45}\text{Fe}_{1.95}\text{Co}_{0.05}\text{As}_2$ with a T_c of 32.5 K. The high quality of the material is marked by a pronounced peak at T_c as well as by a low residual specific heat $\gamma_0 = 2.4 \text{ mJ/mol K}^2$. We will discuss the implications of the new specific heat results on the symmetry of the order parameter in this system.

¹The work at MPI has been supported by the DFG through SPP 1458

8:24AM A22.00003 Gap structure of the iron-based superconductor KFe_2As_2 via thermal conductivity, A. JUNEAU-FECTEAU, R.T. GORDON, J.-PH. REID, N. DOIRON-LEYRAUD, L. TAILLEFER, University of Sherbrooke, Canada, M.A. TANATAR, R. PROZOROV, Ames Laboratory and Iowa State University, USA, T. SAITO, H. FUKAZAWA, Y. KOHORI, Chiba University and JST-TRIP, Japan, K. KIHOU, C.H. LEE, A. IYO, H. EISAKI, AIST and JST-TRIP, Japan — The thermal conductivity of the iron-based superconductor KFe_2As_2 was measured at temperatures down to 50 mK in magnetic fields up to 15 T, as a way to probe the superconducting gap structure. A large residual linear term in the $T = 0$ limit is observed in zero field, showing that the gap structure contains nodes, consistent with a previous report [J.K. Dong et al., PRL 104, 087005 (2010)]. We discuss the possible interpretations for the nature of these nodes, in light of three different theoretical proposals: accidental line nodes in an extended s -wave state which are either horizontal [K. Suzuki et al., arXiv:1108.0657] or vertical [S. Maiti et al., arXiv:1111.0306], or symmetry-imposed vertical line nodes in a d -wave state [R. Thomale et al., PRL 107, 117001 (2011)].

8:36AM A22.00004 Gap structure of iron-based superconductors via directional thermal conductivity, JEAN-PHILIPPE REID, University of Sherbrooke — Because the structure of the superconducting gap as a function of direction reflects the pairing interaction, it can shed light on the nature of the pairing mechanism. In the iron pnictides, the experimental situation in this respect remains unclear and so far suggests the lack of a universal picture. Here I present a systematic study of the superconducting gap structure through directional thermal conductivity measurements [1] on hole-doped K-Ba122 [2,3], electron-doped Co-Ba122 [4,5], self-doped LiFeAs [6] and the chalcogenide FeTeSe. We observe a general trend for the evolution of the superconducting gap with doping. At optimal doping, the gap structure is nodeless and isotropic (3D). Away from optimal doping, nodes appear on the Fermi surface at the edges of the superconducting dome, as seen for K-Ba122 and Co-Ba122. This strongly suggests that the presence of these nodes is accidental and therefore not imposed by symmetry. It would instead depend on the competition between intra- and inter-band interactions controlled by the evolving band structure and Fermi surface, and by the onset of antiferromagnetic order.

9:12AM A22.00005 Proximity fingerprint of $s_{\pm}$ superconductivity¹, ALEXEI KOSHELEV, VALENTIN STANEV, Materials Science Division, Argonne National Laboratory — We suggest a straightforward and unambiguous test to identify possible opposite signs of superconducting order parameter in different bands proposed for iron-based superconductors ($s_{\pm}$ -state). We consider proximity effect in a weakly coupled sandwich composed of a $s_{\pm}$ -superconductor and thin layer of s -wave superconductor. In such system the s -wave order parameter is coupled differently with different $s_{\pm}$ -gaps and it typically aligns with one of these gaps. This forces the other $s_{\pm}$ -gap to be anti-aligned with the s -wave gap. In such situation the aligned band induces a peak in the s -wave density of states (DoS), while the anti-aligned band induces a dip. Observation of such contact-induced negative feature in the s -wave DoS would provide a definite proof for $s_{\pm}$ -superconductivity.

9:24AM A22.00006 Doping dependence of the specific heat of single crystal $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$ ¹,

CARLOS CHAPARRO, LEI FANG, HELMUT CLAUS, GEORGE CRABTREE, VALENTIN STANEV, WAI-KWONG KWOK, ULRICH WELP, Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439, USA, MORTEN ESKILDSEN, Department of Physics, University of Notre Dame, Notre Dame, IN 46556, USA, ANDREAS RYDH, Department of Physics, Stockholm University, SE-10691 Stockholm, Sweden — We present a systematic study of the specific heat transitions on a series of $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$ single crystals with phosphorous doping ranging from near optimum doped $x = 0.3$ to strongly over doped $x = 0.55$. Our results reveal that $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$ follows the scaling $\Delta C/T_c \sim T_c^2$ remarkably well.² The clean-limit nature of this material imposes new restraints on theories aimed at explaining the scaling. We find that the Ginzburg-Landau parameter decreases significantly with doping whereas the superconducting anisotropy is $\Gamma \sim 2.6$, independent of doping.

9:36AM A22.00007 Gap Symmetry in KFe_2As_2 ¹, SAURABH MAITI, Dept. of Physics, University of Wisconsin-Madison,

MAXIM KORSHUNOV, L.V. Kirensky Institute of Physics, Siberian Branch of Russian Academy of Sciences, Russia; Siberian Federal University, Russia., ANDREY CHUBUKOV, Dept. of Physics, University of Wisconsin-Madison — We revisit the issue of the gap symmetry in KFe_2As_2 , which is an Fe-pnictide superconductor with only hole pockets. Previous theoretical studies mostly argued for a d -wave gap in KFe_2As_2 since transport and thermodynamic measurements point to the presence of the gap nodes. However, a d -wave gap is inconsistent with recent laser-based angle-resolved photoemission measurements. We propose the scenario for a nodal s -wave superconductivity induced by a non-magnetic intra-band and inter-band interactions between fermions near the two hole pockets at Γ point. The superconducting gap that we find changes sign between the two hole pockets at Γ point and has $\cos 4\theta$ angular dependence and can have accidental nodes on one or several hole pockets. We argue that strong angle dependence is the consequence of near-degeneracy between inter-pocket and intra-pocket interaction on the hole pockets. We also provide a connection between the relative phase of 4θ oscillations and the shapes of the Fermi surface and discuss the implications in the light of photoemission and tunneling experiments.

9:48AM A22.00008 Disorder induced transition between $s_{\pm}$ and s_{++} states Fe-based superconductors¹, M.M. KORSHUNOV, Kirensky Institute of Physics, Krasnoyarsk 660036, Russia, D.V. EFREMOV, O.V. DOLGOV, Max-Planck-Institut FKF, D-70569 Stuttgart, Germany, A.A. GOLUBOV, Faculty of Science and Technology and MESA+ Institute of Nanotechnology, University of Twente, The Netherlands, P.J. HIRSCHFELD, Department of Physics, University of Florida, Gainesville, Florida 32611, USA — The symmetry and structure of the superconducting gap in recently discovered Fe-based materials is one of the main challenges in this exciting new field (see, e.g. P.J. Hirschfeld, M.M. Korshunov, and I.I. Mazin, Rep. Progr. Phys. 2011). We have reexamined the problem of disorder in 2-band superconductors, and shown within the framework of the T -matrix approximation that the suppression of T_c can be described by a single parameter depending on the intra- and interband impurity scattering rates. T_c is shown to be more robust against nonmagnetic impurities than would be predicted in the trivial extension of Abrikosov-Gor'kov theory. We find disorder-induced transition from the $s_{\pm}$ state to a gapless and then to a fully gapped s_{++} state, controlled by the sign of the average coupling constant.

¹Partial support was provided by DOE DE-FG02-05ER46236 (PJH and MMK), and RFBR 09-02-00127, Presidium of RAS program N5.7, Russian FCP GK P891, President of Russia MK-1683.2010.2 (MMK)

10:00AM A22.00009 Doping - dependent anisotropic superconducting gap in $\text{Na}_{1-\delta}\text{FeAs}$ and $\text{NaFe}_{1-x}\text{Co}_x\text{As}$ pnictides, KYUIL CHO, M.A. TANATAR, N. SPYRISON, H. KIM, R. PROZOROV, The Ames Laboratory, IA, USA, G. TAN, J. YAN, P. DAI, C. ZHANG, Oak Ridge National Laboratory, TN, USA — London penetration depth, λ (T), was measured in single crystals of self electron-doped $\text{Na}_{1-\delta}\text{FeAs}$ and chemically electron-doped $\text{NaFe}_{1-x}\text{Co}_x\text{As}$ superconductors. Doping level δ in self-doped ones was controlled by the deintercalation of Na^+ ions, stimulated by ultrasonic treatment. Use of the two doping techniques allowed us to cover the whole doping phase diagram from underdoped parent NaFeAs to heavily Co-overdoped compositions, with the optimal doping, $T_c \sim 25$ K, achieved for $x = 0.025$. Use of two protocols also allowed us to monitor the effect of disorder, introduced by chemical substitution in Fe sublattice. The low-temperature variation of λ (T), measured as a function of doping, was analyzed using a power-law fit, $\Delta\lambda = A T^n$. The exponent, n , changes from $n \sim 1.85$ at the optimal doping to much lower values in the underdoped, $n \sim 1.1$, and heavily overdoped, $n \sim 1.3$, samples. This doping-evolution of λ (T) cannot be explained by isotropic gap with scattering and suggests that while the superconducting gaps are isotropic at the optimal doping, at least one of them develops strong anisotropy at the dome edges. This scenario appears to be common for many other Fe-based superconductors.

10:12AM A22.00010 Proximity effect of iron-based superconductor in conventional s -wave superconducting thin films, NICK GROLL, THOMAS PROSLIER, ALEX KOSHELEV, VALENTIN STANTEV, DUCK-YOUNG CHUNG, Argonne National Laboratory — The proximity effect has been proposed as a mechanism to unambiguously identify the possible $s_{\pm}$ -state in iron-based superconductors.¹ With a thin s -wave superconductor atop a $s_{\pm}$ -superconductor it is suggested that the s -wave order parameter will couple to the $s_{\pm}$ -gaps differently, inducing a correction to the s -wave density of states that can be probed using electron tunneling spectroscopy. In this talk, we will present recent results of the superconducting proximity effect in s -wave MoGe thin films sputtered on top of bulk superconducting $\text{Ba}_{0.6}\text{K}_{0.4}\text{Fe}_2\text{As}_2$ ($T_c=35\text{K}$) pnictide. Electron tunneling spectroscopy measurements were performed for several MoGe film thicknesses using a homemade point contact setup. Finally, results will also be presented for similar measurements using two conventional s -wave superconductors.

10:24AM A22.00011 Volovik effect in the $s_{\pm}$ state of $\text{Ba}_{0.67}\text{K}_{0.33}\text{Fe}_2\text{As}_2$ from high field NMR¹, SANGWON OH, ANDREW MOUNCE, WILLIAM HALPERIN, Northwestern University, CHENGLIN ZHANG, PENGCHENG DAI, The University of Tennessee, PHILIP KUHN, ARNEIL REYES, National High Magnetic Field Laboratory — The spatially averaged density of states of an unconventional d -wave superconductor is magnetic field dependent, proportional to $H^{1/2}$, owing to the Doppler shift of quasiparticle excitations in a background of vortex supercurrents. [1, 2] This phenomenon, called the Volovik effect, is absent in an s -wave state; however, it has been predicted [3] to exist for a sign changing $s_{\pm}$ state with a characteristic field dependence, proportional to H . We have observed this behavior in the ^{75}As NMR spin-lattice relaxation rate of a single crystal of $\text{Ba}_{0.67}\text{K}_{0.33}\text{Fe}_2\text{As}_2$ studied over a wide range of fields up to 28 T. Our spatially resolved measurements show that Doppler contributions to the rate increase toward the vortex core, consistent with the superconducting state having unconventional $s_{\pm}$ symmetry.

10:36AM A22.00012 Origin of the variety of superconducting gap structure in iron-based superconductors: competition between orbital and spin fluctuations, SEIICHIRO ONARI, TETSURO SAITO, HIROSHI KONTANI, Nagoya University — To understand the pairing mechanism in iron-based superconductors, we study the three-dimensional gap structure based on the orbital fluctuation theory. We focus on the fully-gapped state in (i) heavily electron-doped KFe_2Se_2 [1], nodal gap structure in (ii) isovalent-doped $\text{BaFe}_2(\text{As,P})_2$, and strongly band-dependent gap structure in (iii) hole-doped $(\text{Ba,K})\text{Fe}_2\text{As}_2$. Based on the three-dimensional ten orbital model for (i), we obtain orbital-fluctuation-mediated fully-gapped s_{++} wave state without sign reversal. For (ii), we reproduce the loop-shaped nodal structure on the electron-Fermi surface, due to the competition between orbital and spin fluctuations. For (iii), we obtain a drastic change in the gap structure by hole-doping, reflecting the variation of orbital fluctuations due to the topological change of electron-pockets. These results indicate the significant role of orbital fluctuations in iron-based superconductors. [1] Saito et al., PRB **83**, 140512(R) (2011)

10:48AM A22.00013 Microscopic Mechanism for a Pairing State with Time-Reversal Symmetry Breaking in Iron-Based Superconductors, WERNER HANKE, Theoretical Physics, University of Würzburg, SHOU-CHENG ZHANG, Department of Physics, Stanford University, CHRISTIAN PLATT, Theoretical Physics, University of Würzburg, RONNY THOMALE, Department of Physics, Stanford University — The multipocket Fermi surfaces of iron-based superconductors promote pairing states with both $s_{\pm}$ -wave and dx^2-y^2 -wave symmetry. We argue that the competition between these two order parameters could lead to a time-reversal-symmetry breaking state with $s + id$ -pairing symmetry in the iron-based superconductors, and propose several scenarios in which this phase may be found. To understand the emergence of such a pairing state on a more rigorous footing, we start from a microscopic 5-orbital description representative for the pnictides. Using a combined approach of functional renormalization group and mean-field analysis, we identify the microscopic parameters of the $s + id$ -pairing state. There, we find the most promising region for $s + id$ -pairing in the electron doped regime with an enhanced pnictogen height.

Monday, February 27, 2012 8:00AM - 11:00AM — Session A23 DCMF: Metals Magnetic 255

8:00AM A23.00001 Bulk electronic structure of FeRh undergoing metamagnetic transition via hard x-ray photoemission, ALEXANDER GRAY, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, DAVID COOKE, Department of Physics, University of California, Berkeley, PETER KRUGER, CNRS Université de Bourgogne, CATHERINE BORDEL, Department of Physics, University of California, Berkeley, ERIC FULLERTON, Center for Magnetic Recording Research, University of California, San Diego, SHIGENORI UEDA, KEISUKE KOBAYASHI, NIMS Beamline Station at SPring-8, FRANCES HELLMAN, Department of Physics, University of California, Berkeley, CHARLES FADLEY, Department of Physics, University of California, Davis — In this study changes in the electronic structure accompanying a temperature-induced metamagnetic transition from anti-ferromagnetic to ferromagnetic order are investigated in strained epitaxial FeRh thin films via valence-band and core-level hard x-ray photoelectron spectroscopy with a photon energy of 6 keV. At such high photon energy, the resulting inelastic mean-free paths of the photoemitted electrons and therefore the average probing depths are on the order of 60 Å, corresponding to about 20 unit cells and ensuring truly bulk-sensitive measurement. Clear differences between the AFM and FM states are observed across the entire valence-band spectrum and these are well reproduced using density functional theory. Changes in the Fe 2p core-levels of Fe are also observed and interpreted using Anderson impurity model calculations. These results suggest that significant electronic structure changes are involved in this AFM-FM transition.

8:12AM A23.00002 Random magnet with competing anisotropies in $\text{Fe}_x\text{Ni}_{1-x}\text{F}_2$ alloys¹, TRENT JOHNSON, FELIO PEREZ, TUDOR STANESCU, DAVID LEDERMAN, West Virginia University — A series of epitaxial (110) $\text{Fe}_x\text{Ni}_{1-x}\text{F}_2$ films were deposited on (110) MgF_2 via molecular beam epitaxy. The Fe concentration x was determined by measuring the lattice parameter along the [110] direction using x-ray diffraction. The film thicknesses and the roughness of each interface were found by fitting of x-ray reflectivity data. The magnetic ordering as a function of x was analyzed by SQUID magnetometry. Enhancement of the Néel temperature in alloys as well as evidence of spontaneous magnetization along the c -axis after field-cooling were observed for samples with $x > 0.1$; for samples with $x < 0.1$ the magnetization was perpendicular to the c -axis. Two phase transitions were observed for alloy samples with $x > 0.1$. The phase diagram of the upper transition was consistent with mean field theory of a system with competing anisotropies. The transition at lower temperatures was unaffected by the application of a magnetic field, whereas the upper temperature transition was broadened by the application of fields as small as 50 Oe. This suggests the presence of a spin-glass phase at lower temperatures, followed by melting of the spin glass prior to the main transition to paramagnetic behavior as the temperature is raised.

8:24AM A23.00003 Structural and electronic origin of large magnetostrictive $Fe_{1-x}Ga_x$ alloys¹

, HUI WANG, Shenyang National Laboratory of Materials Science, Institute of Metal Research and International Centre of Materials Physics, Chinese Academy of Scie, YANNING ZHANG, RUQIAN WU, LIZHI SUN, University of California, Irvine, SONSHENG XU, ZHIDONG ZHANG, Shenyang National Laboratory of Materials Science, Institute of Metal Research and International Centre of Materials Physics, Chinese Academy of Scie — $Fe_{1-x}Ga_x$ binary alloys exhibiting large magnetostriction and excellent ductility have great potentials for various applications. The origin of large magnetostriction has not been thoroughly studied, especially at high Ga concentration ($x > 18.75\%$). We conduct extensive ab initio molecular dynamics simulation of $Fe_{1-x}Ga_x$ alloys to generate atomic structures; and find that the alloys adopt the disordered A2 structure for $x < 18.75\%$ and the A2+D0₃ mixed structures for $18.75\% < x < 23.4\%$, respectively. The formation of D0₃-like structure play a key role for the decrease of magnetostriction beyond $x = 19\%$. Interestingly, the magnetostriction may greatly enhance, up to $\lambda_{001} = 850$ ppm in ternary alloys with incorporation of 3 – 5% Cu and Zn.

8:36AM A23.00004 Thin film deposition of Mn₂Ga under various growth condition , MINGYANG LI, LI

GAO, XIN JIANG, MAHESH SAMANT, BRIAN HUGHES, KEVIN ROCHE, IBM Almaden Research Center, CLAUDIA FELSER, University of Mainz, STUART PARKIN, IBM Almaden Research Center — The tetragonal DO_{22} phase of $Mn_{3-x}Ga$ is a ferromagnetic Heusler with perpendicular magnetic anisotropy. It has high spin polarization, high Curie temperature and low magnetic moment, and thus becomes a good candidate for spin-transfer-torque magnetic random access memory. This work reports the epitaxial growth of tetragonal Mn_2Ga thin films using sputtering method. The effect of various substrates, buffer layers, and substrate temperature on the film roughness is presented and compared. The formation of Mn_2Ga islands are observed at the beginning of growth on most buffer layers by reflection-high-energy-electron-diffraction. The smoothest film with root-mean-square roughness 0.10nm is obtained by using Pt buffer layer. The magnetic properties are also compared.

8:48AM A23.00005 Magneto Caloric Effect in Ni-Mn-Ga alloys: First Principles and Experimental studies , KHORGOLKHUU ODBADRAKH, DON NICHOLSON, Oak Ridge National Laboratory, GREGORY BROWN, Florida State University, AURELIAN RUSANU, ORLANDO RIOS, JASON HODGES, ATHENA SAFA-SEFAT, GERARD LUDTKA, MARKUS EISENBACH, BOYD EVANS, Oak Ridge National Laboratory — Understanding the Magneto-Caloric Effect (MCE) in alloys with real technological potential is important to the development of viable MCE based products. We report results of computational and experimental investigation of a candidate MCE materials Ni-Mn-Ga alloys. The Wang-Landau statistical method is used in tandem with Locally Self-consistent Multiple Scattering (LSMS) method to explore magnetic states of the system. A classical Heisenberg Hamiltonian is parametrized based on these states and used in obtaining the density of magnetic states. The Curie temperature, isothermal entropy change, and adiabatic temperature change are then calculated from the density of states. Experiments to observe the structural and magnetic phase transformations were performed at the Spallation Neutron Source (SNS) at Oak Ridge National Laboratory (ORNL) on alloys of Ni-Mn-Ga and Fe-Ni-Mn-Ga-Cu. Data from the observations are discussed in comparison with the computational studies. This work was sponsored by the Laboratory Directed Research and Development Program (ORNL), by the Mathematical, Information, and Computational Sciences Division; Office of Advanced Scientific Computing Research (US DOE), and by the Materials Sciences and Engineering Division; Office of Basic Energy Sciences (US DOE).

9:00AM A23.00006 First principles determination of the rhombohedral magnetostriction of $Fe_{100-x}Ga_x$ and $Fe_{100-x}Al_x$ ($x < 20$) alloys¹ , RUQIAN WU, YANNING ZHANG, University of California, Irvine — Extensive efforts have been dedicated to investigate the extraordinary magnetostriction of Galfenol ($Fe_{100-x}Ga_x$) and Alfenal ($Fe_{100-x}Al_x$) alloys, which are very promising magnetostrictive materials for various applications such as sensors, transducers and spintronic devices. In contrast to the strong response of the tetragonal magnetostriction (λ_{100}) to the Ga/Al concentration (x), the rhombohedral magnetostriction, λ_{111} , vs. x curves for both FeGa and FeAl alloys show negative and steady values for $0 < x < 15$. Strikingly, the sign of λ_{111} changes at $x = 18$, a concentration that corresponds to the first peak of λ_{100} - x curves. Through highly-accurate full potential linearized augmented plane-wave method (FLAPW), our theoretical results nicely reproduce the main features of experimental λ_{111} - x curves, except the opposite sign of λ_{111} of pure Fe. Detailed analyses on the structural and electronic properties of Galfenol provide deeper understandings of the origins of the sign change, as well as the large magnetostriction anisotropy in these alloys. Possible reasons on the disagreement between the calculated and observed rhombohedral magnetostriction of bcc Fe will also be given.

¹Work was supported by the ONR (Grant No: ONR N00014-11-1-0444). Calculations were performed on the DOD supercomputers.

9:12AM A23.00007 Intrinsic Magnetic Properties of $L1_0$ Derivates¹ , RALPH SKOMSKI, Dept. of Physics & Astronomy and NCMN, University of Nebraska, PRIYANKA MANCHANDA, PANKAJ K. SAHOTA, ARTI KASHYAP, IIT Jaipur, India, BALAMURUGAN BALASUBRAMANIAN, Dept. of Physics & Astronomy and NCMN, University of Nebraska, J.E. SHIELD, Dept. Mechanical Engineering, University of Nebraska, D.J. SELLMYER, Dept. of Physics & Astronomy and NCMN, University of Nebraska — It is investigated how atomic substitutions modify the magnetization, exchange and anisotropy of $L1_0$ -ordered ferromagnets. Emphasis is on properties of interest in permanent magnetism, including the reduction of raw-materials costs by substituting iron-series transition metals for expensive heavy (4d/5d) transition-metal elements. In particular, VASP calculations are used to determine the magnetizations of the Fe-Co-Pt, Mn-Al-C and Fe-Ni-S systems. We perform supercell calculations to determine the moments of Fe and Co in various $L1_0$ derivates with chemical disorder. The local magnetic moments exhibit a subtle dependence on the environment, not only in each Fe-Co layer but also through alternating 4d/5d layers. However, the magnitude of these spatial fluctuations is not very large, and after configurational averaging, the moments exhibit very simple dependencies on the concentrations of the involved atoms. The FeNi system is also interesting because $L1_0$ -ordered FeNi was originally discovered in meteorites (tetrataenite), formed with cooling times in excess of one million years.

9:24AM A23.00008 Growth of Mn₂TiSn alloy and its magnetic and structural characterizations¹ , YUNG HUH, Physics Department, South Dakota State University, Brookings, 57007, P. KHAREL, V.R. SHAH, X.Z. LI, N. AL-AQTASH, K. TARAWNEH, E.S. KRAGE, R.F. SABIRIANOV, R. SKOMSKI, D.J. SELLMYER, NCMN, University of Nebraska, Lincoln, NE 68588 — A ternary inter-metallic alloy Mn_2TiSn is one of the candidates predicted to be a Heusler compound with high spin polarization and Curie temperature well above room temperature, which is suitable for spintronic applications. Mn_2TiSn powder samples were prepared by arc melting and annealing under controlled environment to study magnetic and structural properties. Temperature and field dependent magnetization measurements show the sample is ferromagnetically ordered with a Curie temperature above 400 K. The low temperature magnetization at 10 K is about 2.5 emu/g under 100 Oe. The coercivity increases as temperature decreases from 1 kOe at room temperature to 2.4 kOe at 10 K. Theoretical calculation from the high field data shows the anisotropy energy is 4.0×10^5 ergs/cm³ at 300 K but it becomes slightly more than doubled at 10 K. TEM and XRD characterizations reveal that the compound crystallizes in the hexagonal structure (D0₁₉, P6₃/mmc) rather than the theoretically proposed L2₁ cubic structure, which is supported by the first-principle structure calculations where the total energy per unit cell volume is preferred for the hexagonal structure.

¹This research is supported by ARO (W911NF-10-2-0099) (DJS, PK, XZL, VRS), NSF-MRSEC (NSF-DMR-0820521) (YH, EK, RFS, KT, NA and RS) and NCMN (Central Facility support).

9:36AM A23.00009 Unusual temperature dependence of the magnetic anisotropy constant in barium ferrite $\text{BaFe}_{12}\text{O}_{19}$, FAN ZHAO, JUN WANG, WEI WU, Ningbo University, GUO-MENG ZHAO, California State University, Los Angeles — We report magnetic hysteresis loops in a wide temperature range (4-700 K) for silica-coated barium ferrite $\text{BaFe}_{12}\text{O}_{19}$ nanoparticles. The saturation magnetization M_s and the first magnetic anisotropy constant K are determined simultaneously from the magnetic hysteresis loop using the law of approach to saturation. It is remarkable that K is linearly proportional to M_s and varies precisely with temperature as $K(T) = K(0)[1 - (T/T_C)^{1.58}]$ in the whole temperature range below the Curie temperature T_C (740 K). The unusual temperature dependence of the anisotropy constant and its linear relation with the saturation magnetization in $\text{BaFe}_{12}\text{O}_{19}$ are not predicted from the existing theoretical models.

9:48AM A23.00010 First principles study of magnetic properties of Zn-Sn substituted M-type Sr-hexaferrite, SEONG-GON KIM, LAALITHA LIYANAGE, Department of physics and astronomy, Mississippi state university, JEFF HOUZE, None, SUNGHO KIM, Center for advanced vehicular systems, Mississippi state university — Site occupancy and magnetic properties of Zn-Sn substituted M-type Sr-hexaferrite $\text{SrFe}_{12-x}(\text{Zn}_{0.5}\text{Sn}_{0.5})_x\text{O}_{19}$ with $x = 1$ were studied using density functional theory and generalized gradient approximation (GGA). Using the GGA+U method the description of strongly correlated $3d$ electrons of Fe was improved. Our results show that Zn and Sn atoms prefer to occupy $4f_1$ and $4f_2$ sites respectively. Favorable Zn-Sn substituted configurations show an increase in saturation of magnetization (M_s), and a decrease in magnetic anisotropy energy (MAE), over the pure M-type Sr-hexaferrite ($x = 0$). Experimental observations agree with the decrease of MAE and the increase of M_s for Zn-Sn substituted Sr-hexaferrite.

10:00AM A23.00011 The Origin of Secondary Hematite Phase in Non-stoichiometric Co-ferrite Prepared by Ceramic Method¹, DAVID JILES, Electrical and Computer Engineering Department, Iowa State University, Ames, IA 50011, USA, CAJETAN NLEBEDIM, Ames Laboratory, US Department of Energy, Ames, IA 50011, USA, ANTHONY MOSES, Wolfson Centre for Magnetics, School of Engineering, Cardiff University, Cardiff CF24 3AA, UK, MAGNETICS RESEARCH GROUP TEAM, MAGNETICS RESEARCH GROUP TEAM, WOLFSON CENTRE FOR MAGNETICS TEAM — Surprising results have shown the formation of a secondary phase of hematite in co-ferrite. Co-ferrite based materials have been increasingly studied for magnetoelastic and magnetoelectric applications. Enhancement of the properties for such applications can be made by cation substitution, heat treatment or processing. Often, samples whose compositions deviate from stoichiometry or targeted compositions are made. It is not yet known, how far from stoichiometric composition one would go to create other phases; which would also affect the properties. This study shows that, when samples are made by the ceramic method, a secondary hematite phase forms with the spinel Co-ferrite phase. The origin of the hematite phase is related to the processing temperature, sintering environment and deviation from stoichiometric composition. Consequently, deviation from targeted or stoichiometric compositions may explain why properties of co-ferrite reported in literature vary.

¹Research at Ames Lab. was supported by Dept. of Energy-Basic Energy Sciences (Contract No. DE-AC02-07CH11358); research at Cardiff University was supported by UK EPSRC (Grant No. EP/D057094).

10:12AM A23.00012 Magnetic Characterization of heavily proton-irradiated MnAl Hall bars¹, MARC COSTANTINE, NATTAWUT ANUNIWAT, YISHEN CUI, STU WOLF, JIWEI LU, University of Virginia, BRAD WEAVER, Navy Research laboratory — τ -MnAl has L1_0 structure with the perpendicular magnetic anisotropy and it attracts some interests due to the potential application in magnetic recording media and spintronics. We fabricate $\sim 2\mu\text{m}$ wide Hall bar devices from 40 nm MnAl thin film to study the transport properties. Anomalous Hall Effect (AHE) resistance loops of the devices and out-of-plane magnetization loops of unpatterned films mimic one another. This correlation shows that the electrical transport of the material is strongly spin dependent at room temperature. Crystallinity and chemical ordering characterization are performed using X-ray diffraction on unpatterned films. Both patterned and unpatterned films are then exposed to 2 MeV-energy protons for 2 hours at Naval Research Laboratory for displacement damages study. The magnetic and magneto-transport properties were not degraded after the irradiation, which shows promising radiation hardness for future spintronics devices. The heavier, more energetic beam sources and larger dose radiations will be performed and discussed.

¹We acknowledge the financial support from DARPA and DTRA.

10:24AM A23.00013 Structural and magnetic properties of high anisotropy $\text{HfCo}_{7-x}\text{Fe}_x$ alloys¹, BALAMURUGAN BALASUBRAMANIAN, BHASKAR DAS, RALPH SKOMSKI, SHAH VALLOPILLY, JEFFREY SHIELD, DAVID SELLMYER, Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, NE 68588. — An increasing demand of rare-earth elements in recent years intensifies the search for rare-earth free permanent magnetic materials with magnetocrystalline anisotropy $K_1 = 1 \text{ MJ/m}^3$. The present study reports melt-spun HfCo_7 alloys with a high K_1 of 1.3 MJ/m^3 along with an appreciable saturation-magnetic polarization (J_s) of 8.9 kG. A substitution of Fe for Co in $\text{HfCo}_{7-x}\text{Fe}_x$ further improves K_1 and J_s to 1.5 MJ/m^3 and 10.4 kG, respectively. XRD studies of HfCo_7 are in agreement with an orthorhombic structure and also reveal a lattice expansion on substituting Fe for Co. These results show that $\text{HfCo}_{7-x}\text{Fe}_x$ can be a promising candidate for permanent-magnet and other significant applications. In brief, the structural and magnetic properties of $\text{HfCo}_{7-x}\text{Fe}_x$ alloys ($0 \leq x \leq 1$) investigated using XRD, EDX, TEM, and SQUID magnetometer will be presented.

¹This work is supported by DOE (D.J.S.), ARPA-E (B.B., J.E.S.), BREM (B.D., R.S.), and NCMN (S.R.V.)

10:36AM A23.00014 Calciothermic Preparation of Sm-Co From Nanostructured Precursor Oxides¹, BRIAN KELLY, Department of Physics and Astronomy, University of Delaware, GERALD POIRIER, Princeton Institute for the Science and Technology of Materials, Princeton University, KARL UNRUH, Department of Physics and Astronomy, University of Delaware — A calciothermic reduction/diffusion process has been developed for the preparation of Sm-Co alloys with good magnetic properties using nanostructured Co- and SmCo -oxide powders as precursors. The precursor oxides were obtained from an aqueous solution of $\text{Sm}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$, $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, and citric acid which, after the removal of excess water, spontaneously reacts to form a fine mixture of Co_3O_4 and SmCoO_3 nanoparticles. These nanoparticles were then mixed with metallic Ca granules, sealed under inert gas in Nb tubes, and heated to temperatures between 850 and 1000 °C for various lengths of time. The products of the reduction/diffusion reaction were studied by scanning electron microscopy with elemental analysis, vibrating sample magnetometry, and x-ray diffraction. These measurements revealed that (in addition to the oxidation product CaO) the products of the reduction/diffusion process were micron-sized particles of essentially single phase SmCo_5 with a coercivity in excess of 40 kOe and a Curie temperature of about 950 °C.

10:48AM A23.00015 Theoretical search for new permanent magnets with no rare earth atoms, LIQIN KE, VLADIMIR ANTROPOV, Ames Laboratory, MARK VAN SCHILFGAARDE, King's College, London, UK — We use the density functional theory and Quasiparticle Self-Consistent GW approximation to investigate the crystal and electronic structure, magnetic moment, anisotropy, and exchange coupling of Fe_{16}N_2 , $\text{Fe}_{13}\text{Al}_3$, Co_7Hf and $\text{Zr}_2\text{Co}_{11}$. Both methods show similar results for magnetization and electronic structure. The experimentally unknown crystal structures of Co_7Hf and $\text{Zr}_2\text{Co}_{11}$ are obtained using structural optimization. We also discuss possible usage of these materials as permanent magnets.

Monday, February 27, 2012 8:00AM - 11:00AM –

Session A24 FIAP: Materials: Synthesis, Growth and Processing (Bulk and Films) 256

8:00AM A24.00001 Epitaxial Growth of Zinc Oxide on Single Crystalline Gold Plates, KATHRYN GREENBERG, JOHN JOO, MOR BARAM, DAVID CLARKE, EVELYN HU, Harvard University School of Engineering and Applied Sciences — Although metal-oxide interfaces are the critical components of many electronic and optical devices, it is rare to find epitaxial metal-oxide structures. We demonstrate for the first time, a method for the low temperature, epitaxial growth of zinc oxide (ZnO) on single crystalline gold plates. The gold plates, up to 100 μ m in width, are grown from a gold-surfactant complex. Even with the large lattice mismatch between (111) gold and (0001) ZnO, we are able to form epitaxial zinc oxide at 90°C on top of the single crystal gold plates. This epitaxial growth is confirmed using transmission electron microscopy, electron diffraction, and electron backscatterer diffraction. Micro-photoluminescence is also performed to investigate the optical properties of the epitaxial zinc oxide. We remove the grown ZnO membranes from the gold plates using a stamping and etching process. These membranes can potentially be used to fabricate high quality microdisks and photonic crystals. The metal-oxide interfaces that we have fabricated may have the ability to be used in a number of technologically important applications, including as better electrical contacts and for improved light extraction from planar LED structures.

8:12AM A24.00002 Forward Raman scattering in ZnO: observation of phonon polaritons¹, D.A. TENNE, T. ENGMAN, A.K. FARRAR, Department of Physics, Boise State University, Boise, ID 83725, USA — Single crystal wurtzite ZnO samples have been studied by forward Raman scattering. Spectra were measured at 295 and 75 K using 442 and 448 nm laser lines for excitation below the fundamental absorption edge. Measuring spectra in forward geometry at varied scattering angles allowed achieving small and variable magnitudes of phonon wave vector necessary to observe a polariton effect. The observed frequencies of the polaritons formed by A₁ TO phonons will be compared to the calculated dispersion of phonon polaritons in ZnO.

¹Supported in part by NSF Grant DMR-1006136

8:24AM A24.00003 SiGe Nanomembranes: Defect-Free Single-Crystalline Substrates for Growth of Strained Si/SiGe Heterostructures¹, DEBORAH M. PASKIEWICZ, BOY TANTO, DONALD E. SAVAGE, PAUL G. EVANS, MARK A. ERIKSSON, MAX G. LAGALLY, University of Wisconsin-Madison — Silicon-Germanium semiconductor alloys play a pivotal role in the strain engineering of heterostructures for microelectronic devices; however, high quality, single crystalline, defect free films with more than minimal Ge concentration do not exist. The lattice mismatch between Si and bulk SiGe results in biaxial tensile strain in thin Si films and leads to electronic band offsets that allow for the confinement of electrons in the strained Si layer, i.e., a two-dimensional electron gas. Many of the current techniques used to create relaxed SiGe rely on plastic relaxation of the alloy, which impose strain variations and inject crystalline defects into all epitaxial layers grown on top. These defects can significantly degrade the performance of any device in the active layer. We demonstrate the fabrication of SiGe nanomembranes (NM): fully elastically relaxed, smooth, single-crystalline sheets of SiGe alloy. These SiGe NMs can be transferred to new handling substrates, bonded, and used as templates for growth of new defect-free materials. We compare the material quality of strained Si/SiGe heterostructures grown on SiGe NMs with those created on SiGe substrates relaxed via dislocations.

¹Research supported by DOE and NSF.

8:36AM A24.00004 XRD analysis of high purity germanium single crystals grown by Czochralski method, GANG YANG, GUOJIAN WANG, WENCHANG XIANG, MUHAMMAD KHIZAR, YUTONG GUAN, YONGCHEN SUN, DONGMING MEI, CHAOYANG JIANG, BRUCE GRAY, University of South Dakota — Two high purity germanium (HPGe) crystals were grown in argon and hydrogen atmosphere by Czochralski method, respectively. Both XRD 2θ scanning and rocking curve (ω -scanning) were used to investigate the quality of the grown crystals. XRD 2θ scanning results show that an extremely strong (400) peak at 2θ of 66.15° and a very feeble (200) peak at 31.56° were observed in three samples cut from the crystal grown in Ar atmosphere, indicating the crystals with <100> orientation. However, there is an obvious split on (400) peak for three samples, which could be attributed to defects in the crystal. Additionally, according to the reflection and extinction law of germanium crystal with face-centered cubic lattice, the reflection of 200 should be forbidden. The presence of (200) peak at 31.56° could be resulted from XRD multiple-beams scattering. For the crystal grown in hydrogen atmosphere, only very strong and non-split (400) peak at 2θ of 66.15° was observed in all three samples. The ω -scanning results of two crystals at the fixed 2θ of 66.15° show that the crystal grown in hydrogen atmosphere has much more highly symmetric rocking curve with narrower FWHM, which exhibits that the crystal grown in hydrogen atmosphere has very high quality. This work is supported by DOE grant DE-FG02-10ER46709 and the state of South Dakota.

8:48AM A24.00005 Growth and characterization of room temperature antiferromagnetic I-Mn-V semiconductors¹, X. MARTI, Charles University in Prague, T. JUNGWIRTH, P. WADLEY, H. REICHLÖVA, V. NOVAK, Institute of Physics ASCR, O. STELMAKHOVYCH, K. UHLIROVA, Charles University in Prague, P. BERAN, Nuclear Physics Institute ASCR, M. CUKR, Institute of Physics ASCR, F. MACA, Institute of Physics ASCR, Czech Republic, A.B. SHICK, Institute of Physics ASCR, J. MASEK, Institute of Physics ASCR, Czech Republic, P. HORODYSKÁ, P. NEMEC, V. HOLY, Charles University in Prague, J. ZEMEK, P. KUZEL, Institute of Physics ASCR, I. NEMEC, Charles University in Prague, B. GALLAGHER, R. CAMPION, C.T. FOXON, University of Nottingham, J. WUNDERLICH, Hitachi Cambridge Laboratory — The integration of ferromagnetism and semiconductors has been studied extensively, but devices operate well below room temperature. Recent theoretical and experimental works have opened a new route for spintronics based on antiferromagnets. Remarkably, high-temperature antiferromagnetic order is much more compatible with semiconductors than the ferromagnetic order. In our work we focus on the family of I-Mn-V antiferromagnetic semiconductor. We report on our synthesis of bulk and thin-film epilayers of the I-Mn-V compounds and on their basic electrical and magnetic properties. We will discuss the utility of these materials for designing antiferromagnetic semiconductor spintronic devices.

9:00AM A24.00006 Nonequilibrium growth of GaInAsSb on GaSb across the immiscibility region by molecular beam epitaxy for midinfrared materials¹ , ASLI YILDIRIM, JOHN PRINEAS, Department of Physics and Astronomy, and Optical Science and Technology Center, University of Iowa, Iowa City, IA, 52242 — GaInAsSb is a potentially important mid-infrared material, because alloys can in theory be grown with cut-off wavelengths from 1.7 to 4.9 μm . That potential has been hampered in the past by the presence of large alloy immiscibility regions. In this work, 2 μm bulk GaInAsSb layers lattice-matched to GaSb substrates were grown across the entire compositional range, including the immiscibility region, by molecular beam epitaxy. Lower than typical growth temperatures (410-450 °C) were used to limit the adatom diffusion length and move growth conditions further from equilibrium. Using a variety of techniques to characterize the optical, structural, and morphological quality of films, no phase separation was observed to occur for any alloy concentration. High resolution X-ray scans showed one narrow peak, and a single bright photoluminescence peak was observed for all samples. Smooth GaInAsSb surfaces were observed for all samples by AFM measurements, and XTEM images also show GaInAsSb layers to be homogeneous and defect free, with no sign of phase separation. EDS studies have been done, and results show low alloy scatter.

¹This work is supported by NSF DMR 100-6956

9:12AM A24.00007 Electronic and Structural Properties of InGaZnO Thin Films , D.S. WILLIAMS, S. SALLIS, L.F.J. PIPER, B.E. WHITE, Binghamton University — We examine the effects of oxygen partial pressure during deposition and the structural changes resulting from a post-deposition anneal on the transport properties of InGaZnO. Amorphous oxygen-deficient samples sputter-deposited from a target with an atomic ratio of 2:2:1:7 at 50 watts DC in a 3 mTorr argon atmosphere have a resistivity of 0.16 ohm-centimeters. Amorphous oxygen-rich samples deposited similarly, except for a 10% oxygen partial pressure, are insulating. For both samples, the as-deposited surfaces show a consistent grain size of approximately 30 nm. A subsequent rapid thermal anneal at 600°C for 10 seconds leads to the coalescing and vertical growth of the grains with a resultant thinning of the background matrix. After anneal, the resistivity of the oxygen-deficient sample is decreased to 0.003 ohm-centimeters and 0.005 ohm-centimeters for the oxygen-rich sample. X-ray diffraction, scanning electron microscopy, atomic force microscopy and x-ray photoelectron spectroscopy data are presented to explain these changes and suggest possible methods of tuning the properties of InGaZnO for future use in thin film transistors, flexible electronics, transparent conductors and thermoelectric materials.

9:24AM A24.00008 Low temperature atomic layer deposition of $\alpha\text{-Fe}_2\text{O}_3$ ¹ , JEFFREY KLUG, THOMAS PROSLIER, Argonne National Laboratory, NICHOLAS BECKER, Argonne National Laboratory and Illinois Institute of Technology, JEFFREY ELAM, MICHAEL PELLIN, Argonne National Laboratory — There is significant interest in the use of $\alpha\text{-Fe}_2\text{O}_3$ (hematite) as a semiconducting thin film in a variety of applications including solar energy conversion, water oxidation, and gas sensing. In many such applications, devices may depend on non-planar geometries where traditional thin film deposition techniques are limited by line-of-sight constraints. Atomic layer deposition (ALD) is a gas-phase synthesis technique utilizing sequential self-saturating surface chemical reactions to produce uniform coatings with atomic scale control on substrates with arbitrary shape. However, ALD processes explored for Fe_2O_3 to date generally suffer from either extremely low growth rates, narrow temperature windows for self-saturating growth, or precursors with limited reactivity. In this respect, we will present a detailed study of a new, previously unexplored process for ALD of $\alpha\text{-Fe}_2\text{O}_3$ at technologically relevant temperatures between 200-300°C. Self-limiting growth at ~ 0.7 Å/cycle was confirmed via situ quartz crystal microbalance. The results of in situ process characterization and ex situ analysis of film structure, morphology, composition, and electrical properties will be presented.

9:36AM A24.00009 Impact of atmosphere on HPGe crystal growth¹ , GUOJIAN WANG, GANG YANG, WENCHANG XIANG, JAYESH GOVANI, MUHAMMAD KHIZAR, YUTONG GUAN, DONGMING MEI, Department of physics, University of South Dakota — The growth of high-purity germanium crystals for radiation detectors is being developed at the University of South Dakota. High-purity germanium crystals were grown in argon and hydrogen atmosphere, individually. The growth parameters were compared and analyzed. The relationship between thermal field and crystal quality was discussed. Based on the thermal properties of argon and hydrogen gases, different thermal fields were designed to grow lower dislocation density of high-purity germanium crystals.

¹This work is supported by DOE grant DE-FG02-10ER46709 and the state of South Dakota.

9:48AM A24.00010 Performance optimization of diffused Li on Ga/In eutectic, In/Sn solder and eutectic Ga/In Ohmic contacts to n-high purity-crystalline (100) Ge , KHIZAR KHAN, YANG GANG, GUOJIAN WANG, WENCHANG XIANG, YUTONG GUAN, DONGMING MEI, Department of Physics, University of South Dakota, Vermillion, SD 57069 — Performance optimization study of novel contacts such as diffused lithium on Ga/In eutectic (75.5/24.5 wt%), In/Sn solder (95.0/5.0 wt%) and Ga/In eutectic (75.5/24.5 wt%) to n-high purity-crystalline <100> Ge (HP-SC-Ge) has been presented. Ultrasonically clean samples taken from same substrate were used to process the contacts followed by their characterization utilizing current-voltage (I-V), Hall-effect and AFM measurements. Extreme care was introduced to minimize the effect of parasitic oxide layers. Contacts such as diffused Li on eutectic Ga/In and In/Sn solder were processed in an inert glove box and characterized at 305 K (RT) and 77 K (LN) respectively. Comparative study revealed that Ga/In eutectics contacts behave throughout linear and stable, showing strong hall-effect to that of its counter parts. This was attributed due to the high adsorption behavior of anions at liquid (Ga-In) contacts and improved wettability. Whereas, for In/Sn solder case, the contacts processing considerations were substantially different, mainly because of its poor solder flow, excessive void formation, and heterogeneous phase distribution responsible for process yield loss. For diffused Li on Ga/In eutectic contacts, the linearity of the obtained Ohmic profiles was not consistent due to the high reactivity of the Li with HP-SC-Ge substrate. This work is supported by DOE grant DE-FG02-10ER46709 and the state of South Dakota.

10:00AM A24.00011 Crystal-growth Underground Breeding Extra-sensitive Detectors¹ , DONGMING MEI, The University of South Dakota, CUBED COLLABORATION — CUBED (Center for Ultra-Low Background Experiments at DUSEL) collaborators from USD, SDSMT, SDSU, Sanford Lab, and Lawrence Berkeley National Laboratory are working on the development of techniques to manufacture crystals with unprecedented purity levels in an underground environment that may be used by experiments proposed for DUSEL. The collaboration continues to make significant progress toward its goal of producing high purity germanium crystals. High quality crystals are being pulled on a weekly basis at the temporary surface growth facility located on the USD campus. The characterization of the grown crystals demonstrates that the impurity levels are nearly in the range of the needed impurity level for detector-grade crystals. Currently, the crystals are being grown in high-purity hydrogen atmosphere. With an increase in purity due to the zone refining, the group expects to grow high-purity crystals by the end of 2011. The one third of the grown crystals will be manufactured to be detectors; the remaining will be fabricated in to wafers that have large applications in electro and optical devices as well as solar panels. This would allow the research to be connected to market and create more than 30 jobs and multi millions revenues in a few years.

10:12AM A24.00012 Lattice matched quaternary alloy, BGaAsBi: growth and characterisation¹, DANIEL BEATON, AARON PTAK, KIRSTIN ALBERI, ANGELO MASCARENHAS, National Renewable Energy Lab — The ternary semiconductor alloy GaAs_{1-x}Bi_x has been the focus of many recent studies due to the large decrease in the fundamental band gap, $\Delta E_g \simeq -85 \text{ meV/\%}$ for small incorporated amounts. However, the large size of the bismuth atom relative to the arsenic it replaces results in significant lattice mismatch to GaAs substrates. We now report on the lattice matched quaternary alloy, B_yGa_{1-y}As_{1-x}Bi_x. Incorporating a smaller atom (boron) along with the larger atom (bismuth) allows for a reduction of the epi-layer strain and lattice matched compositions, [B]:[Bi] $\simeq$ 1. The benefit of the choice of boron is that it does not effect the band structure of the host GaAs; no change in the band gap is observed with increasing boron content. Samples were grown by molecular beam epitaxy under conditions conducive to bismuth incorporation: low growth temperatures and low V:III ratios. Both high-resolution X-ray diffraction (XRD) and secondary ion mass spectroscopy were used to verify material composition and photoluminescence used to measure the band gap, and these results will be presented. The increasing observation of a distribution of shallow, in-gap boron related defects will also be discussed.

¹This work is supported by the DOE, BES and MS&E.

10:24AM A24.00013 Optimization of high purity germanium (HPGe) crystals growth rate through the simulation and modeling of growth system geometry¹, JAYESH GOVANI, DONGMING MEI, GUOJIAN WANG, GANG YANG, Physics Department, University of South Dakota, Vermillion, SD 57069 U.S.A — The growth rate and quality of high-purity germanium (HPGe) single crystals depend largely on the control of the thermal field such as the temperature profile and heat transfer. The control parameters of the thermal field can only be regulated externally through the growth system geometry, hydrogen and argon gas pressure, flow rate, pulling rate, and power and frequency of a RF heater. Since quantitative determination of the control parameters is exceptionally challenging and expensive, computer modeling and simulation of Cz growth processes play an imperative role in the advances of innovative pulling procedures and augmentation of Ge crystal quality. We present a detailed modeling and simulation study of radial and vertical temperature gradient, radial and vertical heat flux, temperature profile, thermo-elastic stresses, and defect density analysis for different crystal positions and diverse growth system geometry. We also virtually studied the consequences of targeted growth rate on temperature gradient and induction heating. A comparative analysis of simulated and available experimental results is also presented. In this effort, we have demonstrated the importance of simulation and modeling as it helps reducing the number of growth experiments significantly for the optimization of crystal quality and targeted growth rate.

10:36AM A24.00014 Passivation Layer by SiC Thin Film Deposition for High Efficiency Solar Cells, MAHDI HAGHZEDEH, ECE U. Mass Lowell, DANIEL SCHMIDT, Plastics Eng U. Mass Lowell, JOEL THERRIEN, ECE U. Mass Lowell — Deposition of a polymer derived SiC thin film as a novel, chemically and physically stable passivation layer to enhance the efficiency of solar cells by way of reducing surface recombination was studied. Starfire Matrix Polymer number 10 (SMP-10) is used to produce thin films of SiC on ion implanted silicon wafers. To ascertain the best method to deposit, three methods were tested: spin coating, spray coating, and dip coating are used. Various concentrations of SMP-10 diluted in xylene as an appropriate solvent are examined. To test the films, a contactless inductive coupling method is used. The thinner layers of SiC are grown by a lower percentage of SMP-10 (5%), higher spin speed in spin coating (3000 RPM), and lower pulling out speed in dip coating (50 mm/minute). All of the methods yield controllable, repeatable, and uniform thin films. Although eliminating oxygen as an impurity in the passivation layer remains a challenge, the described approach has promise as a simple, low-cost passivation layers for higher efficiency solar cells.

10:48AM A24.00015 Growth of ZnO Nanowire Arrays for Advanced Ultraviolet Detectors, JOHN ZELLER, Magnolia Optical Technologies, Inc., TARIQ MANZUR, Naval Undersea Warfare Center, 1176 Howell Street, Newport, RI 02841, A.F. MEHDI ANWAR, Department of Electrical Engineering, University of Connecticut, Storrs, CT 06269, ASHOK K. SOOD, Magnolia Optical Technologies, Inc., 52-B Cummings Park, Woburn, MA 01801 — Zinc oxide (ZnO) provides a unique wide bandgap biocompatible material system exhibiting both semiconducting and piezoelectric properties. Bulk ZnO has a bandgap of 3.37 eV that corresponds to emissions in the solar blind ultraviolet (UV) spectral band (240-280 nm). We have grown highly ordered vertical arrays of ZnO nanowires using the metal organic chemical vapor deposition (MOCVD) technique on Si, silicon dioxide, c-plane sapphire, and GaN epitaxial substrates. UV detectors based on ZnO nanowires offer the highest UV sensitivity and lowest visible sensitivity for applications such as missile plume detection and threat warning. The development of UV detectors based on vertical nanowire arrays requires an innovative fabrication approach involving precise deposition of metal contacts, where UV sensor performance depends to a large extent on the growth conditions as well as on the substrate used. We will present experimental results on the structural, electrical, and optical properties of ZnO nanowires grown for UV sensing applications.

Monday, February 27, 2012 8:00AM - 11:00AM –
Session A25 DCOMP GSCCM DMP: Focus Session: Simulation of Matter at Extreme Conditions - Energetic Materials 257A

8:00AM A25.00001 Instability of planar detonation front in energetic materials, MIKALAI BUDZEVICH, VASILY ZHAKHOVSKY, AARON LANDERVILLE, University of South Florida, CARTER WHITE, Naval Research Laboratory, IVAN OLEYNIK, University of South Florida — Detonation wave propagation in solid energetic materials (EMs), as described by the standard AB model, was studied using a novel moving window molecular dynamics (MW-MD) technique. Parameters of the AB model were modified to investigate the mechanisms of detonation propagation in EMs as a function of the activation barrier for the chemical reaction $AB+B \rightarrow A+BB + 3 \text{ eV}$. For barriers below 0.2 eV, the detonation front structure remained planar regardless of the cross-section of the sample. For higher activation barriers, the one-dimensional planar detonation evolves into a cellular detonation upon increase of one of the transverse dimensions of the sample. The cellular detonation transforms into a stable three-dimensional turbulent-like detonation upon simultaneous increase of both transverse dimensions of the sample. These various instabilities of the planar detonation front in solid EMs observed in our MW-MD simulations mirror the major regimes of gas-phase detonation, thus confirming the universal nature of detonation phenomena.

8:12AM A25.00002 Shock-induced chemical reactions in organic materials and explosives, DANA DATTELBAUM, STEPHEN SHEFFIELD, SHAWN MCGRANE, PETER GOODWIN, Los Alamos National Laboratory, SHOCK AND DETONATION PHYSICS TEAM — Interrogating chemical reactions behind a shock front is immensely difficult and, as a result, the details of shock-induced chemistry remain poorly understood. Previous research has shown that dimerizations, polymerizations, ring-opening and decomposition reactions can occur under shock compression, depending on molecular structure. Questions regarding the thresholds for incipient reaction, the nature of first and subsequent reaction steps, and the influence of shock input conditions on reaction kinetics remain to be answered. Here, we have applied *in-situ* electromagnetic gauging at multiple Lagrangian positions to elucidate the evolution of multiple-wave structures associated with shock-induced reactions of several simple functional groups: carbon-carbon double ($-C=C-$) and triple bonds, and nitriles. The relative order of group reactivity under single shock conditions for these simple molecules is discussed. From measurements of the reactive flow, we have obtained detailed information about the temporal evolution of the waves, and global kinetic rates associated with transformation(s) between partially- and fully-reacted states. Near the reactive thresholds, evolution in particle velocities point to reaction timescales on the order of tens-to-hundreds of nanoseconds. We further compare evidence of reaction from gas gun-driven experiments to recent results using laser-driven shocks. Spectroscopic details will be presented from both types of experiments.

8:24AM A25.00003 Molecular dissociation under extreme conditions¹, IGOR SCHWEIGERT, US Naval Research Laboratory — Molecular dissociation under extreme temperatures and pressures is the first step towards thermal or shock initiated decomposition of energetic materials. Fast dissociation rates are challenging to measure, but amenable to first principles calculations. We combine transition-state theory with molecular dynamics simulations based on density-functional theory to predict the temperature-dependent dissociation rates in the gas and the condensed phase. Current applications focus on gas-, solution-, and liquid-phase thermal dissociation of nitramines. These studies will be discussed in the context of developing mesoscale models of initiation of energetic materials.

¹This work is supported by the Naval Research Laboratory via the Jerome and Isabella Karle Distinguished Scholar Fellowship and by the Office of Naval Research, both directly and through the Naval Research Laboratory.

8:36AM A25.00004 Thermodynamic Properties of energetic materials from density functional theory with van der Waals corrections, AARON LANDERVILLE, University of South Florida, MICHAEL CONROY, Naval Research Laboratory, MIKALAI BUDZEVICH, YOU LIN, University of South Florida, CARTER WHITE, Naval Research Laboratory, IVAN OLEYNIK, University of South Florida — The calculation of thermodynamic properties for energetic materials from first-principles offers the promise to provide key parameters for mesoscopic and continuum-level simulations of explosives performance for a wide range of pressures and temperatures. While density functional theory with empirical van der Waals corrections, together with corrections for temperature and zero-point effects, can give excellent agreement between calculated and experimentally determined equations of state, quantities such as heat capacities and coefficients of thermal expansion suffer from inaccuracies in the lower frequencies of the calculated vibration spectrum. Additional approaches are discussed to account for the lowest intermolecular modes to increase the accuracy in prediction of thermal properties.

8:48AM A25.00005 Relating polymorphism and decomposition of RDX under static and dynamic compression¹, ZBIGNIEW DREGER, YOGENDRA GUPTA, Insitute for Shock Physics, Washington State University — Knowledge of the reactive behavior of energetic crystals at static high pressures and high temperatures (HP-HT) is an important step toward understanding the shock wave initiation of these crystals. Vibrational spectroscopy in a diamond anvil cell was used to examine the behavior of RDX crystals at the pressures and temperatures relevant to shock wave initiation. Phase boundaries between three RDX polymorphs (α , γ , and ε) were determined up to 12 GPa and 600 K. Decomposition kinetics for the ε - and γ -phases were examined at various pressures and temperatures, and were found to have positive volumes of activation. CO_2 , N_2O and H_2O were identified as the main decomposition species. Static HP-HT results were used to identify and understand the following processes in shocked RDX: $\alpha - \gamma$ phase transition, identification of the crystal phase at decomposition, and the role of pressure and temperature in accelerating the RDX decomposition under shock compression. This work demonstrated that static HP-HT results provide an important complementary route to elucidate the physical and chemical processes in shocked RDX crystals.

9:00AM A25.00006 Atomistic Simulations of Orientation and Shock Velocity Dependences on Pentaerythritol Tetranitrate Detonation, TZU-RAY SHAN, AIDAN THOMPSON, RYAN WIXOM, ANN MATTSSON, Sandia National Laboratories, Albuquerque, NM 87185, SANDIA TEAM — Predicting the behavior of energetic materials requires a detailed description of how chemical reaction, energy and pressure fronts propagate during initial stages of detonation. In this talk, classical molecular dynamics (MD) simulations are used to examine orientation and shock velocity dependences in single crystal pentaerythritol tetranitrate (PETN). This work utilizes an empirical, variable charge reactive force field (ReaxFF) that is implemented in the LAMMPS package with a time-averaged bond-order method for on-the-fly chemical species identification. The accuracy of ReaxFF is validated by comparisons of activation barriers for dissociation of a single PETN molecule along various dissociation channels with higher-fidelity, but more expensive, density functional theory (DFT) calculations. The response of single-crystal PETN to shock compression is simulated using the multi-scale shock technique (MSST) along the insensitive (100) directions, as well as the sensitive (001) and (110) directions, at steady shock velocities ranging from 6-10 km/s. Hugoniot curves, particle velocities of shocked molecules, and evolution of reaction products with time from MD simulations with ReaxFF will be discussed and compared to that from DFT calculations.

9:12AM A25.00007 Atomic-Scale Theoretical Studies of Energy Transfer, Inelastic Deformation, and Void Collapse in Molecular Crystals and Polymers, THOMAS D. SEWELL, Department of Chemistry, University of Missouri-Columbia, Columbia, MO 65211 — Recent atomic-scale theoretical studies of shock waves in polyatomic molecular crystals and polymers will be presented, with an emphasis on the results and interpretation of molecular dynamics simulations for pentaerythritol tetranitrate (PETN), hexahydro-1,3,5-trinitro-1,3,5-triazine (RDX), nitromethane, and poly(butadiene) (PBD). The effects of structural and mechanical anisotropy on the material response are of particular interest. Among the topics to be discussed are orientation dependent energy transfer pathways and inelastic deformation mechanisms subsequent to shock wave passage in initially defect-free nitromethane and PETN crystals, shock-induced collapse of variously shaped voids in crystalline RDX, and details of shock wave propagation and energy localization in bulk PBD and at the PBD/RDX interface.

9:48AM A25.00008 Explosive initiation of pentaerythritol tetranitrate (PETN) by laser irradiation, ROMAN TSYSHEVSKIY, ONISE SHARIA, MAIJA KUKLJA, Materials Science and Engineering Department, University of Maryland, College Park, MD — Understanding of explosive decomposition of energetic materials triggered by laser irradiation is of great importance for design of new economical formulations with high performance and tunable sensitivity. Earlier, laser irradiation was only considered as a source of heat. Nowadays, it is realized that optical excitation may set off initiation of rapid chemical reactions and govern further decomposition in energetic materials. However, mechanisms of this phenomenon are yet to be established. We present quantum-chemical calculations of the electronic structure of molecular and crystalline PETN to explore the effect of common impurities on its optical properties. We found that charged or excited PETN molecules exhibit significantly different electronic, optical, and chemical behavior. For example, new decomposition pathways that were not available in the ground state become favorable in the charged state of PETN. Three calculated lowest excitation energies of ionized PETN require 0.6, 0.7 and 1.13 eV, which is considerably lower than those for equilibrium PETN. The activation energy of the rate limiting decomposition stage is within 9-12 kcal/mole, while it is 35 kcal/mole in the ground state. We discuss possible ways that originate charge transfer in PETN and presented results in the context of recent experimental data.

10:00AM A25.00009 Condensation of carbon during high explosive detonation, LAURENCE FRIED, SORIN BASTEA, RAUL GARZA, Lawrence Livermore National Lab — The formation of nano-carbon clusters is believed to be responsible for the non-ideal detonation behavior of carbon-rich explosives, such as triamino-trinitrobenzene (TATB). We have developed a new model of carbon formation during detonation. The model is based on the assumption that carbon cluster growth has features of both activated Arrhenius kinetics and diffusion controlled kinetics. In our model the variation of temperature, density, and viscosity throughout the high explosive reaction zone and expansion is calculated using a thermochemical model linked to a hydrodynamic code. We compare our model to new experimental results on the size scaling of detonations in TATB-based explosives.

10:12AM A25.00010 Surface-induced effect on sensitivity of beta and delta HMX crystals, ONISE SHARIA, MAIJA KUKLJA, Department of Materials Science and Engineering, University of Maryland, College Park — It is accepted that sensitivity of energetic materials depends on many factors, including presence of defects, surfaces, interfaces, or voids. However, details of atomistic mechanisms that govern sensitivity to initiation of detonation and correlations between structure, morphology, and degradation of chemical bonds are far from being understood. In this talk, we present quantum chemical calculations combined with transition state theory to analyze chemical decomposition reactions in beta and delta HMX crystals. We calculate the activation barriers and reaction rates in the ideal crystals and materials containing internal surfaces, vacancies, and voids. We show that N-NO₂ homolysis is the most favorable decomposition reaction in all cases. We discuss whether a large space available in the vicinity of voids facilitates the N-NO₂ break in comparisons to an ideal crystal, and if this effect is enhanced in the delta phase in comparison to beta phase. The conclusions and revealed trends are presented in the context of experimental data.

10:24AM A25.00011 ABSTRACT WITHDRAWN —

10:36AM A25.00012 1,1-Diamino-2,2-Dinitroethylene Under High-Pressure-High-Temperature¹, MATTHEW BISHOP, University of Alabama at Birmingham, NENAD VELISAVLJEVIC, Los Alamos National Laboratory, ZHENXIAN LIU, Carnegie Institution of Washington, MATRIN GALLEY, University of Nevada Las Vegas — 1,1-Diamino-2,2-dinitroethylene (FOX-7) is an insensitive high explosive (IHE) which shows promise for use in low vulnerability ammunitions. With performance comparable to RDX and HMX, there is a growing interest in understanding the behavior under denotation conditions. Through the use of diamond anvil cell (DAC) technology and electrical resistive heating, the vibrational behavior of FOX-7, in both the mid and far-IR, were recorded at multiple isotherms under elevated pressure-temperature (PT). Energy-dispersive x-ray diffraction (XRD) was also employed along with a multi-anvil press for further investigating pressure-temperature phase space. Future planned experiments will focus on using high-resolution angular-dispersive XRD and neutron diffraction techniques to resolve high pressure-temperature structural information and obtain P-V-T data. The experiments on FOX-7 have revealed previously uninvestigated knowledge on the elevated-PT decomposition and phase boundaries allowing for a more developed basis for the behavior of FOX-7 under detonation conditions.

¹Los Alamos National Laboratory (LANL) is operated by Los Alamos National Security (LANS), LLC for the Dept. of Energy and National Nuclear Safety Admin. Support for this research was provide by DOE/NNSA Science Campaign 2 under the HE Science Program.

10:48AM A25.00013 Study on the deflagration-to-detonation transition course of porous energetic material, LAN WEI, PENGCHENG HAO, HEFEI DONG, XIAOMIAN HU, JIANSHI ZHU, Institute of Applied Physics and Computational Mathematics — The deflagration-to-detonation transition (DDT) course of energetic material with different porosity ratio was studied utilizing a one-dimensional two-phase flow code. The equations were numerically solved by space-time conservation element and solution element (CE/SE) method. The distribution of physical quantities such as pressure and temperature were obtained together with their evolution history. The physical rules before detonation were mainly analyzed and the effect of convection on the chemical reaction of energetic material was emphasized on.

Monday, February 27, 2012 8:00AM - 11:00AM —

Session A26 DCOMP DMP: Focus Session: Physics of Energy Storage Materials - Materials, Stability and Transport 257B

8:00AM A26.00001 Nanostructured Materials for Portable and Stationary Energy Storage, YI CUI, Stanford University — Storing energy electrochemically involves electronic and ionic processes and chemical transformation inside and at the interface of materials. The ability to understand and design nanostructures and their interfaces afford the great opportunities for controlling these fundamental processes, which can ultimately lead to high performance energy storage devices. Here I will present several exciting examples on designing nanostructures and their interfaces to realize high performance energy storage devices. One example is on designing nanowires and heterostructured nanowires for ultrahigh capacity storage of lithium ions in silicon anodes and sulfur cathodes. The challenges associated with large volume expansion, electron and ion transport, and solid-electrolyte-interphase (SEI) have been addressed. Another example is to design open framework stucture of nanocrystals, which facility facile insertion of sodium and potassium ions. The high power, high energy efficiency and low-cost aqueous batteries can be enabled for grid scale stationary storage.

8:36AM A26.00002 Enhanced electrochemical performance in LiFePO₄/graphene nanocomposite cathode material for lithium ion batteries, KULWINDER DHINDSA, B. MANDAL, M.W. LIN, M. NAZRI, Wayne State University, P. VAISHNAVA, Kettering University, V. NAIK, University of Michigan-Dearborn, G.A. NAZRI, R. NAIK, Z.X. ZHOU, Wayne State University — We synthesized LiFePO₄/graphene nano-composite employing a sol-gel method, where graphene oxide solution was added to the LiFePO₄ precursors during the synthesis. Electrical measurement reveals that the addition of 10% graphene (by weight) to LiFePO₄ increases its conductivity by 5 orders of magnitude. SEM images of the composite show that the material consists of LiFePO₄ nanoparticles (with a mean particle size ~ 50 nm) homogeneously mixed with graphene sheets; the latter provides a three-dimensional conducting network for Li⁺ ion and electron transport. A large specific capacity of 170 mAh/g was observed at a discharge rate of C/2. To further increase the conductivity and inhibit particle size growth of LiFePO₄ (thus to increase the rate capacity), we coated the nanoparticles with a thin carbon layer by adding 0.25M lauric acid as precursor in addition to graphene oxide during the synthesis. The respective roles of graphene and lauric-acid-induced carbon coating in the specific capacity and charge-discharge rate of the LiFePO₄ cathode material will be discussed.

8:48AM A26.00003 Simultaneous enhancement of electronic and Li⁺ ion conductivity in LiFePO₄¹, JAEKWANG LEE, Oak Ridge National Laboratory and Vanderbilt University, STEPHEN J. PENNYCOOK, Oak Ridge National Laboratory, SOKRATES T. PANTELIDES, Vanderbilt University — The electronic conductivity is generally highly sensitive to the electronic properties of a material while the ionic conductivity is mainly sensitive to the structural properties. Thus, the simultaneous control of both is very challenging. Furthermore, many electrochemical systems for advanced energy technologies require materials in which both ionic and electronic conductivities are optimized. Here we explore the influence of biaxial strain on the electronic and Li⁺ ion conductivities of the battery cathode material LiFePO₄ by performing first-principles calculations. We show that biaxial tensile strain leads to simultaneous increases in electronic and ionic conductivities of LiFePO₄. The results unveil a generic mechanism that should be present in other materials with polaronic transport and provide a promising new approach to enhance the performance of energy-related materials.

¹This research was supported in part by the DoE Basic Energy Sciences.

9:00AM A26.00004 Optimization of the surface stability of the LiMn_2O_4 spinel by employing DFT calculations, ALTAF KARIM, KRISTIN PERSSON, Lawrence Berkeley National Laboratory — One of the most important materials for the lithium batteries electrodes is LiMn_2O_4 . We used GGA+U method to calculate the bulk and surface properties of LiMn_2O_4 . Our calculations show that the both correct AFM and electron localization (GGA+U) are necessary to obtain the semiconducting, Jahn-Teller distorted electronic ground state of LiMn_2O_4 . Further we calculated energies of different surfaces such as (100), (110), and (111) to study their stability. Our calculations show that (111) surface has the lowest energy which makes it more stable than other surfaces and it also confirms the experimental results, whereas (101) and (001) similar energies. Absolute surface energies change with +U value, but the ratios between the energies are very similar. Based on these calculations we constructed the equilibrium (Wulff) shape of LiMn_2O_4 particle, which is similar to the cubo-octahedral shape with predominant {1 1 1} facets as it was found in experiments. Our density of states calculations show that the bulk and (100) are semiconducting, whereas (110) and (111) surfaces exhibit metallic behavior. We also calculated the LiMn_2O_4 bulk and surface potentials as a function of lithium concentration.

9:12AM A26.00005 Atomistic Simulation Studies of Nanostructured TiO_2 ¹, PHUTI NGOEPE, MALILI MATSHABA, University of Limpopo, DEAN SAYLE, Cranfield University — TiO_2 has been confirmed as a safe anode material in lithium ion batteries due to its higher Li-insertion potential, ($\sim 1.5\text{V}$) in comparison with commercialised carbon anode materials. Recently in order to attain high rate capabilities of TiO_2 anode, for application in lithium ion batteries with both high power and high energy density, intensive attention has been paid to various TiO_2 nanostructures, such as nanoparticles, nanowires and mesoporous structures. In the current study, amorphisation recrystallization method is used to produce nano-porous, sheets and bulk structures for TiO_2 which have been extensively studied experimentally. Simulated X-ray diffraction patterns are produced from such structures and compared with the experimental XRDs. The simulated microstructures are analysed and compared with available high resolution transmission experimental results. Lithiation of TiO_2 nanostructures is considered and discussed in the context of current investigations and concentration profiles of different ions are shown in the structures. Semi-empirical models based on DFT tightbinding methods, are introduced for TiO_2 and lithiated its forms.

¹We acknowledge the support of SARCHI under the National Research Foundation.

9:24AM A26.00006 First-principles study of electronic structures and phase transitions of lithiated molybdenum disulphide¹, JUN LI, XIAOBO CHEN, Ningbo Institute of Material Technology and Engineering, Chinese Academy of Sciences, Ningbo 315201 PR China, NINGBO INSTITUTE OF MATERIAL TECHNOLOGY AND ENGINEERING TEAM — By first-principles calculations, electronic structures of MoS_2 , intercalation-induced 2H to 1T phase transition and reversibility are investigated. It is revealed that change of interlayer stacking from 2H to 3R imposes negligible influence on the band structure and stability of MoS_2 . In contrast, the change of intralayer stacking from 2H to 1T changes the character of p-d repulsion, resulting in a semiconductor-to-metal transition. We demonstrate that the Kohn-Sham band energy, rather than the coulomb repulsion energy, plays dominant roles in both the phase stabilization and transition during Li intercalation. It is found that the evolution of 1T phase is crucially determined by chemical hardness, which underlies the cycle irreversibility. Due to the charge-density-wave (CDW) phase, Li extraction is impeded by the enhancement of Li-host binding. It is indicated that the cycle reversibility can be improved by electron-donor doping in MoS_2 , because the resultant pre-reduction of Mo and S eliminates the electron transfer from Li to host.

¹Programs supported by the Ningbo Natural Science Foundation, grant no. 2011A610207, by Department of Science and Technology, Zhejiang Province, grant no. 2011C21031, and by the National Natural Science Foundation of China (NSFC), grant no. 11174301.

9:36AM A26.00007 Simulating Dendritic Formation on the Cathode of Lithium-ion Batteries, NING SUN, DILIP GERSAPPE, Department of Materials Science and Engineering, Stony Brook University — The Lattice-Boltzmann method was used to simulate the process of dendrite formation on the cathode of lithium-ion batteries. "In-Situ" maps of the electrodeposition process under constant charging current conditions were obtained. The results showed preferential dendrites formation on higher curvature spots of the cathode, because of the higher electrical field intensity. Different morphologies were obtained due to different initial roughness of the electrode. A mossy-like electrode can be observed after deposition on a rough electrode with randomly generated initial conditions. A tree-like dendrite can be observed when depositing on a single small dendrite. A smooth surface can be obtained when the initial electrode is ideally smooth. The influence of current density was also studied.

9:48AM A26.00008 Density functional and molecular dynamics studies of solid electrolyte $\text{Li}_7\text{La}_3\text{Zr}_2\text{O}_{12}$, MICHELLE JOHANNES, KHANG HOANG, NOAM BERNSTEIN, Naval Research Laboratory — Garnet-type structured $\text{Li}_7\text{La}_3\text{Zr}_2\text{O}_{12}$ (LLZO) is considered as a promising candidate for Li-ion battery solid electrolytes because of its high ionic conductivity and electrochemical and chemical stability. We use first-principles density-functional theory calculations and molecular dynamics simulations to reveal the underlying mechanism that drives a tetragonal to cubic transition at elevated temperatures, and also to explain why the cubic phase can be stabilized with the incorporation of a certain amount of impurities such as Al. We show that the relationship between the observance of a cubic phase and the measurement of a substantially higher ionic conductivity is a secondary effect not directly attributable to the presence of Al in the crystal structure. Suggestions for enhancing the ionic conductivity in LLZO will also be discussed.

10:00AM A26.00009 First principles investigation of the superionic electrolyte $\text{Li}_7\text{P}_3\text{S}_{11}$ ¹, NICHOLAS LEPLY, N.A.W. HOLZWARTH, Wake Forest University — $\text{Li}_7\text{P}_3\text{S}_{11}$ has been shown to be a promising superionic conductor for solid state rechargeable batteries with a room temperature conductivity as high as 10^{-3} S/cm and a thermal activation energy as small as $E_A=0.12\text{ eV}$.² We have performed first principles modeling studies³ on this material in order to explain its stability and Li ion migration properties. Our investigation considers optimized crystal structures, migration involving both vacancy and interstitial mechanisms, as well as related materials. We find optimized crystal structures in reasonable agreement with experiment,⁴ and the lowest calculated activation energy barrier was found to be $E_A=0.15\text{ eV}$ in good agreement with the experimental value.

10:12AM A26.00010 Solid Electrolyte for Advanced Lithium Batteries, GHOLAM-ABBAS NAZRI, BALAJI P MANDAL, Wayne State University, MARYAM NAZRI, Applied Sciences Inc., VAMAN NAIK, University of Michigan - Dearborn, PREM VASHINAVA, Kettering University, RATNA NAIK, Wayne State University, ENERGY STORAGE AND GENERATION TEAM — Lithium battery is a promising energy storage system due to its high energy density and high rate capability and its application ranges from micro to large scale megawatt batteries. The current technology is using liquid electrolyte that limits its application due to flammable nature of the electrolyte, particularly at high temperatures, and difficulty in fabrication and miniaturization of the device. We report a novel solid electrolyte with high lithium ion conductivity as a replacement for the current liquid electrolyte, particularly for electronic applications. The solid state lithium ion conductor is based on lithium germanium phosphorous sulfide compound. The compound is prepared by solid state reaction at 500 °C. The crystallinity and phase purity of the sample is checked by XRD. We also measured ionic conductivity of the sample using both 4-probe and impedance techniques. High lithium ion conductivity at room temperature is observed. In this study we have investigated the dynamics of ion conduction, XRD, and Raman spectra of the super ion conductor. Electrochemical performance of the solid electrolyte in a lithium cell and its stability against high voltage cathodes and lithium anode will also be presented.

10:24AM A26.00011 First principles computer simulations of $\text{Li}_{10}\text{GeP}_2\text{S}_{12}$ and related lithium superionic conductors¹, N.A.W. HOLZWARTH, Wake Forest University — A recent paper by Kamaya *et al.*² reported a new crystalline superionic conductor having a compact tetrahedral structure and a stoichiometry of $\text{Li}_{10}\text{GeP}_2\text{S}_{12}$. The room temperature conductivity was reported to be 0.01 S/cm, comparable to liquid electrolyte conductivities and five times higher the compositionally related thio-LISICON material $\text{Li}_{3.25}\text{Ge}_{0.25}\text{P}_{0.75}\text{S}_4$ developed earlier.³ This talk will present a progress report on our work to perform first principles computer simulations for these materials focussing on the structural, stability, and Li ion mobility properties of idealized crystalline models. From the perspective of our previous studies of Li ion conductivity in lithium thiophosphate electrolytes,⁴ the effects of introducing Ge can be assessed.

10:36AM A26.00012 Exploring Li^+ Potential Energy Surface in Poly(ethylene oxide)-based Sulfonate Ionomers¹, HUAI-SUEN SHIAU, MICHAEL J. JANIK, RALPH H. COLBY, Pennsylvania State University, University Park — Ion-containing polymers are of interest as single-ion conductors for use as electrolytes in electrochemical devices, including lithium ion batteries. Current ion conductivities of the best ionomers are roughly 100X too small for practical applications and have a small fraction of their Li^+ counterions participating in conduction. We are using ab initio methods to investigate the Li^+ conduction mechanism, and specifically the role of transient positive triple ions ($\text{Li}^+\text{A-Li}^+$) in the conduction process. The positive triple ion has a lower energy separated state that allows for facile transport, if there is a pair within 1.4 nm. We will discuss the competition between cation solvation with ether oxygen atoms and cation-anion interaction. The importance of anion-anion separation in altering Li^+ hopping barriers will be examined, as well as the variation in hopping rates with solvent identity. Ab initio calculations are used to evaluate the relative energy of ion states (contact and separated states), and this analysis is used to explain experimental phenomena of Li^+ mobility in ionomers.

¹NSF

10:48AM A26.00013 Ab initio molecular dynamics simulations of organic electrolytes, electrodes, and lithium ion transport for Li-ion batteries, P.R.C. KENT, P. GANESH, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge 37831, DE-EN JIANG, Chemical Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, O. BORODIN, Electrochemical Branch, U.S. Army Research Laboratory, Adelphi MD 20783 — Optimizing the choice of electrolyte in lithium ion batteries and an understanding of the solid-electrolyte interphase (SEI) is required to optimize the balance between high-energy storage, high rate capability, and lifetime. We perform accurate ab initio molecular-dynamics simulations of common cyclic carbonates and LiPF₆ to build solvation models which explain available Neutron and NMR spectroscopies. Our results corroborate why ethylene carbonate is a preferred choice for battery applications over propylene carbonate and how mixtures with dimethyl carbonate improve Li-ion diffusion. We study the role of functionalization of graphite-anode edges on the reducibility of the electrolyte and the ease of Li-ion intercalation at the initial stages of SEI formation. We find that oxygen terminated edges readily act as strong reductive sites, while hydrogen terminated edges are less reactive and allow faster Li diffusion. Orientational ordering of the solvent molecules precedes reduction at the interphase. Inorganic reductive components are seen to readily migrate to the anode edges, leading to increased surface passivation of the anode. We are currently quantifying Li-intercalation barriers across realistic SEI models, and progress along these lines will be presented.

Monday, February 27, 2012 8:00AM - 11:00AM —

Session A27 DCMP: Invited Session: Excitonic and Correlation Effects in Single-Layer Graphene
258AB

8:00AM A27.00001 Dynamic screening and the effective fine structure constant of graphene¹, PETER ABBAMONTE, University of Illinois — Electrons in graphene behave, in the low energy sector, like massless Dirac fermions. The degree to which Coulomb correlations influence these fermions is still subject to debate. In this talk I will describe inelastic x-ray scattering experiments on crystals of graphite, to which we have applied newly developed reconstruction algorithms to image the dynamical screening of charge in (effectively) a freestanding graphene sheet. We found that the polarizability of the Dirac fermions in graphene is amplified by excitonic effects in the particle-hole spectrum, which enhances screening of interactions among low energy quasiparticles. I will argue that interactions should be characterized by an effective, screened fine-structure constant, $\alpha_g^*(\mathbf{k}, \omega)$, which our measurements suggest converges to the value $\alpha_g^* = 0.14 \pm 0.092$ in the small wave vector limit. This value is smaller than the bare $\alpha_g = 2.2$, and suggests that the strength of interactions in graphene is similar to that in band semiconductors like Si or GaAs. I will discuss the implications of this result for other Dirac systems, such as nodal quasiparticles in cuprates and topological insulator surface states.

8:36AM A27.00002 Observation of strong excitonic effects in the optical spectrum of graphene¹, TONY HEINZ, Columbia University —

¹This work was done in collaboration with K. F. Mak and J. Shan (Case Western Reserve University).

9:12AM A27.00003 Electron-electron interaction and excitonic effects in graphene systems¹

STEVEN G. LOUIE, University of California at Berkeley and Lawrence Berkeley National Laboratory — Owing to the unique electronic structure of graphene and enhanced electron-electron and electron-hole interactions in lower dimensions, graphene structures exhibit interesting and novel electronic and optical properties. We discuss in this talk results from recent theoretical studies on several graphene systems. First-principles calculations, based on the GW-Bethe-Salpeter Equation approach, have predicted very strong features in the optical absorption spectra of single-layer graphene and multi-layer graphene, arising from resonant excitons. Many of these features have since been observed experimentally. We also explore the effects of charge carrier doping and of having an external electric field on the absorbance of graphene and bilayer graphene. Graphene nanoribbons are semiconductors that, owing to electron-electron interactions, also exhibit extraordinarily magnetic and excitonic effects. Another intriguing phenomenon is one in the magneto-optical response of graphene, which involves resonant transitions of absorption of a photon together with the simultaneous creation of an intervalley, intra-Landau level exciton and a K-phonon. Finally, first-principles results on the plasmon satellite structures in the spectral function of graphene computed with the GW method and beyond are presented. We discuss the origin of these phenomena and make comparison with experiments.

¹This work was supported by NSF, U.S. Department of Energy, and ONR MURI program.

9:48AM A27.00004 Graphene Update, ANDRE GEIM¹, University of Manchester — I will overview the latest experimental progress

made by our group in Manchester. This will cover several subjects with particular attention being paid to interaction effects that have been observed in graphene and its double layer heterostructures.

¹Other contributing authors: Leonid Ponomarenko, Roman Gorbachev, Kostya Novoselov, Daniel Elias, Liam Britnell, Rashid Jalil, Sasha Mayorov, Paco Guinea, Misha Katsnelson, Volodya Fal'ko and Irina Grigorieva

10:24AM A27.00005 Electron-electron interactions in doped graphene sheets¹, MARCO POLINI, NEST,

Istituto Nanoscienze-CNR — In this talk I will review some of the most important electronic properties of graphene. I will first discuss the appearance of plasmaron satellite bands in both angle-resolved photoemission [1] and STM spectra [2,3], emphasizing the important role of the sublattice pseudospin degree of freedom. I will then illustrate some unusual features, which appear only beyond the widely used Random Phase Approximation, characterizing plasmons and Drude weight of the electron gas in this material [4].

Monday, February 27, 2012 8:00AM - 11:00AM –

Session A28 DMP: Focus Session: Dopants and Defects in Semiconductors - ZnO 258C

8:00AM A28.00001 The trends of oxygen vacancy levels in metal oxides, WANJIAN YIN, SUHUI WEI,

MOWAFAK AL-JASSIM, National Renewable Energy Laboratory, YANFA YAN, Department of Physics, University of Toledo, OH — Most of the d or d^{10} oxides such as ZnO, SnO₂, In₂O₃, and TiO₂ are wide-bandgap n -type semiconductors even though they are not intentionally doped. For quite a long time, it was commonly believed that oxygen vacancies (V_O) in metal oxides are the electron donors because the formation energy of V_O in metal oxides is low and the electrical conductivity of the n -type oxides is closely linked to the formation of V_O . However, recent theoretical and experimental studies have put this point of view in question especially with different calculation methods involved. We present a detailed analysis of the wavefunction characters of oxygen vacancy in conventional metal oxides and unveil the chemical trend of oxygen vacancy transition energy levels with respect to the conduction-band minimum (CBM). We show that in the type- s and type- p metal oxides, where the character of an oxygen vacancy level is similar to that of the CBM, the oxygen vacancy levels are generally deep and become deeper when the cation size decreases. In type- d metal oxides, the oxygen vacancy levels are generally shallow and can sometimes even be above the CBM. Our analysis is confirmed by the calculated trends of oxygen vacancy levels in representative metal oxides using hybrid density functional analysis. It also provides guidelines to search a metal oxide that has shallow V_O donor levels, such as the one found in BiVO₄.

8:12AM A28.00002 Highly Efficient Defect Emission from ZnO and ZnO:S, JAY SIMMONS, Department

of Chemistry, Duke University, Durham, North Carolina 27708, JOHN FOREMAN, U.S. Army Aviation and Missile Research Development and Engineering Center, Redstone Arsenal, AL 35898, JIE LIU, Department of Chemistry, Duke University, Durham, North Carolina 27708, HENRY EVERITT, Department of Physics, Duke University, Durham, North Carolina 27708 — Bulk Zinc Oxide (ZnO) is a wide, direct band gap semiconductor with an energy of 3.4 eV that contains two emission bands: the UV band-edge emission and the green defect emission band. We have shown that the external quantum efficiency of the green band can exceed 50%. To investigate the mechanism of efficient defect emission, vacuum annealed (ZnO:Zn) and sulfur-doped (ZnO:S) ZnO were investigated because of their strong defect emission and suppressed UV band edge emission. Continuous wave low temperature photoluminescence (PL) and PL excitation (PLE) spectra were measured for the two compounds. It was found that bound excitons, not free photo-excited carriers, mediate the defect emission in ZnO:Zn, while the defect emission from ZnO:S seems to originate from a Zn-S complex formed in the crystal lattice. Temperature-dependent PLE spectra for the defect and band edge emission were measured to estimate trapping and activation energies of the bound excitons. XPS and X-Ray diffraction studies were also performed to ascertain the concentration and nature of sulfur doping in the ZnO lattice. The results presented here offer hope that engineering defects in ZnO materials may significantly improve the quantum efficiency for white light phosphor applications.

8:24AM A28.00003 Acceptors in bulk and nanoscale ZnO¹, M.D. MCCLUSKEY, Washington State University —

Zinc oxide (ZnO) is a semiconductor that emits bright UV light, with little wasted heat. This intrinsic feature makes it a promising material for energy-efficient white lighting, nano-lasers, and other optical applications. For devices to be competitive, however, it is necessary to develop reliable p-type doping. Although substitutional nitrogen has been considered as a potential p-type dopant for ZnO, theoretical and experimental work indicates that nitrogen is a deep acceptor and will not lead to p-type conductivity. This talk will highlight recent experiments on ZnO:N at low temperatures. A red/near-IR photoluminescence (PL) band is correlated with the presence of deep nitrogen acceptors. PL excitation (PLE) measurements show an absorption threshold of 2.26 eV, in good agreement with theory. Magnetic resonance experiments provide further evidence for this assignment. The results of these studies seem to rule out group-V elements as shallow acceptors in ZnO, contradicting numerous reports in the literature. If these acceptors do not work as advertised, is there a viable alternative? Optical studies on ZnO nanocrystals show some intriguing leads. At liquid-helium temperatures, a series of sharp IR absorption peaks arise from an unknown acceptor impurity. The data are consistent with a hydrogenic acceptor 0.46 eV above the valence band edge. While this binding energy is still too deep for many practical applications, it represents a significant improvement over the ~ 1.3 eV binding energy for nitrogen acceptors. Nanocrystals present another twist. Due to their high surface-to-volume ratio, surface states are especially important. Specifically, electron-hole recombination at the surface give rises to a red luminescence band. From our PL and IR experiments, we have developed a “unified” model that attempts to explain acceptor and surface states in ZnO nanocrystals. This model could provide a useful framework for designing future nanoscale ZnO devices.

¹Work at WSU supported by DOE and NSF.

9:00AM A28.00004 Origin of the “Red” Luminescence Band in Bulk N-doped ZnO, E.R. GLASER,

N.Y. GARCES, Naval Research Laboratory, M.C. TARUN, M.D. MCCLUSKEY, Washington State U. — Optically detected magnetic resonance (ODMR) at 24 GHz was performed on bulk ZnO crystals doped with nitrogen impurities (of high interest for p-type conductivity) to provide more details on the origin of a recently reported red/near-IR photoluminescence (PL) band.¹ PL at 7K revealed strong bandedge excitonic recombination at 3.364 eV, a broad “green” emission band at 2.45 eV, and a broad “red” PL band near 1.7 eV. Two luminescence-increasing ODMR signals were found on this “red” emission. The first was a sharp feature with g-value of 1.957 and FWHM of 1 mT and is attributed to shallow donors based on electron spin resonance (ESR) of n-type ZnO. The second feature exhibited a g-value near 2 and a broad, asymmetric lineshape with FWHM of ~ 10 mT. A simulation of the spectrum showed that the broad resonance could be fit as the sum of three equally spaced lines with magnetic field splitting value and relative intensities in close agreement to those observed for deep nitrogen acceptors as identified from previous ESR studies. Thus, the ODMR results strongly suggest that the “red” PL is due to radiative recombination involving residual shallow donors and deep nitrogen acceptor centers.

9:12AM A28.00005 Elevated Temperature Dependent Transport Properties of As- and P-doped Zinc Oxide, B. CAI, M. L. NAKARMI, Department of Physics, Brooklyn College and Graduate Center of the CUNY, Brooklyn, NY, T. ODER, M. MCMASTER, A. SMITH, N. VELPUKONDA, Department of Physics and Astronomy, Youngstown State University, Youngstown, Ohio —

Achieving highly conductive p-type zinc oxide (ZnO) is desired for the development of ZnO based optoelectronic devices. Understanding electrical properties of ZnO, doped with p-type dopants, is necessary for improving p-type conductivity. We employed temperature dependent Hall effect measurement to study the electrical transport properties of As- and P-doped ZnO epilayers. The samples were grown on sapphire substrates by magnetron sputtering technique. From the Hall effect measurements performed at elevated temperatures ranging from 20 to 750 K, we observed double activation processes in both As- and P-doped ZnO epilayers. We will compare the results of uniform doped and delta-doped samples. Correlation between electrical properties from these Hall effect measurements and optical properties from low temperature photoluminescence measurements will also be discussed.

9:24AM A28.00006 Impurity complexes and conductivity of Ga-doped ZnO¹, DENIS DEMCHENKO,

Virginia Commonwealth University — Using hybrid functional theory compared with experimental measurements, we investigate the influence of gallium impurities and their complexes on electrical properties of ZnO. In contrast to the behavior of isolated Ga impurities and native defects, the calculated formation energies of Ga complexes are consistent with experimental data. We show that for high levels of Ga doping the acceptor behavior of $(\text{Ga}_{\text{Zn}} - \text{V}_{\text{Zn}})$ and $(\text{Ga}_{\text{Zn}} - \text{O}_i)$ complexes explains the conductivity measurements and compensation levels in ZnO. The computed binding energies of these complexes are in agreement with the binding energies obtained from the measurements of the temperature dependence of carrier mobility. The binding energy dependence on the Fermi level, as well as the computed barrier heights for the formation of complexes are also consistent with the latest experiments on annealing of Ga doped ZnO samples. Our results show that the formation of defect complexes is essential for capturing the physics Ga defects in ZnO.

¹This work used computational facilities of the VCU Center for High Performance Computing.

9:36AM A28.00007 Cu-Doping of ZnO by Nuclear Transmutation and Electrical and Optical Characterization of Cu Acceptors¹, FARIDA SELIM, MARIANNE TAURN, JIANFENG JI, DONALD WALL, Washington State University,

LYNN BOATNER, Oak Ridge National Laboratory, MATTHEW MCCLUSKEY, Washington State University, SELIM TEAM², COLLABORATION WITH MCCLUSKEY GROUP COLLABORATION, BOATNER COLLABORATION, WALL COLLABORATION — Cu doping is known to have a large effect on the electrical and optical properties of ZnO, its role is different from other dopants, and a fundamental understanding of this role is lacking. One problem of ZnO doping is arising from the difficulty in controlling dopant locations in conventional doping methods. In this work we doped Zn single crystals with copper acceptors by means of the nuclear transmutation doping (NTD) method, which gives highly uniform dopant distributions and has a much higher probability of controlling the dopant locations in the lattice. The Cu doping was confirmed by the infrared absorption signature of Cu^{2+} at 5780 cm^{-1} . Hall-effect measurements indicated that the Cu acceptor level lies 0.160 eV below the conduction band minimum. With respect to optical properties, an interesting low-temperature thermal stimulated luminescence has been observed in as-grown and doped ZnO single crystals. This low-temperature luminescence can reveal the density of donors and acceptors in ZnO and their location in the band gap.

¹Funding was provided by the National Science Foundation (DMR-1006772) and DMR-1004804) and DOE BES.

9:48AM A28.00008 The G0W0 band gap of ZnO: effects of plasmon-pole models, GABRIEL ANTONIUS,

University of Montreal, MARTIN STANKOVSKI, DAVID WAROQUIERS, ANNA MIGLIO, Université Catholique de Louvain, HEMANT DIXIT, University of Antwerpen, KIROUBANAND SANKARAN, MATTEO GIANTOMASSI, XAVIER GONZE, Université Catholique de Louvain, MICHEL COTE, University of Montreal, GIAN-MARCO RIGNANESE, Université Catholique de Louvain, UNIVERSITY OF MONTREAL TEAM, UNIVERSITE CATHOLIQUE DE LOUVAIN TEAM, UNIVERSITY OF ANTWERPEN TEAM — Carefully converged calculations are performed for the band gap of ZnO within the G0W0 approximation. The results obtained using four different well-established plasmon-pole models are compared with those of explicit calculations without such models (the contour-deformation approach). We evaluate the difference between plasmon-pole models that enforce the f-sum rule and those that are fitted to reproduce the low energy response. In the case of ZnO, plasmon-pole models enforcing the f-sum rule underestimate the low-frequency region of the dielectric function probably because of the presence of semi-core states in these calculations. Our results confirm that the band gap of ZnO is underestimated in the G0W0 approach as compared to experiment.

10:00AM A28.00009 Evidence for surface states in ZnO nanostructures using non-linear optical spectroscopy, BENJOY ANAND, Sri Satya Sai Institute of Higher Learning, MARTIN EGBLEWOGBE, University of Ghana, RAMAKRISHNA PODILA, Department of Physics, Clemson University, REJI PHILIP, Raman Research Institute, APPARAO RAO, Department of Physics, Clemson University — An unexpected presence of ferromagnetic (FM) ordering in nanostructured ZnO has been reported previously. Recently, from our detailed magnetization studies and *ab initio* calculations, we attributed this FM ordering in nanostructured ZnO to the presence of surface states, and a direct correlation between the magnetic properties and crystallinity of ZnO was observed. Such defect induced surface states appear as green/yellow emission in the photoluminescence spectrum of ZnO nanostructures. In this study, through a systematic sample preparation of both pristine and Co-doped ZnO nanostructures, and detailed PL and nonlinear optical measurements, we confirm that the observed FM ordering is due to the presence of surface states.

10:12AM A28.00010 Terahertz properties of Tm (Tm=Cu, Ag) doped ZnO thin films, MI HE, XINGQUAN ZOU, TOM WU, ELBERT CHIA, Nanyang Technological University — Optical properties of $\text{Zn}_{0.95}\text{Tm}_{0.05}\text{O}$ (Tm=Cu, Ag) thin films are studied by terahertz time-domain spectroscopy (THz-TDS) at different temperatures (10K – 300K) in the frequency range extending from 0.22 – 3 THz. The measured complex dielectric response and conductivity are well fitted by a Drude-based model. Comparing with undoped ZnO thin films, the doping effect of Ag and Cu is investigated.

10:24AM A28.00011 The growth of non-polar ZnO and $\text{ZnO}/\text{Mg}_{0.25}\text{Zn}_{0.75}\text{O}$ epi-films by radio-frequency magnetron sputtering, BI-HSIUAN LIN, Department of Photonics and Institute of Electro-Optical Engineering, National Chiao Tung University, Taiwan, WEI-REIN LIU, Division of Scientific Research, National Synchrotron Radiation Research Center, Taiwan, SHAO-TING HSU, Department of Photonics and Institute of Electro-Optical Engineering, NCTU, Taiwan, CHIA-HUNG HSU, Division of Scientific Research, NSRRC, Taiwan, WEN-FENG HSIEH, Department of Photonics and Institute of Electro-Optical Engineering, NCTU, Taiwan, NCTU TEAM, NSRRC TEAM, NCKU TEAM — High quality non-polar ZnO and $\text{ZnO}/\text{Mg}_x\text{Zn}_{1-x}\text{O}$ ($x = 0.15, 0.25$) epi-films have been successfully grown on m-plane and r-plane sapphire by using RF magnetron sputtering. The structural properties, including crystalline quality, strain state, and defect structures, of the ZnO and $\text{ZnO}/\text{Mg}_x\text{Zn}_{1-x}\text{O}$ layers are thoroughly examined by synchrotron x-ray scattering, transmission electron microscopy and atomic force microscopy. We found the surface morphology of the a-plane oriented ZnO epi-films is smoother than that of m-plane oriented one. Moreover, the surface of $\text{Mg}_{0.25}\text{Zn}_{0.75}\text{O}$ epi-layer is significantly better than the ZnO epi-film and exhibits the same orientation dependence. The optical properties of these samples are also investigated by temperature, polarization and power dependent photoluminescence, and polarization dependent Raman spectroscopy. The results reveal the a-plane ZnO epi-film grown on r-sapphire with a $\text{Mg}_{0.25}\text{Zn}_{0.75}\text{O}$ buffer layer is promising for bright UV emission application.

10:36AM A28.00012 Excitonic Energy Shifts in Isotopically Controlled $I - III - VI_2$ Chalcopyrites: CuGaS_2 and AgGaS_2 ¹, J.S. BHOSALE, H. ALAWADHI, I. MIOTKOWSKI, A.K. RAMDAS, Purdue University, R. LAUCK, M. CARDONA, MPI for Solid State Research — CuGaS_2 and AgGaS_2 tetrahedrally co-ordinated chalcopyrites are “genealogically related” to $II - VI$ semiconductors like ZnS. We have investigated the shifts in their excitonic signatures by controlling the isotopic mass of the I , III or VI_2 constituent in the crystals grown by physical vapor deposition. The excitonic signatures are observed in wavelength modulated reflectivity employing a high S/N, LED based technique.² For example it reveals a 3.9 meV shift for the A exciton in $\text{Ag}^{71}\text{GaS}_2$ with respect to that of natural AgGaS_2 ; a smaller increase occurs in ZnS ³. These effects have been related to electron-phonon interaction caused by the zero-point vibrations. Similar effects, but with an opposite sign, have been observed for Cu-isotopes in CuGaS_2 as well as in the Cu-monohalides CuCl, CuBr, and CuI⁴; their origin is receiving considerable attention at present though not yet understood. In this context the excitonic temperature dependence^{5,6} will be discussed.

10:48AM A28.00013 Hybrid Hartree-Fock density functional study of transition-metal doped ZnO, JESUAN BETANCOURT, ALAN KALITSOV, JULIAN VELEV, University of Puerto Rico — Dilute magnetic semiconductors (DMS) obtained by doping semiconductors with transition metals (TM) hold much promise for spintronics. Transition metal doped ZnO (ZnO:TM) has been investigated for a possible room-temperature DMS. Density functional theory gives incorrect prediction for the band gap of ZnO which leads to diverging interpretations for the magnetic behavior of ZnO:TM [1,2]. Here we report Heyd-Scuseria-Ernzerhof (HSE) hybrid functional study of the electronic structure of ZnO:TM (TM=Cu, Ni, Co, Fe, Mn). The hybrid functional corrects for both the bandgap problem on the host and the lack of correlation in the impurity, without the use of *ad-hoc* intra-atomic potentials. Our results show although the HSE opens the band gap of the host, the Hubbard splitting of the impurity levels makes the empty impurity levels reside in the host conduction band. This leaves open the possibility for spin polarized carriers. We discuss the validity of the results and explore their implications for the magnetic behavior of ZnO:TM. [1] H. Raebiger, S. Lany, and A. Zunger, Physical Review B 79, 165202 (2009). [2] P. Gopal and N. A. Spaldin, Phys. Rev. B 74, 094418 (2006).

8:36AM A29.00002 Wigner Tomography of Classical and Non-Classical States in a Superconducting Anharmonic Oscillator, NADAV KATZ, ROI RESH, OFER FOGEL, Hebrew University, RADOSLAW BIALZCAK, JOHN MARTINIS, UCSB, YONI SHALIBO, Hebrew University — The Wigner quasi-probability distribution is a powerful tool for characterizing a quantum state and understanding the state dynamics in oscillators. Until now, there have been numerous measurements of this function in harmonic oscillators, and in particular in superconducting devices. However no similar measurement on anharmonic systems has been reported. We utilize the wide-range energy tunability in the multi-level Josephson phase qubit, biased in the small anharmonicity regime, to directly measure the Wigner function of various states. We measure non-classical superpositions of Fock-type states, as well as coherent-like states in this anharmonic system. This method provides an alternative to standard state tomography techniques which usually involve a long calibration process and have limited scalability for multi-level states.

8:48AM A29.00003 Geometric Phases, Noise and Non-adiabatic Effects in Multi-level Superconducting Systems, S. BERGER, M. PECHAL, A.A. ABDUMALIKOV, L. STEFFEN, A. FEDOROV, A. WALLRAFF, S. FILIPP, ETH Zurich — Geometric phases depend neither on time nor on energy, but only on the trajectory of the quantum system in state space. In previous studies [1], we have observed them in a Cooper pair box qubit, a system with large anharmonicity. We now make use of a superconducting transmon-type qubit with low anharmonicity to study geometric phases in a multi-level system. We measure the contribution of the second excited state to the geometric phase and find very good agreement with theory treating higher levels perturbatively. Furthermore, we quantify non-adiabatic corrections by decreasing the manipulation time in order to optimize our geometric gate. Geometric phases have also been shown to be resilient against adiabatic field fluctuations [2]. Here, we analyze the effect of artificially added noise on the geometric phase for different system trajectories.

9:00AM A29.00004 Observing the geometric phase of a superconducting harmonic oscillator, M. PECHAL, S. BERGER, A.A. ABDUMALIKOV, J.M. FINK, J.A. MLYNEK, L. STEFFEN, A. WALLRAFF, S. FILIPP, ETH Zurich — Steering a quantum harmonic oscillator state along cyclic trajectories leads to a path-dependent geometric phase [1]. However, the linearity of the system precludes its observation without a non-linear quantum probe. We therefore make use of a superconducting qubit serving as an interferometer to measure the adiabatic geometric phase of a harmonic oscillator realized as an on-chip resonant circuit [2]. We study the geometric phase for a variety of trajectories and show that, in agreement with theory, it is proportional to the area enclosed by the trajectory in the space of coherent states. At the transition to the non-adiabatic regime, oscillatory dephasing effects caused by residual qubit-resonator entanglement are observed and analyzed. We also discuss the possibility of using the harmonic oscillator geometric phase to implement two-qubit phase gates.

9:12AM A29.00005 All-resonant control of superconducting resonator qudits¹, FREDERICK STRAUCH, Williams College — Quantum information processing with using superpositions of Fock states in superconducting resonators holds great promise for multi-level (i.e. qudit) quantum logic. Previous theoretical work has shown that a combination of dispersive and resonant interactions allow for general qudit logic operations. Here I introduce an all-resonant approach to control resonator qudits. This scheme allows for faster logic operations and will be compared to previous methods for Fock state generation and entangled state synthesis.

9:24AM A29.00006 Readout of Spin Systems with Superconducting Circuits¹, NATANIA ANTLE, KATER MURCH, R. VIJAY, STEVEN WEBER, ELI LEVENSON-FALK, I. SIDDIQI, UC Berkeley, QNL — We present progress in coupling superconducting circuitry, in particular linear resonators and dispersive magnetometers, to an ensemble of spins. Species with a zero-field splitting (ZFS), such as bismuth doped silicon or NV centers in diamond, are particularly attractive as the absence of a strong magnetic bias field facilitates compatibility with superconducting devices. We present studies of the spin linewidth, and progress towards the observation of collective strong coupling. Furthermore, we will present data on the operation of a highly sensitive nanobridge SQUID magnetometer with a flux sensitivity of $26 \text{ n}\Phi_0/\sqrt{\text{Hz}}$ and tens of MHz of signal bandwidth. We also discuss the resilience of our superconducting measurement circuitry to in-plane magnetic fields, which can be used to tune the spin splitting.

¹This research is supported by the NSF E3S center and the AFOSR.

9:36AM A29.00007 Hybrid quantum circuit with a superconducting qubit coupled to a spin ensemble¹, YUIMARU KUBO, CECILE GREZES, ANDREAS DEWES, DENIS VION, CEA-Saclay, JUNICHI ISOYA, University of Tsukuba, VINCENT JACQUES, ANAIS DREAU, JEAN-FRANCOIS ROCH, ENS de Cachan, IGOR DINIZ, ALEXIA AUFFEVE, CNRS-Grenoble, DANIEL ESTEVE, PATRICE BERTET, CEA-Saclay — We report the experimental realization of a hybrid quantum circuit combining a superconducting qubit and an ensemble of electronic spins. The qubit, of the transmon type, is coherently coupled to the spin ensemble consisting of nitrogen-vacancy (NV) centers in a diamond crystal via a frequency-tunable superconducting resonator acting as a quantum bus [1,2]. Using this circuit, we prepare arbitrary superpositions of the qubit states that we store into collective excitations of the spin ensemble and retrieve back later on into the qubit [3]. These results constitute a first proof of concept of spin-ensemble based quantum memory for superconducting qubits.

10:00AM A29.00009 Hybrid qubit-resonator systems: From strong to ultrastrong coupling, from equilibrium to non equilibrium phases, DAVID ZUECO, THOMAS HÜMMER, MARK JENKINS, MARÍA JOSÉ MARTÍNEZ-PÉREZ, Universidad de Zaragoza - ICMA, GEORG REUTHER, Universitat Augsburg, JUAN JOSÉ GARCÍA-RIPOLL, CSIC, FERNANDO LUIS, Universidad de Zaragoza - ICMA, PETER HÄNGGI, Universitat Augsburg — Hybrid systems : spin ensembles coupled to superconducting circuits have received a lot of attention recently. In a seminal experiment it has been demonstrated strong coupling between a NV-center spins ensemble and a flux qubit. The ensemble maps to a bosonic mode, thus this setup is a realization of a qubit-resonator model. In this talk we propose molecular magnets, instead of NV centers, as ensembles and we show that with them it is possible to reach the ultra strong coupling (the coupling is around 40% of the qubit-resonator frequencies). Finally, we emphasize the potentiality of these architectures for exploring many body physics by building arrays made of flux qubits and crystal spins. We will discuss non equilibrium signatures of Mott insulator - Superfluid phases and its feasibility within current technology.

10:12AM A29.00010 Quantum transducer in circuit optomechanics¹, NICOLAS DIDIER, ROSARIO FAZIO, Scuola Normale Superiore, NEST and Istituto NanoScienze-CNR, Pisa, Italy — Mechanical resonators are becoming macroscopic quantum objects with great potential. It is however difficult to measure and manipulate the phonon state due to the tiny motion in the quantum regime. We show that a superconducting microwave resonator linearly coupled to the mechanical mode constitutes a powerful probe and an interesting quantum source. This coupling is rendered much stronger than the usual radiation pressure interaction by adjusting a gate voltage and gives rise to coherent oscillations between phonons and photons. The phenomenon of phonon blockade is detected from the statistics of the light field [1] and a quantum tomography of the mechanical resonator is obtained after transferring the state to the microwave cavity. Quantum phonon states can also be synthesized from the cavity and hybrid entanglement can be engineered between phonons and photons. Mechanical resonators can furthermore be coupled to a large variety of quantum systems such as spins, optical photons, cold atoms, and Bose Einstein condensates. They act as a quantum transducer between an auxiliary quantum system and a microwave resonator, which is used as a quantum bus. The quantum communications are controlled with the individual gate voltages. [1] N. Didier et al., Phys. Rev. B **84**, 054503 (2011).

8:00AM A30.00001 Stark tuning spin qubits in diamond for quantum optical networks, VICTOR ACOSTA, CHARLES SANTORI, ANDREI FARAON, ZHIHONG HUANG, Hewlett Packard Laboratories, Palo Alto, CA, KAI-MEI FU, University of Washington, Dept. of Physics, ALASTAIR STACEY, DAVID SIMPSON, TIMOTHY KARLE, BRANT GIBSON, LIAM MCGUINNESS, KUMARAVELU GANESAN, SNJEZANA TOMLJENOVIC-HANIC, ANDREW GREENTREE, STEVEN PRAWER, University of Melbourne, School of Physics, RAYMOND BEAUSOLEIL, Hewlett Packard Laboratories, Palo Alto, CA — Integrated diamond networks based on cavity-coupled spin impurities offer a promising platform for scalable quantum computing. A key ingredient for this technology involves heralding entanglement by interfering indistinguishable photons emitted by pairs of identical spin qubits. Here we demonstrate the required control over the internal level structure of nitrogen-vacancy (NV) centers located within 100 nm of the diamond surface using the DC Stark effect. By varying the voltages applied to lithographically-defined metal electrodes, we tune the zero-phonon emission wavelength of a single NV center over a range of ~ 0.5 nm. Using high-resolution emission spectroscopy, we directly observe electrical tuning of the relative strengths of spin-altering lambda transitions to arbitrary values. Under resonant excitation, we apply dynamic feedback to stabilize the optical transition against spectral diffusion. Progress on application of gated control to single NV centers coupled to single-crystal diamond photonic crystal cavities and other nanophotonic structures will be presented. This work was supported by DARPA and the UC Regents.

8:12AM A30.00002 Decoherence-protected quantum gates for a hybrid spin register in diamond¹, V.V. DOBROVITSKI, Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands, T. VAN DER SAR, Ames Laboratory and Iowa State University, Z.-H. WANG, Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands, M.S. BLOK, Ames Laboratory and Iowa State University, Ames, Iowa 50011, USA, H. BERNIEN, T.H. TAMINIAU, Ames Laboratory and Iowa State University, D.M. TOYLI, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, D.A. LIDAR, Depts of Electrical Engineering, Chemistry, and Physics, and Center for Quantum Information Science and Technology, University of Southern California, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, R. HANSON, Ames Laboratory and Iowa State University — Protecting the dynamics of coupled quantum systems from decoherence by the environment is a key challenge for solid-state quantum information processing. An idle qubit can be efficiently insulated from the environment via dynamical decoupling, but quantum gate operations are, in general, disrupted by the decoupling. This problem is particularly salient for hybrid systems, where different types of qubits evolve and decohere at vastly different rates. Here we present an efficient scheme for combining the dynamical decoupling with the quantum gate operation, using the internal resonance in the coupled-spin system. We theoretically demonstrate and experimentally achieve high-fidelity operation of a two-spin register made of the

8:24AM A30.00003 Quantum Optics with Spins and Photons in Diamond, YIWEN CHU, EMRE TOGAN, MIKHAIL LUKIN, Harvard University — Quantum control of interactions between photons and solid-state systems has important applications in quantum information, metrology, and the study of material properties. The nitrogen-vacancy (NV) color center in diamond is one such solid-state system that has shown great promise as an optically addressable spin qubit and highly sensitive magnetometer. We present recent work on coherent control of spin-photon interactions in a complex solid-state environment using coherent population trapping (CPT). The intrinsic magnetic field sensitivity of our CPT scheme allows us to measure the instantaneous Overhauser field associated with the ¹³C bath present in the diamond crystal. We show that this quantum measurement technique can be used to prepare a state of the ¹³C bath that has much reduced uncertainty in the associated Overhauser field. Such a state is verified by observing a modification and narrowing of the transmission window. The preparation of a more well-defined configuration of the nuclear spin environment could lead to an increase in the coherence times of the NV electronic spin qubit, which in turn has applications in increasing the sensitivity of NV-based magnetometers.

8:36AM A30.00004 Substitutional nickel impurities in diamond: decoherence-free subspace for quantum information processing, THOMAS CHANIER, CRAIG PRYOR, MICHAEL E. FLATTE', University of Iowa — Magnetic color centers in diamond have received interest as qubits for quantum information processing due to diamond's wide band gap and long spin lifetimes which offer the possibility to initialize, manipulate and readout the quantum state of the qubit. Ni-related impurities have been known to form various color centers in diamond and here we propose the use of a substitutional Ni impurity as a qubit. The electronic and magnetic properties of a neutral substitutional nickel impurity in diamond are studied using density functional theory in the generalized gradient approximation. The spin-one ground state consists of two electrons with parallel spins, one located on the nickel ion in the 3d⁹ configuration and the other distributed among the nearest-neighbor carbons. The exchange interaction between these spins is due to p-d hybridization and is controllable with compressive hydrostatic or uniaxial strain. For sufficient strain the antiparallel spin configuration becomes the ground state. Hence, the Ni impurity forms a controllable two-electron exchange-coupled system that should be a robust qubit for solid-state quantum information processing.

8:48AM A30.00005 Cooling Nuclear Spins in Diamond via Dark State Spectroscopy, ADI PICK, MICHAEL GULLANS, EMRE TOGAN, YIWEN CHU, Harvard University, SUSANNE YELIN, University of Connecticut, MIKHAIL LUKIN, Harvard University, CUA TEAM, ITAMP TEAM — Optical cooling methods in atomic physics, developed over the last half century, enable reaching temperatures as low as a few nK. Some of these methods can be applied for cooling spin ensembles in solid state systems. We describe a method for cooling the nuclear spins of ¹³C impurities in diamond, via optical manipulation of the electronic spin associated with an NV⁻ center. We present the physical mechanism which leads to optical pumping of the nuclear spin ensemble into particular nuclear states. The method relies on optically driving three electronic levels in the Λ configuration, and on using the formation of dark states under the conditions of Coherent Population Trapping, (CPT). The dynamics of the nuclear ensemble during this cooling process can be described analytically by using statistical tools, including anomalous random walk models and Levy flights. I survey the theoretical results of the model and discuss some predictions for experimental signatures of Levy flights in this system.

9:00AM A30.00006 Decoherence imaging of spin ensembles by a scannable single nitrogen-vacancy center in diamond, LAN LUAN, MICHAEL GRINOLDS, SUNGKUN HONG, PATRICK MALETINSKY, RONALD WALSWORTH, MIKHAIL LUKIN, AMIR YACOBY, Harvard University — Measuring the decoherence of the spin state of a single nitrogen-vacancy (NV) center in diamond has been proposed as a sensitive method for detecting ensembles of electron or nuclear spins. Using a scanning NV center magnetometer with a single NV residing about 10 nm from the scanning device surface, we explore the effect of T₂ as the device is brought in close proximity to a sample surface. We observe that the spin coherence of the NV center is strongly reduced when it comes into contact with the sample. We are able to restore the coherence by performing dynamic decoupling schemes on the NV spin, suggesting that the sample-induced decoherence originates from the fluctuating magnetic field of a surface spin ensemble. The decoherence diminishes when we increase the NV to sample surface distance by 10nm either vertically or laterally. These experiments demonstrate the potential for using the coherence of a single NV spin to locally detect and spatially map spin ensembles.

9:12AM A30.00007 Investigating spin decoherence in nanodiamonds using a multi-frequency electron spin resonance, A. DAS, V. STEPANOV, Z. KOBOS, Z.H. WANG, S. TAKAHASHI, University of Southern California — Nitrogen-vacancy (NV) centers in nanodiamonds (NDs) are extremely useful for applications of nanoscale magnetic sensing as well as for conducting fundamental science because of their unique spin properties including capability to initialize the NV spin state and their long decoherence time even at room temperature. Various sizes of nanodiamonds are commercially available. Spin properties of NV centers in NDs are often quite different from those of bulk diamonds. Possible reasons for the difference are surface defects and surface distortions and strains. In this presentation, we will discuss spin properties and spin decoherence in various NDs studied by X-band (10 GHz) and high field (230 and 115 GHz) spectrometers. We will also study properties of environmental noises in NDs using dynamical decoupling techniques.

9:24AM A30.00008 Deep Level Tight-Binding Model for Transition Metal Dopant States in Diamond, VICTORIA KORTAN, CUNEY SAHIN, MICHAEL FLATTÉ, University of Iowa Department of Physics and Astronomy — Diamond is a promising system for quantum information processing [1], providing the possibility of single-spin-photon entanglement, as well as the potential for high-speed spin manipulation at room temperature (such as has been demonstrated for the electronic spin associated with an NV center [2]). Ion implantation has been demonstrated for controllable positioning of NV centers; in principle other dopants could be so implanted as well. For example, transition-metal dopants could potentially be used as optically and electrically active single spin qubits [3]. Here we use a deep level tight binding model to study the electronic trends and defect wave functions of transition-metal dopants in diamond. Starting with the Green's functions of homogeneous diamond (within an spd^s* tight-binding model), a Koster-Slater approach is used to evaluate the defect state. This work is supported by an AFOSR MURI.

9:36AM A30.00009 A method to measure hyperfine interaction beyond standard statistical limit¹, KILHYUN BANG, WEN YANG², L. J. SHAM, Department of Physics, University of California San Diego — We propose a method to measure the hyperfine interaction between a single electron spin and a nuclear spin and apply it to the trapped electron and the ¹⁵N nuclear spin in a diamond nitrogen-vacancy (NV) center. The electron spin is prepared in a pure quantum state and the nuclear spin acquires an unknown partial polarization as a consequence of the preparation of the electron state. The proposed quantum measurement protocol is independent of the incoherence of the initial nuclear spin state. The model utilizes the time τ of a sequence of quantum operations as well as the number N of repeated sequences to increase the accuracy and the precision of the estimation. The deleterious effect of the electron spin decoherence on the precision during time τ is included in the simulation. While in the statistical limit the standard deviation (measure of imprecision) of the estimation is proportional to $1/\sqrt{N}$, the quantum operations in time τ enables the imprecision to decrease faster as $1/\tau$ instead of the equivalent statistical limit of $1/\sqrt{\tau}$. Thus, the net imprecision of the estimation dips below the statistical limit. The robustness test of our simulation shows that experimental implementation of such a precision measurement is possible.

9:48AM A30.00010 Towards Probing Living Cell Function with NV Centers in Nanodiamonds, ALEXANDER SUSHKOV, IGOR LOVCHINSKY, NICHOLAS CHISHOLM, Harvard University, DAVID HUNGER, Ludwig-Maximilians-Universität, ALEXEY AKIMOV, P.N. Lebedev Physical Institute, PEGGY LO, AMY SUTTON, JACOB ROBINSON, NORMAN YAO, STEVEN BENNETT, HONGKUN PARK, MIKHAIL LUKIN, Harvard University — We report on recent progress in using the nitrogen-vacancy (NV) center in nanodiamonds as a local probe of paramagnetic free radical concentrations in living cells. The ability to monitor the local magnetic environment within the cell provides us a new tool to study organelle function during normal operation or in response to applied stimuli. Our approach involving biologically inert, robust sensor of local magnetic fields with nanoscale resolution opens up a new interface between quantum and biological sciences.

10:00AM A30.00011 Anomalous decoherence of a nitrogen-vacancy center in a nuclear spin bath¹, REN-BAO LIU, NAN ZHAO, ZHEN-YU WANG, Department of Physics, The Chinese University of Hong Kong — A spin loses its coherence in its noisy environment. It is generally believed that stronger noise causes faster decoherence. Here we show that in a quantum bath, the case can be the opposite. We predict that the double-transition of a nitrogen-vacancy center spin-1 in diamond can have longer coherence time than the single transitions, even though the former suffers twice stronger noise from the nuclear spin bath than the latter. This anomalous decoherence effect is due to manipulation of the bath evolution via flips of the center spin.

10:12AM A30.00012 Manipulation of ¹³C nuclear spins in diamond via dynamical decoupling control of the electron spin¹, HOI-CHUN PO, REN-BAO LIU, Department of Physics, The Chinese University of Hong Kong — Utilizing the anisotropic nature of the hyperfine coupling between a negatively charged nitrogen-vacancy (NV) center spin and a moderately separated ¹³C nuclear spin, we present a scheme to efficiently control the ¹³C spin in 3 to 4 pulse cycles. This scheme uses only microwave pulses tuned to swap the NV center spin between the $m_s = 0$ and $m_s = 1$ states. With a strong magnetic field of the order of 10^3 G along the NV center symmetry axis, the nuclear spin can be flipped in approximately 10 μ s. We also numerically study the effect of various sources of errors in realistic scenario and demonstrate that the fidelity of the scheme is satisfactory. The pulse sequences can be readily generalized to perform any single qubit operation on the nuclear spin.

10:24AM A30.00013 Narrowing Overhauser field by coherent population trapping, ZHAN-FENG JIANG, REN-BAO LIU JIANG, Department of Physics, The Chinese University of Hong Kong, Shatin, New Territories, Hong Kong, China — By optical coupling to an excited state, an electron spin may be trapped to a coherent dark state when the Overhauser field has a proper value. At the same time, the fluctuation of nuclear spins is suppressed. Although the electron may jump out of the dark state due to the Fermi-contact hyperfine interaction between the electron and the nuclei, it still has a predominant probability to stay at the dark state. The narrowing of the Overhauser field prolongs the coherent time of the electron spin. The Overhauser field is always suppressed as the external magnetic field varies in a large range. A window with a long coherent time forms when we scan the external magnetic field. This work is supported by Hong Kong RGC/GRF Project CUHK402209 and NSFC/RGC Joint Project N-CUHK403/11.

10:36AM A30.00014 Spin echo probe of quantum criticality in the one-dimensional transverse-field Ising model, SHAOWEN CHEN, KE CHEN, RENBAO LIU, Department of Physics, The Chinese University of Hong Kong — We study the detection of quantum phase transition in the one dimensional transverse-field Ising model. In the model, we attach a spin-1/2 to the Ising spin chain as a probe and study the decoherence behavior of the probing spin with spin echo techniques. We evaluate the effective spectrum density of the local field that the Ising spin chain impart to the probing spin and identify the contributions from the thermal fluctuations and quantum fluctuations to the probe spin decoherence. The output of our work provides a better understanding of the quantum phase transition of this model. This work is supported by Hong Kong RGC/GRF Project CUHK 402410 and NSFC/RGC Joint Project N-CUHK403/11.

Monday, February 27, 2012 8:00AM - 11:00AM –
Session A31 GMAG DMP: Focus Session: Topological Insulators - Exotic Phases and Phase Transitions 260

8:00AM A31.00001 Quantum Anomalous Hall Effect in Magnetic Topological Insulator GdBiTe₃¹, HAI-JUN ZHANG, XIAO ZHANG, SHOU-CHENG ZHANG, Department of Physics, McCullough Building, Stanford University, Stanford, CA 94305-4045 — The quantum anomalous Hall (QAH) state is a two-dimensional bulk insulator with a non-zero Chern number in absence of external magnetic fields. Protected gapless chiral edge states enable dissipationless current transport in electronic devices. Doping topological insulators with random magnetic impurities could realize the QAH state, but magnetic order is difficult to establish experimentally in the bulk insulating limit. Here we predict that the single quintuple layer of GdBiTe₃ film could be a stoichiometric QAH insulator based on *ab-initio* calculations, which explicitly demonstrate ferromagnetic order and chiral edge states inside the bulk gap. We further investigate the topological quantum phase transition by tuning the lattice constant and interactions. A simple low-energy effective model is presented to capture the salient physical feature of this topological material.

¹This work is supported by the Army Research Office (No.W911NF-09-1-0508) and the Keck Foundation.

8:12AM A31.00002 First-principles study of magnetic ion doping in thin film Bi₂Se₃: electronic structure and topological phase¹, JINO IM, HOSUB JIN, ARTHUR J. FREEMAN, Northwestern University — We study the quantum anomalous Hall state in magnetic ion-doped Bi₂Se₃ thin films. By using first-principles density functional theory, we investigate this electronic structure and identify its topological phase. We find that magnetic ion doping induces the exchange field splitting and changes the spin-orbit coupling strength. As the doping concentration increases, the exchange field splitting strength increases and the spin-orbit coupling strength may decrease depending on the type of magnetic ion. Based on these results, we show that the quantum anomalous Hall state in the doped Bi₂Se₃ thin film emerges at a certain range of doping concentration. The Hall conductance of the doped Bi₂Se₃ thin film will also be discussed with various doping concentrations.

¹Supported by the DOE (Grant No. DE-FG02-88ER45372)

8:24AM A31.00003 Charge 4e Superconductivity from Quantum Spin Hall phase, EUN GOOK MOON, CENKE XU, University of California Santa Barbara — We present how to achieve charge 4e superconductor as a ground state studying non-relativistically induced quantum numbers of Skyrmions. It is shown that induced charge of Skyrmions interacting with fermion with quadratic band touching dispersion is twice bigger than one of Skyrmions with Dirac-like fermion. We also show that the former Skyrmions are always bosons while the latter ones are determined by the number of fermion flavors. Possible physical realization is discussed focusing on Skyrmions of quantum spin Hall order parameter in bi-layer graphene. Properties of quantum phase transition between charge 4e superconductor and quantum spin Hall phase are also discussed.

8:36AM A31.00004 Majorana fermions in semiconductor nanowires with realistic physical parameters, TUDOR STANESCU, West Virginia University — Semiconductor nanowires proximity coupled to s-wave superconductors represent a unique solid state platform for realizing and observing the elusive Majorana fermion. The existence and stability of the Majorana bound states localized at the ends of the wire depend on a set of parameters that includes the chemical potential, the external magnetic field, the spin-orbit coupling, the strength of the semiconductor-superconductor coupling, and the strengths of various types of disorder. It is critical to determine whether or not the parameter regimes that ensure the stability of the Majoranas are consistent with realistic experimental conditions. In this talk I will summarize the results of a theoretical study of multiband semiconductor nanowires that focuses on understanding the key experimental conditions required for the realization and detection of Majorana fermions. I will show that multiband occupancy not only lifts the stringent constraint of one-dimensionality, but also allows having higher carrier density in the nanowire. This significantly enhances the stability of the topologically nontrivial phase against various types of disorder, such as short-range impurities in the bulk superconductor, disorder at the semiconductor-superconductor interface, and disorder in the semiconductor nanowire. The detailed study of the parameter space for multiband semiconductor nanowires establishes the realistic likelihood of the existence of zero-energy Majorana modes within laboratory conditions.

9:12AM A31.00005 Topological States and Adiabatic Pumping in Quasicrystals¹, YAAKOV KRAUS, YOA V LAHINI, ZOHAR RINGEL, MOR VERBIN, ODED ZILBERBERG, Weizmann Institute of Science — We find a connection between quasicrystals and topological matter, namely that quasicrystals exhibit non-trivial topological phases attributed to dimensions higher than their own [1]. Quasicrystals are materials which are neither ordered nor disordered, i.e. they exhibit only long-range order [2]. This long-range order is usually expressed as a projection from a higher dimensional ordered system. Recently, the unrelated discovery of Topological Insulators [3] defined a new type of materials classified by their topology. We show theoretically and experimentally using photonic lattices, that one-dimensional quasicrystals exhibit topologically-protected boundary states equivalent to the edge states of the two-dimensional Integer Quantum Hall Effect. We harness this property to adiabatically pump light across the quasicrystal, and generalize our results to higher dimensional systems. Hence, quasicrystals offer a new platform for the study of topological phases while their topology may better explain their surface properties.

9:24AM A31.00006 Skyrmion quantum numbers and quantized pumping in two dimensional topological chiral magnets¹, BOHM-JUNG YANG, NAOTO NAGAOSA, Correlated Electron Research Group (CERG), RIKEN Advanced Science Institute, Wako, Saitama 351-0198, Japan — We investigate the general conditions to achieve the adiabatic charge and spin polarizations and quantized pumping in 2D magnetic insulators possessing inhomogeneous spin structures. In particular, we focus on the chiral ferrimagnetic insulators which are generated via spontaneous symmetry breaking from correlated two dimensional topological insulators. Adiabatic deformation of the inhomogeneous spin structure generates the spin gauge flux, which induces adiabatic charge and spin polarization currents. The unit pumped charge/spin are determined by the product of two topological invariants which are defined in momentum and real spaces, respectively. The same topological invariants determine the charge and spin quantum numbers of skyrmion textures. It is found that in noncentrosymmetric systems, a new topological phase, dubbed the topological chiral magnetic insulator, exists in which a skyrmion defect is a spin-1/2 fermion with electric charge e . Considering the adiabatic current responses of generic inhomogeneous systems, it is shown that the quantized topological response of chiral magnetic insulators is endowed with the second Chern number.

9:36AM A31.00007 Beyond Floquet theory: new paradigms for robust topological phenomena in strongly driven systems, MARK RUDNER, Harvard/Ohio State University, MICHAEL LEVIN, University of Maryland, EREZ BERG, Harvard — The discoveries of the quantized Hall effect [1] and Thouless' quantized adiabatic pumping [2] revealed the existence of a new class of extremely robust quantum phenomena which can be observed with high fidelity, largely independent of sample details. The immunity of these remarkable effects to a variety of perturbations can be understood in terms of a topological structure associated with the systems' wave functions. The rapid development of powerful tools for controlling solid state and atomic systems over the last decade has motivated the exploration of topological phenomena in driven systems. Recently, Kitagawa and coworkers [3] discussed analogs of previously known topological phenomena in terms of the Floquet operators of periodically-driven systems. Intriguingly, this work also revealed new robust phenomena, such as the existence of robust chiral edge modes in a 2D system with vanishing Chern numbers for all bulk Floquet bands. Here we construct the topological invariant which distinguishes phases with and without chiral edge modes, and discuss generalizations to other 1D and 2D systems.

9:48AM A31.00008 Emergent Topological Phases with Multiple Bands and Artificial Gauge Fields, ALEXANDRU PETRESCU, Yale University Physics Department, New Haven, CT, 06520 USA, KARYN LE HUR, Yale University Physics Department, New Haven, CT, 06520 USA and Center for Theoretical Physics (CPHT), Ecole Polytechnique, Palaiseau 91128, France — Particles on a two-dimensional Kagome lattice have attracted growing attention recently in relation to topological insulators and topological phases. Such Kagome structures can be engineered in optical lattices and can also be loaded with bosons. Similar tight-binding models might also be realized in photonic QED circuits. In this work, we investigate in detail the 3-band model emerging from such a tight-binding model on the two-dimensional Kagome lattice in the presence of artificial gauge fields and identify novel phases of matter such as bulk metals with helical edge states. We investigate the stability of edge modes inside a topological metallic phase and the role of lattice anisotropies and disorder, as well as relation to current experiments.

10:00AM A31.00009 Possible interaction driven topological phases in (111) bilayers of LaNiO_3 , YING RAN, KAI-YU YANG, Department of Physics, Boston College, Chestnut Hill, MA, 02467, WENGUANG ZHU¹, DI XIAO, SATOSHI OKAMOTO, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, ZIQIANG WANG, Department of Physics, Boston College, Chestnut Hill, MA, 02467 — We use the variational mean-field approach to systematically study the phase diagram of a bilayer heterostructure of the correlated transition metal oxide LaNiO_3 , grown along the (111) direction. The Ni^{3+} ions with d^7 (or e_g^1) configuration form a buckled honeycomb lattice. We show that as a function of the strength of the on-site interactions, various topological phases emerge. In the presence of a reasonable size of the Hund's coupling, as the correlation is tuned from intermediate to strong, the following sequence of phases is found: (1) a Dirac half-semimetal phase, (2) a quantum anomalous Hall insulator (QAH) phase with Chern number one, and (3) a ferromagnetic nematic phase breaking the lattice point group symmetry. The spin-orbit couplings and magnetism are both dynamically generated in the QAH phase.

10:12AM A31.00010 Quantum Phase Transitions in the Kane-Mele-Hubbard Model¹, ZI YANG MENG, Center for Computation and Technology, Louisiana State University, MARTIN HOHENADLER, Institute for Theoretical Physics and Astrophysics, University of Wuerzburg, THOMAS C. LANG, STEFAN WESSEL, Institute for Theoretical Solid State Physics, RWTH Aachen University, ALEJANDRO MURAMATSU, Institut fuer Theoretische Physik III, Universitaet Stuttgart, FAKHER F. ASSAAD, Institute for Theoretical Physics and Astrophysics, University of Wuerzburg — We study the ground state phase diagram of the Kane-Mele-Hubbard model on the two-dimensional honeycomb lattice. At half-filling the phase diagram is mapped out using projective auxiliary field quantum Monte Carlo simulations. We present a refined phase boundary for the quantum spin liquid. The topological (quantum spin-Hall) insulator at finite Hubbard interaction strength is adiabatically connected to the ground state of the Kane-Mele model. For the magnetic phase at large Hubbard interaction strength, we show that the magnetic order is restricted to the transverse direction. The transition from the topological band insulator to the antiferromagnetic Mott insulator is in the universality class of the three-dimensional XY model. The numerical data also suggest that the spin liquid to topological insulator and spin liquid to Mott insulator transitions are both continuous.

10:24AM A31.00011 Topological Phase Transitions for Interacting Finite Systems¹, KAI SUN, University of Maryland, College Park, CHRISTOPHER VARNEY, MARCOS RIGOL, Georgetown University, VICTOR GALITSKI, University of Maryland, College Park — We investigate topological phase transitions in interacting systems via the observation of a topologically protected level crossing. This level crossing is robust and sharply defines a topological transition even in finite-size systems. For Chern insulators, this technique gives the same topological transition point as obtained in the Chern number calculation (via flux insertion). However, in the presence of space inversion symmetry, we proved that if the topological index changes by an odd integer at the topological transition, the level crossing can only arise under (some of) the four high-symmetry boundary conditions. This discovery provides a very efficient way to detect topological phase transitions, which reduces the computational load dramatically. In contrast to the standard Chern number technique, which requires to compute the ground state wave function for hundreds of different boundary conditions, our technique achieves the same result by calculating the excitation gap for only four different boundary conditions. We demonstrate this technique in the Haldane-Fermi-Hubbard model utilizing exact diagonalization. Generalization to time-reversal invariant $\mathbb{Z}_2$ topological insulators will also be discussed.

10:36AM A31.00012 Topological phases and phase transitions in a two-dimensional fermionic lattice, CRISTIANE MORAIS SMITH, WOUTER BEUGELING, Utrecht University, NATHAN GOLDMAN, Universite libre de Bruxelles — A topological state of matter is characterized by a topological invariant, which is protected against disorder effects. For the quantum Hall effect, the Hall conductivity is protected since it is carried by chiral edge states, induced by a magnetic field. Systems with large spin-orbit coupling exhibit the quantum spin Hall effect, where the protected quantity is the spin Hall conductivity, carried by helical edge states. In our theoretical study of a fermionic tight-binding model we show that the interplay between the magnetic field and the spin-orbit coupling generates spin-imbalanced chiral phases and exotic phase transitions between helical and chiral spin textures. We explore the experimental possibilities to observe these phase transitions in cold-atom systems, for which the necessary strengths of the magnetic field and spin-orbit coupling are accessible. As a second application, we investigate the spectrum of topological phases in HgTe quantum wells doped with Mn ions (in collaboration with Molenkamp's group). We show that this doping leads to interesting reentrant effects of both the Hall and spin Hall conductivities.

10:48AM A31.00013 Phase Structure of the Topological Anderson Insulator, DONGWEI XU, Oklahoma State University, VINCENT E. SACKSTEDER, JUNJIE QI, JIE LIU, Institute of Physics, Chinese Academy of Sciences, HUA JIANG, Peking University, X. C. XIE, Oklahoma State University, Peking University — We report the phase structure of disordered HgTe topological Anderson insulator in a 2-D geometry. We use exact diagonalization to calculate the spectrum and eigenstate structure, and recursive green's functions to calculate the conductance. All observables are measured at several system sizes, allowing us to determine phase transitions and two critical points. The quantized-conductance TAI phase contains two phases: TAI-I lying in a bulk band gap, and TAI-II where bulk states exist but are localized. We find that the TAI-II phase persists at disorder strengths where there is no bulk band gap; a bulk band gap is not necessary to obtain conductance quantization. In a previous work the weak-disorder edge of the TAI phase was explained as a transition into the bulk gap (TAI-I), but we find also a direct transition into the ungapped (TAI-II) quantized phase. Effective medium theory (SCBA) predicts well the boundaries and interior of the TAI-I phase, but fails at larger disorders including the interior of the TAI-II phase. When the system size is smaller than the bulk localization length, the quantized TAI region is bounded by either the bulk band edge or the localization length, but when the system size is large it is bounded by a transition of edge states.

Monday, February 27, 2012 8:00AM - 11:00AM — Session A32 DCMF: Topological Insulators: Quantum Hall Effect 261

8:00AM A32.00001 Weak antilocalization in HgTe quantum wells and topological surface states: Massive versus massless Dirac fermions¹, EVELINA HANKIEWICZ, GRIGORY TKACHOV, Wuerzburg University — HgTe quantum wells and surfaces of three-dimensional topological insulators support Dirac fermions with a single-valley band dispersion. In this work we conduct a comparative theoretical study of the weak antilocalization in HgTe quantum wells (QWs) and topological surface states. The difference between these two single-valley systems comes from a finite band gap (effective Dirac mass) in HgTe quantum wells in contrast to gapless (massless) surface states in topological insulators. The finite effective Dirac mass implies a broken internal symmetry, leading to suppression of the weak antilocalization in HgTe quantum wells and transition to the weak localization regime as a function of the gap or carrier density. In particular, we show how the difference in the behavior of the weak localization corrections for HgTe QWs allows to distinguish topological versus normal insulators. Further for the topological surface states we predict specific weak-antilocalization magnetoconductivity in a parallel magnetic field due to their exponential decay in the bulk. The relevant experiments will be discussed.

8:12AM A32.00002 Topological insulators in magnetic fields: Quantum Hall effect and edge channels with non-quantized θ -term, LARS FRITZ, MATTHIAS SITTE, ACHIM ROSCH, University of Cologne/ Germany, EHUD ALTMAN, Weizmann Institute — We investigate how a magnetic field induces one-dimensional edge channels when the two-dimensional surface states of three-dimensional topological insulators become gapped. The Hall effect, measured by contacting those channels, remains quantized even in situations, where the θ -term in the bulk and the associated surface Hall conductivities, σ_{xy}^S , are not quantized due to the breaking of time-reversal symmetry. The quantization arises as the θ -term changes by $\pm 2\pi n$ along a loop around n edge channels. Model calculations show how an interplay of orbital and Zeeman effects leads to quantum Hall transitions, where channels get redistributed along the edges of the crystal. The network of edges opens new possibilities to investigate the coupling of edge channels.

8:24AM A32.00003 The topological Hubbard model and its high-temperature quantum Hall $\nu = 1$ state, TITUS NEUPERT, Condensed Matter Theory Group, Paul Scherrer Institute, Switzerland, LUIZ SANTOS, Department of Physics, Harvard University, SHINSEI RYU, Department of Physics, University of Illinois at Urbana-Champaign, CLAUDIO CHAMON, Physics Department, Boston University, CHRISTOPHER MUDRY, Condensed Matter Theory Group, Paul Scherrer Institute, Switzerland — The quintessential two-dimensional lattice model that describes the competition between the kinetic energy of electrons and their short-range repulsive interactions is the repulsive Hubbard model. We study a time-reversal symmetric variant of the repulsive Hubbard model defined on a planar lattice: Whereas the interaction is unchanged, any fully occupied band supports a quantized spin Hall effect. We show that at $1/2$ filling of this band, the ground state develops spontaneously and simultaneously Ising ferromagnetic long-range order and a quantized charge Hall effect when the interaction is sufficiently strong. We ponder on the possible practical applications, beyond metrology, that the quantized charge Hall effect might have if it could be realized at high temperatures and without external magnetic fields in strongly correlated materials.

8:36AM A32.00004 Magnetic field dependence of the edge channels in HgTe quantum wells¹, BENEDIKT SCHARF, ALEX MATOS-ABIAGUE, JAROSLAV FABIAN, Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany — In recent years much attention has been devoted to topological insulators, that is, materials which are insulating in the bulk, but have conducting states at their surface. This new class of topological states has first been observed experimentally in HgTe quantum wells. In such a two-dimensional topological insulator, which is also synonymously referred to as a quantum spin Hall insulator, these surface states are one-dimensional, helical edge channels. Here we study a HgTe quantum well in the presence of a constant perpendicular magnetic field. Using tight-binding calculations as well as deriving an analytical expression to determine the electron dispersion and states, we solve the effective low-energy Hamiltonian of this system in a finite-strip geometry. Our main focus is on the behavior of these solutions with increasing magnetic field. In particular, we describe the evolution of the edge states as the system crosses from the quantum spin Hall to the quantum Hall regime.

8:48AM A32.00005 Phase Diagram of Massive Dirac Fermions with Tunable Interactions in High Magnetic Fields¹, R.N. BHATT, Department of Electrical Engineering and Princeton Center for Theoretical Science, Princeton University, Princeton, NJ 08544, Z. PAPIC, Department of Electrical Engineering, Princeton University, Princeton, NJ 08544, Y. BARLAS, National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL 32310, D.A. ABANIN, Princeton Center for Theoretical Science, Princeton University, Princeton, NJ 08544 — We study the strongly correlated states of massive fermions in two dimensions with Berry's phase π and 2π , in the limit of high magnetic fields. Due to the chiral band structure and massive carriers, the effective Coulomb interactions depend on the external magnetic field, and lead to a number of phases within a single low-lying Landau level. The tunability of the interactions allows the study of the transitions between phases in a more direct manner than in GaAs-based systems where the form of the interactions is independent of the magnetic field. We map the phase diagram at partial fillings $\nu = 1/3, 1/2, 3/5$ of the low-lying Landau levels, and find transitions between fractional quantum Hall states, compressible Fermi-liquid-like states, as well as charge-density-waves. We also find a new, broad regime of the effective interactions which favor the paired non-Abelian states. Our study identifies the strongly correlated phases expected in high-mobility graphene, bilayer graphene, topological insulators, and other materials with the non-trivial Berry phases, and provides a realistic method for studying the phase transitions between them.

9:00AM A32.00006 Isotropic Landau levels of relativistic and non-relativistic fermions in 3D flat space, YI LI, CONGJUN WU, University of California, San Diego — The usual Landau level quantization, as demonstrated in the 2D quantum Hall effect, is crucially based on the planar structure. In this talk, we explore its 3D counterpart possessing the full 3D rotational symmetry as well as the time reversal symmetry. We construct the Landau level Hamiltonians in 3 and higher dimensional flat space for both relativistic and non-relativistic fermions. The 3D cases with integer fillings are Z_2 topological insulators. The non-relativistic version describes spin-1/2 fermions coupling to the Aharonov-Casher $SU(2)$ gauge field. This system exhibits flat Landau levels in which the orbital angular momentum and the spin are coupled with a fixed helicity. Each filled Landau level contributes one 2D helical Dirac Fermi surface at an open boundary, which demonstrates the Z_2 topological nature. A natural generalization to Dirac fermions is found as a square root problem of the above non-relativistic version, which can also be viewed as the Dirac equation defined on the phase space. All these Landau level problems can be generalized to arbitrary high dimensions systematically.

9:12AM A32.00007 Topological property for magnetic flux tubes in a two-dimensional electron gas, LU-YAO WANG, National Chiao Tung University, dept. of Electrophysics, ZHIGUO LV, Shanghai Jiao Tong University, dept. of Physics, CHON-SAAR CHU, National Chiao Tung University, dept. of Electrophysics — We have studied the energy spectrum in the presence of square magnetic flux-tubes in a two-dimensional electron gas. Our finding is that the Dirac-like dispersion can be formed out between the third and the fourth magnetic subbands without including the Zeeman interaction. This Dirac-like dispersion is not band-inverted type with a global gap. This Dirac-like dispersion becomes band-inverted when the Zeeman interaction is included. We expect that the inverted magnetic subbands due to the Zeeman interaction can be recognized as the topological insulator. This topology property can be supported by the Chern number from the magnetic subbands.

9:24AM A32.00008 Pi-flux as a universal probe of two-dimensional topological insulators¹, VLADIMIR JURICIC, Instituut-Lorentz for Theoretical Physics, Leiden University, The Netherlands, ANDREJ MESAROS, Department of Physics, Boston College, Chestnut Hill, MA 02467, USA, ROBERT-JAN SLAGER, JAN ZAAANEN, Instituut-Lorentz for Theoretical Physics, Leiden University, The Netherlands — We show that the existence of a Kramers pair of zero-energy modes bound to a vortex carrying π -flux is a generic feature of topologically nontrivial phases in the $M-B$ model, describing HgTe quantum wells, and therefore this vortex represents the bulk probe of the band topology [1]. We explicitly find the form of the zero-energy states by analytically solving Dirac equation which contains a momentum-dependent Schrödinger mass, besides the usual Dirac mass term. A particular regularization of the vortex potential yields the modes exponentially localized and regular at the origin that carry nontrivial charge or spin quantum number.

9:36AM A32.00009 Strongly driven Floquet topological insulator in semiconductor quantum wells, XUEDA WEN, CHING-KAI CHIU, Physics Department, UIUC, PHYSICS DEPARTMENT, UIUC COLLABORATION — Floquet topological insulator in a weak-field driven semiconductor quantum well was proposed most recently. In this article we extend the situation to strongly driving field, which can generate high-order harmonic resonances. With appropriate form of driving field, it is found that whether topological transition can happen depends on the number of resonances N we can observe. If N is odd, topological transition can happen; if N is even, topological transition cannot happen. This phenomenon may be observed in semiconductor quantum wells by applying a strongly oscillating magnetic field. In addition, our discussion can be extended to other systems such as p-wave superconductors and spin chains.

9:48AM A32.00010 Quantum Hall effect in a one-dimensional dynamical system¹, JONATHAN EDGE, JAN DAHLHAUS, Leiden University, JAKUB TWORZYDLO, University of Warsaw, CARLO BEENAKKER, Leiden University — We construct a periodically time-dependent Hamiltonian with a phase transition in the quantum Hall universality class [1]. This Hamiltonian is closely related to that of a discrete time quantum walker, but additionally it allows us to study effects of disorder. A particular choice for the form of the Hamiltonian enables us to determine the time evolution of the system in one of the dimensions exactly. Simulations of the system can thus be performed in one dimension, thereby reducing the computational effort required. We investigate the topological phase transition associated with tuning between different quantum Hall plateaux and determine the critical exponent for the divergence of the localisation length. Our scheme can in principle also be implemented in cold atoms experiments, opening the doors to investigating the quantum Hall phase transition in a one-dimensional cold atoms set up.

10:12AM A32.00012 Berry Curvature and Phonon Hall Effect, TAO QIN, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, JUNREN SHI, International Center for Quantum Materials, Peking University, Beijing 100871, China — Abstract We establish the general phonon dynamics of magnetic solids by incorporating the Mead-Truhlar correction in the Born-Oppenheimer approximation. The effective magnetic-field acting on the phonons naturally emerges, giving rise to the phonon Hall effect. A general formula of the intrinsic phonon Hall conductivity is obtained by using the corrected Kubo formula with the energy magnetization contribution properly incorporated. The resulting phonon Hall conductivity is fully determined by the phonon Berry curvature and the dispersions. Based on the formula, the topological phonon system could be rigorously defined. In the low temperature regime, we predict that the phonon Hall conductivity is proportional to T^3 for the ordinary phonon systems, while that for the topological phonon systems has the linear T dependence with the quantized temperature coefficient.

10:24AM A32.00013 Dissipationless Phonon Hall Viscosity, SUK-BUM CHUNG, MAISSAM BARKESHLI, XIAO-LIANG QI, Stanford University — We study the acoustic phonon response of crystals hosting a gapped time-reversal symmetry breaking electronic state. The phonon effective action can in general acquire a dissipationless “Hall” viscosity, which is determined by the adiabatic Berry curvature of the electron wave function. This Hall viscosity endows the system with a characteristic frequency, ω_v ; for phonons of frequency ω , it shifts the phonon spectrum by an amount of order $(\omega/\omega_v)^2$ and it mixes the longitudinal and transverse sound waves with a relative amplitude ratio of ω/ω_v and with a phase shift of $\pm\pi/2$, to lowest order in ω/ω_v . We study several examples, including the integer quantum Hall states, the quantum anomalous Hall state in $\text{Hg}_{1-y}\text{Mn}_y\text{Te}$ quantum wells, and a mean-field model for $p_x + ip_y$ superconductors. We discuss situations in which the phonon response is directly related to the gravitational response, for which striking predictions have been made. When the electron-phonon system is viewed as a whole, this provides an example where measurements of Goldstone modes may serve as a probe of adiabatic curvature of the gapped sector of a system.

10:36AM A32.00014 3D Topological Insulators in the Continuum with Nearly Flat Bands, CONGJUN WU, YI LI, University of California, San Diego, XIANGFA ZHOU, University of Science and Technology of China — We propose a three-dimensional topological insulating state in the harmonic potential with a strong spin-orbit coupling breaking the inversion symmetry. The system gives rise to Landau-level like quantization with the full 3D rotational symmetry and time-reversal symmetry. The radial quantization generates the energy gap between neighboring bands. The states inside each band are characterized by their angular momentum over which the dispersions are suppressed by spin-orbit coupling and thus nearly flat and without Bloch-wave states. Surface states exhibit helical Dirac Fermi surfaces which are described by the Z2 index. Similar analysis in 2D shows the existence of topological insulators in the harmonic potential with strong Rashba spin-orbit coupling. These topological insulating states can be achieved from the dimensional reduction of the quantum Hall states in 3D and 4D flat space.

10:48AM A32.00015 Photo-induced quantum Hall insulators without Landau levels, TAKUYA KITAGAWA, Department of Physics, Harvard University, TAKASHI OKA, Department of Physics, Faculty of Science, University of Tokyo, LIANG FU, Physics Department, Harvard University, ARNE BRATAAS, Department of Physics, Norwegian University of Science and Technology, EUGENE DEMLER, Department of Physics, Harvard University — In this talk, we demonstrate that non-equilibrium transport of graphene under the application of off-resonant light displays a near quantization of Hall conductance. While previous studies of topological phenomena under coherent drives focused on the effective topological band structure, electron occupations in the non-equilibrium systems, which are so far neglected, play a crucial role to determine the transport properties. Using the formalism that consistently take this into account, we show that the topological band structures can directly manifest themselves in the transport properties in Landauer-type configurations under the application of off-resonant light. We give an intuitive explanation of the induction of Chern numbers in the band structure, by showing that the virtual photon absorption/emissions of electrons produces an effective second-order hopping with phase accumulation, leading to the effective Haldane model. Our proposal opens the perspective to realize so-called quantum Hall systems without Landau levels in materials such as graphene and three dimensional topological insulators under coherent drives.

Monday, February 27, 2012 8:00AM - 11:00AM – Session A33 GERA: Physics of Photovoltaics 106

8:00AM A33.00001 Search of novel photovoltaic absorbers from first-principles spectroscopic screening of hundreds of materials¹, LIPING YU, National Renewable Energy Laboratory, ALEX ZUNGER, University of Colorado Boulder — Screening for candidate PV absorbers from numerous existing materials would require a good selection criterion. Initial selection criteria generally rest on the intrinsic material properties and abundance, postponing defect and contact issues to after the list of candidates has been narrowed down. The currently available Shockley-Queisser efficiency formula gives a universal efficiency vs band gap curve (no matter whether the gap is direct or indirect) and ignore all radiative recombination loss, and has proven over the years to be insufficient. Here we propose a calculable selection criterion of “spectroscopic limited maximum efficiency (SLME)” which considers the type of band gap (direct allowed, direct forbidden and indirect), the shape of absorption spectra and material-dependent radiative recombination loss by a simple model. First-principles quasiparticle calculations of SLME for ~300 generalized I-III-VI and ~500 I-V-VI materials identify over 40 candidates with higher SLME than currently used best thin-film absorbers. Analysis of the electronic structure of the top candidates reveals an interesting mechanism for high absorptivity and shows that some indirect gap materials can even be better than direct gap materials.

8:12AM A33.00002 ABSTRACT WITHDRAWN —

8:24AM A33.00003 First-principles electronic structure of β -FeSi₂ and FeS₂, PENGXIANG XU, TIMO SCHENA, STEFAN BLÜGEL, GUSTAV BIHLMAYER, Peter Gruenberg Institut & Institute for Advanced Simulation, Forschungszentrum Juelich and JARA, 52425 Juelich, Germany — Applying density functional theory in the framework of the full-potential linearized augmented plane-wave (FLAPW) method [1], we investigated electronic structure of potential future photovoltaic materials - β -FeSi₂ and FeS₂ in their bulk phases and for selected surface orientations and terminations. Their band gaps are examined using hybrid functionals as well as many-body perturbation theory in the GW-approximation to get insight of their photovoltaic performance. The gap nature in β -FeSi₂ changes from direct to indirect as suitable strain field is induced in the structure by epitaxially matching with Si substrate. Furthermore, we also studied the atomic and electronic structure of β -FeSi₂ and FeS₂ thin films for different orientations with different terminations. The most stable orientations are determined by comparing their cohesive energy. Detailed electronic structure calculations show that surface states originating from Fe play an important role and might determine their photovoltaic properties.

8:36AM A33.00004 The effect of surface stoichiometry on the band gap of the pyrite FeS₂(100) surface¹, YANNING ZHANG, JUN HU, MATT LAW, RUQIAN WU, University of California, Irvine — Iron pyrite (FeS_2) is experiencing a resurgence of interest for use in solar photovoltaic and photoelectrochemical cells. The main hurdle to the use of pyrite is the low open-circuit voltage of pyrite devices, which may result from gap states created by surface and bulk defects. Recently, systematic spin-polarized DFT calculations were performed for a series of pyrite $\text{FeS}_2(100)$ surfaces to clarify the effect of surface stoichiometry on stability, electronic structure, and band gap. It was found that while stoichiometric and S-poor $\text{FeS}_2(100)$ surfaces are semiconductors with band gaps of 0.56-0.72 eV, S-rich surfaces are small-gap semiconductors ($E_g < 0.3$ eV) or metals. The stoichiometric $\text{FeS}_2(100)$ surface is spin polarized in the topmost layer (2 μ_B per Fe) and displays a band of Fe d_{z^2} gap states centered 0.2 eV above the valence band edge. Our calculations suggest that the low open-circuit voltage of pyrite solar cells may result from a narrowed surface band gap. S-poor surfaces may provide larger photovoltages than S-rich surfaces. The segregation process of sulfur vacancy under different surface conditions are also being studied, so as to provide useful guidelines for the design and fabrication of better pyrite photovoltaic materials and devices.

¹We thank the NSF SOLAR Program (Award CHE-1035218) and the UCI School of Physical Sciences Center for Solar Energy for support of this work. Calculations were performed on parallel computers at NERSC and at NSF supercomputer centers.

8:48AM A33.00005 Band gap engineering of Zn based II-VI semiconductors through uniaxial strain, SATYESH YADAV, RAMPI RAMPRASAD, University of Connecticut — The electronic structure of bulk wurtzitic ZnX ($X=O, S, Se, \text{ and } Te$) under uniaxial strain along the [0001] direction is investigated using hybrid density functional theory calculations and many-body perturbation theory. It is found that uniaxial tensile and large compressive strains decrease the band gap, similar to what has been predicted by semilocal density functional theory (DFT) calculations [Yadav et. al, Phys. Rev. B, **81**, 144120 (2010)]. Moreover, the change in the band gap under uniaxial strains predicted by semilocal DFT is in good quantitative agreement with the present results at all strains considered, thereby bringing a measure of redemption to conventional (semi)local DFT descriptions of the electronic structure of at least this class of insulators. The present results have important implications for band gap engineering through strain, especially for complex systems containing a large number of atoms (e.g., nanowires) for which higher-level calculations may be too computationally intensive.

9:00AM A33.00006 Searching Stable Cu_xS Structure for Photovoltaic Application, QIANG XU, BING HUANG, YUFENG ZHAO, National Renewable Energy Lab, YANGFA YAN, Department of Physics and Astronomy The University of Toledo, ROMMEL NOUFI, SU-HUAI WEI, National Renewable Energy Lab — Employing the density-functional theory (DFT) methods, we systematically search for the most energetically favorable Cu_xS compounds in a wide range of $1.2 < x \leq 2.0$ guided by the experimentally identified four minerals, i.e., the chalcocite ($x = 2$), djurite ($x = 1.94$), digenite ($x = 1.80$), and anilite ($x = 1.75$) compounds. For the chalcocite Cu_2S , all its three phases have direct band gaps of 1.3-1.4 eV, with the chalcocite low phase being more stable than other two phases, i.e., the chalcocite high and the chalcocite cubic. According to our calculation, the poor durability of the Cu_2S is mainly due to the energetically favorable formation of Cu vacancies. The calculated formation heat as a function of x shows that the anilite $Cu_{1.75}S$ is the most stable structure. Unfortunately, this material is not a good light absorber because of its metallic feature. We propose that doping of the anilite $Cu_{1.75}S$ with interstitial Sn atoms may result in a compound $Cu_{1.75}Sn_{0.125}S$ with an optimum direct band gap of 1.37 eV. Such a material has the ability of light absorption similar to the chalcocite Cu_2S .

9:12AM A33.00007 Si Nanoparticles embedded in solid matrices for solar energy conversion: electronic and optical properties from first principle calculations, STEFAN WIPPERMANN, Department of Chemistry, University of California, Davis 95616, TIANSHU LI, Department of Civil and Environmental Engineering, George Washington University, Washington, D.C. 20052, DARIO ROCCA, Department of Chemistry, University of California, Davis 95616, GERGELY ZIMANYI, Department of Physics, University of California, Davis 95616, GIULIA GALLI, Department of Chemistry, University of California, Davis 95616, MULTIPLE EXCITON GENERATION IN ALL-INORGANIC NANOSTRUCTURED SOLAR CELLS COLLABORATION¹ — In device applications for solar energy conversion, nanoparticles are often embedded in a solid matrix, either crystalline or amorphous. At present a detailed understanding of the influence exerted by the embedding matrix on absorption of sunlight by the nanoparticle, and the role of the nanoparticle-matrix interface remains elusive. Building on a previous study of Si nanoparticles embedded in SiO_2 [1], we investigate Si nanoparticles embedded in ZnS , used in recent experiments as a charge transport layer. A realistic model of the nanoparticle-matrix interface is created by performing ab-initio molecular dynamics simulations, and electronic and optical properties of the embedded Si nanocrystals, are obtained by first principles.

¹NSF/Solar funded collaboration (grant No. DMR-1035468)

9:24AM A33.00008 Multiple exciton generation in silicon nanoparticles¹, MARTON VOROS, Department of Atomic Physics, Budapest University of Technology and Economics, ADAM GALLI, Hungarian Academy of Sciences, Research Institute for Solid State Physics and Optics, DARIO ROCCA, Department Of Chemistry, University of California, Davis, GIULIA GALLI, Department Of Chemistry, Department Of Physics, University of California, Davis, GERGELY ZIMANYI, Department Of Physics, University of California, Davis — Multiple Exciton Generation (MEG) in semiconductor nanocrystals is considered to be a promising path to improve the efficiency of solar energy conversion. Recent experimental and theoretical studies indicate that MEG is more efficient in nanoparticles (NPs) than in the bulk only on a relative energy scales in units of the gap. The primary cause of this is that quantum confinement increases the energy gap substantially in NPs. MEG will be a true breakthrough when nanocrystals are identified whose impact ionization rate is enhanced even on the absolute energy scale. For this search, we calculated impact ionization rates of silicon NPs with diameters up to 2 nm using density functional theory. Our calculations clearly demonstrate that surface reconstruction creates classes of new states at low energies, de facto lowering the NP gap and thus holding the promise of increasing MEG even on the absolute energy scale. Our calculations include static screening within the random-phase approximation. We show that a full treatment of the transition matrix elements is essential to obtain correct results due their strong energy dependence.

¹Support from Grant NSF DMR-1035468 is acknowledged.

9:36AM A33.00009 All-Carbon Photovoltaics, MARCO BERNARDI, PRIYANK KUMAR, NICOLA FERRALIS, Massachusetts Institute of Technology, SHENQIANG REN, University of Kansas, JEFFREY C. GROSSMAN, Massachusetts Institute of Technology — We present an alternative scheme for nanostructured solar cells, where carbon nanomaterials are the only constituents of a bulk-heterojunction active layer and fulfill the role of absorbers, donors and acceptors, in the absence of conjugated polymers. Ab-initio simulations were employed to calculate the band alignment for interfaces between carbon nanotubes, fullerene derivative PCBM and reduced graphene oxide, showing the presence of Type-II and Schottky heterojunctions useful for charge separation in the active layer. Accordingly, we prepared all-carbon solar cells with optimized proportions of these three components that achieved AM1.5 efficiencies up to 1.5%, with fill factors up to 70% and increased thermal stability and lifetime compared to polymer-based devices. Our results show the potential of all-carbon solar cells as an alternative to polymer based ones: the key combination of high carrier mobility, visible and IR absorption and stability under illumination makes them suitable for next-generation flexible photovoltaics.

9:48AM A33.00010 Porous Silicon Applications for Photovoltaic Solar Cell Devices¹, GULSEN KOSOGLU, MEHMET YUMAK, UGUR DINC, OZHAN OZATAY, YANI SKARLATOS, CARLOS CARCIA CARCIA, Bogazici University Physics Department — The photovoltaic industry searches for low cost, energy competitive solar cell modules, and the usual material used is crystalline silicon, which has been covering 90% of the solar module market for a long time. Porous silicon (P-Si) is used in photovoltaic applications as an ultra efficient anti-reflection coating, while a graded layer with an expanded band gap offers increased absorption in the visible spectrum regions. We have built P-Si solar cell devices having considered different physical Si wafer parameters such as crystal orientation, resistivity, and doping levels; which crucially affect the device efficiency. Porous Si wafers, prepared after etching crystalline silicon in high HF concentrations, exhibit fluorescence in the purple wavelength region of the visible spectrum under UV illumination. We are now in the process of improving the efficiency of the device by modulating the structure of the P-Si wafer, and studying its photovoltaic characteristics.

¹Bogazici University Research Funding:5782 TUBITAK Grand Funding:209T099 Bogazici University Infrared Funding:6121

10:00AM A33.00011 Quantum-dot nanostructures for effective harvesting, detection, and conversion of IR radiation , NIZAMI VAGIDOV, ANDREI SERGEEV, ANDREI ANTIPOV, Electrical Engineering Department, University at Buffalo, SUNY, KIMBERLY SABLON, JOHN LITTLE, U.S. Army Research Laboratory, Adelphi, VLADIMIR MITIN, Electrical Engineering Department, University at Buffalo, SUNY — Our novel approach to improve harvesting, detection, and conversion of IR radiation is based on engineering of three-dimensional potential barriers introduced by quantum dots with built-in charge due to inter-dot doping. The barriers around dots exponentially suppress capture processes and increase the photoelectron lifetime. The built-in-dot charge also strongly enhances the coupling of QD structures to IR radiation. Both effects radically improve the responsivity of IR photodetectors and photovoltaic efficiency of quantum-dot solar cells. Here we report a 50% increase in photovoltaic efficiency in quantum-dot solar cells as well as 25 times increase of the photoresponse of quantum-dot infrared photodetectors when the built-in-dot charge increases up to six electrons per dot. We also present results of modeling of photoelectron kinetics and discuss perspectives of IR photodetectors and solar cells based on quantum dots with built-in charge.

10:12AM A33.00012 ABSTRACT HAS BEEN MOVED TO K1.00149 —

10:24AM A33.00013 Device analysis of vertically aligned single-core nanocoaxial solar cells , T. KIRKPATRICK, C. ANDRONACHE, M.J. BURNS, M.J. NAUGHTON, Boston College — Analytical expressions for device transport are derived and numerically calculated for an array of vertically aligned single-core nanocoaxial solar cells. Total current of the device is derived as a function of the geometrical configuration of the photovoltaic junction, and expressions for rectifying current behavior are subsequently solved for and analyzed. Fundamental differences and similarities in the physics of device performance are inferred based on the analytical expressions for planar, nanowire, and nanocoaxial solar cells. To emphasize the physical difference of device performance pertaining to geometrical configuration, a comparison between planar and nanocoaxial device performance is analyzed for an amorphous silicon p-i-n junction solar cell.

Session A34 DCP: Focus Session: Impact of Ultrafast Lasers I: X-rays and THz 107A

8:00AM A34.00001 Ultrafast X-ray Laser Studies of Chemical Dynamics , KELLY GAFFNEY, SLAC National Accelerator Laboratory and Stanford University — First light at the LCLS x-ray free electron laser at the SLAC National Accelerator Laboratory marked the beginning of hard x-ray laser science 2009. With pulse energies in excess of a milliJoule and pulse durations as short as 5 femtoseconds in duration, the LCLS provides a novel and potentially transformative approach for investigating chemical dynamics in complex systems. Understanding the coupled evolution of electrons and nuclei during chemical transformations remains the central and vexing challenge in the study of chemical reaction dynamics. Ultrafast optical electronic spectroscopy can monitor both the nuclear and the electronic evolution that occurs during a chemical reaction, but this joint sensitivity often impedes the robust interpretation of experimental measurement. The LCLS provides the opportunity to simultaneously measure electronic dynamics with x-ray fluorescence and nuclear dynamics with elastic x-ray scattering, providing a robust means for disentangling the coupled motions of electrons and nuclei during excited state internal conversion and intersystem crossing. These exciting new opportunities will be discussed in the context of recent studies of photo-induced spin crossover dynamics in iron(II) tris-bipyridine. $[\text{Fe}(\text{bpy})_3]^{2+}$.

8:36AM A34.00002 Coherently controlled orientation and alignment of molecules in the gas phase by intense THz fields , SHARLY FLEISCHER, YAN ZHOU, ROBERT W. FIELD, KEITH A. NELSON, Department of Chemistry, Massachusetts Institute of Technology — We report the use of intense terahertz (THz) pulses to orient polar molecules in the gas phase. Short THz fields exert torques that drive coherent molecular rotational motion, and multiple interactions with strong THz fields can yield multiple-quantum rotational coherences with the prospect of high degrees of orientation (dipoles pointing in the same direction in space) and alignment (molecular axes parallel to each other regardless of dipole orientation). THz-induced molecular orientation offers new possibilities in gas-phase x-ray diffraction, molecular orbital mapping through high harmonic generation and photoelectron angular distribution imaging, and other applications. We demonstrate significantly enhanced coherent control using two THz pulses with an optimized relative time delay. We show in the case of atmospheric water that a short, strong THz field induces long-lived coherent THz emission (free induction decay) that drives significant further rotational responses in a pre-excited polar gas sample. This class of experiments enables broad new capabilities for molecular spectroscopy and control beyond those afforded through molecular alignment by intense optical fields, which do not produce any net orientation.

8:48AM A34.00003 Capturing the Coupled Dynamics of Electrons, Atoms and Spins in Molecules and Materials using Ultrafast X-Rays , MARGARET MURNANE, JILA, University of Colorado at Boulder — No abstract available.

9:24AM A34.00004 Using time-resolved Ru L-edge X-ray absorption spectroscopy to capture photoinduced transient electronic structure in a solar cell dye molecule , BENJAMIN VAN KUIKEN, MICHAEL LYNCH, MUNIRA KHALIL, Department of Chemistry, University of Washington, Seattle, WA 98195, NILS HUSE, HANA CHO, MATTHEW STRADER, ROBERT SCHOENLEIN, Lawrence Berkeley National Laboratory, Berkeley, CA 94720 — Understanding the electronic structure of transition metal dye molecules used in dye-sensitized solar cells (DSSC) is critical for determining the functioning of these devices. Ru^{II} dyes such as Ru(dcbpy)₂(NCS)₂ (termed RuN3) have been components in some of the most effective DSSCs. We use synchrotron-based picosecond Ru L-edge X-ray absorption spectroscopy (XAS) to monitor changes the changes in the electronic structure of RuN3⁴⁻ that accompany the ¹A₁ to ³MLCT conversion initiated with a 400 nm light pulse. The results are interpreted by simulating the Ru L₃ X-ray absorption spectra of the ¹A₁ and ³MLCT states with time-dependent density functional theory (TD-DFT). We observe the formation of the Ru^{III} oxidation state of RuN3⁴⁻ within the 70 ps time resolution of our experiment. The TD-DFT simulation allows us to assign a spectral feature in the Ru L-edge spectrum as a probe of the electronic structure of the NCS ligands due to overlap between Ru 4d and NCS π^* orbitals. A 1.2 eV blue shift in this feature between ground and ³MLCT state corresponds to depletion in charge density on the NCS ligands in the excited state. We will discuss in detail the local electronic structure around the Ru atom in the transient ³MLCT state measured by time-resolved XAS.

9:36AM A34.00005 Ultrafast molecular processes mapped by femtosecond x-ray diffraction

, THOMAS ELSAESSER, Max-Born-Institute, 2 a Max-Born-St., Berlin, 12489 — X-ray diffraction with a femtosecond time resolution allows for mapping photoinduced structural dynamics on the length scale of a chemical bond and in the time domain of atomic and molecular motion. In a pump-probe approach, a femtosecond excitation pulse induces structural changes which are probed by diffracting a femtosecond hard x-ray pulse from the excited sample. The transient angular positions and intensities of diffraction peaks give insight into the momentary atomic or molecular positions and into the distribution of electronic charge density. The simultaneous measurement of changes on different diffraction peaks is essential for determining atom positions and charge density maps with high accuracy. Recent progress in the generation of ultrashort hard x-ray pulses (Cu K_{α} , wavelength $\lambda = 0.154$ nm) in laser-driven plasma sources has led to the implementation of the powder diffraction and the rotating crystal method with a time resolution of 100 fs. In this contribution, we report new results from powder diffraction studies of molecular materials. A first series of experiments gives evidence of a so far unknown concerted transfer of electrons and protons in ammonium sulfate $[(NH_4)_2SO_4]$, a centrosymmetric structure. Charge transfer from the sulfate groups results in the sub-100 fs generation of a confined electron channel along the c-axis of the unit cell which is stabilized by transferring protons from the adjacent ammonium groups into the channel. Time-dependent charge density maps display a periodic modulation of the channel's charge density by low-frequency lattice motions with a concerted electron and proton motion between the channel and the initial proton binding site. A second study addresses atomic rearrangements and charge dislocations in the non-centrosymmetric potassium dihydrogen phosphate $[KH_2PO_4]$, KDP. Photoexcitation generates coherent low-frequency motions along the LO and TO phonon coordinates, leaving the average atomic positions unchanged. The time-dependent maps of electron density demonstrate a concomitant oscillatory relocation of electronic charge with a spatial amplitude of the order of a chemical bond length, two orders of magnitude larger than the vibrational amplitudes. The coherent phonon motions drive the charge relocation, similar to a soft mode driven phase transition between the ferro- and paraelectric phase of KDP.

10:12AM A34.00006 Time-resolved X-ray fragmentation probing of molecular isomerization

, VLADIMIR PETROVIC, Department of Physics, Stanford University, MARCO SIANO, Blackett Laboratory, Imperial College London, UK, JAMES L. WHITE, Department of Applied Physics, Stanford University, PHILIP H. BUCKSBAUM, Departments of Physics and Applied Physics, Stanford University, AMO14110 COLLABORATION — Short intense X-ray pulses, now available at FELs, are already having a strong impact on the AMO science. In addition to scattering or resonant absorption, it is possible to use X-ray radiation to probe processes on molecular timescales through non-resonant absorption by initiating a molecular fragmentation in a time-resolved manner. Core-ionized molecules composed of light elements predominantly relax through Auger decay into multiply charged molecular ions, which subsequently fragment through Coulomb repulsion. The fragmentation patterns (ion time-of-flight spectra, ion-kinetic energy release, Auger spectra, etc.) encode information about instantaneous nuclear geometry and momenta. Unlike intense IR laser field fragmentation, X-ray fragmentation occurs in the weak-field regime. In order to test the potential of time-resolved X-ray fragmentation for probing isomerization, we selected the example of ring opening of 1,3-cyclohexadiene. In a time-resolved UV-pump - X-ray fragmentation-probe experiment performed at Linac Coherent Light Source at SLAC we observed an increase in the average ion-KER and an increase in the number of lighter fragments upon photoexcitation. We discuss how the evolving fragmentation patterns reflect the structural change that the molecule is undergoing.

10:24AM A34.00007 A Femtosecond Time-Resolved Transient X-ray Absorption Study of Light-Induced Coupling and Transparency in Xenon

, MING-FU LIN, UXSL/CSD Lawrence Berkeley Lab and UC Berkeley, ADRIAN PFEIFFER, UC Berkeley, DANIEL NEUMARK, STEPHEN LEONE, UXSL/CSD Lawrence Berkeley Lab and UC Berkeley, OLIVER GESSNER, UXSL/CSD Lawrence Berkeley Lab. — We have performed a femtosecond time-resolved transient x-ray absorption spectroscopy study to monitor the light induced coupling between bright and dark states in xenon exposed to infrared (780 nm) laser pulses with intensities up to 5×10^{13} W/cm². Significant transient variations in the inner-shell absorption spectra between ~ 63 eV and ~ 69 eV photon energy are observed. Near time zero, the transmission at 67 eV increases from 6(1) % (field-free) to 14(3) % (laser dressed). Transient absorption and transient transparency effects are interpreted within a picture of strong-field induced coupling between core-excited $4d^{-1}(^2D_{5/2})6p(^2P_{3/2})$ and $4d^{-1}(^2D_{3/2})6p(^2P_{1/2})$ states at 65.1 and 67 eV, respectively, and nearby dark states with *ns* and *nd* characters. The major features of the transient absorption spectra can be well described within a three-level (Autler-Townes) coupling scheme. Employing this model, a dipole-moment for the $4d^{-1}(^2D_{3/2})6p(^2P_{1/2})$ to $4d^{-1}(^2D_{3/2})6s(^2S_{1/2})$ transition of 0.4(0.1) Debye is derived.

10:36AM A34.00008 High Resolution THz Studies of Crystalline Channel Hydrates

, DAVID PLUSQUELLIC, SHIN CHOU, ZEESHAN AHMED, KEVIN DOUGLASS, JULIA SCHERSCHLIGT, National Institute of Standards and Technology — In this study, we use vibrationally state-resolved THz spectroscopy to examine the phonon mode structure of several peptides and carbohydrates co-crystallized with water. Studies are performed before and after the water is removed under vacuum on a range of systems for water in hydrophobic and hydrophilic environments. Predictions from first principles calculations are used to model the observed spectra and to obtain detailed energetic information on the dehydration processes. A new phase-coherent heterodyne method based on chirped THz pulses may be discussed.

Monday, February 27, 2012 8:00AM - 10:48AM —

Session A35 DCP: Focus Session: DFT I: Strongly Correlated Systems; GW and Many-Body Perturbation Theory 107B

8:00AM A35.00001 Real-Space DFT Models for Strong Correlation

, ERIN JOHNSON, University of California, Merced — Accurate treatment of strongly-correlated electrons remains an important challenge for density-functional theory. Most functionals underestimate the energy lowering arising from non-dynamical electron correlation, as in stretched covalent bonds, open-shell singlet states, and many transition-metal compounds, including semiconductors. We develop a new density-functional approach combining physical insight from chemical structure with real-space modeling of the exchange-correlation hole, based on the Becke-Roussel exchange functional. The method is capable of predicting correct dissociation limits and describing strong correlation in many-electron systems.

8:36AM A35.00002 DFT+DMFT versus DFT+U description of Mott insulators: DMFT restores spin and orbital symmetry and removes metastable states

, BERNARD AMADON, CEA, DAM, DIF, F 91297 Arpajon, France — In the last twenty years, the development of methods based on the coupling of Density Functional Theory in the Local Density Approximation and Hubbard-like terms has led to a successful description of many strongly correlated systems. These methods include DFT+U which contains a static description of interaction and the combination of DFT with Dynamical Mean Field Theory (DFT+DMFT) which adds fluctuations to the description of interactions. We present implementations of DFT+U and DFT+DMFT in the same framework, and with the same approximations. We show, in agreement with previous results in the literature, and even in the simple Hubbard I approximation to DMFT, that DFT+DMFT is able to describe Mott insulator without any breaking of spin and orbital symmetry. We show that this improvement simply removes the appearance of metastable states, and thus solve a practical and physical problem encountered in particular in the description of actinides oxides in DFT+U calculations.

8:48AM A35.00003 Renormalized second-order perturbation theory for the electron correlation energy: concepts and benchmarks, PATRICK RINKE, XINGUO REN, MATTHIAS SCHEFFLER, Fritz-Haber-Institute der MPG, Berlin, Germany, GUSTAVO SCUSERIA, Rice University, Houston, USA — We present a renormalized second-order perturbation theory (R2PT) for the electron correlation energy that combines the random-phase approximation (RPA), second-order screened exchange (SOSEX) [1], and renormalized single excitations (rSE) [2]. These three terms all involve a summation of certain types of diagrams to infinite order, and can be viewed as a “renormalization” of the direct, the exchange and the single excitation (SE) term of 2nd-order Rayleigh-Schrödinger perturbation theory based on an (approximate) Kohn-Sham reference state. A preliminary version of R2PT has been benchmarked for covalently-bonded molecular systems and chemical reaction barrier heights [3] and shows an overall well balanced performance. We have extended this, by including “off-diagonal” diagrams into the rSE term and expect this refined version of R2PT to be more generally applicable to electronic systems of different bonding characteristics. Extended benchmarks of van-der-Waals-bonded molecules and crystalline solids will be presented. [1] A. Grüneis *et al.*, J. Chem. Phys. **131**, 154115 (2009). [2] X. Ren *et al.*, Phys. Rev. Lett. **106**, 153003 (2011). [3] J. Paier *et al.*, arXiv:cond-mat/1111.0173.

9:00AM A35.00004 Efficient GW methods implemented in molecular orbital space: Ionization energy and electron affinity of conjugated molecules¹, SAN-HUANG KE, Department of Physics, Tongji University, 1239 Siping Road, Shanghai 200092, China — An efficient all-electron non-selfconsistent GW (G^0W^0) method is proposed, which is based on the full random-phase approximation and implemented in the molecular-orbital space with algorithms for reducing the error coming from the incompleteness of the basis set. The convergence of its result with regard to the size of the basis set is examined. Based on this, we further implement a quasiparticle self-consistent GW (QSGW) approach with Gaussian basis functions. The high computational efficiency allows us to deal with larger molecules from the first principles, and we applied our methods to calculate the ionization energy (IE) and electron affinity (EA) of ten conjugated molecules with up to 32 atoms. The G^0W^0 result improves the Hartree-Fock result significantly, especially for EA, and, furthermore, the QSGW improves the G^0W^0 and gives results of both IE and EA in very good agreement with the available experimental data and also with the results from the Δ SCF calculation using the B3LYP functional. This indicates that our all-electron *ab initio* GW calculation can describe very well molecular electronic structures, making the QSGW approach a good candidate for investigating electronic and transport properties of molecular systems.

¹Work supported by the Shanghai Pujiang Program under Grant No. 10PJ1410000 and by the MOST 973 Project under Grant No. 2011CB922204 as well as by the National Natural Science Foundation of China under Grant No. 11174220

9:12AM A35.00005 Exact DFT with the density matrix renormalization group¹, E. MILES SToudenMIRE, Dept. of Physics and Astronomy, University of California, Irvine — The density matrix renormalization group (DMRG) is a powerful, controlled numerical method traditionally applied to lattice models of strongly correlated electrons in 1D and 2D. By extending DMRG to simulate electronic structure models on a 1D quasi-continuum grid, we can compute exact Kohn-Sham (KS) potentials and even perform exact full KS calculations.² On their own, the continuum DMRG calculations provide significant insight into the structure of strongly correlated many-body wavefunctions both for smaller molecules and chains exceeding one hundred atoms. Combining DMRG with the machinery of density functional theory allows us to explore the reasons for the success or failure of standard DFT approximations and to better understand which many-body effects are faithfully reproduced by the KS system.

¹This work is funded by the U.S. Department of Energy (Grant No. DE-FG02-08ER46496)

²E.M. Stoudenmire, Lucas O. Wagner, Steven R. White, Kieron Burke, arXiv:1107.2394

9:48AM A35.00006 Exact density functionals for 1d systems¹, LUCAS WAGNER, E. SToudenMIRE, Department of Physics and Astronomy, University of California, Irvine, KIERON BURKE, Department of Physics and Astronomy and Department of Chemistry, University of California, Irvine, STEVEN WHITE, Department of Physics and Astronomy, University of California, Irvine — The success of modern density functional theory (DFT) can be attributed to the Kohn-Sham (KS) scheme, for which density functional approximations are both practical and rather simple. We are often left in the dark, however, when trying to understand why certain approximations fail, or how well they approximate the true functional. To study such questions, an exact implementation of KS-DFT is required. Though exact KS-DFT is as difficult as solving the original many-body problem, the density matrix renormalization group (DMRG) gives us a powerful tool to do this. DMRG is a highly efficient wavefunction solver in 1d, which we use to solve model continuum systems with a long-range soft-Coulomb interaction between particles. Using DMRG, we implement exact KS-DFT and investigate its inner workings. Results for some atom chains are discussed and compared to HF and LDA calculations. Preprint at arXiv:1107.2394.

¹With deep appreciation for DOE grant DE-FG02-08ER46496.

10:00AM A35.00007 Exact Kohn-Sham eigenstates versus quasi-particles in simple models of strongly correlated electrons, JAIME FERRER¹, DIEGO CARRASCAL², Departamento de Física, Universidad de Oviedo, Spain — We present analytic expressions for the exact density functional and Kohn-Sham Hamiltonian of simple tight-binding models of correlated electrons. These are the single- and double-site versions of the Anderson, Hubbard and spinless fermion models. The exact exchange and correlation potentials are fully non-local. The analytic expressions allow to compare the Kohn-Sham eigenstates of exact density functional theory with the many-body quasi-particle states of these correlated-electron systems. The exact Kohn-Sham spectrum describes correctly many of the non-trivial features of the many-body quasi-particle spectrum, as for example the precursors of the Kondo peak. However, we find that some pieces of the quasi-particle spectrum are missing because the many-body phase-space for electron and hole excitations is richer.

²CINN (CSIC - Universidad de Oviedo), Spain

10:12AM A35.00008 Spectroscopic Fingerprinting of Small Molecules via Many-Body Perturbation Theory, PETER DOAK, Molecular Foundry, LBNL; Department of Chemistry, UC-Berkeley, PIERRE DARANCET, JEFFREY NEATON, Molecular Foundry, LBNL — Quantitative understanding of the photophysics of small organic molecules is an important challenge and relevant to a range of energy conversion applications. Existing first-principles methods, such as time-dependent density functional theory, coupled cluster, and other quantum chemistry-based approaches can sometimes provide onset energies with good accuracy, but agreement at higher energies - a more complete spectral fingerprint - is frequently less adequate. Here we use DFT and many-body perturbation theory, within the GW approximation and the Bethe-Salpeter Equation approach, to compute the UV-Vis absorption spectra for a range of small molecules, comparing closely to room-temperature, solution-phase measurements of onsets and spectra. First-principles molecular dynamics is used to prepare snapshots of finite temperature conformations. The effects of continuum and explicit solvation models are considered. The importance of dynamic disorder, delocalized unoccupied states, and solvation are thoroughly discussed in the context of experiments. Support: DOE via the Molecular Foundry and Helios SERC, and NSF via NCN. Computational support provided by NERSC.

10:24AM A35.00009 Going beyond DFT for Organic/Titanium Dioxide interfaces¹, LEONARDO

M. MARION JORGE, MARCELO ALVES-SANTOS, MARÍLIA J. CALDAS, Instituto de Física - Universidade de São Paulo — There is increasing interest in organic/oxide interfaces, particularly for light harvesting and light-emitting devices, and it is important to obtain theoretical information for basic quantities such as the energy-level alignment across the interface. Accurate descriptions of the electronic structure of the composite system, as e.g. [1], are however scarce. The method used should give reliable results for both organic and oxide materials, to guarantee a good description of the hybrid system. In this work we have explored different DFT functionals (PZ-LDA, and those that include a fraction of Exact-Exchange as PBE0, HSE and B3LYP [2]) and compared the results with those obtained by Many-Body Perturbation theory with the GW approximation[3]. We have chosen as prototype systems TiO₂, both bulk crystal and model surface, and Thiophene. We have found that none of the used DFT schemes give optimal results for both organic and inorganic systems at the same time, so moving beyond DFT is mandatory.

10:36AM A35.00010 Accurate potential energy surfaces for transition-metal complexes with

DFT+U(R), HEATHER KULIK, Stanford University — We introduce an improvement to the Hubbard U augmented density functional approach known as DFT+U that incorporates variations in the value of self-consistently calculated, linear-response U with changes in geometry. This approach overcomes the one major shortcoming of previous DFT+U studies, i.e. the use of an averaged Hubbard U when comparing energies for different points along a potential energy surface is no longer required. While DFT+U is quite successful at providing accurate descriptions of localized electrons (e.g. d or f) by correcting self-interaction errors of standard exchange correlation functionals, we show several examples from diatomic molecules to porphyrins to surface science applications where this position-dependent DFT+U(R) provides a significant two- to four-fold improvement over DFT+U predictions. DFT+U(R) reduces errors in binding energies, frequencies, and equilibrium bond lengths by applying the linear-response, position-dependent U(R) at each point. We also propose a metric for whether a standard DFT+U approach is sufficient by determining the strength of the dependence of U on changes in coordinates.

Monday, February 27, 2012 8:00AM - 11:00AM – Session A36 DCP: Focus Session: New Energy I 107C

8:00AM A36.00001 Facing our Energy Challenges in a New Era of Science, ERIC ROHLFING, US

Department of Energy, Office of Science, Office of Basic Energy Sciences — As our nation and the world face daunting challenges in energy supply and the environmental consequences of energy use, how can basic science contribute to transforming the way in which we generate and use energy? How can we use the power of modern science, notably chemical physics, to accelerate the transition to a more sustainable energy future? In this talk, I shall present some of the current strategic thinking from the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences (BES). In particular, I shall present how the department is approaching the entire R&D spectrum for energy technologies and how BES engages the scientific community to identify basic research needs for advancing energy technologies.

8:36AM A36.00002 Semiconductor nanostructures for artificial photosynthesis, PEIDONG YANG, UC,

Berkeley — Nanowires, with their unique capability to bridge the nanoscopic and macroscopic worlds, have already been demonstrated as important materials for different energy conversion. One emerging and exciting direction is their application for solar to fuel conversion. The generation of fuels by the direct conversion of solar energy in a fully integrated system is an attractive goal, but no such system has been demonstrated that shows the required efficiency, is sufficiently durable, or can be manufactured at reasonable cost. One of the most critical issues in solar water splitting is the development of a suitable photoanode with high efficiency and long-term durability in an aqueous environment. Semiconductor nanowires represent an important class of nanostructure building block for direct solar-to-fuel application because of their high surface area, tunable bandgap and efficient charge transport and collection. Nanowires can be readily designed and synthesized to deterministically incorporate heterojunctions with improved light absorption, charge separation and vectorial transport. Meanwhile, it is also possible to selectively decorate different oxidation or reduction catalysts onto specific segments of the nanowires to mimic the compartmentalized reactions in natural photosynthesis. In this talk, I will highlight several recent examples in this lab using semiconductor nanowires and their heterostructures for the purpose of direct solar water splitting.

9:12AM A36.00003 Oxygen Evolution Electrocatalysis on Cobalt Oxide surfaces¹, MICHAL BAJDICH,

JCAP-North, LBL, Berkeley, CA 94720, JENS K. NORSKOV, SUNCAT, SLAC, Stanford, CA 94025, MONICA GARCÍA-MOTA, Department of Chemical Engineering, Stanford University, Stanford, CA 94305, ALEXIS T. BELL, JCAP-North, LBL, Berkeley, CA 94720 — The oxidation of water for hydrogen production using sunlight is of high importance to photo-fuel cell research. The electrochemical approach via heterogeneous catalysis to water splitting is a very promising route. The key challenge of this method lies in reduction of the losses, i.e., over-potential, for the oxygen evolution reaction (OER) on the anode. In this work, we investigate the dependence of theoretical over-potential of OER on type of anode by applying standard density functional theory (DFT). We attempt to explain recent experimental observation of enhanced activity on gold supported Cobalt Oxide surfaces [1]. We explore variety of possible CoO structures and associated surfaces which could emerge under operating conditions of catalyst. Finally, we also explore the influence of environment and admixtures of CoO with other elements.

¹support from Joint Center for Artificial Photosynthesis (heterogeneous catalysis)

9:24AM A36.00004 High-throughput synthesis and screening of photon absorbers and photo-catalysts for solar fuel cells, SLOBODAN MITROVIC, MARTIN MARCIN, SEAN LIN, JIAN JIN, Joint Center for Artificial Photosynthesis,

California Institute of Technology — Joint Center for Artificial Photosynthesis is a D.O.E. Energy Innovation Hub conceived to develop solar fuel cell technologies by bringing together the critical mass of scientist and engineers nationwide. The High-Throughput Experimentation group at JCAP is developing pipelines for accelerated discovery of new materials - photon absorbers, photoelectrochemical and electrochemical catalysts - using combinatorial approaches (ink-jet, sol-gel, physical vapor deposition). Thin films of semiconducting metal-oxides, sulfides, nitrides and phosphides are synthesized and screened in high-throughput according to their optical and photoelectrochemical properties, as well as structure and phase. Vast libraries of materials and data are generated and made available to inside and outside research groups. Here we present data on binary, ternary and quaternary metal-oxide systems prepared by the ink-jet technology. The systems include tungsten-based photo-absorbers and nickel-iron-based catalysts for water splitting.

9:36AM A36.00005 Transport in and chemistry on transition metal oxides for energy conversion , EMILY CARTER, Princeton University — We use quantum mechanics techniques to search for robust, efficient, and inexpensive materials for solid oxide fuel cells (SOFCs) that convert fuels to electricity, photovoltaics (PVs) that convert sunlight to electricity, and photo-catalytic electrodes (PCEs) that convert sunlight, CO₂, and H₂O into fuels. In our SOFC research, we focus on cathode optimization, often considered the limiting factor. If oxide ion diffusion and electron transport can be enhanced, along with rapid dissociative adsorption of dioxygen, lower temperatures can be used, which would facilitate wider deployment. In the solar energy conversion arena, the cost-efficiency tradeoff for PV materials motivates new options. I will discuss why it is difficult to find effective PCE materials; in particular I will enumerate the very significant constraints beyond those on PVs that they must satisfy to achieve high efficiency. Limiting oneself to abundant elements further constrains the design space. As a result, we are focusing primarily on first row transition metal oxide materials. Key properties of conventional and novel materials, along with some new design principles, will be discussed. The work is revealing which dopants or mixed oxides are likely to provide the most efficient energy conversion materials.

10:12AM A36.00006 A comparison in activity between transition-metal oxides and transition metals , ALEKSANDRA VOJVODIC, Stanford University, FELIX STUDDT, FRANK ABILD-PEDERSEN, THOMAS BLIGAARD, SLAC National Accelerator Laboratory, JENS NØRSKOV, Stanford University — Transition-metal oxides are widely used materials in catalysis as substrates and promoters, but also as the active catalyst materials themselves. We compare the reactivity of transition-metal oxides with the one of transition metals. The comparison is exemplified for the ammonia synthesis reaction. First we show that there exist characteristic Brønsted-Evans Polanyi (BEP) relations (linear relations between transition state and dissociation energies) for dissociation of molecules on transition-metal oxides in the rutile and perovskite structure. It is well-known that the (211) metal surface is several orders of magnitude more reactive than the (111) metal surface due to the lower BEP line for the 211 facet. We find that both rutiles and perovskites follow BEP relations that are lower than the one of the 211 facet. Second we utilize the established BEP relations together with calculated adsorption energetics in a micro-kinetic model to obtain a volcano plot for the catalytic activity. We find that oxides have a higher turn over frequency as compared with metals. Hence, oxides intrinsically have a great advantage in terms of catalytic activity which opens up for catalyst design.

10:24AM A36.00007 Energy conversion and fuel production from electrochemical interfaces¹ , NENAD MARKOVIC, Argonne National Laboratory — Design and synthesis of energy efficient and stable electrochemical interfaces (materials and double layer components) with tailor properties for accelerating and directing chemical transformations is the key to developing new alternative energy systems – fuel cells, electrolyzers and batteries. In aqueous electrolytes, depending on the nature of the reacting species, the supporting electrolyte, and the metal electrodes, two types of interactions have traditionally been considered: (i) direct – covalent bond formation between adsorbates and electrodes, involving chemisorption, electron transfer, and release of the ion hydration shell; and (ii) relatively weak non-covalent metal-ion forces that may affect the concentration of ions in the vicinity of the electrode but do not involve direct metal-adsorbate bonding. The range of physical phenomena associated with these two classes of bonds is unusually broad, and are of paramount importance to understand activity of both metal-electrolyte two phase interfaces and metal-Nafion-electrolyte three phase interfaces. Furthermore, in the past, researcher working in the field of fuel cells (converting hydrogen and oxygen into water) and electrolyzers (splitting water back to H₂ and O₂)) seldom focused on understanding the electrochemical compliments of these reactions in battery systems, e.g., the lithium-air system. In this lecture, we address the importance of both covalent and non-covalent interactions in controlling catalytic activity at the two-phase and three-phase interfaces. Although the field is still in its infancy, a great deal has already been learned and trends are beginning to emerge that give new insight into the relationship between the nature of bonding interactions and catalytic activity/stability of electrochemical interfaces. In addition, to bridge the gap between the “water battery” (fuel cell ↔ electrolyzer) and the Li-air battery systems we demonstrate that this would require fundamentally new knowledge in several critical areas. We conclude that understanding the complexity (simplicity) of electrochemical interfaces would open new avenues for design and deployment of alternative energy systems.

¹Work done in collaboration with R. Subbaraman, D. Tripkovic, D. Strmcnik, N. Danilovic, G. Wiberg, Chao Wang, K-C Chang, D. van der Vliet, A. Paulikas, and V. Stamenkovic, Argonne National Laboratory, Materials Science Division.

Session A37 FEd SPS: Research Collaboration between Mentors and Undergraduate Students

108

8:00AM A37.00001 Atomic, molecular and optical physics at Bethel¹ , CHAD HOYT, DAN KLEMME, Bethel University — An example of the close connection between research and advanced labs at Bethel University is the recent realization of cold lithium atoms in a magneto-optical trap (MOT). Several aspects of the cooling and trapping research took root in the laboratory components of the Optics and Lasers upper-level courses. These included a wavelength meter with sub-picometer accuracy and precision, stabilized laser diodes and molecular and atomic spectroscopy. Work on the MOT began in 2008 and has involved students (a total of 12, including several post-General Physics sophomores) working during summers, course projects and senior research. Lithium MOTs offer challenges (e.g. low vapor pressure) and advantages in an undergraduate lab with respect to the more common rubidium systems. Lasers for lithium are at 671 nm, a more practical red color that can still take advantage of inexpensive laser diodes and broadband optical coatings. Its relatively simple atomic structure makes lithium amenable for stringent comparisons between theory and experiment. Recent high precision absolute frequency measurements using an atomic beam disagree. Cold-atom spectroscopy of lithium could help resolve questions about the atomic structure of lithium.

¹NASA MN Space Grant Consortium, CID Inc.

8:12AM A37.00002 Lithium in a Magneto-Optical Trap , DAN KLEMME, CHAD HOYT, Bethel University — We recently cooled and trapped $\sim 10^7$ neutral ^7Li atoms in a magneto-optical trap. Our laser source is a home-built external cavity diode laser at 671 nm and a semiconductor tapered amplifier. Acousto-optic modulators are used to generate five different laser detunings that are necessary for repumping between hyperfine states in the trapping and slowing laser beams. The laser is locked by phase-sensitive detection of fluorescence produced by a frequency-modulated laser beam normally incident to the lithium atomic beam. The laser is tuned to the $2S_{1/2}(F=2) \rightarrow 2P_{3/2}(F')$ D2 transition. Two coils of wire with ~ 100 A of current flowing through them in an anti-Helmholtz orientation generate the magnetic field gradient whose magnitude increases from zero with distance from the center of the trap. We describe a few preliminary measurements on the trapped atoms such as temperature, atom number, and loading/unloading times. Eventually, the cold lithium will be used to demonstrate single-photon cooling in an optical dipole trap. Additionally, we plan to use the trap to do high-resolution, cold atom spectroscopy.

8:24AM A37.00003 Undergraduate Research in Theoretical Physics at Goucher College: Thermal Properties of Extreme Type-II Superconductors in High Magnetic Fields¹, SASHA DUKAN, JULIAN IRWIN, Department of Physics and Astronomy, Goucher College, MD 21204 — The subject matter of this faculty/student collaborative research involves the complex theoretical task of calculating the thermodynamic properties of strongly coupled extreme type-II superconductors starting from the high-field limit of the Landau level pairing scheme. In these systems, the low temperature and high magnetic field regime of the phase diagram fundamentally differs from the familiar low-field mixed phase, primarily by the appearance of gapless quasiparticle excitations in the energy spectrum. This theoretical/computational research was performed over the past three years in collaboration with Goucher College undergraduate students majoring in physics, mathematics and computer science. These students used their analytical and computational skills to develop computer programs and to calculate numerically the thermal properties of realistic superconducting materials. I will describe how this project created an intellectual environment where students developed an awareness of theoretical physics research and its impact on emerging technologies as well as its possible contribution to the solutions for the global energy challenge.

¹This work is supported by NSF grant no. DMR-0856415.

8:36AM A37.00004 Thermal properties of Extreme Type-II Superconductors in High Magnetic Fields¹, JULIAN IRWIN, SASHA DUKAN, Department of Physics and Astronomy, Goucher College, MD21204 — The subject matter of our investigation involves the complex theoretical task of calculating the specific heat of a two-gap extreme type-II superconductor. In extreme type-II superconductors, at low temperatures and high magnetic fields, Landau level quantization of electronic energies results in the appearance of gapless excitations at highly symmetrical points on the Fermi surface. The careful measurements of thermal properties like specific heat in the superconducting mixed state at low temperatures and high magnetic fields can reveal this novel gapless behavior. We present a detailed theoretical and numerical study of a realistic, disordered superconductor in high magnetic field and compare our calculated specific heat to available experimental data for the well-known two-gap superconductors NbSe₂ and LuNi₂B₂C. We also discuss the alterations to the location and number of gapless excitations caused by the inclusion of off-diagonal electronic pairing.

¹This work is supported by NSF grant no. DMR-0856415.

8:48AM A37.00005 Undergraduate Studies on Compressible Flows and Shock Waves¹, KEITH STEIN, JENNIFER SCHOMMER, BENJAMIN HEPPNER, Bethel University — The Bethel University physics department believes advanced lab projects and undergraduate research experiences are crucial in the development of our students, particularly those that pursue graduate studies in physics, engineering and other applied fields. Open-ended advanced lab projects are key components in several upper level physics courses. Student project work in a specific course is often enhanced by student experiences in other upper level physics courses or other research experiences. For example, projects in *Fluid Mechanics* (PHY420) are often enriched by experiences that students bring from projects in *Optics* (PHY330) and *Computer Methods in Physics* (PHY350). We present examples from recent undergraduate projects on compressible flows and shock waves. Special attention is given to a project involving the design, construction, and initial testing of a small supersonic blowdown tunnel. This facility was initially constructed as part of a project in *Fluid Mechanics* (fall 2010). Subsequent student research projects have included high-speed video shadowgraph imaging (summer 2011) and the development of a MATLAB GUI to allow for side-by-side comparisons between simulation and ongoing experiments with the tunnel (fall 2011).

¹Minnesota Space Grant Consortium

9:00AM A37.00006 Graphical User Interface for Supersonic Flow and Shock Waves in a Converging-Diverging Nozzle¹, JENNIFER SCHOMMER, KEITH STEIN, BENJAMIN HEPPNER, Bethel University — A graphical user interface (GUI) is developed to study the compressible flow in a converging-diverging (CD) nozzle. Related experiments are carried out with a small supersonic blowdown tunnel in the Bethel University physics department. The tunnel is constructed with two 5-gallon pressure tanks which are connected by a CD nozzle. Flow in the nozzle goes through three stages during the operation of the blowdown tunnel. The first stage is highly transient and culminates with the development of the quasi-static flow condition throughout the nozzle. In the second stage, flow is fully developed with sufficient driving pressure to sustain supersonic flow in the entire divergent section of the nozzle. In the final stage, the driving pressure is no longer sufficient and a normal shock recedes from the exit of the nozzle to the throat. The GUI is created with MATLAB and focuses on modeling the second and third stage of the flow in the nozzle. Modeling in stage two is based on a 1D isentropic flow assumption, whereas stage three is based on 1D isentropic flow along with normal shock relations. Additional functions of the GUI are being implemented to allow for side-by-side comparisons between simulation and ongoing experiments.

¹Minnesota Space Grant Consortium

9:12AM A37.00007 Characterization of Gold Nanoparticles for Radiotherapy Applications, YOSHI ARAKI, JAMES ROONEY, TABBETHA DOBBINS, Rowan University — Gold nanoparticles (AuNPs) are able to conjoin with biological molecules and efficiently absorb light for conversion into heat energy. Thus, they are being investigated for treatment of near surface carcinomas. In this research, we synthesize AuNPs using two different approaches to yield variation in particle size and monodispersity. Transmission electron microscopy was used to characterize particle size and shape while UV-Visible spectrophotometry characterized their absorption wavelength. Presently, fibroblast cells are being used to establish protocols for cell growth, exposure to nanoparticles, irradiation, and cell viability. The future direction of this work is to synthesize a variety of nanoparticles in order to determine the optimal shape, size and composition for photothermal radiotherapy treatment.

9:24AM A37.00008 Absorption and Agglomeration of Gold Nanoparticles as a means to Probe Cell Metabolic Activity for Radiotherapy Applications, ADAM STEFANKIEWICZ, FRANK HOLDER, TABBETHA DOBBINS, Rowan University — Poly(lactic-co-glycolic acid) (PLGA) surface treatment of gold nanoparticles (AuNPs) enable those particles to cross the cellular wall. Once within the cell, absorption spectral shifts, predicted by the Mie Theory equation, occur because the dielectric constant of the matrix differs from that surrounding the cell. This phenomena will lead to particle agglomeration (due to changes in surface energy of the particles) and shifts in the Mie absorption spectra. Both phenomena are being explored in fibroblast cells as a means to track cell type and cellular metabolic activity. UV-Vis spectrophotometry and scanning electron microscopy (SEM) are incorporated to analyze the resulting particle/cell mixtures. Early results will be presented.

9:36AM A37.00009 Research in growth, characterization, and applications of wide bandgap materials at a Primarily Undergraduate Institution¹, CHRISTOPHER MOORE, ROBERT LOUDER, Coastal Carolina University — Zinc oxide (ZnO) is a wide bandgap semiconductor that has attracted a great deal of attention with demonstrated applications in ultraviolet (UV) light detection, air-quality monitoring, missile warning systems, gas detection, and utilization as light-emitting diodes. Our undergraduate research group has been characterizing the growth of various ZnO film and nanowire systems, and we have fabricated and characterized ZnO-based devices, such as UV photodetectors, gas sensors, and photocatalysts. The materials and characterization systems with which we are working and our small niche within the broader field combine to address many of the challenges associated with undergraduate research. In this talk, we will discuss these challenges and how we have overcome them. We will also discuss how we have taken small amounts of money and crumbling facilities and produced a strong research group that involves 3-5 undergraduate students per semester, publishes approximately two peer-reviewed articles per year with undergraduate co-authors, and has achieved a steady stream of external funding.

¹Funding for this work provided by NSF DMR #1104600.

9:48AM A37.00010 Photocatalytic activity of ZnO thin films prepared by DC sputter deposition and thermal oxidation, ROBERT LOUDER, CHRISTOPHER MOORE, Coastal Carolina University — Zinc oxide (ZnO) is a wide-bandgap semiconductor with a broad range of applications, such as photocatalysis. The photocatalytic properties of ZnO result from the highly-oxidizing holes and reducing electrons that are induced on the ZnO surface by ultraviolet (UV) light. The efficiency of electron-hole pair formation is therefore critical for photocatalysis, and thus the optical quality of the films in the UV region is of critical importance. ZnO thin films have been fabricated using DC sputter deposition of Zn-metal films followed by thermal oxidation at different temperatures (300, 600, and 900°C). Characterization of the optical properties of the resulting ZnO thin films through photoluminescence indicates that increasing oxidation temperature leads to reduced UV excitonic emission. The photocatalytic activities of the films were also characterized by measuring the efficiency of degradation of Rhodamine B dye in solution. The photocatalytic efficiency of the film annealed at a temperature of 300°C was higher compared to those of the films annealed at temperatures of 600°C and 900°C. The increased photocatalytic efficiency is attributed to the increased optical quality of the films that results from lower oxidation temperatures.

10:00AM A37.00011 Investigating the Role of Disorder in the Two-Dimensional Superfluid Transition, D.R. LUHMAN, L.R. WADLEIGH, P.G. BUMCROT, Carleton College — The superfluid transition in two-dimensional helium films is an example of a Berezinskii-Kosterlitz-Thouless transition. Characteristic features of the superfluid transition, such as the abrupt onset of superfluidity, have been observed to be significantly altered in disordered two-dimensional systems. We are in the initial stages of experiments aimed at understanding the role of disorder in the two-dimensional superfluid transition. Disorder is introduced into the system by adsorbing helium films to CaF₂ surfaces with varying roughness. Quantitative characterization of the roughness of these films is crucial to understanding the superfluid transition in a disordered environment and is our current focus. The overall scope and goals of our experiments will be presented along with some of the challenges of doing low temperature physics in the undergraduate setting. The important role that undergraduates have played in these experiments will also be discussed.

10:12AM A37.00012 Characterization of CaF₂ surfaces using Adsorption-Desorption Isotherms and Atomic Force Microscopy, L.R. WADLEIGH, D.R. LUHMAN, P.G. BUMCROT, Carleton College — We are interested in using rough CaF₂ films to study the superfluid transition in two-dimensional helium systems. These experiments require quantitative information regarding the topography of the CaF₂ surfaces. The surface roughness of CaF₂ films is known to increase with film thickness as has been shown with previous atomic force microscopy (AFM) measurements [1]. We have fabricated a series of CaF₂ samples of different film thicknesses and thus different surface roughnesses. These surfaces were studied using AFM and adsorption-desorption isotherm measurements with liquid nitrogen at T=77 K. The isotherm measurements allow us to determine the pore size distribution of each CaF₂ film thickness. We find the emergence of hysteretic capillary condensation due to deep pores in the CaF₂ as the film thickness increases. The development of these deep pores is also seen in our AFM measurements. Our combined results provide a detailed description of CaF₂ surface roughness which can be utilized in the planned superfluid experiment. [1] D.R. Luhman and R.B. Hallock, Phys. Rev. E **70**, 051606 (2004).

10:24AM A37.00013 Surface plasmon microscopy with low-cost metallic nanostructures for biosensing I, NATHAN LINDQUIST, Bethel University, SANG-HYUN OH, University of Minnesota, LAUREN OTTO, Bethel University — The field of plasmonics aims to manipulate light over dimensions smaller than the optical wavelength by exploiting surface plasmon resonances in metallic films. Typically, surface plasmons are excited by illuminating metallic nanostructures. For meaningful research in this exciting area, the fabrication of high-quality nanostructures is critical, and in an undergraduate setting, low-cost methods are desirable. Careful optical characterization of the metallic nanostructures is also required. Here, we present the use of novel, inexpensive nanofabrication techniques and the development of a customized surface plasmon microscopy setup for interdisciplinary undergraduate experiments in biosensing, surface-enhanced Raman spectroscopy, and surface plasmon imaging. A Bethel undergraduate student performs the nanofabrication in collaboration with the University of Minnesota. The rewards of mentoring undergraduate students in cooperation with a large research university are numerous, exposing them to a wide variety of opportunities. This research also interacts with upper-level, open-ended laboratory projects, summer research, a semester-long senior research experience, and will enable a large range of experiments into the future.

10:36AM A37.00014 Surface plasmon microscopy with low-cost metallic nanostructures for biosensing II, LAUREN OTTO, Bethel University, SANG-HYUN OH, University of Minnesota, NATHAN LINDQUIST, Bethel University — Due to diffraction, traditional far-field optical microscopy cannot achieve the resolution necessary for applications in nano-scale imaging, sensing, and spectroscopy. However, the manipulation of surface plasmon waves in metallic nanostructures offers a solution. Surface plasmons are evanescent electromagnetic waves sustained by the oscillations of free electrons at the surface of a metal film. As plasmons propagate on the surface, they will probe the surface with high sensitivity and large field intensities. Furthermore, since plasmons are sensitive to within only 10-100 nm from the metallic surface and exhibit large electric field intensities, they have been explored for applications in biosensing and surface-enhanced Raman spectroscopy. We present the development of a microscopy setup for surface plasmon biosensing and the use of reliable, repeatable, low-cost nanofabrication techniques based on template stripping. High-quality nano-patterns are fabricated and used for proof-of-concept biosensing and surface-enhanced Raman spectroscopy experiments. In our customized microscopy setup, holographic illumination with arbitrary laser patterns is made possible by a spatial light modulator. This aids in the careful optical characterization of our nanofabricated samples.

Monday, February 27, 2012 8:00AM - 11:00AM —
Session A39 DCOMP: Electronic Structure: Theory and Numerical Methods 109B

8:00AM A39.00001 Ab initio calculation of atomic level stress in intermetallic compounds and glasses¹, MADHUSUDAN OJHA, University of Tennessee, DON M. NICHOLSON, Oak Ridge National Lab, TAKESHI EGAMI, University of Tennessee — The atomic level stress is largely unexplored as a characterization tool that is sensitive to the local atomic environment. Local quantities, such as magnetic moment and volume, are directly related to the local pressure. For example the local Voronoi volume and pressure have the expected inverse relationship and magnetic moments are reduced due to reduced volume associated with pressure. For a simple system with one atom per unit cell at equilibrium the local stresses are zero. An atom in a multicomponent system can find itself under pressure that results from its cage of surrounding atoms. The atomic level stress is calculated with the Locally Self-consistent Multiple scattering (LSMS) method for Al-Au and Cu-Zr compounds and glasses, and trends are compared to the results for simple B2 compounds with atoms of different sizes.

¹The work at the University of Tennessee and Oak Ridge National Laboratory was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Materials Science and Engineering Division.

8:12AM A39.00002 Towards ab initio simulation of solid state materials at 10 nm scale¹, YANG WANG, Pittsburgh Supercomputing Center, Carnegie Mellon University, G. MALCOLM STOCKS, DON M. NICHOLSON, ODBADRAKH KHORGOLKHUU, AURELIAN RUSANU, Oak Ridge National Laboratory — For the simulation of nanostructured materials and materials with structural defects, it is necessary to consider large size unit cells consisting of thousands or more atoms. It is especially true for our investigation of radiation damage effects on the structural materials. We found that for a reasonably high energy radiation, large unit cell samples at least at 10 nm scale are needed in order for allowing the thermal energy introduced into the sample by the radiation to have sufficient space to dissipate. In this presentation, we point out that, for ab initio electronic structure calculation of a system with a unit cell at such a large scale, it is essential to pay careful attention to numerical stability. We show some numerical pitfalls that will arise as a result of large number of atoms getting involved. The round-off errors accumulated in the calculation of long-range Coulomb interactions, in particular, can lead to divergence of self-consistent iterations. We discuss our approach for circumventing these numerical difficulties.

¹This research is based upon work supported as part of the Center for Defect Physics in Structural Materials (CDP), an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences.

8:24AM A39.00003 Distributed Network-Based Verification and Validation of Electronic Structure Computations using ETEST¹, GARY YUAN, Graduate Group in Applied Science, University of California Davis, Davis CA 95616, FRANCOIS GYGI, Department of Computer Science, University of California Davis, Davis CA 95616 — ETEST is a web-based framework for verification and validation of electronic structure computations [1,2]. It enables automatic comparison and post-processing of simulation data obtained using Abinit, Quantum-Espresso, Siesta, Exciting, Qbox and VASP. We present new features of ETEST that extend its operation to a distributed network of servers. This capability enables sharing, verification, validation, comparison, and post-processing of simulations across a decentralized network of ETEST servers hosted by different institutions. Examples of cross-server operations including multiple servers will be demonstrated.

8:36AM A39.00004 Calculation of quasi particle energies using a spectral decomposition of the static dielectric matrix: application to molecules and nanoparticles¹, T. ANH PHAM, University of California, Davis, HUY-VIET NGUYEN, University of California, Davis and Center for Computational Physics, Institute of Physics, Vietnam, DARIO ROCCA, GIULIA GALLI, University of California, Davis — We present a novel approach to evaluate quasi particle energies within many body perturbation theory, that substantially improves both the computational efficiency and the numerical accuracy of existing techniques.² We use a spectral decomposition of the static dielectric matrix as a basis for the frequency dependent density-density response function, and density functional perturbation theory to avoid the explicit calculation of empty electronic states. A Lanczos-chain algorithm is employed that allows for the evaluation of spectra over a wide frequency range. The numerical accuracy of computed quasi particle energies is controlled by a single parameter. The efficiency and accuracy of our approach are demonstrated by computing vertical ionization potentials and electron affinities of several molecules and diamondoids. Our results are in good agreement with experiment and those reported in the literature using Quantum Monte Carlo calculations.

²Huy-Viet Nguyen, T. Anh Pham, D. Rocca and G. Galli (preprint).

8:48AM A39.00005 First-principles calculations of quasiparticle energies of open-shell condensed matter systems¹, JOHANNES LISCHNER, UC Berkeley and Lab Berkeley National Lab, JACK DESLIPPE, UC Berkeley, MANISH JAIN, STEVEN G. LOUIE, UC Berkeley and Lab Berkeley National Lab — We present a Green's function approach to quasiparticle excitations of open-shell systems within the GW approximation. It is shown that accurate calculations of the characteristic multiplet structure require a precise knowledge of the self energy and, in particular, its poles. We achieve this by constructing the self energy from appropriately chosen mean-field theories on a fine frequency grid. We present results for the nitrogen dioxide molecule and the negatively charged nitrogen-vacancy defect in diamond, which are in good agreement with experiment and other high-level theories.

¹This work was supported by National Science Foundation Grant No. DMR10-1006184, the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by DOE at Lawrence Berkeley National Laboratory's NERSC facility

9:00AM A39.00006 On the accuracy of the G^0W^0 method: From Si to ZnO ¹, PEIHONG ZHANG, ZHIJUN YI, BI-CHING SHIH, Department of Physics, University at Buffalo, State University of New York, Buffalo, New York 14260, JACK DESLIPPE, STEVEN G. LOUIE, Department of Physics, University of California, Berkeley and Materials Science Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720 — The *ab initio* GW method has been recognized as one of the most powerful theories in predicting quasiparticle excitations in solids. Due to computational limitations, earlier GW calculations usually made use of certain generalized plasmon-pole approximations to carry out frequency integration of the electron self-energy. In addition, often the convergence of the calculated results with respect to various cutoff parameters (such as the number of conduction bands and the size of the dielectric matrix) was not investigated in details. With advances in computational methodology and technology, fully converged GW calculations with explicit frequency integration become possible. In this talk, we will discuss fully converged G^0W^0 results for a range of materials, ranging from the most “theory friendly” system Si to the widely discussed and controversial system ZnO . We will compare explicit frequency integration vs various generalized plasmon-pole models. We will also discuss effects of various cutoff parameters used in GW calculations.

9:12AM A39.00007 A Comparison of Different Treatments of Spin-Orbit Coupling within the GW Approach¹, BRAD BARKER, University of California-Berkeley, Lawrence Berkeley National Laboratory, JACK DESLIPPE, Lawrence Berkeley National Laboratory, OLEG V. YAZYEV, Ecole Polytechnique Federale de Lausanne (EPFL), Switzerland, STEVEN G. LOUIE, University of California-Berkeley, Lawrence Berkeley National Laboratory — Spin-orbit coupling is responsible for the unique electronic properties of many fascinating materials such as topological insulators. We have developed and implemented an approach in which the effects of spin-orbit interactions to the quasiparticle band structure are incorporated within the GW approach, employing spinor wavefunctions computed at the DFT level with fully relativistic pseudopotentials. We compare these results to separate calculations where spin-orbit coupling is applied as a perturbation either before or after the GW calculation of the band structure. We apply these methods to the properties of materials with heavy ion cores to determine possible differences from the different schemes.

9:24AM A39.00008 Dielectric screening : Effects of Core Polarization on Phonons and Quasiparticle Bands¹, AMANDEEP KAUR, ERIK YLVISAKER, University of California, Davis, DEYU LU, Brookhaven National Lab, Upton, NY, GIULIA GALLI, WARREN PICKETT, University of California, Davis — We investigate the influence of core polarization on the dielectric screening of atoms, molecules and solids with focus on non metallic systems. We compare results for dielectric band structures and for the eigenvalues of the dielectric matrix obtained by varying the number of valence electrons included in our calculations. We show that (semi)-core electronic states may substantially influence the dielectric screening, even if they lie very deep in energy compared to the outermost valence electrons. We then discuss how the changes in dielectric screening observed when including (semi)-core electrons affect computed quasi particle energies at the GW level, and phonon frequencies, e.g. the LO-TO splitting. We focus on closed shell atoms, including Be, Mg, Ca, Ar, Zn, simple diatomic molecules and simple ionic solids, e.g. LiH and NaH.

9:36AM A39.00009 Novel approach to electron partitioning and definitive oxidation state assignment in solids, LAI JIANG, SERGEY LEVCHENKO¹, ANDREW RAPPE, University of Pennsylvania — Oxidation state of an atom is usually defined by partitioning electrons to the nucleus based on charge density distribution, which inherits uncertainty from the probabilistic nature of wavefunctions. Here we propose a first principle approach to electron partitioning in insulating solids based on wavefunction topology. By calculating polarization change upon shifting an atomic sublattice to its periodic image, the charge transferred during nuclei displacement can be derived. To rationalize, in Wannier representation the Berry’s phase polarization is directly related to the position of Wannier Center (WC) of each band, therefore a quantized charge flow is determined by the number of WCs that move together with (*i. e.* belong to) the nucleus. We provide both rigorous mathematical definition of oxidation states in this scheme and results from calculations of various sample systems that corroborate with oxidation states assigned by conventional chemical insight.

9:48AM A39.00010 On the Formation of XLi_3N_2 Compounds ($X = Sc-Zn$), JAN HERBST, LOUIS HECTOR, JR., GM R&D Center — Ternary lithium nitrides XLi_3N_2 are known to form for the 3d transition elements $X = Sc, Fe$. We explore the formation of such compounds for other 3d elements by means of density functional theory using the crystal structures of $ScLi_3N_2$ and $FeLi_3N_2$ as templates. Enthalpies of formation including electronic and phonon contributions are calculated for the most stable structures. Thermodynamic stability with respect to known binary and ternary compounds is investigated in order to assess prospects for phase formation. In the case of $FeLi_3N_2$ we find an antiferromagnetic state lower in energy than the ferromagnetic state previously identified.

10:00AM A39.00011 Surface Studies with Combined Free Energy Functionals of Electronic and Liquid Densities¹, KENDRA LETCHWORTH WEAVER, RAVISHANKAR SUNDARARAMAN, TOMÁS ARIAS, Department of Physics, Cornell University — The microscopic structure of both a solid surface and a contacting liquid can be dramatically affected by the interaction between the two systems, particularly at the interface between a polar surface and a polar liquid. We present a study of oxide and metallic surfaces in an aqueous electrolyte environment with Joint Density Functional Theory (JDFT), a computationally efficient alternative to molecular dynamics simulations which replaces thermal sampling with a single variational principle for the free energy of the full system. Within the rigorous framework of JDFT, we introduce classical density-functionals for ionic species and describe how to couple them with existing functionals for liquid water and traditional electronic density-functionals. Calculations employ a liquid water functional, which captures bulk properties and microscopic structure over the entire phase diagram of the liquid, and a density-only coupling functional between the electronic and liquid systems, which can reproduce solvation free energies of small molecules to within chemical accuracy. With this microscopically accurate description of the liquid-solid interface structure, we gain physical insight which could direct future studies of catalysis and electrode stability in electrochemical systems.

10:12AM A39.00012 Origin of magnetic interactions and their influence on the structural properties of Ni₂MnGa and related compounds, BURAK HIMMETOGLU, MATTEO COCCIONI, University of Minnesota — In this work, we perform first principles DFT calculations to investigate the interplay between magnetic and structural properties in Ni₂MnGa. We demonstrate that the relative stability of austenite (cubic) and non-modulated martensite (tetragonal) phases depend critically on magnetic interactions between Mn atoms. While standard approximate DFT functionals stabilize the latter phase, a more accurate treatment of electronic localization and magnetism obtained with DFT+U suppresses the non-modulated tetragonal structure for the stoichiometric compound, in better agreement with the experiments. This observation can be explained using the Anderson impurity model, where Mn atoms are treated as periodic magnetic impurities embedded in Ga *p* and Ni *d* conduction electrons that mediate RKKY type magnetic interactions between Mn *d* electrons. Using this picture we show that the structural properties of the material are determined by the competition between super-exchange interactions mediated through Ni *d* and Ga *p* states. Finally, we show that off-stoichiometric compositions with excess Mn promote transition to a non-modulated tetragonal structure, in agreement with experiments.

10:24AM A39.00013 Redshift of excitons in carbon nanotubes caused by the environment polarizability: A BSE study, MICHAEL ROHLFING, University of Osnabrueck, Germany — Optical excitations of molecular systems can be modified by their physical environment. We analyze the underlying mechanisms within many-body perturbation theory (GW approximation and Bethe-Salpeter equation, BSE), which is particularly suited to study non-local polarizability effects on the electronic structure. Here we focus on the example of a semiconducting carbon nanotube, which observes redshifts of its excitons when the tube is touched by another nanotube or other physisorbates. We show that the redshifts mostly result from the polarizability of the attached ad-system. Electronic coupling may enhance the redshifts, but depends very sensitively on the structural details of the contact.

10:36AM A39.00014 Vibrational properties of correlated systems from ab-initio calculations, MATTEO COCCIONI, BURAK HIMMETOGLU, Department of Chemical Engineering and Materials Science, University of Minnesota, ANDREA FLORIS, Department of Physics, King's College London — In this talk I will present a recent extension of Density Functional Perturbation Theory to the DFT+U energy functional that allows to compute the vibrational properties of materials from their correlated ground state. The new computational tool, named DFPT+U, is used to investigate the phonon spectrum of MnO and NiO. The more accurate account of electronic correlation through the Hubbard-corrected functional results in a significant improvement in the agreement between the computed phonon frequencies and available experiments. In particular, we obtain a significant reduction in the splitting between the center-zone optical modes (due to the antiferromagnetic order) that confirms the importance of electronic localization in the description of magnetic couplings between metal ions. The order of the split optical modes is also shown to correlate with the occupation of the *d* states of the transition metal atoms opening for the possibility to use measurements of the vibrational frequencies to investigate certain aspects of the electronic structure of these compounds. In the last part of the talk I will also present the application of DFPT+U to Cu compounds and will discuss the possibility to use it to compute the electron-phonon coupling of high *T_c* superconductors.

10:48AM A39.00015 Effect of strong correlations on the electronic and transport properties of porphyrin wires¹, VICTOR MANUEL GARCIA SUAREZ, Departamento de Fisica, Universidad de Oviedo AND CINN (CSIC) AND Physics Department, Lancaster University, RUBEN FERRADAS, Departamento de Fisica, Universidad de Oviedo AND CINN (CSIC), JAIME FERRER, Departamento de Fisica, Universidad de Oviedo AND CINN (CSIC) AND Physics Department, Lancaster University, THEORY GROUP, CONDENSED MATTER TEAM — Recent transport experiments performed on porphyrin molecules show that wires based on these molecules could be used to design future nanoscale elements with low attenuation as a function of distance and able to work at room temperature. Apart from their rather good transport properties, which come from the conjugation of their molecular backbone, porphyrins are also very interesting due to the fact that they have a metallic element in the middle that affects their electronic properties and could also introduce magnetic effects. In this talk I will show first-principles simulations based on density functional on the electronic and transport properties of porphyrin wires between gold leads, paying special attention to the effect of using different metallic elements in the central part of the molecule (Fe, Co, Ni, Zn and Cu). Strong correlations are introduced in the form of LDA+U. The results show that the metallic element plays a crucial role in the electronic structure of the molecule around the HOMO and LUMO orbitals and introduces magnetic effects that affect the transport properties.

Session A40 DBIO DPOLY: Focus Session: Protein Association I: Phase Separation, Crystallization, Self-Assembly 156A

8:00AM A40.00001 TBD, ROBERT HAYRE, UC-Davis — No abstract available.

8:36AM A40.00002 Phase Separation in Solutions of Monoclonal Antibodies¹, GEORGE BENEDEK², YING WANG, ALEKSEY LOMAKIN, Massachusetts Institute of Technology, RAMIL LATYPOV, Amgen, Inc — We report the observation of liquid-liquid phase separation (LLPS) in a solution of humanized monoclonal antibodies, IgG2, and the effects of human serum albumin, a major blood protein, on this phase separation. We find a significant reduction of phase separation temperature in the presence of albumin, and a preferential partitioning of the albumin into the antibody-rich phase. We provide a general thermodynamic analysis of the antibody-albumin mixture phase diagram and relate its features to the magnitude of the effective inter-protein interactions. Our analysis suggests that additives (HSA in this report), which have moderate attraction with antibody molecules, may be used to forestall undesirable protein condensation in antibody solutions. Our findings are relevant to understanding the stability of pharmaceutical solutions of antibodies and the mechanisms of cryoglobulinemia.

8:48AM A40.00003 Concentrated dispersions of equilibrium protein nanoclusters that reversibly dissociate into active monomers¹ , THOMAS M. TRUSKETT, KEITH JOHNSTON, JENNIFER MAYNARD, AMEYA BORWANKAR, MARIA MILLER, BRIAN WILSON, AILEEN DININ, TARIK KHAN, KEVIN KACZOROWSKI, The University of Texas at Austin — Stabilizing concentrated protein solutions is of wide interest in drug delivery. However, a major challenge is how to reliably formulate concentrated, low viscosity (i.e., syringeable) solutions of biologically active proteins. Unfortunately, proteins typically undergo irreversible aggregation at intermediate concentrations of 100-200 mg/ml. In this talk, I describe how they can effectively avoid these intermediate concentrations by reversibly assembling into nanoclusters. Nanocluster assembly is achieved by balancing short-ranged, cosolute-induced attractions with weak, longer-ranger electrostatic repulsions near the isoelectric point. Theory predicts that native proteins are stabilized by a self-crowding mechanism within the concentrated environment of the nanoclusters, while weak cluster-cluster interactions can result in colloidal-stable dispersions with moderate viscosities. I present experimental results where this strategy is used to create concentrated antibody dispersions (up to 260 mg/ml) comprising nanoclusters of proteins [monoclonal antibody 1B7, polyclonal sheep Immunoglobulin G and bovine serum albumin], which upon dilution in vitro or administration in vivo, are conformationally stable and retain activity.

9:00AM A40.00004 Aggregation behavior of bovine and porcine insulin in presence of inhibitors , KIERSTEN BATZLI, BRIAN LOVE, University of Michigan — Insulin aggregation can be problematic when the insulin is in pharmaceutical solution, as well as when aggregates form in insulin pumps or subcutaneously at port sites. Pharmaceutical insulins often include an added stabilizer, such as metacresol, but even with this added compound the protein may degrade, aggregate and become less effective. With greater understanding of the kinetics of aggregation associated with insulin aggregation, a more effective stabilizer may be identified to inhibit aggregation. Bovine and porcine insulin in pharmaceutically relevant concentrations of 5 mg/ml were induced to denature and aggregate at elevated temperature and low pH and the aggregation behavior was characterized as a function of time and temperature by rheology and small angle x-ray scattering (SAXS). Aggregation behavior was probed in both neat solution and with the addition of known inhibiting compounds. The efficacy of the inhibiting compounds at retarding the protein aggregation was found to be related to the hydrophobicity of the compounds and potential inhibitors of interest were identified.

9:12AM A40.00005 Design rules for the self-assembly of a protein crystal , THOMAS HAXTON, STEPHEN WHITELAM, Lawrence Berkeley National Laboratory — The need to crystallize proteins for X-ray studies has motivated theories of protein crystallization. These theories, based largely on the behavior of isotropic spheres that form close-packed crystals, predict that assembly is enhanced near the metastable critical point associated with phase separating into a vapor of proteins (protein-poor solution) and a liquid of proteins (protein-rich solution). However, most protein crystals are open structures stabilized by anisotropic interactions, and many assemble best above the critical point. Using theory and simulation, we show that optimal assembly of one such crystal, a model surface-layer protein crystal, is not predicted by the critical point but can be predicted by a combination of two design rules: the thermodynamic driving force must be on the order of the thermal energy, and interactions must be made as nonspecific as possible without promoting liquid-vapor phase separation. In experimental terms, our results suggest adjusting solution conditions in order to impose a defined supersaturation at the liquid-vapor critical point. Our findings suggest that self-assembly of open crystals is more akin to viral capsid self-assembly than to the crystallization of spherical colloids.

9:24AM A40.00006 Protein Crystal Nucleation and Growth , SATHISH AKELLA, SETH FRADEN, Brandeis University, BRANDEIS UNIVERSITY TEAM — We have developed a microfluidic emulsion based technique to determine the homogeneous and heterogeneous nucleation rates of protein crystallization under conditions of high supersaturation. We utilize the fact that the nucleation rate is constant if no crystal nucleus is formed and count the number of protein droplets with no crystals with time, which decays exponentially with decay constant inversely proportional to nucleation rate and drop volume. We report results of experiments on nucleation and growth rates of lysozyme crystallization. The emulsions are placed on a temperature gradient stage allowing simultaneous measurement of rates as a function of temperature. We routinely scan 30,000 drops in each experiment.

9:36AM A40.00007 ABSTRACT WITHDRAWN —

9:48AM A40.00008 Water dynamics during the association of hiv capsid proteins studied by all-atom simulations¹ , NAIYIN YU, MICHAEL HAGAN, Brandeis University — The C-terminal domain of the HIV-1 capsid protein (CA-C) plays an important role in the assembly of the mature capsid. We have used molecular dynamics simulations combined with enhanced sampling methods to study the association of two CA-C proteins in atomistic detail. In this talk we will discuss the dynamics of water during the association process. In particular, we will show that that water in the interfacial region does not undergo a liquid-vapor transition (de-wetting) during association of wild type CA-C. However, mutation of some hydrophilic residues does lead to a dewetting transition. We discuss the relationship between the arrangement of hydrophilic and hydrophobic residues and dewetting during protein association. For the HIV capsid protein, the arrangement of hydrophilic residues contributes to maintaining weak interactions, which are crucial for successful assembly.

10:00AM A40.00009 Interfacial Microrheology of Lysozyme Layers During Formation at the Air-Water Interface , DANIEL ALLAN, DANIEL REICH, ROBERT LEHENY, Johns Hopkins University — Proteins can adsorb to the air-water interface to form viscoelastic layers. Characterizing the rheology of such layers is challenging, due to the confined geometry, the fragility of the layers, and the possibility of mesoscale spatial heterogeneity. Passive microrheology — using the thermal motion of colloidal probes to interrogate the mechanical response of the surrounding medium — is a suitable technique for addressing these difficulties. In particular, this approach sheds light on the properties of incipient protein layers that are characterized by modest interfacial viscosities. We describe microrheology studies of lysozyme layers at the air-water interface, in which we determine the evolving interfacial shear response through the viscoelastic transition that signifies layer formation. Spatial heterogeneity in the interfacial rheology is identified and discussed within the framework of layer formation as a gel transition. Layers formed by adsorption of protein from the aqueous subphase and by spreading protein directly onto the interface are compared and studied across a range of concentrations, demonstrating the sensitivity of layer properties to the rate and manner of protein accretion.

10:12AM A40.00010 Measurements of Diffusion within Concentrated Bovine α -Crystallin Suspensions¹, NUWAN KARUNARATNE, JUSTIN BERRY², LARENCE LURIO, Northern Illinois University, GEORGE THURSTON, Rochester Institute of Technology, JANAE DEBARTOLO, SURESH NARAYANAN, ALEC SANDY, JOHN WEIZEORICK, Advanced Photon Source, Argonne National Laboratory — α -Crystallin is a major protein component of the vertebrate eye lens. The chaperone-like behavior of these water soluble proteins play a key role in maintaining lens transparency by preventing condensation of other lens proteins. We report photon correlation spectroscopy measurements, both X-ray Photon Correlation Spectroscopy (XPCS) and Dynamic Light Scattering (DLS), indicating protein diffusion within suspensions of α -Crystallin. Measurements were carried out at 2°C, 10°C and 35°C, over a wide range of concentrations from the diluted limit to the regime close to the physiological lens concentration. In the diluted regime, DLS measurements can be modeled by a single exponential fit indicating a single relaxation mode and at higher concentrations two relaxation modes can be identified by fitting the data to a double exponential decay function, a clear indication of the polydispersed nature of the concentrated samples. XPCS measurements show dynamics at the highest concentration but cannot resolve the faster dynamics (below 20ms) at lower concentration. We also provide estimates for the viscosity of α -Crystallin suspensions as a function of temperature and protein volume fraction using the falling ball method.

10:24AM A40.00011 Master Equation Approach to Protein Assembly – Degradation of Protein Aggregates, GEORG MEISL, University of Cambridge — Protein aggregation is dependent on several microscopic processes such as nucleation, elongation and fragmentation of aggregates. Applying simple chemical kinetics to these processes allows one to derive master equations describing the entire system. In almost all cases they take the form of highly non-linear coupled differential equations for which no exact analytical solutions can be derived. Nonetheless an analytical description of the problem is absolutely essential to determine the relative importance of different microscopic processes and develop a rational approach to finding cures. Using a self consistent approach, my group has recently made headway in finding approximate analytical solutions for several systems and successfully applied them to explain a wide range of experimental observations (Knowles et al., Science 326, 1533 (2009)). I have generalised this description to include degradation of aggregates by various cellular processes. These degradation processes are thought to play an important role in vivo in determining when aggregation speed becomes critical and leads to disease.

10:36AM A40.00012 Intermediate-range order in protein suspensions, YUN LIU, University of Delaware/NIST, LIONEL PORCAR, PETER FALUS, Institut Laue-Langevin, WEI-REN CHEN, Oak Ridge National Laboratory, EMILIANO FRATINI, University of Florence, KUNLUN HONG, Oak Ridge National Laboratory, PIERO BAGLIONI, University of Florence — Intermediate-range order (IRO) has been widely observed in vitreous silica, water ice, metallic glass, and even in ionic liquids. Our recent work demonstrates that there is IRO present in a colloidal suspension, such as protein solution, when both a short-range attraction and long-range repulsion are present. We have verified this experimentally using lysozyme solutions, where a peak (IRO peak) seen in small angle neutron scattering (SANS) has been mistakenly called a cluster peak as it has once been considered an indication of a cluster rich phase in solution. By combining both SANS and neutron spin echo (NSE) techniques, we clearly show that there is no direct relation between cluster formation and the presence of an IRO peak. By investigating the short time dynamics using NSE, we show that the formation of clusters is still indeed possible at high concentrations.

10:48AM A40.00013 An energy landscape approach to protein aggregation, ALEXANDER BUELL, TUOMAS KNOWLES, University of Cambridge, Department of Chemistry — Protein aggregation into ordered fibrillar structures is the hallmark of a class of diseases, the most prominent examples of which are Alzheimer's and Parkinson's disease. Recent results (e.g. Baldwin et al. J. Am. Chem. Soc. 2011) suggest that the aggregated state of a protein is in many cases thermodynamically more stable than the soluble state. Therefore the solubility of proteins in a cellular context appears to be to a large extent under kinetic control. Here, we first present a conceptual framework for the description of protein aggregation (see AK Buell et al., Phys. Rev. Lett. 2010) that is an extension to the generally accepted energy landscape model for protein folding. Then we apply this model to analyse and interpret a large set of experimental data on the kinetics of protein aggregation, acquired mainly with a novel biosensing approach (see TPJK Knowles et al, Proc. Nat. Acad. Sc. 2007). We show how for example the effect of sequence modifications on the kinetics and thermodynamics of human lysozyme aggregation can be understood and quantified (see AK Buell et al., J. Am. Chem. Soc. 2011). These results have important implications for therapeutic strategies against protein aggregation disorders, in this case lysozyme systemic amyloidosis.

Monday, February 27, 2012 8:00AM - 11:00AM –
Session A41 DBIO DPOLY DMP: Focus Session: Structure and Dynamics of Membranes 156B

8:00AM A41.00001 A Neutron View of Proteins in Lipid Bilayers¹, STEPHEN WHITE, University of California at Irvine, Dept. of Physiology and Biophysics — Despite the growing number of atomic-resolution membrane protein structures, direct structural information about proteins in their native membrane environment is scarce. This problem is particularly relevant in the case of the highly-charged S1-S4 voltage-sensing domains responsible for nerve impulses, where interactions with the lipid bilayer are critical for the function of voltage-activated potassium channels. We have used neutron diffraction, solid-state nuclear magnetic resonance spectroscopy, and molecular dynamics simulations to investigate the structure and hydration of bilayer membranes containing S1-S4 voltage-sensing domains. Our results show that voltage sensors adopt transmembrane orientations, cause a modest reshaping of the surrounding lipid bilayer, and that water molecules intimately interact with the protein within the membrane. These structural findings reveal that voltage sensors have evolved to interact with the lipid membrane while keeping the energetic and structural perturbations to a minimum, and that water penetrates into the membrane to hydrate charged residues and shape the transmembrane electric field.

8:36AM A41.00002 Curvature Forces in Membrane Lipid-Protein Interactions¹, MICHAEL F. BROWN, Departments of Chemistry and Biochemistry and Physics, University of Arizona, Tucson AZ 85721 — Membrane protein conformational changes, folding, and stability may all involve elastic deformation of the bilayer. Non-specific properties of the bilayer play a significant role in modulating protein conformational energetics. A flexible-surface model (FSM) describes the balance of curvature and hydrophobic forces in lipid-protein interactions. The FSM describes elastic coupling of membrane lipids to integral membrane proteins. Curvature and hydrophobic matching to the lipid bilayer entails a stress field that explains membrane protein stability. Rhodopsin provides an important example, where solid-state NMR and FTIR spectroscopy characterize the energy landscape of the dynamically activated receptor. Time-resolved UV-visible and FTIR spectroscopic studies show how membrane lipids affect the metarhodopsin equilibrium due to non-specific material properties. Influences of bilayer thickness, nonlamellar-forming lipids, detergents, and osmotic stress on rhodopsin function are all explained by the new biomembrane model. By contrast, the older fluid-mosaic model fails to account for such effects on membrane protein activity. According to the FSM proteins are regulated by membrane lipids whose spontaneous curvature most closely matches the activated state within the lipid membrane.

¹Work supported by NIH Grants EY012049 and EY018891.

8:48AM A41.00003 Thickness fluctuations in pure lipid bilayers, MICHIOHRO NAGAO, NIST and Indiana University, ANDREA WOODKA, PAUL BUTLER, NIST, LIONEL PORCAR, BELA FARAGO, ILL — Recently neutron spin echo (NSE) revealed dynamical processes in a surfactant membrane system around the length scale of the membrane thickness where the classical Helfrich treatment breaks down. This excess dynamics (on top of the bending fluctuations) observed in a nonionic surfactant, water and oil system, was attributed to thickness fluctuations of the membrane. In the case of bilayers formed with the nonionic surfactant in water the thickness fluctuation amplitude was estimated to be a few angstroms. In the study presented here, we apply the technique to explore thickness fluctuations in lipid bilayers. The result shows clear evidence of thickness fluctuations above T_m , where the lipid tails display liquid ordering, while none are discernable below T_m . The estimated amplitude of the observed membrane thickness fluctuations is approximately 4 Å. These results are consistent with theoretical expectation and recent molecular dynamics simulations. Varying the lipid tail length from 14 carbons to 18 carbons per tail does not appear to affect to the dynamics very much.

9:00AM A41.00004 A Simple Analysis of Small-Angle Neutron Scattering Data to Estimate Thickness Fluctuations of the Membrane, TAKUMI HAWA, VICTOR LEE, School of Aerospace and Mechanical Engineering, The University of Oklahoma — Small-angle neutron scattering (SANS) and neutron spin echo (NSE) experiments are one of the most important laboratory techniques to investigate structure and dynamic properties of biological and nanotechnology-related membrane systems. Due to the sensitivity of about 1 100 nm length scales, these experimental techniques provide extensive information over a wide variety of technological and scientific applications. Recently, the author and his colleagues studied swollen lamellar structure systems consisting of nonionic surfactant, water, and oil using SANS/NSE and molecular dynamics (MD) simulation. They proposed a new experimental technique to measure the thickness fluctuations of surfactant layers and verified their approach using MD simulations. In this talk a possible simpler approach to estimate the membrane thicknesses and fluctuations directly from the isotropic scattering intensities in the two-dimensional SANS profile will be proposed. Generally, this characteristic feature is reproduced using various scattering theories to estimate the membrane thickness; however, the thickness fluctuation amplitude has never been estimated from the SANS profile. The results obtained from the approach will be compared with the experimental results obtained by Nagao and co-workers.

9:12AM A41.00005 High-resolution Structures of Protein-Membrane Complexes by Neutron Reflection and MD Simulation: Membrane Association of the PTEN Tumor Suppressor, MATHIAS LOESCHE, Carnegie Mellon University — The lipid matrix of biomembranes is an in-plane fluid, thermally and compositionally disordered leaflet of 5 nm thickness and notoriously difficult to characterize in structural terms. Yet, biomembranes are ubiquitous in the cell, and membrane-bound proteins are implicated in a variety of signaling pathways and intra-cellular transport. We developed methodology to study proteins associated with model membranes using neutron reflection measurements and showed recently that this approach can resolve the penetration depth and orientation of membrane proteins with Ångström resolution if their crystal or NMR structure is known. Here we apply this technology to determine the membrane binding and unravel functional details of the PTEN phosphatase, a key player in the PI3K apoptosis pathway. PTEN is an important regulatory protein and tumor suppressor that performs its phosphatase activity as an interfacial enzyme at the plasma membrane-cytoplasm boundary. Acting as an antagonist to phosphoinositide-3-kinase (PI3K) in cell signaling, it is deleted in many human cancers. Despite its importance in regulating the levels of the phosphoinositoltriphosphate $PI(3,4,5)P_3$, there is little understanding of how PTEN binds to membranes, is activated and then acts as a phosphatase. We investigated the structure and function of PTEN by studying its membrane affinity and localization on in-plane fluid, thermally disordered synthetic membrane models. The membrane association of the protein depends strongly on membrane composition, where phosphatidylserine (PS) and phosphatidylinositol diphosphate ($PI(4,5)P_2$) act synergetically in attracting the enzyme to the membrane surface. Membrane affinities depend strongly on membrane fluidity, which suggests multiple binding sites on the protein for $PI(4,5)P_2$. Neutron reflection measurements show that the PTEN phosphatase “scoots” along the membrane surface (penetration < 5 Å) but binds the membrane tightly with its two major domains, the C2 and phosphatase domains. In the bound state, PTEN's regulatory C-terminal tail is displaced from the membrane and organized on the far side of the protein, ~ 60 Å away from the bilayer surface, in a rather compact structure. The combination of binding studies and neutron reflection allows us to distinguish between PTEN mutant proteins and ultimately may identify the structural features required for membrane binding and activation of PTEN. Molecular dynamics simulations, currently in progress, refine this structural picture further.

9:48AM A41.00006 Application of Small-Angle Neutron and X-ray Scattering in Determining Lipid Bilayer Structure¹, JIANJUN PAN, FREDERICK A. HEBERLE, Neutron Scattering Science Division, Oak Ridge National Laboratory, NORBERT KUCERKA, Canadian Neutron Beam Centre, National Research Council, Chalk River, Ontario, Canada, STEPHANIE TRISTRAM-NAGLE, Department of Physics, Carnegie Mellon University, MICHELLE SZYMANSKI, MARY KOEPFINGER, Douglass Residential College, Rutgers University, JOHN KATSARAS, Neutron Scattering Science Division, Oak Ridge National Laboratory — Accurately determining lipid structure in biologically relevant fluid bilayers is not straightforward. We have recently developed a hybrid experimental/computational technique (i.e., the scattering density profile, or SDP model), which exploits the fact that neutron and X-ray scattering are sensitive to different bilayer thicknesses - the large difference in neutron scattering length density (SLD) between prolated lipid and deuterated water defines the overall bilayer thickness, while X-ray scattering resolves the headgroup-headgroup distance due to the large scattering contrast between the electron-rich phosphate groups and the hydrocarbon/aqueous medium. A key step in the SDP analysis is the use of MD simulations to parse the lipid molecule into fragments whose volume probability distributions follow simple analytical functional forms. Given the appropriate atomic scattering lengths, these volume probabilities can simultaneously predict both the neutron and X-ray SLD profiles, and hence the scattering form factors. Structural results for commonly used phosphatidylcholine and phosphatidylglycerol lipids will be given.

¹This work acknowledges the support of ORNL, NIST, and Cornell High Energy Synchrotron Source.

10:00AM A41.00007 Growth Mechanism of Lipid-Based Nanodiscs – a Model Membrane for Studying Kinetics of Particle Coalescence¹, ANDREW HU, University of Connecticut, Mechanical Engineering, MU-PING NIEH, University of Connecticut, Institute of Materials Science, Chemical Materials & Biomolecular Engineering, ANTHONY DIZON, University of Connecticut, Chemical Materials & Biomolecular Engineering, MING LI, University of Connecticut, Institute of Materials Science, TAI-HSI FAN, University of Connecticut, Mechanical Engineering — Lipid-based nanodiscs composed of long- and short- chain lipids [namely, dimyristoyl phosphatidylcholine (DMPC), dimyristoyl phosphatidylglycerol (DMPG) and dihexanoyl phosphatidylcholine (DHPC)] constantly form at high lipid concentrations and at low temperatures (i.e., below the melting transition temperature of DMPC, T_m). The initial size of these nanodiscs (at high total lipid concentration, $C_L > 20$ wt.%) is relatively uniform and of similar dimension (according to dynamic light scattering and small angle neutron scattering experiments), seemingly independent of thermal history. Upon dilution, the nanodiscs slowly coalesce and grow in size with time irreversibly. Our preliminary result shows that the growth rate strongly depends on several parameters such as charge density, C_L and temperature. We have also found that the nanodisc coalescence is a reaction limit instead of diffusion limit process through a time-resolved study.

¹Funding supported by NSF CMMI - 1131587.

10:12AM A41.00008 Swellable Model POPC/POPG/DHPC Membrane with a Lamellar Long-Range Order¹, MING LI, MU-PING NIEH, Department of Chemical, Materials & Biomolecular Engineering, Institute of Materials Science, University of Connecticut, Storrs, CT 06269, USA — A physiological relevant biomimetic model membrane is of great necessity for the structural characterization of membrane protein. This presentation will report a small-angle neutron scattering (SANS) result on two lipid bicellar series composed of 1-palmitoyl-2-oleoyl-*sn*-glycero-3-phosphocholine (POPC)/1,2-dihexanoyl-*sn*-glycero-3-phosphocholine (DHPC) and POPC/DHPC/1-palmitoyl-2-oleoyl-*sn*-glycero-3-phospho-(1'-*rac*-glycerol) (POPG). Instead of the multi-lamellae vesicle (MLV) structure observed in zwitterionic POPC/DHPC mixture, the perforated lamellae (PL) structure is found in POPC/POPG/DHPC upon addition of small amount of charged lipid, POPG $\{R=[\text{POPG}]/([\text{POPC}]+[\text{POPG}])=0.01\}$. The PL phase exists from 10 to 60 degree C and the interlamellar spacing (d-spacing) varies from 12.9 to 49.0 nm as the lipid concentration changes from 25 to 7.5% wt where the lamellae still indicate long-range order. The effect of temperature and charge density (R) on structural variation will be discussed in this presentation.

¹We gratefully acknowledge the support from National Science Foundation (NSF-CMMI1131589).

10:24AM A41.00009 Mobility of water and selected atoms in bilayer DMPC membranes¹, F.Y. HANSEN, Technical University of Denmark, H. TAUB, M. BAI, A. MISKOWIEC, University of Missouri-Columbia — Molecular dynamics simulations have been used to determine the mobility of water molecules as a function of their positions in a fully hydrated free standing DMPC membrane at 303 K. In a 10 Å thick water layer with bulk density just outside the membrane, the mobility of the water molecules is reduced by about a factor of two relative to bulk. For water molecules penetrating deeper into the membrane there is an increasing reduction in the mobility with up to two orders of magnitude for those deepest into the membrane. A comparison with the mobility of selected atoms in the lipid molecules shows that about 5 water molecules/lipid molecule move on the same time scale as the lipid molecules and may therefore be considered to be so tightly bound to them that they essentially follow their motion. The simulation results are quantitatively compared with quasielastic neutron scattering results on single-supported bilayer DMPC membranes.

¹Supported by NSF Grant Nos. DMR-0705974 and DGE-1069091

10:36AM A41.00010 Structure of single-supported DMPC lipid bilayer membranes as a function of hydration level studied by neutron reflectivity and Atomic Force Microscopy¹, A. MISKOWIEC, P. SCHNASE, M. BAI, H. TAUB, U. Mo., F.Y. HANSEN, Tech. U. of Denmark, M. DUBEY, S. SINGH, J. MAJEWSKI, LANSCE — We have recently been investigating the diffusion of water on single-supported DMPC lipid bilayer membranes at different levels of hydration, using high-resolution quasielastic neutron scattering (QNS). To aid in the interpretation of these QNS studies, we have conducted neutron reflectivity (NR) measurements on SPEAR at LANSCE to characterize the structure of similarly prepared samples. Protonated DMPC membranes were deposited onto SiO₂-coated Si(100) substrates and characterized by Atomic Force Microscopy (AFM) at different levels of hydration. We find reasonable agreement between the membrane thickness determined by NR and AFM at room temperature. We also find consistency between the scattering length density (SLD) profile in the vicinity of the upper leaflet of the supported DMPC membrane and that found in a molecular dynamics simulation of a freestanding membrane at 303 K. However, the fit to the reflectivity curve can be improved by modifying the SLD profile near the leaflet closest to the SiO₂ surface.

¹Supported by NSF Grant Nos. DMR-0705974 and DGE-1069091.

10:48AM A41.00011 Cholesterol Flip-Flop Dynamics in a Phospholipid Bilayer: A 10 Microsecond All-Atom Molecular Dynamics Simulation, KEN-ICHI NOMURA, AMIT CHOUBEY, RAJIV KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, Collaboratory for Advanced Computing and Simulations, University of Southern California, Los Angeles, California 90089-0242, USA — Cholesterol (CHOL) molecules play a key role in modulating the rigidity of cell membranes, and controlling intracellular transport and signal transduction. Using all-atom molecular dynamics and the parallel replica approach, we study the effect of CHOL molecules on mechanical stresses across a dipalmitoylphosphatidylcholine (DPPC)-CHOL bilayer, and the mechanism by which CHOL molecules migrate from one bilayer leaflet to the other (flip-flop events). On average, we observe a CHOL flip-flop event in half-a-microsecond. Once a CHOL flip-flop event is triggered, the inter-leaflet migration occurs in about 62 nanoseconds. The energy barrier associated with flip-flop events is found to be 73 kJ/mol. Results for membrane rigidity as a function of CHOL concentration will also be presented.

Monday, February 27, 2012 8:00AM - 10:48AM –
Session A42 DBIO DPOLY: Focus Session: Cytoskeleton and Biomechanics - Biochemical mechanisms 156C

8:00AM A42.00001 Stochastic simulations of the growth dynamics and organization of lamellipodia-like actin networks, LONGHUA HU, GAREGIN PAPOIAN, Department of Chemistry and Biochemistry, University of Maryland — Cell migration is essential to many biological processes such as embryonic development, wound healing and immune response. The crawling movement of cells is a complex process that involves the protrusion of the leading edge of a cell, adhesion to the substrate, generation of the traction force to move cell body and the subsequent release of adhesions. Lamellipodia are flat sheet-like membrane protrusions at the leading edge of the crawling cells. The dynamic remodeling of the dendritically branched actin network in lamellipodia generates force to drive the movement of cells. We have developed a simplified, three-dimensional computational model to study the growth of lamellipodia-like actin networks. Our model integrates the essential biochemical regulation processes as well as the mechanical aspect of actin polymerization, where the interactions between the semi-flexible filaments and the plasma membrane are taken into account. Using stochastic simulations, we study how membrane tension and external resistance on membrane affect the growth dynamics and organization of the actin network.

8:12AM A42.00002 How ion binding affects actin filament stability and flexural rigidity, HYERAN KANG, MICHAEL BRADLEY, BRANNON MCCULLOUGH, Yale University, ANAËLLE PIERRE, ENS de Cachan, France, ELENA GRINTSEVICH, UCLA, ENRIQUE DE LA CRUZ, Yale University — Actin filaments are semi-flexible biopolymers essential for the mechanical support and cell motility. Ions strongly affect actin polymerization and the flexibility of actin filaments; however, the molecular basis for how ions are coupled to the mechanics of actin filaments remains elusive. Here, we demonstrate a linkage between cation binding and both actin filament polymerization and flexural rigidity. Our results show that the thermodynamic stability and flexural rigidity of actin filament increase with cation concentration in a manner that implicates specific cation binding as opposed to general electrostatic screening. Using structural bioinformatics, we identify two distinct cation-binding sites within the F-actin structure that help explain how specific cation binding is linked to actin polymerization and flexural rigidity. Site-specific substitution of a charged amino acid residue at one of the sites modulates the cation concentration-dependence of filament bending stiffness, consistent with a bound cation at this site increasing the flexural rigidity of actin filaments. Mutation of a charged amino acid at the other site causes "polymerization incompetent" G-actin.

8:24AM A42.00003 Mechanotransduction through the plasma membrane & cytoskeleton, KRISTINA HAASE, ANDREW PELLING, University of Ottawa — Mechanical forces initiate immediate and long-term changes in cells; however the exact mechanisms remain unclear, albeit crucial for understanding the pathology of disease. We used combined confocal and atomic force microscopy (AFM) to investigate changes in cell morphology and elasticity in response to a mechanical stimulus. The AFM was used as a nano-indentor to gauge the response of the membrane and cytoskeleton (CSK) of HeLa cells. We observed their viscoelastic nature by probing cells transfected with a green fluorescent protein localized at the plasma membrane. Inhibition of acto-myosin contractility (AMc) resulted in a significant decrease of cellular elasticity, and a corresponding increase in mean deformation. We also investigated the rate at which the membrane and CSK deform and relax in response to a local force. The response to a local perturbation is nearly instantaneous for control cells and shows no statistical difference when compared to cells treated with CSK-inhibiting drugs. Inhibition of AMc affects the rate of recovery, in comparison to control cells which recover quite quickly (30-60s). Overall, we demonstrated short and long-term deformation and subsequent recovery of both the cell membrane and actin network in response to a local force.

8:36AM A42.00004 Leading at the Front: How EB Proteins Regulate Microtubule Dynamics, TAVIARE HAWKINS, University of Massachusetts-Amherst — Microtubules are the most rigid of the cytoskeletal filaments, they provide the cell's scaffolding, form the byways on which motor proteins transport intracellular cargo and reorganize to form the mitotic spindle when the cell needs to divide. These biopolymers are composed of alpha and beta tubulin monomers that create hollow cylindrical nanotubes with an outer diameter of 25 nm and an inner diameter of 17 nm. At steady state concentrations, microtubules undergo a process known as dynamic instability. During dynamic instability the length of individual microtubules is changing as the filament alternates between periods of growth to shrinkage (catastrophe) and shrinkage to growth (rescue). This process can be enhanced or diminished with the addition of microtubule associated proteins (MAPs). MAPs are microtubule binding proteins that stabilize, destabilize, or nucleate microtubules. We will discuss the effects of the stabilizing end-binding proteins (EB1, EB2 and EB3), on microtubule dynamics observed in vitro. The EBs are a unique family of MAPs known to tip track and enhance microtubule growth by stabilizing the ends. This is a different mechanism than those employed by structural MAPs such as tau or MAP4.

9:12AM A42.00005 Redundancy and cooperativity in the mechanics of compositely crosslinked cytoskeletal networks, J.M. SCHWARZ, Physics Department, Syracuse University, D.Q. QUINT, School of Natural Sciences, University of California-Merced, MOUMITA DAS, Physics Department, Syracuse University — The cytoskeleton contains many types of crosslinkers. Some crosslinkers allow free rotations between filaments and others do not. The mechanical interplay between different crosslinkers is an open issue in cytoskeletal mechanics. Therefore, we develop a theoretical framework based on rigidity percolation to study a generic filamentous system containing both stretching and bond-bending forces to address this issue. The framework involves both analytical calculations via effective medium theory and numerical simulations on a percolating triangular lattice with very good agreement between both. We find that the introduction of angle-constraining crosslinkers to a semiflexible filamentous network with freely-rotating crosslinks can cooperatively lower the onset of rigidity to the connectivity percolation threshold—a result speculated for years but never before obtained via effective medium theory. In other words, the system can attain rigidity at the lowest concentration of material possible. We further demonstrate that introducing angle-constraining crosslinks results in mechanical behaviour similar to just freely-rotating crosslinked semiflexible filaments, indicating redundancy. Our results also impact upon collagen and fibrin networks in biological and bio-engineered tissues.

9:24AM A42.00006 The origins of strain stiffening in fibrin networks, LOUISE JAWERTH, Harvard University, STEFAN MUENSTER, University of Erlangen, Nuremberg, DAVID WEITZ, Harvard University — Fibrin networks form the structural scaffold of blood clots; their non-linear mechanical properties are crucial to stem the flow of blood at a site of vascular injury. A hallmark of these networks is strain stiffening: a stiffness that increases non-linearly as a network is strained. Deformations of the fibers and the network combine to control the mechanical properties of the bulk and must lead to the strain stiffening behavior of the networks; however, the details of this process are unknown. Here, we study fibrin networks undergoing shear on a confocal microscope and compare this to bulk rheological measurements. We track individual fiber branchpoints as function of system strain. We characterize the non-affinity of the motion and show that the low strain, linear regime corresponds to highly non-affine motion while the high strain, nonlinear regime corresponds to affine motion. Moreover, we show that the non-linear bulk response can be well approximated by considering the fibers to be linear elastic elements with soft compressive behavior and, therefore, is a result of the topology of the network itself rather than nonlinearity of its constituents.

9:36AM A42.00007 Semiflexible filament networks viewed as fluctuating beam frames, TIANXIANG SU¹, PRASHANT PUROHIT, University of Pennsylvania — We present a new method combining structural and statistical mechanics to study the entropic elasticity of semiflexible filament networks. We view a filament network as a frame structure and use structural mechanics to determine its static equilibrium configuration under applied loads in the first step. To account for thermal motion around this static equilibrium state, we then approximate the potential energy of the deformed frame structure up to the second order in kinematic variables and obtain a deformation-dependent stiffness matrix characterizing the flexibility of the network. Using statistical mechanics, we then evaluate the partition function, free energy and thermo-mechanical properties of the network in terms of the stiffness matrix. We show that penalty methods commonly used in finite elements to account for constraints, are applicable even when statistical and structural mechanics are combined in our method. We apply our framework to understand the expansion, shear, uniaxial tension and compression behavior of some simple filament networks. We are able to capture the stress-stiffening behavior due to filament reorientation and stretching out of thermal fluctuations, as well as the reversible stress-softening behavior due to filament buckling.

¹Currently at Harvard University

9:48AM A42.00008 Spindle Assembly and Architecture: From Laser Ablation to Microtubule Nucleation, DANIEL NEEDLEMAN, JAN BRUGUES, VALERIA NUZZO, ERIC MAZUR, Harvard University — Spindles are arrays of microtubules that segregate chromosomes during cell division. It has been difficult to validate models of spindle assembly due to a lack of information on the organization of microtubules in these structures. Here we present a novel method, based on femtosecond laser ablation, capable of measuring the detailed architecture of spindles. We used this method to study the metaphase spindle and find that microtubules are shortest near poles and become progressively longer towards the center of the spindle. These data, in combination with mathematical modeling, high resolution imaging, and biochemical perturbations, are sufficient to reject previously proposed mechanisms of spindle assembly. Our results support a new model of spindle assembly in which microtubule polymerization dynamics are not spatially regulated, microtubule transport locally sorts microtubules – determining their proper organization in the spindle without moving them appreciable distances –, and the profile of microtubule nucleation controls the length of the spindle.

10:00AM A42.00009 Coupling stochastic kinetics and mechanics uncovers new dynamics induced by focal adhesions in filopodia, MARIA MINAKOVA, GAREGIN PAPOIAN, University of Maryland at College Park — Cell motility recently became a target for physical chemists and biophysicists. It is generally understood that in real biological systems, chemical and mechanical processes are coupled, sometimes in a very complex manner. Focal adhesions (FAs) represent a biologically relevant example of multi molecular assemblies that serve a mechanical function and have intriguing biochemical properties. FAs and their role in filopodial dynamics have been extensively studied experimentally from a biological standpoint. Although there are many biochemical studies of FAs kinetics in the literature, only a few works study FA dynamics from a physical perspective. In our work we developed a robust stochastic model of the filopodia coupled to mechanical properties of FAs, retrograde flow and the substrate. We carried out extensive simulations of the filopodial stochastic growth on the timescales of minutes, as well as a detailed theoretical description of a steady state, mapping multi dimensional phase space of mechanical and kinetic parameters onto various dynamics regimes. The combination of mean field analyses with detailed microscopic simulations provides a united platform for treating mechanochemical processes underlying complex behavior of the filopodial system.

10:12AM A42.00010 Growth Cone Biomechanics in Peripheral and Central Nervous System

Neurons , JEFFREY URBACH, DANIEL KOCH, WILL ROSOFF, Georgetown University, HERBERT GELLER, NIH — The growth cone, a highly motile structure at the tip of an axon, integrates information about the local environment and modulates outgrowth and guidance, but little is known about effects of external mechanical cues and internal mechanical forces on growth-cone mediated guidance. We have investigated neurite outgrowth, traction forces and cytoskeletal substrate coupling on soft elastic substrates for dorsal root ganglion (DRG) neurons (from the peripheral nervous system) and hippocampal neurons (from the central) to see how the mechanics of the microenvironment affect different populations. We find that the biomechanics of DRG neurons are dramatically different from hippocampal, with DRG neurons displaying relatively large, steady traction forces and maximal outgrowth and forces on substrates of intermediate stiffness, while hippocampal neurons display weak, intermittent forces and limited dependence of outgrowth and forces on substrate stiffness. DRG growth cones have slower rates of retrograde actin flow and higher density of localized paxillin (a protein associated with substrate adhesion complexes) compared to hippocampal neurons, suggesting that the difference in force generation is due to stronger adhesions and therefore stronger substrate coupling in DRG growth cones.

10:24AM A42.00011 An Atomic Force Microscopy based investigation of specific biomechanical properties for various types of neuronal cells

, ELISE SPEDDEN, Physics and Astronomy, Tufts University, JAMES WHITE, Physics and Astronomy and Biomedical Engineering, Tufts University, DAVID KAPLAN, Biomedical Engineering and Chemical Engineering, Tufts University, CRISTIAN STAIL, Physics and Astronomy, Tufts University — Here we describe the use of Atomic Force Microscope (AFM) based techniques to characterize and explore the influence of biochemical and biomechanical cues on the growth and interaction of neuronal cells with surrounding guidance factors. Specifically, we use AFM topography and AFM force spectroscopy measurements to systematically investigate the morphology, elasticity, and real time growth of neuronal processes in the presence of different types of extracellular matrix proteins and growth factors. We therefore create a series of systems containing specified neuron densities where the type of the underlying growth promoting protein is different from sample to sample. For each system we measure key biomechanical parameters related to neuronal growth such as height and elastic modulus at multiple growth points on several types of neurons. We show that systematic measurements of these parameters yield fundamental information about the role played by substrate-plated guidance factors in determining elastic and morphological properties of neurons during growth.

10:36AM A42.00012 Nuclear Physics in a biological context

, DENNIS DISCHER, Univ. Pennsylvania — A solid tissue can be soft like fat or brain, stiff like striated muscle and heart, or rigid like bone – and of course every cell has a nucleus that contributes in some way small or large to tissue mechanics. Indeed, nuclei generally exhibit rheology and plasticity that reflects both the chromatin and the nuclear envelope proteins called lamins, all of which change in differentiation. Profiling of tissue nuclei shows that the nuclear intermediate filament protein Lamin-A/C varies over 30-fold between adult tissues and scales strongly with micro-elasticity of tissue, while other nuclear envelope components such as Lamin-B exhibit small variations. Lamin-A/C has been implicated in aging syndromes that affect muscle and fat but not brain, and we find nuclei in brain-derived cells are indeed dominated by Lamin-B and are much softer than nuclei derived from muscle cells with predominantly Lamin-A/C. In vitro, matrix elasticity can affect expression of nuclear envelope components in adult stem cells, and major changes in Lamin-A/C are indeed shown to direct lineage with lower levels favoring soft tissue and higher levels promoting rigid tissue lineage. Further molecular studies provide evidence that the nucleus transduces physical stress. References: (1) J.D. Pajerowski, K.N. Dahl, F.L. Zhong, P.J. Sammak, and D.E. Discher. Monday, February 27, 2012 8:00AM - 10:24AM –

Session A43 FPS: Invited Session: Broader Impacts of Research-NSF Policy and Individual Responsibility 157AB

8:00AM A43.00001 Science, the Scientists and Values

, ALAN LESHNER, AAAS — Although individual scientists engage in research for diverse reasons, society only supports the enterprise because it benefits humankind. We cannot always predict how that will happen, or whether individual projects will have clear and direct benefits, but in the aggregate, there is widespread agreement that we are all better off because of the quality and diversity of the science that is done. However, what scientists do and how it benefits humankind is often unclear to the general public and can at times be misunderstood or misrepresented. Moreover, even when members of the public do understand what science is being done they do not always like what it is showing and feel relatively free to disregard or distort its findings. This happens most often when findings are either politically inconvenient or encroach upon issues of core human values. The origins of the universe can fit into that latter category. This array of factors contributes to the obligation of scientists to reach out to the public and share the results of their work and its implications. It also requires the scientific community to engage in genuine dialogue with the public and find common ground where possible.

8:36AM A43.00002 The APS and the Impact on Physics and Society

, BARRY C. BARISH, California Inst of Technology, LIGO 18-34 — No abstract available.

9:12AM A43.00003 Why Physicists Have a Responsibility to Society

, CHARLES FERGUSON, Federation of American Scientists — The debate and controversy over the NSF criterion on broader societal impacts of NSF-funded research have served the important function of challenging the physics community to reexamine why public money should support pure and applied physics research and what is the role of physicists in society. I will argue that the criterion, while well intentioned, appears ill informed and runs the risk of creating a check list of activities that will seemingly fulfill physicists' responsibility to connect their work to larger societal issues. Moreover, I will argue in favor of having a portion of government-funded research for scientific investigations based primarily, if not solely, on the intellectual and scientific merits of the proposals. Most government-funded research is already connected to larger societal impacts such as national defense, energy research, and economic issues. While I will call for reassessment of the NSF criterion on broader societal impacts, my talk will explain why physicists, as citizens and scientists, must reenergize their efforts to positively effect society and will offer advice about how they can do so.

9:48AM A43.00004 The Broader Impact Criteria- What's the solution? A panel discussion

, DON PROSNITZ, None — The need for social control of science—especially 20th and now 21st century science—has been debated for decades. Science is supported by society, and research results ultimately have large societal impacts. Physicists arguing for increased research budgets invariably point out the collateral benefits to society—often economic—of their discovery-based research. Congress agreed, and attempted to institutionalize this metric in the 'America COMPETES Reauthorization Act of 2010' by insisting that researchers illustrate how their work will provide for (among other things) increased economic competitiveness of the United States and increased National Security. Is such a metric inevitable in these days of constrained resources? Is it desirable or even implementable? Can benefits be predicted, or are the most important societal consequences of basic research serendipitous? This talk will examine these questions, including looking at how other nations are attempting to deal with the issue, and present some suggestions for satisfying both society's insistence on a return on their investment and scientists' need for unfettered exploration. The program will conclude with a Q and A and panel discussion with all of the session's speakers.

Monday, February 27, 2012 8:00AM - 11:00AM –

Session A44 DPOLY DBIO: Focus Session: Hydrophobic Interactions and Hydrogen Bonding Networks in Polymeric and Soft Matter Systems 157C

8:00AM A44.00001 More than one dynamic crossover in protein hydration water¹, GIANCARLO FRANZESE, Universitat de Barcelona, Spain, MARCO G. MAZZA, TU Berlin, Germany, KEVIN STOKELY, Center for Polymer Studies, Boston University, MA, SARA PAGNOTTA, Centro de Física de Materiales, Donostia-San Sebastian, Spain, FABIO BRUNI, Università di Roma Tre, Italy, H. EUGENE STANLEY, Center for Polymer Studies, Boston University, MA — We study by theory, simulations and experiments, the dynamics of the hydrogen bond (HB) network of a percolating layer of water hydrating lysozyme powder. Using dielectric spectroscopy we measure the temperature dependence of the relaxation time of proton charge fluctuations. These fluctuations are associated with the dynamics of the HB network of water molecules adsorbed on the protein surface. Using Monte Carlo simulations and mean-field calculations, we study the dynamics and thermodynamics of a coarse-grained model that successfully reproduces the properties of hydration water. Both experimental and model analyses are consistent with the interesting possibility of two dynamic crossovers, (i) at ≈ 252 K, and (ii) at ≈ 181 K. Because the experiments agree with the model, we can relate the two crossovers to the presence at ambient pressure of two specific heat maxima. The first is caused by fluctuations in the HB formation, and the second, at a lower temperature, is due to the reordering of the HB network.

¹NSF Grant CHE 0908218, MICINN-FEDER (Spain) grant FIS2009-10210

8:12AM A44.00002 The effect of salt solutes on the relaxation dynamics of water from 65 to 720 GHz, NGUYEN VINH, MARK SHERWIN, JIM ALLEN, ITST, Department of Physics, University of California, Santa Barbara, KEVIN PLAXCO, Department of Chemistry and Biochemistry, University of California, Santa Barbara — During the past decade, a variety of measurement techniques have provided evidence that ions and other solute molecules effect the structure and dynamics of the water molecules directly surrounding them. Most of these experiments have employed infrared spectroscopy which explores vibrational relaxation of the hydration shell by observing intramolecular vibrations. Terahertz spectroscopy, in contrast is sensitive to intermolecular dynamics. Here we use a vector network analyzer based *terahertz dielectric relaxation spectrometer* operating over the frequency range from 65 to 720 GHz. The literature on relaxation dynamics of water is extensive and variable. But these measurements clarify the situation and confirm that the dynamics of water over this regime are best described in terms of three Debye relaxation processes with the characteristic times of 8.56, 1.1 ps and 179 fs (at 25.0 °C). Remarkably, while the relaxation times themselves are not sensitive to salt concentration, the relative strength of the relaxation modes depends in a systematic way on the solute molarity. We discuss these results by relating the salt concentration dependent strength of the three processes to the dynamics and structure of first three hydration shells. Our measurements shed light on the dynamics of hydration shells around solute molecules in a biologically relevant environment.

8:24AM A44.00003 Investigating How Contact Angle Effects the Interaction between Water and a Hydrophobic Surface, ADELE POYNOR, CAITLYN NEIDIG, Allegheny College — By definition hydrophobic substances hate water. What happens when water is forced into contact with a hydrophobic surface? One theory is that an ultra-thin low-density region forms near the surface. Contact angle is a measure of how hydrophobic a surface is. We have employed an automated home-built Surface Plasmon Resonance (SPR) apparatus to investigate the effect of varying the contact angle on the depletion layer

8:36AM A44.00004 Mesoscale inhomogeneities in an aqueous ternary system, DEEPA SUBRAMANIAN, STEPHEN HAYWARD, ELIA ALTABET, Department of Chemical and Biomolecular Engineering, University of Maryland, College Park, MD 20742, PETER COLLINGS, Department of Physics and Astronomy, Swarthmore College, Swarthmore, PA 19081, MIKHAIL ANISIMOV, Department of Chemical and Biomolecular Engineering, University of Maryland, College Park, MD 20742 — Aqueous solutions of certain low-molecular-weight organic compounds, such as alcohols, amines, or ethers, which are considered macroscopically homogeneous, show the presence of mysterious mesoscale inhomogeneities, order of a hundred nm in size. We have performed static and dynamic light scattering experiments in an aqueous ternary system consisting of tertiary butyl alcohol and propylene oxide. Tertiary butyl alcohol is completely soluble in water and in propylene oxide, and forms strong hydrogen bonds with water molecules. Based on results of the study, we hypothesize that the mesoscale inhomogeneities are akin to a micro phase separation, resulting from a competition between water molecules and propylene oxide molecules, wanting to be adjacent to amphiphilic tertiary butyl alcohol molecules. Coupling between two competing order parameters, super-lattice binary-alloy-like (“antiferromagnetic” type) and demixing (“ferromagnetic” type) may explain the formation of these inhomogeneities. Long-term stability investigation of this supramolecular structure has revealed that these inhomogeneities are exceptionally long-lived non-equilibrium structures that persist for weeks or even months.

8:48AM A44.00005 Statistical Mechanics of Thermosensitive Nanoparticle Binding: Quantifying Hydrophobic Interactions in Bulk Solution, ALESSIO ZACCONE, Cavendish Laboratory, University of Cambridge, JEROME CRASSOUS, University of Lund, BENJAMIN BERI, Cavendish Laboratory, University of Cambridge, MATTHIAS BALLAUFF, Helmholtz Zentrum Berlin — We present a novel method which allows one to quantify the binding energy between complex hydrophobic nanoparticles in bulk aqueous solutions by means of light scattering. We tested the method on the case of thermosensitive nanoparticles made of a solid polymeric core onto which a thermosensitive p-NIPAM microgel shell is grafted. The microgel shrinks above a critical T at which the hydrophobic attraction sets in. By means of a novel statistical mechanics model to interpret the data, we manage to demonstrate that the binding energy as a function of T of thermosensitive nanoparticles behaves like in the case of neat two-level systems, with a rather sharp transition from hard-sphere (hydrophilic) to attractive (hydrophobic) at the critical temperature. The model allows us to make a clear quantitative connection between the binding energy and the entropy change of the grafted microgel upon going from hydrophilic to hydrophobic (in turn related to the microgel structure). The methods presented in this work can be applied to quantify the binding energy of complex biomolecules in bulk solution, which is a major challenge in biophysics nowadays. Reference: A. Zaccane, J.J. Crassous, B. Beri, and M. Ballauff, Phys. Rev. Lett. 107, 168303 (2011).

9:00AM A44.00006 Effect of Valence of Counterions on the Structure of Charged Membranes, a Computer Simulation Study, BAOFU QIAO, MONICA OLVERA DE LA CRUZ, Department of Materials Science, Northwestern University — Phospholipids have been investigated for a long period, due to its ability of self-assembling into bilayer structures which resemble biological membranes. But most of the studies have been limited on the neutral phosphatidylcholine based lipids. The understanding of charged membranes (e.g., phosphatidylserine) is very limited due to the repulsion between the charged groups on lipids. In the present work, we investigated the effect of different counter-ions on the structures of charged membranes formed by 1,2-dilauroyl-sn-glycero-3-phospho-L-serine. Three kinds of counterions were investigated, from monovalent, to divalent, to trivalent ions. Molecular dynamics simulations were performed at all-atom level. We have calculated the area per lipid. And the interaction between counterions and COO⁻ groups was found to dominate over that between counterions and PO₄⁻ groups.

9:12AM A44.00007 Deconstructing Classical Water Models at Interfaces and in Bulk: Hydrophobic Interactions and Hydrogen Bonding¹

, JOHN D. WEEKS, Institute for Physical Science and Technology and Department of Chemistry and Biochemistry University of Maryland, College Park, MD — Using concepts from perturbation and local molecular field theories of liquids we divide the potential of the SPC/E water model into short and long ranged parts. The short ranged parts define a minimal reference network model that captures very well the structure of the local hydrogen bond network in bulk water while ignoring effects of the remaining long ranged interactions. This deconstruction can provide insight into the different roles that the local hydrogen bond network, dispersion forces, and long ranged dipolar interactions play in determining a variety of solvation and other properties of SPC/E and related classical models of water. We use these short ranged models along with local molecular field theory to quantify the influence of these interactions on the structure of hydrophobic interfaces and the crossover from small to large scale hydration behavior. The implications of our findings for theories of hydrophobicity and possible refinements of classical water models will also be discussed.

9:48AM A44.00008 A SAFT-based classical density functional for water

, DAVID ROUNDY, JESSICA HUGHES, ERIC KREBS, Oregon State University — We present a new classical density functional for water based on a combination of Statistical Associating Fluid Theory (SAFT-VR) with the Fundamental Measure Theory (FMT) functional for the hard-sphere fluid. In the homogeneous limit, our functional reduces to the published optimal SAFT model of Clark *et al* [1]. By adding a single fitting parameter, we reproduce the bulk surface tension of water within a wide temperature range. We will present results for hydrophobic hard rods and spheres, including the temperature dependence of the hydrophobic interaction.

10:00AM A44.00009 Morphology and chirality control self-assembly of sickle hemoglobin inside red blood cells¹

, XUEJIN LI, HUAN LEI, Division of Applied Mathematics, Brown University, Providence, RI 02912, BRUCE CASWELL, School of Engineering, Brown University, Providence, RI 02912, GEORGE KARNIADAKIS, Division of Applied Mathematics, Brown University, Providence, RI 02912 — Sickle cells exhibit abnormal morphology and membrane mechanics in the deoxygenated state due to the polymerization of the interior sickle hemoglobin (HbS). In this study, the dynamics of self-assembly behavior of HbS in solution and corresponding induced cell morphologies have been investigated by dissipative particle dynamics approach. A coarse-grained HbS model, which contains hydrophilic and hydrophobic particles, is constructed to match the structural properties and physical description (including crowding effects) of HbS. The hydrophobic interactions are shown to be necessary with chirality being the main driver for the formation of HbS fibers. In the absence of chain chirality, only the self-assembled small aggregates are observed whereas self-assembled elongated step-like bundle microstructures appear when we consider the chain chirality. Several typical cell morphologies (sickle, granular, elongated shapes), induced by the growth of HbS fibers, are revealed and their deviations from the biconcave shape are quantified by the asphericity and elliptical shape factors.

10:12AM A44.00010 Secondary structure formation in peptide amphiphile micelles

, MATTHEW TIRRELL, Institute for Molecular Engineering, University of Chicago — Peptide amphiphiles (PAs) are capable of self-assembly into micelles for use in the targeted delivery of peptide therapeutics and diagnostics. PA micelles exhibit a structural resemblance to proteins by having folded bioactive peptides displayed on the exterior of a hydrophobic core. We have studied two factors that influence PA secondary structure in micellar assemblies: the length of the peptide headgroup and amino acids closest to the micelle core. Peptide length was systematically varied using a heptad repeat PA. For all PAs the addition of a C12 tail induced micellization and secondary structure. PAs with 9 amino acids formed beta-sheet interactions upon aggregation, whereas the 23 and 30 residue peptides were displayed in an alpha-helical conformation. The 16 amino acid PA experienced a structural transition from helix to sheet, indicating that kinetics play a role in secondary structure formation. A p53 peptide was conjugated to a C16 tail via various linkers to study the effect of linker chemistry on PA headgroup conformation. With no linker the p53 headgroup was predominantly alpha helix and a four alanine linker drastically changed the structure of the peptide headgroup to beta-sheet, highlighting the importance of hydrogen bonding potential near the micelle core.

10:24AM A44.00011 Friction and Hydration Repulsion Between Hydrogen-Bonding Surfaces

, ROLAND NETZ, Free University Berlin, Germany — The dynamics and statics of polar surfaces are governed by the hydrogen-bonding network and the interfacial water layer properties. Insight can be gained from all-atomistic simulations with explicit water that reach the experimentally relevant length and time scales. Two connected lines of work will be discussed: 1) On surfaces, the friction coefficient of bound peptides is very low on hydrophobic substrates, which is traced back to the presence of a depletion layer between substrate and water that forms a lubrication layer. Conversely, friction forces on hydrophilic substrates are large. A general friction law is presented and describes the dynamics of hydrogen-bonded matter in the viscous limit. 2) The so-called hydration repulsion between polar surfaces in water is studied using a novel simulation technique that allows to efficiently determine the interaction pressure at constant water chemical potential. The hydration repulsion is shown to be caused by a mixture of water polarization effects and the desorption of interfacial water.

Session A45 DPOLY: Focus Session: Thin Film Block Copolymers - Directed Assembly 159

8:00AM A45.00001 Directed Ordering of Block Copolymer Thin Films with Flexible Interfaces for Functional Materials¹

, ALAMGIR KARIM, University of Akron — Orientation control of block copolymer (BCP) films is important for advanced technological applications. We present studies on directed ordering of block copolymer thin films on rigid substrates such as quartz to elastomeric PDMS and flexible Kapton substrates for tunable orientation of microphase separated poly(styrene) – block -poly(methylmethacrylate) (PS-PMMA) cylinder and lamellae forming BCP films. Although the crosslinked PDMS has low surface energy, its surface energy can be tuned by exposing to UV-Ozone (UVO) that presents an opportunity to change BCP-PDMS interfacial energy to control BCP orientation across full range of orientation and film wettability. On the other hand, Kapton offers a near neutral surface for PS-PMMA without surface modification. Via a modified version of a dynamic thermal processing termed cold zone annealing-sharp (CZA-S), we obtain a wide range of orientations of the block copolymer films in unfilled and nanoparticle filled systems with an interest in photovoltaic systems. With CZA-S, vertical orientation of PS-PMMA can be obtained in films as thick as 1 micron with etchable PMMA domains for membrane applications. GISAXS characterization of these etched BCP membranes reveals up to 5 orders of diffraction indicating hexagonally packed vertical nanopores that extend throughout the film. Under similar thermal gradient, but static conditions, temporally stable vertical cylinders form only within a narrow zone of maximum temperature gradient. Primary CZA-S ordering mechanism thus involves propagating this narrow vertically oriented zone of BCP cylinders created at the maximum thermal gradient section, across the film. An optimal speed is needed since the process competes with preferential surface wetting dynamics that favors parallel orientation. These results are reproduced on large area flexible films on a prototype dynamic R2R assembly platform with incorporated multi-CZA gradient for thin (100 nm) BCP films currently.

8:36AM A45.00002 Facile Route to Vertically Aligned High-Aspect Ratio Block Copolymer Films via Dynamic Zone Annealing¹, GURPREET SINGH, MANISH KULKARNI, Department of Polymer Engineering, University of Akron, Akron OH 44325, KEVIN YAGER, Center for Functional Nanomaterials, Brookhaven National Laboratory, Upton, NY 11973, DETLEF SMILGIES, 3Cornell High Energy Synchrotron Source, Cornell University, Ithaca, New York 14853, DAVID BUCKNALL, Materials Science and Engineering, Georgia Institute of Technology, Atlanta, GA 30332, ALAMGIR KARIM, Department of Polymer Engineering, University of Akron, Akron OH 44325 — Directed assembly of block copolymers (BCP) can be used to fabricate a diversity of nanostructures useful for nanotech applications. The ability to vertically orient etchable high aspect ratio (~30) ordered BCP domains on flexible substrates via continuous processing methods are particularly attractive for nanomanufacturing. We apply sharp dynamic cold zone annealing (CZA-S) to create etchable, and predominantly vertically oriented 30nm cylindrical domains in 1 μ m thick poly(styrene-*b*-methylmethacrylate) films on low thermal conductivity rigid (quartz) and flexible (PDMS & Kapton) substrates. Under similar static conditions, temporally stable vertical cylinders form within a narrow zone above a critical temperature gradient. Primary ordering mechanism of CZA-S involves sweeping this vertically orienting zone created at maximum thermal gradient. An optimal speed is needed since the process competes with preferential surface wetting dynamics that favors parallel orientation. GISAXS of etched BCP films confirms internal morphology.

8:48AM A45.00003 Controlling Domain Orientation in Thin Films of Lamellar AB and ABA Block Copolymers, NIKHILA MAHADEVAPURAM, THAI VU, GILA STEIN, University of Houston — Thin films of block copolymers are very popular for low cost, large area nanopatterning. To generate a nanoporous template, the domains must be oriented perpendicular to the substrate. This talk will discuss the effects of copolymer architecture on surface energetics and domain orientations. We consider lamellar copolymers based on polystyrene (PS) and poly(methyl methacrylate) (PMMA) blocks. All films are cast on “neutral” substrates, and the resulting structures are evaluated with microscopy and grazing-incidence small-angle X-ray scattering. For PS-PMMA diblock copolymers, domain orientations are very sensitive to process conditions. The desired perpendicular orientation is most reliably obtained at high annealing temperatures where PS and PMMA have similar melt surface tensions. For PMMA-PS-PMMA triblock copolymers, the perpendicular domain orientation is stable for all film thicknesses and annealing temperatures that were studied, consistent with recent works that consider architectural effects when calculating the copolymer surface tension. These data suggest that triblocks are easier to use for nanopatterning. However, we also find that diblock and triblock films contain a high density of tilted domains, and such defects should be minimized for most applications.

9:00AM A45.00004 Diblock and Triblock Copolymer Thin Films on a Substrate with Controlled Selectivity¹, YONG-BIAO YANG, JAEUP KIM, UNIST, JUNHAN CHO, Dankook University — We study the morphology developments in linear ABC triblock and also AB diblock copolymer films on neutral and selective substrates, using a self-consistent field theory (SCFT). For the ABC copolymer films, various nanopatterns with tunable square morphologies evolved due to the effects of the substrate preferable to interior (B) block. The domain patterns became diversified from those parallel to the substrate with substrate selectivity for end-block or those vertical to the substrate without substrate selectivity. Furthermore, in order to figure out an economical and efficient way to fabricate useful passive pattern transfer layers potentially applicable to microelectronic processes and ultrahigh density storage media, we scrutinized conditions for generating square symmetries using symmetric AB diblock copolymers deposited on substrates created from ABC triblock copolymer films. It was found that a thinner film with relatively weak incompatibility can produce square patterns.

9:12AM A45.00005 Microdomain Orientation of PS-*b*-PMMA Thin Films on the PS grafted Substrates, DU YEOL RYU, RUI GUO, EUNHYE KIM, Yonsei University — The phase transitions and morphologies, specifically the orientation of lamellar microdomains of symmetric polystyrene-*b*-poly(methyl methacrylate) (PS-*b*-PMMA) were investigated with grazing incidence small-angle x-ray scattering (GISAXS) and transmission electron microscopy (TEM). The microdomain orientation in thin films of PS-*b*-PMMA on the substrates with brushed (or grafted) polymers was influenced by the interfacial interactions, where grafting density of underlying PS layers are controlled by the reaction parameters such as time and temperature during grafting to the substrates. When grafting density range of PS brush is adjusted, such a simple and facile route provides the perpendicular orientation of cylindrical and lamellar microdomains in PS-*b*-PMMA films.

9:24AM A45.00006 Orientation control of cold zone annealed Block copolymer films on tunable gradient surface energy substrates using combinatorial methods, MANISH KULKARNI, GURPREET SINGH, ALAMGIR KARIM, The University of Akron — Microphase morphologies of poly(styrene)-block-poly(methylmethacrylate) (PS-PMMA) block co-polymer (BCP) films coated on various tunable surface energy gradient (SEG) substrates were compared. Substrates were prepared by coating silane self assembled monolayer (SAM) and hydrophobic sol-gel based layer of silica (xerogel) on quartz and exposed to UV-ozone radiation by placing them on an accelerating stage that oxidizes the surface to generate SEG. The combinatorial thickness gradient samples of BCP film were prepared by flow coating the BCP solution orthogonal to the SEG. Samples were annealed using novel cold zone annealing (CZA) method with a sharp thermal gradient (50 °C/mm) to obtain highly ordered BCP morphologies. Effect of CZA annealing rate and film thickness on BCP morphologies of the SAM treated and untreated quartz as well as xerogel substrates were compared. It was observed that BCP films coated on the untreated quartz substrates exhibited hexagonally packed perpendicular cylindrical morphologies whereas higher area fraction of parallel cylinders was observed for SEG xerogel substrates for higher surface energies (>40 mJ/m²). BCP 2D surface morphologies studied using AFM, were confirmed to extend to the interior of the film (3D) by GISAXS.

9:36AM A45.00007 Block Copolymer Ordering on Soft, Patternable and Flexible Substrates, ARZU HAYIRLIOGLU, GURPREET SINGH, ALAMGIR KARIM, Department of Polymer Engineering, The University of Akron, Akron, 44325, OH — Directed assembly of cylinder and lamellae forming block copolymer films via flexible PDMS substrate is examined to investigate the ordering properties of polystyrene-*b*-poly(methyl methacrylate) (PS-*b*-PMMA) films. We study the cases where the PS-*b*-PMMA films are either directly coated on patterned PDMS flexible substrates, or coated on a flat PDMS substrate with a top patterned and flexible PDMS confinement. The surface energy of the PDMS substrates was modified to vary from 20 to 68 mJ/m² by exposing them to UV-ozone (UVO) for controlled wettability and orientation control. We replicated different patterned media and observed perpendicular lamellar orientation and parallel cylindrical orientation on patterned flexible substrate at higher surface energies in preliminary measurements. Characterization of orientation was investigated with Grazing-Incidence Small Angle X-ray Scattering (GISAXS) measurement as well as with Atomic Force Microscope (AFM) results. Optical Microscope (OM) was also used to study of the surface morphology of the BCP films.

9:48AM A45.00008 Controlling the alignment and the morphology of bilayer BCP films using templated self-assembly, AMIR TAVAKKOLI K. G., MIT, Dept. of Electrical Engineering and Computer Science, KEVIN W. GOTRIK, ADAM F. HANNON, ALFREDO ALEXANDER-KATZ, CAROLINE A. ROSS, MIT, Dept. of Materials Science and Engineering, KARL K. BERGGREN, MIT, Dept. of Electrical Engineering and Computer Science — Templated self-assembly of block copolymer (BCP) thin films can control the alignment of BCP microdomains in a single layer using chemical and topographical methods. However, controlling the alignment and the morphology of BCP microdomains in two different layers simultaneously and fabricating complicated three-dimensional (3D) structures is relatively unexplored. This control is useful for the fabrication of multilevel thin film devices. Also, the forces and energetics governing BCP self-assembly are better understood at the bulk scale. This paper discusses how to control the BCP in two different layers by using a majority-block-functionalized post template. We showed by using an array of majority block functionalized posts, we could fabricate very complicated three-dimensional structures and we were able to control the BCP in two different layers. We fabricated three dimensional junctions and bends in two different levels of the BCP, bottom and top. Moreover, we showed we could fabricate periodic superstructures as well as changing the morphology of the BCP in one of the layers from the original cylinders to ellipsoids, spheres, and bicontinuous cylinders and having two different morphologies on top of each other.

10:00AM A45.00009 Controlling the Block Copolymer Patterns via Combining Graphoepitaxy and Surface Guidance¹, HYUNJUNG JUNG, Korea University, SUMI LEE, EUN AE KWAK, Samsung Electronics, SANGHOON WOO, Korea University, FRANK LEIFARTH, CRAIG HAWKER, University of California, Santa Barbara, JUNE HUH, DU YEOL RYU, Yonsei University, JOONA BANG, Korea University — One of the key issues for the block copolymer patterning is controlling the pattern array. Using directed assembly of block copolymer on the chemically patterned surfaces guarantee highly uniform array or controlled non-regular array. In this system, the chemically patterned surface can induce well resisted array over arbitrary large areas. However, this method requires expensive and complicated e-beam lithography and thus is not readily applicable to mass production process. Alternatively, another method is the graphoepitaxy method. In this case, the self-assembly of block copolymer is guided by the topographical wall of lithographically pre-patterned substrates. But, it has limitation on the pitch size of wall to obtain the highly ordered patterns. In this work, we demonstrate a new type of fabrication method to achieve highly controlled and uniform block copolymer patterns. Our approach is to combine the graphoepitaxy method and hexagonally surface guiding patterns from crosslinkable block copolymers. When the lamellar forming block copolymers were prepared on hexagonal patterns, a highly aligned stripe was obtained and the alignment was significantly improved comparing to the case when no hexagonal surface patterns were used.

¹Samsung Electronics

10:12AM A45.00010 Macroscopic Ordering of Block Copolymers into Sequenced Patterns on Topographically Corrugated Surface, SUNGJUNE PARK, LARISA TSARKOVA, STEPHANIE HILT, DWI an der RWTH Aachen e. V., Lehrstuhl für Makromolekulare Materialien und Oberflächen, RWTH Aachen University, Germany, STEFAN ROITSCH, JOACHIM MAYER, Gemeinschaftslabor für Elektronenmikroskopie, RWTH Aachen University, Germany, ALEXANDER BÖKER, DWI an der RWTH Aachen e. V., Lehrstuhl für Makromolekulare Materialien und Oberflächen, RWTH Aachen University, Germany — For the guided block copolymer assembly we used corrugated SiCN ceramic substrates which were fabricated by a facile replication process using non-lithographic PDMS masters. During thermal annealing of polystyrene-b-polybutadiene diblock copolymer, the material transport was guided by the wrinkled substrate to form regular modulations in the film thickness. As a consequence of the thickness-dependent morphological behavior of block copolymers, the film surface appears as sequenced patterns of alternative microphase separated structures. The ordering process is attributed to the formation of reverse terraces which match the substrate topography, so that the resulting surface patterns are free from the surface relief structures within macroscopically-large areas. The issues of the film thickness, the substrate surface energy and the pattern geometry are addressed. Our approach demonstrates an effective synergism of external confinement and internal polymorphism of block copolymers towards complex hierarchically-structured patterned surfaces.

10:24AM A45.00011 Block copolymer thin films with long-range lateral order, ILJA GUNKEL, Lawrence Berkeley National Laboratory, TING XU, University of California, Berkeley, ALEXANDER HEXEMER, Lawrence Berkeley National Laboratory, THOMAS RUSSELL, University of Massachusetts, Amherst — We investigated thin block copolymer films on silicon wafers as well as faceted surfaces of sapphire. Thin films were prepared by spin-coating block copolymer solutions on the corresponding substrates. Subsequent annealing in organic solvent vapors served as a means to induce lateral long-range order in the thin films. The resulting block copolymer structures were analyzed by AFM and GISAXS.

10:36AM A45.00012 Combining block copolymer lithography with nano-imprinting lithography: Mass-producing sub-20nm unidirectional line patterns, XIAODAN GU, SUNG WOO HONG, THOMAS P. RUSSELL, University of Massachusetts Amherst, UMASS AMHERST TEAM — A facile, simple pathway for mass production of highly aligned sub 20 nm unidirectional line patterns over arbitrarily large areas is reported. The directed self-assembly of block copolymers and nano-imprint lithography technique are combined together for this purpose. Polystyrene-b-poly(4-vinylpyridine) (PS-b-P4VP) was self-assembled on the faceted sapphire substrates to generate unidirectionally aligned cylindrical microdomains oriented parallel to the substrate. The nanoporous trench patterns were achieved by selective reconstruction of the cylindrical P4VP microdomains followed by oxygen plasma etching. The resulting 1D trench nanopatterns were characterized by scanning force microscopy, scanning electron microscopy, and grazing incident small angle x-ray scattering (GISAXS), yielding an orientation parameter of 0.974. A cyclic-siloxane was cast onto the polymeric trench nanopatterns and cured to make a negative replica. After demolding, the cross-linked siloxane replica was used as a second master to mass-produce unidirectionally aligned nanolines on various substrates with high fidelity, quality, and yield by nano-imprinting lithography technique. Importantly, this strategy works for both thermal and UV-assisted imprinting. The methodology may afford an easy approach for mass production of ideal templates for the fabrication of magnetic storage media, optical devices, and arrays of conducting wires.

10:48AM A45.00013 Offset block copolymer printing using brushless substrates and elastomeric stamps, HYO SEON SUH, University of Wisconsin - Madison, HYUNSIK YOON, DO KYEONG KWON, KOOKHEON CHAR, Seoul National University, M. SERDAR ONSES, JEONG IN LEE, PAUL NEALEY, University of Wisconsin - Madison — The block copolymer (BCP) films have been utilized as the useful templates for the nanopatterning because of their ability to form quite small feature size with a relatively easy and cheap method. Recently, the control of orientation as well as the perfect registration with long range order of nanostructures in BCP films has been achieved by directing the assembly of BCP films with the chemical or topographical templates. However, such control of nanostructures and utilization of BCP films are limited on Si wafers since the templates are usually prepared by the semiconductor fabrication process. In this study, we will introduce a technique that overcomes such limitation on the application of BCP films. The chemical pattern prepared by e-beam lithography on the substrate without polymer brushes or mats was used as a template for the directed assembly of BCP films. Because the adhesion between this template and a BCP film is fairly weak, the directed assembled BCP films on this template could be easily transferred to the other substrates with adhesion-controlled elastomeric stamps. We believe that this transfer method, or printing method, would expand the applications of BCP films to areas where the nanotemplates are required.

Monday, February 27, 2012 8:00AM - 11:00AM –

Session A46 DPOLY: Invited Session: Inherently Strained Polymers and Soft Materials 160AB

8:00AM A46.00001 Switching Shape of Nematic Elastomers, KENJI URAYAMA, Department of Materials Chemistry, Kyoto University — Nematic elastomers (NEs) are a novel class of materials. NEs possess both the elastic properties of rubbers and the orientational properties of liquid crystals. The combination of these two properties makes the shape of NEs very sensitive to external stimuli. We focus on the thermally induced deformation of the NE films inherently possessing the two types of inhomogeneous director alignments, i.e., hybrid and twist alignments. In the NEs with hybrid alignments (HNEs), the director continuously changes by 90 degree from planar alignment to vertical alignment between the top and bottom surfaces. In the twist NEs, the director parallel to the surfaces smoothly rotates by 90 degree around the thickness axis, and the director at the mid-plane is parallel to the long or short axis of the film. In the HNEs and TNEs, the director change along the normal of the films causes the planes at different depth to respond differently to temperature variation, and the films are thus expected to change shape. We experimentally demonstrate that (i) depending on the width/thickness ratio, the TNE ribbons form the spiral ribbons or helicoids whose spiral or helical pitch markedly depends on temperature [1], and (ii) the HNE ribbons exhibit giant bending in response to temperature variation [2]. We theoretically interpret these experimental observations on the basis of the elastic models with the data of thermally induced uniaxial deformation of the corresponding NEs with globally planar alignment.

8:36AM A46.00002 Surface shape memory in polymers, PATRICK MATHER, Syracuse University — Many crosslinked polymers exhibit a shape memory effect wherein a permanent shape can be prescribed during crosslinking and arbitrary temporary shapes may be set through network chain immobilization. Researchers have extensively investigated such shape memory polymers in bulk form (bars, films, foams), revealing a multitude of approaches. Applications abound for such materials and a significant fraction of the studies in this area concern application-specific characterization. Recently, we have turned our attention to surface shape memory in polymers as a means to miniaturization of the effect, largely motivated to study the interaction of biological cells with shape memory polymers. In this presentation, attention will be given to several approaches we have taken to prepare and study surface shape memory phenomenon. First, a reversible embossing study involving a glassy, crosslinked shape memory material will be presented. Here, the permanent shape was flat while the temporary state consisted of embossed parallel grooves. Further the fixing mechanism was vitrification, with T_g adjusted to accommodate experiments with cells. We observed that the orientation and spreading of adherent cells could be triggered to change by the topographical switch from grooved to flat. Second, a functionally graded shape memory polymer will be presented, the grading being a variation in glass transition temperature in one direction along the length of films. Characterization of the shape fixing and recovery of such films utilized an indentation technique that, along with polarizing microscopy, allowed visualization of stress distribution in proximity to the indentations. Finally, very recent research concerning shape memory induced wrinkle formation on polymer surfaces will be presented. A transformation from smooth to wrinkled surfaces at physiological temperatures has been observed to have a dramatic effect on the behavior of adherent cells. A look to the future in research and applications for surface shape memory in polymers will round out the talk.

9:12AM A46.00003 Cell Forces and Cytoskeletal Order Parameters, DENNIS DISCHER, Univ. Pennsylvania — Nematic, Smectic and Isotropic Order parameters have found wide-spread use in characterizing all manner of soft matter systems, but have not yet been applied to characterize and understand the structures within living cells, particularly cytoskeletal structures. Several examples will be used to illustrate the utility of such analyses, ranging from experiments on stem cells attached to or in various elastic matrices to embryonic heart tissue and simulations of membrane cytoskeletons under all manner of stressing. Recently developed theory will be shown to apply in general with account of cell contractility, matrix elasticity and dimensionality as well as cell shape and a newly defined "cytoskeletal polarizability." The latter property of cells is likely different between different cell types due to different amounts of key cytoskeletal components with some types of stem cells being more polarizable than others. Evidence of coupling to the nucleus as a viscoelastic inclusion will also be presented.

9:48AM A46.00004 Tension in Highly Branched Polymers¹, MICHAEL RUBINSTEIN, University of North Carolina — We propose a systematic method of designing branched macromolecules capable of building up high tension in their covalent bonds, which can be controlled by changing solvent quality. This tension is achieved exclusively due to intramolecular interactions by focusing lower tensions from its numerous branches to a particular section of the designed molecule. The simplest molecular architecture, which allows this tension amplification, is a so-called pom-pom macromolecule consisting of a relatively short linear spacer and two z -arm stars at its ends. Tension developed in the stars due to crowding of their branches is amplified by a factor of z and focused to the spacer. There are other highly branched macromolecules, such as molecular brushes - comb polymers with high density of side branches, that have similar focusing and amplification properties. In addition molecular brushes transmit tension along their backbone. Adsorption or grafting of these branched molecules on a substrate results in further increase in tension as compared to molecules in solution. Molecular architectures similar to pom-pom and molecular brushes with a high tension amplification parts can be used in numerous sensor applications. Unique conformations of molecular brushes in a pre-wetting layer allow direct visualization by atomic force microscope. Detailed images of individual molecules spreading along the surface enable critical evaluation of theories of chain dynamics in polymer monolayer. Strong spreading of densely branched macromolecules on a planar substrate can lead to high tension in the molecular backbone sufficient to break covalent bonds.

10:24AM A46.00005 New strategies in adaptive polymer gels, EUGENIA KUMACHEVA, University of Toronto — Plants possess a remarkable ability to change their shape in response to the changes in ambient conditions. These transitions are believed to be governed by the non-uniform accumulation of elastic energy and the release of localized stresses. The self-shaping behaviour of plants offers a new paradigm for creating adaptable materials by-design, however currently prediction of three-dimensional transformations in soft matter remain a challenge. Here we report on the nature-inspired strategy for the generation of complex three-dimensional structures by programming stimuli-responsive deformations of a composite planar polymer gel sheet. This work constitutes a major step towards the preprogrammed design of adaptable soft materials with applications in sensing and actuation.

Monday, February 27, 2012 8:00AM - 11:00AM —
Session A47 DPOLY: Focus Session: Gelation and Glass Transition in Colloids and Soft Matter Systems I 160C

8:00AM A47.00001 Gelation kinetics of gelatin using particle tracking microrheology, JOSEPH HARDCASTLE, Boston University, RAMA BANSIL, Boston University — Previous studies with gelatin have observed four distinct stages during the physical gelation process [Normand et al. Macromolecules, 2000, 33, 1063]. In this presentation we report measurements of microrheology in an effort to examine the time evolution of the gel on short length scales and time scales. By tracking latex particles in gelatin solution at different temperatures we can follow the microrheological changes and kinetics of the gelation process. Using the generalized Stokes-Einstein relation viscoelastic properties of these quasi-static gel states the evolution of the storage and loss moduli, G' and G'' , are examined as functions of both time and temperature. The data show that both G' and G'' exhibit power law scaling versus frequency with the same exponent. The temperature and concentration dependence of the frequency at which the system crosses over from viscous to elastic behavior will be presented.

8:12AM A47.00002 Temperature Dependent Dynamics and Structure of Soft Colloids, PRAVEEN AGARWAL, SAMANVAYA SRIVASTAVA, LYNDEN ARCHER, Cornell University — We have investigated the effect of temperature on the structure and dynamics of a particular class of soft colloids created by densely grafting polymer chains to the nanoparticle surface. These materials are able to display fluid like properties even in the absence of any external solvent and are termed as self-suspended fluids. Temperature dependent rheology of these materials has displayed several interesting features including increased solid like response with increase in temperature. Tethered polymer chain in this particular system is *cis* 1-4 polyisoprene, which is a type-A dielectric and allows the effect of temperature change on the global dynamics of the tethered chain to be separately investigated with broadband dielectric spectroscopy. Furthermore, we have investigated the effect of temperature change on the nanoparticle structure and dynamics with the help of small angle X-ray scattering (SAXS) and X-ray photon correlation spectroscopy (XPCS). Based on our finding, we have provided an alternative description of the jamming phase diagram applicable to this system.

8:24AM A47.00003 Confinement-induced solidification of attractive colloidal suspensions, JACINTA CONRAD, MELISSA SPANNUTH, Chemical and Biomolecular Engineering, University of Houston — Using a model colloidal-polymer suspension, we show that confinement induces solidification in attractive colloidal suspensions via a fundamentally different route from that active in hard sphere colloidal suspensions. For a range of polymer concentrations, the suspensions undergo a phase transition from a colloidal fluid with clusters to a colloidal gel with increasing confinement while polymer and particle concentration are held constant. Surprisingly, the effects of confinement appear at much larger thicknesses in attractive colloidal suspensions than in hard sphere suspensions. We find that solidification in confined attractive suspensions is not driven by structuring of the colloids at the walls or by shear-induced migration or clustering. Instead, by analyzing the cluster size distributions in the fluid phase as a function of confinement, we find that the strength of the interparticle attraction increases as the samples are confined. We further demonstrate that this change in the strength of attraction leads to increasingly arrested particle dynamics as colloidal gels are confined.

8:36AM A47.00004 Gelation of self-assembled bile acid-PEG conjugates, SATU STRANDMAN, FRANTZ LE DEVEDEC, X.X. ZHU¹, University of Montreal — The aggregation of macromolecules and low-molar-mass compounds into elongated self-assemblies such as wormlike micelles, fibers, or tubules increases the viscosity of the solutions and often leads to gelation due to network formation, even in organic solvents. Such one-dimensional nanostructures are promising candidates for drug delivery vehicles, packing materials for separation, templates for metal nanowires, biocides, and photo- or biocatalysis. An interesting group of compounds capable of this type of self-organization are bile acids, which are endogenous steroids known to form gels at high concentrations and appropriate pH conditions. Grafting poly(ethylene oxide) on bile acids via anionic polymerization brings along thermoresponsiveness represented by lower critical solution temperature (LCST), while self-assembling occurs below another threshold temperature leading to a gelation at high concentrations, as shown by rheological experiments. The latter transition is assigned to the nanotube formation of pegylated bile acids, visualized by electron microscopy.

8:48AM A47.00005 The Role of Charge Interactions in Colloidal Gelation, EMILY RUSSELL, Harvard University, JORIS SPRAKEL, Wageningen University, THOMAS KODGER, DAVID WEITZ, Harvard University — We demonstrate the gelation of a novel system of oppositely charged colloidal particles. The particles are charged by grafting a polyelectrolyte brush from the surface, and suspended in a polar solvent with added monovalent salt. Confocal microscopy allows us to study in detail the three-dimensional structure and dynamics of these binary gels as we vary the particle volume fraction, interaction strength, and relative number ratio of the two particle species, and we find a transition between a gel and a fluid state with each of these parameters. We find that the mean contact number of particles in the gel decreases as we approach the gel line, in contrast to what has been reported in the literature for depletion gels.

9:00AM A47.00006 Anomalous Phase Transitions in Soft Colloid-Polymer Binary Mixtures¹, JAYDEEP BASU, AJAY KANDAR, Department of Physics, Indian Institute of Science, Bangalore, India, SURESH NARAYANAN, ALEC SANDY, XSD, APS, Argonne National Laboratory, USA — We have shown earlier [1] that these PGNPs resemble star polymers or spherical brushes in terms of their morphology in the melt. However, these particles show dynamics in melt which is quite different from other soft colloidal particles. Since most of the work on soft colloidal particles have been performed in solutions we have now explored the phase behavior of the PGNPs in good solvent using microscopic structural and dynamical measurements on binary mixtures of homopolymers and soft colloids consisting of polymer grafted nanoparticles. We observe anomalous structural and dynamical phase transitions of these binary mixtures, including appearance of spontaneous orientational alignment and logarithmic structural relaxations, as a function of added homopolymers of different molecular weights. Our experiments points to the possibility of exploiting the phase space in density and homopolymer size, of such hybrid systems, to create new materials with unique properties. Reference: 1. 9:12AM A47.00007 Injectable Solid Peptide Hydrogel as Cell Carrier: Effects of Shear Flow on Hydrogel and Cell Payload¹, DARRIN POCHAN, University of Delaware — Peptides were designed to intramolecularly fold into β -hairpins once they are exposed to physiological conditions and then consequently self-assemble into a rigid hydrogel with a network structure of branched and entangled, 3nm-wide fibrils. These physical hydrogels can be injected as preformed solids, because they can shear-thin and consequently flow under an appropriate shear stress but immediately recover back into solids on removal of the stress with gel stiffness restoring over time. In this work, mechanisms of gel shear-thinning and immediate recovery were elucidated by investigating gel behavior during and after flow via mechanical and structural characterizations. Importantly, hydrogel flow behavior was studied in a capillary geometry that mimicked the actual situation of syringe injection. Hydrogel flow profiles were obtained via fluorescent particle tracking and the profile shape was found dependent on flow rate and gel stiffness. Hydrogel nanostructure was probed with small angle neutron and x-ray scattering. The results demonstrate that these hydrogels can be excellent candidates for tissue regeneration substrates and injectable therapeutic delivery vehicles.

9:24AM A47.00008 Shear-driven gelation of dilute colloidal suspensions, EMANUELA DEL GADO, ETH Zurich, ALESSIO ZACCONE, University of Cambridge, DANIELE GENTILI, HUA WU, MASSIMO MORBIDELLI, ETH Zurich, MICROSTRUCTURE AND RHEOLOGY, ETH ZURICH TEAM, CHEMISTRY AND APPLIED BIOSCIENCES, ETH ZURICH TEAM — Shear-driven solidification of dilute colloidal suspensions has dramatic impact on their applications, ranging from industrial making of paints to artificial or natural microfluidic devices and is a prototype of far from equilibrium transitions. In a set of experiments on a dilute charge-stabilized colloidal suspension, we have monitored shear-induced aggregation in a fully controlled way and rationalized the effect of the shear stress from the initially liquid suspension to the final solid. By combining light scattering, rheology and microscopy images, we show that the suspension changes, under shear, into a suspension of non-Brownian aggregates whose packing fraction increases with the shearing time. Upon flow cessation, these aggregates can eventually form cohesive random packings where each inter-aggregate bond involve a large number of colloidal bonds. Such solidification mechanism is thus a hybrid between colloidal gelation and the packing-driven jamming of non-Brownian suspensions.

9:36AM A47.00009 Aggregation and network formation in aqueous methylcellulose near the sol-gel transition, SARA ARVIDSON, JOHN MCALLISTER, JOSEPH LOTT, FRANK BATES, TIMOTHY LODGE, University of Minnesota — Methylcellulose (MC) is a semi-flexible polymer which can be soluble in water at low temperatures, depending on the average number of methoxyl groups on each repeat unit. Upon heating, soluble MCs pass through a lower critical solution temperature (LCST) and undergo thermoreversible gelation, which is well described by Winter-Chambon critical gelation theory. The relaxation exponent (n) exhibits a smooth variation with concentration, approaching $n = 1$ at low concentration and $n = 0.5$ high concentration. We selected a set of commercial MC for materials with similar degrees of substitution, but known for their significant variations in gelation temperature in water. MCs which gel at higher temperatures also exhibit a plateau in elastic modulus at low frequencies, which indicates two relevant length scales coexist just below the gel point. Scattering experiments (static, dynamic, and small angle x-ray and neutron) are compared to rheological measurements to reveal the MC chain structures and aggregation associated with phase separation and gelation and enable a mechanistic understanding of these phenomena.

9:48AM A47.00010 Effect of particle stiffness on glassy dynamics of dense colloidal liquids, RAYMOND SEEKELL, Notre Dame University, PRASAD SARANGAPANI, MedImmune, LLC, Y. ÉLAINE ZHU, Notre Dame University — “Fragile” glassy materials show a non-Arrhenius dependence of relaxation time with temperature close to the glass transition and have been extensively studied for molecular glass formers as model “hard-sphere” colloidal suspensions, but we lack a complete understanding of “strong” glass formers which show an Arrhenius dependence on temperature approaching the glass transition. In this work, we investigate the glassy dynamics of microgels of varied particle stiffness in dense aqueous suspensions using confocal microscopy. Poly(N-isopropylacrylamide) (PNIPAM) microgel particles of variable stiffness in aqueous media are synthesized by precipitation polymerization varying the cross-linking density to resemble “strong” glass forming liquids owing to their directional elastic interparticle interactions at increased microgel volume fraction. The fragility effect on the glassy dynamics in dense colloidal suspension is investigated as we tune the behavior from “soft-sphere” to “hard-sphere” limits. We find that dynamic heterogeneity, specifically string-like motion, is more pronounced as stiffness increases.

10:00AM A47.00011 Thermo-adjustable mechanical properties of polymer, lipid-based complex fluids, MILLICENT FIRESTONE, SUNGWON LEE, Argonne National Laboratory — Combined rheology (oscillatory and steady shear) and SAXS studies reveal details on the temperature-dependent, reversible mechanical properties of nonionic polymer, lipid-based complex fluids. Compositions prepared by introduction of the polymer as either a lipid conjugate or a triblock copolymer form an elastic gel as the temperature is increased to 18 °C. The network is produced from PEO chain entanglement and physical crosslinks confined within the intervening aqueous layers of a multilamellar structured lyotropic mesophase. Although the complex fluids are weak gels, tuning of the gel strength can be achieved by temperature adjustment. The sol state formed at reduced temperature arises as a consequence of the well-solvated PEO chains adopting a non-interacting, conformational state. Complex fluids prepared with the triblock copolymers exhibit greater tunability in viscoelasticity than those containing the PEGylated-lipid conjugate because of the temperature-dependent water solubility of the central PPO block. The water solubility of PPO at reduced temperatures results in the polymer being expelled from the self-assembled amphiphilic bilayer, causing collapse of the swollen lamellar structure and loss of the PEO network. At elevated temperatures, the triblock reinserts into the bilayer producing an elastic gel. These studies identify macromolecular architectures for the facile preparation of dynamic soft materials possessing a range of mechanical properties that can be tuned by modest temperature control.

10:12AM A47.00012 Mechanics of networks of aliphatic fibers in aqueous surfactant media¹, GIULIANO ZANCHETTA, Department of Physics, University of Fribourg, MARCO CAGGIONI, VINCENZO GUIDA, Procter & Gamble, VERONIQUE TRAPPE, Department of Physics, University of Fribourg — We investigate the structural and rheological properties of aliphatic fibers dispersed in aqueous solutions of anionic surfactants, typically used in liquid detergents to provide yield stress. This system displays an onset to solid-like properties that depends on fiber concentration. In this contribution we will discuss how tuning the state of the surfactant background influences the fiber-fiber interactions and the mechanical properties of the gel.

¹We acknowledge funding from Procter & Gamble.

10:24AM A47.00013 Elimination of branching in self- assembled beta hairpin peptide fibrils, SAMEER SATHAYE, DARRIN POCHAN, Department of Materials Science and Engineering, University of Delaware, POCHAN GROUP TEAM — Hydrophobic collapse of amphiphilic -hairpin peptides (e.g. MAX1 VKVKVKVKV^DPPTKVKVKVKV-NH₂) into fibrils and their hierarchical assembly into branched, hydrogel networks has been extensively studied. A physically crosslinked hydrogel network is formed due to fibrillar entanglement and branched defects in hydrophobic collapse during fibril formation. Alternating valine residues with side chains of the same size are responsible for the hydrophobic collapse of the molecule into a b-hairpin and fibril nanostructure with branching. In a new sequence LNK1 (LNK1 (Nal)K(Nal)KAKAKV^DPPTKAKAK(Nal)K(Nal)-NH₂) the non-beta turn valines were replaced with Naphthylalanine and alanine amino acid residues, with hydrophobic side chains of larger and smaller volume, respectively, than valine. Thus, formation of a “lock and key” type structure was attempted in the hydrophobic core of the peptide fibrils that would eliminate fibril branching. The folding and network formation of LNK1 has been studied by Circular Dichroism spectroscopy (CD), Transmission Electron Microscopy (TEM) and Oscillatory Rheology. Preliminary rheological characterization suggests the elimination of branching in the fibrils and also a possibility that LNK1 networks, unlike MAX1, are just nanofibrillar suspensions rather than permanently physically crosslinked hydrogels.

10:36AM A47.00014 Bond orientational order in randomly-packed colloidal spheres¹, ELI SLOUTSKIN, ALEXANDER BUTENKO, Physics Department, Bar-Ilan University — Systems of jammed particles are abundant, yet poorly understood. These systems are often naively assumed to be disordered, such that only short-range correlations are present and all spatial directions are equivalent. Yet, the mechanical stability of these materials implies that a network of mechanical forces percolates through the sample, which may give rise to long-range correlations and symmetry breaking. We directly measure, by confocal microscopy, the positions of hard colloids, which are sedimented by centrifugation, to form a jammed matter. We follow the centrifugation process in motion, measuring the density profile of our particles along the sample. Strikingly, while only short-range positional order exists in our system, both in the fluid and in the jammed state, the orientations of the bonds between the nearest neighbors are correlated in the jammed state, throughout the system. This breaks the rotational symmetry of the jammed state. Moreover, the rotational symmetry is correlated with the direction of gravity, suggesting that the mechanical network of forces plays an important role in our system. This breaking of rotational symmetry, observed in our system, must have an impact on a wide range of properties in other, more complex, randomly packed systems.

10:48AM A47.00015 Anharmonicity in Amino Acids¹, HERCULANO MARTINHO, THAMIRES LIMA, MARIANA ISHIKAWA, Universidade Federal do ABC — Two special dynamical transitions of universal character have been recently observed in macromolecules (lysozyme, myoglobin, bacteriorhodopsin, DNA, and RNA) at $T^* \sim 100 - 150$ K and $T_D \sim 180 - 220$ K. The underlying mechanisms governing these transitions have been subject of debate. In the present work it is reported a survey on the temperature dependence of structural, vibrational and thermodynamical properties of a nearly anhydrous amino acid (orthorhombic polymorph of the amino acids L-cysteine and L-proline at a hydration level of 3.5%). The temperature dependence of X-Ray diffraction, Raman spectroscopy, and specific heat were considered. The data were analyzed considering amino acid-amino acid, amino acid-water, and water-water phonon-phonon interactions, and molecular rotors activation. Our results indicated that the two referred temperatures define the triggering of very simple and specific events that govern all the interactions of the biomolecule: activation of CH_2 rigid rotors ($T < T^*$), phonon-phonon interactions between specific amino acid and water dimer vibrational modes ($T^* < T < T_D$), and water rotational barriers surpassing ($T > T_D$).

Monday, February 27, 2012 8:00AM - 11:00AM – Session A48 DPOLY: Charged and Ion-Containing Polymers 161

8:00AM A48.00001 Influence of Plasticizer on Ion Aggregation in Single-ion Polymer Conductors, HANQING ZHAO, DAN KING, PAUL PAINTER, RALPH COLBY, JAMES RUNT, Penn State University — In this study, we add a miscible small molecule plasticizer to a polyester copolymer ionomer. The latter is synthesized from oligomeric polyethylene oxide (molecular weight = 600) separated by the lithium salt of 85 percent sulfonated dimethyl isophthalate units. Materials with different plasticizer contents are systematically investigated by FTIR spectroscopy, X-ray scattering and dielectric spectroscopy. Decreased T_g and a corresponding Increase in cation mobility are expected in these plasticized systems. Ionic conductivity depends on both the number of ions and their mobility, which in turn depends on the relationship between ion states (free ions, ion pairs and ion aggregates). With FTIR, we characterize and quantify the ionic structures in order to investigate how their ratio changes with plasticizer content. X-ray scattering reveals the change in ion aggregation. Further, dielectric spectroscopy is used to study ion conductivity and polymer dynamics of these materials.

8:12AM A48.00002 Atomistic molecular dynamics simulations of model ionomers, DAN BOLINTINEANU, MARK STEVENS, AMALIE FIRSCHKNECHT, Sandia National Laboratories — Ionomers are polymers that contain a small fraction of ionic groups. Due to their unique electrical properties, ionomers are being investigated as potential solid electrolytes in mobile battery applications. However, a lack of fundamental understanding of the relationship between ionomer chemistry, morphology and ion transport have hindered such efforts. To this end, we report atomistic molecular dynamics (MD) simulations of a model ionomer (polyethylene-co-acrylic acid) neutralized with different ions at various neutralization levels. The structure factor computed from the simulations is in good agreement with experimental X-ray scattering data, which provides strong validation of the simulation methods. Our simulations provide additional insight into the shape and size distribution of ionic clusters; in particular, we observe large networks of string-like clusters, and report quantitative features of these structures as a function of ionic group spacing in the polymer backbone, counterion type and neutralization level. We also investigate several features of ion transport in these systems. Since ion diffusion is slow relative to the time scales accessible to our simulations, we limit discussion to local, qualitative features of the ion transport mechanism.

8:24AM A48.00003 Weak polyelectrolytes grafted to nanoparticles and flat surfaces, STEPHEN BARR, ATHANASSIOS PANAGIOTOPOULOS, Chemical and Biological Engineering, Princeton University — The charge distribution on polyelectrolytes is a key factor which controls their conformation and interactions. In weak polyelectrolytes, this distribution is determined by a number of factors, including the solvent conditions and the local environment. We investigate this using grand canonical titration Monte Carlo simulations of a coarse grained polymer model. In this method, each polymer bead is able to change its ionization state based on its dissociation constant, the pH of the solution, and interactions with other particles in the system. We focus on a system of polymers with one end tethered to the surface of a nanoparticle and determine both the charge and the polymer conformation as the pH and solvent quality are varied. We compare the results to both a fixed charge model and to polyelectrolytes grafted to a flat surface.

8:36AM A48.00004 Large scale molecular dynamics study of polymer-surfactant complex, MONOJOY GOSWAMI, BOBBY SUMPTER, Oak Ridge National Laboratory, Oak Ridge, TN — In this work, we study the self-assembly of cationic polyelectrolytes mediated by anionic surfactants in dilute or semi-dilute and gel states. The understanding of the dilute system is a requirement for the understanding of gel states. The importance of polyelectrolyte with oppositely charged colloidal particles can be found in biological systems, such as immobilization of enzymes in polyelectrolyte complexes or nonspecific association of DNA with protein. With the same understanding, interaction of surfactants with polyelectrolytes shows intriguing phenomena that are important for both in academic research as well as industrial applications. Many useful properties of PE surfactant complexes come from the highly ordered structures of surfactant self-assembly inside the PE aggregate. We do large scale molecular dynamics simulation using LAMMPS to understand the structure and dynamics of PE-surfactant systems. Our investigation shows highly ordered ring-string structures that have been observed experimentally in biological systems. We will investigate many different properties of PE-surfactant complexation which will be helpful for pharmaceutical, engineering and biological applications.

8:48AM A48.00005 Near Edge X-ray Absorption Fine Structure Studies of Cu Ion-Containing PAMAMOS Dendrimer Networks, ROBERT BUBECK, PETAR DVORNIC, Michigan Molecular Institute, DANIEL FISCHER, NIST — There is continuing interest in the development of nanocomposites containing metal ions based on the use of dendrimers as the host matrix. One may utilize functionalized dendrimer interiors to complex the added constituent and serve as a template for the organization of the resulting nanoscale structures. Potential applications of include: catalysts, biotechnology, functional membranes, molecular sensors, etc. We report on recent results obtained using near edge X-ray absorption fine structure (NEXAFS) to characterize $\text{Cu}(2+)$ covalent interactions in three-dimensionally cross linked dendrimer networks. These networks were made from radially-layered poly(amidoamine-organosilicon), PAMAMOS, dendrimers having generation 4 (G4) polyamidoamine (PAMAM) interiors surrounded by one layer of organosilicon, OS, exterior branch cells. Lower generation homologues (i.e., G1 through G3) were also examined on a more limited basis. The nitrogen and carbonyl moieties contained in the PAMAM dendrimer interior were shown to be highly interactive with metallic cations, in large measure because of the dendrimer geometry. Similar measurements on chemically similar but much less physically constraining hyperbranched polymers indicated very limited interaction with the amine and carbonyl moieties.

9:00AM A48.00006 Mean-Field Modeling of the Encapsulation of Weakly Acidic Particles in Polyelectrolyte Dendrimers, THOMAS LEWIS, VENKAT GANESAN, University of Texas at Austin — The unique architecture of dendrimers has attracted interest in a wide-variety of biomedical applications such as drug delivery. Dendrimers act as covalent micelles and have been shown experimentally to internalize hydrophobic molecules inside their cavities. Moreover, many drugs of low water solubility are weakly acidic and have been shown to form complexes with polybasic dendrimers, with the encapsulation ability being dependent upon the solution pH. Furthermore, the grafting of neutral water soluble chains such as polyethylene glycol (PEG) have shown to increase the encapsulation of poorly soluble drug molecules. In order to gain insight into the equilibrium behavior of drug-dendrimer complexes, we have developed and numerically solved a Self-Consistent Field Theory approach for both grafted and non-grafted annealed charged dendrimer molecules in the presences of drug molecules. Specifically, this work examines the effect of drug size, dendrimer generation, grafting chain length, and solution pH upon dendrimer encapsulation abilities.

9:12AM A48.00007 Structure-Property Relationships in Precise Acid-Containing Polymers ,

FRANCISCO BUITRAGO, University of Pennsylvania, KATHLEEN OPPER¹, KENNETH WAGENER, University of Florida, KAREN WINEY, University of Pennsylvania, KAREN WINEY'S LAB TEAM, KENNETH WAGENER'S LAB TEAM — Acid-containing polymers have specific interactions that produce complex and hierarchical morphologies providing a remarkable combination of mechanical properties, namely being both dissipative and resilient. Despite the widespread industrial use of such materials, rigorous structure-property relationships remain elusive due to structural heterogeneity in the available copolymers. Recently, linear polyethylenes with pendent acid groups separated by a precisely controlled number of carbon atoms have been synthesized by acyclic diene metathesis (ADMET) polymerization. X-ray scattering shows that the molecular uniformity of these acid copolymers results in morphologies with nearly monodisperse acid aggregates and polyethylene crystals assembled in highly organized hierarchical structures. Taking advantage of these ordered morphologies to obtain well-defined mechanical data, we probe the elastic modulus, yield stress and second yield stress of precise acid-containing polymers as a function of the number of carbon atoms between acid groups, acid type (acrylic and phosphonic), and mono- or geminal acid functionalization.

9:24AM A48.00008 ABSTRACT HAS BEEN MOVED TO S1.00320 —

9:36AM A48.00009 Block copolymer ion gels for gas separation , YUANYAN GU, Department of Chemistry,

University of Minnesota, TIMOTHY LODGE, Department of Chemistry and Department of Chemical Engineering and Materials Science, University of Minnesota — Carbon dioxide removal from light gases (eg. N₂, CH₄, and H₂) is a very important technology for industrial applications such as natural gas sweetening, CO₂ capture from coal-fire power plant exhausts and hydrogen production. Current CO₂ separation method uses amine-absorption, which is energy-intensive and requires frequent maintenance. Membrane separation is a cost-effective solution to this problem, especially in small-scale applications. Ionic liquids have recently received increasing interest in this area because of their selective solubility for CO₂ and non-volatility. However, ionic liquid itself lacks the persistent structure and mechanical integrity to withstand the high pressure for gas separation. Here, we report the development and gas separation performances of physically crosslinked ion gels based on self-assembly of ABA-triblock copolymers in ionic liquids. Three different types of polymers was used to achieve gelation in ionic liquids. Specifically, a triblock copolymer ion gel with a polymerized ionic liquid mid-block shows performances higher than the upper bound of well-known "Robeson Plot" for CO₂/N₂.

9:48AM A48.00010 Transport and phase behavior in anion-conducting diblock copolymers ,

GUILLAUME SUDRE, Lawrence Berkeley National Laboratory, SEBNEM INCEOGLU, University of California, Berkeley , NITASH BALSARA, UC Berkeley and LBNL — Anion-exchange membranes can be used in various applications such as direct methanol fuel cells or devices for artificial photosynthesis. Consequently, these membranes have to conduct the anions efficiently, remain insoluble in water or methanol, and be impermeable to various gases. Block copolymers are good candidates to reach these aims. Their ability to self-assemble, particularly into bi-continuous phases, makes it possible to use one polycationic block that would conduct the anions, while a second neutral block can be designed as a structural block to insure the mechanical stability of the system. Our study focuses on the relationship between phase behavior and anion conductivity of diblock copolymers as a function of molecular weight, composition and cationic groups. We have chosen to use a model system made of styrene for the neutral block, and of chloromethylstyrene for the second block since it is easily cationizable with various functionalities, reacting easily with e.g. trimethylamine or n-butylimidazole. This model system is synthesized by nitroxide-mediated radical polymerization with molecular weights between 2 to 40 kg/mol and fractions of chloromethylstyrene in the range of 15-40 mol%. The results obtained from small-angle X-ray scattering showed lamellar morphologies for most systems. The temperature-dependence of the conductivity was assessed by performing measurements on membranes that were either immersed in water or in a controlled atmosphere at 98% of relative humidity.

10:00AM A48.00011 Polyelectrolyte Uptake by PEMs at High Salt¹ , DAVID HOAGLAND, Dept. of Polymer

Sci. and Eng., Univ. of Massachusetts Amherst, ZHAOHUI SU, BO PENG, XINGJIE ZAN, State Key Laboratory of Polymer Physics and Chemistry, Changchun Institute of Applied Chemistry — Upon a jump in salt concentration, a polyelectrolyte multilayer (PEM) constructed by the layer-by-layer process will swell, and in consequence, uptake from solution a large additional mass of the capping polyelectrolyte. Here, swelling and uptake are monitored in time by the quartz crystal microbalance with dissipation (QCM-D) method as a function of elevated salt concentration (0.75M<[NaCl]<2.5 M) during the uptake of poly(styrene sulfonate) (PSS, MW~70,000 g/mol) by poly(diallyldimethylammonium chloride)/PSS PEMs made at [NaCl]=0.5M. For [NaCl] less than ~1 M, PSS adds only at/near the PEM surface, while for higher [NaCl], PSS fully permeates the PEM, contributing a PSS mass approaching, even exceeding, that already present; higher salt concentration leads to faster and greater PSS uptake. Above [NaCl]=1.0 M, uptake is diffusive, characterized by surprisingly large and sharply [NaCl]-dependent diffusion coefficients (~10⁻¹⁴ – 10⁻¹² cm²/s). This uptake process opens a general opportunity for facile bulk and surface modifications of PEMs.

10:12AM A48.00012 Polyelectrolytes in Salt Solutions: Molecular Dynamics Simulations ,

ANDREY DOBRYNIN, JAN-MICHAEL CARRILLO, University of Connecticut — We performed MD simulations of polyelectrolyte solutions in the presence of salt. Polyelectrolyte solutions were modeled as an ensemble of chains of charged LJ particles with explicit counterions and salt ions. Our simulations have shown that in dilute and semidilute polyelectrolyte solutions the electrostatic chain persistence length scales with ionic strength as $I^{-1/2}$. This is due to counterion condensation on the polymer backbone. In dilute polyelectrolyte solutions the chain size decreases with increasing salt concentration as $R \propto I^{-1/5}$, which is in line with the scaling of the persistence length on the ionic strength, $l_p \propto I^{-1/2}$. In semidilute solution at low salt concentrations the chain size decreases with increasing polymer concentration, $R \propto c_p^{-1/4}$, while at high salt concentrations it is, $R \propto I^{-1/8}$. Our simulations confirmed that the peak position in the polymer scattering function scales with the polymer concentration in dilute polyelectrolyte solutions as $c_p^{1/3}$. In semidilute polyelectrolyte solutions at low salt concentrations the peak shifts towards larger values of $q^* \propto c_p^{1/2}$ while at high salt concentrations the peak location depends on the ionic strength as $I^{-1/4}$. The simulations confirmed a general scaling relations between a quantity $X(I)$ in salt solutions and corresponding quantity $X(I_0)$ in salt-free solutions, $X(I) = X(I_0)(I/I_0)^\beta$ with exponents; $\beta=-1/2$ for persistence length l_p , $\beta=1/4$ for solution correlation length, $\beta=-1/5$ and $\beta=-1/8$ for chain size R in dilute and semidilute solution, respectively.

10:24AM A48.00013 Electrostatic persistence length of flexible polyelectrolytes: resolving the controversy between theory and experiments , WEI QU, ERIK LUIJTEN, Northwestern University — The salt concentration

dependence of the electrostatic persistence length l_e of flexible polyelectrolytes has been the subject of extensive debate over the past two decades. Although theoretically a consensus has been reached regarding the correctness of the extension by Khokhlov and Khachaturian (KK) of the well-known Odijk-Skolnick-Fixman (OSF) theory to flexible polyelectrolytes, one crucial question remains: the strong disagreement between the OSF-KK prediction and various experimental observations. We present the results of extensive simulations of a flexible polyelectrolyte in solution to elucidate the origin of this discrepancy, and demonstrate that it originates from neglecting ionic excluded volume in the theoretical treatment.

10:36AM A48.00014 Layer-by-Layer Assembly of Charged Nanoparticles on Porous Substrates: Molecular Dynamics Simulations¹, JAN-MICHAEL CARRILLO, ANDREY DOBRYNIN, Institute of Materials Science and Department of Physics, University of Connecticut — We performed molecular dynamics simulations of multilayer assembly of oppositely charged nanoparticles on porous substrates with cylindrical pores. The film was constructed by sequential adsorption of oppositely charged nanoparticles in layer-by-layer fashion from dilute solutions. The multilayer assembly proceeds through surface overcharging after completion of each deposition step. There is almost linear growth in the surface coverage and film thickness during the deposition process. The multilayer assembly also occurs inside cylindrical pores. The adsorption of nanoparticles inside pores is hindered by the electrostatic interactions of newly adsorbing nanoparticles with the multilayer film forming inside the pores and on the substrate. This is manifested in saturation of the average thickness of the nanoparticle layers formed on the pore walls with increasing number of deposition steps. The distribution of nanoparticles inside cylindrical pore was nonuniform with significant excess of nanoparticles at the pore entrance.

10:48AM A48.00015 Diffusion of Polyelectrolyte Chains within Multilayer Films, SVETLANA SUKHISHVILI, LI XU, ALIAKSANDR ZHUK, Stevens Institute of Technology, NJ 07030, JOHN ANKNER, Spallation Neutron Source, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA — Using a series of polycations synthesized by atom transfer radical polymerization, we investigate the relative importance of the effects of hydrophobicity, polymer charge density, and steric hindrance to charge pairing on chain dynamics within polyelectrolyte complexes (PECs) and within polyelectrolyte multilayer (PEM) films. First, by applying fluorescence correlation spectroscopy (FCS), ellipsometry and fluorescence recovery after photobleaching (FRAP), we found that the dynamics of chain exchange within PECs is directly correlated with the mode (linear vs. exponential) of PEM film growth. Second, through a combination of neutron reflectometry (NR) and FRAP techniques to the same PEM types, we found that diffusion of polyelectrolyte chains within multilayer films is highly anisotropic, with diffusion coefficients being 10^4 - 10^5 higher in a direction parallel to the substrate compared to that perpendicular. Chain mobility was also controlled by ionic strength of annealing solutions and steric hindrance to ionic pairing of interacting polyelectrolytes.

This work was supported by the National Science Foundation under Award DMR-0906474 (S.S.). Neutron measurements were performed at the Spallation Neutron Source at the Oak Ridge National Laboratory, managed by UT-Battelle, LLC, for the DOE under contract No. DE-AC05-00OR22725.

Session A49 DPOLY: Focus Session: Long-time, Entangled Dynamics in Polymers - Linear, Transient, Non-linear Rheology, Tubes 162A

8:00AM A49.00001 Microscopic theory of the tube confinement potential and relaxation of entangled needle liquids under stress, DANIEL SUSSMAN, KEN SCHWEIZER, University of Illinois at Urbana-Champaign — We have developed a first-principles theory of the transverse confinement potential in an entangled needle fluid based on exactly enforcing uncrossability at the two-rod level while self-consistently renormalizing many-particle effects [Sussman & Schweizer PRL 107, 078102 (2011); J. Chem. Phys. 135, 131104 (2011)]. The predicted tube radius and long-time diffusion constant are consistent with the asymptotic reptation scaling laws under quiescent conditions, but in contrast with the usual tube model strong anharmonicities soften the confinement potential in a manner that quantitatively agrees with experiments on heavily entangled F-actin solutions. This weakening of entanglement constraints has multiple dramatic consequences under applied deformation: tube dilation, accelerated reptation, reduction of the transverse entropic barrier, and a critical stress or strain beyond which tube localization is destroyed. The degree-of-entanglement-dependent competition between reptative and transverse-hopping relaxation is established as a function of stress and strain. A mapping between rigid rods and flexible chain systems is also proposed, allowing predictions to be made for the tube diameter, entanglement onset, and transport properties of chain polymer liquids.

8:12AM A49.00002 Rheology of linear monodisperse polyethylene melts from atomistic Molecular Dynamics simulations¹, NIKOS KARAYIANNIS, Institute of Optoelectronics and Microsystems (ISOM) and ETSII, Polytecnic University of Madrid (UPM), Spain, JORGE RAMIREZ, Department of Chemical Engineering, ETSI Industriales, Polytecnic University of Madrid (UPM), Spain, ALEXEI LIKHTMAN, Department of Mathematics, University of Reading, United Kingdom — In our contribution we present results from very long, Molecular Dynamics simulations of linear monodisperse polyethylene (PE) chains with lengths ranging from 0.5 to 18 entanglements. We adopt a hierarchical modeling approach: in the first step we employ Monte Carlo simulations consisting of chain-connectivity altering algorithms to ensure full scale equilibration. Secondly, massive parallel MD simulations are conducted in the canonical ensemble. Besides the standard dynamical information, the stress relaxation curves are calculated for all PE systems. By bridging present atomistic results with the tube theory through the newly-introduced slip-spring model [Likhtman, Macromolecules 38, 6128 (2005)] we are able to calculate the plateau modulus and viscosity for well entangled, industrially relevant PE melts. In all cases, comparison between available experimental data and present simulation findings reveals a very good to excellent agreement. The proposed multi-scale methodology is generally applicable and can be extended to polymers of different molecular architecture and chemical constitution, as well as blends and more complex interfacial systems.

8:24AM A49.00003 Intermolecular constraints in the dynamics of semiflexible entangled polymer melts, MARINA GUENZA, University of Oregon — We present a Langevin equation for the contemporary dynamics of a group of interpenetrating semiflexible entangled polymer chains. The theory explicitly accounts for the intermolecular intermonomer repulsion between a pair of chains, generated by their inability to cross each other, i.e. the phenomenon of entanglements. The “effective” potential experienced by the chains arises from the repulsion between two monomers belonging to different chains, propagating through the chain connectivity, and the dynamics of chain interdiffusion and relaxation. With time the local hard-core potential is overcome by the relative motion of the polymers and the system relaxes. The same formalism applies to both unentangled and entangled melts. Short chains do not experience entanglements, because their relaxation process is faster than the average time that is necessary for the chain to diffuse a distance comparable to the mesh size, or length between two entanglements. Finally no a priori hypothesis has to be made about the processes that drive relaxation as the formalism is simply the conventional Rouse approach, generalized to treat the motion of interacting macromolecules, whose chains cannot cross each other.

8:36AM A49.00004 Long-Time Dynamics in Polymers: Experimental Results¹ , SINDEE SIMON, Department of Chemical Engineering, Texas Tech University — The long-time dynamics in several polymeric systems have been investigated with a focus on the relationship between the bulk and shear viscoelastic responses. Materials studied include polystyrene, a three-arm star polystyrene, and two polycyanurates of different crosslink densities. A custom-built pressurizable dilatometer has been used to measure the time-dependent bulk modulus, as well as the pressure-volume-temperature behavior in these materials. The temperature-dependent shift factors are used to test the TV⁷ thermodynamic scaling law proposed in the literature for segmental relaxation times. The thermodynamic scaling law successfully reduces the data for all of the materials; however, $T - T_g$ scaling also successfully reduces the data and differences in implications of the two scaling approaches will be discussed. Comparison of the retardation spectra for the bulk and shear responses shows that at extremely long times, the chain mechanisms available to the shear response are not available to the bulk; for times related to the glassy dynamics, the two responses have similar slopes, indicating that they may have similar underlying molecular mechanisms, but the magnitudes are different, a finding that remains to be explained.

¹Funding from the National Science Foundation DMR-0606500

9:12AM A49.00005 Tube Dynamics of Mildly Entangled Polymers: Semiflexibility Effects , JIAN QIN, SCOTT MILNER, Dept. of Ch. E. at Penn. State Univ., USA, PAVLOS STEPHANOPOULOS, Dept. of Math. & Stat. at Univ. of Cyprus, Cyprus, VLASIS MAVRANTZAS, Dept. of Ch. E. at Univ. of Patras, Greece — The prevailing theory of polymer rheology rests on a careful analysis of tube dynamics, tested by comparing predicted rheological response functions to experimental measurements. We provide a direct test of this theory by analyzing the tube dynamics of recently simulated mildly entangled polyethylene melt. The tube dynamics is obtained by defining the tube primitive path, *i.e.*, the tube center line, as the short-time average of molecular dynamics trajectories, and by monitoring how the tangent-tangent correlations evolve with time. It was found that the tube is semiflexible, and that the tube relaxation rate obtained from simulation results cannot be accounted for by the prevailing theory, since the effect of contour length fluctuations built into the theory is too strong. This discrepancy is particularly relevant to the mildly entangled system. To fix this, we incorporated semiflexibility into the theory, which was originally designed for flexible tubes, and found that the corrected theory describes the simulation results nearly quantitatively.

9:24AM A49.00006 A critical analysis of typical assumptions in the theory of entangled polymer dynamics in elongational flows , MARAT ANDREEV, RENAT KHALIULLIN, JAY SCHIEBER, Illinois Institute of Technology, Department of Chemical and Biological Engineering — The discrete slip-link model (DSM) was developed to describe the dynamics of entangled polymer melts of arbitrary chain architecture in arbitrary deformation. The model is able to predict linear viscoelasticity of monodisperse linear, polydisperse linear and star-branched systems. The model also shows good agreement with dielectric relaxation experiments. In this work we apply DSM to non-linear flows of monodisperse linear polystyrene and polyisoprene melts without any adjustable parameters. Model predictions for shear flow agree very well with experimental results. The DSM is able to capture the transient response as well as the steady state viscosity. However, for elongational flow, agreement is unsatisfactory at large strains. We explore a number of simplifications of the model and their effect on flow predictions, including: finite extensibility, convective constraint release and activation of dangling ends. Only after discarding all approximations and assumptions as a source of discrepancy between DSM predictions and experimental data can we conclude whether additional physics concepts are necessary to describe non-linear rheology of entangled polymer melts.

9:36AM A49.00007 Exploring the role of long-chain branching in large deformation of entangled melts , GENGXIN LIU, Department of Polymer Science , University of Akron, Akron, OH, United States, KWSTAS NTETSIKAS, APOSTOLOS AVGEROPOULOS, Department of Materials Science and Engineering, University of Ioannina, Ioannina, Greece, SHI-QING WANG, Department of Polymer Science , University of Akron, Akron, OH, United States, UNIVERSITY OF AKRON COLLABORATION, UNIVERSITY OF IOANNINA COLLABORATION — Most of our past studies have focused on nonlinear responses to large deformation of entangled polymers made of linear flexible chains. Little is known about nonlinear rheological behavior of entangled polymers containing long-chain branching (LCB), apart from the literature work on low-density polyethylene (LDPE). In this work, we present a first study to compare linear polyisoprene with a well-defined dendritic polyisoprene. Consistent with the extensional rheological behavior of LDPE, we find LCB to impede shear yielding so that the entanglement network could extend significantly more before failure during uniaxial extension. This study also investigated its shear deformation behavior to explain the absence of necking like failure in uniaxial extension. The research is funded, in part, by a grant from the National Science Foundation (DMR-1105135).

9:48AM A49.00008 Similarity and difference between simple shear and uniaxial extension of entangled polymers¹ , HAO SUN, SHI-QING WANG, Department of Polymer Science, University of Akron — There is ample evidence to show that the essential physics governing yielding of entangled polymers is the same, independent of the mode of deformation, *e.g.*, shear versus extension. In either of these two most commonly studied forms of deformation, the elastic retraction force associated with the chain deformation cannot grow without bound during continuous deformation. In practice, a transition from the initial dominantly elastic deformation to flow (irreversible deformation) inevitably takes place. Such yielding can produce strain localization in large deformation of well entangled polymer melts. Apart from the superficial difference related to the confusion about the “strain hardening” behavior, a true difference in the respective responses of entangled melts to shear and extension arises when the strain rate is sufficiently high. The entanglement network can still yield on its path to the eventual flow state upon startup shear. However, startup extension could cause the entanglements to lock in, and the melt undergoes rubber-like rupture instead of yielding. This presentation raises the question of whether shear is an intrinsically different deformation from uniaxial extension in the extremely high rate limit.

¹The research is funded, in part, by a grant from the National Science Foundation (CMMI-0926522).

10:00AM A49.00009 Large-deformation and long-time behavior of entangled melts in complex geometries , XIANGYANG ZHU, SHI-QING WANG, University of Akron — Recent particle-tracking velocimetric (PTV) observations have revealed strain localization either during startup shear beyond the stress overshoot or after a large step shear of entangled polymers [*e.g.*, *Macromolecules*, **42**, 6261 (2009)]. The physical pictures leading to these decohesion events have been put forward [J. Chem. Phys. **127**, 064903(2007); J. Rheol. **53**, 1389 (2009)]. In this presentation we apply the particle-tracking velocimetric method [Macromol. Mater. Engr. **292**, 15 (2007)] to study similar strain localization phenomena originating from yielding of the entanglement network in other forms of deformation including uniaxial extension, “squeeze flow” and extrusion of polymers from a wide open space into a narrow opening. The striking discontinuities in the velocity profile can all be understood in terms of a shear yielding criterion. The research is funded, in part, by a grant from the National Science Foundation (CMMI-0926522)

10:12AM A49.00010 Barrier to chain retraction: where we are six years after the first report of shear inhomogeneity in entangled polymers?¹, SHI-QING WANG, POUYAN BOUKANY, YANGYANG WANG, SHIWANG CHENG, Polymer Science, University of Akron — At APS2006, we reported the first PTV observations of macroscopic motions after shear cessation from step strain on an entangled polybutadiene solution (Macromolecules **2007**, 40, 8031). Since then we have shown that the classical polystyrene solutions display similar non-quiescent relaxation, invalidating the agreement between the data based on PS solutions and the Doi-Edwards damping function. Based on polymer melts we found that this network breakup phenomenon also occurs after a step strain produced with a rate that according to the tube model is too low to generate chain stretching (Macromolecules **2009**, 42, 6261). Does the current tube model possess the necessary ingredients to depict these findings? Here we present new experimental data that further supports the concept of a finite cohesion level for the entanglement network: There is a finite confining force that keeps chains engaged in the network, ensures the structural integrity and allows linear response behavior to take place. In contrast, the tube model perceives barrier-free chain retraction on the Rouse time for any amount of imposed strain, which would necessarily lead to destruction of the original network. Our experiments show that this does not appear to be the case.

¹This work is supported, in part, by a grant from NSF (DMR-0804726).

10:24AM A49.00011 Neutron Reflectivity Study of Interdiffusion of Ionomers into Van der Waals Polymer Thin Films, THUSITHA ETAMPAWALA, DILRU RATNAWEERA, SIDATH WIJESINGHE, DVORA PERAHIA, Department of Chemistry, Clemson University, Clemson, SC, JAROSLAW MAJEWSKI, Lujan Neutron Scattering Center, Los Alamos National Laboratory, Los Alamos, NM — The slow dynamic processes in amorphous ionic polymers are affected by physical cross-links resulting from clustering of the ionic groups. Therefore in addition to entanglement barriers, the motion of the polymers is coupled to the dynamics of the ionic clusters where the resulting dynamics is an interplay between the effects of the two types of barriers. Using neutron reflectometry we have probed a model system where interfacial diffusion of a Van der Waals polymer, polystyrene, into its sulfonated analogs. Results controlling the molecular weights that determine the overall number of entanglements as well as the degree of sulfonation which affects the strength and number of the ionic clusters will be presented. Comparison to the diffusion of polystyrene into polystyrene will resolve the effects of the ionic clusters from those of entanglements. The presence of the physical cross-links slows down the dynamics significantly with respect to that of polystyrene and an asymmetric process where the non-ionic blocks migrate into the ionic one is observed. Further rearrangements take place at a later stage.

10:36AM A49.00012 Development of Interfacial Strength and Entanglements During Welding of Polymers, TING GE, MARK O. ROBBINS, Johns Hopkins University, FLINT PIERCE, GARY S. GREEST, Sandia National Laboratories, DVORA PERAHIA, Clemson University — Thermal welding is a common means of joining polymer parts. Interfacial strength increases with welding time t_w as polymer chains diffuse across the interface. The microscopic origin of this interfacial strength enhancement was investigated with large scale molecular simulations employing a coarse-grained bead-spring model. Polymer surfaces were held together at a temperature well above the glass transition temperature T_g . States at t_w up to 10^9 time steps were then quenched to a temperature below T_g for mechanical tests. We test the interfacial strength by shearing the weld along a direction parallel to the interface. The maximum shear stress $\sigma_{\max}$ before failure is used to characterize the interfacial strength. We find that $\sigma_{\max}$ increases as $t_w^{1/4}$ before saturating to its bulk value. This agrees with previous experiments by a lap-joint shear method [1]. In addition, our analysis shows that the dominant shear failure mode changes from chain pull-out at the interface for small t_w , to chain scission for large t_w . We examine the average contour length $\langle l \rangle$ of chains that have diffused across the interface. As predicted by the reptation dynamics, $\langle l \rangle$ increases as $t_w^{1/4}$. We also track the evolution of entanglements using the *Primitive Path Analysis* (PPA) algorithm [2]. Our results show that the total number of interfacial entanglements is directly related to interfacial strength and also increases as $t_w^{1/4}$.

10:48AM A49.00013 Using the parallel plates geometry for nonlinear rheological measurements, ZAHRA FAHIMI, Institute for Complex Molecular Systems and Department of Mechanical Engineering, Eindhoven University of Technology, 5600 MB Ein, The Netherlands, CHASE P. BROEDERSZ, Lewis-Sigler Institute for Integrative Genomics and the Department of Physics, Princeton University, Princeton, NJ 08544, USA, HANS M. WYSS, Institute for Complex Molecular Systems and Department of Mechanical Engineering, Eindhoven University of Technology, 5600 MB Ein, The Netherlands — Conventional wisdom dictates that studying the mechanical response of viscoelastic materials in the nonlinear regime should be done either with a cone-plate or a Couette geometry, where the applied strain is homogeneous in the measuring volume. However, the use of parallel plates would have important advantages in a wide range of applications. For instance solid-like hydrogel materials can often be processed readily into flat films. We show that the nonlinear viscoelastic behavior can also be obtained from measurements in a parallel plate geometry. By tracing the torque response and its derivative with respect to the applied strain, we obtain a general stress strain relation, which indeed captures the proper material behavior. The approach does not require any assumptions for the material's viscoelastic behavior. We show practical examples different classes of soft materials to illustrate that our approach enables access to the full nonlinear response of these materials, including the detailed shape of the stress response in large amplitude oscillatory shear measurements. Our approach should be applicable to a wide range of soft materials, including hydrogels, colloidal suspensions, or biological tissues.

Session A50 DPOLY: Liquid Crystalline Order in Polymers, Soft Matter, and Complex Fluids

162B

8:00AM A50.00001 Shape Memory as a Process: Optimizing Polymer Design for Shape Recovery, RICHARD VAIA, HILMAR KOERNER, KYUNGMIN LEE, ROBERT STRONG, MATTEW SMITH, HUABIN WANG, TIM WHITE, LOON-SENG TAN, Air Force Research Laboratory — Shape memory is a process that enables the reversible storage and recovery of mechanical energy through a change in shape. Polymers provide a unique alternative to kinematic designs and other materials (e.g. metallic alloys) for applications requiring large deformation and novel control options. The effect control of storage and relaxation of strain energy associated with chain deformation depends on the nonlinear visco-elastic behavior and glassy dynamics of the polymer network. Considering the molecular understanding of rubbery elasticity, chain entanglements in concentrated polymer liquids, affine deformation of networks, and glass fragility, heuristic guidelines can be formulated to optimize the molecular design of a polymer for shape memory. These are applied to the development of a polymer system for shape memory processes at high-temperature (200°C). The low-crosslink density polyimide exhibits very rapid shape recovery, excellent fixity, high creep resistance, and good cyclability. Furthermore, the molecular design affords a very narrow temperature range for programming and triggering shape change that can also be accessed by photo-isomerization of the cross-link nodes.

8:12AM A50.00002 Shape and Memory in Liquid Crystalline Elastomers, ANSELM GRIFFIN, WANTING REN, PHILIP MCMULLAN, WHITNEY KLINE, MOHAN SRINIVASARAO, Georgia Tech — As part of an ongoing effort to understand the origins of shape memory in liquid crystalline elastomers (LCE), we have synthesized and examined a series of SmC main-chain LCEs. Uniaxial stretching of these polydomain films at room temperature produces a monodomain structure that can, upon removal of load, retain the monodomain and a significant level of strain. Although these films show ordinary elastic response at temperatures near the isotropization (clearing) temperature, at room temperature – far below the clearing temperature – the mechanical response is anelastic. Experimental studies of isothermal strain recovery vs time after unloading will be presented along with details of the temperature profile for strain recovery of these LCEs. A rationale for the shape memory behavior is proposed that involves moving of crosslink points in the smectic lamellar arrangement during the stretching event and trapping of these crosslinks in different positions at low temperatures. This trapping is driven by the chemical segregation of the crosslink points from the mesogenic unit which can be thermally overcome at elevated temperatures allowing full elastic recovery.

8:24AM A50.00003 Phase Behavior of Disk-Coil Macromolecules, YONGJOO KIM, EDWARD HA, ALFREDO ALEXANDER-KATZ, MIT — We explore the self-assembly of disk-coil macromolecules using Monte Carlo simulations in the NPT ensemble. Our study focuses on the role that coil length compared to the size of the disk has on the phase behavior of the system as well as the effect of stacking interactions between the disks. As a function of temperature T , we find a disordered phase at high T and lamellar, perforated lamellar, and cylinder phases at intermediate T . If we further lower the temperature, the disk-rich regions spontaneously order, and we find ordered lamellar, ordered perforated lamellar, and ordered cylinder phases depending on the strength of the stacking interactions. The appearance of any of these phases is, however, strongly dependent on the length of the coil. In addition to constructing a comprehensive phase diagram, we further analyze the correlations in the system, as well as the director vector field of the disks, and use it to construct an order parameter. We show that the latter changes drastically at the ordering transition points. We find that the ordered cylinder phase has a high degree of parallel packing. Our results are important to understand the self-assembly of supramolecular structures of disk-coil amphiphiles that are ubiquitous in nature, such as the chlorophyll molecule.

8:36AM A50.00004 Liquid Crystal Phases of Semiflexible Polymers, IAN MACKAY, DON SULLIVAN, University of Guelph — Liquid crystal polymers exhibit orientational order (nematic phase) and position order (smectic phase). Previous work on semiflexible polymers using self-consistent field theory studied the isotropic-nematic and nematic-smectic transition for homogenous and diblock copolymers. The nematic phase is stabilized by excluded-volume effects between wormlike cylindrical segments. The smectic phase is further stabilized by excluded-volume effects between terminal end segments. Because models of semiflexible polymers include orientational degrees of freedom, in addition to the usual positional degrees of freedom, they are computationally more demanding to study. Spectral decomposition applied to segment orientations has previously been used to make computation feasible. However this method does not converge well for strongly ordered states, which arise in many real systems. I describe a Crank-Nicolson finite difference method applied to the orientations which is expected to converge well for highly ordered systems. This method also exhibits better numerical stability and accuracy and may thus serve as a better foundation for further studies of highly ordered systems. I also describe a modification to the spectral method which can compute the tilted Smectic C phase.

8:48AM A50.00005 Photomechanical mechanism and structure-property considerations in the generation of photomechanical work in glassy, azobenzene liquid crystal polymer networks, KYUNG MIN LEE, Air Force Research Laboratory, Wright-Patterson AFB, NELSON TABIRYAN, BEAM Engineering for Advanced Measurements Company, TIMOTHY BUNNING, TIMOTHY WHITE, Air Force Research Laboratory, Wright-Patterson AFB — Azobenzene-containing polymeric materials have shown shape adaptive responses when irradiated with light. We contrast the photogenerated mechanical response of glassy, polydomain azobenzene liquid crystal polymer networks (azo-LCN) upon exposure to either UV or blue-green irradiation. The profound differences in the fundamental photomechanical response to exposure to light in these wavelength regimes are dictated by distinctive photochemical mechanisms, elucidated through UV/VIS spectroscopic examination of the materials before and after irradiation with UV and blue-green light. The glassy, photoresponsive polymeric materials were subjected to structure-property examination to ascertain the role of crosslink density, azobenzene concentration, and azobenzene connectivity (crosslinked or pendant) on the photomechanical output.

9:00AM A50.00006 Surface wrinkling in liquid crystal elastomer bilayers¹, ADITYA AGRAWAL, Rice University, PAUL LUCHETTE, Kent University, WALTER CHAPMAN, Rice University, PETER MUHORAY, Kent University, RAFAEL VERDUZCO, Rice University — Mechanically-induced surface wrinkling patterns, also known as strain-induced elastic buckling instability for mechanical measurements (SIEBIMM), represent a versatile and high throughput technique for thin film metrology. However, the technique requires clamping and mechanically straining bilayer samples, which can introduce errors and present challenges with small samples. Here, we present a modified approach in which thin films are deposited on top of a stimuli-responsive liquid crystal elastomer (LCE). Temperature changes induce a spontaneous and controllable shape-change in the LCE substrate, without the need for clamping or mechanically straining. We show that LCE bilayers can be used to accurately measure the modulus of nanoscale poly(styrene) films, down to 20 nm thick films. Furthermore, the surface wrinkle orientation can be controlled using different preparation methods and reoriented in a single sample with temperature changes only. In the case of thick (over 500 nm) PS films, the bilayer flexes in response to temperature changes. This work shows that LCE bilayers are useful systems for thin film metrology and controlled assembly using well-defined surface structures.

9:12AM A50.00007 Field-induced orientational order of liquid crystals in random environments¹, LENA LOPATINA, JONATHAN SELINGER, Liquid Crystal Institute, Kent State University — Over the last twenty years, there has been extensive theoretical and experimental work on liquid crystals in disordered polymer networks and other random environments. It was shown that the disordered environment disrupts the long-range order of the liquid crystal. Recently, D.-K. Yang has performed new experiments, in which an electric field is applied to the polymer-disordered liquid crystal, leading to a large Kerr effect, i.e. field-induced long-range orientational order [1]. This experimental approach offers new opportunities for liquid-crystal displays. To understand the experiments and improve the applications, we perform Monte Carlo simulations of a nematic liquid crystal in a disordered polymer network. These simulations show the formation of randomly oriented domains of uniform directors. We study the response to an applied field by calculating the Kerr coefficient for variable system parameters. Furthermore, using an Imry-Ma-like approach we predict the domain size as a function of temperature and material properties of the system, and estimate the induced orientational order parameter due to an electric field. The simulations and analytic results agree well with each other and with the experiments.

9:24AM A50.00008 Highly viscous liquid crystalline mixtures: the alternative to liquid crystalline elastomers, PETR SHIBAIEV, CRISTINA SCHLESIER, LEAH NEWMAN, SCOTT MCDONALD, Fordham University, Department of Physics — Novel highly viscous liquid crystalline materials based on mixtures of glass forming oligomers and low molar mass liquid crystals were recently designed [1, 2] and studied. In this communication the novel data are presented, the analysis and discussion are extended. It is shown that viscoelastic properties of the materials are due to the physical entanglements between cyclic oligomers and low molar mass mesogens, not due to the chemical crosslinks between molecular moieties. However, the mechanical properties of these viscoelastic materials resemble those of chemically crosslinked elastomers (elasticity and reversibility of deformations). The properties of chiral and non-chiral materials loaded with ferromagnetic nanoparticles are discussed in detail. Cholesteric materials undergo gigantic color changes in the wide spectral range under the deformation that allows distant detection of deformation and determination the anisotropy of deformation and its type. The materials doped with laser dyes become mechanically tunable lasers themselves and emit coherent light while pumped by external laser. A simple model is suggested to account for the observed effects; physical properties of the novel materials and liquid crystalline elastomers are compared and discussed.

9:36AM A50.00009 Linear aggregation and liquid crystalline ordering: from semi-flexible polymers to rigid rods¹, TATIANA KURIAKOVA, Brown University, ZACH KOST-SMITH, M.D. BETTERTON, MATTHEW A. GLASER, Colorado University, Boulder — Reversible self-assembly of filamentous aggregates is ubiquitous in soft matter and biophysics. Examples include worm-like micelles, patchy colloids, chromonic liquid crystals, DNA and RNA, and protein polymers and fibrils. These rod-like aggregates can form liquid-crystal (LC) phases; the liquid-crystal order then couples to the aggregation, promoting the formation of longer aggregates in the LC phases. We study the coupled aggregation and liquid crystalline ordering of a minimal system of sticky cylinders that interact primarily by hard-core interactions but can stack and bind end to end, making use of both analytic theory and Monte Carlo simulation. Accurate treatment of aggregate flexibility is essential for quantitative comparison of theoretical and experimental phase diagrams and other properties. Our analytic model describes aggregates as wormlike chains in an effective aligning nematic field, and allows self-consistent determination of this field within a density functional theory formalism over a broad range of aggregate flexibilities. We compare the analytic results for isotropic-nematic phase equilibrium with simulations performed in our group as well as similar work from the Sciortino group [De Michele et al., arXiv:1108.6135].

9:48AM A50.00010 Liquid Crystal Elastomer Motors¹, PETER PALFFY-MUHORAY, Liquid Crystal Institute, Kent State University, XIAOYU ZHENG, Dept. of Mathematical Sciences, Kent State University — Motors produce motion due to the transfer of energy, but not of momentum, to the device. In LCE motors, motion arises due to changes in the shapes of solid samples. Here we consider motors where the shape change is a bend, rather than an elongation or contraction. We focus on the light-driven motor of Ikeda et al.; we analyze in detail the physical mechanisms which bring about the motion, and discuss the momentum current which is generated. We present the results of numerical simulations, and compare these with experimental observations.

¹This work was supported under NSF DMR- 0606357.

10:00AM A50.00011 Orientational fluctuations of amorphous nematogenic solids, FANGFU YE, Georgia Institute of Technology, BING LU, University of Illinois at Urbana-Champaign, PAUL GOLDBART, Georgia Institute of Technology — Amorphous nematogenic solids (ANS) are media comprising rod-like nematogens that have been randomly linked to form elastically deformable macroscopic networks. Classes of ANS include chemical nematogen gels (i.e., networks of small molecules) and liquid crystalline elastomers (built from crosslinked nematogen-containing macromolecules), as well as biophysical networks such as those composed of actin filaments. We use a method inspired by the cavity approach to construct a replica free energy for these random systems, and investigate the correlations of the thermal fluctuations of the orientational alignment of the nematogens at spatially separated points. We identify two qualitatively distinct regimes: (a) a weakly localized regime, in which the correlations decay exponentially with separation; and (b) a strongly localized regime, characterized by correlations that also decay but oscillate as they do.

10:24AM A50.00013 Non-Monotonic Concentration Effects in the Phase Behavior and Nematic Orders: Mixtures of Side-Chain Liquid Crystalline Polymers and Low-Molecular-Weight Liquid Crystals¹, BILIN ZHUANG, ZHEN-GANG WANG, California Institute of Technology — Mixtures of side-chain liquid crystal polymers (SCLCPs) and low-molecular-weight liquid crystals (LMWLCs) are novel materials with applications such as optical data storage, non-linear optics, solid polymer electrolytes, chromatography and display materials. Recent experiments showed that the nematic-isotropic transition temperature and the nematic orders of each component vary non-monotonically with concentration. Existing theories, which combine the Flory-Huggins theory for isotropic mixing and the Maier-Saupe theory for nematic order, cannot explain such non-monotonicity. Here, we extend the existing theories by, first, incorporating the local steric constraints between the side-chain and the polymer backbone on the SCLCPs, and second, accounting for the crowding effects at high SCLCP concentrations. The new extended theory is able to resolve the discrepancies between the predictions of existing theories and the experimental observations.

10:36AM A50.00014 Effect of blending on nematic order in semiflexible polymers, KIRAN KHANAL, JUTTA LUETTNER-STATHMANN, Departments of Physics and Chemistry, University of Akron — Semiflexible polymers of sufficient stiffness exhibit liquid crystalline order at sufficient polymer concentrations. In this work, we investigate blends of flexible and semiflexible polymers with the aid of Monte Carlo simulations of a bond-fluctuation model. The model is an extension of Shaffer's bond-fluctuation model, where chain stiffness is controlled by including different forms of bending penalties, and includes attractive interactions between monomers. From simulations for a range of values of the bending energy, density, and temperature, we determine the effect of concentration of the flexible polymer on liquid crystalline order and domain formation.

Session A51 DCMP DFD: Colloids I: Beyond Hard Spheres Boston Convention Center 154

8:00AM A51.00001 Photonic Droplets Containing Transparent Aqueous Colloidal Suspensions with Optimal Scattering Properties, JIN-GYU PARK, SOFIA MAGKIRIADOU, Department of Physics, Harvard University, YOUNG-SEOK KIM, Korea Electronics Technology Institute, VINOTHAN MANOHARAN, Department of Physics, Harvard University, HARVARD UNIVERSITY TEAM, KOREA ELECTRONICS TECHNOLOGY INSTITUTE COLLABORATION — In recent years, there has been a growing interest in quasi-ordered structures that generate non-iridescent colors. Such structures have only short-range order and are isotropic, making colors invariant with viewing angle under natural lighting conditions. Our recent simulation suggests that colloidal particles with independently controlled diameter and scattering cross section can realize the structural colors with angular independence. In this presentation, we are exploiting depletion-induced assembly of colloidal particles to create isotropic structures in a millimeter-scale droplet. As a model colloidal particle, we have designed and synthesized core-shell particles with a large, low refractive index shell and a small, high refractive index core. The remarkable feature of these particles is that the total cross section for the entire core-shell particle is nearly the same as that of the core particle alone. By varying the characteristic length scales of the sub-units of such 'photonic' droplet we aim to tune wavelength selectivity and enhance color contrast and viewing angle.

8:12AM A51.00002 Curvature-Induced Capillary Interaction between Spherical Particles at a Liquid Interface¹, NESRIN SENBIL, CHUAN ZENG, BENNY DAVIDOVITCH, ANTHONY D. DINSMORE, University of Massachusetts Amherst — Capillary interactions among particles adsorbed at a fluid interface are important in a variety of natural and technological systems but still pose many mysteries. Capillary interactions induced by buoyancy, referred to as the "Cheerios" effect, have been studied for years. Here, we experimentally investigate how anisotropic interfacial shape affects capillary forces among millimeter-sized spheres. The Cheerios model predicts that particles with densities that are higher and lower compared to the fluids adsorbed at an initially flat interface will repel. Our experiments, however, clearly show that they can attract one another at the short range. We explain our results with a model, in which each sphere creates an anisotropic curvature at the position of the other sphere. To satisfy the constant contact-angle boundary condition, the interface is deformed with quadrupolar symmetry around each sphere. This quadrupolar deformation creates a short-ranged, attractive capillary force. The range of size and density ratios at which we observe a dominant short-range attraction is consistent with the model. Our results show how interfacial shape may be used to direct the assembly of interfacial particles.

8:24AM A51.00003 Using Micron-Sized Ellipsoids as a New Tool for Microrheology, DAVID C. KILGORE, KENNETH W. DESMOND, ERIC R. WEEKS, Emory University — Microrheology is a well-established technique, and in its simplest form it allows you to measure the viscosity of a fluid by examining the diffusion of microspheres, provided the diameter of the microspheres is known. We are developing a similar technique using ellipsoids, where the viscosity can be calculated without prior knowledge of the length and width of the ellipsoid. The asymmetry of ellipsoids provides a distinct advantage, allowing for the diffusion to be decomposed into two translational motions and one rotational motion. For each of these diffusive motions, we can measure a diffusion constant and relate the constant to the three unknowns: the length and width of the ellipsoid, and the viscosity. By measuring the three diffusion constants, we can determine the three unknowns. To verify this technique, we produce ellipsoids in the lab and suspend them in a viscous solution for three-dimensional imaging of the diffusion with a confocal microscope. We are able to get good agreement between the microrheological measurements and macroscopic viscosity measurements.

8:36AM A51.00004 Non-capillary binding of colloidal particles to liquid interfaces, DAVID KAZ, UC Berkeley, RYAN MCGORTY, UC San Francisco, VINOTHAN MANOHARAN, Harvard University — We observe colloidal polystyrene particles binding reversibly to an oil-water interface through the combination of a repulsive electrostatic force and an attractive van der Waals force. Previously studied interactions of an aqueous colloidal particle and a liquid interface have generally fallen into two categories: 1) electrostatic repulsion indicated by the dependence on salt and 2) capillary adsorption where surface tension brings the particle in contact with both phases and is indicated by practically irreversible binding. With our technique of pushing individual colloidal particles towards a planar oil-water interface and observing their motion in three-dimensions with holographic microscopy we have observed both interactions. However, our observations indicate that under certain conditions the electrostatic repulsion, which is due to repulsive image charges, is weak enough for a particle to experience a van der Waals attraction while strong enough to prevent a particle from penetrating the interface and becoming bound through capillary action. We observe individual particles transition between repulsive and attractive interactions with the interface suggesting that these colloidal particles have a heterogeneous surface charge.

8:48AM A51.00005 Memory effects in soap film arrangements, NICOLAS VANDEWALLE, STEPHANE DORBOLO, GEOFFROY LUMAY, JULIEN SCHOCKMEL, MARTIAL NOIRHOMME, GRASP, Institute of Physics B5a, University of Liege, B4000 Liege — We report experiments on soap film configurations in a triangular prism for which the shape factor can be changed continuously. Two stable configurations can be observed for a range of the shape factor h . A hysteretic behaviour is found, due to the occurrence of another local minima in the free energy. Experiments demonstrate that soap films can be trapped in a particular configuration being different from a global surface minimization. This metastability can be evidenced from a geometrical model based on idealized structures. Depending on the configuration, providing clues on the structural relaxations taking place into 3D foams, such as T1 rearrangements. The composition of the liquid is also investigated leading to dynamical picture of the transition. (Phys. Rev. E 83, 021403 (2011))

9:00AM A51.00006 Droplet-based microfluidics and the dynamics of emulsions, JEAN-CHRISTOPHE BARET, QUENTIN BROSSEAU, BENOIT SEMIN, XIAOPENG QU, Max-Planck Institute for Dynamics and Self-Organization, DROPLETS, MEMBRANES AND INTERFACES TEAM — Emulsions are complex fluids already involved for a long time in a wide-range of industrial processes, such as, for example, food, cosmetics or materials synthesis [1]. More recently, applications of emulsions have been extended to new fields like biotechnology or biochemistry where the compartmentalization of compounds in emulsion droplets is used to parallelise (bio-) chemical reactions [2]. Interestingly, these applications pinpoint to fundamental questions dealing with surfactant dynamics, dynamic surface tension, hydrodynamic interactions and electrohydrodynamics. Droplet-based microfluidics is a very powerful tool to quantitatively study the dynamics of emulsions at the single droplet level or even at the single interface level: well-controlled emulsions are produced and manipulated using hydrodynamics, electrical forces, optical actuation and combination of these effects. We will describe here how droplet-based microfluidics is used to extract quantitative informations on the physical-chemistry of emulsions for a better understanding and control of the dynamics of these systems [3].

9:12AM A51.00007 Pseudo-Steady Liquid Transport in Aqueous Foams during Filling of a Container, MICHAEL CONROY¹, RAMAGOPAL ANANTH², Naval Research Laboratory — Various applications of aqueous foams involve filling a container or a column (e.g., fractionation), where the foam is formed and processed. However, existing studies in the literature do not treat the filling stage and only describe liquid transport within a static foam bed. We developed a theory that predicts liquid loss from the foam and the liquid distribution within its interior during the filling and post-filling stages. During the filling stage, the theory predicts that the foam reaches a pseudo-steady state characterized by a time-independent drainage rate and liquid fraction. The pseudo-steady-state liquid fraction appears above a thin, liquid-saturated boundary layer that exists at the bottom of the foam bed. During the post-filling stage, the theory predicts that the drainage rate decreases with time, similar to static foams beds studied by others. The theory compares well with our previously reported volume-averaged macroscopic model and drainage measurements for dry (high-expansion) foams. We will show that drainage during the filling stage is significant when the fill time is comparable to the intrinsic drainage time scale of the foam.

9:24AM A51.00008 Coarsening of Two Dimensional Foams on a Curved Surface, ADAM ROTH, University of Pennsylvania, CHRIS JONES, Cornell University, DOUG DURIAN, University of Pennsylvania — We report on foam coarsening and statistics of bubble distributions in a closed, two dimensional, hemispheric cell of constant curvature. Using this cell it is possible to observe individual bubbles and measure their coarsening rates. Our results are consistent with the modification to von Neumann's law predicted by Avron and Levine. We observed the relative frequencies of bubbles with a given number of sides and found a shortage of bubbles with few sides as compared to a flat two dimensional cell. We also measured the value of $m(n)$, the average number of sides of an n sided bubble, and found general agreement with the Aboav-Weaire law, although there was greater deviation than for a flat cell.

9:36AM A51.00009 Analysis of emulsion stability in acrylic dispersions¹, SURESH AHUJA, Retired — Emulsions either micro or nano permit transport or solubilization of hydrophobic substances within a water-based phase. Different methods have been introduced at laboratory and industrial scales: mechanical stirring, high-pressure homogenization, or ultrasonics. In digital imaging, toners may be formed by aggregating a colorant with a latex polymer formed by batch or semi-continuous emulsion polymerization. Latex emulsions are prepared by making a monomer emulsion with monomer like Beta-carboxy ethyl acrylate (β -CEA) and stirring at high speed with an anionic surfactant like branched sodium dodecyl benzene sulfonates, aqueous solution until an emulsion is formed. Initiator for emulsion polymerization is 2-2'-azobis isobutyramide dehydrate with chain transfer agent are used to make the latex. If the latex emulsion is unstable, the resulting latexes produce a toner with larger particle size, broader particle size distribution with relatively higher latex sedimentation, and broader molecular weight distribution. Oswald ripening and coalescence cause droplet size to increase and can result in destabilization of emulsions. Shear thinning and elasticity of emulsions are applied to determine emulsion stability.

10:00AM A51.00011 Dynamics of charged particles in nonpolar solvent in response to an electric field, TINA LIN, DAVID WEITZ, Harvard University — In nonpolar solvent, surfactant molecules aggregate to form charge-stabilizing reverse micelles. This enables surface charging of colloidal particles suspended in nonpolar solvent. We investigate the dynamics of such charged particles in response to an externally applied electric field. By combining microfluidics and confocal microscopy, we directly visualize the transport of particles between two parallel electrodes. We use direct visualization to measure the electrophoretic mobility of each particle and determine the effect of added surfactant on the measured mobility. In addition, we find that the presence of surfactant has a significant effect on the transport dynamics of the charged particles.

10:12AM A51.00012 Controlling Aggregation in Non-Polar Asphaltene Suspensions Through Electrostatics, SARA HASHMI, ABBAS FIROOZABADI, Yale University — Asphaltenes, the most aromatic and largest molecular weight components of petroleum fluids, can undergo a liquid-liquid phase transition in conditions including highly non-polar environments. Phase separation begins with molecular association and proceeds to and through the colloidal length-scale until complete sedimentation or deposition. Non-ionic polymeric dispersants can stabilize asphaltenes at the colloidal scale in non-polar suspensions. We perform a variety of experiments which suggest that stabilization occurs by adsorption of dispersant onto the asphaltenes, truncating the progress of precipitation. In particular, dynamic light scattering (DLS) and phase-analysis light scattering (PALS) measurements indicate that electrostatic repulsion is responsible for stabilizing asphaltene colloids against further aggregation. Aggregation time increases exponentially with dispersant concentration, as expected for particles interacting through a combination of attractive dispersion forces and repulsive electrostatics. However, contrary to current understandings of electrostatic stabilization in non-polar systems, the charges in colloidal asphaltene suspensions seem to arise from the asphaltene colloids themselves rather than from dispersant micelles.

10:24AM A51.00013 The Electric Double Layer Structure Around Charged Spherical Interfaces¹, ZHENWEI YAO, MARK BOWICK, XU MA, Syracuse University — We derive a formally simple approximate analytical solution to the Poisson-Boltzmann equation for the spherical system via a geometric mapping. Its regime of applicability in the parameter space of the spherical radius and the surface potential is determined, and its superiority over the linearized solution is demonstrated. In addition, the influence of nonuniform surface potential on the electric double layer structure is studied for large spheres in the weak potential limit.

10:36AM A51.00014 ABSTRACT WITHDRAWN —

10:48AM A51.00015 First experimental determination of permanent and induced electric dipolar moments of colloidal cellulose nanocrystals dispersed in apolar solvents¹, BRUNO FRKA-PETESIC, BRUNO JEAN, LAURENT HEUX, CERMAV-CNRS — Scientists and industrialists show a growing interest for cellulose nanocrystals (CNCs) since these rod-like nanoparticles display excellent mechanical properties that make them perfect candidates for the design of high performance biobased composites. Furthermore, CNCs can be obtained as colloidal suspensions in apolar solvents that form chiral nematic (cholesteric) liquid crystals. Our aim is to obtain homogeneous unidimensional structures to enhance the optical and/or mechanical properties of CNCs-based architectures at a macroscopic scale. Using electric fields, CNCs suspensions from either cotton or tunicate were successfully oriented in the direction of an electric field, in both AC and DC configurations. To probe the electric field induced orientation of the CNCs, a birefringence experimental set-up has been developed. While applying short electric DC field pulses, static and transient birefringence has been measured in diluted isotropic suspensions. From these measurements, we determined both the permanent and induced electric dipolar moments of the CNCs, whose effects appeared to be of the same order of magnitude. The results are discussed regarding to the CNC type and the apolar solvent used.

Monday, February 27, 2012 8:00AM - 11:00AM – Session A52 GSNP: Using Chaos to Control Quantum Systems 153C

8:00AM A52.00001 Regularization of tunneling rates in quantum chaotic systems, LOUIS PECORA, Naval Research Laboratory — Prototypical systems of two potential wells separated by a tunneling barrier exhibit the unexpected and counter-intuitive results that regular, non-chaotic systems have tunneling rates that fluctuate with energy dramatically over several orders of magnitude whereas the fully chaotic wells have orders of magnitude smaller fluctuations. All calculations were found from the Schrodinger equation using the Boundary Element Method. A random, plane wave theory explains the magnitude of the average tunneling rates as well as their fluctuations. We show that we can tune the amount of variance in tunneling rates by changing the shape of the quantum wells implying possible device design capabilities for nanodevices that operate in the electron ballistic regime.

8:36AM A52.00002 Relativistic quantum Darwinism in Dirac fermion and graphene systems, XUAN NI, Arizona State University, LIANG HUANG, Arizona State University; Lanzhou University, Gansu, China, YING-CHENG LAI, Arizona State University, LOUIS PECORA, Naval Research Laboratory — We solve the Dirac equation in two spatial dimensions in the setting of resonant tunneling, where the system consists of two symmetric cavities connected by a finite potential barrier. The shape of the cavities can be chosen to yield both regular and chaotic dynamics in the classical limit. We find that certain pointer states about classical periodic orbits can exist, which are signatures of relativistic quantum Darwinism (RQD). These localized states suppress quantum tunneling, and the effect becomes less severe as the underlying classical dynamics in the cavity is chaotic, leading to regularization of quantum tunneling. Qualitatively similar phenomena have been observed in graphene. A physical theory is developed to explain relativistic quantum Darwinism and its effects based on the spectrum of complex eigenenergies of the non-Hermitian Hamiltonian describing the open cavity system.

8:48AM A52.00003 Relativistic quantum chaos—an analytic Dirac equation approach¹, LIANG HUANG, HONGYA XU, School of Physical Science and Technology, Lanzhou University, YING-CHENG LAI, School of Electrical, Computer, and Energy Engineering, Arizona State University — Relativistic quantum chaos has attracted much attention since the discovery of graphene in 2004. Using graphene billiard as an apparatus of relativistic quantum particles, relativistic quantum scars, level spacing statistics, and relativistic quantum scattering have been widely investigated recently. However, since graphene has two non-equivalent Dirac points which can be coupled together by various processes, it has been wondered that whether the observed phenomena are inherent to the relativistic movement or caused by the discrete graphene lattice structure and boundary terminations. Based on Berry et al.'s work on neutrino billiards, we developed a conformal transformation method to solve the 2D Dirac equation in a confined region resembling chaotic billiards in the classical limit. This method solves both the eigen-energies and the eigen-wavefunctions of the 2D massless Dirac fermions. Level spacing statistics and relativistic quantum scars for a heart-shaped billiard are investigated and comparisons with graphene billiards are made.

9:00AM A52.00004 Using Local Perturbations To Manipulate and Control Pointer States in Quantum Dot Systems, RICHARD AKIS, GIL SPEYER, DAVID FERRY, Arizona State University, ROLAND BRUNNER, University of Leoben, Austria — Recently, scanning gate microscopy (SGM) was used to image scarred wave functions in an open InAs quantum dot[1]. The SGM tip provides a local potential perturbation and imaging is performed by measuring changes in conductance. Scarred wave functions, long associated with quantum chaos, have been shown in open dots to correspond to pointer states[2], eigenstates that survive the decoherence process that occurs via coupling to the environment. Pointer states modulate the conductance, yielding periodic fluctuations and the scars, normally thought unstable, are stabilized by quantum Darwinism [3]. We shall show that, beyond probing, pointer states can be manipulated by local perturbations. Particularly interesting effects occur in coupled quantum dot arrays, where a pointer state localized in one dot can be shifted over into another with a perturbation in a completely different part of the system. These nonlocal effects may perhaps be exploited to give such systems an exotic functionality. [1] A. M. Burke, R. Akis, T. E. Day, Gil Speyer, D. K. Ferry, and B. R. Bennett, Phys. Rev. Lett. 104, 176801 (2010). [2] D. K. Ferry, R. Akis, and J. P. Bird, Phys. Rev. Lett. 104, 176801 (2004). [3] R. Brunner, R. Akis, D. K. Ferry, F. Kuchar, and R. Meisels, Phys. Rev. Lett. 101, 024102 (2008).

9:12AM A52.00005 Periodic Orbit Scar in Propagation of Wave Packet, MITSUYOSHI TOMIYA, HIROYOSHI TSUYUKI, SHOICHI SAKAMOTO, Faculty of Science and Technology, Seikei University, ERIC HELLER, Department of Physics, Harvard University — The scar-like enhancement is found in the accumulation of the time-evolving wave packet in stadium billiard. The time-average of the absolute square of the time-evolving wave functions in the stadium billiard is investigated numerically and semiclassically. Nowadays nano- or subnano-sized devices are getting more and more available. This kind of dynamical properties is essential, when the devices actually work. The enhancement appears along an unstable periodic orbit, when the Gaussian wave packet is launched as the initial state along the orbit. Introducing the window function which is closely related to the eigenfunction expansion coefficients of the wave packet, the localization around the periodic orbit is clarified by the semiclassical approximation that it is due to essentially the same mechanism of the scar states in stationary states. The “smooothed” window function is well estimated by the intensity spectrum in Prof. Heller’s theory of the long-time semiclassical dynamics. The key parameters that determine its shape are actually classical quantities: the size of the initial wave packet and the Lyapunov exponent.

9:24AM A52.00006 Chaotic Ionization of Bidirectionally Kicked Rydberg Atoms, KORANA BURKE, Boston University, KEVIN MITCHELL, UC Merced, SHUZHEN YE, F. BARRY DUNNING, BRENDAN WYKER, Rice University — A highly excited quasi one-dimensional Rydberg atom exposed to periodic alternating external electric field pulses exhibits chaotic behavior. The ionization of this system is governed by a geometric structure of phase space called a homoclinic tangle and its turnstile. We present and explain the results from an experiment designed to probe the structure of the phase space turnstile. We create time-dependent Rydberg wave packets, subject them to alternating applied electric fields (kicks), and measure the survival probability. We show that the survival probability of the electron depends not only on the initial electron energy, but also on the phase space position of the electron with respect to the turnstile—the portion of the electron wave packet inside the turnstile ionizes quickly, after one period of the applied field, while that portion outside the turnstile ionizes after multiple kicking periods. Finally, we use the turnstile geometry to explain the dependence of ionization on the kicking period. This procedure describes a very robust yet simple way to control chaotic ionization of an atomic system.

9:36AM A52.00007 Quantized Intrinsically Localized Modes¹, PETER RISEBOROUGH, Physics Department — We have calculated the quantized $n = 2$ breather spectra of both the β and the α Fermi-Pasta-Ulam lattices. The breather spectra are composed of resonances in the two-phonon continuum and branches of infinitely long-lived excitations. The non-linear attributes of these excitations become more pronounced at elevated temperatures. The calculated $n = 2$ breather and the resonance of the β -lattice hybridize and exchange identity at the zone boundary, and are in reasonable agreement with the results of previous calculations using the number conserving approximation. However, by contrast the breather spectrum the α -lattice couples resonantly with the single-phonon spectrum and cannot be calculated within a number conserving approximation. Furthermore we show that, for sufficiently strong non-linearity, the α -lattice breathers can be observed directly through the single-phonon inelastic neutron scattering spectrum. As the temperature is increased, the single-phonon dispersion relation for the α -lattice becomes progressively softer as the lattice instability is approached. We compare our theoretical results with the recent experimental observation of breathers in NaI by Manley *et al.*

9:48AM A52.00008 Using quantum chaos to control the production of bipartite entangled states, LOCK CHEW, Nanyang Technological University, NING CHUNG, National University of Singapore — Recently, we have shown that it is possible for the entanglement dynamics to depend on the global classical dynamical regime instead of the local classical behavior. We observe that as the corresponding classical system becomes more chaotic, the rate of entanglement production increases with the emergence of larger entanglement entropy in the steady state. This suggests that quantum chaos can be used to control the generation of highly entangled quantum states, which are typically more robust against the effects of decoherence from the environment. Furthermore, the dependence of our system on the global classical dynamical regime indicates that the mode of production is insensitive to errors in the preparation of the initial separable coherent states. In this talk, I will present our recent results of using the additional control of quantum squeezing to further enhance the entanglement of the dynamically generated quantum states. I will show that the concomitant application of quantum squeezing and quantum chaos leads to a more entangled state at a faster production rate relative to squeezing without quantum chaos.

10:00AM A52.00009 Entanglement Entropy and Entanglement Spectrum for Two-Dimensional Classical Spin Configuration, HIROAKI MATSUEDA, Sendai National College of Technology — In quantum spin chains at criticality, two types of scaling for the entanglement entropy exist: one comes from conformal field theory (CFT), and the other is for entanglement support of matrix product state (MPS) approximation. On the other hand, quantum spin-chain models can be mapped onto two-dimensional (2D) classical ones. Motivated by the scaling and the mapping, we introduce new entanglement entropy for 2D classical spin configuration as well as entanglement spectrum, and examine their basic properties in the Ising and the three-state Potts models on the square lattice. They are defined by the singular values of the reduced density matrix for a Monte Carlo snapshot. We find scaling relations of the entropy analogous to the CFT and the MPS results. At criticality, the spin configuration is fractal, and various sizes of ordered clusters coexist. Then, the original snapshot can be decomposed into a set of images, and they have different length scales, respectively. This is the origin of the scaling. Based on these observations as well as calculation of the entanglement spectrum, we conclude that the amount of information of only one snapshot at criticality is equal to that of 1D quantum critical systems.

10:12AM A52.00010 Fluctuation theorem for a double quantum dot coupled to a point-contact electrometer, YASUHIRO UTSUMI, Department of Physics Engineering, Faculty of Engineering, Mie University, DMITRI GOLUBEV, MICHAEL MARTHALER, GERD SCHOEN, Karlsruhe Institute of Technology, MIE UNIVERSITY, JAPAN COLLABORATION, KARLSRUHE INSTITUTE OF TECHNOLOGY, GERMANY COLLABORATION — We study the fluctuation theorem in single-electron sequential tunneling regime. We consider single-electron transport through a double quantum dot (DQD) monitored by a capacitively coupled quantum point-contact (QPC) electrometer. In this setup it is possible to perform a direction resolved real-time electron counting experiment. We derive the full counting statistics for the coupled DQD - QPC system and obtain the joint probability distribution of the charges transferred through the DQD and the QPC. We show that the joint probability distribution satisfies the fluctuation theorem for 4-terminal system. For two-terminal DQD, the effective temperature should be introduced to recover the fluctuation theorem. The system can be described by a master equation with tunneling rates depending of the counting fields and satisfying a generalized local detailed-balance relation. Furthermore, we derive universal relations between the non-linear corrections to the current and noise, which can be verified in experiment.

10:24AM A52.00011 Electromagnetic fluctuations in non-equilibrium: Casimir forces and heat transfer, MATTHIAS KRUGER, MIT, Department of Physics, 77 Massachusetts Ave, Cambridge, MA 02139, THORSTEN EMIG, Laboratoire de Physique Theorique et Modeles Statistiques, CNRS UMR 8626, Universite Paris-Sud, 91405 Orsay cedex, France, GIUSEPPE BIMONTE, Dipartimento di Scienze Fisiche, Universita di Napoli Federico II, Complesso Universitario MSA, Via Cintia, I-80126 Napoli, Italy and INFN Sezione, VLADYSLAV GOLYK, ALEXANDER MCCAULEY, MEHRAN KARDAR, MIT, Department of Physics, 77 Massachusetts Ave, Cambridge, MA 02139 — It is well known that quantum Casimir forces play an important role in micro- or nanostructures. Recently, the role of temperature in thermal non-equilibrium raised theoretical as well as experimental interest. If the objects are held at different temperatures, the interactions depend on all temperatures in the system, and show many effects which are absent in equilibrium. Additionally, the objects exchange thermal energy by electromagnetic fields, known as radiative heat transfer, which is fundamentally different from macroscopic cases described by the well known laws of Planck or Stefan-Boltzmann. We discuss recent theoretical progress describing such effects, and illustrate the dependence of both quantities on the shapes as well as the distances of the objects.

10:36AM A52.00012 A First-Principles Method of Determining van der Waals Forces in Dissipative Media¹, YI ZHENG, ARVIND NARAYANASWAMY, Department of Mechanical Engineering, Columbia University — Lifshitz theory of van der Waals (vdW) force and energy between two planar objects is strictly valid when the medium separating two planar objects is vacuum. Generalization of Lifshitz theory to the case when intervening medium is a dissipative material, as opposed to vacuum, is a surprisingly difficult undertaking because there is no expression for the electromagnetic stress tensor in dissipative materials. Here, we derive the expression for vdW energy and pressure in planar multilayered dissipative media by computing the work done in assembling the multilayered structure from its constituent thin films. In doing so, we avoid any calculations of the Maxwell stress tensor in any medium but vacuum. Even though this work has proven to be a corroboration of Dzyaloshinskii, Lifshitz, and Pitaevskii, it has thrown new light on our understanding of vdW forces and suggests that it should be possible to achieve the similar result for objects with arbitrary shapes.

¹This work has been funded partially by the National Science Foundation through Grant CBET-0853723.

10:48AM A52.00013 Heat radiation from long cylindrical objects, VLADYSLAV GOLYK, MATTHIAS KRUGER, MEHRAN KARDAR, Massachusetts Institute of Technology — The heat radiated by objects small or comparable to the thermal wavelength can be very different from the classical blackbody radiation as described by the laws of Planck and Stefan-Boltzmann. We derive methods based on scattering of electromagnetic waves to explore the dependence on size, shape, as well as material properties. In particular, we discuss the radiation from a long cylinder at uniform temperature, describing in detail the degree of polarization of the emitted radiation by nanowires and carbon nanotubes.

Monday, February 27, 2012 8:00AM - 11:00AM — Session A53 GSNP: Disordered and Glassy Systems I 153B

8:00AM A53.00001 The dependence of fragility of glass forming liquids on interparticle interactions and density, SRIKANTH SASTRY, SHILADITYA SENGUPTA, Jawaharlal Nehru Centre for Advanced Scientific Research, FREDERIC AFFOUARD, FILIPE VASCONCELOS, Universite Lille, JNCASR COLLABORATION — The fragility of a glass forming liquid quantifies the rapidity of the change in viscosity and relaxation times with temperature and is an important material property. We study the influence of interparticle interactions on the fragility of a set of model glass formers using computer simulations. We consider both the kinetic fragility, given by the temperature variation of relaxation times, and the thermodynamic fragility obtained by the temperature variation of the configurational entropy. The Adam-Gibbs relation describes the temperature variation of relaxation times in terms of the variation of the configurational entropy, and thus we expect the kinetic and thermodynamic fragilities to be consistent with each other. We however find that the kinetic fragility increases with increasing softness of the interaction potential, with thermodynamic fragility showing the opposite trend. We rationalize our results by considering the full form of the Adam-Gibbs relation, which requires knowledge in addition of the high temperature activation energies, and explore the role of recent ideas on the scaling of temperature and density in systems exhibiting behavior akin to those with inverse power law interactions.

8:12AM A53.00002 Frequency and Wavevector Dependence of the Atomic Level Stress-Stress Correlation Function in a Model Supercooled Liquid¹, VALENTIN A. LEVASHOV, JAMES R. MORRIS, TAKESHI EGAMI, University of Tennessee and Oak Ridge National Laboratory — Temporal and spatial correlations among the local atomic level shear stresses were studied for a model liquid iron by molecular dynamics simulation [PRL 106,115703]. Integration over time and space of the shear stress correlation function $F(r, t)$ yields viscosity via Green-Kubo relation. The stress correlation function in time and space $F(r, t)$ was Fourier transformed to study the dependence on frequency, E , and wave vector, Q . The results, $F(Q, E)$, showed damped shear stress waves propagating in the liquid for small Q at high and low temperatures. We also observed additional diffuse feature that appears as temperature is reduced below crossover temperature of potential energy landscape at relatively low frequencies at small Q . We suggest that this additional feature might be related to dynamic heterogeneity and boson peaks. We also discuss a relation between the time-scale of the stress-stress correlation function and the alpha-relaxation time of the intermediate self-scattering function $S(Q, E)$.

8:24AM A53.00003 Measuring Dynamical Facilitation in Supercooled Liquids and Related Materials, Yael Elmatad, Center for Soft Matter, Physics Department, New York University, New York NY USA, AARON KEYS, Chemistry Department, University of California, Berkeley, Berkeley CA USA and Lawrence Berkeley National Laboratory, Berkeley, CA USA — We provide a physical interpretation for excitation dynamics in kinetically constrained lattice models in the context of supercooled liquids and granular materials. Several physical quantities such as instanton times, onset temperatures, and particle displacement fields are derived. These quantities are used to interpret measurements of dynamical facilitation previously performed for atomistic and molecular supercooled liquids and granular materials. We show that these previous measurements provide strong evidence that dynamical facilitation plays a key role in glassy materials.

8:36AM A53.00004 Excitations are localized and relaxation is hierarchical in glass-forming liquids, AARON KEYS, LESTER HEDGES, Lawrence Berkeley National Laboratory, JUAN GARRAHAN, University of Nottingham, SHARON GLOTZER, University of Michigan, DAVID CHANDLER, University of California, Berkeley — For several atomistic models of glass formers, at conditions below their glassy dynamics onset temperatures, T_o , we use importance sampling of trajectory space to study the structure, statistics and dynamics of excitations responsible for structural relaxation. Excitations are detected in terms of persistent particle displacements of length a . At supercooled conditions, for a of the order of or smaller than a particle diameter, we find that excitations are associated with correlated particle motions that are sparse and localized, occupying a volume with an average radius that is temperature independent and no larger than a few particle diameters. We show that the statistics and dynamics of these excitations are facilitated and hierarchical. Excitation energy scales grow logarithmically with a . Excitations at one point in space facilitate the birth and death of excitations at neighboring locations, and space-time excitation structures are microcosms of heterogeneous dynamics at larger scales. This nature of dynamics becomes increasingly dominant as temperature T is lowered. We show that slowing of dynamics upon decreasing temperature below T_o is the result of a decreasing concentration of excitations and concomitant growing hierarchical length

8:48AM A53.00005 Anomalous properties of liquids for a family of models with short range tetrahedral interactions, SERGEY BULDYREV, Yesiva University, GIANCARLO FRANZESE, University of Barcelona — Liquids with tetrahedral symmetry of the first coordination shell often display anomalous thermodynamic and dynamic behavior. The main reason for these anomalies is that pressurizing such liquids leads to the disordering of this local symmetry by the particles migrating from the second to the first coordination shell. This in some case may lead to the increase of entropy upon pressurizing and consequently to the volume increase upon cooling. Molecular simulations of various models with tetrahedral symmetry are able to reproduce this anomalous behavior. We study a family of simple models in which we can gradually change the degree of tetrahedrality and investigate the associated changes of the phase diagram by discrete molecular dynamics. A molecule in these models consist of a hard sphere and four point particles attached to the center of the hard sphere by directional bonds arranged in tetrahedral geometry. Each of these four particles has a narrow attractive square well so that the particles belonging to different molecules can attract to each other. We also impose a condition which does not allow a point particle in one molecule to include in its attractive well more than one point particle belonging to different molecules. We investigate how the phase diagram of the system depends on the parameters of the models. None of these models has a liquid-liquid phase transition in the accessible region of the phase. However, adding weak attractive square well to the hard sphere, or wider weak attractive square wells to the point particles can create a liquid-liquid critical point. A comparison with other simple models of the anomalous liquids is made.

9:00AM A53.00006 Stretched-exponential relaxation and hidden power laws in a solidifying 2D liquid¹, ALEXANDER PATASHINSKI, Northwestern University, RAFAL ORLIK, Orlik-software LLC, Poland, ANTONI MITUS, Polytechnic University, Wroclaw, Poland, BARTOSZ GRZYBOWSKI, MARK RATNER, Northwestern University — In a 2D Lennard-Jones liquid, the number of particles keeping their memorized nearest neighbors is found to decay stretched-exponentially; the probability for a particle to keep the same 6 nearest neighbors for a time t can be fitted with a power law. Using the lists of nearest neighbors (nn -lists) as a topological order parameter, we studied the dynamics of the structure underlying these signature features of complexity in materials. The nn -changes randomly appear along the boundaries of better ordered blocks at a time scale of the order of particles vibration period; these boundaries, and the shapes of the blocks, perform a next time-scale random motion. Particles diffusion includes periods of slow and fast diffusion. We discuss the feed-back interactions between nn -changes, block boundaries motion, and orientation relaxation in the system.

9:12AM A53.00007 Sheared athermal soft-particle suspensions near jamming: dependence of effective diffusion on packing density and system size, KAMRAN KARIMI, CRAIG MALONEY, Carnegie Mellon University — We perform numerical simulations to study diffusion in a model bi-disperse frictionless athermal soft-particle suspension of disks in two dimensions (2D) using the so-called “mean field” version of Durian’s bubble model. We measure the effective transverse diffusion coefficient D_{eff} in shear flows at various volume fraction ϕ and shearing rate $\dot{\gamma}$. For $\phi > \phi_c$, where ϕ_c is identified with the random close packing limit, in the quasi-static limit, D_{eff} shows a pronounced linear system size dependence with very weak dependence on ϕ . For $\phi < \phi_c$, D_{eff} , in the quasi-static limit, increases with increasing ϕ and shows very little system size dependence. We discuss how the behavior of D_{eff} is related to non-trivial correlations in the spatial structure of the displacement fields *at long times* in the Fickian regime.

9:24AM A53.00008 Decoupling of Rotational and Translational Diffusion in Supercooled Colloidal Fluids¹, KAZEM V. EDMOND², Emory University, MARK T. ELSESSER³, New York University, GARY L. HUNTER, Emory University, HYUNJOO PARK, DAVID J. PINE, New York University, ERIC R. WEEKS, Emory University — Using high-speed confocal microscopy, we directly observe the three-dimensional rotational dynamics of rigid clusters of microspheres suspended in dense colloidal suspensions. The clusters are highly ordered packings of fluorescently-labeled PMMA particles, fabricated using a recently developed emulsification technique. Our colloidal suspensions serve as an excellent model of hard spheres, perhaps the simplest system with a glass transition, while the clusters probe the system’s local rotational and translational dynamics. Far from the colloidal liquid’s glass transition, both rotational and translational motion of the clusters are purely Brownian. However, in the liquid’s supercooled regime, we observe a decoupling between the two types of motion: as the glass transition is approached, rotational diffusion slows down even more than translational diffusion. The nature of the decoupling is in good agreement with theoretical predictions and experiments with molecular glass formers. Our observation supports the notion that supercooled liquids are not merely liquids with large viscosities but that diffusion takes place by fundamentally changed mechanisms.

9:36AM A53.00009 Thermodynamics versus network topology of network glasses, LE YAN, MATTHIEU WYART, Center for Soft Matter Research, Physics Department, New York University — Under cooling, the thermodynamics and the dynamics of super-cooled liquids are strongly correlated. The thermal evolutions of these quantities, characterizing the liquid fragility, depend greatly on the specific liquid considered. To date, there is no understanding of what controls these properties at a microscopic level. In chalcogenide glasses, the coordination of the covalent network can be changed continuously by varying their composition. Experiments show that as the coordination is increased, the jump of specific heat varies non-monotonically and is minimal at coordination near the Maxwell threshold where the covalent network becomes rigid. At such a composition the liquid is strong. We introduce a simplified model for the thermal evolution of networks that captures this observation.

9:48AM A53.00010 Elastic properties of compressed emulsions, IVANE JORJADZE, JASNA BRUJIC, NYU — Visualizing the packing of a dense emulsion in 3D as a function of the external pressure allows us to characterize the geometry and the local stress distribution inside this jammed system. We first test the scaling laws of the pressure and average coordination number over two orders of magnitude in density. We find deviations from theoretical exponents due to the non-affine motion of the particles. Second, we observe that the distribution of forces changes from a broad exponential at the jamming point to a narrower Gaussian-like distribution under high compression. Finally, we calculate the density of states from the measured force network in the approximation of a harmonic potential. Close to jamming, the number of low frequency modes is high, while the application of pressure shifts the distribution to higher frequencies, indicative of a rigid network. The confocal images reveal the structural features associated with the low frequency modes, as well as their localization within the packing. These data are then compared with published results from numerical simulations.

10:00AM A53.00011 Glassy Dynamics of Charge Density Waves in Chromium¹, HYEKYUNG KIM, JONATHAN LOGAN, University of Chicago, OLEG SHPYRKO, University of California San Diego, ERIC ISAACS, Argonne National Laboratory; University of Chicago — Charge-density waves provide theoretically tractable systems for exploring longstanding questions posed by the physics of elastic media in the presence of quenched disorder. Interaction of quenched pinning fields and phase elasticity of CDWs results in a complex energetic landscape of metastable states, which in turn gives rise to “glassy” phenomena such as aging and hysteresis. Using synchrotron x-rays we have observed aging of CDW order parameter Q in bulk chromium following thermal quench to out-of-equilibrium configuration. Although temperature stabilization occurs in under two minutes, Q relaxes exponentially over the course of hours toward metastable configurations that depend on sample history.

10:12AM A53.00012 Local collapse of the atomic cage in a liquid flow, TAKUYA IWASHITA, TAKESHI EGAMI, University of Tennessee — The local structure of a model glass under steady shear was studied by molecular dynamics simulation for both high ($T > T_g$) and low ($T < T_g$) temperature ranges. The local structure was presented in terms of the anisotropic pair-density function (PDF). We found that the local structure was strained over a limited range of distances, and the length-scale of the strained region was dependent on the strain rate, extrapolating to zero at a critical strain rate. A strong correlation between the local collapse, represented by cutting of the atomic bond, and the structural strain in the PDF was found. At low temperatures local failure happens in a serrated manner, caused mechanically by shear. At high temperatures the local failure occurs more randomly, which is governed by thermal fluctuation. An anomalous behavior was observed as temperature approaches to T_g . The results suggest that except for the supercooled state above T_g local failure occurs by cutting of a single bond. Only in the supercooled state multiple bonds have to be cut for flow to occur. A possible relation to the dynamic heterogeneity is discussed.

10:24AM A53.00013 Local Perturbation of Quasi Two-Dimensional Colloidal Glasses¹, KEVIN APTOWICZ, West Chester University, TIM STILL, KE CHEN, PETER YUNKER, ARJUN YODH, University of Pennsylvania — Colloids are promising and widely used model systems to investigate the phase behavior of matter at length scales and timescales accessible to optical microscopy. We utilize disordered quasi two-dimensional colloidal systems in the jammed state to study the properties of glasses. It was recently found in simulation and experiment that so-called 'soft spots', where low frequency quasi-localized modes concentrate, are the locations in glasses prone to rearrangements. Therefore, we utilize short laser pulses to perturb colloidal glasses locally. By varying the pulse intensity of the laser, the strength of the perturbation is tunable, which allows us to induce either elastic or plastic deformations in the glasses. With this experimental geometry in combination with video microscopy, we investigate the correlation between locally induced rearrangements in the colloidal glass and the location of soft spots determined from analysis of the system's vibrational eigenmodes. The dependence of the mechanical response of a glass on the local environment in terms of these dynamic heterogeneities and their persistence is discussed.

10:36AM A53.00014 X-ray investigation of colloidal glasses under shear, DMITRY DENISOV, TRIET DANG, Van der Waals-Zeeman Institute, University of Amsterdam, Netherlands, BERND STRUTH, Deutsches Elektronen-Synchrotron, Hamburg, Germany, PETER SCHALL, Van der Waals-Zeeman Institute, University of Amsterdam, Netherlands — Understanding glassification or dynamical arrest is one of the grand challenges of material science and is a topic of great current interest. It is a central observation in soft matter systems as well as glass forming molecular systems that – with increasing density or decreasing temperature – the motion of the particles or molecules slows down and eventually becomes arrested. Understanding this dynamical arrest as well as relaxations in the arrested state are fundamental problems, which to a large degree remain unanswered. We use a novel combination of rheological measurement and small angle x-ray scattering (at the synchrotron DESY in Hamburg) to study structure factor of dense suspensions under shear and during relaxation. The suspensions consist of silica particles 50nm in diameter. We observe clear changes of inter particles distances and configurations due to the different shear rates. Together with future dynamic x-ray measurements we aim to develop a universal scale-bridging understanding of dynamic arrest.

10:48AM A53.00015 Boundaries Matter for Confined Colloidal Glasses, GARY L. HUNTER, Emory University, KAZEM V. EDMOND, New York University, ERIC R. WEEKS, Emory University — We confine dense colloidal suspensions within emulsion droplets to examine how confinement and properties of the confining medium affect the colloidal glass transition. Samples are imaged via fast confocal microscopy. By observing a wide range of droplet sizes and varying the viscosity of the external continuous phase, we separate finite size and boundary effects on particle motions within the droplet. Suspensions are composed of binary PMMA spheres in organic solvents while the external phases are simple mixtures of water and glycerol. In analogy with molecular super-cooled liquids and thin-film polymers, we find that confinement effects in colloidal systems are not merely functions of the finite size of the system, but are strongly dependent on the viscosity of the confining medium and interactions between particles and the interface of the two phases.

Session A54 GSNP: Focus Session: Complex and Co-evolving Networks - Cascades in Networks

152

8:00AM A54.00001 Percolation of Double-Layer Networks with Different Topologies Under Random Attacks, DI ZHOU, JIANXI GAO, Center for Polymer Studies and Department of Physics, Boston University, SHLOMO HAVLIN, Mineva Center and Department of Physics, Bar-Ilan University, H.EUGENE STANLEY, Center for Polymer Studies and Department of Physics, Boston University — We report on the effects of topology on failure propagation models for systems consisting of two interdependent networks, which are either SF networks with different parameters, or different types of networks. Pairs of interdependent networks are known to exhibit a percolation transition upon failure accumulation. The topology of the nets significantly change the critical density of failure for the total disruption of the two net composite system. When the system is not fully coupled, the existence of a very small fraction of SF network will hold the system from fragment. When the critical threshold p_c doesn't change, robustness measure R is introduced. The consequences of the study may provide insights for future network architectures and their evolution to improve their robustness and enhancing the protection of critical infrastructure.

8:12AM A54.00002 Statistics of interacting networks with extreme preferred degrees: Simulation results and theoretical approaches¹, WENJIA LIU, BEATE SCHMITTMANN, R.K.P. ZIA, Virginia Tech Physics Dept — Network studies have played a central role for understanding many systems in nature - e.g., physical, biological, and social. So far, much of the focus has been the statistics of networks in isolation. Yet, many networks in the world are coupled to each other. Recently, we considered this issue, in the context of two interacting social networks. In particular, We studied networks with two different preferred degrees, modeling, say, introverts vs. extroverts, with a variety of "rules for engagement." As a first step towards an analytically accessible theory, we restrict our attention to an "extreme scenario": The introverts prefer zero contacts while the extroverts like to befriend everyone in the society. In this "maximally frustrated" system, the degree distributions, as well as the statistics of cross-links (between the two groups), can depend sensitively on how a node (individual) creates/breaks its connections. The simulation results can be reasonably well understood in terms of an approximate theory.

8:24AM A54.00003 Correlated multiplexity in random and co-evolving multiplex networks, JUNG YEOL KIM, KYU-MIN LEE, K.-I. GOH, I.-M. KIM, Korea Univ. — Nodes in a complex networked system often engage in multiple types of interactions among them; they form a *multiplex* network with multiple layers that can be interdependent and co-evolve. In many real-world complex systems, such multiple network layers are not randomly coupled but correlated. Such a correlated multiplexity can imprint nontrivial structural correlations in the multiplex network, which in turn can impact the dynamical processes on it. Here we present some recent results on the correlated multiplexity in multiplex networks. First we show how the correlated multiplexity can dramatically alter the giant component properties of multiplex random networks. Secondly we introduce an evolution model of co-evolving multiplex networks by generalizing the well-known Barabási-Albert-type model, to show how the co-evolution of network layers can induce and modulate the degree of correlated multiplexity.

8:36AM A54.00004 Cascades of overload failures in spatial networks¹, ANDREA ASZTALOS, SAMEET SREENIVASAN, BOLESŁAW SZYMANSKI, GYORGY KORNISS, Rensselaer Polytechnic Institute — Our daily life imposes increasing demands on infrastructural networks such as the power grid, transportation network, water supply, etc. Understanding the vulnerabilities of these systems is crucial to securing them. To this end, we study the effect of spatial constraints on network resilience against cascading overloads. Specifically, we consider distributed and shortest path flows on spatially embedded networks and study the model of cascading failures (Motter and Lai (2002)) triggered by the removal of a single or multiple nodes. We present results of intentional attacks on highly loaded and high degree nodes as well as a comparison between spatially concentrated and randomly distributed, multiple attacks.

¹Supported in part by DTRA.

8:48AM A54.00005 Multiplexity-facilitated cascade dynamics in networks, KYU-MIN LEE, Department of Physics and Institute of Basic Science, Korea University, CHARLES BRUMMITT, Department of Mathematics and Complexity Sciences Center, University of California, Davis, KWANG-IL GOH, Department of Physics and Institute of Basic Science, Korea University — Most complex network studies thus far have been focused on single-layer framework. It becomes increasingly clear, however, that many real-world complex systems are *multiplex* —nodes interact with multiple types of interactions (links) which coexist, co-depend, and co-evolve. The interplay of such multiplex interactions may confer nontrivial consequences on network dynamics. Here we present recent results on how such multiplexity affects cascade dynamics on networks. We found the cascade progression is greatly facilitated by multiplexity. Layers that are unable to achieve global cascades in isolation can cooperatively achieve them by multiplex coupling. Therefore, the multiplex network can be dramatically more vulnerable to global cascades than single-layer or simplex networks. Implication of these results on cascade prediction and control in social and economic dynamics is also discussed.

9:00AM A54.00006 Cascades of failures in various models of interdependent networks, SERGEY BULDYREV, BENJAMIN KADISH, NATHANIEL SHERE, MITCHEL AHARON, GABRIEL CWILICH, Yeshiva University — Complex networks appear in almost every aspect of science and technology. Recently an analytical framework for studying the percolation properties of interacting networks has been developed [1]. These studies however have several limitations. The real networks do are not randomly connected. They are often embedded into two dimensional space. The dependency links are not connecting nodes at random but have tendency to connect nodes with similar degrees, or nodes which are close to each other in Euclidian space. Moreover, the network failures may occur not only to the loss of connectivity but also due to overload of nodes with high betweenness. We have study these situations analytically and by computer simulations and found the conditions at which networks collapse in an abrupt first order like transition when the entire network becomes non-functional or fail gradually like in a second order transition as a greater fraction of nodes is removed in the initial attack or failure.

[1] **S. V. Buldyrev**, R. Parshani, G. Paul, H. E. Stanley, and S. Havlin, “Catastrophic cascade of failures in interdependent networks,” *Nature* **464**, 1025-1028 (2010)

9:12AM A54.00007 Robustness of a Network of Networks¹, JIANXI GAO², Boston University, SERGEY V. BULDYREV³, Department of Physics, Yeshiva University, H. EUGENE STANLEY, Boston University, SHLOMO HAVLIN⁴, Department of Physics, Bar-Ilan University, Israel — Network research has been focused on studying the properties of a single isolated network, which rarely exists. We develop a general analytical framework for studying percolation of n interdependent networks. We illustrate our analytical solutions for three examples: (i) For any tree of n fully dependent Erdős-Rényi (ER) networks, each of average degree $\bar{k}$, we find that the giant component $P_\infty = p[1 - \exp(-\bar{k}P_\infty)]^n$ where $1 - p$ is the initial fraction of removed nodes. This general result coincides for $n = 1$ with the known second-order phase transition for a single network. For any $n > 1$ cascading failures occur and the percolation becomes an abrupt first-order transition. (ii) For a starlike network of n partially interdependent ER networks, P_∞ depends also on the topology—in contrast to case (i). (iii) For a looplike network formed by n partially dependent ER networks, P_∞ is independent of n .

9:24AM A54.00008 Robustness of interdependent networks under targeted attack, XUQING HUANG, Center for Polymer Studies and Department of Physics, Boston University, JIANXI GAO, Department of Automation, Shanghai Jiao Tong University, SERGEY BULDYREV, Department of Physics, Yeshiva University, SHLOMO HAVLIN, Minerva Center and Department of Physics, Bar-Ilan University, H. EUGENE STANLEY, Center for Polymer Studies and Department of Physics, Boston University — When an initial failure of nodes occurs in interdependent networks, a cascade of failure between the networks occurs. Earlier studies focused on random initial failures. Here we study the robustness of interdependent networks under targeted attack on high or low degree nodes. We introduce a general technique which maps the targeted-attack problem in interdependent networks to the random-attack problem in a transformed pair of interdependent networks. We find that when the highly connected nodes are protected and have lower probability to fail, in contrast to single scale-free (SF) networks where the percolation threshold $p_c = 0$, coupled SF networks are significantly more vulnerable with p_c significantly larger than zero. The result implies that interdependent networks are difficult to defend by strategies such as protecting the high degree nodes that have been found useful to significantly improve robustness of single networks.

9:36AM A54.00009 Information Spreading in Context, DASHUN WANG, Center for Complex Network Research, Northeastern University, ZHEN WEN, HANGHANG TONG, CHING-YUNG LIN, IBM T.J. Watson Research Center, CHAOMING SONG, ALBERT-LASZLO BARABASI, Center for Complex Network Research, Northeastern University — Information spreading processes are central to human interactions. Despite recent studies in online domains, little is known about factors that could affect the dissemination of a single piece of information. In this paper, we address this challenge by combining two related but distinct datasets, collected from a large scale privacy-preserving distributed social sensor system. We find that the social and organizational context significantly impacts to whom and how fast people forward information. Yet the structures within spreading processes can be well captured by a simple stochastic branching model, indicating surprising independence of context. Our results build the foundation of future predictive models of information flow and provide significant insights towards design of communication platforms.

9:48AM A54.00010 Power-grid Network Partitioning and Cluster Optimization with Applications to Florida and Texas¹, PER ARNE RIKVOLD, IBRAHIM ABOU HAMAD, BRETT ISRAELS, Florida State University, SVETLANA V. POROSEVA, University of New Mexico — Cascading power-grid failures pose serious threats to lives and property, and it is desirable to contain them within a limited geographical area. One method to achieve this is Intelligent Intentional Islanding (I3): the purposeful partitioning of a grid into weakly connected “islands” of closely connected generators and loads. If such islands can be quickly isolated, the spread of faults can be limited. An additional constraint is that generating capacity and power demand within each island should be closely balanced to ensure self-sufficiency. I3 thus corresponds to constrained community detection in a network. After a matrix-based initial agglomeration of nearby loads and generators, we implement Monte Carlo simulated annealing to simultaneously optimize load-balance and internal connectivity of the resulting islands. The optimized network of islands is treated as a new network with the first-generation islands as the new nodes (“supergenerators” and “superloads”), and the same agglomeration and MC procedures are iteratively applied, reminiscent of real-space renormalization. Applications to the Floridian [1] and Texan high-voltage grids are demonstrated.

10:00AM A54.00011 Computational Analysis of Topological Survivability of Large-Scale Engineering Networks with Heterogeneous Nodes, SVETLANA POROSEVA, Mechanical Engineering, University of New Mexico — The scale and complexity of modern networks, their integration, and the size of population and businesses they have impact on, make their massive damage catastrophic for the society and economy. Such damage is usually caused by adverse events and is not considered by traditional design practices. In the modern society, the likelihood of adverse events has substantially increased. Therefore, there is a need in evaluating the ability of a network to survive such damage. As the network topology is a key factor to consider, the goal of our research is to develop computational tools for quantifying its effect on the network survivability. “Selfish” algorithm will be presented that addresses exponential-time complexity associated with the problem of generation and analysis of all fault combinations possible in a given network. The reduction of computational complexity is achieved by mapping an initial network topology with multiple sources and sinks onto a set of simpler smaller topologies with multiple sources and a single sink. Application to the Texas power grid will be considered.

10:12AM A54.00012 Cascading failures in interdependent lattice networks: from first order to second order phase transition¹, WEI LI, Center for Polymer Studies and Department of Physics, Boston University, Boston, MA 02215 USA, AMIR BASHAN, Department of Physics, Bar-Ilan University, Ramat-Gan 52900, Israel, SERGEY BULDYREV, Department of Physics, Yeshiva University, 500 West 185th Street, New York, New York 10033, USA, EUGENE STANLEY, Center for Polymer Studies and Department of Physics, Boston University, Boston, MA 02215 USA, SHLOMO HAVLIN, Department of Physics, Bar-Ilan University, Ramat-Gan 52900, Israel — We study a system composed of two interdependent lattice networks A and B, where nodes in network A depend on a node within a certain shuffling distance r of its corresponding counterpart in network B and vice versa. We find, using numerical simulation that percolation in the two interdependent lattice networks system shows that for small r the phase transition is second order while for large r it is a first order.

¹We wish to thank DTRA for financial support and Dr. Robin Burk for encouraging discussions. We acknowledge the partial support of this research through the Dr. Bernard W. Gamson Computational Science Center at Yeshiva College.

10:24AM A54.00013 Cascading behaviors in random directed dependency networks¹, YANQING HU, City College of New York Levich Institute and Department of Physics, AMIR BASHAN, SHLOMO HAVLIN, Department of Physics, Bar-Ilan University, Ramat-Gan 52900, Israel, HERNAN MAKSE, City College of New York Levich Institute and Department of Physics — Cascading behaviors have been studied only for some specific dependency network systems. In this paper, we present a more general and realistic network system with both random connectivity and directed dependency links. Using percolation approach, we obtained the universal boundaries among first order transition, second order transition and unstable regimes, which depend only on less than fourth moment of degree distribution and the fractions of zero and one directed dependency link nodes. Moreover, besides the connectivity degree distribution, we also find the final state of dynamical cascading process is determined by out degree distribution of directed dependency links, and the in degree distribution only influence cascading speed.

10:36AM A54.00014 Loops in hierarchical channel networks¹, ELENI KATIFORI, MARCELO MAGNASCO, Rockefeller University — Nature provides us with many examples of planar distribution and structural networks having dense sets of closed loops. An archetype of this form of network organization is the vasculature of dicotyledonous leaves, which showcases a hierarchically-nested architecture. Although a number of methods have been proposed to measure aspects of the structure of such networks, a robust metric to quantify their hierarchical organization is still lacking. We present an algorithmic framework that allows mapping loopy networks to binary trees, preserving in the connectivity of the trees the architecture of the original graph. We apply this framework to investigate computer generated and natural graphs extracted from digitized images of dicotyledonous leaves and animal vasculature. We calculate various metrics on the corresponding trees and discuss the relationship of these quantities to the architectural organization of the original graphs. This algorithmic framework decouples the geometric information from the metric topology (connectivity and edge weight) and it ultimately allows us to perform a quantitative statistical comparison between predictions of theoretical models and naturally occurring loopy graphs.

Monday, February 27, 2012 11:15AM - 2:15PM — Session B1 DAMOP: Atom Interferometry and New Techniques with Ultracold Atoms 203

11:15AM B1.00001 Low-temperature, high-density magneto-optical trapping of potassium using the open $4S \rightarrow 5P$ transition at 405 nm, DYLAN JERVIS, DAVID MCKAY, DAN FINE, GRAHAM EDGE, University of Toronto, JOHN PORCO-SIMPSON, University of California Santa Barbara, JOSEPH THYWISSEN, University of Toronto — We report the laser cooling and trapping of neutral potassium on an open transition. Fermionic ^{40}K is captured using a magneto-optical trap (MOT) on the closed $4S_{1/2} \rightarrow 4P_{3/2}$ transition at 767 nm and then transferred, with unit efficiency, to a MOT on the open $4S_{1/2} \rightarrow 5P_{3/2}$ transition at 405 nm. Because the $5P_{3/2}$ state has a smaller line width than the $4P_{3/2}$ state, the Doppler limit is reduced. We observe temperatures as low as $63(6) \mu\text{K}$, the coldest potassium MOT reported to date. The density of trapped atoms also increases, due to reduced temperature and reduced expulsive light forces. We measure a two-body loss coefficient of $\beta = 2 \times 10^{-10} \text{ cm}^3 \text{ s}^{-1}$, and estimate an upper bound of $8 \times 10^{-18} \text{ cm}^2$ for the ionization cross section of the $5P$ state at 405 nm. The combined temperature and density improvement in the 405 nm MOT is a twenty-fold increase in phase space density over our 767 nm MOT, showing enhanced pre-cooling for quantum gas experiments. A qualitatively similar enhancement is observed in a 405 nm MOT of bosonic ^{41}K .

11:27AM B1.00002 Four techniques to achieve deeper Fermi degeneracy in Fermi-Bose mixtures, ROBERTO ONOFRIO, Department of Physics and Astronomy, University of Padova and ITAMP, Harvard-Smithsonian Center for Astrophysics — The study of exotic superfluid phases of ultracold atoms requires the achievement of deeper Fermi degeneracy with respect to the one already available. I will describe four techniques for efficient sympathetic cooling of Fermi gases with a different species Bose gas: bichromatic optical dipole [1] and light-assisted magnetic trapping [2], quasi one-dimensional Fermi-Bose mixtures [3], and fast adiabatic cooling [4].

11:39AM B1.00003 Optimized sympathetic cooling of atomic mixtures via fast adiabatic strategies, STEPHEN CHOI, Department of Physics, University of Massachusetts, Boston, MA 02125, ROBERTO ONOFRIO¹, Dipartimento di Fisica Galileo Galilei, Universit  di Padova, Via Marzolo 8, Padova, Italy, BALA SUNDARAM, Department of Physics, University of Massachusetts, Boston, MA 02125 — The talk will explore the extent to which frictionless cooling techniques may be useful in sympathetic cooling of Fermi gases. It is argued that optimal cooling of an atomic species may be obtained by means of sympathetic cooling with another species whose trapping frequency is dynamically changed to maintain constancy of the Lewis-Riesenfeld adiabatic invariant, which in turn determines the temporal-profile of the changing frequency. An important motivating factor is that an usually undesired feature of these techniques, i.e., the fact that the atomic cloud does not increase its phase-space density and therefore its degeneracy, turns into a crucial asset when viewed from the perspective of maintaining the gas in the nondegenerate regime, thus making it an optimal coolant. Advantages and limitations of this cooling strategy are discussed, with particular regard to the possibility of cooling Fermi gases to a deeper degenerate regime. We also show that the links between the suggested method and quantum squeezing.

11:51AM B1.00004 Quantum degenerate Bose-Fermi mixture of chemically different atomic species with widely tunable interactions¹, JEE WOO PARK, CHENG-HSUN WU, IBON SANTIAGO, Massachusetts Institute of Technology, TOBIAS TIECKE, Harvard University, PEYMAN AHMADI, MARTIN ZWIERLEIN, Massachusetts Institute of Technology — We have created a quantum degenerate Bose-Fermi mixture of ²³Na and ⁴⁰K with widely tunable interactions via broad interspecies Feshbach resonances. Twenty Feshbach resonances between ²³Na and ⁴⁰K were identified. The large and negative triplet background scattering length between ²³Na and ⁴⁰K causes a sharp enhancement of the fermion density in the presence of a Bose condensate. As explained via the asymptotic bound-state model (ABM), this strong background scattering leads to a series of wide Feshbach resonances observed at low magnetic fields. Our work opens up the prospect to create chemically stable, fermionic ground state molecules of ²³Na-⁴⁰K where strong, long-range dipolar interactions will set the dominant energy scale.

12:03PM B1.00005 Condensate Fraction in a BEC Dimer, DAVID CAMPBELL, Boston University, HOLGER HENNIG, Harvard University, DIRK WITTHAUT, Max Planck Institute for Dynamics and Self-Organization, Goettingen — Recent experiments studying a Bose Einstein Condensate (BEC) in a two-mode system, equivalent to a “dimer,” have shown that many qualitative dynamical features of the BEC can be understood from motions in the underlying classical (two-dimensional) phase space (ϕ , z). Using a Bose-Hubbard model for the dimer, we focus on quantum deviations from motions in the classical phase space. We introduce a “quantum” phase space (QPS), which we define as the minimum condensate fraction $c(\tau; \phi, z)$ of initial coherent states (ϕ, z) in the time interval $[0, \tau]$. We find that lines of equal condensate fraction in the QPS do mimic the classical trajectories of constant energy in many respects, such that the QPS clearly reflects Josephson oscillations and self-trapping. However, novel quantum features beyond the classical description appear at finite time τ . These include symmetry breaking and enhanced $c(\tau; \phi, z)$ near the classical hyperbolic fixed point and along a ridge near the classical separatrix. These features of the QPS can be readily studied in current experiments.

12:15PM B1.00006 Resonant Hawking radiation in Bose-Einstein condensates¹, FERNANDO SOLS, IVAR ZAPATA, Universidad Complutense de Madrid (Spain), MATHIAS ALBERT, Universite de Geneve (Switzerland), RENAUD PARENTANI, Universite Paris-Sud, Orsay (France) — We study double-barrier interfaces separating regions of asymptotically subsonic and supersonic flow of Bose-condensed atoms [1]. These setups contain at least one black hole sonic horizon from which the analogue of Hawking radiation should be generated and emitted against the flow in the subsonic region. Multiple coherent scattering by the double-barrier structure strongly modulates the transmission probability of phonons, rendering it very sensitive to their frequency. As a result, resonant tunneling occurs with high probability within a few narrow frequency intervals. This gives rise to highly non-thermal spectra with sharp peaks. We find that these peaks are mostly associated with decaying resonances and only occasionally with dynamical instabilities. Even at achievable non-zero temperatures, the radiation peaks can be dominated by spontaneous emission, i.e. enhanced zero-point fluctuations, and not, as is often the case in analogue models, by stimulated emission.

12:27PM B1.00007 Momentum Resolved Optical Lattice Modulation Spectroscopy for Bosons in Optical Lattice¹, RAJDEEP SENSARMA, Condensed Matter Theory Center, University of Maryland, College Park, KRISHNENDU SENGUPTA, Indian Association for cultivation of Science, Kolkata, India, SANKAR DAS SARMA, Condensed Matter Theory Center, University of Maryland, College Park — We propose a new method of optical lattice modulation spectroscopy for studying the spectral function of ultracold bosons in an optical lattice. We show that different features of the single particle spectral function in different quantum phases can be obtained by measuring the change in momentum distribution after the modulation. In the Mott phase, this gives information about the momentum dependent gap to particle-hole excitations as well as their spectral weight. In the superfluid phase, one can obtain the spectrum of the gapless Bogoliubov quasiparticles as well as the gapped amplitude fluctuations. The distinct evolution of the response with modulation frequency in the two phases can be used to identify these phases and the quantum phase transition separating them.

12:39PM B1.00008 Population of atoms in the output of an atom Michelson interferometer, EBUBECHUKWU ILO-OKEKE, ALEX ZOZULYA, Worcester Polytechnic Institute — A cloud of Bose-Einstein condensate (BEC) sitting at the center of a weakly confining trap in an atom Michelson interferometer is split into two clouds that travel along different paths. The two clouds evolve and accumulate relative phase between them due to field of interest, confining potential and interatomic interactions. At the end of the interferometric cycle, the two clouds are recombined and the population of atoms found in the cloud at rest and the moving clouds depends on the relative phase. We derive an expression for the probability of counting any number of atoms within each cloud after recombination, study the dependence of the probability on the relative phase and relate our findings with experiments.

12:51PM B1.00009 Prototyping method for Bragg-type atom interferometers¹, BRANDON BENTON, MICHAEL KRYGIER, JEFFREY HEWARD, Georgia Southern University, MARK EDWARDS, Georgia Southern University and NIST, CHARLES CLARK, Joint Quantum Institute and NIST — We present a method for rapid modeling of new Bragg ultracold atom-interferometer (AI) designs useful for assessing the performance of such interferometers. The method simulates the overall effect on the condensate wave function in a given AI design using two separate elements. These are (1) modeling the effect of a Bragg pulse on the wave function and (2) approximating its evolution during the intervals between the pulses. The actual sequence of these pulses and intervals is then followed to determine the approximate final wave function from which the interference pattern can be calculated. The exact evolution between pulses is assumed to be governed by the Gross-Pitaevskii equation (GPE). We have developed both 1D and 3D versions of this method and have determined their validity by comparing their predicted interference patterns with those obtained by numerical integration of the 1D GPE and with the results of an experiment performed at NIST. We find good agreement between the 1D interference patterns predicted by this method and those found by the GPE. We show that we can reproduce the results of the NIST experiment and that this method provides estimates of 1D interference patterns 10,000 times faster than direct integration of the GPE.

¹This work supported by NSF grant number PHY-0758111

1:03PM B1.00010 Applications of chirped Raman adiabatic rapid passage to atom interferometry¹, KRISH KOTRU, DAVID L. BUTTS, C. S. Draper Laboratory, Inc., and MIT Dept. of Aeronautics and Astronautics, JOSEPH M. KINAST, DAVID M.S. JOHNSON, ANTONIJE M. RADOJEVIC, BRIAN P. TIMMONS, RICHARD E. STONER, C. S. Draper Laboratory, Inc. — We present robust atom optics, based on chirped Raman adiabatic rapid passage (ARP), in the context of atom interferometry. Such ARP light pulses drive coherent population transfer between two hyperfine ground states by sweeping the frequency difference of two fixed-intensity optical fields with large single photon detunings. Since adiabatic transfer is less sensitive to atom temperature and non-uniform Raman beam intensity than standard Raman pulses, this approach should improve the stability of atom interferometers operating in dynamic environments. In such applications, chirped Raman ARP may also provide advantages over the previously demonstrated stimulated Raman adiabatic passage (STIRAP) technique, which requires precise modulation of beam intensity and zeroing of the single photon detuning. We demonstrate a clock interferometer with chirped Raman ARP pulses, and compare its stability to that of a conventional Raman pulse interferometer. We also discuss potential improvements to inertially sensitive atom interferometers. Copyright © 2011 by The Charles Stark Draper Laboratory, Inc. All rights reserved.

1:15PM B1.00011 Berry-gauge tuned Bose-Einstein condensate gyroscope¹, RUDRA KAFLE, Worcester Polytechnic Institute, Worcester, MA 01609, EDDY TIMMERMANS, T- 4, Los Alamos National Laboratory, Los Alamos, NM 87544 — If stable, the many-body ground state of a dilute gas of ultra-cold, bosonic atoms occupying a superposition of two internal (hyperfine) states is a Bose-Einstein condensate (BEC) of effective spin 1/2 bosons. The superfluid BEC dynamics admits long-lived quantized vortex states in which the complex phase of the superfluid order parameter, which we call the charge phase, undergoes an integer number of 2π windings along a multiply connected path - a closed trajectory that encloses a region in which the superfluid density vanishes. In response to an overall rotation of the ring, a quantization event can occur that can be used to sense rotation. Unfortunately, the sensitivity of the ring BEC gyroscope would be limited as the quantization event sets in at a rotation frequency that is not as low as the frequencies measured by other devices such as ring laser gyroscopes. We show that the recently realized synthetic magnetic fields, in which the controlled position dependence of the spin results in an effective gauge field, can tune the BEC ring gyroscope to trigger a quantization event at much smaller rotation frequency. In addition, the effective gauge field can undergo its own quantization events in which the spin vector undergoes an integer number of 2π or 4π windings.

1:27PM B1.00012 Frustration and glassiness in spin models with cavity-mediated interactions, SARANG GOPALAKRISHNAN, University of Illinois at Urbana-Champaign, BENJAMIN LEV, Stanford University, PAUL GOLDBART, Georgia Institute of Technology — Optical cavity photons can mediate interatomic interactions that are both long-ranged and sign-changing, thus enabling the realization of models and phases (such as supersolids [1]) that are inaccessible in conventional optical lattices. Here, we introduce a general scheme for realizing frustrated magnetic models possessing spin-glass states, using three-level atoms trapped at fixed positions inside a transversely pumped multimode cavity. We show that the effective Hamiltonian for such a system is analogous to the Hopfield associative-memory model [2], and, like the Hopfield model, possesses a spin glass phase for a sufficiently large ratio of the number of cavity modes to atoms. We argue that the spin glass phase should be accessible with realistic experimental parameters, discuss experimental signatures of the spin glass phase, and address the impact of dissipative processes such as cavity photon decay on the realizable phases and phase transitions.

1:39PM B1.00013 Manipulation of ultracold rubidium atoms using a single linearly chirped laser pulse¹, SVETLANA MALINOVSKAYA, THOMAS COLLINS, Stevens Institute of Technology — At ultracold temperatures, atoms are free from thermal motion, which makes them ideal objects of investigations in the fields of high precision spectroscopy, metrology, quantum computation, producing Bose condensates, etc. The quantum state of ultracold atoms may be created and manipulated by optical pulses of rather low intensity and by making use of quantum control methods. Here, we discuss how the field phase variation, pulse duration and intensity, when perform in conformity, may yield a desired population distribution within the hyperfine structure of alkali atoms. We theoretically investigate ultracold Rb vapor using picosecond chirped pulses of kW/cm^2 beam intensity and show a possibility of controllable population transfer between hyperfine levels of $5^2S_{1/2}$ state through Raman resonances. Satisfying the one-photon resonance condition with the $5^2P_{1/2}$ or $5^2P_{3/2}$ state allows us to enter the adiabatic region of population transfer at very low field intensities, such that corresponding Rabi frequencies are less or equal to the hyperfine split. This methodology provides with a robust way to create a specifically designed superposition state in Rb in the basis of the hyperfine levels and perform state manipulation.

1:51PM B1.00014 Optical response of dark exciton Bose-Einstein condensate, MIKHAIL EREMENTCHOUK, MICHAEL LEUENBERGER, University of Central Florida — We study the optical response of Bose-Einstein condensate (BEC) formed by dark excitons in semiconductors. We consider the example of GaAs, where dark excitons are formed by heavy-holes and electrons with opposite signs of projections of their spins resulting in natural fragmentation of the condensate. Direct coupling of such excitons is dipole prohibited and, therefore, the optical response of semiconductor with dark condensate is provided through interaction of light with bright exciton states. We show that the Coulomb interaction of optically excited bright excitons with dark excitons residing in the BEC leads to effective renormalization of characteristics of bright excitons — e.g. their mass decreases — depending on the density of the condensate. As a result the exciton resonances experiences red-shift with decreasing amplitude. This provides an opportunity for indirect spectroscopy of dark exciton BEC.

2:03PM B1.00015 Electron field noise sensing with a scanning ion, ZACHARY FISHER, MICHAEL GUTIERREZ, MOLU SHI, DANIEL LI, YUFEI GE, PETER HERSKIND, ISAAC CHUANG, Research Laboratory of Electronics, Massachusetts Institute of Technology — Controlled shuttling of ions in a planar ion trap can serve as highly sensitive method for probing the electric field.¹ We apply this idea to the measurement of field noise effects on a microfabricated planar trap as a function of ion position. In particular, by shuttling an ion between different trapping zones, the field noise can be determined near different material surfaces, in particular dielectric materials. Surface effects on these materials are suspected to cause field fluctuations that decohere the motional state of trapped ions. By shuttling the ion to a determined location and measuring the electric field noise, a measure of the electric field noise can be determined as a function of proximity to dielectrics. A systematic examination of field noise due to dielectric versus metallic surfaces is valuable in, for example, a trapped-ion cavity QED system, where the high-reflectivity mirrors used in the optical cavities are large, exposed dielectric regions.²

Monday, February 27, 2012 11:15AM - 2:15PM – Session B2 FIP: Invited Session: Science Diplomacy: Africa and the Middle East 204AB

11:15AM B2.00001 ASP2012: Fundamental Physics and Accelerator Sciences in Africa, CHRISTINE DARVE¹, European Spallation Source — Much remains to be done to improve education and scientific research in Africa. Supported by the international scientific community, our initiative has been to contribute to fostering science in sub-Saharan Africa by establishing a biennial school on fundamental subatomic physics and its applications. The school is based on a close interplay between theoretical, experimental, and applied physics. The lectures are addressed to students or young researchers with at least a background of 4 years of university formation. The aim of the school is to develop capacity, interpret, and capitalize on the results of current and future physics experiments with particle accelerators; thereby spreading education for innovation in related applications and technologies, such as medicine and information science. Following the worldwide success of the first school edition, which gathered 65 students for 3-week in Stellenbosch (South Africa) in August 2010, the second edition will be hosted in Ghana from July 15 to August 4, 2012. The school is a non-profit organization, which provides partial or full financial support to 50 of the selected students, with priority to Sub-Saharan African students.

¹on behalf of the ASP2012 organizing committees

11:51AM B2.00002 The African Laser Centre: Transforming the Laser Community in Africa, SEKAZI MTINGWA, Massachusetts Institute of Technology — We describe the genesis and programs of the African Laser Centre (ALC), which is an African nonprofit network of laser users that is based in Pretoria, South Africa. Composed of over thirty laboratories from countries throughout the continent of Africa, the ALC has the mission of enhancing the application of lasers in research and education. Its programs include grants for research and training, equipment loans and donations, student scholarships, faculty grants for visits to collaborators' institutions, conferences, and technician training. A long-term goal of the ALC is to bring a synchrotron light source to Africa, most probably to South Africa. One highly popular program is the biennial conference series called the US-Africa Advanced Studies Institute, which is funded by the ALC in collaboration with the U.S. National Science Foundation and the International Center for Theoretical Physics in Trieste. The Institutes typically bring about thirty faculty and graduate students from the U.S. to venues in Africa in order to introduce U.S. and African graduate students to major breakthroughs in targeted areas that utilize lasers. In this presentation, we will summarize the ALC achievements to date and comment on the path forward.

12:27PM B2.00003 SESAME – A light source for the Middle East¹, HERMAN WINICK, SLAC National Accelerator Laboratory — Developed under UNESCO and modelled on CERN, SESAME (Synchrotron-light for Experimental Science and Applications in the Middle East) is an international research centre in construction in Jordan, enabling world-class research while promoting peace through scientific cooperation. Its centerpiece, a new 2.5 GeV 3rd Generation Electron Storage Ring (133m circumference, 26nm-rad emittance, 12 places for insertion devices), will provide intense light from infra-red to hard X-rays. The Council (Bahrain, Cyprus, Egypt, Iran, Israel, Jordan, Pakistan, Palestinian Authority, Turkey), provides the annual budget. Concrete shielding is complete, and a staff of 21 is installing the refurbished 0.8 GeV BESS Y I injector system, a gift from Germany. The facility can serve 25 simultaneous experiments. Beamline equipment has been provided by Daresbury (UK), the Helmholtz Assoc. (Germany), the Swiss Light Source, LURE (France), the Univ. of Liverpool, Elettra (Italy) and US labs. Jordan has contributed \$3.3M, in addition to a building and land. The EU has contributed \$4.8M. Commitments confirmed by Members look set to provide most of \$35M needed to complete construction of the ring and 3 beamlines. A training program has been underway since 2000. See www.sesame.org.jo

¹Support by the Office of Basic Energy Sciences, Office of Science, US Department of Energy

1:03PM B2.00004 Marshak Lectureship: The Turkish Accelerator Center, TAC, OMER YAVAS¹, Accelerator Technologies Institute, Ankara University, Ankara, Turkey — The Turkish Accelerator Center (TAC) project is comprised of five different electron and proton accelerator complexes, to be built over 15 years, with a phased approach. The Turkish Government funds the project. Currently there are 23 Universities in Turkey associated with the TAC project. The current funded project, which is to run until 2013 aims

1. To establish a superconducting linac based infra-red free electron laser and Bremsstrahlung Facility (TARLA) at the Golbasi Campus of Ankara University,
 - (a) To establish the Institute of Accelerator Technologies in Ankara University, and
2. To complete the Technical Design Report of TAC. The proposed facilities are a 3rd generation Synchrotron Radiation facility, SASE-FEL facility, a GeV scale Proton Accelerator facility and an electron-positron collider as a super charm factory.

In this talk, an overview on the general status and road map of TAC project will be given. National and regional importance of TAC will be expressed and the structure of national and international collaborations will be explained.

¹On behalf of TAC Collaboration

1:39PM B2.00005 Andrei Sakharov Prize Lecture: Physics and Freedom in Ethiopia, MULUGETA BEKELE, Department of Physics, Addis Ababa University — I will highlight my forty years involvement in physics education and research in Ethiopia and draw lessons that could be learnt from it.

Monday, February 27, 2012 11:15AM - 2:15PM –

Session B3 DCMP: Invited Session: Superconducting Coherence, Fluctuations & Inhomogeneity in Mesoscopic & Low-Dimensions 205AB

11:15AM B3.00001 Emergence of h/e -period oscillations in the critical temperature of small superconducting rings and critical velocity in one-dimensional superconductors, TZU-CHIEH WEI, CN Yang Institute for Theoretical Physics, Stony Brook University — When a large ring of superconductor is threaded by a magnetic flux, the resistance and the critical temperature exhibit oscillations in a flux quantum of $h/2e$. The flux quantum of an electron circling a thread flux on a clean metallic ring is on the contrary h/e . When the radius starts to shrink, electrons that compose of Cooper pairs may be able to roam around the ring individually without costing too much energy. An h/e period should thus arise. We discuss the emergence of h/e -period oscillations in the critical temperature of small superconducting rings and a few scenarios of superconducting-normal metal transitions. Interestingly, a threading flux is equivalent to a momentum boost in the circumferential direction of the ring. We also discuss a related issue as to how high a flow velocity one-dimensional superconductors can sustain before superconductivity gives way to this instability and the system becomes normal.

11:51AM B3.00002 Manipulating superconducting fluctuations in ultrasmall loops and quasi one-dimensional wires of Al¹, NEAL STALEY, The Pennsylvania State University — Superconducting fluctuations and the control of these fluctuations have been a problem of long-standing interest, with recent impetus provided by its relevance to the pursuit of very high temperature superconductivity through the engineering of global phase coherence. In quasi one-dimensional superconductors, fluctuations due to thermal or quantum processes lead to phase slips, and the appearance of a finite electrical resistance. We found that the critical current in mesoscopic quasi one-dimensional wires of Al is influenced by the bulk measurement electrodes, and in fact increases with magnetic field at low fields, suggesting that the phase slips are suppressed by the loss of superconductivity in the bulk electrodes. Manipulation of superconducting fluctuations is also possible in ultrasmall loops, where the strength of the fluctuations is controlled by the loop's size in comparison with ξ and the enclosed flux. For ultrasmall loops with a circumference $\sim \pi\xi(0)$, de Gennes predicted more than three decades ago that superconductivity could be completely destroyed near half-integer-flux quanta even to zero temperature. Furthermore, the resulting destructive regime, likely dominated by quantum fluctuations at low temperatures, was predicted to be suppressed with the addition of a superconducting side branch. We observed this Little-Parks-de Gennes effect in ultrasmall Al loops prepared by e-beam lithography and we found that the addition of a superconducting side branch restores the lost phase coherence. We will present our most recent data and discuss the implications of our experimental observations.

¹Work done in collaboration with Ying Liu, and supported by NSF under Grant DMR 0908700 and Penn State MRI Nanofabrication Lab under NSF Cooperative Agreement 0335765, NNIN with Cornell University.

12:27PM B3.00003 Magnetic-field-induced superconductivity and damping of phase slips in Zn nanowires¹, YU CHEN², Department of Physics, University of California-Santa Barbara — We report an observation that Zn nanowires connected with Zn electrodes, after being driven resistive by the current, re-entered their superconducting state upon the application of a small magnetic field [1, 2]. A detailed experimental investigation was carried out, with variation of parameters such as magnetic field orientation, wire length, etc.. The results provide solid evidence that this is a nonequilibrium effect associated the coupling with the boundary electrodes. There are two characteristic length scales involved, approaching either of which weakens the effect. Most importantly, we demonstrated that it is more appropriate to consider the effect to be a stabilization of superconductivity that has been suppressed by an applied current. Although we do not present a formal theory to explain all of our results here, the effect is most likely a consequence of the damping of phase fluctuations by quasiparticles which are created in the electrodes by small magnetic fields.

1:03PM B3.00004 Quantum liquid crystals: spontaneously modulated Fermi superfluids¹, YEN LEE LOH, University of North Dakota — What happens to a BCS superconductor when the numbers of up and down fermions are unequal? This is a fascinating and difficult problem in many-body physics. The most exciting possibility is that pairing and polarization compete to produce a modulated superfluid state, known as an Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) phase. This is a quantum liquid crystal exhibiting microscale phase separation, in which the excess fermions self-organize into domain walls where the pairing amplitude changes sign. There is a growing body of indirect evidence for the existence of FFLO states. As an example, I present our recent work on Al thin film superconductors in parallel magnetic fields [1]. Just below the Chandrasekhar-Clogston spin paramagnetic transition, our tunneling density of states measurements reveal a significant population of subgap states. These excess states cannot be explained in terms of conventional superconductivity, but they are a natural consequence of disordered FFLO physics. There is also hope for realizing FFLO in ultracold gases of neutral fermionic atoms. Continuum FFLO states are very fragile, but our calculations suggest that FFLO states are greatly stabilized by an optical lattice. For a cubic lattice with suitable parameters, up to 80% of the fermions participate in the FFLO phase [2]. Furthermore, we propose an interferometric technique to detect pairing amplitude modulations, which may provide the first *direct* evidence of FFLO [3].

Session B4 DAMOP: Hybrid Systems, Optomechanics and Macroscopic Systems at the Quantum Limit I 205C

11:15AM B4.00001 Observing quantum phenomena in cavity optomechanics¹, NATHANIEL BRAHMS, DAN W. C. BROOKS, SYDNEY SCHREPPLER, THIERRY BOTTER, DAN M. STAMPER-KURN, Univ of California - Berkeley — Recent efforts have produced optomechanical systems whose mechanical elements are prepared at or near their quantum ground state. But what manifestly quantum effects can be measured with these new systems? Here we present results from our experiment, using the collective motion of an ultracold atom ensemble as a mechanical oscillator. The motion is driven by shot noise in the light's radiation pressure, allowing us to observe the production of nonclassical states of light by optomechanics – here, quadrature-squeezed light. Notably, this nonlinear optical effect occurs with only 40 pW of pump power. We also measure the quantization of the oscillator, by observing a 3:1 asymmetry in the light it scatters to low- and high-energy optical sidebands. Analyzing the light emitted from the cavity moreover provides a spectroscopic record of the energy exchanged between light and motion, allowing us to directly quantify the necessary diffusive heating of a quantum backaction-limited position measurement.

11:27AM B4.00002 Cryogenic optomechanics with a 261kHz mechanical oscillator, DONGHUN LEE, ANDREW JAYICH, Yale University, JACK SANKEY, McGill University, CHEN YANG, LILY CHILDRESS, MITCHELL UNDERWOOD, KJETIL BORKJE, STEVE GIRVIN, JACK HARRIS, Yale University — Mechanical motion can interact with light via radiation pressure force. With recent experimental advances over the last few years, such optomechanical coupling has been used to reach quantum ground state of mechanical oscillators, which opens interesting new regime of observing quantum mechanics in macroscopic objects. The optomechanical devices used in this talk consist of a dielectric SiN membrane located inside a high finesse optical cavity. Combining cryogenic cooling in He3 refrigerator and resolved sideband laser cooling enables us to cool the membrane's mechanical mode (whose mechanical frequency is 261kHz) to less than 60 phonons. We will describe some technical challenges in our experiments such as the role of classical phase noise of the cooling laser at the mechanical frequency and our efforts to significantly reduce it via a filter cavity.

11:39AM B4.00003 Ultraefficient Cooling of Resonators: Beating Sideband Cooling with Quantum Control, XIAOTING WANG, SAI VINJANAMPATHY, University of Massachusetts at Boston, FREDERICK STRAUCH, Williams College, KURT JACOBS, University of Massachusetts at Boston — There is presently a great deal of interest in cooling high-frequency micro- and nano-mechanical oscillators to their ground states. The present state of the art in cooling mechanical resonators is a version of sideband cooling, which was originally developed in the context of cooling trapped ions. Here we present a method based on quantum control that uses the same configuration as sideband cooling—coupling the resonator to be cooled to a second microwave (or optical) auxiliary resonator—but will cool significantly colder. This is achieved by applying optimal control and varying the strength of the coupling between the two resonators over a time on the order of the period of the mechanical resonator. As part of our analysis, we also obtain a method for fast, high-fidelity quantum information transfer between resonators.

11:51AM B4.00004 Postselected optomechanical superpositions¹, BRIAN PEPPER, UC Santa Barbara, ROOHOLLAH GHOBADI, University of Calgary / Sharif University of Technology, EVAN JEFFREY, University of Leiden, CHRISTOPH SIMON, University of Calgary, DIRK BOUWMEESTER, UC Santa Barbara / University of Leiden — We present a scheme for achieving macroscopic quantum superpositions in weakly coupled optomechanical systems by using single photon postselection. This method allows the creation of macroscopic superpositions with currently achievable device parameters, and allows observation of decoherence on a timescale unconstrained by the system's optical decay time. This method relieves many of the challenges associated with previous optical schemes for measuring macroscopic superpositions, and only requires the devices to be in the weak coupling regime. Prospects for observing novel decoherence mechanisms are also discussed.

12:03PM B4.00005 Coupling a single spin in diamond to the quantum motion of a mechanical cantilever, STEVEN BENNETT, SHIMON KOLKOWITZ, QUIRIN UNTERREITHMEIER, Harvard University, PETER RABL, IQOQI-University of Innsbruck, ANIA BLESZYNSKI-JAYICH, University of California, Santa Barbara, JACK HARRIS, Yale University, MIKHAIL LUKIN, Harvard University — We present theoretical considerations for a magnetized mechanical cantilever coupled to a single electronic spin associated with a nitrogen-vacancy (NV) defect center in diamond. This coupled system has recently been implemented in an experiment where the NV spin was used to detect the thermal motion of a magnetic force microscope cantilever at room temperature, reading out the spin state optically using the spin-selective fluorescence of the NV. The possibility to extend this system to the quantum regime opens the door to applications such as readout and transfer of quantum information, as well as interesting theoretical questions. For example, it should be possible to reach the regime of strong coupling between the spin and the motion of the cantilever, in analogy to cavity quantum electrodynamics. We discuss the prospects for reaching the strong coupling regime and the conditions for measuring the onset of quantum effects, such as measuring the zero point motion of the cantilever using the spin as a detector.

12:15PM B4.00006 Thermally induced parametric instability in back-action evading measurement of micromechanical quadrature near the zero-point level, JUNHO SUH, MATT SHAW, AARON WEINSTEIN, KEITH SCHWAB, California Institute of Technology — Back-action evading (BAE) measurement of mechanical resonators allows, in principle, detection of a single quadrature of motion with sensitivity far below the standard quantum limit, limited in practice only by the non-idealities in the measurement. We report the results of experiments utilizing two-tone BAE in a tightly coupled cavity quantum electro-mechanical system ($\omega_c=7.1\text{GHz}$, $\omega_m=10\text{MHz}$, $g=14\text{MHz/nm}$). Due to excess dissipation in the microwave cavity, we observe a parametric instability induced by the thermal shift of mechanical resonance frequency. This bounds the minimum position imprecision on one quadrature and we measure the imprecision reaching twice the zero-point motion. We discuss the device requirements to avoid this thermal mechanism and perform measurements below the zero-point level.

12:27PM B4.00007 Mechanical squeezing via parametric amplification and feedback control¹, ANDREW DOHERTY, Centre for Engineered Quantum Systems, University of Sydney, A. SZORKOVSKY, G.I. HARRIS, W.P. BOWEN, Centre for Engineered Quantum Systems, The University of Queensland — We discuss the mechanical squeezing that can result from position measurement and feedback applied to a parametrically driven mechanical oscillator. If the parametric drive is optimally detuned from resonance, correlations between the quadratures of motion allow unlimited steady-state squeezing. This contrasts to a parametric drive alone, which is limited to 3dB of squeezing. Compared to back-action evasion, we demonstrate that the measurement strength, temperature and efficiency requirements for quantum squeezing are significantly relaxed.

12:39PM B4.00008 Asymmetric absorption and emission of energy by a macroscopic mechanical oscillator in a microwave circuit optomechanical system, JENNIFER HARLOW, TAUNO PALOMAKI, JOSEPH KERCKHOFF, JILA, University of Colorado and NIST, JOHN TEUFEL, RAYMOND SIMMONDS, NIST Boulder, KONRAD LEHNERT, JILA, University of Colorado and NIST — We measure the asymmetry in rates for emission and absorption of mechanical energy in an electromechanical system composed of a macroscopic suspended membrane coupled to a high-Q, superconducting microwave resonant circuit. This asymmetry is inherently quantum mechanical because it arises from the inability to annihilate the mechanical ground state. As such, it is only appreciable when the average mechanical occupancy approaches one. This measurement is now possible due to the recent achievement of ground state cooling of macroscopic mechanical oscillators [1,2]. Crucially, we measure the thermal cavity photon occupancy and account for it in our analysis. Failure to correctly account for the interference of these thermal photons with the mechanical signal can lead to a misinterpretation of the data and an overestimate of the emission/absorption asymmetry.

12:51PM B4.00009 Quantum many-body system based on phonons and donors in silicon, Ö. O. SOYKAL, CHARLES TAHAN, Laboratory for Physical Sciences, College Park, MD — Cold atoms in optical lattices have become an indispensable tool for the study of many-body physics. Here, we introduce a novel many-body quantum system based on phonons with potentially useful properties. Theoretical results will be presented on the possibility of interacting systems based on phonitons, hybrid composite objects of a matter excitation and a cavity phonon. We discuss experimentally accessible regimes in silicon phoniton systems involving Mott insulator and superfluid phases. We consider experimental tools to probe these many-body states and give explicit designs for devices where they can be observed.

1:03PM B4.00010 Development of a dispersive read-out technique for quantum measurements of nanomechanical resonators¹, FRANCISCO ROUXINOL, MATT LAHAYE, Syracuse University — The development of techniques to observe non-classical behavior of micro- and nano- scale mechanical structures has received considerable attention in recent years because of the potential to use these systems for fundamental studies of quantum mechanics as well as their possible role as new technologies for applications ranging from the sensing of weak forces to quantum communication. One important route for observing such behavior is the coupling of micro- and nanomechanical resonators with superconducting qubits. Under certain conditions, qubit-coupled mechanical devices are formally analogous to Jaynes-Cummings systems which have been used in fields such as cavity QED for explorations of matter-radiation interactions and the quantum nature of light. Correspondingly, experiments in the last couple of years have begun to develop superconducting qubits as tools to manipulate and measure quantum states of mechanics. In this talk, we will discuss our efforts to integrate charge-type superconducting qubits as elements for dispersive (non-resonant) read-out and control of nanomechanical resonators, including preliminary system design and the prospects of implementing this system for read-out of the number-state statistics of nanomechanical modes.

1:15PM B4.00011 Measuring Quantum Optomechanical Self-induced Oscillations: Photon Correlation and Homodyne Tomography¹, JIANG QIAN, School of Engineering, Case Western Reserve University, FLORIAN MARQUARDT, Department of Physics, FAU Erlangen-Nuremberg, AASHISH CLERK, Department of Physics, McGill University, KLEMENS HAMMERER, Institute for Theoretical Physics, University of Hannover — Motivated by recent experimental advances in fabricating systems with large optomechanical couplings, we study the self-induced mechanical oscillations in the strong quantum regime for a single cell optomechanical system. We show that, under strong optomechanical coupling $g_M \geq \kappa$, the *persistent* state of the mechanical oscillator can have non-classical, *strongly negative* Wigner density, which can be measured by non-destructive homodyne tomography. We further propose to detect the onset of the quantum self-induced oscillation using the easier-to-measure photon two-point correlation functions $g^{(2)}(t)$. We show that there are two distinct signatures in the long-term time-average and the line-shape of $g^{(2)}(t)$ at the onset of self-induced oscillations. We show that $g^{(2)}(t)$ exhibits long-term coherence extending much beyond the optical decay time $1/\kappa$, the decay of which in the red- and blue-detune regime we explain using models of optomechanical cooling and phase noise.

1:27PM B4.00012 Controllable Coherent Transfer between a Superconducting Resonator and a Mechanical Oscillator, TAUNO PALOMAKI, JENNIFER HARLOW, JOSEPH KERCKHOFF, REED ANDREWS, JILA, NIST and the University of Colorado, Boulder, JOHN TEUFEL, RAYMOND SIMMONDS, National Institute of Standards and Technology, Boulder, KONRAD LEHNERT, JILA, NIST and the University of Colorado, Boulder — We report experimental results of controllable coupling between a 7.5 GHz superconducting resonator and a 10 MHz mechanical oscillator. Through time domain measurements, we demonstrate controlled coherent energy transfer between these two systems. Furthermore, by utilizing a Josephson parametric amplifier we have been able to verify coherent transfer of small amplitude states. We compare these results to frequency domain measurements and discuss experimental limitations.

1:39PM B4.00013 Using interference for high fidelity quantum state transfer in optomechanics¹, YING-DAN WANG, AASHISH A. CLERK, McGill University — We present a theoretical study of a two-cavity optomechanical system (e.g. a single mechanical resonator coupled to both a microwave and an optical cavity), investigating how interference can be used to perform mechanically-mediated quantum state transfer between the two cavities. We show that this optomechanical system possesses an effective "mechanically-dark" mode which is immune to mechanical dissipation; utilizing this feature allows highly efficient transfer of intra-cavity states, as well as of itinerant photon states. Simple analytic expressions for the fidelity of transferring both Gaussian and non-Gaussian states are provided. Our work has relevance to ongoing experimental efforts in quantum optomechanics (e.g., C. A. Regal and K. W. Lehnert, *J. Phys.: Conf. Ser.* 264, 012025 (2011); A. H. Safavi-Naeini and O. Painter, *New J. Phys.* 13, 013017 (2011)).

1:51PM B4.00014 Adiabatic State Conversion and Photon Transmission in Optomechanical Systems¹, LIN TIAN, University of California, Merced — Light-matter interaction in optomechanical systems in the strong coupling regime can be explored as a tool to transfer cavity states and to transmit photon pulses. Here, we show that quantum state conversion between cavity modes with different wavelengths can be realized with high fidelity by adiabatically varying the effective optomechanical couplings. During this adiabatic process, the quantum state is preserved in the dark mode of the cavities, similar to the adiabatic transfer schemes in EIT systems. The fidelity for gaussian states is derived by solving the Langevin equation in the adiabatic limit and shows negligible dependence on the mechanical noise. We also show that an input pulse can be transmitted to an output channel with a different wavelength via the effective optomechanical couplings. The condition for optimal transmission is derived in the frequency domain. Input pulses with a narrow spectral width can be transmitted with high fidelity. For input pulses with a large spectral width, the shape of the output pulses can be manipulated by applying time-dependent effective couplings. (1) L. Tian, arXiv:1111.2119. (2) L. Tian and H. L. Wang, Phys. Rev. A 82, 053806 (2010).

2:03PM B4.00015 Single atom array to form a Rydberg ring¹, MINGSHENG ZHAN, PENG XU, XIAODONG HE, MIN LIU, JIN WANG, Wuhan Institute of Physics and Mathematics, Chinese Academy of Sciences — Single atom arrays are ideal quantum systems for studying few-body quantum simulation and quantum computation [1]. Towards realizing a fully controllable array we did a lot of experimental efforts, which include rotating single atoms in a ring optical lattice generated by a spatial light modulator [2], high efficient loading of two atoms into a microscopic optical trap by dynamically reshaping the trap with a spatial light modulator [3], and trapping a single atom in a blue detuned optical bottle beam trap [4]. Recently, we succeeded in trapping up to 6 atoms in a ring optical lattice with one atom in each site. Further laser cooling the array and manipulation of the inner states will provide chance to form Rydberg rings for quantum simulation.

Monday, February 27, 2012 11:15AM - 2:15PM —
Session B5 DCMP DMP: Surface Electronic & Lattice Properties: Interfaces, Spin Effects, Etc. 206A

11:15AM B5.00001 Spatially Resolved Nano-Scale Characterization of Electronic States in SrTiO₃(001) Surfaces by STM/STS, KATSUYA IWAYA, TAKEO OHSAWA, RYOTA SHIMIZU, Tohoku University, TOMIHIRO HASHIZUME, Hitachi, Ltd., TARO HITOSUGI, Tohoku University, TOHOKU UNIVERSITY COLLABORATION, HITACHI, LTD. COLLABORATION, TOKYO INSTITUTE OF TECHNOLOGY COLLABORATION, JAPAN SCIENCE AND TECHNOLOGY AGENCY COLLABORATION — We have performed low temperature scanning tunneling microscopy/spectroscopy (STM/STS) measurements on TiO₂-terminated SrTiO₃(001) thin film surfaces. The conductance map exhibited electronic modulations that were completely different from the surface structure. We also found that the electronic modulations were strongly dependent on temperature and the density of atomic defects associated with oxygen vacancies. These results suggest the existence of strongly correlated two-dimensional electronic states near the SrTiO₃ surface, implying the importance of electron correlation at the interfaces of SrTiO₃-related heterostructures.

11:27AM B5.00002 The Structure of High Polarization Surface of the Antiferromagnet Cr₂O₃, NING WU, XIN ZHANG, KEISUKE FUKUTANI, XI HE, CHRISTIAN BINEK, PETER DOWBEN, Department of Physics and Astronomy and the Nebraska Center for Materials and Nanoscience, University of Nebraska-Lincoln, Lincoln, NE 68588, USA, WAI-NING MEI, Department of Physics, University of Nebraska at Omaha, Omaha, NE 68182-0266, USA, ZHAOXIAN YU, School of Physics and Engineering, Zhongshan University, Guangzhou 510275, Peoples Republic of China, UNL TEAM, UNO COLLABORATION, ZHONGSHAN COLLABORATION — Manipulation of magnetically ordered states by electrical means is among the most promising approaches towards novel spintronic devices. Electric control of the exchange bias can be realized when the passive antiferromagnetic pinning layer is replaced by a magneto-electric antiferromagnet, like the prototypical magneto-electric Cr₂O₃(0001), so long as there is also a finite remanent magnetization at the surface or boundary. We have demonstrated that a very unusual high polarization surface magnetic order exists at the surface of the Cr₂O₃(0001) surface and is robust against surface roughness from spin polarized inverse photoemission, and X-ray magnetic circular dichroism. We have also performed LEED (low energy electron diffraction) I(V) analysis to explore the surface structure above and below Neel Temperature (308 K). Temperature dependent LEED was also carried out at several different electron kinetic energies and Debye temperature was extracted. The surface and bulk Debye temperatures were obtained by fitting Debye temperature as a function of electron kinetic energy.

11:39AM B5.00003 Resonance Photoemission and Spin Polarization of Fe_xCo_{1-x}S₂¹, XIN ZHANG, NING WU, PETER DOWBEN, Nebraska Center for Materials and Nanoscience, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln, NE 68588-0299, CHRIS LEIGHTON, MICHAEL MANNO, Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN 55455, USA, ELIO VESCOVO, Brookhaven National Laboratory, National Synchrotron Light Source, Upton, New York 11973, USA — The electronic structure in the region of the Fe/Co 3d band for Fe_xCo_{1-x}S₂ has been investigated by photoemission and spin polarized photoemission. The comparison between the results for different content of doped Fe was made, specifically x=0, 0.05, 0.10, 0.15 and 1. While the surface spin polarization of Fe_xCo_{1-x}S₂, measured by spin polarized ultraviolet photoemission, was reduced compared with the bulk value, we see that the spin polarization increases with Fe doping level for textured thin films. The resonance photoemission spectroscopy shows that sulfur bands have strong resonance at the photon energy of the Co 2p core level, indicating strong hybridization between Co and sulfur bands in Fe_xCo_{1-x}S₂ (small x) however, the ultraviolet photoelectron spectroscopy (UPS) of FeS₂ exhibits a slightly different d-band density of states than Fe_xCo_{1-x}S₂.

¹Work at UNL and UMN was supported by their respective NSF MRSEC's.

11:51AM B5.00004 Theoretical Band Offsets in c-Si/Si-XII Heterojunctions¹, JAMAL MUSTAFA, BRAD MALONE, MARVIN COHEN, STEVEN LOUIE, University of California at Berkeley and Lawrence Berkeley National Lab — Many different phases of silicon can be formed under pressure, with some being metastable at standard temperatures and pressures. For one such phase, Si-XII, experiments have recently suggested it to be a semiconductor, confirming theoretical predictions that it has a narrow gap in its electronic band structure. Current-voltage measurements show rectifying behavior in c-Si/Si-XII heterojunctions, indicative of a band discontinuity at the interface. We present computations that quantify this band discontinuity using bulk band structures obtained with Density Functional Theory within the Local Density Approximation. In particular, we demonstrate the use of a semiconductor's intrinsic charge neutrality level to determine band lineups.

¹This work was supported by National Science Foundation Grant No. DMR10-1006184 and the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by the DOE at LBNL's NERSC facility.

12:03PM B5.00005 Band Alignment in Transparent Conducting Oxide Schottky Junctions, RAFAEL JARAMILLO, SHRIRAM RAMANATHAN, Harvard University — Better understanding and control of band alignment in oxide-semiconductor heterostructures is essential for improving the performance of devices such as sensitized solar cells and quantum dot based light emitting devices. We will present studies of Schottky junctions formed between Al-doped ZnO (AZO) conducting oxide thin films and lightly doped silicon. AZO films with varying oxygen content have been synthesized by control of oxygen pressure during growth. Transport measurements (I-V and C-V) on devices are used to illustrate the degree to which the oxide stoichiometry can be used to engineer the junction characteristics.

12:15PM B5.00006 Interface Band Structure Effects upon Hot Electron Transport Across Non-Epitaxial Metal-Semiconductor Interfaces, JOHN GARRAMONE, Department of Materials Science & Engineering, McCormick School of Engineering & Applied Science, Northwestern University, Evanston, IL 60208-3108, JOE ABEL, College of Nanoscale Science and Engineering, University at Albany, SUNY, Albany, New York 12203, USA, SALVADOR BARRAZA-LOPEZ, Department of Physics, University of Arkansas, Fayetteville, AR 72710, USA, VINCENT LABELLA, College of Nanoscale Science and Engineering, University at Albany, SUNY, Albany, New York 12203, USA — The interface band structure of a semiconductor is shown to affect the transport of hot electrons across a non epitaxial metal-semiconductor interface. This is observed by measuring the hot electron attenuation length of Ag utilizing ballistic electron emission microscopy (BEEM). The attenuation length is observed to increase sharply for energies approaching the Schottky barrier height when deposited upon Si(001) substrates and decrease slightly when deposited upon Si(111) substrates. A theoretical description demonstrates that this is due to conservation of parallel momentum and differences in interface band structure of the two silicon orientations. At higher tip biases the attenuation lengths converge allowing extraction of the inelastic and elastic scattering lengths in the silver.

12:27PM B5.00007 A numerical simulation study of inverse doped surface layer in Schottky barrier modification, SUBHASH CHAND, PRIYANKA KAUSHAL, Department of Physics, National Institute of Technology, Hamirpur-177 005 (HP) — The Poisson's and continuity equations are solved by iterative method to obtain the potential and electron and hole concentrations inside the semiconductor near the metal semiconductor interface for different inverse layer thickness and doping concentrations. The barrier height (BH) and ideality factor (IF) obtained by fitting of simulated current voltage data into thermionic emission diffusion current equation. The derived BH increases with increase in inverse layer thickness as well as with increase in the inverse layer doping concentration and then saturates at maximum value. The IF first rises with increase in inverse layer thickness and then attaining a maximum value at a particular thickness it decreases approaching unity value for large inverse layer thickness. It is observed that for large inverse layer thickness the BH attains a maximum value with unity IF. Thus, there are two regimes, namely, non-ideal regime corresponding to less inverse layer thickness where the BH has increased less and IF is more than unity and ideal regime corresponding to large inverse layer thickness where the BH attains maximum value with unity IF.

12:39PM B5.00008 Density functional calculations of the Schottky barrier height and effective work function in Ni/oxide interfaces, HYEON-KYUN NOH, YOUNG JUN OH, ALEX TAEKYOUNG LEE, K.J. CHANG, Department of Physics, Korea Advanced Institute of Science and Technology — In high-k/metal gate stacks of complementary metal-oxide semiconductor devices, it is important to control the effective work functions of metals such that they should match to the doping levels of poly-Si gates. However, it is known that metal work functions are strongly affected by interface dipoles and defects. In this work, we perform first-principles density-functional calculations to study the Schottky barrier heights and the effective metal work functions in Ni/SiO₂ and Ni/HfO₂ interface structures. We use the advanced approaches such as hybrid density functional and quasi-particle GW calculations for the exchange-correlation potential and discuss the limitations of GGA calculations. We also examine the effects of O-vacancy defects introduced at the interface on the Schottky barrier height and the effective work function. We find that, in the Ni/HfO₂ interface, the *p*-type Schottky barrier height tends to increase with increasing of the defect density due to the charge transfer at the interface, whereas it is little affected in the Ni/SiO₂ interface.

12:51PM B5.00009 Models for (001) epitaxial interfaces between CdTe and ZnO¹, JOHN JAFFE, TIFFANY KASPAR, TIMOTHY DROUBAY, Pacific Northwest National Laboratory — Epitaxial interfaces between ZnO and CdTe appear difficult to achieve given their different crystal structures (CdTe is zinc blende with conventional lattice constant $a = 6.482$ Å, ZnO is hexagonal wurtzite with $a = 3.253$ Å and $c = 5.213$ Å.) However, ZnO also occurs in a metastable zinc-blende structure with an fcc primitive lattice constant close to the hexagonal a value. Since this value is close to half of the CdTe conventional (simple cubic) lattice constant, (001)-oriented cubic ZnO films might grow epitaxially on a CdTe (001) surface in an $R45^\circ \sqrt{2} \times \sqrt{2}$ configuration. Many alignments of the interfacial layers are possible, and we describe density-functional calculations on several of these to identify the most likely, and to predict valence-band offsets between CdTe and ZnO for each. Growth of ZnO on Te-terminated CdTe (001) is predicted to produce small or even negative (CdTe below ZnO) valence band offsets, resulting in a Type I band alignment. Growth on Cd-terminated CdTe is predicted to produce large positive offsets for a type II alignment as needed, for example, in solar cells. Calculations with the GGA + U method (with $U = 7.5$ eV for Zn 3d states) gave a valence band offset of +1.8 eV while a hybrid HSE06 + U calculation gave +2.6 eV. An experimental measurement on a ZnO film grown on CdTe (001) yielded a value of +2.2 eV for the valence band offset.

¹Supported by PNNL LDRD funding.

1:03PM B5.00010 The crystalline Si₃N₄/Si interface; the electronic structure of defects, ESPEN FLAGE-LARSEN, ESPEN SAGVOLDEN, OLE MARTIN LOEVVIK, DAN MICHAEL OLSEN HEGGOE, JESPER FRIIS, SINTEF Materials and Chemistry, P.O. Box 124 Blindern, Forskningsveien 1, N-0314 Oslo, Norway, CHANG-MING FANG, University of Vienna, Faculty of Physics and Center for Computational Materials Science, Sensengasse 8/12, A-1090 Vienna, Austria — A semiconducting beta-Si₃N₄(0001)/Si(111) interface model without dangling bonds is presented, and its geometric and electronic structure is compared to previous models based on calculations in a density functional theory framework. Furthermore nitrogen and phosphorus defects in the silicon layer are investigated, in particular how these defects modify the electronic structure and the electronic properties of the interface as a function of their distance to it. The local geometric structure of the nitrogen and phosphorus defects is also investigated close to the interface.

1:15PM B5.00011 Epitaxial n-ZnO on p-Si with native SiO_x reduced by Al buffer¹, C.F. CHANG, J.H. WANG, H.J. HUANG, Z.W. HUANG, P.V. WADEKAR, K.H. HUANG, C.W. LIN, J.J. LIN, S.C. SHENG, L.W. TU, S.W. YEH, N.J. HO, Q.Y. CHEN², National Sun Yat-Sen University, C.H. LIAO, R.O.C. Military Academy — RF sputtering was employed to deposit n-type zinc oxide epitaxial thin films on p-type silicon substrates to form p-i-n diodes. A buffer layer of crystalline metal oxide was introduced by redox reaction between an aluminum layer and the native SiO₂. The aluminum layer was sputtered to various thicknesses and then annealed in situ for different times. The epitaxial relations follow (111) *S_i*/(0001) *ZnO* and [110] *S_i*/[1120] *ZnO*, though certain degree of mosaicity was observed wavering around the [112] *S_i* axis. Cross-sectional TEM observations of the interfaces, x-ray crystallography via ω -2 θ and rocking scans in regards to the perfection of the structures and orientations are agreeable. The current-voltage characteristics of the p-i-n diodes show promising outlooks for light emitting and photovoltaic applications.

²Corresponding author, also at Texas Center for Superconductivity, University of Houston

1:27PM B5.00012 Emergence of orbital angular momentum due to broken inversion symmetry and its contribution to Rashba-type splitting, CHOONG H. KIM, Seoul National University, Seoul, Korea, JIN-HONG PARK, Sungkyunkwan University, Suwon, Korea, SEUNG RYONG PARK, University of Colorado at Boulder, Boulder, Colorado, USA, BEOM YOUNG KIM, Yonsei University, Seoul, Korea, JAEJUN YU, Seoul National University, Seoul, Korea, CHANGYOUNG KIM, Yonsei University, Seoul, Korea, JUNG HOON HAN, Sungkyunkwan University, Suwon, Korea — We demonstrate that the chiral orbital angular momentum (OAM) structure can emerge as a result of broken inversion symmetry especially at the metal surfaces. The surface-normal electric field is responsible for chiral OAM states even if spin-orbit interaction is negligible. Such chiral OAM structure can be measured by a circular dichroism (CD) in angle-resolved photoemission spectroscopy (ARPES). To confirm the existence of OAM and its detection by CD-ARPES, we perform simulation of CD-ARPES for Cu surface states by first-principles calculation and the results agree well with our CD-ARPES experiment. Addition of the spin-orbit interaction to the chiral OAM structure produces a chiral spin angular momentum (SAM) pattern and the corresponding Rashba-type band splitting. We assert that OAM polarization should be a more widespread feature than the chiral spin structure which requires strong spin-orbit coupling.

1:39PM B5.00013 Chiral Orbital Angular Momentum and Circular Dichroism ARPES in p- and d-orbital Bands, JIN-HONG PARK, JUNG HOON HAN, Sungkyunkwan University — We derive explicit formulas relating the circular dichroism angle-resolved photoemission (CD-ARPES) signal to the existence of nonzero chiral orbital angular momentum (OAM) in the band structure. The existence of nonzero chiral OAM is a generic feature of surface states that break inversion symmetry, as pointed out in several recent articles [1-3]. We propose that CD-ARPES setup is an effective probe of the OAM of quasi-particles occupying the surface states. Explicit formulas for the *p*- and *d*-orbital bands are derived to show that the CD-ARPES signal is proportional to the OAM in the momentum space.

1:51PM B5.00014 A first principles study of water adsorption on α -Pu (020) surface¹, JIANGUANG WANG, ASOK K. RAY, Department of Physics, University of Texas at Arlington, Arlington, Texas 76019, USA — Adsorptions of water in molecular (H₂O) and dissociative (OH+H, H+O+H) configurations on the α -Pu (020) surface have been studied using *ab initio* methods. The full-potential FP/LAPW+lo method has been used to calculate the adsorption energies at the scalar relativistic with no spin-orbit coupling (NSOC) and fully relativistic with spin-orbit coupling (SOC) theoretical levels. It is found that the SOC effect increases the adsorption energies by ~ 0.30 eV for the two dissociative adsorptions. Weak physisorptions have been observed for the molecule H₂O on the α -Pu (020) surface with primarily a covalent bonding, while the two dissociative adsorptions are chemisorptive with ionic bonding. At the SOC level, the most stable adsorption energy is 0.58eV, the corresponding values being 5.44 eV and 5.73 eV for the partial dissociation and complete dissociation cases, respectively. Completely dissociative adsorption at a long bridge site for the dissociated O atom and two short bridge sites for the two dissociated H atoms is the most stable adsorption site. Hybridizations of O(2p)-H(1s)-Pu(5f)-Pu(6d) are observed for the two dissociative adsorptions, implying that some of the Pu-5f electrons become further delocalized and participate in chemical bonding.

2:03PM B5.00015 Characterization of Hydrogen Interactions with δ -Pu using Electronic Structure Theory¹, CHRISTOPHER D. TAYLOR, Los Alamos National Laboratory, SARAH C. HERNANDEZ, University of Texas at Arlington — The generalized gradient approximation to density functional theory was used to study surface, bulk, defect, and reaction states of hydrogen in δ -Pu. The quasi-disordered anti-ferromagnetic arrangement gave a volume of 24.1 Å³ and a bulk modulus of 48.1 GPa for δ -Pu, in reasonable agreement with the experimental values of 24.9 Å³ and 30-35 GPa. This arrangement was thus subsequently used for all calculations. We have determined that hydrogen interactions with δ -Pu are exothermic in character at all levels ranging from dissociative chemisorption to interstitial absorption, the formation of hydrogen-vacancy complexes, and generation of a hydride phase. The exothermic character of these interactions appears to be the reason for the rapid hydriding reaction, which has been determined experimentally to be essentially a barrierless process. The anionic character is observed to be retained. Our studies also indicate that vacancies do not appear to be strong traps for hydrogen, since the interstitial absorption sites are exothermic in nature. We will propose a scheme by which hydrogen interacts with Pu. Results will be compared with previous studies in the literature where available.

Monday, February 27, 2012 11:15AM - 2:15PM —
Session B6 DCMP DMP: Thermal Properties of Graphene and Graphene Derivatives 206B

11:15AM B6.00001 Nanoscale Thermal Transport in Graphene Interfaces, RUI MAO, BYOUNGDON KONG, North Carolina State University, THUSHARI JAYASEKERA, Southern Illinois University, MARCO BUONGIORNO-NARDELLI, KI WOOK KIM, North Carolina State University, NORTH CAROLINA STATE UNIVERSITY TEAM — We have investigated nanoscale thermal transport in epitaxial graphene systems using first-principles calculations and the Landauer formalism for phonon transport. Two types of interfaces are investigated: graphene-dielectric and graphene-metal heterojunctions. Hexagonal boron nitride (h-BN), SiC and SiC with hydrogen passivation (SiC-H) are studied as potential dielectric substrate materials for graphene devices. As for graphene-metal contacts, we have considered Au and Ti as prototypical systems for physisorbed and chemisorbed metal contacts, respectively. The interfacial thermal resistances of h-BN/G system is $5.3 \cdot 10^{-9} \text{ Km}^2/\text{W}$ at room temperature, which is approximately one order of magnitude smaller than that of SiC/G system ($55\text{-}79 \cdot 10^{-9} \text{ Km}^2/\text{W}$). Further analysis shows that heat conduction at the graphene interfaces is dominated by low-lying acoustic phonons and the thermal resistances strongly depend on atomic details at the interface such as lattice mismatch, disorder and surface reconstruction. Our work demonstrates the importance of developing a microscopic description of phonon dynamics at heterogeneous interfaces to engineer and design devices with optimal thermal management.

11:27AM B6.00002 Isotope impurity doping in graphene, JOAQUIN RODRIGUEZ-NIEVA, MIT, RIICHIRO SAITO, Tohoku University, Japan, MILDRED S. DRESSELHAUS, MIT — Isotope impurities provide a powerful technique to study phonon related properties of graphene. The advantage of this approach is that phonon frequencies or thermal properties can be modified so that we can identify the origin of the interaction in the unknown optical spectra without changing either the electrical or chemical properties. In the presence of a ^{13}C isotope impurity in a normally ^{12}C lattice, the phonon wavefunction of graphene becomes localized. When we discuss the electron-phonon interaction of graphene, we treat phonons in terms of a delocalized wavefunction. However, in real graphene, we know that 2% of the atoms are ^{13}C and thus phonons have a finite lifetime, which results in a natural width in the Raman spectra. Many experimental results were obtained recently related to isotopic doping of graphene and carbon nanotubes and its effect on Raman spectra. In this work, we calculate the localization length of the phonons as well as the power law dependence for this effect. At the same time, we calculate the phonon lifetime of the different phonon modes within first order perturbation theory to elucidate the physical mechanisms behind isotope doping and to provide further insight into the experimental results.

11:39AM B6.00003 Polarization and electric field dependent electron-phonon interaction in graphene and graphene oxide, SATYAPRAKASH SAHOO, RAM S. KATIYAR, Department of Physics, University of Puerto Rico, San Juan, PR 00936-837 — Raman spectroscopy has been emerged as one of the important tool to understand various physical properties of graphene and graphene oxide. In this study, polarized Raman scattering has been performed to understand the electron-phonon interaction in connection with the second order Raman scattering process (2D band) in monolayer, bilayer and suspended bilayer graphene. The 2D Raman band shows strong polarization dependent irrespective of number of graphene layers. This effect has been explained on the basis of anisotropic photon scattering through the nodes at the K-point of the Brillouin zone in graphene during optical absorption. We also explored the electron-phonon interaction in graphene oxide in presence of electric field. The in-situ Raman studies show significant changes in the D and G Raman bands. In particular, the splitting of G band was observed with increase in voltage which indicates the electric field can alter the deformation-potential mediated electron-phonon interaction in graphene oxide. The electrical conductivity of graphene oxide was also found to increase dramatically with increase in voltage.

11:51AM B6.00004 High-fidelity phonon transport simulation in graphene devices using efficient, variance-reduced Monte Carlo methods, COLIN LANDON, NICOLAS HADJICONSTANTINO, Mechanical Engineering, MIT — In this talk we consider thermal transport in graphene at sufficiently small scales that diffusive transport (Fourier's law) is no longer valid. In this regime, the Boltzmann transport equation may be used to describe thermal transport, and Monte Carlo is the typical solution method, especially in the context of device simulation. Unfortunately, due to the slow rate of convergence of Monte Carlo solutions with the number of samples, such simulations can be prohibitively costly. By employing a recently developed variance-reduced Monte Carlo method, we are able to efficiently simulate the Boltzmann equation for phonon transport without resorting to approximations for reducing the problem complexity or dimensionality, such as neglecting phonon-phonon scattering events, or modeling boundary scattering as a homogeneous relaxation (scattering) process. We use our simulations to characterize the error associated with these approximations in the context of thermal transport in graphene devices, but also to study thermal transport in novel two-dimensional geometries.

12:03PM B6.00005 Thermal transport in graphene-based nanostructures¹, ZLATAN AKSAMIJA, IRENA KNEZEVIC, University of Wisconsin-Madison — Thermal conductivity of graphene and graphene-based nanostructures, such as graphene nanoribbons (GNRs), CVD-grown polycrystalline graphene (PCG), and nano-patterned single-layer graphene (SLG), is of great interest due to their potential applications as logic devices, high-frequency amplifiers, and heat spreaders in future nanoelectronic circuits. Both line edge roughness (LER) and substrate scattering have been shown to impact thermal transport and reduce graphene's record thermal conductivity; however, the combination of these two mechanisms, which will both be present simultaneously in supported nanostructures, has not been explored previously, and their combined impact on thermal transport has not been assessed. We solve the phonon Boltzmann transport equation and calculate the thermal conductivity tensor in a variety of suspended and supported graphene nanostructures. We show that there is a competition between LER and substrate scattering processes, leading to a high degree of directional anisotropy of thermal conductivity. We demonstrate that transport in narrow ribbons ($W < 100 \text{ nm}$) and PCG or nano-SLG with small feature sizes is dominated by roughness scattering and highly anisotropic. We discuss different avenues of controlling thermal transport in graphene-based devices.

¹This work has been supported by the Computing Innovation Fellows Project (NSF award No. 0937060 to the Computing Research Association, sub-award CIF-146 to the University of Wisconsin) and by the AFOSR YIP program (award No. FA9550-09-1-0230).

12:15PM B6.00006 Measurements of Thermal Conductivity and Thermopower in Suspended Single and Few Layer Graphene, INSUN JO, Department of Physics, The University of Texas at Austin, Austin, TX78712, USA, MICHAEL PETTES, Department of Mechanical Engineering, The University of Texas at Austin, Austin, TX78712, USA, ZHEN YAO, Department of Physics, The University of Texas at Austin, Austin, TX78712, USA, LI SHI, Department of Mechanical Engineering, The University of Texas at Austin, Austin, TX78712, USA — Detailed study on thermal conductivity and thermopower in suspended single and few layer graphene has been hampered by experimental challenges mainly due to the difficulty of obtaining suspended samples larger than a few micrometers. Here, we report on a high-yield process for the fabrication of suspended graphene samples of one to few atomic layers on micro-thermometer devices, which allow us to investigate electrical and thermal conductivity, and thermopower from 4 K to 500 K. We find that the thermal conductivity values in suspended graphene are largely limited by scattering with surface residues in as-made devices, and they can reach values comparable to those of bulk graphite after thorough cleaning of the sample surfaces. In addition, temperature-dependent thermopower results in suspended graphene are reported.

12:27PM B6.00007 Thermal Transport in Graphene from Large-scale Molecular Dynamics Simulations, LUIZ FELIPE PEREIRA, DAVIDE DONADIO, Max Planck Institute for Polymer Research — Carbon-based materials display exceptional thermal properties. The thermal conductivity of carbon allotropes can range five orders of magnitude. In the bulk, amorphous carbon is a very poor heat conductor, with $\kappa \approx 0.01$ W/m/K, whereas diamond has the highest thermal conductivity among elemental solids, $\kappa \approx 2000$ W/m/K at room temperature. Even broader ranges can be achieved by considering carbon nanostructures. Thermal conductivities as large as 5000 W/m/K have been measured for suspended graphene and carbon nanotubes. In spite of intense investigations, there is much controversy over the actual value of the thermal conductivity of graphene, both experimentally and theoretically. Here, we present results from equilibrium and non-equilibrium molecular dynamics simulations aimed at understanding the mechanism of heat transport in graphene. In particular, we investigate the influence of finite-size and uniaxial strain on the thermal conductivity of graphene, performing large scale molecular dynamics simulations of micrometer-size models containing up to 10^6 atoms.

12:39PM B6.00008 Tunable thermal transport and negative differential thermal conductance in graphene nanoribbons, JIUNING HU, YAN WANG, AJIT VALLABHANENI, XIULIN RUAN, YONG CHEN, Purdue University — We have studied thermal transport in graphene nanoribbons (GNRs) using classical nonequilibrium molecular dynamics simulations. We show that the calculated thermal conductivity of GNRs can be dramatically tuned by the shape, isotope composition, defects, and chirality and hydrogen passivation of the edges [1-2]. For GNRs under large temperature bias beyond the linear response, we have studied negative differential thermal conductance (NDTC) [3]. The NDTC is found to vanish for a sufficiently long GNR whose temperature is fixed at one end. Furthermore, for diffusive thermal transport obeying differential Fourier's law in a generic one-dimensional system, we analytically show that NDTC requires temperature dependent thermal conductivity and simultaneously varying temperatures at both ends. We have also studied asymmetrical GNRs and observed thermal rectification [1] and direction dependent NDTC [3]. Our studies may be useful for nanoscale thermal managements and thermal signal processing using GNRs and understanding low dimensional thermal transport in general.

12:51PM B6.00009 Heat Transport in Graphene, SERAP YIGEN, VAHID TAYARI, JOSHUA O. ISLAND, JAMES PORTER, A.R. CHAMPAGNE, Department of Physics, Concordia University, Montreal, QC, Canada — We fabricated suspended graphene devices and measured their thermal conductivity, κ , as a function of both temperature, T, and charge carrier density, n. Heat transport is a powerful tool to obtain information about both the phononic and electronic properties of graphene. Recent heat transport experiments in graphene have shown a high κ , but a detailed mapping of graphene's heat conductivity versus T and n is not yet available. The measurement technique we developed is a two-point method which uses graphene as its own heat source (Joule heating) and thermometer (resistivity). We report κ at temperatures ranging from 6 to 350 Kelvin, and at charge carrier densities close to the Dirac point up to about $1.5 \times 10^{11}/\text{cm}^2$, in graphene crystals whose length varies from 250 nm up to one micron. We observed that the thermal conductivity increases by over two orders of magnitude over the temperature range, and that it also increases with the crystal's length. κ can be tuned by an order of magnitude with gate voltage, opening the possibility of creating room temperature heat transistors.

1:03PM B6.00010 Raman Measurements of Thermal Transport in Suspended Monolayer Graphene of Variable Sizes in Vacuum and Gaseous Environments, SHANSHAN CHEN, ARDEN MOORE, WEIWEI CAI, JI WON SUK, JINHO AN, COLUMBIA MISHRA, CHARLES AMOS, CARL MAGNUSON, University of Texas at Austin, JUNYONG KANG, Xiamen University, Xiamen, China, LI SHI, RODNEY RUOFF, University of Texas at Austin, XIAMEN UNIVERSITY TEAM — Using micro-Raman spectroscopy, the thermal conductivity of a graphene monolayer grown by chemical vapor deposition and suspended over holes with different diameters ranging from 2.9 to 9.7 μm was measured in vacuum, thereby eliminating errors caused by heat loss to the surrounding gas. The obtained thermal conductivity values of the suspended graphene range from (2.6 ± 0.9) to $(3.1 \pm 1.0) \times 10^3 \text{ Wm}^{-1} \text{ K}^{-1}$ near 350 K without showing the sample size dependence predicted for suspended, clean, and flat graphene crystal. The lack of sample size dependence is attributed to the relatively large measurement uncertainty as well as grain boundaries, wrinkles, defects, or polymeric residue that are possibly present in the measured samples. Moreover, from Raman measurements performed in air and CO_2 gas environments near atmospheric pressure, the heat transfer coefficient for air and CO_2 was determined and found to be $(2.9 \pm 5.1 / -2.9)$ and $(1.5 \pm 4.2 / -1.5) \times 10^4 \text{ Wm}^{-2} \text{ K}^{-1}$, respectively, when the graphene temperature was heated by the Raman laser to about 510 K.

1:15PM B6.00011 Effect of electron-electron interactions in thermoelectric power in graphene, FERESHTE GHAHARI, YURI ZUEV, Columbia University, Department of Physics, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, Japan, PHILIP KIM, Columbia University, Department of Physics — Thermoelectric power (TEP) of graphene is previously measured in the disorder limited transport regime where the semiclassical Mott relation agrees with experimental data. In this presentation, we report the TEP measurement on graphene samples deposited on hexa boron nitride substrates where drastic suppression of disorder is achieved. Our results show that at high temperatures where the inelastic scattering rate due to electron-electron (e-e) interactions is higher than the elastic scattering rate by disorders, the measured TEP exhibit a large enhancement compared to the expected TEP from the Mott relation. We also investigated TEP in the quantum Hall regime at a high magnetic fields, where we observed symmetry broken integer quantum Hall and fractional quantum Hall states due to the strong e-e interactions.

1:27PM B6.00012 Derivative relations between electrical and thermoelectric quantum transport coefficients in graphene¹, XINFEI LIU, Department of Physics and Astronomy, University of California, Riverside, ZHONGSHUI MA, School of Physics, Peking University, JING SHI, Department of Physics and Astronomy, University of California, Riverside — We find that the empirical relation between the longitudinal and Hall resistivities (i.e. R_{xx} and R_{xy}) and its counterpart between the Seebeck and Nernst coefficients (i.e. S_{xx} and S_{xy}), both originally discovered in conventional two-dimensional electron gases [1,2], hold surprisingly well for graphene in the quantum transport regime except near the Dirac point. These empirical relations can be described by the following equations:

$$R_{xx} = \alpha_r \cdot \frac{B}{n} \frac{dR_{xy}}{dB}, \quad S_{yx} = \alpha_s \cdot \frac{B}{n} \frac{dS_{xx}}{dB}$$

Here R and S are electrical resistivity and thermoelectric conductivity tensor respectively. The validity of the relations is cross-examined by independently varying the magnetic field and the carrier density in graphene. We demonstrate that the pre-factor, α_s , does not depend on carrier density in graphene. By tuning the carrier mobility therefore the degree of disorders, we find that the pre-factor stays unchanged. Our experimental results validate both derivative relations for massless Dirac fermions except near the Dirac point.

1:39PM B6.00013 Ultra-sensitive thermal measurements of graphene: pathway to single microwave photon detector, KIN CHUNG FONG, KEITH SCHWAB, Caltech — As a result of the linear energy spectrum and low dimensionality, electrons in graphene have astoundingly small thermal conductance and heat capacitance. By developing a large bandwidth, high sensitivity Johnson noise measurement technique at microwave frequency, we can measure the temperature of graphene electrons down to a precision of 0.1 mK within 1 second. This enables us to study the thermal properties of this wonder material: for instance, we have measured the energy transfer from electrons to phonons at 1 pW/K μm^2 level and a record-low heat capacity, only about 100 kJ/ μm^2 , at low temperature. We have applied these exotic thermal quantities to make a graphene bolometer and mixer. Our measurement data agree well with the theory that the proposed graphene calorimeter should have single photon sensitivity from IR down to microwave regime at ultra-low temperature.

1:51PM B6.00014 Nano Peltier cooling device from geometric effects using a single graphene nanoribbon, WAN-JU LI, Purdue University, DAO-XIN YAO, Sun Yat-sen University, ERICA CARLSON, Purdue University — Based on the phenomenon of curvature-induced doping in graphene we propose a class of Peltier cooling devices, produced by geometrical effects, without gating. We show how a graphene nanoribbon laid on an array of curved nano cylinders can be used to create a targeted cooling device. Using theoretical calculations and experimental inputs, we predict that the cooling power of such a device can approach $1\text{ kW}/\text{cm}^2$, on par with the best known techniques using standard lithography methods. The structure proposed here helps pave the way toward designing graphene electronics which use geometry rather than gating to control devices.

2:03PM B6.00015 Electrical breakdown of graphene and few-layer graphene structures, ABHISHEK SUNDARARAJAN, D. PATRICK HUNLEY, DOUGLAS R STRACHAN, University of Kentucky — The electrical breakdown of graphene and few-layer graphene (FLG) structures are investigated. To better understand the dynamics of these nano-scale thermal effects, we investigate graphene and FLG structures of various dimensions and find that significant joule heating occurs inducing the structures to evolve. A distinct change in the behavior during electrical stressing indicates that different mechanisms and geometrical effects occur at the various stages of evolution. The results could have implications on the development of high current carrying nanoscale graphene devices. Supported in part by NSF Award No. DMR-0805136, the Kentucky NSF EPSCoR program through award EPS-0814194, and the University of Kentucky Center for Advanced Materials.

Monday, February 27, 2012 11:15AM - 2:15PM –
Session B7 DCOMP DMP: Focus Session: Computational Design of Materials - Nanostructured and Energy Materials 207

11:15AM B7.00001 The Harvard Clean Energy Project: High-throughput screening of organic photovoltaic materials using first-principles electronic structure theory, JOHANNES HACHMANN, ROBERTO OLIVARES-AMAYA, SULE ATAHAN-EVRENK, Harvard University, CARLOS AMADOR-BEDOLLA, Universidad Nacional Autonoma de Mexico, ALAN ASPURU-GUZZIK, Harvard University — We present the Harvard Clean Energy Project (CEP) which is concerned with the computational screening and design of new organic photovoltaic materials. CEP has established an automated, high-throughput, in silico framework to study millions of potential candidate structures. This presentation discusses the CEP branch which employs first-principles computational quantum chemistry for the characterization of molecular motifs and the assessment of their quality with respect to applications as electronic materials. In addition to finding specific structures with certain properties, it is the goal of CEP to illuminate and understand the structure-property relations in the domain of organic electronics. Such insights can open the door to a rational, systematic, and accelerated development of future high-performance materials. CEP is a large-scale investigation which utilizes the massive computational resource of IBM's World Community Grid. In this context, it is deployed as a screensaver application harvesting idle computing time on donor machines. This cyberinfrastructure paradigm has already allowed us to characterize 3.5 million molecules of interest in about 50 million DFT calculations.

11:27AM B7.00002 The Harvard Clean Energy Project: High-throughput screening of organic photovoltaic materials using cheminformatics, machine learning, and pattern recognition, ROBERTO OLIVARES-AMAYA, JOHANNES HACHMANN, Harvard University, CARLOS AMADOR-BEDOLLA, Universidad Nacional Autónoma de México, AIDAN DALY, ADRIAN JINICH, SULE ATAHAN-EVRENK, Harvard University, SERGIO BOIXO, University of Southern California, ALAN ASPURU-GUZZIK, Harvard University — Organic photovoltaic devices have emerged as competitors to silicon-based solar cells, currently reaching efficiencies of over 9% and offering desirable properties for manufacturing and installation. We study conjugated donor polymers for high-efficiency bulk-heterojunction photovoltaic devices with a molecular library motivated by experimental feasibility. We use quantum mechanics and a distributed computing approach to explore this vast molecular space. We will detail the screening approach starting from the generation of the molecular library, which can be easily extended to other kinds of molecular systems. We will describe the screening method for these materials which ranges from descriptor models, ubiquitous in the drug discovery community, to eventually reaching first principles quantum chemistry methods. We will present results on the statistical analysis, based principally on machine learning, specifically partial least squares and Gaussian processes. Alongside, clustering methods and the use of the hypergeometric distribution reveal moieties important for the donor materials and allow us to quantify structure-property relationships. These efforts enable us to accelerate materials discovery in organic photovoltaics through our collaboration with experimental groups.

11:39AM B7.00003 Thermodynamic Stability of Semiconductors for Photocatalytic Water Splitting¹, SHIYOU CHEN, LIN-WANG WANG, Lawrence Berkeley National Laboratory, MATERIALS SCIENCES DIVISION TEAM — Band structure engineering design of the light-absorbing semiconductors for water splitting has attracted wide attention recently. One of such design is to use the Z-scheme where a photocathode is connected with photoanode to reduce (generate H₂) and oxidize (generate O₂) water respectively. This requires the conduction band of photocathode and valence band of photoanode to straddle the redox levels of water. However, equally important in this design is the thermodynamic stability of the semiconductors in the aqueous solution upon illumination, i.e., the semiconductors may be oxidized (or reduced) before the water is oxidized (or reduced), causing the corrosion of the photoanode (photocathode). We will present our theoretical study on the thermodynamic stability of a series of photocatalytic semiconductors, including metal oxides, sulfides and nitrides, through the combination of phenomenological models for the semiconductor corrosion and the first-principles total energy and band alignment calculations. We find that almost all sulfides and nitrides are unstable as photoanode, while most of oxides are stable. This limits the choice of the photoanode materials for oxygen evolution. In contrast, for photocathode, most of the considered semiconductors are stable and resistant to reduction, indicating a much wider choice of the photocathode materials for hydrogen evolution.

¹The work is supported by the Joint Center of Artificial Photosynthesis and the BES/SC of DOE under the contract No. DE-AC02-05CH11231, and the computation is performed using the NERSC and NCCS supercomputers.

11:51AM B7.00004 Rational design of competitive electrocatalysts for the oxygen reduction reaction in hydrogen fuel cells, SERGEY STOLBOV, University of Central Florida Physics Department, MARISOL ALCÁNTARA ORTIGOZA, Karlsruher Institut für Technologie, Institut für Festkörperphysik, Karlsruhe, Germany — The large-scale application of one of the most promising clean and renewable sources of energy, hydrogen fuel cells, still awaits efficient *and* cost-effective electrocatalysts for the oxygen reduction reaction (ORR) occurring on the cathode. We demonstrate that truly rational design renders electrocatalysts possessing both qualities. By unifying the knowledge on surface morphology, composition, electronic structure and reactivity, we solve that sandwich-like structures are an excellent choice for optimization. Their constituting species couple synergistically yielding reaction-environment stability, cost-effectiveness and tunable reactivity. This cooperative-action concept enabled us to predict two advantageous ORR electrocatalysts. Density functional theory calculations of the reaction free-energy diagrams confirm that these materials are more active toward ORR than the so far best Pt-based catalysts. Our designing concept advances also a general approach for engineering materials in heterogeneous catalysis.

12:03PM B7.00005 First principles design of the Pd/Co/Pd sandwich-like structure as a promising electrocatalyst for the oxygen reduction reaction on hydrogen fuel cell cathode, SEBASTIAN ZULUAGA, SERGEY STOLBOV, University of Central Florida — In the search of Pt free catalytic materials, experiments have shown an enhancement in the catalytic activity of Pd-Co alloys over Pd surfaces, comparable to the one obtained with Pt, as well as a Pd enrichment of the topmost layers. In this work we present the rational design of a new catalyst material towards the oxygen reduction reaction (ORR) consisting on Pd(111) surface sandwiched with Co as the second layer (Pd/Co/Pd). The calculated reaction free energy diagrams confirm that the proposed sandwich-like structure is highly active towards ORR. The higher catalytic activity of the Pd/Co/Pd system is traced to the change in the electronic local density of states of the Pd surface atoms. Namely the hybridization of the Pd d-states with the Co majority-spin band causes a low-energy shift of the Pd d-band. This results in a reduction of surface reactivity which is favorable for ORR. We have also studied from first principles the stability of the system and evaluated the dissolution potential of Pd in Pd/Co/Pd. The results suggest that the system will be stable in the reaction environment.

12:15PM B7.00006 Computational Design of Co-Doping Method for Indium-Reduced Chalcopyrite-Type Photovoltaic Materials, KAZUNORI SATO, Graduate School of Engineering Science, Osaka University, PRESTO-JST, YOSHIMASA TANI, HIROSHI KATAYAMA-YOSHIDA, Graduate School of Engineering Science, Osaka University — Chalcopyrite-type semiconductor CuInSe_2 (CIS) is one of the most promising materials for low cost photovoltaic solar-cells. However, from the point of resource security, high concentration of In in CIS is serious disadvantage. In this paper, we propose co-doping method to reduce the concentration of In in CIS-based photovoltaic materials, i.e., 2In are replaced by Zn and Sn. According to the electronic structure calculations by the KKR-CPA-LDA [1] with the self-interaction correction [2], the substitution of Zn and Sn for In does not alter the electronic structure of CIS so much. We extend our co-doping method to enhance the efficiency of solar energy conversion. In addition to Zn+Sn co-doping, we introduce S impurities at Se sites. Due to the phase separation it is found that nano-structures with high concentration of S are self-organized under the layer-by-layer crystal growth condition. Since type-II band alignment is expected between $\text{Cu}(\text{Zn}, \text{Sn})\text{Se}_2$ and $\text{Cu}(\text{Zn}, \text{Sn})\text{S}_2$, we can expect efficient electron-hole separation in decomposed $\text{Cu}(\text{Zn}, \text{Sn})(\text{Se}, \text{S})_2$ [3].

12:27PM B7.00007 Effect of carbon and nitrogen doping on the structure of amorphous GeTe phase change material¹, JEAN-YVES RATY, Physics Department B5, University of Liege, 4000 Sart-Tilman Belgium, GIADA GHEZZI, SYLVAIN MAITREJEAN, PIERRE NOÉ, ANNE ROULE, CEA-Leti, Minattec, 17 rue des Martyrs, 38054 Grenoble, France, CHRISTOPHE BICHARA, CINAM-CNRS, Campus de Luminy, Case 913, 13288 Marseille Cedex 9, France, FRANÇOISE HIPPERT, LMPG-Grenoble, Minattec 3, Parvis L. Néel, 38016 Grenoble, France — Carbon and Nitrogen-doped GeTe are promising materials for use in phase change memories since the addition of C or N increases the stability of the amorphous phase. By combining ab initio molecular dynamics and X-ray scattering experiments, we show that carbon deeply modifies the structure of the amorphous phase through long carbon chains, tetrahedral and triangular units centred on carbon. A clear signature of these units is the appearance of an additional interatomic distance around 3.3 Å in the pair correlation function. Besides, the first Ge-Ge and Ge-Te distances are almost not affected by doping. The implications for the vibrational and thermal properties are finally discussed.

¹JYR acknowledges support from the FNRS and from the University of Liège (ARC).

12:39PM B7.00008 Towards Efficient Solar Cells: Optimizing Non-Equilibrium Hyperdoping Methods, TOBIAS M. SCHNEIDER, MICHAEL P. BRENNER, Harvard School of Engineering and Applied Sciences — Electrical and optical properties of semiconductors are mainly controlled by the concentration of dopants. While the highest dopant concentrations reachable in most traditional doping methods are limited by the equilibrium solubility of the dopant in the pure semiconductor material, much higher concentrations are observed after femtosecond laser treatment of silicon in a sulfur containing atmosphere. Due to altered optical properties *laser-hyperdoped* silicon is considered a promising material for next generation photovoltaic cells. To control the dopant concentration distribution and thereby tune physical properties of the material, we apply advanced adjoint based optimization techniques to the models describing the laser induced melting and diffusion processes. This allows to determine optimal process protocols generating a desired concentration distribution. Applying advanced PDE-constrained optimization techniques to laser hyperdoping thereby opens new avenues for improving the efficiency of photovoltaic cells.

12:51PM B7.00009 First-Principles Materials Design of Chalcopyrite-Type Photovoltaic Materials with Self-Organized Nano-Structures, YOSHIMASA TANI, Graduate School of Engineering Science, Osaka University, KAZUNORI SATO, Graduate School of Engineering Science, Osaka University, PRESTO-JST, HIROSHI KATAYAMA-YOSHIDA, Graduate School of Engineering Science, Osaka University — $\text{Cu}(\text{In}, \text{Ga})\text{Se}_2$ (CIGS) is a chalcopyrite-type semiconductor and one of the most promising materials for low cost photovoltaic solar-cells. In this paper, based on first-principles calculations, we propose that spinodal decomposition will enhance the conversion efficiency in CIGS. Our calculations are based on the KKR-CPA-LDA [1] with the self-interaction correction [2]. From the calculated mixing energy of CIGS, it is found that the system favors the spinodal decomposition. We also perform Monte Carlo simulations and find that quasi-one-dimensional nano-structures with high concentration of impurities are formed under the layer-by-layer crystal growth condition in CIGS [3]. It is expected that the photo-generated electron-hole pairs are efficiently separated by the type-II interface and then effectively transferred along the quasi-one-dimensional structures in CIGS. Moreover, we can expect multiplication of generated carriers due to the multi-exciton effects in nano-structures [3].

1:03PM B7.00010 Computational Nano-materials Design of Self-Organized Cd(Te,S) and Cd(Te,Se) Type II Nanowire (Konbu-Phase) by Spinodal Nano-Decomposition for High-Efficiency Photovoltaic Solar-Cells, HIROSHI KATAYAMA-YOSHIDA, MASAMUNE OSHITANI, Graduate School of Engineering Science, Osaka University, KAZUNORI SATO, Graduate School of Engineering Science, Osaka University and PRESTO-JST — Based on multi-scale simulations combined ab initio electronic structure calculation (KKR-CPA) and Monte Carlo simulation (MCS) of the two-dimensional layer-by-layer crystal growth, we have designed the self-organized quasi-one-dimensional nano-structures (Konbu-Phase) fabricated by two-dimensional spinodal nano-decomposition for high-efficiency photovoltaic solar cells (PVSCs) in Cd(Te_{1-x}S_x), and Cd(Te_{1-x}Se_x). The Konbu-Phase enhances the nano-scale electron-hole separation in PVSCs due to their Type II band alignment. The Konbu-Phase also increases the efficiency of PVSCs by multi-exciton formation using the inverse Auger effect in the self-organized quasi-one-dimensional nanostructures. We also discuss how to fabricate Konbu-Phase starting from the uniform nano-particles made by the photo-chemical reactions. Reference: M. Oshitani, K. Sato, H. Katayama-Yoshida, Applied Physics Express 4 (2011) 022302.

1:15PM B7.00011 Half-Heusler semiconductors as piezoelectrics, ANINDYA ROY, UC Santa Barbara, JOSEPH W. BENNETT, KARIN M. RABE, DAVID VANDERBILT, Rutgers University — We use a first-principles rational-design approach to demonstrate the potential of semiconducting half-Heusler compounds as a previously-unrecognized class of piezoelectric materials. We scan a large number of compounds, testing for insulating character and calculating structural, dielectric, and piezoelectric properties. Of the 792 compounds considered, 234 are found to be nonmetallic, of which 189 are further found to be elastically stable. We compare the computed structural parameters to available experimental values for the half-Heusler compounds considered that have been experimentally studied, as reported in the Inorganic Crystal Structure Database. Calculated piezoelectric coefficients (d_{14}) and electromechanical coupling factors (k_{14}) are often high enough to compare favorably with those of piezoelectrics currently in use. We analyze how factors such as electronegativity and ionic radius influence the piezoelectricity of the compound. Moreover, we show that even if toxic or expensive elements are excluded, we are still left with many combinations having reasonably high piezoelectric response. Our results provide guidance for the experimental realization and characterization of high-performance materials of this class that may find practical applications.

1:27PM B7.00012 Oxygen transport in ceria: a first-principles study¹, SIMAK SERGEI, Linköping University, Linköping, Sweden — Ceria (CeO₂) is an important material for environmentally benign applications, ranging from solid-oxide fuel cells (SOFC) to oxygen storage [1-2]. The key characteristic needed to be improved is the mobility of oxygen ions. Optimization of ionic transport in ceria has been the topic of many studies. In particular, it has been discovered how the ionic conductivity in ceria might be improved by choosing the proper kind and concentration of dopants [3]. In this presentation we will approach the problem from a different direction by adjusting structural parameters of ceria via the change of external conditions. A systematic first-principles study of the energy landscape and kinetics of reduced ceria as a function of external parameters reveals a physically transparent way to improve oxygen transport in ceria.

1:39PM B7.00013 First Principles Optical Absorption Spectra of Organic Molecules Adsorbed on Titania Nanoparticles, KOPINJOL BAISHYA, SERDAR OGUT¹, University of Illinois at Chicago, ERSEN METE, Balikesir University, OGUZ GULSEREN, Bilkent University, SINASI ELLIALTIÖGLU, Middle East Technical University, Turkey — We present results from first principles computations on passivated rutile TiO₂ nanoparticles in both free-standing and dye-sensitized configurations to investigate the size dependence of their optical absorption spectra. The computations are performed using time-dependent density functional theory (TDDFT) as well as GW-Bethe-Salpeter-Equation (GWBSE) methods and compared with each other. We interpret the first principles spectra for free-standing TiO₂ nanoparticles within the framework of the classical Mie-Gans theory using the bulk dielectric function of TiO₂. We investigate the effects of the titania support on the absorption spectra of a particular set of perylene-diimide (PDI) derived dye molecules, namely brominated PDI (Br₂C₂₄H₈N₂O₄) and its glycine and aspartine derivatives.

1:51PM B7.00014 Stoichiometric anti-phase boundaries in monolayer boron-nitride¹, SIMONE S. ALEXANDRE, LIDIA C. GOMES, HELIO CHACHAM, RICARDO W. NUNES, U. F. Minas Gerais - Brazil — We propose a stoichiometric structure for domain boundaries in monolayer boron nitride, on the basis of the seeds of extended topological defect lines that have been observed in graphene under electronic irradiation [1]. The structure consists of a periodic extended line defect with an atomic structure consisting of alternating fourfold and eightfold BN rings. The structure is shown to be lower in energy than non-stoichiometric counterparts, and to lead to the formation of shallow electron and hole bands inside the band gap of the BN bulk matrix. We suggest that the existence of such defect bands may be experimentally observed in optical experiments.

2:03PM B7.00015 Understanding Heat Dissipation in Carbon Nanotube Resonators: New Insights from Molecular Dynamics Simulation, RAJAMANI RAGHUNATHAN, Department of Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge, MA 02139, P. ALEX GREANEY, School of Mechanical, Industrial and Manufacturing Engineering Oregon State University, Corvallis, OR 97331, JEFFREY C. GROSSMAN, Department of Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge, MA 02139 — Dissipation in carbon nanotube (CNT) resonators under conditions of steady state continuous driving has been simulated within classical molecular dynamics (MD) making use of a newly developed “Phonostat” algorithm. A previous study on heat flow in CNT resonators using MD simulation showed an anomalous heat dissipation and gateway kind of behavior was proposed. Here, we focus on characterizing the “gateway” modes and identify the pathways of heat dissipation by clamping such modes using our phonostat algorithm. In this present study we see three or four different sets of heat flow behavior when different sets of gateway modes are clamped as against a single heat flow behavior presented in the previous study. Our new results are explained in terms of filling of different subsets of phonon modes and the magnitude of friction between them. Our simulation results show that controlling these gateway modes is the key to improve the quality factor (Q) of CNT resonators for sensing applications, which has been a major challenge till now.

Monday, February 27, 2012 11:15AM - 2:15PM –
Session B8 DMP GMAG: Focus Session: Frustrated magnetism - Spin ice 208

11:15AM B8.00001 Spin dynamics in the frozen state of the dipolar spin ice material $\text{Dy}_2\text{Ti}_2\text{O}_7$, H.M. REVELL, L.R. YARASKAVITCH, S. MENG, University of Waterloo, K.A. ROSS, H.M.L. NOAD, McMaster University, H.A. DABKOWSKA, Brockhouse Institute for Materials Research, B.D. GAULIN, McMaster University, J.B. KYCIA, University of Waterloo — Low temperature magnetic ac susceptibility measurements of single crystal dipolar spin ice $\text{Dy}_2\text{Ti}_2\text{O}_7$ are presented. The measured dynamics qualitatively agree with simulations based on current magnetic monopole theory, but not with thermal relaxation measurements, whose dynamics freeze out at a slower rate. The relaxation is found to exhibit thermally activated Arrhenius behavior with an activation energy of 9.79 K. A comparison between the measurement results of $\text{Ho}_2\text{Ti}_2\text{O}_7$ and $\text{Dy}_2\text{Ti}_2\text{O}_7$ will also be made.

11:27AM B8.00002 Anderson-Higgs transition in quantum spin ice $\text{Yb}_2\text{Ti}_2\text{O}_7$, L.J. CHANG, Department of Physics, National Cheng Kung University, Tainan 70101, Taiwan, S. ONODA, Condensed Matter Theory Laboratory, RIKEN, Wako, Saitama 351-0198, Japan, Y. SU, Juelich Centre for Neutron Science JCNS-FRM II, Forschungszentrum Juelich GmbH, Outstation at FRM-II, Lichtenbergstrasse 1, D-85747 Garching, Germany, Y.-J. KAO, Department of Physics, and Center of Quantum Science and Engineering, National Taiwan University, Taipei 10607, Taiwan, K.D. TSUEI, National Synchrotron Radiation Research Center, HsinChu 30076, Taiwan, Y. YASUI, Department of Physics, Division of Material Science, Nagoya University, Furo-cho, Chikusa-ku, Nagoya 464-8602, Japan, K. KAKURAI, Quantum Beam Science Directorate, Japan Atomic Energy Agency, Tokai, Ibaraki 319-1195, Japan, M.R. LEES, Department of Physics, University of Warwick, Coventry CV4 7AL, United Kingdom — We have carried out polarized elastic neutron-scattering experiments on single crystals $\text{Yb}_2\text{Ti}_2\text{O}_7$ from 1 K to 0.04 K. The results reveal that the diffuse [111]-rod scattering [1] is suppressed below $T_c \sim 0.21$ K, where magnetic Bragg peaks and a full depolarization of neutron spins are observed with the thermal hysteresis, indicating a first-order ferromagnetic transition. Theoretically, a quantum spin ice state [2] above T_c has been realized from an effective classical model where $\langle 111 \rangle$ Ising moments, i.e., pseudospin-1/2 interact mainly through a magnetic dipolar interaction [3], and a transition from magnetic Coulomb phase to Higgs phase has emerged at T_c in $\text{Yb}_2\text{Ti}_2\text{O}_7$. [1] K. A. Ross *et al.*, Phys. Rev. Lett. **103**, 227202 (2009). [2] S. Onoda *et al.*, J. Phys.: Conf. Series, in press. [3] S. T. Bramwell and M. J. P. Gingras, Science **294**, 1495 (2001).

11:39AM B8.00003 Schwinger-boson approach to spin-liquid and Higgs phases in quantum spin ice: $\text{Yb}_2\text{Ti}_2\text{O}_7$ and $\text{Pr}_2\text{Zr}_2\text{O}_7$, SHIGEKI ONODA, Condensed Matter Theory Laboratory, RIKEN — The most generic pseudospin-1/2 quantum spin ice model for rare-earth magnetic pyrochlore oxides, that include $\text{Yb}_2\text{Ti}_2\text{O}_7$ and $\text{Pr}_2\text{TM}_2\text{O}_7$ (TM=Sn, Zr, Hf, and Ir), is studied by means of a Schwinger-boson approach. From a projective symmetry group and a mean-field analysis on this magnetically anisotropic model, we classify and analyze quantum spin liquid phases in the space of four coupling constants, including both $U(1)$ and Z_2 spin liquids that are characterized by power-law decaying and exponentially decaying spin correlations, respectively, as well as Higgs phases showing long-range orders. We apply the analysis to cases of the model parameters extracted from both microscopic arguments and the fitting to neutron-scattering experiments of some of the above materials and clarify the dynamical magnetic excitation spectra that take the continuum form due to the deconfined monopolar spinons. The relevance to recent experimental results is discussed.

11:51AM B8.00004 Dynamical strings in quantum spin ice, YUAN WAN, OLEG TCHERNYSHYOV, Johns Hopkins University — Spin ice is a highly frustrated ferromagnet displaying rich emergent phenomena. Recently, new spin ice materials such as $\text{Yb}_2\text{Ti}_2\text{O}_7$ and $\text{Pr}_2\text{Zr}_2\text{O}_7$ have stood out as possible candidates for quantum spin ice, in which quantum fluctuations could play a major role. In this talk, we discuss new emergent phenomena in quantum spin ice in an external magnetic field applied along the (100) lattice direction. When quantum monopoles are confined by the external field, the open string binding a monopole pair (Dirac string) becomes a dynamical object with a field-dependent tension. The motion of an open string includes longitudinal expansion and contraction and transverse fluctuations. The emergent quantum string theory in this context allows for simple analytical solution and straightforward numerical simulation. Moreover, vibrational modes of the string can be detected by experimental techniques such as neutron scattering and THz spectroscopy.

12:03PM B8.00005 Higgs transitions of spin ice, STEPHEN POWELL, University of Maryland, College Park — Spin ice is a frustrated magnetic material displaying a variety of interesting phenomena. At low temperature, it exhibits a “Coulomb phase”, in which there is no magnetic order and correlations have power-law forms at long distances. In this talk, I will describe the effects of applying perturbations that favor ordered states and show that the resulting phase transitions cannot be described by the standard Landau paradigm. They are instead naturally viewed as Higgs transitions of an emergent gauge theory; this perspective leads to long-wavelength theories for the critical properties. I will present specific examples of transitions described by this approach that result from perturbations such as an applied magnetic field or additional spin-spin interactions.

12:15PM B8.00006 Loop statistics in the Coulomb phase, LUDOVIC JAUBERT, OIST, Okinawa, Japan, MASUD HAQUE, RODERICH MOESSNER, MPI-PkS, Dresden, Germany — The Coulomb phase is a classical gauge field theory arising in frustrated systems with “divergence free” constraints, such as spin ice [1]. In this talk, we show how this phase can be understood as a loop model, and characterized by their loop length distribution and fractal dimensions [2]. Comparing similar models in 2- and 3-dimensions allows us to extract insights from connections to Stochastic-Loewner Evolution (SLE) processes, percolation and polymer physics. We mention implications of these results for related models and experiments (Heisenberg magnets, itinerant electrons [3]).

12:27PM B8.00007 Similarities and differences between spin and water ice models, IVAN RYZHKIN, Institute of Solid State Physics RAS — In the present contribution we provide a brief survey of the amazing analogy between spin and water ice basically from the water ice physics point of view. Special attention is paid to the following question: which of the theoretical concepts developed in ice physics could be applied to the study of spin ice and other frustrated systems. We show that the analogy between ground states of these systems can be extended other properties. In Section 1 we outline the history and present state of the analogy, and thoroughly investigate the similarity between quasi-particle excitations in ordinary ice (point defects in the ice proton system) and in spin ice (magnetic monopoles). The magnetic monopole concentration is shown to have a break in its temperature dependence arising due the magnetic Coulomb interaction (melting of the Coulomb phase). In Section 2 we develop a theory of magnetic charge transport, study the magnetic relaxation as well as the screening of magnetic field in spin ice. The transport analogy between spin and water ice is shown to be of limited nature: it is impossible to produce a stationary magnetic current in the commonly accepted model of spin ice. An extended spin ice model is suggested which is free from this disadvantage. In Section 3 we discuss the problem of how the magnetic ordering is modified near the free surface of spin ice or near its interface with other magnets. The study is based on the concepts previously used in water ice physics. In concluding Section 4 we discuss the differences between water and spin ice models (differences in numerical relations between appropriate constants, limited nature of transport analogy) and indicate some other problems which are not considered in this contribution (thermal effects of charge currents, quantum properties of the models, effect of frustrations on electron energy spectrum).

1:03PM B8.00008 Spin Ice correlations in a macroscopic system¹, PAULA MELLADO, ANDRES CONCHA, L. MAHADEVAN, School of Engineering and Applied Sciences, Harvard University — We report the realization of spin ice like correlations in a macroscopic array of ferromagnetic rods arranged in a honeycomb lattice. We found that this system has a rich dynamics that can be rationalized as the result of the interplay between the viscous rotation of each rod and Coulomb like interactions between magnetic charges located at the ends of the magnets. The dynamical response of this system has also been explored by using an external magnetic dipole moving at a distance h from the lattice. A clear separation between the interaction strengths permitted us to observe localized as well as a collective dynamics depending on the value of two dimensionless numbers; one associated with the two relevant time scales of the system and the other related with the strength of internal and external magnetic forces. This new spin-ice realization will allow the manipulation of parameters almost impossible to control on its microscopic relatives, such as inertia, vacancies, and quenched geometrical disorder between others.

¹This work was supported by the Kavli Institute and the MacArthur Foundation.

1:15PM B8.00009 Internal field distribution in spin ice materials, CLAUDIO CASTELNOVO, GABRIELE SALA, Royal Holloway University, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems, SHIVAJI SONDHI, Princeton University — At low temperatures, spin ice is populated by a finite density of magnetic monopoles — point like topological defects with a mutual magnetic Coulomb interaction. Here we study the distribution of magnetic fields inside spin ice. This is of conceptual importance as it reflects the monopolar fields set up by defects in a spin ice configuration. We discuss its manifestations in experiments involving local field probes, such as NMR or muon spin rotation. Averaged over the bulk of the sample, this distribution resembles one set up by a random spin arrangement. However, somewhat counter intuitively, the density of low-field locations decreases as the local ferromagnetic correlations imposed by the ice rules develop. The $1/r^2$ Coulomb field of a single monopole is visible in (magnetic) voids of the lattice where lattice-scale effects due to the immediate proximity of other spins are suppressed.

1:27PM B8.00010 Probing the spin ice state in the cubic pyrochlore $\text{Ho}_2\text{Ge}_2\text{O}_7$, ALANNAH HALLAS, University of Manitoba, HAIDONG ZHOU, National High Magnetic Field Laboratory, STEVEN BRAMWELL, University College London, CHRIS WIEBE, University of Winnipeg, JASON GARDNER, National Institute of Standards and Technology — Spin ices are a remarkable magnetic ground state that can arise in geometrically frustrated pyrochlores, $\text{A}_2\text{B}_2\text{O}_7$, when magnetic rare earth ions are situated on the vertices of a lattice of corner sharing tetrahedra. Competing nearest-neighbor and long-range dipolar interactions result in a short-range ordered ground state for each tetrahedron in which two spins point in and two spins point out [1]. The excitations in spin ices are equally remarkable; spin ices are the only known hosts of magnetic monopoles, emergent quasiparticles with a net magnetic charge. The cubic pyrochlore $\text{Ho}_2\text{Ge}_2\text{O}_7$ was prepared with a high temperature and high pressure technique. Preliminary DC susceptibility, heat capacity and X-ray diffraction experiments confirmed that $\text{Ho}_2\text{Ge}_2\text{O}_7$ has the bulk properties of a spin ice including residual entropy equal to the Pauling value for water ice [2]. The results of a polarized neutron scattering experiment performed at ILL as well as AC susceptibility and heat capacity measurements will be presented, and compared to the canonical spin ices.

[2] H. Zhou *et al.*, Nature Communications **2**, 478 (2011).

1:39PM B8.00011 Far infrared time domain terahertz spectroscopic study of $\text{Ho}_2\text{Ti}_2\text{O}_7$, LIDONG PAN, R. VALDES AGUILAR, Department of Physics & Astronomy, Johns Hopkins University, R.J. CAVA, Department of Chemistry, Princeton University, S.M. KOOHPAYEH, Institute for Quantum Matter, Department of Physics & Astronomy, Johns Hopkins University, N. PETER ARMITAGE, Department of Physics & Astronomy, Johns Hopkins University — We report a far infrared time domain terahertz spectroscopic study of the spin ice material holmium titanate. The complex dielectric constant was obtained in the terahertz frequency range. Several low energy excitations were identified from the optical spectra. We will discuss the possible nature of those excitations and their relevance to the spin ice physics.

1:51PM B8.00012 Calorimetric Study of Diluted Spin Ice Materials, TAORAN LIN, University of Waterloo, XIANGLIN KE, Pennsylvania State University, MISCHA THESBERG, McMaster University, PETER SCHIFFER, Pennsylvania State University, ROGER MELKO, MICHEL GINGRAS, University of Waterloo — Spin ice materials $\text{Dy}_2\text{Ti}_2\text{O}_7$ and $\text{Ho}_2\text{Ti}_2\text{O}_7$ have been the subject of ongoing interest for over ten years. The cooperative magnetic ground state can be mapped onto the proton disordered ground state in water ice, and its residual entropy follows the same Pauling's estimate. Interestingly it was found in a previous study that, upon dilution of the magnetic rare earth ions Dy^{3+} and Ho^{3+} by non-magnetic substitutes Y^{3+} , the residual entropy depends non-monotonically on the dilution level. In this work we investigate through Monte Carlo simulations microscopic models to account quantitatively for the calorimetric experimental measurements, and thus also the residual entropies as a function of dilution. Features of the dilution physics in the specific heat are captured quantitatively by the microscopic models and the interplay between dilution and frustration is understood on the basis of a Bethe lattice calculation. The effect of the dipolar interactions between magnetic spins are exposed numerically for various dilution concentrations. Our work explains the previous discrepancy of the residual entropy between different species of rare earth ions and the generalized Pauling's estimate.

2:03PM B8.00013 Spin Ice: Magnetic Excitations without Monopole Signatures using Muon Spin Rotation, SARAH DUNSIGER, Physik Department, Technische Universität München, D-85748 Garching, Germany, MICHEL GINGRAS, Department of Physics and Astronomy, University of Waterloo, Waterloo, Ontario, N2L 3G1, Canada, GRAEME LUKE, Department of Physics and Astronomy, McMaster University, Hamilton, Ontario L8S 4M1, Canada, YASUTOMO UEMURA, Department of Physics, Columbia University, New York, New York 10027, USA — Theory predicts the low-temperature magnetic excitations in spin ices consist of deconfined magnetic charges, or monopoles. A recent transverse-field (TF) muon spin rotation (μSR) experiment [S. T. Bramwell *et al.*, Nature **461**, 956 (2009)] reports results claiming to be consistent with the temperature and magnetic field dependence anticipated for monopole nucleation — the so-called second Wien effect. We demonstrate via a new series of μSR experiments in $\text{Dy}_2\text{Ti}_2\text{O}_7$ that such an effect is not observable in TF μSR . Rather, as found in many highly frustrated magnetic materials, we observe spin fluctuations which become temperature independent at low temperatures, behavior which dominates over any possible signature of thermally nucleated monopole excitations.

Monday, February 27, 2012 11:15AM - 2:15PM —
Session B9 DMP GMAG: Focus session: Complex Bulk Oxides: Iridates 209

11:15AM B9.00001 Dipoles on monopoles in spin ice, DANIEL KHOMSKII, Koeln University — Close connection of electricity and magnetism is one of the cornerstones of modern physics. This connection plays crucial role both from the fundamental point of view and in practical applications, including recent advance in spintronics and in the study and development of multiferroic materials. A new breakthrough was the recent proposal of Castelnovo, Moessner and Sondhi that in spin ice systems, e.g. in some pyrochlores, one can model the magnetic monopoles – the objects displaying the properties of isolated magnetic charges. Such monopoles are a hot topic nowadays. Usually one discuss mainly their thermodynamic and magnetic properties. I will show that every *magnetic monopole* in spin ice should have an *electric dipole* attached to it. This can be seen from the results obtained for frustrated Hubbard system [1]. Both the electronic mechanism discussed in [1] and the lattice effects (magnetostriction) lead to the conclusion that for 3in/1out and 3out/1in tetrahedra there should appear an electric dipole directed from the center of tetrahedron to the “special” spin. This will lead to electric activity of monopoles, and to possibility to address and influence them not only by magnetic, but also by an electric field. Several consequences of this effect will be discussed. In general, the analogy between electricity and magnetism goes even further than usually assumed: whereas electrons have *electric charge* and spin, i.e. *magnetic dipole*, magnetic monopoles in spin ice have both *magnetic charge* and *electric dipole*.

11:51AM B9.00002 Raman scattering study of the pressure- and field-dependent phases of Sr_2IrO_4 ¹, Y. GIM, M. KIM, S.L. COOPER, Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, 104 South Goodwin Avenue, Urbana, Illinois 61801-2902, G. CAO, Department of Physics and Astronomy, University of Kentucky, Lexington Kentucky 40506 USA — Transition metal oxides (TMOs) with a perovskite structure are of interest due to the many fascinating phenomena they exhibit. Among TMOs, iridates with 5d orbitals exhibit an unexpected insulating state due to large spin-orbit coupling. With the extended nature of the 5d orbital giving rise to a strong crystal field, the competition between the onsite Coulomb interaction and spin-orbit coupling—which have comparable energy scales—opens up the possibility for studying novel phases that develop when tuning this competition with using an external perturbation with magnetic field or pressure. In this talk we present temperature, magnetic field and pressure dependent Raman study of Sr_2IrO_4 , which provides an opportunity Pressure- and field-tuned Raman spectroscopy provides an opportunity to explore the novel phases of this material under extreme conditions.

¹Work is supported by the National Science Foundation under Grant NSF DMR 08-56321.

12:03PM B9.00003 Quantum Hall effects in a Weyl semimetal: Possible application in pyrochlore iridates, KAI-YU YANG, Boston College, YUAN-MING LU, Boston College/UC Berkeley, YING RAN, Boston College — There has been much interest in pyrochlore iridates $\text{A}_2\text{Ir}_2\text{O}_7$ where both strong spin-orbital coupling and strong correlation are present. A recent local density approximation calculation [X. Wan, A. M. Turner, A. Vishwanath, and S. Y. Savrasov, Phys. Rev. B 83, 205101 (2011)] suggests that the system is likely in a three-dimensional topological semimetallic phase: a Weyl semimetal. Such a system has zero carrier density and arrives at the quantum limit even in a weak magnetic field. In this talk, I will discuss two quantum effects of this system in a magnetic field: a pressure-induced anomalous Hall effect and a magnetic-field-induced charge density wave at the pinned wave vector connecting Weyl nodes with opposite chiralities. A general formula of the anomalous Hall coefficients in a Weyl semimetal is also given. Both proposed effects can be probed by experiments in the near future and can be used to detect the Weyl semimetal phase.

12:15PM B9.00004 Electronic ground state properties of Iridate oxides from x-ray absorption spectroscopy¹, DANIEL HASKEL, M.A. LAGUNA MARCO, N.M. SOUZA-NETO, J.C. LANG, Argonne National Laboratory, G. FABBRIS, Washington University in St. Louis and Argonne National Laboratory, G. CAO, University of Kentucky, M. VAN VEENENDAAL, Northern Illinois University and Argonne National Laboratory — Element (Ir)- and orbital (5d)-specific $L_{2,3}$ edge x-ray absorption and magnetic circular dichroism measurements are used to probe the nature of the electronic ground state in magnetic insulators BaIrO_3 [1] and Sr_2IrO_4 [2,3]. A spin-only description of the magnetic ground state is directly ruled out by the measurements. Instead, the measurements show spin-orbit entanglement in 5d states resulting in a larger orbital (L_z) than spin (S_z) contribution to the magnetic moment, even in the presence of strong crystal field and band effects. Measured x-ray absorption cross sections at spin-orbit split $L_{2,3}$ edges impose constraints on the nature of the ground state [3]. Experiments under chemical- (doping) and applied-pressure conditions provide evidence for a delicate interplay between electronic bandwidth and Coulomb interactions leading to the gapped, spin-orbit coupled ground state of these complex oxides.

12:27PM B9.00005 Lattice-driven magnetoresistivity and metal-insulator transition in single-layered iridates¹, O.B. KORNETA, T.F. QI, L.E. DE LONG, G. CAO, Department of Physics and Astronomy and Center for Advanced Materials, University of Kentucky, M. GE, China High Magnetic Field Lab and University of Science and Technology of China, S. PARKIN, Department of Chemistry, University of Kentucky, P. SCHLOTTMANN, Department of Physics, Florida State University — Sr_2IrO_4 exhibits a novel insulating state driven by spin-orbit interactions. Here we report two novel phenomena, namely a large magnetoresistivity that is extremely sensitive to the orientation of magnetic field but exhibits no apparent correlation with the magnetization, and a robust metallic state that is induced by dilute electron (La^{3+}) or hole (K^{+}) doping on Sr^{2+} ions in Sr_2IrO_4 . This study reveals that a strong spin-orbit interaction alters the balance between the competing energies so profoundly that (1) the spin degree of freedom alone is no longer a dominant force; (2) underlying transport properties delicately hinge on the Ir-O-Ir bond angle via a strong magnetoelastic coupling; and (3) a highly insulating state in Sr_2IrO_4 is proximate to a metallic state, and the transition is governed by lattice distortions that can be controlled via either magnetic field or chemical doping.

¹This work was supported by NSF through grants DMR-0856234 (GC) and EPS-0814194(GC, LED), and by DoE through grants DE-FG02-97ER45653 (LED) and DE-FG02-98ER45707 (PS)

12:39PM B9.00006 Time-resolved optical study of magnetism in Sr_2IrO_4 , DAVID HSIEH, DARIUS TORCHINSKY, FAHAD MAHMOOD, MIT, GANG CAO, University of Kentucky, NUH GEDIK, MIT — We report a time-resolved optical pump-probe study of the Jeff=1/2 Mott insulator Sr_2IrO_4 . The temperature dependence of the electronic relaxation rate exhibits clear anomalies at magnetic ordering temperatures of 240K and 100K, which are consistent with the development of bulk decay channels via emission of magnetic excitations. We will then discuss time-resolved second harmonic generation studies and contrast the magnetic properties of the surface and the bulk.

12:51PM B9.00007 Unusual ferromagnetism and strong spin-orbit coupling in Post-Perovskite CaIrO_3 ¹, LUKE MARSHALL, JINGUANG CHENG, JIANSI ZHOU, JOHN B. GOODENOUGH, Texas Materials Institute, The University of Texas at Austin, DANIEL HASKEL, Advanced Photon Source, Argonne National Laboratory, MICHEL VAN VEENENDAAL, Advanced Photon Source, Argonne National Laboratory and Department of Physics, Northern Illinois University — Strong spin-orbit coupling (SOC) and strong correlations have been considered essential in understanding the unusual physical properties of the 4d and 5d transition-metal oxides, such as the SOC driven Mott insulating state in Sr_2IrO_4 . Recently, an unusual atomic-like orbital moment and strong SOC have been confirmed experimentally in $9R - \text{BaIrO}_3$ through analysis of the branching ratio at the Ir $L_{2,3}$ absorption edges as obtained from x-ray absorption and x-ray magnetic circular dichroism (XMCD) measurements. We have applied the same techniques to probe unusual ferromagnetism and SOC in the post-perovskite (pPv) CaIrO_3 , which is an insulator and exhibits weak ferromagnetism below $T_C \approx 110\text{K}$. The branching ratio at the Ir $L_{2,3}$ absorption edges, which is close to unity in pPv CaIrO_3 , appears to indicate an even stronger spin-orbit interaction in the pPv CaIrO_3 than in $9R - \text{BaIrO}_3$. However, it has been challenging to model the Ir 5d orbital moment, as probed by the XMCD measurements, due to the understood local octahedral-site distortions.

1:03PM B9.00008 Exploring Magnetic Ordering in $\text{Sr}_3\text{Ir}_2\text{O}_7$ ¹, SOVIT KHADKA, CHETAN DHITAL, Physics Department, Boston College, WEI TIAN, Oak Ridge National Laboratory, TN, USA, STEPHEN WILSON, Physics Department, Boston College — Iridium oxide members of the Ruddlesden-Popper series have generated a great deal of interest recently due to their novel Mott insulating phases within these 5d-electron systems. These surprising Mott phases have been proposed to form due to a delicate interplay between spin orbit coupling effects and electronic correlation [1]. Here we present measurements probing the nature of the spin correlations and charge behavior in the bilayer variant of the Ruddlesden-Popper series, $\text{Sr}_3\text{Ir}_2\text{O}_7$. Our neutron scattering results reveal an antiferromagnetic spin structure and will be discussed in parallel with transport and bulk magnetization measurements detailing the electronic behavior in this material.

1:15PM B9.00009 Doping a Spin-Orbit Mott Insulator: Topological Superconductivity from the Kitaev-Heisenberg Model and Possible Application to $(\text{Na}_2/\text{Li}_2)\text{IrO}_3$, YI-ZHUANG YOU, Institute for Advanced Study, Tsinghua University, Beijing, China, ITAMAR KIMCHI, ASHVIN VISHWANATH, Department of Physics, University of California, Berkeley, CA, USA — We study the effects of doping a Mott insulator on the honeycomb lattice where spins interact via direction dependent Kitaev couplings J_K , and weak antiferromagnetic Heisenberg couplings J . This model is known to have a spin liquid ground state and may potentially be realized in correlated insulators with strong spin orbit coupling. The effect of hole doping is studied within a t - J - J_K model, treated using the SU(2) slave boson formulation, which correctly captures the parent spin liquid. We find superconductor ground states with spin triplet pairing that spontaneously break time reversal symmetry. Interestingly, the pairing is qualitatively different at low and high dopings, and undergoes a first order transition with doping. At high dopings, it is smoothly connected to a paired state of electrons propagating with the underlying free particle dispersion. However, at low dopings the dispersion is strongly influenced by the magnetic exchange, and is entirely different from the free particle band structure. Here the superconductivity is fully gapped and topological, analogous to spin polarized electrons with $p_x + ip_y$ pairing. These results may be relevant to honeycomb lattice iridates such as A_2IrO_3 ($\text{A} = \text{Li}$ or Na) on doping.

1:27PM B9.00010 Correlated Itinerant Electrons in Pyrochlore $\text{Bi}_2\text{Ir}_2\text{O}_7$ ¹, G. CAO, O.B. KORNETA, T.F. QI, Department of Physics and Astronomy and Center for Advanced Materials, University of Kentucky, XIANGANG WAN, Department of Physics, Nanjing University, Nanjing, China — Strong spin-orbit coupling in the 5d-based iridates rigorously competes with other relevant energies, and motivates novel insulating states. Therefore, a metallic state does not commonly occur in the iridates, but the unusual balance between different degrees of freedom in the iridates almost guarantee that it will exhibit extraordinary properties when it does occur. Here we report anomalous transport and thermodynamic properties including Hall effect of single-crystal $\text{Bi}_2\text{Ir}_2\text{O}_7$ along with our electronic structure calculations utilizing a LSDA+U scheme. The results will be discussed along with comparisons drawn with other pyrochlore iridates and related materials.

1:39PM B9.00011 Measurement of the Mott insulating gap of Sr_2IrO_4 with a scanning tunneling microscope¹, J. NICHOLS, University of Kentucky, G. CAO, K.-W. NG, john.nichols@uky.edu — Recently the 5d transition metal oxide Sr_2IrO_4 has become a material of interest. This is due to comparable interaction strengths between crystal field splitting, the Coulomb interaction, and spin-orbit coupling, resulting in a Mott insulating ground state that has a finite resistance even at cryogenic temperatures. In order to fully understand this material it is important to measure the Mott insulating gap. A scanning tunneling microscope is an excellent tool for studying this material for its ability to directly measure this gap. Our preliminary results show this gap measured on single crystals to be ~ 50 meV which is comparable to the activation energy of this sample. We will discuss our current STM results and compare our results with other optical conductivity data obtained from this material.

1:51PM B9.00012 Mapping the fluctuating Ir^{4+} dimers across the phase diagram of $\text{Cu}(\text{Ir}_{1-x}\text{Cr}_x)_2\text{S}_4$ ($0 \leq x \leq 0.6$)¹, E.S. BOZIN, Brookhaven National Laboratory, Y.S. HOR, J.F. MITCHELL, Argonne National Laboratory, S.J.L. BILLINGE, P. JUHAS, Brookhaven National Laboratory, Columbia University — Elucidating the role of fluctuations in systems with competing interactions, such as $\text{Cu}(\text{Ir}_{1-x}\text{Cr}_x)_2\text{S}_4$, enables comprehensive understanding of their physical properties. While CuIr_2S_4 exhibits complex behavior with metal-insulator transition accompanied by charge ordering and Ir^{4+} -spin-dimerization at 226 K, CuCr_2S_4 displays ferromagnetic metallic behavior ($T_C \sim 377$ K) understood within the double exchange model. Intermediate composition range sees suppression of end-member properties, with broad features observed in susceptibility around 180 K attributed to Cr^{3+} low spin to high-spin crossover [1]. Robust fluctuating Ir^{4+} dimers are detected and their evolution examined across the phase diagram by the X-ray atomic pair distribution function method. Although their long range order is destroyed already by $x \approx 0.05$, Ir^{4+} dimers exist locally at low temperature at all compositions studied. We provide detailed account of the Cr-doping and temperature dependence of the local dimers, and estimate characteristic length-scale on which they are observable. Fluctuating dimers disappear on heating, for intermediate compositions at temperatures above 180 K.

2:03PM B9.00013 Coupling of Orbital and Magnetic Orders to Colossal Negative Thermal Expansion in Novel Mott Insulators¹, T.F. QI, O.B. KORNETA, S. PARKIN, L.E. DE LONG, G. CAO, Center for Advanced Materials, University of Kentucky, P. SCHLOTTMANN, Department of Physics, Florida State University — Ca_2RuO_4 is intimately associated with both **negative volume thermal expansion (NVTE)** and **negative linear thermal expansion (NLTE)** when doped by a 3d transition metal ion M for Ru. The NVTE and NLTE observed in this system constitutes a compelling and extraordinary example in that (1) the coefficient of NVTE and NLTE reaches $-213 \times 10^{-6} \text{ K}^{-1}$ and $-148 \times 10^{-6} \text{ K}^{-1}$, respectively, constituting **colossal negative thermal expansion (NTE)**; (2) the NTE anomalies closely track the onset temperatures of orbital and magnetic orders, in sharp contrast to classic NTE that shows no relevance to physical properties; (3) the NTE and physical properties can be effectively tuned via varying M and x in $\text{Ca}_2\text{Ru}_{1-x}\text{M}_x\text{O}_4$; (4) the NTE occurs near room temperature and extends over a wide temperature interval ranging from 100 K to 350 K. Moreover, NTE and Invar effect commonly exist in these 4d-based ruthenates and 5d-based iridates, e.g. $\text{Sr}_{n+1}\text{Ir}_n\text{O}_{3n+1}$ and BaIrO_3 . These novel NTE materials provide a much-needed paradigm for functional materials with anomalous thermal expansion and electronic characteristics.

Session B10 DCMP DAMOP: Invited Session: Equilibration and Relaxation in Cold Atoms 210A

11:15AM B10.00001 Timescales for equilibration and adiabaticity in optical lattices¹, STEFAN NATU, Cornell University — What are the timescales governing local and global dynamics in strongly correlated systems? How do we probe this dynamics in an isolated quantum system without coupling the system to leads? High in-situ resolved experiments on bosons in optical lattices are answering precisely these questions by imaging the gas following a sudden change of the lattice potential. The results are striking. Experiments have revealed a disparity as large as two orders of magnitude between fast equilibration of local number fluctuations and slow global mass redistribution. In this talk, I will provide a simple model which captures all the relevant physics. Additionally, I will show that the fast timescales for local dynamics challenge the accepted notions of adiabaticity times, invalidating routinely used techniques such as band-mapping as useful probes of quantum many body systems. 11:51AM B10.00002 Pomeranchuk effect and spin-gradient cooling of Bose-Bose mixtures in an optical lattice, WALTER HOFSTETTER, Goethe-University Frankfurt — We theoretically investigate finite-temperature thermodynamics and demagnetization cooling of two-component Bose-Bose mixtures in a cubic optical lattice, by using bosonic dynamical mean-field theory (BDMFT). We calculate the finite-temperature phase diagram, and remarkably find that the system can be heated from the superfluid into the Mott insulator at low temperature, analogous to the Pomeranchuk effect in ^3He . This provides a promising many-body cooling technique. We examine the entropy distribution in the trapped system and discuss its dependence on temperature and an applied magnetic field gradient. Our numerical simulations quantitatively validate the spin-gradient demagnetization cooling scheme proposed in recent experiments.

12:27PM B10.00003 The amplitude mode at the superfluid-mott insulator transition, DAVID PEKKER, Caltech — We study a two dimensional gas of repulsively interacting bosons in the presence of both an optical lattice and a trap using optical lattice modulation spectroscopy. The strongly interacting superfluid supports two types of low energy modes associated with the symmetry breaking at the phase transition: gapless phase (Goldstone) modes and gapped amplitude (Anderson-Higgs) modes. Both experimentally and in theoretical simulations lattice modulation spectroscopy shows an onset of absorption at a frequency associated with the amplitude mode gap, followed by a broad absorption peak at higher frequencies. From the simulations, we learn that energy is being absorbed by various amplitude modes, which inside a trap resemble the modes of a (gapped) drum. Our main results are: (1) despite coupling to the phase modes, modulation spectroscopy shows a sharp absorption onset at the frequency associated with the amplitude mode gap; (2) as we approach the Mott transition the gap softens and finally disappears at the transition point; (3) in the weak coupling regime, deep in the superfluid phase, the amplitude mode disappears.

1:03PM B10.00004 Two-dimensional Fermi gases, MICHAEL KOEHL, University of Cambridge — Pairing of fermions is ubiquitous in nature and it is responsible for a large variety of fascinating phenomena like superconductivity, superfluidity of ^3He , the anomalous rotation of neutron stars, and the BEC-BCS crossover in strongly interacting Fermi gases. When confined to two dimensions, interacting many-body systems bear even more subtle effects, many of which lack understanding at a fundamental level. Most striking is the, yet unexplained, effect of high-temperature superconductivity in cuprates, which is intimately related to the two-dimensional geometry of the crystal structure. In particular, the question how many-body pairing is established at high temperature and whether it precedes superconductivity are crucial questions to be answered. We will report on recent experiments of pairing in a two-dimensional atomic Fermi gas in the regime of strong coupling. We perform angle-resolved photoemission spectroscopy to measure the spectral function of the gas and we observe a many-body pairing gap even above the predicted superfluid transition temperature.

1:39PM B10.00005 Relaxation Dynamics and Pre-thermalization in an isolated Quantum System¹, JÖRG SCHMIEDMAYER, Vienna Center for Quantum Science and Technology (VCQ), Atominstitut, TU-Wien — Understanding non-equilibrium dynamics of many-body quantum systems is crucial for understanding many fundamental and applied physics problems ranging from decoherence and equilibration to the development of future quantum technologies such as quantum computers which are inherently non-equilibrium quantum systems. One of the biggest challenges is that there is no general approach to characterize the resulting quantum states. In this talk I will present how to use the full distribution functions of a quantum observable to study the relaxation dynamics in one-dimensional quantum systems and to characterize the underlying many body states. Interfering two 1 dimensional quantum gases allows to study how the coherence created between the two many body systems by the splitting process [1] slowly dies by coupling to the many internal degrees of freedom available [2]. To reveal the nature of the quantum states behind this de-coherence we analyze the interference of the two evolving quantum systems. The full distribution function of the shot to shot variations of the interference patterns [3,4], especially its higher moments, allows characterizing the underlying physical processes [5]. Two distinct regimes are clearly visible in the experiment: for short length scales the system is characterized by spin diffusion, for long length scales by spin decay [6]. After a rapid evolution the distributions approach a steady state which can be characterized by thermal distribution functions. Interestingly, its (effective) temperature is over five times lower than the kinetic temperature of the initial system. Our system, being a weakly-interacting Bosons in one dimension, is nearly integrable and the dynamics is constrained by constants of motion which leads to the establishment of a generalized Gibbs ensemble and pre-thermalization. We therefore interpret our observations as an illustration of the fast relaxation of a nearly integrable many-body system to a quasi-steady state through de-phasing. The observation of an effective temperature significant different from the expected kinetic temperature supports the observation of the generalized Gibbs state [6].

Monday, February 27, 2012 11:15AM - 2:15PM – Session B11 DMP: Focus Session: Graphene/BN 210B

11:15AM B11.00001 Tunneling spectroscopy of graphene boron nitride heterostructures¹, DAVID GOLDHABER-GORDON, Stanford University — We report on the fabrication and measurement of a graphene tunnel junction using hexagonal boron nitride as a tunnel barrier between graphene and a metal gate. The tunneling behavior into graphene is altered by the interactions with phonons and the presence of disorder. We extract properties of graphene and observe multiple phonon-enhanced tunneling thresholds. Finally, differences in the measured properties of two devices are used to shed light on mutually-contrasting previous results of scanning tunneling microscopy in graphene.

¹This work can be found on arXiv:1108.2686v1 and was done in collaboration with F. Amet, J. R. Williams, A. G. F. Garcia, M. Yankowitz, K. Watanabe and T. Taniguchi

11:51AM B11.00002 Spin and valley quantum Hall ferromagnetism in graphene on hexa-Boron nitride substrates, ANDREA YOUNG, CORY DEAN, LEI WANG, HECHEN REN, PAUL CADDEN-ZIMANSKY, Columbia University, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS, JIM HONE, KEN SHEPARD, PHILIP KIM, Columbia University — In graphene subjected to a quantizing magnetic field, the strong Coulomb interactions and fourfold combined spin/valley degeneracy lead to an approximate SU(4) isospin symmetry within individual Landau levels). At partial filling, exchange interactions can drive the ground state to polarize ferromagnetically within this expanded isospin space, manifesting experimentally as additional integer quantum Hall plateaus outside the normal sequence. Here we report the observation of a wide number of these quantum Hall isospin ferromagnetic states. Using tilted field magnetotransport, we classify the states appearing at different Landau Level filling factors by their real spin structure. We find evidence for real spin polarized states supporting Skyrmionic excitations, charge- or spin- density order, and valley textured excitations at different filling factors. We also observe unexpected reentrant behavior in tilted field in the higher Landau levels. Our results confirm graphene as a highly isotropic SU(4) ferromagnet, in which symmetry breaking is dictated by the interplay between the Zeeman effect, lattice scale interactions, and disorder.

12:03PM B11.00003 Atomic Scale Observation of Electron-Electron Interactions in Single-Layer Graphene Devices on Boron Nitride Dielectrics, SUYONG JUNG, JUNGSEOK CHAE, NIKOLAI ZHITENEV, JOSEPH STROSCIO, National Institute of Standards and Technology, ANDREA YOUNG, CORY DEAN, LEI WANG, JAMES HONE, KEN SHEPARD, PHILIP KIM, Columbia University, NIST COLLABORATION, COLUMBIA UNIVERSITY COLLABORATION — We have performed scanning tunneling spectroscopy measurements on gated-graphene devices in the quantum Hall regime under varying disorder potential landscapes. Relatively thin hexagonal boron-nitride (h-BN) crystals are mechanically exfoliated on SiO₂/Si substrates and single-layer graphene films are later transferred on pre-located h-BN crystals. In this device scheme, we can investigate the interactions of Dirac particles with local impurities ranging from strongly disordered to weakly perturbed environments by adjusting the thickness of h-BN crystals, while varying both the Fermi-energy with respect to a Dirac point and magnetic field. In the h-BN devices, we have observed that the electron-hole puddles are larger in lateral size than those observed on SiO₂ devices, and resonance scatterings are significantly reduced due to weakened disorder potentials. Accordingly, we start observing well-defined Landau levels (LLs) as early as 0.5 T and the width of individual LLs, broadened by the scattering of charged carriers, is much narrower than those from graphene on SiO₂. In high magnetic fields, we observe the electronic structure of graphene devices is significantly altered by the electron-electron interactions and the formation of large interaction energy gaps. We will discuss the spatial, orbital quantum number, and magnetic field dependence of the observed interaction gaps.

12:15PM B11.00004 Landau Level Lifetimes and Residual Disorder in Single Layer Graphene on Boron-Nitride Substrates, JUNGSEOK CHAE, SUYONG JUNG, NIKOLAI B. ZHITENEV, JOSEPH A. STROSCIO, National Institute of Science and Technology, ANDREA YOUNG, CORY DEAN, LEI WANG, JAMES C. HONE, KEN L. SHEPARD, PHILIP KIM, Columbia University, NIST COLLABORATION, COLUMBIA UNIVERSITY COLLABORATION — Realization of the intrinsic electronic properties of graphene devices has been limited by charge scattering and surface roughness found when graphene is placed on SiO₂ substrates. Recently, graphene devices fabricated on hexagonal boron-nitride (h-BN) dielectrics have shown superior device performance compared with graphene placed directly on SiO₂ substrates. We have performed scanning tunneling microscopy / spectroscopy (STM / STS) measurements to investigate the local electronic structure of graphene devices on h-BN substrates as a function of charge density and magnetic field. The disorder potential is significantly reduced compared with graphene in direct contact with SiO₂. Correspondingly, the widths of Landau levels (LLs) are much narrower becoming comparable to those measured in epitaxial graphene on SiC. The energy and the spatial dispersion of LLs is used to analyze the Fermi velocity of the Dirac particles at different charge densities, an electron-hole asymmetry, and discrete splittings of LLs due to residual spatially varying disorder potential.

12:27PM B11.00005 STM of graphene on boron nitride, BRIAN LEROY, University of Arizona — Graphene on hexagonal boron nitride (hBN) has been shown to have significantly improved mobility and charge inhomogeneity based on electrical transport measurements. Using scanning tunneling microscopy, we have observed that the surface roughness is reduced by one order of magnitude as compared to graphene on SiO₂ devices. Near the Dirac point, graphene breaks up into a series of electron and hole puddles due to potential fluctuations. Using scanning tunneling spectroscopy, we have shown that the potential fluctuations are also reduced by an order of magnitude on hBN. The ultraflat and clean nature of graphene on hBN devices allows for the observation of scattering from buried step edges. The energy and spatial dependence of the scattering gives information about the dispersion relation of graphene and the chiral nature of the quasiparticles. In this talk, I will also discuss our recent spectroscopy measurements on hBN.

1:03PM B11.00006 Thickness Dependence of Electrical Breakdown in h-BN dielectric using C-AFM microscopy, AVINASH NAYAK, DONGHYI KOH, DEJI AKINWANDE, UT Austin — For nano-scale graphene transistor applications, hexagonal boron nitride (h-BN) is a highly desirable dielectric material that is being investigated not only because of its intrinsic properties but also because of its low lattice mismatch with hexagonal graphene. Currently, SiO₂ limits the carrier mobility of graphene due to substrate phonon coupling. Therefore, h-BN can be employed for mobility enhancement beyond the values achievable on standard dielectric. Decreasing the device dimensionality however, requires a more detailed understanding of electrical breakdown at the nanoscale. We will present on the intrinsic breakdown electric field (E_{BF}) of h-BN thin films in a metal-insulator-metal (MIM) configuration. This nanoscaled MIM structure is measured using conductive-atomic-force microscopy (C-AFM). Here, C-AFM is used to extract breakdown voltage for various thicknesses of mechanically exfoliated h-BN flakes. We measure the dielectric properties of h-BN flakes that vary from 2nm to 25nm and determine the ultimate scalability of hBN dielectrics.

1:15PM B11.00007 Transport in graphene-boron nitride heterostructures, FRANCOIS AMET, ANDREI GARCIA, JAMES WILLIAMS, DAVID GOLDBABER-GORDON, Stanford University — Transferring graphene on hexagonal boron nitride permits the fabrication of high mobility graphene devices. We report on in-plane transport measurements on dual gated graphene systems using boron nitride as a substrate. The low amount of disorder allows for ballistic effects to be probed, as we can gate-define regions narrower than the mean free path. This work is supported by the Center on Functional Engineered Nano-Architectonics.

1:27PM B11.00008 Tunable and Sizable Band Gap of Single Layer Graphene Sandwiched between Hexagonal Boron Nitride, JIAXIN ZHENG, HERUGE QU, QIHANG LIU, RUI QIN, JING ZHOU, DAPENG YU, ZHENGXIANG GAO, JING LU, State Key Laboratory of Mesoscopic Physics and Department of Physics, Peking University, Beijing 100871, P. R. China, GUANGFU LUO, SHIGERU NAGASE, Department of Theoretical and Computational Molecular Science, Institute for Molecular Science, Okazaki 444-8585, Japan, WAI-NING MEI, Department of Physics, University of Nebraska at Omaha, Omaha, Nebraska 68182-0266, USA — It is a big challenge to open a tunable and sizable band gap of single layer graphene without big loss in structural integrity and carrier mobility. By using density functional theory calculations, we show that the band gap of single layer graphene can be opened to 0.16 (without electrical field) and 0.34 eV (with a strong electrical field) when sandwiched between two hexagonal boron nitride single layers in a proper way. The zero-field band gaps are increased by about 50% when many-body effects are included. Ab initio quantum transport simulation of a dual-gated FET out of such a sandwich structure further confirms an electrical field-enhanced transport gap. The tunable and sizeable band gap and structural integrity render this sandwich structure a promising candidate for high-performance single layer graphene field effect transistors.

1:39PM B11.00009 ABSTRACT WITHDRAWN —

1:51PM B11.00010 High quality charge- and spin transport in graphene on commercially available boron nitride¹, PAUL ZOMER, MARCOS GUIMARAES, SAROJ DASH, NIKOLAOS TOMBROS, BART VAN WEES, Zernike Institute for Advanced Materials, University of Groningen — In order to overcome the limitations that a silicon oxide substrate imposes on the electronic transport properties of graphene, hexagonal boron nitride (h-BN) has proven to be an excellent alternative. We present a fast, simple and accurate transfer technique of graphene, which yields atomically flat graphene flakes on h-BN that are almost completely free of bubbles or wrinkles. Using this transfer technique we prepared single- and bilayer graphene electronic devices on commercially available hexagonal boron nitride and extract mobilities as high as 125 000 cm²/Vs at room temperature and 275 000 cm²/Vs at 4.2 K. The high electronic quality is further confirmed by magnetotransport measurements, which show the development of the 1e²/h Landau level already at 5T (P. J. Zomer et al. arXiv:1110.1045v1). Finally, we present very recent results of spin transport in high mobility h-BN supported graphene flakes (P. J. Zomer et al. in preparation). In conclusion, the potential of commercially available boron nitride combined with our transfer technique makes high mobility graphene devices more accessible.

¹This work is financially supported by the Dutch Foundation for Fundamental Research on Matter (FOM) and NWO and is realized using NanoLab NL facilities.

2:03PM B11.00011 Examining CVD graphene quality using hexagonal boron nitride substrates¹, WILL GANNETT, WILLIAM REGAN, Dept of Physics, University of California, Berkeley and Materials Sciences Division, LBNL, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Material Laboratory, National Institute for Materials Science, Tsukuba, Japan, MICHAEL CROMMIE, ALEX ZETTL, Dept of Physics, University of California, Berkeley and Materials Sciences Division, LBNL — Chemical vapor deposition (CVD) of graphene has proven to be the most inexpensive and scalable synthesis technique for continuous graphene monolayers. However, CVD graphene typically has a lower mobility than that from exfoliation. This is likely due to a combination of intrinsic (defect and grain boundary) and extrinsic (substrate and contamination) effects. By fabricating CVD graphene transistors on hexagonal boron nitride (h-BN) substrates, we are able to reduce the extrinsic substrate interactions that otherwise occur with silicon dioxide layers. This greatly improves the mobility in our devices (up to 29000 cm²/Vs). While such improvements from h-BN have been previously observed in exfoliated graphene devices, its success with CVD graphene is particularly notable because it shows that the low mobilities observed in CVD graphene are not from intrinsic effects, and that current synthesis techniques are more than sufficient to consistently produce graphene with >10000 cm²/Vs. Furthermore, our research reveals that characterization of CVD growth recipes by measuring mobilities on silicon dioxide is insufficient, as scattering from the oxide will dominate, revealing little information about intrinsic graphene quality.

¹This research was supported in part by the U.S. Department of Energy, the National Science Foundation, and the Office of Naval Research.

Monday, February 27, 2012 11:15AM - 2:15PM —
Session B12 DCMP: Graphene: Electronic Structure and Interactions - Bilayer Graphene 210C

11:15AM B12.00001 Berry phase and pseudospin winding number in bilayer graphene¹, CHEOL-HWAN PARK, MIT and University of Oxford, NICOLA MARZARI, EPFL and University of Oxford — In 2006, two seminal studies on the novel quantum Hall effect of bilayer graphene [K. S. Novoselov et al., Nat. Phys. **2**, 177 (2006); E. McCann and V. I. Fal'ko, Phys. Rev. Lett. **96**, 086805 (2006)] appeared. Those papers claim that a non-trivial Berry phase of 2π in bilayer graphene is responsible for the novel quantum Hall effect described. Since then, it has become widely accepted by people working on the novel physics of graphene nanostructures that bilayer graphene has a non-trivial Berry phase of 2π (different from 0, as for conventional two-dimensional electron gas). In this talk, we show that (i) the relevant Berry phase for bilayer graphene is the same as that for a conventional two-dimensional electron gas and especially that (ii) what is actually obtained in the quantum Hall measurements is not the absolute value of the Berry phase of graphene multilayers but the pseudospin winding number. The results of our study ask for a re-interpretation of the numerous works related to the Berry phase in graphene multilayers.

¹We thank Steven G. Louie, Alessandra Lanzara, Choonkyu Hwang, and Davide Ceresoli for fruitful discussions, and Intel Corporation for support (CHP).

11:27AM B12.00002 Electron-hole asymmetry and band mass renormalization in bilayer graphene: elucidating the role of electron-electron interactions with first-principles GW calculations, LIANG Z. TAN, STEVEN G. LOUIE, Department of Physics, University of California at Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory — The electron-hole asymmetry and the band masses of bilayer graphene are fundamental quantities in various phenomena and in the applications of this material. *A priori*, both of these quantities can depend on a number of microscopic mechanisms, including single-particle effects such as next-nearest neighbor hopping amplitude, as well as many-body effects such as the electron-electron interaction. We calculate the low energy electronic structure of bilayer graphene from first-principles, within the GW approximation. Our results indicate that both the electron-hole asymmetry and the band mass are strongly renormalized by electron-electron interactions. Our results are in good agreement with recent Shubnikov-de Haas experiments on bilayer graphene.

11:39AM B12.00003 Spontaneous broken time reversal symmetry and persistent current states in bilayer graphene, JEIL JUNG, Department of Physics, University of Texas at Austin, USA, MARCO POLINI, NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, I-56126 Pisa, Italy, ALLAN MACDONALD, Department of Physics, University of Texas at Austin, USA — We report on the possibility of electron interaction driven spontaneously broken time reversal symmetry states in bilayer graphene through Fermi surface instability (aka Pomeranchuk instability) in both $\ell = 0$ and $\ell = 1$ channels. The conditions for spontaneous current carrying equilibrium states are most favorable in the regime of high interlayer potential difference and finite doping. These states are accompanied by valley polarization, which leads to a finite Hall conductivity that is approximately proportional to carrier density. Ref. cond-mat arXiv:1111.1765

11:51AM B12.00004 Time-reversal symmetry breaking states in bilayer graphene, LIJUN ZHU, VIVEK AJI, CHANDRA VARMA, University of California, Riverside — The time-reversal symmetry breaking states in bilayer graphene which do not break translational symmetry can be classified by the spatial symmetry of the spontaneous current patterns. Among the four possible states, only one has anomalous Hall effect. In a simple model with near-neighbor interactions, we compare their energies in the mean-field approximation. We also compare which of the states is compatible with the observed gapped state in bilayer graphene.

12:03PM B12.00005 Spontaneous symmetry breaking in bilayer graphene¹, MAXIM KHARITONOV, Center for Materials Theory, Rutgers University — Recent experiments [1-4] provided compelling evidence for the correlated electron behavior in undoped bilayer graphene at both zero and finite magnetic field. The key question concerns the nature of the broken-symmetry phases realized experimentally. I will present the phase diagram for the zero-density state in the quantum Hall regime ($\nu = 0$ state) obtained within the framework of quantum Hall ferromagnetism. Comparing these results with the experimental data of Refs. [1,4], I will argue that the $\nu = 0$ insulating state realized in bilayer graphene is the canted antiferromagnetic phase. I will also show that the (canted) antiferromagnetic phase can persist at all magnetic fields down to zero and argue that this is the most likely scenario for the insulating state observed in Ref. [4].

12:15PM B12.00006 Transport Spectroscopy of Symmetry-Broken Insulating States in Bilayer Graphene, JAIRO VELASCO JR., LEI JING, WENZHONG BAO, YONGJIN LEE, University of California Riverside, PHILIP KRATZ, Stanford University, VIVEK AJI, MARC BOCKRATH, JEANIE LAU, CHANDRA VARMA, University of California Riverside, RYAN STILLWELL, DMITRY SMIRNOV, Florida State University, FAN ZHANG, JEIL JUNG, ALLAN MACDONALD, University of Texas Austin — The flat bands in bilayer graphene (BLG) are sensitive to electric fields E directed between the layers, and magnify the electron-electron interaction effects, thus making BLG an attractive platform for new two-dimensional (2D) electron physics. Theories have suggested the possibility of a variety of interesting broken symmetry states, some characterized by spontaneous mass gaps, when the electron-density is at the carrier neutrality point (CNP). The theoretically proposed gaps in bilayer graphene are analogous to the masses generated by broken symmetries in particle physics and give rise to large momentum-space Berry curvatures accompanied by spontaneous quantum Hall effects. Though recent experiments have provided convincing evidence of strong electronic correlations near the CNP in BLG, the presence of gaps is controversial. Here we present transport measurements in ultra-clean double-gated BLG, using source-drain bias as a spectroscopic tool to resolve a gap of ~ 2 meV at the CNP. The gap can be closed by an electric field $E \sim 15$ mV/nm but increases monotonically with a magnetic field B , with an apparent particle-hole asymmetry above the gap, thus providing a spectroscopic mapping of the ground states in BLG.

12:27PM B12.00007 Transport in Bilayer Graphene at the Charge Neutrality Point, WENZHONG BAO, University of Maryland at College Park, JAIRO VELASCO, University of California, Riverside, FAN ZHANG, University of Texas at Austin, Austin, LEI JING, University of California, Riverside, BRIAN STANDLEY, California Institute of Technology, DMITRY SMIRNOV, National High Magnetic Field Laboratory, Tallahassee, ALLAN MACDONALD, University of Texas at Austin, Austin, MARC BOCKRATH, CHUNNING LAU, University of California, Riverside, DEPARTMENT OF PHYSICS AND ASTRONOMY, UNIVERSITY OF CALIFORNIA, RIVERSIDE TEAM — Bilayer graphene (BLG) at the charge neutrality point is strongly susceptible to electronic interactions, and expected to undergo a phase transition into a state with spontaneous broken symmetries. We experimentally investigate transport properties of a large number ultra-clean BLG devices as functions of temperature, disorder, out-of-plane electric field, and charge density. We will discuss the results in terms of various theoretical models and possible phase transitions arising from the rich many body physics in this 2D system.

12:39PM B12.00008 Unconventional Landau levels in biased bilayer graphene, YEN-HUNG HO, WU-PEI SU, Physics Dept. and Texas Center for Superconductivity, University of Houston, Texas, USA, SING-JYUN TSAI, MING-FA LIN, Physics Dept., National Cheng Kung University, Taiwan — We utilize a generalized tight-binding model to study how the bias electric field impacts the magneto-electronic properties of graphene bilayer. With the availability of Landau wave function, the distribution among its sublattices enables the detailed observation of the Landau levels. The external electric field induces different electric potential on respective layers, which in turn lifts the inter-valley degeneracy. In addition, in a certain field range, Landau levels are coupled with each other and reveal the anomalous behavior: despite the serious hybridization of wave functions, these states in energy are still well-behaved Landau levels. These significant changes are directly reflected in the magneto-optical spectra, including the splitting of absorption peaks as well as the enhancement or quenching in response to field strength.

12:51PM B12.00009 Interaction-Enhanced Coherence in Graphene and Topological Insulator Bilayers¹, INTI SODEMANN, DMYTRO PESIN, ALLAN MACDONALD, University of Texas at Austin — We analyze the interlayer coherence properties of graphene and topological insulator electron-hole bilayers by solving imaginary-axis Dirac-model gap equations in the random phase approximation. By accounting self-consistently for the dynamical screening of Coulomb interactions in the gapped phase, we find that the gap can rise to values of the order of the Fermi energy in the strong interactions regime. For graphene, we comment on the supportive role of remote bands not included in our two-band Dirac model.

¹Work supported by the Nano-electronics Research Initiative (NRI) through the Southwest Academy for Nano-electronics (SWAN)

1:03PM B12.00010 Analysis of fermions on a honeycomb bilayer lattice with finite-range interactions in the weak-coupling limit¹, ROBERT THROCKMORTON, OSKAR VAFEK, Florida State University, National High Magnetic Field Laboratory — We extend previous analyses of fermions on a honeycomb bilayer lattice via weak-coupling renormalization group (RG) methods with extremely short-range and extremely long-range interactions to the case of finite-range interactions. In particular, we consider different types of interactions including screened Coulomb interactions, much like those produced by a point charge placed either above a single infinite conducting plate or exactly halfway between two parallel infinite conducting plates. We map out the phases that the system enters as a function of the range of the interaction. For spin- $\frac{1}{2}$ fermions, we discover that the system enters an antiferromagnetic phase for short ranges of the interaction and a nematic phase at long ranges, in agreement with the previous work. Our results can help reconcile the recent results of two seemingly contradictory experiments. We also consider the effects of an applied magnetic field on the system in the antiferromagnetic phase via variational mean field theory, obtaining results in qualitative agreement with the experimental data. We find that the antiferromagnetic order parameter increases with field, at first quadratically at low fields, then as $B/\ln(B/B_0)$ at higher fields.

1:15PM B12.00011 Wave-packet dynamics in twisted bilayer graphene, LEDE XIAN, School of physics, Georgia Tech, ZHENGFEI WANG, School of physics, Georgia Tech; Department of Materials Science and Engineering, University of Utah, MEI-YIN CHOU, School of physics, Georgia Tech — It has been shown recently that high-quality epitaxial graphene (EPG) can be grown on the SiC substrate that exhibits interesting physical properties. In particular, the multilayer graphene films grown on the C-face show rotational disorder. It is expected that the twisted layers exhibit unique new physics that is distinct from that of either single layer graphene or graphite. In this work, the time-dependent wave-packet propagation in twisted bilayer graphene (TBG) is studied based on a tight-binding model with parameters derived from density functional theory. Our results demonstrate intriguing dynamical behavior of electrons in TBG, which is related to the specific interlayer coupling. By varying the twist angle and the initial wave packet, we can effectively control the propagation of electrons in TBG.

1:27PM B12.00012 Fermi-velocity reduction in twisted bilayer graphene: large-scale density-functional calculations, KAZUYUKI UCHIDA, JUN-ICHI IWATA, SHINNOSUKE FURUYA, ATSUSHI OSHIYAMA, University of Tokyo — Twisted bilayer graphene (BLG) in which two graphene layers are rotated with a certain angle has been observed experimentally and its electronic structure has been studied using mainly tight-binding models [1]. We here report large-scale electronic-structure calculations with local-density approximation in the density-functional theory that clarify salient nature of the twisted BLG with the small rotation angles. The calculations have been done using the real-space density-functional theory (RSDFT) scheme which we have developed for the next-generation massively parallel computers. Implementation of the ultrasoft pseudopotential scheme in RSDFT allows us to treat thousands -of-carbon-atom systems in moderate-size computers. We have found that the Fermi velocity of the Dirac electron in the twisted BLG is substantially reduced compared with that in single layer graphene when the twist angle is small enough. This corroborates the observed reduction in the tight-binding models. We have also found that the wave functions at the Fermi level is strongly localized at AA-stacked region in the BLGs, opening a possibility of new magnetic functions.

1:39PM B12.00013 A Full electric-field tuning of thermoelectric power in a dual-gated Bi-layer graphene device¹, WEI-LI LEE, CHANG-RAN WANG, WEN-SEN LU, LEI HAO, TING-KUO LEE, Institute of Physics, Academia Sinica, Taipei, Taiwan, FENG LIN, I-CHUN CHENG, Department of Electrical Engineering and Graduate Institute of Photonics and Optoelectronics, National Taiwan University, Taipei, Taiwan, JIANG-ZHANG CHEN, Institute of Applied Mechanics, National Taiwan University, Taipei, Taiwan — By using high quality microcrystals of hexagonal boron nitride as top gate dielectric, we fabricated dual-gated bilayer graphene devices. We demonstrate a full electric field tuning of thermoelectric power resulting from the opening of a band-gap by applying a perpendicular electric field on bilayer graphene. We uncover a large enhancement in thermoelectric power at low temperature. At 15 K, the thermoelectric power can be amplified by more than four-fold attaining a value of $\sim 50\mu\text{V/K}$ at a displacement field of 0.8 V/nm . Our result may open up a new possibility in thermoelectric application using graphene-based device.

1:51PM B12.00014 Phase diagram of the honeycomb bilayer from functional renormalization, MICHAEL SCHERER, STEFAN UEBELACKER, CARSTEN HONERKAMP, Institute for Theoretical Solid State Physics, RWTH Aachen University — The phase diagram for interacting electrons on the honeycomb bilayer with Bernal stacking is explored by means of the functional renormalization group. For half-filling and including a range of repulsive onsite, nearest-neighbor and next-to-nearest neighbor interactions we analyze the emergent instabilities and find antiferromagnetic, two types of charge-density-waves and quantum spin Hall order. The presented phase diagram covers the relevant region for the bilayer graphene parameters which overlaps with the phase boundary between the antiferromagnetic state and the quantum spin Hall state. We comment on the effect of small dopings.

2:03PM B12.00015 The Hubbard model on the bilayer honeycomb lattice with Bernal stacking

, THOMAS C. LANG, STEFAN ÜBELACKER, Institute for Theoretical Solid State Physics, RWTH Aachen University, ZI YANG MENG, Center for Computation and Technology, Louisiana State University, MICHAEL SCHERER, CARSTEN HONERKAMP, Institute for Theoretical Solid State Physics, RWTH Aachen University, ALEJANDRO MURAMATSU, Institute for Theoretical Physics III, University of Stuttgart, FAKHER F. ASSAAD, Institute for Theoretical Physics and Astrophysics, University of Würzburg, STEFAN WESSEL, Institute for Theoretical Solid State Physics, RWTH Aachen University — Using a combination of quantum Monte Carlo, the functional renormalization group and mean-field theory we study the Hubbard model on the bilayer honeycomb as a model for interacting electrons on bilayer graphene. The free bands consisting of two Fermi points with quadratic dispersions lead to a finite density of states, which triggers the antiferromagnetic instability and spontaneously breaks sublattice and spin rotational symmetry once a local Coulomb repulsion is introduced. We show that the antiferromagnetic instability is insensitive to the inclusion of extended Coulomb interactions and discuss effects on the sublattice magnetization and of finite size systems in numerical approaches.

Monday, February 27, 2012 11:15AM - 2:15PM –

Session B13 DMP GMAG: Focus Session: Low-Dimensional and Molecular Magnetism - 1D Magnetism/single-chain magnets - Theory 211

11:15AM B13.00001 Ferromagnetic versus helical order in edge sharing CuO₂ chains - a computational study, HELGE ROSNER, Max Planck Institute for Chemical Physics of Solids Dresden, Germany, ULRIKE NITZSCHE, Leibniz Institute for Solid State and Materials Research Dresden, ALEXANDER TSIRLIN, Max Planck Institute for Chemical Physics of Solids Dresden, Germany, ROMAN KUZIAN, STEFAN-LUDWIG DRECHSLER, Leibniz Institute for Solid State and Materials Research Dresden — The magnetic ground state of edge sharing CuO₂ spin 1/2 Heisenberg chains with nearest neighbor exchange J_1 and second neighbor exchange J_2 depends delicately on structural details of the crystal structure, like Cu-O-Cu bond angles, Cu-O distances and the position of the cations. Without taking into account a renormalization by the interchain coupling, a critical ratio $\alpha = -J_2/J_1$ separates a ferromagnetic from a helical ground state (FM for $\alpha < 1/4$, helical for $\alpha > 1/4$). Here, we present a density functional based band structure study that investigates the different influences of various structural parameters for Li₂ CuO₂ as example compound. We find that the ferromagnetic and antiferromagnetic contributions develop rather differently for the same structural changes. Therefore, the key parameter α for the ground state is especially sensitive for small structural changes that might be induced by temperature or pressure variation.

11:27AM B13.00002 Quantum criticality of dipolar spin chains, ALDO ISIDORI, ANNIKA RUPPEL, ANDREAS KREISEL, PETER KOPIETZ, Institute for Theoretical Physics, University of Frankfurt, 60438 Frankfurt, Germany, ALEXANDER MAI, REINHARD M. NOACK, Physics Department, University of Marburg, 35032 Marburg, Germany — We show that a one-dimensional chain of Heisenberg spins, interacting with long-range dipolar forces in a magnetic field perpendicular to the chain, exhibits a quantum critical point belonging to the two-dimensional Ising universality class. Within linear spin-wave theory (corresponding to the so-called Gaussian approximation) the long-wavelength magnon dispersion is characterized by a logarithmic singularity in the magnon velocity for vanishing momenta, due to the long range nature of dipolar interactions in one-dimension. However, in the vicinity of the critical point this logarithmic correction is renormalized to zero by the effects of quantum fluctuations, signaling the reemergence of scale invariance, in accordance with the Ising critical scenario. The quantum critical regime where linear spin-wave theory breaks down is studied using two independent non-perturbative methods, namely the density-matrix renormalization group (DMRG) and the functional renormalization group (FRG). The Ginzburg regime where non-Gaussian fluctuations are important is found to be rather narrow on the ordered side of the transition, and very broad on the disordered side.

11:39AM B13.00003 Spin transport in spin chains: Possible applications for spintronics, KEVIN VAN HOOGDALAM, DANIEL LOSS, University of Basel — One of the main issues in modern electronics is that as devices get ever smaller the removal of waste energy generated by Joule heating becomes problematic. A possible solution to this problem is offered by spintronics in non-itinerant systems. Here, we theoretically propose the spin-equivalent in such systems of several different components that are used in traditional electronics: the resistance, the diode, and the capacitance. The system we consider here consists of an antiferromagnetic spin chain with anisotropic exchange interaction, connected to two three-dimensional spin reservoirs. We use inhomogeneous Luttinger liquid theory to describe the system, and non-equilibrium methods to calculate the relevant transport properties.

11:51AM B13.00004 Fractionalization of electron's spin and orbital degrees of freedom in 1D¹, KRZYSZTOF WOHLFELD, MARIA DAGHOFFER, SATOSHI NISHIMOTO, IFW Dresden, Germany, GINIYAT KHALIULLIN, FKF-MPG Stuttgart, Germany, JEROEN VAN DEN BRINK, IFW Dresden, Germany — We show that electron's spin and orbital degrees of freedom can fractionalize in 1D antiferromagnets: although the orbital excitations are inherently coupled to spinons in antiferromagnetic Mott insulators, in 1D they separate into a *pure* orbiton and a single spinon. This is similar to the spin-charge separation in 1D but corresponds to an exotic regime where spinons are faster than holons [1]. The resulting large dispersion of the pure orbiton can be detected in e.g. quasi-1D cuprates [2]. [1] K. Wohlfeld, M. Daghofer, S. Nishimoto, G. Khaliullin, and J. van den Brink, Phys. Rev. Lett. **107**, 147201 (2011). [2] J. Schlappa *et al.*, to be published (2011).

12:03PM B13.00005 Accurate determination of the Gaussian transition in spin-1 chains with single-ion anisotropy, BRUCE NORMAND, SHIJIE HU, XIAOQUN WANG, Department of Physics, Renmin University of China, Beijing 100872, China, LU YU, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — The Gaussian transition in the spin-one Heisenberg chain with single-ion anisotropy is extremely difficult to treat, both analytically and numerically. We introduce an improved DMRG procedure with strict error control, which we use to access very large systems. By considering the bulk entropy, we determine the Gaussian transition point to 4-digit accuracy, $D_c/J = 0.96845(8)$, resolving a long-standing debate in quantum magnetism. With this value, we obtain high-precision data for the critical behavior of quantities including the ground-state energy, gap, and transverse string-order parameter, and for the critical exponent, $\nu = 1.472(2)$. Applying our improved technique at $J_z = 0.5$ highlights essential differences in critical behavior along the Gaussian transition line.

12:15PM B13.00006 Generalized Fidelity Susceptibilities as Applied to the $J_1 - J_2$ Heisenberg Chain, MISCHA THESBERG, ERIK S. SORENSEN, McMaster University — In this talk slightly generalized quantum fidelity susceptibilities for the antiferromagnetic Heisenberg $J_1 - J_2$ chain will be introduced. The differential change in these fidelities differ from the typical fidelity in that they are measured with respect to a term other than the one used for driving the system towards a quantum phase transition. We study three fidelity susceptibilities; χ_ρ , χ_D and χ_{AF} , which are related to the spin stiffness, the dimer order and antiferromagnetic order, respectively. I will discuss how these quantities can accurately identify the quantum critical point at $J_2=0.241167J_1$ in this model. This phase transition, being in the Berezinskii-Kosterlitz-Thouless universality class, is controlled by a marginal operator and is therefore particularly difficult to observe. In addition more recent work on the anisotropic Heisenberg triangular model will be discussed.

12:27PM B13.00007 Excitation structure of frustrated spin chains with dimerization and the description by the effective field theory¹, SHINTARO TAKAYOSHI, MASAKI OSHIKAWA, Institute for Solid State Physics, University of Tokyo — Heisenberg antiferromagnetic chain with alternating exchange interaction is an important model, which describes magnetic properties of real materials. Field theoretical approach is a powerful tool to investigate such kind of one-dimensional quantum magnets, and it is known that this lattice model is related with corresponding sine-Gordon effective field theory through the bosonization technique. We investigate the excitation spectrum and the correspondence between $S = \frac{1}{2}$ and 1 frustrated chain with dimerization and their effective field theories by both analytical and numerical methods, focusing on the mass ratio r of second breather to soliton. In the result, the $S = \frac{1}{2}$ and 1 cases are understood in a unified way. r becomes $\sqrt{3}$, the value predicted from sine-Gordon model by the introduction of next-nearest neighbor coupling $J_2 = J_{2c}$ where the marginal term in effective field theory vanishes. The universality class of transition is Tomonaga-Luttinger liquid and first order for $J_2 < J_{2c}$ and $J_2 > J_{2c}$, respectively. We also consider the effect of the marginal term on r quantitatively by using form factor perturbation theory and renormalization analysis.

12:39PM B13.00008 Statistically interacting particles with shapes, DAN LIU, Physics Department, University of Rhode Island — Ising spin $s = \frac{1}{2}, 1, \frac{3}{2}$ chains with nearest and next-nearest neighbor coupling are interpreted as systems of floating particles. The particles are classified into species according to structure and into categories according to function. Species are distinguished by motifs consisting of several consecutive spins that interlink by sharing one or two sites. The four categories include compacts, hosts, tags, and hybrids. All particles from one set are excited from a selected Ising product state serving as pseudo-vacuum. Compacts and hosts float in segments of pseudo-vacuum. Tags are located inside hosts. Hybrids are tags with hosting capability. All particles are free of binding energies but subject to a generalized Pauli principle. In the Ising context, all particle energies are functions of the Hamiltonian parameters. However, the exact statistical mechanical analysis can be performed for particles with arbitrary energies. The entropy is a function of the particle populations from each species. Applications to jamming of granular matter in narrow channels and to DNA overstretching are in the works.

12:51PM B13.00009 Fisher zeros and correlation functions in Ising models, FELICITAS BEICHERT, CHRIS HOOLEY, University of St Andrews, VADIM OGANESYAN, City University of New York, RODERICH MOESSNER, Max-Planck-Institute for the Physics of Complex Systems — Phase transitions take place at singular points of the free energy. These correspond to zeros of the partition function when one tuning parameter is extended into the complex plane (so called Lee-Yang or Fisher zeros). It has been known since the 1960s that transition temperatures and critical exponents can be calculated from the distributions of these partition function zeros. We use this technique to calculate the spin-spin correlation function for the 1d Ising model and notice that it forms a spiral with a wavevector dependent on the position of the complex temperature on the contour of zeros. To extend this we will look at results from the 2d Ising model as well as the Ising model in a transverse field.

1:03PM B13.00010 Integrability in anyonic quantum spin chains via a composite height model, PAATA KAKASHVILI, Rutgers University, EDDY ARDONNE, NORDITA — Recently, properties of collective states of interacting non-abelian anyons have attracted a considerable attention. We study an extension of the ‘golden chain model’, a model of interacting Fibonacci anyons, where two- and three-body interactions are competing. Upon fine-tuning the interaction, the model is integrable. This provides an additional integrable point of the model, on top of the integrable point, when the three-body interaction is absent. To solve the model, we construct a new, integrable height model, in the spirit of the restricted solid-on-solid model solved by Andrews, Baxter and Forrester. The model is solved by means of the corner transfer matrix method. We find a connection between local height probabilities and characters of a conformal field theory governing the critical properties at the integrable point. In the antiferromagnetic regime, the criticality is described by the Z_k parafermion conformal field theory, while the $su(2)_1 \times su(2)_1 \times su(2)_{k-2}/su(2)_k$ coset conformal field theory describes the ferromagnetic regime.

1:15PM B13.00011 Out of equilibrium energy dynamics in low dimensional quantum magnets, STEPHAN LANGER, MARKUS HEYL, LMU Munich, IAN MCCULLOCH, U Queensland, Brisbane, Australia, FABIAN HEIDRICH-MEISNER, LMU Munich — We investigate the real-time dynamics of the energy density in spin-1/2 XXZ chains using two types of quenches resulting in initial states which feature an inhomogeneous distribution of local energies [1]. The first involves quenching bonds in the center of the chain from antiferromagnetic to ferromagnetic exchange interactions. The second quench involves an inhomogeneous magnetic field, inducing both, an inhomogeneous magnetization profile [2] and local energy density. The simulations are carried out using the adaptive time-dependent density matrix renormalization group algorithm. We analyze the time-dependence of the spatial variance of the bond energies and the local energy currents which both yield necessary criteria for ballistic or diffusive energy dynamics. For both setups, our results are consistent with ballistic behavior, both in the massless and the massive phase. For the massless regime, we compare our numerical results to bosonization and the non-interacting limit finding very good agreement. The velocity of the energy wave-packets can be understood as the average velocity of excitations induced by the quench.

1:27PM B13.00012 Dissipative phases in the one-dimensional Kondo-Heisenberg model¹, ALEJANDRO LOBOS, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742, USA, MIGUEL A. CAZALILLA, Centro de Física de Materiales CSIC-UPV/EHU and Donostia International Physics Center, E-20018, San Sebastian, Spain, PIOTR CHUDZINSKI, DPMC-MaNEP, University of Geneva, 24 Quai Ernest-Ansermet CH-1211 Geneva, Switzerland — Atomic-sized magnetic structures built on clean metallic surfaces are currently under intense investigation [1]. Besides their potential uses in quantum information storage and processing, these systems allow to ask fundamental questions in condensed matter physics. In particular, the interplay between the Kondo effect (i.e., the screening of the atomic magnetic moment by conduction electrons) and Heisenberg exchange interactions between magnetic impurities has been recently investigated with scanning tunneling microscopy (STM) [2]. Inspired by the above developments, we study an one-dimensional chain of $S=1/2$ Kondo impurities coupled by anisotropic Heisenberg-Ising exchange and embedded in a two-dimensional metallic substrate. Remarkably, in the case of easy-plane exchange, we find a novel quantum phase exhibiting long-range order at zero temperature. We discuss implications of the existence of this phase for possible experiments. References: [1] R. Wiesendanger, RMP 81, 1495 (2009). [2] P. Wahl et al, PRL 98, 056601 (2007) and references therein.

1:39PM B13.00013 String solutions and Mott physics in quasi-one-dimensional antiferromagnets, MASANORI KOHNO, WPI Center for Materials Nanoarchitectonics, NIMS, Japan — Mott insulators are caused by repulsive interactions between electrons, whereas band insulators are due to full filling of a single-particle band. In the one-dimension (1D) Hubbard model, the upper Hubbard band (UHB) has been identified with k - Λ string solutions [1]. Similarly, in the 1D spin-1/2 antiferromagnetic Heisenberg model, the high-energy magnetic excitations in a magnetic field have been identified primarily with 2-string solutions [2]. We can intuitively understand the correspondence between the high-energy states and the UHB, by mapping the Heisenberg model to the hard-core boson model with repulsive interactions. Furthermore, noting that the high-energy states persist in anisotropic triangular antiferromagnets [3], we can interpret the high-energy magnetic excitations observed in quasi-1D antiferromagnets such as Cs_2CuCl_4 and $\text{CuCl}_2 \cdot 2\text{N}(\text{C}_5\text{D}_5)$ in a magnetic field in the context of the Mott physics: the high-energy magnetic excitations, whose origin can be traced back to the string solutions, are due to repulsive interactions between hard-core bosons (down-spins) mapped from the Heisenberg model. [1] M.K., Phys. Rev. Lett. 105, 106402 (2010). [2] M.K., Phys. Rev. Lett. 102, 037203 (2009). [3] M.K., Phys. Rev. Lett. 103, 197203 (2009).

1:51PM B13.00014 A family of spin- S chain representations of $\text{SU}(2)$ level k Wess-Zumino-Witten models, MARTIN GREITER, Institut fuer Festkoerperphysik, KIT, Postfach 3640, 76021 Karlsruhe, Germany, RONNY THOMALE, Department of Physics, Stanford University, Stanford, CA 94305, USA, STEPHAN RACHEL, Department of Physics, Yale University, New Haven, CT 06520, USA, PETER SCHMITTECKERT, Institute fuer Nanotechnologie, KIT, 76344 Eggenstein-Leopoldshafen, Germany — We investigate a family of spin- S chain Hamiltonians recently introduced by one of us [M. Greiter, Mapping of Parent Hamiltonians, Springer Tracts in Modern Physics, Vol 244 (Springer, Berlin, 2011)]. For $S = 1/2$, it corresponds to the Haldane-Shastry model. For general spin S , we numerically show that the low-energy theory of these spin chains is described by the $\text{SU}(2)_k$ Wess-Zumino-Witten model with coupling $k = 2S$. In particular, we investigate the $S = 1$ model whose ground state is given by a Pfaffian for even number of sites N . We reconcile aspects of the spectrum of the Hamiltonian for arbitrary N with trial states obtained by Schwinger projection of two Haldane-Shastry chains.

2:03PM B13.00015 Inhomogeneous Spin Chains and Luttinger Liquids, NICHOLAS SEDLMAYR, JAN OHST, JESKO SIRKER, SEBASTIAN EGGERT, University of Kaiserslautern — We consider a one-dimensional spin chain with inhomogeneous coupling, which can also be modeled as an inhomogeneous Luttinger liquid. The Luttinger liquid paradigm has proved a very successful theoretical tool for investigating one-dimensional wires. However, there remain open questions about what happens when such a system becomes inhomogeneous. The mapping between the spin chain and the Luttinger liquid allows us to use both numerics and field theory to analyze the problem. Of particular interest is the case where the Luttinger liquid is attached to external leads, as is necessary for example when measuring the conductance of the wire. In this paper we use an abrupt shift in the parameters of the Luttinger liquid to model these connections and see how this affects its behavior. In particular we analyze the relevant back-scattering perturbations at the connections, and identify a case where this relevant operator can be tuned to zero within an otherwise still inhomogeneous system. This of course has consequences not only for transport in the Luttinger liquid system but also for the magnetic susceptibility of the spin chain.

Session B14 GMAG DMP FIAP: Focus Session: Spins in Semiconductors - Spin Relaxation in Semiconductors and Diamond 212

11:15AM B14.00001 3D Electron Spin Relaxation Control by Electric Field in Quantum Wells, XAVIER MARIE¹, Université de Toulouse — We have measured the electron spin relaxation time in (111)-oriented GaAs quantum wells by time-resolved photoluminescence. By embedding the QWs in a PIN or NIP structure we demonstrate the tuning of the conduction band spin splitting and hence the spin relaxation time with an applied external electric field applied along the growth z direction. The application of an external electric field of 50 kV/cm yields a two-order of magnitude increase of the spin relaxation time which can reach values larger than 30 ns; this is a consequence of the electric field tuning of the spin-orbit conduction band splitting which can almost vanish when the Rashba term compensates exactly the Dresselhaus one [1]. The spin quantum beats measurements under transverse magnetic field prove that the D'Yakonov-Perel (DP) spin relaxation time is not only increased for the S_z electron spin component but also for both S_x and S_y . These results contrast drastically with the (001) and (110) quantum wells. The role of the cubic Dresselhaus terms on the spin relaxation anisotropy will finally be discussed. The tuning or suppression of the DP electron spin relaxation demonstrated here for GaAs/AlGaAs quantum wells grown on (111) substrates is also possible in many other III-V and II-VI zinc-blende nanostructures since the principle relies only on symmetry considerations. 11:51AM B14.00002 Rotating Frame Spin dynamics of a Single Nitrogen Vacancy Center in Diamond Nanocrystal¹, ABDELGHANI LARAQUI, CARLOS MERILES, Department of Physics, City College of New York - CUNY — We investigate the spin dynamics of a nitrogen-vacancy (NV) center contained in individual diamond nanocrystals with an average diameter of 70 ± 20 nm in the presence of continuous microwave excitation. Upon periodic reversal of the microwave phase, we observe a train of rotary (Solomon) echoes that effectively extends the system coherence lifetime to reach several tens of microseconds, depending on the microwave power and phase inversion rate [1]. Starting from a model where the NV center interacts with a bath of paramagnetic defects on the nanocrystal surface, we use average Hamiltonian theory to compute the signal envelope from its amplitude at the echo maxima. A comparison between the effective Rabi and Solomon propagators shows that the observed response can be understood as a form of higher-order decoupling from the spin bath. The observed rotary echoes can be thought of as the rotating frame analog of Hahn's spin echoes, implying that the present scheme may find use for nanodiamond-based magnetic sensing. [1] A. Laraoui, C. A. Meriles, Phys. Rev. B **84**, 161403(R) (2011).

12:03PM B14.00003 Persistence of single spin coherence above room temperature in diamond¹, D.M. TOYLI, D.J. CHRISTLE, B.B. BUCKLEY, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA, A. ALKAUSKAS, C.G. VAN DE WALLE, Materials Department, University of California, Santa Barbara, California, CA — The nitrogen vacancy (NV) center in diamond is unique among single spin systems because of its robust optical spin initialization, optical spin readout, and room temperature spin coherence. However, there is not yet an understanding of what processes limit the NV center's spin properties at higher temperatures. We address this question by performing pulsed electron spin resonance and spin-resolved optical lifetime measurements on single defects at elevated temperatures [1]. The measurements demonstrate that the NV center's spin coherence remains robust at high temperatures while its spin-dependent photoluminescence diminishes above 600 K due to nonradiative relaxation. These results provide an enhanced understanding of the NV center orbital structure and also suggest the possibility of using single spins in diamond for nanoscale thermometry with sensitivities on the order of $100 \text{ mK Hz}^{-1/2}$ over a broad temperature range.

12:15PM B14.00004 Optically trapped fluorescent nanodiamonds¹, VIVA R. HOROWITZ, BENJAMIN J. ALEMÁN, DAVID CHRISTLE, ANDREW N. CLELAND, DAVID D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — The electronic spin state of the nitrogen-vacancy (NV) center in diamond has gained considerable interest because it can be optically initialized, coherently manipulated, and optically read out at room temperature. In addition, nanoparticle diamonds containing NV centers can be integrated with biological and microfluidic systems. We have constructed and characterized an optical tweezers apparatus to trap fluorescent nanodiamonds in a fluid and measure their fluorescence. Particles are held and moved in three dimensions using an infrared trapping laser. Fluorescent detection of these optically trapped nanodiamonds enables us to observe nanoparticle dynamics and to measure electron spin resonance of NV centers. We will discuss applications using the electron spin resonance of trapped NV centers in nanodiamonds for magnetic field imaging in fluidic environments.

¹This work is funded by AFOSR and DARPA.

12:27PM B14.00005 Nuclear Polarization of Nanodiamond, EWA REJ, DAVID REILLY, School of Physics, The University of Sydney, NSW, 2006 — Nanoparticles with long nuclear spin relaxation times are candidates for use in the context of targeted therapeutic delivery [1] and magnetic resonance imaging [1,2]. We report progress towards the development of contrast agents [3] based on ¹³C in nanodiamond. Nuclear relaxation and electron spin resonance data is presented for particles produced using detonation and the high-pressure high temperature technique. We describe the development of a milli-Kelvin nuclear polarization setup that makes use of a dilution refrigerator and X-band microwave resonator with fast sample exchange. 12:39PM B14.00006 Spin Lifetime Measurements of GaAsBi Films¹, BRENNAN PURSLEY, Department of Applied Physics, University of Michigan, G. VARDAR, Department of Materials Science and Engineering, University of Michigan, R.S. GOLDMAN, Department of Materials Science and Engineering and Department of Physics, University of Michigan, V. SIH, Department of Physics, University of Michigan — Substituting a small amount of As with Bi, the largest non-radioactive group V element, leads to a large reduction in the GaAs band gap and expected large spin-orbit effects ². Both properties are advantageous with potential applications ranging from infrared detectors to spin valves. Compressively strained GaAsBi films with varying bismuth compositions were grown on GaAs using molecular-beam epitaxy. Spin lifetimes were measured using the Hanle effect, a magneto-optical technique where an out-of-plane spin polarization is generated by circularly polarized light and then made to precess about an in-plane magnetic field. A Lorentzian lineshape can be fit to the field-dependent photoluminescence polarization to extract gT_s , where g is the Lande g-factor and T_s is a function of the carrier recombination time and spin dephasing time and provides a lower bound for both. Temperature and power dependent measurements were conducted and our extracted values for gT_s vary from 100ps to 1ns.

12:51PM B14.00007 Carrier and Spin Dynamics in Narrow Gap Multi Quantum Well Structures¹, MITHUN BHOWMICK, KELLY MCCUTCHEON, GITI A. KHODAPARAST, Virginia Tech, TETSUYA D. MISHIMA, MICHAEL B. SANTOS, University of Oklahoma, DIPTA SAHA, GARY D. SANDERS, CHRISTOPHER J. STANTON, University of Florida — We studied carrier/spin dynamics in several $InSb/Al_xIn_{1-x}Sb$ multiple-quantum well structures using several time resolved differential transmission schemes in the mid-infrared. Our results demonstrate the unique and complex dynamics in InSb heterostructures that can be important for electronic and optoelectronic devices. We present experimental observations and compare them with theoretical calculations. Calculations are based on the 8-band Pidgeon-Brown model generalized to include confinement potential as well as pseudomorphic strain. Optical properties are calculated within the golden rule approximation and compared with one and two color, time-resolved pump-probe differential transmission.

1:03PM B14.00008 Electric field-driven coherent spin reorientation and spin rephasing of optically generated electron spin packets in InGaAs¹, SEBASTIAN KUHNEN, KLAUS SCHMALBUCH, MARKUS HAGEDORN, PAUL SCHLAMMES, MARTEN PATT, II. Physikalisches Institut, RWTH Aachen University, Germany, MIHAIL LEPSA, Peter Gruenberg Institut (PGI-9), Forschungszentrum Juelich GmbH, Germany, GERNOT GUENTHERODT, BERND BESCHOTEN, II. Physikalisches Institut, RWTH Aachen University, Germany — Full electric-field control of spin orientations is one of the key tasks in semiconductor spintronics. We demonstrate that electric field pulses can be utilized for phase-coherent 2π spin rotation of optically generated electron spin packets in InGaAs epilayers using time-resolved Faraday rotation. Through spin-orbit interaction, the electric-field pulses act as local magnetic field pulses (LMFP). By the temporal control of the LMFP, we can turn on and off electron spin precession and thereby rotate the spin direction into arbitrary orientations in a 2-dimensional plane [1]. Moreover, using two subsequent pulses of opposite polarity allows us to perform spin echo measurements by reversing the spin precession direction. Although our spin transport experiment is in the diffusive regime, we unexpectedly observe that electric field-induced spin dephasing is reversible to a large extent.

1:15PM B14.00009 Using spin fluctuations to reveal long hole spin lifetimes and hole-nuclear coupling in (In,Ga)As quantum dots¹, YAN LI, S.A. CROOKER, National High Magnetic Field Lab, Los Alamos National Lab, D. REUTER, A.D. WIECK, Ruhr-Universität Bochum, D.R. YAKOVLEV, M. BAYER, Technische Universität Dortmund — “Spin noise spectroscopy” is a recently-developed technique for passively measuring the spin dynamics of electrons and holes via their intrinsic random spin fluctuations. In accord with the fluctuation-dissipation theorem, the frequency spectra of this spin noise alone reveals spin dephasing times and Landé g -factors. Using these methods we measure hole spins confined in self-assembled (In,Ga)As/GaAs quantum dots (QDs). Owing to their p -type wavefunctions, holes experience much less hyperfine interaction with lattice nuclei as compared with confined electrons, leading in principle to long spin decoherence times which are favorable for potential qubit applications. We observe very long hole spin correlation times (~ 400 ns) in zero magnetic field, ultimately limited by dephasing from hole-nuclear hyperfine interactions. Suppressing this dephasing with small longitudinal fields (< 100 G) directly reveals the hyperfine coupling strength, and unveils intrinsic hole spin relaxation times up to $\sim 5 \mu\text{s}$. Importantly, the lineshape of the noise evolves from a Lorentzian to a power-law as the hole-nuclear dephasing is suppressed.

¹We acknowledge support from LANL LDRD program.

1:27PM B14.00010 Spin lifetimes in InGaAs quantum wells¹, YU-TSUNG TSAI, ANDREAS RUSS, THOMAS SCRACE, ATHOS PETROU, SUNY at Buffalo, Buffalo, NY, PINGYUE SONG, HANAN DERY, University of Rochester, Rochester, NY, GEORGE KIOSEOGLOU, University of Crete, Heraklion, Greece, CONNIE LI, BEREND JONKER, Naval Research Laboratory, Washington DC — We have carried out Hanle spin relaxation time measurements in InGaAs quantum well structures as well as in Fe-based spin-LEDs that incorporate InGaAs QWs. In the InGaAs QW structures the spin lifetime T_S at $T = 5$ K is equal to 2 ns while in spin LEDs T_S is only 0.17 ns. For the undoped QWs, T_S increases from 2 ns at 5 K to 4.5 ns at 15 K and then decreases monotonically. On the other hand, T_S in the LEDs increases monotonically with temperature. The origin for the difference in the spin lifetimes between undoped QWs and that within a LED structure can be understood by considering the corresponding differences in the band structure between the symmetric quantum well and the spin-LED. In the latter, the Rashba spin-orbit interaction due to the built-in asymmetry brings about a significant enhancement in spin relaxation. In addition, bias conditions in the spin-LED play a crucial role in determining the temperature trend of the spin relaxation. The bias voltage tunes the electron density and accordingly the spin dephasing could be either suppressed or enhanced by electron-electron scattering.

1:39PM B14.00011 T_1 spin lifetimes in n-doped quantum wells and dots, JOHN COLTON, KEN CLARK, DANIEL CRAFT, JANE CUTLER, DAVID MEYER, TYLER PARK, Brigham Young University — We have used a pump probe technique to measure T_1 spin lifetimes in n -type GaAs quantum wells and InAs self-assembled quantum dots. The circularly polarized pump laser pulse aligns the spins; the linearly polarized probe laser pulse probes the spin states of the selected well (or dots) via the Kerr (or Faraday) effect at some later time. Results for the quantum well sample include a spin-filling effect that depends on the direction from which the probe laser wavelength approaches that of the well, and spin lifetimes ranging from 50 to 2000 ns (depending on temperature and field conditions). The InAs quantum dots, doped such that each dot has approximately one extra electron, display T_1 lifetimes longer than 5 ms at 1 T and 1.5 K.

1:51PM B14.00012 Frequency-domain optical probing of coherent spins in semiconductors, JESSE BEREZOVSKY, JOHNATHON FREY, Case Western Reserve University — We have demonstrated a technique for measuring GHz-scale coherent spin dynamics in semiconductors using narrow-linewidth modulated lasers. This scheme, based on the Faraday effect, is carried out by adding a sinusoidal modulation at frequency Ω to continuous-wave pump and probe lasers. The result is to effectively shift the Fourier component of the Faraday rotation signal at Ω to zero frequency, where it can be measured by a low-bandwidth detector. By producing the Fourier transform of the time-domain spin dynamics, this method yields the same information as pulsed pump-probe measurements without the need for complex pulsed lasers, and with minimal spectral bandwidth, allowing for high-resolution spectroscopic measurements. The ability to perform Faraday rotation measurements with narrow-linewidth lasers is essential for observing spins in individual quantum dots, or for avoiding unintentional carrier excitation. We have employed this technique to observe coherent spin dynamics in CdSe nanocrystals using standard diode lasers. By fitting these results to the expected model, we can extract electron g -factors, and spin coherence and dephasing times in agreement with time-domain measurements.

2:03PM B14.00013 Quadratic magnetic field dependence of magnetoelectric photocurrent, JUNFENG DAI, HAI-ZHOU LU, SHUN-QING SHEN, FU-CHUN ZHANG, XIAODONG CUI, The University of Hong Kong, DEPARTMENT OF PHYSICS, THE UNIVERSITY OF HONG KONG TEAM, CENTRE OF THEORETICAL AND COMPUTATIONAL PHYSICS, THE UNIVERSITY OF HONG KONG TEAM — We experimentally study the spin and electric photocurrents excited by a linearly polarized light via direct interband transitions in an InGaAs/InAlAs quantum well. In the absence of a magnetic field, the linearly polarized light induces a pure spin current due to the spin-orbit coupling, which may be transformed into a measurable electric current by applying an in-plane magnetic field. The induced electric photocurrent is linear with the in-plane magnetic field. Here, we report a quadratic magnetic field dependence of the photocurrent in the presence of an additional perpendicular component of the magnetic field. We attribute the observation to the Hall effect of magnetoelectric photocurrent.

Monday, February 27, 2012 11:15AM - 2:15PM —

Session B15 DMP FIAP GMAG: Focus Session: Spins in Metals: Spin Torque Switching and Magnetic Anisotropy Control 213

11:15AM B15.00001 Switching Energy Barrier and Current Reduction in MTJs with Composite Free Layer¹, VIKTOR SVERDLOV, ALEXANDER MAKAROV, SIEGFRIED SELBERHERR, Institute for Microelectronics, TU Wien — We investigate the properties of a penta-layer magnetic tunnel junction (MTJ) with a composite soft layer by exhaustive micromagnetic simulations. The structure CoFe/spacer (1nm)/Py (4nm)/spacer (1nm)/ CoFe (Py is Ni₈₁Fe₁₉) with an elliptical cross-section (major axes 90nm and 35nm, correspondingly) is considered. The system with the composite soft layer is obtained by removing a central stripe of 5nm width from the monolithic free layer. The MTJ with a composite free layer switches two to three times faster than the one with a monolithic layer [1]. We have found that in the MTJ structure with the composite layer the switching energy barrier is decreased and becomes equal to the shape anisotropy energy barrier responsible for thermal stability. This results in a switching current density reduction. The physical reasons for the switching energy barrier reduction are discussed.

11:27AM B15.00002 Switching Distributions in all perpendicular spin-valve nanopillars under thermal activation and spin-transfer torques, DANIEL GOPMAN, DANIEL BEDAU, Department of Physics, New York University, STEPHANE MANGIN, C. LAMBERT, Institute Jean Lamour, UMR CNRS 7198, Nancy University, ERIC FULLERTON, CMRR, University of California at San Diego, JORDAN KATINE, San Jose Research Center, Hitachi-GST, ANDREW KENT, Department of Physics, New York University — The free layer switching field distributions of spin-valve nanopillars with perpendicular magnetization have been studied. The distributions are consistent with expectations of a model based on thermal activation over a single field dependent energy barrier. However, at zero applied current there is a strong asymmetry between the P and AP states and the reverse, with energy barriers more than 50% higher for P to AP transitions. The inhomogeneous dipolar field from the polarizer is demonstrated to be at the origin of this symmetry breaking¹. I will show results on the effects of varying lateral geometry on this symmetry breaking. Also, I will introduce a low-cost method for studying the switching current distributions that applies a continuous waveform to sweep the dc current and simultaneously probe the magnetoresistance. This method permits the acquisition of over 10⁶ switching events in six hours, which presents the possibility to obtain deep statistics on the reversal process. The effect of the magnitude and direction of applied dc currents on the thermal stability of a nanomagnet has been investigated and the results will be examined within the acquired statistics. Supported by NSF Grant DMR-1006575.

¹D. B. Gopman *et al.*, arXiv:1111.1342v1 [cond-mat.mes-hall]

11:39AM B15.00003 Landau-Lifshitz Bloch Macrospin Simulations of Magnetization Switching Dynamics in Perpendicular Anisotropy CoNi/Pd Magnetic Multilayer Thin Films, UFUK KILIC, Bogazici University, Department of Physics, GIOVANNI FINOCCHIO, Dipartimento di Fisica della Materia e Ingegneria Elettronica, University of Messina, ISMAIL VOLKAN INLEK, IBRAHIM CINAR, GULEN AKTAS, OZHAN OZATAY, Bogazici University, Department of Physics — Heating magnetic multilayer thin films close to their Curie temperature (T_c) for brief periods of time, in the presence of a magnetic field, will potentially enable ultra-high density magnetic recording while maintaining thermal stability of perpendicular anisotropy magnetic media. This idea is to be exploited in thermally assisted magnetic recording (TAR) technology, which is currently being pursued by many academic and industrial research labs. In our study, we have performed macrospin simulations of the magnetization switching based on the numerical solution of Landau-Lifshitz-Bloch equation at such elevated temperatures (close to T_c) for a strongly exchange coupled and high perpendicular anisotropy CoNi/Pd magnetic multilayer thin film structure (T_c=448 K). We will discuss the results of a comprehensive model for this material system taking into account temperature dependencies of anisotropy, saturation magnetization and transverse and longitudinal susceptibilities and their effects on the switching process.

11:51AM B15.00004 Statistical and Time Resolved Studies of Switching in Magnetic Tunnel Junction based Orthogonal Spin Transfer Devices, HUANLONG LIU, DANIEL BEDAU, DIRK BACKES, New York University, JURGEN LANGER, Singulus Technologies AG, PRADEEP MANANDHAR, Spin Transfer Technologies, ANDREW KENT, New York University, Spin Transfer Technologies, NEW YORK UNIVERSITY TEAM, SINGULUS TECHNOLOGIES AG TEAM, SPIN TRANSFER TECHNOLOGIES TEAM — We report statistical and single-shot time-resolved studies of spin transfer switching in OST-MRAM devices. These devices consist of a perpendicular polarizer integrated into a layer stack with an in-plane magnetized free and reference layer, which form the electrodes of a magnetic tunnel junction [1]. The perpendicular polarizer provides an initial torque – designed to reduce the incubation delay in switching. The demagnetization field created during the switching can further accelerate the reversal process [2]. The devices switch reliably at 0.7 V and 500 ps duration for both voltage polarities. We record the change of the device resistance in real time during the pulse to obtain the time needed to initiate the switching τ_{start} and the time between the initiation and the end of the switching τ_{switch} for every single switching event. τ_{switch} is determined to be less than a few hundreds of picoseconds, on the order of the precession time due to the demagnetization field and we find evidence for precession reversal under certain conditions. We further present results on the effects of pulse amplitude and applied field on τ_{start} and τ_{switch} . This work was supported by Spin Transfer Technologies. [1] H. Liu *et al.*, APL 97, 242510 (2010). [2] A. D. Kent *et al.*, APL 84, 3897 (2004).

12:03PM B15.00005 Magnon contribution to the spin torque and magnetoresistance properties of FeCoB/MgO/FeCoB magnetic tunnel junctions, YUN LI, HSIN-WEI TSENG, Cornell University, Ithaca, NY 14853, JOHN READ, JORDAN KATINE, HGST, San Jose, California, 95135, DANIEL RALPH, ROBERT BUHRMAN, Cornell University, Ithaca, NY 14853 — We have studied the spin-torque excited ferromagnetic resonance (ST-FMR) and the tunneling magnetoresistance (TMR) properties of FeCoB/MgO/FeCoB magnetic tunnel junctions as a function of temperature from 300K to 10K. We find that while the TMR increases by ~ 50% upon cooling to 10 K, the in-plane spin torque and the perpendicular or field-like torque both decrease substantially. The results demonstrate that while magnon-assisted tunneling degrades TMR, it acts to significantly enhance ST in MTJs, in accord with theoretical prediction. Moreover, the bias-dependent structure in both the asymmetry of the in-plane ST and the parallel conductance of the MTJ is more pronounced at low temperature, indicative of this asymmetry being due substantially to the interfacial electronic structure of the electrodes.

12:15PM B15.00006 Magnetic field dependence of spin torque switching in nanoscale magnetic tunnel junctions, LIU YANG, GRAHAM ROWLANDS, Department of Physics and Astronomy, University of California, Irvine, CA, JORDAN KATINE, Hitachi Global Storage Technologies, San Jose, CA 95135, JURGEN LANGER, Singulus Technologies AG, 63796 Kahl/Main, Germany, ILYA KRIVOROTOV, Department of Physics and Astronomy, University of California, Irvine, CA — Magnetic random access memory based on spin transfer torque effect in nanoscale magnetic tunnel junctions (STT-RAM) is emerging as a promising candidate for embedded and stand-alone computer memory. An important performance parameter of STT-RAM is stability of its free magnetic layer against thermal fluctuations. Measurements of the free layer switching probability as a function of sub-critical voltage at zero effective magnetic field (read disturb rate or RDR measurements) have been proposed as a method for quantitative evaluation of the free layer thermal stability at zero voltage. In this presentation, we report RDR measurement as a function of external magnetic field, which provide a test of the RDR method self-consistency and reliability.

12:27PM B15.00007 Shot noise in double barrier epitaxial magnetic tunnel junctions, FARKHAD ALIEV, JUAN PEDRO CASCALES, DAVID HERRANZ, ANDRES GOMEZ-IBARLUCEA, Universidad Autonoma de Madrid Spain, CORIOLAN TIUSAN, MICHEL HEHN, AMANDINE DULLUARD, CHRISTINE BELLOUARD, Nancy-Universite France, TOMASZ SZCZEPANSKI, VITALII DUGAEV, Rzeszow University of Technology Poland, JOZEF BARNAS, Adam Mickiewicz University Poznan Poland — Shot noise has been shown to be an effective tool to study statistics of electron tunnelling in single barrier magnetic tunnel junctions [1-2]. Here we report on shot noise and tunnelling magnetoresistance measurements in fully epitaxial Fe/MgO/Fe/MgO/Fe double barrier magnetic tunnel junctions. We observed that the shot noise is essentially determined by the barriers' symmetry and relative magnetic configuration. Enhanced barrier asymmetry effectively suppresses electron correlations, and the noise approaches the Poissonian limit. The proposed model of sequential tunnelling (with spin relaxation) through the magnetic layer inside the tunnel barrier satisfactory explains the experimental observations. 12:39PM B15.00008 Planar approximation for spin-transfer devices with tilted polarizer¹, YA. B. BAZALIY, University of South Carolina — Planar spin-transfer devices with dominating easy-plane anisotropy can be described by an effective one-dimensional equation for the in-plane angle [1-3]. Such a description provides an intuitive qualitative understanding of the magnetic dynamics. We apply the effective planar equation to describe magnetic switching and precession states in devices with a tilted polarizer [4]. The approach allows one to understand the dynamic regimes and sketch the switching diagram without performing the detailed calculations.

12:51PM B15.00009 Modification of the Stoner-Wohlfarth Astroid by a Spin-Polarized Current¹, SHU YAN, ZHELIN SUN², YA. B. BAZALIY, Department of Physics and Astronomy, University of South Carolina, Columbia, SC 29208 — Conventional Stoner-Wohlfarth astroid describes the field-induced switching of a nanomagnet with a uniaxial anisotropy. Both theory and experiments show that the spin-transfer torque can change the switching behavior of nanomagnets and therefore modify the astroid. Such a modification was recently analyzed in the limit of small currents [1]. To explore the modification of the astroid by a current of arbitrary magnitude we propose an exact method capable of finding the switching boundaries for a magnet described by an LLG equation with the Slonczewski's spin-torque term. Our approach takes into account both the local destabilization of equilibria and the equilibrium collisions. The self-crossing nature of the modified astroid is explained and a novel region with three stable equilibria is predicted in our result.

1:03PM B15.00010 Origin of perpendicular magnetic anisotropy in Co/Ni multilayers on Ti layer, SEE-HUN YANG, IBM Almaden Research Center, KUEI-HUNG THOMS, Industrial Technology Research Institute, LUC THOMAS, STUART PARKIN, IBM Almaden Research Center — Magnetic materials in which their magnetic moment direction is oriented perpendicular to the plane of the magnetic layers in thin film heterostructures have been much studied for their potential application to spintronic devices. In particular, theories of current induced excitation, via the phenomenon of spin torque transfer, show that perpendicularly magnetized layers can be more easily excited or their magnetization direction switched than in-plane magnetized layers. In particular, Co/Ni multilayers are promising due to high spin polarization and small Gilbert damping compared to Co/Pt or Fe/Pt. However, their perpendicular magnetic anisotropy (PMA) is highly sensitive to the underlayer that is critical in device performance because, for instance, the current shunting can substantially reduce the spin transfer torque in magnetic racetrack memory. We observed an excellent PMA in annealed Co/Ni on Ti underlayer whose resistance is significantly greater than those of Co/Ni, thereby minimizing the current shunting. It is found that the PMA does not simply originate from magneto-crystalline effect (spin-orbit interaction) but mainly from magnetoelastic effect caused by compressive strain along (111) direction. We will present systematic results and quantitative analyses.

1:15PM B15.00011 Perpendicular magnetization of CoFeGe alloy films induced by MgO interface¹, MANLI DING, University of Virginia, SEBASTIAN SCHAFER, University of Alabama, XIAOPU LI, University of Virginia, TIM MEWES, University of Alabama, JOSEPH POON, University of Virginia — The perpendicular magnetization of CoFeGe alloy films was achieved in the structures of CoFeGe/MgO with the perpendicular magnetic anisotropy energy density (K_u) of $\sim 1 \times 10^6 \text{ erg/cm}^3$. The CoFeGe thickness dependence of K_u was investigated, indicating that the perpendicular anisotropy of CoFeGe is contributed by the interfacial anisotropy between CoFeGe and MgO. High-resolution transmission electron microscope images clearly show formation of bcc crystalline structure of CoFeGe well lattice matched with the (100)-oriented MgO barrier. Gilbert damping constant for the films was evaluated by using ferromagnetic resonance measurement.

1:27PM B15.00012 Voltage-Induced Ferromagnetic Resonance in Magnetic Tunnel Junctions, JIAN ZHU, University of California, Irvine, JORDAN KATINE, Hitachi Global Storage Technologies, GRAHAM ROWLANDS, YU-JIN CHEN, ZHENG DUAN, University of California, Irvine, JUAN ALZATE, PRAMEY UPADHYAYA, University of California, Los Angeles, JUERGEN LANGER, Singulus Technologies, PEDRAM KHALILI AMIRI, KANG WANG, University of California, Los Angeles, ILYA KRIVOROTOV, University of California, Irvine — We demonstrate excitation of ferromagnetic resonance in CoFeB/MgO/CoFeB magnetic tunnel junctions (MTJs) by the combined action of voltage-controlled magnetic anisotropy (VCMA) and spin transfer torque (ST). Our measurements reveal that GHz-frequency VCMA torque and ST in low-resistance MTJs have similar magnitudes, and thus that both torques are equally important for understanding high-frequency voltage-driven magnetization dynamics in MTJs. As an example, we show that VCMA can increase the sensitivity of an MTJ-based microwave signal detector to the sensitivity level of semiconductor Schottky diodes.

1:39PM B15.00013 Spin Torque in Asymmetric CoFeB/MgO/FeB Magnetic Tunnel Junctions

, HSIN-WEI TSENG, Cornell University, YUN LI, Cornell Univ., JOHN READ, Hitachi Global Storage Technology, San Jose, CA, DANIEL RALPH, ROBERT BUHRMAN, Cornell Univ., CORNELL UNIV. TEAM, HITACH GLOBAL STORAGE TECHNOLOGY COLLABORATION — Recent studies have shown that the use of asymmetric electrodes in MTJs can significantly affect spin torque (ST) behavior. We will report on the measurement via spin torque ferromagnetic resonance (ST-FMR) and switching phase diagram (SPD) studies of the in-plane and field-like (out-of-plane) torque of low resistance, asymmetric IrMn/FeB/MgO/FeCoB) and IrMn/FeCoB/MgO/FeB MTJ nanopillars in the as-grown state (TMR~22%) and the annealed state (TMR~90%), and in comparison to that of symmetric counterparts; IrMn/FeB/MgO/FeB) and Ir/Mn/FeCoB/MgO/FeCoB MTJs. For the asymmetric MTJs only, the ST-FMR data show a strong field-like torque for low voltage bias V that reverses sign when the free and pinned layers are reversed. At the higher V regime explored by the SPD the equivalent linear term in the field-like torque can dominate over the in-plane torque, resulting in either the parallel or antiparallel alignment being favored for both bias polarities, depending on the composition of the free layer.

1:51PM B15.00014 Influence of growth parameters on the spin-filtering properties of epitaxial ferrite tunnel barriers¹

¹, J.-B. MOUSSY², S. MATZEN³, CEA-Saclay, R. MATTANA⁴, F. PETROFF⁵, UMR CNRS/Thales, G.-X. MIAO⁶, J.S. MOODERA⁷, Francis Bitter Magnet Lab., CEA TEAM, UMR CNRS/THALES TEAM, MIT TEAM — In spintronics, spin-filtering is a physical phenomenon which has the potential to produce highly spin-polarized currents by the spin-selective transport of electrons across a ferromagnetic tunnel barrier. The insulating ferrites MnFe_2O_4 , CoFe_2O_4 and NiFe_2O_4 , whose Curie temperatures are above 300K, are promising candidates for spin-filtering at room temperature. In this work, we report on the in-depth study of structural, chemical and physical properties of epitaxial ferrite ultra-thin films and associated spin-filtering measurements as a function of different growth parameters. We analyze the effect of oxidation on the physical properties and the resultant spin-polarization. The influence of structural defects on the spin-filter efficiency is also put on view by tunneling magnetoresistance. Finally, we show the impact of the $\text{MgAl}_2\text{O}_4(001)$ substrates on the magnetic behavior of cobalt ferrite tunnel barriers revealing the important role played by strains in the spin-filter properties.

2:03PM B15.00015 Magnetoelectric Control of Magnetic Anisotropy in Ultrathin Fe Films¹

UWE BAUER, Massachusetts Institute of Technology, Cambridge, USA, MAREK PRZYBYLSKI, JURGEN KIRSCHNER, Max-Planck-Institut für Mikrostrukturphysik, Halle, Germany, GEOFFREY S. D. BEACH, Massachusetts Institute of Technology, Cambridge, USA — Magnetoelectric switching of the magnetization vector could enable new low-power logic devices and non-volatile memory cells. Magnetoelectric switching typically requires complex multiferroic oxides or strain coupled magnetostrictive/piezoelectric composites. However, recently it has been demonstrated that surface magnetic anisotropy in ultrathin ferromagnetic metal films can be directly controlled by application of a strong electric field [1]. In this work we apply an electric field across a high- k oxide stack of MgO and ZrO_2 to induce charge at the surface of an ultrathin Fe film. By using high- k dielectric materials more charge can be induced at the surface of the ferromagnetic film and the efficiency of the magnetoelectric effect can be enhanced. Under application of just a few volts across the oxide stack we observe a strong magnetoelectric effect which results in a shift of the spin reorientation thickness by 0.5 atomic layers and a change in perpendicular surface anisotropy of $\sim 120 \mu\text{J}/\text{m}^2$. Moreover, by engineering the high- k oxide stack we realize a novel charge pumping mechanism that permits optical imprinting of the magnetic state in the continuous Fe film. [1] T. Maruyama *et al.* Nature Nanotechnology 4, 158 - 161 (2009)

11:15AM B16.00001 Charge and magnetic order in the triangular lattice Hubbard model at one-third filling¹

, MATTHEW ENJALRAN, Southern CT State University — Experimental work over the last decade on layered triangular lattice materials with itinerant electrons has increased the motivation to study these systems theoretically. As in insulating magnets, frustration in itinerant systems enriches the phase diagram of the material. In a class of organic charge transfer salts and sodium cobalt oxide spin liquid, superconducting, charged ordered, and magnetically ordered phases have been observed. With the kinetic energy of electrons, a Hubbard type model on a triangular lattice is an appropriate starting point to study much of the correlated physics of these systems. We consider a single band Hubbard model on a triangular lattice with variable electron filling and anisotropic hopping. Within mean-field theory we observe a transition at one-third filling on the isotropic lattice to a charge ordered antiferromagnet on a honeycomb sublattice at a critical interaction $U_c/t = 5.0$. We will also present preliminary results for other regions of the phase diagram.

11:27AM B16.00002 Electronic reconstruction of doped Mott insulator heterojunctions¹

, M. CHARLEBOIS, Université de Sherbrooke, S.R. HASSAN, R. KARAN, IMSc Chennai, India, M. DION, D. SENECHAL, A.-M.S. TREMBLAY, Université de Sherbrooke — Correlated electron heterostructures became a possible alternative when thin-film deposition techniques achieved structures with a sharp interface transition [1]. Soon thereafter, Okamoto & Millis introduced the concept of “electronic reconstruction” [2]. We study here the electronic reconstruction of doped Mott insulator heterostructures based on a Cluster Dynamical Mean Field Theory (CDMFT) calculations of the Hubbard model in the limit where electrostatic energy dominates over the kinetic energy associated with transport across layers. The grand potential of individual layers is first computed within CDMFT and then the electrostatic potential energy is taken into account in the Hartree approximation. The charge reconstruction in an ensemble of stacked planes of different nature can lead to a distribution of electron charge and to transport properties that are unique to doped-Mott insulators.

11:39AM B16.00003 Solving the Parquet Equations for the Hubbard Model beyond Weak Coupling, KA-MING TAM, Louisiana State University, HERBERT FOTSO, Georgetown University, SHUXIANG YANG, TAE-WOO LEE, J. RAMANUJAM, JUANA MORENO, MARK JARRELL, Louisiana State University — We find that imposing the crossing symmetry in the iteration process considerably extends the range of convergence for solutions of the parquet equations for the Hubbard model. When the crossing symmetry is not imposed, the convergence of both simple iteration and more complicated continuous loading (homotopy) methods are limited to high temperatures and weak interactions. We modify the algorithm to impose the crossing symmetry without increasing the computational complexity. We also imposed time reversal and a subset of the point group symmetries, but they did not further improve the convergence. We elaborate the details of the latency hiding scheme which can significantly improve the performance in the computational implementation. With these modifications, stable solutions for the parquet equations can be obtained by iteration more quickly even for values of the interaction that are a significant fraction of the bandwidth and for temperatures that are much smaller than the bandwidth. This may represent a crucial step towards the solution of two-particle field theories for correlated electron models.

11:51AM B16.00004 Correlation effects of one band hubbard model beyond the Gutzwiller Approximation, JUN LIU, YONGXIN YAO, CAI-ZHUANG WANG, KAI-MING HO, Iowa State University and Ames Lab — A novel scheme is introduced to go beyond the Gutzwiller approximation (GA). Starting from the scheme, we can see how the standard GA is recovered by relaxing physical constraints step by step. This not only adds to validity of the current scheme, but provides new insights into understanding the GA. Performance of the scheme on several testing cases is superior to the standard GA. We studied the one band Hubbard model in one, two and three dimensions to revisit relevant conclusions made under the GA as well as the slave boson formalism.

12:03PM B16.00005 Local electronic nematicity in the 2-dimensional Hubbard model¹, KUN FANG, GAYANATH FERNANDO, University of Connecticut, ARMEN KOCHARIAN, California State University — Recent measurements on magnetic and transport properties of some strongly correlated materials show a local electronic nematic phase which locally breaks the C_4 symmetry but keeps translational symmetry. We studied the 2-dimensional Hubbard model using the variational cluster approach and found a similar phase. The results showed this local nematicity is a property of the electron liquid and would appear even if there is no lattice distortion. Calculations of spin correlation were performed and compared to results from magnetic neutron scattering of real materials, which showed a distinct asymmetry along x and y directions.

12:15PM B16.00006 Evolution of insulator-metal-insulator transitions under staggered lattice potentials, AARAM JOO KIM, MOO YOUNG CHOI, Department of Physics and Astronomy and Center for Theoretical Physics, Seoul National University, Seoul 151-747, Korea, GUN SANG JEON, Department of Physics, Ewha Womans University, Seoul 120-750, Korea — It is known that in the ionic Hubbard model metallic phases exist between band and Mott insulators in the presence of staggered lattice potentials. We investigate how the phase diagram depends on the strength of the staggered lattice potential, by means of the dynamical mean-field theory combined with the continuous-time quantum Monte Carlo method. Observed at finite temperatures is the crossover between metallic and band insulating phases while a first-order transition ending up with a critical point shows up between the metallic and Mott insulating phases. It is discussed how such transition behaviors evolve as the lattice potential grows at low temperatures.

12:27PM B16.00007 Mott transition and ferrimagnetism in the Hubbard model on the anisotropic kagome lattice, ATSUSHI YAMADA, KAZUHIKO SEKI, Department of Physics, Chiba University, ROBERT EDER, Karlsruhe Institute of Technology, YUKINORI OHTA, Department of Physics, Chiba University — Mott transition and ferrimagnetism are studied in the Hubbard model on the anisotropic kagome lattice using the variational cluster approximation and the phase diagram at zero temperature and half-filling is analyzed. The ferrimagnetic phase rapidly grows as the geometric frustration is relaxed, and the Mott insulator phase disappears in moderately frustrated region, showing that the ferrimagnetic fluctuations stemming from the relaxation of the geometric frustration is enhanced by the electron correlations. In metallic phase, heavy fermion behavior is observed and mass enhancement factor is computed. Enhancement of effective spatial anisotropy by the electron correlations is also confirmed in moderately frustrated region, and its effect on heavy fermion behavior is examined.

12:39PM B16.00008 Graphene two-leg ladder. A system with conducting, insulating and superconductive properties, GEORGE KARAKONSTANTAKIS, STEVEN KIVELSON, Stanford University — We use DMRG to study the ground-state phases of the Hubbard model defined on a one dimensional ladder of edge-sharing hexagons - a model which may be relevant to the electronic structure of polyacenes or graphene strips. At half filling we find a robust insulating phase with a large spin-gap, even at small U/t which, as a function of the strength of the third-neighbor hopping, exhibits a non-trivial cross-over from a band -insulator to a Mott insulator. The doped system exhibits a variety of conducting phases. Possible relevance of our results to the recently discovered high temperature superconductivity in K doped dibenzopentacene will be discussed, as well.

12:51PM B16.00009 Dominant superconducting fluctuations in the 1D extended Holstein-extended Hubbard model, SHAN-WEN TSAI, University of California, Riverside, KA-MING TAM, Louisiana State University, DAVID K. CAMPBELL, Boston University — The search for realistic 1D models that exhibit dominant superconducting (SC) fluctuations has a long history. In these 1D systems, the effects of commensurate band fillings - strongest at half-filling - and electronic repulsions typically lead to a finite charge gap and the favoring of insulating density wave ordering over superconductivity. We study a model - the extended Hubbard-extended Holstein (EHEH) model - with non-local electron-phonon interactions, in addition to electron-electron interactions. The EHEH model unambiguously possesses dominant superconducting fluctuations at half filling in a large region of parameter space. Using multi-scale functional renormalization group for the full model and a renormalization group for a bosonized form of the model, we prove the existence of dominant SC fluctuations in this model. Dominant SC fluctuations arise because the spin-charge coupling at high energy is weakened by the non-local electron-phonon interaction and the charge gap is destroyed by the suppression of the Umklapp process. The existence of the dominant SC pairing instability in this half-filled 1D system suggests that non-local boson-mediated interactions may be important in the superconductivity observed in high T_c cuprate and organic superconductors.

1:03PM B16.00010 Ground state and finite temperature behavior of $1/4$ -filled zigzag ladders¹

, R. TORSTEN CLAY, JEONG-PIL SONG, SAURABH DAYAL, Mississippi State University, SUMIT MAZUMDAR, University of Arizona — We consider the simplest example of lattice frustration in the $1/4$ -filled band, a one-dimensional chain with next-nearest neighbor interactions. For this zigzag ladder with electron-electron as well as electron-phonon interactions we present numerical results for ground state as well as thermodynamic properties. In this system the ground state bond distortion pattern is independent of electron-electron interaction strength. The spin gap from the ground state of the zigzag ladder increases with the degree of frustration. Unlike in one-dimension, where the spin-gap and charge ordering transitions can be distinct, we show that in the ladder they occur simultaneously. We discuss spin gap and charge ordering transitions in $1/4$ -filled materials with one, two, or three dimensional crystal structures. We show empirically that regardless of dimensionality the occurrence of simultaneous or distinct charge and magnetic transitions can be correlated with the ground state bond distortion pattern.

¹This work was supported by DOE grant DE-FG02-06ER46315.

1:15PM B16.00011 Phases of the two-leg Hubbard ladder in the large U limit

, LI LIU, HONG YAO, STEVEN KIVELSON, Stanford University, STEVEN WHITE, University of California, Irvine, DUNG-HAI LEE, University of California, Berkeley — We study the phase diagram of the two-leg Hubbard ladder in the large U limit using the density matrix renormalization group (DMRG). Already in the limit of infinite on-site repulsion U , we find a rich phase diagram in which commensurability effects are unexpectedly prominent: A fully spin-polarized “Nagaoka” metallic phase occurs for electron density, n , in the range $1 > n > n_1$, where $n_1 \approx 0.8$ is not obviously locked by any commensurability. There is an insulating, anti-ferromagnetic commensurate plaquette phase at $n=3/4$, and two-phase coexistence for $n_1 > n > 3/4$. For $3/4 > n > n_2 \approx 0.6$, there is a partially spin-polarized metallic state with a magnetization peak centered at $n=2/3$. For the most part, the ground state is a paramagnetic Luttinger liquid for $n_2 \geq n$, although an antiferromagnetic phase with a substantial charge gap (and which may or may not have a small spin-gap) arises at $n=1/2$. Interesting soliton excitations with fractional charge are found for the plaquette phase at $n=3/4$. We have also explored the evolution of these phases as a function of decreasing (but still large) U , both by studying the t - J model and of the underlying Hubbard model.

1:27PM B16.00012 Quantum Phase Transitions in an Ionic Hubbard Model in One Dimension

, JI-WOO LEE, SUNG MOON KIM, KYO YEON CHO, Myongji University — We study quantum phase transitions in an ionic Hubbard model in one dimension. This model accounts for electrons in alternating potentials with a lattice period of 2. For a specified alternating potential of strength Δ , we change the local repulsion between spin-up and spin-down electrons, U , for the model to exhibit a quantum phase transition from a band insulator to a Mott insulator. Via exact diagonalization with a modified Lanczos method, we find that, as we tune U , the ground-state energy shows a level crossing at half-filling. We obtain a phase diagram of the model by using a finite-size scaling method. Also, we find an interesting feature of double occupancy around the phase transitions.

1:39PM B16.00013 Ground state properties of the ionic Hubbard model on a two-leg triangular ladder at $3/4$ filling

, IVÁN GONZÁLEZ, Centro de Supercomputación de Galicia — We study numerically the ionic Hubbard model on a two-leg triangular ladder at $3/4$ filling. This model is believed to be the minimal microscopic model describing the physics of Na_xCoO_2 at $x = 0.5$, and shows a rich phase diagram that depends on a delicate balance between the Coulomb interaction U , the hopping amplitude t , and the ionic potential Δ . Motivated by experiments analyzing the dopant distribution on $\text{Na}_{0.5}\text{CoO}_2$, we focus in the case of a stripe-type ionic potential. In the correlated limit where the Coulomb interaction is large, the ground state of the model is a charge-transfer insulator for large ionic potential and turns metallic for zero ionic potential. Electronic structure calculations point to the regime $\Delta \sim |t|, t < 0$ as the one relevant for $\text{Na}_{0.5}\text{CoO}_2$, but previous calculations [1] have not fully clarify the nature of ground state of the model in such regime. The aim of this work is to study the metal-insulator transition that occurs in the region $U \gg \Delta \sim |t|$ of the phase diagram as well as the magnetic and charge structures of the associated ground states.

1:51PM B16.00014 Quantum Monte Carlo Studies on Attractive Hubbard Model with Anisotropic Spin-dependent Hopping on Two-leg Ladder Lattice¹

, HO KIN TANG, The Chinese University of Hong Kong, ZHONG BING HUANG, HuBei University, JIN HUA SUN, HAI QING LIN, The Chinese University of Hong Kong — Using spin-dependent hopping, it is possible to have a fully paired state with a gap for single fermion excitation and gapless Cooper pair excitation, called ‘Cooper-pair Bose-metal’ phase. Recently, the existence of this phase was suggested by a density matrix renormalization group studies² on the attractive Hubbard Model with two-leg ladder geometry and anisotropic spin-dependent hopping. We here present a detailed Quantum Monte Carlo (QMC) studies on this model to investigate its finite temperature properties, including correlation function, s-wave and d-wave pairing function, and finally to deduce the existence and behavior of ‘Cooper-pair Bose-metal’ phase.

2:03PM B16.00015 An Exotic Spin Mode in a Non-Polarized Fermi Liquid With Net Spin-Current

, YI ZHANG, KEVIN BEDELL, Boston College, Department of Physics — We find an exotic spin excitation in an ordered magnetic system with an order parameter with a net spin current but no net magnetization. Starting from a Fermi liquid theory, similar to that for a weak ferromagnet, this excitation emerges from a state that is protected by a Pomeranchuk instability. We derive the propagating mode using Landau kinetic equation, using two different approaches and find that the dispersion of the mode is the same for both approaches in leading order.

Monday, February 27, 2012 11:15AM - 2:03PM –

Session B17 DMP GERA FIAP: Focus Session: Thermoelectrics - Nanowires and Other Nanostructures 252A

11:15AM B17.00001 Thermoelectric Transport in Bismuth Telluride Nanoplates, Semiconductor Nanowires, and Silicide Nanocomposites: Effects of Low Dimensionality, Surface States, Interface Structures, and Crystal Complexity , LI SHI, The University of Texas at Austin — This presentation will review recent measurement results of thermoelectric properties of individual bismuth telluride nanoplates, semiconductor nanowires, and silicide nanocomposites. In experiments with these realistic nanostructured materials, a number of factors influence the transport properties. For example, unintentional doping, interface roughness and impurities can often obscure the predicted effects of the low-dimensional electronic density of states and the protected surface states, the latter of which have been suggested for bismuth telluride and other thermoelectric materials, now also referred as topological insulators. Similarly, impurities and defects as well as contact thermal resistance can play an important role in phonon transport in nanostructures, making it nontrivial to quantify the actual effects of phonon-surface scattering and other intriguing low-dimensional phonon transport phenomena. Because of these experimental complications, diverse theoretical interpretations of experimental results have appeared in the literature, and will be discussed. Moreover, the effects of twin defects and crystal complexity on thermoelectric transport in nanostructures will be examined based on measurement results of III-V and silicide nanostructures.

11:51AM B17.00002 Universal Scaling Relations for the Thermoelectric Power Factor of Semiconducting Nanostructures , JANE CORNETT, ODED RABIN, University of Maryland — We present a model for the power factor (PF) of wires and thin films which bridges between strongly confined and bulk behavior. Relevant scattering mechanisms are considered in the framework of the relaxation time approximation. Previous models for the transport properties of nanostructured thermoelectric materials predicted vast improvements in the PF values over bulk due to discretization of the electron density-of-states function as the result of confinement. Using this model, we find that the PF of nanowires and thin films in fact falls below the bulk value for most of the experimentally-accessible size range. We find a non-monotonic relationship between PF and system size in all systems studied—regardless of the particular materials parameters and dominant scattering mechanisms. The effects of the size, dimensionality, temperature, carrier concentration and dominant scattering mechanism in single-carrier semiconductors will be discussed. In the framework of the *constant* relaxation time approximation, universal scaling relations for the power factor of all single-carrier semiconductors are obtained.

12:03PM B17.00003 Thermal conductivity of silicon nanowires: interplay between core defects and surface roughness , YUPING HE, GIULIA GALLI, UC Davis — Recent experiments [1] suggested that the thermal conductivity (κ) of Si nanowires may be reduced by about two orders of magnitude compared to that of bulk Si (κ_{bulk}), making them attractive materials for thermoelectric applications. Size reduction plays an important role [2] in determining such reduction but it does not fully account for recent measurements [1]. We investigated κ in wires with 15 nm diameter (comparable to experimental sizes) using large scale molecular dynamics simulations. We show that, unlike the case of thin [3] (2-3 nm diameter) rods, the presence of an amorphous layer at the surface accounts only for a decrease by a factor of 4 in κ with respect to that of wires with smooth surfaces. It is the combined effect of defects in the core and rippled surfaces that enables a decrease up to a factor of 90 with respect to κ_{bulk} . Work supported by DOE/SciDAC-e.

12:15PM B17.00004 Electric-Field Guided Synthesis of Standalone Nanowire Arrays for Thermoelectric Applications¹ , YEW SAN HOR, Department of Physics, Missouri University of Science and Technology — Theoretical studies have suggested that figure of merits of thermoelectric materials can be improved through fabrications of nanoscaled thermoelectric materials. Thin films are expected to result in up to a seven fold improvement in efficiency over bulk materials; even greater enhancement, up to 15 times in efficiency, is expected for very thin wires. Researchers have already succeeded in increasing the efficiency by making thin-layered materials and nanowires of a non-thermoelectric material, i.e. silicone. For practical applications, however, arrays of standalone nanowires or isolated thermoelectric nanowire devices without any template will be required. Here I present an electromagnetic field guided nanostructured synthesis of an array of standalone thermoelectric nanowires. This technique utilizing electric field as a guide in building highly ordered nanostructures will be an elegant, “bottom-up” method for nanofabrication without the need of a template. An array of quasi-one dimensional chalcogenide nanowires has been successfully grown in between two conducting plates. Thermoelectric transport measurements including thermalconductivity, thermoelectric power and figure of merit can be easily performed in the device, without any need of complicated electron beam lithography technique.

¹Supported by University of Missouri Research Board.

12:27PM B17.00005 Thermoelectric Property Characterization of Suspended Silicon Nanowires , ANNIE WEATHERS, Department of Mechanical Engineering, The University of Texas at Austin, Austin, TX 78712, USA, FENG ZHOU, Materials Science and Engineering Program, The University of Texas at Austin, Austin, TX 78712, USA, INSUN JO, Department of Physics, The University of Texas at Austin, Austin, TX 78712, USA, MICHAEL T. PETTES, JAEHYUN KIM, LI SHI, Department of Mechanical Engineering, The University of Texas at Austin, Austin, TX 78712, USA — A key challenge in the measurement of thermal and electrical properties of suspended nanowires (NWs) is the ability to obtain clean, reliable electrical and thermal contact between the nanowire and device. We report on a technique for aligning NWs to sub-micron accuracy on a suspended device made of two SiNx membranes with the assistance of a polymethyl methacrylate (PMMA) carrier layer. Electrical and thermal contact is made by using electron beam lithography to pattern a window in the PMMA over the device electrodes, followed by oxide etching and surface passivation in wet etchant, metal deposition through a shadowmask, and lift-off. We demonstrate this technique on rough Si nanowires grown by metal-assisted chemical etching. The whole assembly is clean and without contamination. Thermoelectric properties and their correlation with crystal structure will be discussed

12:39PM B17.00006 Thermoelectric Properties of Low-Dimensional Si and Ge Based Nanostructures , NEOPHYTOS NEOPHYTOU, HANS KOSINA, Technical University of Vienna — Low-dimensional thermoelectric nanostructures based on Si and Ge are promising candidates for high performance energy conversion and generation applications. 1D nanowires (NWs) and 2D superlattices of Si, Ge and Si/SiGe have experimentally demonstrated excellent performance. In these confined systems the electrical conductivity, the thermal conductivity, and the Seebeck coefficient can be designed to some degree independently so as to achieve enhanced ZT values as compared to the related bulk material values. In this work, we calculate the thermoelectric coefficients of scaled Si and Ge NWs and thin-layers. We use the sp3d5s* tight-binding model for the electronic structure and linearized Boltzmann transport theory. Our calculations include structures of feature sizes up to 12nm containing over 5500 atoms. This study indicates that the confinement length scale can be exploited as a degree of freedom in designing the material properties. We examine n-type and p-type materials of different cross section sizes and confinement/transport orientations and provide optimization directions for power factor improvement. Finally, using measured values for the lattice thermal conductivity, the ZT is estimated.

12:51PM B17.00007 Gate Controlled Tuning of Seebeck Coefficient in InAs Nanowires, JOHANNES GOOTH, PHILLIP WU, SOFIA SVENSSON, HEINER LINKE, Lund University — Here we present measurements of the Seebeck Coefficient in InAs nanowires grown by Chemical beam epitaxy. Nanowires were mechanically transferred onto a SiO₂ substrate with a global metallic backgate, and Ohmic contacts to a single nanowire were made by standard electron beam lithography techniques. We were able to tune the measured thermovoltage in the nanowire by field effect gating and correlate this behavior with the conductance through the nanowire. Interestingly, large enhancements in the thermoelectric power factor were seen at low temperature for certain gate voltages. Such controllability allows for optimizing the thermoelectric response of the nanowire at different substrate temperatures.

1:03PM B17.00008 Phonon transmission and thermal transport in GaAs-AlAs superlattices from first-principles, KEIVAN ESFARJANI, ZHITING TIAN, MARIA LUCKYANOVA, TENGFEI LUO, GANG CHEN, MIT, NANO-ENGINEERING TEAM — Using the Green's function method and Landauer's formula, we formulate phonon transport in a 3D superlattice. The theory is harmonic and describes coherent (elastic) transport of heat through a periodic structure which may also have disorder present at its interfaces. We compute the force constants from first-principles density functional calculations and use them to compute the transmission, and the thermal conductance of a GaAs-AlAs superlattice versus length and temperature. We also investigate the effect of mass disorder at the interface and anharmonicity, to locate the transition from coherent to incoherent transport. Results are finally compared with experimental measurements.

1:15PM B17.00009 Phonon density of states in nanocrystalline Si_{1-x}Gex explored by inelastic neutron scattering, STEPHEN WILSON, CHETAN DHITAL, ZHIFENG REN, Department of Physics, Boston College, Chestnut Hill MA, DOUG ABERNATHY, Spallation Neutron Source, Oak Ridge National Lab, Oak Ridge Tennessee — Recently there have been significant advances in the efficiencies of traditional thermoelectric compounds gained via the creation of thermoelectric nanocomposites possessing substantially reduced thermal conductivity relative to their bulk counterparts [1,2]. The dramatic reduction in the heat transport of these nanocomposites is often attributed to the increased interface scattering of phonons or induced surface/boundary modes; however notably little work has been put into exploring the detailed changes in the phonon density of states in many of these functional nanocomposite samples. Here we present inelastic neutron scattering measurements exploring the phonon density of states in a series of Si_{1-x}Gex thermoelectric nanocomposites. The evolution of the phonon spectral weight distribution and linewidths as a function of Ge-doping will be discussed and compared to the known bulk phonon density of states in this system.

1:27PM B17.00010 Ab-initio investigation of thermal transport in alloyed and nanostructured materials¹, DMITRI VOLJA, Massachusetts Institute of Technology, Department of Materials Science and Engineering, Cambridge, MA, BORIS KOZINSKY, Robert BOSCH LLC Research and Technology Center, Cambridge MA, JIVTESH GARG, Massachusetts Institute of Technology, Department of Materials Science and Engineering, Cambridge, MA, MARCO FORNARI, Central Michigan University, Department of Physics, Mount Pleasant, MI, NICOLA MARZARI, Ecole Polytechnique Federale de Lausanne — A whole spectra of intriguing physical properties appears in conventional materials when structural features reach nanoscale. Since thermal conductivity is controlled by the heat carriers' mean free paths, it becomes of paramount importance to understand and engineer the role of alloying and nanostructuring on transport coefficients. First-principles calculations often provide accurate microscopic parameters, but at significant computational cost even for ideal, perfect systems. We present a hybrid classical-quantum method to compute thermal conductivity from both harmonic and anharmonic terms using Boltzmann transport formalism. We combine first-principles calculations of harmonic terms and force-field calculations of third-order and fourth-order force constant. Results for SiGe will be discussed to show the validity of approach. We also discuss the effects of nanostructuring by introducing boundary scattering contributions, as well as mechanisms of filler rattling in thermoelectric skutterudites.

1:39PM B17.00011 ZT enhancement using nanocomposite materials, PAUL HANEY, National Institute of Standards and Technology — The effect of interface scattering on the performance of disordered, nanocomposite thermoelectric materials is studied theoretically (within a linear response formalism), using effective medium theory, and direct numerics. The general relation between interfacial and bulk transport properties which results in an enhanced ZT is determined. Given these requirements of interfacial transport properties, a series of microscopic calculations of interface scattering are presented to assess the feasibility of using nanocomposites for ZT enhancement.

1:51PM B17.00012 Anderson Localization of Phonons in Random Multilayer Thin Film Thermoelectrics, ANTHONY FRACHIONI, BRUCE WHITE, Binghamton University — Anderson localization of phonons in random multilayer thin films has been explored as a means for reducing lattice thermal conductivity in thermoelectric materials. Silicon based systems have been explored due to silicon's high crust abundance and Seebeck coefficient. Reverse non-equilibrium molecular dynamics simulations have been used to determine the thermal conductivity of silicon in which randomly selected atomic planes (20% of lattice planes) are subject to mass increase. The simulation results indicate that the lattice thermal conductivity of silicon can be decreased by a factor of over ten thousand (to 15 mW/m·K). Based on models in which the charge carrier mean free path is limited by scattering from the planes with mass disorder, the mobility of silicon is expected to reach values of 10 cm²/V·s. At this mobility the thermoelectric figure of merit, ZT, is found to be greater than ten when the mass ratio of the disordered planes to that of silicon approaches 10. These results indicate that the pursuit of nanostructured silicon thermoelectric materials in the form of random multilayers may provide a path to efficient and sustainable thermoelectric materials.

Session B18 DMP: Focus Session: Nanostructures and Metamaterials, Growth, Structure, and Characterization – Metamaterials with Gain and Active 252B

11:15AM B18.00001 Metamaterials with Gain¹, ORTWIN HESS, Imperial College London — Nanoplasmonic metamaterials are the key to an extreme control of light and allow us to conceive materials with negative or vanishing refractive index. Indeed, metamaterials enable a multitude of exciting and useful applications, such as subwavelength focusing, invisibility cloaking, and “trapped rainbow” stopping of light. The realization of these materials has recently advanced from the microwave to the optical regime. However, at optical wavelengths, metamaterials may suffer from high dissipative losses owing to the metallic nature of their constituent nanoplasmonic meta-molecules. It is therefore not surprising that overcoming loss restrictions by gain is currently one of the most important topics in metamaterials’ research. At the same time, providing gain on the nanoplasmonic (metamolecular) level opens up exciting new possibilities such as a whole new type of metamaterial nano-laser with a cavity length of about a tenth of the wavelength. The talk gives an overview of the state of the art of gain-enhanced metamaterials. Particular focus will be placed on nano-plasmonic metamaterials (such as double-fishnet metamaterials) with integrated laser dyes as gain medium. The successful compensation of loss by gain is demonstrated on the meta-molecular level. On the basis of a comprehensive, microscopic Maxwell-Bloch Langevin approach of spatio-temporal light amplification and lasing in gain-enhanced nanoplasmonic (negative-index) metamaterials a methodology based on the discrete Poynting’s theorem is introduced that allows dynamic tracing of the flow of electromagnetic energy into and out of “microscopic” channels (light field, plasmons, gain medium). It is shown that steady-state amplification can be achieved in nanoplasmonic metamaterials. Finally, a complex spatio-temporal interplay of light-field and coherent absorption dynamics is revealed in the lasing dynamics of a nanoplasmonic gain-enhanced double-fishnet metamaterial.

¹Support by the Leverhulme Trust is gratefully acknowledged.

11:51AM B18.00002 Metamaterials with gain and interpretation of transmission in pump-probe experiments¹, THOMAS KOSCHNY, Ames Laboratory and Dept. of Phys. and Astronomy, Iowa State University, Ames, Iowa 50011, U.S.A., ZHIXIANG HUANG, Ames Lab and Dept. of Phys., Iowa State Univ., Ames, Iowa 50011, U.S.A. and Anhui Univ., China, COSTAS M. SOUKOULIS, Ames Lab and Dept. of Phys., Iowa State Univ., Ames, Iowa 50011, U.S.A. and IESL, FORTH, Heraklion, Greece — We establish a new approach for pump-probe simulations of metallic metamaterials coupled to the gain materials. It is of vital importance to understand the mechanism of the coupling of metamaterials with the gain medium. Using a four-level gain system, we have studied light amplification of arrays of metallic split-ring resonators (SRRs) with a gain layer underneath. We find that the differential transmittance $\Delta T/T$ can be negative for SRRs on the top of the gain substrate, which is not expected, and $\Delta T/T$ is positive for the gain substrate alone. These simulations agree with pump-probe experiments and can help to design new experiments to compensate the losses of metamaterials. We numerically investigate loss compensation and transmission in pump-probe experiments in resonant metamaterials with gain using an FDTD algorithm coupled to semiclassical rate equations. We explain experimentally observed negative differential transmission by gain-dependent impedance.

12:03PM B18.00003 Spontaneous emission enhancement in a plasmonic nanocavity¹, KASEY RUSSELL, TSUNG-LI LIU, SHANYING CUI, EVELYN HU, Harvard University School of Engineering and Applied Sciences — Recently, metallic optical cavities containing coupled emitters have been fabricated that operate at visible frequencies. These cavities are capable of tightly confining light, greatly modifying the electromagnetic density of states in the location of the optical emitters. Here, we present measurements from a metal-based optical cavity that greatly modifies both the spectral and temporal characteristics of the coupled emitters. Our design is based on plasmonic coupling between a silver nanowire and a planar silver substrate, with a layer of optical emitters within the gap between the two silver components. The field confinement of the structure results in a 1000-fold enhancement of the spontaneous emission rate of the coupled emitters. These results suggest that metal-based optical cavities can allow quantum cavity electrodynamics of emitters such as colloidal quantum dots and organic dyes.

12:15PM B18.00004 Directionally emitting plasmon laser and circuits, RENMIN MA, XIAOBO YIN, RUPERT OULTON, VOLKER SORGER, XIANG ZHANG, UC Berkeley — Scaling down of the laser promises unprecedented ultra-dense and ultra-fast integrated photonics. The research of nanoscale lasers is rapidly advancing and a variety of approaches have been explored including whispering gallery lasers, photonic crystal lasers, metallic lasers. However, a major obstacle of integrating nanolasers with other components is the strong divergence of emission from a sub-wavelength laser cavity due to the diffraction of light. Here, we demonstrate a deep sub-wavelength plasmon laser that directs more than 70% of its radiation into an embedded semiconductor waveguide. The laser naturally integrates photonic and electronic functionality allowing both efficient electrical modulation and wavelength multiplexing. A maximum modulation depth of 11 dB for a small 1 V of bias sweep is achieved. We demonstrate an ultra-compact plasmonic circuit integrating five independently modulated multi-colored laser sources multiplexed onto a single semiconductor waveguide, illustrating the potential of plasmon lasers for large scale, ultra-dense photonic integration.

12:27PM B18.00005 Electromagnetically induced transparency and absorption in metamaterials: self-consistent theory and experiments¹, PHILIPPE TASSIN, Ames Lab/Iowa State Univ. and Vrije Univ. Brussel, LEI ZHANG, ADITYA JAIN, RONGKUO ZHAO, THOMAS KOSCHNY, Ames Lab/Iowa State Univ., COSTAS SOUKOULIS, Ames Lab/Iowa State Univ. and FORTH — There has recently been a lot of interest in slow-light metamaterials that provide transparency windows combining low absorption with high group delay. This phenomenon was explained by a two-resonator model involving a radiative resonator that couples directly to the incident field and a dark resonator that can only be excited through coupling with the radiative resonator. However, in our most recent experiments on wire/SRR metamaterials, we have observed a much richer behavior—we measure not only transparency windows with incisions in the absorption spectrum (electromagnetically induced transparency), but also narrow spectral features with absorption larger than the background absorption of the radiative element (electromagnetically induced absorption). We have developed a model in which the coupling of the electromagnetic waves to the radiative resonator is treated explicitly. An important attribute of this model, which is in excellent agreement with our experiments and full-wave simulations, is the self-consistent treatment of the spectral broadening of the bright resonator originating from the dipole radiation as opposed to the bare linewidth due to dissipation. We discuss the conditions under which electromagnetically induced transparency/absorption can be observed.

¹This work was supported by Ames Laboratory (U.S. DOE) and the U.S. Office of Naval Research (Award No. N000141010925).

12:39PM B18.00006 Lighting up dark plasmon modes with electron beam, KIN HUNG FUNG, Massachusetts Institute of Technology, ANIL KUMAR, University of Illinois at Urbana-Champaign, NICHOLAS X. FANG, Massachusetts Institute of Technology — Dark plasmon modes couple weakly with free-space photons. It is, therefore, generally believed that far-field detection of dark plasmon modes is difficult. In this talk, we discuss how an electron beam can light up dark plasmon modes and show theoretically and experimentally that bright and dark modes in a single metal bowtie nanoantenna can be studied at the far field using cathodoluminescence spectroscopy.

12:51PM B18.00007 Direct modulation of lanthanide emission at sub-lifetime scales using electric and magnetic dipole transition, SINAN KARAVELI, AARON J. WEINSTEIN, RASHID ZIA, Brown University — Lanthanide ions, such as trivalent Europium (Eu³⁺) and Erbium (Er³⁺) are technologically important, high quantum yield light emitters that exhibit both magnetic dipole (MD) and electric dipole (ED) transitions. It is well known that the transition rate of an emitter in an inhomogeneous optical environment, e.g. an emitter near a mirror, is modified due to self-interference effects, leading to either enhancement or inhibition of spontaneous emission. However, due to the opposite symmetry of their emitted fields, ED and MD transitions exhibit differing self-interference. Here, we leverage this difference to show large spectral tuning and sub-lifetime dynamic modulation of Eu³⁺ emission. Specifically, we use a moving gold mirror to selectively enhance the ED and MD transitions in Eu³⁺ doped Y₂O₃. Controlling the emitter-mirror distance allows us to tune the emission spectra from 580 nm to 715 nm. Modulating the mirror position with a piezoelectric crystal allows us to dynamically tune the Eu³⁺ emission at speeds faster than the excited state lifetime.

1:03PM B18.00008 Strong Coupling of Molecular Absorption and Mid-Infrared Metamaterial Resonances, JOSHUA MASON, University of Massachusetts, Lowell, GRAHAM ALLEN, Connecticut College, VICTOR PODOLSKIY, University of Massachusetts, Lowell, DANIEL WASSERMAN, University of Illinois, Urbana Champaign — Here we present numerical, analytical, and experimental evidence for strong optical coupling between a mid-infrared perfect absorber thin-film metamaterial and a molecular absorption resonance within a dielectric medium. Clear anti-crossing behavior is exhibited numerically and experimentally when the metamaterial resonance is scanned through the dielectric molecular resonance; a coupled oscillator model is used to present a further analytical description. The anti-crossing is used to demonstrate and quantify the strength of the optical coupling within the thin film. Such a device can potentially be developed for mid-infrared sensing applications and actively tunable metamaterial optical components.

1:15PM B18.00009 Magnetic Dipole Emission Lines in Trivalent Lanthanide Ions, CHRISTOPHER DODSON, RASHID ZIA, Brown University — Magnetic dipole (MD) transitions offer a unique opportunity to study light-matter interactions beyond the electric dipole approximation. Modified spontaneous emission from MD transitions can serve as an ideal way to study optical magnetic fields in metamaterials and related nanostructures. While many MD absorption lines have been identified, only a few MD emission lines in solid state systems are widely known. Here we seek to expand the known MD emission lines by calculating all such transitions in the trivalent lanthanide ions. We use intermediate coupling to construct a detailed free-ion Hamiltonian including electrostatic, spin-orbit, two- and three-body, spin-spin, spin-other-orbit, and electrostatically correlated spin-orbit interactions. Determining the free-ion energy levels allows the calculation of ground-state MD absorption lines, and their respective oscillator strengths, as well as spontaneous emission rates for all MD mediated transitions. Many strong MD emission lines are predicted throughout the visible and near infrared spectrum. Corresponding electric quadrupole transitions were also calculated and found to have negligible contribution. If time permits, we will also present direct experimental measurements characterizing these new MD emission lines.

1:27PM B18.00010 Self-assembled quantum dots as active emitters for silicon photonic crystal nanocavities, THOMAS ZABEL, NORMAN HAUKE, STEFAN LICHTMANNECKER, FABRICE LAUSSY, RICHARD GEIGER, JONATHAN FINLEY, Walter Schottky Institut, Technical University Munich, Germany, GERHARD ABSTREITER, Walter Schottky Institut, Technical University Munich, Institute for Advanced Study, Technical University Munich, Germany, DOMINIQUE BOUGEARD, Institut fuer Experimentelle und Angewandte Physik, University Regensburg, Germany, YASUHIKO ARAKAWA, University of Tokyo, Inst. for Nano Quant. Inform. Electr., Inst. of Ind. Sci., Tokyo, Japan, Institute for Advanced Study — We present a study of the properties of active (Si)Ge self-assembled quantum dot (QD) emitters coupled to Si photonic crystal (PC) nanocavities up to room temperature and evaluate the potential of such nanostructures for the realization of efficient silicon based light sources in the near-infrared regime. The Si-Ge system allows the formation of type I and type II band alignment QD, depending on the epitaxy conditions. We first discuss the emission properties of different types of QD. In particular we present type I SiGe islands designed to produce a strong emission due to a large wave function overlap of confined electrons and holes. We then investigate the coupling properties of (Si)Ge QD emitters to 2D Si PC cavities. We interpret the experimentally observed correlation between the photoluminescence intensity of the QDs and the quality factor of the PC cavity using simulations based on a dissipative master-equation approach [1]. As a further step towards efficient light sources, we currently study the coupling of electrically pumped (Si)Ge QDs to 2D PC in contacted diode structures. [1] N. Hauke, et al. Phys. Rev. B 84, 085320 (2011)

1:39PM B18.00011 Broadband Transparency of Graded Anisotropic Metamaterial¹, KA SHING HUI, HON PING LEE, LEI SUN, KIN WAH YU, The Chinese University of Hong Kong — We have investigated the scattering of electromagnetic waves from a graded anisotropic sphere whose dielectric permittivity is radially anisotropic, with different radial and tangential components described by the graded Drude model. The Rayleigh scattering cross section (RSCS) has been calculated analytically and numerically by the Rayleigh scattering theory. The electric polarization and the electromagnetic field distribution are also examined in a quasi-static condition. Due to the scattering cancellation mechanism, the results reveal that the RSCS can be rather smaller over a wider frequency range, indicating the so called broadband transparency. Furthermore, compared with the non-graded and graded isotropic structure, the anisotropic structure leads a better broadband transparency.

¹Supported by the General Research Fund of the HKSAR Government

1:51PM B18.00012 Reconfigurable Gradient Index using VO₂ Memory Metamaterials, MICHAEL GOLDFLAM, University of California San Diego, TOM DRISCOLL, UCSD and Duke University, BRIAN CHAPLER, OMAR KHATIB, University of California San Diego, NAN JOKERST, SABARNI PALIT, DAVID SMITH, Duke University, BONG-JUN KIM, ETRI, GIWAN SEO, University of Science and Technology, HYUN-TAK KIM, ETRI and UST in Korea, MASSIMILIANO DI VENTRA, DIMITRI BASOV, University of California San Diego — We have demonstrated tuning of a metamaterial device that incorporates a form of spatial gradient control. Electrical tuning of the metamaterial was achieved through a vanadium dioxide layer which interacts with an array of split ring resonators. Through design of the device and contact geometry, we achieved a spatial gradient in the magnitude of permittivity, writeable using a single transient electrical pulse. This induced gradient in our device was observed on spatial scales on the order of one wavelength at 1 THz. Thus we have demonstrated the viability of elements for use in future devices with potential applications in beamforming and communications.¹ Various contact geometries are currently being investigated with the goal of implementing finer control over gradients and expanding on the possible applications of such devices.

¹M. D. Goldflam, et. al., Appl. Phys. Lett. 99, 044103 (2011).

2:03PM B18.00013 Waves and rays in meta-microcavities: from positive “n” to negative “n” and from order to chaos¹, NATALIA M. LITCHINITSER, SUNY at Buffalo, JORGE V. JOSE, Indiana University — The emergence of metamaterials and, in particular, negative index metamaterials (NIMs) triggers reconsideration of many fundamental physical phenomena. Importantly, the majority of unique properties of NIMs stand out when NIMs are combined with conventional positive index materials (PIMs). In this talk, we consider the wave and ray properties of electromagnetic wave interaction in two-dimensional microcavities that contain a combination of PIM and NIM with negative dielectric permittivity and magnetic permeability. We consider closed and open cavities and total and partial reflection and refraction at the boundaries between the media with different indices of refraction. By using a combination of analytic and numerical methods we are able to classify the different types of possible solutions in this type of mixed PIM-NIM regions. In particular, we derive the special properties of whispering gallery modes as well as the constructive and destructive interference due to wave refraction/reflection across different refractive media boundaries. Finally, we discuss possible practical applications of this type of mixed refractive indices microcavities.

Monday, February 27, 2012 11:15AM - 2:15PM —
Session B19 FHP: Invited Session: One Hundred Fifty Years of Maxwell's Equations (1862-2012) 253AB

11:15AM B19.00001 The discovery of Maxwell's equations, FRANCIS EVERITT, Stanford University — In January 1865, Maxwell at age 34 wrote a letter to his cousin Charles Cay describing various doings, including his work on the viscosity of gases and a visit from two of the world's leading oculists to inspect the eyes of his dog “Spice”. He added, “I have also a paper afloat, with an electromagnetic theory of light, which, till I am convinced to the contrary, I hold to be great guns.” That paper “A Dynamical Theory of the Electromagnetic Field” was his fourth on the subject. It was followed in 1868 by another, and then in 1873 by his massive two volume Treatise on Electricity and Magnetism. Even so, by the time of his death in 1879 as he was beginning a radically revised edition of the Treatise, much remained to be done. We celebrate here the 150th anniversary of Maxwell's first astonished realization in 1862 of the link between electromagnetism and light. So revolutionary was this that 15 or more years went by before Lorentz, Poynting, FitzGerald, and others came to address it, sometimes with improvements, sometimes not. Not until 1888 did Hertz make the essential experimental discovery of radio waves. What is so remarkable about Maxwell's five papers is that each presents a complete view of the subject radically different from the one before. I shall say something about each, emphasizing in particular Maxwell's most unexpected idea, the displacement current, so vastly more interesting than the accounts of it found in textbooks today. Beyond lie other surprises. The concept of gauge invariance, and the role the vector potential would play in defining the canonical momentum of the electron, both go back to Maxwell. In 1872 came a paper “On the Mathematical Classification of Physical Quantities”, which stands as an education in itself. Amid much else, there for the first time appears the distinction between axial and polar vectors and those new operational concepts related to quaternion theory: *curl*, *divergence*, and *gradient*.

11:51AM B19.00002 Maxwellians and the Remaking of Maxwell's Equations, BRUCE HUNT, University of Texas — Although James Clerk Maxwell first formulated his theory of the electromagnetic field in the early 1860s, it went through important changes before it gained general acceptance in the 1890s. Those changes were largely the work of a group of younger physicists, the Maxwellians, led by G. F. FitzGerald in Ireland, Oliver Lodge and Oliver Heaviside in England, and Heinrich Hertz in Germany. Together, they extended, refined, tested, and confirmed Maxwell's theory, and recast it into the set of four vector equations known ever since as “Maxwell's equations.” By tracing how the Maxwellians remade and disseminated Maxwell's theory between the late 1870s and the mid-1890s, we can gain a clearer understanding not just of how the electromagnetic field was understood at the end of the 19th century, but of the collaborative nature of work at the frontiers of physics.

12:27PM B19.00003 Using Maxwell's Equations in the late 1800s, JED BUCHWALD, Caltech — Between the publication of Maxwell's *Treatise on Electricity and Magnetism* in 1873 and the early 1900s his field equations were not considered to be fundamental by many Cambridge-trained physicists. Instead, they were thought to derive from Hamilton's principle given an appropriate energy expression. Such an expression usually assigned a velocity or a position function to field quantities, though this was not invariably done. Precisely because the Hamiltonian, and not the derivative field equations, was taken to be basic, new effects could be generated by adding terms to the energy expression. This was how the Faraday and Kerr magneto-optic effects were handled. The program however never did generate a method for incorporating dissipative phenomena, as Oliver Heaviside (who disliked the use of Hamilton's principle) demonstrated. The procedure was in the end decisively abandoned when J. G. Leathem, a student of Joseph Larmor a Cambridge, demonstrated that it could not handle a particularly subtle magneto-optic process.

1:03PM B19.00004 Maxwell and quantum optics, ROY GLAUBER, Harvard Univ — No abstract available.

1:39PM B19.00005 Taking Off From Maxwell's Equations, FRANK WILCZEK, Massachusetts Institute of Technology — I will discuss how we are still discovering new continents in the conceptual world opened up by Maxwell's equations. I will very briefly sketch, in particular, how very natural extensions of those equations describe superconductivity and the deep structure of fundamental particle interactions. Then I'll show how a newer cluster of extensions connects ideas about (perhaps no longer all that) exotic quantum particles and materials.

Monday, February 27, 2012 11:15AM - 2:15PM —
Session B20 FEd FIAP: Invited Session: Astronomy's Detectors and Physics Education 253C

11:15AM B20.00001 The basic physics of astronomical detectors, our eyes on the Universe, JAMES BELETIC, Teledyne Imaging Sensors — The universe is an amazingly huge place. While humankind has directly explored Earth's sister planets with space probes, we don't have the means to venture beyond the solar system, and so almost all information about the universe comes from sensing light that happens our way. Astronomy is constantly striving to find better ways to sense the feeble amount of energy from distant stars and galaxies. This quest has led to a new generation of large telescopes on the ground and in space. Possibly more important than the development of bigger telescopes is the rapid advancement in solid state detector technology. In the x-ray, visible and infrared wavelengths, the most advanced detectors are based on two fundamental technologies: (1) nearly perfect detector materials that efficiently convert photon energy to electrical charge, and (2) very sensitive transistors that convert a few electrons into a measurable voltage. This talk presents the basic physics of astronomical detectors and provides an introduction to the more specialized talks that follow in this session of presentations. Since detectors of light are critical to nearly every aspect of scientific research and involve a wide range of physical phenomena, this session of talks will provide the audience with physics lessons that can be readily incorporated in an undergraduate physics curriculum.

11:51AM B20.00002 Advanced CCD and CMOS image sensor technology at MIT Lincoln Laboratory, VYSHNAVI SUNTHARALINGAM, Advanced Imaging Technology, MIT Lincoln Laboratory, 244 Wood Street Lexington, MA 02420-9108 — The Advanced Imaging Technology (AIT) program area at Lincoln Laboratory addresses a broad range of complex imaging problems by using a wide variety of silicon-based imager technologies, including charge-coupled devices (CCDs), active-pixel sensors (APSs), photodiode arrays, and Geiger-mode avalanche-photodiode (GMAPD) arrays that are single-photon sensitive. Many of these devices, including some very large imaging devices that require low defect levels, are fabricated by us from silicon wafers in our class-10 Microelectronics Laboratory. We also operate a fully equipped packaging facility that is capable of developing and performing innovative device packaging of imaging (and other) devices. In this talk, we present an overview of Lincoln Laboratory's image sensor technologies, describe how they work and how they are built. We discuss several imaging device parameters that can be optimized for high sensitivity. These include quantum efficiency (including fill-factor), charge-transfer efficiency (moving the charge from the pixel to the output port without loss or added spurious charge), and the noise to read this charge out. The overall goal is to convert most or all of the photons that impinge on the device to photoelectrons and then to read out these photoelectrons without losing any and without adding read noise. Further, we will describe design elements or methods that can help with different specific applications: the orthogonal-transfer CCD (OTCCD), an electronic shutter for back illuminated imagers, the Geiger-mode avalanche photodiode (GMAPD) circuit element, and three-dimensionally integrated CMOS focal planes. Several examples of application to high-sensitivity, high-speed, and broad-wavelength range problems will be presented.

12:27PM B20.00003 Gamma-ray Bursts, Black Holes, and Exoplanets: How CCD Detectors have Revolutionized Astronomy, GEORGE RICKER, Massachusetts Institute of Technology — I will tell the story of my research group's role in the development of astronomical charge-coupled detectors (CCDs) by relating the contributions of four MIT research students to projects which we have undertaken together over the past three decades. These projects have empowered observations extending over four decades of the electromagnetic spectrum, enabling discoveries ranging from gamma-ray burst emitting collapsars at cosmological distances, to accretion-driven black holes in the Galaxy, and to exoplanets in the solar neighborhood. This story will illustrate the key contributions which student researchers can make when a novel detector technology arrives on the scene. Finally, I will also describe some of the ways in which their early education in these possibilities has impacted my students' future careers as astronomers and experimental physicists.

1:03PM B20.00004 Coupling physics to understanding the performance of detector arrays, ZORAN NINKOV, Rochester Institute of Technology — Over the last few decades developments in microelectronics have led to the development of arrays of detectors that can be used to measure unprecedentedly small levels of signal. Such arrays have been used over to detect electromagnetic radiation ranging in energy from the X-ray through sub-millimeter wavelengths and also particles. Perhaps nowhere have the improvements been more astonishing than in devices available for the visible part of the spectrum (400 – 1000 nm). The most successful detector array in this spectral region is the Charge Coupled Detector (CCD) whose inventors were recognized with the Nobel Prize in Physics in 2009. In this talk I will review some of the detectors and technologies that are used in low light level imaging. I will also describe a full year sequence of classes (i.e. a theory class, a CCD camera building class and a CCD camera performance measurement class) that students at the Rochester Institute of Technology can take to make them knowledgeable as to the physics underlying the operation and performance of such detector arrays. Finally I will discuss the associated laboratory classes that students must take to measure the performance of the camera they have built and what aspects of fundamental physics are integrated into their understanding. These classes have been taken by both calculus and non-calculus trained students. The classes appeal to students with both types of backgrounds as it couples an understanding of Physics to something that they have built and use.

1:39PM B20.00005 Detecting the Cosmic Microwave Background at the Frontier of Cosmology and in the Classroom, JOHN KOVAC, Harvard University, Departments of Astronomy and of Physics — The 3K blackbody Cosmic Microwave Background (CMB), while exceedingly faint, is the most abundant light in the Universe, permeating all of space as a relic of the hot, dense, primordial fireball. Its detection in 1965 established the Big Bang as the standard model of cosmology and earned its co-discoverers Penzias and Wilson a Nobel Prize. Over the past two decades, advances in detector technology driven by CMB research have produced telescopes with ever-increasing numbers of photon background-limited microwave detectors, capable of mapping fine structure of the CMB to micro-Kelvin precision. These have had enormous impact, determining the geometry of the universe, quantifying the dark matter and dark energy that dominate it, and detecting the faint polarization arising from the primordial seeds of structure. The current frontier is defined by new arrays of thousands of superconducting, polarized detectors producing maps approaching nano-Kelvin precision. In this decade, these measurements will answer questions about the physics driving the earliest moments of the Big Bang and will survey the large-scale structure of the universe, determining neutrino masses and constraining the nature of dark energy. The advanced detector technology fueling this frontier provides superb device-physics training for graduate students and postdocs working on current-generation CMB telescopes. At the same time, careful experimental techniques developed for CMB observations can now be combined with inexpensive high-quality satellite TV detectors to allow even undergraduates to detect the CMB, reproducing Penzias and Wilson's famous discovery. I describe one such undergraduate class at Harvard, which builds CMB telescopes from scratch in a few weeks with a modest budget, teaching students about microwave techniques and detectors and allowing them to find their own evidence for the Big Bang.

Session B21 DMP: Focus Session: Search for New Superconductors: Methodologies and New Materials 254A

11:15AM B21.00001 An Enlightened Combinatorial Search for New Superconductors¹, IVAN SCHULLER, Center for Advanced Nanoscience, UCSD — I describe a methodology for the fast search for new superconducting materials. This method consists of a parallel synthesis of a highly inhomogeneous alloy covering large areas of the metallurgical phase diagram combined with a very sensitive, fast, microwave-based method, which allows large non-superconducting portions of the sample to be discarded. Once an inhomogeneous sample containing a minority phase superconductor is identified, we revert to well-known, thorough identification methods, which include standard physical and structural methods. We show how a systematic structural study helps in avoiding miss-identification of new superconducting materials when there are indications from other methods of new discoveries. The application of these ideas to the La-Si-C system, which exhibits promising normal state properties, sometimes correlated with superconductivity, will be discussed. Although this system shows indications of a new superconducting compound, the careful analysis described here shows that the superconductivity in this system can be attributed to intermediate binary and single phases. Searches in other Rare Earth-Si based systems will also be described. Work done in collaboration with J. de la Venta, Ali C. Basaran, J. G. Ramirez, T. Grant, A. J. S. Machado, M. R. Suchomel, R. T. Weber, Z. Fisk, P. Gupta, O. Shpyrko and D. Basov.

¹Work supported by an AFOSR MURI grant.

11:51AM B21.00002 Search for New Superconductors in RE-Si and Al-B Systems: a High Pressure High Temperature Approach¹, MIGUEL ANGEL ALARIO-FRANCO, Universidad Complutense de Madrid, JOSE DE LA VENTA, ALI BASARAN, IVAN K. SCHULLER, University of California - San Diego, TED GRANT, ZACHARY FISK, University of California - Irvine — We have searched for the presence of superconductivity in the RE-Si and Al-B systems using HP-HT synthesis. The RE-Si system has some of the common features that are present in high TC superconducting materials. We have synthesized Ce, Pr, Nd and Gd silicides undoped and doped with C and B. On the other hand, AlB₂ has some similarities with the superconducting MgB₂. We have tried to synthesize AlB₂ way off stoichiometry using HP-HT and thin films Phase Spread Alloy. The Al_{0.67}B₂ would be the MgB₂ equivalent and good reason to expect superconductivity. We discuss the results for both systems after a careful analysis of several physical properties (SQUID, Modulated Microwave Absorption) and x-ray powder diffraction.

¹This study was supported by an AFOSR MURI “Search For New Superconductors For Energy And Power Applications.”

12:03PM B21.00003 Search for new materials: phase spread alloy thin film fabrication and characterization, MOSES MARSH, ALI BASARAN, JOSE DE LA VENTA, OMAR KHATIB, OLEG SHPYRKO, DMITRI BASOV, IVAN SCHULLER, University of California, San Diego — We use the phase spread alloy (PSA) method of fabricating compositionally heterogeneous thin films as an efficient way to produce and screen new, interesting materials (e.g. superconductors, magnetoresistive compounds, etc.). This method uses co-sputtering to deposit material with smoothly varying element concentration across a substrate. Both local and non-local probes are used to verify the composition of the sample. Using the La-Si-C system as an example, we perform x-ray fluorescence from a synchrotron source, x-ray diffraction from a lab source, atomic force microscopy, and infrared spectroscopy on one sample to verify the presence of different phases and their properties.

12:15PM B21.00004 Search for new superconductors in rare-earth silicide systems¹, ALI BASARAN, JOSE DE LA VENTA, IVAN K. SCHULLER, University of California, San Diego, TED GRANT, ZACHARY FISK, University of California, Irvine — We have searched for the presence of superconductivity in the RE₅Si₃ system doped with C or B as a light element (RE: La, Ce, Pr, and Eu). High temperature superconductors and RE₅Si₃ systems have some common properties. Both systems have a layered tetragonal crystal structure. They are multi-element compounds and are also doped with a light element to introduce the superconductivity. In this study, multiphase bulk samples were made using arc-melting. Phase spread alloy thin films were also prepared in a sputtering system. We used magnetic field modulated microwave absorption spectroscopy (MFMMMS), which is a very sensitive contactless technique to detect superconductivity, as the first screening for the existence of superconductivity in an inhomogeneous sample. We will present some of our results from MFMMMS and SQUID measurements and compare them with structural refinement from X-Ray data.

¹This study was made possible by the generous support of AFOSR MURI “Search for New Superconductors for Energy and Power Applications.”

12:27PM B21.00005 Superconductivity in the K-Mo-O system¹, L.M.S. ALVES, C.A.M. DOS SANTOS, Escola de Engenharia de Lorena, Universidade de Sao Paulo, N. DILLEY, Quantum Design, Inc., M.D.R. MARQUES, J.A. AGUIAR, Universidade Federal de Pernambuco, Recife, PE — The rutile-type structure belongs to space group $P4_2/mnm$. Some transition metals form dioxides with variants rutile structure are known as pseudorutiles. These dioxides have interesting physical properties but they are still poorly understood. MoO₂ is one of them. Polycrystalline samples of MoO₂ can be easily prepared using stoichiometric amounts of Mo and MoO₃ through solid state reaction at temperatures near 700 °C. This material is a highly conductive oxide and exhibits Mo-Mo metallic bonds along *c*-axis. On the other hand, previous results show that the physical properties of the MoO₂ are substantially changed with potassium doping [1]. This work unambiguously demonstrates that the K_xMoO₂ system exhibits superconductivity. Electrical resistivity and magnetization measurements were carried out from 2 to 300 K. The electrical and magnetic measurements show that the superconducting critical temperature ranges from 3 to 10 K. The phase composition responsible for the superconductivity is still under investigation.

¹This material is based upon support by FAPESP (2009/14524-6, 2009/54001-2 e 2010/06637-2), FACEPE (0589/1.05-08), and CNPq/NSF (490182/2009-7).

12:39PM B21.00006 High spin-low spin transition in insulating CaMn₂Sb₂¹, J.W. SIMONSON, G. SMITH, M.C. ARONSON, Department of Physics and Astronomy, Stony Brook University — Layered manganese pnictides are often interesting compounds to compare with the iron pnictide superconductors. To this end, we have synthesized high quality flux-grown single crystals of CaMn₂Sb₂, which forms in a trigonal CaAl₂Si₂-type structure characterized by corrugated triangular Mn layers. Previously reported as a bad metal, we observe instead that this compound exhibits a distinct insulating trend in temperature-dependent resistivity measurements, including an enhancement of up to two orders of magnitude between 200 K and T_N = 85 K. Measurements of ac susceptibility exhibit an orientation- and highly field-dependent plateau across the same temperature range, while heat capacity measurements reveal a sharp feature at 85 K as well as a broad anomaly centered near 195 K. Curie-Weiss behavior above 300 K indicates the presence fluctuating moments with prevailing ferromagnetic interactions, corresponding to less than half the static moment reported for the antiferromagnetic ordered state. These results imply a temperature-induced high spin-low spin insulator-insulator transition.

¹Research supported by a DOD National Security Science and Engineering Fellowship via the AFOSR.

12:51PM B21.00007 An infrared study of electron delocalization in Mn-based relatives of the pnictides, KIRK POST, University of California, San Diego, JACK SIMONSON, CARLOS MARQUES, GREG SMITH, Department of Physics and Astronomy, Stony Brook University, OMAR KHATIB, University of California, San Diego, ZHIPING YIN, MARIA PEZZOLI, Department of Physics, Rutgers and Stony Brook University, GABRIEL KOTLIAR, Department of Physics and Astronomy, Rutgers University, DIMITRI BASOV, University of California, San Diego, MEIGAN ARONSON, Department of Physics and Astronomy, Stony Brook University — Current data suggest that the viability of parent compounds to become superconducting is intimately tied to electron correlations.^{1,2} Further comparisons between the ground states of the cuprate and pnictide parent compounds indicate that doping across an electron delocalization transition (EDT) may be key to obtaining a higher critical temperature.³ These insights lead us to study the Mn-based compounds that are isostructural with pnictides and are antiferromagnetic insulators like the cuprates. Specifically, we have explored the effects of doping on LaMnPO_{1-x}F_x and Ca_{1-x}La_xMn₂Sb₂ via optical spectroscopy, transport, and magnetic measurements in parallel to theoretical band structure calculations. Our studies show that LaMnPO is highly resistant to electron delocalization. Likewise, in CaMn₂Sb₂, full delocalization was not attained even though a shift in the band edge was observed.

1:03PM B21.00008 Strong Electronic Correlations in YMn_2Ge_2 , DANIEL MCNALLY, JACK SIMONSON, GREG SMITH, MEIGAN ARONSON, Department of Physics and Astronomy, Stony Brook University, Stony Brook, NY 11794, USA — Exotic phases, like superconductivity, often emerge near electron delocalization transitions in strongly interacting systems. Magnetization, heat capacity and resistivity measurements were performed on single crystals of the antiferromagnetic metal YMn_2Ge_2 , which is isostructural to the ThCr_2Si_2 -type iron pnictides. Above the antiferromagnetic ordering temperature $T_N=425$ K, the magnetic susceptibility displays Curie-Weiss like behaviour with a fluctuating moment $\mu = 3.3 \mu_B/\text{Mn atom}$, larger than the ordered moment of $2.2 \mu_B/\text{Mn atom}$. Heat capacity measurements yield a Sommerfeld coefficient $\gamma = \frac{C}{T} = 8.5 \text{ mJ/mol Mn K}^2$, nearly three times larger than $\gamma_{Ru} = 3.3 \text{ mJ/mol Mn K}^2$ for its non-magnetic isostructural analog YRu_2Ge_2 , indicating strong electronic correlations in YMn_2Ge_2 . The quasiparticle mass enhancement $\frac{m^*}{m_{Ru}} = \frac{\gamma}{\gamma_{Ru}} = 2.6$ is similar to the value observed in the 122-type iron pnictides. Fermi-liquid behaviour of the resistivity $\rho = \rho_0 + AT^2$ is observed over a very broad range of temperatures between 0.5 K and 300 K, with the resistivity at low temperature $\rho(0.5 \text{ K}) = 8 \mu\Omega \text{ cm}$ indicating high sample quality

1:15PM B21.00009 Magnetic, Thermal and Transport Properties of $\text{LaNi}_2(\text{Ge}_{1-x}\text{P}_x)_2$ ¹, R.J. GOETSCH, V.K. ANAND, ABHISHEK PANDEY, D.C. JOHNSTON, Ames Lab. and Dept. Phys. Astron., Iowa State Univ., Ames, IA 50011 — Polycrystalline samples of $\text{LaNi}_2(\text{Ge}_{1-x}\text{P}_x)_2$ ($x = 0, 0.25, 0.50, 0.75, 1$) with the tetragonal ThCr_2Si_2 structure were investigated by heat capacity C_p , magnetic susceptibility χ , and electrical resistivity ρ measurements for temperatures $1.8 \text{ K} \leq T \leq 300 \text{ K}$. The $\rho(T)$ data for each sample reveal metallic behavior that follows the Bloch-Grüniesen theory. The low- T $C_p(T)$ data for the series yielded Sommerfeld coefficients $\gamma = 6\text{--}12 \text{ mJ/mol K}^2$ and Debye temperatures $\Theta_D = 300\text{--}480 \text{ K}$. The $\chi(T)$ data showed nearly T -independent paramagnetism except for LaNi_2Ge_2 , where data up to 1000 K exhibit a broad peak at $\approx 300 \text{ K}$. A possible onset of superconductivity is seen for LaNi_2P_2 at 2.1 K. Analytic functions accurately representing the Bloch-Grüniesen and Debye functions are presented that are very useful for fitting $\rho(T)$ and lattice $C_p(T)$ data, respectively.

1:27PM B21.00010 Superconductivity in $\text{WO}_{2.6}\text{F}_{0.4}$ synthesized by reaction of WO_3 with Teflon¹, DAIGOROU HIRAI, ESTEBAN CLIMENT-PASCUAL², ROBERT CAVA, Princeton University — $\text{WO}_{3-x}\text{F}_x$ ($x < 0.45$) perovskite-like oxyfluorides were prepared by a chemically reducing fluorination route using the polymer polytetrafluoroethylene (Teflon). The symmetry of the crystal structures of $\text{WO}_{3-x}\text{F}_x$ changes from monoclinic to tetragonal to cubic as the fluorine content increases. Fluorine doping changes insulating WO_3 to a metallic conductor, and superconductivity ($T_c = 0.4 \text{ K}$) was discovered in the samples with fluorine contents of $0.41 < x < 0.45$. This easy fluorination method may be applicable to other systems and presents an opportunity for finding new oxyfluoride superconductors.

1:39PM B21.00011 Type-I Superconductivity in Ytterbium Diantimonide, LIANG L. ZHAO, Rice University, STEFAN LAUSBERG, MANUEL BRANDO, Max Planck Institute for Chemical Physics of Solids, H. KIM, M.A. TANATAR, R. PROZOROV, Ames Laboratory, E. MOROSAN, Rice University — The layered antimonide compound YbSb_2 crystallizes with a ZrSi_2 -type orthorhombic structure, different from other rare earth diantimonides. Unusual for a binary compound, Type-I superconductivity has been observed in YbSb_2 . In this talk, we present the results from anisotropic magnetization, resistivity, heat capacity and magneto-optical Faraday effect measurements on YbSb_2 single crystals, showing a clear superconducting transition at $T_c = 1.25 \text{ K}$. The estimated electron-phonon coupling $\lambda = 0.51$, together with the jump in electronic specific heat $\Delta C_{es}/\gamma T_c = 1.36$, indicate the system to be a weak-coupling BCS superconductor. Magnetization, as well as heat capacity measured under field, clearly suggest a Type-I behavior, which is confirmed by the estimated Ginzburg-Landau parameter $\kappa = 0.13$. According to the H - T phase diagram, the critical field H_c is around 60 Oe.

1:51PM B21.00012 $\text{Cu}_{1-x}\text{BiSO}$: the first Fe-pnictide-structured compound without Fe or Pnictogen¹, LUCIANO ORTENZI, Max Planck Institute for Solid State Research, Stuttgart, SILKE BIERMANN, Centre de Physique Théorique, Ecole Polytechnique, France, OLE KROGH ANDERSEN, Max Planck Institute for Solid State Research, Stuttgart, Germany, IGOR I. MAZIN, Naval Research Laboratory, Washington, DC 20375, USA, LILIA BOERI, Max Planck Institute for Solid State Research, Stuttgart, Germany — The electronic structure of 1111 transition metal pnictides offers a large variety of low-energy phenomena depending on the electronic filling explored. Based on first principles calculations I study the electronic filling d^{10-x} represented by $\text{Cu}_{1-x}\text{BiSO}$: a band insulator that becomes metallic upon hole doping. I argue that the electron-phonon coupling is very strong in this material, and probably drives superconductivity. The critical temperature is however strongly depressed by the proximity to ferromagnetism. The competition between these two different order parameters brings about a high tunability of the system that can go from conventional to unconventional superconductivity by varying such parameters as doping or pressure.

¹This research was supported by the Deutsche Forschungsgemeinschaft under Priority Program 1458

2:03PM B21.00013 Possible Evidence for Novel Superconductivity in LaRu_3Si_2 , HAI-HU WEN, SHENG LI, BIN ZENG, XIANGANG WAN, JIAN TAO, FEI HAN, HUAN YANG, ZHIHE WANG, Physics Department, Nanjing University, China, CENTER FOR SUPERCONDUCTING PHYSICS AND MATERIALS TEAM — Superconductivity in LaRu_3Si_2 with the honeycomb structure of Ru has been investigated. It is found that the normal state specific heat C/T exhibits a deviation from the Debye model down to the lowest temperature. A relation $C/T = \gamma_n + \beta T^2 \cdot \text{AtIn}T$ which concerns the electron correlations can fit the data very well. The suppression to the superconductivity by the magnetic field is not the mean-field like, which is associated well with the observation of strong superconducting fluctuations. The field dependence of the induced quasiparticle density of states measured by the low temperature specific heat shows a non-linear feature, indicating the significant contributions given by the delocalized quasiparticles. The Wilson ratio estimated here is about 3.3, indicating also a strong correlation effect. Interestingly, the Fe-doping can suppress the superconductivity very easily, while Co-doping kills the superconductivity very slowly. The possible reasons are discussed. All these results suggest that the electronic correlation effect exists in LaRu_3Si_2 and superconductivity may be novel.

Session B22 DMP DCOMP: Focus Session: Fe-based Superconductors- ARPES and Fermi Surfaces 254B

11:15AM B22.00001 Distinct Fermi Surface Topology in $A_x\text{Fe}_{2-y}\text{Se}_2$ Revealed by ARPES

DAIXIANG MOU, National Lab for Superconductivity, Institute of Physics, Chinese Academy of Sciences — The discovery of superconductivity with a transition temperature above 30 K in $A_x\text{Fe}_{2-y}\text{Se}_2$ (A =alkali metal or Thallium) triggered a new wave of research on the iron-based superconductors. The new $A_x\text{Fe}_{2-y}\text{Se}_2$ superconductor exhibits many unique characteristics which make it a new platform to uncover the pairing mechanism of the iron-based superconductors. In this talk, we will show the electronic structures of $A_x\text{Fe}_{2-y}\text{Se}_2$ by means of ARPES, including Fermi Surface topology, superconducting gap structure and electron dynamics. The observed Fermi surface topology with only electron-like pockets is distinct from other iron-based superconductors and challenges the pairing mechanism based on scattering between electron-like and hole-like Fermi surface sheets. Nearly isotropic superconducting gap without nodes is revealed for all Fermi surface sheets which favors s-wave pairing symmetry. Other related topics, such as Fe vacancy order and phase separation, will also be discussed from viewpoint of our ARPES results.

11:51AM B22.00002 Role of Degeneracy, Hybridization, and Nesting in the Properties of Multi-Orbital Systems

ANDREW NICHOLSON, QINGLONG LUO, WEIHAO GE, University of Tennessee and Oak Ridge National Laboratory, JOSE RIERA, Universidad Nacional de Rosario, MARIA DAGHOFER, IFW Dresden, GEORGE MARTINS, Oakland University, ADRIANA MOREO, ELBIO DAGOTTO, University of Tennessee and Oak Ridge National Laboratory — To understand the role that degeneracy, hybridization, and nesting play in the magnetic and pairing properties of multiorbital Hubbard models we here study numerically two types of two-orbital models, both with hole-like and electron-like Fermi surfaces (FS's) that are related by nesting vectors $(\pi, 0)$ and $(0, \pi)$ [1]. In one case the bands that determine the FS's arise from strongly hybridized degenerate dxz and dyz orbitals, while in the other the two bands are determined by non-degenerate and non-hybridized s-like orbitals. In the weak coupling regime it is shown that only the model with hybridized bands develops metallic magnetic order, while the other model exhibits an ordered excitonic orbital-transverse spin state that is insulating and does not have a local magnetization. Thus this state would be observed by ARPES experiments, but not by neutron scattering. However, both models display similar insulating magnetic stripe ordering in the strong coupling limit when Coulomb interactions create strong hybridization of the orbitals.

12:03PM B22.00003 Thermoelectric power of $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$, $0 \leq x \leq 0.025$: tracking changes in Fermi surface topology¹

H. HODOVANETS, E.D. MUN, A.N. THALER, S.L. BUD'KO, P.C. CANFIELD, Ames Laboratory/ Iowa State University, Ames, IA 50011, USA — Temperature-dependent, in-plane, thermoelectric power (TEP) data will be presented for single crystals of $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$, ($0 \leq x \leq 0.025$). Previously reported TEP data for this system showed a big jump in the TEP data from $x=0.02$ to $x=0.024$ suggesting a Lifshitz transition, a result which was later confirmed by ARPES measurement. Given that TEP and ARPES delineated a rather large region for the Lifshitz transition to occur, and the underdoped side of the phase diagram is poorly explored, newly careful measurements of TEP on tightly spaced concentrations of Co, $0 \leq x \leq 0.025$, were carried out. The data show clear evidence of a Lifshitz transition, but instead of a discontinuous jump in TEP between $0 \leq x \leq 0.025$, there is a more gradual evolution in the $S(T)$ plots as x is increased.

¹Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

12:15PM B22.00004 Angle-resolved photoemission spectroscopy study of $\text{Ba}(\text{Fe}_{1-x}\text{Ru}_x)_2\text{As}_2$

TIAN QIAN, NAN XU, PIERRE RICHARD, Institute of Physics, Chinese Academy of Sciences, GUANGHAN CAO, ZU'AN XU, Zhejiang University, HONG DING, Institute of Physics, Chinese Academy of Sciences — Ru-doped BaFe_2As_2 compounds were discovered to show superconductivity in a relatively wide doping range. We have performed angle-resolved photoemission spectroscopy measurements on a series of Ru-doped BaFe_2As_2 samples. We observed that band dispersions become more three-dimensional and Fermi velocities increase significantly with Ru doping. We will report these results and discuss implications to its superconductivity.

12:27PM B22.00005 What role does the Fermi surface play in tuning the properties of iron arsenic superconductors?¹

R.S. DHAKA, CHANG LIU, R.M. FERNANDES, RUI JIANG, T. KONDO, A. THALER, J. SCHMALIAN, S.L. BUD'KO, P.C. CANFIELD, ADAM KAMINSKI, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, USA — External control parameters such as pressure or chemical substitution are the key to extend the phase space and achieve high temperature (T_c) superconductivity in the FeAs family. These materials show interesting properties where it is important to understand the role of Fermi surfaces (FS's) in the mechanism of yielding higher T_c . Here, we use angle-resolved photoemission to study the electronic structure of the $\text{Ba}(\text{Fe}_{1-x}\text{Ru}_x)_2\text{As}_2$ as a function of Ru concentration (x). We find that the substitution of Ru for Fe is isoelectronic, i. e., it does not change the value of the chemical potential. More interestingly, there are no measured significant changes in the shape of the FS or in the Fermi velocity over a wide range [1]. We contrast this unusual behavior with the Co substitution, where even small substitutions induce large changes not only in the size of the FS pockets but also in the FS topology [2]. Given that the suppression of the antiferromagnetic and structural phase has been associated with the emergence of the superconducting state, Ru substitution must achieve this via a mechanism that does not involve changes of the Fermi surface. We speculate that this mechanism relies on magnetic dilution that leads to the reduction of the effective Stoner enhancement.

12:39PM B22.00006 Fermi surface in BaFe_2As_2 via SdH measurements on detwinned crystals¹

TAICHI TERASHIMA, NOBUYUKI KURITA, MEGUMI TOMITA, SHINYA UJI, Natl. Inst. Mat. Sci., KUNIHITO KIHOU, CHUL-HO LEE, YASUhide TOMIOKA, TOSHIMITSU ITO, AKIRA IYO, HIROSHI EISAKI, AIST, TIAN LIANG, MASAMICHI NAKAJIMA, SHIGEYUKI ISHIDA, SHIN-ICHI UCHIDA, Univ. Tokyo, HISATOMO HARIMA, Kobe Univ. — We have completely determined the Fermi surface in the antiferromagnetic orthorhombic phase of BaFe_2As_2 by measuring Shubnikov-de Haas oscillations in detwinned single crystals (T. Terashima et al., PRL 107, 176402 (2011)). The determined Fermi surface consists of one hole and two electron pockets, and the carrier compensation is satisfied, the carrier number being 0.024 holes and electrons per primitive unit cell. The Fermi surface can well be accounted for by an LSDA band-structure calculation using the experimental crystal structure. The mass enhancements m^*/m_{band} are found to be 2–3. The Sommerfeld coefficient estimated from the determined Fermi surface and effective masses agrees well with an experimental value. Previous ARPES reports are not very consistent with our determined Fermi surface.

12:51PM B22.00007 Fermi surface topology and low-lying electronic structure of a new iron-based superconductor $\text{Ca}_{10}(\text{Pt}_3\text{As}_8)(\text{Fe}_2\text{As}_2)_5$, CHANG LIU, MADHAB NEUPANE, SU-YANG XU, Joseph Henry Laboratory and Dept. of Physics, Princeton University, Y.J. WANG, Department of Physics, Northeastern University, NI NI, J.M. ALLRED, Department of Chemistry, Princeton University, L.A. WRAY, Joseph Henry Laboratory and Dept. of Physics, Princeton University; Advanced Light Source, Lawrence Berkeley National Laboratory, HSIN LIN, R.S. MARKIEWICZ, ARUN BANSIL, Department of Physics, Northeastern University, ROBERT J. CAVA, Department of Chemistry, Princeton University, M. ZAHID HASAN, Joseph Henry Laboratory and Dept. of Physics, Princeton University — We report a first study of low energy electronic structure and Fermi surface topology for the recently discovered iron-based superconductor $\text{Ca}_{10}(\text{Pt}_3\text{As}_8)(\text{Fe}_2\text{As}_2)_5$ (the 10-3-8 phase, with $T_c \sim 8$ K), via angle resolved photoemission spectroscopy (ARPES). Despite its triclinic crystal structure, ARPES results reveal a fourfold symmetric band structure with the absence of Dirac-cone-like Fermi dots (related to magnetism) found around the Brillouin zone corners in other iron-based superconductors. Considering that the triclinic lattice and structural supercell arise from the Pt_3As_8 intermediary layers, these results indicate that those layers couple only weakly to the FeAs layers in this new superconductor at least near the surface, which has implications for the determination of its potentially novel pairing mechanism.

1:03PM B22.00008 Recent advance in ARPES data analysis of dispersive features in Fe-based superconductors, PENG ZHANG, PIERRE RICHARD, TIAN QIAN, XI DAI, HONG DING, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, YIMING XU, Materials Sciences Division, Lawrence Berkeley National Laboratory — Angle-resolved photoemission spectroscopy (ARPES) is a powerful tool to image the electronic band dispersion of materials, especially in multi-band systems such as the Fe-based superconductors. Here we present a new method to visualize ARPES data based on the mathematical concept of curvature, which improves the advantages and the reliability of the second derivative method in tracking the positions of extrema from the experimental data. We apply it to the Fe-based superconductors. We reveal clear kink features and FS contours, making it easier to capture the essential physics from the data.

[1] P. Zhang, P. Richard, T. Qian, Y.-M. Xu, X. Dai and H. Ding, *A precise method for visualizing dispersive features in image plots*, Rev. Sci. Instrum. **82**, 043712 (2011).

1:15PM B22.00009 Fermi Surfaces of Iron-Pnictide High- T_c Superconductors from the Limit of Local Magnetic Moments¹, MIGUEL ARAUJO, Universidade de Evora, Portugal, PEDRO SACRAMENTO, Instituto Superior Tecnico, Lisbon, JOSE RODRIGUEZ, California State University at Los Angeles — We study a 2-orbital t-J model for an isolated square lattice of iron atoms, which stack up to form an iron-pnictide high- T_c superconductor. The two orbitals in question are the degenerate $d_{\pm} = 3d_{(x \pm iy)z}$ ones, which maximize the Hund's Rule coupling. First-neighbor and second-neighbor hopping (t) and Heisenberg exchange (J) are included. A Schwinger-boson-slave-fermion mean-field analysis yields a hidden half metal state in which holes hop through a $\backslash_{d+} \backslash_{d-}$ spin background without much hopping across orbitals. This state is characterized by an inner and an outer Fermi surface pocket centered at the Γ point. The Fermi surface pockets resemble those predicted by band structure calculations that include all five 3d orbitals. By sweeping the Hund's coupling, we also identify a quantum-critical point (QCP) where zero-energy spin-wave excitations exist at the momenta associated with commensurate spin-density-wave (cSDW) order. These low-energy spin-waves result in nested Fermi-surface pockets centered at cSDW momenta. Exact diagonalization of one hole in the 2-orbital t-J model over a 4×4 square lattice yields low-energy spectra that are consistent with the nested Fermi surfaces that are predicted to exist at the QCP.

1:27PM B22.00010 dHvA measurements of the Fermi surface of LiFeP and its relation to the nodal gap structure, A. CARRINGTON, C. PUTZKE, I. GUILLAMON, University of Bristol, A.I. COLDEA, M.D. WATSON, University of Oxford, D. VIGNOLLES, D. LEOEUF, LNCMI-Toulouse, A. MCCOLLAM, HMFL-Nijmegen, I.I. MAZIN, NRL-Washington, S. KASAHARA, T. TERASHIMA, T. SHIBAUCHI, Y. MATSUDA, Kyoto University — The iron-pnictides are highly unusual in that there appears to be considerable variation in the structure of the superconducting gap across the different materials. The 111 compounds, LiFeX ($X=\text{As}, \text{P}$) superconduct at ambient pressure in their undoped stoichiometric form. LiFeP ($T_c=5\text{K}$) was found to have superconducting gap nodes whereas LiFeAs ($T_c=17\text{K}$) does not. Linking these differences in gap structure to Fermi surface features could provide a key test of microscopic theories which seek to explain superconductivity in iron pnictides. Here we report de Haas-van Alphen effect data which determine, almost completely, the *bulk* Fermi surface of LiFeP . The topology of the Fermi surface, which consists of quasi nested electron and hole sheets, is in good agreement with DFT band structure calculations when allowance for small band energy shifts is made. We find that one hole sheet has an anomalously small mass enhancement (compared to the others) which suggest it interacts weakly. This is probably because of its mixed orbital character rather than for any geometrical reason. We suggest that this could be the driver for node formation in this material.

1:39PM B22.00011 Evidence of Strong Coupling in Antiferromagnetic Ordered Iron Chalcogenide $\text{Fe}_{1.02}\text{Te}$ Observed by Photoemission, ZHONGKAI LIU, Stanford University, RUIHUA HE, Lawrence Berkeley National Laboratory, DONGHUI LU, SLAC National Accelerator Laboratory, MING YI, Stanford University, YULIN CHEN, MAKOTO HASHIMOTO, ROB MOORE, SLAC National Accelerator Laboratory, SUNGKWAN MO, Lawrence Berkeley National Laboratory, JIN HU, TIJIANG LIU, ZHIQIANG MAO, Tulane University, THOMAS DEVEREAUX, SLAC National Accelerator Laboratory, ZAHID HUSSAIN, Lawrence Berkeley National Laboratory, ZHI-XUN SHEN, Stanford University, STANFORD UNIVERSITY TEAM, SLAC NATIONAL ACCELERATOR LABORATORY TEAM, TULANE UNIVERSITY COLLABORATION, LAWRENCE BERKELEY NATIONAL LABORATORY COLLABORATION — The role of many-body effects is one of the central questions for unconventional superconductivity. For the recently discovered iron-based superconductors, the strength of electronic correlations is still an unsettled issue. For one of them, iron chalcogenides, a strong correlation scenario has both been proposed by theory and suggested by experiments. However, the metallic behavior in the antiferromagnetic ordered state in $\text{Fe}_{1.02}\text{Te}$ seems to deviate from such scenario. Our discovery of evidence of strong coupling in electronic bandstructure probed by angle resolved photoemission (ARPES) reconciles this contrast. Our finding also highlights the non-trivial enrichment of many-body effects when multiple ingredients of interactions reinforce each other.

1:51PM B22.00012 Three-dimensionality and orbital characters of Fermi surface in $\text{Tl}_{0.5}\text{Rb}_{0.3}\text{Fe}_{1.63}\text{Se}_2$ ¹, SHANCAI WANG, Renmin University of China, PIERRE RICHARD, NAN XU, GANG XU, Institute of Physics, Chinese Academy of Sciences Beijing 100190, China, YU LI, GENFU CHEN, Renmin University of China, TIAN QIAN, HONG DING, Institute of Physics, Chinese Academy of Sciences Beijing 100190, China — We report a comprehensive study of the tridimensional electronic bands in the recently discovered Iron-selenide superconductor $\text{Tl}_{0.5}\text{Rb}_{0.3}\text{Fe}_{1.63}\text{Se}_2$ ($T_c \sim 32$ K) with angle-resolved photoemission spectroscopy (ARPES). We determined the orbital characters and the k_z dependence of the low-energy electronic structure by tuning the polarization and the photon energy of the incident photons. We observed a small 3D electron pocket near the Brillouin Zone (BZ) center and a 2D like electron pocket near the zone boundary. The photon energy dependence, the polarization analysis and the LDA calculations suggest a significant contribution from the Se $4p_z$, Fe $3d_{xy}$ and the Fe $3d_{z^2}$ orbitals. Comparing with iron-pnictide superconductors, the emergence of Se $4p_z$ states may be the cause of the different magnetic properties between iron-chalcogenides and iron-pnictides.

2:03PM B22.00013 ARPES measurements of superconducting gaps in iron-chalcogenide superconductors, PIERRE RICHARD, H. MIAO, T. QIAN, Y.-B. SHI, N. XU, X.-P. WANG, P. ZHANG, H. DING, X. DAI, Institute of Physics, Chinese Academy of Sciences, J.-P. HU, Purdue University, Y.-M. XU, Lawrence Berkeley National Laboratory, Y. TANAKA, K. NAKAYAMA, K. UMEZAWA, T. SATO, T. TAKAHASHI, Tohoku University, H.-B. YANG, Z.-J. XU, J.-S. WEN, G.-D. GU, Brookhaven National Laboratory — The size and momentum dependence of the superconducting gap are crucial to the determination of the mechanism leading to Cooper pairing. Previous ARPES results on iron-pnictides superconductors reveal nearly-isotropic superconducting gaps with size varying from one Fermi surface to another. Here we show that this scheme is also valid in the iron-chalcogenide superconductors. We demonstrate that the superconducting gaps can be fitted by a single function derived from local pairing scenarios. Our finding of an apparent universality in iron-based superconductivity is a serious challenge to weak coupling approaches and rather favors pairing from local antiferromagnetic exchange interactions.

Session B23 DCMP: Superconductivity Theory I: Cluster DMFT, t-J model, renormalization group 255

11:15AM B23.00001 Pair Structure and the Pairing Interaction in a Bilayer Hubbard model, THOMAS MAIER, Oak Ridge National Laboratory, DOUGLAS SCALAPINO, University of California, Santa Barbara — The bilayer Hubbard model with an intra-layer hopping t and an inter-layer hopping $t_{\perp}$ provides an interesting testing ground for several aspects of what has been called unconventional superconductivity. One can study the type of pair structures which arise when there are multiple Fermi surfaces. One can also examine the pairing for a system in which the structure of the spin-fluctuation spectral weight can be changed. Using a dynamic cluster quantum Monte Carlo approximation, we find that near half-filling, if the splitting between the bonding and anti-bonding bands $t_{\perp}/t$ is small, the gap has B_{1g} ($d_{x^2-y^2}$ -wave) symmetry but when the splitting becomes larger, A_{1g} ($s^{\pm}$ -wave) pairing is favored. We also find that in the $s^{\pm}$ pairing region, the pairing is driven by inter-layer spin fluctuations and that T_c is enhanced.

11:27AM B23.00002 Influence of the cluster-shape on the d-wave-transition temperature T_c in the dynamical cluster approximation: A case study for the 2D repulsive Hubbard model, PETER STAAR, ETH Zurich, THOMAS MAIER, Oak Ridge National Laboratory (ORNL), THOMAS SCHULTHESS, ETH Zurich, ITP ETH ZURICH - ORNL TEAM — The dynamical cluster approximation (DCA) is a systematic extension beyond the single site approximation of dynamical mean field theory to include non-local correlations. The method maps the infinite lattice self-consistently on a cluster with N_c sites, which is embedded into a mean field. Since the correlations within the cluster are treated exactly, it is ideal to investigate phase-transitions such as d-wave superconductivity. Since a Quantum Monte Carlo integration is used to obtain the DCA self-consistency, the sign-problem prevents us to solve large cluster problems ($N_c > 32$). Meanwhile, the transition temperatures T_c from smaller clusters fluctuate due to a large dependency on the cluster-shape. Here, we investigate whether this cluster-dependency originates from the quantum impurity problem, or from the mesh on which we solve the Bethe-Salpeter (BS) equation. By exploiting the localized nature of the self-energy Σ and the vertex function Γ in real space, we can reconstruct these functions on arbitrary fine meshes in momentum-space and investigate its impact on the solutions of the BS equation. We will show that the 8-site cluster has a finite T_c for small doping-levels and that the 16-site clusters have converged transition temperatures.

11:39AM B23.00003 Superconductivity and the Pseudogap in the 2d Hubbard model¹, EMANUEL GULL, Columbia University, OLIVIER PARCOLLET, Institut de Physique Théorique (IPhT), CEA, ANDREW J. MILLIS, Columbia University — Using a numerically exact continuous-time quantum Monte Carlo impurity solver and the DCA cluster dynamical mean field method with cluster sizes up to 16, we have been able to access the superconducting phase of the two dimensional Hubbard model for parameters believed to be relevant to high temperature copper oxide superconductivity. We present results for the phase diagram, the gap to transition temperature ratio, and the interplay of the pseudogap and the superconducting gap. The gap results are obtained by direct inference from imaginary frequency data and analytically continued spectral functions.

11:51AM B23.00004 Strongly correlated superconductivity and Mott transition¹, A.-M.S. TREMBLAY, Université de Sherbrooke, SORDI GIOVANNI, ILL, Grenoble, France, PATRICK SEMON, Université de Sherbrooke, K. HAULE, Rutgers University — Whether the pseudogap temperature T^* intercepts or merges with the superconducting dome is one of the key questions in the field of high-temperature superconductors. We study the normal and the d-wave superconducting phases at finite temperature in the two-dimensional Hubbard model within cellular dynamical mean-field theory and continuous-time quantum Monte Carlo. Above the critical value for the Mott transition, the superconducting T_c has a dome-like shape as a function of doping. The pseudogap temperature T^* intercepts the superconducting dome. Removing superconductivity, one finds that in the normal state, T^* ends at a finite-doping first-order transition that occurs at temperatures below the superconducting dome. That first order transition between a pseudogap metal and a strongly correlated metal is linked to the Mott transition at half-filling. Refs: G. Sordi et al., PRL 104, 226402 (2010); G. Sordi et al., PRB 84, 075161 (2011); G. Sordi et al., arXiv:1110.1392 (2011).

12:03PM B23.00005 Multi-band Hubbard Model Simulation for Unconventional Superconducting System¹, SHI-QUAN SU, MICHAEL S. SUMMERS, THOMAS A. MAIER, Oak Ridge National Lab — To simulate the new experiment findings on unconventional superconductor materials such as Cuprates and iron pnictides, it is inevitable to go beyond single-band model and capture the physics from multi-band effects. We carried out a novel Dynamical Cluster Quantum Monte Carlo study on multi-band Hubbard model, implementing the Continuous Time Quantum Monte Carlo algorithm as quantum solver. We studied various of single-particle properties aiming to observe the experiment concerned issues such as the spontaneous symmetry breaking to nematic order.

¹Shi-Quan Su works under contract number DE-AC05-00OR22750 between the U.S. Department of Energy and Oak Ridge Associated Universities. A portion of this research was conducted at the Center for Nanophase Materials Sciences.

12:15PM B23.00006 Scaling of the transition temperature of hole-doped cuprate superconductors with the charge-transfer energy, CHUCK-HOU YEE, Rutgers University, CEDRIC WEBER, University of Cambridge, KRISTJAN HAULE, GABRIEL KOTLIAR, Rutgers University — We use first-principles calculations to extract two essential microscopic parameters, the charge-transfer energy and the inter-cell oxygen-oxygen hopping, which correlate with the maximum superconducting transition temperature T_{cmax} across the cuprates. We explore the superconducting state in the three-band model of the copper-oxygen planes using cluster Dynamical Mean-Field Theory with an exact diagonalization impurity solver. We find that variations in the charge-transfer energy largely accounts for the trend in T_{cmax} across the cuprate families.

12:27PM B23.00007 A contractor-renormalization study of Hubbard plaquette clusters, DROR ORGAD, SHIRIT BARUCH, Hebrew University of Jerusalem — We implement the contractor-renormalization method to study the checkerboard Hubbard model on various finite-size clusters as function of the inter-plaquette hopping t' and the on-site repulsion U at low hole doping. We find that the pair-binding energy and the spin gap exhibit a pronounced maximum at intermediate values of t' and U , thus indicating that moderate inhomogeneity of the type considered here substantially enhances the formation of hole pairs. The rise of the pair-binding energy for $t' < t'_{\max}$ is kinetic-energy driven and reflects the strong resonating valence bond correlations in the ground state that facilitate the motion of bound pairs as compared to single holes. Conversely, as t' is increased beyond $t'_{\max}$ antiferromagnetic magnons proliferate and reduce the potential energy of unpaired holes and with it the pairing strength. For the periodic clusters that we study the estimated phase ordering temperature at $t' = t'_{\max}$ is a factor of 2–6 smaller than the pairing temperature.

12:39PM B23.00008 Effects of disorder in the Checkerboard Hubbard model, PETER SMITH, MALCOLM P. KENNETT, Simon Fraser University — The checkerboard Hubbard model (CHM) is an unusual example of a model for strongly correlated electrons that has a region in parameter space where a controlled perturbative solution is possible. The square lattice in two dimensions is divided into four-site plaquettes for which the intra-plaquette hopping (t) is stronger than the inter-plaquette hopping (t'). We study the ground state properties of the CHM in the presence of disorder using exact diagonalization on clusters of up to twelve sites as a function of t'/t , disorder strength and interaction strength. We consider both site and bond disorder and calculate the pair binding energy and the spin gap. We comment on the implications of our results for superconductivity in this model.

12:51PM B23.00009 Superconducting pair-pair correlations in the half-filled Hubbard model on the anisotropic triangular lattice: absence of long-range order¹, S. DAYAL, R. T. CLAY, Mississippi State University, MS, S. MAZUMDAR, University of Arizona, AZ — We report calculations of superconducting pair-pair correlations for the half-filled band Hubbard model on an anisotropic triangular lattice using the path-integral renormalization group (PIRG) method. Mean-field studies have suggested that $d_{x^2-y^2}$ superconductivity occurs near the boundary between metallic and antiferromagnetic phases in this model. We calculate bond orders, spin structure factors, and superconducting pair-pair correlations at zero temperature. Our results are consistent with previous studies of the metal-insulator transition and antiferromagnetism in this model. However, we do not find any parameter region where pair-pair correlations are enhanced by the Hubbard U , except for trivial enhancement of on-site correlations. The superconducting pair-pair correlations at larger distances decrease monotonically with increasing U , with a distance dependence approaching that of noninteracting fermions, indicating the absence of frustration-driven superconductivity within the model.

1:03PM B23.00010 Two temperature scales in the d-wave pair correlation length of the 2D t-J model, WILLIAM PUTIKKA, Physics Department, Ohio State University — Two temperature scales are observed in the d-wave pair correlation length for doping $\delta \sim 0.25$. Both the s-wave and d-wave pair correlation lengths increase with decreasing temperature starting at very high temperatures. By $T \sim 3J$ both symmetries have grown to $\sim 1/3$ of a lattice spacing. For $T > 3J$ the s-wave correlation length is a few percent larger than d-wave. At $T \sim 3J$ both symmetries are saturating, with the growth in the correlation length flattening for both symmetries. The s-wave correlation length does not grow at lower temperatures. The d-wave correlation length does resume growing at $T \sim 0.8J$, with the growth at low temperatures much stronger than it was at high temperatures. The d-wave correlation length reaches a size of one lattice spacing at $T \sim 0.25J$ with no sign of saturating. Interestingly, both of these temperature scales also occur in the t-J model momentum distribution $n_{\mathbf{k}}$. The features that are found in the temperature dependence of the 2D $n_{\mathbf{k}}$ on the zone diagonal are very similar to the temperature dependence of the 1D t-J model $n_{\mathbf{k}}$. These observations can be understood by having spin-charge separated degrees of freedom.

1:15PM B23.00011 Two routes to disorder-induced magnetism and nematicity in the cuprates, BRIAN M. ANDERSEN, Niels Bohr Institute, University of Copenhagen, PETER J. HIRSCHFELD, University of Florida, RASMUS B. CHRISTENSEN, Niels Bohr Institute, University of Copenhagen, SIEGFRIED GRASER, Augsburg University — We study disorder-induced magnetism within the Gutzwiller approximation applied to the t-J model relevant for cuprate superconductors. We identify two distinct disorder-induced magnetic phases depending on the strength of the scatterers. For weak potential scatterers, charge reorganization may push local regions in-between the impurities across the magnetic phase boundary, whereas for strong scatterers a local static magnetic moment is formed around each impurity. We calculate the density of states and find a universal low-energy behavior independent of both disorder and magnetization. However, the magnetic regions are characterized by larger (reduced) superconducting gap (coherence peaks) [1]. Recent studies have highlighted the role of a electronic nematic liquid underdoped cuprates. We calculate the spin susceptibility with a small explicitly broken rotational symmetry to show how the induced spin response asymmetry is enhanced by correlations. In the disorder-induced stripe phase, impurities become spin nematogens with a C2 symmetric impurity resonance state, and the disorder-averaged spin susceptibility remains only C2 symmetric at low energies, similar to recent data from neutron scattering on underdoped YBCO [2].

1:27PM B23.00012 Band structure effects on superconductivity in the weak-coupling Hubbard model, WEEJEE CHO, SRINIVAS RAGHU, STEVEN KIVELSON, Stanford University — The repulsive Hubbard model is the paradigmatic model for the study of unconventional superconductivity. In order to explore the influence of various features of the band structure on the magnitude and character of the pairing, we use a well-controlled perturbative renormalization group (RG) method to study the weak coupling limit of the model on the square lattice with various modifications: The first is the checkerboard model described by the strong hopping t and the weak hopping t' . The second is the bilayer model described by the intra-layer hopping t and the inter-layer hopping $t_{\perp}$. We obtain the pairing symmetry and strength as functions of the relevant band parameters. Large changes in the effective pairing strength are found and their origins explained.

1:39PM B23.00013 Effects of longer-range interactions on unconventional superconductivity¹, SRINIVAS RAGHU, Stanford University, EREZ BERG, Harvard University, ANDREY CHUBUKOV, University of Wisconsin, Madison, STEVEN KIVELSON, Stanford University — We analyze the effect of the non-vanishing range of electron-electron repulsion on the mechanism of unconventional superconductivity. We present asymptotically exact weak-coupling results for dilute electrons in the continuum and for the 2D extended Hubbard model, as well as density-matrix renormalization group results for the two-leg extended Hubbard model at intermediate couplings, and approximate results for the case of realistically screened Coulomb interactions. We show that T_c is generally suppressed in some pairing channels as longer range interactions increase in strength, but superconductivity is not destroyed. Our results confirm that electron-electron interaction can lead to unconventional superconductivity under physically realistic circumstances.

¹NSF-DMR-0906953 (AVC), DMR-0758356 (SAK), DMR-0757145, DMR-0705472 (EB)

1:51PM B23.00014 Three-particle interactions in effective one-band models for unconventional superconductivity, STEFAN MAIER, CARSTEN HONERKAMP, RWTH Aachen — We discuss different approximations for effective low-energy interactions in multiband models for weakly interacting correlated electrons. In the study of Fermi surface instabilities of the conduction band(s), the standard approximation consists in keeping just those terms in the bare interactions that couple only to the conduction band(s), while corrections due to virtual excitations into bands away from the Fermi surface are typically neglected. In order to include important aspects of these virtual interband excitations, we present an improved truncation of the functional renormalization group (fRG) that keeps track of the three-particle vertex in the conduction band. Within a simplified two-patch treatment of a two-band model, we demonstrate that these corrections can have a rather strong effect in parts of the phase diagram by changing the critical scale for *d*-wave pairing close to a phase boundary. The improved truncation scheme is applied as well to the Emery model within a multi-patch channel-decomposed fRG.

2:03PM B23.00015 Effective interactions in multi-band systems from constrained summations, CARSTEN HONERKAMP, RWTH Aachen University, Germany — The application of many-body techniques for the study of correlation effects and unconventional superconductivity requires the formulation of an effective low-energy model that contains only the relevant bands near the Fermi level. However the bands away from the Fermi level are known to renormalize the low-energy interactions substantially. Here we compare different schemes to derive low-energy effective theories for interacting electrons in solids. The frequently used constrained random phase approximation (cRPA) is identified as a particular resummation of higher-order interaction terms that includes important parts of the leading virtual corrections. We then propose an adapted renormalization group scheme that includes the cRPA, but also allows one to go beyond the cRPA approximation. We study a simple two-band model in order to demonstrate the differences between the different approximations.

Monday, February 27, 2012 11:15AM - 2:15PM — Session B24 FIAP: Electronic Structure: Theory and Spectra 256

11:15AM B24.00001 Valence band effective Hamiltonians in nitride semiconductors, ATCHARA PUNYA, NUCHARÉE SCHWERTFAGER, WALTER LAMBRECHT, Department of Physics, Case Western Reserve University, 10900 Euclid Avenue, Cleveland, OH 44106 — Valence band effective Hamiltonians are useful to determine the electronic states of shallow impurities, quantum wells, quantum wires and quantum dots within the effective mass approximation. Although significant experimental and theoretical work has been performed, basic parameters such as the Rashba Sheka Pikus (RSP) Hamiltonian parameters are still uncertain. In this work, the electronic band structures of AlN, GaN and InN, all in the wurtzite crystal structure, as well as the RSP Hamiltonian parameters are determined by using the QSGW approximation in a FP-LMTO implementation. The corrections offered by this approach beyond the LDA are important to obtain the splittings and effective masses accurately. The present GW implementation, which allows for a real space representation of the self-energy, enables us to interpolate exactly to a fine *k*-mesh and hence to obtain accurate effective masses. We find the crystal field splitting in GaN (12 meV) in much closer agreement with experiment than previous work and obtain a negative SO coupling for InN. Moreover, we have generalized the method of invariants to crystals with orthorhombic symmetry, such as ZnSiN₂, ZnGeN₂, ZnSnN₂ and CdGeN₂ and determined the corresponding Hamiltonian parameters.

11:27AM B24.00002 ABSTRACT WITHDRAWN —

11:39AM B24.00003 Hybrid Density Functional Study of (Hg,Cd)Te Systems, JEREMY W. NICKLAS, JOHN W. WILKINS, The Ohio State University — The HgCdTe alloy is used in high-performance infrared detection applications with a band gap range extending across the infrared spectrum. HgTe in particular has sparked interest for its topological insulating behavior in quantum well devices due to its band inverted nature. We test the quality of the newer hybrid screened functional, HSE, on the two contrasting materials: HgTe (semimetal) and CdTe (semiconductor) to see how well it performs under a range of computational setups [1]. A direct comparison of HSE with the standard DFT functional PBE to experiment for the HgCdTe alloy reveals HSE is able to reproduce the experimental crossover composition of 17% Cd concentration when the alloy goes from a semimetal to semiconductor, whereas PBE overestimates this composition at 67% Cd concentration. HSE also predicts a higher valence band offset of 0.53 eV in the HgTe/CdTe heterostructure than previous first-principle and early experimental results, but in good agreement with the more recent experimental results. Supported by DOE-Basic Energy Science DOE-BES-DMS (DEFG02-99ER45795). Computing resources are provided by NERSC and OSC.

11:51AM B24.00004 Ab-initio description of satellites in graphite, MATTEO GUZZO, LORENZO SPONZA, CHRISTINE GIORGETTI, FRANCESCO SOTTILE, Ecole Polytechnique, FR, DEBORA PIERUCCI, MATHIEU G. SILLY, FAUSTO SIROTTI, Synchrotron SOLEIL, FR, JOSHUA J. KAS, JOHN J. REHR, U. Washington, LUCIA REINING, Ecole Polytechnique, FR — The GW method from Many-Body Perturbation Theory has been very successful in describing photoemission spectra in a variety of systems. In particular, GW is known to give good quasiparticle properties like band-gaps, but it has shown some limitations in the description of complex correlation effects like satellites. Satellite peaks in photoemission come from higher-order excitations and are still poorly studied in the valence bands. In perturbative GW the spectral function can describe additional features beside the quasiparticle peaks, but these satellites are known to be too weak and too low in energy, as it appears from calculations on the Homogeneous Electron Gas and some real materials. We have recently shown that including additional diagrams in the Green's function (similarly to what has been done with the cumulant expansion) we obtain an excellent description of satellites series in the test case of bulk silicon, where GW is unable to cope. We now focus on a more complex system, i.e. graphite, with this same approach. Using our newly measured XPS valence data, we investigate the effects of anisotropies on satellites and give a prediction on the spectral changes following the transition towards a single graphene layer.

12:03PM B24.00005 Isotope dependence of band gap in semiconductors, TAKASHI KORETSUNE, SUSUMU SAITO, Tokyo Institute of Technology — Recently, carrier confinement was observed in diamond superlattice consisting of pure ¹²C and ¹³C layers. This interesting phenomenon comes from large isotope dependence of fundamental gap width in diamond. To understand this carrier confinement and design related nanodevices, we investigate the effect of electron-phonon couplings on quasiparticle energies in semiconductors composed of carbon and other light elements using first-principles methods based on the density functional theory. The calculated isotope dependence as well as temperature dependence of band gap in diamond is found to agree well with the experiment. We also discuss the isotope dependence in binary compounds such as boron nitride and silicon carbide.

12:15PM B24.00006 Clarification of the relations between stacking structures of sp^3 network materials and their band gaps, YU-ICHIRO MATSUSHITA, SHINNOSUKE FURUYA, ATSUSHI OSHIYAMA, The University of Tokyo — Silicon carbide (SiC) has been discovered in various polymorphs. Each polymorph is characterized by its stacking of atomic planes. The band gap varies substantially in each polymorph from 2.40 eV to 3.33 eV in spite that the local atomic structures are identical to each other [1]. The mechanism of this intriguing property have been poorly understood. To clarify the fundamental reasons for this band-gap variation, we have performed the electronic-structure calculations in the density functional theory. We have found that the Kohn-Sham orbital at the conduction-band bottom distributes broadly around the interstitial channel, thus floating in the matter. The way of the floating depends on the stacking of the atomic planes and determines the band gap in each polymorph. We also find that the floating state appears in other sp^3 -bonded materials, and the band-gap variation is common to the covalent materials. References [1] Properties of Silicon Carbide edited by G. L. Harris (INSPEC, London, 1995).

12:27PM B24.00007 Nonequilibrium “melting” of a charge density wave insulator via an ultrafast infrared laser pulse¹, WEN SHEN, YIZHI GE, AMY LIU, Georgetown University, H.R. KRISHNAMURTHY, India Institute of Science, TOM DEVEREAUX, Stanford University, JIM FREERICKS, Georgetown University — In equilibrium, electrons interacting with lattice vibrations have a transition either to a charge density wave phase (a static modulation of the electronic charge) or to a superconductor (electron pairs move without resistance). If the coupling is weak, the system orders in the Bardeen-Cooper-Schrieffer scenario, where the ordering occurs at some transition temperature T_c and a gap simultaneously forms in the density of states. In strong-coupling, preformed pairs bind at a high temperature (forming a gap in the density of states) and the ordering only occurs at a lower temperature. We employ an exact solution of a model for pump-probe time-resolved photoemission spectroscopy to show how, in nonequilibrium, a third scenario arises: the gap disappears in the presence of a nonzero order parameter, and then reforms well after the pulse has passed. This nonequilibrium “phase transition” scenario qualitatively describes all of the available experiments on the ultrafast melting of a charge density wave.

12:39PM B24.00008 Engineering Electronic Band Structure for New Elpasolite Scintillators, MAO-HUA DU, Koushik Biswas, DAVID SINGH, Oak Ridge National Laboratory — The utilization of scintillator materials is one of the primary methods for radiation detection. Elpasolites are a large family of quaternary halides that have recently attracted considerable interest for their potential applications as γ -ray and neutron scintillators. A large number (on the order of 10^3) of different chemical compositions exist in the elpasolite family of compounds. This wide range of compositions offers numerous opportunities for fine-tuning the material chemistry to target specific scintillation properties, but they also pose significant challenges in identifying the most promising ones. Many elpasolite scintillator materials currently under development suffer from low light output and long scintillation decay time. The low light output is partially due to a large band gap while the long scintillation decay time is a result of the slow carrier transport to Ce impurities, where carriers recombine to emit photons. We suggest that these problems may be mitigated by optimizing the band gap and carrier mobility by selecting constituent elements of proper electronegativity. For example, cations with lower electronegativity may lower the conduction band and increase the conduction band dispersion simultaneously, resulting in higher light output and faster scintillation. We demonstrate by first-principles calculations that the strategy of manipulating electronegativity can lead to a number of new elpasolite compounds that are potentially brighter and faster scintillators.

12:51PM B24.00009 Origin of the variation of exciton binding energy in semiconductors, MARC DVORAK, ZHIGANG WU, Colorado School of Mines — Electron-hole interaction plays a crucial role in optical properties, and the exciton binding energy (E_b) in technologically important semiconductors varies from merely a few meV to around 100 meV, which is not well understood. In this work, we investigate the origin of the variation of E_b in semiconductors, employing first-principle calculations based on the density functional theory (DFT) and the many-body perturbation theory with Green's function (GW/BSE). Our results clearly show that E_b decreases as the spread of electron distribution, which measures the magnitude of electron delocalization, increases. This is due to the increased electronic screening when electrons tend to be more delocalized. Furthermore, the spread distribution of the top valence electrons is of central importance in determining excitonic screening, which leads to weakly bound electrons and holes in semiconductors. Thus, the variation of exciton binding energy in semiconductors can be understood from the computed magnitude of electron delocalization of top valence bands of these materials using DFT.

1:03PM B24.00010 Modeling Shallow Core-Level Transitions in the Reflectance Spectra of Gallium-Containing Semiconductors, NICHOLAS STOUTE, DAVID ASPNES, North Carolina State University, DE ASPNES GROUP TEAM — The electronic structure of covalent materials is typically approached by band theory. However, shallow core level transitions may be better modeled by an atomic-scale approach. We investigate shallow d-core level reflectance spectra in terms of a local atomic-multiplet theory, a novel application of a theory typically used for higher-energy transitions on more ionic type material systems. We examine specifically structure in reflectance spectra of GaP, GaAs, GaSb, GaSe, and $\text{GaAs}_{1-x}\text{P}_x$ due to transitions that originate from Ga3d core levels and occur in the 20 to 25 eV range. We model these spectra as a Ga^{+3} closed-shell ion whose transitions are influenced by perturbations on 3d hole-4p electron final states. These are specifically spin-orbit effects on the hole and electron, and a crystal-field effect on the hole, attributed to surrounding bond charges and positive ligand anions. Empirical radial-strength parameters were obtained by least-squares fitting. General trends with respect to anion electronegativity are consistent with expectations. In addition to the spin-orbit interaction, crystal-field effects play a significant role in breaking the degeneracy of the d levels, and consequently are necessary to understand shallow 3d core level spectra.

1:15PM B24.00011 Ab-initio study of dilute nitride substitutional and split-interstitial impurities in gallium antimonide (N-GaSb)¹, PRIYAMVADA JADAUN, HARI P. NAIR, SETH R. BANK, SANJAY K. BANERJEE, The University of Texas at Austin — We present an ab-initio density functional theory study of dilute-nitride GaSb. Adding dilute quantities of nitrogen causes rapid reduction in bandgap of GaSb (~ 300 meV for 2% N). Due to this rapid reduction in bandgap, dilute-nitrides provide a pathway for extending the emission of GaSb based type-I diode lasers into the mid-infrared wavelength region (3-5 micron). In this study we look at the effect of substitutional N impurity on the electronic properties of our system and compare it with the band-anticrossing model, a phenomenological model, which has been used to explain giant band bowing observed in dilute-nitride alloys. We also study the effect of Sb-N split interstitials which are known to be non-radiative recombination centers. Furthermore we also discuss the stability of the Sb-N split interstitial relative to substitutional nitrogen to determine if the split interstitials can be annihilated using post-growth annealing to improve the radiative lifetime of the material which essential for laser operation.

¹NSF Teragrid machine Ranger at Texas Advanced Computing Center.

1:27PM B24.00012 Electronic properties of InP in terms of an ab-initio LDA, YURIY MALOZOVSKY, LASHOUNDA FRANKLIN, Department of Physics, Southern University and A&M College, Baton Rouge, LA 70813, CHINEDU EKUMA, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, GUANG-LIN ZHAO, DIOLA BAGAYOKO, Department of Physics, Southern University and A&M College, Baton Rouge, LA 70813 — We present results from ab-initio local density approximation (LDA) calculations of electronic and related properties of zinc blende indium phosphide (InP). Our computations employed the Ceperley and Alder LDA potential and the linear combination of atomic orbital (LCAO) formalism. The implementation of the LCAO formalism followed the Bagayoko, Zhao, and Williams (BZW) method. Consequently, we solved self consistently both the Kohn Sham equation and the one giving the ground state charge density in terms of the wave functions of the occupied states. Self-consistency, for the latter equation, requires a search for the optimal basis set. This search entails increases of the size of the basis set and the related modifications of angular symmetry and of available radial functions. Our calculated, direct band gap of 1.398 eV (1.40 eV), at the Γ point, is in excellent agreement with experimental values. The calculated density of states (DOS) also agree with experimental finding. The calculated electron and hole effective masses differ by 10% from some corresponding experimental ones. We discuss the equilibrium lattice constant and optical properties.

1:39PM B24.00013 Self Consistent Calculations of Electronic Properties of Systems with an Energy or a Band Gap, DIOLA BAGAYOKO, LASHOUNDA FRANKLIN, Department of Physics Southern University and A&M College, Baton Rouge, LA 70813, CHINEDU EKUMA, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, YURIY MALOZOVSKY, Department of Physics Southern University and A&M College, Baton Rouge, LA 70813 — We re-examine the process of performing self consistent calculations of electronic and related properties of finite systems (with an energy gap) and of crystals with a band gap. This work applies to calculations utilizing density functional and $X\alpha$ potentials and to other approaches that entail solving a system of inherently coupled equations. In particular, the local density approximation (LDA) is defined by a system of equations that reduces to two equations upon the selection of V_{xc} . We show how the Bagayoko, Zhao, and Williams (BZW) method solves the relevant system of equations and leads to results in excellent agreement with experimental ones. We discuss such results for w-ZnO, rutile TiO₂, w-CdS, zb-CdS, zb-InP, Ge, Ca B₆, and other materials. Work funded by the National Science Foundation, through LASiGMA [NSF Award EPS-1003897 and No. NSF (2010-15)-RII-SUBR], LONI [Award No. 2-10915], and Ebonyi State, Federal Republic of Nigeria.

1:51PM B24.00014 Infrared Refractive Index of Silicon: Parity and Sum-Rule Tests¹, WILLIAM KARSTENS, Saint Michaels College, MITIO INOKUTI², Argonne National Laboratory, DAVID Y. SMITH, University of Vermont and Argonne National Laboratory — We have resolved conflicting reports for the IR refractive index of silicon using general considerations of linear response theory. We find that use of unphysical series expansions in the analysis of channel spectra has been a significant source of systematic error. Recognition that the index is an even function of photon energy is crucial for analysis of these measurements and clarifies data presentation. In the region of high IR transparency of elemental semiconductors, the index may be expanded in a rapidly convergent Taylor series. Coefficients of terms in the $(2n)^{th}$ power of energy are proportional to the $(2n+1)^{th}$ inverse moment of the electronic absorption spectrum. In the favorable case of intrinsic Si, the electronic absorption is sufficiently well known that independent values of the intercept, slope and curvature of plots of index vs. the square of photon energy may be calculated. Index data sets with parameters significantly different from these suffer from systematic errors or refer to impure samples. Using these parity and sum-rule tests we have prepared a composite index data set for intrinsic silicon that represents a best fit to reliable measurements from microwaves to the visible. Applications to germanium and diamond will be discussed.

2:03PM B24.00015 Electronic Structure of NiFe₂O₄ using screened Hybrid Functionals, HUNTER SIMS, MINT Center and Dept. of Physics, University of Alabama, DIPANJAN MAZUMDAR, MINT Center, University of Alabama, SANJOY SARKER, MINT Center and Dept. of Physics, University of Alabama, ARUNAVA GUPTA, MINT Center, University of Alabama, QI SUN, JAN MUSFELDT, Department of Chemistry, University of Tennessee — As an insulating ferrimagnet with a high Curie temperature, NiFe₂O₄ (NFO) may be a promising candidate for future spin-based applications. Recent demonstration of spin-Seebeck effect in magnetic insulators indicates that important new phenomena may be discovered in such materials. Unfortunately, density functional theory cannot give a full account of its properties; most notably, LDA calculations find it to be metallic. LDA+U yields an insulator but underestimates the band gap. The recently-implemented screened hybrid functionals method (HSE06) represents only a moderate increase in computational effort compared to traditional DFT. This method allows one to modify the PBE-approximated exchange potential with a portion of the Hartree-Fock exchange. We present LDA, LDA+U, and HSE06 calculations of the density of states and band structure of NFO. We show that hybrid methods greatly improve agreement with the experimental band gap over LDA +U. We find that NFO is an indirect band gap system with the spin-down channel having the lower, indirect gap, whereas the majority channel possess a direct gap with over a 0.5eV difference with the minority gap. Comparison of our theoretical results with recent optical measurements on NFO thin films is also presented.

Session B25 DCOMP GSCCM DMP: Focus Session: Simulation of Matter at Extreme Conditions - Shock-Induced Chemistry 257A

11:15AM B25.00001 Extending DFT to Long Time-Scales: Using the Density Functional Tight Binding Approach for Materials Under Extreme Temperatures and Pressures¹, NIR GOLDMAN, Lawrence Livermore National Laboratory — We report here on density functional tight binding (DFTB) simulations of covalently bonded materials over a pressure range of 10 – 2,000 GPa and a temperature range of 300 – 30,000 K using both standard and new interaction potentials we have created for these conditions. Density Functional Theory (DFT) has been shown to accurately reproduce the high pressure-temperature chemistry, phase boundaries, and EOS of many materials. DFT-MD simulations, though, scale poorly with computational effort and thus are generally limited to nanometer system sizes and picosecond time-scales. In contrast, chemical kinetic effects and phase changes can span up to nanosecond timescales and significantly longer length scales. The DFTB method holds promise as a high throughput simulation capability by providing orders of magnitude increase in computational efficiency while retaining most of the accuracy of Kohn-Sham DFT. We show that DFTB interaction potentials can be created by (a) fitting the DFTB repulsive energy to measured and computed compression data, and (b) using an extended basis set that includes *d*-orbital interactions, as needed. Our new potential for carbon yields accurate material properties for diamond, graphite, the BC8 phase, and simple cubic carbon, as well as for the shock Hugoniot of diamond compressed up to the conducting liquid. We also discuss simulations of the long-time scale reactivity of H₂O₂ under detonation conditions, and shock compression of astrophysical ice mixtures and the subsequent synthesis of pre-biotic materials. Our results provide a straightforward method by which DFTB can be made to provide equation of state and long-time scale chemical kinetic data at a similar accuracy to standard quantum codes. Our approach could be extended to any number of materials related to geology and planetary science, including silicon, SiO₂, and hydrocarbon systems.

¹This work was performed under the auspices of the US Department of Energy by Lawrence Livermore National Laboratory (LLNL) under Contract DE-AC52-07NA27344.

11:51AM B25.00002 Pressure-induced Polymerization in Substituted Acetylenes, RAJA CHELLAPPA, DANA DATTELBAUM, STEPHEN SHEFFIELD, Los Alamos National Laboratory — A fundamental understanding of shock-induced chemical reactions in organics is still lacking and there are limited studies devoted to determining reaction mechanisms, evolution of bonding, and effect of functional group substitutions. The fast timescale of reactions occurring during shock compression create significant experimental challenges (diagnostics) to fully quantify the mechanisms involved. Static compression provides a complementary route to investigate the equilibrium phase space and metastable intermediates during high pressure chemistry, although at a much slower timescale. In this study, we present our results from our ongoing high pressure in situ synchrotron x-ray diffraction and vibrational spectroscopy experiments on substituted acetylenes: tert-butyl acetylene [TBA: $(\text{CH}_3)_3\text{C}\equiv\text{CH}$] and ethynyl trimethylsilane [ETMS: $(\text{CH}_3)_3\text{SiC}\equiv\text{CH}$]. We observed that the onset pressure of chemical reactions (at room temperature) in these compounds is significantly higher in static compression (TBA: 11 GPa and ETMS: 26 GPa) when compared to shock input pressures (TBA: 6.1 GPa and ETMS: 6.6 GPa). The products were polymeric in nature, recovered to ambient conditions with little degradation and fully characterized using spectroscopy, calorimetry, and other techniques to identify reaction mechanisms.

12:03PM B25.00003 Non-equilibrium Molecular Dynamics Studies of Interfacial Chemistry in Shocked Ni/Al Nanolaminates¹, JASON QUENNEVILLE, Spectral Sciences, Inc., NARESH THADHANI, Georgia Institute of Technology — The response of Ni/Al composite materials to shock loading has been studied using non-equilibrium molecular dynamics and an EAM force field. The simulation cells consist of layered Ni and Al laminates with at least 3 million particles in a 1:1 mole ratio. The main thrust of our research is to gain a better understanding of the chemistry that occurs at the Ni/Al interface when the real material is shocked. Initial geometries were chosen so as to identify the factors important to reaction in the complex macro-scale material. Specifically, we vary the orientation of the interface with respect to the shock wave and the geometry of the interface (*i.e.*, deviation from planarity) to study how mixing and reactivity of Ni and Al are affected. Our results show a clear dependence of pressure and temperature on interface orientation, in agreement with continuum-scale simulations.

12:15PM B25.00004 Near-Equivalency of Inter and Intramolecular Hydrogen Bonding Under High-Pressure, M. RIAD MANAA, LAURENCE FRIED, Lawrence Livermore National Laboratory — Triamino-trinitro-benzene (TATB, $\text{C}_6\text{H}_6\text{N}_6\text{O}_6$) exhibits unusually strong intramolecular hydrogen bonding as evidenced by the high rotational energy barrier of the nitro and amino groups. In the condensed phase, the competing intermolecular hydrogen bonding becomes pronounced at high-pressure in its graphitic-like crystal structure. We report density functional theoretical calculations of the equation of state of TATB under hydrostatic compression of up to 250 GPa. Our results show increasing bond equivalency between the intramolecular and intermolecular hydrogen bonds of the amino and nitro groups in the region $30 < P < 70$ GPa, beyond which the difference between the two bond distances remains constant. This approximate bond equivalency is manifested by a rapid decrease of the intermolecular -NO—HN- distance along the b lattice direction from 2.6 Å at the zero pressure equilibrium geometry to 1.72 Å at 67 GPa, and by a decrease of the intramolecular -NO—HN- bond from 1.65 Å to 1.57 Å for the same pressure region. It is expected that vibrational motions involving the NO—HN modes are sensitive to the nearly equivalent hydrogen bonding, as recent spectroscopic IR analysis of the NH_2 stretches revealed.

12:27PM B25.00005 Modeling of electron-ion coupling in shocked materials, EVAN REED, Stanford University — This work describes and implements a quasi-statistical approach to electron-ion coupling in shocked matter. By combining this approach with the multi-scale shock technique (MSST) and a tight-binding model, the magnitude and role of electronic excitations in shocked energetic materials are studied theoretically using quantum molecular dynamics simulations. Focusing on the detonating primary explosive HN_3 (hydrazoic acid), this work finds that the material transiently exhibits a high level of electronic excitation characterized by carrier densities in excess of 10^{21} cm^{-3} , or one electronic excitation for every 8 molecules. Electronic excitations enhance the kinetics of chemical decomposition by about 30%. The electronic heat capacity has a minor impact on the temperatures exhibited, on the order of 100 K.

12:39PM B25.00006 Quantum-based Molecular Dynamics Simulations of Shock-induced Reactions with Time-resolved Raman Spectra, MARC CAWKWELL, EDWARD SANVILLE, JOSHUA COE, ANDERS NIKLASSON, Los Alamos National Laboratory — Shock-induced reactions in liquid hydrocarbons have been studied using quantum-based, self-consistent tight-binding (SC-TB) molecular dynamics simulations with an accurate and transferable model for interatomic bonding. Our SC-TB code LATTE enables explicit simulations of shock compression using the universal liquid Hugoniot. Furthermore, the effects of adiabatic shock heating are captured precisely using Niklasson's energy conserving extended Lagrangian Born-Oppenheimer Molecular Dynamics formalism. We have been able to perform relatively large-scale SC-TB simulations by either taking advantage of the sparsity of the density matrix to achieve $O(N)$ performance or by using graphics processing units to accelerate $O(N^3)$ algorithms. We have developed the capability for the on-the-fly computation of Raman spectra from the Fourier transform of the polarizability autocorrelation function via the density matrix perturbation theory of Niklasson and Challacombe. These time-resolved Raman spectra enable us compare the results of our simulations with identical diagnostics collected experimentally. We will illustrate these capabilities with a series of simulations of shock-induced reaction paths in a number of simple molecules.

12:51PM B25.00007 Molecular Simulation of Shock Hugoniot for Polymers, T. SIRK, T. CHANTAWANSRI, E. BYRD, B. RICE, J. ANDZELM, Army Research Laboratory — The behavior of polymers under extreme conditions (high pressure and temperature) is of interest for a variety of applications, such as polymer-bonded explosives, coatings, adhesives, and light-weight armor. Material properties and response at extreme conditions can be determined through shock experiments, which are often difficult to measure experimentally because of difficulties in traversing a large range of pressures (up to hundreds of gigapascals) and temperatures (thousands of kelvin) with available instrumentation. In addition, interesting behavior, such as observed behind a shock front, occurs at extremely short time- and length-scales (nanoscale), which poses problems in characterizing the material using current experimental capabilities. To further understand shocked systems, simulation methods such as molecular dynamics (MD) and quantum mechanics (QM) can be used to provide insight into atomic-level phenomena. Using classical MD and QM, we have calculated the principle shock Hugoniot curves for four polymers: poly[methyl methacrylate], poly[ethylene], poly[styrene], and hydroxyl-terminated poly[butadiene]. In the MD calculations, we considered both a non-reactive (*i.e.* PCFF) and reactive (*i.e.* ReaxFF) forcefield, respectively, where calculations were performed in LAMMPS. The QM calculations were performed with density functional theory (DFT) using dispersion corrections as implemented in CP2K. We have applied both atom centered pseudopotentials (DCACPs) and Grimme van der Waals corrections in our study. Overall, results obtained by QM show much better agreement with available experimental data for the range of up to 20 GPa than classical force fields. At pressures where reactions can occur the short simulation time available in MD modeling prevents us from fully exploring possible reaction pathways.

1:03PM B25.00008 Amorphous Polymeric Nitrogen from Dynamic Shock Simulation¹, TODD BEAUDET, WILLIAM MATTSON, BETSY RICE, U.S. Army Research Laboratory — In recent years there has been significant interest in polymeric phases of nitrogen at low pressure for potential application as an energetic material. This interest was bolstered by experimental evidence of metastable amorphous polymeric nitrogen at low pressure.^{2,3} While considerable theoretical work has been done on many crystal phases of nitrogen, simulating amorphous polymeric nitrogen has been more challenging. Starting from first principles dynamic shock simulation of cubic-gauche nitrogen⁴ we demonstrate a form of polymeric nitrogen at low pressure that may be directly related to amorphous polymeric nitrogen.

1:15PM B25.00009 ABSTRACT WITHDRAWN —

1:27PM B25.00010 Ethane and Xenon mixing: density functional theory (DFT) simulations and experiments on Sandia's Z machine, RUDOLPH MAGYAR, SETH ROOT, THOMAS MATTSSON, KYLE COCHRANE, Sandia National Laboratories — The combination of ethane and xenon is one of the simplest binary mixtures in which bond breaking is expected to play a role under shock conditions. At cryogenic conditions, xenon is often understood to mix with alkanes such as Ethane as if it were also an alkane, but this model is expected to break down at higher temperatures and pressures. To investigate the breakdown, we have performed density functional theory (DFT) calculations on several xenon/ethane mixtures. Additionally, we have performed shock compression experiments on Xenon-Ethane using the Sandia Z - accelerator. The DFT and experimental results are compared to hydrodynamic simulations using different mixing models in the equation of state. Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a wholly owned subsidiary of the Lockheed Martin company, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

1:39PM B25.00011 Dynamic Response of a Carbon Fiber – Epoxy Composite, SCOTT ALEXANDER¹, WILLIAM REINHART, Sandia National Laboratories — The dynamic response of carbon fiber reinforced epoxy composite materials was investigated under planar impact loading. The samples were unidirectional (all carbon fibers oriented in a single direction) with fiber fill volumes from 62 to 68%. Gun driven planar impact tests with impact velocities of 0.1-2.0 km/s were conducted allowing samples to be compressed up to about 15 GPa. Velocity interferometry was used to measure particle velocities from which the compressed state of the samples was determined. Wave speeds for shocks traveling along the carbon fibers are significantly higher than for those traveling transverse to the fibers or through the bulk epoxy. As a result, the dynamic material response is dependent on the relative shock - fiber orientation. Shocks traveling along the fiber direction exhibit both elastic and plastic characteristics over the stress range tested. Shocks traveling transverse to the fibers show only a single wave response similar to but slightly stiffer than the bulk response of the epoxy. Results will be presented detailing these findings which provide a basis for modeling this class of directional composite materials.

¹Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin company, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL8

1:51PM B25.00012 Calculation of Transport Coefficients in Binary Yukawa Mixtures¹, TOMORR HAXHIMALI, ROBERT RUDD, Lawrence Livermore National Laboratory — We employ classical molecular dynamics (MD) to estimate species diffusivity and viscosity in binary Yukawa Mixtures. The Yukawa potential is used to describe the screened Coulomb interaction between the ions, providing the basis for models of dense stellar materials, inertial confined plasmas, and colloidal particles in electrolytes. We calculate transport coefficients in equilibrium simulations using the Green-Kubo relation over a range of thermodynamic conditions including the viscosity and the self-diffusivity for each component of the mixture. The inter-diffusivity (or mutual diffusivity) can then be related to the self-diffusivities by using a generalization of the Darken equation. We have also employed non-equilibrium MD to estimate inter-diffusivity during the broadening of the interface between two regions each with a high concentration of either species. The main motivation in this work is to build a model that describes the transport coefficients in binary Yukawa mixtures over a broad range of thermodynamic conditions.

¹This work was performed under the auspices of the US Dept. of Energy by Lawrence Livermore National Security, LLC under Contract DE-AC52-07NA27344.

2:03PM B25.00013 Fracture of Constructional Materials with the Covering at Shock-Wave Loadings, PAVEL RADCHENKO, Institute of Strength Physics and Materials Science SB RAS, Russia, ANDREY RADCHENKO, Tomsk State University of Architecture and Building, Russia — The behavior of constructional materials with a covering subjected to shock load is numerically modeled. The covering on a material is applied by the method of high velocity oxygen fuel. The materials created by a similar method, are widely applied in aerospace branch, both for creation of engines and for creation of details of cases. Possibility of application of multilayered coverings essentially expands the spectrum of researches for the analysis of separate layer influence on behavior of a design as a whole. Features of behavior of this sort of materials is an actual problem as well as construction of authentic models of behavior of materials with coverings as a whole. Influence of a material of a covering, quantity of layers and their geometrical parameters on fracture and shock-wave processes in a material is investigated. The range of velocities of interaction from 50 to 2000m/sec is considered. As projectiles steel cylinders and spheres were used.

Session B26 DCOMP DMP: Focus Session: Physics of Energy Storage Materials - Advanced Materials 257B

11:15AM B26.00001 How can one tell if a lithium-ion battery will last for 10 years in experiments that only take a few weeks?¹, JEFF DAHN, Dalhousie University — Lithium-ion batteries are now being used in electric vehicles. There are four main factors which will determine the success of Li-ion batteries in this application: a) safety; b) cost; c) performance and d) lifetime. Each of the factors is presently the subject of much debate and much R+D. I will only speak about lifetime here. Testing the lifetime of Li-ion batteries for automotive applications under **realistic** conditions of temperature and number of cycles per day is very time consuming. In fact, such a test should take a decade or more, if the batteries are expected to last a decade in the field. Tests of such duration slow the product improvement cycle immensely. In this lecture, I will discuss how high precision measurements of the coulombic efficiency of Li-ion cells and batteries can be used to predict the relative lifetimes, on the decade-long scale, of these devices in measurements that only take a few weeks. The measurements enable the rapid comparison of technologies using new electrode materials, electrolyte additives and cell designs so that the product improvement cycle can be significantly shortened. I will describe the requirements of the instruments needed to make these measurements and point out that nothing suitable is, as yet, commercially available. There is a major need for such equipment and an associated business opportunity.

¹In collaboration with Chris Burns, Aaron Smith, Nupur Sinha, and Hannah Dahn, Dalhousie University.

11:51AM B26.00002 Organic electrodes for high rate capability Lithium-ion batteries, Y.Y. ZHANG, Y.Y. SUN, Rensselaer Polytechnic Institute, S.X. DU, H.J. GAO, Institute of Physics, Chinese Academy of Sciences, S.B. ZHANG, Rensselaer Polytechnic Institute — Lithium-ion batteries (LIBs) for power-intensive applications such as in electric vehicles require high discharge rate, i.e., high Li diffusion rate (or low Li diffusion barrier) in electrode and electrolyte materials. Based on first-principles calculations, we found that organic salt, di-lithium terephthalate (Li2TPA), a promising anode material recently tested in experiment, could have high rate capability. We further predict that di-potassium terephthalate (K2TPA) could exhibit even lower Li diffusion barrier. The calculated Li diffusion barrier in fully lithiated K2TPA is only 150 meV, which yields Li diffusion rate orders of magnitude higher than that in Li-intercalated graphite at room temperature. The calculated anode voltage vs metal lithium and specific energy density are 0.62 V and 209 mAh/g, respectively. In addition, the volume change of K2TPA in charging/discharging is only 5%, much smaller than that in Li-intercalated graphite. These unique advantages call for further investigation of the organic salts, both the TPA-based and beyond, for power-intensive LIB applications either as anode or cathode materials.

12:03PM B26.00003 First Principles Study for Lithium Intercalation and Diffusion Behavior in Orthorhombic Nb2O5 Electrochemical Supercapacitor, CHI-PING LIU, FEI ZHOU, VIDVUDS OZOLINS, University of California, Los Angeles — Unlike batteries, electrochemical supercapacitors require not only high energy density, but also very fast rates of electronic and ionic transport. Experimental results show that niobium oxide exhibits an outstanding power density and fast ionic charging rates. We investigate lithium intercalation and diffusion behavior in orthorhombic niobium oxide (T-Nb2O5) by using first-principles density-functional theory (DFT) calculations. We find that the Li ions can only intercalate in the 001 family of lattice planes with the lowest niobium occupancy due to electrostatic-repulsion between Li+ and Nb5+. Besides, since Li diffusion along the z direction is hindered by a high diffusion barrier (2.64 eV), the overall Li intercalation and diffusion can only occur within 001 planes. Furthermore, the diffusion barriers within the 001 planes are found to have a broad distribution of values from around 50 meV to 1000 meV; the diffusion barrier is determined by the neighboring oxygen-oxygen distance. The barrier remains low (around 60 meV) when the neighboring oxygen distance along the diffusion path is larger than 3.9 Å, thus leading to fast Li ion diffusion. These results explain the excellent performance of Nb2O5 as a cathode material for electrochemical supercapacitors.

12:15PM B26.00004 Multiscale Simulations of Energy Storage in Polymers, V. RANJAN, NC State University, Raleigh, A. VAN DUIN, Penn State University, State College, M. BUONGIORNO NARDELLI, J. BERNHOLC, NC State University, Raleigh and ORNL, Oak Ridge, TN — Polypropylene is the most used capacitor dielectric for high energy density storage. However, exotic materials such as copolymerized PVDF and, more recently, polythiourea, could potentially lead to an order of magnitude increase in the stored energy density [1,2]. In our previous investigations we demonstrated that PVDF-CTFE possesses non-linear dielectric properties under applied electric field. These are characterized by transitions from non-polar to polar phases that lead enhanced energy density. Recent experiments [3] have also suggested that polythiourea may be another potential system with high energy-density storage and low loss. However, the characteristics of this emerging material are not yet understood and even its preferred crystalline phases are not known. We have developed a multiscale approach to predicting polymer self-organization using the REAX force field and molecular dynamics simulations. We find that polythiourea chains tend to coalesce in nanoribbon-type structures and prefer an anti-polar interchain ordering similar to PVDF. These results suggest a possible role of topological phase transitions in shaping energy storage in this system.

12:27PM B26.00005 Addressing the challenges of solar thermal fuels via atomic-scale computational design and experiment, ALEXIE KOLPAK, TIMOTHY KUCHARSKI, JEFFREY GROSSMAN, Massachusetts Institute of Technology — By reversibly storing solar energy in the conformations of photo-isomers, solar thermal fuels (STFs) provide a mechanism for emissions-free, renewable energy storage and conversion in a single system. Development of STFs as a large-scale energy technology has been hampered by technical challenges that beset the photo-isomers of interest: low energy density, storage lifetime, and quantum yield; UV absorption; and irreversible degradation upon repeated cycling. In this talk, we discuss our efforts to design new STFs that overcome these hurdles. We present computational results on various STFs based on our recently proposed photo-isomer/template STF concept [Kolpak and Grossman, Nano Letters 11, 3156 (2011)], as well as new experimental results on azobenzene-functionalized carbon nanotube STFs. Our approach yields significant improvements with respect to STFs studied in the past, with energy densities similar to Li-ion batteries, storage lifetimes > 1 year, and increased quantum yield and absorption efficiency. Our strategy also suggests mechanisms for inhibiting photo-isomer degradation. With a large phase space yet to be explored, there remain numerous possibilities for property enhancement, suggesting that STFs could become a competitive renewable energy technology.

12:39PM B26.00006 Photoswitchable Molecular Rings for Solar-Thermal Energy Storage, ENGİN DURGUN, ALEXIE M. KOLPAK, JEFFREY C. GROSSMAN, Massachusetts Institute of Technology — Solar-thermal fuels reversibly store solar energy in the chemical bonds of molecules by photoconversion, and can release this stored energy in the form of heat upon activation. Many conventional photoswitchable molecules could be considered as solar thermal fuels, although they suffer from low energy density and short lifetime in the photo-excited state, rendering their practical use unfeasible. We present a new approach to design systems for solar thermal fuel applications, wherein well-known photoswitchable molecules are connected by different linker agents to form molecular rings. This approach allows for a significant increase in both the amount of stored energy per molecule and the stability of the fuels. Our results suggest a range of possibilities for tuning the energy density and thermal stability as a function of the type of the photoswitchable molecule, the ring size, and/or the type of linkers.

12:51PM B26.00007 Physics of Materials for Sodium-Ion Batteries, JAY WHITACRE, Carnegie Mellon University — Sodium is used as a functional ionic species in a variety of electrochemical energy storage devices. This talk will examine several manifestations of sodium ion use, and will focus deeply on a novel class of aqueous electrolyte sodium ion batteries that have been developed over the past 5 years. While these new systems are typically lower in energy density, they are very robust and low in cost, making them appealing for a number of stationary energy storage applications. Specific topics to be covered include: sodium ion intercalation compounds, sodium/carbon interaction at potentials below 0V vs NHE, the behavior of porous thick electrodes in different electrolyte solutions, and the future outlook for sodium ion battery research.

1:27PM B26.00008 Computational studies of carbon-onions for electrochemical capacitor applications, P. GANESH, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, P.R.C. KENT, Center for Nanophase Materials Sciences and Computer Science and Mathematics Division, V. MOCHALIN, Department of Materials Science and Engineering, Drexel University, LUKAS VLCEK, Chemical Sciences Division, Oak Ridge National Laboratory Oak Ridge, ADRI VAN DUIN, Department of Mechanical and Chemical Engineering, Penn State University — Supercapacitors bridge the gap between conventional batteries and electrolytic capacitors. Recently, onion-like carbon structures have [1] shown to have capacitances four orders of magnitude higher and energies an order of magnitude higher than conventional capacitors, making them the fastest growing competitors for energy storage. We study the formation of carbon-onions from nanodiamonds using reactive force-fields [2]. Our study suggests that the temperature and mechanical stability as well as the final-equilibrium structure are strongly dependent on the inclusion of long-range forces. We are currently developing reactive-force fields to allow mesoscopic modeling of reactions of carbon nanostructures with aqueous electrolytes. Progress along these lines will also be presented. This material is based upon work supported as part of the Fluid Interface Reactions, Structures and Transport (FIRST) Center, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences.

1:39PM B26.00009 Supercapacitor Electrodes with High-energy and power densities prepared from monolithic NiO/Ni Nanocomposite¹, QI LU, University of Delaware — Despite significant progresses in the development for high-performance supercapacitors, it lacks techniques to realize the full potential of electrode material by achieving simultaneously tailored pore structure, electrode conductivity, and crystallinity. Moreover, the problem of being difficult for industrial scale manufacture still exists. For an attempt to address all these issues, we recently developed a simple and cost-effective process, which is also scalable, for achieving supercapacitor electrodes with both high energy and power densities. We first produce nickel nanoparticles with a modified polyol method. A simple mechanical compaction of nanoparticles and a followed thermal treatment result in compact, stable, highly porous Ni/NiO electrodes that do not require a support. During the charging process, OH⁻ electrolytic ions are bound to the NiO, giving off electrons. The process is reversed when the stored electrical energy is drawn off as current. The high granularity NiO provides a large inner surface area, and the conductive network of the metal particles is maintained. High energy density of about 60 Wh kg⁻¹ and power density of 10 kW kg⁻¹ were simultaneous achieved with a slow charge/fast discharge process.

1:51PM B26.00010 An ab-initio approach to modeling high temperature thermodynamics of non stoichiometric ceria, CHIRANJEEVI BALAJI GOPAL, AXEL VAN DE WALLE, None — Ceria is a very promising material for fuel cell electrolytes because of its high oxygen ion diffusivity. Also, its ability to thermodynamically create oxygen vacancies in its structure at high temperatures and get oxidized at low temperatures has found use in thermochemical splitting of water to generate hydrogen. Although the experimental phase diagram for ceria is well established in the composition of interest, there have not been significant attempts at studying the oxygen vacancy thermodynamics at elevated temperatures from first principles. We performed GGA+*U* calculations ceria to study the electronic structure and ground state energies of various concentrations and configurations of oxygen vacancies in ceria. The energies are then fitted to a Cluster expansion Hamiltonian to efficiently model the interactions between the different species: Ce³⁺, Ce⁴⁺, O²⁻ and oxygen vacancies. Lattice Monte Carlo simulations are then performed to obtain the free energy as a function of temperature and oxygen chemical potential through thermodynamic integration. We are also investigating the effect of lattice vibrational contribution to the phase diagram by including a temperature dependent cluster expansion.

2:03PM B26.00011 Defect-Induced Segregation and Lattice Stability of BSCF Perovskites¹, MAIJA KUKLJA, ONISE SHARIA, Materials Science and Engineering Department, University of Maryland, College Park, MD, USA, YURI MASTRIKOV, Institute for Solid State Physics, University of Latvia, Kengaraga str. 8, Riga LV-1063, Latvia, EUGENE KOTOMIN, Max Planck Institute for Solid State Research, Heisenbergstr., 1, D-70569, Stuttgart, Germany — Among novel advanced materials for clean energy, Ba_xSr_{1-x}Co_{1-y}Fe_yO_{3-δ} (BSCF) are considered as promising materials for cathodes in solid oxide fuel cells (SOFC) and oxygen permeation membranes. BSCF exhibits a good oxygen exchange performance, mixed ionic and electronic conductivity, high oxygen vacancy concentration, and low diffusion activation barrier, which largely define the oxygen reduction chemistry. However, understanding the interplay between the structural disorder and crystalline stability in BSCF is extraordinarily complex and essentially unexplored. We present first principles calculations of an ideal BSCF crystal and the crystal containing point defects, Frenkel and Schottky disorders, cation and antisite exchanges, and a set of relevant solid-solid solutions. We discuss possible mechanisms of defect-induced (in)stability, solid-state decomposition reactions, and phase transitions of the BSCF lattice as a function of oxygen vacancy concentration for cubic and hexagonal BSCF in the context of available experiments. This research explains the observed SOFC performance reduction and provides insights on enhancing energy conversion.

Session B27 DCMP: Invited Session: Magneto-Electric and Magneto-Optical Properties of Topological Insulators 258AB

11:15AM B27.00001 Magneto-Optical Properties of Electrically Gated Topological Insulators¹

, DENNIS DREW, CNAM, Physics Department, University of Maryland — Topological insulators (TI) are a predicted new quantum state of matter in which spin-orbit coupling gives rise to topologically protected surface states with unpaired spin-helical Dirac cones. TIs are predicted to have exotic properties including Majorana fermions induced by the proximity effect from a superconducting film, an intrinsic magnetoelectric effect and hybridized spin-plasmon modes. The magneto-electric effect leads to Faraday and Kerr rotations quantized in units of the fine structure constant. This effect corresponds to $1/2$ integer quantum Hall step and is predicted both in field and in the absence of a magnetic field when magnetic order gaps the Dirac spectrum. A key difference between this half integer QHE in TIs and the usual integer QHE is that the former cannot be measured by a dc transport experiment. I will describe experiments designed to measure the Kerr rotation in Bi₂Se₃, one example of a topological insulator. Gating the surface isolates the surface response from the bulk signals due to unavoidable bulk carriers from defects and impurities. Preliminary results will be presented on the surface state Kerr rotation for Bi₂Se₃ doped with Mg (ungapped) and Bi₂Se₃ doped with Sm (magnetically gapped).

11:51AM B27.00002 Magneto-Electric Effect in Three-Dimensional Topological Insulators from Surface Magnetic Disorder and Ferromagnetic Thin Film

, KENTARO NOMURA, Institute for Materials Research, Tohoku Univdsity — Topologically nontrivial gapped phases can be characterized by the bulk topological indices and the surface gapless modes. The topological magneto-electric (ME) effect is a novel manifestation of the bulk-surface correspondence in which the bulk magnetization is generated by a circulating quantized Hall current flowing at the surface of topological insulators. To realize the topological ME effect, there are two difficulties: (a) one needs to attach an insulating ferromagnetic layer with the magnetization normal to the surface all pointing out or in. (b) The Fermi energy must be tuned accurately within the small gap of the surface Dirac spectrum opened by the exchange interaction. In this talk we discuss the anomalous quantized Hall current on the surface of a magnetically doped topological insulator, basing on the two-dimensional surface Dirac Hamiltonian with magnetic disorder. The scaling analysis indicates that, in sharp contrast to the time-reversal-invariant cases, the all surface states tend to be localized while the Hall conductivity is quantized no matter whether the Fermi level resides within or out of the surface gap. This resolves problem(b). Furthermore it is shown that this also resolves problem (a) with the simultaneous application of magnetic and electric fields parallel or antiparallel to each other. By this method, doped local spins can be controlled by the bulk energy which can overcome the magnetic anisotropy and Zeeman splitting at the surface. We also comment on the generalization of the topological responses to the case of topological superconductors and superfluids. This work was done in collaboration with Naoto Nagaosa, Shinsei Ryu, and Akira Furusaki. K. Nomura and N. Nagaosa, Phys. Rev. Lett. 106, 166802 (2011); K. Nomura, S. Ryu, A. Furusaki, N. Nagaosa, arXiv:1108.5054.

12:27PM B27.00003 Scotch Tape and Spectroscopy, Probing and Manipulating the surface of a Topological Insulator¹

, KENNETH BURCH, Department of Physics and Institute of Optical Sciences, U. of Toronto — Recently there has been a great deal of interest in studying the surfaces of materials with topologically non-trivial electronic states. In addition to probing the surfaces of topological insulators it is highly desirable to put them in proximity with other materials (ferromagnets and superconductors) to induce new particles such as Majoranna Fermions. I will discuss our groups efforts to study these materials using mechanical exfoliation and a variety of spectroscopic techniques (Raman, IR and tunneling). In addition I will detail a new method we have devised that enables us to produce high temperature superconductivity in a topological insulator via the proximity effect.

¹This work was supported by NSERC,CFI,NSF and ORF

1:03PM B27.00004 Giant terahertz Faraday rotation in graphene

, ALEXEY KUZMENKO, University of Geneva — The Faraday rotation of the polarization of light in a medium, where the time-reversal symmetry is broken due to external magnetic field, is an optical analogue of the Hall effect. We recently demonstrated that graphene, the thinnest existing material, can turn the polarization of terahertz radiation by several degrees in modest magnetic fields, which is a spectacular manifestation of the cyclotron resonance. In this talk I will review our Faraday rotation spectroscopy studies of single-layer and twisted multilayer epitaxial graphene with an emphasis on the physical information that one can extract from these measurements and potential applications.

1:39PM B27.00005 Ultrafast Probing of Dynamical Spin-Charge Coupling in Topological Insulators¹

, NUH GEDIK, MIT — The three-dimensional topological insulator (TI) is a new quantum phase of matter that exhibits quantum-Hall-like properties, even in the absence of an external magnetic field. Charge carriers on the surface of a TI behave like a two-dimensional gas of massless helical Dirac fermions for which the spin is ideally locked perpendicular to the momentum. In this talk, I will discuss recent experiments in which we used the angular momentum of circularly polarized ultrafast laser pulses to directly visualize and manipulate the spin-charge coupling in TIs. By using laser pulses in the UV region, we performed novel time of flight based angle-resolved photoemission spectroscopy that enabled simultaneously mapping all three components of spin over the entire Dirac cone of a TI. We find that an idealized description of helical Dirac fermions only applies within a small energy window about the Dirac point, beyond which strong textural deformations occur. Utilizing the pump-probe technique, we selectively obtained time-resolved dynamics of surface and bulk excitations. By using circularly polarized laser pulses in the optical region, we achieved preferential excitation of spin species on one side of the surface Dirac cone, resulting in a charge imbalance in momentum space and thus causing a current flow with a direction dependent on photon helicity.

Monday, February 27, 2012 11:15AM - 2:15PM —

Session B28 DMP: Focus Session: Dopants and Defects in Semiconductors - Nitrides 258C

11:15AM B28.00001 Optical signatures of defects in nitride semiconductors

, ANDREW ARMSTRONG, Sandia National Laboratories — Despite successful commercialization of GaN-based light emitting diodes (LEDs) and high frequency transistors, crystal defects continue to have a strong and often undesired impact on the opto-electronic properties of the III-Nitride family of materials. Fully realizing the potential of this fascinating materials system requires a better understanding of the physical origin of defects, their dependence on both substrate quality and epitaxial growth conditions, and their influence on electrical and optical properties. This talk will discuss the use of deep level optical spectroscopy (DLOS) to quantitatively study defect states in GaN-based materials. As a photocapacitance technique, DLOS is able to probe defect levels that are otherwise inaccessible to thermally-stimulated defect spectroscopies in wide band gap materials, such as the III-Nitrides. DLOS quantifies both the energy level and density of defects and probes defect states with nanoscale depth resolution. Beyond the canonical application of DLOS to thin films, this talk will describe new developments of DLOS to quantitatively study defect states in a wide variety of structures with nanoscale dimensionality, including InGa_N/GaN multi-quantum wells and AlGa_N/GaN core-shell nanowires. The microscopic origin of observed defect states and their influence on the electrical and optical properties of GaN-based LEDs and nanowire devices will be discussed. The reported studies establish DLOS as a critical technique for nanoscale dimensional defect metrology that is able to advance the development of conventional and emerging opto-electronic devices.

11:51AM B28.00002 Shallow versus deep nature of Mg acceptors in nitride semiconductors¹, JOHN LYONS, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara — Although Mg doping is the only known method for achieving p-type conductivity in nitride semiconductors, Mg is not a perfect acceptor. Hydrogen is known to passivate the Mg acceptor, necessitating a post-growth anneal for acceptor activation. Furthermore, the acceptor ionization energy of Mg is relatively large (200 meV) in GaN, thus only a few percent of Mg acceptors are ionized at room temperature. Surprisingly, despite the importance of this impurity, open questions remain regarding the nature of the acceptor. Optical and magnetic resonance measurements on Mg-doped GaN indicate intriguing and complex behavior that depends on the growth, doping level, and thermal treatment of the samples. Motivated by these studies, we have revisited this topic by performing first-principles calculations based on a hybrid functional. We investigate the electrical and optical properties of the isolated Mg acceptor and its complexes with hydrogen in GaN, InN, and AlN. With the help of these advanced techniques we explain the deep or shallow nature of the Mg acceptor and its relation to optical signals often seen in Mg-doped GaN. We also explore the properties of the Mg acceptor in InN and AlN, allowing predictions of the behavior of the Mg dopant in ternary nitride alloys.

¹This work was supported by NSF and by the Solid State Lighting and Energy Center at UCSB.

12:03PM B28.00003 Effect of Doping Profile and Concentration on the Near-Infrared Optical Properties of AlGaIn/GaN and AlInN/GaN Heterostructures, MAYRA CERVANTES, COLIN EDMUNDS, DONGHUI LI, LIANG TANG, JIAYI SHAO, GEOFF GARDNER, MICHAEL MANFRA, OANA MALIS, Purdue University — Intersubband (ISB) devices utilizing III-nitrides have recently attracted attention for near- and far- infrared optoelectronic applications. In order to achieve efficient ISB transitions, large doping densities are typically required ($>10^{18} \text{ cm}^{-3}$). The large impurity density has significant effects on the band structure and material quality, effects that are reflected in important device parameters such as transition energies and linewidths. To determine the optimal doping concentration and profile for III-N intersubband devices, we carried out a systematic study of optical and structural properties of strained AlGaIn/GaN and lattice-matched AlInN/GaN heterostructures grown by MBE on quasi-bulk GaN substrates. The lattice-matched AlInN/GaN system is targeted because it allows growth of thick strain-free materials. However, it also presents some considerable growth challenges due to the vastly different optimal growth conditions for Al and In containing nitrides. The transition energy and line profile were determined by direct and photoinduced absorption measurements, while the material quality was assessed using TEM and high resolution x-ray diffraction. The FWHM of the ISB transition at $1.9 \mu\text{m}$ was found to vary up to 60% with the position of delta doping in the quantum well.

12:15PM B28.00004 Field-enhanced vacancy diffusion in AlGaIn¹, KEITH H. WARNICK, YEVGENIY PUZYREV, Dept. of Physics and Astronomy, Vanderbilt University, TANIA ROY, Dept. of Electrical Engineering and Computer Science, Vanderbilt University, DANIEL M. FLEETWOOD, Dept. of Electrical Engineering and Computer Science, Dept. of Physics and Astronomy, Vanderbilt University, RONALD D. SCHRIMPF, Dept. of Electrical Engineering and Computer Science, Vanderbilt University, SOKRATES T. PANTELIDES, Dept. of Physics and Astronomy, Vanderbilt University; Materials Science and Technology Division, Oak Ridge National Laboratory — Room-temperature (RT) native defect diffusion does not generally occur in semiconductors because of high activation energies ($>1.5 \text{ eV}$). However, recent observations of plastic deformation in AlGaIn/GaN High Electron Mobility Transistors (HEMTs) have been attributed to diffusive processes. Here we report first-principles density-functional calculations of the formation and migration energies of vacancies, including the effect of strain and electric fields. We find that triply-negatively charged cation vacancies are the enablers of self-diffusion, as follows: though strain alone is insufficient, we find significant activation barrier lowering due to the applied electric field acting on charged vacancies, reducing cation vacancy barriers in AlGaIn to $\sim 1 \text{ eV}$ or lower where RT diffusion becomes significant. The described mechanism of electric field enhanced vacancy diffusion is relevant for other materials, including several oxides that also feature charged vacancies with low formation energy.

¹This work was supported in part by ONR MURI grant N-00014-08-1-0655 and by the McMinn Endowment at Vanderbilt University.

12:27PM B28.00005 Role of native defects and related complexes in absorption and luminescence of AlN¹, QIMIN YAN, ANDERSON JANOTTI, Materials Department, University of California at Santa Barbara, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, CHRIS G. VAN DE WALLE, Materials Department, University of California at Santa Barbara — AlN is a wide-band-gap material that has been considered as a substrate for GaN-based optoelectronic devices, or in its own right for deep ultraviolet light-emitting diodes and laser diodes. The band gap of 6.2 eV in principle allows transparency in the visible to UV range, but in practice AlN crystals exhibit several sub-band-gap absorption and emission bands, likely due to the presence of native defects and impurities (the most common being oxygen). Using first-principles calculations with the screened hybrid functional of Heyd, Scuseria, and Ernzerhof (HSE), we investigate the structural, electronic, and optical, properties of N and Al vacancies, and their complexes with O impurities in AlN. Defect charge transition levels and stable charge states are determined from the calculated formation energies, and absorption and emission energies are obtained by constructing configuration coordinate diagrams. Our results indicate that Al vacancies and O impurities are responsible for several absorption/emission lines observed experimentally, in particular for the absorption band around 2.85 eV (which gives AlN crystals a yellowish color) and the emission around 3.20 eV emission (375 nm), often observed in O-doped AlN. Mechanisms for each of these processes will be discussed in detail.

¹This work was supported by NSF and by the UCSB SSLEC.

12:39PM B28.00006 Effective mass calculations for shallow acceptors in nitrides¹, JACOB EMMERT-ARONSON, W.R.L. LAMBRECHT, CWRU — In the effective mass approximation for shallow acceptors in semiconductors, the defect eigenstates are written as a product of a slowly varying envelope function and the band extrema Bloch functions. The Kohn-Luttinger Hamiltonian describing the valence band manifold in zincblende, or its generalization for other crystals structures, then becomes a set of coupled differential equations for the envelope function. These can be solved by a variational approach with hydrogenic type basis functions. We have implemented this approach for the appropriate Hamiltonians for zincblende, wurtzite and an orthorhombic crystal structure occurring for II-IV-N₂ semiconductors. The Hamiltonian parameters used were extracted from first-principles GW calculations. The central cell correction to the Coulomb potential was added based on pseudopotential differences as proposed by Mireles and Ulloa (Phys. Rev. B 58, 3879 (1998)). Results are presented for various acceptors in GaN, AlN, InN, ZnGeN₂ and ZnSnS₂. The effects of varying the crystal field splitting parameter, and the type of pseudopotentials (including or not semicore d-states) were investigated.

¹Supported by SOURCE at CWRU

12:51PM B28.00007 Evidence for mobile electrons in p-type GaN:Mg¹, MARY ELLEN ZVANUT, WILLIAM WILLOUGHBY, University of Alabama at Birmingham — Although Mg-doping is the only successful means of achieving p-type conductivity in GaN, little is known about the local environment of the impurity. Our work focuses on a unique phenomena revealed in the electron paramagnetic resonance (EPR) spectrum attributed to Mg: an angular dependent line-shape suggesting the presence of free carriers. 10 GHz EPR measurements were made at 4 K with the magnetic field in the plane of the c-axis. Samples included 0.5 – 1.5 μm thick Mg-doped GaN films grown on sapphire by molecular beam epitaxy or chemical vapor deposition. As expected, the angular dependence of the g value reflects axial symmetry. Unexpected is the line shape change from pure Lorentzian with the magnetic field 30° from the c-axis to increasingly Dysonian upon rotation. The latter reflects the presence of mobile carriers due to, for instance, an interfacial conducting layer, polarization charge, or loosely bound electrons from Ga near neighbors. The new EPR analysis suggests local fields surround the Mg impurity which influence the acceptor's response.

¹Samples were grown at Ga Tech, Sandia National Lab, and Duke University. The work is supported by NSF.

1:03PM B28.00008 A Combined Excitation Experiment and the Emission Nature of Eu in GaN, JONATHAN POPLAWSKY, Physics Department, Lehigh University, ATSUSHI NISHIKAWA, YASUFUMI FUJIWARA, Division of Materials and Manufacturing Sciences, Osaka University, VOLKMAR DIEROLF, Physics Department, Lehigh University — We have developed a fiber based confocal optical microscope that operates inside of a commercial SEM instrument (JEOL 6400) enabling the excitation of a sample either by a laser or by electron beam, and hence combining the complimentary techniques of photoluminescence (PL) and cathodoluminescence (CL). The capabilities of the instrument are demonstrated by experiments involving the excitation of europium ions in-situ doped in Mg doped GaN thin films. The combination of the Eu and Mg defect create new optically active centers (Eu/Mg centers) that absorb energy from electron-hole pairs (EHP) more efficiently than the normal Eu centers in non co-doped GaN (Eu centers). However, the luminescence from these centers decrease as a function of EHP exposure time. The instrument used enables us to perform PL studies before and after electron beam exposure to investigate the nature of this effect. We use a below band gap PL excitation source tuned to resonantly excite the Eu centers using their ⁷F₀ to ⁵D₀ transitions. This allows us to determine their relative numbers and monitor changes of each of the relevant centers. Utilizing these data, the nature of the decrease in emission is investigated with our new and unique experimental apparatus.

1:15PM B28.00009 Magneto-Optical Studies of Rare Earth Doped III-V Nitrides, BRANDON MITCHELL, NATHANIEL WOODWARD, JONATHAN POPLAWSKY, VOLKMAR DIEROLF, Lehigh University, H.X. JIANG, Texas Tech Institute — We investigated the site selective optical and magneto-optical properties of Neodymium doped Gallium and Aluminum Nitride and Erbium doped Gallium Nitride. For our current study, we applied magnetic fields parallel and antiparallel to the C-axis of the crystals and observed the resulting Zeeman splitting both in excitation and emission transitions. On the basis of these measurements, we determined the effective g-factors of all the states involved in the Nd³⁺ transitions. For erbium doping, we observed the Zeeman splitting of the ⁴I_{13/2} and ⁴I_{15/2} levels. Due to small crystal field splitting and large Zeeman splitting, the assignment of levels and corresponding g-factors is very complex. In addition, we observed unexpected asymmetries in the emission intensities when we compared the spectra obtained for fields parallel and antiparallel to the growth direction. The degree of this asymmetry depends on the substrate material and is unambiguously related to the strain and resulting internal fields that are induced by lattice mismatch. The asymmetry behavior parallels the ferromagnetic behavior that is induced by the rare earth ions in GaN and hence our observation suggests that magnetization can be controlled by strain.

1:27PM B28.00010 Origins of Persistent Photoconductivity in Highly Mismatched Semiconductor Alloys, R.L. FIELD III, Department of Physics, University of Michigan, G. VARDAR, Department of Materials Science and Engineering, University of Michigan, Y. JIN, Department of Physics, University of Michigan, T. DANNECKER, Tyndall National Institute, University College Cork, Y.Q. WANG, Materials Science and Technology Division, Los Alamos National Laboratory, C. KURDAK, Department of Physics, University of Michigan, R.S. GOLDMAN, Department of Materials Science and Engineering, University of Michigan — Persistent photoconductivity (PPC) is a nonequilibrium phenomenon in which an illumination-induced increase in conductivity of a semiconductor persists following the termination of illumination. The PPC effect has been explained in terms of the large-lattice-relaxation (LLR) model, in which photoexcited carriers are unable to relax to equilibrium due to an energy barrier between shallow donor and deep donor complex (DX) center configurations. To date, an experimental identification of atomistic configurations in support of a model for the PPC effect has yet to be reported. Here, we examine the origins of the PPC effect in GaAsN alloy films, providing the first direct correlation between the concentration of interstitials and the strength of the PPC effect. Thus, the PPC effect in GaAsN is attributed to a change in the bond orientation or a shift in the center of mass of either N-N or N-As pairs. Similar investigations of GaAsBi alloy films will be discussed.

1:39PM B28.00011 Influence of excitation frequency on A₁(LO) and E₂ Raman modes in In rich In_{1-x}Ga_xN thin films, AMBESH DIXIT, Wayne State University (Current IIT Rajasthan, India), J.S. THAKUR, R. NAIK, Wayne State University, V.M. NAIK, University of Michigan-Dearborn — MBE grown In_{1-x}Ga_xN ($x = 0, 0.1, 0.3$ and 0.54) thin films with bandgap energies varying from 0.77 to 1.85 eV have been investigated using Raman spectroscopy with 1.58 and 2.41 eV excitation energies. The carrier mobility for InN film is 900 cm²/V-s and decreases with increasing x with its value being 20 cm²/V-s for In_{0.46}Ga_{0.54}N. We observe a one-mode behavior of the A₁(LO) and E₂ modes. An enhancement in intensity of A₁(LO) and 2A₁(LO) replica modes in In_{1-x}Ga_xN films with bandgap energies close to the excitation energy is observed. For samples with $x > 0$, the A₁(LO) mode shows a higher intensity relative to E₂ mode which indicates a resonant enhancement of the A₁(LO) mode due to Frölich interaction. We find that the energies of longitudinal optical modes (A₁(LO) and 2A₁(LO)) vary nonlinearly, unlike the E₂ mode, with increasing Ga fraction. The width and asymmetry of the A₁(LO) band is higher for the lower excitation energy (1.58 eV). This is perhaps due to the structural disorder in the deeper regions of the films or due to the distribution of regions with different indium fractions. This may explain the lower carrier mobilities observed in In_{1-x}Ga_xN films with higher values of x .

1:51PM B28.00012 Defect and Impurity Properties of Hexagonal Boron-nitride, BING HUANG, SU-HUAI WEI, National Renewable Energy Lab — By using both GGA and hybrid functional calculations, we have systematically calculated the properties of defects and impurity in hexagonal boron-nitride (*h*-BN). Our calculations show that the defect configurations and the local bond lengths around defects are sensitive to their charge states. The possible highest negative charge states of defects are largely determined by the nearly-free-electron state at the conduction band minimum. The in-gap defect levels got from hybrid functional calculations are much deeper than those got from GGA calculations. The formation energies of neutral defects calculated by hybrid functional and GGA are close to each other, but the defect transition energy level between charge states and neutral state respect to valence band maximum are quite different in GGA and hybrid functional calculations. Finally, we show that the charged defect configurations as well as the transition energy levels exhibit interesting layer effects.

2:03PM B28.00013 Non-linear piezoelectric polarization in III-V and nitride semiconductors, PIERRE-YVES PRODHOMME, ANNIE BEYA-WAKATA, GABRIEL BESTER, Max-Planck-Institut für Festkörperforschung — Piezoelectricity can have a large impact on the electronic and optical properties of quantum well and quantum dots based devices such as lasers, light emitting diodes, infrared photodetectors. In particular it has been shown to be important in III-V and nitride semiconductors. The piezoelectric effect in quantum Well or in Quantum Dots is usually taken into account by neglecting the non linear term in the piezoelectric tensor. We have calculated the second order piezoelectric tensor for all the III-V (including the nitrides) semiconductors in the Wurtzite and Zincblende structure. And we have derived a relation between the proper and the improper second order piezoelectric coefficients. This relation is used to calculate the proper coefficients which are the experimentally measurable ones. We have calculated the piezoelectric field in several Quantum wells and compare our values to experiment. We show that the second order can be so large for Zinc-Blende materials that it cancels the first order term, we demonstrate also that for Nitrides this effect is much lower. However we show that for severely strained structure such as quantum dots or thin films, the second order piezoelectric effect can even exceed the spontaneous polarization in the nitrides.

Monday, February 27, 2012 11:15AM - 1:51PM –
Session B29 GQI: Focus Session: Quantum Optics with Superconducting Circuits: Many-Body Physics, Phase Transitions, & Bistability 259A

11:15AM B29.00001 Cavity-Free Photon Blockade Induced by Many-Body Bound States¹, HUAIXIU ZHENG, DANIEL GAUTHIER, HAROLD BARANGER, Duke University — We show theoretically that a variety of strong quantum nonlinear phenomena occur in a completely open one-dimensional waveguide coupled to an N-type four-level system. This system could be realized, for example, in experiments using superconducting circuits. We focus on photon blockade, photon-induced tunneling, bunching or anti-bunching, and the creation of single-photon states, all in the absence of a cavity. Many-body bound states appear due to the strong photon-photon correlation mediated by the four-level system. These bound states cause photon blockade, generating a sub-Poissonian single-photon source [1]. Such a source is crucial for quantum cryptography and distributed quantum networking; our work thus supports the notion that open quantum systems can play a critical role in the manipulation of individual, mobile quanta, a key goal of quantum communication. 11:27AM B29.00002 Experimental investigation of a nonequilibrium delocalization-localization transition of photons in circuit quantum electrodynamics, JAMES RAFTERY, DEVIN UNDERWOOD, WILLIAM SHANKS, SRIKANTH SRINIVASAN, ANTHONY HOFFMAN, HAKAN TURECI, ANDREW HOUCK, Princeton University — Strong photon-qubit coupling in the circuit quantum electrodynamics architecture may lead to quantum phase transitions of light. Recent theoretical and experimental efforts have been made toward examining such quantum phase transitions in large systems; however, interesting crossovers may also exist in significantly smaller and more controllable systems. A sharp nonequilibrium self-trapping transition of light has been predicted in a system comprising two coupled resonators each containing a single qubit. A delocalized regime, where photons coherently oscillate between the two cavities, transitions via dissipation into a localized regime, where photons cannot tunnel. We realized this system experimentally using two capacitively coupled superconducting microwave coplanar waveguides each containing a single transmon qubit. We present our experimental investigation of the system using time and frequency domain measurements to probe its dynamics.

11:39AM B29.00003 Disorder in a Kagome Lattice of Superconducting Coplanar Waveguide Resonators¹, DEVIN UNDERWOOD, WILL SHANKS, ANTHONY HOFFMAN, Department of Electrical Engineering, Princeton University, JENS KOCH, Department of Physics and Astronomy, Northwestern University, ANDREW HOUCK, Department of Electrical Engineering, Princeton University — It has been proposed that arrays of electromagnetic cavities, coupled to two level quantum systems can be used to realize quantum phase transitions of polaritons. One possible experimental realization is a circuit quantum electrodynamics architecture, in which transmon qubits are coupled to superconducting coplanar waveguide resonators (CPWRs); however, for this to be successful, arrays of resonators must be fabricated with low disorder. Results will be reported on characterization of an array of 12 niobium resonators on a sapphire substrate in a honeycomb pattern with the photonic lattice sites forming a Kagome star. These arrays were characterized by measuring many devices of the same design, and using statistical methods for analysis. Furthermore we investigate the origins of disorder, and its dependence on fluctuations in the CPWR geometry.

11:51AM B29.00004 Double symmetry breaking and 2D quantum phase diagram in spin-boson systems, PIERRE NATAF, Laboratoire Maeriaux et Phenomenes Quantiques, Universite Paris Diderot-Paris 7 et CNRS — When the collective coupling between a chain of spins (two-levels systems) and a bosonic mode becomes comparable with the two-level transition frequency, superradiant quantum phase transitions for the cavity vacuum can occur, for instance within the Dicke model [1]. Here, the quantum ground state properties of two independent chains of pseudo-spins interacting with the same bosonic field are investigated [2]. Each chain is coupled to a different quadrature of the field, leading to two independent symmetry breakings for increasing values of the two spin-boson interaction constants. A 2D phase diagram is provided with 4 different phases that can be characterized by the complex bosonic coherence of the ground states and can be manipulated via non-abelian Berry effects. Possible realizations of such model in circuit QED are discussed, generalizing the previous proposals to implement the standard Dicke model [3,4].

12:03PM B29.00005 Quantum hysteresis in coupled qubit-radiation systems¹, O.L. ACEVEDO, F.J. RODRIGUEZ, L. QUIROGA, Universidad de los Andes, N.F. JOHNSON, University of Miami — We study theoretically the dynamical response of a set of solid-state qubits arbitrarily coupled to a radiation field which is confined in a cavity. Driving the coupling strength in round trips, between weak and strong values, we quantify the hysteresis or irreversible quantum dynamics. The matter-radiation system is modeled as a finite-size Dicke model which has previously been used to describe equilibrium (including quantum phase transition) properties of systems such as quantum dots in a microcavity, and superconducting circuit QED. Here we extend this model to address *non-equilibrium* situations. Analyzing the system's quantum fidelity, we find that the near-adiabatic regime exhibits the richest phenomena, with a strong asymmetry in the internal collective dynamics depending on which phase is chosen as the starting point. We identify significant deviations from the conventional Landau-Zener-Stuckelberg formulae, in particular from cycles starting in the superradiant phase. In the diabatic or impulsive regime, the system remains quenched and there is little hysteresis. By contrast, depending on the specifications of the cycle, the radiation subsystem can exhibit the emergence of non-classicality, complexity and sub-Planckian structures as evidenced by its Wigner function.

12:15PM B29.00006 Coupled Qubit-Cavity Arrays: Evolution of resonance with hopping, FELIX NISSEN, University of Cambridge, JONATHAN KEELING, Scottish Universities Physics Alliance, University of St Andrews — Recent experiments on the light-matter interaction in superconducting qubits have sparked interest in the prospect of studying collective behaviour of coupled qubit-cavity arrays. Any such behaviour will necessarily be non-equilibrium, as the photon loss present in real cavities must be compensated by pumping. We study an array of coupled qubit-cavity systems, with the simplest pumping scheme, using a coherent field. Such pumping might be thought to destroy any interesting physics by imposing coherence on the system. Yet we show that the emerging phenomena are remarkably rich, focussing on the evolution from the antiresonance feature known in the Jaynes-Cummings model [1] as one increases hopping strength between the coupled cavities. We study both the coherent field (as can be measured by homodyne detection) and the fluorescence spectrum, comparing numerical simulations to analytic approximations valid in the limits of large and small hopping. The steady state coherent field depends non-monotonically on the hopping strength, as a crossover occurs from polariton blockade physics at small hopping to semiclassical behaviour at large hopping.

12:27PM B29.00007 Superradiant Phase Transitions and the Standard Description of Circuit QED, OLIVER VIEHMANN, JAN VON DELFT, Physics Department, ASC, and CeNS, LMU Munich, FLORIAN MARQUARDT, Institute for Theoretical Physics, FAU Erlangen-Nuremberg — We investigate the equilibrium behavior of a superconducting circuit QED system containing a large number of artificial atoms. It is shown that the currently accepted standard description of circuit QED via an effective model fails in an important aspect: it predicts the possibility of a superradiant phase transition, even though a full microscopic treatment reveals that a no-go theorem for such phase transitions known from cavity QED applies to circuit QED systems as well. We generalize the no-go theorem to the case of (artificial) atoms with many energy levels and thus make it more applicable for realistic cavity or circuit QED systems.

12:39PM B29.00008 Photon thermalization and condensation in circuit QED by engineered dissipation, DAVID MARCOS, ANDREA TOMADIN, Institute for Quantum Optics and Quantum Information of the Austrian Academy of Sciences, SEBASTIAN DIEHL, Institute for Theoretical Physics, University of Innsbruck, PETER RABL, PETER ZOLLER, Institute for Quantum Optics and Quantum Information of the Austrian Academy of Sciences — The ability to engineer the coupling between a quantum system and its environment opens the possibility to dissipatively prepare entangled and quantum many-body states. Of particular interest is the case in which the system undergoes a phase transition driven by the coupling to a reservoir. Here we show how to engineer dissipation in the context of coupled cavity arrays, and more specifically in circuit QED. We propose an implementation based on coupled LC resonators and superconducting qubits, which under asymmetric coherent driving, leads to thermalization of photons to the symmetric state between neighboring sites. Above a critical threshold of the driving intensity, a macroscopic occupation of this symmetric mode is found.

12:51PM B29.00009 Stabilizing manifolds of quantum states by reservoir engineering¹, ZAKI LEGHTAS, INRIA Paris-Rocquencourt, KURTIS GEERLINGS, SHYAM SHANKAR, Applied Physics Dept. Yale University, MAZYAR MIRRAHIMI, INRIA Paris-Rocquencourt, MICHEL DEVORET, Applied Physics Dept. Yale University, QLAB TEAM, SISYPHE TEAM — We consider the problem of stabilizing a manifold of states by reservoir engineering. Qubits are coupled to resonators in the strong dispersive limit for which the dispersive shift is much larger than the cavity decay rate. The resonators are driven by microwave fields. By adequately choosing the frequencies of these fields, we can transfer the entropy of the quantum system into its environment. This stabilization is autonomous and continuous in time, and does not rely on a precise control of the drive field amplitudes. The scheme does not require any knowledge of measurement outcomes thus simplifying its experimental realization. Experimental data on dynamical cooling of a transmon qubit coupled to a compact resonator will be shown. Finally, applications to quantum error correction will be discussed.

1:03PM B29.00010 Adiabatic state preparation of interacting two-level systems, RICHARD BRIERLEY, CELESTINO CREATORE, Cavendish Laboratory, JJ Thomson Avenue, Cambridge, CB3 0HE, UK, PETER LITTLEWOOD, Argonne National Laboratory, 9700 S Cass Ave., Argonne, IL 60439, USA, PAUL EASTHAM, School of Physics, Trinity College, Dublin 2, Ireland — We consider performing adiabatic rapid passage (ARP) using frequency-swept optical pulses to excite a collection of interacting two-level systems. Such a model arises in a wide range of many body quantum systems, such as circuit QED or interacting quantum dots, where a nonlinear component couples to light. We analyse the one-dimension case using the Jordan-Wigner transformation. In the mean field limit, the system can be described by a Lipkin-Meshkov-Glick Hamiltonian. Both approaches provide complementary insights into the behaviour of an interacting model under ARP, suggesting our results are generically applicable. We find ARP can still be used for state preparation in the presence of interactions but the parameters required to achieve full occupation depend on the strength of the interaction. In particular, for a fixed pulse time, stronger interactions require a larger pulse bandwidth, introducing new restrictions on the pulse form required.

1:15PM B29.00011 Collective quantum coherence in large superconducting circuits with approximate S_N symmetry, DAVID FERGUSON, Northwestern University, ANDREW HOUCK, Princeton University, JENS KOCH, Northwestern University — The vast majority of superconducting circuits consist of a minimum number of circuit elements, following an implicit conjecture that any increase in circuit complexity thwarts quantum coherence. Recent experiments have evidenced that this conjecture is not compelling and quantum coherence can persist for much larger circuits [1]. A tool for the design of future circuits, we present theory for the fluxonium qubit, a device which includes a large number, N , of array junctions. Taking into account the degrees of freedom of all junctions and the approximate S_N permutation symmetry, we identify the relevant collective mode and pinpoint an approximate decoupling of additional modes. This allows us to derive the effective models previously used. We also discuss corrections going beyond these models which include subspaces of states that transform as non-trivial representations of the permutation group.

1:27PM B29.00012 Quantum crossover of the switching rate of a modulated oscillator, VITTORIO PEANO, Michigan State University, LINGZHEN GUO, MICHAEL MARTHALER, Karlsruhe Institute of Technology, MARK DYKMAN, Michigan State University, GERD SCHOEN, Karlsruhe Institute of Technology — Experiments with Josephson bifurcation amplifiers have reached the regime where switching between coexisting stable vibrational states is due to quantum fluctuations. In switching the oscillator goes over the effective dynamical barrier that separates the states. It was found earlier that, for small damping, the barrier height calculated for $T \rightarrow 0$ is smaller than for $T = 0$. Respectively, the switching rates calculated in these two limits are exponentially different, the effect of fragility. If other parameters are fixed, both barrier heights are proportional to the number of bound quantum states localized mostly in the basin of attraction of the corresponding stable state. Here we show that for large but finite values of the number of states the $T = 0$ solution is stabilized. For some temperature T_c there occurs a sharp crossover to the finite-temperature regime. Our analytical results are corroborated by numerical results.

1:39PM B29.00013 Observation of single artificial atom optical bi-stability and its application to single-shot readout in circuit quantum electrodynamics, LUYAN SUN, Department of Physics and Applied Physics, Yale University, ERAN GINOSSAR, Advanced Technology Institute and Department of Physics, University of Surrey, MIKHAEL GUY, MATTHEW REED, HANHEE PAIK, Department of Physics and Applied Physics, Yale University, LEV S. BISHOP, Joint Quantum Institute and Condensed Matter Theory Center, Department of Physics, University of Maryland, ADAM SEARS, ANDREI PETRENKO, TERESA BRECHT, LUIGI FRUNZIO, STEVEN GIRVIN, ROBERT SCHOELKOPF, Department of Physics and Applied Physics, Yale University — The high power transient behavior of superconducting qubit-cavity systems has recently been used to perform high fidelity readout of transmon qubits [1]. We show that in the steady state, the system exhibits a bi-stable behavior that can be observed on the single-shot level, with the cavity state switching stochastically between dim and bright states. The switching times are shown to be long compared to the cavity and qubit lifetimes. Some features of the bi-stability can be explained by mean field theory, while its switching dynamics is studied with large scale simulations. Understanding these dynamics will be crucial for studying the transient response, an essential aspect of the qubit readout. We will discuss progress on optimizing readout by shaping the measurement pulse.

Monday, February 27, 2012 11:15AM - 2:15PM – Session B30 GQL: Quantum Error Correction and Quantum Control 259B

11:15AM B30.00001 Fault-tolerant quantum computation with asymmetric Bacon-Shor codes¹, PETER BROOKS, JOHN PRESKILL, California Institute of Technology — Bacon-Shor codes are quantum subsystem codes which are constructed by combining together two quantum repetition codes, one protecting against Z (phase) errors and the other protecting against X (bit flip) errors. In many situations, for example flux qubits, the noise is biased such that faults that produce Z errors are much more common than faults that produce X errors; in these cases it is natural to consider an asymmetric Bacon-Shor code where the code protecting against Z errors is longer than the code protecting against X errors. This work describes fault-tolerant constructions for gadgets that achieve universal fault-tolerant quantum computation using asymmetric Bacon-Shor codes. Gadgets take advantage of the Bacon-Shor structure by breaking up into parallel smaller gadgets that act on a single row or column, with majority voting of the separate results. For a bias of $\epsilon/\epsilon' = 10^4$, we prove a threshold around 2.5×10^{-3} . The effective error strength is shown to decrease rapidly (faster than polynomial) with decreasing ϵ . Therefore it may be practical to use Bacon-Shor codes directly with no additional concatenation. This could greatly reduce the resource overhead required for fault-tolerant computation with biased noise.

11:27AM B30.00002 Quantum Error Correction: Optimal, Robust, or Adaptive? Or, Where is The Quantum Flyball Governor?¹, ROBERT KOSUT, SC Solutions, MATTHEW GRACE, Sandia National Laboratories — In *The Human Use of Human Beings: Cybernetics and Society* (1950), Norbert Wiener introduces feedback control in this way:

“This control of a machine on the basis of its actual performance rather than its expected performance is known as *feedback* ... It is the function of control ... to produce a temporary and local reversal of the normal direction of entropy.”

The classic classroom example of feedback control is the all-mechanical flyball governor used by James Watt in the 18th century to regulate the speed of rotating steam engines. What is it that is so compelling about this apparatus? First, it is easy to understand how it regulates the speed of a rotating steam engine. Secondly, and perhaps more importantly, *it is a part of the device itself*. A naive observer would not distinguish this mechanical piece from all the rest. So it is natural to ask, where is the *all-quantum* device which is self regulating, ie, the Quantum Flyball Governor? Is the goal of quantum error correction (QEC) to design such a device? Developing the computational and mathematical tools to design this device is the topic of this talk.

¹Support from ONR/MURI and IARPA QCS.

11:39AM B30.00003 Unified approach to approximate quantum error correction via the transpose channel, PRABHA MANDAYAM, The Institute of Mathematical Sciences, Taramani, Chennai - 600 113, India, HUI KHOON NG, DSO National Laboratories, and Centre for Quantum Technologies, NUS, Singapore — Much of the existing work on error correction focuses on the standard paradigm of perfect quantum error correction (QEC), where the recovery operation perfectly reverses the effects of a noise channel. Recent studies on approximate QEC(AQEC) have demonstrated possible advantages that arise from relaxing the requirement for perfect correction. However, while the recovery operation for perfectly correctable codes is well-known, finding the recovery for approximately correctable codes often requires difficult numerical procedures. We demonstrate an analytical, universal and near-optimal recovery map-the transpose channel- for AQEC codes, with optimality defined in terms of the worst-case fidelity. Using the transpose channel, we provide an alternative interpretation of the QEC conditions and generalize them to a set of conditions for AQEC codes. This forms the basis of a simple algorithm for finding AQEC codes. Our analytical approach is a departure from earlier work relying on exhaustive numerical search for the optimal recovery map, with optimality defined based on entanglement fidelity. Our results can also be extended to the general case of approximate operator quantum error correction, thus bringing us closer to a unified, analytical framework for AQEC.(Ref:PRA,81,062342(2010))

11:51AM B30.00004 Design of additive quantum codes via the codeword-stabilized framework¹, LEONID P. PRYADKO, ILYA DUMER, ALEXEY A. KOVALEV, UC, Riverside — Codeword stabilized (CWS) construction defines a quantum code by combining a classical binary code with some underlying graph state. In general, CWS codes are non-additive but become additive stabilizer codes if derived from a linear binary code. Generic CWS codes typically require complex error correction; however, we show that the CWS framework is an efficient tool for constructing good stabilizer codes with simple decoding. We start by proving the lower Gilbert-Varshamov bound on the parameters of an additive CWS code which can be obtained from a given graph. We also show that cyclic additive CWS codes belong to a previously overlooked family of single-generator cyclic stabilizer codes; these codes are derived from a circulant graph and a cyclic binary code. Finally, we present several families of simple stabilizer codes with relatively good parameters, including a family of the smallest toric-like cyclic CWS codes which have length, dimension, and distance as follows: $[[t^2 + (t+1)^2, 1, 2t+1]]$, $t = 1, 2, \dots$

12:03PM B30.00005 Error-threshold for topological subsystem quantum error-correcting codes

, RUBEN S. ANDRIST, Department of Physics, ETH Zurich, HECTOR BOMBIN, Perimeter Institute for Theoretical Physics, MIGUEL ANGEL MARTIN-DELGADO, Departamento de Fisica, Universidad Complutense, HELMUT G. KATZGRABER, Department of Physics and Astronomy, Texas A&M University and ETH Zurich — In general, stability against noise in a quantum computer can be achieved by storing quantum information redundantly. For instance, topological quantum error correction averts decoherence effects by encoding qubits in non-local degrees of freedom, while actively correcting for local errors. The key merit of these topological stabilizer codes lies in the intrinsic locality of the operations for syndrome measurement and error correction. Topological subsystem codes further facilitate practical applications by requiring only measurements of adjacent qubit pairs. We numerically determine the error threshold of topological subsystem codes for the depolarizing channel by mapping the problem onto a classical statistical spin model with bond disorder, which is analyzed via large-scale Monte Carlo simulations. In this picture, faulty qubits correspond to antiferromagnetic interactions between classical spins and the point in the disorder–temperature phase diagram where ferromagnetic order is lost corresponds to the error threshold of the underlying quantum bit system.

12:15PM B30.00006 Correlated Errors in the Surface Code¹

, DANIEL LOPEZ, Universidade Federal do ABC - Brazil, E. R. MUCCILO, University of Central Florida, E. NOVAIS, Universidade Federal do ABC - Brazil — A milestone step into the development of quantum information technology would be the ability to design and operate a reliable quantum memory. The greatest obstacle to create such a device has been decoherence due to the unavoidable interaction between the quantum system and its environment. Quantum Error Correction is therefore an essential ingredient to any quantum computing information device. A great deal of attention has been given to surface codes, since it has very good scaling properties. In this seminar, we discuss the time evolution of a qubit encoded in the logical basis of a surface code. The system is interacting with a bosonic environment at zero temperature. Our results show how much spatial and time correlations can be detrimental to the efficiency of the code.

12:27PM B30.00007 Quantum Circuits for Measuring Levin-Wen Operators

, NICK BONESTEEL, Dept. of Physics and NHMFL, Florida State University, DAVID DIVINCENZO, Forschungszentrum Juelich & RWTH Aachen — We give explicit quantum circuits (expressed in terms of Toffoli gates, CNOTs and single qubit rotations) which can be used to perform quantum non-demolition measurements of the commuting set of vertex and plaquette operators that appear in the Levin-Wen model [1] for the case of doubled Fibonacci anyons. Such measurements can be viewed as syndrome measurements for the quantum error correcting code defined by the ground states of the Levin-Wen model — a scenario envisioned in [2]. A key component in our construction is a quantum circuit $\mathcal{F}$ that acts on 5 qubits at a time and carries out a so-called F -move, a unitary operation whose form is essentially fixed by a self-consistency condition known as the pentagon equation. In addition to our measurement circuits we also give an explicit 7 qubit circuit which can be used to verify that $\mathcal{F}$ satisfies the full pentagon equation as well as a simpler 2 qubit circuit which verifies the essential nontrivial content of this equation.

12:39PM B30.00008 Exchange-Only Dynamical Decoupling in the 3-Qubit Decoherence Free Subsystem¹

, BRYAN FONG, JACOB WEST, HRL Laboratories, LLC — The Uhrig dynamical decoupling sequence achieves high-order decoupling of a single system qubit from its dephasing bath through the use of bang-bang Pauli pulses at appropriately timed intervals [1]. This high-order decoupling property of the Uhrig sequence has been extended to decouple general noise from single [2] and multiple [3] qubit systems, using single-qubit Pauli pulses. For the 3-qubit decoherence free subsystem (DFS) and related subsystem encodings, Pauli pulses are not naturally available operations; instead, exchange interactions provide all required encoded operations [4]. Here we demonstrate that exchange interactions alone can achieve high-order decoupling against general noise in the 3-qubit DFS. We present decoupling sequences for a 3-qubit DFS coupled to classical and quantum baths and evaluate the performance of the sequences through numerical simulations. References: [1] G. S. 12:51PM B30.00009 Upper bounds on coherence preservation in dynamical decoupling¹

, KAVEH KHODJASTEH, Dartmouth College, TAMÁS ERDÉLYI, Texas A&M University, LORENZA VIOLA, Dartmouth College — We explore the fundamental limits on coherence preservation by dynamical decoupling in terms of control time scales and the spectral bandwidth of the environment. Our main focus is a decohering qubit controlled by arbitrary sequences of π pulses. Using methods from mathematical analysis, we establish a non-perturbative lower bound for the coherence loss in terms of the minimum pulse separation and the cutoff frequency of the environment. We argue that similar bounds are applicable to a variety of open-loop unitary control methods while we find no explicit dependence of such lower bounds on the total control time. We use these findings to generate bandwidth adapted dynamical decoupling sequences that can preserve a qubit up to arbitrary long times within the best fidelities theoretically possible given the available control resources. Our analysis reinforces the impossibility of fault-tolerance accuracy thresholds under purely reversible error control.

¹Supported by NSF Grant No. PHY-090372

1:03PM B30.00010 Generalized Uhrig Dynamical Decoupling for Multi-Level Quantum Systems

, SUJEET SHUKLA, LIANG JIANG, JOHN PRESKILL, Institute for Quantum Information, Caltech, ADILET IMAMBEKOV, Department of Physics and Astronomy, Rice University — Dynamical decoupling can efficiently suppress decoherence induced by the system-environment interaction. Recently, Uhrig proposed an efficient dynamical decoupling scheme, which uses only N pulses to suppress dephasing noise to $O(T^{N+1})$ for a qubit system with total time evolution T . We generalize Uhrig's dynamical decoupling scheme from 2-level to L -level quantum systems. We find that $M = (L - 1)N$ pulses are sufficient to suppress dephasing noise to $O(T^{N+1})$. We observe interesting patterns in the timing of these pulses, which depend on both L and N with various asymptotic forms for large L or large N .

1:15PM B30.00011 Universal Dynamical Decoupling and Quantum Walks in Functional Spaces

, ADILET IMAMBEKOV, Department of Physics and Astronomy, Rice University, LIANG JIANG, Institute for Quantum Information, Caltech — We investigate the universal dynamical decoupling (DD) schemes, which can restore the coherence of quantum system independent of the details of system-environment interaction. We introduce a general mapping between DD sequences and quantum walks in functional spaces, and use it to prove the universality of various DD schemes such as quadratic DD, nested Uhrig DD, and Uhrig concatenated DD, as well as previously known universal schemes of concatenated DD, Uhrig DD and concatenated Uhrig DD.

1:27PM B30.00012 Protecting adiabatic quantum computation by dynamical decoupling, GREGORY QUIROZ, DANIEL LIDAR, University of Southern California — Adiabatic quantum computation (AQC) relies heavily on a system's ability to remain in its ground state with high probability throughout the entirety of the adiabatic evolution. System-environment interactions present during the evolution manifest decoherence, thereby increasing the probability of excitation. In this work, it is shown that the existence of such noise-producing terms can be dramatically reduced by Dynamical Decoupling (DD). In particular, we consider a multi-qubit system subjected to a classical bath modeled by random Gaussian-correlated noise. The performance of deterministic schemes such as Concatenated Dynamical Decoupling (CDD) and Nested Uhrig Dynamical Decoupling (NUDD) are analyzed for Grover's search algorithm and the two-qubit Satisfiability (2-SAT) problem. The CDD evolution substantially increases noise suppression with increasing concatenation level. In contrast, improvements in performance are only observed for specific sequence orders in the NUDD scheme. These results are verified for both adiabatic evolutions in terms of the total adiabatic run time and minimum pulse interval.

1:39PM B30.00013 ABSTRACT WITHDRAWN —

1:51PM B30.00014 Polar codes for achieving the classical capacity of a quantum channel, SAIKAT GUHA, Raytheon BBN Technologies, MARK WILDE, McGill University — We construct the first near-explicit, linear, polar codes that achieve the capacity for classical communication over quantum channels. The codes exploit the channel polarization phenomenon observed by Arikan for classical channels. Channel polarization is an effect in which one can synthesize a set of channels, by "channel combining" and "channel splitting," in which a fraction of the synthesized channels is perfect for data transmission while the other fraction is completely useless for data transmission, with the good fraction equal to the capacity of the channel. Our main technical contributions are threefold. First, we demonstrate that the channel polarization effect occurs for channels with classical inputs and quantum outputs. We then construct linear polar codes based on this effect, and the encoding complexity is $O(N \log N)$, where N is the blocklength of the code. We also demonstrate that a quantum successive cancellation decoder works well, i.e., the word error rate decays exponentially with the blocklength of the code. For a quantum channel with binary pure-state outputs, such as a binary-phase-shift-keyed coherent-state optical communication alphabet, the symmetric Holevo information rate is in fact the ultimate channel capacity, which is achieved by our polar code.

2:03PM B30.00015 Improved coded optical communication error rates using joint detection receivers¹, ZACHARY DUTTON, SAIKAT GUHA, JIAN CHEN, JONATHAN HABIF, RICHARD LAZARUS, Raytheon BBN Technologies — It is now known that coherent state (laser light) modulation is sufficient to reach the ultimate quantum limit (the Holevo bound) for classical communication capacity. However, all current optical communication systems are fundamentally limited in capacity because they perform measurements on single symbols at a time. To reach the Holevo bound, joint quantum measurements over long symbol blocks will be required. We recently proposed and demonstrated the "conditional pulse nulling" (CPN) receiver – which acts jointly on the time slots of a pulse-position-modulation (PPM) codeword by employing pulse nulling and quantum feedforward – and demonstrated a 2.3 dB improvement in error rate over direct detection (DD). In a communication system coded error rates are made arbitrary small by employing an outer code (such as Reed-Solomon (RS)). Here we analyze RS coding of PPM errors with both DD and CPN receivers and calculate the outer code length requirements. We find the improved PPM error rates with the CPN translates into >10 times improvement in the required outer code length at high rates. This advantage also translates increase the range for a given coding complexity. In addition, we present results for outer coded error rates of our recently proposed "Green Machine" which realizes a joint detection advantage for binary phase shift keyed (BPSK) modulation.

11:15AM B31.00001 Adler-Bell-Jackiw anomaly in Weyl semi-metals: Application to Pyrochlore Iridates, VIVEK AJI, University of California at Riverside — Weyl semimetals are three dimensional analogs of graphene where the energy of the excitations are a linear function of their momentum. Pyrochlore Iridates are conjectured to be examples of such a system, with the low energy physics described by twenty four Weyl nodes. An intriguing possibility is that these materials provide a physical realization of the Adler-Bell-Jackiw anomaly. In this talk we report on the properties of pyrochlore iridates in an applied magnetic field. We find that the dispersion of the lowest Landau level depends on the direction of the applied magnetic field. As a consequence the magneto-conductivity in an electric field, applied parallel to the magnetic field is highly anisotropic, providing a detectable signature of the semi-metallic state.

11:27AM B31.00002 Dirac Semimetal in Three Dimensions, STEVE YOUNG, Makineni Laboratories, Department of Chemistry, University of Pennsylvania, SAAD ZAHEER, JEFFREY TEO¹, CHARLES KANE, EUGENE MELE, Department of Physics and Astronomy, University of Pennsylvania, ANDREW RAPPE, Makineni Laboratories, Department of Chemistry, University of Pennsylvania — In a Dirac semimetal the conduction and valence bands contact at discrete points in the Brillouin zone, dispersing linearly away from these critical points with the low energy physics described by a four band Dirac Hamiltonian. In 2D this situation is realized in graphene in the absence of spin-orbit coupling. 3D Dirac semimetals are predicted to exist at the phase transition between a topological insulator and an ordinary insulator when inversion symmetry is preserved. Here we show that 3D Dirac points can also be protected by crystallographic symmetries in particular space groups and enumerate the criteria necessary to identify these groups. As an example of a Dirac semimetal, we present calculations for β -Cristobalite BiO_2 which exhibits Dirac points at the three symmetry related X points of the FCC Brillouin zone. We find that β -Cristobalite BiO_2 is metastable, so it can be physically realized as a 3D analog to graphene. We provide a systematic approach that includes crystallographic symmetry arguments and physical and chemical considerations to identify other such materials and rule out possible alternatives such as HgTe . This would greatly expand the range of applications that take advantage of properties arising from Dirac points.

¹Present Address: Department of Physics, University of Illinois at Urbana-Champaign

11:39AM B31.00003 Semi-metal and Topological Insulator in Perovskite Iridates, VIJAY SHANKAR V, JEAN-MICHEL CARTER, Department of Physics, University of Toronto, M. AHSAN ZEB, Cavendish Laboratory, University of Cambridge, HAE-YOUNG KEE, Department of Physics, University of Toronto — The two-dimensional (2D) layered perovskite Sr_2IrO_4 was proposed to be a spin-orbit (SO) Mott insulator, where the effect of Hubbard interaction is amplified on a narrow $J_{eff} = \frac{1}{2}$ band due to strong spin-orbit coupling. On the other hand, the three-dimensional (3D) orthorhombic perovskite SrIrO_3 remains metallic. We construct a tight-binding model for SrIrO_3 to understand the physical origin of the metallic behaviour and study possible metal-insulator transitions. In particular, we identify possible perturbations that turn the material into a topological insulator.

11:51AM B31.00004 Topological Insulators and Semimetals with Point Group Symmetries¹, CHEN FANG, Princeton University, MATTHEW GILBERT, University of Illinois at Urbana Champaign, XI DAI, Chinese Academy of Sciences, ANDREI BERNEVIG, Princeton University — In this work, we study the theory of topological phases in systems with point group symmetries (PGSs) in one-, two- and three-dimension. The systems we study in general do not require time-reversal symmetry, and hence may be realized in both non-magnetic and magnetic materials. We show that a point group symmetry introduces new quantum numbers which reveal themselves in the entanglement spectrum as mid-gap states. PGSs also define a series of topological semimetals, in which the band touching points are protected by certain symmetries. We apply our theory to 3D ferromagnetic semimetal HgCr_2Se_4 which possesses a double-vortex band crossing protected by C_4 rotation symmetry.

12:03PM B31.00005 Diamagnetism of Weyl semimetals, SI WU, ALEXANDER ZYUZIN, ANTON BURKOV, University of Waterloo — We present a study of the diamagnetic orbital response in a Weyl semimetal, the recently discovered gapless topological phase of matter. Weyl semimetal is a three-dimensional (3D) material, characterized by the presence of isolated Dirac (Weyl) point nodes in its band structure. It can be thought of as the closest 3D analog of graphene. It is known from graphene studies that two-dimensional (2D) Dirac fermions have a highly nontrivial singular diamagnetic response to an applied perpendicular magnetic field, reflecting the quantum critical nature of the ground state of undoped graphene. Here we investigate the analogous orbital response of 3D Dirac fermions in a Weyl semimetal to an applied magnetic field. As in 2D graphene, we find strong signatures of quantum criticality in the diamagnetic response of 3D Weyl semimetal. In particular, we find that the orbital susceptibility has a characteristic logarithmic dependence on the applied field, deviation of the chemical potential from the charge-neutral position and temperature. This unusual diamagnetic response can be used for experimental characterization of Weyl semimetals.

12:15PM B31.00006 Weyl Semimetal in a Topological Insulator Multilayer, ANTON BURKOV, University of Waterloo, LEON BALENTS, Kavli Institute for Theoretical Physics, UCSB — We propose a simple realization of the three-dimensional (3D) Weyl semimetal phase, utilizing a multilayer structure, composed of identical thin films of a magnetically-doped 3D topological insulator (TI), separated by ordinary-insulator spacer layers. We show that the phase diagram of this system contains a Weyl semimetal phase of the simplest possible kind, with only two Dirac nodes of opposite chirality, separated in momentum space, in its bandstructure. This Weyl semimetal has a finite anomalous Hall conductivity, chiral edge states, and occurs as an intermediate phase between an ordinary insulator and a 3D quantum anomalous Hall insulator. We discuss unusual transport properties of the Weyl semimetal, and in particular point out quantum critical-like scaling of the DC and optical conductivity.

12:27PM B31.00007 3D Weyl Semimetal in a Honeycomb Array of Topological Nano-wires, MOHAMMAD VAZIFEH, MARCEL FRANZ, Department of Physics and Astronomy, University of British Columbia — The Weyl semimetal phase has been recently introduced and suggested to exist in strongly correlated pyrochlore iridates as well as in the non-interacting layered Normal/Topological band insulator systems. This unusual phase has a number of interesting properties in the bulk and at the surface arising from the appearance of isolated point-like hedge-hog topological defects (known as Weyl-Dirac points) in the Bloch-state manifold. Here we discuss the possible emergence of this phase in a honeycomb arrangement of the parallel topological insulator nano-rods each exposed to a half-integer multiple of magnetic flux quantum. We consider direct hopping between rods as well as the electron-electron interaction between them. We discuss how the initially degenerate Weyl points can be separated in the Brillouin zone by various perturbations breaking either inversion or time-reversal symmetry.

12:39PM B31.00008 Charge transport in Weyl semimetals, PAVAN HOSUR, SIDDHARTH PARAMESWARAN, U C Berkeley, USA, ASHVIN VISHWANATH, U C Berkeley, USA; Lawrence Berkeley National Lab, USA — Weyl semimetals are three-dimensional phases with band touchings, whose low-energy excitations are governed by the Weyl equation. They can be thought of as higher dimensional cousins of graphene. Recent theoretical work predicted certain pyrochlore iridates such as $\text{Y}_2\text{Ir}_2\text{O}_7$ to be in this phase. We study charge transport in Weyl semimetals in the presence of Coulomb interactions or disorder at temperature T and compare our results to existing data on $\text{Y}_2\text{Ir}_2\text{O}_7$ and $\text{Eu}_2\text{Ir}_2\text{O}_7$. In the interacting clean limit, we determine the conductivity by solving a quantum Boltzmann equation within a “leading log” approximation and find it to be proportional to T , upto logarithmic factors arising from the flow of couplings. In the noninteracting disordered case, we compute the finite-frequency Kubo conductivity and show that it exhibits distinct behaviors for low and high frequencies compared to T . The behavior of Weyl semimetals in a magnetic field will also be briefly discussed.

12:51PM B31.00009 Magnetic Instability on the Surface of Topological Insulators, ADY STERN, YUVAL BAUM, Weizmann Institute of Science — Gapless surface states that are protected by time reversal symmetry and charge conservation are among the manifestations of 3D topological insulators. In this work we study how electron-electron interaction may lead to spontaneous breaking of time reversal symmetry on surfaces of such insulators. We find that a critical interaction strength exists, above which the surface is unstable to spontaneous formation of magnetization, and study the dependence of this critical interaction strength on temperature and chemical potential.

1:03PM B31.00010 Plasmons in Topological Insulators, GODFRY GUMBS, Department of Physics and Astronomy, Hunter College, City University of New York, 695 Park Avenue, New York, NY 10065, USA, OLEKSIY ROSLYAK, Department of Physics and Astronomy, Hunter College, City University of New York, 695 Park Avenue, New York, NY 10065, USA, DANHONG HUANG, Air Force Research Laboratory, Space Vehicles Directorate, Kirtland Air Force Base, NM 87117, USA — A theory is presented for calculating the plasmon mode dispersion relation in three-dimensional topological insulators (TI). There are two-dimensional (2D) conducting surface states. The conducting states localized close to the surface of the semi-infinite slab have a well defined Dirac cone. The bulk energy gap is large and comparable with room temperature. We investigate plasmon excitations of those surface bound electrons in the long wavelength limit employing the random-phase approximation. Results from our calculations show that for a quasi-1DTI, the plasmon dispersion relation is given by $\omega_p \approx q(1 - \omega_0 \ln(q))$ where $\omega_0 = \frac{2e^2}{\pi\epsilon_0} \frac{3}{10}$. On the other hand, for the conventional 1DEG, the plasmon dispersion satisfies $\omega_p \approx q\sqrt{-\omega_0 \ln(q)}$, with $\omega_0 = 2n_{1D}e^2/\epsilon_0 m$ and n_{1D} denoting the linear electron density. The plasmons in 1DTI are density-independent as they are in metallic armchair graphene nanoribbons but obey different dispersion relation. The material parameters we chose correspond to Bi_2Te_3 crystals.

1:15PM B31.00011 Topological Insulators with electron-electron interactions, DAVID SCHMELTZER, City College of NY — We consider the effect of interaction for the 3 dimensional Topological insulators. We show that effectively the system is equivalent to non-interacting Topological Insulators in 4+1 dimensions.

1:27PM B31.00012 Actinide Topological Insulator Materials with Strong Interaction¹, XIAO ZHANG, HAIJUN ZHANG, Department of Physics, Stanford University, CLAUDIA FELSER, Johannes Gutenberg University of Mainz, SHOU-CHENG ZHANG, Department of Physics, Stanford University — Topological band insulators have recently been discovered in spin-orbit coupled two and three dimensional systems. In this work, we theoretically predict a class of topological Mott insulators where interaction effects play a dominant role. In actinide elements, simple rocksalt compounds formed by Pu and Am lie on the boundary of metal to insulator transition. We show that interaction drives a quantum phase transition to a topological Mott insulator phase with a single Dirac cone on the surface.

¹This work is supported by the ARO with grant number W911NF-09-1-0508.

1:39PM B31.00013 Fractional quantum Hall effect and plasmons in topological insulators¹, ASHLEY DASILVA, Pennsylvania State University — I will discuss theoretical studies of the effect of Coulomb interactions at the topological insulator surface in the presence of a magnetic field. Coulomb interaction can cause composite fermion formation and the fractional quantum Hall effect. We predict the stability of the fractional quantum Hall effect by considering the form of the effective interparticle interaction: if it is sufficiently short ranged, then there will be composite fermion formation. We will also study plasmons and magnetoplasmons of the surface states both for an ideal topological insulator and for a topological insulator with bulk conduction.

¹This work was supported by the PSU MRSEC under NSF grant number DMR-0820404

1:51PM B31.00014 Half quantum spin Hall effect on the surface of weak topological insulators¹, CHAOXING LIU, Institute for Theoretical Physics and Astrophysics, University of Wuerzburg, 97074 Wuerzburg, Germany, XIAOLIANG QI, SHOUCHENG ZHANG, Department of Physics, McCullough Building, Stanford University, Stanford, CA 94305-4045 — We investigate interaction effects in three dimensional weak topological insulators (TI) with an even number of Dirac cones on the surface. We find that the surface states can be gapped by a surface charge density wave (CDW) order without breaking the time-reversal symmetry. In this sense, timereversal symmetry alone can not robustly protect the weak TI state in the presence of interactions. If the translational symmetry is additionally imposed in the bulk, a topologically non-trivial weak TI state can be obtained with helical edge states on the CDW domain walls. In other words, a CDW domain wall on the surface is topologically equivalent to the edge of a two-dimensional quantum spin Hall insulator. Therefore, the surface state of a weak topological insulator with translation symmetry breaking on the surface has a “half quantum spin Hall effect,” in the same way that the surface state of a strong topological insulator with time-reversal symmetry breaking on the surface has a “half quantum Hall effect.” The on-site and nearest neighbor interactions are investigated in the mean field level and the phase diagram for the surface states of weak topological insulators is obtained.

¹CXL acknowledge financial support by the Alexander von Humboldt Foundation of Germany and is grateful for the hospitality of the Institute for Advanced Study in Tsinghua University.

2:03PM B31.00015 2D symmetry protected topological orders and their protected gapless edge excitations, XIE CHEN, Massachusetts Institute of Technology, ZHENG-XIN LIU, Tsinghua University, XIAO-GANG WEN, Massachusetts Institute of Technology — Topological insulators/superconductors with time reversal or particle-hole symmetry protected gapless edge excitations have been well characterized and classified in free fermion systems. However, it is not clear in general interacting boson or fermion systems, when such symmetry protected topological(SPT) orders exist with gapless edge excitations that are protected even against strong interactions. Here, we present a systematic construction of 2D interacting bosonic models with non-trivial SPT orders for any on-site symmetry of group G . We demonstrate the non-trivialness of the models by rigorously proving that the gapless edge excitations of the system is stable against any interaction as long as symmetry is not broken. We prove this result by developing the tool of matrix product unitary operator to study the nonlocal symmetry transformation on the edge degrees of freedom and revealing its relation to the non-trivial 3-cocycles of the symmetry group G . This relation between SPT orders and group cocycles has actually been established in 1D interacting systems and led to a complete classification of 1D SPT orders. We show here that this relation also extends to > 2 spatial dimensions and possibly provides a (partial) classification of SPT orders in all interacting systems.

Session B32 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides - Relaxors, Nanostructures, and Morphotropic Phase Boundary 261

11:15AM B32.00001 Symmetry determination of piezoelectric $(1-x)\text{Pb}(\text{Mg}_{1/3}\text{Nb}_{2/3})\text{O}_3$ - $x\text{PbTiO}_3$ single crystal near morphotropic phase boundary, KYOUHYUN KIM, DAVID PAYNE, JIAN-MIN ZUO, University of Illinois, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING COLLABORATION — The symmetry of $(1-x)\text{Pb}(\text{Mg}_{1/3}\text{Nb}_{2/3})\text{O}_3$ - $x\text{PbTiO}_3$ single crystal (PMN- x PT) is investigated at the morphotropic phase boundary with $x=31\%$. The XRD result indicates that the average symmetry of annealed PMN-31%PT single crystal is in close agreement with the monoclinic M_C (Pm) phase, but with strain. The local symmetry of PMN-31PT are then investigated at three different directions of $[001]_C$, $[010]_C$, $[011]_C$ and $[111]_C$ by using convergent electron diffraction (CBED) technique with a probe size of 2 nm. The dynamical theory is used to simulate the CBED patterns for the reported phases of PMN- x PT. The CBED results show that significant deviations of the experimental CBED patterns from the simulations. The deviations in the CBED results are considered as a result from a local distortion induced by the different B cations of Mg^{2+} , Nb^{5+} and Ti^{4+} . The local symmetry of PMN-31%PT is not defined by any reported phases and the symmetry of PMN-31%PT seen in X-ray diffraction is the average of local structures

11:27AM B32.00002 Phase diagram and skin effect of the relaxor ferroelectric $(1-x)\text{Pb}(\text{Mg}_{1/3}\text{Nb}_{2/3})\text{O}_3+x\text{PbTiO}_3$, PETER GEHRING, DANIEL PHELAN, EFRAIN RODRIGUEZ, National Institute of Standards and Technology, ZUO-GUANG YE, Simon Fraser University — We revisit the phase diagram of the relaxor ferroelectric PMN- x PT using neutron powder diffraction to test suggestions that defects in the oxygen stoichiometry and/or strain affect the ground state crystal structure. Two identical sets of PMN- x PT powders were prepared with $x = 0.10, 0.20, 0.30$, and 0.40 . One set was annealed in air at 873K for 2h. For a given composition and temperature the same structural phase is observed in each set, thus indicating that the effects of strain and oxygen vacancies are minimal. But the distortions measured in the annealed samples are consistently smaller than those in the as-grown samples. In addition, the average grain size of the annealed samples is approximately twice that of the as-grown samples (1.2 ± 0.6 microns vs 0.6 ± 0.3 microns). This result is consistent with a skin effect in which Ti-poor bulk crystals show significantly smaller distortions than do powders of the same composition. The diffraction patterns for both the as-grown and annealed samples with compositions $x = 0.10$ and $x = 0.20$ are best refined using the monoclinic Cm space group, which agrees with recent speculation by Singh et al., Phys. Rev. B **74**, 024101 (2006).

11:39AM B32.00003 Model for Relaxor Ferroelectrics¹, GIAN GUZMAN-VERRI, CHANDRA VARMA, Department of Physics and Astronomy, University of California at Riverside — We consider a model of a lattice made of polarizable unit cells with local and dipole interactions and disorder. Without disorder, it is well known that dipole interactions alone do not lead to ferroelectricity. We show by a cluster expansion in disorder and by a high temperature series expansion that in the presence of sufficient disorder, the model with both local and dipole interactions has locally correlated regions at low temperatures but has no long-range order. We compare our results with measurements of the static and dynamic structure factor by neutron scattering [1]. References: 1. S.N. Gvasaliya, B. Roessli, R.A. Cowley, P. Huber, S. Lushnikov, J. Phys.: Condens. Matter **17** 4343 (2005).

11:51AM B32.00004 Molecular Dynamics Studies of Structure, Dynamics and Dielectric Response in a Relaxor Ferroelectric, ILYA GRINBERG, University of Pennsylvania — Since the first synthesis of the classic $\text{PbMg}_{1/3}\text{Nb}_{2/3}\text{O}_3$ (PMN) material in 1961, relaxor ferroelectrics have been the subject of ongoing experimental and theoretical investigation due to their fundamental scientific interest and their importance in technological applications. We use atomistic molecular dynamics simulations to study relaxor behavior in the 0.75PMN-0.25PT material. Even for a fairly small simulation size of 1000 atoms, the system exhibits frequency dispersion and deviation from the Curie-Weiss law typical of relaxor materials. Analysis of the time autocorrelation functions for individual atoms allows us to identify the Nb atoms with a high concentration of neighboring Ti atoms as the nucleation sites for the relaxor behavior. This is due to the higher coupling between the cation displacements induced by the presence of overbonded oxygen atoms. We also analyze local structure and dynamics in PMN-PT using instantaneous, time-averaged and frequency resolved pair distribution functions (PDF). We find that dynamic Pb and Ti off-centering is present even in the paraelectric phase, below T_b the rate of growth of local Pb off-centering increases, followed by the freezing in of the local displacement direction at an intermediate temperature T_c and a transition to a ferroelectric-like phase at T_f . Thus there is a sequence of four phases, PE, dynamic relaxor, mixed dynamic and frozen phase, and the non-ergodic frozen relaxor phase. We identify the average instantaneous local cation off-centering as the order parameter for the dynamic relaxor phase, and the time-averaged local cation off-centering as the order parameter for the two lower-temperatures relaxor phases. Examination of the dynamic PDF data reveals the shape and the range of correlation between the cation displacements. We also show that the relaxor phase is characterized by the appearance of strong nearest-neighbor correlation between the off-center displacements along the Cartesian directions.

12:27PM B32.00005 First-principles calculations of finite temperature Sc and O NMR parameters in $\text{Pb}(\text{Sc}_{2/3}\text{W}_{1/3})\text{O}_3$ ¹, HENRY KRAKAUER, ERIC J. WALTER, JEREMY ELLDEN, GINA L. HOATSON, ROBERT L. VOLD, College of William and Mary — Understanding the dynamics of complex relaxor ferroelectrics is important to characterizing their large electromechanical coupling. Preliminary NMR measurements of Sc electric-field-gradients (EFG) in $\text{Pb}(\text{Sc}_{2/3}\text{W}_{1/3})\text{O}_3$ (PSW) show a strong temperature dependence in the range $T = 250 - 330$ K. To understand this behavior, we use the first-principles GIPAW² method within the Quantum Espresso (QE) package³ to calculate ⁴⁵Sc and ¹⁷O chemical-shifts and EFG tensors. To study finite temperature effects, we incorporate the thermal expansion of the lattice and sample thermal disorder, using the phonon degrees of freedom. As in our previous studies of perovskites,⁴ we show that the ¹⁷O chemical shifts in PSW also exhibit a linear correlation with the nearest-neighbor B-O bond length.

12:39PM B32.00006 Critical Slowing Down in the Relaxor Ferroelectric $\text{K}_{1-x}\text{Li}_x\text{TaO}_3$ (KLT), LING CAI, JEAN TOULOUSE, Lehigh University, Physics Department — In this report, we illustrate an essential characteristic of mixed crystals such as KLT: the strong dependence of their macroscopic properties on the spatial distribution of the mixed ions in the crystal. As a prototypical relaxor ferroelectric, KLT exhibits a large dielectric constant, low frequency dispersion and a broad relaxation peak. Lithium randomly substitutes for potassium and, because of its smaller size, moves off-center in one of six possible $\langle 100 \rangle$ directions thus forming a local dipole. Correlations between these dipoles lead to the appearance of Polar Nanodomains (PNDs), the size and polarization of which depend on local density fluctuations or type of distribution of the Li ions (random homogeneous or locally clustered). The dielectric constant of two KLT crystals with almost identical average Li concentrations displays two radically different behaviors, which can be traced to two very different distributions of the lithium ions in the two crystals. This is particularly striking of the critical behaviors in the two separate crystals. A first order structural transition is observed in one crystal but critical slowing down is observed in the other. The type of spatial distribution present in each crystal can be inferred from the dielectric results.

12:51PM B32.00007 EIT-like effect due to hetero-phase oscillations near the phase transition of relaxor ferroelectrics, JEAN TOULOUSE, RADHA K. PATTNAIK¹, Lehigh University, LYNN A. BOATNER, Oak Ridge National Laboratory — We report the observation of a remarkable “transparency window” in the dielectric resonant absorption spectrum of the relaxor ferroelectric $\text{K}_{1-x}\text{Li}_x\text{TaO}_3$ (KLT) in the vicinity of its weakly first order transition. This phenomenon is shown to be conceptually similar to the electro-magnetically induced transparency (EIT) phenomenon observed in certain atomic vapors. In KLT however, it reveals the presence of hetero-phase (cubic-tetragonal) fluctuations and provides unique information on the nature and mechanism of the phase transition in relaxors.

¹Present address: Lafayette College pattnair@lafayette.edu

1:03PM B32.00008 Temperature evolution of the linear birefringence in striated single crystals of $\text{KTa}_{1-x}\text{Nb}_x\text{O}_3$ (KTN), DANIEL JACKSON, Dept. of Phys., Lehigh University, Bethlehem PA, 18015, USA, RADHA PATTNAIK, Phys. Dept., Lafayette College, Easton, PA 18042, USA, AHARON AGRANAT, Dept. of Appl. Phys., The Hebrew University of Jerusalem, Jerusalem 91904, Israel, JEAN TOULOUSE, Dept. of Phys., Lehigh University, Bethlehem PA, 18015, USA — We report the temperature evolution of a special linear birefringence in 3 crystals of $\text{KTa}_{1-x}\text{Nb}_x\text{O}_3$ (KTN), with $x=0.155$, 0.27 and 0.36 respectively, upon approaching the cubic-tetragonal phase transition. This birefringence, which is in violation of crystalline symmetry conditions, is caused by growth striations in the crystal that give rise to local strain and result in an average uniaxial behavior due to the photoelastic effect. Simultaneously, the set of parallel striations acts as a volume phase grating which can produce diffracted beams. Upon approaching the phase transition, the measured birefringence displays a rapid temperature dependence which is due to the formation of polar nano-domains (PND). These are incipient tetragonal uniaxial domains preferentially oriented with their c-axis perpendicular to the plane of the striations. As the birefringence increases, the diffraction efficiency unexpectedly decreases, indicating that the phase grating amplitude is occluded by the PND formation. The striation pattern is well defined in the 15.5% crystal, more diffuse in the 36% crystal, and there are no obvious striations in the 27% crystal. Experimental results are presented and a simple phenomenological model for the birefringence behavior is proposed and discussed.

1:15PM B32.00009 Strain effects on Coherent Epitaxial Ferroelectric $\text{Pb}(\text{Zr}_{0.2}\text{Ti}_{0.8})\text{O}_3$, ASIF KHAN, SAYEEF SALAHUDDIN, UC Berkeley — A comprehensive study of strain coupling to ferroelectricity in coherent epitaxial $\text{Pb}(\text{Zr}_{0.2}\text{Ti}_{0.8})\text{TiO}_3$ thin films is presented. The epitaxial strain variants are obtained by growing coherent PZT thin films on three different substrates, SrTiO_3 , DyScO_3 and GdScO_3 by pulsed laser deposition technique. The strain sensitivity of remnant polarization is found to be less in the epitaxial strain variants with larger tetragonality. Despite the fact that the tetragonality of PZT is more sensitive to the epitaxial strain than that of BaTiO_3 , the polarization-strain coupling is weaker in PZT than in BTO. These results underpins that the strong sensitivity of ferroelectricity to epitaxial strain is not a universal characteristic of complex oxide ferroelectrics and may depend on the intricate details of individual material systems.

1:27PM B32.00010 Structural and Ferroelectric Properties of Epitaxial ultrathin $\text{PbZr}_{0.52}\text{Ti}_{0.48}\text{O}_3$ Films Prepared on $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3/(\text{LaAlO}_3)_{0.3}(\text{Sr}_2\text{AlTaO}_6)_{0.7}$ Substrates, NORA ORTEGA, DANILO BARRIONUEVO, Department of Physics and Institute of Functional Nanomaterials, University of Puerto Rico, ASHOK KUMAR, University of Puerto Rico, RAM KATIYAR, Department of Physics and Institute of Functional Nanomaterials, University of Puerto Rico — The existence of ferroelectricity in ultrathin films opens the possibility to further miniaturize devices based on FE materials, i.e. ferroelectric tunnel junctions take advantage of tunnel electroresistance effect. We have fabricated epitaxial $\text{PbZr}_{0.52}\text{Ti}_{0.48}\text{O}_3$ thin and ultrathin films using pulsed laser deposition on (001) on $\text{La}_{2/3}\text{Sr}_{1/3}\text{MnO}_3/(\text{LaAlO}_3)_{0.3}(\text{Sr}_2\text{AlTaO}_6)_{0.7}$ (LSMO/LSAT) substrates. The film thickness ranged between 3 to 100 nm. X-ray diffraction analysis revealed PZT and LSMO films are (001) oriented perovskite structure. Atomic force microscopy of the PZT/LSMO(40nm)/LSAT structures show the surface is smoothness, densely packed, and free of cracks. The surface roughness on a $3 \times 3 \mu\text{m}^2$ area of the 100 nm and 3 nm thick films is ~ 2 nm and ~ 0.3 nm respectively. Well defined ferroelectric loop was observed in Pt/PZT(100nm)/LSMO(40nm)/LSAT structure with a remanent polarization $\sim 38 \mu\text{C}/\text{cm}^2$ and a coercive field ~ 80 kV/cm. The ferroelectric nature of the PZT ultrathin films (7–3 nm) was characterized using piezo force microscopy, a clear contrast between up and down ferroelectric domains was observed after writing positive and negative polarized in $2 \times 2 \mu\text{m}^2$ and $1 \times 1 \mu\text{m}^2$ areas respectively.

1:39PM B32.00011 Ab Initio Investigation of Free Energy Landscape near Morphotropic Phase Boundary, DUCHAO LV, Department of Materials Science and Engineering, The Ohio State University, JU LI, Department of Nuclear Science and Engineering and Department of Materials Science and Engineering, Massachusetts Institute of Technology, YUNZHI WANG, Department of Materials Science and Engineering, The Ohio State University, XIAOBING REN, Ferroic Physics Group, National Institute for Materials Science, FRONTIER INSTITUTE OF SCIENCE AND TECHNOLOGY TEAM¹ — For pressure induced morphotropic phase boundary (MPB) in PbTiO_3 , although ground states have been investigated intensely, the overall free energy landscapes and so the transition paths are never systematically considered by ab initio method. Also there is little information about the oxygen octahedral tilts in monoclinic (M), orthorhombic (O) and triclinic (Tri) structures. In this work, in order to obtain the free energy landscapes, necessary oxygen octahedral tilts are considered not only in tetragonal (T) and rhombohedral (R) but also in M, O and Tri. According to the landscapes in the vicinity of MPB, firstly, the T-R transition path is not unique, since T-R and T-O-R paths have similar barriers; secondly, T-R barrier is ultra-low. Those explain the easy polarization rotation and so the ultra-high piezoelectric constant. Also, ground states are obtained by considering the oxygen octahedral tilts in T, R, M and O, and our results consist with the conclusion by J. Frantti, et.al in 2007. The fully relaxed M is actually T or R, which is indicated by the free energy landscapes. The ground state goes directly from T to R through MPB.

1:51PM B32.00012 ABSTRACT WITHDRAWN —

2:03PM B32.00013 Measuring the curves of dispersion for dielectrics using a low-energy laser and a thermal source of radiation, ROBERT LANNING, CRISTIAN BAHRIM, DON DUPLAN, Lamar University, WEI-TAI HSU, National Central University, Taiwan — We propose a simple and accurate method for finding curves of dispersion for solid and liquid dielectrics using polarized light reflected by their surface near the Brewster angle. A precision of 0.0001 for indices of refraction can be achieved from running a parabolic fit through the experimental data for the parallel component of the reflectance normalized to the total reflectance in a region only 15 degrees wide around the Brewster angle [1]. This precision allows accurate measurements of small changes in the indices of refraction that cannot be measured with other existing methods. For example, such changes can be produced by the temperature variation on the dielectric surface. In this paper we show that using a low-energy laser beam (such as the inexpensive red diode laser of 650 nm) and a thermal (blackbody) source of radiation one can easily generate precise curves of dispersion in the visible and ultraviolet spectrum for any dielectric transparent to this radiation. Our interpretation is based on the Lorentz model for the interaction between dipoles on the dielectric surface and the incident optical field. The average thermal energy of the blackbody source can be associated to an effective frequency. This thermal energy contributes to a higher frequency of oscillation of these dipoles and can be measured as a slight increase in the value of the refractive index. The project was partially supported by the McNair Scholars Program and STAIRSTEP-NSF-DUE grant# 0757057. [1] Bahrim C and Hsu W-T, 2009 *Am. J. Phys.* **77** (4) 337-343.

Session B34 DCP: Focus Session: Impact of Ultrafast Lasers II: Multidimensional Methods

107A

11:15AM B34.00001 Control over coherent light fields enables multidimensional coherent spectroscopy and multispectral coherent control, KEITH A. NELSON, Department of Chemistry, MIT — Using a combination of spatial and temporal shaping of optical laser fields, fully coherent spectroscopy and coherent control can be carried out to high order from optical to THz spectral ranges. A single beam with a single femtosecond pulse can be transformed into multiple beams and multiple pulses, reconfigurably under computer control with no human alignment needed, retaining full phase coherence among all the noncollinear fields. This enables multiple-quantum 2D and 3D Fourier transform optical spectroscopy of excitons and exciton-polaritons in inorganic quantum wells and microcavities, in organic J-aggregate films, and in inorganic/organic hybrid structures, the results of which will be discussed. Spatiotemporal shaping also enables coherent control over THz phonon-polariton waves in ferroelectric crystals. The THz waves can be coherently superposed to reach extremely large field amplitudes both in the host crystals and in free space, and the fields can be further enhanced in dipolar antenna and metamaterial structures, enabling highly nonlinear coherent spectroscopy and coherent control in the THz regime. Results from solid, liquid, and gas phases, including multiple-quantum rotational coherences in molecular gases and THz-induced phase transitions in crystalline solids, will be presented. Prospects for further generalization of the approach all the way to the hard x-ray regime will be discussed.

11:51AM B34.00002 Solvent Influenced Fluxionality Studied by Ultrafast Chemical Exchange Spectroscopy, MATTHEW ROSS, Program in Applied Physics, University of Michigan, KEVIN KUBARYCH, Department of Chemistry, University of Michigan — Two-dimensional infrared spectroscopy (2DIR) allows unprecedentedly detailed understanding of the dynamics of chemical systems in the condensed phase. Carbonyl vibrations of small transition metal complexes report intramolecular dynamics and solvent-solute interactions due to their strong oscillator strengths and moderate environmental sensitivity. We studied the fluxional dynamics of iron pentacarbonyl ($\text{Fe}(\text{CO})_5$), which is unique in that it contains nearly perfectly uncoupled vibrational modes. We seek to probe the “molecularity” of condensed phase activated barrier crossings beyond the continuum Kramers theory picture. Using 2DIR chemical exchange spectroscopy, we show how the dynamics of Berry pseudorotation, the only significant mechanism for vibrational mode mixing on our experimental timescale, is sensitive to interactions with the environment. In a wide range of solvents, we have investigated the effects of hydrogen bonding with alcohols and friction from high viscosity alkanes. In addition, we have monitored vibrational energy redistribution as a solvation shell probe. Moreover, recently implemented mid-infrared pulse shaper based methods allow increased flexibility in experimental design, enabling experimental techniques that are not possible using passive optics.

12:03PM B34.00003 Constant-Speed Vibrational Signaling along Polyethyleneglycol Chain up to 60Å Distance, ZHIWEI LIN, IGOR RUBTSOV, Tulane University — A series of azido-PEG-succinimide ester oligomers with a number of repeating PEG units of 0, 4, 8, and 12 (azPEG0, 4, 8, and 12) was investigated using a relaxation-assisted two-dimensional infrared (RA 2DIR) spectroscopy method. The RA 2DIR method relies on the energy transport in molecules and is capable of correlating the frequencies of vibrational modes separated by large through-bond distances. Excitation of the azido group in the compounds at ca. 2100 cm⁻¹ generates an excess energy which propagates in the molecule as well as dissipates into the solvent. We discovered that a part of the excess energy propagates ballistically via the covalent backbone of the molecules with a constant speed of ca. 550 m/s. The transport is described as a propagation of a vibrational wavepacket having a mean-free-path length of ca. 11Å. The discovery has the potential for developing new efficient signal transduction strategies for molecular electronics and biochemistry. It also permits extending the distances accessible in RA 2DIR structural measurements up to ca. 60Å.

12:15PM B34.00004 Two dimensional electronic spectroscopy of coherent energy transfer processes., GREG ENGEL, University of Chicago — No abstract available.

12:51PM B34.00005 Effects of Symmetry on Intense-field Ionization of Heterocyclic Organic Molecules¹, TIMOTHY SCARBOROUGH, DAVID FOOTE, CORNELIS UITERWAAL, University of Nebraska - Lincoln — We report on the ultrafast photoionization of pyridine, pyridazine, pyrimidine and pyrazine. These four molecules represent a systematic series of perturbations into the structure of a benzene ring which explores the substitution of a C-H entity with a nitrogen atom, creating a heterocyclic structure which remains isoelectronic with benzene. Other than pyridine, each molecule has the same molecular formula, with the only difference being the placement of the perturbing nitrogen atoms (ortho-, meta- or para-substitutions). Differences in the intense-field behavior of these molecules are caused by the symmetry of the perturbation to the benzene system, primarily influenced through the interactions of lone-pair states surrounding the nitrogen atoms. Data is recorded under intense-field, single-molecule conditions. 50 fs, 800 nm pulses are focused into the molecular vapor, and ion mass spectra are recorded for intensities of $\sim 10^{13}$ W/cm² to $\sim 10^{15}$ W/cm². We measure ion yields in the absence of the focal volume effect without the need for deconvolution of the data. For all targets, stable singly- and doubly-charged parent ions (C_{6-n}H_{6-n}N_n⁺⁽⁺⁾) are observed with features suggesting resonance enhancement (REMPI).

1:03PM B34.00006 Experimental determination of Hamiltonian via 3D Fourier-transform spectroscopy¹, HEBIN LI, ALAN BRISTOW, MARK SIEMENS, GALAN MOODY, STEVEN CUNDIFF, JILA, University of Colorado and National Institute of Standards and Technology, Boulder, CO 80309 — Prediction and control of quantum mechanical processes requires knowledge about the system Hamiltonian. For coherent control, information about interfering quantum pathways or the underlying Hamiltonian is essential for achieving deterministic control. Even in cases of closed-loop control, a priori knowledge about the system Hamiltonian provides guidance for designing an efficient learning algorithm and a good initial guess for faster convergence. The complete Hamiltonian of a complicated system, especially the effects of inter-particle interactions and coupling to the environments, can only be determined experimentally. Here we demonstrate an experimental determination of the Hamiltonian of an atomic vapor, achieved by using 3-dimensional Fourier transform (3DFT) spectroscopy. The 3DFT spectra provide complete information about the third-order coherent response of the vapor. The contributions from different quantum pathways are unambiguously isolated such that the components of the Hamiltonian, including energy levels, dipole moments and relaxation rates, can be determined. The 3DFT spectroscopy opens an avenue towards identifying the Hamiltonian of complex molecular systems, which can be useful for designing coherent control strategies and for studying the molecular dynamics.

1:15PM B34.00007 Nonradiative-decay mechanisms in CdSe nanoparticles: MUPPETS (multiple population-period transient spectroscopy) in excitonic systems¹, MARK BERG, KALYANASIS SAHU, SEAN KERN, Dept of Chemistry and Biochemistry, University of South Carolina — Nonradiative decay in semiconductor nanoparticles on the picosecond to nanosecond time scale is complex and poorly understood. Here, two-dimensional (2D) incoherent spectroscopy (MUPPETS) is applied to these processes in CdSe nanoparticles. For the first time, MUPPETS is extended to multilevel, excitonic systems to yield an analog of 2D coherent correlation spectroscopies. In core-only CdSe particles, the transfer of an excited electron from the core to the surface follows a highly dispersed, power-law decay in 1D measurements. 2D-MUPPETS measurements show that the rate dispersion is not due to relaxation nor due to multi-step kinetics, but results solely from particle-to-particle heterogeneity in the barrier to the surface. A model in which surface defects are distributed within the dipolar electric field of the particle accounts for the power-law decay. A second study of CdSe:ZnS core-shell particles uses correlation MUPPETS to distinguish biexcitons from photoproducts with a fast relaxing single exciton. Even when both species have similar lifetimes, they are distinguishable by having opposite signs and different symmetries in the two time intervals of a 2D experiment. Potential correlations between biexciton and exciton rates are sought, but are not found.

Monday, February 27, 2012 11:15AM - 1:51PM —
Session B35 DCP: General Theory 107B

11:15AM B35.00001 The evolution of dielectric properties of sodium, silicon and argon clusters¹, KOBLAR JACKSON, Department of Physics, Central Michigan University, Mt. Pleasant, MI 48859, MINGLI YANG, Institute of Atomic and Molecular Physics, Sichuan University, Chengdu 610065, China, LI MA, Department of Physics, Northwest University, Xi'an 710069, China, JULIUS JELLINEK, Chemical Sciences and Engineering Division, Argonne National Laboratory, Argonne, IL 60439, USA — We used a computational scheme based on site-specific polarizabilities to study the evolution of the dielectric properties of sodium, silicon and argon clusters. In this approach, the total cluster polarizability is decomposed into local dipole (LD) and charge-transfer (CT) parts. The local dipole part measures the redistribution of charge within an atomic volume, while the CT part describes the movement of charge between volumes. We find distinct differences in the relative contributions of the LD and CT components to the total polarizability as a function of cluster size for the different cluster types and relate this to the development of metallic behavior. The method also directly probes the extent of electrostatic screening of the cluster interior to an applied electric field.

¹This work was supported by the Office of Basic Energy Sciences, Division of Chemical Sciences, Geosciences and Biosciences, U.S. Department of Energy under Contracts No. DE-AC02-06CH11357 (JJ) and DE-SC0001330 (KAJ).

11:27AM B35.00002 Topological Solitons between Two Magic Number In-clusters on a Si(100) Surface Break the Even/Odd Symmetry in the Self-Selection of Their Distance, YUH-LIN WANG, M.Y. LAI, J.P. CHOU, C.M. WEI, Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei, Taiwan, O.A. UTAS, N.V. DENISOV, V.G. KOTLYAR, D. GRUZNEV, A. MATETSKY, A.V. ZOTOV, A.A. SARANIN, Institute of Automation and Control Processes, Vladivostok, Russia — Depositing particles randomly on a 1D lattice is expected to result in an equal number of particle pairs separated by even or odd lattice units. Unexpectedly, the even-odd symmetry is broken in the self-selection of distances between indium magic-number clusters on a Si(100)-2x1 reconstructed surface. Cluster pairs separated by even units are less abundant because they are linked by silicon atomic chains carrying topological solitons, which induce local strain and create localized electronic states with higher energy. Our findings reveal a unique particle-particle interaction mediated by the presence or absence of topological solitons on alternate lattices.

11:39AM B35.00003 Determination of ground state structures of selected medium-sized clusters via first-principles global search, JIJUN ZHAO, Dalian University of Technology — Due to the existence of numerous local isomers on the potential energy surface, determining the most stable structures of medium-sized clusters is one of the most challenging tasks in cluster physics. Recent years, we have explored the potential energy surface of medium-sized clusters using first-principles calculations combined with global search methods like genetic algorithm and simulate annealing. The examples on a few selected examples such as B_{80}/B_{101} , $Na_{1-3}Si_{1-11}$, and $(WO_3)_{2-12}$ clusters will be briefly illustrated. The size-dependent electronic properties of these clusters will also be discussed and compared with available experimental data.

11:51AM B35.00004 Novel building blocks for materials by design: Janus particles and other patchy colloids¹, RIGOBERTO HERNANDEZ, MATTHEW C. HAGY, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA 30332-0400 — The emergent assembly of nonisotropically structured colloidal particles can lead to novel materials with requisite optical or mechanical properties. We have developed two models—one that includes detailed interactions between particles and another that coarse-grains the interactions—so as to explore the equilibrium and dynamics effected by varying interaction heterogeneities. In particular, we have performed a series of simulations of systems consisting of Janus particles—in which each of two hemispheres can be characterized by a single interaction type such as charge or degree of hydrophobicity. The equilibrium structure of Janus clusters has been the subject of experimental and theoretical studies by Grannick and coworkers. We find that the bulk Janus systems give rise to surprising equilibrium structure and dynamics which can be tuned through both the volume fraction and the interactions. The coarse-grained model provides surprisingly good agreement with the more detailed particle-model for the equilibrium structure while overestimating the relaxation rates.

12:03PM B35.00005 Structure and Diffusion of Nanoparticles at the Liquid-Vapor Interface, SHENGFENG CHENG, GARY GREST, Sandia National Laboratories — Large-scale molecular dynamics has been used to simulate a layer of nanoparticles diffusing on the surface of a liquid. Both a low viscosity liquid, represented by Lennard-Jones monomers, and a high viscosity liquid, represented by linear homopolymers, are studied. The organization and diffusion of the nanoparticles are studied as the coverage and the contact angle between the nanoparticles and liquid are varied. Results are compared to simulations of identical nanoparticles in two-dimensions. We show that when the interaction between the nanoparticles and liquid is reduced the contact angle increases and the nanoparticles ride higher on the liquid surface, which enables them to diffuse faster. In this case the short range order is also reduced as seen in the pair correlation function. For low contact angles, nanoparticles diffuse into the liquid for high coverages.

12:15PM B35.00006 Supersymmetric Quantum Mechanics For Atomic Electronic Systems¹, THOMAS MARKOVICH, MASON BIAMONTE, DON KOURI, University of Houston — We employ our new approach to non-relativistic supersymmetric quantum mechanics (SUSY-QM), (J. Phys. Chem. A 114, 8202(2010)) for any number of dimensions and distinguishable particles, to treat the hydrogen atom in full three-dimensional detail. In contrast to the standard one-dimensional radial equation SUSY-QM treatment of the hydrogen atom, where the superpotential is a scalar, in a full three-dimensional treatment, it is a vector which is independent of the angular momentum quantum number. The original scalar Schrödinger Hamiltonian operator is factored into vector “charge” operators: $\vec{Q}$ and $\vec{Q}^\dagger$. Using these operators, the first sector Hamiltonian is written as $H_1 = \vec{Q}^\dagger \cdot \vec{Q} + E_0^1$. The second sector Hamiltonian is a tensor given by $H_2 = \vec{Q}\vec{Q}^\dagger + E_0^1$ and is isospectral with H_1 . The second sector ground state, $\vec{\psi}_0^{(2)}$, can be used to obtain the excited state wave functions of the first sector by application of the adjoint charge operator. We then adapt the aufbau principle to show this approach can be applied to treat the helium atom.

12:27PM B35.00007 Ion correlations in the electrical double layer near liquid/liquid interfaces, GUILLERMO IVAN GUERRERO GARCIA, MONICA OLVERA DE LA CRUZ, Department of Chemistry and Department of Materials Science and Engineering, Northwestern University, Evanston, Illinois 60208, USA — Equilibrium properties of the electrical double layer of monovalent salts near the interface between two immiscible electrolyte solutions are studied via Monte Carlo simulations, for several electrolyte concentrations. The corresponding results are collated with experimental data and the classical Verwey-Niessen theory of point ions. The observed differences between the simulation data and the mean field approach of “back-to-back” electrical double layers stresses the importance of including properly ionic correlations near dielectric discontinuities.

12:39PM B35.00008 Molecular Dynamics Simulation of Adsorption of Methane and Chloromethane on Molybdenum via Hybrid EAM/OPLS Interactions¹, GARY LEUTY, MESFIN TSIGE, Department of Polymer Science, The University of Akron — The question of liquid adsorption on the surface of a solid substrate has been of major interest to computational science even from its inception. Accurate depictions of adsorption phenomena require accurate modeling of both phases of the simulated system. In cases in which accuracy of the models leads to the adoption of potentially inconvenient or incompatible force fields, questions arise as to whether joint systems can perform as well as needed to gather optimal data. The current investigation uses molecular dynamics (MD) tools to focus, in part, on how well-developed models for liquid simulation (OPLS, built on a Lennard-Jones foundation) can combine with tested models for metals (based on functionals of electron density) to describe the adsorption of methane and chloromethane on the surface of molybdenum. Comparisons have been made between the differences in effect of a hybrid EAM/OPLS system and systems focusing solely on Lennard-Jones-based interactions, as well as the effect of large asymmetry and polarity differences in adsorbate species, on the structure and dynamics of layers adsorbed directly at the surface of the metal substrate. Preliminary results suggest that the surface landscape and corrugation play a significant role in choice of surface binding sites.

12:51PM B35.00009 First Principles Study of Adsorption of O_2 on Al Surface with Hybrid Functionals, HENGRUI LIU, HONGJUN XIANG, XIN GAO GONG, Key Laboratory for Computational Physical Sciences (MOE) and Surface Physics Laboratory, Fudan University — Adsorption of O_2 molecule on Al surface has been a long standing puzzle for the first principles calculation. We have studied the adsorption of O_2 molecule on the Al(111) surface using hybrid functionals. In contrast to the previous LDA/GGA, the present calculations with hybrid functionals successfully predict that O_2 molecule can be absorbed on the Al(111) surface with a barrier around 0.2~0.4 eV, which is in good agreement with experiments. Our calculations predict that the LUMO of O_2 molecule is higher than the Fermi level of the Al(111) surface, which is responsible for the barrier of the O_2 adsorption.

1:03PM B35.00010 Octaselenododecane ($C_4H_8Se_8$): a novel polyselenoether crown macrocycle¹, STEVEN RICHARDSON, Howard University, MICHAEL MEHL, MARK PEDERSON, Naval Research Laboratory — In this work we have used density-functional theory (DFT/GGA-PBE) to calculate the structural, electronic, and vibrational properties of octaselenododecane ($C_4H_8Se_8$), a novel twelve-membered crown-shaped heterocycle which contains four diselenide groups.² Our all-electron DFT calculations have yielded results that are in excellent agreement with the observed experimental x-ray diffraction data and infrared and Raman vibrational spectra for the solid state phase of octaselenododecane. In addition to obtaining good general agreement with the selected IR and Raman frequencies reported to lie within the range of 282-2925 cm^{-1} , we have obtained other vibrational modes which have not been reported in the literature. In particular, we have computed a Raman active mode at 267 cm^{-1} which is in good agreement with the experimental band at 282 cm^{-1} and have determined that it represents significant asynchronous stretches of diselenide groups within the heterocycle. Our gas phase calculations also show the presence of strong low frequency distortions that are suppressed in the crystal due to close Se-Se intramolecular interactions.

¹We are grateful to the Office of Naval Research for financial support of this work.

1:15PM B35.00011 Bias Dependent Switching Behavior of STM-Induced Melamine/Cu(001) Switch, TATSUHIKO OHTO, KOICHI YAMASHITA, Department of Chemical System Engineering, The University of Tokyo, HISAO NAKAMURA, Nanosystem Research Institute (NRI), RICS, AIST, IVAN RUNGGER, STEFANO SANVITO, School of Physics and CRANN, Trinity College Dublin — The manipulation or stimulation of molecules using Scanning Tunneling Microscopy (STM) is a technique that recently has deserved deep attention for its potential applications in molecular electronics. The melamine/Cu(001) system was found to show switching behavior in very wide range of applied bias. Although its mechanism was analyzed by a statistic model, the relationship between the switching rate and bias is still far to be fully clarified. In this context, we performed a campaign of exhaustive first-principles calculations to obtain most of the parameters for resonance model; such model is able to predict the switching rate as functions of bias and current. The energy barrier was calculated using the nudged elastic band method, with the aid of recent implementation of current-induced forces into SMEAGOL code, which is based on the nonequilibrium Green's function method with Density Functional Theory. The electron-phonon coupling and then the Inelastic Tunneling Spectroscopy signal are calculated to validate the one-phonon approximation. The spatial distribution of molecular orbitals and their coupling with vibrational modes are very useful to understand the switching behavior.

1:27PM B35.00012 ABSTRACT WITHDRAWN —

1:39PM B35.00013 Kirkwood-Buff analysis of liquid mixtures in AdResS: Towards an open boundary simulation scheme, DEBASHISH MUKHERJI, Max-Planck Institute for Polymer Research, NICO VAN DER VEGT, Center for Smart Interfaces, TU Darmstadt, KURT KREMER, Max-Planck Institute for Polymer Research, LUIGI DELLE SITE, Department of Mathematics, FU Berlin — Many biophysical processes in water are determined by interactions of cosolvents with the hydration shells of dissolved (bio)molecules. Computational approaches to study these systems are mostly limited to the closed boundary simulations. While closed boundaries are perfectly suitable in many cases, problems arise when concentration fluctuations are large, or intimately linked to the physical phenomenon. For example, in non-ideal mixtures of water/cosolvent and a biomolecule, the excess of water/cosolvent, close to a protein surface, leads to water/cosolvent depletion elsewhere. This complicates a comparison with experiments that are conducted under osmotic conditions. Therefore, we use Adaptive Resolution Simulation (AdResS) scheme, which describes a small sub-volume of a much larger system in atomistic detail, maintaining thermodynamic equilibrium with a surrounding coarse grained reservoir. We show that the Kirkwood-Buff integrals (KBI), which directly connect thermodynamic properties to the molecular distributions, can be efficiently calculated within the small open boundary all atom region and the coarse-grained reservoir maintains the correct particle fluctuations. Results will be presented for the methanol/water mixture and solvation of amino acids in urea/water mixture.

Monday, February 27, 2012 11:15AM - 2:15PM —
Session B36 DCP: Focus Session: New Energy II 107C

11:15AM B36.00001 Theories of plasmon enhanced optical processes important in solar energy, GEORGE SCHATZ, Northwestern University — This talk will focus on the development of electronic structure methods that can be combined with electrodynamics calculations to describe enhancement in chemical reaction rates that arise from plasmon excitation of noble metal nanoparticles. Two types of enhancement are described: passive and active. In the passive case, the nanoparticle produces an enhanced electromagnetic field that acts externally to the nanoparticle to enhance a photochemical process, while in the active case, plasmon excitation leads to electron transfer to or from the noble metal nanoparticle. Examples and applications of each type will be described.

11:51AM B36.00002 Porphyrin Molecular Multilayer Thin-Films on Gold (111) Electrodes for Electro-optical Applications, ALEXANDRA KRAWICZ, Chemistry Department, RPI, GUOQUANG QIAN, KIM LEWIS*, Physics Department, RPI, PETER DINOLFO*, Chemistry Department, RPI — We have developed a Layer-by-Layer (LbL) method for the fabrication of thin-film molecular multilayers on gold (111) electrodes. Copper(I) catalyzed azide-alkyne cycloaddition (CuAAC) coupling reactions were used for surface attachment and subsequent LbL deposition of porphyrin building blocks. The electrochemical and photophysical properties of the thin-films can be tuned through synthetic modification of the individual components, resulting in new porphyrin multilayers for applications in light harvesting and molecular electronics. Herein, we demonstrate the reproducible growth trends and optical properties of these films. Multilayer growth was followed by UV-Vis absorption and reflectance spectroscopy. Film thickness (FT) and optical constants were obtained from spectroscopic ellipsometry. Topology and surface roughness was examined by TM-AFM, while the copper content was quantified by XPS. The redox characteristics were studied by electrochemical methods, whereas the conductance of individual porphyrin constructs was examined by STM using the molecular break junction method. The multilayers show consistent linear growth in absorbance and FT over tens of layers and continuity in their molecular structure.

12:03PM B36.00003 Nonadiabatic Excited-State Molecular Dynamics (NA-ESMD): Numerical tests of convergence and parameters, TAMMIE NELSON, Los Alamos National Laboratory, SEBASTIAN FERNANDEZ-ALBERTI, Universidad Nacional de Quilmes, VLADIMIR CHERNYAK, Wayne State University, ADRIAN ROITBERG, University of Florida, Gainesville, SERGEI TRETIKOV, Los Alamos National Laboratory — Nonadiabatic molecular dynamics simulations, involving multiple coupled potential energy surfaces, often requires a large number of independent trajectories in order to achieve the desired convergence of the results, and simulation relies on different parameters that should be tested and compared. In addition to influencing the speed of the simulation, the chosen parameters combined with frequently implemented approximations can lead to unanticipated changes in the accuracy of the simulated dynamics. We have previously developed a nonadiabatic excited state molecular dynamics (NA-ESMD) methodology employing Tully's fewest switches surface hopping (FSSH) algorithm. In this study, we seek to investigate the impact of the number of trajectories and the various parameters on the simulation of the photoinduced dynamics of distyrylbenzene (a small oligomer of polyphenylene vinylene) within our developed framework. Various user-defined parameters are analyzed: classical and quantum integration time steps, and the number of trajectories used for statistical averaging. Common approximations such as reduced number of nonadiabatic coupling terms and the classical path approximation (CPA) are also investigated.

12:15PM B36.00004 Probing Nanointerfaces of Nanoparticle-Based Solar Energy Conversion: Molecular Dynamics on the Angstrom Scale¹, RICHARD OSGOOD², Columbia University, Laboratory for Light-Surface Interactions, Center for Integrated Science and Engineering — Charge-induced surface chemistry following solar-illumination of nanometer-scale semiconductor particles is one possible route to low-cost solar energy conversion. Because of their high surface to volume ratio interfaces play a major role in the performance of this technology and thus the physics of charges interacting with adsorbed molecules is of central interest. In this talk, after a brief review of related work, we will focus on our advances in understanding molecular-dissociation-dynamics at the interface of nanometer-scale TiO₂ crystals and large organic molecules. Clearly the standard probes of beam-based molecule dynamics are not easily adaptable to small nanointerfaces. Instead our work uses STM imaging to examine dynamics of fragments following tip-induced electron injection into organic molecules on TiO₂ (110) and on ~10nm nanocrystals (110). Our experiments have used halogenated anthracene to probe the efficiency and fragment trajectory following dissociative electron capture. Our work has examined nanoparticle synthesis, adsorbate-molecule orientation, thermal and injected-electron chemistry, and adsorbate charge-mediated fragmentation trajectories.

12:51PM B36.00005 Band gap engineering iron pyrite for sustainable solar energy conversion, ALISON HATT, Lawrence Berkeley National Lab, ALEXANDER SEBENIUS, Harvard University, JEFFREY NEATON, Lawrence Berkeley National Lab — In the quest to develop sustainable materials for solar energy conversion, iron pyrite (FeS₂) holds great promise as a solar absorber. The electronic band gap of FeS₂, however, is not well matched to the solar spectrum. Here we explore chemical doping as a strategy to engineer the band gap of FeS₂, as has been successfully demonstrated with other semiconducting materials. Using first-principles calculations, we first establish the relationship between pressure, lattice distortions, and the electronic structure of FeS₂, and rationalize the results in terms of distortions in the crystal-field splitting of Fe. We then investigate the effects of doping FeS₂ with transition metal elements, wherein our strategy is guided by the knowledge of band gap dependence on local distortions.

1:03PM B36.00006 Photochemistry of chemisorbed and physisorbed O₂ on reduced rutile TiO₂(110), GREG KIMMEL, Pacific Northwest National Laboratory — The ultraviolet (UV) photon-stimulated reactions of oxygen on TiO₂(110) are studied. For chemisorbed O₂, the photochemistry depends on the O₂ coverage. For small coverages, only ~14% desorbs while the rest either dissociates during UV irradiation, or remains molecularly adsorbed on the surface. For the maximum coverage of chemisorbed oxygen, the fraction of O₂ that photodesorbs is ~40%. However when physisorbed O₂ is also present, ~70% of the initially chemisorbed O₂ photodesorbs. Experiments using O₂ isotopologues show that UV irradiation results in exchange of atoms between the chemisorbed and physisorbed oxygen. Annealing chemisorbed oxygen to 350 K maximizes these exchange reactions. The exchange products photodesorb in the plane perpendicular to the bridge-bonded oxygen rows at an angle of 45°. Remarkably, the chemisorbed species is stable under multiple cycles of UV irradiation with physisorbed O₂, and the atoms in the chemisorbed species can be changed from ¹⁸O to ¹⁶O and then back to ¹⁸O via the exchange reactions. The results show that annealing oxygen adsorbed on TiO₂(110) to ~350 K produces a stable chemical species with interesting photochemical properties. Possible forms for the photoactive species include O₂ adsorbed in a bridging oxygen vacancy or tetraoxygen.

1:39PM B36.00007 Energy Materials in Extreme Environments, RUSSELL J. HEMLEY, Director, Geophysical Laboratory, Carnegie Institution of Washington — The critical shortage of abundant, affordable, and clean energy calls upon novel materials with extreme properties for energy production, storage, conversion, and transfer that are superior to materials that now exist or are in use today. Twenty-first century energy technology also demands enhanced performance from existing materials under extreme environments of pressure, temperature, chemistry, radiation, and electromagnetic fields. Investigating the behavior of materials in extreme pressures and temperatures, in particular, provides the fundamental knowledge needed to address these problems. These studies are leading to the discovery of both new materials with enhanced performance as well as new physical and chemical phenomena, and take advantage of advances at national x-ray, infrared, neutron, and laser facilities. An important example is the continued study of hydrogen-rich materials, from investigations of transformations in pure hydrogen, which has now been pressurized well above 300 GPa, to the discovery of new hydrogen storage materials and hydriding reactions induced by extreme conditions. Other examples include studies of carbon-based materials, which are also deepening our understanding of carbon sources and cycling within the planet.

Monday, February 27, 2012 11:15AM - 2:15PM –
Session B37 SPS: SPS Undergraduate Research I 108

11:15AM B37.00001 BREAK –

11:27AM B37.00002 Committee Work or How I Learned to Stop Complaining and Love the Process, CABOT ZABRISKIE, Old Dominion University — Over the course of their career, most American scientists, be it at an independent university, government lab, or in the private sector, will at some point receive public funding to perform their research. Yet most of these individuals have only a vague sense of how their money was originally allocated. Most may be familiar with the intricacies of NSF, NIST, or any one of the agencies that compose the alphabet soup of the Federal Government, but what about before that, when the money and subsequent directives are being allocated to these agencies? In other words, what about congress? In an effort to better understand this process and to contribute to the reciprocal understanding by congress I embarked on a 10 week internship with the House Committee on Science, Space, and Technology, funded by the John and Jane Mather Foundation as part of the SPS Summer Internship Program. In my time with the committee I was able to attend multiple hearings and seminars on the Hill and see how policies with regard to science are created. In this talk I will discuss my experience and observations, for example that no one wished to be viewed as anti-science and that even those who are looked upon as very critical are often more critical of the opposing side of the aisle than of the actual science itself. In fact, I saw that the biggest hindrance to science in the political setting is the lack of understanding of just what it is. This the same problem faced by the general public and the steps toward fixing this issue may very well be the same.

11:39AM B37.00003 Wetting in Color: Designing a colorimetric indicator for wettability, KEVIN RAYMOND, IAN B. BURGESS, NATALIE KOAY, MATHIAS KOLLE, MARKO LONCAR, JOANNA AIZENBERG, Harvard University — Colorimetric litmus tests such as pH paper have enjoyed wide commercial success due to their inexpensive production and exceptional ease of use. While such indicators commonly rely on a specific photochemical response to an analyte, we exploit structural color, derived from coherent scattering from wavelength-scale porosity rather than molecular absorption or luminescence, to create a Wetting-in-Color-Kit (WICK). This inexpensive and highly selective colorimetric indicator for organic liquids employs chemically encoded inverse-opal photonic crystals to translate minute differences in liquids' wettability to macroscopically distinct, easy-to-visualize color patterns. The highly symmetric re-entrant inter-pore geometry imparts a highly specific wetting threshold for liquids. We developed surface modification techniques to generate built-in chemistry gradients within the porous network. These let us tailor the wettability threshold to specific liquids across a continuous range. As wetting is a generic fluidic phenomenon, we envision that WICK could be suitable for applications in authentication or identification of unknown liquids across a broad range of industries.

11:51AM B37.00004 EPR spectral study and modeling of lithium borovanadate $\text{RLi}_2\text{OB}_2\text{O}_3\text{KV}_2\text{O}_5$ glasses¹, BRANDON POLLPETER, BLANE BAKER, BIKESH DAHAL, William Jewell College, STEVE FELLER, Coe College — Utilizing electron paramagnetic resonance EPR spectroscopy, lithium borovanadate $\text{RLi}_2\text{OB}_2\text{O}_3\text{KV}_2\text{O}_5$ glasses with R = 0.4 and K ranging from 0.1 to 0.5 were analyzed in order to elucidate the environment of unpaired $3d^1$ electrons. Transitions associated with coupling of such electrons to vanadium nuclear spins were identified and modeled to reveal both g factor and A factor values. For a system with K = 0.3, representative data include: $g_{\parallel} = 1.9242$, $g_{\perp} = 1.9693$, $A_{\parallel} = 184.3768 \text{ cm}^{-1}$, $A_{\perp} = 64.6568 \text{ cm}^{-1}$, $\Delta g_{\parallel} = 0.0781$, $\Delta g_{\perp} = 0.0330$, and $\Delta g_{\parallel}/\Delta g_{\perp} = 2.3670$. A comparison revealing $g_{\parallel} < g_{\perp} < g_e$ is indicative of localized electrons residing in tetragonally-distorted octahedral sites. A slight increase observed in $\Delta g_{\parallel}/\Delta g_{\perp}$ values when K = 0.1 to K = 0.3 is further evidence of a possible elongation of the octahedral site associated with increasing K values. This pattern, however, is not present in systems with K values greater than 0.3, suggesting that perhaps no further elongation of the site is possible due to bond constraints. A comprehensive model will be presented to summarize data for the entire family of lithium borovanadates studied here.

12:03PM B37.00005 Metal-Metal Oxide Nanocomposite for Solar Cell Applications¹, H. GEMAR, K. GHOSH, Department of Physics, Astronomy and Materials Science, Missouri State University, Springfield, MO 65897 — Currently, there is a large need for alternative energies and one good option is solar cells. A High efficiency solar cell generally consists of a number of thin layers: active layer consisting of a material having high absorption in the solar spectrum, transparent conducting layer, *p*- and *n*-type materials used to fabricate the junction, and electrodes for good Ohmic contacts. The presence of metal nanoparticles in metal oxide films improves significantly the solar absorbance of metal oxide films. The absorption depends on the bandgap of metal oxides which can be tuned by incorporation of metal nanoparticles. Tuning of the bandgap and absorption are the very important parameters to fabricate the solar cell devices. Thin films of M-MO (M = transition metals Co and Ni) nanocomposite have been grown on quartz substrate using pulse laser deposition technique. Structural properties have been characterized using X-ray diffraction and scanning electron microscopy. Electrical properties with and without light and absorption spectra have been measured using I-V characterization and UV-VIS spectroscopy techniques. Detailed results will be discussed in the presentation.

¹This work is supported by National Science Foundation (Award Number DMR-0907037).

12:15PM B37.00006 Electrical Characterization of Flexible Titanium Dioxide Memristors, VICTORIA ROSBOROUGH, NADINE GERGEL-HACKETT, Mary Baldwin College — The memristor is a new fundamental circuit element with a resistance that depends on the magnitude and polarity of the voltage applied to it and the length of time that voltage is applied. Memristors are also nonvolatile, which means that when the bias is removed, a memristor retains its last resistive state. While memristors have potential applications ranging from alternative computer architectures to memory in inexpensive lightweight wearable sensors, the mechanism behind its switching is not well understood. One of the major questions to be resolved is whether memristive switching is electric field dependent or charge dependent. In the former case, a minimum bias is needed for switching to occur. In the latter case, a minimum amount of charge needs to pass through the device to cause switching. I will present the results of electrically characterizing flexible memristors that consist of a nm-thick layer of titanium dioxide sandwiched between two metal contacts in an effort to help establish whether their switching is charge or field-driven.

12:27PM B37.00007 Two-Dimensional Ordering of DNA Origami Using Stacking Bonds, YOSUKE SUGISHITA, LEE WIZDA, PRASHANT SHARMA, Department of Physics, Suffolk University — Utilizing the DNA Origami method we have designed nano-scale self-assembled structures. These structures are made using a 7000 base pair long single stranded DNA as a scaffold that is held in place by shorter single stranded DNA molecules using Watson-Crick DNA base pairings. The staples were chosen to attach at certain specific sites of the scaffold DNA so that a well-defined planar structure of double stranded DNA can be created at room temperature. In designing these origami structures we made use of the computer application caDNAo. Two geometrical structures with differing symmetries were created using the same scaffold. Edges of these structures were modified in such a way that the double stranded DNA of one structure's edge can stack onto the edge of the second structure. Similar modifications were recently shown by Woo and Rothmund (Nat Chem., 1755-4330, 2011) to enable the formation of extended DNA origami structures. We intend to extend this method to create two-dimensional square and triangular lattice structures. We discuss our experimental results and implications of this method for nano-scale self-assembly.

12:39PM B37.00008 Synthesis of Magnetic Nanoparticles for Biosensing Studies Using Magneto-Impedance Technology¹, ROSEMARY SHELLEN, Covenant College, RAMON RUIZ, KRISTEN STOJAK, NICHOLAS LAURITA, ANURAG CHATURVEDI, University of South Florida, PHILLIP BROUSSARD, Covenant College, MANH-HUONG PHAN, HARIHARAN SRIKANTH, University of South Florida — Polymer nanocomposites (PNCs) have been shown to be a compact and durable solution for applications such as electromagnetic interference shielding and magnetically tunable microwave devices. We report studies aimed at exploring applications of PNCs to aid in bio-sensing, using the Giant Magneto-Impedance (GMI) effect. GMI is a change in the ac impedance of a ferromagnetic conductor in a varying dc magnetic field, and has been shown to be about 500 times more sensitive than its counterpart, Giant Magneto-Resistance (GMR). In our study, magnetite (Fe_3O_4) nanoparticles (mean size, $6 \pm 2 \text{ nm}$) were synthesized by thermal decomposition and dispersed in a polymer provided by the Rogers Corporation to create PNCs with 20, 50, and 80 wt% compositions. The GMI of an amorphous magnetic ribbon was measured with and without the PNCs layered on the ribbon. The effects of nanoparticle concentration on the GMI sensitivity were studied, with a view toward applications in highly sensitive bio-molecular detection.

12:51PM B37.00009 Development of a Protocol to Study the Conformational Stability of Protein Using the Model Protein Cytochrome *c*¹, JESSICA STAVOLE, BENJAMIN OPPERMAN, Department of Biology, Xavier University, JUSTIN LINK, Department of Physics, Xavier University — The function of a protein is inherently dependent upon the proper folding and the resulting tertiary structure of the molecule. The development of an unfolding procedure is desirable so that the structural stability of a protein molecule can be determined through the change in thermodynamic properties of the unfolding reaction. The protein cytochrome *c* has long been used in protein structural studies and monitored by circular dichroism (CD), absorption, and fluorescence spectroscopic techniques. Single amino acid mutations of wild type cytochrome *c* were unfolded both chemically and thermally using the developed protocol and the unfolding was monitored by CD spectroscopy. Thermodynamic properties such as Gibbs free energy, enthalpy and melting temperature were used to interpret the results. The mutant proteins were calculated to have different thermodynamic properties than that of the native cytochrome *c* during the unfolding process. When denatured at a lower pH, the proteins thermally unfolded more readily. The objective of this session is to present recent work addressing the denaturation of wild type and mutant proteins.

1:03PM B37.00010 Genotyping and phenotyping of an epigenetic modifier *Unstable factor for orange1 (Ufo1)* in maize, KARISA BOWERSOX, Lock Haven University of Pennsylvania, SURINDER CHOPRA, Penn State University — Pericarp color 1 is a model system for the study of epigenetic gene regulation. It has more than 100 alleles that contribute to the color of the pericarp and cob glume of maize. Unstable factor for orange 1 (Ufo1) is a spontaneous dominant mutation that leads to a gain in pigmentation due to a decrease in methylation in *p1* genes. This decrease in methylation of cytosine in the DNA leads to changes in chromatin structure. Finding the mechanism for this spontaneous mutation can lead to way of preventing the mutation increasing production colorless maize for food production. Through genotyping and phenotyping fine gene mapping, gene expression and whole genome profiling can be accomplished for plants with the Ufo1 mutation present.

1:15PM B37.00011 Computational and Electronic Analog Implementation of the Hodgkin-Huxley Model of Action Potentials in Neurons¹, PETER SMITH, JUSTIN LINK, Xavier University — Alan Loyd Hodgkin and Andrew Huxley's mathematical model of action potential initiation and propagation in neurons is one of the greatest hallmarks of biophysics. Two techniques for implementing the Hodgkin-Huxley model were explored: computational and electronic analog. Computational modeling was done using NEURON 7.1. NEURON is a free, robust, and relatively user friendly simulation environment that enables quantitatively accurate computational modeling of neurons and neural networks. An analog electronic circuit was built using field-effect transistors (FETs) to simulate the non-linear, voltage-dependent (sodium and potassium) conductances that are responsible for membrane excitability. While the electronic analog qualitatively reproduces many of the key features of the action potential including overall shape, inactivation period, and propagation, it was difficult to quantitatively reproduce the Hodgkin-Huxley model. In addition, while the relative cost to build circuits equivalent to small membrane patches is minimal (~\$50), implementation of larger cells or networks would prove uneconomical. Still, both techniques are viable avenues toward introducing interdisciplinary research into either a computational or electronics lab setting at the undergraduate level.

1:27PM B37.00012 First-principles calculation of structural and electronic properties of memantine (Alzheimer's disease) and adamantane (anti-flu) drugs¹, KIRSTEN MIDDLETON, GUOPING ZHANG, Department of Physics, Indiana State University, THOMAS F. GEORGE, University of Missouri-St. Louis — Memantine is currently used as a treatment for mild to severe Alzheimer's disease, although its functionality is complicated. Using various density functional theory calculations and basis sets, we first examine memantine alone and then add ions which are present in the human body. This provides clues as to how the compound may react in the calcium ion channel, where it is believed to treat the disease. In order to understand the difference between calcium and magnesium ions interacting with memantine, we compute the electron affinity of each complex. We find that memantine is more strongly attracted to magnesium ions than calcium ions within the channel. By observing the HOMO-LUMO gap within memantine in comparison to adamantane, we find that memantine is more excitable than the anti-flu drug. We believe these factors to affect the efficiency of memantine as a treatment of Alzheimer's disease.

¹Thanks to the Department of Energy grant #DE-FG02-06ER46304, the Department of Chemistry and Physics at Indiana State University, Eric Glendening for his help with Gaussian and other calculations, and Payton Kuhnle for her calculations with memantine.

1:39PM B37.00013 Construction and Operation of a Differential Hall Element Magnetometer¹, MATTHEW W. CALKINS, Dept. Physics, Univ. Florida, PHILIP D. JAVERNICK, Dept. Chem. and Physics, Augusta State Univ., PEDRO A. QUINTERO, YITZI M. CALM, MARK W. MEISEL, Dept. Physics, Univ. Florida and NHMFL — A Differential Hall Element Magnetometer (DHEM) was constructed to measure the magnetic saturation and coercive fields of small samples consisting of magnetic nanoparticles that may have biomedical applications. The device consists of two matched Hall elements that can be moved through the room temperature bore of a 9 Tesla superconducting magnet. The Hall elements are wired in opposition such that a null response, to within a small offset, is measured in the absence of a sample that may be located on top of one unit. A LabVIEW program controls the current through the Hall elements and measures the net Hall voltage while simultaneously moving the probe through the magnetic field by regulating a linear stepper motor. Ultimately, the system will be tested to obtain a figure of merit using successively smaller samples. Details of the apparatus will be provided along with preliminary data.

¹We acknowledge early contributions to this work by Alex M. Sincore and Elisabeth S. Knowles. Supported by NSF DMR-0701400 (MWM), UF Dept. Physics REU (DMR-0851707), NHMFL REU (DMR-0654118), and the State of Florida

1:51PM B37.00014 Magnetostriction of engineered magnetorheological elastomers, WILLIAM RIEGER, CHRIS KASSNER, PARIS VON LOCKETTE, SAMUEL LOFLAND, Rowan University — We have completed a study of the magnetostriction and poison ratio of several types of magnetorheological elastomers (MREs), including both hard and soft magnetic materials in silicone rubber matrices. While both random and aligned soft magnetic particles gave large (~1%) magnetostriction, hard magnetic powders provided minimal actuation, regardless of whether they were aligned or not. In addition, we have created engineered lattices of magnetic wires and find the actuation highly dependent on the sample shape, and the angle of the magnetic field with respect to the alignment axis. We also propose some new structures based on hard magnetic wires which should provide piezomagnetic response.

2:03PM B37.00015 Physical Patterns Associated with 27 April 2011 Tornado Outbreak¹, FERNANDA RAMOS, University of Puerto Rico at Mayaguez, THOMAS SALEM, National Weather Service, Memphis, TN — The National Weather Service office in Memphis, Tennessee has aimed their efforts to improve severe tornado forecasting. Everything is not known about tornadogenesis, but one thing is: tornadoes tend to form within supercell thunderstorms. Hence, 27 April 2011 and 25 May 2011 were days when a Tornado Outbreak was expected to arise. Although 22 tornadoes struck the region on 27 April 2011, only 1 impacted the area on 25 May 2011. In order to understand both events, comparisons of their physical features were made. These parameters were studied using the Weather Event Simulator system and the NOAA/NWS Storm Prediction database. This research concentrated on the Surface Frontal Analysis, NAM40 700mb Dew-Points, NAM80 250mb Wind Speed and NAM20 500mb Vorticity images as well as 0-6 km Shear, MUCAPE and VGP mesoscale patterns. As result of this research a Dry-Line ahead of a Cold Front, Dew-points $\sim 5^{\circ}\text{C}$ and higher, and high Vorticity values were synoptic patterns that influenced to the formation of supercell tornadoes. Finally, MUCAPE and VGP favored the possibility of tornadoes occurrence on 25 May 2011, but shear was the factor that made 27 April 2011 a day for a Tornado Outbreak weather event.

Monday, February 27, 2012 11:15AM - 2:15PM – Session B39 DCOMP: Electronic Structure: Calculations I 109B

11:15AM B39.00001 Acceleration of Hartree-Fock Exchange Computations using Recursive Subspace Bisection¹, IVAN DUCHEMIN, Department of Applied Science, University of California Davis, Davis CA 95616, FRANCOIS GYGI, Department of Computer Science, University of California Davis, Davis CA 95616 — We use the recursive subspace bisection algorithm [1] to accelerate the computation of the Hartree-Fock exchange operator in electronic structure computations involving hybrid density functionals. This approach leads to a reduction of the computational cost of the exchange operator from $O(N^3 \log N)$ to $O(N^2 \log N)$ and allows for controlled accuracy through a threshold parameter. The subspace bisection method is extended to invariant subspaces including excited states. Applications to molecular dynamics simulations and computations of energy band gaps in large systems using the PBE0 hybrid functional will be presented.

11:27AM B39.00002 A Discontinuous Galerkin Framework for Electronic Structure Calculations, ANDREW BACZEWSKI, BALASUBRAMANIAM SHANKER, SUBHENDRA MAHANTI, BENJAMIN LEVINE, Michigan State University — It is generally accepted that a good basis set for any calculation should possess a number of salient features, including systematic improvability, adaptive resolution of multiscale features, and fidelity in capturing the pertinent physics. Considering the progenitors of most modern electronic structure basis sets to be Gaussian-type orbitals or plane waves, descendants of these methods have inherited features that address either systematic improvability (plane waves) or adaptive resolution (Gaussians) separately, and use a variety of tricks to differentiate the core and valence physics. Discontinuous Galerkin methods provide a framework for defining adaptive local basis sets, that may be based on these canonical basis sets, that can be mixed and matched to simultaneously achieve all of these goals. Our group is presently developing a new electronic structure code to enable Density Functional and Hartree-Fock calculations within this framework, particularly in the context of all-electron formulations wherein the accurate resolution of both core and valence states is necessary. Numerous implementation details will be addressed, including the incorporation of hardware- and software-based acceleration, such as GPU-based parallelism, and fast electrostatics solvers.

11:39AM B39.00003 New method of optimizing the Jastrow factor for solids with the transcorrelated method, MASAYUKI OCHI, Department of Physics, The University of Tokyo, SHINJI TSUNEYUKI, Department of Physics, The University of Tokyo, ISSP, The University of Tokyo — Transcorrelated (TC) method[1-5] is one of the promising theories for *ab initio* electronic structure calculation of solids. It is one of the wave-function-based approaches which are considered to be advantageous for high-accuracy calculation. In the TC method, the total wave function is approximated as the Jastrow-Slater-type wave function, and the many-body Hamiltonian is similarity-transformed by the Jastrow factor. Then we solve an SCF equation and optimize one-body orbitals in the Slater determinant with relatively low computational cost. On the other hand, optimization of the Jastrow factor has been computationally much more demanding although it is indispensable to high-accuracy calculation. In this study, a new method of optimizing the Jastrow factor is developed by use of variance minimization of the total energy. It is demonstrated that, by truncating the basis-set expansion of the variance, the optimization is realized with low computational cost. [1] S. F. Boys and N. C. Handy, Proc. R. Soc. London Ser. A 309, 209 (1969). [2] S. Ten-no, Chem. Phys. Lett. 330, 169 (2000). [3] N. Umezawa and S. Tsuneyuki, J. Chem. Phys. 119, 10015 (2003). [4] R. Sakuma and S. Tsuneyuki, J. Phys. Soc. Jpn. 75, 103705 (2006). [5] H. Luo, J. Chem. Phys. 133, 154109 (2010).

11:51AM B39.00004 Adaptive local basis set for Kohn-Sham density functional theory in a discontinuous Galerkin framework, LIN LIN, Lawrence Berkeley National Laboratory, JIANFENG LU, Courant Institute, New York University, LEXING YING, The University of Texas at Austin, WEINAN E, Princeton University — Uniform discretization of the Kohn-Sham Hamiltonian generally results in a large number of basis functions per atom in order to resolve the rapid oscillations of the Kohn-Sham orbitals around the nuclei even in the pseudopotential framework. Atomic orbitals and similar objects significantly reduces the number of basis functions, but these basis sets generally require fine tuning of the parameters in order to reach high accuracy. We present a novel discretization scheme that adaptively and systematically builds the rapid oscillations of the Kohn-Sham orbitals around the nuclei as well as environmental effects into the basis functions. The resulting basis functions are localized in the real space, and are discontinuous in the global domain. The continuous Kohn-Sham orbitals and the electron density are evaluated from the discontinuous basis functions using the discontinuous Galerkin (DG) framework. Our method is implemented in parallel and the current implementation is able to handle systems with at least thousands of atoms. Numerical examples indicate that our method can reach very high accuracy (less than 1meV) with a very small number ($4 \sim 40$) of basis functions per atom.

12:03PM B39.00005 Retrofit of the HSE density functional¹, JONATHAN MOUSSA, PETER SCHULTZ, Sandia National Labs, JAMES CHELIKOWSKY, UT Austin — The original parameterization of the Heyd-Scuseria-Ernzerhof (HSE) density functional was dependent on the choice of a hybrid fraction and a range-separation length for separating out a portion of the exchange energy to compute exactly. For backward compatibility with the PBE0 functional, the hybrid fraction was fixed to 0.25. Here, we examine the full hybrid fraction / separation length phase space. With respect to multiple error metrics, the phase space does not have a well-developed point of minimum error. Instead, there is a “valley” of functionals with increasing hybrid fraction and decreasing separation length of similarly good quality. This enables a reduction of the separation length without degrading the accuracy of the HSE06 parameterization, which in turn reduces the computational cost of evaluating the exchange energy.

¹Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's NNSA under contract DE-AC04-94AL85000.

12:15PM B39.00006 Projector Augmented Wave formulation of orbital-dependent exchange-correlation functionals¹, XIAO XU, N.A.W. HOLZWARTH, Wake Forest University — The use of orbital-dependent exchange-correlation functionals within electronic structure calculations has recently received renewed attention for improving the accuracy of the calculations, especially correcting self-interaction errors. Since the Projector Augmented Wave (PAW) method² is an efficient pseudopotential-like scheme which ensures accurate evaluation of all multipole moments of direct and exchange Coulomb integrals, it is a natural choice for implementing orbital-dependent formalisms. Using Fock exchange as an example of an orbital-dependent functional, we developed the formulation and numerical implementation of the approximate optimized effective potential formalism of Kreiger, Li, and Iafrate (KLI)³ within the PAW method, comparing results with the analogous Hartree-Fock treatment.⁴ Test results are presented for ground state properties of two well-known materials – diamond and LiF. This formalism can be extended to treat orbital-dependent functionals more generally.

12:27PM B39.00007 Solution of the Bethe-Salpeter equation without empty electronic states: Applications to solids, nanostructures and molecules¹, DARIO ROCCA, YUAN PING, UC Davis, DEYU LU, Brookhaven National Laboratory, GIULIA GALLI, UC Davis — A method to solve the Bethe-Salpeter equation that avoids the explicit calculation of empty electronic states and the storage and inversion of dielectric matrices has been recently introduced [1-3]. This approach is suitable to compute the absorption spectra of large systems in a wide energy range and without relying on the Tamm-Dancoff approximation. We show the accuracy and scalability of this method by presenting calculations of absorption spectra of solids, molecules and nanostructures, including Si quantum dots and nanowires. In the case of nanowires, we discuss the influence of size and surface reconstruction on the optical properties.

12:39PM B39.00008 Iterative diagonalization of non-Hermitian eigenproblems in time-dependent density-functional and many-body perturbation theory¹, ZHAOJUN BAI, DARIO ROCCA, UC Davis, REN-CANG LI, UT Arlington, GIULIA GALLI, UC Davis — We present a technique for the iterative diagonalization of random-phase approximation (RPA) matrices, which are encountered in the framework of time-dependent density-functional theory (TDDFT) and in the solution of the Bethe-Salpeter equation (BSE) [1]. The non-Hermitian character of these matrices does not permit a straightforward application of standard iterative techniques used, i.e., for the diagonalization of ground state Hamiltonians. We first introduce a new block variational principle for RPA matrices. We then develop an algorithm for the simultaneous calculation of multiple eigenvalues and eigenvectors, with convergence and stability properties similar to techniques used to iteratively diagonalize Hermitian matrices. The algorithm is validated by computing multiple low-lying excitation energies of molecules at both the TDDFT and BSE level.

12:51PM B39.00009 New *ab initio* approaches for calculating the microscopic electron-density response matrix, KATHLEEN SCHWARZ, Cornell University Department of Chemistry, JEEHYE LEE, T.A. ARIAS, Cornell University, Department of Physics — The electron-density response matrix is a key quantity for excitation calculations such as GW-BSE. Typically, the response matrix is obtained at the level of the random phase approximation (RPA), with the wavefunction from local density approximation (LDA) density functional theory. The expense of this approach grows quickly with the number of atoms, and its accuracy depends on both the accuracy of the LDA and the RPA. We investigate a series of approaches to overcome these difficulties, based on an eigenvalue decomposition of the molecular response matrix.

1:03PM B39.00010 Cluster expansion of the electron-density response function: GW+BSE with molecular environments, JEEHYE LEE, T.A. ARIAS, Cornell University, Department of Physics — Molecular excitations in dielectric environments have drawn great interest because environmental manipulation provides the possibility to engineer photo-excitation processes. In exciton calculation the environments often are replaced by dielectric continuum media. These approaches have been successful for solvated molecules, but they lack molecular detail, and hence miss microscopic features. We present a new method to represent environments that allows a more accurate treatment of a wide range of systems by employing cluster expansions of environmental response functions. This initial work, at the GW+BSE level, presents results for shifts in excitation energies due to environments consisting of either individual molecules or conjugated polymers.

1:15PM B39.00011 Unified description of ground and excited states of finite systems: the self-consistent *GW* approach, FABIO CARUSO, PATRICK RINKE, XINGUO REN, Fritz Haber Institute, Berlin, Germany, ANGEL RUBIO, Universidad del Pais Vasco, San Sebastian, Spain, MATTHIAS SCHEFFLER, Fritz Haber Institute, Berlin, Germany — Fully self-consistent *GW* calculations – based on the iterative solution of the Dyson equation – provide an approach for consistently describing ground and excited states on the same quantum mechanical level. Based on our implementation in the all-electron localized basis code FHI-aims [1], we show that for finite systems self-consistent *GW* reaches the same final Green function regardless of the starting point. The results show that self-consistency systematically improves ionization energies and total energies of closed shell systems compared to perturbative *GW* calculations (G_0W_0) based on Hartree-Fock or (semi)local density-functional theory. These improvements also translate to the electron density as demonstrated by a better description of the dipole moments of hetero-atomic dimers and the similarity with the coupled cluster singles doubles (CCSD) density. The starting-point independence of the self-consistent Green function facilitates a systematic and unbiased assessment of the performance of the *GW* approximation for finite systems. It therefore constitutes an unambiguous reference for the future development of vertex corrections and beyond *GW* schemes. [1] V. Blum *et al.*, *Comp. Phys. Comm.* **180**, 2175 (2009).

1:27PM B39.00012 Stress formulation in the all-electron full-potential linearized augmented plane wave method, NAUYUKI NAGASAKO, Toyota Central R&D labs., Inc., TAMIO OGUCHI, ISIR, Osaka University — Stress formulation in the linearized augmented plane wave (LAPW) method has been proposed in 2002 [1] as an extension of the force formulation in the LAPW method [2]. However, pressure calculations only for Al and Si were reported in Ref.[1] and even now stress calculations have not yet been fully established in the LAPW method. In order to make it possible to efficiently relax lattice shape and atomic positions simultaneously and to precisely evaluate the elastic constants in the LAPW method, we reformulate stress formula in the LAPW method with the Soler-Williams representation [3]. Validity of the formulation is tested by comparing the pressure obtained as the trace of stress tensor with that estimated from total energies for a wide variety of material systems. Results show that pressure is estimated within the accuracy of less than 0.1 GPa. Calculations of the shear elastic constant show that the shear components of the stress tensor are also precisely computed with the present formulation [4].

1:39PM B39.00013 Real Space DFT by Locally Optimal Block Preconditioned Conjugate Gradient Method, VINCENT MICHAUD, HONG GUO, McGill University — Real space approaches solve the Kohn-Sham (KS) DFT problem as a system of partial differential equations (PDE) in real space numerical grids. In such techniques, the Hamiltonian matrix is typically much larger but sparser than the matrix arising in state-of-the-art DFT codes which are often based on directly minimizing the total energy functional. Evidence of good performance of real space methods - by Chebyshev filtered subspace iteration (CFSI) - was reported by Zhou, Saad, Tiago and Chelikowsky [1]. We found that the performance of the locally optimal block preconditioned conjugate gradient method (LOGPCG) introduced by Knyazev [2], when used in conjunction with CFSI, generally exceeds that of CFSI for solving the KS equations. We will present our implementation of the LOGPCG based real space electronic structure calculator.

1:51PM B39.00014 Bridging density-functional and many-body perturbation theory: orbital-density dependence in electronic-structure functionals, ANDREA FERRETTI, S3 Center, CNR - Istituto Nanoscienze, Modena, Italy., ISMAILA DABO, CERMICS, Universite Paris-Est, MATTEO COCCIONI, CEMS, University of Minnesota, NICOLA MARZARI, Department of Materials, Oxford University — Energy functionals which depend explicitly on the orbital densities (ODD), instead of the total charge density, appear when applying self-interaction corrections to density-functional theory. In these cases (e.g. the Perdew-Zunger [1] and the non-Koopmans [2] approaches) the total energy loses invariance under unitary rotations of the orbitals, and the minimization of the functionals leads to orbital-dependent Hamiltonians. We show that it is possible to identify the orbital-dependency of densities and potentials with an effective and discretized frequency-dependency, in close analogy to the quasi-particle approximation of frequency-dependent self-energies and naturally oriented to interpret electronic spectroscopies [3]. Some of the existing ODD functionals are analyzed from this new perspective. Numerical results for the electronic structure of gas-phase molecules (within the Koopmans-corrected class of functionals) are computed and found in excellent agreement with photoemission (UPS) data. 2:03PM B39.00015 A new type of pseudopotentials: effective atomic pseudopotentials, JAIRO RICARDO CARDENAS, ROBY CHERIAN, GABRIEL BESTER, Max Planck Institute for Solid State Research — We derive a new type of pseudopotentials from conventional norm-conserving pseudopotentials for the treatment of a large number of atoms. The pseudopotentials are not aimed at the calculation of the total energy, but of band edge states relevant for optical processes. We describe the pseudopotential construction and benchmark its quality and transferability by comparison to standard DFT calculations.

Session B40 DBIO DPOLY: Focus Session: Cytoskeleton and Biomechanics - Entanglement and Crosslinking 156A

11:15AM B40.00001 Seeing is believing: New insight into structure-mechanics relationships in entangled and crosslinked microtubule networks, MEGAN VALENTINE, Department of Mechanical Engineering, University of California Santa Barbara — The microtubule cytoskeleton is essential in maintaining the shape, strength and organization of cells and its misregulation has been implicated in neurological disorders and cancers. To better understand the structure-mechanics relationships in microtubule networks, we measure the force-dependent viscoelastic responses of entangled and sparsely crosslinked microtubule networks to precise microscale manipulation. We use magnetic tweezers devices to apply calibrated step stresses and measure the resultant strain as a function of time. At short times the material behaves as an elastic solid. The linear regime is large, with gentle stiffening observed in entangled networks above ~70% strains. Crosslinked networks are stiffer, and show an extended linear regime. At longer times, we find a creeping regime, suggesting that structural rearrangements of the network dominate the mechanical response. To understand the molecular origins of this behavior, we use a newly-developed portable magnetic tweezers device to observe the network morphology using a confocal microscope while simultaneously applying point-like stresses to embedded magnetic particles. We observe substantial network compression in front of the bead with no evidence of long-length scale filament flow, and find that the spatial extent of the deformation field depends sensitively on network architecture and connectivity. Our results are important to understanding the role of the cytoskeleton in regulating cargo transport in vivo, as well as the basic physics of non-affine deformations in rigid rod polymer networks.

11:51AM B40.00002 Actin filament curvature biases branching direction, EVAN WANG, VIVIANA RISCA, UC Berkeley, OVIJIT CHAUDHURI, Harvard University, JIA-JUN CHIA, Johns Hopkins University, PHILLIP GEISSLER, DANIEL FLETCHER, UC Berkeley — Actin filaments are key components of the cellular machinery, vital for a wide range of processes ranging from cell motility to endocytosis. Actin filaments can branch, and essential in this process is a protein complex known as the Arp2/3 complex, which nucleate new "daughter" filaments from pre-existing "mother" filaments by attaching itself to the mother filament. Though much progress has been made in understanding the Arp2/3-actin junction, some very interesting questions remain. In particular, F-actin is a dynamic polymer that undergoes a wide range of fluctuations. Prior studies of the Arp2/3-actin junction provides a very static notion of Arp2/3 binding. The question we ask is how differently does the Arp2/3 complex interact with a straight filament compared to a bent filament? In this study, we used Monte Carlo simulations of a surface-tethered worm-like chain to explore possible mechanisms underlying the experimental observation that there exists preferential branch formation by the Arp2/3 complex on the convex face of a curved filament. We show that a fluctuation gating model in which Arp2/3 binding to the actin filament is dependent upon a rare high-local-curvature shape fluctuation of the filament is consistent with the experimental data.

12:03PM B40.00003 Condensation of F-Actin by Dimensional Reduction, ROBIJN BRUINSMA, Department of Physics and Astronomy, UCLA, CYRON CHRISTIAN, KEI MUELLER, Mechanical Engineering, Technical University, Munich, Germany, ANDREAS BAUSCH, Chair Cell Biophysics E27, Technical University, Muenchen, Germany, WOLFGANG WALL, Mechanical Engineering, Technical University, Munich, Germany — We present a Brownian Dynamics simulation of the equilibrium condensation of F-actin in the presence of linker molecules. The filaments are modeled as worm-like chains, using finite element analysis. At low linker concentrations, the systems forms a gel whose physical properties do not depend on the linker molecules. If the linker concentration is increased then for isotropic linkers only a single mode of condensation is encountered: bundle formation. If the linker molecules impose a preferential angle between F-actin filaments, then condensation takes place either into a either a hexatic or squaratic two-dimensional liquid crystal phase or into a heterogeneous cluster. Condensation is driven by competition between linker and filament entropy, which imposes dimensional reduction on the F-actin aggregate.

12:15PM B40.00004 Stress Enhanced Gelation in α -Actinin-4 Cross-linked Actin Networks, NORMAN YAO, Harvard University, CHASE BROEDERSZ, Princeton University, MARTIN DEPKEN, Vrije Universiteit, DANIEL BECKER, Brigham and Women's Hospital and Harvard Medical School, MARTIN POLLAK, Beth Israel Deaconess Medical Center and Harvard Medical School, FREDERICK MACK-INTOSH, Vrije Universiteit, DAVID WEITZ, Harvard University — A hallmark of biopolymer networks is their exquisite sensitivity to stress, demonstrated for example, by pronounced nonlinear elastic stiffening. Typically, they also yield under increased static load, providing a mechanism to achieve fluid-like behavior. In this talk, I will demonstrate an unexpected dynamical behavior in biopolymer networks consisting of F-actin cross-linked by a physiological actin binding protein, α -Actinin-4. Applied stress actually enhances gelation of these networks by delaying the onset of structural relaxation and network flow, thereby extending the regime of solid-like behavior to much lower frequencies. By using human kidney disease-associated mutant cross-linkers with varying binding affinities, we propose a molecular origin for this stress-enhanced gelation: It arises from the increased binding affinity of the cross-linker under load, characteristic of catch-bond-like behavior. This property may have important biological implications for intracellular mechanics, representing as it does a qualitatively new class of material behavior.

12:27PM B40.00005 Simulations and theory of model microtubule self-assembly¹, MARK STEVENS, SHENGFENG CHENG, Sandia National Labs, ANKUSH AGGARWAL, U. California at Los Angeles — We used molecular dynamics simulations to study the self-assembly of artificial microtubules. The model monomer has a wedge-shape to promote formation of rings that stack to form tubules. Attractive interaction sites are on the sides for ring formation and top/bottom for filament growth. We have studied the assembly kinetics and dynamics as a function of these lateral and vertical interaction strengths. A full structure diagram was calculated. The range of interaction strengths that best form tubules has been determined. We found that tubules form better when the lateral strength is stronger than the filamental strength, which contrast the picture for microtubules. The interaction strengths must be weak enough to allow for reformation of the clusters that initially form. Besides tubules, a variety of structures form depending on the interaction parameters. Interestingly, helical tubes and other helical structures are frequently observed despite the fact that the minimum energy substructure is a nonhelical ring. We have used a simple Flory-Huggins type theory to characterize the structure diagram.

12:39PM B40.00006 Dynamical Length-Regulation of Microtubules, ANNA MELBINGER, LOUIS REESE, ERWIN FREY, Ludwig-Maximilians University, Munich — Microtubules (MTs) are vital constituents of the cytoskeleton. These stiff filaments are not only needed for mechanical support. They also fulfill highly dynamic tasks. For instance MTs build the mitotic spindle, which pulls the doubled set of chromosomes apart during mitosis. Hence, a well-regulated and adjustable MT length is essential for cell division. Extending a recently introduced model [1], we here study length-regulation of MTs. Thereby we account for both spontaneous polymerization and depolymerization triggered by motor proteins. In contrast to the polymerization rate, the effective depolymerization rate depends on the presence of molecular motors at the tip and thereby on crowding effects which in turn depend on the MT length. We show that these antagonistic effects result in a well-defined MT length. Stochastic simulations and analytic calculations reveal the exact regimes where regulation is feasible. Furthermore, the adjusted MT length and the ensuing strength of fluctuations are analyzed. Taken together, we make quantitative predictions which can be tested experimentally. These results should help to obtain deeper insights in the microscopic mechanisms underlying length-regulation.

12:51PM B40.00007 On the origins and extent of mechanical variation among cells, JOHN MALONEY¹, Massachusetts Institute of Technology, ERIC LEHNHARDT², Arizona State University, KRISTYN VAN VLIET³, Massachusetts Institute of Technology — Why would any one biological cell be mechanically different from another from the same population? Prompted by findings of broad distributions of cell stiffness within populations, we investigate possible origins of intrinsic mechanical heterogeneity among single cells. Through optical stretching, a non-contact technique for deforming cells in the suspended state, we obtain the creep compliance and complex modulus of single cells. Measurements of hundreds of human mesenchymal stem cells and murine fibroblasts in the time and frequency domains reveal that mechanical heterogeneity is not detectably dependent on cell lineage, cell cycle, cytoskeletal crosslinking, or repeated loading. However, adenosine triphosphate (ATP) depletion reduces heterogeneity of both stiffness and fluidity values. We explore the connection between these two parameters by positing that mechanical variation predominantly arises from Gaussian fluctuations in cell fluidity, which can be interpreted as emergent agitation in the energy landscape of soft glassy materials. Our findings ultimately link relatively small structural variations within cytoskeletal networks to large mechanical differences among cells and cell populations.

1:03PM B40.00008 Non-Equilibrium Cell Mechanics Studied with a Dual Optical Trap, FLORIAN SCHLOSSER, FLORIAN REHFELDT, CHRISTOPH F. SCHMIDT, Drittes Physikalisches Institut, Georg-August-Universitaet Goettingen, Germany — Cells communicate with their surroundings biochemically, but at the same time also sense the active and passive mechanical properties of their micro-environment. Cells can “feel” mechanical stress and they generate contractile forces through their actomyosin network to actively probe the mechanical response of the material they adhere to or are embedded in. These mechanosensory interactions result in cellular responses. We have used a dual optical trap to perform force measurements on cells suspended between two fibronectin-coated beads. We analyzed the correlated fluctuations of the beads with high spatial and temporal resolution. Using a combination of active and passive microrheology, we can simultaneously determine the (non-thermal) forces generated by the cells and actively probe their visco-elastic response properties. Here, we present data on contractile forces and elastic response of 3T3 fibroblasts, demonstrating that the transmitted force depends on the trap stiffness (i.e. rigidity of the environment). Using biochemical perturbations, we have studied the contributions of different cytoskeletal elements to the active and passive mechanical properties of the cell.

1:15PM B40.00009 M & M's: Mechanosensitivity and Mechanotransduction in Myoblasts¹, ZEINAB AL-REKABI, ANDREW PELLING, University of Ottawa — The effect of external mechanical stimulation of muscle precursor cells (myoblasts) during exercise is a crucial step in myogenesis. This effect takes place many hours later while muscles are in a resting state; however it remains unclear to what extent the role of force application has on the promotion of myogenesis. Here, we combine Traction Force Microscopy (TFM) and Atomic Force Microscopy (AFM) to directly measure the magnitude of generated cellular traction forces (CTFs) in myoblasts, as a result of controlled mechanical loading. Precise nanonewton forces (1 & 10 nN) were applied to live cells with the AFM tip while simultaneous TFM measurements were performed. The experiment was performed on substrates ranging in elastic moduli (E), (16-89 kPa) mimicking resting and active muscle tissue, respectively. The results of this analysis demonstrated that the magnitude of CTFs was dependent on substrate E , as expected. However, CTFs only increased in response to applied force (compared to controls) on substrates with E greater than 62 kPa. Our results suggest that muscle precursor cells are most sensitive to mechanical force when the surrounding muscle tissue is stiff and contracted, whereas myogenesis itself proceeds optimally on softer, resting tissue.

¹NSERC Create in Quantitative Biomedicine

1:27PM B40.00010 Polymer Coated Surface Acoustic Wave Biosensor for Living Cells, LIAN DAI, ECE U. Mass Lowell, JIANPING ZHANG, ABICHE DEWILDE, GANG WANG, Biology U. Mass Lowell, KENNETH MARX, Chemistry U. Mass Lowell, SUSAN BRAUNHUT, Biology U. Mass Lowell, JOEL THERRIEN, ECE U. Mass Lowell — A shear horizontal surface acoustic wave (SH-SAW) biosensor is fabricated on quartz wafer for measurement of mechanical properties of living cells. The SAW device was fabricated with a top film of polymer (PMMA, SU-8) to avoid immense attenuation in aqueous media. Several models were designed to operate under different frequencies such as 20MHz, 40MHz and 80MHz and higher in order to identify how frequency affect the sensitivity. A network analyzer was used to capture the resonant frequency of inter-digitated transducers (IDT) of SAW, and it is found that resonant frequency shift is closely correlated to the cell deposition on the sensing area of SAW.

1:39PM B40.00011 Modeling spinal cord biomechanics¹, CARLOS LUNA, Fischell Department of Bioengineering, University of Maryland, SAMEER SHAH, Departments of Orthopaedic Surgery and Bioengineering University of California, San Diego, AVIS COHEN, Department of Biology and Institute of Systems Research, University of Maryland, HELIM ARANDA-ESPINOZA, Fischell Department of Bioengineering, University of Maryland — Regeneration after spinal cord injury is a serious health issue and there is no treatment for ailing patients. To understand regeneration of the spinal cord we used a system where regeneration occurs naturally, such as the lamprey. In this work, we analyzed the stress response of the spinal cord to tensile loading and obtained the mechanical properties of the cord both in vitro and in vivo. Physiological measurements showed that the spinal cord is pre-stressed to a strain of 10%, and during sinusoidal swimming, there is a local strain of 5% concentrated evenly at the mid-body and caudal sections. We found that the mechanical properties are homogeneous along the body and independent of the meninges. The mechanical behavior of the spinal cord can be characterized by a non-linear viscoelastic model, described by a modulus of 20 KPa for strains up to 15% and a modulus of 0.5 MPa for strains above 15%, in agreement with experimental data. However, this model does not offer a full understanding of the behavior of the spinal cord fibers. Using polymer physics we developed a model that relates the stress response as a function of the number of fibers.

1:51PM B40.00012 Matrix elasticity perturbation and Lamin-A/C expression in stem cells modulate their mechanics and lineage specification¹, IRENA IVANOVSKA, DENNIS DISCHER, University of Pennsylvania — Commitment of stem cells to different lineages is regulated by many cues in their local microenvironment. They are particularly sensitive to the mechanical properties of their extracellular matrix. Nuclear lamins are fibrous proteins providing structural function and transcriptional regulation in the cell nucleus. In particular Lamin A/C levels could influence cellular mechanical sensitivity. Here we show that perturbation of the extracellular matrix and nucleus mechanics can direct stem cells lineage specification. We studied the behavior of human mesenchymal stem cells (hMSC) cultured on thin highly ordered collagen nanofilms. To tune the mechanical properties of the nanofilms we used the enzyme transglutaminase as a crosslinking agent. AFM imaging and manipulation is used to examine the nano topography and mechanical properties of the films and cells. Film stiffening affects cells morphology, cytoskeleton organization and their elastic response. hMSCs cultured for two weeks on collagen nanofilms initially tune their stiffness with matrix elasticity but later continuously change it with time. We observed upregulation of osteogenic markers on cross-linked films and increased lamin A/C expression. We show that manipulating Lamin-A/C expression in stem cells also directs cell lineage with knockdown favoring adipogenesis and over expression favoring osteogenesis. We found positive correlation between matrix and nucleus mechanics and that they have a synergistic effect on hMSCs differentiation potential.

¹HFSP Long-Term Fellowship

2:03PM B40.00013 Simulation of Second Harmonic Generation from Heterogeneous Microtubule Structures, NOAH LANGOWITZ, CHE-HANG YU, DANIEL NEEDLEMAN, Harvard University — Second harmonic generation imaging is a coherent nonlinear microscopy with contrast arising from certain asymmetric endogenous structures in cells, including spindle microtubules. As a second-order nonlinear optical process, SHG requires a noncentrosymmetric macromolecular organization to generate signal, so it can be used as a measure of microtubule polarity within spindles or other microtubule structures. We developed a simulation of SHG microscopy accounting for 3-dimensional orientation and circularly polarized excitation in order to quantify the dependence of SHG signal on microtubule density, spacing, polarity, and rotational order. SHG can be used to assess spindle polarity in living cells using simultaneous ratio imaging with two-photon excited fluorescence from labeled tubulin. The results from simulation are used to quantify microtubule polarity from SHG and TPEF images of spindles in the one-cell *C. elegans* embryo and *Xenopus* oocyte extract.

Monday, February 27, 2012 11:15AM - 2:15PM –
Session B41 DBIO: Lipid Bilayers and Biological Membranes 156B

11:15AM B41.00001 Computer Simulation of Cytoskeleton-Induced Blebbing of Lipid Membranes¹, MOHAMED LARADJI, EIRC J. SPANGLER, University of Memphis, CAMERON W. HARVEY, University of Notre Dame, JOEL D. REVALEE, University of Michigan, P.B. SUNIL KUMAR, Indian Institute of Technology Madras, India — Blebs are balloon-shaped membrane protrusions that form during many physiological processes such as cytokinesis, cell motility and apoptosis. Using computer simulation of a particle-based model for self-assembled lipid bilayers coupled to an elastic meshwork, we investigated the phase behavior and kinetics of blebbing. We found that for small values of the mismatch parameter, defined as the ratio between the area of the lipid bilayer divided by the rest area of the cytoskeleton, the equilibrium state is that of a homogeneous vesicle with the cytoskeleton conforming to the bilayer. However, for large values of a mismatch parameter, the equilibrium state is that of a blebbed vesicle. We also found that blebbing can be induced when the cytoskeleton is subject to a localized ablation or a uniform compression. The obtained results are qualitatively in agreement with the experimental evidence and the model opens up the possibility to study the kinetics of bleb formation in detail. For more information see Spangler *et al.*, Phys. Rev. E **84**, 051906 (2011).

11:27AM B41.00002 Coarse-grained simulation of lipid vesicles with “n-atic” orientational order¹, JUN GENG, JONATHAN SELINGER, ROBIN SELINGER, Liquid Crystal Institute, Kent State University, Ohio 44242, USA — We perform coarse-grained simulation studies of fluid lipid vesicles with in-plane “n-atic” orientational order associated with the shape of lipid head group, to test the theoretical predictions of Park, Lubensky and MacKintosh [1] for resulting vesicle shape and defect structures. Our simulation model uses a single layer coarse-grained implicit-solvent approach proposed by Yuan et al [2], with addition of an extra vector degree of freedom representing in-plane orientational order. We carry out simulation studies for n=1 to 6, examining in each case the spatial distribution of defects and resulting deformation of the vesicle. An initially spherical vesicle (genus zero) with n-atic order has a ground state with 2n vortices of strength 1/n, as expected, but the observed equilibrium shapes are sometimes quite different from those predicted theoretically. For the n=1 case, we find that the vesicle may become trapped in a disordered, long-lived metastable state with extra +/- defects whose pair-annihilation is inhibited by local changes in membrane curvature, and thus may never reach its predicted ground state.

11:39AM B41.00003 Morphologies of Elastic Membranes with Fluctuating Connectivity, CHLOE FUNKHOUSER, RASTKO SKNEPNEK, MONICA OLVERA DE LA CRUZ, Northwestern University — We numerically investigate the effects of topological defects in single-component two-dimensional elastic membranes with spherical topology allowing changes in shape. The membrane is simulated as a closed, triangulated elastic surface in three dimensions, where the vertices are permitted to move in space and the connectivity of the triangulation is able to fluctuate. Fluctuations in connectivity allow the creation of topological defects. A Monte Carlo simulated annealing method is utilized to explore optimal shapes and connectivities. The familiar defect-driven buckling transition [Seung & Nelson, *PRA* 1988, 38:1005] from a sphere to an icosahedron is shifted as a result of the fluctuating connectivity.

11:51AM B41.00004 Cooperative Motion in Lipid Bilayer Membranes, BENEDIKT HARTMANN, FRANCIS STARR, Wesleyan University — Lipid bilayer membranes, like the cell membrane, are complex biological systems. Transport of specific molecules in and out of cells are controlled by these membranes. Therefore, it is vital to understand the detailed dynamics that ultimately control membrane transport. We use molecular dynamics simulations of a coarse-grained and solvent-free lipid model that has been previously shown to spontaneously assemble a bilayer structure. Approaching the crossover to the gel-like state of the bilayer, the lipid dynamics become extremely slow. We analyze the cooperativity of the lipid motion and compare it with the cooperativity that has been well-characterized in liquids nearing a glass transition. Future simulations will examine the generality of this behavior using more realistic models, and comparing with experiments.

12:03PM B41.00005 How the antimicrobial peptides destroy bacteria cell membrane: Translocations vs. membrane buckling¹, LEONARDO GOLUBOVIC, West Virginia University, LIANGHUI GAO, LICUI CHEN, WEIHAI FANG, Beijing Normal University — In this study, coarse grained Dissipative Particle Dynamics simulation with implementation of electrostatic interactions is developed in constant pressure and surface tension ensemble to elucidate how the antimicrobial peptide molecules affect bilayer cell membrane structure and kill bacteria. We find that peptides with different chemical-physical properties exhibit different membrane obstructing mechanisms. Peptide molecules can destroy vital functions of the affected bacteria by translocating across their membranes via worm-holes, or by associating with membrane lipids to form hydrophilic cores trapped inside the hydrophobic domain of the membranes. In the latter scenario, the affected membranes are strongly corrugated (buckled) in accord with very recent experimental observations [G. E. Fantner *et al.*, *Nat. Nanotech.*, 5 (2010), pp. 280-285].

¹Supported by the National Science Foundation of China (Grant No. 20873007)

12:15PM B41.00006 Interaction of PLGA and trimethyl chitosan modified PLGA nanoparticles with mixed anionic/zwitterionic phospholipid bilayers studied using molecular dynamics simulations¹, BRIAN NOVAK, Louisiana State University, Center for Computation and Technology, CARLOS ASTETE, CRISTINA SABLIOV, Louisiana State University, Department of Biological and Agricultural Engineering, DOREL MOLDOVAN, Louisiana State University, Department of Mechanical Engineering — Poly(lactic-co-glycolic acid) (PLGA) is a biodegradable polymer. Nanoparticles of PLGA are commonly used for drug delivery applications. The interaction of the nanoparticles with the cell membrane may influence the rate of their uptake by cells. Both PLGA and cell membranes are negatively charged, so adding positively charged polymers such as trimethyl chitosan (TMC) which adheres to the PLGA particles improves their cellular uptake. The interaction of 3 nm PLGA and TMC-modified-PLGA nanoparticles with lipid bilayers composed of mixtures of phosphatidylcholine and phosphatidylserine lipids was studied using molecular dynamics simulations. The free energy profiles as function of nanoparticles position along the normal direction to the bilayers were calculated, the distribution of phosphatidylserine lipids as a function of distance of the particle from the bilayer was calculated, and the time scale for particle motion in the directions parallel to the bilayer surface was estimated.

12:27PM B41.00007 Atomic Force Microscopy Study of Changes to the Mechanical Properties of *Pseudomonas aeruginosa* Cells Induced By Antimicrobial Peptides, SHUN LU, JOHN DUTCHER, University of Guelph — The cell envelope of Gram-negative bacteria plays a key role in the maintenance of cell shape and the selective transfer of small molecules in and out of the cell. Both the inner and outer membranes of the cell envelope can be major targets for antimicrobial peptides, which can ultimately compromise the mechanical integrity of the cell. We have applied a new, AFM-based creep deformation technique (1) to study changes to the mechanical properties of individual *Pseudomonas aeruginosa* cells as a function of time of exposure to polymyxin B (PMB), a well-known cyclic antimicrobial peptide. The results can be understood in terms of simple viscoelastic models of arrangements of springs and dashpots. These measurements provide a direct measure of the mechanical integrity of the bacterial cell, and time-resolved creep deformation experiments reveal that the time of action for PMB is very fast (of the order of a minute). This measurement provides new insight into the mechanism of action of antimicrobial peptides. (1) V. Vadillo-Rodriguez, T. J. Beveridge, and J. R. Dutcher, *J. Bacteriol.* 190, 4225-4232 (2008).

12:39PM B41.00008 Interactions between HIV-1 Neutralizing Antibodies and Model Lipid Membranes imaged with AFM, STEFAN ZAUSCHER, GREGORY HARDY, MUNIR ALAM, Duke University, JOSEPH SHAPTER, Flinders University — Lipid membrane interactions with rare, broadly neutralizing antibodies (NABs), 2F5 and 4E10, play a critical role in HIV-1 neutralization. Our research is motivated by recent immunization studies that have shown that induction of antibodies that avidly bind the gp41-MPER antigen is not sufficient for neutralization. Rather, it is required that antigen designs induce polyreactive antibodies that recognize MPER antigens as well as the viral lipid membrane. However, the mechanistic details of how membrane properties influence NAb-lipid and NAb-antigen interactions remain unknown. Furthermore, it is well established that the native viral membrane is heterogeneous, representing a mosaic of lipid rafts and protein clustering. However, the size, physical properties, and dynamics of these regions are poorly characterized and their potential roles in HIV-1 neutralization are also unknown. To understand how membrane properties contribute to 2F5/4E10 membrane interactions, we have engineered biomimetic supported lipid bilayers (SLBs) and use atomic force microscopy to visualize membrane domains, antigen clustering, and antibody-membrane interactions at sub-nanometer z-resolution. Our results show that localized binding of HIV-1 antigens and NABs occur preferentially with the most fluid membrane domain. This supports the theory that NABs may interact with regions of low lateral lipid forces that allow antibody insertion into the bilayer.

12:51PM B41.00009 Modeling curvature-dependent subcellular localization of a small sporulation protein in *Bacillus subtilis*, VAIBHAV WASNIK, Department of Physics, Clark University, NED WINGREEN, Princeton University, RANJAN MUKHOPADHYAY, Department of Physics, Clark University — Recent experiments suggest that in the bacterium, *B. subtilis*, the cue for the localization of small sporulation protein, SpoVM, that plays a central role in spore coat formation, is curvature of the bacterial plasma membrane. This curvature-dependent localization is puzzling given the orders of magnitude difference in lengthscale of an individual protein and radius of curvature of the membrane. Here we develop a minimal model to study the relationship between curvature-dependent membrane absorption of SpoVM and clustering of membrane-associated SpoVM and compare our results with experiments.

1:03PM B41.00010 Relationship between peptide amino acid sequence and membrane curvature generation, NATHAN SCHMIDT, DAVID KUO, GHEE HWEE LAI, ABHIJIT MISHRA, GERARD WONG, Bioengineering Dept, UCLA — Amphipathic peptides and amphipathic domains in proteins can perturb and restructure biological membranes. For example, it is believed that the cationic, amphipathic motif found in membrane active antimicrobial peptides (AMPs) is responsible for their membrane disruption mechanisms of action. And ApoA-I, the main apolipoprotein in high density lipoprotein contains a series of amphipathic α -helical repeats which are responsible for its lipid associating properties. We use small angle x-ray scattering (SAXS) to investigate the interaction of model cell membranes with prototypical AMPs and consensus peptides derived from the helical structural motif of ApoA-I. The relationship between peptide sequence and the peptide-induced changes in membrane curvature and topology is examined. By comparing the membrane rearrangement and corresponding phase behavior induced by these two distinct classes of membrane restructuring peptides we will discuss the role of amino acid sequence on membrane curvature generation.

1:15PM B41.00011 Family of pH-Low-Insertion-Peptides (pHLIPs), DHAMMIKA WEERAKKODY, ANNA MOSHNIKOVA, Department of Physics, University of Rhode Island, VALENTINA MOSHNIKOVA, College of William and Mary, MAK THAKUR, BETHANY ROSSI, University of Rhode Island, DONALD ENGELMAN, Department of Molecular Biophysics and Biochemistry, Yale University, OLEG ANDREEV, YANA RESHETNYAK, Department of Physics, University of Rhode Island — pHLIP (pH (Low) Insertion Peptide) is a novel delivery system for targeting of acidic diseased tissue such as solid tumors, sites of inflammation, arthritis and other pathological states. The molecular mechanism of pHLIP action is based on pH-dependent insertion and folding of pHLIP in membrane. We performed sequence variation and investigated 16 pHLIP variants with main goals of understanding the main principles of peptide-lipid interactions and tune delivery capability of pHLIP. The biophysical studies including thermodynamics and kinetics of the peptides interaction with a lipid bilayer of liposomes and cellular membranes were carried out. We found that peptides association to membrane at neutral and low pH could be modulated by 3-4 times. The apparent pK of transition from surface bound to membrane-inserted state could be tuned from 6.5 to 4.5. The rate of peptide's insertion across a bilayer could be enhanced 100 times compared to parent pHLIP. As a result, blood clearance and tumor targeting were modulated in a significant degree. The work is supported by NIH grants CA133890 to OAA, DME, YRK.

1:27PM B41.00012 Membrane-associated peptide folding: pH triggered insertion and helical structure formation¹, ALEXANDER KARABADZHAK, Department of Molecular Biophysics and Biochemistry, Yale University, DHAMMIKA WEERAKKODY, MAK THAKUR, Physics Department, University of Rhode Island, DONALD ENGELMAN, Department of Molecular Biophysics and Biochemistry, Yale University, VLADISLAV MARKIN, Department of Neurology, University of Texas Southwestern Medical Center, OLEG ANDREEV, YANA RESHETNYAK, Physics Department, University of Rhode Island — We are interested in the molecular events that occur when a peptide inserts across a membrane or exits from it. pHLIP (pH (Low) Insertion Peptide) provides an opportunity to study membrane insertion/exit and folding/unfolding, since its insertion is modulated by pH and since it forms helical structure as it inserts. We found that pHLIP inserts across a POPC phospholipid bilayer in several steps: first is the rapid formation (100 ms) of an interfacial helix, which is then followed by a slow insertion pathway that contains several intermediates. We show that while the number of protonatable residues at the inserting end does not affect the formation of helical structure in the membrane, it correlates with the time for transmembrane insertion, the number of intermediate states on the folding pathway, and the rate of unfolding and exit. We conclude that particular intermediate states on the folding and unfolding pathways are not mandatory and, in the simple case of a polypeptide with a non-charged and non-polar inserting end, the folding and unfolding is well described as an all-or-none transition. A model for membrane-associated insertion/folding and exit/unfolding is proposed.

¹The work is supported by NIH grants CA133890 and GM073857 to OAA, DME, YRK.

1:39PM B41.00013 Modulation of the transmembrane helix insertion pathway by polar cargo, DAYANJALI WIJESINGHE, ALEXANDER KARABADZHAK, Department of Physics, University of Rhode Island, VLADISLAV MARKIN, Department of Neurology, University of Texas Southwestern Medical Center, DONALD ENGELMAN, Department of Molecular Biophysics and Biochemistry, Yale University, OLEG ANDREEV, YANA RESHETNYAK, Department of Physics, University of Rhode Island — In an earlier study, we found a series of kinetic steps in the pH-triggered insertion of the pHLIP® (pH (Low) Insertion Peptide). In the present work we observe that the polarity of the inserting end, including its cargo, modulates the number of intermediates, and that insertion can be described as a two state process for a simple case. Each investigated pHLIP variant preserve the pH-dependent properties of surface binding to membrane at neutral pH and insertion at low pH to form a transmembrane helix. However, there are thermodynamic and kinetic properties that are determined by the degree of cargo polarity. The presence of a polar cargo at the peptide's inserting end leads to the appearance of two additional intermediate states on the insertion pathway of the pHLIP-2E peptide, which itself (when no cargo is attached) shows an all-or-none transition from the partially unstructured membrane-surface to the transmembrane state described well by the two-state model at 800 ms timescale. We discuss the utility of our observations for the design of new delivery agents for the direct translocation of polar therapeutic and diagnostic cargo molecules across cellular membranes. The work is supported by NIH grants CA133890 to OAA, DME, YRK.

1:51PM B41.00014 Exploration of phase separation in heterogeneous lipid monolayers, CURT DECARO, SAMBUNATH BERA, Northern Illinois University, ZHANG JIANG, Argonne National Laboratory, MRINMAY MUKHOPADHYAY, Spring-8, CAROL THOMPSON, Northern Illinois University — A Langmuir monolayer is a well established model of a single leaflet of a lipid membrane. In this work, we investigate the phase separation behavior of a model Langmuir monolayer as a function of both Langmuir surface pressure and ratio of saturated lipid : unsaturated lipid : cholesterol. The specifics of domain separation behavior, or “rafting,” in membranes are generally thought to be responsible for much of the behavior of living membranes, specifically in protein integration and transport. Off-specular x-ray scattering is used to probe in-plane structure of the membrane at the sub-micron scale. Additionally, atomic force microscopy imaging is taken on samples transferred to a rigid support. In-plane order is found to grow as a function of surface pressure. Also, the in-plane order is found to depend on cholesterol concentration in the monolayer. The phase space of the in-plane order as a function of lipid and cholesterol concentration is presented.

2:03PM B41.00015 Domain formation in multicomponent lipid bilayers coupled to elastic substrate, MD ZULFIKAR ALI, RANJAN MUKHOPADHYAY, Clark University — We will discuss the physics that governs the lipid localization and domain formation in multicomponent lipid bilayers coupled to an elastic substrate. Lipid localization and domain formation has been studied extensively in biological cell membranes. In this talk we will extend a previous model for membrane energetics to account for the coupling between the bending and the local lipid composition of the two leaflets. Our aim is to determine the relationship between the localization and domain formation in the presence of lipid flip-flops between the two leaflets and the effect of intrinsic curvature of the lipids. Using a lattice model for the membrane, we simulate the system and study the effect of lipid flip-flop on lipid organization in the membrane.

Monday, February 27, 2012 11:15AM - 2:15PM —

Session B42 DBIO DFD: Focus Session: BioChip Physics-Detection and Transport 156C

11:15AM B42.00001 On-chip Metamaterials for Ultra-sensitive Spectroscopy and Identification of Biomolecules, HATICE ALTUG, Boston University — Infrared absorption spectroscopy is a unique tool for identifying and characterizing molecular bonds. For most organic and inorganic molecules (such as proteins, chemical toxins and gases), vibrational and rotational modes are spectroscopically accessible within the mid-infrared (mid-IR; 3-20 μm) regime of the electromagnetic spectrum. Characteristic vibrational modes are associated with unique IR absorption spectral bands that are bond-specific. Because of that, the IR wavelength range is also known as “finger print” region. However, because of the Beer-Lambert law, its sensitivity has been limited to perform analytical/functional studies on small samples often available from biological specimens. In this talk we will describe how we use plasmonic metamaterials to overcome these challenges. We will introduce tailoring of the resonances to selectively address fingerprint signatures of proteins. We will also describe novel designs and fabrication methods to exploit extreme near-field enhancements in small gaps for vibrational signal enhancements.

In collaboration with In collaboration with Ronen Adato, Serap Aksu, Alp Artar, Arif Cetin, and Boston University.

11:51AM B42.00002 Ultrasensitive Plasmonic Biosensors for Direct Detection of Biomarker Proteins with The Naked Eye, AHMET ALI YANIK, Harvard University Medical School and Massachusetts General Hospital, JOHN CONNOR, Boston University Medical School, GENNADY SHVETS, University of Texas, Austin, HATICE ALTUG, Boston University Electrical and Computer Engineering — We introduce an ultrasensitive label free biodetection technique based on asymmetric plasmonic Fano resonances. Our sensors bring a number of advantages: (i) ultrasensitive detection limits surpassing gold standard Kretschmann configuration plasmon sensors, (ii) detection of biomarker molecules with “the naked eye”, (iii) massive multiplexing capabilities. By exploiting extraordinary light transmission phenomena through high quality factor sub-radiant dark modes, we experimentally demonstrate record high figures of merits for intrinsic detection limits surpassing the gold standard BioCore devices. Our experiments show an order of magnitude improved device performances over the state of art metamaterial and other plasmonic biosensors. Steep dispersion of the plasmonic Fano resonance profiles in engineered plasmonic sensors exhibit dramatic light intensity changes to the slightest perturbations within their local environment. As a spectacular demonstration, we show direct detection of a single monolayer of biomolecules with naked eye using these Fano resonances and the associated Wood’s anomalies. The demonstrated sensing platform offers point-of-care diagnostics in resource poor settings by eliminating the need for fluorescent labeling and optical detection instrumentation (such camera, spectrometer, etc.).

12:03PM B42.00003 High-Throughput On-Chip Diagnostic System for Circulating Tumor Cells, JAEHOON CHUNG, HUILIN SHAO, RALPH WEISSLEDER, HAKHO LEE, Center for Systems Biology, Massachusetts General Hospital — We have developed a novel, low-cost and high-throughput microfluidic device for detection and molecular analysis of circulating tumor cells (CTCs). The operation is based upon a size-selective cell separation, which was enabled by a weir-style physical barrier with a gap in the fluidic channel. The new system is a versatile CTC analysis platform with many advantages. First, it supports extremely high throughput operation, since the use of weir structure reduces fluidic resistance and enables flow-through separation ($> 20,000$ -fold CTC enrichment from whole blood at the flow rate of 10 mL/h). Second, the CTC-chip facilitates visual verification and enumeration of CTCs during/after operation. By implementing microwell-shaped structures on the physical barrier, CTCs can be individually captured at sites for single-cell resolution analyses. Furthermore, the captured cells could be profiled in situ by introducing antibodies or small molecular probes. The chip thus assumes not only high detection sensitivity but also molecular specificity for CTC identification. Finally, the CTC-chip can retrieve captured CTCs. By reversing the flow direction, the cells can be dislodged from their capture sites and collected for downstream investigation.

12:15PM B42.00004 Mass transport to suspended waveguide biosensors, JASON GAMBA, CHAITANYA MURTHY, ANDREA ARMANI, University of Southern California — The response of a biosensor is controlled both by the kinetics of analyte adsorption as well as the mass transport to the device. Improving the affinity between a target molecule and the functionalized sensor can pose significant challenges in terms of biochemistry and surface chemistry. The careful design of sample flow systems presents a more convenient route for decreasing the time required for a measurement. Using finite element methods, we model mass transport to a novel integrated photonic biosensor suspended within a microfluidic channel in an effort to understand how boundary layer flow patterns may be engineered to improve the transient response of the device. By monitoring the surface concentration of bound analyte over a range of inlet concentrations and vertical positions within the channel, we compare the behavior of suspended devices to that of planar sensors located on the floor of the channel. Thinner boundary layers and increased effective sensing area lead to consistently faster transient responses for the suspended sensor, with optimal performance resulting from the symmetric placement of the sensor with respect to the channel height.

12:27PM B42.00005 Weighing single cells in two fluids: measuring mass, volume and density, FRANCISCO FEIJÓ DELGADO, WILLIAM GROVER, NATHAN CERMAK, ANDREA BRYAN, SCOTT MANALIS, Massachusetts Institute of Technology — The Suspended Microchannel Resonator (SMR) is a highly sensitive cantilever-based mass sensor shown to be capable of weighing the buoyant mass of living single cells. We have engineered SMR-based microfluidic systems to achieve consecutive weighing of single cells in two different fluids, with controlled exposure times. By choosing fluids of two different densities, the paired buoyant mass measurements are used to characterize single-cell volume, mass and density. With density precision of $0.001 \text{ g}\cdot\text{cm}^{-3}$, we explore the application of our techniques to samples ranging from bacterial to mammalian cells and show that cellular density is a tightly regulated biological property within populations, up to 100-fold more so than the other size parameters.

12:39PM B42.00006 Label-free screening of niche-to-niche variation in satellite stem cells using functionalized pores , MATTHEW R. CHAPMAN, Biophysics Graduate Group, UC Berkeley, KARTHIK BALAKRISHNAN, Dept. Mechanical Engineering, UC Berkeley, MICHAEL J. CONBOY, Dept. Bioengineering, UC Berkeley, SWOMITRA MOHANTY, Dept. Mechanical Engineering, UC Berkeley, ERIC JABART, Dept. Bioengineering, UC Berkeley, HAIYAN HUANG, Dept. Statistics, UC Berkeley, JAMES HACK, Dept. Mechanical Engineering, UC Berkeley, IRINA M. CONBOY, Dept. Bioengineering, UC Berkeley, LYDIA L. SOHN, Dept. Mechanical Engineering, UC Berkeley — Combinations of surface markers are currently used to identify muscle satellite cells. Using pores functionalized with specific antibodies and measuring the transit time of cells passing through these pores, we discovered remarkable heterogeneity in the expression of these markers in muscle (satellite) stem cells that reside in different single myofibers. Microniche-specific variation in stem cells of the same organ has not been previously described, as bulk analysis does not discriminate between separate myofibers or even separate hind-leg muscle groups. We found a significant population of Sca-1+ satellite cells that form myotubes, thereby demonstrating the myogenic potential of Sca-1+ cells, which are currently excluded in bulk sorting. Finally, using our label-free pore screening technique, we have been able to quantify directly surface expression of Notch1 without activation of the Notch pathway. We show for the first time Notch1-expression heterogeneity in unactivated satellite cells. The discovery of fiber-to-fiber variations prompts new research into the reasons for such diversity in muscle stem cells.

12:51PM B42.00007 Demonstration and analysis of the harmonic dithering technique for a high-sensitivity silicon waveguide biosensor , KANGBAEK KIM, ROBERT M. PAFCHECK, THOMAS L. KOCH, Lehigh University — A label-free biosensor readout technique is demonstrated based on a silicon-on-insulator ring resonators and a harmonic dithering technique using a distributed feedback (DFB) laser and a lock-in amplifier. The 400 μm ring resonator is integrated with a microfluidic sample delivery channel formed with Polydimethylsiloxane (PDMS). Dithering the frequency of the DFB laser across the Lorentzian lineshape of the drop port at high frequency eliminates $1/f$ noise, and broadband noise is reduced by narrow-band detection with the lock-in amplifier. Biosensor system noise is analyzed and compared with more conventional readout methods, and in our case is dominated by thermal noise of the receiver, shot noise, and relative intensity noise (RIN) of the DFB laser. Because the readout automatically latches onto the drop port and does not require a complex scanning process, this methodology may provide a pathway for high-sensitivity, real-time, and low-cost biosensing.

1:03PM B42.00008 Label-free detection of DNA on silicon surfaces using Brewster angle straddle interferometry (BASI) , XIAO WANG, University of Rochester School of Medicine and Dentistry, Department of Biochemistry and Biophysics, 601 Elmwood Ave., Box 712, Rochester, NY, 14642, LEWIS ROTHBERG, University of Rochester, Department of Chemistry, Rochester, NY 14627 — Label-free sensing of biomolecular interactions is of great importance for drug screening and a variety of clinical assays. Ultrasensitive detection of dsDNA on silicon substrates can be achieved using our new label-free sensing method - Brewster angle straddle interferometry (BASI) which exploits the removal of destructive interference to detect binding of target molecules on a silicon surface functionalized by probe molecules. By exploiting the fact that reflections of p-polarization undergo 180 degree phase shifts above the Brewster angle and none below it, we are able to use unprocessed silicon substrates with native oxide serving as the interference layer. Destructive interference in the geometry we use results in reflectivities $\sim 0.01\%$. Reflectivity from the chip is a quantitative measure of the amount of bound target molecules and can be imaged in real time in microarray format. We demonstrate detection of DNA intercalation on pyrene modified surfaces. The substrates are shown to exhibit excellent binding toward dsDNAs. This work provides an avenue for understanding the binding specificity of small molecule-DNA interactions that can be potentially helpful in developing anticancer agents.

1:15PM B42.00009 Real-time molecular detection using a nanoscale porous silicon waveguide biosensor , XING WEI, JEREMY MARES, SHARON WEISS, Vanderbilt University — A grating-coupled porous silicon waveguide with an integrated PDMS flow cell is demonstrated as a platform for real-time detection of chemical and biological molecules. This sensor platform not only allows for quantification of molecular binding events, but also provides a means to improve understanding of diffusion and binding mechanisms in constricted nanoscale geometries. The large internal surface area of porous silicon enables the capture of molecules inside the waveguide, which causes a large perturbation of the guided mode field and improves detection sensitivity by more than one order of magnitude as compared to evanescent wave-based detection methods. Molecular binding events in the waveguide are monitored by real-time angle-resolved reflectance measurements. Diffusion, adsorption and desorption coefficients of different sized chemical linker and nucleic acid molecules are determined based on the rate of change of the measured resonance angle. Both the magnitude of the waveguide resonance angle shift and kinetic parameters are observed to depend on molecule size. Experimental results are shown to be in good agreement with calculations based on rigorous coupled wave analysis and finite element simulation.

1:27PM B42.00010 On-chip Magnetic Separation and Cell Encapsulation in Droplets , A. CHEN, T. BYVANK, A. BHARDE, B.L. MILLER, J.J. CHALMERS, R. SOORYAKUMAR, The Ohio State University, W.-J. CHANG, University of Wisconsin-Milwaukee, R. BASHIR, University of Illinois at Urbana-Champaign — The demand for high-throughput single cell assays is gaining importance because of the heterogeneity of many cell suspensions, even after significant initial sorting. These suspensions may display cell-to-cell variability at the gene expression level that could impact single cell functional genomics, cancer, stem-cell research and drug screening. The on-chip monitoring of individual cells in an isolated environment could prevent cross-contamination, provide high recovery yield and ability to study biological traits at a single cell level. These advantages of on-chip biological experiments contrast to conventional methods, which require bulk samples that provide only averaged information on cell metabolism. We report on a device that integrates microfluidic technology with a magnetic tweezers array to combine the functionality of separation and encapsulation of objects such as immunomagnetically labeled cells or magnetic beads into pico-liter droplets on the same chip. The ability to control the separation throughput that is independent of the hydrodynamic droplet generation rate allows the encapsulation efficiency to be optimized. The device can potentially be integrated with on-chip labeling and/or bio-detection to become a powerful single-cell analysis device.

1:39PM B42.00011 Chip-based magnetic cytometer for high-throughput cellular profiling in unprocessed biological samples , DAVID ISSADORE, JAEHOON CHUNG, HUILIN SHAO, MONTY LIONG, RALPH WEISSELEDER, HAKHO LEE, Massachusetts General Hospital / Harvard Medical School — Quantitative, high-throughput measurement of biomarkers in individual cells is a cornerstone of biomedical research, but prohibitive size, cost, and requisite sample processing have kept this technology from being more widely adapted in the clinic. We have developed a miniaturized magnetic cytometer (μMCM), a hybrid semiconductor / microfluidic chip, to rapidly measure the magnetic moments of individual immunomagnetically tagged cells. The use of magnetic detection enables measurements to be done on native specimens, thus decreasing the loss of rare cells and removing the need for expensive sample processing equipment. Benefiting from the high speed and sensitivity of semiconductor technology, the μMCM offers high-throughput operation (upwards of 10^7 cells/sec) with a detection resolution of ~ 2000 magnetic nanoparticles/cell. The clinical utility of the μMCM was demonstrated by detecting scant tumor cells (20 cells) in whole blood and by molecularly profiling cells from solid tumor to monitor longitudinal drug efficacy.

1:51PM B42.00012 Miniature magnetic resonance system for robust and portable diagnostics¹, CHANGWOOK MIN, DAVID ISSADORE, JAEHOON CHUNG, HUILIN SHAO, MONTY LIONG, Massachusetts General Hospital, RALPH WEISSLEDER, Massachusetts General Hospital/Harvard Medical School, HAKHO LEE, Massachusetts General Hospital — We have recently developed a new diagnostic platform, microNMR(μ NMR), specifically designed for clinical applications. This new μ NMR system performs rapid, accurate, and robust measurements of cells, proteins and small molecules in point-of-care settings. The system utilizes magnetic nanoparticles (MNPs) to amplify the analytical signals in NMR detection. When molecularly-specific MNPs identify their targets, the particles induce large, amplified changes in the transverse relaxation of water protons by producing local magnetic fields. A major challenge in achieving reliable NMR detection is the fluctuation of NMR frequency (f_0) with temperature, which originates from the temperature-dependent drift of the magnetic field. To overcome the challenge, we have implemented a new, automated feedback controller that keeps track of f_0 and reconfigures measurement settings. The mechanism enables robust μ NMR measurements in realistic clinical environments (4-50 °C). Moreover, the μ NMR interfaces with mobile devices for its operation, maximizing the portability of μ NMR. The clinical utility of the new μ NMR system is demonstrated by detecting and molecularly profiling cancer cells from patient samples.

¹This work is supported in part by National Institutes of Health Grants 2R01-EB004626, HHSN268201000044C, U54-CA119349, and T32-CA79443.

2:03PM B42.00013 Paper Inside? - New Thinking for Biochip and Other Applications, ANDREW STECKL, University of Cincinnati — The drive to improve the performance and reduce the cost of electronic, photonic and fluidic devices is starting to focus on the use of materials that are exotic for these applications but actually readily available in other fields. In this talk the use of paper in biochip and other applications will be reviewed. Paper is a very attractive material for many device applications: very low cost, available in almost any size, versatile surface finishes, portable and flexible. From an environmental point of view, paper is a renewable resource and is readily disposable (incineration, biodegradable). Applications of paper-based electronics currently being considered or investigated include biochips, sensors, communication circuits, batteries, smart packaging, displays. The potential advantages of paper-based devices are in many cases very compelling. For example, biochips fabricated on paper can use the capillary properties of paper to operate without the need of external power sources, greatly simplifying the design and reducing the cost. For e-reader devices, in addition to flexibility, the ideal solution for providing the look-and-feel of ink on paper is to have *e-paper on paper*.

Monday, February 27, 2012 11:15AM - 2:15PM – Session B43 DBIO: Invited Session: Physical Mechanisms of Cell Growth 157AB

11:15AM B43.00001 Processive motions of MreB micro-filaments coordinate cell wall growth¹, ETHAN GARNER, Harvard — Rod-shaped bacteria elongate by the action of cell-wall synthesis complexes linked to underlying dynamic MreB filaments, but how these proteins function to allow continued elongation as a rod remains unknown. To understand how the movement of these filaments relates to cell wall synthesis, we characterized the dynamics of MreB and the cell wall elongation machinery using high-resolution particle tracking in *Bacillus subtilis*. We found that both MreB and the elongation machinery move in linear paths across the cell, moving at similar rates (~ 20 nm / second) and angles to the cell body, suggesting they function as single complexes. These proteins move circumferentially around the cell, principally perpendicular to its length. We find that the motions of these complexes are independent, as they can pause and reverse, and also as nearby complexes move independently in both directions across one surface of the cell. Inhibition of cell wall synthesis with antibiotics or depletions in the cell wall synthesis machinery blocked MreB movement, suggesting that the cell wall synthetic machinery is the motor in this system. We propose that bacteria elongate by the uncoordinated, circumferential movements of synthetic complexes that span the plasma membrane and insert radial hoops of new peptidoglycan during their transit.

¹Watching the motions of the cell wall synthesis machinery and underlying cytoskeleton in *B. subtilis* with high precision particle tracking.

11:51AM B43.00002 Spatial Patterning of Newly-Inserted Material during Bacterial Cell Growth¹, TRISTAN URSELL, Stanford University — In the life cycle of a bacterium, rudimentary microscopy demonstrates that cell growth and elongation are essential characteristics of cellular reproduction. The peptidoglycan cell wall is the main load-bearing structure that determines both cell shape and overall size. However, simple imaging of cellular growth gives no indication of the spatial patterning nor mechanism by which material is being incorporated into the pre-existing cell wall. We employ a combination of high-resolution pulse-chase fluorescence microscopy, 3D computational microscopy, and detailed mechanistic simulations to explore how spatial patterning results in uniform growth and maintenance of cell shape. We show that growth is happening in discrete bursts randomly distributed over the cell surface, with a well-defined mean size and average rate. We further use these techniques to explore the effects of division and cell wall disrupting antibiotics, like cephalaxin and A22, respectively, on the patterning of cell wall growth in *E. coli*. Finally, we explore the spatial correlation between presence of the bacterial actin-like cytoskeletal protein, MreB, and local cell wall growth. Together these techniques form a powerful method for exploring the detailed dynamics and involvement of antibiotics and cell wall-associated proteins in bacterial cell growth.

In collaboration with Kerwyn Huang, Stanford University.

¹Genentech Bio-X Fellowship

12:27PM B43.00003 Mechanics of cell division in fission yeast, FRED CHANG, Columbia University — Cytokinesis is the stage of cell division in which a cell divides into two. A paradigm of cytokinesis in animal cells is that the actomyosin contractile ring provides the primary force to squeeze the cell into two. In the fission yeast *Schizosaccharomyces pombe*, cytokinesis also requires an actomyosin ring, which has been generally assumed to provide the force for cleavage. However, in contrast to animal cells, yeast cells assemble a cell wall septum concomitant with ring contraction and possess large (MPa) internal turgor pressure. Here, we show that the inward force generated by the division apparatus opposes turgor pressure; a decrease in effective turgor pressure leads to an increase in cleavage rate. We show that the ring cannot be the primary force generator. Scaling arguments indicate that the contractile ring can only provide a tiny fraction of the mechanical stress required to overcome turgor. Further, we show that cleavage can occur even in the absence of the contractile ring. Instead of the contractile ring, scaling arguments and modeling suggest that the large forces for cytokinesis are produced by the assembly of cell wall polymers in the growing septum.

1:03PM B43.00004 Decoding the topology of vascular organization¹, ELENI KATIFORI, Rockefeller University — Distribution and structural networks permeate virtually all life, from the cellular to the organismic level. They have allowed organisms to grow in size and complexity by ensuring efficient distribution of nutrients and structural support. Given their importance, these vascular and structural webs have been under strong evolutionary selection and their form frequently reflects important aspects of their function. We discuss the design principles behind the evolution of the architecture and topology of vascular and structural networks and present some examples (leaf venation, arterial vasculature of the neocortex and others) that elucidate them.

¹This work was supported in part by the NSF under Grant PHY-1058899

1:39PM B43.00005 Mechanics and Dynamics of Plant Cell Division¹, JACQUES DUMAIS, Harvard University — The division of eukaryotic cells involves the assembly of complex cytoskeletal structures to exert the forces required for chromosome segregation and cytokinesis. In plants, tensional forces within the cytoskeleton constrain cells to divide according to a small number of area minimizing configurations. We have shown that the probability of observing a particular division configuration increases inversely with its relative area according to an exponential probability distribution known as the Gibbs measure. The distribution is universal up to experimental accuracy with a unique constant that applies for all plants studied irrespective of the shape and size of their cells. Using a maximum entropy formulation, we were able to demonstrate that the empirically observed division rule is predicted by the dynamics of the tense cytoskeletal elements controlling the positioning of the division plane. Finally, by framing this division rule as a dynamical system, we identified a broad class of attractors that are predictive of cell patterns observed in plants. Plant cell division thus offers a remarkable example of how interactions at the molecular level can lead to strikingly complex behaviors at the cellular and multicellular levels.

Monday, February 27, 2012 11:15AM - 2:15PM –
Session B44 DPOLY DBIO: Focus Session: Translocation through Nanopores - Measurements and Theoretical Models 157C

11:15AM B44.00001 Sequence-dependent ion current modulations in biological and synthetic nanopores¹, ALEKSEI AKSIMENTIEV, University of Illinois at Urbana-Champaign — The possibility of DNA sequence detection by measuring the blockade ionic current in nanopores has been the driving force for the spectacular development of the nanopore research field. Nevertheless, fifteen years after the first measurements, the molecular mechanism(s) of ion current modulation by the sequence of DNA nucleotides remains elusive. Here, we report the results of extensive all-atom molecular dynamics and Brownian dynamics simulations of three nanopore systems: a biological nanopore MspA, a solid-state nanopore and a graphene nanopore, aimed at elucidating the microscopic mechanism of the ion current modulation. In the case of solid-state and graphene nanopores, we determined the effect of sequence convolution on the ionic current value by simulating the ionic current blockades produced by all 64 permutations of the DNA nucleotide triplets. In the case of MspA, we determined the effect of the sequence, the global orientation, and the conformation of a DNA strand on the distribution of the ion current blockades. Based on the results of our simulations, we suggest possible routes for increasing the resolution of DNA sequence detection by measuring the nanopore ionic current and describe the inherent limitations of the method.

¹Support by grants from NSF (DMR-0955959) and NIH (R01-HG005115).

11:51AM B44.00002 Unexpected stop-and-go when DNA is pulled through a network, JUAN GUAN, BO WANG, SUNG CHUL BAE, STEVE GRANICK, University of Illinois Urbana Champaign — We perform single-molecule imaging of lambda-DNA chains when DC electric fields drive them through agarose networks in which they are heavily entangled. Velocity is decidedly unsteady. Exhaustive statistics reveal how motion switches between “mobile” and “pause” states, the latter differing from well-known “hooking.” As these observations appear to be inconsistent with the prevailing theories of DNA electrophoresis, we are also engaged in measurements that discriminate between motion of the chain ends and the chain centers, by direct two-color fluorescence imaging.

12:03PM B44.00003 Non-Equilibrium DNA Dynamics Probed by Delayed Capture and Recapture by a Solid-State Nanopore¹, MIRNA MIHOVILOVIC, ERIN TEICH, NICHOLAS HAGERTY, DEREK STEIN, Brown University — We studied the relaxation of λ -DNA following its translocation through a voltage-biased solid-state nanopore. The translocation process drives DNA into a non-equilibrium state because the ~ 2 ms translocation time is roughly fifty times shorter than the polymer's characteristic (Zimm) relaxation time. By reversing the applied voltage at controlled delay times after a translocation event, the nanopore probed the configurations of recaptured molecules at various stages of relaxation. We monitored the disruptions of the ionic current through the nanopore and computed the integrated charge deficits (ECDs) resulting from DNA translocations. As the delay time between voltage reversals was decreased from 50 ms to 5 ms, the distribution of ECDs shifted to lower values. Furthermore, an increasing fraction of recapture events occurred in a shorter interval from the voltage reversal than the delay time. These observations are explained by the expansion of the DNA coil as it approaches equilibrium. Finally, we show that recapturing a molecule multiple times and averaging the ECDs reduces the measurement error, which is useful for molecular diagnostic applications. The variance decreases approximately as the inverse number of passes through the pore.

¹This material is based upon work supported by the National Science Foundation under Grant No. CBET0846505 and Intel Corp.

12:15PM B44.00004 Forced Translocation of Polymer through Nanopore: Deterministic Model and Simulations, YANQIAN WANG, UNC-Chapel Hill, SERGEY PANYUKOV, P. N. Lebedev Phys. Inst., Russ. Acad. of Sci., QI LIAO, Inst. of Chem., Chin. Acad. of Sci., MICHAEL RUBINSTEIN, UNC-Chapel Hill — We propose a new theoretical model of forced translocation of a polymer chain through a nanopore. We assume that DNA translocation at high fields proceeds too fast for the chain to relax, and thus the chain unravels loop by loop in an almost deterministic way. So the distribution of translocation times of a given monomer is controlled by the initial conformation of the chain (the distribution of its loops). Our model predicts the translocation time of each monomer as an explicit function of initial polymer conformation. We refer to this concept as “fingerprinting”. The width of the translocation time distribution is determined by the loop distribution in initial conformation as well as by the thermal fluctuations of the polymer chain during the translocation process. We show that the conformational broadening Δt of translocation times of m -th monomer $\Delta t \propto m^{1.5}$ is stronger than the thermal broadening $\delta t \propto m^{1.25}$. The predictions of our deterministic model were verified by extensive molecular dynamics simulations.

12:27PM B44.00005 Force-Driven Translocation of a Polymer through a Nanopore, PAYAM ROWGHANIAN, PhD student, ALEXANDER GROSBERG, Professor, NYU CSMR TEAM¹ — We study the far from equilibrium translocation of a DNA molecule through a nanopore. The pore is much narrower than the DNA, so the electrically driven DNA undergoes dramatic deformations during its passage. Using an idealized model in which the DNA is assumed to be a very long and flexible homopolymer driven by a force exerted only in the pore, we modify a previously developed method by introducing the concept of “iso-flux trumpet”. We show that although the speed of the process is determined by the friction of the trailing part with the solvent, friction dissipates a small portion of the work performed by the electric field on the polymer, and the work is mostly dissipated by the irreversible stretching and destretching of the polymer squeezed into the small pore. Moreover, due to such stretches essentially caused by the membrane, a net heat transfer occurs during translocation from the post-translocation to the pre-translocation side of the membrane. The current theory can be improved by accounting for the nonzero field outside the pore and by considering the coupling between electric and hydrodynamic fields. The forces exerted by such fields on the DNA bulk not only alter the passage dynamics, but also introduce deformations on the initial conformation of the polymer.

¹I am Professor Grosberg's student at the Center for Soft Matter Research at NYU's physics department.

12:39PM B44.00006 Non-equilibrium tension propagation as a unifying description of driven polymer translocation, TIMO IKONEN, TAPPIO ALA-NISSILA, Aalto University School of Science, Finland, ANIKET BHATTACHARYA, University of Central Florida, WOKYUNG SUNG, Pohang University of Science and Technology, South Korea — We present results from a new Brownian dynamics model of driven polymer translocation¹, in which non-equilibrium memory effects due to tension propagation (TP) along the cis side subchain are included as a time-dependent friction. To solve the effective friction, we develop a finite chain length TP formalism, expanding on the work of Sakaue^{1,2}. The model yields results in excellent quantitative agreement with molecular dynamics simulations in a wide range of parameters. Our results show that non-equilibrium TP along the cis side subchain dominates the dynamics of driven translocation. In addition, the model explains the different scaling of translocation time with chain length observed both in experiments and simulations as a combined effect of finite chain length and pore-polymer interactions.

12:51PM B44.00007 Graphene Nano-Electrodes for DNA Sequencing: an Ab initio Perspective, R.H. SCHEICHER, J. PRASONGKIT, A. GRIGORIEV, Uppsala University, Y. HE, M. LIU, Institute of Microelectronics, Chinese Academy of Sciences, R. AHUJA, Uppsala University — The proposal was made that a graphene nanogap could be used to probe the transverse conductance of individual nucleotides in DNA to rapidly identify the associated base sequence. Experimentally, the characteristic drop in ionic current associated with translocation events of DNA passing through a graphene nanopore was measured. Using first-principles methods, we evaluated the performance of two graphene nano-electrodes configurations for nucleobase identification. In the first study, Nano Lett. **11**, 1941 (2011), we investigated the electronic transport properties of the four nucleotides when located in a graphene nanogap by employing density functional theory and the non-equilibrium Green's function method. In particular, we determined the electrical current variation at finite bias due to changes in the nucleotides orientation. Our second study, Adv. Funct. Mater. **21**, 2674 (2011), utilized molecular dynamics simulations in conjunction with electronic transport calculations to explore specifically the effect of the hydrogenated graphene edges on the translocating DNA. It is found that edge-hydrogenated graphene electrodes facilitate the temporary formation of weak H-bonds with suitable atomic sites in the nucleotides.

1:03PM B44.00008 Preprotein translocation across the endoplasmic reticulum membrane in milieus crowded by proteins, JOSÉ ANTONIO VÉLEZ, ORLANDO GUZMÁN, Universidad Autónoma Metropolitana Iztapalapa, FERNANDO NAVARRO, Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional — Translocation of preproteins chains between the cytoplasm and the endoplasmic reticulum lumen takes place in a milieu crowded primarily by proteins. We compute translocation and retrotranslocation times for chains of different length in a milieu crowded by spherical agents at volume fractions equivalent to that found in cells. These numerical times obtained from a diffusion-equation model subject to a potential given by the free energy of one chain, indicate that crowding increases the translocation time by up to five times compared to those in dilute conditions for average-size chains and by up to a thousand times for long chains. Retrotranslocation times become smaller than translocation ones, in approximately 75%. Translocation rates obtained in this work are similar to those found in a theoretical model for Brownian-ratchet translocation and coincide with in vitro experimental results (1-8 aminoacid/s) only in the limit of very long chains; for shorter chains, translocation rates are much faster. Our prediction that for long chains translocation rates would be significantly slowed by crowding can be tested experimentally using vesicles. Discrepancy of time-scales with experiments for short chains indicates that other factors beside crowding must be included in our model.

1:15PM B44.00009 Nanopore Mass Spectrometry¹, DEREK STEIN, JOSEPH BUSH, MIRNA MIHOVILOVIC, WILLIAM MAULBETSCH, WOYOUNG MOON, CARTHENE BAZEMORE-WALKER, PETER WEBER, Brown University — We describe a concept for single-DNA analysis called nanopore mass spectrometry, which seeks to combine the benefits of nanopores with the speed, sensitivity, and robustness of single base detection by mass spectrometry. The basic idea is to cleave the individual nucleotides from a DNA polymer as they transit a nanopore in sequence, and to identify each one by determining its charge-to-mass ratio in a mass spectrometer. We describe how nanopore mass spectrometry can address the challenges faced by other nanopore-based DNA analysis approaches. We also describe the design, construction, and testing of a prototype instrument that interfaces a nanopore ion source with a quadrupole mass filter and a single ion detector. We are using this new instrument to test the key scientific questions bearing on our analysis strategy: 1) Can DNA nucleotides be reliably transferred from their native liquid phase into the vacuum environment of a mass spectrometer? 2) Can nucleotides be detected with near 100% efficiency? 3) Can DNA polymers be controllably cleaved to isolate ionized bases or nucleotides in the mass spectrometer?

1:27PM B44.00010 Direct observation of DNA translocation influenced by electrically gated nanopores, GENKI ANDO, HIROKI MORIYA, KENTA TSUKAHIRA, SATOSHI YANO, TOSHIYUKI MITSUI, Department of Physics and Mathematics, Aoyama Gakuin University — One of remarkable recent developments in the solid state nanopore based DNA analysis is adding the ability to control electric potential near nanopore as a gate electrode by patterning metal in or on nanopore. In this approach, better control of DNA translocations for example, slowing down the translocation speed might be expected. We have fabricated insulator-metal-insulator nanopores of rather large 100 nm pore in diameter. The 100 nm diameter pores allow us to observe the translocation of lambda-DNA molecules directly by means of fluorescence microscopy without heavy clogging of the DNA molecules into the pores. By controlling gate voltage on metal relative to the cis and trans voltages, the translocation rates of DNA are able to change. Interestingly, applying pulse voltage to the gate metal near 100 ms to reverse the direction of the electric field near the cis side of nanopore reverses the direction of the DNA translocation instantaneously. This in fact provides us a new way to repeat translocation of the same DNA molecule. Furthermore, repeating the pulse tends to clear off the clogged DNA molecules in nanopore. We will present more details of these phenomena caused by the gate voltages.

1:39PM B44.00011 Thermophoretic stretch of a polymer confined to a nanofluidic channel, MARTIN BERTRAND, BELA JOOS, University of Ottawa — The precise manipulation of macromolecules by thermophoresis is quite promising. Indeed, Thamdrup *et al.* (Nano Lett., **10**, 2010) successfully moved double-stranded DNA (dsDNA) filaments in microfluidic geometries and subsequently inserted them into nano-channels using thermophoretic forces originating from highly localized thermal gradients and also showed that once in the channel, DNA can be symmetrically stretched under thermophoresis. This last procedure could be used to better expose the backbone of a nano-confined polymer to study its properties or the binding activity of some enzyme. We present a novel approach to model this symmetric stretch using blobs and the Flory free-energy of a polymer chain. Our model describes the monomer concentration profile reported in the aforementioned study. A value close to what is found in the literature is obtained for the Soret coefficient of the segments of dsDNA, characterizing thermophoresis. We further corroborate the validity of our model using molecular dynamics simulations. In these calculations, excluded volume interactions are shown to play a key role especially when temperatures are close to the solvent's θ value.

1:51PM B44.00012 Small Interfering RNA Transfection Across a Phospholipid Membrane, KEN-ICHI NOMURA, VAN NGO, AMIT CHOUBEY, RAJIV KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, Collaboratory for Advanced Computing and Simulations, Department of Physics and Astronomy, University of Southern California, Los Angeles, California — Small interfering RNA (siRNA) molecules play a pivotal role in silencing gene expression via the RNA interference mechanism. We have performed steered MD simulations to study the transfection of a bare siRNA and siRNA/Oleic Acid (OA) complex across the dipalmitoylphosphatidylcholine (DPPC) bilayer at $T = 323$ K. Bare siRNA induces the formation of frustrated lipid gel domains, whereas in the presence of siRNA/OA complex the membrane is found to be in the liquid-ordered phase. In both cases the stress profiles across the membrane indicate that the membrane is under tension near the head groups and highly compressed at the water-hydrophobic interface. During transfection, the membrane is deformed and the lateral stress is significantly lowered for the bare siRNA and siRNA/OA complex. The bare siRNA transfects through a lipid-nanopore of hydrophilic head-groups and hydrophobic carbon chains, whereas the siRNA/OA complex transfects through a lipid-nanopore of hydrophilic head groups.

2:03PM B44.00013 DNA base-specific modulation of μ A transverse edge currents through a metallic graphene nanoribbon with a nanopore, KAMAL K. SAHA, Department of Physics and Astronomy, University of Delaware, Newark, DE 19716, MARIJA DRNDIĆ, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19104, BRANISLAV K. NIKOLIĆ, Department of Physics and Astronomy, University of Delaware, Newark, DE 19716 — We study two-terminal devices for DNA sequencing which consist of a zigzag graphene nanoribbon (ZGNR) and a nanopore in its interior through which the DNA molecule is translocated. Using the nonequilibrium Green functions combined with density functional theory, we demonstrate that each of the four DNA nucleobases inserted into the nanopore, whose edge carbon atoms are passivated by either hydrogen or nitrogen, will lead to a unique change in the device conductance. Unlike other recent biosensors based on transverse electronic transport through translocated DNA, which utilize small (of the order of pA) tunneling current across a nanogap or a nanopore yielding a poor signal-to-noise ratio, our device concept relies on the fact that in ZGNRs local current density is peaked around the edges so that drilling a nanopore away from the edges will not diminish the conductance. Inserting a nucleobase into the nanopore affects the charge density in the surrounding area, thereby modulating edge conduction currents whose magnitude is of the order of μ A at bias voltage $\simeq 0.1$ V. The proposed biosensors could also be realized with other nanowires supporting transverse edge currents, such as chiral GNRs or wires made of two-dimensional topological insulators.

Session B45 DPOLY: Focus Session: Thin Film Block Copolymers - Swelling and Ordering 159

11:15AM B45.00001 ABSTRACT WITHDRAWN —

11:27AM B45.00002 Effect of Solvent Removal Rate on the Morphology of Solvent Vapor Annealed ABA Triblock Copolymer Thin Films, JULIE N. L. ALBERT, WEN-SHIUE YOUNG, RONALD L. LEWIS, III, TIMOTHY D. BOGART¹, JASMINE R. SMITH², THOMAS H. EPPS, III, University of Delaware — Solvent vapor annealing (SVA) treatments can be used to kinetically trap unique self-assembled nanostructures in block copolymer thin films that are not achievable by traditional thermal annealing methods. In this work, we kinetically trapped the thin film morphologies of a cylinder-forming ABA triblock copolymer at key points during the solvent removal process following SVA in order to gain insight into the re-ordering mechanisms associated with solvent removal. Specifically, we identified morphology transformations as a function of solvent removal rate, showed that the mechanism for cylinder reorientation involved the propagation of changes at the free surface through the film as a front, and validated a film etching scheme to image the through-film morphology using successive ultra-violet ozone (UVO) etching steps followed by atomic force microscopy (AFM). This facile real-space analysis of the thin film internal structure is more easily implemented in comparison to cross-sectional imaging. The results and methodology of our work are significant not only for improving our understanding of block copolymer thin film self-assembly, but also for tailoring solution processing methods to fabricate nanostructured materials (e.g., for nanotemplate and membrane applications) in general.

11:39AM B45.00003 Obtaining Perpendicular Block Copolymer Morphologies with Solvent Annealing, KEVIN GOTRIK, JEONG GON SON, ADAM HANNON, CAROLINE ROSS, Massachusetts Institute of Technology — Being able to control block copolymer (BCP) thin film morphology and orientation is of interest for lithographic applications where creation of feature sizes ranging from 10-100nm is desirable. Perpendicular oriented cylinders and lamellae are especially valuable due to their high aspect ratios but are difficult to achieve in BCP systems with a large Flory-Huggins interaction parameter (χ). We explore the morphological phase behavior that films (30-200nm) of poly(styrene-*b*-dimethylsiloxane) (PS-PDMS, 45kg/mol, $\chi=0.26$) exhibit under different solvent conditions with focus on conditions that produce perpendicular microdomains. The microdomains are revealed by selectively etching the PS with an oxygen plasma (50W CF4). Variation in the solvent vapor conditions results in selective swelling of the different blocks of the copolymer depending on the relative Hildebrand solubility parameters (e.g. PS- 18.5, toluene-18.3 MPa^{1/2}), affecting the microdomain morphologies, and the solvent evaporation and deswelling process influences the orientation of the microdomains. Two different strategies are presented involving solvent vapor annealing that result in perpendicular morphologies in films of PS-PDMS and the results are compared with self-consistent field theory modeling of solvent-polymer systems.

11:51AM B45.00004 Mesoscale Dynamics of Solvent Evaporation in Block Copolymer Thin Films, SEAN PARADISO, SU-MI HUR, KRIS DELANEY, HECTOR CENICEROS, CARLOS GARCIA-CERVERA, GLENN FREDRICKSON, University of California, Santa Barbara — Block copolymer thin films are being investigated for a wide variety of applications ranging from separation membranes, organic photovoltaics, and lithographic masks. In order to accelerate defect annihilation in the periodic structures that develop within these films, solvent annealing techniques are often employed that exploit control over solvent atmosphere to modify the free surface thermodynamics and evaporation rate in an attempt to influence the alignment of ordered domains. The inherently non-equilibrium nature of this problem complicates standard theoretical treatments based on relative free energy calculations, so we have employed a dynamical extension of Self-Consistent Field Theory coupled with a solvent evaporation mechanism to gain insights into the interplay between component-surface interactions, evaporation rate, and observed film morphology. The effects of these factors on the micro-phase separation trajectory of the film will be discussed.

12:03PM B45.00005 Optimizing the Combination of Solvent Annealing and Directed Self-Assembly in Thin Film Block Copolymer Systems Using Self-Consistent Field Theory, ADAM HANNON, KEVIN GOTRIK, ALFREDO ALEXANDER-KÄTZ, CAROLINE ROSS, Massachusetts Institute of Technology — We show how self-consistent field theory simulations can be used to optimize the combination of solvent annealing and directed self-assembly using topographical and chemical templating in order to achieve an ultimate goal of arbitrary pattern generation in thin film block copolymer systems. The simulations use a combination of field boundary conditions to model topographical features such as posts and chemically distinct surfaces along with a variety of compositions to model a range of solvent, homopolymer, and block copolymer multi-component blends [Macromolecules 2010, 43, 8290–8295]. Computational results are compared with experimental systems that use polydimethylsiloxane, polystyrene, and polyferrocenylsilane polymers, heptane, toluene, and chloroform solvents, and electron beam lithography created hydrogen silsesquioxane posts. By varying the different polymers used and thus their χ interaction parameters, the relative fractions of solvent and different polymer blocks, and surface feature affinity and shape, the optimal requirements to create arbitrary complex features for nanolithography applications will be demonstrated.

12:15PM B45.00006 Sub-10 nm block copolymer patterns with mixed morphology and period using electron irradiation and solvent annealing, JEONG GON SON, Korea Institute of Science and Technology, JAE-BYUM CHANG, KARL K. BERGGREN, CAROLINE A. ROSS, MIT — High resolution patterns with controllable period and feature geometry are of intense interest for nanolithography applications, but to date this has been challenging to accomplish from a single block copolymer, which produces patterns of a fixed period and morphology. Here we show how patterns consisting of coexisting sub-10 nm spheres and cylinders and sphere patterns with a range of periods can be created using a combination of serial solvent anneal processes and electron-beam irradiation of selected areas of a film of poly(styrene-block-dimethylsiloxane). We also additionally combined with topographical templates consisting of either removable polymeric regions to make patterns with highly aligned lines, dots and featureless regions, or post arrays which can simultaneously align and register the line and dot arrays. These techniques offer the possibility of forming a wide range of aperiodic pattern geometries including single lines or ordered line segments, and significantly extend the ability of block copolymer lithography to produce patterns essential for nanoscale device fabrication.

12:27PM B45.00007 Raster solvent vapor annealing of block copolymer thin films, JONATHAN SEPPALA, RONALD LEWIS, THOMAS EPPS, University of Delaware — Nanoscale phase separation in block copolymer (BCP) thin films makes them attractive for a variety of applications such as membranes, organic electronics, and nanoscale templating. Annealing BCP thin films (thermal or solvent) promotes ordering of their microphase-separated structures into useful patterns. Solvent vapor annealing (SVA) is an attractive approach as it avoids thermal degradation and provides greater flexibility in morphology control compared to thermal annealing through overall film swelling and preferential swelling of one or more blocks. SVA is typically conducted in an annealing chamber that permits exposure of the film to a controlled vapor environment. However, control over the vapor environment locally may be more desirable for nano-patterning applications. In this work we introduce raster solvent vapor annealing, a method that gives us precise control over the annealed region and excellent point control of the resulting morphology allowing for specific mixed morphologies on a single sample. The simplest setup, needle directed solvent vapor with controlled solvent flow rate and rastering speed, allows “drawn” ordered parallel and perpendicular cylinders in a cylinder forming BCP thin film. The efficacy of this method will be discussed in the oral presentation.

12:39PM B45.00008 Confined drying of copolymer solutions¹, DAUBERSIES LAURE, LENG JACQUES, SALMON JEAN-BAPTISTE, None — We developed a simple tool for the rapid screening of phase diagrams of polymer and surfactant solutions. Our technique is based on the controlled drying of a droplet solution in a confined geometry. A μL -sized droplet of an aqueous solution is confined between two wafers (diameter 3 cm), separated by a controlled thickness ($\approx 150 \mu\text{m}$). The confinement casts a well-defined timescale to the drying kinetics, mainly governed by the wafer area. Indeed, water removal only occurs through a diffusive process from the edge of droplet to the edge of the wafer. Confinement also permits a simple 2D description, and allows simple observations of the drying. We studied the drying of an aqueous solution of a triblock copolymer (Pluronic, P104) thanks to three different techniques: polarized microscopy, fluorescent microscopy, and Raman imaging. With our tool and techniques, we not only build an accurate phase diagram of the solution (with one microliter only) but also measure both the mutual diffusion coefficient and the activity of the solution as a function of its concentration, including the Flory-Huggins parameter.

¹towards thermodynamical and kinetics data.

12:51PM B45.00009 Rapid Self- Assembly and Perpendicular Alignment in lamellar PS-b-PEO System for Fabrication of Sub 20 nm Nanolithography Templates, PARVANEH MOKARIAN-TABARI, University College Cork and Centre for Research on Adaptive Nanostructures and Nanodevices (CRANN), Trinity College Dublin, Ireland, TIMOTHY W. COLLINS, University College Cork and Tyndall National Institute, RAMSANKAR SENTHAMARAIKANNAN, JUSTIN D. HOLMES, MICHAEL A. MORRIS, University College Cork and Centre for Research on Adaptive Nanostructures and Nanodevices (CRANN), Trinity College Dublin, Ireland — Creating perpendicular alignment in lamellar block copolymer systems has considerable industrial and commercial significance. In general, these lamellar systems require careful interface engineering to obtain vertical orientation of the blocks. To avoid the strong preferential adsorption of one block to either the substrate or the polymer/air interface, the surface must be ‘neutralised’ by chemical brushes or external forces e.g. solvent fields. Reported here is a stepwise thermo/solvent annealing process called “combinatorial annealing” allowing the formation of perpendicular domains of polystyrene-b-polyethylene oxide (PS-b-PEO) lamellar structures while avoiding brush or other surface modification. The Thermo/solvent annealing is done in a commercial microwave reactor and perpendicular alignment is observed within a few minutes. This BCP has a very small minimum feature size, relevant to the fabrication of nano-features in electronic devices and results are presented here.

1:03PM B45.00010 Controlled Deposition of Ordered Block Copolymer Thin Films by Electrospray¹, HANQIONG HU, Department of Chemical Engineering, Yale University, SOFIA RANGOU, APOSTOLOS AVERGOPOULOS, Department of Materials Science and Engineering, University of Ioannina, Greece, CHINEDUM OSUJI, Department of Chemical Engineering, Yale University — Electrospray offers a potentially useful platform for the controlled delivery of a variety of materials, but surprisingly, its application to block copolymer thin film deposition remains unexplored. Here we show that under appropriate conditions, well ordered films of PEO cylinder-forming poly(styrene-b-ethylene oxide) may be continuously deposited by electrospray. Ordered film formation is predicated on fast thermal equilibration relative to rate of deposition. We conduct time-resolved observations and investigate the effects of process parameters that underpin film morphology including solvent selectivity, substrate temperature and flow rate of the electrospray feed solution. For the particular system studied, we uncover a wide temperature window from 90°C to 160°C and an ideal flow rate (2 $\mu\text{L}/\text{min}$) for ordered film growth, but no strong influence of solvent selectivity was observed. PEO cylinders were observed to align with their long axes perpendicular to the substrate at optimal spray conditions.

¹NSF support (DMR-0847534) is gratefully acknowledged.

1:15PM B45.00011 Two distinct timescales in the ordering of symmetric diblock copolymer films, ROBERT D. PETERS, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1 — At equilibrium, an ordered symmetric diblock copolymer film forms lamellae parallel to the substrate interface. Furthermore, unless a film's thickness is exactly commensurate with the intrinsic height of the layered structure, the free surface will break up into holes or islands with a thickness corresponding to one lamellae. This ensures that the preferred lamellar spacing of the film is achieved while volume is conserved. We study the internal dynamics of ordering as a lamellar forming thin film transitions from the disordered state to its equilibrium morphology. In particular, before the free surface nucleates to form islands or holes, a film must begin by ordering internally. Using ellipsometry, we measure small changes in the internal film structure as the diblock orders prior to any change of the free surface topology. We probe two distinct timescales along the pathway to an equilibrium state: 1) An initial ordering time where molecules begin to align and form lamellae; and 2) an incubation time where the structure remains constant before nucleation of holes or islands. We will show the effect that film height and commensurability has on these two timescales, allowing us to better understand the effect of confinement on the ordering dynamics of lamellar forming thin films.

1:27PM B45.00012 The hydration and ordering of lamellar block copolymer films prior to the formation of polymer vesicles¹, YOHEI KAMATA, Kuraray Co., Ltd., ANDREW PARNELL, Department of Physics and Astronomy, University of Sheffield, ANDREW DENNISON, ROBERT BARKER, PHILIPP GUTFREUND, Institut Laue-Langevin, MAXIMILIAN SKODA, ISIS, STFC, Rutherford-Appleton Lab, SHAOMIN MAI, Department of Chemistry, University of Sheffield, RICHARD JONES, Department of Physics and Astronomy, University of Sheffield — Polymersomes – vesicles based on self-assembled bilayers in turn composed of amphiphilic copolymers – are good candidates for molecular delivery systems; hydrophilic molecules can be enclosed within the aqueous core, to be released by a trigger, which disrupts the vesicle's wall. The key to the use of these polymer vesicles as effective molecular delivery system is in the ability to efficiently encapsulate a molecular payload within the vesicle. To understand the formation mechanism of polymer vesicles via the thin film rehydration method, we have evaluated the hydration and ordering of PEO-PBO diblock copolymer thin films in a controlled water vapor atmosphere. We have performed Neutron Reflectivity, Ellipsometry and Atomic Force Microscopy measurements during the hydration process. These results show that the film swells slowly in the initial stage. It then swells rapidly at a certain critical point and makes ordered structure at the same time. The lamellae are gradually oriented parallel to the substrate with increasing water absorption.

¹We acknowledge ISIS and ILL neutron sources for access to these facilities.

1:39PM B45.00013 Effect of thickness on microdomain orientation in shear-aligned, cylinder-forming PS-PHMA thin films, RALEIGH DAVIS, Princeton University, PAUL CHAIKIN, New York University, RICHARD REGISTER, Princeton University — Previous work has shown that application of a shear stress can impart well-defined orientational order to the microdomains of cylinder-forming poly(styrene)-b-poly(n-hexylmethacrylate) (PS-PHMA) thin films. Unlike many block copolymer thin films, PS-PHMA tend not to form terraces (islands/holes). As a result, film thickness plays an important role in determining the orientation of the cylindrical microdomains. Here we study the effect of film thickness on the morphology of aligned and unaligned PS-PHMA films. Films with a gradient in thickness were generated, via flow coating, and then imaged using atomic force microscopy to examine the microdomain morphology before and after shear alignment. As a function of thickness the unsheared film morphology oscillated between dots (either spheres or cylinders oriented perpendicularly to the substrate) and lines (cylinders oriented parallel to the substrate), with the highest fraction of lines occurring at film thicknesses corresponding to an integral number of cylinder domain spacings. For thicknesses larger than three domain spacings, the oscillation ceased and complete coverage by line patterns was observed. Once shear-aligned, the thicknesses that exhibited the largest fraction of lines pre-shear, showed the highest quality of alignment post-shear.

1:51PM B45.00014 GISAXS simulation and analysis on GPU clusters¹, SLIM CHOUROU, ABHINAV SARJE, XIAOYE LI, Computational Research Division, Lawrence Berkeley National Laboratory, ELAINE CHAN, ALEXANDER HEXEMER, Advanced Light Source, Lawrence Berkeley National Laboratory — We have implemented a flexible Grazing Incidence Small-Angle Scattering (GISAXS) simulation code based on the Distorted Wave Born Approximation (DWBA) theory that effectively utilizes the parallel processing power provided by the GPUs. This constitutes a handy tool for experimentalists facing a massive flux of data, allowing them to accurately simulate the GISAXS process and analyze the produced data. The software computes the diffraction image for any given superposition of custom shapes or morphologies (e.g. obtained graphically via a discretization scheme) in a user-defined region of k-space (or region of the area detector) for all possible grazing incidence angles and in-plane sample rotations. This flexibility then allows to easily tackle a wide range of possible sample geometries such as nanostructures on top of or embedded in a substrate or a multilayered structure. In cases where the sample displays regions of significant refractive index contrast, an algorithm has been implemented to perform an optimal slicing of the sample along the vertical direction and compute the averaged refractive index profile to be used as the reference geometry of the unperturbed system. Preliminary tests on a single GPU show a speedup of over 200 times compared to the sequential code.

2:03PM B45.00015 Modeling Line Edge Roughness in Lamellar Block Copolymer Systems¹, PAUL PATRONE, University of Maryland, College Park; and NIST Gaithersburg, GREGG GALLATIN, NIST Gaithersburg — Block copolymers offer an appealing alternative to current lithographic techniques with regard to fabrication of the next generation microprocessors. However, if copolymers are to be useful on an industrial manufacturing scale, they must meet or exceed lithography specifications for placement and line edge roughness (LER) of resist features. Here we discuss a field theoretic approach to modeling the LER in the lamellar phase of a strongly segregated block copolymer system. Our model is based on the Leibler-Ohta-Kawasaki free energy functional, which takes the Flory-Huggins parameter and index of polymerization as inputs. We consider a domain with a finite number of phase separated microdomains; at the system boundary, we apply conditions akin to a chemical pinning field. Using a path integral formalism, we determine how fluctuations of the microdomain boundaries depend on distance from the system boundary, number of microdomains, the Flory-Huggins parameter, and index of polymerization.

Monday, February 27, 2012 11:15AM - 2:15PM –
Session B46 DPOLY: Invited Session: Industrial Applications of Advanced Polymer-Based Nanomaterials 160AB

11:15AM B46.00001 Polymer and Material Design for Lithography From 50 nm Node to the sub-16 nm Node¹, PETER TREFONAS, The Dow Chemical Company — Microlithography is one of the technologies which enabled the Information Age. Developing at the intersection of optical physics, polymer science and photochemistry, the need for ever smaller high fidelity patterns to build integrated circuits is currently pushing the technology evolution from 193 nm immersion lithography to extreme ultraviolet lithography (13.5 nm) to alternate patterning technologies such as directed self assembly (DSA) of block copolymers. Essential to the success of this progression is a rapid application of new concepts and materials in polymer science. We will discuss the requirements for 193 immersion lithography and how advanced acrylic random polymers are being designed with chemical amplification functionality to meet these needs. The special requirements of a water immersion lithography led to the invention and rapid commercial application of surface assembled embedded barrier layer polymers. Design of polymers for EUV lithography is having to respond to much different challenges, prominent being the dearth of photons in the exposure step, and the other being how to maximize the efficiency of photoacid production. In parallel, alternative lithographic approaches are being developed using directed self assembly of block copolymers which realize pattern frequency multiplication. We will update with our progress in the applications of polymers designed for DSA.

11:51AM B46.00002 Development of nanostructured surfaces for ice protection applications¹, AZAR ALIZADEH, GE Global Research — Ice accretion on surfaces of aircrafts, wind turbine blades, oil and gas rigs and heat exchangers, to name a few examples, presents long recognized problems with respect to efficiency and cost of operation. For instance, significant ice accretion on critical surfaces of an aircraft will cause problems during lift off (and will change the aerodynamics of the wings during flight). On the other hand, ice built up on wind turbine blades in cold climates ($T < -20^{\circ}\text{C}$) drastically reduces the efficiency of power generation. Despite considerable number of studies and significant progress toward development of icephobic coatings, development of *robust ice-resistance* or *anti-icing coatings* is still elusive. Several approaches towards development of anti-icing surfaces have recently postulated that the superhydrophobic properties of hierarchically textured coatings, with contact angles $> 150^{\circ}$, may lead to a significant reduction and perhaps elimination of snow and ice accretion. However, the exact mechanism of delayed icing on these surfaces is still under debate. Here we present a systematic study of early stages of ice formation upon water droplet impact on a range of hydrophobic, hydrophilic, textured and chemically patterned surfaces. We show that, in addition to a significant reduction in ice-adhesion strength on superhydrophobic surfaces, decreasing the water-substrate contact area plays a *dual* role in delaying ice nucleation: first by reducing heat-transfer and second by reducing the probability of heterogeneous nucleation at the water-substrate interface. The study presented here also offers a comprehensive perspective on the efficacy of textured surfaces for practical non-icing applications.

12:27PM B46.00003 Tough Block Copolymer Organogels and Elastomers as Short Fiber Composites¹, EDWARD J. KRAMER, Departments of Materials and Chemical Engineering, UCSB — The origins of the exceptional toughness and elastomeric properties of gels and elastomers from block copolymers with semicrystalline syndiotactic polypropylene blocks will be discussed. Using synchrotron X-radiation small angle (SAXS) and wide angle X-ray scattering (WAXS) experiments were simultaneously performed during step cycle tensile deformation of these elastomers and gels. From these results the toughness can be attributed to the formation, orientation and elongation of the crystalline fibrils along the tensile direction. The true stress and true strain ε_H during each cycle were recorded, including the true strain at zero load $\varepsilon_{H,p}$ after each cycle that resulted from the plastic deformation of the sPP crystals in the gel or elastomer. The initial Young's modulus E_{init} and maximum tangent modulus E_{max} in each cycle undergo dramatic changes as a function of $\varepsilon_{H,p}$, with E_{init} decreasing for $\varepsilon_{H,p} \leq 0.1$ and then increasing slowly as $\varepsilon_{H,p}$ increases to 1 while E_{max} increases rapidly over the entire range of $\varepsilon_{H,p}$ resulting in a ratio of $E_{max}/E_{init} > 100$ to 1000 at the highest maximum (nominal) strain. Based on SAXS patterns from the deformed and relaxed gels, as well as on previous results on deformation of semicrystalline random copolymers by Strobl and coworkers, we propose that the initial decrease in E_{init} and increase in E_{max} with $\varepsilon_{H,p}$ are due to a breakup of the network of the original sPP crystal lamellae and the conversion of the sPP lamellae into fibrils whose aspect ratio increases with further plastic deformation, respectively. The gel elastic properties can be understood quantitatively as those of a short fiber composite with a highly deformable matrix. At zero stress the random copolymer midblock chains that connect the fibrils cause these to make all angles to the tensile axis (low E_{init}), while at the maximum strain the stiff, crystalline sPP fibrils align with the tensile axis producing a strong, relatively stiff gel. The evolution of the crystalline structure during deformation is confirmed by WAXS and FTIR measurements.

1:03PM B46.00004 Interfacial, Thin Film, and Structural Measurements to Facilitate Polymer Nanomanufacturing, CHRISTOPHER SOLES, NIST Polymers Division — There is a growing interest in coupling the relatively mature roll-to-roll manufacturing processes with advanced lithographic patterning methods to enable high volume manufacturing of technologies with the added functionality that can only be realized by nanoscale patterning. Nanoimprint lithography is particularly attractive for roll-to-roll processes because the patterning is achieved through a simple embossing technique that relies upon the mechanical deformation of a liquid, melt, or solid material via a squeeze-flow process. Embossing techniques on a roll-to-roll substrate are routinely encountered in the graphic arts community. The difference with nanoimprint lithography is that the printed features can be on the order of 10 nm or smaller. In this presentation we will look at some of the difficulties encountered when these roll-to-roll embossing processes are scaled to the nanoscale. In particular we will look at issues related to the viscous flow of high molecular mass polymer melts into the nanoscale cavities with high throughput. We will show how fast nanoscale squeeze-flow patterning can lead to significant plastic deformation of the polymer melt. This can have implications on the ability of the material to fill the mold and the residual stresses that are generated in the pattern through the imprint process. Techniques to quantitatively evaluate these processes will be discussed and related to fundamental concepts of polymer physics.

1:39PM B46.00005 Self-Healing Polymer Networks, FRANCOIS TOURNILHAC, Ecole Supérieure de Physique et Chimie Industrielles (Paris) — Supramolecular chemistry teaches us to control non-covalent interactions between organic molecules, particularly through the use of optimized building blocks able to establish several hydrogen bonds in parallel. This discipline has emerged as a powerful tool in the design of new materials through the concept of supramolecular polymers. One of the fascinating aspects of such materials is the possibility of controlling the structure, adding functionalities, adjusting the macroscopic properties of and taking profit of the non-trivial dynamics associated to the reversibility of H-bond links. Applications of these compounds may include adhesives, coatings, rheology additives, high performance materials, etc. However, the synthesis of such polymers at the industrial scale still remains a challenge. Our first ambition is to design supramolecular polymers with original properties, the second ambition is to devise simple and environmentally friendly methods for their industrial production. In our endeavours to create novel supramolecular networks with rubbery elasticity, self-healing ability and as little as possible creep, the strategy to prolongate the relaxation time and in the same time, keep the system flexible was to synthesize rather than a single molecule, an assembly of randomly branched H-bonding oligomers. We propose a strategy to obtain through a facile one-pot synthesis a large variety of supramolecular materials that can behave as differently as associating low-viscosity liquids, semi-crystalline or amorphous thermoplastics, viscoelastic melts or self-healing rubbers.

Session B47 DPOLY: Focus Session: Jamming, Glass Transition, and Gelation in Colloids and Soft Matter Systems 160C

11:15AM B47.00001 Geometrical analysis of suspension flows near jamming¹, MATTHIEU WYART, New York University — The viscosity of suspensions was computed early on by Einstein and Batchelor in the dilute regime. At high density however, their rheology remains mystifying. As the packing fraction increases, steric hindrance becomes dominant and particles move under stress in a more and more coordinated way. Eventually, the viscosity diverges as the suspension jams into an amorphous solid. Such a jamming transition is reminiscent of critical points: the rheology displays scaling and a diverging length scale. Jamming bears similarities with the glass transition where steric hindrance is enhanced under cooling, and where the dynamics is also observed to become more and more collective as it slows down. In all these examples, understanding the nature of the collective dynamics and the associated rheology remains a challenge. Recent progress has been made however on a related problem, the unjamming transition where a solid made of repulsive soft particles is isotropically decompressed toward vanishing pressure. In this situation various properties of the amorphous solid, such as elasticity, transport or force propagation, display scaling with the distance to threshold. Theoretically these observations can be shown to stem from the presence of soft modes in the vibrational spectrum, a result that can be extended to thermal colloidal glasses as well. Here we focus on particles driven by shear at zero temperature. We show that if hydrodynamical interactions are neglected an analogy can be made between the rheology of such a suspension and the elasticity of simple networks, building a link between the jamming and the unjamming transition. This analogy enables us to unify in a common framework key aspects of the elasticity of amorphous solids with the rheology of dense suspensions, and to relate features of the latter to the geometry of configurations visited under flow.

11:51AM B47.00002 Finite Size Effects at the Jamming Transition, CARL GOODRICH, University of Pennsylvania, SIDNEY NAGEL, University of Chicago, ANDREA LIU, University of Pennsylvania — Packings of spheres at zero temperature and shear stress exhibit a jamming/unjamming transition as a function of density. For spheres that repel when they overlap and do not otherwise interact, packings are jammed with a nonzero static shear modulus when the density, ϕ , exceeds a critical density, ϕ_c . This jamming transition displays characteristics of both first and second order phase transitions with, for example, a discontinuous jump in the coordination number (average number of interacting neighbors per particle) and a power-law increase in the shear modulus. In addition, multiple length scales have been identified that diverge as ϕ decreases towards ϕ_c , emphasizing the second order nature of the transition. The existence of diverging length scales suggests that quantities such as the coordination number and shear modulus should exhibit finite size scaling as ϕ_c is approached, but until now this has not been observed. We report the first measurements of finite size scaling at the jamming transition of soft frictionless repulsive spheres and explore the implications of these results on our current understanding of the jamming transition.

12:03PM B47.00003 ABSTRACT HAS BEEN MOVED TO Y50.00015 –

12:15PM B47.00004 Stability of jammed systems to generalized boundary deformations¹, OLEG KOGAN, SAM SCHOENHOLZ, ANDREA LIU, University of Pennsylvania, SIDNEY NAGEL, University of Chicago, LIU GROUP, UNIV. OF PENNSYLVANIA COLLABORATION, NAGEL GROUP, UNIV. OF CHICAGO COLLABORATION — At zero temperature and applied stress, amorphous packings of repulsive spheres exhibit a jamming transition to rigidity. As pointed out by Torquato and Stillinger, some of these “collectively jammed” configurations may not be stable with respect to boundary deformations, while others, “strictly jammed,” may be stable with respect to any change of the boundaries. We explore this by considering systems with periodic boundary conditions at packing fractions above the jamming transition as comprising the basis of an infinite square (or cubic) lattice. The displacement fields of particles corresponding to normal modes of vibration are generally not consistent with the periodic boundary conditions used to construct the basis packing. Therefore, by studying the vibrational modes we determine the linear response to boundary deformations that do not respect the periodicity of the initial system. Hence, we are able to explore the stability of packings with respect to a large class of boundary deformations. We discover that some configurations have modes with negative energies, indicating instability. We report the effects of system size and packing fraction upon the probability that a collectively jammed packing is also stable with respect to boundary deformations.

12:27PM B47.00005 Vestige of $T = 0$ jamming transition at finite temperature in 3D, THOMAS CASWELL, MARGARET GARDEL, SIDNEY NAGEL, University of Chicago, ZEXIN ZHANG, ARJUN YODH, University of Pennsylvania — When a random packing of spheres at $T = 0$ is compressed to the jamming transition, the system becomes rigid and the first peak of the pair-correlation function, $g(r)$, diverges [1]. We study the manifestation of this signature and the associated particle dynamics when the temperature, T , is no longer negligible. To this end, we employ a three-dimensional packing of monodisperse, micron-size, colloids made from n-isopropyl acrylimide (NIPAM). NIPAM particles change size and hence the packing fraction of the system in response to environmental temperature. Thus by changing sample temperature we can probe all packing fractions of interest using a single sample. These particles are compressible so the system can reach packing fractions and configurations inaccessible to hard colloids. We observe a vestige of the $T = 0$ divergence as a maximum in the first peak of $g(r)$ versus packing fraction coincident with dynamical arrest of the particles. The general features in 3D are in agreement with a previous study in a two-dimensional bi-disperse NIPAM system [2]. We report the dependence of $g(r)$ and particle motion on packing fraction.

12:39PM B47.00006 Localization model for relaxation in glass-forming materials¹, DAVID S. SIMMONS, MARCUS T. CICERONE, JACK F. DOUGLAS, National Institute of Standards and Technology — As a material approaches its glass transition, its structural relaxation time τ rapidly increases as its particles become localized. A model relating this relaxation time increase to an experimentally accessible measure of localization (e.g. the Debye-Waller factor $\langle u^2 \rangle$) would have a fundamental impact on our understanding of glass formation and would be practically useful in the design of new materials. After examining such a relationship proposed by Leporini and coworkers and finding it to be inadequate, we develop an activated transport model that accurately describes relaxation data from a variety of simulated and experimental glass-forming materials. This model naturally extends the Hall-Wolynes and free volume models relating τ to $\langle u^2 \rangle$ (or free volume). The model parameters are physically meaningful and reflect the anharmonicity and anisotropy of particle localization. The Vogel-Fulcher-Tamman relation also describes relaxation in the simulated and experimental glass-forming materials we considered, and by exploring consistency between these two relations we gain new insight into the characteristic temperatures of glass formation in terms of the extent of particle localization.

12:51PM B47.00007 Lattice Model of Dynamic Heterogeneity in Glassy Systems¹ , NICHOLAS B. TITO, JANE E.G. LIPSON, Dartmouth College, SCOTT T. MILNER, The Pennsylvania State University — Free volume in a fluid provides space for molecular motion; this creates local mobility and avoids “kinetic jamming” as the sample is rapidly cooled towards its glass transition. This physical picture has recently garnered significant interest in the polymer materials realm, where free volume is suspected to be the key factor in suppressing the glass transition of a polymer thin film near its exposed surfaces. We have developed a simple kinetic model that describes how free volume is transported in a near-glassy liquid. Model simulation results reveal that spatial fluctuations of free volume grow large near the glass transition, and this gives rise to hallmark glassy characteristics such as dynamic heterogeneity, intermittency and, ultimately, kinetic arrest. We will also discuss the response of glassy and molten states to perturbations, as a probe for characterising fluctuations near the glass transition.

1:03PM B47.00008 Building a Colloidal Proxy for Binary Metallic Glasses , RYAN KRAMB, National Research Council, KATHARINE JENSEN, Harvard University, LOGAN WARD, Ohio State University, RICHARD VAIA, DANIEL MIRACLE, Air Force Research Laboratory — Current experimental techniques for determining the atomic structure of metallic glasses and testing structural theories such as the efficient cluster packing model are limited to diffraction and scattering. These techniques give only average structural information that could result from many different unique structures. Simulations of metallic glasses, on the other hand, give the exact structure of every atom in the system, but are limited by computing power to a few thousand atoms which are equilibrated over a few nanoseconds. This leads to uncertainties in the reliability of reproducing real metallic glass structures. To overcome these deficiencies, we have created a proxy experimental system that can be treated much like a simulation. We have synthesized suspensions of larger, colloidal scale particles (2-3 μ m in diameter) to build pseudo binary metallic glasses. Using confocal microscopy imaging techniques, we determine the three dimensional position of hundreds of thousands of individual particles (atoms), and calculate structural information such as the radial distribution function, Voronoi volume, and partial coordination numbers. We compare these results to both theoretical calculations and experimental results of real metallic glasses. The focus here will be on a building a proxy for the CuZr binary system.

1:15PM B47.00009 Contact processes in crowded environments , SHILYANG XU, Physics Department, Syracuse University, B. CHAKRABARTI, Physics Department, Rutgers University, J.M. SCHWARZ, Physics Department, Syracuse University — Periodically sheared colloids at low densities demonstrate a dynamical phase transition from an inactive to active phase as the strain amplitude is increased. To begin to answer the question of what happens to this system at higher densities, we investigate a conserved-particle-number contact process with a three-body interaction as opposed to the usual two-body interaction. In particular, one active (diffusing) particle collides with two inactive (non-diffusing) particles such that they can become active. In mean-field, this system exhibits a continuous absorbing phase transition belonging to conserved directed percolation universality class. Simulations on 2D lattices support our result. In contrast, the three-body interaction with two active particles colliding and activating one inactive particle exhibits a first-order transition. Inspired by kinetically-constrained models of the glass transition, we investigate the “caging effect” at even higher particle densities to look for a second dynamical phase transition back to an inactive phase. While mean-field calculations demonstrate a continuous transition, 2D lattice simulations show a hint of a first-order transition, suggesting a possible fluctuation-driven transition due to the highly localized geometric constraint.

1:27PM B47.00010 Experiments on Rearrangements and Forces in 2D Emulsion Hopper Flow , XIA HONG, KENNETH DESMOND, DANDAN CHEN, ERIC WEEKS, Physics Dept., Emory University, WEEKS' LAB TEAM — We did experiments with a quasi-two-dimensional binary emulsion flowing through a hopper. Our samples are oil-in-water emulsion confined between two close-spaced parallel plates, so that the droplets are deformed into pancake shapes. In this system, there is only viscous friction and no static friction between droplets. The hopper flow induces a high rate of rearrangement events allowing us to understand how stresses and forces change during the process. By imaging the droplets during flow, we observed T1 events, which are topological changes when droplets exchange neighbors. Simultaneously, we measured forces between the droplets using a technique we have developed and studied the evolution of forces between droplets during rearrangements.

1:39PM B47.00011 The Role of Solvent-Solute Interactions on The Behavior of Low Molecular Mass Organo-Gelators , KEVIN CAVICCHI, LI FENG, Department of Polymer Engineering, University of Akron — Low molecular mass organo-gelators (LMOGs) are a class of small molecules that can self-assemble in organic solvents to form three-dimensional fibrillar networks. This has a profound effect on the viscoelastic properties of the solution causing physical gelation. These gels have uses in a range of industries including cosmetics, foodstuffs, plastics, petroleum and pharmaceuticals. A fundamental question in this field is: What makes a good LMOG? This talk will discuss the relationships between the viscoelastic properties and thermodynamic phase behavior of LMOG/solvent solutions. The regular solution model was used to fit the liquidus line and sol/gel transition temperature vs. concentration in different solvents to determine LMOG-solvent interaction parameters ($\chi = A/T$). This parameter A was found to scale with the solubility parameter of the solvent, especially for non-polar solvents. This demonstrates that gelation is strongly linked to LMOG solubility and indicates that the bulk thermodynamic parameters of the LMOG (solubility parameter and melting temperature) are useful to predict the solution behavior of LMOGs.

1:51PM B47.00012 Effects of penalty function type on the history-penalized metabasin escape algorithm for supercooled liquids , RAVI HEUGLE, XI LIN, Boston University — The history-penalized metabasin escape algorithm provides an autonomous transition state pathway for a trapped system to escape from deep metastable energy minima and larger basins of attraction. The effects of penalty function type on the efficiency of the algorithm are demonstrated by sampling portions of the potential energy surface of a binary Lennard-Jones liquid close to the glass transition temperature. Our results indicate that optimal penalty functions prefer both large 3N+1 dimensional volumes and the ability to force the system over a large range. The Gaussian, which until now has served as the standard penalty function used for activation, serves as the benchmark against other representative penalty function types. Analysis shows that the triangle function results in four fold improvements in efficiency over the Gaussian, thereby furthering the reach of simulation into timescale regimes largely inaccessible to molecular dynamics.

2:03PM B47.00013 Nonlinear effective medium theory of disordered spring networks , M. SHEINMAN, VU University, C.P. BROEDERSZ, Princeton University, F.C. MACKINTOSH, VU University — Disordered soft materials, such as fibrous networks in biological contexts exhibit a nonlinear elastic response. We study such nonlinear behavior with a minimal model for networks of simple Hookian elements with disordered spring constant. We develop a mean-field approach to calculate the differential elastic bulk modulus for the macroscopic network response of such networks under large isotropic deformations. We find that the nonlinear mechanics depends only weakly on the lattice geometry and is governed by the average network connectivity. In particular, the nonlinear response is controlled by the isostatic connectivity, which depends strongly on the applied strain. Our predictions for the strain dependence of the isostatic point as well as the strain-dependent differential bulk modulus agree well with numerical results in both two and three dimensions. In addition, by using a mapping between the disordered network and a regular network with random forces, we calculate the non-affine fluctuations of the deformation field and compare it to the numerical results. Finally, we discuss the limitations and implications of the developed theory.

Monday, February 27, 2012 11:15AM - 2:15PM —
Session B48 DPOLY: Electrically and Optically Active Polymers 161

11:15AM B48.00001 Micellar Electrolytes in Organic Electrochemical Transistors, FABIO CICOIRA, Ecole Polytechnique de Montréal, TARABELLA GIUSEPPE, CNR-IMEM Parma, GAURAV NANDA, Ecole Polytechnique de Montréal, SALVATORE IANNOTTA, CNR-IMEM Parma, CLARA SANTATO, Ecole Polytechnique de Montréal — Organic electrochemical transistors (OECTs) are promising for applications in sensing and bioelectronics. OECTs consist of a conducting polymer film (transistor channel) in contact with an electrolyte. A gate electrode immersed in the electrolyte controls the doping/dedoping level of the conducting polymer. OECTs can be operated in aqueous electrolytes, making possible the implementation of organic electronic materials at the interface with biology. The inherent signal amplification of OECTs has the potential to yield sensors with low detection limits and high sensitivity. In this talk we will present recent studies on OECTs using ionic surfactants (such as hexadecyl-trimethyl-ammonium bromide) as electrolytes. As the conducting polymer we used PEDOT:PSS, i.e. (Poly(3,4 ethylenedioxythiophene) doped with Poly(styrene sulphonate). Interestingly, ionic surfactant electrolytes result in large transistor current modulation, especially beyond the critical micellar concentration (CMC). Since micelles play a primary role in biological processes and drug-delivery systems, the use for micellar electrolytes opens new exciting opportunities for the use of OECTs in bioelectronics.

11:27AM B48.00002 Quadratic Electro-Optic Effect in the Nonconjugated Conductive Co-polymer Iodine-doped Styrene-Butadiene-Rubber Measured at 633 nm and 1550 nm, GURUDUTT TELANG, MRINAL THAKUR, Photonic Materials Research Laboratory, Auburn University, AL — The quadratic electro-optic effect in the nonconjugated conductive co-polymer film of styrene-butadiene-rubber (SBR) has been measured using field-induced birefringence method. Thin films of styrene-butadiene-rubber have been prepared on various substrates from a chloroform solution and characterized using optical absorption spectroscopy, FTIR and DSC before and after doping with iodine. The optical absorption spectrum at low doping shows two peaks: one at 4.27 eV and the other at 3.2 eV corresponding to the radical cation and charge-transfer transition. FTIR data indicate C-H vibration bands (964 cm^{-1} and 910 cm^{-1}) of polybutadiene decrease upon doping due to transformation of the double bonds into radical cations. The Kerr coefficients as measured at 633 nm and at 1550 nm are $3.1 \times 10^{-10}\text{ m/V}^2$ and $1.3 \times 10^{-10}\text{ m/V}^2$ respectively. These exceptionally large values have been attributed to the subnanometer metallic domains formed upon doping and charge-transfer involving isolated double-bonds.

11:39AM B48.00003 Photoluminescence of P3HT nanoparticles¹, IRENE DUJOVNE, JOELLE LABASTIDE, UMass Amherst, Chem. Dept., MINA BAGHGAR, UMass Amherst, Phys. Dept., AIDAN MCKENNA, UMass Amherst, Chem. Eng. Dept., AUSTIN M. BARNES, UMass Amherst, Phys. Dept., D. VENKATARAMAN, MICHAEL D. BARNES, UMass Amherst, Chem. Dept. — Polythiophenes are semiconducting polymers that have been designed to crystallize. The photophysics of semicrystalline polythiophene and polythiophene-blends are the focus of intense research efforts across different disciplines. In these systems there is a competition between charge separation and recombination. Exciton diffusion length in organic-semiconductors is a major road-block for efficient solar energy harvesting devices since, for direct bandgap organic materials, this distance is about 10 nanometers. Thus, efficient extraction of photogenerated electrons and holes requires engineering polymer domain dimensions in this size range. In our initial investigations of the photophysics of isolated P3HT nanoparticles (15 - 130 nm), we have observed several intriguing size-dependent features in the single-particle photoluminescence (PL) connected with exciton diffusion and dissociation dynamics. In addition to the short-time behavior, we also observe size-dependent differences in PL decay at long times. In the 10 - 100 ns time regime, the PL originates not from radiative transitions of bound excitons, but rather from charge-separation followed by bi-polaron recombination—and thus provides an interesting measure of exciton fission probability within the nanoparticle.

11:51AM B48.00004 Crystallizing Conjugated Polymer Chains of P3HT Stretched for Dramatic Enhancements in Optoelectronic Efficiencies, CHIH-HUNG CHANG, ARNOLD C.-M. YANG, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu 300, Taiwan — Previously the amorphous conjugated polymer MEH-PPV was shown to illustrate huge enhancement in photoluminescence (PL) efficiencies upon stretching to large molecular strains. In this work the crystallizing polymer of poly(3-hexylthiophene) (P3HT), dispersed in the polystyrene (PS) matrix, was stretched in the PS local deformation zones to study the effect of molecular deformation. A huge enhancement of the PL intensity was observed that when normalized to the fraction of the strained polymer corresponded to an increase of 15 folds, significantly larger than that of the stretched MEH-PPV. Moreover, when examined under a con-focal micro-PL (spot size $\sim 5\mu\text{m}$), the emission from the local deformation zones subject to a high stress ($\sim 40\text{MPa}$) manifested marked increase of the intrachain emission relative to the effect on the interchain. These emission peak positions, however, were unaffected by the stretching. The PL enhancements were attributed to the depression of electron-phonon interactions of the stretched P3HT chains. Constraining conjugated polymers to yield high efficiencies thus may provide a feasible way for improving the performance of polymer-based devices.

12:03PM B48.00005 Manipulating meso-structure and electrical conductivity in polymer-acid doped polyaniline by exploiting redox chemistry, JACOB TARVER, JOLINE FAN, YUEH-LIN LOO, Department of Chemical & Biological Engineering, Princeton University — Template synthesis of polyaniline on poly(2-acrylamido-2-methyl-1-propane sulfonic acid) yields electrostatically stabilized particles that can be aqueously dispersed and cast into thin films; electrical conductivity in these films scales with inter-particle connectivity. Solvent annealing with dichloroacetic acid induces structural relaxation of the polymer acid, thereby eliminating the particulate nature of thin films and consequently increasing their conductivity by up to two orders of magnitude (from 0.4 to 40 S/cm). Alternatively, the electrostatic interactions between polyaniline and its template can be neutralized through chemical reduction with hydrazine monohydrate, after which the polymer acid can be plasticized by water vapor to encourage structural relaxation. Exposure to nitric oxide leads to oxidation of polyaniline and concurrent reassociation with its polymer acid dopant. Enhanced conductivity is observed following this redox process, and is attributed to extensive polymer chain relaxation and the simultaneous elimination of the particulate nature of template-synthesized polyaniline.

12:15PM B48.00006 An Integrated Electrochromic Nanoplasmonic Optical Switch, ALEC TALIN, ERICH WALTER, NIST, AMIT AGRAWAL, Syracuse University, TING XU, HENRI LEZEC, NIST — We describe an electrochemically-driven optical switch based on absorption modulation of surface plasmon polaritons (SPPs) propagating in a metallic nanoslit array waveguides containing the electrochemical polymer polyaniline (PANI). Optical transmission modulation of near 100% is achieved by electrochemically switching PANi between oxidized and reduced states using voltages below 1 V. High spatial overlap and long interaction length between the SPP and the active material are achieved by preferential growth of PANi on the nanoslit sidewalls. The resulting orthogonalization between the directions of light propagation, and that of charge transport from the electrolyte to ultra-thin active material inside the nanoslit waveguide offers significant promise for the realization of electrochromic devices with record switching speeds.

12:27PM B48.00007 Resistive Switching in Ag Nanowire/Polymer Composite Materials, JAMIE FORD, ROSE MUTISO, KAREN WINEY, University of Pennsylvania — Bulk composites of electrically conductive nanoparticles within an insulating polymer matrix are insulating when the conductive particle concentration is below the electrical percolation threshold and conductive above it. However, we have observed reversible resistive switching with increasing voltage at room temperature in Ag nanowire/polystyrene composites with nanowire concentrations close to the percolation threshold. We have found the reversibility of the observed switching behavior to be temperature dependent which implies a diffusive process is involved. We propose the basis for resistive switching in these materials is the formation of field-induced filaments between adjacent nanowires that extend the percolated electrical network and increase the overall conductivity of the system. Here, we will compare our observations of resistive switching in Ag nanowire/polystyrene and Ag nanowire/poly(methylmethacrylate) bulk nanocomposites, explore the breadth of metal nanowire and polymer systems that exhibit resistive switching, and explore the underlying mechanism for filament formation.

12:39PM B48.00008 Far-infrared through visible optical characterization of polymer-based electrochromic devices on single-walled carbon nanotube electrodes¹, ZAHRA NASROLLAHI, SVETLANA V. VASILYEVA, EVAN P. DONOGHUE, ANDREW G. RINZLER, D.B. TANNER, Department of Physics, University of Florida, Gainesville, Florida 32611 — Electrochromic polymers (ECPs) exhibit reversible optical modulation in a wide spectral range as a function of an externally applied voltage. In this work, ECPs have been used in absorptive/transmissive electrochromic devices as candidates for smart window applications. The electrochromic devices were fabricated on flexible polyethylene substrates and used ECPs sandwiched between thin films of single-walled carbon nanotubes serving as conductive and flexible electrodes. Unlike ITO, the nanotube films are highly transmissive in the visible and infrared region of the spectrum. The transmission and reflection of the individual device components as well as assembled devices were measured over a wide spectral range (FIR to UV). The devices were switched in situ in the spectrometers. The optical constants of the constituent layers were calculated using the Drude-Lorentz model. The devices demonstrated high transmission contrasts between their colored and bleached states in the VIS, NIR, and MIR spectra, enabling electrically tunable control over the transmission or reflection of both light and heat. This control could lead to reduced heating or cooling costs in real world applications and the flexible nature of the device components allows many applications.

¹The authors gratefully acknowledge Nanoholdings LLC for funding of this research.

12:51PM B48.00009 Consequence of the miscibility and mesostructure of the photoactive layer on organic solar cell performance, ENRIQUE GOMEZ, DEREK KOZUB, KIARASH VAKHSHOURI, The Pennsylvania State University — Recent work has found that mixed phases exist in polythiophene/fullerene solar cells. Nevertheless, the consequence of miscibility between the electron donor and acceptor is not fully understood. Through model polythiophene/fullerene mixtures, we have characterized charge transport in amorphous mixed phases. These results suggest that partial miscibility may be important for device performance, due to the interplay between minimizing large scale phase separation and maximizing charge transport in the photoactive layer. However, in some systems crystallization of either the electron donor or acceptor complicates the role of miscibility on device performance by modifying the composition of amorphous phases. As a result, we utilize grazing-incidence small angle X-ray scattering results to quantitatively describe solar cell device performance from the structure of the photoactive layer.

1:03PM B48.00010 Magnetic field alignment of supramolecular perylene/block copolymer complexes for electro-optic thin films¹, MANESH GOPINADHAN, PAWEL MAJEWSKI, Department of Chemical Engineering, Yale University, RYAN SHADE, EMMA DELL, NALINI GUPTA, LUIS CAMPOS, Department of Chemistry, Columbia University, CHINEDUM OSUJI, Department of Chemical Engineering, Yale University — The realization of nanostructured electro-optic materials by self-assembly is complicated by the persistence of structural defects which render the system properties isotropic on macroscopic length scales. Here we demonstrate the use of magnetic fields to facilitate large area alignment of a supramolecular system consisting of a poly(styrene-*b*-acrylic acid) (PS-*b*-PAA) diblock copolymer host and a semiconducting perylene ligand. Hydrogen bonding between the carboxylic acid groups of PAA and imidazole head group of the perylene species results in hierarchically ordered materials with smectic perylene layers in a matrix of hexagonally packed PS cylinders at appropriate stoichiometries. The smectic layers and the PS domains are strongly aligned by the application of large ($> 2T$) magnetic fields in a manner reflective of the positive diamagnetic anisotropy and the planar anchoring of perylene units at the PS interface. We use a combination of SAXS studies in-situ with applied magnetic fields, GISAXS and polarized optical transmission measurements to characterize the system. Magnetic fields thus offer a viable route for directing the self-assembly of functional materials based on rigid chromophores and further, that supramolecular approaches can be complementary to such efforts.

¹NSF support (DMR-0847534) is gratefully acknowledged.

1:15PM B48.00011 Structure/property relationships in high hole mobility regioregular PT based copolymers, LOUIS PEREZ, LEI YING, GUILLERMO BAZAN, EDWARD KRAMER, University of California - Santa Barbara — The synthesis of novel solution processable conjugated polymers with high hole mobilities is an active field of study due to the potential to fabricate low cost, high through-put, lightweight organic field effect transistors (OFET). Two regioregular copolymers, based on cyclopenta[2,1-*b*:3,4-*b'*]dithiophene (CDT) and pyridal[2,1,3]thiadiazole (PT) structural units, have been prepared by using polymerization reactions involving reactants specifically designed to avoid random orientation of the PT heterocycle. Compared to their regiorandom counterpart, the regioregular polymers exhibit a two orders of magnitude increase in hole mobility from 0.005 to 0.6 cm²V⁻¹ s⁻¹. Grazing incidence wide angle X-ray scattering (GIWAXS), near edge X-ray absorption fine structure (NEXAFS) spectroscopy, and transmission electron microscopy were carried out to obtain further insight into possible differences of structural order within the bulk and interfaces of the thin films. It was found that the backbone regioregularity leads to significant differences in the structural arrangement of the chains and indicates the importance of regioregularity for achieving optimal electronic properties.

1:27PM B48.00012 Electric Field Effect on Adhesion of Poly(ethylene oxide) Physical Hydrogels, VICTOR BARINOV, BILAL MARIE, Polytechnic Institute of New York University — The objective of this study was to characterize the effect of electric field on adhesion of poly(ethylene oxide) physical hydrogels to an aluminum substrate. The normal load necessary to disbond two plain aluminum surfaces joined by a thin layer of a poly(ethylene oxide) physical hydrogel can be reduced by about at least one order of magnitude if a reduced normal load is applied to aluminum-hydrogel interfaces simultaneously with an electric potential difference. Two aluminum surfaces joined by the hydrogel serve as a cathode and an anode. The current densities of about ten amperes per square meter determine the tenths-of-watt power dissipated in a sample. The effect of electric field on the adhesion strength of poly(ethylene oxide) hydrogels to aluminum depends on polymer concentration.

1:39PM B48.00013 Optical behavior of the conjugated polymer MEH-PPV thin films stretched in bi-layer dewetting by an unstable layer, PO-TSUN CHEN, ARNOLD C.-M. YANG, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan 30013 — Molecular packing and chain conformation play important roles in the optoelectronic performance of conjugated polymer thin films. It has been shown that by virtue of stretching via dewetting, the photoluminescence (PL) efficiencies of rarefied MEH-PPV thin films may be dramatically enhanced. To result similar effects in the stable non-diluted pristine MEH-PPV thin films, bi-layer dewetting was attempted in samples of MEH-PPV thin films (~7nm) covered by one layer of polystyrene (PS) (~40nm) that dewetted in toluene vapor to form droplets (height ~300 nm) and ultrathin residual layer (~3nm) on the substrate. The instability was initiated from the PS layer in which small pinholes first emerged upon the intake of the solvent vapor. The pinholes then expanded and deepened into the underlying MEH-PPV, forcing the conjugated film to dewet. As a result of the stretching induced by the dewetting, the PL peak blue-shifted 20 nm to 540 nm and the intensity was enhanced around 10 times. Revealed by the position-sensitive confocal PL data, the huge enhancement came from both the droplet and residual layer, caused by molecular separation and stretching. Electroluminescence devices are being made based on these stretched MEH-PPV films.

1:51PM B48.00014 High pressure optical studies of donor-acceptor polymer heterojunctions, KESHAB PAUDEL, MEERA CHANDRASEKHAR, SUCHI GUHA, University of Missouri, Columbia — Bulk heterojunction polymer solar cells are based on a composite blend of two materials with electron donating and electron accepting properties. We present optical studies of a ladder-type poly(para-phenylene) and a regioregular poly(3-hexylthiophene) polymer blended with a fullerene derivative under hydrostatic pressure. The photoluminescence and absorption spectra reveal different pressure coefficients for the pristine polymer compared with the blended system. Using a phenomenological model to determine the volume change of the system under pressure, we attribute the difference in the pressure coefficient to a change in the band-edge offset at the heterojunction upon enhanced interaction. The band-edge offset is found to increase with increasing pressures for both the ladder-type and thiophene systems.

2:03PM B48.00015 Electrical transport properties of FeCl₃ doped poly(phenylenevinylene-co-3,4-ethylenedioxythiophene), KYUNG HO KIM, AJEONG CHOI, JUN-MO PARK, SUNG JU HONG, JOON BEOM SHIM, TAE-LIM CHOI, YUNG WOO PARK, Seoul National University — Poly(arylenevinylene) copolymers, in which 3,4-ethylenedioxythiophene (EDOT) and dialkoxy phenylenes are alternatively linked by vinylene unit, were synthesized by the Horner-Emmons reaction. The samples were doped with FeCl₃ and the temperature dependence of conductivity, magnetoresistance (MR), and thermoelectric power (TEP) were measured. The temperature dependence of conductivity follows $\exp[-(T_0/T)^{1/2}]$ and positive MR is observed up to $H = 14$ tesla. The TEP can be described by $S(T) = A + B/T + CT$. These behaviors are understood in the frame of charging energy limited tunneling conduction between metallic islands separated by insulating barriers.

Session B49 DPOLY: Focus Session: Long-time, Entangled Dynamics in Polymers - Rods, Rings, Fibers, Particle Tracking 162A

11:15AM B49.00001 An improved dissipative particle dynamics model for simulation of entangled polymers, JAN ANDZELM, YELENA SLOZBERG, TIMOTHY SIRK, JOHN BRENNAN, Army Research Laboratory, MARTIN LISAL, Academy of Sciences of the Czech Republic, ARL COLLABORATION, PRAGUE COLLABORATION — We develop an improved polymer model to capture entanglements within the DPD framework by using simplified bond-bond repulsive interactions to prevent bond crossings. We show that structural and thermodynamic properties can be improved by applying a segmental repulsive potential (SRP) that is a function of the distance between the midpoints of the segments, rather than the minimum distance between segments. The alternative approach, termed the modified segmental repulsive potential (mSRP), is shown to produce chain structures and thermodynamic properties that are similar to the softly-repulsive, flexible chains of standard DPD. Parameters for the mSRP are determined from topological, structural and thermodynamic considerations. The effectiveness of the mSRP in capturing entanglements is demonstrated by calculating the diffusion and mechanical properties of an entangled polymer melt. This improved DPD method was used in simulations for entangled polymer networks to explore impact of branched architectures on the mechanical response to the tensile and compressive deformation.

11:27AM B49.00002 Theory of the nonlinear rheology of topologically entangled rod fluids, KEN SCHWEIZER, DANIEL SUSSMAN, University of Illinois at Urbana-Champaign — Our first-principles microscopic theory of the tube confinement field and dynamics of topologically entangled rod fluids is extended to describe nonlinear rheology. Stress generically weakens tube constraints, resulting in a competition between reptation and transverse activated entropic barrier hopping. For a step-strain deformation, four distinct nonlinear relaxation regimes are predicted with increasing strain amplitude: quiescent-like reptation, strongly accelerated reptation due to stress-induced tube dilation, relaxation dominated by lateral barrier hopping, and, beyond a critical strain of order unity, an initially complete destruction of the tube constraint (microscopic yielding) followed by a re-entanglement process with complex kinetics and multi-step stress relaxation. A theory for continuous start up shear has also been formulated. In the nonlinear regime, deformation-rate-dependent stress overshoots are predicted. In the nonequilibrium steady state, strong shear thinning occurs determined largely by the rate-dependent dilated tube diameter. At very high Weissenberg numbers, a stress plateau in the flow curve is predicted and relaxation is controlled by a convective-constraint-release-like process that self-consistently emerges within the theory.

11:39AM B49.00003 Theoretical and computational studies of entangled rod-coil block copolymer diffusion, MUZHOU WANG, ALFREDO ALEXANDER-KATZ, B.D. OLSEN, Massachusetts Institute of Technology — Despite continued interest in the thermodynamics of rod-coil block copolymers for functional nanostructured materials in organic electronics and biomaterials, relatively few studies have investigated the dynamics of these systems which are important for understanding diffusion, mechanics, and self-assembly kinetics. Here, the diffusion of coil-rod-coil block copolymers through entangled melts is simulated using the Kremer-Grest molecular dynamics model, demonstrating that the mismatch between the curvature of the rod and coil blocks results in dramatically slower reptation through the entanglement tube. For rod lengths near the tube diameter, this hindered diffusion is explained by a local curvature-dependent free energy penalty produced by the curvature mismatch, resulting in a rough energy surface as the rod moves along the tube contour. Compared to coil homopolymers which reptate freely along the tube, rod-coil block copolymers undergo an activated diffusion process which is considerably slower as the rod length increases. For large rods, diffusion of the rod through the tube only occurs when the coil blocks occupy straight entanglement tubes, which requires “arm retraction” as the dominant relaxation mechanism.

11:51AM B49.00004 Memory and transient forces in coarse grain simulations of complex polymers, WIM BRIELS, University of Twente — No abstract available.

12:27PM B49.00005 Self-Consistent Field Theory of Gaussian Ring Polymers¹, JAEUP KIM, YONG-BIAO YANG, UNIST, WON BO LEE, Sogang University — Ring polymers, being free from chain ends, have fundamental importance in understanding the polymer statics and dynamics which are strongly influenced by the chain end effects. At a glance, their theoretical treatment may not seem particularly difficult, but the absence of chain ends and the topological constraints make the problem non-trivial, which results in limited success in the analytical or semi-analytical formulation of ring polymer theory. Here, I present a self-consistent field theory (SCFT) formalism of Gaussian (topologically unconstrained) ring polymers for the first time. The resulting static property of homogeneous and inhomogeneous ring polymers are compared with the random phase approximation (RPA) results. The critical point for ring homopolymer system is exactly the same as the linear polymer case, $\chi N = 2$, since a critical point does not depend on local structures of polymers. The critical point for ring diblock copolymer melts is $\chi N \approx 17.795$, which is approximately 1.7 times of that of linear diblock copolymer melts, $\chi N \approx 10.495$. The difference is due to the ring structure constraint.

12:39PM B49.00006 Self-consistent field theory for polymer dynamics, DOUG GRZETIC, ROBERT WICK-HAM, Department of Physics, University of Guelph, AN-CHANG SHI, Department of Physics and Astronomy, McMaster University — We develop a self-consistent field theory (SCFT) for polymer dynamics. We reformulate a Rouse model for interacting monomers as a dynamical functional integral over field variables, using standard techniques. Novel aspects include our use of the functional Fokker-Planck equation to describe single-chain dynamics, and our extremization of the functional integral, resulting in a set of self-consistent equations for the time-dependent monomer density and the mean force field on a monomer. Our theory is distinct from published dynamical SCFTs that combine elements of equilibrium SCFT with phenomenological dynamical evolution schemes. The time scale in our theory is known exactly; no phenomenological kinetic coefficient needs to be introduced. Dynamical quantities in our theory have analogs in equilibrium SCFT, allowing sophisticated numerical techniques developed for equilibrium SCFT to be applied directly to study the dynamics. Our approach is flexible and can be used, for example, to study polymer melt dynamics. To test the self-consistent nature of the theory in space-time, we examine the simple case of the dynamics of trapped, interacting particles, and binary mixtures, in one dimension.

12:51PM B49.00007 Structure Formation in Semi-Dilute Polymer Solution during Electrospinning, EYAL ZUSSMAN, YAKOV PALEY, ARKADII ARINSTEIN, KIM SHUSTER, Department of Mechanical Engineering, Technion-Israel Institute of Technology — In our recent work it was shown that longitudinal stretching of electrospun highly entangled semi-dilute polymer solution caused by jet hydrodynamic forces, transforms the topological network to an almost fully-stretched state within less than 1 mm from the jet start (PRE, 2011). Further evolution of the polymer network is related to a disentanglement of polymer chains and transformation of the topological network structure. As was shown by Malkin et al., (Rheol. Acta, 2011) high deformation rate of a topological polymer network, results in reptations of macromolecules caused by uncompensated local forces, whereas Brownian motion effect is negligible. Based on this conclusion, we examine the disentanglement process, using a mechanical pulley-block system assembled from multiple pulleys suspended by elastic springs, and taut string connecting two blocks. Each pulley corresponds to a topological knot; the taut string corresponds to a reptated chain; the springs correspond to surrounded polymer chains; and the blocks correspond to local deformation force. It turned out that the system is sensitive to system parameters. The pulleys can approach each other and the string stops to move. Such a behavior corresponds to formation of bundle of knots of entangled chains. In other conditions, the string continuously moves while the pulleys do not approach each other which corresponds to disentanglement of polymer chains. These experiments clarify the disentanglement kinetics in rapid-deformed polymer system.

1:03PM B49.00008 Edge electrospinning from a fluid-filled bowl for high throughput production of quality nanofibers, J.R. BOCHINSKI, Department of Physics, NC State University, N.M. THOPPEY, R.E. GORGA, Fiber and Polymer Science Program, NC State University, L.I. CLARKE, Department of Physics, NC State University — We present a stationary, edge-cylinder geometry for high throughput electrospinning that utilizes a reservoir filled with polymer solution and a concentric cylindrical collector [Nanotechnology 22, 345303 (2011)]. In this “bowl” electrospinning configuration, under high voltage initiation, multiple jets spontaneously form on the fluid surface, rearrange until they are approximately equidistant along the reservoir-edge and spin towards the collector, producing high quality fibers after the voltage is reduced to a working value. The technique produced poly(ethylene oxide) nanofibers with average diameter of 225 nm and a demonstrated throughput ~ 40 times higher than traditional single-needle electrospinning. The electric field patterns generated by traditional, bowl, and our previously reported edge-plate [Polymer 51, 4928 (2010)] geometries show significant similarity in field magnitude and gradient along a path towards the collector, which may underlie the ability to form similar quality fibers. We discuss how the interaction between fluid properties and the applied electric field determines the effective flow rate, jet stability versus time, throughput, and fiber quality.

1:15PM B49.00009 Size-dependent behavior of as-spun nanofiber vs. polymer molecular weight, ARKADII ARINSTEIN, Department of Mechanical Engineering, Technion - Israel Institute of Technology — The size-dependent behavior of nano-objects is a well-known and widely-accepted phenomenon, but up to now it has no satisfactory explanation. From the physical point of view, such a behavior is to be related to an internal scale parameter which is comparable with the scale of the system. Recently Ji et al. showed that the elastic moduli of polystyrene nano-fibers of different molecular weights can be described by one universal curve as a function of fiber radius, scaled by radius of gyration R_g (EPL, 84, 56002, 2008). However, the crossover to the size-dependent behavior in the above dependence occurs at $R/R_g \sim 25 - 30$, therefore the radius of gyration, R_g , is too small in order to play a role of the required scale parameter. This discrepancy requires an explanation. Utilizing a number of well-known scaling dependences, on the base of the model of confinement mechanism of polymer nanofiber reinforcement, proposed by us earlier, it is demonstrated that elastic modulus of polymer nanofibers is described by the function $F[(R/R_g)^\alpha]$ ($\alpha \sim 1.5$). This function, conforming to experimental observation, increases at small argument values, whereas for large argument values tends to value of the bulk elastic modulus, in doing so the crossover scale to the size-dependent behavior also agrees with experimental data.

1:27PM B49.00010 Mechanical properties and morphology of polymer gels, YELENA SLOZBERG, TIMOTHY SIRK, JOHN BRENNAN, JAN ANDZELM, RANDY MROZEK, JOSEPH LENHART, Army Research Laboratory, Aberdeen, Maryland, USA — Understanding morphology and mechanical response of polymeric gels is of particular importance to design materials with required energy dissipation characteristics. We will present our latest results for polymer gels based on 1) self-assembled block copolymers and 2) chemically cross-linked polymers. The dissipative particle dynamics (DPD) was used to predict morphology in good agreement with atomic force microscopy. We have performed DPD non-equilibrium oscillatory shear calculations predicting elastic modulus of unentangled gels that correlates well with experimental rheology data. However, this methodology fails to predict mechanics of entangled polymer networks due to unphysical chain crossing brought by the soft potentials used in DPD simulations. Recently, we have introduced an improved segmental repulsion potential that removes the bond crossing allowing for reptation dynamics. The improved DPD method was used in simulations for entangled gels to explore impact of branched architecture of solvent on the mechanical response to the tensile deformation. Novel architectures of solvent resulting in a dramatic increase of the elastic modulus were identified. The topological analysis was applied to understand contributions of chemical cross-links and entanglements to the stress.

1:39PM B49.00011 Rapid, accurate single particle tracking based on radial symmetry center determination, RAGHUVeer PARTHASARATHY, University of Oregon, Dept. of Physics — Accurately tracking particles in images is a crucial task for applications as diverse as super-resolution microscopy, membrane biophysics, and microrheology. Tracking errors can easily propagate into flawed conclusions about mechanisms underlying particle dynamics. The commonly used method of locating the center of a particle by direct fitting a Gaussian function to a measured intensity profile is very accurate, but is computationally intensive and not generalizable to non-point-like particles. Its slowness is a necessary consequence of numerically searching a large parameter space. I introduce a new approach to sub-pixel particle tracking based on exploiting radial symmetry, valid for any radially symmetric particle intensity profile. I provide an algorithm that analytically, non-iteratively calculates the best-fit symmetry center to determine the particle location. Over a wide range of signal-to-noise ratios, this approach yields accuracies nearly identical to those of Gaussian fitting with execution times over two orders of magnitude faster and with greater robustness in the presence of nearby particles. This algorithm is tested on simulated data as well as real images from several experimental systems, including colloidal assemblies and single fluorescent proteins.

1:51PM B49.00012 Molecular Simulations of Passive Particle Rheology, RAJESH KHARE, MIR KARIM, Department of Chemical Engineering, Texas Tech University, TSUTOMU INDEI, JAY SCHIEBER, Department of Chemical and Biological Engineering, Illinois Institute of Technology — In this work, we demonstrate that nanoscale viscoelastic properties of polymer melts can be obtained from molecular dynamics (MD) simulations by using an approach analogous to the experimental passive microrheology. We carry out MD simulations of a system consisting of a probe particle that is embedded in a polymer melt represented using the bead-spring model. The mean squared displacement of the probe particle determined from these MD simulations is analyzed to calculate the storage and the loss moduli of the medium. Our results indicate that calculation of the viscoelastic properties from the straightforward Generalized Stokes Einstein Relationship leads to unphysical values for these quantities in the high frequency regime. We show that this problem can be alleviated by accounting for the inertial effects in the system. Our particle rheology simulation results are quantitatively compared with the literature results that were obtained from other simulation approaches. Results will also be presented for the effects of the particle size, rigidity and the chain length on the viscoelastic properties.

2:03PM B49.00013 NMR-based Molecular Rheology of Entangled Polymers in Bulk and in Nanoscopic Confinement¹, KAY SAALWACHTER, MARIE-LUISE TRUTSCHER, FABIAN VACA CHAVEZ², Martin-Luther-Univ. Halle-Wittenberg — We demonstrate the use of simple proton low-field NMR to probe the validity of the tube model of polymer dynamics. The method yields a time-domain measure of the segmental orientation autocorrelation function $C(t)$, which in turn is directly related to the stress relaxation modulus $G(t)$, thus providing a true molecular measure of rheologically relevant quantities. The fixed-tube model does not describe actual data well, and current work focuses on deuteron labeling schemes to investigate the relevance of contour-length fluctuation (CLF) or constraint release (CR) effects. As first results, we found that unexpectedly, CR processes are responsible for modified chain modes faster than actual reptation [1], and also that the dynamics is inhomogeneous along a given chain, stressing also the significance of CLF. We also present recent results for melt dynamics in nanoscopic confinement of long cylindrical channels of 20-400 nm diameter [2]. We consistently observe a fraction of chains whose dynamics is less isotropic on long time scales, i.e., in the Doi-Edwards regimes III (reptation) and IV (disentangled dynamics)

Session B50 DPOLY: Focus Session: Nano to Mesoscale Structures in Ordered Systems: Liquid Crystalline Structure and Interactions 162B

11:15AM B50.00001 Molecular Assembly and Liquid Crystal Properties of a Near-IR Absorbing Dye, PETER COLLINGS, ELIZABETH MILLS, Swarthmore College — The molecules of the near-IR absorbing dye IR-806 spontaneously assemble in water at very low concentrations, forming a liquid crystal phase at room temperature when the concentration is above 0.6 wt%. Unlike most chromonic liquid crystal systems, macroscopic phase separation between the isotropic and liquid crystal phases is not observed. Also unlike most chromonic liquid crystal systems, the absorption spectrum of IR-806 changes dramatically as the concentration increases and molecular assembly proceeds. Analysis of the absorption spectra provides evidence of an isodesmic assembly process at an extremely low concentration, followed by a second non-isodesmic assembly process at a higher concentration just before the liquid crystal phase appears.

11:27AM B50.00002 Studies on Sunset Yellow Chromonic liquid crystals by Polarized Raman and X-ray Scattering¹, MOHAN SRINIVASARAO, Georgia Institute of Technology, XUXIA YAO, Intel Corp., JUNG OK PARK, Georgia Institute of Technology, LEELA JOSHI, Kent State University, SHIN-WOONG KANG, Chonbuk National University, DENA MAE AGRA-KOOIJMAN, SATYENDRA KUMAR, Kent State University — Sunset Yellow FCF (SSY) molecules aggregate into columns in water and form chromonic liquid crystalline phases. Nematic SSY is aligned both in a flat capillary and in the magnetic field with columns pointing perpendicular to the long axis of capillary and perpendicular to the magnetic field direction, respectively. Temperature and concentration dependence of order parameters, both $\langle P_{200} \rangle$ and $\langle P_{400} \rangle$, are calculated based on polarized Raman measurement. The scission energy, E , determined from the Arrhenius thermal evolution of the longitudinal correlation length, is found to be around $4.3k_B T$ in the nematic N phase based on x-ray measurement. Flow behavior of 1.1 M nematic SSY chromonic solution under steady shear is predicted using the order parameters measured and the aspect ratios of columns.

¹This study was partially supported by NSF (DMR-0706235) and DOE (Office of Basic Energy Sciences, DE-SC0001412).

11:39AM B50.00003 Photoisometric liquid crystals integrated with plasmonic nano-structures, GARY WALSH, Electrical Engineering Boston University; US Army NSRDEC, SYLVANUS LEE, Mechanical Engineering Boston University, BRIAN KIMBALL, US Army NSRDEC, LUCA DAL NEGRO, Electrical Engineering and Materials Science Boston University — Optically switching photoisometric liquid crystals can be used for a variety of applications. However, the dependence of the efficiency of photoisometric processes on optical fluence requires power levels too high for many practical applications. Recently it has been shown that symmetry breaking in deterministic aperiodic plasmonic nano-structures boosts the efficiency of nonlinear processes by producing significant spatial field localization. This technology has the potential to dramatically enhance the performance of photoisometric liquid crystal devices. In this work, we combine photoisometric liquid crystals with lithographically fabricated periodic and aperiodic plasmonic nano-particle arrays in microfluidic channels to enhance their all optical switching properties. Using rigorous analytical multiple scattering methods we engineer particle arrays for near field enhancement at a control wavelength and the diffraction properties of a probe beam at another. Optical pump probe measurements of retardance and absorption are used to characterize the liquid crystal's structure factor as function pump power. The effects of plasmonic particle arrays on the switching dynamics on the photoisometric liquid crystals are also experimentally explored.

11:51AM B50.00004 Elasticity of lyotropic chromonic liquid crystal Sunset Yellow probed by magnetic Frederiks transition¹, SHUANG ZHOU, YU. A. NASTISHIN², M.M. OMELCHENKO, L. TORTORA, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, Kent, OH 44242, V.G. NAZARENKO, O.P. BOIKO, Institute of Physics, prospect Nauky 46, Kiev-39, 03039, Ukraine, T. OSTAPENKO, S.N. SPRUNT, J.T. GLEESON, Department of Physics, Kent State University, Kent, OH 44242, O.D. LAVRETOVICH³, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, Kent, OH 44242 — By using director reorientation in the magnetic field, we determine the concentration and temperature dependencies of the splay K_1 , twist K_2 , and bend K_3 elastic constants (normalized by the anisotropy of the diamagnetic susceptibility) for a nematic lyotropic chromonic liquid crystal (LCLC) Sunset Yellow. In a sharp contrast to thermotropic liquid crystals, the Frederiks effects in LCLC show a hysteresis, which is more pronounced at high concentration and low temperatures. We attribute the hysteresis to the changes in self-assembled structure of LCLC aggregates under the influence of field-imposed deformations.

12:03PM B50.00005 Electric Field Induced Stable Micro Rotor in Nematic Liquid Crystal Drops Constrained on Thin Cellulosic Fibers, MARIA HELENA GODINHO, YONG GENG, PEDRO ALMEIDA, Faculdade de Ciências e Tecnologia, Universidade Nova de Lisboa, JOÃO FIGUEIRINHAS, IST - Technical University of Lisbon, EUGENE TERENTJEV, Cavendish Laboratory, University of Cambridge, FCT/UNL TEAM, FCT/UNL TEAM, IST TEAM, CAVENDISH LABORATORY TEAM — We directly visualize the response of nematic liquid crystal drops of toroidal topology constrained on thin fibers, suspended in air, to an AC applied electric field $\mathbf{E}$. This new localized liquid crystal system can exhibit non-trivial point defects, which may become energetically unstable against expanding into ring disclinations depending on the fiber constraining geometries. The director anchoring tangential near the fiber surface and homeotropic at the air interface, making a hybrid shell distribution that in turn causes a ring of disclination line around the main axis of the fiber at the center of the droplet. Upon application of $\mathbf{E}$, the disclination ring first expands and slightly moves along the fiber main axis, followed by the appearance of a stable “spherical particle” orbiting around the fiber at the center of the liquid crystal drop. The rotation speed of this particle was found to vary linearly with the applied voltage. This constrained liquid crystal geometry seems to meet the essential requirements in which soliton like particles can develop and exhibit stable orbiting in three dimensions upon application of an external electric field. This is another example of a soft energy transducer system which allows, at the micro scale, the transfer in a continuous way of electrical to mechanical energy.

12:15PM B50.00006 Synthesis and investigations of mesogen encapsulated gold nanoparticles¹, CHIH-HAO YU, CHRIS J. WELCH, BAI J. TANG, CHRIS J. SCHUBERT, GEORG H. MEHL, Department of Chemistry, University of Hull, UK — Nematic mesogen encapsulated gold nanoparticles with defined size and shapes are currently of great interest for a wide range of applications for electro-optical device or metamaterials. However the synthesis of most of the materials reported so far is quite cumbersome. Thus there is the need for new routes to synthesize more advanced compounds. A suitable strategy could be based on functionalizing the organic shell. In this contribution we report a new method to prepare gold nanoparticles with a bifunctional capping agent enabling control over their size and also act as a linking group for the connection with the mesogenic groups. The result showed monolayer coated gold nanoparticles without any co-ligands and lower the isotropic point. Physical and optical properties of the nematic gold nanoparticles have been characterized by HRTEM, EDS, NMR, DSC, TGA, XRD, and OPM. The results show stable nematic mesophase formation at room temperature. The investigate system displays a typical nematic schlieren texture, and a decreased viscosity when compared to other LC Au NPs. Structure properties relationships will be discussed and the materials will be compared to earlier research.

12:27PM B50.00007 Nonlinear Diffusion on a Sphere¹, XIAOYU ZHENG, Dept. of Mathematical Sciences, Kent State University, PETER PALFFY-MUHORAY, Liquid Crystal Institute, Kent State University — We are interested in describing orientation of non-spherical particles such as liquid crystal molecules, nanoparticles and colloidal particles due to interactions with each other and with external fields. Since the orientation of a rod-like particle corresponds to a point on a unit sphere, the time evolution of the orientational distribution function corresponds to nonlinear diffusion on a sphere. We use a direct cell-based method to solve the Smoluchowski equation describing the behavior. We construct the Voronoi tessellation on the sphere, and regularize it. We then use a finite volume method to compute the particle density in the cells. Numerical results show the time evolution of the orientational probability density function. These results can describe the behavior of nanorod suspensions in electric fields.

12:39PM B50.00008 Elastic Torque on a Ferromagnetic Disk within a Nematic Liquid Crystal, JOEL B. ROVNER, DAN S. BORGNIA, CLAYTON P. LAPOINTE, DANIEL H. REICH, ROBERT L. LEHENY, Department of Physics and Astronomy, Johns Hopkins University — An aspherical particle suspended in a nematic liquid crystal will impose an orientationally dependent energy due to coupling to the nematic elasticity. This energy depends strongly on the anchoring conditions on the surface of the inclusion, its shape, as well as the proximity of other boundary conditions on the fluid such as those set by the container. To study these properties, ferromagnetic nickel disks with homeotropic surface anchoring were suspended in the liquid crystal 4-cyano-4'-pentylbiphenyl (5CB) in a planar cell. The disks, 300 nm in thickness and 10 μm in diameter, possess a permanent magnetic moment confined to the disk's plane. In the absence of any external torque the disks align with the normal to their faces parallel to the director. Rotating of the disks from this preferred orientation creates an elastic deformation that is manifested by an opposing torque. Balancing this torque with the torque from an external magnetic field for various angles of rotation, we have mapped out the orientationally dependent energy. Over a large range of angles the torque shows a linear dependence as predicted by an electrostatic analogy.

12:51PM B50.00009 Anomalous diffusion of colloidal particles in a nematic liquid crystal¹, ISRAEL LAZO, OLEG D. LAVRETOVICH², Kent State University, TARAS TURIV, ALEXANDER BRODIN, VASSILI NAZARENKO, Institute of Physics NAS Ukraine — We explore the Brownian motion of colloidal microspheres in a nematic liquid crystal within time scales below 100ms that was not accessible in previous experiments. Our experimental results point towards an apparent sub-diffusion of the colloids with a mean square displacement $\text{MSD} \propto t^{1/2}$. For longer time scales, the particles exhibit normal diffusion with two anisotropic diffusion constants parallel and perpendicular to the nematic director $\mathbf{n}$ [1]. The nonlinear effect vanishes when the host is heated up to the isotropic phase; therefore the subdiffusive behavior can be attributed to the coupling of slow director fluctuations of the nematic with the colloidal particle dynamics. We also discuss the role of finite accuracy of measurements.

1:03PM B50.00010 Colloids at a Chiral Liquid Crystal-Isotropic Liquid Interface, ANNE PAWSEY, JUHO LINTUVUORI, TIFFANY WOOD, JOB THIJSEN, DAVIDE MARENUZZO, PAUL CLEGG, University of Edinburgh — Whilst the behavior of particles trapped at liquid-liquid interfaces is relatively well understood the behavior as one of the phases begins to break translational symmetry is almost completely unexplored. Here the particles seed defects in the partially ordered liquid and new, effective, particle-particle interactions are induced. We use a chiral (cholesteric) liquid crystal which has a characteristic length scale, the pitch length, similar to the particle size. Our system consists of particles with planar anchoring which are trapped at an interface between the liquid crystal and an isotropic liquid (silicone oil which induces homeotropic anchoring). The creation of the cholesteric "fingerprint" texture allows the deformation of the cholesteric around a particle to be easily visualized. This allows us to determine the nature of the defects created and their symmetries. We have clear trends for the distribution of particles with respect to the interface as a function of particle size. Inspired by computer simulations we study the position of small particles (diameter < pitch length) within the fingerprint texture. The behavior of the unadorned interface between the chiral liquid crystal and the oil is also explored.

1:15PM B50.00011 Deformable Colloids in the Presence of a Liquid Crystal, FRANCES MACKAY, COLIN DENNISTON, University of Western Ontario — Spherical colloidal particles immersed in a liquid crystal experience a non-uniform pressure, as well as directional interactions among one another due to the defects they induce in the surrounding liquid crystal. Here, we use a lattice-Boltzmann algorithm to investigate the behavior of initially circular, 2D deformable colloids placed in a nematic liquid crystal. The colloidal particles, which are represented using a bead-spring model, are of a sufficient physical size to ensure that the anchoring of the liquid crystal molecules on their surface has a significant impact on the background liquid crystal. We present the resulting equilibrium particle shapes for a range of surface elasticities, and investigate the interaction between pairs of particles.

1:27PM B50.00012 Multistable alignment of nematic liquid crystals on patterned surfaces, TIMOTHY ATHERTON, Tufts University — A nematic in contact with a substrate patterned to promote a spatially-varying easy axis experiences a large elastic distortion adjacent to the surface and relaxes to a uniform state in the bulk. The bulk ordering may be thought of as an effective easy axis which, unlike conventional surface treatments, can be easily controlled by adjusting the geometry of the pattern. In this work, the behavior of a nematic film confined between substrates periodically patterned with rectangles is examined analytically. It is shown that multiple stable configurations exist and the effective azimuthal anchoring energy may be arbitrarily controlled by changing the aspect ratio of the rectangles. The various effects of flexoelectricity and saddle-splay elasticity, both important because of large spatial gradients in molecular orientation near the surface, are also considered. Prospects for applications of these surfaces in electrooptic devices such as displays are discussed.

1:39PM B50.00013 Direct Nanomechanical Measurement of an Anchoring Transition in a Nematic Liquid Crystal Subject to Hybrid Anchoring Conditions, BRUNO ZAPPONE, CNR-IPCF, Liquid Crystal Lab., Univ. of Calabria, Italy, MARINA RUTHS, Dept. of Chemistry, Univ. of Massachusetts Lowell — A Surface Forces Apparatus was used to measure the normal force between two solid curved surfaces confining a film of nematic liquid crystal (5CB, 4'-n-pentyl-4-cyanobiphenyl) under hybrid planar-homeotropic anchoring conditions. Upon reduction of the surface separation D , we measured an increasingly repulsive force in the range $D = 35\text{--}80$ nm, reaching a plateau in the range $D = 10\text{--}35$ nm, followed by a short-range oscillatory force at $D < 5$ nm. The oscillation period was comparable to the cross-sectional diameter of the liquid crystal molecule and characteristic of a configuration with the molecules parallel to the surfaces. These results show that the director field underwent a confinement-induced transition from a splay-bend distorted configuration at large D , which produces elastic repulsive forces, to a uniform planar configuration with broken homeotropic anchoring, which does not produce additional elastic forces as D is decreased. These findings, supported by measurements of the birefringence of the confined film at different film thicknesses, provide the first direct visualization of an anchoring transition at the nanometer scale.

1:51PM B50.00014 Unified theory of chiral smectic A monolayers and π -wall defects, C. NADIR KAPLAN, MARK J. ZAKHARY, THOMAS GIBAUD, EDWARD BARRY, ROBERT B. MEYER, ZVONIMIR DOGIC, Brandeis University — Monodisperse suspensions of the rodlike chiral fd viruses are condensed into one rod length thick colloidal monolayers of aligned rods by depletion forces. Twist deformations of the molecules are expelled to the monolayer edge as in a chiral smectic A (Sm-A*) liquid crystal, and a cholesteric (Ch) region forms at the edge. Coalescence of two such isolated monolayers results in a cholesteric wall sandwiched between two regions of aligned fd viruses, dubbed π -wall defects. Based on the analogy of Sm-A* with superconductors, we develop a unified theory of the π -wall defects and the monolayer edge structure. Our model yields the molecular tilt profiles, the local thickness change, and the crossover from Sm-A*-to-Ch behavior across the monolayer and the π -wall. These allow us to determine the line tension as a function of the depletant polymer concentration and the chirality of the viruses, in agreement with experiment.

2:03PM B50.00015 Molecular Tilt on Monolayer-Protected Nanoparticles, XU MA, Department of Physics, Syracuse University, Syracuse, New York, USA, LUCA GIOMI, School of Engineering and Applied Sciences, Harvard University, Cambridge, Massachusetts, USA, MARK BOWICK, Department of Physics, Syracuse University, Syracuse, New York, USA, APALA MAJUMDAR, Oxford Centre for Collaborative Applied Mathematics, University of Oxford, OX1 3LB, UK — We present a simple Ginzburg-Landau model to describe the order of ligands coating small metal nanoparticles (NPs). Two dimensionless parameters are introduced: a preferential tilt angle and a ratio epsilon between the energy cost due to spatial variations in the tilt of the coating molecules and that of the van der Waals interactions which favors uniform tilt. Even for the ground state, topological defects are present due to the topology of the NPs. The ground state for spherical particles is an ordered bipolar defective texture (B) for small epsilon and an untilted phase (U) for large epsilon. Octahedral particles have an additional phase (6V) at small epsilon characterized by the presence of six topological defects.

Session B51 DBIO GSNP: Focus Session: Evolutionary Systems Biology I - Evolutionary Dynamics and Rugged Fitness Landscapes 154

11:15AM B51.00001 Optimal lineage principle for age-structured populations, EDO KUSSELL, New York University — Populations whose individuals exhibit age-dependent growth have often been studied using temporal dynamics of age distributions. In this talk, I examine the dynamics of age along lineages. We will see that the lineage point-of-view provides fundamental insights into evolutionary pressures on individuals' aging profiles. I will describe a variational principle that enables exact results for lineage statistics, in a variety of models. I will also discuss measurements on continuously dividing bacterial populations growing in microfluidics devices.

11:51AM B51.00002 Why Do Complex Systems Age?, DERVIS VURAL, Harvard University and University of Illinois at Urbana Champaign, GREGORY MORRISON, L. MAHADEVAN, Harvard University — Aging can be defined as the increase in probability of death with time. The observation that organisms, colonies, ecosystems, as well as larger social structures age and die in very similar ways suggest that the reasons underlying aging does not depend sensitively on molecular or cellular details. In this work we argue that aging is an inevitable outcome of the neutral co-evolution of non-aging components which with time become increasingly interdependent. Starting from this hypothesis, we construct generic dependency networks and obtain mortality rate as a function of time, as well as mean life expectancy as a function of organism size, complexity and metabolic rate.

12:03PM B51.00003 Learning about evolution from sequence data, ADEL DAYARIAN, BORIS SHRAIMAN, KITP — Recent advances in sequencing and in laboratory evolution experiments have made possible to obtain quantitative data on genetic diversity of populations and on the dynamics of evolution. This dynamics is shaped by the interplay between selection acting on beneficial and deleterious mutations and recombination which reshuffles genotypes. Mounting evidence suggests that natural populations harbor extensive fitness diversity, yet most of the currently available tools for analyzing polymorphism data are based on the neutral theory. Our aim is to develop methods to analyze genomic data for populations in the presence of the above-mentioned factors. We consider different evolutionary regimes - Muller's ratchet, mutation-recombination-selection balance and positive adaption rate - and revisit a number of observables considered in the nearly-neutral theory of evolution. In particular, we examine the coalescent structure in the presence of recombination and calculate quantities such as the distribution of the coalescent times along the genome, the distribution of haplotype block sizes and the correlation between ancestors of different loci along the genome. In addition, we characterize the probability and time of fixation of mutations as a function of their fitness effect.

12:15PM B51.00004 Population genetics inside a cell: Mutations and mitochondrial genome maintenance, SIDHARTHA GOYAL, Kavli Institute for Theoretical Physics, University of California Santa Barbara, BORIS SHRAIMAN, University of California Santa Barbara, DAN GOTTSCHLING, Fred Hutchinson Cancer Research Center — In realistic ecological and evolutionary systems natural selection acts on multiple levels, i.e. it acts on individuals as well as on collection of individuals. An understanding of evolutionary dynamics of such systems is limited in large part due to the lack of experimental systems that can challenge theoretical models. Mitochondrial genomes (mtDNA) are subjected to selection acting on cellular as well as organelle levels. It is well accepted that mtDNA in yeast *Saccharomyces cerevisiae* is unstable and can degrade over time scales comparable to yeast cell division time. We utilize a recent technology designed in Gottschling lab to extract DNA from populations of aged yeast cells and deep sequencing to characterize mtDNA variation in a population of young and old cells. In tandem, we developed a stochastic model that includes the essential features of mitochondrial biology that provides a null model for expected mtDNA variation. Overall, we find approximately 2% of the polymorphic loci that show significant increase in frequency as cells age providing direct evidence for organelle level selection. Such quantitative study of mtDNA dynamics is absolutely essential to understand the propagation of mtDNA mutations linked to a spectrum of age-related diseases in humans.

12:27PM B51.00005 Rare beneficial mutations can halt Muller's ratchet, DANIEL BALICK, Physics Department, University of California, Santa Barbara, SIDHARTHA GOYAL, KITP, UCSB, ELIZABETH JERISON, Physics Department, Harvard University, RICHARD NEHER, MPI for Developmental Biology, Tübingen, BORIS SHRAIMAN, KITP and Physics Department, UCSB, MICHAEL DESAI, Physics Department and OEB, Harvard University — In viral, bacterial, and other asexual populations, the vast majority of non-neutral mutations are deleterious. This motivates the application of models without beneficial mutations. Here we show that the presence of surprisingly few compensatory mutations halts fitness decay in these models. Production of deleterious mutations is balanced by purifying selection, stabilizing the fitness distribution. However, stochastic vanishing of fitness classes can lead to slow fitness decay (i.e. Muller's ratchet). For weakly deleterious mutations, production overwhelms purification, rapidly decreasing population fitness. We show that when beneficial mutations are introduced, a stable steady state emerges in the form of a dynamic mutation-selection balance. We argue this state is generic for all mutation rates and population sizes, and is reached as an end state as genomes become saturated by either beneficial or deleterious mutations. Assuming all mutations have the same magnitude selective effect, we calculate the fraction of beneficial mutations necessary to maintain the dynamic balance. This may explain the unexpected maintenance of asexual genomes, as in mitochondria, in the presence of selection. This will affect in the statistics of genetic diversity in these populations.

12:39PM B51.00006 Clustering and Phase Transitions on a Neutral Landscape¹, ADAM SCOTT, DAWN KING, Center for Neurodynamics - Department of Physics & Astronomy - University of Missouri at St. Louis, NEVENA MARIC, Department of Mathematics & Computer Science - University of Missouri at St. Louis, SONYA BAHAR, Center for Neurodynamics - Department of Physics & Astronomy - University of Missouri at St. Louis — The problem of speciation and species aggregation on a neutral landscape, subject to random mutational fluctuations rather than selective drive, has been a focus of research since the seminal work of Kimura on genetic drift. These ideas have received increased attention due to the more recent development of a neutral ecological theory by Hubbell. De Aguiar et al. recently demonstrated, in a computational model, that speciation can occur under neutral conditions; this study bears some comparison with more mathematical studies of clustering on neutral landscapes in the context of branching and annihilating random walks. Here, we show that clustering can occur on a neutral landscape where the dimensions specify the simulated organisms' phenotypes. Unlike the De Aguiar et al. model, we simulate *sympatric* speciation: the organisms cluster phenotypically, but are not spatially separated. Moreover, we find that clustering occurs not only in the case of assortative mating, but also in the case of asexual fission. Clustering is not observed in a control case where organisms can mate randomly. We find that the population size and the number of clusters undergo phase-transition-like behavior as the maximum mutation size is varied.

12:51PM B51.00007 Mutational pathways to drug resistance through a maximally-rugged fitness landscape, ADAM PALMER, ERDAL TOPRAK, Department of Systems Biology, Harvard Medical School, Boston, MA, USA, SEUNGSOO KIM, ADRIAN VERES, Faculty of Arts and Sciences, Harvard University, Cambridge, MA, USA, SHIMON BERSHTEIN, Department of Chemistry and Chemical Biology, Harvard University, Cambridge, MA, USA, ROY KISHONY, Department of Systems Biology, Harvard Medical School, Boston, MA, USA — Recent laboratory evolution experiments have identified surprising properties in the evolution of trimethoprim resistance in *E.coli* through mutation of the drug's target, DHFR: (1) mutations are acquired in a reproducibly ordered manner; (2) multiple resistant endpoints exist; and (3) some pathways include mutation reversion or conversion. Here we investigate how these properties emerge from the fitness landscape of DHFR by characterizing all combinations of observed DHFR mutations. We see that the effects of mutations are so profoundly dependent on other mutations that sign-epistasis is nearly maximised, and the distributions of most mutations' effects are indistinguishable from randomly increasing or decreasing resistance. This almost 'maximally-rugged' fitness landscape contains multiple separated peaks in drug resistance, and 20% of favourable mutational steps are the loss or conversion of a previously acquired mutation. Select pathways through the rugged landscape avoid a common tradeoff between growth and resistance. Empirical characterization of this fitness landscape has identified that ordered but sometimes indirect mutational pathways to multiple endpoints arises from near-maximal levels of sign epistasis.

1:03PM B51.00008 Hidden Randomness between Fitness Landscapes Limits Reverse Evolution, LONGZHI TAN, STEPHEN SERENE, HUI XIAO CHAO, JEFF GORE, Massachusetts Institute of Technology — Natural populations must constantly adapt to the ever-changing environment. A fundamental question in evolutionary biology is whether adaptations can be reversed by returning the population to its ancestral environment. Traditionally, reverse evolution is defined as restoring an ancestral phenotype (physical characteristics such as body size), and the classic Dollo's Law has hypothesized the impossibility of reversing complex adaptations. However, this "law" remains ambiguous unless reverse evolution can be studied at the level of genotypes (the underlying genome sequence). We measured the fitness landscapes of a bacterial antibiotic-resistance gene and analyzed the reversibility of evolution as a global, statistical feature of the landscapes. In both experiments and simulations, we find that an adaptation's reversibility declines as the number of mutations it involves increases, suggesting a probabilistic form of Dollo's Law at the molecular level. We also show computationally that slowly switching between environments facilitates reverse evolution in small populations, where clonal interference is negligible or moderate. This is an analogy to thermodynamics, where the reversibility of a physical process is maximized when conditions are modified infinitely slowly.

1:15PM B51.00009 Exploring the fitness landscape of poliovirus, SIMONE BIANCO, ASHELY ACEVEDO, RAUL ANDINO, CHAO TANG, University of California San Francisco — RNA viruses are known to display extraordinary adaptation capabilities to different environments, due to high mutation rates. Their very dynamical evolution is captured by the quasispecies concept, according to which the viral population forms a swarm of genetic variants linked through mutation, which cooperatively interact at a functional level and collectively contribute to the characteristics of the population. The description of the viral fitness landscape becomes paramount towards a more thorough understanding of the virus evolution and spread. The high mutation rate, together with the cooperative nature of the quasispecies, makes it particularly challenging to explore its fitness landscape. I will present an investigation of the dynamical properties of poliovirus fitness landscape, through both the adoption of new experimental techniques and theoretical models.

1:27PM B51.00010 Scaling laws and universality for the strength of genetic interactions in yeast, ANDREA VELENICH, M.I.T., MINGJIE DAI, Harvard University, JEFF GORE, M.I.T. — Genetic interactions provide a window to the organization of the thousands of biochemical reactions in living cells. If two mutations affect unrelated cellular functions, the fitness effects of their combination can be easily predicted from the two separate fitness effects. However, because of interactions, for some pairs of mutations their combined fitness effect deviates from the naive prediction. We study genetic interactions in yeast cells by analyzing a publicly available database containing experimental growth rates of 5 million double mutants. We show that the characteristic strength of genetic interactions has a simple power law dependence on the fitness effects of the two interacting mutations and that the probability distribution of genetic interactions is a universal function. We further argue that the strength of genetic interactions depends only on the fitness effects of the interacting mutations and not on their biological origin in terms of single point mutations, entire gene knockouts or even more complicated physiological perturbations. Finally, we discuss the implications of the power law scaling of genetic interactions on the ruggedness of fitness landscapes and the consequent evolutionary dynamics.

1:39PM B51.00011 Speeding up Evolutionary Search by Small Fitness Fluctuations, JAKUB OTWINOWSKI, Department of Physics, Emory University, SORIN TANASE-NICOLA, Department for Cell and Molecular Biology, Uppsala University, ILYA NEMENMAN, Departments of Physics and Biology and Computational and Life Sciences Initiative, Emory University — We consider a fixed size population that undergoes an evolutionary adaptation in the weak mutation rate limit, which we model as a biased Langevin process in the genotype space. We show analytically and numerically that, if the fitness landscape has a small highly epistatic (rough) and time-varying component, then the population genotype exhibits a high effective diffusion in the genotype space and is able to escape local fitness minima with a large probability. We argue that our principal finding that even very small time-dependent fluctuations of fitness can substantially speed up evolution is valid for a wide class of models.

1:51PM B51.00012 ABSTRACT HAS BEEN MOVED TO J42.00011 —

2:03PM B51.00013 Experimental observation of critical slowing down as an early warning of population collapse, DAAN VORSELEN, Department of Physics and Astronomy, VU University, Amsterdam, The Netherlands., LEI DAI, KIRILL KOROLEV, JEFF GORE, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA — Near tipping points marking population collapse or other critical transitions in complex systems small changes in conditions can result in drastic shifts in the system state. In theoretical models it is known that early warning signals can be used to predict the approach of these tipping points (bifurcations), but little is known about how these signals can be detected in practice. Here we use the budding yeast *Saccharomyces cerevisiae* to study these early warning signals in controlled experimental populations. We grow yeast in the sugar sucrose, where cooperative feeding dynamics causes a fold bifurcation; falling below a critical population size results in sudden collapse. We demonstrate the experimental observation of an increase in both the size and timescale of the fluctuations of population density near this fold bifurcation. Furthermore, we test the utility of theoretically predicted warning signals by observing them in two different slowly deteriorating environments. These findings suggest that these generic indicators of critical slowing down can be useful in predicting catastrophic changes in population biology.

Monday, February 27, 2012 11:15AM - 2:15PM —
Session B52 GSNP: Granular Media: Flow and Structure 153C

11:15AM B52.00001 Simulations of Granular Particles Under Cyclic Shear, JOHN ROYER, PAUL CHAIKIN, Center for Soft Matter Research, New York University — We perform molecular dynamics (MD) simulations of spherical grains subjected to cyclic, quasi-static shear in a 3D parallelepiped shear cell. This virtual shear cell is constructed out of rough, bumpy walls in order to minimize wall-induced ordering and has an open top surface to allow the packing to readily dilate or compact. Using a standard routine for MD simulations of frictional grains, we simulate over 1000 shear cycles, measuring grain displacements, the local packing density and changes in the contact network. Varying the shear amplitude and the friction coefficient between grains, we map out a phase diagram for the different types of behavior exhibited by these sheared grains. With low friction and high enough shear, the grains can spontaneously order into densely packed crystals. With low shear and increasing friction the packing remains disordered, yet the grains arrange themselves into configurations which exhibit limit cycles where all grains return to the same position after each full shear cycle. At higher shear and friction there is a transition to a diffusive state, where grains continue rearrange and move throughout the shear cell.

11:27AM B52.00002 A Continuous Time Random Walk Description of Monodisperse, Hard-Sphere Colloids below the Ordering Transition, JEREMY LECHMAN, FLINT PIERCE, Sandia National Laboratories — Diffusive transport is a ubiquitous process that is typically understood in terms of a classical random walk of non-interacting particles. Here we present the results for a model of hard-sphere colloids in a Newtonian incompressible solvent at various volume fractions below the ordering transition ($\sim 50\%$). We numerically simulate the colloidal systems via Fast Lubrication Dynamics — a Brownian Dynamics approach with corrected mean-field hydrodynamic interactions. Colloid-colloid interactions are also included so that we effectively solve a system of interacting Langevin equations. The results of the simulations are analyzed in terms of the diffusion coefficient as a function of time with the early and late time diffusion coefficients comparing well with experimental results. An interpretation of the full time dependent behavior of the diffusion coefficient and mean-squared displacement is given in terms of a continuous time random walk. Therefore, the deterministic, continuum diffusion equation which arises from the discrete, interacting random walkers is presented. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

11:39AM B52.00003 Shear failure of granular materials, ERIC DEGIULI, NEIL BALMFORTH, Dept. Mathematics, UBC, JIM MCELWAINE, DAMTP, University of Cambridge, CHRISTIAN SCHOOF, Dept. Earth and Ocean Sciences, UBC, IAN HEWITT, Dept. Mathematics, UBC — Connecting the macroscopic behavior of granular materials with the microstructure remains a great challenge. Recent work connects these scales with a discrete calculus [1]. In this work we generalize this formalism from monodisperse packings of disks to 2D assemblies of arbitrarily shaped grains. In particular, we derive Airy's expression for a symmetric, divergence-free stress tensor. Using these tools, we derive, from first-principles and in a mean-field approximation, the entropy of frictional force configurations in the Force Network Ensemble. As a macroscopic consequence of the Coulomb friction condition at contacts, we predict shear failure at a critical shear stress, in accordance with the Mohr-Coulomb failure condition well known in engineering. Results are compared with numerical simulations, and the dependence on the microscopic geometric configuration is discussed.

[1] E. DeGiuli & J. McElwaine, PRE 2011. doi: 10.1103/PhysRevE.84.041310

11:51AM B52.00004 A simple analytic theory for the statistics of avalanches in sheared granular materials, KARIN DAHMEN, University of Illinois at Urbana Champaign, YEHUDA BEN-ZION, University of Southern California, Los Angeles, JONATHAN UHL, private — Slowly sheared granular materials at high packing fractions deform via slip avalanches with a broad range of sizes. Conventional continuum descriptions are not expected to apply to such highly inhomogeneous, intermittent deformations. Here, we show that it is possible to analytically compute the dynamics using a simple model that is inherently discrete. This model predicts quantities such as the avalanche size distribution, power spectra and temporal avalanche profiles as functions of the grain number fraction and the frictional weakening. A dynamical phase diagram emerges with quasi-static avalanches at high number fractions, and more regular, fluid-like flow at lower number fractions. The predictions agree with experiments and simulations for different granular materials, motivate future experiments and provide a fresh approach to data analysis. The simplicity of the model reveals quantitative connections to plasticity and earthquake statistics. (Reference: K.A. Dahmen, Y. Ben-Zion, J.T. Uhl, Nature Physics 7, 554-557 (2011).)

12:03PM B52.00005 Simulation of 2D Granular Hopper Flow¹, ZHUSONG LI, MARK SHATTUCK, CUNY Graduate Center and the Benjamin Levich Institute and Physics Department of The City College of New York — Jamming and intermittent granular flow are big problems in industry, and the vertical hopper is a canonical example of these difficulties. We simulate gravity driven flow and jamming of 2D disks in a vertical hopper and compare with identical companion experiments presented in this session. We measure and compare the flow rate and probability for jamming as a function of particle properties and geometry. We evaluate the ability of standard Hertz-Mindlin contact mode to quantitatively predict the experimental flow.

¹Supported by NSF (CBET-0968013)

12:15PM B52.00006 Forces on intruders in granular media, IBAR DELACRUZ, STEPHAN KOEHLER, WPI — We measure the forces acting on intruders moving in different directions in a granular medium consisting of mono-disperse spherical glass beads. We present the dependence of the drag force on the intruder's geometry and surface roughness, bead size, dragging speed and immersion depth. We also determine the distribution of the forces on the intruder's surfaces. We compare our results with lithostatic pressure ($p = \rho gz$).

12:27PM B52.00007 2D Granular Impact Dynamics with Photoelastic Particles¹, ABE CLARK, Duke University, LOU KONDIS, New Jersey Institute of Technology, R.P. BEHRINGER, Duke University — What is the response of a granular material to a high speed impact from a foreign object? To answer this question, we use a large 2D granular system which is impacted from above by an intruder. Using photoelastic discs and a high-speed camera (frame rates at 7,000-775,00 fps at varied resolution, typically 40,000 fps at 584x256 pixels), we are able to observe the dynamics in this process in a way which has not been done previously. Data consists of the trajectory of the intruder, as well as either particle positions or interparticle force information. High frame rates allow observation of complex acoustic waves during the impact process. We examine the effects of varying the initial velocity, density, shape, and size of the intruder, with the goal of extracting the grain-scale mechanisms responsible for the dissipation of the intruder's kinetic energy. In comparing our data to macroscopic frictional models used in past work, we observe good agreement with the low-frequency behavior in our experiments, but we also observe large high-frequency fluctuations in the acceleration which are inherently granular, and not captured by these models. The large fluctuations are well correlated to the emission of localized intermittent stress pulses, seen in the photoelastic response.

¹This work is supported by DTRA, grant HDTRA1-10-0021

12:39PM B52.00008 Cooperative rotations of 2d frictional disks under oscillatory shear, MITCHELL MAILMAN, MICHELLE GIRVAN, WOLFGANG LOSERT, university of Maryland — We explore the dynamics of the contact network under cyclic shear, with a particular focus on cooperative rolling and sliding contacts, using a molecular dynamics (MD) simulation approach and external fixed pressure. We systematically study the formation and persistence of clusters of cooperatively rolling grains for a range of reversal amplitudes. The propensity for cooperative rotation dictates structural properties of the contact network: loop configurations of even numbers of grains are able to rotate without sliding, while odd numbers of grains must have at least one sliding contact. We report on the statistics of loop structures in the contact network, as well as their relationships to cooperatively rotating grains. Finally, we demonstrate a characteristic scale over which grains can cooperatively rotate as well as the dependence on friction parameters.

12:51PM B52.00009 High-speed measurement of axial grain transport in a rotating drum¹, FRANK VAN BUSSEL, Max Planck Institute for Dynamics and Self-Organization, ZEINA KHAN, Chemical Engineering, Texas Tech University, MARC SCHABER, RALF SEEMANN, Experimental Physics, Saarland University, MARIO SCHEEL, MARCO DIMICHIEL, European Synchrotron Radiation Facility — Over short timescales granular mixtures separate by size when tumbled in a partially filled horizontal drum. The smaller grains move toward the axis of rotation to form a central core; undulations in this core gradually increase in amplitude until they grow into axial bands. Using non-invasive high-speed synchrotron x-ray particle tracking, we investigate the axial transport properties of tracer particles traveling amongst glass spheres. This new technique allows us to gather data on time scales not previously possible. When the tracers are present in larger proportions the mixtures we used should have different tendencies to segregate axially according to size ratio; one of our findings, however, is that when the tracer concentration is low the single-particle dynamics of these mixtures do not depend on the relative particle sizes in any appreciable way. This implies that the potential for a mixture to axially segregate cannot be inferred from the microscopic dynamics of individual small particles. A second finding is that while the slope of the mean-squared displacement is close to that expected from diffusive transport, as determined from the single-particle dynamics, more detailed analyses indicate anomalous transport.

¹The authors thank the ESRF for providing the synchrotron radiation facilities under proposal LTP MA-800.

1:03PM B52.00010 Jamming of Cylindrical Grains in Vertical Channels¹, G. WILLIAM BAXTER, GREGORY SPIER, NICHOLAS BARR, FIONA STEEL, Penn State Erie, The Behrend College — We study jamming of low aspect-ratio cylindrical Delrin grains in a vertical channel. These cylindrical grains resemble antacid tablets, poker chips, or coins since their height is less than their diameter. Grains are allowed to fall through a vertical channel with a square cross section where the channel width is greater than the diameter of a grain and constant throughout the length of the channel with no obstructions or constrictions. Within this channel, grains are sometimes observed to form jams, stable structures supported by the channel walls with no support beneath them. The probability of jam occurrence and the strength or robustness of a jam is effected by the grain dimensions and channel size. We will present experimental measurements of the jamming probability and jam strength in this system and discuss the relationship of these results to other experiments and theories.

¹Supported by an Undergraduate Research Grant from Penn State Erie, The Behrend College.

1:15PM B52.00011 Ordered and disordered granular sphere packings obtained by epitaxial growth, ANDREEA PANAITESCU, ARSHAD KUDROLI, Clark University — We study granular packings obtained by depositing spheres on a substrate under the influence of gravity. By exploiting the direct particle tracking enabled by X-ray tomography, the nature of the order and disorder is investigated using statistical measures including density pair correlation function, and the orientational order parameter. We find that by using a low deposition rate, impinging particles with sufficient energy can overcome friction and come to rest in a potential minimum of a periodic substrate, giving rise to ordered face-centered cubic structures. However, impinging particles with large kinetic energy can dislodge particles in the substrate leading to disorder as mobile particles cooperatively form arches while they come to rest. Thus, a wide range of volume fractions and packing structures is accessed by simply controlling the nature of the substrate and deposition rate and energy, along with the shape of the impinging particles. We contrast the ordered and disordered phases observed as a function of packing fraction with our previous study with cyclically sheared packings. In that study, compaction, nucleation and growth of face centered cubic and hexagonal close packed crystalline order was observed after hundreds of thousands of shear cycles.

1:27PM B52.00012 Tunable acoustic switching and rectification in one-dimensional granular crystals, NICHOLAS BOECHLER, Massachusetts Institute of Technology, GEORGIOS THEOCHARIS, CHIARA DARAI, California Institute of Technology — We study a new mechanism for tunable acoustic switching and rectification, which we experimentally demonstrate in a one-dimensional granular crystal. The granular crystal is composed of an array of statically compressed elastic spherical particles that interact nonlinearly via Hertzian contact. The granular crystal is uniform except for a single light-mass defect placed near one boundary of the crystal. Because of the interplay of the periodicity, nonlinearity, dissipation, and asymmetry of the granular crystal, vibrations applied near the defect position cause the system response to bifurcate from periodic non-transmitting states to quasiperiodic and chaotic transmitting states with broadband frequency content. We illustrate the nature of this bifurcation using numerical simulations and compare these results to experimental observations. Because the bifurcation causes a sharp transition between states, this mechanism can lead to phononic switching and sensing. Furthermore, as switches and rectification devices are fundamental components used for controlling the flow of energy in numerous applications, we envision that this mechanism could more generally enable the design of advanced photonic, thermal, and acoustic materials and devices.

1:39PM B52.00013 Granular compaction under confinement, NATHAN MUEGGENBURG, Lake Forest College — A granular pack that is vertically vibrated undergoes rearrangements and often progresses to more dense configurations. The experiments presented here study the role of dilation in this granular compaction process. By applying a confining force to the granular pack during vibration, the dilation is inhibited and the compaction is greatly reduced. In general, systems with different accelerations during vibration will compact differently. However, these systems will compact in the same manner if the confining force is tuned to result in the same amount of dilation. Under large confining forces, there is very little dilation. In this regime, the compaction is significantly slowed and may approach a steady state packing fraction of approximately 0.60, consistent with ideas of a critical packing fraction for the onset of dilation.

1:51PM B52.00014 Densest columnar structures of hard spheres from sequential deposition¹, HO-KEI CHAN, Foams & Complex Systems, School of Physics, Trinity College Dublin, Ireland, ABERYSTWYTH UNIVERSITY COLLABORATION — The rich variety of densest columnar structures of identical hard spheres inside a cylinder can surprisingly be constructed from a simple and computationally fast sequential deposition of cylinder-touching spheres, if the cylinder-to-sphere diameter ratio D is within $[1, 2.7013]$. This provides a direction for theoretically deriving all these densest structures and for constructing such densest packings with nano-, micro-, colloidal or charged particles, which all self-assemble like hard spheres [*Rapid Communication*, Physical Review E (in press)].

2:03PM B52.00015 Discrete Calculus as a Bridge between Scales, ERIC DEGIULI, Dept. Mathematics, UBC, JIM MCELWAINE, DAMTP, University of Cambridge — Understanding how continuum descriptions of disordered media emerge from the microscopic scale is a fundamental challenge in condensed matter physics. In many systems, it is necessary to coarse-grain balance equations at the microscopic scale to obtain macroscopic equations. We report development of an exact, discrete calculus, which allows identification of discrete microscopic equations with their continuum equivalent [1]. This allows the application of powerful techniques of calculus, such as the Helmholtz decomposition, the Divergence Theorem, and Stokes' Theorem. We illustrate our results with granular materials. In particular, we show how Newton's laws for a single grain reproduce their continuum equivalent in the calculus. This allows introduction of a discrete Airy stress function, exactly as in the continuum. As an application of the formalism, we show how these results give the natural mean-field variation of discrete quantities, in agreement with numerical simulations. The discrete calculus thus acts as a bridge between discrete microscale quantities and continuous macroscale quantities.

Monday, February 27, 2012 11:15AM - 2:15PM — Session B53 GSNP: Disordered and Glassy Systems II 153B

11:15AM B53.00001 Nanoscale dynamics of binary metallic glass $\text{Cu}_x\text{Hf}_{1-x}$ films¹, JACOB BURGESS, University of Alberta Department of Physics, National Institute for Nanotechnology, CHRIS HOLT, University of Alberta Department of Chemical and Materials Engineering, National Institute for Nanotechnology, DAVID FORTIN, GREG POPOWICH, University of Alberta Department of Physics, ERIK LUBER, DAVID MITLIN, University of Alberta Department of Chemical and Materials Engineering, National Institute for Nanotechnology, MARK FREEMAN, University of Alberta Department of Physics, National Institute for Nanotechnology — Scanning probe microscopy provides a valuable tool for investigating nanoscale structure of thin films. Less commonly it can be applied to study the low speed dynamical behavior of these systems as well. Presented here are scanning tunneling microscope investigations of sputtered glass $\text{Cu}_x\text{Hf}_{1-x}$ films which reveal the nanocrystalline structure of the films as well as hopping dynamics of crystal clusters on the surface. A correction for limited bandwidth and a range of activation energies is developed in the context of an Arrhenius process to allow extraction of the average energy barrier for cluster hopping. Concentration of the component metals in the films was varied allowing observation of the change in cluster size as well as the transition to the amorphous state. A second form of dynamics, more diffusive in character, was found for amorphous samples.

11:27AM B53.00002 Isothermal Pressurizations and Glass Transition Dynamics in the Intermediate Glass-Forming Liquid Glycerol¹, WILLIAM OLIVER, University of Arkansas, Department of Physics, TITUS MORRIS, Michigan State University, Department of Physics and Astronomy, TIM RANSOM, University of Arkansas, Department of Physics — Brillouin scattering data along both a 75 °C and 100 °C isotherm to pressures as high 6 GPa are reported for glycerol an intermediate strength glass forming liquid. This represents the highest pressure data of any type reported for glycerol, and enables us to probe directly the alpha relaxation process at these high pressures. Acoustic mode frequencies and linewidths are obtained from fits to the spectra. These frequency shifts and linewidths are fit for each isotherm with an iterative technique in which parameters are adjusted until self consistency is obtained. The Tait equation of state along with a complex expression for the dynamical longitudinal modulus, $M(\omega)$, and quantitative models for other physical quantities such as the adiabatic index are used in our analysis. A Cole-Davidson function is used to model the dynamical modulus, and self-consistent fits indicate that the stretching parameter, β , is pressure independent with a value of 0.37 consistent with other low pressure acoustic results in the literature. Final values for the pressure dependent dynamical longitudinal modulus and relaxation time are obtained. In contrast to the results of recent pressure-dependent dielectric studies, there does not appear to be a second process that obscures the alpha process.

11:39AM B53.00003 Fast Scanning Calorimetry study of non-equilibrium relaxation in 2-Ethyl-1-Hexanol¹, VLAD SADTCHENKO, DEEPANJAN BHATTACHARYA, The George Washington University, Department of Chemistry, CANDACE PANE, The University of Aberdeen — Fast scanning calorimetry (FSC), capable of heating rates in excess of 1000000 K/s, was combined with vapor deposition technique to investigate non-equilibrium relaxation in micrometer thick ultraviscous of 2-Ethyl-1-Hexanol (2E1H) films under high vacuum conditions. Rapid heating of 2E1H samples prepared at temperatures above approximately 145 K (standard glass transition temperature of 2E1H, T_{gs}), resulted in well manifested dynamic glass transitions at temperatures tens of degrees higher than T_{gs}. Furthermore, strong and complex dependence of dynamic glass transition temperature on the sample's initial state, i.e., the starting temperature of FSC scan was also observed. We discuss implications of these results for contemporary models of non-equilibrium relaxation in glasses and supercooled liquids.

11:51AM B53.00004 Fluctuating Relaxation Times in Glass-forming Liquids, GCINA A. MAVIMBELA, HORACIO E. CASTILLO, Department of Physics and Astronomy, Ohio University, Athens OH, AZITA PARSAEIAN, Materials Research Center, Northwestern University, Evanston IL — The presence of fluctuating local relaxation times, $\tau(\vec{r}, t)$ has been used for some time as a conceptual tool to describe dynamical heterogeneities [?]. Here we report on a new method for determining the local phase field, $\phi(\vec{r}, t) \equiv \int^t \frac{dt'}{\tau(\vec{r}, t')}$ from snapshots $\{\vec{r}(t_i)\}_{i=1\dots M}$ of the positions of the particles in a system, and we apply it to extract $\phi(\vec{r}, t)$ from simulations of glass forming models. By studying how the phase field depends on the number of snapshots, we find that it is a well defined quantity. By studying fluctuations of the phase field, we find that they describe heterogeneities well at long distance scales. We also determine how the stretching exponent β depends on the coarse graining volume, in order to test the hypothesis that relaxation in small regions is exponential and it only becomes non-exponential when considering large regions of the system.

12:03PM B53.00005 Mapping dynamical heterogeneity in structural glasses to correlated fluctuations of the time variables, KARINA E. AVILA, HORACIO E. CASTILLO, Ohio University, AZITA PARSAEIAN, Northwestern University — Dynamical heterogeneity is believed to play an important role in the dynamical behavior of slowly relaxing disordered materials. In this work, we test one hypothesis for its origin, namely that it emerges from soft (Goldstone) modes associated with a broken continuous symmetry under time reparametrizations. We do this by constructing coarse grained observables and decomposing the fluctuations of these observables into transverse components, which are associated with the postulated time-fluctuation soft modes, and a longitudinal component, which is unrelated to them. We perform our test on data obtained in simulations of four models of structural glasses. We find that as temperature is lowered and timescales are increased, the time reparametrization fluctuations become increasingly dominant. In particular, the ratio between the strengths of the transverse fluctuations and the longitudinal fluctuations grows as a function of the dynamical susceptibility χ_4 , which represents the strength of the dynamical heterogeneity; and the correlation volumes for the transverse fluctuations are approximately proportional to those for the dynamical heterogeneity, while the correlation volumes for the longitudinal fluctuations remain small and approximately constant.

12:15PM B53.00006 High Pressure Brillouin Scattering in the Fragile Glass Former Cumene¹, TIM RANSOM, WILLIAM OLIVER, University of Arkansas — In recent years full-spectrum analysis in light-scattering has been utilized to explore the liquid-glass transition at variable temperature and ambient pressure. In this study we present temperature- and pressure-dependent Brillouin scattering results for the fragile glass-former cumene. Both equal-angle forward scattering and depolarized backscattering geometries are used, and high pressures are attained by the use of a diamond anvil cell mounted in a custom temperature-controlled housing. Opening up the variable pressure regime to full-spectrum analysis will allow more stringent tests of mode-coupling theory as well as greater insight into the behavior of glass-forming systems.

¹We gratefully acknowledge support from NSF under grant NO.: DMR-0552944

12:27PM B53.00007 Molecular modeling of ultra-stable vapor deposited glasses, SADANAND SINGH, DEVIN AVERETT, CHI-CHENG CHIU, JUAN J. DE PABLO, University of Wisconsin-Madison — Recent studies have shown that physical vapor deposition can be used to prepare glasses of small organic molecules with remarkably high kinetic stability and low enthalpy, particularly when compared to ordinary glasses prepared by cooling the supercooled liquid. The thermophysical properties of these new ultra-stable glasses are equivalent to those of common glasses after thousands of years of aging. However, experimental studies have so far been limited to relatively few types of molecules. We propose a molecular modeling scheme to prepare stable glasses that mimics the experimental procedure of vapor deposition. For simple disaccharides, such as trehalose, the thermophysical properties of our simulated glasses are consistent with those measured experimentally. We also prepare stable glasses of trehalose and glycerol mixtures, which are of interest for their use in stabilization of biomolecules in the glass state. Results for model binary Lennard-Jones glasses, which have been studied extensively in the literature, are also discussed. We find that the most stable glasses formed by vapor deposition are equivalent to ordinary glasses formed by cooling at a rate approximately 10 orders of magnitude slower than those accessible by ordinary cooling methods.

12:39PM B53.00008 Dynamic heterogeneity above and below the mode-coupling temperature

, ELIJAH FLENNER, GRZEGORZ SZAMEL, Chemistry Department, Colorado State University — We study the temperature dependence of the spatial extent of the dynamic heterogeneity in a soft sphere system near the so-called mode-coupling temperature T_c . We utilize a recently introduced procedure¹ to calculate the ensemble independent dynamic susceptibility $\chi_4(\tau_\alpha)$ and the dynamic correlation length $\xi(\tau_\alpha)$ at the alpha relaxation time τ_α . Above T_c , we find that $\chi_4(\tau_\alpha) \sim \xi(\tau_\alpha)^3$ and $\xi(\tau_\alpha) \sim \ln(\tau_\alpha)$, which is the same behavior found in a binary hard-sphere system. We track these relationships below T_c to examine the recently reported non-monotonic temperature dependence of dynamic correlations found in the same system². Finally, we examine the relationship between dynamic susceptibilities that can be determined from experiments and the dynamic correlation length $\xi(\tau_\alpha)$.

12:51PM B53.00009 Fast Scanning Calorimetry studies of glassy and supercooled water¹

, DEEPANJAN BHATTACHARYA, The George Washington University, CANDACE PAYNE, The University of Aberdeen, VLAD SADTCHENKO, The George Washington University — Despite intense efforts, development of a comprehensive system of relationships between various condensed phases of water remains an illusive goal. The lack of consensus on the nature of supercooled and glassy water is due primarily to the lack of kinetic and thermodynamic data at temperatures from 150 to 235 K. Because supercooled water undergoes rapid crystallization near 235 K, application of standard experimental methods is virtually impossible. With the objective of gaining insights into properties of water, we have developed an experimental approach which relies on rapid (1000000 K/s) heating of micro- and mesoscopic aqueous samples prepared by vapor deposition in vacuum at cryogenic temperatures. Due to high heating rates, this Fast Scanning Calorimetry approach, makes it possible to bypass crystallization and to obtain new data on molecular kinetics and thermodynamics in glassy water in previously inaccessible temperature interval. We will report the results of our FSC studies and discuss their impact on fundamental and applied research areas where glassy and supercooled water plays significant role.

1:03PM B53.00010 Volume and structural analysis of super-cooled water under high pressure

, SOLOMON F. DUKI¹, Department of Physics and Astronomy, Rowan University, 201 Mullica Hill Road, Glassboro, NJ 08028-1701, MESFIN TSIGE², Department of Polymer Science, Goodyear Polymer Center 1021, The University of Akron, Akron, OH 44325-3909 — Motivated by recent experimental study of super-cooled water at high pressure [1], we performed atomistic molecular dynamic simulations study on bulk water molecules at isothermal-isobaric ensemble. These simulations are performed at temperatures that range from 40 K to 380 K using two different cooling rates, 10K/ns and 10K/5ns, and pressure that ranges from 1atm to 10000 atm. Our analysis for the variation of the volume of the bulk sample against temperature indicates a downward concave shape for pressures above certain values, as reported in [1]. The same downward concave behavior is observed at high pressure on the mean-squared-displacements (MSD) of the water molecules when the MSD is plotted against time. To get further insight on the effect of the pressure on the sample we have also performed a structural analysis of the sample.

1:15PM B53.00011 A field theory approach to the dynamics of classical particles

, DAVID MCCOWAN, GENE MAZENKO, University of Chicago — For nearly 30 years, mode-coupling theory (MCT) has been regarded as the *de facto* theoretic description of dense fluids and the transition from the fluid to glassy state. But MCT is limited by its ad hoc construction and lacks a mechanism to institute corrections. We present a new fundamental theory for the kinetics of systems of classical particles which represents a unification of kinetic theory, Brownian motion and field theory. It is developed from first principles via a self-consistent perturbation in terms of an effective two-body potential, and we use this theory to investigate the existence of ergodic-nonergodic (ENE) transitions near the liquid-glass transition. After a brief introduction of the theory, we will address the development of a kinetic equation of the memory function form. The memory function kernel (or self-energy) determined by the theory shares properties with the MCT form, however our theory provides the crucial advantage of well-defined, perturbative corrections.

1:27PM B53.00012 N.Q.R measurements of low energy Chiral structures in powdered glassy

As_2Se_3 , CHRIS NELSON, A.P.S — Experimental and theoretical work on the As-chalcogen glasses have shown that in the glassy state the local cylindrical symmetry associated with the elemental pyramidal unit is preserved. Here we introduce a local paracrystalline model of glassy As_2Se_3 . This model is based on a tight binding calculation of the electric field gradient (EFG) at the core of an As atom located at the apex of the pyramidal structure. This EFG is shown to be hyper sensitive to the bond angles and bond lengths the As atom forms with the chalcogen nearest neighbors, as well as the hybrid angle formed with second neighbor As atoms. A continuous variation of the bonding parameters produces a unique set of these pyramidal units which are shown to fit the NQR data for powdered glassy samples. The best fit to the NQR data indicates that the pyramidal units organize themselves into Chiral structures in the glass. A plot of the electronic energy per molecular site shows that the chiral structures have on average a lower electronic energy than a random configuration.

1:39PM B53.00013 Slow relaxations in glasses: full aging and beyond

, YOSEPH IMRY, The Weizmann Institute of Science, ARIEL AMIR, Harvard University, YUVAL OREG, The Weizmann Institute of Science, STEFANO BORINI, INRIM, Torino — Experiments performed in the last years demonstrated slow relaxations and aging in the conductance of a large variety of materials. Here, we present experimental and theoretical results for conductance relaxation and aging for the case-study example of porous silicon. The relaxations are experimentally observed even at room temperature over time scales of hours, and when a strong electric field is applied for a time t_w , the ensuing relaxation depends on t_w . We derive a theoretical curve and show that all experimental data collapse onto it with a single time scale as a fitting parameter. This time scale is found to be of the order of thousands of seconds at room temperature. The generic theory suggested is not fine-tuned to porous silicon, and thus we believe the results should be universal, and the presented method should be applicable for many other systems manifesting memory and other glassy effects. Reference: Phys. Rev. Lett. **107**, 186407 (2011)

1:51PM B53.00014 Voids and molecuar hydrogen in hydrogenated amorphous silicon

, RAJENDRA TIMILSINA, PARTHAPRATIM BISWAS, The University of Southern Mississippi — Nuclear magnetic resonance (NMR) and Infrared (IR) spectroscopy experiments show that hydrogen microstructure consists of clustered and diluted hydrogen atoms as well as voids and hydrogen molecules in hydrogenated amorphous silicon. Several theoretical studies have also attempted that whether the microstructure incorporates voids and hydrogen molecules or not, by introducing hydrogen atoms within artificially created cavities, after relaxing the models of hydrogenated amorphous silicon. However, no theoretical study, up until now, has conclusively demonstrated that the voids and molecular hydrogen are built-in features of the microstructure. We generate several realistic models of hydrogenated amorphous silicon at different hydrogen concentrations by developing an information-based inverse method. The models not only satisfy structural and electronic properties but also provide correct NMR line spectra as compare to NMR experiments. The microstructure at high (>15%) hydrogen concentration shows the presence of voids and some hydrogen molecules within the voids. The voids with molecular hydrogen are built-in configurations of the microstructure because they evolve themselves while relaxing the models via the first-principles density functional method.

2:03PM B53.00015 Structural and microscopic relaxations in glycerol: an IXS study, ALESSANDRO CUNSOLO, Brookhaven National Laboratory — We present an Inelastic X Ray Scattering study of the THz dynamics of room temperature glycerol at pressures spanning the 0.66-3 Kbar range. We propose a comparison with ultrasound absorption results available in literature, which leads to infer the presence of two distinct relaxation phenomena, a slow and a fast one. Although the former relaxation has been thoroughly studied in glycerol by lower frequency spectroscopic techniques, no experimental evidences of the latter were so far reported in literature. A line-shape modeling based upon the memory function formalism allows us to observe that the characteristic timescale of the fast relaxation ranges in the sub-picosecond, tends to decrease with increasing the wave-vector and is rather insensitive to pressure changes. More in general, the observed phenomenology definitely reveals the microscopic, single particle, nature of this additional relaxation process.

Session B54 GSNP: Focus Session: Complex and co-evolving networks - Modeling Social and Biological Networks 152

11:15AM B54.00001 Human travel and time spent at destination: impact on the epidemic invasion dynamics, CHIARA POLETTI, MICHELE TIZZONI, ISI Foundation, Turin, Italy, VITTORIA COLIZZA, INSERM and Univ Pierre et Marie Curie, UMR-S 707, Paris, France — Human mobility has a strong impact on the spatial spread of infectious diseases. Analyses of metapopulation models, that consider the epidemic spreading on a network of populations, show that topological and traffic fluctuations favor the global epidemic invasion. These studies consider markovian mobility (i.e. the memory of the origin of traveling individuals is lost) or non-markovian mobility with homogeneous timescales (i.e. individuals travel to a destination and come back with a homogenous rate). However, the time spent at destination is found to exhibit wide fluctuations. Such varying length of stay crucially affects the mixing among individuals and hence the disease transmission dynamics. In order to explore this aspect, we present a modeling framework that, by using a time-scale separation technique, allows analyzing the behavior of spreading processes on a complex metapopulation network with non-markovian mobility characterized by heterogeneously distributed timescales. Analytical and numerical results show how the degree of heterogeneity of the length of stay is able, alone, to drive a phase transition between local outbreak and global invasion. This highlights the importance of the interplay between mobility and disease timescales in the propagation of an epidemic.

11:27AM B54.00002 Effect of Spatial-Dependent Utility on Social Group Domination, NATHANIEL RODRIGUEZ, ANDREW MEYERTHOLEN, University of Redlands — The mathematical modeling of social group competition has garnered much attention. We consider a model originated by Abrams and Strogatz [Nature 424, 900 (2003)] that predicts the extinction of one of two social groups. This model assigns a utility to each social group, which is constant over the entire society. We find by allowing this utility to vary over a society, through the introduction of a network or spatial dependence, this model may result in the coexistence of the two social groups.

11:39AM B54.00003 Evolution of opinions on social networks in the presence of competing committed groups, SAMEET SREENIVASAN, Dept. of Computer Science, Dept. of Physics, Rensselaer Polytechnic Institute, JIERUI XIE, BOLESŁAW SZYMANSKI, Dept. of Computer Science, Rensselaer Polytechnic Institute, JEFF EMENHEISER, MATT KIRBY, GYORGY KORNISS, Dept. of Physics, Rensselaer Polytechnic Institute — Using a model of pairwise social influence, the *binary agreement* model (Xie et. al, Phys. Rev. E 84, 011130 (2011)), we study how the presence of two groups of individuals committed to competing opinions, affect the steady-state opinion of influencable individuals on a social network. We assume that two groups committed to distinct opinions A and B , and constituting fractions p_A , p_B of the total population respectively, are present in the network. We show using mean-field theory that the phase diagram of this system in parameter space (p_A, p_B) consists of two regions, one where two stable steady-states coexist, and the remaining where only a single stable steady-state exists. For finite networks (complete graphs, Erdős-Rényi networks and Barabási-Albert networks), these two regions are separated by two first order transition lines which terminate and meet tangentially at $p_A = p_B \approx 0.1623$, which constitutes a second-order transition point. Finally, we quantify how the exponentially large switching times between steady states in the co-existence region depend on the distance from the second-order transition point for equal committed fractions.

11:51AM B54.00004 Strategy of Competition between Two Groups based on an Inflexible Contrarian Opinion Model, QIAN LI, Boston University, LIDIA BRAUNSTEIN, Universidat Nacional de Mar del Plate-CONICET, SHLOMO HAVLIN, Bar Ilan University, GENE STANLEY, Boston University — We introduce an inflexible contrarian opinion (ICO) model in which a fraction p of inflexible contrarians within a group holds a strong opinion opposite to the opinion held by the rest of the group. At the initial stage, stable clusters of two opinions, A and B exist. Then we introduce inflexible contrarians which hold a strong B opinion into the opinion A group. Through their interactions, the inflexible contrarians are able to decrease the size of the largest A opinion cluster, and even destroy it. We see this kind of method in operation, when companies send free new products to potential customers in order to convince them to adopt their product and influence others to buy it. We study the ICO model, using two different strategies, on both ER and SF networks. In strategy I, the inflexible contrarians are positioned at random. In strategy II, the inflexible contrarians are chosen to be the highest degrees nodes. We find that for both strategies the size of the largest A cluster decreases to zero as p increases as in a phase transition. At a critical threshold value p_c the system undergoes a second-order phase transition that belongs to the same universality class of mean field percolation. We find that even for an ER type model, strategy II is significantly more effective.

12:03PM B54.00005 Consensus in evolving networks of mobile agents, ANDREA BARONCHELLI, Universitat Politecnica de Catalunya, ALBERT DÍAZ-GUILERA, Universitat de Barcelona — Populations of mobile and communicating agents describe a vast array of technological and natural systems, ranging from sensor networks to animal groups. Here, we investigate how a group-level agreement may emerge in the continuously evolving networks defined by the local interactions of the moving individuals. We adopt a general scheme of motion in two dimensions and we let the individuals interact through the minimal naming game, a prototypical scheme to investigate social consensus. We distinguish different regimes of convergence determined by the emission range of the agents and by their mobility, and we identify the corresponding scaling behaviors of the consensus time. In the same way, we rationalize also the behavior of the maximum memory used during the convergence process, which determines the minimum cognitive/storage capacity needed by the individuals. Overall, we believe that the simple and general model presented in this talk can represent a helpful reference for a better understanding of the behavior of populations of mobile agents.

12:15PM B54.00006 Epidemic and information co-spreading in adaptive social networks, YUNHAN LONG, The College of William and Mary, THILO GROSS COLLABORATION, LEAH B. SHAW TEAM — We model simultaneous evolution of an epidemic and information about the epidemic on an adaptive social network. The classical Susceptible-Infectious-Susceptible (SIS) model is extended. Susceptible and infectious nodes are each divided into informed and uninformed types. Informed nodes affect the network structure by rewiring their network connections adaptively to avoid disease exposure. The impacts of mass media information and communication on the disease spreading and network structure are explored, and stochastic simulations are compared with a moment closure approximation. When the rewiring rate is high, the infection and information levels of the population show periodic oscillations for certain ranges of contact rate, and the moment closure approximation predicts similar dynamics. The epidemic threshold in the presence of rewiring and information is considered. Our results indicate that information can play a significant role in minimizing disease spread.

12:27PM B54.00007 Asymptotically inspired moment-closure approximation for adaptive networks, MAXIM SHKARAYEV, LEAH SHAW, College of William and Mary — Adaptive social networks, in which nodes and network structure co-evolve, are often described using a mean-field system of equations for the density of node and link types. These equations constitute an open system due to dependence on higher order topological structures. We propose a moment-closure approximation based on the analytical description of the system in an asymptotic regime. We apply the proposed approach to two examples of adaptive networks: recruitment to a cause model and epidemic spread model. We show a good agreement between the improved mean-field prediction and simulations of the full network system.

12:39PM B54.00008 Epidemics on Interacting Networks, MARK DICKISON, Boston University, SHLOMO HAVLIN, Bar-Ilan University, H.E. STANLEY, Boston University — Epidemic spreading is of great importance in public health, as well as in related fields such as infrastructure. While complex network models have been used with great success to analyze epidemic behavior on single networks, the reality is that our world is made up of a system of interacting networks that do not necessarily share common characteristics. I introduce a model for constructing interacting networks and show that the phase transition depends on the parameters κ_T , κ_A and κ_B , where $\kappa_T = \langle k^2 \rangle / \langle k \rangle$ over the nodes in both networks, including internetwork links, and κ_A and κ_B are over the networks considered individually, with no internetwork links. For strongly interacting networks ($\kappa_T > \kappa_A$ and κ_B), there exists only one phase transition, between a disease-free phase and an epidemic phase across both networks. For weakly interacting networks ($\kappa_T < \kappa_A$ or κ_B), a third, “mixed,” phase exists, where the disease enters an epidemic on one network alone. The analytic predictions are confirmed by Monte-Carlo simulations.

12:51PM B54.00009 Epidemic spreading on interacting networks with preferred degrees¹, SHIVAKUMAR JOLAD, R.K.P. ZIA, B. SCHMITTMANN, Virginia Tech — We discuss the SIS contact process on a network of two interacting communities, each with its own preferred degree of connections. Postulating various rules for an individuals to form intra-community and inter-community links, we find novel stationary (active) states, in addition to the expected absorbing states. The dynamics of infected individuals in the two communities can be quite different. Using Monte Carlo techniques, we explore the effects on both the network structure and the contact process due to different types of interactions between the communities. We will also present a mean field analysis of contact processes on a generic M interacting communities and compare these results with the simulation data.

1:03PM B54.00010 Scaling theory of human dynamics and network science, CHAOMING SONG, DASHUN WANG, ALBERT-LASZLO BARABASI, Center for Complex Network Research, Northeastern University — The increasing availability of large-scale real data has fueled simultaneous advances in network theory, aiming to characterize the scaling of complex networks, and human dynamics, capturing the temporal characteristics of human activity patterns. Yet, these two areas remain disjoint, with their separate scaling laws and modeling framework. Here we show that the exponents characterizing the degree and link weight distribution of the underlying social network can be expressed in terms of the dynamical exponents characterizing human activity patterns, establishing the first formal link between the two areas.

1:15PM B54.00011 Network model explains why cancer cells use inefficient pathway to produce energy, JOO SANG LEE, Department of Physics and Astronomy, Northwestern University, JOHN MARKO, Department of Molecular Biosciences, Northwestern University, ADILSON MOTTER, Department of Physics and Astronomy, Northwestern University — The Warburg effect—the use of the (energetically inefficient) fermentative pathway as opposed to (energetically efficient) respiration even in the presence of oxygen—is a common property of cancer metabolism. Here, we propose that the Warburg effect is in fact a consequence of a trade-off between the benefit of rapid growth and the cost for protein synthesis. Using genome-scale metabolic networks, we have modeled the cellular resources for protein synthesis as a growth defect that increases with enzyme concentration. Based on our model, we demonstrate that the cost of protein production during rapid growth drives the cell to rely on fermentation to produce ATP. We also identify an intimate link between extensive fermentation and rapid biosynthesis. Our findings emphasize the importance of protein synthesis as a limiting factor on cell proliferation and provide a novel mathematical framework to analyze cancer metabolism.

1:27PM B54.00012 Physiological Networks: towards systems physiology¹, RONNY P. BARTSCH, Harvard Medical School and Division of Sleep Medicine, Brigham and Womens Hospital, Boston, MA 02115, USA, AMIR BASHAN, Department of Physics, Bar-Ilan University, Ramat-Gan, Israel, JAN W. KANTELHARDT, Institute of Physics, Martin-Luther-Universitaet Halle-Wittenberg, Halle (Saale), Germany, SHLOMO HAVLIN, Department of Physics, Bar-Ilan University, Ramat-Gan, Israel, PLAMEN CH. IVANOV, Harvard Medical School and Division of Sleep Medicine, Brigham and Womens Hospital, Boston, MA 02115, USA — The human organism is an integrated network where complex physiologic systems, each with its own regulatory mechanisms, continuously interact, and where failure of one system can trigger a breakdown of the entire network. Identifying and quantifying dynamical networks of diverse systems with different types of interactions is a challenge. Here, we develop a framework to probe interactions among diverse systems, and we identify a physiologic network. We find that each physiologic state is characterized by a specific network structure, demonstrating a robust interplay between network topology and function. Across physiologic states the network undergoes topological transitions associated with fast reorganization of physiologic interactions on time scales of a few minutes, indicating high network flexibility in response to perturbations. The proposed system-wide integrative approach may facilitate new dimensions to the field of systems physiology.

1:39PM B54.00013 Detecting and evaluating communities in complex human and biological networks, GREG MORRISON, L. MAHADEVAN, Harvard University School of Engineering and Applied Sciences — We develop a simple method for detecting the community structure in a network can by utilizing a measure of closeness between nodes. This approach readily leads to a method of coarse graining the network, which allows the detection of the natural hierarchy (or hierarchies) of community structure without appealing to an unknown resolution parameter. The closeness measure can also be used to evaluate the robustness of an individual node's assignment to its community (rather than evaluating only the quality of the global structure). Each of these methods in community detection and evaluation are illustrated using a variety of real world networks of either biological or sociological importance and illustrate the power and flexibility of the approach.

1:51PM B54.00014 Small-world organization of self-similar modules in functional brain networks, MARIANO SIGMAN, Buenos Aires University, LAZAROS GALLOS, HERNAN MAKSE, City College of New York — The modular organization of the brain implies the parallel nature of brain computations. These modules have to remain functionally independent, but at the same time they need to be sufficiently connected to guarantee the unitary nature of brain perception. Small-world architectures have been suggested as probable structures explaining this behavior. However, there is intrinsic tension between shortcuts generating small-worlds and the persistence of modularity. In this talk, we study correlations between the activity in different brain areas. We suggest that the functional brain network formed by the percolation of strong links is highly modular. Contrary to the common view, modules are self-similar and therefore are very far from being small-world. Incorporating the weak ties to the network converts it into a small-world preserving an underlying backbone of well-defined modules. Weak ties are shown to follow a pattern that maximizes information transfer with minimal wiring costs. This architecture is reminiscent of the concept of weak-ties strength in social networks and provides a natural solution to the puzzle of efficient information flow in the highly modular structure of the brain.

2:03PM B54.00015 Unraveling the rules of evolution in the yeast protein-protein interaction network, YULIANG JIN, HERNAN MAKSE, Levich Institute and Physics Department, the City College of New York, THOMAS WEINMAIER, DMITRIJ TURAEV, THOMAS RATTEL, Department of Computational Systems Biology, University of Vienna — A question of fundamental importance is to understand the dynamical principles according to which biological networks have acquired their topological structures and functional modules. Here, we perform an empirical study of the yeast protein-protein interactions (PPI), combined with theoretical modeling of the genomic duplication-divergence processes. Our duplication-divergence model agrees with experimental data, and provides a novel approach to reconstruct ancestral PPI networks. Following the phylogenetic tree, our analysis unravels that the ancient networks evolve into the present day yeast network by a multiplicative growth. The rule of multiplicative growth demonstrates the relationship between the topological exponents and the evolution growth rates of interactions. An important consequence of this evolutionary principle is the emergence of self-similar modular structure, which is confirmed by the analysis of functional modules of proteins.

C1.00001 POLYMERS AND SOFT MATTER PHYSICS —

C1.00002 Partition function zeros and phase transitions of a square-well polymer¹, PYIE-PHYO AUNG, Hiram College, MARK TAYLOR, Department of Physics, Hiram College, OH, 44234 — The zeros of the canonical partition functions for flexible square-well polymer chains have been computed for chains up to length 256 for a range of square-well diameters. We have previously shown that such chain molecules can undergo a coil-globule and globule-crystal transition as well as a direct coil-crystal transition [1]. Here we show that each of these transitions has a well-defined signature in the complex-plane map of the partition function zeros. The freezing transitions are characterized by nearly circular rings of uniformly spaced roots, indicative of a discontinuous transition. The collapse transition is signaled by the coalescence of roots onto an elliptical horse-shoe segment pinching down towards the positive real axis. For sufficiently small square-well diameter the elliptical collapse ring merges with the circular freezing ring yielding the direct coil-crystal transition. The root density of all rings increases with increasing chain length and the leading roots move towards the positive real axis, implying a divergence of the specific heat in the thermodynamic limit (as originally proposed by Yang and Lee).

C1.00003 Modeling Amphiphilic Solutes in a Jagla Solvent, ZHIQIANG SU, Center for Polymer Studies and Dept of Physics, Boston University, SERGEY V. BULDYREV, Dept of Physics, Yeshiva University, PABLO G. DEBENEDETTI, Dept of Chemical and Biological Engineering, Princeton University, PETER J. ROSSKY, Dept of Chemistry and Biochemistry, College of Natural Science, The University of Texas at Austin, H.EUGENE STANLEY, Center for Polymer Studies and Dept of Physics, Boston University — Methanol is an amphiphilic solute whose aqueous solutions exhibit distinctive physical properties. The volume change upon mixing, for example, is negative across the entire composition range, indicating strong association. We explore the corresponding behavior of a Jagla solvent, which has been previously shown to exhibit many of the anomalous properties of water. We consider two models of an amphiphilic solute: (i) a “dimer” model, which consists of one hydrophobic hard sphere linked to a Jagla particle with a permanent bond, and (ii) a “monomer” model, which is a limiting case of the dimer, formed by concentrically overlapping a hard sphere and a Jagla particle. Using discrete molecular dynamics, we calculate the thermodynamic properties of the resulting solutions. We systematically vary the set of parameters of the dimer and monomer models and find that one can readily reproduce the experimental behavior of the excess volume of the methanol-water system as a function of methanol volume fraction. We compare the pressure and temperature dependence of the excess volume and the excess enthalpy of both models with experimental data on methanol-water solutions and find qualitative agreement in most cases. We also investigate the solute effect on the temperature of maximum density and find that the effect of concentration is orders of magnitude stronger than measured experimentally.

C1.00004 Localized entrapment of green fluorescent protein within nanostructured polymer films¹, JOHN ANKNER, Oak Ridge National Laboratory, VERONIKA KOZLOVSKAYA, University of Alabama at Birmingham, HUGH O'NEILL, QIU ZHANG, Oak Ridge National Laboratory, EUGENIA KHARLAMPIEVA, University of Alabama at Birmingham — Protein entrapment within ultrathin polymer films is of interest for applications in biosensing, drug delivery, and bioconversion, but controlling protein distribution within the films is difficult. We report on nanostructured protein/polyelectrolyte (PE) materials obtained through incorporation of green fluorescent protein (GFP) within poly(styrene sulfonate)/poly(allylamine hydrochloride) multilayer films assembled via the spin-assisted layer-by-layer method. By using deuterated GFP as a marker for neutron scattering contrast we have inferred the architecture of the films in both normal and lateral directions. We find that films assembled with a single GFP layer exhibit a strong localization of the GFP without intermixing into the PE matrix. The GFP volume fraction approaches the monolayer density of close-packed randomly oriented GFP molecules. However, intermixing of the GFP with the PE matrix occurs in multiple-GFP layer films. Our results yield new insight into the organization of immobilized proteins within polyelectrolyte matrices and open opportunities for fabrication of protein-containing films with well-organized structure and controllable function, a crucial requirement for advanced sensing applications.

C1.00005 Time-resolved WAXD/SAXS Characterization on the Crystallization of Silica Filled HDPE Nanocomposite¹, XIAOWEI LI, CHRISTIAN BURGER, YIMIN MAO, BENJAMIN HSIAO, Stony Brook University — The isothermal crystallization behavior of high density polyethylene/silica (HDPE-SiO₂) with different SiO₂ loading of 2% and 5%, along with the pure HDPE sample was studied by using the time-resolved wide angle X-ray diffraction (WAXD) and small angle X-ray scattering (SAXS) techniques. For isothermal crystallization at 120 °C, WAXD profiles show HDPE-Si₂% has the highest ending crystallinity index, while HDPE-Si₅% has the lowest value. Avrami exponent of pure HDPE is about 3.9, while HDPE-Si₂% has a value of 3.2 which is typically heterogeneous nucleation behavior due to the addition of silica in HDPE. SAXS patterns show that the silica inside HDPE has mass fractal structure. The mass fractal dimension is determined by using the fitting method and the value is less than 3 for all HDPE-SiO₂ samples. The structure of HDPE-SiO₂ is sketched based on the obtained results.

C1.00007 Ionic conductivity of imidazole-functionalized liquid crystal mesogens, SUPACHAREE ROD-DECHA, MITCHELL ANTHAMATTEN, University of Rochester — Imidazole has been investigated as a novel anhydrous proton conducting functional group that could enable higher temperature operation ($> 120\text{ }^{\circ}\text{C}$) of polymer electrolyte fuel cells. Its amphoteric behavior can support Grotthuss-like proton transport; however molecular mobility and a high concentration of imidazole groups are needed to achieve high ionic conductivity. Our hypothesis is that liquid crystal ordering, particularly in layered smectic phase, can facilitate formation of 2D proton transport and promote proton conductivity. We have designed and synthesized two imidazole-terminated liquid crystal mesogens, and the ionic conductivities in the liquid crystalline and isotropic states have been measured. Here we report on synthesis and characterization of diacylhydrazine liquid crystals bearing imidazole terminal groups. The proton conductivity of products is compared to pure liquid imidazole and to liquid crystal mesogens without imidazole groups.

C1.00008 New Soft Matter Soft X-ray Scattering Facility and the Advanced Light Source with Real Time Analysis, ELIOT GANN, North Carolina State University, ANTHONY YOUNG, Lawrence Berkeley National Laboratory, BRIAN COLLINS, HONGPING YAN, North Carolina State University, HOWARD PADMORE, Lawrence Berkeley National Laboratory, HARALD ADE, North Carolina State University, ALEX HEXEMER, CHENG WANG, Lawrence Berkeley National Laboratory — We present the development and first experiments at a new user scattering facility at the Advanced Light Source at Lawrence Berkeley National Laboratory designed to elucidate the structure of polymer thin films, including a number of systems important for understanding organic devices. These experiments utilize enhanced contrast mechanisms available due to resonance effects to gain sensitivity to morphology which other probes and harder X-ray beams cannot probe. We present the development of new characterization and calibration techniques as well as procedures to mitigate the unique problems that come with scattering in this energy range. These allow us to obtain quantitative scattering profiles and thus ensemble morphological information of these devices. In addition, we present a live analysis package which does initial data reduction in real time while scattering data is being collected.

C1.00009 Phase behavior of silica-polypeptide colloidal particles immersed in liquid crystal forming mesogens, MELISSA COLLINS, ERICK SOTO-CANTU, PAUL RUSSO, Louisiana State University — Silica-polypeptide composite particles (Silica-PCPs) are core-shell colloids. The size and function of the silica core are easily controlled. Established synthesis methods ensure uniformly sized cores and provide the ability to have magnetic or fluorescent inclusions within them. The interactions of the polypeptides in the shell with those unbound in solution can be explored by small/wide angle x-ray scattering (SAXS/WAXS) and polarized optical microscopy (POM) to identify the concentration at which the solution changes from isotropic to ordered. Silica-PCPs/untethered polymer/solvent systems are studied to determine the phase behavior in a non-aqueous environment, free from complications arising from electrostatic effects. The tendency of poly(γ -benzyl-L-glutamate) to form liquid crystalline phases on its own is affected by the presence of Silica-PCPs.

C1.00010 ABSTRACT WITHDRAWN —

C1.00011 A Novel 3D-Lattice Model of Fibrillar Polymeric Material, C. BRAD BENNETT, JAMES KRUCZEK, D.A. RABSON, W. GARRETT MATTHEWS, SAGAR A. PANDIT, University of South Florida — To elucidate a possible mechanism for simple material properties of fibrillar polymeric bulk material containing cross-links between constituent components, we introduce a 3D-lattice model that depends on cross-link number density (ρ) and the ratio (χ) of cross-link bond strength to thermal energy. The model predicts a phase transition in specific heat capacity occurring for χ between approximately 0.5 and 1.5, dependent on ρ . We present evidence that the properties of the represented phases are consistent with those of a solid phase and a liquid phase. These results indicate that variations in ρ or χ alone may provide a convenient basis for Nature to provide a range of material properties with limited resources.

C1.00012 PolyGraph: a Polymer Visualization system¹, ASHOK CUTKOSKY*, NAJEEB TARAZI*, EREZ LIEBERMAN AIDEN, Harvard University — Rapid advances in computational hardware and parallelization have made complex simulations of large polymers increasingly ubiquitous. However, visualizing such simulations remains a challenge. Here we present PolyGraph, a Blender-powered visualization system for complex polymer simulations. As a specific example, we study molecular dynamics simulations of condensing polymers. We illustrate our initial simulation results, suggesting that formation of local beads is an initial step in the condensation process. (This finding is consistent with earlier conjectures about polymer condensation.) PolyGraph makes it possible to create precise and visually appealing clips of polymer simulations. *contributed equally

C1.00013 Confinement of Block Copolymer Nanocomposites within Nanoporous Templates, SEYEDALI MONEMIAN, LASHANDA KORLEY, Department of Macromolecular Science and Engineering, Case Western Reserve University — This research investigates the impact of surface-functionalized nanoparticles (NPs) on self-assembly of confined block copolymer (BCP) systems. Lamellar and cylindrical BCP morphologies were explored with variations in NP diameters and functional groups. The bulk and templated microphase-separated structures were characterized. The addition of addition of NPs resulted in a variety of morphological transitions due to a combination of selective localization of NPs and confinement.

C1.00014 Surface Modification for Controlling the Orientation of Block Copolymers in thin film and in Cylindrical Nanopores¹, XIN-GUAN LIN, FENG-CHENG LIN, SHIH-HUANG TUNG, Institute of Polymer Science and Engineering National Taiwan University, SOFT NANOMATERIALS GROUP TEAM — A series of benzocyclobutene-functionalized random copolymers of styrene and 4-vinylpyridine were synthesized by nitroxide-mediated controlled radical polymerization with BPO and TEMPO. Our research was to use these random copolymers of P(S-r-BCB-r-4VP) to control the orientation of microdomains in block copolymers (BCPs) of poly(styrene-*b*-4-vinylpyridine) (PS-*b*-P4VP) thin films and in cylindrical nanopores of anodized aluminum oxide (AAO) membranes. On P(S-r-BCB-r-4VP)-modified substrate, we found that in some particular compositions of random copolymer, the parallel orientation of the microdomains is switched to be perpendicular in PS-*b*-P4VP thin film. We also introduced P(S-r-BCB-r-4VP) solution into the nanopores of the AAO and nanotubes formed after solvent evaporation and pyrolysis. And then BCPs of PS-*b*-P4VP were drawn into the P(S-r-BCB-r-4VP)-modified nanopores in the melt via capillary action to form P(S-r-BCB-r-4VP) coated nanorods of PS-*b*-P4VP. Similarly, in some particular compositions of random copolymer, we observed that the interactions of the blocks with the walls are not strong or if the interactions are balanced, then the orientation of the microdomains will change from being parallel to being perpendicular to the confining walls.

C1.00015 Fast Fabrication of Hierarchically-Structured Nanocomposites in Thin Films, JOSEPH KAO, PETER BAI, SEONG-JUN JEONG, VIVIAN PENG-WEI CHUANG, TING XU, UC Berkeley — Significant attention has been given to developing bottom-up routes to direct hierarchical assemblies of nanoparticles in thin films for applications such as novel electronics, energy harvesting modules, and photonic materials. It remains challenging to control the self-assembly of the nanocomposites in a short period of time using methods compatible with scalable manufacturing. Here, we report a facile method utilizing solvent vapor annealing to precisely control the morphologies of nanocomposite thin films (PS-*b*-P4VP(PDP)_x with nanoparticles) in the time scale of minutes. By controlling the solvent vapor pressure during the annealing process, the orientations of the microdomains and the nanoparticles can be tailored. Long range-ordered lateral morphologies of the nanocomposites can be obtained. In-situ GISAXS experiments show that the fast assembly process may be attributed to the nature of the supramolecules. The rate of solvent evaporation has been identified as a critical factor in controlling the final morphologies of the nanocomposites.

C1.00016 Fabrication of Three-Dimensional Bilayered Nanostructures via Block Copolymers¹, SANGHOON WOO, Korea University, SUMI LEE, EUN AE KWAK, Samsung Electronics, HYUNJUNG JUNG, Korea University, FRANK LEIBFARTH, CRAIG HAWKER, University of California, Santa Barbara, JUNE HU, DU YEOL RYU, Yonsei University, JOONA BANG, Korea University — The self-assembly of block copolymers (BCPs) has been received wide attention because of their great potentials in various advanced lithographic applications. For specific applications, one of the most significant is controlling the orientation of the microdomains. In this study, we synthesized ketene-based cross-linkable cylinder forming BCPs, PMMA-*b*-P(S-r-ketene), in which 3.0 mol

¹Samsung Electronics

C1.00017 Fabrication of square arrays of inverted pyramids using ABC triblock terpolymer, HONG KYOON CHOI, CAROLINE ROSS, HANG YU, CARL THOMPSON, Department of Materials Science and Engineering, MIT — Nanolithography using Self-assembly of block copolymer thin film is promising technique to fabricate a wide range of useful devices. Previously, we have reported that we could achieve square array which is one of most important device geometry by using Polyisoprene-*b*-polystyrene-*b*-polyferrocenylsilane triblock terpolymer. In this presentation, self-assembled PI-*b*-PS-*b*-PFS triblock terpolymer thin film was used as an etching mask to fabricate array of silicon inverted pyramids. Solvent annealed thin film PI-*b*-PS-*b*-PFS triblock terpolymer forms a square array of PFS and PI alternation cylinders in a PS matrix with a period of 44 nm. When this square arrayed polymer film immersed into hexane, a good solvent for PI and poor solvent for PS and PFS, an ordered square array of holes was produced by PI phase coming out from its cylindrical post and covering the surface. By using this hole patterned polymer film as an etching mask, KOH anisotropic silicon etching produce square array of inverted pyramids of period 44nm etched into silicon substrate. These square arrays of inverted pyramids are used to template the dewetting of metal film to form metal nanoparticle arrays. Produced ordered metal nanoparticles can be used as magnetic memory arrays and also useful as catalysts for nanowires/nanotube growth.

C1.00018 Hierarchical buckling of block copolymer thin films on PDMS substrates, DOKYEONG KWON, HYO SEON SUH, KOOKHEON CHAR, Seoul National University, THE NATIONAL CREATIVE RESEARCH INITIATIVE CENTER FOR INTELLIGENT HYBRIDS TEAM — Buckling of thin films on low modulus substrates such as polydimethylsiloxane (PDMS) is the well-known phenomenon in buckling instability originating from moduli mismatch between the substrate and a top film. Recently, many studies on the microstructure created by the buckling have been reported but most of the work has typically employed either metal or semiconductor thin films and few utilized the block copolymers (BCP) as the covering films. Here, we present the buckling of oriented BCP thin films, placed by a novel off-set printing, on PDMS substrates. Buckling instability was induced by either swelling of the PDMS substrate with chemical vapor or the mechanical strain, resulting in the hierarchical structure of BCP microdomains. Due to the buckling of the BCP thin films, we observed the structural change or transitions of the films depending on the alignment of BCP domains with respect to the buckled direction of the substrates.

C1.00019 Surface Properties of Bottlebrush Copolymer Thin Films¹, XIANYU LI, STACY PRUKOP, RAFAEL VERDUZCO, Rice University — Bottlebrush polymers are novel macromolecules with polymeric side-chains. Due to their large size and densely crowded side-chains, bottlebrush polymers are candidates for a number of potential applications, including rheological modifiers, drug-delivery vehicles, and polymeric photonics. However, the structural details of bottlebrush polymers in solution and in the bulk are poorly understood. For example, while the overall size of bottlebrush polymers has been measured, the polymer stiffness and side-chain conformation have not been quantified. Here, we present a study of the surface properties of well-defined bottlebrush polymer and copolymer thin films. Surface property measurements provide a method to investigate polymeric side-chain conformation and flexibility. Bottlebrush polymers with mixed and copolymer side-chains are prepared via living ring-opening metathesis polymerization of norbornene-functionalized macromonomers. Contact angle measurements, x-ray photoelectron spectroscopy, and atomic force microscopy measurements on bottlebrush polymer thin films show that polymeric side-chains have significant conformational flexibility and that bottlebrush polymers with mixed and copolymer side-chains can be used to prepare stimuli-responsive surfaces.

C1.00020 Self-assembled nanostructures in a cross-linkable block copolymer, CHUNLIN HE, Department of Chemical & Biochemical Engineering, University of Colorado at Boulder, IAN CAMPBELL, University of Colorado at Boulder, MARK STOYKOVICH, Department of Chemical & Biochemical Engineering, University of Colorado at Boulder — The self-assembly of block copolymers in films 50~100 nm thick provides an attractive approach to patterning nanoscale features. Chemical and thermal stability of the morphology in thin films is critical for the generation of robust templates for subsequent fabrication processes, and can be improved by cross-linking the copolymer domains. Atom transfer radical polymerization was used to synthesize PS/PMMA block copolymers with cross-linkable units capable of reacting through an acid-catalyzed mechanism or by photoinitiation with UV exposure. The self-assembly behavior of lamellar-forming block copolymers with or without cross-linkable units were compared in thin films through top-down characterization. We have developed approaches to decouple the self-assembly process from the cross-linking process, and characterized the cross-linking density and reaction rates within the nanostructured domains. The cross-linked nanostructures exhibit enhanced solvent and thermal stability, and have been demonstrated for the fabrication of three-dimensional block copolymer nanostructures in thick films using a layer-by-layer approach.

C1.00021 Tuning the Morphology of Solvent Annealed Thin Films of Polystyrene-b-Polyethylene Oxide with Controlled Saturations of Water and Toluene Vapors, BRIAN C. STAHL, EDWARD J. KRAMER, CRAIG J. HAWKER, University of California, Santa Barbara — Solvent annealing can be used to facilitate the self-assembly of block copolymer thin films and has several advantages over thermal annealing including room-temperature processing, domain orientation control and the ability to anneal polymers not amenable to thermal processing. We have developed a controlled process design for performing solvent annealing that incorporates continuous flows of solvent-saturated carrier gas, multiple simultaneous co-solvents and in-situ metrology. This new method is modular and applicable to a wide range of block copolymer and solvent systems. The control over annealing and quenching conditions afforded by this new technique allows us to reproducibly control the domain orientation and periodicity in thin films of cylinder-forming polystyrene-b-polyethylene oxide (PS-b-PEO) annealed in environments with high saturations of water and toluene vapors without modifying the block copolymer or substrate. By adjusting the humidity of the quenching gas flow we are able to control the orientation of the PEO cylinders, and by adjusting the humidity during annealing we are able to tune the domain spacing of PEO cylinders oriented perpendicular to the substrate.

C1.00022 Laterally confined diblock copolymers, ROBERTA DESSI, MARCO PINNA, ANDREI ZVELINDOVSKY, University of Central Lancashire — With the help of cell dynamics simulation we investigate the self-assembly of cylinder-forming diblock copolymer thin films laterally confined within square and non-square geometries. The size of the confinement affects the ordering of the block copolymer domains and their symmetry. We found hexagonally packed cylinders and square packed cylinders by changing the box size of the system. In particular we performed several simulations to find that if the size of the pattern is comparable with the natural bulk period of the copolymer the packing symmetry changes from hexagonal to square. In this case the ordering induced by the pattern edges becomes dominant allowing the square lattice to be more stable than the hexagonal one.

C1.00023 Self-Assemble Behavior of Polystyrene-tethered Hydrophilic POSS Nanoparticle in Thin Film, I-FAN HSIEH, XINFEI YU, KAN YUE, STEPHEN CHENG, The University of Akron, DEPARTMENT OF POLYMER SCIENCE, THE UNIVERSITY OF AKRON TEAM — Recently, block copolymer thin films are of great interest in their applications of surface patterning. However, due to the restriction of the polymer material properties, the etch contrast between two phases is usually low and the smallest pattern block copolymer can create is around 10 nm. By taking the advantage of the hybrid property of POSS nanoparticle, we can produce the thin film pattern with great etch contrast with only a few nanometers in size. PS-tethered hydrophilic POSS can self assemble to form nano-pattern in both bulk and thin film state. As the PS molecular weight increases, the thin film morphology can transfer from lamella to cylinder then to sphere as block copolymer does. But because of the nature of the POSS particle, we discover a new packing symmetry in the cylinder phase that has not been discovered in block copolymer thin film system. Unlike block copolymer which has higher order-disorder transition temperature in thin film, PS-POSS thin film also shows some unique phase transition behavior during heating, and this transition behavior also affected by the different functional group attached on POSS particles.

C1.00024 Morphology of ABC linear triblock polymer melts: self-consistent-field theoretic simulation approach¹, MOUGE MOHAGHEGHI, BAMIN KHOMAMI, Dept. of Chemical and Biomolecular Eng., University of Tennessee, Knoxville, TN — It is well known that block copolymer morphologies resulting from microphase separation finds wide spread use in many applications, including nanolithographic templates, membranes, and electronic arrays. In this study, we have performed self-consistent field theoretic based simulations to examine the plethora of self-assembled morphologies obtained in symmetric linear ABC Tri-block polymer melts in bulk and confined films. Specifically in bulk systems, the conditions leading to lamellae, tetragonal cylinders, sphere, perforated lamellae, and network morphologies have been elucidated at various volume fractions of middle (B) block. In general, the predicted morphologies are in good agreement with the limited number of published experimental studies. The effect of confinement on the microphase separation is also studied by performing simulations of two neutral parallel walls. Overall, we observe lamellar and cylindrical domains that are oriented parallel to the walls; however, lamellar domains could become perpendicular to the neutral walls when the natural period of lamellae is incommensurate with the film thickness. Our calculations form the basis for understanding the stability of parallel and perpendicular orientations in thin films of ABC tri-block polymeric systems.

¹This work is supported by NSF through funding grant EPS-1004083.

C1.00025 Hierarchical silver concentric ring patterns of block copolymer microdomains for high efficient SERS, DUSIK BAE, JIN KON KIM, Pohang University of Science and Technology — We fabricated the half-onion like microdomains of polystyrene-block-poly(methyl methacrylate) copolymer (PS-b-PMMA) when it was confined within hemi-spherical anodic aluminum oxide (AAO) template. The ring number of the concentric ring patterns was easily controlled by changing the molecular weights of the block copolymers, which was verified by scanning and transmission electron microscopes and atomic force microscope. We also deposited silver with 6nm height selectively on the PS microdomains. A number of silver ring patterns were varied from 5 to 8 depending on the molecule weights of the block copolymer. This silver ring structures showed high surface enhanced Raman scattering (SERS) with a maximum enhancement factor of 10^7 .

C1.00026 Effect of tacticity on the interfacial structural properties of adsorbed polystyrene thin films, YERGOU TATEK, Addis Ababa University, MESFIN TSIGE, The University of Akron — We have carried out atomistic Molecular Dynamics simulations to investigate interfacial structural properties of thin films of polystyrene (PS) adsorbed onto solid substrates. The films are made of PS stereoregular chains, that are, isotactic PS or syndiotactic PS. Three types of surfaces of different phobicity and roughness were considered in the present work: hydroxylated silica, graphite and amorphous silica. The structural properties were studied in terms of side chains, end groups and backbone concentration and orientation in the interfacial regions (substrate/film and film/vacuum). Moreover the effect of temperature was investigated by adsorbing the films at different temperatures, below and above the glass transition temperature. Our results were compared to results obtained previously by our group on the adsorption of films made of atactic polystyrene.

C1.00027 Memory Effects of Multistage Crosslinking and Scission on Stress in Polymer Networks, JOANNE BUDZIEN, Physics and Engineering Department, Frostburg State University — While the independent network model (INM) typically used for polymers is excellent for networks that truly are independent, the model has to be modified for networks that are not independent. Such dependent networks can be the result of scission occurring in strain states where crosslinking also occurs. The overall material retains a memory of the strain/crosslinking/scission history because of the bias in how the crosslinks are introduced. These memory effects mean that the resulting zero-stress state (the shape to which the sample will return at equilibrium) varies depending on the sample preparation history, in contrast to the INM where only the number of crosslinks in each network should matter. In this talk, I will present recent results of molecular dynamics simulations where coarse-grained polymer models undergo sequential crosslinking and scission in multiple strain states. The effects of entanglements will also be considered.

C1.00028 Reduction of Dielectric Hysteresis in Multilayered Film via Nanoconfinement¹, LEI ZHU, MATHEW MACKEY, DONALD SCHUELE, Department of Macromolecular Science and Engineering, Case Western Reserve University, Cleveland, Ohio 44106-7202, LIONEL FLANDIN, LEPMI, UMR 5279, CNRS, Université de Savoie, F-73376 Le Bourget Du Lac Cedex, France, MASON WOLAK, JAMES SHIRK, US Naval Research Laboratory, Washington, DC 20375, USA, ANNE HILTNER, ERIC BAER, Department of Macromolecular Science and Engineering, Case Western Reserve University, Cleveland, Ohio 44106-7202 — Micro-/nano-layer coextrusion was used to fabricate polycarbonate (PC)/poly(vinylidene fluoride) (PVDF) layered films with significantly reduced dielectric losses while maintaining high energy density. The high-field polarization hysteresis was characterized for layered films as a function of PVDF layer thickness (6000 to 10 nm) and composition (10 to 70 vol.% PVDF), and was found to decrease with decreasing layer thickness and PVDF content. To gain a mechanistic understanding of the layer thickness (or nanoconfinement) effect, wide angle X-ray diffraction, polarized Fourier transform infrared spectroscopy, and broadband dielectric spectroscopy were employed. The results revealed that charge migration, instead of dipole flipping, was responsible for the hysteresis in multilayered films.

C1.00029 Fullerene-based shape amphiphiles towards hierarchical supramolecular assemblies, CHIH-HAO HSU, The University of Akron, CHIEN-LUNG WANG, National Chiao Tung University, HAO-JAN SUN, The University of Akron, YINGFENG TU, Soochow University, STEPHEN CHENG, The University of Akron — Self-assembly is an elegant strategy which is used to create assemblies with tunable properties in nature as well as the artificial supramolecular systems. The self-assembly of [60]fullerene (C60) has drawn an tremendous amount of interest due to the exceptional optical and optoelectronic properties of C60. By constructing hierarchical supramolecular structures of C60 derivatives, the molecular functionality of C60 can be accumulated, amplified, and then transferred to bulk material properties. This research focuses on manipulating the balance of non-covalent interactions among C60 derivatives into molecular alignments in the supramolecular structure. The aliphatic tails and spacers in the C60 derivatives will improve the solubility and provide sufficient mobility for the effective packing of C60s. The differences in shape and intermolecular interaction between C60s and alkyl chains allow these molecules to arrange themselves in microphase-separated mesostructures. The hierarchical structure built up by C60 derivatives can be obtained via the highly-ordered packing of C60 in mesostructures. By adding an additional bisamide group to the molecular structure, the balance of the intermolecular interactions and the spatial packing can be tuned to exhibit supramolecular polymorphism.

C1.00030 Chain Packing and Trajectory of Isotactic Polypropylene α Crystals studied by Solid-State NMR¹, ZHEN LI, YAN CAO, TOSHIKAZU MIYOSHI, STEPHEN CHENG, The University of Akron — Isotactic polypropylene (ipp) is one of the simplest polyolefins and the crystalline structures, have been extensively studied. Ipp crystallizes as α form via isothermal crystallization from the melt state. Packing structures of α form has been used as structural markers of crystallization process. With the development of high resolution solid-state NMR (SS-NMR) technique, it becomes a powerful tool to investigate order-disorder of chain packing in the crystalline regions. We performed a series of experiments on different samples crystallized at different temperatures and studied the formation of α crystals influenced by different parameters, such as molecular weight, catalyst type and stereo, region regularity. Using selectively ¹³C enriched ipp samples we detect inter-nuclear correlations between the neighboring stems. This information provides chain reentry information. We figure out relationship between the chain reentry and chain packing of ipp α crystals. The recent discovery of the ipp α_2 single crystal offers a great opportunity to understand this topic also.

C1.00031 Tube Visualization and Properties from Isoconfigurational Averaging, JIAN QIN, WINDSOR BISBEE, SCOTT MILNER, Dept. of Ch. E. at Penn. State Univ. — We introduce a simulation method to visualize the confining tube in polymer melts and measure its properties. We studied bead-spring ring polymers, which conveniently suppresses constraint release and contour length fluctuations. We allow molecules to cross and reach topologically equilibrated states by invoking various molecular rebridging moves in Monte Carlo simulations. To reveal the confining tube, we start with a well equilibrated configuration, turn off rebridging moves, and run molecular dynamics simulation multiple times, each with different initial velocities. The resulting set of “movies” of molecular trajectories defines an isoconfigurational ensemble, with the bead positions at different times and in different “movies” giving rise to a cloud. The cloud shows the shape, range and strength of the tube confinement, which enables us to study the statistical properties of tube. Using this approach, we studied the effects of free surface, and found that the tube diameter near the surface is greater than the bulk value by about 25%.

C1.00032 Unfolding of Collapsed Polymers in Shear Flow Enhanced by Colloidal Suspensions: Effect of Colloid Banding Structures in Confining Channels, HSIEH CHEN, ALFREDO ALEXANDER-KATZ, MIT — Very recently, using hydrodynamic simulations we have demonstrated that colloidal suspensions can greatly enhance the unfolding of collapsed single polymers in shear flow. Furthermore, we have shown that the enhancement may be suppressed if the colloid size is commensurate with the confining channel height, where the colloids form well-defined banding structures. In this study, we analyze the colloid banding structures in details and their relations to the polymer unfolding. We find that, for the colloid volume fractions up to 30%, the colloids form simple cubic (sc), hexagonal (hex), or the mixture of sc + hex structures depending on the commensurability of the colloid size and the channel height. By directly changing the height of the confining channels, we show that the collapsed polymers have the highest unfolding when the channel height is non-commensurate with either sc or hex structures.

C1.00033 Slippage of polymers: Influence of the chemical structure, MISCHA KLOS, Experimental Physics, Saarland University, OLIVER BÄUMCHEN, Dept. of Physics & Astronomy, McMaster University, MATTHIAS LESSEL, KARIN JACOBS, Experimental Physics, Saarland University — The continuing miniaturization of microfluidic devices causes a growing importance of the solid/liquid interface for the flow dynamics. Our experiments probe slippage using the dewetting process of thin polymer films on hydrophobic substrates. As hydrophobic coatings we use amorphous polymers (AF1600, AF2400) and different types of highly ordered self-assembled silane monolayers on top of ultraflat silicon substrates. Polystyrene (PS) of low molecular weight shows slip lengths between several hundreds of nanometers and even micrometers on silane surfaces [1], whereas on AF1600 nearly no slip is observable. However, slip can be induced by increasing the molecular weight of the PS [2]. Recent studies using scattering techniques showed an ordering effect of PS at the solid/liquid interface depending on the structure of the substrate [3]. Will the situation change if, instead of PS, polymethyl methacrylate (PMMA) is used? To probe the influence of the polymers composition on slippage, we show very first results of the dewetting dynamics of PMMA on AF2400.

C1.00034 Glass transition in ultra thin polymeric films measured by differential AC-Chip calorimetry, CHRISTOPH SCHICK, HEIKO HUTH, University of Rostock, DONGSHAN ZHOU, Nanjing University, MATHIAS AHRENBERG, University of Rostock — The film thickness dependency of glass transition in polymer films is still controversially discussed. For different experimental probes different dependencies are observed and a generally accepted link to molecular mobility is not yet established. Calorimetry has proven to provide useful information about glass transition, because it establishes a direct link to energetic characterization [1]. In several cases a direct comparison with results from other dynamic methods like dielectric spectroscopy is possible giving further insights. For thin films in the $\mu\text{m} \dots \text{nm}$ range standard calorimetric methods are mostly not applicable. We set up a differential AC-chip calorimeter capable to measure the glass transition in nanometer thin films with pJ/K sensitivity in a relative broad frequency range [2]. Changes in heat capacity can be measured for sample masses below one nanogram as needed for the study of the glass transition in nanometer thin polymeric films. The glass transition in thin films was determined at well defined experimental time scales. No thickness dependency of the glass transition temperature was observed within the error limits - neither at constant frequency nor for the traces in the activation diagrams. [1] C. Schick, Glass transition under confinement-what can be learned from calorimetry, *Eur. Phys. J. Special Topics* **189** (2010) 3-36. [2] H. Huth, A.A. Minakov, and C. Schick, Differential AC-Chip Calorimeter for Glass Transition Measurements in Ultrathin Films, *J. Polym. Sci. B Polym. Phys.* **44** (2006) 2996-3005.

C1.00035 Viscoelastic behavior of polymer in confined system, GUIDUK YU, BONG SEOCK KIM, JUNGWOOK KIM, KYUSOON SHIN, Department of Chemical and Biological Engineering, Seoul National University — Materials under nanoconfinement have been studied to exhibit interesting static and dynamic behaviors deviated from those in bulk state. In this study, we analyzed viscoelastic behavior of polymer confined to mesoscopic space. Polystyrene was adopted as the material to be probed, and anodized alumina was used as the substrates providing mesoscopic confinement. Controlling the confining conditions, the viscoelastic behavior of polystyrene was examined. Analyzing the surface tensions of the materials, we also considered the effect of interfacial tension on the thermodynamic stability of polymer in the confined geometry. In this presentation, we qualitatively explain the effects of confinement dimension and interface in comparison with that not in confined system.

C1.00036 Confinement effects on thermal frontal polymerization, PREETA DATTA, KIRILL EFIMENKO, JAN GENZER, NCSU — Frontal polymerization systems belong to the broader class of reaction-diffusion systems. In thermal frontal polymerization, the interplay of heat diffusion and Arrhenius reaction kinetics gives rise to a moving reactive front; propagation occurs through a positive feedback mechanism. We seek to understand how spatial confinement can change the system dynamics and cause to deviate the system from bulk behavior. In highly confined systems, the front propagates slower and the front profile is flatter than in bulk. The polymerization product shows a decrease in polydispersity index (<1.5) for high confinement. The molecular weights of the samples do not exhibit simple unimodal distributions, unlike bulk. In specimens at the highest degree of confinement the molecular weight of the resultant polymer decreases with increasing distance from the external heating source. In highly confined systems a smaller number of radicals are generated, resulting in a slower propagation step and polymer chains of more uniform length; front propagation is slow as it is reaction-limited. In contrast, for bulk or unconfined systems, higher heat generation rates, leading to faster polymerization with higher polydispersity in molecular weight; front propagation is fast as it is diffusion-limited.

C1.00037 Temperature Dependence of Polymer Diffusion in MWCNT/PS Nanocomposites¹, WEI-SHAO TUNG, University of Pennsylvania, NIGEL CLARKE, University of Sheffield, RUSSELL J. COMPOSTO, KAREN I. WINEY, University of Pennsylvania — Temperature dependence of homopolymer diffusion can be explained by the WLF equation. Here, we explore whether the WLF equation applies to polymer diffusion in nanocomposites. Previously, we found the diffusion coefficient shows a minimum with increasing MWCNT concentration. By studying the temperature dependence of polymer diffusion in this system, we will investigate the relative importance of entropic barriers or enthalpy interactions between polymer chain and fillers. Our composites contain MWCNT and polystyrene and are fabricated by a coagulation method. Using forward recoil elastic scattering (FRES), we probe the depth profile of tracer polymer (dPS) and obtain the diffusion coefficients by fitting the profile with Fick's second law.

C1.00038 Effect of confinement on reaction rates within polymer nanotemplates, CECILE MALARDIER-JUGROOT, XIA LI, Royal Military College of Canada — The most efficient catalysts have been developed and optimized by living systems. Indeed, in vivo enzyme-catalyzed reactions are several orders of magnitude more efficient than platinum based catalyzed reactions. However, the rate of reaction and equilibrium interactions are considerably reduced when the biological systems are studied in vitro. This phenomenon is largely attributed to the effect of confinement or macromolecular crowding present in the cell. Confinement can also be observed in an aqueous solution containing surfactants (amphiphilic copolymers). For example, copolymers can self-assemble into well defined ordered structures such as micelles, nanotubes, vesicles; and the geometries and shapes of a given copolymer can be controlled by their solvent affinity. The hollow nanoarchitectures obtained by self-assembly can be used as a model template to study confinement within a soft shell system to mimic biosystems. These systems provide a very controlled environment for the study of confinement. In this paper we will present the effect of confinement on polymerisation reactions combining both simulation and experimental characterisation for a comprehensive study of the effect of confinement on the interactions among confined molecules.

C1.00039 Influence of Thermal History in Crystallization of Physically Confined 2-Decanol, SAMUEL AMANUEL, ALEXANDREA SAFIQ, HILLARY BAUER, JARGALSAIKHAN DULMAA, AMER KHRAISAT, Department of Physics and Astronomy, Union College, Schenectady, NY 12308 — Bulk 2-decanol exhibits substantial hysteresis between its melting (-3°C) and freezing (-23°C) temperatures. When it is physically confined, the melting and freezing temperature are lowered and still exhibit hysteresis. Any presence of partially melted crystals, however, can trigger crystallization at higher temperatures upon subsequent cooling, suggesting that the hysteresis is thermal history dependant. The history, however, can be erased at temperatures higher than melting point. The lowest temperature at which the thermal history can be erased is physical size dependent. For example, 2-decanol physically confined in 100 nm has to be heated to a temperature between -10°C and -5°C to erase its history while 2-decanol confined in 300 nm has to be heated to a temperature between -2°C and 2°C .

C1.00040 Polymer Diffusion in Nanocomposites having attractive particle- polymer interactions¹, CHIA-CHUN LIN, SANGAH GAM, Department of Materials Science and Engineering, University of Pennsylvania, JEFFREY S. METH, DuPont Nanocomposite Technologies, Central Research & Development, E.I. DuPont de Nemours & Co., Inc, NIGEL CLARKE, Department of Physics and Astronomy, The University of Sheffield, KAREN I. WINEY, RUSSELL J. COMPOSTO, Department of Materials Science and Engineering, University of Pennsylvania — The addition of fillers into polymeric materials has drawn tremendous attention because of the remarkable mechanical and functional properties exhibited by these composites. Previously, we studied diffusion in a weakly interacting system and found that the reduced diffusion coefficient (D/D_0) scaled with the confinement parameter, defined as the inter-particle distance relative to the tracer size. Using elastic recoil detection, tracer diffusion of deuterated poly(methacrylate) is studied in a poly(methyl methacrylate) matrix containing silica nanoparticles with number average diameters of 12.8 and 28.8 nm. Because the silica contains surface hydroxyl groups, PMMA nanocomposites are a model system for studying diffusion in strongly attractive polymer-nanoparticle systems. In contrast to the weakly interacting system, the reduced diffusion coefficient in the matrix with smaller nanoparticles is less than that with larger nanoparticles and this difference increases as the confinement parameter decreases (i.e., more crowded system). The reduced diffusion coefficient is also analyzed in terms of the surface to volume ratio of the nanoparticles.

C1.00041 Anomalous yet Brownian , SUNG CHUL BAE, BO WANG, JUAN GUAN, STEVE GRANICK, University of Illinois —

The items on the growing list of exceptions to Gaussian statistics have been given system-specific interpretations that fail to provide a universal picture of how Fickian diffusion can be non-Gaussian for diffusion over distances that much exceed the size of the diffusing object. Here, based on experiments in four separate systems, we present a general reasoning which indicates that the measured dynamics can be decomposed into a wide set of diffusivities that reflect slowly-varying, heterogeneous microscopic fluctuations. The identification of non-Gaussian yet Fickian diffusivity with long-lived environmental fluctuations allows us to conclude that non-Gaussian diffusivity should characterize much mobility in soft matter.

C1.00042 Glass Transition Temperature Gradient evidenced by NMR and Calorimetry , FRANCOIS LEQUEUX, HELENE MONTES, SIMM/ESPCI Paris France, AURELIE PAPON, SILCEA, LAURENT GUY, SILCEA Rhodia France, KAY SAALWAECHTER, Halle University Germany — Polymer, when confined, exhibit a dynamics different from the bulk one. However, measurements on unique films are rather difficult. One of the commonly accepted hypothesis is that there is a gradient of glass transition temperature in the vicinity of the solid surfaces. We have developed since ten years model nano-composite systems consisting in monodisperse spherical particles dispersed in an elastomer matrix. From Neutron Scattering, we can deduce the density of polymer located at any distance from any silica surface. We have then measured by NMR the magnetization relaxation at various temperatures above the glass transition temperature and its vicinity. From these measurements we were able to fit the whole set of data at various temperatures by a unique relation for the glass transition temperature T_g as a function of the distance z from a solid surface $T_g(z) = T_g(1 + \delta/z)$, with a unique parameter δ . In addition, the same law holds with the same parameter δ in the presence of solvent. Moreover, the parameter measured by NMR allows predicting quantitatively the Differential Scanning Calorimetry response, even after an aging step.

C1.00043 End Group Effects on the Hydrogel Formation of PEO-PPO-PEO Triblock Copolymers , AARON COHEN, CHANG Y. RYU, Rensselaer Polytechnic Institute, GYOO Y. JUNG, HEE SUNG HWANG, Postech — Pluronic F108, a triblock copolymer consisting of outer polyethylene oxide (PEO) chains and an inner polypropylene oxide (PPO) chains, has been shown to be an effective hydrogel matrix for DNA separation by capillary electrophoresis using single-stranded conformation polymorphism. This presentation will discuss a new pathway to potentially enhance the separation abilities of F108 by altering the chain end groups of the block copolymers. F108 is believed to form a micelle in aqueous solutions with the hydrophobic group in the interior, thus we expect considerable interaction between the DNA sample and the end groups found at the hydrophilic brush layers of the micelle. The rheological properties of end group derivatives of F108, in combination of small angle x-ray scattering, can reveal structural differences in the micelles. In particular, gelation temperature of the end group derivatives can be linked to differences in the micelle structure. Dynamic light scattering can also be used to determine the effects of chain end groups on the hydrodynamic size of the block copolymer micelles in dilute solution.

C1.00044 Self-assembly of polystyrene-*b*-poly(4-vinylpyridine) and polystyrene-*b*-poly(ethylene oxide) in small molecules melt¹ , CHENG-HAO YU, YU-HAO CHUANG, SHIH-HUANG TUNG, Institute of Polymer Science and Engineering, National Taiwan University, Taipei 10617, Taiwan, SOFT NANOMATERIALS GROUP TEAM — It is well known that amphiphilic block copolymers in selective solvents self-assemble into micellar structures, where solvophilic blocks tend to contact with solvents while solvophobic blocks are shielded from the solvents. Different from the conventional micellization in liquid systems, we report that block copolymer poly(styrene-*block*-4-vinylpyridine) (PS-*b*-P4VP) and poly(styrene-*block*-ethylene oxide) (PS-*b*-PEO) can self-assemble in melted small molecules at high temperature and the structures can be retained in “solid state” after being cooled down to room temperature. Transmission electron microscopy (TEM) was used to probe the structures and we found that a series of self-assembled structures, including spherical micelles, wormlike micelles and vesicles can be obtained by varying the length of block copolymers and the morphologies are dependent on annealing temperature and time. Since these nano-structures can be retained in solid state, we also demonstrate to extract the nano-structures by removing small molecules using appropriate solvents. These extracted structures, especially the vesicles, which are loaded with solid molecules, are potential applications of nanocapsules and controlled release

¹Financial support from National Science Council under Contract NSC 99-2221-E-002-021-MY3.

C1.00045 Nanoparticle-Loaded Multifunctional Block Copolymer Micelles , JINHYE BAE, JIMMY LAWRENCE, CAROLINE MIESCH, ALEXANDER RIBBE, Polymer Science and Engineering Department at University of Massachusetts Amherst, WEIKUN LI, School of Chemistry and Chemical Engineering at Huazhong University of Science and Technology, TODD EMRICK, Polymer Science and Engineering Department at University of Massachusetts Amherst, JINTAO ZHU, School of Chemistry and Chemical Engineering at Huazhong University of Science and Technology, RYAN HAYWARD, Polymer Science and Engineering Department at University of Massachusetts Amherst — We have studied the incorporation of pre-synthesized hydrophobic inorganic nanoparticles within the cores of amphiphilic polystyrene-*block*-poly(ethylene oxide) (PS-PEO) diblock copolymer micelles formed through solvent-evaporation-induced interfacial instabilities of emulsion droplets. Using iron oxide, gold, and cadmium selenide nanoparticles coated with native alkane ligands, highly uniform encapsulation is obtained for cylindrical micelles, while spherical micelles can be enriched to ~ 90 % of loaded micelles through simple magnetic or centrifugal purification steps. Multiple different types of nanoparticles can easily be incorporated into each micelle, yielding multi-functional micelles. The ability to encapsulate both spherical and rod-like particles of different core chemistries and sizes ranging from ~ 1 to 20 nm, without the necessity of coating particles with specially designed ligands, makes this a versatile route to prepare hybrid micelle structures.

C1.00046 Phase Behavior of Star-shaped polystyrene-*block*-poly(methyl methacrylate) Copolymers , SANGSHIN JANG, HONGCHUL MOON, YOUNGMIN LEE, JIN KON KIM, Department of Chemical Engineering, Pohang University of Science and Technology — Star-shaped polystyrene-*block*-poly(methyl methacrylate) copolymer (PS-*b*-PMMA) was synthesized by utilizing α -cyclodextrin (α -CD) as a junction point of the star-shaped block copolymer. Eighteen hydroxyl groups on α -CD were substituted with bromine by the reaction with α -bromoisobutyl bromide for atom transfer radical polymerization. We found that the number of bromine substituted arms per one α -CD was higher than 16 measured by nuclear magnetic resonance and Matrix-assisted laser desorption/ionization. We could control molecular weight of this unusual kind of block copolymer depending on polymerization times. Those polymers were characterized by gel permeation chromatography and nuclear magnetic resonance. Phase behavior of these star-shaped block copolymers were investigated.

C1.00047 Kinetics of micellization for diblock copolymers in selective solvents studied using self-consistent field theory , RAGHURAM THIAGARAJAN, DAVID MORSE, Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN — The kinetic barriers to association and dissociation of diblock copolymers in various selective solvents are calculated using self-consistent field theory. The variation of these kinetic barriers for both crew cut as well as hairy micelles are studied. The kinetic barriers are found to be very sensitive to temperature and become prohibitive except in a modest range of temperature near the critical micelle temperature. The dependence of kinetic barriers upon the chain and block lengths, and solvent quality are also studied.

C1.00048 Blending of Diblocks and Triblocks with identical hydrophilic block for multicompartment and multigeometry nanostructures, ZHENG ZENG, JIAHUA ZHU, YINGCHAO CHEN, University of Delaware, SHIYI ZHANG, Texas A&M University, DARRIN POCHAN, University of Delaware, KAREN WOOLEY, Texas A&M University, POCHAN'S GROUP TEAM, WOOLEY'S GROUP TEAM — Unique micellar morphologies, such as toroids, disks, and helices, have been obtained from a single triblock copolymer PAA-PMA-PS poly(acrylic acid)-b-poly(methyl acrylate)-b-poly(styrene) (PAA-PMA-PS) through a self-assembly process in dilute water/THF(tetrahydrofuran) solvent mixtures in the presence of organic multiamine molecules. Aiming to better understand their formation and explore novel structures, diblock copolymers, e.g. PAA-PMA and PAA-PS, were mixed with PAA-PMA-PS to co-assemble at desired solution conditions to produce known nanostructures (e.g. toroid, disk, helix formations). By taking advantage of the kinetic pathway of assembly and multiamine-PAA complexation, the additional diblock copolymers can be trapped in the same micelle with the triblock PAA-PMA-PS. Interesting transitions were found in toroid/disk/helix formations by changing the amount of the added diblock copolymers. The morphologies of the blended nanoparticles was characterized with cryogenic and conventional transmission electron microscopy, dynamic light scattering, and small angle neutron scattering.

C1.00049 Kinetic control of block copolymer self-assembly into multicompartment and novel geometry nanoparticles¹, YINGCHAO CHEN, University of Delaware, XIAOJUN WANG, University of Tennessee, KE ZHANG, Northwestern University, KAREN WOOLEY, Texas A&M University, JIMMY MAYS, University of Tennessee, VIRGIL PERCEC, University of Pennsylvania, DARRIN POCHAN, University of Delaware, UNIVERSITY OF DELAWARE COLLABORATION, TEXAS A&M UNIVERSITY COLLABORATION, UNIVERSITY OF TENNESSEE COLLABORATION, UNIVERSITY OF PENNSYLVANIA COLLABORATION — Micelles with the segregation of hydrophobic blocks trapped in the same nanoparticle core have been produced through co-self-assembly of two block copolymers in THF/water dilute solution. The dissolution of two block copolymer sharing the same polyacrylic acid PAA blocks in THF undergoes consequent aggregation and phase separation through either slow water titration or quick water addition that triggers the micellar formation. The combination and comparison of the two water addition kinetic pathways are the keys of forming multicompartment structures at high water content. Importantly, the addition of organic diamine provides for acid-base complexation with the PAA side chains which, in turn, plays the key role of trapping unlike hydrophobic blocks from different block copolymers into one nanoparticle core. The kinetic control of solution assembly can be applied to other molecular systems such as dendrimers as well as other block copolymer molecules. Transmission electron microscopy, cryogenic transmission electron microscopy, light scattering have been applied to characterize the micelle structures.

¹Thanks for the NSF grant MASC312153, Thanks for the keck lab in UD

C1.00050 Dynamic Processes in Diblock Copolymer Micelles with a Semi-Crystalline Core, AVANTIKA SINGH, MEGAN ROBERTSON, University of Houston — Amphiphilic diblock copolymers, which form micelle structures in selective solvents, offer a great advantage of tunability in physical characteristics as compared to low molecular weight surfactants. Their micelles in aqueous solvents have been a subject of great interest in drug delivery applications for their high loading capacity and targeted drug delivery. The aim of this work is to understand the dynamic processes underlying the self-assembly of diblock copolymer micelle systems which have a semi-crystalline core. The present work focuses on amphiphilic diblock copolymers containing blocks of poly(ethylene oxide) (a hydrophilic polymer) and polycaprolactone (a hydrophobic polymer), which spontaneously self-assemble into spherical micelles in water. Polycaprolactone is a semi-crystalline polymer. A variety of experimental techniques are used to probe the kinetic processes occurring during micelle self-assembly, including time-resolved neutron scattering, dynamic light scattering, pulsed field gradient nuclear magnetic resonance, and fluorescence resonance energy transfer experiments.

C1.00051 Long Circulating Micelles based on Helix Bundle-Forming Peptide-Polymer Conjugates, JESSICA SHU, UC Berkeley, HE DONG, Retired, NIKHIL DUBE, UC Berkeley, JAI WOONG SEO, UC Davis, YU FEI MA, UC Berkeley, KATHERINE FERRARA, UC Davis, TING XU, UC Berkeley — Stable, multi-functional organic nanoparticles that combine long in vivo circulation, the ability to cross vessel walls to reach tumor tissues and controlled disassembly for eventual clearance will have a significant impact in nanomedicine. Although current self-assemblies of amphiphiles provide a versatile platform to generate modular organic nanoparticles, it remains a significant challenge to simultaneously control nanoparticle size in the range of 10-30 nm, enhance particle stability and tailor disassembly within suitable timescales. We have advanced this goal by designing a new family of amphiphiles based on coiled-coil 3-helix bundle forming peptide-polymer conjugates. By attaching a polymer chain to the middle of a helical peptide, the protein tertiary structures are used to position entropic forces of compressed polymer chains comprising the headgroups so as to effectively slow down the subunit desorption rate and enhance the in vivo stability. The resultant monodispersed nanoparticles are composed of subunits, < 4 nm in size, that form highly stable 15-17 nm diameter particles and demonstrate an in vivo circulation half life-time of 28 hrs, minimal accumulation in the liver and spleen and effective urinary clearance. By uniquely combining the configurational entropy of a polymer chain with a common protein structure, i.e. coiled-coil helix bundle, and a lipid core, self-assembled nanoparticles have been engineered with tunable stability and disassembly.

C1.00052 Physics of Polymersomes: lateral segregation experiments and raft simulations, DENNIS DISCHER, Univ. Pennsylvania — Coupling between the inner and outer leaflets of a bilayer plays an important role in biomembrane function, particularly in inducing and registering rafts across leaflets for various cellular signals. However, mechanisms of raft registration remain elusive and several alternatives have been proposed, ranging from electrostatic coupling to chain interdigitation. A general mechanism has been suggested by recent experiments on Polymersomes in which binary mixtures of diblock copolymer amphiphiles exhibit domain registration upon ligand-induced segregation. Using coarse grained molecular dynamics (CGMD) simulations rooted in atomistics, raft registration arises spontaneously in bilayers with a calcium- or ligand-crosslinked ordered phase segregating from a liquid disordered phase. When rafts are not registered, a thickness mismatch between phases induces a “bump” in the apposing liquid phase leaflet, and the associated localized curvature guides rafts together stabilizing the registered state. The absence of explicit charge in the model and the fact that domain size modulates transmembrane coupling demonstrate that collective interactions are sufficient for raft registration. C1.00053 Controlling the Morphology of TiO2 Nanorods/Polythiophene Composites for Bulk Heterojunction Solar Cells Using H-Bonding¹, YING LIN, QINGSHUO WEI, JAMES J. WATKINS, Department of Polymer Science and Engineering, University of Massachusetts Amherst — We demonstrate how the morphology of solution-processable hybrid bulk heterojunction solar cells, within an active layer consisting of modified poly(3-hexylthiophene) (P3HT) and TiO2 nanorods, can be controlled by H-Bonding. The hybrid bulk heterojunction solar cells suffer from the problems of the aggregation of inorganic nanocrystals and the interface between nanocrystals and the polymer matrix. To address these issues, we utilize P3HT-based block copolymer (BCP), in which one block is P3HT and the other block is a P3HT derivative containing a poly(ethylene glycol) (PEG) oligomer side chain. In the mean time, we functionalized the TiO2 nanorods with dyes having multiple COOH groups. This design both enables self-assembly of the devices via micropase segregation into well-defined morphologies and provides a means for establishing strong preferential interaction between TiO2 nanorods and the PEG side chain. This strong, preferential H-bonding limits the aggregation of the TiO2 nanorods and modifies the interfacial properties between donor and acceptor. TEM showed the self-assembly structure of the TiO2 nanorods in polymer matrix. Using this modified thiophene copolymer, hybrid devices are made with power conversion efficiencies 50% higher than that of conventional P3HT homopolymer.

C1.00054 Magnetic Nanoparticle/Block Copolymer Hybrid Materials for the Fabrication of Electromagnetic Devices¹, XINYU WANG, DAVID MESGUICH, JAMES WATKINS, University of Massachusetts Amherst — Significant efforts have been directed towards incorporating inorganic nanoscopic materials into well-defined, phase-separated block copolymer systems to create hybrid materials with intriguing optical, electrical or magnetic properties. Lin et al. recently reported the use of strong interactions between NPs and one segment of weakly segregated BCP systems to drive the assembly of well-ordered morphologies while confining the NPs specifically in the desired spherical, cylindrical or lamellar domains. Here we use this approach to assemble magnetic nanoparticles of high permeability into well ordered systems. Magnetic nanoparticles (MNPs) were synthesized and subsequent surface functionalization and/or ligand exchange reactions were carried out to decorate the NP surfaces with hydrogen-bonding donating groups and good particle dispersibility in polar solvents. The ligand attachment was confirmed by TGA and FTIR. The morphology evolution of BCP/MNPs composites was examined by SAXS. Such ferromagnetic structures with precise geometric control in nanoscale would enable the cost-effective fabrication of more advanced devices for AC electromagnetic applications such as miniaturized antennas with extended bandwidth, integrated microwave electronics and efficient power transformers.

C1.00055 Novel Approach to Quantify Dispersion of Spherical Nanoparticles in Polymer Nanocomposites¹, DENIZ RENDE, NIHAT BAYSAL, RAHMI OZISIK, Rensselaer Polytechnic Institute — Nanocomposites have emerged as promising materials due to improved conductivity, toughness, and permeability when compared to conventional bulk polymers. Controlling the dispersion of the nanoparticles in a polymer matrix is still one of the greatest challenges that limit our ability to achieve the aforementioned property enhancements. Nanoparticles tend to agglomerate due to strong interparticle interactions. The dispersion of nanoparticles in polymers is generally determined by transmission electron microscopy (TEM) or scanning electron microscopy (SEM). However, in these studies quantification of dispersion depends on the visual observations and is prone to subjective conclusions; thereby hampering possible comparison between samples. Considering its importance, little effort has been put forward to quantify the dispersion of nanoparticles in polymers. In the current study, we have applied network theory approach to quantify the dispersion of spherical particles. A network is a collection of nodes, which are entities (such as nanoparticles), and edges that connect pairs of nodes (distances between nanoparticles). By employing nodes and edges, we constructed interaction networks, which were then analyzed in terms of global topological measures: degree distribution, clustering coefficient, and average distance. We show that this approach is a powerful tool to quantify dispersion of spherical nanoparticles in a polymer matrix.

¹Partial support was provided by NSF Grant No. 1003574 and RPI. DR is also supported by TUBITAK 2219 program.

C1.00056 Mesoscopic Iron-Oxide Nanorod Polymer Nanocomposite Films, ROBERT FERRIER, University of Pennsylvania, KOHJI OHNO, University of Kyoto, RUSSELL COMPOSTO, University of Pennsylvania — Dispersion of nanostructures in polymer matrices is required in order to take advantage of the unique properties of the nano-sized filler. This work investigates the dispersion of mesoscopic (200 nm long) iron-oxide rods (FeNRs) grafted with poly(methyl methacrylate) (PMMA) brushes having molecular weights (MWs) of 3.7K, 32K and 160K. These rods were then dispersed in either a poly(methyl methacrylate) or poly(oxyethylene) (PEO) matrix film so that the matrix/brush interaction is either entropic (PMMA matrix) or enthalpic and entropic (PEO matrix). Transmission electron microscopy (TEM) was used to determine the dispersion of the FeNRs in the polymer matrix. The results show that the FeNRs with the largest brush were always dispersed in the matrix, whereas the rods with the shorter brushes always aggregated in the matrix. This suggests that the brush MW is a critical parameter to achieve dispersion of these mesoscopic materials. This work can be extended to understand the dispersion of other types of mesoscopic particles

C1.00057 Additive Driven Self Assembly in Poly(ethylene glycol) monomethyl ether monomethacrylate-block-Poly(ethyl methacrylate) Copolymers, CHENG LI, University of Massachusetts Amherst, WENXU ZHANG, UMass Amherst, EDWARD COUGHLIN, JAMES WATKINS, University of Massachusetts Amherst — Recent work in our labs has demonstrated the concept of additive driven assembly by hydrogen bond interactions between poly(ethylene oxide) segments of a disordered PEO containing block copolymer and a nanoparticle or organic additive induces strong segregation in the composite to yield well ordered morphologies. In some cases, these interactions were introduced by light-activated deprotection of functional groups on the additive to enable regioselective, photo-induced order in block copolymer films. While PEO crystallization in these polymers is suppressed by strong interaction between the additive and the PEO segments at high additive loadings, crystallization of the PEO block with no loading or at low additive loadings is highly undesirable for many applications. To remedy this issue, we prepared PEGMEMA-PEMA using RAFT living polymerization. This block copolymer phase mixed, noncrystallizable at room temperature. The incorporation of organic additives with multiple carboxylic acid groups or functionalized nanoparticles induces phase segregation in these systems. Furthermore, the use of additives in which the hydrogen bond donating group is protected with an acid labile group in combination with a photo acid generator enables photo-induced order of the composite films.

C1.00058 Correlating nanoscale structural changes to macromolecular gel formation in Laponite containing Pluronic F127 photogel systems, K. ANNE JUGGERNAUTH, Macromolecular Sci. & Eng. Research Center, Materials Sci & Eng Dept, University of Michigan, BRIAN LOVE, Materials Sci & Eng Dept, University of Michigan, UNIVERSITY OF MICHIGAN TEAM — Polymer nanocomposites has been a growing scientific field over the last 20 years. Recently, there has been increasing interest on nanocomposite systems with active responses to external stimuli such as heat, magnetic fields and light. The focus of this work is on a reversible thermoresponsive system, Pluronic F127 with added inorganic disk-shaped nanoparticles of Laponite. We further modify this system with the addition of a photoacid generator to enable photogelation. However, the nanoscale particle-particle and polymer-particle interactions within this Laponite/ block copolymer system are not well understood. We report on the photogelation kinetics of this system and further probe the interactions and rearrangement kinetics with heat and light exposure using in-situ synchrotron small angle x-ray scattering.

C1.00059 Gold-Decorated Supraspheres of Block Copolymer Micelles, M.P. KIM, D.J. KANG, A.G. KANNON, KAIST, D.-W. JUNG, G.R. YI, Chungbuk National Univ., B.J. KIM, KAIST — Gold-decorated supraspheres displaying various surface morphologies were prepared by infiltration of gold precursor into polystyrene-b-poly(2-vinylpyridine) (PS-b-P2VP) supraspheres under acidic condition. The supraspheres were fabricated by emulsifying PS-b-P2VP polymer solution into surfactant solution. Selective swelling of P2VP in the suprasphere by gold precursor under acidic condition resulted in the formation of gold-decorated supraspheres with various surface structures. As evidenced by TEM and SEM images, dot pattern was formed in the case of smaller supraspheres than 800 nm; whereas fingerprint-like pattern was observed in larger supraspheres than 800 nm. Gold nanoparticles were located inside P2VP domains near the surface of prepared supraspheres as confirmed by TEM. The optical property of the supraspheres was characterized using UV-vis absorption spectroscopy and the maximum absorption peak at around 580 nm was observed, which means that gold nanoparticles densely packed into P2VP domain on the suprasphere. Our approach to prepare gold-decorated supraspheres can be extended to other metallic particles such as iron oxide or platinum nanoparticles, and those precursors can be also selectively incorporated into the P2VP domain.

C1.00060 Self-Assembly of CdSe Nanorods by Controlled Solvent Evaporation and Applied Electric Field, SIRINYA CHANTARAK, TODD EMRICK, THOMAS P. RUSSELL, Polymer Science & Engineering Department, University of Massachusetts, Amherst — We report the synthesis of CdSe nanorods (NRs) having variable aspect ratios and their vertical alignment into a hexagonal arrays over a large area. NRs with a constant diameter of 6 nm and lengths, tunable to over 100 nm, were obtained by controlling the concentration of ligands in solution and injection of Se at defined time intervals. Hexagonal arrays of aligned, alkane covered CdSe nanorods within a polymer matrix were achieved by controlled solvent evaporation in the presence of an applied electric field. The nature of the solvent identity, substrate hydrophobicity, and strength of applied voltage were optimized such that close packing of nanorods was achieved over a large area. Such organized nanocomposites hold potential application in organic-inorganic bulk heterojunction photovoltaic devices.

C1.00061 Emulsions of Polymer Blends Stabilized by Janus Particles, KYLE BRYSON, RYAN HAYWARD, THOMAS RUSSELL, University of Massachusetts - Amherst — Particle-stabilized emulsions of both immiscible and partially miscible polymer blends have recently received renewed interest. In particular, bicontinuous stabilized emulsions are attractive for their three-dimensional expression of the properties of each component, but a true incarnation of this structure has yet to be demonstrated in polymer systems, due to the difficulties in preparing particles that neutrally wet both polymer phases. Janus particles, which possess different surface chemistries on two halves of the particles, afford a way to bypass the necessity of neutral wettability. Both theory and experiment have shown enhanced interfacial adsorption energies for Janus particles, in comparison to homogeneous particles. To investigate these concepts, silica particles were homogeneously and anisotropically functionalized and dispersed in fluid mixtures; interfaces were created by thermally induced phase separation or mechanical mixing. The resulting structures were characterized by laser-scanning confocal microscopy and transmission electron microscopy. The results elucidate the role of particle wettability on the structure of stabilized emulsions.

C1.00062 Crystallization of Polymers at liquid/liquid interface templated by single-walled carbon nanotubes, WENDA WANG, CHRISTOPHER LI, Drexel University, SOFT MATTER RESEARCH GROUP TEAM — Nanosized single-walled carbon nanotube rings were fabricated by using a Pickering emulsion-based method. By tuning a water/oil/SWNT miniemulsion system, SWNT rings with a diameter of ~200 nm can be readily achieved. The formation mechanism is attributed to the bending force induced by the curved liquid/liquid interface. Crystallization of polyethylene homo- and copolymers using this unique SWNT rings as the nucleation agent was conducted at the curved liquid/liquid interface. Crystal structure, hybrid morphology and crystallization kinetics were systematically studied. The structure of controlled alternating patterns on SWNT rings has great potential in various applications in large-scale integrated circuits and single-electron devices.

C1.00063 Effect of Nanoparticle Size on Nanoparticle Spatial Distribution in a Diblock Copolymer Supramolecular Thin Film, PETER BAI, JOSEPH KAO, MATTHEW LUCAS, PAUL ALIVISATOS, TING XU, University of California, Berkeley — The self-assembly of nanoparticles (NPs) opens many pathways towards generation of functional nanostructured materials with desirable optical, mechanical and electrical properties. A great challenge in this field is the effective control of NP spatial distribution within the block copolymer matrix, which is crucial in tailoring the macroscopic properties of the polymer/nanoparticle composites. We systematically investigated the effect of NP size on the spatial distribution of nanoparticles upon blending with a diblock copolymer based supramolecule in thin film. The spatial distribution of NPs in thin film was observed to be strongly dependent on NP size. These observations can be explained by the increase in entropic penalty of incorporating larger NPs associated with the deformation of the BCP block to accommodate the NPs. This effect is observed for NPs with different chemistries and could serve as a promising route to creating multifunctional thin film nanocomposites.

C1.00064 Direct Nanorod Assembly Using Block Copolymer-Based Supramolecules, KARI THORKESSON, ALEXANDER MASTROIANNI, Department of Materials Science and Engineering, UC Berkeley, PETER ERCIUS, National Center for Electron Microscopy, Lawrence Berkeley National Laboratory, TING XU¹, Department of Materials Science and Engineering, UC Berkeley; Materials Sciences Division, Lawrence Berkeley National Laboratory — One-dimensional nanomaterials with high aspect ratios, such as nanorods, exhibit unique and useful anisotropic optical, magnetic, and electrical properties. The collective properties of 1-D nanomaterials depend on their spatial arrangements, interparticle ordering, and macroscopic alignment. Developing routes to control their organization with high precision is critical to generate functional materials. We have investigated the co-assemblies of nanorods and block copolymer (BCP)-based supramolecules that self-assemble into spherical, lamellar and cylindrical morphologies. By varying energetic contributions from the rod-rod interactions and the deformation of the supramolecule, a wide library of nanorod assemblies including highly aligned arrays, continuous networks, and clusters can be readily accessed. Since macroscopic alignment of BCP microdomains can be obtained by application of external fields, present studies open up a new route to manipulate macroscopic alignments of nanorods. Fundamentally, these studies have demonstrated that in these blends, the energetic contributions from the polymer chain deformation and rod-rod interactions are comparable and can be tailored to disperse nanorods with control over inter-rod ordering and their relative alignment.

C1.00065 Magnetically aligned polymers and nanocomposites for energy harvesting and energy storage applications¹, PAWEŁ MAJEWSKI, MANESH GOPINADHAN, CANDICE PELLIGRA, Yale University, SHANJU ZHANG, California Polytechnic State University, LISA PFEFFERLE, Yale University, LUIS CAMPOS, Columbia University, CHINEDUM OSUJI, Yale University — The realization of anisotropic, nanostructured, functional materials by self-assembly is impaired by the persistence of structural defects which render the properties of the system isotropic on macroscopic length scales. We present three distinct systems including ZnO nanowire-semiconducting polymer composites, Li-ion conducting block copolymer membranes, and perylene-based block copolymers where self-assembly under a magnetic field yields alignment and global anisotropy of their physical properties. The resulting aligned nanostructured systems are attractive for ordered heterojunction photovoltaics, high performance solid polymer electrolyte membranes and electro-optical devices, respectively. Our results demonstrate that magnetic fields offer a viable route for directing the self-assembly of certain soft functional materials. The ready scalability of this approach makes it potentially important from a technological standpoint.

¹The funding from NSF under DMR-0847534 and DMR-0934520 is gratefully acknowledged.

C1.00066 Absorption of nanoparticles onto curved surfaces, CHIH-YU JAO, Virginia Tech Dept of Physics, JIHAENG YI, ISHAC L. N. KANDAS, BO LIU, YONG XU, Virginia Tech ECE Dept., HANS D. ROBINSON, Virginia Tech Dept of Physics — We study the adsorption of gold nanospheres onto cylindrical and spherical glass surfaces from stagnant aqueous particle suspensions. The curved surfaces were obtained as tapers and microspheres fabricated from optical fibers and were coated with a nm-thick layer of the polycation polyallylamine hydrochloride, causing irreversible adsorption of the negatively charged spheres. Our results fit well with theory, which predicts that the rates of particle adsorption will depend strongly on the surface geometry. In particular, *adsorption is significantly faster on curved than on planar surfaces* at times long enough that the particle diffusion length is large compared to the surface curvature. This is of particular importance for plasmonic sensors and other devices where particles are deposited from a suspension onto surfaces which may have non-trivial geometries.

C1.00067 Thermodynamics of ligand-coated nanoparticle complexation with lipid bilayers, REID VAN LEHN, Massachusetts Institute of Technology, RANDY CARNEY, KISLON VOITCHOVSKY, FRANCESCO STELLACCI, MARIA RICCI, Ecole Polytechnique Federale de Lausanne, ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology — Recently, nanoparticles (NPs) coated with a mixed alkanethiol surface monolayer were observed to spontaneously penetrate cell membranes via a non-endocytotic mechanism. Penetration seems to depend on the structure of the ligand monolayer; particle uptake was greatest when the surface self-assembled into a striped morphology consisting of alternating domains of hydrophilic and hydrophobic ligands. Furthermore, these 'striped' particles form stable complexes with single component lipid bilayers, implying that cellular penetration may be related to bilayer interactions. Bilayer complexation is surprising, however, because the width of the striped domains is less than the thickness of the bilayer core, implying that charged ligands are exposed to hydrophobic lipid tails. In this work, we provide a thermodynamic analysis of NP-bilayer complexation supported by implicit bilayer simulations. Our results show that complexation is related to the deformation of both the ligand monolayer and the bilayer to maximize favorable hydrophobic interactions while minimizing unfavorable insertion of charges into the bilayer core. This study will improve our understanding of bilayer interactions and enable the design of ligand-coated nanoparticles for drug delivery and biosensing applications.

C1.00068 Morphological robustness in polythiophene/fullerene mixtures¹, SAMEER VAJJALA KESAVA, DEREK KOZUB², Pennsylvania State University, CHENG WANG, ALEXANDER HEXEMER, Advanced Light Source, Lawrence Berkeley National Laboratory, ENRIQUE GOMEZ, Pennsylvania State University, ENRIQUE GOMEZ TEAM, ALEXANDER HEXEMER TEAM — The morphology of the photoactive layer of organic solar cells evolves differently under different processing conditions such as annealing temperature, annealing time and casting solvent. Hence, characterizing it is crucial in understanding its effect on device performance. In our study, we used Grazing Incidence Small Angle X-ray Scattering (GISAXS) and Energy-Filtered Transmission Electron Microscopy (EFTEM) to characterize the in-plane morphology of poly(3-hexylthiophene-2,5-diyl) (P3HT)/[6,6]-phenyl-C₆₁-butyric acid methyl ester (PCBM) mixtures. We found that the characteristic length scale determined through GISAXS did not vary significantly for different processing conditions thus making P3HT/PCBM a robust system. For example, different spin-casting solvents did not significantly affect lateral phase separation, and consequently, device performance was similar once thickness effects are accounted for.

C1.00069 Thin-film fabrication and electric field induced poling of an azo dye-doped cyclic olefin copolymer¹, JONATHAN CHOI, The College of New Jersey, BASTIAN BRAEUER, Beuth University of Applied Sciences, PADMA GOPALAN, University of Wisconsin-Madison, DAVID MCGEE, The College of New Jersey — Cyclic olefin copolymers (COC) exhibit high transparency, low birefringence, and a high glass transition temperature, which make them promising as host materials for nonlinear optical chromophores. However, the non-polar COC environment limits chromophore loading, resulting in potentially weak nonlinear optical functionality. In this research, we fabricated COC films doped with the azo dye Disperse Red 1 (DR1), and corona poled the films to establish dipolar chromophore order. Second-harmonic generation experiments were used to probe chromophore orientational order during the poling process and to monitor the subsequent temporal relaxation. Preliminary experiments indicated a maximum loading of 5 wt% DR1 in COC, and that the effective second order nonlinear optical coefficient decayed by 50% within two weeks following poling.

C1.00070 Temperature Dependent Study of Regioregular and Regiorandom Poly (3-hexyl thiophene)s, XIAOBO SHEN, THOMAS RUSSELL, University of Massachusetts Amherst — Structure evolution of bulk regioregular (rr) and regiorandom (rra) poly (3-hexyl thiophene)s (P3HT) with temperature has been characterized by wide angle X-ray diffraction (WAXD). Different thermal behaviors associated with the inter- and intra-molecular packing were shown as regioregularity changes. Transition temperature of ~100°C for crystalline rr-P3HT has been assigned to side chain melting point where the thermal expansion along the edge-on direction shows a turning point separating solid and molten hexyl side chains. Meanwhile, $\pi - \pi$ stacking distance was observed to initially decrease and then increase upon heating, with a minimum at ~100°C. The average inter-molecular distance of rra-P3HT was independent of temperature while the average intra-molecular distance increased upon heating. Molten rr-P3HT and rra-P3HT show same inter- and intra-molecular distance. Temperature UV-Vis absorption and photovoltaic device performance were also measured.

C1.00071 Additive-Driven Assembly of Block Copolymer-Nanoparticle Hybrid Materials for Solution Processable Floating Gate Memory, QINGSHUO WEI, YING LIN, ERIC ANDERSON, ALEJANDRO BRISENO, SAMUEL GIDO, JAMES WATKINS, Department of Polymer Science and Engineering, University of Massachusetts Amherst — The preparation of well-ordered hybrid materials at nanoscale is not only fundamentally interesting but also of significant importance for the development of next generation functional devices. In this study, we present a simple approach for the preparation of well-ordered polymer/NP composites through the concept of additive-driven assembly, and its application for the fabrication of floating gate organic FET memory devices. The addition of gold NPs that selectively hydrogen bond with pyridine in poly(styrene-*b*-2-vinyl pyridine) is shown to induce an ordered structure. This enables the fabrication of well-ordered hybrid materials with lamellar domains at Au NP loadings of more than 40 wt%. The fabrication of floating gate memory devices was demonstrated by the ordered Au NPs / block copolymer hybrid film as a charge trapping layer, which is sandwiched between a SiO₂ dielectric layer and a poly(3-hexylthiophene) semiconductor layer. This approach enables us to fabricate well-ordered charge storage layers by solution processing and to achieve facile control of the memory windows by changing the density of gold NPs. The devices show high carrier mobility (> 0.1 cm²/Vs), controllable memory windows (0~50V), high *on/off* ratio (>10⁵) between memory states and long retention times (>10⁴ s). This approach is potentially suitable for roll-to-roll printing techniques to make flexible, large area and high density devices.

C1.00072 Classification of Semiconducting Polymeric Mesophases to Optimize Device Post-Processing, CHAD SNYDER, RYAN NIEUWENDAAL, DAVID VANDERHART, LEE RICHTER, R. JOSEPH KLINE, DEAN DELONGCHAMP, National Institute of Standards and Technology, MARTIN HEENEY, IAIN MCCULLOCH, Imperial College of London — Semiconducting polymers form a variety of phases and mesophases that respond differently to post-deposition solvent or thermal treatments. Here it is shown that classification of these materials into their appropriate mesophases can be a useful tool to optimize their post-deposition treatments. Calorimetry is used to quantify differences between very similar materials, using a well-established framework based on the kinetics and thermodynamics of phase changes. By way of example, this classification scheme is used to identify differences in the presence and distribution of mesophases in three polymers, poly(3-hexylthiophene) and two isomeric bithiophene-thiophene copolymers (pBTBT and pATBT). The diverse phase structure is notable in light of the molecular similarity of the three polymers, and it has impact on optimum post-processing conditions for maximum electrical performance in thin film transistor devices.

C1.00073 Conformation Effects on the Photoluminescence Behavior of Anchored MEH-PPV Pancakes and Brushes, KUO SHENG SHIH, PO-TSUN CHEN, ARNOLD C.-M. YANG, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan 30013 — Single molecular layer of poly[2-methoxy-5-(2'-ethylhexyloxy)-1,4-phenylenevinylene] (MEH-PPV) grafted on primed silicon wafer were synthesized, forming brushes (chain spacing 0.54 nm via graft-from) or pancakes (~7 nm to 34 nm via graft-to). For the tight-packed brushes, the PL emission peak, residing in the range from 434 nm to 550 nm depending on the chain length, was generally unchanged when transferring between the dry and solvent immersion states. However, for the pancakes, the emission peak blue-shifted dramatically (up to 100 nm) when dried in the air relative to that in the solvent. These shifts were fully reversible in the dry-wet cycles. The large blue shifts of the anchored pancakes were attributed to the mechanical stretching of entangled MEH-PPV segments in contact with substrate upon solvent loss. In contrast, the blue shifts disappeared and small red shifts emerged instead for extremely slowly drying (24 hrs drying time), revealing the stress-relaxation pathways in the equilibrium conditions. The drying-induced blue shift was also observed in the un-anchored drop-casting samples but the reversibility vanished. Finally, a large enhancement of PL intensity was accompanied with the blue shifts, manifesting the effect of the molecular constraints.

C1.00074 Properties of Alq₃ waveguides containing embedded metal layers, NIRANJALA WICKREMasinghe, XIAOSHENG WANG, JONATHAN THOMPSON, Department of Physics, University of Cincinnati, Cincinnati, OH 45221, HEIDRUN SCHMITZER, Department of Physics, Xavier University, Cincinnati, OH 45207, HANS PETER WAGNER, Department of Physics, University of Cincinnati, Cincinnati, OH 45221 — We study the properties of aluminum-quinoline (Alq₃) waveguides with embedded thin (few 10 nm thick) metal layers using the m-line technique at a wavelength of 633 nm. Our goal is to investigate how the guided TM and TE modes and their effective refractive indices are affected by the metal layers. The layered waveguides are fabricated on a glass substrate by organic molecular beam deposition (OMBD). A Mg_{0.9}Ag_{0.1} alloy is used for the metal layers. Pure Alq₃ waveguides serve as reference samples. Our experiments show that TM modes in an Alq₃ waveguide with a single centered metal film are nearly unaffected, except for a slight increase of the bulk refractive index in the sample. TE modes are more strongly affected. Compared to our reference sample, we do not observe the TE₀ and TE₂ mode. Other TE modes whose electric field nodes are at the location of the metal film are visible. A similar behavior is also found in waveguides with embedded multiple metal layers. Our experimental data is compared to a multi-layer model simulation and to an effective-medium model. The results indicate that strategically placed metal layers can potentially be used to tailor waveguides structures.

C1.00075 Mechanical deformations of the metal cathodes of polymer light emitting devices during stability tests¹, ZAC BARCIKOWSKI, JACOB COX, MARIAN TZOLOV², Department of Physics, Lock Haven University of Pennsylvania — The polymer light emitting devices (PLEDs) include materials with substantially different mechanical properties - oxides as anode, organic polymers as light emitter, and metals as cathode. The typical expectation is that this mix of materials would be a problem if there is an exposure to large temperature variation. Our studies on the stability of the PLEDs give evidence that even without substantial heating of the devices, mechanical deformations appear. They are manifested in delamination and loss of contact area with all associated negative impact on the light emission from the devices. Our optical and scanning electron microscopy images show round shaped cathode deformations with enhanced degradation of the polymer along their periphery. In order to check the hypothesis of build-up of mechanical stress in the metal films during their deposition, we have used thermally evaporated aluminum cathodes with different thickness. We have used anodes different than the traditionally used ITO film in order to verify if an oxygen evolution is responsible for the formation of the mechanical deformations. We will show results on how a buffer layer between the light emitting polymer and the cathode influences the formation of the mechanical deformations.

C1.00076 N-type Organic Field Effect Transistor Using Densely Aligned Carbon Nanotube Array Electrodes¹, EDWARDS G. JIMENEZ, School of Electrical Engineering and Computer Science, and Nanoscience Technology Center, University of Central Florida, BIDDUT K. SARKER, Nanoscience Technology Center, and Department of Physics, University of Central Florida, SAIFUL I. KHONDAKER, Nanoscience Technology Center, Department of Physics, and School of Electrical Engineering and Computer Science, University of Central Florida — We present fabrication of n-type organic field effect transistors (OFETs) using densely aligned array carbon nanotube (CNT) electrodes. The CNTs were aligned with a high linear density via dielectrophoresis (DEP) from an aqueous solution. In order to fabricate the CNT electrodes, aligned CNTs were cut by electron beam lithography (EBL) and precise oxygen plasma etching. The OFETs were fabricated in a bottom-contact configuration by depositing a thin film of C60 molecules between the CNT source and drain electrodes, and compared against a controlled OFET with gold electrodes. The room temperature electron transport measurements of the OFETs using CNT electrodes show better transistor characteristics compare to OFETs using gold electrodes due to improved charge injection from densely aligned and open-ended nanotube tips.

C1.00077 Thermal Analysis of defects in Organic Light Emitting Diodes using Thermoreflectance imaging technique, ACHYUT SHRESTHA, Hampshire College, ANDREW DAVIS, KENNETH CARTER, University of Massachusetts-Amherst, JANICE HUDGINGS, Mt. Holyoke College — Organic light emitting diodes (OLEDs) have emerged as a next generation technology for flat panel displays. One of the factors inhibiting commercialization of this technology are their shorter life spans. Various defects induced during fabrication and operation tend to grow with time causing catastrophic failure of the device. In our work, we use thermoreflectance imaging (TR) to study defects in OLEDs. TR is based on measuring the change in reflectivity of the device as a function of temperature. We want to study the defects before catastrophic failure. We're interested in the physical origin of the defects, under what conditions failure occurs, and how defects affect current injection uniformity. Several defects including dark spots and bright spots on the surface of OLEDs are visible through the TR imaging. In our experiment, we are making controlled defects in OLEDs to study specific thermal maps of various kinds of defects. Understanding local temperatures and heat spread via TR imaging will provide better insight into formation of defects, which could be used to increase the lifetime and efficiency of OLEDs.

C1.00078 Correlation of interfacial width with device characteristics in all-polymer thin film transistors based on P(NDI2OD-T2), HONGPING YAN, NCSU, TORBEN SCHUETTERT, Cambridge, CHRISTOPHER MCNEILL, Monash Univ, HARALD ADE, NCSU — The interface between a conjugated polymer and a dielectric is critical to the performance of an organic thin-film transistor device, since charge transport occurs essentially along a 1 nm deep accumulation layer in the semiconducting polymer at the interface with the dielectric. Utilizing resonant soft x-ray reflectivity, we measure the interfacial widths of poly([N,N'-bis(2-octyldodecyl)-11 naphthalene-1,4,5,8-bis(dicarboximide)-2,6-diyl]-alt-5,5'-(2,2'-12 bithiophene)) and differentially cast dielectric layers of polystyrene (PS), poly(methyl methacrylate) (PMMA) or CYTOP, respectively. We demonstrate that devices with PMMA as the dielectric layer show the sharpest interface, whereas CYTOP has the largest. The measured widths correlate with the onset voltages of the thin-film transistor devices and anticorrelate with the activation energies in these three systems. A comparison to the surface roughness prior to differential casting furthermore indicates that deposition of the top dielectric layer affects the thus-formed interfaces to a different extent for various dielectric materials. Overall, the results suggest that further control of the interfacial properties during fabrication is required for ultimate performance.

C1.00079 Effect of bridging atom identity on the morphology of solution-processed small molecule bulk heterojunction photovoltaics, GREGORY SU, NANCY EISENMENGER, GREGORY WELCH, GUILLERMO BAZAN, EDWARD KRAMER, MICHAEL CHABINYC, University of California Santa Barbara — Organic bulk heterojunction photovoltaics have gained much attention based on their potential to be low-cost, large area modules. Solution-processable small molecules are attractive materials due to their well-defined nature and purity. We examine two small molecules that differ by the identity of one atom: 5,5'-bis{7-(4-(5-hexylthiophen-2-yl)thiophen-2-yl)-[1,2,5]thiadiazolo[3,4-c]pyridine}-3,3'-di-2-ethylhexylsilylene -2,2'-bithiophene, (SM_{Si}) and its carbon-bridged analog, (SM_C). Despite having similar absorption spectra and energy levels, SM_{Si} and SM_C have different thermal transitions and device performance. SM_{Si} melts at 215 °C, while SM_C melts at 145 °C, and similarly annealed devices based on blends of SM_{Si} or SM_C with [6,6]-phenyl-C₇₁-butyric acid methyl ester (PC₇₁BM) show power conversion efficiencies of ~3.4% and ~1.0%, respectively. To determine the origin of this difference, techniques including grazing incidence wide angle X-ray scattering, UV-Visible spectroscopy, optical microscopy, and *in situ* current-voltage measurements were employed to monitor morphological changes during thermal annealing. SM_C :PC₇₁BM devices exhibit a greater propensity to crystallize into large domains upon annealing, which is detrimental to performance. These results highlight the connections among structure, morphology, and performance and provide insight into the design and characterization of photovoltaic materials.

C1.00080 High Optical Quality Organic Thin Films for Nonlinear Photonics Fabricated by Molecular Beam Deposition, MARTEN BEELS, Lehigh University, IVAN BIAGGIO TEAM¹ — We use small donor-acceptor substituted organic molecules that sublimate without decomposition to fabricate organic thin films by organic molecular beam deposition. These thin films have thicknesses of the order of micrometers and are well adapted for integrated nonlinear optics. These films are essentially amorphous, without the formation of microcrystals. They combine a high third-order susceptibility of the order of 1000 times that of fused silica with a high optical quality. Surface roughness is below +/- 5 nm for micrometer thick films. The films have been shown to be durable and robust, with a long shelf life (>2 years). We successfully integrated such films with silicon-on-oxide waveguides which have been used to demonstrate ultrafast all-optical switching on the silicon photonics platform, successfully demultiplexing a 170 GBit/s signal to 42 GBit/s.

¹Lehigh University

C1.00081 Nanoscopic Assembly of Organic Semiconductors for Organoelectronic Devices, BENJAMIN J. RANCATORE, CLAYTON E. MAULDIN, Department of Chemistry, UC Berkeley, JEAN M.J. FRÉCHET, College of Chemistry, UC Berkeley, TING XU, Department of Materials Science and Engineering, UC Berkeley — Small molecule organic semiconductors have many advantages over their polymer counterparts, including high purity and well-defined electronic properties. To fabricate organoelectronic devices, they need to form smooth thin films with control over their spatial organization to tailor the electronic percolation pathway. A quaterthiophene (4T) containing alkyl and phenolic moieties was hydrogen-bonded to the 4-vinylpyridine groups of a block copolymer, polystyrene-*b*-poly(4-vinylpyridine) (PS-*b*-P4VP) or a homopolymer, P4VP. These supramolecules can be readily cast into uniform films where the 4Ts form oriented nanostructures without hindering the charge mobility. We also extended this supramolecular approach to blends of symmetrically and asymmetrically-functionalized organic semiconductors at various mixing ratios. Fundamentally, present studies shine light on how to synergize two self-assembly processes, i.e. molecular ordering of organic semiconductors and microphase separation of BCP, and provide useful guidance toward directed hierarchical assemblies in multi-component systems. Present studies may also open a new route for the fabrication of nanostructured thin films of organic semiconductors using solution processing.

C1.00082 Connecting the Nanodots: Programmable Nanofabrication of Fused Metal Shapes on DNA Templates, MAURICIO PILO-PAIS, SARAH GOLDBERG, ENRIQUE SAMANO, HENOK MEBRAHTU, Duke University, THOMAS LABEAN, North Carolina State University, GLEB FINKELSTEIN, Duke University — We present a novel method for producing complex metallic nanostructures of programmable design. DNA origami templates, modified to have DNA binding sites with a uniquely coded sequence, were adsorbed onto silicon dioxide substrates. Gold nanoparticles functionalized with the cDNA sequence were then attached. These seed nanoparticles were later enlarged, and even fused, by electroless deposition of silver. Using this method, we constructed a variety of metallic structures, including rings, pairs of bars, and H shapes. Due to the flexibility of the design these structures may offer great promise for electronic and plasmonic applications.

C1.00083 π -Conjugated Copolymers of Thiophene: Effect of Chain Architecture on the Physical and Optoelectronic Properties for Photovoltaic Applications, JOJO AMONOO, EMMANOUIL GLYNOS, CHELSEA CHEN, ANTON LI, JONAS LOCKE, ANNE MCNEIL, PETER GREEN, University of Michigan, Ann Arbor, JOJO AMONOO, EMMANOUIL GLYNOS, CHELSEA CHEN, ANTON LI COLLABORATION, JONAS R. LOCKE COLLABORATION — We found that polymer chain architecture strongly influences phase separation capabilities of the donor-acceptor blend in bulk heterojunction organic photovoltaic devices. Ni-catalyzed controlled polymerization was utilized to access new conjugated copolymers of 3-hexylthiophene and 3-(hexyloxy)methylthiophene, two donor polymers. Monomer sequence was controlled along the copolymer chain by the rate of addition of the comonomers, to achieve diblock, random and gradient copolymer chain architectures. This allowed us to study the effect of copolymer sequence of polythiophene based copolymer/[6,6]-phenyl-C₆₁-butyric acid methyl ester (PCBM) blend on the structure, nanoscale morphology and local charge transport properties using conductive and photoconductive atomic force microscopy. The gradient configuration showed the largest phase separation behavior with PCBM.

C1.00084 Organic-Inorganic Nanocomposites by Placing Conjugated Polymers in Intimate Contact with Quantum Rods, ZHIQUN LIN, XINCHANG PANG, LEI ZHAO, Georgia Institute of Technology — Semiconductor organic-inorganic nanocomposites were synthesized by directly grafting conjugated polymer poly(3-hexylthiophene) onto cadmium selenide nanorods surface (i.e., P3HT-CdSe NR nanocomposites). The direct grafting was accomplished by two simple yet robust coupling reactions: Heck coupling of vinyl-terminated P3HT with bromobenzylphosphonic acid functionalized CdSe NRs (i.e., BBPA-CdSe), and a newly developed catalyst-free click reaction of ethynyl-terminated P3HT with azide functionalized CdSe NRs. Such rationally designed nanocomposites possessed a well-defined interface between P3HT and CdSe NRs, thereby promoting the effective dispersion of CdSe NRs within the nanocomposites and facilitating their electronic interaction. The success of grafting was confirmed by nuclear magnetic resonance spectroscopy and dynamic light scattering. The occurrence of charge transfer at the P3HT/CdSe interface was evidenced by UV-Vis absorption, photoluminescence (PL), and time-resolved PL studies. Notably, the nanocomposites prepared by the catalyst-free click reaction exhibited a faster charge transfer from P3HT to CdSe. These nanocomposites offer a maximum interfacial area between the constituents for efficient exciton dissociation. As such, it represents a significant advance in rational design and fabrication of organic-inorganic hybrid solar cells with improved power conversion efficiency.

C1.00085 ABSTRACT WITHDRAWN —

C1.00086 Studies on Morphology of Three-component Polymer Solar Cells, YU GU, THOMAS RUSSELL, University of Massachusetts-Amherst — We prepared solar cells with an active layer that contains three components, including poly(3-hexylthiophene) (P3HT), a low bandgap polymer poly[2,6-(4,4-bis(2-ethylhexyl)-4H-cyclopenta[2,1-b;3,4-b']-dithiophene)-alt-4,7-(2,1,3-benzothiadiazole)] (PCPDTBT) and [6,6]-phenyl C61-butyric acid methyl ester (PCBM). P3HT and PCPDTBT have complementary light absorption spectra such that, in parallel, the two cover a very broad range of the solar spectrum. It has been demonstrated that the power conversion efficiency of the P3HT/PCPDTBT/PCBM system is enhanced over that of either P3HT/PCBM or PCPDTBT/PCBM. Understanding the morphology developed for this system, therefore, can provide valuable insight into enhancing the performance of these technologically relevant and providing a fundamental challenge in controlling the phase behavior of such mixtures that undergo ordering. Morphological studies showed that the crystallization dynamics of P3HT was influenced by the presence of PCPDTBT. There are two domains existing in the thin films, one is pure P3HT domains and another is PCBM-rich domains mixed with amorphous PCPDTBT and P3HT.

C1.00087 Diketopyrrolopyrrole (DPP)-based low band gap polymers for efficient solar cells, FENG LIU, YU GU, UMASS-Amherst, CHENG WANG, LBNL, WEI ZHAO, DIAN CHEN, ALEJANDRO BRISENO, THOMAS RUSSELL, UMASS-Amherst — For bulk heterojunction (BHJ) organic photovoltaic (OPV) devices, effective strategies to maximize the performance have to be developed and fundamentally understood. In BHJ-type solar cells, the ability to control and optimize the active layer morphology is critical. A BHJ OPV of diketopyrrolopyrrole (DPP)-based low band gap polymer with phenyl-C71-butyric acid methyl ester (PCBM) was studied. DPP-based polymers are highly crystalline. The use of mixed solvents was critical in developing an optimal BHJ morphology, that was characterized by GISAXS and GIWAXS. In thin films, the polymer adopts an edge-on orientation and the blends are phase separated without thermal annealing. The diffusion of PCBM into the DPP polymer is markedly different from that observed with P3HT. The development of the morphology during solvent evaporation was studied in real-time by x-ray scattering and diffraction.

C1.00088 From carbon dioxide to organic compounds: Novel cathode materials for microbial electrosynthesis, MENG MENG CUI, TIAN ZHANG, HUARONG NIE, HAIYUN LU, DEREK LOVLEY, THOMAS RUSSELL, University of Massachusetts-Amherst — Electrode materials play an important role in the production of organic compound during microbial electrosynthesis, which uses bacteria as a catalysts to reduce carbon dioxide to organic compounds and stores electric energy in carbon-carbon bonds. An ideal electrode generally has high surface area, high electric conductivity, physical and chemical stability, and biocompatibility with bacteria. Based on these criteria, three types of materials were considered for the electrode design: CNTs, metal, and conductive polymers. Through a combination of these three materials, different properties were incorporated onto the electrodes for microbial electrosynthesis. The morphologies of the electrodes were characterized by high resolution TEM, SEM, and laser scanning confocal microscopy. The productivity of organic compounds was also verified.

C1.00089 Dynamics of Poly(ethyleneoxide) in the Presence of LiTFSI: Neutron Spin Echo and Dielectric Spectroscopy Study, CHANGWOO DO, Neutron Scattering Directorate, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, XIAO-GUANG SUN, Chemical Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, MICHAEL OHL, JÜRGEN ALLGAIER, Jülich Centre for Neutron Science, Forschungszentrum Jülich, 52425 Jülich, Germany, MARION GÖTZ, PETER LUNKENHEIMER, ALOIS LOIDL, Center for Electronic Correlations and Magnetism, University of Augsburg, 86135 Augsburg, Germany, DIETER RICHTER, Jülich Centre for Neutron Science, Forschungszentrum Jülich, 52425 Jülich, Germany — Rechargeable lithium-ion batteries based on solid polymer electrolytes (SPEs) offer many advantages over their liquid counterparts. In comparison to a liquid electrolyte, the solid polymer is less flammable and more environmentally friendly. Issues such as microscopic dynamics of lithium ions and their dependence on their polymeric matrix are known to play a key role in determining the ionic conductivity in SPEs. Therefore, understanding of the microscopic dynamic characteristics of the lithium ions in relation with the dynamics of surrounding polymeric matrix is a crucial step for the interpretation of their transportation behavior and ultimately toward the control of their properties. Here, we investigated dynamics of poly(ethylene oxide) (PEO) in the presence of LiTFSI using neutron spin echo and dielectric spectroscopy techniques. Experimental results suggest that the dynamics of PEO is dramatically slowed down and strong correlation between ion transportation and alpha-relaxation of PEO.

C1.00090 Effect of Solvating Plasticizers on Ion Conduction of Polysiloxane Single-ion Conductors with Lithium Tetraphenyl Borate and Cyclic Carbonate Side Chains¹, U. HYEOK CHOI, SIWEI LIANG, Penn State University, MICHAEL O'REILLY, KAREN WINEY, University of Pennsylvania, JAMES RUNT, RALPH COLBY, Penn State University — We synthesize polysiloxane single-ion conductors containing two side groups: cyclic carbonates as a polar group and weak-binding tetraphenyl borate anions with Li⁺ counterions as an ionic group. With increasing ion content, the ionomer T_g increases because of ion aggregation, making the conductivity drop greatly. To enhance segmental mobility and decrease the tendency for ion aggregation, this ionomer was plasticized with poly(ethylene glycol) (M_n = 600, PEG600) to various extents. The room temperature conductivity of the plasticized ionomer is 3 orders of magnitude higher than that of the neat ionomer. Addition of PEG600 increases ion mobility by lowering T_g and increases conducting ion content due to raising the dielectric constant. This suggests that PEG600 plays an important role by solvating Li⁺ so as to lower T_g by dissolving ionic aggregates, consistent with X-ray scattering, which shows the ionomer aggregation peak decreases in intensity as PEG600 is added.

C1.00091 Fine-tuning Structures from Molecules to Nanophases: Insight into the Origin of Superior Organic Photovoltaic Efficiency¹, WEI CHEN, SETH DARLING, Center for Nanoscale Materials, Argonne National Laboratory — Organic photovoltaics (OPV) represent one of the most promising technologies for next-generation solar energy conversion due to their low-cost and scalability. To realize this potential, efficiencies must be improved for which a deeper understanding of the nanoscale morphology and molecular organization is required. Using the state-of-the-art PTB series of conjugated copolymers synthesized at the University of Chicago, we probed the internal structure of these materials both in solution and in films containing polymer/fullerene blends using a suite of tools spearheaded by neutron and x-ray scattering and, thereby, conceive the structural evolution from solution to thin films. Fine-tuning molecular structures via selective atomic replacement on the main chain of PTB copolymers, we gained unique insights into the structure-performance relationships, especially key features such as intermixing of polymers with fullerenes. Progress established in the course of these structural and morphological characterizations outline above will serve as the foundation for further improving the efficiency of polymer solar cells to realize their large-scale commercial use.

¹W. Chen gratefully acknowledges financial support from Argonne Director's Postdoctoral Fellowship. This work is partially supported by a University of Chicago-Argonne Strategic Collaborative Initiative Seed Grant.

C1.00092 Tuning Ion Conducting Pathways Using Holographic Polymerization¹, DERRICK SMITH, CHRISTOPHER LI, BIN DONG, Drexel University, TIMOTHY BUNNING, Air Force Research Lab — While much research has demonstrated repeatable characteristics of electrolyte membranes, the fundamentals behind the interactions during ionic diffusion in solid polymer electrolyte membranes for battery applications are not well understood, specifically the role of nanostructures, which hold the key to improving performance of energy storage devices such as fuel cells and Lithium ion batteries. The challenges in fabricating highly controlled model systems are largely responsible for the interdependent ambiguities between nanostructures and the corresponding ion conducting behavior. In this work, Holographic Polymer Electrolyte Membranes (hPEM) volume gratings comprised of alternating layers of crosslinked polymer resin and lithium ion salt were fabricated using holographic polymerization with an average d-spacing of approximately 200 nm. These one-dimensional confinement structures were used to quantitatively study the anisotropic ionic conductivity between the directions of in-plane and normal to the layers, and the unique ion conducting behavior was correlated with nanoscale phase separation. These volume gratings also offer an exciting route to fabricate multifunctional gratings for optic and sensing applications.

¹NSF DGE-0654313, CMMI-0900162 and DMR-0804838

C1.00093 Tuning interfacial interactions between conjugated polymers and inorganic nanocrystals for control over bulk thermoelectric properties, BORIS RUSS, NELSON COATES, SHANNON YEE, Department of Chemical Engineering, University of California, Berkeley, CA and Lawrence Berkeley National Laboratory, Berkeley, CA, JEFFREY URBAN, Lawrence Berkeley National Laboratory, Berkeley, CA, RACHEL A. SEGALMAN, Department of Chemical Engineering, University of California, Berkeley, CA and Lawrence Berkeley National Laboratory, Berkeley, CA — Electronic transport in conjugated polymers is highly dependent on doping level and chain conformation. Recent advances in next-generation thermoelectric devices rely on the fabrication of conjugated-polymer:inorganic-nanocrystal composites, but little is known about the how the thermoelectric properties are influenced by the doping level or morphology of the conjugated polymer at the organic-inorganic interface. A thorough understanding of the coupling between the molecular orbitals of conjugated polymers and the energy states of inorganic materials in such systems is, therefore, paramount for achieving improvements in these devices. In this study, we present our results on the coupling between Poly-(3-hexylthiophene) (P3HT), a well-studied conjugated polymer, with solution-processed lead selenide (PbSe) nanocrystals of controlled shape and morphology. Conjugated oligomeric ligands are used to tailor the organic/inorganic interface between P3HT/PbSe. Our results address the effects of polymer conformation on the nanocrystal surface, polymer doping levels, and organic-inorganic energy level alignment on the bulk thermoelectric properties of these hybrid materials.

C1.00094 Donor-acceptor block copolymer self-assembly in polymer-based photovoltaics, MICHAEL A. BRADY, SUNG-YU KU, JUSTIN E. COCHRAN, NEIL D. TREAT, CRAIG J. HAWKER, MICHAEL L. CHABINYC, EDWARD J. KRAMER, University of California, Santa Barbara — Polymer-based photovoltaics represent potentially low-cost, solution-processable devices for achieving sustainable energy generation. The optimal polymer-fullerene bulk heterojunction photovoltaic relies on a phase-separated microstructure in which domains of each component exist to allow for exciton dissociation at the interface and transport of each free electron (hole) through the n-type (p-type) domain to the cathode (anode). Due to the kinetically trapped, complex microstructure and phase-impure domains formed in this multi-component system, the development of a single-component material with pure n- and p-type domains is of great interest. Here we explore the microstructural evolution of a diblock copolymer of donor and acceptor segments, P3HT-b-DPP, due to various thermal treatments. Atomic force microscopy (AFM), resonant soft X-ray scattering (RSoXS), and grazing incidence wide-angle X-ray scattering (GIWAXS) are exploited to demonstrate that thermal treatments above the melting transition of each segment lead to an ordered domain structure containing both types of crystals. The effect of cooling rate from the melt on domain size and crystalline structure within those domains is investigated.

C1.00095 Synthesis and Characterization of a Systematic Series of All-Conjugated Diblock Copolymers¹, KENDALL SMITH, RAFAEL VERDUZCO, Rice University — All-conjugated block copolymers can potentially self-assemble into nanoscale structures beneficial for charge separation and transport, but due to synthetic challenges a comprehensive investigation of all-conjugated block copolymers has not been carried out. Here we detail a novel synthetic approach to all-conjugated block copolymers and characterize the structure of a systematic series of materials. The materials are prepared via copper-catalyzed azide-alkyne click chemistry followed by selective solvent removal of homopolymer impurities. This allows us to readily vary the molecular weight and type of each block in order to systematically study the properties of a family of block copolymers. As a system relevant to organic photovoltaics, we investigate a series of diblock copolymers based on poly(9,9-dioctyl-fluorene) and poly(3-alkylthiophene). This series of block copolymers is characterized with respect to phase behavior, including micro-phase segregation and crystallinity, optical properties, and charge mobilities.

C1.00096 Incorporation of Functionalized Metal Oxides into Poly(Ethylene Oxide) Based Solid Polymer Electrolytes for Lithium-Ion Batteries, ERIC ANDERSON, YUYING TANG, University of Massachusetts Amherst Department of Polymer Science and Engineering, CRAIG VERSEK, MARK TUOMINEN, University of Massachusetts Amherst Department of Physics, SAMUEL GIDO, JAMES WATKINS, University of Massachusetts Amherst Department of Polymer Science and Engineering — A detailed study on the influence of size and shape as well as surface properties of metal oxides incorporated into poly(ethylene oxide) based solid polymer electrolytes for lithium-ion batteries is explored. The morphology of the solid polymer electrolyte is determined using small angle x-ray scattering and transmission electron microscopy. The surface properties of the metal oxide are modified through silane chemistry. Surfaces are modified to be hydrophobic, hydrophilic, high dielectric constants, as well as single-ion conductors. The electrochemical properties of the solid polymer electrolyte systems are investigated by electrochemical impedance spectroscopy and cyclic voltammetry. These functionalized metal oxide particles not only reduce crystallinity of poly(ethylene oxide) based solid polymer electrolytes, but also increase the conductivity.

C1.00097 Morphology Study of Bulk Heterojunction Solar Cells Based on PCDTBT, HSIN-WEI WANG, THOMAS RUSSELL, TODD EMRICK, UMass Amherst — To achieve high efficiency, the processing of conditions bulk heterojunction photovoltaic are important so that the desired morphology favoring efficient charge separation, electron and hole transportation can be generated. Solar cells based on poly[N-9'-hepta-decanyl-2,7-carbazole-alt-5,5-(4',7'-di-2-thienyl-2',1',3'-benzothiadiazole) (PCDTBT) as the donor system have been made. The effect of solvent, additives and annealing temperature have been systematically investigated. Grazing incidence small angle scattering (GI-SAXS), wide angle scattering (GI-WAXS), transmission electron microscopy (TEM), scanning electron microscopy (SEM) and atomic force microscopy (AFM) were utilized to study the morphology.

C1.00098 Comb-branched Polymer Electrolytes: Architectural Changes That Promote Increased Li^+ Transport, ROBERT DEMILLE, Department of Chemistry, University of Utah, SOWMYA MURTHY, DMITRY BEDROV, GRANT SMITH, Department of Materials Science and Engineering, University of Utah — The use of solid polymer electrolytes (SPEs) in the batteries of next generation technology applications is promising due to their safety and stability, yet is also hindered by low conductivity and high temperature requirements. Recent simulations of comb-branched poly(epoxide ether)-based SPEs have shown the comb-branched architecture to be able to overcome some of these hindrances. While providing the advantage of preventing crystallinity and allowing the optimization of the backbone to be decoupled from that of the side chain, the comb-branched SPE studied suffers from slow Li^+ cation dynamics due to coordination with the backbone. To improve Li^+ transport, we have modified the architecture of the comb-branched poly(epoxide ether) by attaching the side chains to the backbone with non-coordinating, flexible spacers. Inclusion of these spacers has resulted in a five-fold increase in the diffusion of Li^+ cation effected through 1) an increased side chain flexibility, 2) a decreased interaction of the cation with the dynamically slow backbone, and 3) quick conformational dynamics of the entire side chain. Additionally we report on other desirable architectural changes, such as including carbonate solvating moieties, to comb-branched SPEs allowing enhanced mobility of Li^+ .

C1.00099 Fluid Properties in Electromagnetic Fields¹, SEAN CANTU, University of Houston Clear Lake, SAMINA MASOOD, University of Houston Clear Lake — We study the effect of electromagnetic fields on the fluid properties to see if the modifications in the fluids properties are causing the effect of magnetic fields on the bacterial growth. For this purpose we design a simple experiment to study the changes in spectrum of light through the nutrient broth that is the fluid used to study the bacterial growth.

¹The authors will like to acknowledge TSGC grant for this submission

C1.00100 Electro-coflow as a route to drop generation, JOSEFA GUERRERO, ALBERTO FERNANDEZ-NIEVES, VENKATA R. GUNDABALA, Georgia Tech — We couple electric and hydrodynamic forces in glass-based microfluidic devices to generate droplets in steady state. The size of the drops can be larger, comparable and smaller than the tip diameter, which is the smallest geometric feature of the device.

C1.00101 Water nano-hydrodynamics: The interplay between interfacial viscosity, slip and chemistry, HSIANG-CHIH CHIU, School of Physics, Georgia Institute of Technology, DEBORAH ORTIZ-YOUNG, School of Chemistry, Georgia Institute of Technology, ELISA RIEDO, School of Physics, Georgia Institute of Technology — The understanding and the ability to manipulate fluids at the nanoscale is a matter of continuously growing scientific and technological interest. Fluid flow in nano-confined geometries is relevant for biology, polymer science and geophysics. The applications range from gene sequencing to protein segregation, cell sorting, sensors, nanotribology and diffusion through porous media. Here, we present experiments which show how the interfacial viscosity of water strongly depends on the wetting properties of the confining surfaces. This dependence is fully explained by considering water slippage at the stationary solid surface. The interfacial viscous forces as a function of six surfaces with different wettability are fitted with a modified form of the Newtonian definition of viscosity, which takes into consideration the fluid slip. This simple relationship can explain the viscosity measurements and permits us to extract a “slip parameter” for each investigated surface. This slip parameter is found to increase with the static contact angle of the solid surface as expected from previous work, bringing clear evidence of the relationship between viscosity and slip.

C1.00102 Investigating the hydrodynamics of asymmetrically driven polymer brushes in micro-channels¹, IBRAHIM SOUKI, MOHAMED LARADJI, University of Memphis, P.B. SUNIL KUMAR, Indian Institute of Technology Madras — The interfacial hydrodynamics between a polymer brush, under the influence of an asymmetric external driving field, and the surrounding solvent is explored across varying grafting densities, field strengths, and polymer chain lengths. A soft core model based on dissipative particle dynamics is used along with a 2-body FENE potential and a 3-body harmonic potential which define the internal mechanics of the polymer chains. The morphology of the polymer chains and the shearing produced at the interface layer between the polymer and solvent regimes is investigated as a function of hydrodynamic coupling to the external driving field. The momentum transfer and drag forces at the interface are shown to be the primary factors which lead to coupling and a directed non-zero net flow of the surrounding solvent through the coplanar nano-channel. The aim of the model is to introduce a novel mechanism to circumvent the large pressure gradients necessary to sustain fluid flow through micro/nano-pores as a consequence of Poiseuille's law.

¹This work was supported by NSF (EPS-1004083).

C1.00103 Solid Polymer Electrolytes by Self Assembly of Multi-Ionic Janus POSS Li-Salts in Polyethylene Oxide, STEPHANIE WUNDER, PARAMESWARA RAO CHINNAM, Temple University — Solid polymer electrolytes (SPEs), of which the most investigated has been polyethylene oxide (PEO), have low room temperature (RT) ionic conductivities and low lithium ion transport numbers. PEO is semicrystalline, with a glass transition temperature, T_g , of -60 °C and a melt temperature, T_m , of ~ 65 °C. Since lithium ion conduction occurs in the amorphous phase of PEO, conductivities $> 10^{-4}$ S/cm are only obtained after the crystalline domains have melted. Although high concentrations of lithium salts can eliminate the crystallization that causes the low conductivity at RT, the result is an amorphous liquid, not a solid. In order to impart structural rigidity to a noncrystalline PEO at RT, we have developed Janus-like multi-ionic lithium salts, in which one half of the salt is ionic in character, and the other half is hydrophobic. These salts are highly dissociative, imparting RT conductivities $> 10^{-4}$ S/cm and the hydrophobic ends aggregate. A phase separated morphology is formed in which the hydrophobic moieties form crosslink sites, and impart a solid state morphology, and the Li^+ ions dissociate into the conductive, amorphous PEO phase.

C1.00104 Molecular-based polyhedral crystalline colloids, MELINDA SINDORO, NOBUHIRO YANAI, STEVE GRANICK, University of Illinois at Urbana Champaign — We fabricate a new family of colloids with polyhedral morphology by controlled crystallization of metal ions and organic bridging ligands in the presence of capping reagents. The size and morphology of the crystalline colloids can be tuned by changing the ratio of the metal ions to the organic ligands and the amount of the capping reagents. Unlike spheres that isotropically interact along a curved surface, the polyhedral particles in suspension associate in a directional facet-to-facet fashion, forming clusters whose elemental units are orderly not only in interparticle distance but also mutual orientation. We also present unique supraparticle structures obtained by mixing different particles.

C1.00105 Molecular dynamic simulations of hydrophilically decorated poly-dots, SIDATH WJESINGHE, DVORA PERAHIA, Clemson University, GARY S. GREST, Sandia National Laboratories — The structure and interfacial characteristics of nanoparticles formed by collapsed single conjugated polymer chains decorated with hydrophilic groups, poly *para* phenylene ethynylene (PPE) with substituted carboxylate side chains, have been studied by molecular dynamic simulations. These particles constitute a new type of light emitting/harvesting entities. Their interactions with the surrounding will determine their use where for example, directed interactions with membranes are essential for penetrating into organisms as bio markers. Trapping pre-decorated polymer chains into the nano dimensions with the expectations that some of the decorated groups will statistically reside at the nanoparticle interface has opened the way to control the surface decoration and hence the interactions of these particles. The effects of the distribution of the decorating groups along the polymer backbone on the conformation of the polymer chain within the poly dot and the resulting interfacial distribution of the COONa groups will be presented. The distribution of the hydrophilic groups at the surface of the particles will direct their interactions with the environment.

C1.00106 Optical Force Probe Microscopy of the Pericellular Matrix, LOUIS T. MCLANE, PATRICK CHANG, School of Physics, Georgia Institute of Technology, ANNA GRANQVIST, The Renal Center, The Wallenberg Laboratory for Cardiovascular Research, Sahlgrenska University Hospital, HEIKE BOEHM, New Materials and Biosystems, Max Planck Institute for Metals Research, Stuttgart, Germany, ANTHONY KRAMER, JENNIFER E. CURTIS, School of Physics, Georgia Institute of Technology — The pericellular matrix is a microns-thick grafted polymer film on the surface of cells. Its structure and mechanics influence processes as diverse as filtration, cell adhesion, proliferation, migration, cancer metastasis and possibly mechanotransduction. Optical force probe microscopy enables dynamic and equilibrium measurements of this polymer film on living cells. We show that equilibrium force measurements can be related to the osmotic pressure in the pericellular matrix, leading to a prediction of a spatially varying correlation length (mesh size) profile ranging from ~ 100 nm at the cell surface to 1000 nm near the edge of the cell coat. Assuming the film is brush-like, comparison to polymer brush theory provides estimates of the equilibrium brush length and the grafting density at the surface. The equilibrium length is consistent with that observed during dynamic force measurements, and the grafting density is close to that of maximal packing for the large, space filling molecules in the system - i.e. tethered polymers populated by semi-flexible side chains with cross sections $\sim 80 \times 400$ nm².

C1.00107 Mapping optical trapping energy of nanoparticles via confocal microscopy¹, MIN YAO LIM, Carleton College — Optical traps are highly focused laser beams that can hold and manipulate objects of microscopic scale. They are used to study the motion and energy of particles such as colloids or DNA molecules. In order to achieve this purpose we first propose to determine the energy of optical traps. We use a fluorescent nanoparticle ensemble within the optical trapping volume along with confocal microscopy to map the fluorescence intensity distribution of nanoparticles. This mapping allows us to calculate the trapping energy profile in three dimensions. We repeat this process with different trapping powers to find the depth of the trapping potential well as a function of trapping power. Trapping energy per trapping power thus measured is consistent with results obtained through previous methods such as fluorescence correlation spectroscopy conducted by our research group. With this technique of mapping trapping energy we can further study particle-particle interactions.

¹This research was funded by the National Science Foundation (NSF) Research Experience for Undergraduates (REU) grant PHY-0849416, NSF grant DMR-0923299 and the Karas Undergraduate Research Internship at Lehigh University.

C1.00108 Structural analysis of three-dimensional photonic crystals in nature¹, BEOM-JIN YOON, JUNG OK PARK, MOHAN SRINIVASARAO, School of Materials Science and Engineering, Georgia Institute of Technology, Atlanta, GA — We studied the structural origin of the color and photonic band structure in exoskeletons of Eupholus weevils and dorsal wings of lycaenids butterflies. The internal structures of the insects were systematically investigated using focused ion beam (FIB) milling, and the optical response of the insects was observed by optical microscopy and a microspectrophotometer. A series of sequential SEM images were obtained during the FIB milling process and 3D structures were reconstructed by image processing. The correlation of the structures and the optical responses were studied by theoretical modeling. Diamond-based 3D photonic crystal lattice existed in Eupholus weevils, while gyroid structure was in lycaenids butterflies. The calculated photonic band structures matched the measured optical response. Aluminum oxide and titanium oxide were deposited on the weevils and the butterflies in order to study the effect of refractive index contrast to the photonic band structure and the optical response.

¹This work was partially supported by NSF funding (DMR-0907529).

C1.00109 Structure and Dynamics of Polymer-Coated Nanoparticles in Ionic Liquids Studied by In-Situ Electron Microscopy, PAUL KIM, THOMAS RUSSELL, DAVID HOAGLAND, Polymer Science and Engineering Department, University of Massachusetts, Amherst, MA 01002 — Ionic liquids (ILs) have unique solvent properties, including extremely low vapor pressure and high conductivity, which makes IL-solvated soft matter systems suitable to investigation by electron microscopy. ILs, as two-component solvents, may themselves organize into nanostructures, and these organizations can affect the behavior of dispersed polymers/particles. To understand these effects, the structure and dynamics of nanoparticles IL systems have been studied via multiple-particle tracking with electron microscopy. Several systems consisting of different polymer-coated nanoparticles, different ILs, and different substrates were prepared and analyzed with fluorescent microscopy, scanning electron microscopy (SEM), and transmission electron microscopy (TEM). Spatial and temporal imaging information affords insight into particle-IL and polymer-IL interactions.

C1.00110 Polymer Conformation near the Critical Demixing Point of a Binary Solution, LILIN HE, Oak Ridge National Laboratory, GANG CHENG, Sandia National Laboratory, YURI MELNICHENKO, Oak Ridge National Laboratory — We have used Contrast Matching Small Angle Neutron Scattering (CMSANS) to probe directly the conformation change of polyethylene glycerol (PEO) chains in the critical demixing region of Acetonitrile-d₃ in (D₂O + H₂O) at concentration of the components corresponding to zero-average contrast condition. The d-PEO and h-PEO were mixed to match the scattering length density (SLD) of the critical liquid solution, which allowed us to extract single-chain dimension of polymer molecules in the aggregates near the critical point of the solvent. A non-monotonic variation of R_g was detected as temperature approached the critical temperature of phase demixing of acetonitrile- water solution, which was attributed to the interaction asymmetry of the solvent molecules with polymers predicted by Brochard and de Gennes two decades ago. To our best knowledge, this is the first direct experimental evidence supporting this prediction.

C1.00111 Fluorescent Polystyrene Sulfonate for Polyelectrolyte Studies, WAYNE HUBERTY, XIAOWEI TONG, SREELATHA BALAMURUGAN, DONGHUI ZHANG, PAUL RUSSO, Louisiana State University — The slow-mode decay found by dynamic light scattering for polyelectrolytes in low-salt conditions has perplexed investigators since its first observation. Many characterization methods have suggested temporary or transient aggregation, although there is still no consensus on the cause. Many different polyelectrolytes demonstrate the slow-mode decay, but the sodium salt of polystyrene sulfonate (NaPSS) is the most popular choice for study. Commercially available NaPSS may have hydrophobic patches due to incomplete sulfonation leading to associations apart from any putative ionic mechanisms. Therefore, essentially full sulfonation, or "patchless", NaPSS should be synthesized. To facilitate fluorescence measurements, which can provide new insights to the slow-mode phenomenon, the material must be rendered fluorescent (F-NaPSS). Several approaches to F-NaPSS have appeared; some labeled a previously synthesized NaPSS without concern for its hydrophobic patches. Other strategies include a free radical copolymerization of styrene sulfonate and a vinyl amine to provide side chains viable for labeling. This method is successful, but yields only small amounts of nearly monodisperse polymer after fractionation. In this presentation, a high-yield synthesis of fully sulfonated, low-polydispersity, fluorescently tagged polymer will be discussed.

C1.00112 Electromagnetic Propagation of Waves in Helical Stochastic, REYES ADRIAN, DAVID MENDEZ, Instituto de Fisica Universidad Nacional Autonoma de Mexico — We develop a model for studying the axial propagation of elliptically polarized electromagnetic waves in a spatially random helical media. We start by writing Maxwell equations for a structurally chiral medium whose helical angle contains both a stochastic contribution and a deterministic one, this latter corresponding to a uniform rotation. We write the electromagnetic equations into Marcuvitz Schwinger representation to transform them afterward by using the Oseen transformation. We exhibit that in the Oseen frame, Marcuvitz Schwinger equations turns out to be a linear vectorial stochastic system of equations with multiplicative noise. From this result and utilizing a well known formalism for treating stochastic differential equations, we find the governing equations for the first and second moments of the field amplitudes for a general correlation model for the slope angles, and calculate their corresponding band structure for a particular spectral noise density. We show that the average resulting electromagnetic fields exhibit dissipation and the appearance of a new reflection band whose chirality is the opposite of the one obtained for a simple cholesteric liquid crystals.

C1.00113 Flow Instability of Soft Gels from Pluronic F108 Aqueous Solution Under Steady Shear, HANJIN PARK, Rensselaer Polytechnic Institute, GYOO YEOL JUNG, Pohang University of Science and Technology, CHANG YEOL RYU, Rensselaer Polytechnic Institute — Nonionic surfactants of Pluronic tri-block copolymers have received special interest during the past decades because of the temperature dependent self-assembly characteristics that would lead to the formation of hydrogels upon heating. Here, we investigate the gelation behavior of Pluronic F108, (PEO)132-(PPO)50-(PEO)132, aqueous solution with an aim to elucidate how the shear affects the thermo-reversible transitions between micellar liquids and hydrogels. Specifically, we have studied the rheological characteristics of soft gels as an intermediate state between liquid to hard gels. From steady shear experiments, we found that there exists a shear rate window, where the flow instability of soft gels is observed. On the contrary, non-Newtonian behaviors following power-law are still observed at the shear rates above and below the shear rate window showing the flow instability. Small angle x-ray scattering and dynamic light scattering experiments had been performed to reveal how the temperature dependent rheological behavior correlates with the structural changes in the micellar aqueous solutions of F108.

C1.00114 Fourth-order Fluctuations near the Colloidal Glass Transition, CHRIS WAGENBACH, NATHAN ISRAELOFF, Northeastern University — Fourth-order statistical fluctuations are probed in order to determine the size of cooperative regions as the colloidal glass transition is approached. The experiment makes use of the electrical conductance of a colloidal fluid containing KCl measured through a micropore in a membrane placed in the colloid. The diameter of this micropore is adjusted to be at least ten times the diameter of the colloidal particles. The dynamics of the particles near and within the pore are revealed in the fluctuations of the conductance. For the largest particles, a polydisperse sample of 106 to 125 microns, the dynamics are driven by a mechanical shaking, while for the smaller particles, <10 microns, Brownian motion drives the dynamics. Using a spherical probe, we mapped the conductivity change near the pore which enabled us to determine that the effective volume for the fourth-order fluctuations was $\sim 1.5D^3$, where D is the diameter of the membrane pore. Thus, near the glass transition at a volume fraction of .58, the number of particles probed is about 1700 which is small enough to see the growth of fourth-order fluctuations. It is hoped that this technique can be applied to very small, ~ 100 nm, particles for which the cooperative length can be studied over a wide range of volume fractions.

C1.00115 Migration of Surfactant Vesicles during spontaneous emulsification, DOMINIK MICHLER, NOUSHINE SHAHIDZADEH, RUDOLF SPIRIK, PETER SCHALL, DANIEL BONN, Soft Matter, Van der Waals-Zeeman Instituut, Universiteit van Amsterdam, SHELL COLLABORATION — In aqueous AOT solutions, micrometer sized vesicles appear above the critical micelle concentration. These vesicle move spontaneously towards an oil interface and form an emulsion under the condition of ultra low interfacial tension. We discuss the probable mechanisms that lead to the migration behavior of these vesicles.

C1.00116 Controlling Droplet Impact with Polymer Additives, MICHAEL SMITH, University of Nottingham, VOLFANGO BERTOLA, University of Liverpool — When a water drop falls on to a hydrophobic surface, such as the waxy leaf of a plant, the drop often bounces off leading to wasted agrochemicals which harm the environment. However, adding small quantities ($\sim 100 \mu\text{gml}^{-1}$) of a flexible polymer can completely prevent rebound. This is surprising since the shear viscosity and surface tension of such drops are almost identical to those of pure water. The effect has for some time been explained in terms of the stretching of polymer chains by a velocity gradient in the fluid, resulting in a transient increase in the so-called “extensional viscosity.” We have developed an epi-fluorescent microscope system, to visualise the flow of fluid inside an impacting drop using tracer particles at 2000 fps. Analysis of the velocity as a function of radius showed negligible differences between water and polymer drops except near the edge, indicating that the extensional viscosity cannot be responsible for the anti-rebound effect. To probe the true mechanism, fluorescently labelled λ -DNA was used to visualise the edge of an impacting drop. During the retraction phase, DNA was shown to be stretched by the retreating droplet providing an “effective friction” at the contact line.

C1.00117 Glints of light reveal properties of coiled electrospinning jets in flight, DARRELL H. RENEKER, KAIYI LIU, The University of Akron — Optical observations of jets provide information needed to control features of polymer nanofibers produced by electrospinning. Quantitative information about the location, vector velocity, and rotation of selected segments of the multiply coiled path of an electrospinning jet of polymer solution was provided by a combination of videography, stereography, and stop motion flash photography. Visual observations of a jet depend largely on glints of incident light that are specularly reflected from particular places on the multiply coiled jet path. The traces of moving glints bifurcate when a new turn is added to a coil, at an observed rate of 600 turns per second. The polarization of light, in glints reflected at Brewster's angle, allows measurement of the index of refraction of the fluid in a jet, in flight. Strategic placement of lights to either illuminate, or leave dark, parts of the coils, make both the handedness and changes in handedness of the electrical bending coils apparent to visual observation. The changes occurred at intervals of a few seconds in our experiments. Evidence was found, in the form of ribbon-like glint traces that were polarized, for the occurrence of undulations on the surface of some jets.

C1.00118 Digital Reconstruction of 3D Polydisperse Dry Foam, A. CHIECO, K. FEITOSA, Dept. of Physics and Astronomy, James Madison University, A.E. ROTH, P.T. KORDA, D.J. DÜRIAN, Dept. of Physics and Astronomy, University of Pennsylvania — Dry foam is a disordered packing of bubbles that distort into familiar polyhedral shapes. We have implemented a method that uses optical axial tomography to reconstruct the internal structure of a dry foam in three dimensions. The technique consists of taking a series of photographs of the dry foam against a uniformly illuminated background at successive angles. By summing the projections we create images of the foam cross section. Image analysis of the cross sections allows us to locate Plateau borders and vertices. The vertices are then connected according to Plateau's rules to reconstruct the internal structure of the foam. Using this technique we are able to visualize a large number of bubbles of real 3D foams and obtain statistics of faces and edges.

C1.00119 Asymptotic Behavior in Liquid Drop Coalescence, JOSEPH PAULSEN, JUSTIN BURTON, SIDNEY NAGEL, University of Chicago, SANTOSH APPATHURAI, MICHAEL HARRIS, OSMAN BASARAN, Purdue University — During coalescence, two drops first touch and then merge, as a liquid bridge grows from initially microscopic scales to a macroscopic size comparable to the drop diameter. The initial dynamics of coalescence are expected to be universal, owing to a singularity in the Laplace pressure, which diverges when the curvature of the liquid interface is infinite at the point where the drops first touch. Conventionally, this process has been thought to have just two regimes: a highly viscous one dominated by macroscopic flows pulling the two drops together and an inertial one described by local deformations near the growing neck. We use high-speed imaging, electrical measurements and full Navier-Stokes simulations to reveal a new regime that dominates the asymptotic dynamics of coalescence for any finite viscosity. The character of this new regime improves our understanding of the unexpectedly late viscous-to-inertial crossover [1]. An argument based on force balance and an appropriate choice of length-scales allow the construction of a new phase diagram of coalescence.

[1] J. D. Paulsen, J. C. Burton, S. R. Nagel, PRL 106, 114501 (2011).

C1.00120 Carbon nanotube-induced chirality and macroscopic helical twist in achiral liquid crystals, RAJRATAN BASU, KRYSTA BOCCUZZI, SAMEH FERJANI, Case Western Reserve University, ROBERT LEMIEUX, Queen's University, ROLFE PETSCHKE, CHARLES ROSENBLATT, Case Western Reserve University — A small quantity of carbon nanotubes was dispersed in an achiral liquid crystal, and the mixture was found to exhibit a weak degree of chirality both in the smectic and nematic phases. The induced chirality in the LC was probed by means of the electroclinic effect in the liquid crystal's smectic-*A* and nematic phases, which showed significant pretransitional behavior on approaching the smectic-*A* – smectic-*C* and the nematic – smectic-*A* transition temperatures, respectively, from above. The carbon nanotubes also were found to induce a bulk twist over macroscopic dimensions in an achiral nematic matrix. The nanotube-induced chiral pitch length *P* was determined as a function of average nanotube concentration by measuring the radii of curvature of reverse twist disclination lines in 90° twist nematic cells. The results reveal information about the nanotubes' spatial distribution inside the cells. A concentration for the onset of significant aggregation of the nanotubes can be quantified from the apparent saturation of P^{-1} at higher concentrations. The macroscopic helical twisting power of the nanotubes has been estimated from the results. The results indicate that there is a net chirality associated with the carbon nanotubes, which is transmitted into the achiral liquid crystal.

C1.00121 Pretransitional Clusters in Multicolor Liquid Crystalline Honeycombs¹, GORAN UNGAR, XIANGBIN ZENG, FENG LIU, Dept. Materials Sci. Eng., University of Sheffield, Sheffield, UK, ROBERT KIEFFER, CONSTANCE NÜRNBERGER, CARSTEN TSCHIERKE, Institute of Organic Chemistry, Martin Luther University, Halle, Germany, GILLIAN GEHRING, Dept. Physics & Astronomy, University of Sheffield, Sheffield, UK — X-shaped tetraphilic molecules consisting of a rod-like core with two hydrogen-bonding terminal groups and two mutually incompatible side-chains A and B form a range of honeycomb-like structures in which the rods act as bricks in the walls of polygonal cylinder cells containing the fluid side-chains. Some of these systems exhibit a 2nd-order transition from the high-temperature mixed ("1-color") phase to a low-temperature phase in which the side-chains are separated in A and B cells ("2-color"). This is the situation with triangular, rectangular and square honeycombs. Strong pre-transitional 2-color domains formation is observed above the transition temperature. Particularly interesting is the case of the hexagonal honeycomb, where no fully phase-separated ground state can exist. Here the 2-color "ordered" phase consists of [A] cells and [A(1/4)B(3/4)] cells. The situation is similar to frustrated ferro- and antiferromagnets on a kagome lattice. Instead of the spins flipping, it is the molecules that undergo 180 degree rotations about the axis of their rod-like cores [Science 331, 1302 (2011)].

C1.00122 Compaction of DNA with Lipid Modified Silica Nanoparticles, SUSHMA SAVARALA, STEPHANIE L WUNDER, MARC ILIES, Temple University — There is an increasing interest in modified inorganic nanoparticles, polymers or hybrid polymer-inorganic nanoparticles for use in DNA transfection, rather than viral vectors or liposomes. Adsorption of the DNA to the nanoparticles prevents enzymatic degradation of the DNA, although the reason for this protection is not completely understood. In order to compact the negatively charged DNA, a positively charged surface is required, and for transfection applications, the nanosystems must remain stable in suspension. It is also useful to minimize the amount of cytotoxic cationic lipid needed for DNA compaction in delivery applications. Here we investigate the colloidal stability of supported lipid bilayers (SLBs) composed of mixtures of 1,2-dimyristoyl-sn-glycero-3-phosphocholine (DMPC, 14:0 PC) and 1,2-dimyristoyl-3-trimethylammonium-propane (DMTAP, 14:0 TAP), and their ability to compact plasmid DNA. Ionic strengths and DMPC/DMTAP ratios that resulted in SLB formation, no excess small unilamellar vesicles (SUVs) in the suspensions, and colloidal stability, were determined. DNA/SLB/lipid ratios that resulted in compaction were then investigated.

C1.00123 Tunable and regenerative DNA zipper based spring, PRESTON LANDON, ALEXANDER MO, ALAN GILLMAN, BRIAN MECKES, SRINIVASAN RAMACHANDRAN, RATNESH LAL, Department of Bioengineering and Department of Mechanical and Aerospace Engineering, University of California, San Diego, La Jolla, CA 92093, U.S.A. — We report a DNA zipper based actuator device termed 'DNA- spring' with tunable and repeated cycles of extension and contraction ability. DNA zipper is a double-stranded DNA system engineered to open upon its specific interaction with appropriately designed single strand DNA (ssDNA), opening of the zipper is driven by binding energy differences between the DNA strands. The zipper system is incorporated with defined modifications to function like a spring, capable of delivering approximately 9 pN force over a distance of approximately 13 nm, producing approximately 116 kJ/mol of work. Time-lapse fluorescence and fluorescent DNA gel electrophoresis analysis is utilized to evaluate and confirm the spring action. A second zipper incorporated into the spring provides the ability to couple/decouple to an object/substrate. Such devices would have wide application, including for conditionally triggered molecular delivery systems and as actuators in nano-devices. zippers.

C1.00124 Single particle tracking for a particle in a thermo-osmotic trap, MARK NOLAN CONFESOR, PIK-YIN LAI, Department of Physics and Graduate Institute of Biophysics, National Central University, Taiwan, C.K. CHAN, Institute of Physics, Academia Sinica, Taiwan — Recently Jiang et al. (PRL 102, 2009) showed that colloidal particles in a polymer solution can be trapped by imposing a local temperature gradient. It is believed that the thermophoresis of the polymers leads to a polymer concentration gradient that drives the colloids to get trapped. We investigate the trapping force further by performing single particle tracking of a probe colloidal particle. Our system consists of Polystyrene beads immersed in PEG solution. We impose a temperature gradient by shining an IR laser to a chromium coated surface. We found the particle position distribution to have non-Gaussian tails but quiet symmetric for the radial positions. However we found quiet asymmetric distribution for the axial positions where the particle likes to stay very close to the heated surface. From the distribution we read out the trapping potential. We will present results for the dependence of the trapping potential to particle size and polymer concentration.

C1.00125 Controlled Transport of Functionalized Nanochannel through Lipid Membrane, MEENAKSHI DUTT, Dept of Chemical and Biochemical Engineering, Rutgers University, OLGA KUKSENOK, ANNA C. BALAZS, Chemical Engineering Dept, University of Pittsburgh — Via the Dissipative Particle Dynamics approach, we study the directed transport of a transmembrane nanochannel to a desired location within a lipid bilayer. Each nanochannel encompasses an ABA architecture, with a hydrophobic shaft (B) with two hydrophilic ends (A). One of the ends of the nanochannel is functionalized with hydrophilic functional groups, or hairs. The hydrophilic hairs serve a dual role: (a) control transport across the membrane barrier, and (b) enable the channel relocation to a specific membrane site. Our system comprises a lipid membrane with an embedded transmembrane nanochannel with the hairs extending into solution. First, we hold a suitably functionalized pipette above the membrane while the nanochannel freely diffuses within the membrane. For an optimal range of parameters, we demonstrate that the hairs find the pipette and spontaneously anchor onto it. We then show that by moving the pipette for a range of velocities, we can effectively transport the channel to any location within the membrane. This prototype assembly can provide guidelines for designing a number of systems for biomimetic applications.

C1.00126 Molecular Dynamics Simulations of Phosphatidylinositol Bisphosphate (PIP₂), DAVID SLOCHOWER, PAUL JANMEY, University of Pennsylvania — We are interested in the dynamics of membranes containing the highly charged phospholipid phosphatidylinositol bisphosphate (PIP₂ or PtdInsP₂). We performed a geometry optimization at the Hartree-Fock 6-31+G* level of theory to determine the biological conformation of the phospholipid headgroup in the presence of water and partial charge distribution. The angle between the headgroup and the acyl chains that form an anchor in the membrane is 94°, indicating that the inositol ring may lie flat along the surface of the inner plasma membrane. Next, we employed hybrid quantum mechanics/molecular mechanics simulations to investigate the protonation state of PIP₂ and its interactions with physiological divalent cations such as magnesium and calcium. Based on preliminary data, we propose that the binding of magnesium to PIP₂ is mediated by a water molecule that is absent when calcium binds. These results may explain the ability of calcium to induce the formation of PIP₂ clusters and phase separation from other phospholipids.

C1.00127 Divalent cation-induced cluster formation by polyphosphoinositides in model membranes¹, YU-HSIU WANG, PAUL JANMEY, University of Pennsylvania — Phosphatidylinositol-(4,5)-bisphosphate (PI4,5P2) binds with variable levels of specificity to hundreds of intracellular proteins in vitro. Such restricted targeting of proteins to PIP2 in cell membranes is thought to result in part from the formation of spatially distinct PIP2 pools. The hypothesis that PIP2 forms nanodomains in the membrane by electrostatic interactions with divalent cations is tested using lipid monolayer and bilayer model membranes. Competitive binding between Ca²⁺ and Mg²⁺ to PIP2 is quantified by surface pressure measurements and analyzed by a Langmuir competitive adsorption model. Addition of Ca²⁺, but not Mg²⁺, Zn²⁺ or polyamines to PIP2-coating monolayers induces surface pressure drops coincident with the formation of PIP2 nanodomains visualized by fluorescence, atomic force and electronic microscopy. Studies of bilayer membranes using probe-partitioning fluorescence resonance energy transfer (FRET) and fluorescence correlation spectroscopy (FCS) also reveal Me²⁺-induced domain formation or diffusion retardation which follows the trends: Ca²⁺ >> Mg²⁺ > Zn²⁺, while polyamines have minimal effects. These results suggest that divalent metal ions have substantial effects on PIP2 lateral organization under their physiological concentrations.

C1.00128 Driven Brownian transport through arrays of symmetric obstacles, STEFFEN MARTENS, Humboldt-University Berlin, Department of Physics, Newtonstr. 15, 12489 Berlin, Germany, PULAK K. GHOSH, Advanced Science Institute, RIKEN, Wako-shi, Saitama, 351-0198, Japan, PETER HÄNGGI, University Augsburg, Department of Physics, Universitätsstr. 1, 86135 Augsburg, Germany, FABIO MARCHESONI, Università di Camerino, Dipartimento di Fisica, 62032 Camerino, Italy, FRANCO NORI, Advanced Science Institute, RIKEN, Wako-shi, Saitama, 351-0198, Japan, LUTZ SCHIMANSKY-GEIER, Humboldt-University Berlin, Department of Physics, Newtonstr. 15, 12489 Berlin, Germany, GERHARD SCHMID, University Augsburg, Department of Physics, Universitätsstr. 1, 86135 Augsburg, Germany — The transport of a suspended overdamped Brownian particle driven through a two-dimensional rectangular array of circular obstacles with finite radius is numerically investigated [P. K. Ghosh et. al., *Phys. Rev. E*, submitted (2011)]. Two limiting cases are considered in detail, namely, when the constant drive is parallel to the principal or the diagonal array axes. This corresponds to studying the Brownian transport in periodic channels with reflecting walls of different topologies. The mobility and diffusivity of the transported particle in such channels are determined as functions of the drive and the array geometric parameters. Prominent transport features, like negative differential mobilities, excess diffusion peaks, and unconventional asymptotic behaviors, are explained in terms of two distinct lengths, the size of single obstacles (trapping length) and the lattice constant of the array (local correlation length). Local correlation effects are further analyzed by continuously rotating the drive between the two limiting orientations.

C1.00129 Hydrophobic Drug Encapsulation Mechanisms of an Injectable Self-Assembling Peptide Hydrogel, JESSIE E.P. SUN, University of Delaware, JOEL P. SCHNEIDER, National Cancer Institute at Frederick, DARRIN J. POCHAN, University of Delaware — We examined a beta-hairpin peptide network that is a shear thinning injectable solid with immediate rehealing behavior. These rheological properties result from the entangled and branched fibrillar nanostructure of the hydrogel networks. The fibrils are formed by the intramolecular folding and subsequent intermolecular assembly of the self-assembling peptides. Taking advantage of the nanofibrillar peptide structures, the hydrogel can be used to encapsulate curcumin, a hydrophobic, natural anticancer agent and indian spice. The hydrogel shields curcumin from the environment while depositing it exactly where it is intended through syringe injection, taking advantage of the hydrogel shear thinning and rehealing behavior. How the network envelopes and interacts with the curcumin is examined using fluorescence and electron microscopy methods to better understand the exact mechanisms and behaviors of the gel itself and the gel-curcumin construct.

C1.00130 PNIPAM: an amphiphilic polymer probing the mean energetic state of water, IRMGARD BISCHOFBERGER, University of Fribourg, Department of Physics, PAOLO DE LOS RIOS, EPF Lausanne, Laboratory of Statistical Biophysics, ILIAN JELEZAROV, University of Zürich, Department of Biochemistry, VERONIQUE TRAPPE, University of Fribourg, Department of Physics — We find that the effect of alcohol on the thermodynamic properties of aqueous solutions of poly-N-isopropyl acrylamide (PNIPAM) directly relates to the mixing enthalpy of the water/alcohol mixture itself. This correlation between solution and solvent thermodynamics indicates that the thermodynamics of aqueous solutions of PNIPAM is primarily determined by the mean energetics of the solvent. Such behavior sheds light on the nature of hydrophobic hydration, which we will discuss in this contribution.

C1.00131 Single molecule discrimination as the sequential hypothesis testing, maximum information gain measurement, ALEXEI GOUN, Postdoctoral researcher — Detection of single molecule and single molecule complexes is used widely in the field of molecular biology, biochemistry, physical chemistry. The task is often to discriminate among several distinct possibilities such as which molecule (A,T,C,G) out of the set is present, is the excitation transfer pair in bound or loose state. At present the approach is to accumulate the sufficient statistics for reliable discrimination among the possible outcomes. We suggest the different approaches that adjust the experimental conditions on every step of the measurement in order to maximize the expected information gain of the experiment. The approach is illustrated on the task of single molecule discrimination. Our simulation shows that approach based on sequential hypothesis testing and sequential experimental planning outperforms traditional maximum likelihood hypothesis testing.

C1.00132 Force extension response of single self-associating polymer chains, CHARLES SING, ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology — The structure and dynamics of polymeric molecules plays a crucial role in a number of synthetic and biological processes. Great progress has been made in using force spectroscopy methods, such as optical tweezers and atomic force microscopy, to probe these properties of single molecules in novel ways. While there has been significant advances at using analytical theory to model the behavior of, for example, single domain unfolding or multi-domain unfolding of identical domains, we consider for the first time the force-extension behavior of self-associating homopolymers. We use a Brownian dynamics simulation with a Bell-like association model that represents, in a coarse-grained fashion, biological polymers such as von Willebrand Factor that use domain-domain interactions to modulate a larger quaternary structure. We also present a theoretical description of pulling that utilizes a master equation description of the relevant coordinate of the polymer network's "shortest chain." We can accurately reproduce the force-extension features, notably the appearance of a dissipative plateau upon the increase of the association time scale, and provide a clear conceptual description of the appearance of this feature. Qualitative comparison to von Willebrand pulling in experiment is shown.

C1.00133 Modeling the Strength of β -sheet Structures in Silk Crystals and Protein Molecules, DAVID GRUBB, Materials Science & Engineering, Cornell University — The mechanical response of β -sheet structures to a tensile force directed along the axis of one chain can be modeled as an array of elastic springs. The 3-D potential of H-bonds in β -sheets gives a shear stiffness of 4.5Nm^{-1} and the chain repeat stiffness is 60Nm^{-1} . Nanocrystals $>3.5\text{nm}$ long with ≥ 20 H-bonds/chain are the strong component of spider silk. They behave much like macro-scale objects, and two conditions must be met for pull-out failure: (1) the load on the most stressed H-bond exceeds the bond strength. (2) the energy of the system is lower after failure. (1) is the critical condition, and the predicted pull-out load is 3-4 times the H-bond strength. An energetically favorable 'stick-slip' process is kinetically forbidden. Arrays within a single molecule such as titin have fewer bonds and can fail at low loads by the 'stick-slip' process. The logarithmic rate dependence of failure load observed in AFM is 50pN/decade and the stick-slip prediction is 30pN/decade . Simulations at short times and high loads give slopes $>10\times$ higher, matching the prediction for failure at a single bond.

C1.00134 Searching DNA by Brownian Motion of Transcription Factors, ROBIJN BRUINSMA, Department of Physics and Astronomy, UCLA, ALEXANDER GROSBERG, Theoretical Biophysics, New York University — Transcription factor proteins are able to locate their DNA operator binding site by slide-skip motion along DNA without getting trapped by the large binding energy fluctuations associated with partial recognition. Mirny and Slutsky proposed that this can be avoided by assuming that partial recognition involves increased strain energy of the protein. We present an analytical model for such a search in the form of a 2D random walk with DNA arc-length and an internal configurational parameter as coordinates. This leads to a relation between the nature of the DNA randomness and the optimal choice for the internal energy spectrum.

C1.00135 Anomalous Freezing Behavior of Nanoscale Liposomes¹, ERIC SPANGLER, MOHAMED LARADJI, University of Memphis, SUNIL KUMAR, IIT Madras, Chennai, India — Experiments have shown that the melting transition of small liposomes is broadened when compared to large vesicles or planar membranes. Despite their significant biological and biomedical importance, theoretical and computational studies of the phase behavior and structural properties of small liposomes have been limited. Presented here is a systematic computational study of the phase behavior and structural properties of liposomes using a recently developed coarse-grained particle-based model. Great assiduity was given on the effect of liposome diameter on their thermal and structural properties. Below the melting transition, liposomes are faceted with the gel facets separated by “grain” boundaries that are in the fluid phase. In agreement with experiments, we found that the melting transition is significantly broadened as the liposome diameter is decreased and that the heat capacity exhibits two distinct peaks for diameters less than 33 nm, an indication of a decoupling of the melting transition of the two leaflets. This decoupling is clearly demonstrated by the chain order parameters of the two leaflets, which show that the upper leaflet undergoes a melting transition before the inner leaflet.

¹This work is supported by NSF grants (DMR-075547 and EPS-1004083).

C1.00136 Desalination membranes from functional block copolymer via non-solvent induced phase inversion, HYEMIN SUNG, Korea University, JUSTIN POELMA, FRANK LEIBFARTH, CRAIG HAWKER, University of California, Santa Barbara, JOONA BANG, Korea University — Commercially available reverse osmosis (RO) and forward osmosis (FO) membranes are most commonly derived from materials such as polysulfone, polyimide, and cellulose acetate. While these membranes have improved the efficiency of the desalination process, they suffer from mechanical and chemical stability, fouling issues, and low fluxes. In this study, we combine a well-established membrane formation method, non-solvent-induced phase separation, with the self-assembly of a functional amphiphilic block copolymers. An amine and acid functional polystyrene-block-poly(ethylene oxide-co-allyl glycidyl ether) were chosen for the membranes. Membranes were formed by casting a concentrated polymer solution (12 to 25 wt% polymer) on PET fabric followed by immersion in a non-solvent bath. Scanning electron microscopy revealed an asymmetric porous structure consisting of a dense skin layer on top of a highly porous layer. Membrane performance was investigated using an FO test cell under the seawater condition.

C1.00137 Morphological study on a phospholipid mixture and their Dependence of Temperature, Concentration and Chemical Composition, YING LIU, University of Connecticut Chemical Engineering, YONGKUN YANG, University of Connecticut Polymer Program, MU-PING NIEH, University of Connecticut Chemical Engineering/IMS — A variety of morphologies, such as nanodiscs (bicelles), bilayered ribbons, unilamellar vesicles (ULVs), multi-lamellar vesicles (MLVs) and perforated lamellae exist in phospholipid mixtures composed of a long chain phosphatidylcholine (PC), its charged counterpart (i.e., phosphatidylglycerol, PG with the same hydrophobic chain length) and a short-chain PC. Here, we present a comprehensive structural characterization of such mixtures with various combinations of long-chain (e.g., di-14, di-16, di-18 PC) and short-chain (e.g., di-06, di-07 PC) lipids at a constant charged density using small angle neutron scattering (SANS), dynamic light scattering (DLS) and transmission electron microscopy (TEM). A time-resolved DLS study is also carried out to understand the kinetics of the structural transformation as a function of temperature, lipid concentration and composition. The preliminary data indicate that uniform nanodiscs and/or bilayer ribbons generally exist at low temperature, while at high temperature ULVs or MLVs are obtained. Moreover, the nanodiscs coalesce with each other over a period of time. The fundamental understanding of the structural formation mechanism and kinetics can lead to potential application of this system to bionanotechnology, such as drug carrying and therapeutic imaging.

C1.00138 The Effect of Short-Chain Lipid on the Morphology of Bicellar Mixtures¹, MING LI, University of Connecticut, Storrs, CT, USA, HANNAH MORALES, University of Toronto, Toronto, ON, JOHN KATSARAS, Oak Ridge National Laboratory, Oak Ridge, TN, PETER MACDONALD, University of Toronto, Toronto, ON, MU-PING NIEH, University of Connecticut, Storrs, CT, USA — Lipid bicellar mixtures, composed of long-chain phospholipids (usually dimyristoyl phosphatidylcholine (DMPC) and charged lipid dimyristoyl phosphoglycerol (DMPG)) and a short-chain phospholipid (e.g. dihexanoyl phosphocholine (DHPC) or 3-[[3-Cholamidopropyl]dimethylammonio]-2-hydroxy-1-propanesulfonate (CHAPSO)), are ideal substrates for structural characterization of the membrane protein, because they provide the natural lipid bilayer environment and furthermore can be aligned in the magnetic field. Recently, structural phases of zwitterionic DMPC/DHPC and charged DMPC/DMPG/DHPC bicellar mixtures have been studied extensively. However, the effect of the short-chain lipid on the morphology is still unknown. Here we report the phase diagram of DMPC/CHAPSO and DMPC/CHAPSO/DMPG mixtures by SANS and NMR. Compared with DMPC/DHPC and DMPC/DHPC/DMPG, different temperature dependence of morphology is observed in the counterpart of CHAPSO by SANS. Also, The PFG-NMR result shows different diffusion behaviors of polyethylene glycol associated with the membranes composed of DMPC/CHAPSO and DMPC/CHAPSO/DMPG, which are magnetically alignable. Both SANS and NMR results suggest that a bilayered ribbon is formed in the case of DMPC/CHAPSO, DMPC/CHAPSO/DMPG.

¹We gratefully acknowledge the support from National Science Foundation (NSF-CMMI1131589).

C1.00139 Rheology of Vimentin Intermediate Filament Networks¹, HUAYIN WU, Harvard University — A cell's ability to function is highly dependent on its structure and material properties - its capacity to withstand and respond to forces in its environment. The cytoskeleton, which largely determines the cellular mechanical properties, is comprised of biopolymer networks, including filamentous actin, microtubules, and intermediate filaments (IF). Intermediate filaments are much less studied than actin and microtubules. They are much more varied and specialized as well, and have been suggested as being an important platform in mechanotransduction processes in cells. It is thought that they can withstand very high strains and exhibit strain stiffening behavior. We are characterizing vimentin, a type III IF that is found in all vertebrate cells, using rheological techniques. Vimentin elasticity increases upon addition of multivalent cations, which act like molecular crosslinkers. By varying the concentration of cations, we can extract valuable information about how the networks assemble and function.

¹NIH Program Project Grant Intermediate Filaments, Harvard Materials Research and Engineering Center (DMR-0820484)

C1.00140 Force Dependent Changes in Non-Erythroid Spectrin and Ankyrins, ELENI DEGAGA, MARTIN FORSTNER, Syracuse University — Mechanotransduction in cells describes the process by which external physical stimuli are converted into biochemical activity and plays an important role in many biological functions on both the cell and tissue level. However, the specific mechanisms by which mechanical forces lead to particular molecular and cellular responses are much less understood. We investigate the changes in non-erythroid spectrin and ankyrins as a result of equi-biaxial strain application to live cells in culture. Specifically, we focus on the spectrins' role in the ubiquitination process - a vital process in the regulation of protein degradation- of spectrin and ankyrins. We utilize immune-fluorescence staining and fluorescent fusion proteins for quantitative fluorescence imaging as well as biochemical methods to measure changes in of cell's spectrin and ankyrin content. Protein expression levels and localization between cells exposed to mechanical stimuli of different temporal and spatial profiles are compared. In addition, the threshold behavior of cell proliferation - as measured by number densities - of a variety of cell types as a function of mechano-stimulation is investigated.

C1.00141 Dynamics and Structure of Disordered Peptides from Two-Dimensional Infrared Spectroscopy, MIKE REPPERT, JOSHUA LESSING, CHUNTE PENG, KEVIN JONES, CARLOS BAIZ, ANDREI TOKMAKOFF, Department of Chemistry, Massachusetts Institute of Technology — Two-dimensional infrared (IR) spectroscopy is a powerful tool for investigating the ultra-fast dynamics and association of complex biological macromolecules such as proteins and DNA. In addition to the improved spectral discrimination afforded by a two-dimensional spectrum, the ultra-fast time-resolution inherent to the technique provides unique insight (unobtainable by standard linear IR measurements) into the time-scales of macromolecular conformational fluctuations, particularly for intrinsically disordered systems. Here we discuss the use of accurate line shape modeling of peptide amide I vibrations as an advanced method for extracting structural and dynamic information from experimental spectra. The mixed quantum-classical model makes use of standard MD trajectories and a parametrized site energy and coupling map as inputs for excitonic calculations of the delocalized amide I vibrations. We present examples of the application of this method to extract site-specific structural information (such as hydrogen bond number and turn conformation) as well as insight into conformation dynamics and time-scales from experimental data for disordered peptides.

C1.00142 Vibrational Coherence Spectroscopy Investigation of Cytochrome c equilibrium Unfolding¹, YUHAN SUN, KARUNAKARAN VENUGOPAL, PAUL M. CHAMPION, Department of Physics and Center for Interdisciplinary Research on Complex Systems, Northeastern University, Boston, MA 02115 — Using vibrational coherence spectroscopy (VCS) we studied guanidinium hydrochloride (GdHCl) induced equilibrium unfolding of ferric cytochrome c excited at 412 nm. Upon unfolding, we observed that the strong 50cm^{-1} mode, which dominates the VCS spectrum of native cyt c, loses its intensity relative to the 80cm^{-1} mode. The 224cm^{-1} mode (γ_{24}) also shifts to 205cm^{-1} , reflecting the heme configuration change associated with unfolding. We also compared the amplitude of these unfolding sensitive modes at different GdHCl concentrations using a cyt c-imidazole complex as a model system. The peak of the Soret band does not shift when the cyt c- imidazole complex is unfolded. Because the resonance conditions are invariant, the relative intensities are a direct probe of the heme structural changes. Our results show that the 50cm^{-1} mode dramatically loses amplitude, while the 80cm^{-1} mode stays nearly the same. When compared to other Raman studies, which suggest that the heme adopts a more planer structure when cyt c is unfolded, the 50cm^{-1} mode may reflect a similar structural change as the 569cm^{-1} (γ_{21}) mode. We suggest that these modes are diagnostic of a protein-induced ruffling distortion.

¹We acknowledge NSF (MCB-0744738) and NIH (DK-035090) for supporting the work.

C1.00143 Protein Dynamics Studied via a Disclination Network Based Approach¹, RAHMI OZISIK, OSMAN BURAK OKAN, Rensselaer Polytechnic Institute, KERRI SCHULTZ, Hudson Valley Community College, ARAVIND RAMMOHAN, Corning Research Center — Protein dynamical transition at ca. 200 K is an elusive collective process by which the time-scale distribution of different relaxations is strongly altered (Okan, Atilgan, Atilgan, Biophysical J. 2009, 97, 2080; Atilgan, Aykut, Atilgan, Biophysical J. 2008, 94, 79). It is now confirmed that the backbone topology during this dynamic transition remains intact and there is no structural phase transition during such a dynamic transition. However, the dynamics of backbone torsional jumps shows a freezing behavior below the transition temperature (Atilgan et al., 2008). In the current work, we map the heavy atoms of proteins onto a disclination network and probe temperature dependent dynamics on such a construct. Using a series of 40 ns molecular dynamics cooling simulations spanning the temperature range of 320 K to 160 K with 10 K increments, we track the dynamics of orientational defect networks. The size distribution and defect lifetimes in the disclination network are shown to be central for the dynamical transition in proteins.

¹Partial support was provided by NSF Grant No. 1003574 and RPI.

C1.00144 Acoustic Force Microscopy in Aqueous Environments to Determine Protein Folding Dynamics, STEFAN ZAUSCHER, ZEHR PARLAK, JIANMING ZHANG, TERRY OAS, Duke University — Characterizing the dynamic mechanical response of (bio)molecular thin films can give insight into the dynamics of biomolecules on surfaces. Here, acoustic atomic force microscopy (AFM) methods are promising tools since they enable sensitive mapping of the mechanical properties of samples by introducing high frequency modulation while imaging the topography. We are among the first to show that it is possible to utilize acoustic AFM methods in aqueous environments. Accounting for the indentation dependent, off-resonance cantilever dynamics, we are able to obtain spatially resolved elasticity maps of organic thin films in water. Encouraged by these results, we are testing the hypothesis that the rapid unfolding/refolding cycles of the five B domains of SpA-N, a 291 residue protein, composed of five nearly identical 56 to 61 residue domains, confer a unique form of flexibility to the molecule. To this end we employ a non-resonant, acoustic AFM method in a frequency spectroscopy mode, and measure the viscoelastic properties of SpA-N monolayers quantitatively under physiological conditions. We present evidence that the apparent, frequency-dependent stiffness of SpA-N coincides with the kinetics of individual domain folding cycles.

C1.00145 Analysis of Soybean Microtubule Persistence Length; New Evidence on the Correlation between Structural Composition and Mechanical Properties, MITRA SHOJANIA FEIZABADI, CARLY WINTON, JIMMY BARRIENTOS, Seton Hall University — Recent studies on microtubules composed of different β tubulin isotypes indicate their different functionality in terms of their dynamical behavior or the mechanism of their interaction with chemotherapeutic drugs. Along these lines, the result of our recent study measuring the rigidity of neural and non-neural samples of microtubules with different β tubulin isotype compositions suggests that the distinguished mechanical properties of microtubules, such as rigidity, may also be associated with the different distribution of their β tubulin isotypes. In our current study, we have reported the persistence length of a single soybean microtubule. This plant microtubule has a structural composition different from that of mammalian microtubules. Under the same experimental methods of measurement, the soybean microtubules showed a different persistence length as compared to the value of the persistence length that we estimated in the study of both single Bovine Brain and MCF7 microtubules.

C1.00146 Conformational response of a clay binding protein (EGF) by a coarse-grained Monte Carlo simulation¹, BARRY FARMER, LAWRENCE DRUMMY, RAJESH NAIK, Air Force Research Laboratory, MADHAVI KADAKIA, Wright State University, RAS PANDEY, University of Southern Mississippi — Biofunctionalization of montmorillonite (MMT) clay platelets with epidermal growth factor (EGF) appears to play a critical role in tissue regeneration (cell growth and migration) [1]. How the protein (EGF) binds to clay platelet and conforms is very important in its ability to activate the epidermal growth factor receptor. It is however difficult to monitor such structural response systematically in a current laboratory setting. We investigate the structural response of the protein EGF as it binds to the clay platelet with a coarse-grained model already used to investigate binding of short peptides. Both the EGF protein and the clay platelets are described by nodes tethered together by fluctuating covalent bonds. Each residue interacts with a phenomenological interaction (based on its hydrophathy index). Protein and platelet perform their stochastic motion with the Metropolis algorithm. A number of local (e.g. mobility and structural profiles) and global physical quantities such as gyration radius are examined as a function of temperature. We are able to identify the immobilized segments of protein and the variation of its size as a function of temperature. [1] C.A. Vaiana et al Biomacromolecules xxx (2011)

C1.00147 ABSTRACT HAS BEEN MOVED TO K1.00319 —

C1.00148 Biocompatibility of Titanium, FEREYDOON NAMAVAR, University of Nebraska Medical Center, RENAT SABIRIANOV, University of Nebraska at Omaha, DENES MARTON, UTHSCSA, ALEXANDER RUBINSTEIN, University of Nebraska at Omaha, KEVIN GARVIN, University of Nebraska Medical Center — Titanium is the material of choice for orthopaedic applications because of its known biocompatibility. In order to enhance osteogenic properties of the Ti implants, it is necessary to understand the origin of its biocompatibility. We address the origin of Ti biocompatibility through (1) theoretical modeling, (2) the precise determination of Ti surface chemistry by X-ray photoelectron spectroscopy (XPS), (3) and the study of fibronectin adsorption as a function of Ti (near) surface chemistry by Enzyme-linked immunosorbent assay (ELISA). We compare the protein adsorption on Ti with the native oxide layer and the one coated by TiO₂ in anatase phase using ion beam assisted deposition (IBAD). We show that the thin native sub-stoichiometric titanium oxide layer is crucial for biocompatibility of Ti surface. This is due to the enhancement of the non-specific adsorption of proteins which mediate cell adhesion. Improving the surface oxide quality, i.e. fabricating stoichiometric TiO₂ (using IBAD) as well as nanoengineering the surface topology that matches its dimensions to that of adhesive proteins, is crucial for increased protein adsorption and, as a result, further increases biocompatibility of Ti implant materials.

C1.00149 Partially-Functionalized Isotactic Polystyrene with Blocky Comonomer Segments, ARIEL SIEGEL, WAYNE POWERS, CHANG Y. RYU, Rensselaer Polytechnic Institute, RENSSELAER POLYTECHNIC INSTITUTE COLLABORATION — Isotactic polystyrenes (iPSs) have been functionalized in solution, while the accessibility of functionalizing agent is limited by the formation of crystalline domains at various temperatures. The chemical system used is the borylated isotactic polystyrene system, and we investigated the temperature effects on reaction kinetics to ultimately control the blockiness of borylated segments in the resulting copolymer. The chemical composition of partially borylated iPS reaches a steady state that is dependent on temperature. This synthesis has been performed at many different temperatures, with different steady states being reached at different temperatures. Further analysis by differential scanning calorimetry (DSC) has shown that the higher temperature reactions have greater effect on breaking down the crystal lattice structure of the isotactic polystyrene. As a result, the lower temperature reactions affect the crystalline structure less, and the resulting copolymer has more blockiness.

C1.00150 Rigid amorphous fraction of Nylon 11 determined from TMDSC¹, BIN MAO, PEGGY CEBE, Department of Physics and Astronomy, Tufts University — High precision, high accuracy heat capacity measurements were used to study both neat Nylon 11 and Nylon 11 nanocomposites which had been prepared by different processing procedures. The heat capacity step at the glass transition temperature was characterized from the reversing flow using temperature modulated differential scanning calorimetry, and this allows us to determine the mobile amorphous fraction. Heat fusion was obtained from endotherm area of the total heat flow curve, and was correlated with the degree of crystallinity determined from X-ray diffraction. Based on three phase model of the semicrystalline polymer structure, the rigid amorphous fraction (RAF) in Nylon 11 could be calculated. Studied Nylon 11 samples include solution cast, liquid quenched, and isothermally crystallized films, solution cast films containing multi-walled carbon nanotubes, and electrospun fibers. We observed that a rigid amorphous fraction exists in all Nylon 11 samples, and the amount of RAF is strongly dependent upon the crystalline fraction and the nanofiller content.

¹The authors kindly acknowledge National Science Foundation for financial support through DMR-0602473. X-ray related work was conducted at the Brookhaven National Laboratory, National Synchrotron Light Source, supported by the Department of Energy.

C1.00151 Structure of Oriented PLA/Graphene Nanocomposite Fibers¹, QIAN MA, Tufts University, MAREK PYDA, Poznan University of Medical Sciences, BIN MAO, Tufts University, ERIKA SIMONA COZZA, ORIETTA MONTICELLI, Università di Genova, PEGGY CEBE, Tufts University — Highly-aligned polylactic acid (PLA)/graphene nanocomposite fibers were successfully electrospun. Through a combination of thermal analysis and X-ray scattering, the phase structure, molecular orientation, and fiber shrinkage of the oriented PLA fibers were investigated to evaluate the molecular chain confinement. Calorimetric studies were performed to identify the molecular origin of the post- T_g exothermic peak. We found that the shrinkage of the oriented amorphous polymer serves as a precursor for the cold crystallization revealed by the post- T_g exotherm. Using real-time 2-D wide angle X-ray scattering and molecular retraction tests, we further quantified the orientation level and the oriented amorphous fraction in the as-spun amorphous fibers, and investigated the subsequent formation of oriented crystals during heating under “frozen-in” tension. The preferentially oriented amorphous region that possesses a degree of medium-range order has high similarity with the concept of the rigid amorphous phase that has been widely studied in thermal analysis area, and a new phase structure model was established. Graphene filler has a significant influence on molecular orientation, crystallization behavior, and electrical conductivity of PLA fibers.

¹For support of this research, the authors thank the National Science Foundation, Polymers Program of the Division of Materials Research through DMR-0602473, and the MRI Program under DMR-0520655 for thermal analysis instrumentation.

C1.00152 The Role of Surface Charge of Nucleation Agents on the Crystallization Behavior of Poly(vinylidene fluoride), YING WU, SHAW LING HSU, University of Massachusetts, Amherst — The effect of the surface charge of nucleation agents on the crystallization behavior of poly(vinylidene fluoride) (PVDF) has been investigated. Ion-dipole interaction between the positive surface of nucleation agents and the partially negative CF₂ dipoles of PVDF was considered as a main factor for further lowering free energy barrier for nucleation, and thus increasing significantly the crystallization kinetics. This is in contrast to the behavior observed for nucleation agents possessing either negative surface or neutral charges. Positive nucleation agents led to a remarkable increase in the crystallization temperature (lower supercooling), the melting point and degree of crystallinity of PVDF as compared with that of neat PVDF. The dispersion of each type of nucleation agents is also important. The melting temperature needs to be higher than the melting temperature of PVDF. The detailed crystallization behavior and its kinetics, including the conformational changes of the PVDF chain during the crystallization of neat PVDF and PVDF with specific nucleation agents, have also been investigated. With the addition of positive nucleation agents, the γ and β chain conformations, instead of the α phase, dominate.

C1.00153 Characterization of aging behavior associated with multi-layered polymer laminates

, YING JIN, YING WU, SHAW LING HSU, University of Massachusetts, Amherst — To predict the physical stability of multilayered polymer laminates film, the underlying segmental motion of each layer needs to be characterized as a function of time and temperature. We focused on the dimensional stability of various poly(vinylidene fluoride) (PVDF) and its blends. Because of the significant density difference between the crystals formed and the amorphous phase, dimensional stability or the presence of residual stress is difficult to avoid. We have used a combination of techniques to characterize the effects of various comonomers, nucleation agents or blends on the crystallization behavior, the morphology formed and thus dimensional stability. The stress changes in polymer films were investigated as a function of temperature with the cantilever deflection approach. The volume relaxation with time is observed using density gradient column. The morphological features evolved were also analyzed. The magnitude of the residual stress was quantitatively evaluated. The time evolution reaching a stable structure was also investigated in terms of the local glass transition temperature. We further discussed the changes by adding nuclear agents in order to force the polymer films to reach equilibrium states achieving stability stable in a short time scale.

C1.00154 Optically Fixable and Optically Elastic Photomechanical Responses in Azobenzene Liquid Crystal Polymer Networks

, TIMOTHY WHITE, KYUNG MIN LEE, RICHARD VAIA, TIMOTHY BUNNING, Air Force Research Laboratory, Wright-Patterson AFB — Photoresponsive behaviors in azobenzene functionalized polymers have seen widespread interest for a variety of applications as adaptive materials. In a series of recent works, we have distinguished the photomechanical response of polydomain, monodomain and twisted nematic glassy azobenzene liquid crystal polymer networks (azo-LCNs). Interestingly, these materials primarily exhibit optically fixable shape memory to blue-green irradiation, but in some instances can exhibit “optically elastic” (muscle-like) responses. Towards this end, this contribution will summarize the photomechanical responses of these materials and illustrate some of the underlying contributors that dictate fixable or elastic responses upon removal of the irradiation.

C1.00155 Effect of an external field on nematic order in semiflexible polymers, JUTTA LUETTNER-STRATHMANN, KIRAN KHANAL, Departments of Physics and Chemistry, University of Akron — Semiflexible polymers of sufficient stiffness exhibit liquid crystalline order at sufficient polymer concentrations. In this work, we investigate blends of flexible and semiflexible polymers under a uniform external field with the aid of Monte Carlo simulations of a bond-fluctuation model. The model is an extension of Shaffer's bond-fluctuation model, where chain stiffness is controlled by including different forms of bending penalties, and includes attractive interactions between monomers. From simulations for a range of values of the bending energy, density, and temperature, we determine the effect of an external field on liquid crystalline order and domain formation.

C1.00156 The evaluation of the dynamic data near T_g from a new aspect¹, BEN XU, GREGORY B. MCKENNA, Department of Chemical Engineering, Texas Tech University — In this work, we compare and analyze the G_g obtained by the KWW² and the BSW³ functions for small molecule, polymer and colloidal glass formers in the context of the Dyre shoving model.⁴ The Dyre shoving model relates G_g with temperature by attributing the free-energy barrier for a “flow event” near to T_g to the work done by shoving aside the surrounding molecules; the free-energy barrier is proportional to G_g , which increases as the temperature decreases. Importantly, the model gives a non-singular growth of the relaxation time or viscosity with decreasing temperature and does not invoke ideas related to dynamic heterogeneity and growing length scales, both of which are commonly used in the description of glassy dynamics. To the extent that the material classes investigated seem to be reasonably described by the shoving model, it is suggested that divergence of time scales and length scales may not be essential to the glass transition phenomenon.

C1.00157 Formation of Stable Polymer Glasses via Matrix Assisted Pulsed Laser Evaporation

, KIMBERLY SHEPARD, YUNLONG GUO, RODNEY PRIESTLEY, Princeton University — Via Matrix Assisted Pulsed Laser Evaporation (MAPLE), we are able to form amorphous polymer films that exhibit significant changes in material properties and structure. In the MAPLE method, a pulsed laser ablates a target, consisting of a frozen dilute solution of the desired polymer, in order to produce films of the material. By carefully controlling the growth rate of film formation and the substrate temperature during deposition, we are able to form glassy films with structures that are either less or more dense compared to the standard glass. Interestingly, the morphology of the low and high-density amorphous films is significantly different. The low-density glasses are nanostructured and the high-density glasses are not. In this poster, we discuss how MAPLE can be used to tune the morphology and hence, the properties of polymer glasses.

C1.00158 ABSTRACT WITHDRAWN —

C1.00159 A configurational entropy theory for the non-Arrhenius relaxation in disordered systems¹

, YIZHEN WANG, X. FRANK ZHANG, Bioengineering Program and Mechanical Engineering and Mechanics Dept, Lehigh University, JINXIU ZHANG, School of Physics and Engineering, Sun Yat-sen University, China — Here we develop a novel configurational entropy theory to explain the non-Arrhenius slowdown relaxation behavior in disordered systems on approaching the glass transition. The theory explicitly shows that this intriguing slowdown behavior originates from the growth in the configurational entropy loss (and the structural order degree) of the system, associated with the attractive interaction among relaxing units (RUs). A thermodynamic/kinetic equilibrium state with order singularity at the finite temperature T_c due to the attractive interaction among RUs is predicted. An expression is derived for characterizing the average relaxation time of RUs relaxing towards such equilibrium state. The resultant relaxation time expression offers a novel connection between kinetics and thermodynamics, different from that of the $A - G$ entropy equation, and it is shown to be a generalization of several well-known relations in current use. The theory also implies that the diverging relaxation time at finite temperature arises from the existence of an underlying long-range order phase transition at T_c . Our results could provide a novel understanding of the non-Arrhenius slowdown relaxation behavior in disordered systems on approaching the glass transition.

C1.00160 Purification and Fractionation of PEO-PPO-PEO Triblock Copolymers

, CHANG YEOL RYU, HANJIN PARK, Rensselaer Polytechnic Institute, GYOO YEOL JUNG, Pohang University of Science and Technology — PEO-PPO-PEO triblock copolymers are produced on a commercial scale for nonionic surfactant applications. Anionic polymerization has been employed to produce the block copolymers and it is likely that the triblock copolymer contain low molecular weight contaminants that would interfere with the micellization and gelation in aqueous solution. We have taken advantages of the recent developments on the interaction chromatography (IC) technique to separate the neat triblock copolymers from the as-received triblock copolymers. Because the IC relies on the adsorption of polymers, we were able to purify and fractionate the triblock copolymers on a larger scale than the prep scale SEC. Upon purification of the triblock copolymers, the influence of contaminants in the as-received triblock copolymers will be discussed on the micellization and gelation of the triblock copolymer solution in water.

C1.00161 Size Interplay between Polymer and Nanopores for the Band Broadening of SEC¹, IAN WEISS, POSTECH/Rensselaer Polytechnic Institute, CHANG YEOL RYU, Rensselaer Polytechnic Institute, TAIHYUN CHANG, POSTECH — The size interplay between polymer chains and nanopores plays a key role in governing the retention time of polymer chains in liquid chromatography. These nanopores also contribute to the band broadening of the resulting peaks seen in most liquid chromatography systems including size exclusion chromatography (SEC). We have studied how the relationship between the size of the nanopores and the hydrodynamic radius of the polymers affects the band broadening during SEC. This related to Brown random motion of polymer chains in solution, whose motions are restricted by the presence of nanoporous stationary phase for the SEC. We have prepared model polystyrene samples with extremely narrow polydispersity ($PDI < 1.0001$) using temperature gradient interaction chromatography. Those model samples allow us to directly measure the band broadening of SEC using different size pore columns at various solvent conditions.

¹NSF OISE PIRE 0730243

C1.00162 SANS Mapping of Orientation and Relaxation of Polymer Chains upon Uniaxial Extension¹, HOWARD WANG, LIWEI HUANG, Institute for Material Research and Department of Mechanical Engineering, State University of New York, Binghamton, NY 13902, YANGYANG WANG, Department of Chemistry, University of Tennessee, Knoxville, TN 37996, HAO SUN, SHI-QING WANG, Department of Polymer Science, University of Akron, Akron, Ohio 44325, DAZHI LIU, CARRIE GAO, KE AN, Spallation Neutron Source, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831 — Small angle neutron scattering (SANS) has been used to measure entangled chains in polymer melts upon uniaxial stretching. The degree of anisotropy and the coil dimension are discussed in the light of the applicability of the tube model.

¹Supported by NSF CMMI and DMR

C1.00163 X-ray scattering investigation of structural relaxation in an ordered block copolymer melt subjected to uniaxial extensional flow, WESLEY BURGHARDT, ERICA MCCREADY, Northwestern University — The structural dynamics of an ordered styrene-ethylene butylene-styrened triblock copolymer have been studied in uniaxial extensional flow using in situ x-ray scattering. Experiments were performed in a custom instrument consisting of an SER extensional flow fixture housed in a convection oven designed to facilitate x-ray access. Use of synchrotron radiation provided sufficient time resolution to study the structural response during inception of uniaxial flow, and as a function of time following flow cessation. The sample studied here exhibits hexagonally packed cylindrical microdomains of polystyrene embedded in a poly(ethylene butylene) matrix. Application of extensional flow produces multiple structural effects, including deformation of the microphase-separated morphology, and a complex reorientation process in which elongated PS microdomains progressively orient along the stretching axis. A series of experiments was run in which samples were stretching to varying Hencky strains, allowing investigation of the nature of structural relaxation from a variety of flow-induced structural states induced during extensional flow. Significant differences in structural relaxation are found depending on the total applied extensional strain.

C1.00164 Comparative study of polymer chain dynamics in aqueous solutions by FPR and DLS, KIRIL STRELETZKY, RYAN MCDONOUGH, Cleveland State University, RAFAEL CUETO, PAUL RUSSO, Louisiana State University — Self diffusion of tagged polymer chains in aqueous solutions of hydroxypropylcellulose (HPC) was measured by Fluorescence Photo-bleaching Recovery (FPR) and compared to mutual diffusion of scattering species in the same solutions measured by Dynamic Light Scattering (DLS). The effect of the dye presence on thermodynamic concentration fluctuations observed by DLS was also studied. The observed multimodal spectra in DLS and FPR were analyzed with CONTIN and stretched exponential fits. A set of consistent dissimilarities in the modal distributions of FPR and DLS spectra was found. This indicates a comparative limitation or sensitivity in range of detectable diffusive processes between FPR and DLS in this complex system. In addition, it was found that the fluorescent tag and/or tagging process seem to alter the mutual diffusion processes seen by DLS. In particular, a slower mode which is apparent in the non-tagged sample does not appear in the tagged sample. It seems likely that the dye chemically affects the polymer chains keeping them from clustering with each other, altering the solvent environment preventing formation of polymer clusters responsible for the slow mode usually seen in HPC.

C1.00165 Silicone Elastomer Networks with Tunable Modulus for Cell Mobility Studies, JULIE N.L. ALBERT, KIRILL EFIMENKO, JAN GENZER, North Carolina State University — Silicone elastomer networks provide a versatile platform for studying the effects of compliance and surface chemistry on cell movement. One major advantage of these materials over more commonly used poly(acrylamide) surfaces or hydrogel networks is that they do not swell with water; therefore, the physical properties measured in the dry state are representative of those present under aqueous conditions. In this work, we tuned the moduli of poly(dimethylsiloxane) (PDMS) networks by manipulating the cross-link density *in-situ* during network formation. This regulation of cross-link density was accomplished by cross-linking at polymer chain ends with both difunctional and multi-functional cross-linking agents. The difunctional cross-linkers serve as chain extenders whereas the multifunctional cross-linkers facilitate formation of a chemically cross-linked network. Networks with moduli ranging from ≈ 10 kPa to ≈ 1 MPa were fabricated in this fashion by adjusting the polymer molecular weight, the ratio of difunctional to multifunctional cross-linker, and the ratio of total cross-linker to number of polymer chains. The same approach can be applied to fabricate poly(vinylmethylsiloxane) networks, which can be further tailored through side-chain cross-linking or surface functionalization of pendent vinyl groups.

C1.00166 New Insights into Chain Order Dynamics and Structural Development in Sulfur-Vulcanized Natural Rubber Latex using Multiple Quantum NMR and Synchrotron X-Ray Diffraction, JUSTIN CHE, SHIGEYUKI TOKI, Stony Brook University, JUAN VALENTIN, JUSTO BRASERO, Instituto de Ciencia y Tecnología de Polímeros (CSIC), LIXIA RONG, BENJAMIN S. HSIAO, Stony Brook University, STONY BROOK UNIVERSITY TEAM, INSTITUTO DE CIENCIA Y TECNOLOGÍA DE POLÍMEROS (CSIC) COLLABORATION — Network structure, chain dynamics, and structural development in sulfur-vulcanized natural rubber latex were studied by Multiple-Quantum (MQ) NMR and synchrotron x-ray scattering. Three important processes that can influence rubber network structure and its overall mechanical properties were the main focus and analyzed by both of these techniques: pre-vulcanization, drying, and post-vulcanization. MQ NMR experiments can provide quantitative information regarding networks at very small length scales, including network defects, number of cross-links, and spatial distribution of cross-links. Structural development in natural rubber was studied under uniaxial deformation by in-situ synchrotron x-ray diffraction, which can provide information on network structures at much larger length scales. Molecular orientation and strain-induced crystallization was analyzed by both stress-strain relations and wide-angle x-ray diffraction (WAXD). The morphology of the latex rubber particle during deformation was analyzed by small-angle x-ray scattering (SAXS). The combination of these techniques can provide a considerable amount of information regarding rubber network structure.

C1.00167 Chemotaxis of active, self-oscillating polymer gels in solution, PRATYUSH DAYAL, AMITABH BHATTACHARYA, OLGA KUKSENOK, ANNA C. BALAZS, University of Pittsburgh — Fighting, fleeing and feeding are hallmarks of all living things; all these activities require some degree of mobility. Herein, we undertake the first computational study of self-oscillating polymer gels and show that this system can “communicate” to undergo a biomimetic, collective response to small-scale chemical changes. In this study we harness unique properties of polymer gels that undergo oscillatory Belousov-Zhabotinsky (BZ) reaction. The activator for the reaction is generated within these BZ cilia and diffuses between the neighboring gels. In order to simulate the dynamics of the BZ gels in surrounding fluid we have developed a nonlinear hybrid 3D model which captures the elasto-dynamics of polymer gel and diffusive exchange of BZ reagents between the gel and the fluid. We illustrate that multiple BZ gels in solution exhibit a distinct form of chemotaxis, moving towards the highest activator concentration in the solution. Similar ability to sense and move in response to chemical gradients constitutes a vital function in simple organisms, enabling them to find food and flee from poisons.

C1.00168 Effect of Thickness on the Thermal Properties of Hydrogen Bonded Layer by Layer Assemblies, CHOONGHYUN SUNG, AJAY VIDYASAGAR, KATELIN HEARN, JODIE LUTKENHAUS, Texas A&M University — Layer by layer (LbL) assemblies have attracted a lot of attention for their functional versatility and ease of fabrication. However characterizing thermal properties, especially for ultra thin LbL assemblies, has remained a challenging topic. We have investigated the role of the film thickness on the glass transition temperature (T_g) for poly(ethylene oxide)/poly(acrylic acid) (PEO/PAA) and (PEO)/poly(methacrylic acid) (PEO/PMAA) hydrogen bonded LbL assemblies in both bulk as well as in confined thin films using modulated differential scanning calorimetry (MDSC) and temperature-controlled ellipsometry. PEO/PAA LbL assemblies exhibit a well-defined T_g , both in bulk and thin films. For films less than 100 nm thick, the T_g increased slightly as film thickness decreased. On the other hand, PEO/PMAA LbL assemblies displayed clear glass transitions only after thermal treatment, which produces anhydride crosslinks. Also, the thickness dependence on T_g was less pronounced for PEO/PMAA LbL films. It was also seen that the thermal expansion coefficient (α) increased for film thickness below 200nm. We speculate that interactions between the film and substrate likely influence the thickness-dependent T_g .

C1.00169 Layer-by-Layer Assembly of Polyelectrolyte Chains and Nanoparticles on Porous Substrates: Molecular Dynamics Simulations¹, JAN-MICHAEL CARRILLO, ANDREY DOBRYNIN, Institute of Materials Science and Department of Physics, University of Connecticut — We performed molecular dynamics simulations of a multilayer assembly of oppositely charged polyelectrolyte chains and nanoparticles on porous substrates with cylindrical pores. The film was constructed by sequential adsorption of oppositely charged species in a layer-by-layer fashion from dilute solutions. The multilayer assembly proceeds through surface overcharging after completion of each deposition step. The substrate overcharging fraction fluctuates around 0.5 for nanoparticles-polyelectrolytes systems and around 0.4 for polyelectrolytes-polyelectrolytes systems. The surface coverage increases linearly with the number of deposition steps. The rate of surface coverage increase as a function of the number of deposition steps changes when the pore is closed. The closing of the pore occurs from the pore entrance for nanoparticles-polyelectrolytes systems. In the case of polyelectrolytes-polyelectrolytes systems the pore plug is formed inside the pore and then spreads towards the pore ends.

¹NSF # DMR-1004576

C1.00170 Interaction between Brush Layers of Bottle-Brush Polyelectrolytes: Molecular Dynamics Simulations¹, DANIEL RUSSANO, Boston University, JAN-MICHAEL CARRILLO, ANDREY DOBRYNIN, University of Connecticut — Interactions between tethered layers composed of aggregan (charged bottle-brush) macromolecules are responsible for the molecular origin of the cartilage biomechanical behavior. To elucidate the role of the electrostatic forces in interaction between bottle-brush layers we have performed molecular dynamics simulations of charged and neutral bottle-brush macromolecules tethered to substrates. In the case of charged bottle-brush layers the disjoining pressure P between two brush layers in salt-free solutions increases with decreasing the distance D between substrates as $P \propto D^{-1.8}$. A stronger dependence of the disjoining pressure P on the surface separation D was observed for neutral bottle-brushes, $P \propto D^{-4.6}$, in the same interval of the disjoining pressures. These scaling laws for dependence of the disjoining pressure P on the distance D are due to bending energy of the bottle-brush macromolecules within compressed brush layers. The weaker distance dependence observed in polyelectrolyte bottle-brushes is due to interaction between counterion clouds surrounding the bottle-brush macromolecules preventing strong brush overlap.

¹NSF # DMR-1004576

C1.00171 Synthesis and Physical Behavior of Model Polymer Electrolyte Membranes for Alkaline Fuel Cells, RICK BEYER, SAMUEL PRICE, AARON JACKSON, CHRISTOPHER GOLD, Army Research Laboratory, YUESHENG YE, YOSSEF ELABD, Drexel University — Alkaline fuel cell (AFC) technology holds significant promise for portable power supplies because AFCs are very efficient at temperatures under 200 °C, but also because AFCs can use relatively inexpensive, non-noble metals (Ni, Fe, Co) as the catalyst material. Wide-spread use of the AFC has been prevented by the use of aqueous KOH liquid as the electrolyte, which is easily poisoned by the formation of K_2CO_3 . Development of an semipermeable polymeric alkali anion exchange membrane (AEM) would significantly improve the usefulness of AFCs by eliminating carbonate poisoning and the engineering problems associate with a liquid electrolyte. We have been exploring model copolymers containing phosphonium cations as candidate materials for AEMs. Recent findings on the transport properties and stability of random copolymers of styrene and p-vinylbenzyl-trimethylphosphonium chloride will be presented, as well as ongoing efforts to study the effect of polymer morphology on transport and stability in ionomers based on both phosphonium and ammonium cations.

C1.00172 In-depth Analysis of Proton Mobilities in Sulfonated Block Copolymers, MOON JEONG PARK, SUN JU LEE, SUNG YEON KIM, Department of Chemistry, Division of Advanced Materials Science (WCU), Pohang University of Science and Technology (POSTECH) — Polymer electrolytes are an important component of a wide variety of electrochemical devices such as battery, fuel cell, and chemical sensor owing to their ability to provide a pathway for ion transport between electrodes. Considerable efforts have been devoted to a subject of ion transport mechanisms in polymer electrolytes since the ion mobility in the polymer electrolytes plays a central role in determining the efficiency of the devices. In present study, we carried out an in-depth analysis of proton mobilities in model ionic block copolymers. The system of interests is a series of sulfonated poly(styrene-*b*-methylbutylene) (PSS-*b*-PMB) copolymers. Dilute solutions of PSS-*b*-PMB copolymers in methanol, which indicate highly uniform spherical ionic micelles, were examined yields. In particular, on virtue of the self-assembly nature of block copolymers, the system revealed well-defined ionic PSS domains with different thickness ranging from 3.0 to 7.8 nm. The proton transport in PSS-PMB copolymers was found to be facilitated by the decrease in the ionic domain sizes, which was rationalized by the different proximity of acid groups at the surfaces of ionic domains.

C1.00173 Functionalizing Silica Nanoparticles Designed for Improved Ion Transport, MICHAEL O'REILLY, JAMIE FORD, KAREN WINEY, University of Pennsylvania — Silica nanoparticles have been functionalized with polyethylene oxide and sulfonated polyester to synthesize improved single ion conducting polymer nanocomposites. Our motivation is to minimize ionic aggregation at room temperature by anchoring the sulfonate anion to the surface of a nanoparticle via polymer grafting. The tethered anion's mobility should be restricted, allowing the cation to conduct more easily through the short chain PEO matrix, thereby increasing the free ion content. Secondary benefits of nanoparticle dispersion include suppressed crystallinity and increased viscosity at room temperature in low molecular weight systems where ionic conductivity is elevated.

C1.00174 Effect of water uptake on morphology of polymerized ionic liquid block copolymers and random copolymers, TSEN-SHAN WANG, University of Pennsylvania, YUESHENG YE, YOSSEF ELABD, Drexel University, KAREN WINEY, University of Pennsylvania — Dynamic studies of polymer morphology probe how the physical properties of polymerized ionic liquids are affected by the environment, such as temperature or moisture. For a series of poly(methyl methacrylate-*b*-1-[2-(methacryloyloxy)ethyl]-3-Butylimidazolium X^-) block and random copolymers with hydrophilic counterions ($X^- = Br^-, HCO_3^-, OH^-$), the introduction of water vapor to the system can swell the ionic liquid block, causing enlarged hydrophilic domains and swollen channels for ion conduction. This expected expansion of ionic liquid domains in humid environments can be used to intelligently design these copolymers for use in technological applications. The effect of water vapor exposure in these imidazolium-based acrylate polymers is studied by small-angle X-ray scattering. These morphology results will be discussed alongside complementary studies of water uptake and ion conductivity.

C1.00175 Block Copolymer Exhibiting Simultaneous Electronic and Ionic Conduction, SHRAYESH PATEL, ANNA JAVIER, NITASH BALSARA, University of California, Berkeley and Lawrence Berkeley National Lab — Poly(3-hexylthiophene)-block-Poly(ethylene oxide) (P3HT-PEO) allows for the simultaneous conduction of electronic and ionic charges at the nanometer length scale needed for lithium battery electrodes. In order to study the charge transport properties of P3HT-PEO, we characterized a series of P3HT-PEO block copolymers with and without the addition of lithium bis(trifluoromethanesulfonyl) imide (LiTFSI). We specifically looked at the relationship between morphology and the transport of both electronic and ionic charges. Previously reported work has primarily focused on transport of one charged species. In particular, the results of the study shed light on the effects of LiTFSI on electronic conduction and the intrinsic electronic conduction of the P3HT microphase.

C1.00176 Discontinuous Changes in Ionic Conductivity of a Block Copolymer Electrolyte through the Order-Disorder Transition¹, ALEXANDER TERAN, RODGER YUAN, SCOTT MULLIN, NITASH BALSARA, University of California, Berkeley — Simultaneous small angle X-ray scattering and ionic conductivity measurements of a block copolymer electrolyte as it transitions from an ordered lamellar structure to a disordered phase reveal a discontinuous increase in conductivity at the phase transition. A simple framework for understanding this result is presented, incorporating both morphology factor corrections that account for constraints imposed by the geometry of the conducting phase and 'vehicular' transport of coupled polymer chains and ions.

¹This work was supported by the National Science Foundation

C1.00177 Conformation of polystyrene sulfonate (PSS) and its origin of counterion distribution¹, SHUANGJIANG LUO, QINGBO YANG, JIANG ZHAO, Institute of Chemistry, Chinese Academy of Sciences, LABORATORY OF POLYMER PHYSICS AND CHEMISTRY TEAM — The hydrodynamic radius and electric potential of single chains of polystyrene sulfonate (PSS) is studied, as a function of the molecular weight, by single molecule fluorescence techniques - fluorescence correlation spectroscopy (FCS) and photon count histogram (PCH). The results show different scaling law for low and high molecular weight. When the chain is short ($N < 300$), the scaling power index is about unity, indicating a rod-like conformation, while the index changes to 0.58 when the chain gets longer ($N > 300$), indicating a random coil conformation. The electric potential of the single PSS chains is determined and the results clearly show the decrease of the effective charge density with the increase of molecular weight. The results indicate that the charged chain has increased extent of counterions binding at longer chain length, and therefore takes different conformation.

¹Project supported by National Natural Science Foundation of China (NSFC).

C1.00178 Tuning Thermal Transitions in Dry and Hydrated Polyelectrolyte Layer by Layer Assemblies with Ionic Strength and pH, AJAY VIDYASAGAR, JODIE LUTKENHAUS, Texas A&M University — Layer-by-layer (LbL) assemblies are of significant interest for their potential applications in diverse fields such as energy and drug delivery. However, characterizing their thermal properties has remained a challenge. Here, we present the characterization of dry and of hydrated LbL films containing strong polyelectrolytes poly(diallyldimethylammonium chloride) (PDAC) and poly(styrene sulfonate) (PSS) using modulated differential scanning calorimetry (MDSC) and temperature controlled quartz crystal microbalance with dissipation (QCM-D). Our results suggest that hydrated exponentially growing (assembled from 0.25-1.25 M NaCl solutions) PDAC/PSS LbL films have glass transition temperatures (T_g 's) between 48-51 °C, while linearly growing (assembled from 0 M NaCl) films did not. Other systems explored include poly(allylamine hydrochloride)/poly(acrylic acid) (PAH/PAA) LbL assemblies, which demonstrate linear/exponential growth depending on assembly pH conditions. These results support a standing hypothesis in that linear (or exponential) growth is observed for glassy (or rubbery) LbL films. We have also demonstrated for the first time, thermal transitions in thin PDAC/PSS LbL films using QCM-D by monitoring fluctuations in film hydration and viscoelasticity by probing the film's internal structure as a function of film depth.

C1.00179 Anomalous χ for Polydisperse Polystyrene-*b*-Poly(octyl acrylate)¹, JUMI LEE, Dankook University, HYUNGJU AHN, DU YEOL RYU, Yonsei University, KWANWOO SHIN, Sogang University, JUNHAN CHO, Dankook University — We have performed small-angle neutron scattering (SANS) measurements on a disordered block copolymer from deuterated polystyrene (dPS) and self-adhesive poly(octyl acrylate) (POA) in order to elicit the effective Flory-Huggins χ , which carries the essence of the copolymer phase behavior. The sample for the measurement was prepared by blending two polydisperse dPS-*b*-POAs of different molecular weights for the purpose of adjusting the average size to a proper value. The SANS profiles for the copolymer were fitted to Leibler's scattering function for a polydisperse copolymer system described by Schulz-Zimm distribution. It was shown that the resultant χ as a function of inverse temperature has a strong entropic contribution and a weak enthalpic contribution. By adopting a simple analysis for specific interactions, it was found that the entropically dominated χ for dPS-*b*-POA arises from the steric hindrance of long alkyl side groups of POA.

C1.00180 Thermal Rupture Of Linear Polymer Chains Under Tensile Stress¹, ABHIJIT GHOSH, WON BO LEE, Dept. of Chemical & Biomolecular Engineering, Sogang University — The thermal rupture of a linear alternating copolymer fixed at one end and pulled by a constant force at the other end has been studied using molecular dynamics simulation. The dependence of the first breakage time distribution on the mass ratio of the constituent beads has been studied. The Arrhenian nature of the scission process has been confirmed and an estimate of the effective energy barrier has been made.

C1.00181 Phase Behavior of Hydrogenated Derivatives of Linear ABC Block-Random Copolymers of Styrene and Isoprene, BRYAN BECKINGHAM, RICHARD REGISTER, Princeton University — The capacity to synthesize block-random copolymers, block copolymers with one or more random copolymer blocks, allows for continuous tuning of the inter-block average segmental interaction parameter, χ , through the composition of the random copolymer without changes to system chemistry. By lithium-initiated anionic polymerization in a mixture of cyclohexane and triethylamine, we synthesized an asymmetric near-monodisperse linear ABC block-random copolymer of styrene and isoprene: $S_{30-I_{12}}-Srl_{12}$, where Srl denotes a random copolymer block with 50 wt. % styrene, and block molecular weights are 30-12-12 kg/mol. Upon complete hydrogenation, the VCH-*hI*-VCH-*hI* triblock exhibits microphase separation into a well-ordered two-domain lamellar structure with an order-disorder transition between 180-185 °C via small-angle x-ray scattering. This two-domain lamellar structure is confirmed using electron density modeling of the SAXS peak intensity and domain spacing arguments. A three-domain lamellar structure is expected in the diene-selective hydrogenated derivative, S-*hI*-S-*hI*, due to increased χ between the middle and end blocks. Additional S-*I*-*Srl* and S-*Srl*-*I* triblock copolymers are being synthesized and the effects of block sequence, end block molecular weight, and hydrogenation (S vs. VCH) on phase behavior are being explored.

C1.00182 Fast field theoretic simulation of block copolymers with the mode Monte Carlo method, YONGJOO KIM, ADAM HANNON, CAROLINE ROSS, ALFREDO ALEXANDER-KATZ, MIT — We explore the self assembly of block copolymers by using a field theoretic simulation method. Former studies on field theoretic simulation methods update the fields by Langevin-like dynamics which is a local update of the fields in real space. Our simulation method updates the mode structure (k-space) of the fields and transfers them to real space. By using a Monte Carlo scheme for updating fields, we decrease simulation time by nearly an order of magnitude. We also consider new self-learning searching strategies using this method. We tested our algorithm by simulating the phase diagram for thin films of diblock copolymers in select graphoepitaxial templates and by simulating the self-assembly of nanoparticles and block copolymers.

C1.00183 Fluctuations/Correlations in Symmetric Diblock Copolymers: Simulations and Theories, JING ZONG, DELIAN YANG, QIANG (DAVID) WANG, Department of Chemical and Biological Engineering Colorado State University — Modeling symmetric diblock copolymers as discrete Gaussian chains with soft, finite-range repulsions as commonly used in dissipative-particle dynamics simulations, we have performed fast off-lattice Monte Carlo (FOMC) simulations¹ in a canonical ensemble with variable box lengths to study the thermodynamic and structural properties of both the disordered and lamellar phases. Our FOMC results for the disordered phase are further compared, without any parameter-fitting, to those from the reference interaction site model (RISM) and the polymer reference interaction site model (PRISM) theories, as well as the Gaussian fluctuation theory, based on the same model system. Such direct comparisons unambiguously and quantitatively reveal the consequences of various theoretical approximations and the validity of these theories in describing the fluctuations/correlations in disordered diblock copolymers.

C1.00184 Transformation kinetics of BCC sphere morphology of diblock copolymer under electric field, ANDREI ZVELINDOVSKY, DUNG Q. LY, MARCO PINNA, University of Central Lancashire, UK, TAKASHI HONDA, ZEON Corp., Japan, TOSHIHIRO KAWAKATSU, Tohoku University, Japan — We performed Dynamic Self-Consistent Field simulation of BCC sphere morphology of diblock copolymers under an electric field. Several distinct kinetic pathways were determined. Different pathways were found depending on the strength of the applied electric field and orientation of the BCC domain. The fastest growing mode was found in 111 directions. Dynamic critical exponents were deduced from the simulation data. The results are compared with the previous works on different morphologies and on BCC morphology by different techniques.

C1.00185 Genistein Modified Polymer Blends for Hemodialysis Membranes¹, TENG CHANG, THEIN KYU, The University of Akron, LINDA DEFINE, THOMAS ALEXANDER, Summa Health System — A soybean-derived phytochemical called genistein was used as a modifying agent to polyether sulfone/polyvinyl pyrrolidone (PES/PVP) blends to produce multi-functional hemodialysis membranes. With the aid of phase diagrams of PES/PVP/genistein blends, asymmetric porous membranes were fabricated by coagulating in non-solvent. Both unmodified and genistein modified PES/PVP membranes were shown to be non-cytotoxic to the blood cells. Unmodified PES/PVP membranes were found to reduce reactive oxygen species (ROS) levels, whereas the genistein modified membranes exhibited suppression for ~60% of the ROS levels. Also, the genistein modified membranes revealed significant suppression of pro-inflammatory cytokines: IL-1 β , IL-6, and TNF- α . Moreover, addition of PVP to PES showed the reduced trend of platelet adhesion and then leveled off. However, the modified membranes exhibited suppression of platelet adhesion at low genistein loading, but beyond 15 wt%, the platelet adhesion level rose up.

C1.00186 Solubilization of Genistein in Poly(Ethylene Glycol) via Eutectic Crystal Melting¹, SASIWIMON BUDDHIRANON, THEIN KYU, The University of Akron — Genistein (5,7,4'-trihydroxyisoflavone) is a phytoestrogen found in soybean. It possesses various biological/pharmacological functions, e.g., tyrosine kinase inhibitory, anticarcinogenic, antioxidant, anti-inflammatory, and anti-microbial activities. However, genistein has poor water solubility and skin permeability, which have seemingly prohibited the progress to preclinical evaluation. Eutectic melting approach has been performed as a means of solubilizing genistein in poly(ethylene glycol) (PEG). Eutectic phase diagrams of blends containing genistein and PEG having three different molecular weights, i.e., 44k, 7k, and 500 g/mol, were established by means of DSC and compared with the theoretical liquidus and solidus lines, calculated self-consistently by taking into consideration all interactions including amorphous-amorphous, crystal-amorphous, amorphous-crystal, and crystal-crystal interactions. The eutectic temperatures were found to decrease with decreasing molecular weight of PEG. Guided by the phase diagram, it was found that genistein can be dissolved in PEG500 up to ~7 wt% at room temperature. More importantly, the solubility of genistein in PEG can be improved to meet the end-use criteria of the PEG/genistein mixtures.

C1.00187 Topographically Uniform but Chemically Heterogeneous Nanostructures by Nanoimprinting Demixed Polymer blends, ZHEN WANG, DAE-UP AHN, YIFU DING, University of Colorado at Boulder — This study examined the coarsening process of phase-separated polymer blends under physical confinement. The physical confinement was realized by nanoimprinting phase-separated PS (polystyrene)/PMMA (polymethylmethacrylate) blend thin films. The influences of the imprint temperature, blend composition and film thickness on the morphological evolutions were systematically investigated. All the patterned PS/PMMA films showed topographically uniform structure after nano-imprinting, regardless of the surface roughness caused by the initial stage of the phase separation. The morphologies, or the phase structures, of the PS/PMMA patterns were found to be dictated by the preferential wetting of PMMA onto silicon oxide surface. The interplay of this preferential wetting and the domain coalescence resulted in a range of complex and unique encapsulated structures. Furthermore, by inhibiting such preferential wetting of a blend component using a neutralized surface, non-capsulated morphology can be achieved.

C1.00188 Properties of PET/PLA Electrospun Blends¹, KEVIN LI, PEGGY CEBE, Tufts University — Electrospun membranes were fabricated from poly(ethylene terephthalate), PET, co-spun with poly(lactic acid), PLA. The PLA contained 2% of the D-isomer, which served to limit the overall degree of crystallinity. Membranes were deposited from blended solutions of PET/PLA in hexafluoroisopropanol. The PET/PLA composition ranged from 0/100, 75/25, 50/50, 25/75, and 100/0. Electrospun membranes were made using either a static flat plate or a rotating wheel as the counter electrode, yielding unoriented mats or highly oriented tapes, respectively. We report on our investigation of the crystallinity, crystal perfection, and mechanical properties of these materials using differential scanning calorimetry, wide and small angle X-ray scattering, and dynamic mechanical analysis. In particular, we study the ability of one blend component (PET) to crystallize in the presence of existing crystals of the second blend component (PLA) which crystallizes first and at a lower temperature than PET.

¹Support from the National Science Foundation, Polymers Program, under DMR-0602473 is acknowledged.

C1.00189 Reactive Poly(Amic Acid)/ Poly(Glycidyl Methacrylate-r-Poly(ethylene Glycol) Methyl Ether Methacrylate) Blends as Gas Permeation Membranes, MICHAEL BEAULIEU, JAMES WATKINS, University of Massachusetts Amherst, Polymer Science and Engineering Department — Polymers containing polar moieties, such as ether groups show an affinity for acidic gases, such as CO₂ due to dipole-quadrupole interactions. Polymer blends in which one of the components is poly(ethylene glycol) (PEG) have been studied extensively in literature as a CO₂/light gas permeation membrane, but due to the crystallization and poor mechanical properties have been difficult to incorporate PEG above 60wt%. In this study, a series of random copolymers containing both glycidyl methacrylate and poly(ethylene glycol) methyl ether methacrylate in different ratios are blended with a poly(amic acid) prepolymer made from 4, 4'-oxydianiline and pyromellitic dianhydride to create gas permeation membranes. By using a reactive blend PEG loadings above 70% have been realized with sufficient mechanical properties, and since the side chain on the PEGMA is short these blends do not suffer from crystallization.

C1.00190 Evaluation of Flame Retardancy, Mechanical Properties, and Bicompatibility of HIPS/PBrS Blends¹, LIUDI ZHANG, SEONGCHAN PACK, Stony Brook University, CORALIE BEAULIEU, Polytech'Nantes, France, MIRIAM RAFAILOVICH, Stony Brook University — Our research focused on thermal and mechanical properties of High Impact Polystyrene (HIPS) system. Brominated Polystyrene (PBrS) was incorporated to replace halogenated Flame Retardant (DB) in HIPS blends. We have previously shown that ditallow functionalized clays could become nearly universal class of compatibilizers [si-2006]. Here we show that a new type of surface with Resorcinol bis (biphenyl phosphate) (RDP) could achieve the same goals. We demonstrate the strong compatibilization on the highly immiscible systems of HIPS/PBrS. Furthermore, we show that this system also works well, when a third component, Antimony Trioxide (AO) is added to provide flame retardant properties. Tensile test, dynamic mechanical analysis, and UL-94 flame test were applied to investigate this system. We found that the amount of AO used in flame retardant formulations could be minimized by addition of RDP clay, which could also increase some mechanical properties that Cloisite 20A clay couldn't. Besides, we evaluated the toxicity of Cloisite 20A and RDP clay. Langmuir-Blodgett trough and atomic force microscopy were used to make and check monolayer clay. Confocal Microscopy was used to assess cell morphology. The results showed RDP clay has potential for biomaterial applications.

¹Supported by NSF-DMR-MRSEC

C1.00191 PVDF/PVIm polymer blend films for fuel cell membranes¹, WENWEN HUANG, Tufts University, MENG ZHAO, FAN YANG, Rochester Institute of Technology, LORNE FAROVITCH, Gallaudet University, PARISA HAGHIGHI, LEONARD MACISCO, TYLER SWOB, THOMAS SMITH, Rochester Institute of Technology, PEGGY CEBE, Tufts University — We report the preparation and characterization of binary blend films of poly(vinylidene fluoride) (PVDF) and poly(1-ethyl-3-vinylimidazolium trifluoromethylsulfonimide) (PVIm+TFSI-). The potential utility of such materials in proton exchange membrane fuel cells is of particular interest. Thin PVDF/ PVIm+TFSI- films were fabricated from solutions of dimethyl formamide by doctor blading. The nature of the PVDF crystalline polymorph and degree of crystallinity was evaluated as a function of the volume fraction of imidazolium polymer and thermal treatment. The morphology, thermal and mechanical characteristics of the blend films was studied by wide angle X-ray diffraction, thermogravimetry, calorimetry, and Fourier transform infrared spectroscopy. In these materials, conditions such as choice of solvent, drying conditions, and thermal treatment affect the crystal phase, crystallite size, and degree of crystallinity of PVDF as well as the distribution of PVIm+TFSI-. The beta phase of PVDF crystals dominates in as-cast films, while the alpha phase is observed after cooling from the melt. PVDF imparts mechanical strength and chemical stability to the composite films, and because of its high crystal melting point ($T_m > 160$ C), serves to improve the high temperature stability of resulting films.

¹Support was provided from the NSF grant DMR 0906455.

C1.00192 Polydispersity Effects on Scaling Behavior of Polymers Grafted on Surfaces of Varying Curvature, PAUL DODD, ARTHI JAYARAMAN, University of Colorado at Boulder — Nanoparticle assembly can be tuned by grafting nanoparticle surface with polymers and in turn manipulating the interactions between the particles and medium. Despite past studies showing the importance of graft molecular weight on effective inter-particle interactions in monodisperse polymer grafted nanoparticles, and evidence of non-trivial polydispersity effects in systems containing polymers grafted on flat surfaces, not much work has been done to explore polydispersity effects in polymer grafted nanoparticles. Using Monte Carlo simulations we elucidate how polydispersity (PDI) in grafted chain lengths affects chain conformations, and in turn the scaling behavior in systems of polymer grafted particles, as a function of grafting density and particle size. With increasing PDI the scaling exponent of the grafted chains at intermediate and high grafting density approaches that of a single chain grafted on the nanoparticle of same size. This is because longer chains in polydisperse systems have to stretch less due to reduced crowding from neighboring shorter chains as compared to monodisperse system. Also, due to reduced crowding effects at high PDI, in densely grafted particles the differences in chain conformations arising from varying curvature becomes negligible.

C1.00193 Size Controlled Polymer Coated Nanoparticles as Efficient Compatibilizers for Polymer Blends, T. KWON, T. KIM, F. ALI, D.J. KANG, B.J. KIM, KAIST, J. BANG, Korea Univ., W.B. LEE, Sogang Univ. — Polymer-coated gold nanoparticles (Au) with controlled size and surface were successfully synthesized and applied to tailor the structures and properties of polytriphenylamine (PTPA) and polystyrene (PS) blends. Two different polymer-coated Au NPs with sizes of 5.9 nm (Au1) and 20.7 nm (Au2) were designed to be thermally stable above 200 °C and neutral to both PS and PTPA phases. Hence, both Au NPs localize at the PS/PTPA interface and function as compatibilizers in the PS/PTPA blend. To show the compatibilizing effect of the particles, the morphological behaviors of PS/PTPA blends containing different particle volume fraction of Au NPs were observed using cross-sectional TEM, and for quantitative analysis, the size distribution of PTPA droplets in the PS matrix was obtained for each sample. The number-average droplet diameter (D_n) of the PTPA domain in the blend was dramatically reduced from 1.4 μ m to 500 nm at a small volume fraction of 1.0 vol% Au1. The same trend of decreasing D_n was also observed with the addition of larger Au2, but a higher volume fraction was required to obtain the same amount of reduction in the PTPA droplet size. To demonstrate the effectiveness of Au NPs as compatibilizers, PS-b-PTPA block copolymers were also synthesized and used as compatibilizers.

C1.00194 Remote fluorescence-based sensing of elastic thin-film elastic moduli, AH YOUNG JEE, University of Illinois at Urbana Champaign, MINYUNG LEE, Ewha Womans University — The fluorescence lifetime of dyes embedded within thin polymer films is sensitive to the local mechanical environment. Here we show that this enables direct measurement of elastic properties of thin films and small samples whose investigation by conventional macroscopic mechanical characterization would not be possible. The specific example of poly(ethylene oxide) (PEO) and its nanocomposite thin films is highlighted. The method is also validated by comparison to a family of other polymers of known macroscopic moduli. Being simple, rapid, and reliable, we propose that this analysis can in principle apply generally to a broad class of soft materials and other polymer multilayer films.

C1.00195 Macroscopic Ordering of CNTs in a Liquid Crystalline Polymer Nano-Composite by Shearing , P. KALAKONDA, S. SARKAR, G.S. IANNACCHIONE, WPI, E. GOMBOS, G.S. HOONJAN, G. GEORGIEV, Assumption College, P. CEBE, Tufts U. — We present a series of complimentary experiments exploring the macroscopic alignment of carbon nanotubes (CNTs) in a liquid crystalline polymer (isotactic polypropylene - *iPP*) nano-composites as a function of temperature, shear, and CNT concentration. The phase behavior of *iPP*+CNT, studied by Modulated Differential Scanning Calorimetry, revealed the evolution of the α -monoclinic transition and its dynamics, which are dependent on CNT content and thermal treatment. These results indicate that the CNT nucleates crystal formation from the melt. Spectroscopic ellipsometry reveals a change in the optical constants that are connected to the ordering of CNTs when the *iPP*+CNT is sheared. This anisotropy is also exhibited in measurements of the electrical and thermal conductivities parallel and perpendicular to the shear direction. The amount of order induced into the dispersed CNTs is relatively low for these low concentration samples (< 5 wt%).

C1.00196 Self-assembly Nano-filled Polymer Blends in a Photovoltaic Thin-film Device , DI XU, JOSEPH ORTIZ, DILIP GERSAPPE, Department of Materials Science and Engineering, Stony Brook University — Engineering heterodyne junction solar cells requires a well-defined morphology of the photoactive polymers and the PCBM conductors such that maximum current reaches the electrodes with minimal resistive scattering. One possible method for accomplishing this may be to use polymer phase segregation in combination with the nanoparticles' natural segregation to the interfaces. In this manner, large-scale devices can be formed using self-assembly methods, rather than fixed methods. We have used Molecular Dynamics simulation to predict the morphology of polymer blends and determine which combination of factors would yield the optimal morphology that would contact the electrodes, while producing the largest number of interfaces. Secondly, we were also able to determine the conditions that would cause the particles to segregate and template along the interfaces, which would provide direct conductivity to the electrodes. Using thin film and bulk structures and by manipulating particle size, the attraction between the particle and the polymer component, and the amount of filler within the material, we can explore the formation of cheaper, more effective and efficient networks.

C1.00198 ABSTRACT WITHDRAWN —

C1.00199 ABSTRACT WITHDRAWN —

C1.00200 Transformative Skin: From Anti-biofouling to Reliable Power Cable¹ , XUANHE ZHAO, Soft Active Materials Laboratory, Duke University — This talk will discuss the fundamental physics and potential applications of transformative skin, an electroactive polymer system recently developed at Duke Soft Active Materials Laboratory (SAMs Lab). The working mechanism of the transformative skin is based on the creasing-to-cratering instability in polymers under electrical voltages. The instability can induce failures in power cables and polymer capacitors. By suppressing the instability, one can greatly enhance the reliability and energy density of the cables and capacitors. Surprisingly, the same instability can generate a rich variety of on-demand patterns on polymer surfaces in response to voltages. The feature size of the pattern can be tuned from millimeter to nanometer. The pattern formation and surface deformation can dynamically debond biofilms formed on polymer surfaces, giving extraordinary capability of active antibiofouling.

¹Funding for this research was provided by the NSF's Research Triangle MRSEC (DMR-1121107) and Pratt School of Engineering at Duke University.

C1.00201 Molecular Dynamics Simulation of Diffusivity and Mobility of Ionic Charge Carriers in Model Battery Polymers , SARA WATERS, JON BROWN, New Mexico Institute of Mining and Technology, AMALIE FRISCHKNECHT, Sandia National Labs, JOHN MCCOY, New Mexico Institute of Mining and Technology — Molecular dynamics simulations of poly(ethylene-co-acrylic acid) monomers doped with Lithium ions were conducted using LAMMPS. The drift velocity of the ions resulting from a range of static electric fields were used to compute the ionic mobility. The frequency dependent mobility was also studied by using oscillatory electric fields.

C1.00202 Hypersonic properties of polymer films and multi-layers , JAMES SHARP, PAUL WALKER, ERIC YOUNG, University of Nottingham, VITALI GOUSSEV, Université du Maine, ANDREY AKIMOV, ANTHONY KENT, University of Nottingham — Picosecond acoustic measurements were performed on ultrathin films of polymers and thin film polymer multilayers supported on silicon (Si) substrates using a state of the art THz acoustic technique. In these experiments, a high power laser is used to excite picosecond duration strain pulses in an aluminium film evaporated on the reverse side of the Si substrate. These strain pulses then propagate through the substrate and interact with the polymer film/multi-layer. Vibrations in the film are detected optically using the same (pump-probe) beam which is passed through an optical delay line and reflected from the surface of the polymer film/multi-layer. Ultrathin films of polystyrene and a styrene-butadiene-styrene block copolymer were found to exhibit quantized closed-pipe organ like modes in the 0- 50 GHz regime that were attributed to vibrations of the entire polymer film. Thin film polystyrene/polyvinylpyrrolidone multilayer structures were found to display folded phonon dispersion curves that are characteristic of super-lattice structures. These structures have potential applications in GHz and THz optical switching and biosensing applications.

C1.00203 Local stress in thin polystyrene films , BEKELE GURMESSA, ANDREW CROLL, Department of Physics, North Dakota State University — Thin polymer films have received significant attention due to the deviation of material properties from bulk values. Part of the difficulty in describing the underlying physics is an incomplete understanding of how internal and surface stresses affect thin films. Here we exploit "wrinkling" to create a simple model system in which local stress can be easily tuned. When a thin polymer film bound to an elastic substrate is subjected to a compressive stress the film buckles out of plane. Due to the curvature at each crest and trough of the wrinkles, there arise local stresses in the polymer film. The curvature of the wrinkles is controlled by the modulus of the film and substrate, the film thickness and the applied stress, allowing us to apply an arbitrary local stress. After wrinkling, films are annealed above their glass transition temperature which allows flow and relaxes any stress. The local stress is then transferred to that of a thickness variation in the thin film. Importantly the flow of thin polymer films can be modeled using the well established lubrication theory, resulting in a simple scaling model. Our model allows us to investigate the response of thin films where deviations from bulk behavior are expected, as well as more complex thin diblock polymer films.

C1.00204 Cracking in thin films of colloidal particles on elastomeric substrates , MICHAEL SMITH, JAMES SHARP, University of Nottingham — The drying of thin colloidal films of particles is a common industrial problem (e.g paint drying, ceramic coatings). An often undesirable side effect is the appearance of cracks. As the liquid in a suspension evaporates, particles are forced into contact both with each other and the substrate, forming a fully wetted film. Under carefully controlled conditions the observed cracks grow orthogonal to the drying front, spaced at regular intervals along it. In this work we investigated the role of the substrate in constraining the film. Atomic force microscopy, was used to image the particle arrangements on the top and bottom surfaces of films, dried on liquid and glass substrates. We present convincing evidence that the interface prevents particle rearrangements at the bottom of the film, leading to a mismatch strain between upper and lower surfaces of the film which appears to drive cracking. We show that when the modulus of the substrate becomes comparable to the stresses measured in the films, the crack spacing is significantly altered. We also show that cracks do not form on liquid substrates. These combined experiments highlight the importance of substrate constraint in the crack formation mechanism.

C1.00205 Reaction Kinetics at the Interface between Immiscible Polymers: Competition between Diffusivity and Reactivity¹, GUANGCUI YUAN, MINGJI WANG, CHARLES C. HAN, Institute of Chemistry, Chinese Academy of Sciences — Reactive blending processes at the interface between deuterated bisphenol-A polycarbonate (*d*PC) and amorphous polyamide (*a*PA) bilayer film were characterized by Fourier transform infrared (FTIR) and neutron reflectivity (NR). It was found that the aminolysis occurred during thermal annealing at 160 – 180 °C, inducing simultaneously scission of *d*PC chains and formation of *d*PC-*a*PA copolymer chains. Two or three stages of reaction kinetics as a function of time were probed by FTIR, depending on the competition between chain diffusivity and chemical reactivity for sample annealing at different temperatures. The late stage was controlled by potential barrier arising from previously formed copolymer, and it appeared earlier when annealing at 160 °C than that at higher temperatures. A phenomenon of transient interfacial instability which origin was ascribed to the mismatching in mobility of the polymer chains on either side of the interface was observed by NR. The copolymer once formed, remains localized at the interface and inhibits the diffusion of other reactive polymer chains still present in the bulk phase toward the interface.

C1.00206 Thermal Behaviors of PS Thin Films on Grafted PS Layer with Varied Grafting Density, HOYEON LEE, SUNGMIN PARK, YONGHOON LEE, EUNYOUNG CHOI, DU YEOL RYU¹, Yonsei University, DAVID M. TROMBLY, VENKAT GANESAN², University of Texas — The thermal behavior properties (especially glass transition) are the key parameters for determining the mechanical properties of polymer system. In thin film system, the interfacial interactions at the substrate/polymer and polymer/air influence the transition behavior. In this study, we investigated the inter-relationship between the interfacial interactions arising from grafted polymer layers and the glass transition behavior (T_g) of thin polymer films with same chemical identity. We controlled grafting density of hydroxyl-terminated polystyrene (HO-PS). For polymer chains on the brushes of the same chemical identity with high density, the autophobic dewetting behavior can be attributed to the entropic effects of the polymer and the grafted polymer chains.

C1.00207 Instability of Surface-initiated ATRP Polyelectrolyte Brushes in Aqueous Environments, CASEY GALVIN, ERICH BAIN, Department of Chemical Engineering, North Carolina State University, Raleigh, NC, EVREN OZCAM, Department of Chemical Engineering, University of California - Berkeley, Berkeley, CA, ADAM HENKE, Department of Chemistry, Columbia University, New York, NY, JIRI SROGL, Institute of Chemistry and Biochemistry, Prague, Czech Republic, JAN GENZER, Department of Chemical Engineering, North Carolina State University, Raleigh, NC — Surface-bound macromolecules have been produced using a number of polymerization schemes, including free-radical polymerization (FRP), reversible addition-fragmentation chain transfer polymerization (RAFT), and atom transfer radical polymerization (ATRP). In order to prove useful in any technology, the tethered polymer chains must remain stable in a variety of environments over relatively long timescales. We have investigated the dependence of the pH and ionic strength of aqueous solutions on the stability of surface-bound polyelectrolyte chains (strong and weak) with varying molecular weights and grafting densities. Our findings suggest that the ester bond in the most common form of ATRP surface initiator (BMPUS) will hydrolyze over a broad pH range, leading to chain degrafting. We further compare the stability of a BMPUS derivative which has had the ester bond replaced with an amide bond, as well as a free-radical initiator containing only aliphatic carbons. Results related to the effect of chain tension on brush stability will also be presented. Finally, we discuss the likely mechanism of degrafting, and ways in which to improve stability.

C1.00208 Lateral phase separation of mixed polymer brushes on planar and spherical surfaces, REID VAN LEHN, ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology — A mixed polymer brush consists of two (or more) polymer species grafted to a surface at a high density, inducing the polymers to highly stretch to maximize favorable solvent interactions while minimizing polymer overlap. The enthalpic and entropic interactions between the different polymers give rise to lateral phase behavior on the surface. Understanding this phase separation behavior is interesting for applications in nanotemplating and controlled protein adsorption. In this work, we present a novel theoretical model to quickly predict lateral phase separated morphologies of mixed polymer brushes on planar, cylindrical and spherical surfaces. The model combines a Flory-Huggins model for enthalpic interactions between the polymer components with an Alexander-de Gennes model for the entropy of the brush layers. When there is a length difference between the polymer components, these two interactions along with the conformational entropy of the system lead to a range of morphologies including stripes, dimples, mixing, and complete phase separation. The computational efficiency of this model allows for phase diagrams to be generated with great accuracy. The results of our model thus allow for the fast prediction of lateral morphologies on different geometries.

C1.00209 Photonic multilayer sensors from photo-crosslinkable polymer films, MARIA CHIAPPELLI, RYAN C. HAYWARD, University of Massachusetts Amherst — Photo-crosslinkable copolymers containing pendent benzophenone (BP) groups provide a convenient means to fabricate multilayer polymer films. We describe the preparation of alternating multilayers of photo-crosslinkable poly(N-isopropylacrylamide) (PNIPAM), a water-swellaable, temperature sensitive polymer, and poly(para-methylstyrene) (PpMS), a non-swellaable polymer, by sequential spin-coating and photo-crosslinking. This route provides well-defined layered structures with minimal interfacial broadening between layers and uniformity of thickness from layer to layer as determined by dynamic secondary ion mass spectrometry (d-SIMS). Appropriate choices of layer thicknesses yield 1-D photonic gel sensors. The reflectance peak is shifted through the visible spectrum upon swelling or de-swelling of the PNIPAM layers in water, providing an accessible means for colorimetric temperature sensing.

C1.00210 Template polymerization using a controlled reaction scheme, JAN GENZER, PREETA DATTA, NC State University — We employ a Monte Carlo simulation scheme based on the bond fluctuation model to simulate template polymerization via controlled scheme (i.e., termination and chain transfer reactions are neglected) involving co-polymerization of free monomers and monomers bound to a template that consists of four linear substrates with equispaced sites occupied by bound monomers. A new macromolecule is initiated by activation of an initiator; any monomer (free or bound) that is within the reaction distance (nearest neighbors) of the initiator can be incorporated into the chain. As the chain propagates, it adds new monomers to the macromolecule. Those monomers can either be bulk (i.e. free) monomers or those that are placed on the predefined template. We analyze the effect of the number of spacing of the bound monomers on the composition and monomer distribution in the resultant co-polymer. Our results reveal that the larger the total number of bound monomers in the system and the more dense spacing, the greater is the likelihood of those getting incorporated in the growing chains. In addition, a greater number of bound monomers on the linear template promotes polymerization of most/all of the bound monomers to form a linear array attached to the template.

C1.00211 Wrinkling of Inhomogeneously Strained Thin Polymer Films, YU-CHENG CHEN, ALFRED J. CROSBY, University of Massachusetts - Amherst — Surface wrinkles have received much attention recently due to their potential importance in applications. Wrinkles occur due to a mechanical instability when sufficient strain applied to an incompressible thin film. For wrinkles made with a polymer film supported on a soft elastomer, it has been well-established that the amplitude is directly proportional to the wavelength and the square root of the applied strain. Importantly, the wavelength is largely insensitive to the applied strain and defined by the properties of the film and substrate. These dependences have been confirmed with ideal substrates where the global strain is homogeneously distributed, but the influence of strain inhomogeneity has not been considered previously. Will regions that wrinkle first lead to strain localization, or will the system try to homogenize strain globally? We use a recently developed adhesion contact line method to prepare polystyrene thin films with periodic regions of different wrinkle amplitudes, hence strains, on soft substrates. We find that surfaces with multiple wrinkle amplitudes will approach a single amplitude globally upon the application of sufficiently large strains. We derive relationships to describe this process.

C1.00212 Comparison of surface mobility on low and high molecular weight glasses, MARK EDIGER, University of Wisconsin-Madison, KEEWOOK PAENG, Columbia University, LEI ZHU, Merck & Co., LIAN YU, University of Wisconsin-Madison — The glass transition temperature of thin polymer films and the related issue of mobility at glass surfaces have attracted considerable interest in the last twenty years. We have recently conducted experiments on both polymeric and low molecular weight glass formers that provide information about mobility near the free surface. For several polymers, measurements of dye reorientation on freestanding films show a fast population that can be consistently assigned to the near-surface region. For indomethacin (a low molecular weight glass former), we have directly measured surface diffusion by following the decay of imprinted gratings of different periods. For both high and low molecular weight glassformers, we observed enhanced mobility near the free surface (by factors up to 10^4 and 10^7 , respectively) relative to the bulk dynamics. In both cases, surface mobility has a substantially weaker temperature dependence than bulk mobility near the bulk T_g .

C1.00213 Molecular Bottlebrushes as Tensile Machines for Probing Specific Bonds under Tension, YUANCHAO LI, Department of Chemistry, UNC at Chapel Hill, ALPER NESE, Department of Chemistry, Carnegie Mellon University, NATALIA LEBEDEVA, TYLER DAVIS, Department of Chemistry, UNC at Chapel Hill, KRZYSZTOF MATYJASZEWSKI, Department of Chemistry, Carnegie Mellon University, SERGEI SHEIKO, Department of Chemistry, UNC at Chapel Hill — Significant tension on the order of 1 nN is self-generated along the backbone of bottlebrush macromolecules due to steric repulsion between densely grafted side chains. The intrinsic tension is amplified upon adsorption of bottlebrush molecules onto a substrate and increases with grafting density, side chain length, and strength of adhesion of the substrate. This allows us to employ these molecular bottlebrushes as miniature tensile machines to probe the mechanochemistry of specific bonds. For this purpose, bottlebrush macromolecules with a disulfide linker in the middle of the backbone were synthesized by atom transfer radical polymerization (ATRP). Two processes, (i) homolytic cleavage of disulfide and (ii) scission of disulfide due to reduction by dithiothreitol were monitored through molecular imaging by atomic force microscope (AFM). In both cases, the corresponding rate constants increase exponentially with mechanical tension along the disulfide bond. Moreover, the reduction rate at zero force is found to be significantly lower than that in bulk solution, which suggests an acidic composition of the water surface with $\text{pH}=3.7$. This opens a new application of brush-like macromolecules as surface pH sensors.

C1.00214 Simultaneous Vapor Deposition and Phase Separation of Polymer Films, RAN TAO, MITCHELL ANTHAMATTEN, University of Rochester — Initiated chemical vapor deposition (iCVD) is a solventless, free radical technique used predominately to deposit homogeneous films of linear and crosslinked polymers directly from gas phase feeds. The major goal of this research is to force and arrest phase separation of deposited species by co-depositing non-reactive molecules (porogens) with reactive monomers and crosslinkers. We introduce these species during iCVD to force and quench polymer induced phase separation (PIPS) during film growth as a step toward tunable pore-size, density, and morphology. Polymerization, crosslinking and PIPS are intended to occur simultaneously on the substrate, resulting in a vitrified microstructure. Cahn-Hilliard theory predicts that the length scale of phase separation depends on the polymer-porogen interaction energy, the polymerization rate and the species' mobility. A series of films were grown by varying deposition rate, porogen type, and reagent flowrates. Crosslinkers were introduced to limit the growth of phase separated domains and to provide mechanical support during porogen removal. To elucidate how phase separation competes with polymerization and film growth, deposited films were studied using a combination of electron microscopy, profilometry and spectroscopic techniques.

C1.00215 Controlled viscous and viscoelastic instabilities of polystyrene film on topographically patterned poly(methyl methacrylate), ZHENG ZHANG, DAE UP AHN, YIFU DING, University of Colorado at Boulder — We report the spontaneous morphological evolution of polystyrene (PS) films spin-cast on pre-patterned poly(methyl methacrylate) (PMMA) substrates, at annealing temperatures above the glass transition temperatures of both polymers. The influences of the molecular weights and spin-cast volume of PS on the morphological development were systematically examined. Both were found to modulate the instabilities and result in distinctive morphologies. In particular, thick PS films that fully covered the topographically patterned PMMA substrate would dewet through nucleation and growth of randomly formed holes. However, the rupture of thinner PS films were manifested through formation of arrays of non-axisymmetrically confined threads and subsequent capillary instabilities of these threads. Low and high molecular weights of PS gave rise to two different modes of thin-thread instabilities, identified as varicose and peristaltic mode, respectively.

C1.00216 Novel Synthesis of Surface-Grafted Radical Initiator With Improved Stability and Yield, ERICH BAIN, KEITH DAWES, Department of Chemical and Biomolecular Engineering, North Carolina State University, XINFANG HU, CHRISTOPHER GORMAN, Department of Chemistry, North Carolina State University, JIRI SROGL, Institute of Chemistry & Biochemistry, Academy of Sciences of the Czech Republic, JAN GENZER, Department of Chemical and Biomolecular Engineering, North Carolina State University — Polymers grafted at interfaces are attractive for applications including antifouling coatings, biologically functionalized materials, and responsive surfaces. The “grafting from” approach to form densely packed brushes involves functionalizing a substrate with initiating moieties, and carrying out polymerization, e.g., surface-initiated free-radical polymerization (SI-FRP). Azo initiators for SI-FRP are commonly synthesized by a low-yielding route requiring large amounts of potassium cyanide. Those initiators are linked to a substrate by means of an ester group, rendering tethered polymers susceptible to degrafting by hydrolysis. We present a novel synthetic route to an asymmetric azo initiator, whose yield is nearly double that of previous syntheses. Cyanide usage in the new method is reduced by 72 percent. The spacer linking the initiator to a substrate contains only carbon-carbon bonds, resulting in stable brushes. Results are demonstrated for SI-FRP as well as reverse ATRP and RAFT.

C1.00217 Impact of adhesion on thermal boundary conductance at organic-metal interface¹, Y. JIN, C. SHAO, J. KIEFFER, K.P. PIPE, M. SHTEIN, University of Michigan, Ann Arbor — The thermal boundary conductance (TBC) at the interfaces between a small molecular organic semiconductor (copper phthalocyanine CuPc) and several metals (Al, Mg, Au, Ag) has been measured using the 3- ω method at room temperature. The TBC increases with the interfacial bonding strength of the two dissimilar materials. Our measurements of adhesion between the metal and organic films agree qualitatively with the distances between the metal surface and CuPc molecules measured by Stadtmüller et al. [1]. In contrast to the trend observed for organic-metal interfaces, the TBC of organic-organic interfaces (e.g. CuPc/C60) is insensitive to interface bonding due to the large overlap between materials' phonon density of states. Conventional acoustic and diffuse mismatch models fail to describe the observed trend in TBC. Modifying the acoustic mismatch model (AMM) with an effective spring constant describing interfacial bonding, an accurate trend is obtained. To better understand the influence of the molecular structure on TBC, we performed molecular dynamics simulations of interfacial heat transfer and interfacial bonding. These simulations reveal quantitative discrepancies in the simulated TBC relative to that predicted by the modified AMM model in the regime of poor interfacial adhesion, which we attribute to a greater contribution of anharmonicity. The bonding strength for vacuum deposited films is ~ 2 GPa for CuPc/Ag and CuPc/Au, well within the regime in which anharmonic processes play an important role in interface thermal transport. C1.00218 Ion Correlations at an Electrified Liquid/Liquid Interface, NOUAMANE LAANAIT, MIROSLAV MIHAYLOV, BINYANG HOU, HAO YU, University of Illinois at Chicago, PETR VANYSEK, Northern Illinois University, BINHUA LIN, MATI MERON, CARS, University of Chicago, ILAN BENJAMIN, University of California at Santa Cruz, MARK SCHLOSSMAN, University of Illinois at Chicago — Ion correlations have been suggested as the underlying mechanism of a number of counterintuitive phenomena such as like-charge attraction. Here we present the first molecular-level tests of density profiles predicted by an ion correlations model. Synchrotron x-ray reflectivity reveals ion condensation at the liquid/liquid interface, when polarized with an electric field.¹ Tuning the density of this ionic layer allows for a detailed study of ion correlations as a function of the Coulomb coupling strength in the system. We propose a parameter-free density functional theory that describes ion-ion correlations within a weighted density approximation and explicitly treats ion-solvent effects through a solvent interaction potential simulated by molecular dynamics. Agreement with the x-ray reflectivity and the interfacial excess charge is found over the entire experimental range of ion-ion correlation energies up to nearly $4 k_B T$. These results suggest that ion correlations in the electrical double layer can be accurately described by mapping to a simple Coulomb system, in this case a one-component plasma.

C1.00219 Fluctuations of one-dimensional interface in the directed polymer formulation: role of a finite interface width¹, ELISABETH AGORITSAS, DPMC-MaNEP, University of Geneva (Switzerland), VIVIEN LECOMTE, Laboratoire Probabilités et Modèles Aléatoires, Universités Paris VI and Paris VII (France), THIERRY GIAMARCHI, DPMC-MaNEP, University of Geneva (Switzerland) — An elastic interface living in a disordered medium always exhibits geometrical fluctuations, characterized in particular by the distribution of its relative displacements as a function of the lengthscale r , whose variance defines the interface roughness $B(r)$. Those fluctuations are the manifestation of the probability and associated effective free-energy of the different configurations of the interface, in presence of disorder and at finite temperature. Focusing specifically on the one-dimensional interface, we use the exact mapping of the static interface on the directed polymer in random medium in order to explore both analytically and numerically the role of a finite interface width $\xi > 0$, assuming a short-range elasticity and a random-bond quenched disorder. Confirming the existence of a low-temperature regime where the finite microscopic width plays a crucial role, as predicted by previous Gaussian-Variational-Method predictions [*Phys.Rev.B* 82, 184207 (2010)], we propose a coherent picture of the physics at stake, compatible both with numerical computations and generic scaling arguments.

C1.00220 Wang-Landau simulations of polymer adsorption on diluted surfaces¹, PAULO MARTINS², Instituto de Física, Universidade Federal de Mato Grosso, Cuiabá, MT, Brazil, THOMAS VOGEL, DAVID LANDAU, Center for Simulation Physics, University of Georgia, Athens, GA, USA — We consider a single linear lattice homopolymer in three dimensions that interacts with a diluted planar surface. A fraction p of the total number of the sites on the substrate is attractive, while the remaining $1 - p$ remains neutral. Our focus is on the conformational transitions the polymer can experience under different environmental conditions, for instance, the surface dilution and the strength of the substrate attraction, compared to the intensity of the monomer-monomer interactions. To get insights on the phase diagram we have performed extensive Monte Carlo simulations, by using the Wang-Landau sampling, for different values of the surface attraction ϵ and the concentration of attractive sites p , specially near the surface percolation threshold p_c .

C1.00221 The Behavior of Water at the Interface with Polystyrene¹, SELEMON BEKELE, Tennessee Tech University, MESFIN TSIGE, The University of Akron — Solid-aqueous interfaces are of great importance in many industrial applications ranging from oil recovery to biotechnology. The behavior of interfacial water differs drastically from that of the bulk liquid and strongly depends on the atomistic details of the surface itself. Molecular dynamics simulations have been used extensively to study the structure and dynamics of the interface between a polymeric thin film and water. Using a fully atomistic molecular dynamics simulation, we have examined the structure and dynamics of water and atactic polystyrene (aPS) chains near the aPS-water interface. In this talk, we present results for the contact angle of water and the interfacial surface tension at the aPS-water interface.

C1.00222 MD study of polymer melts confined in thin films and nanopores, HENDRIK MEYER, Institut Charles Sadron, CNRS Strasbourg, France — The structure of chains is strongly affected if they are confined to films or pores smaller than the radius of gyration [1,2]. We report new molecular dynamics simulations of polymer melts confined between structureless walls comparing the thin film and pore confinement. It is shown that the form factor which is measured in scattering experiments is affected in a subtle way by the corrections to ideality [2]. The strong confinement reduces the number of overlapping chains and thus reduces entanglements. This leads to a clear acceleration in thin film confinement. For pore confinement, an acceleration is also found for intermediate pore diameters, but for extreme confinement, chains are segregated and they will block each other. [1] H. Meyer et al *Eur. Phys. J. Sp.Top.* 141 (2007) 167. [2] N. Lee et al *EPL* 93 (2011) 48002.

C1.00223 Adsorption of Derivatized Dextran Polyelectrolytes onto Nanocrystalline Cellulose¹, ALAN ESKER, JOSHUA KITTLE, XIAOSONG DU, Virginia Tech, Department of Chemistry (0212), Blacksburg, VA 24061, FENG JIANG, MAREN ROMAN, Virginia Tech, Department of Wood Science and Forest Products (0323), Blacksburg, VA 24061, HOLGER WONDRAKZEK, ANDREAS KOSCHELLA, THOMAS HEINZE, Center of Excellence for Polysaccharide Research, Friedrich Schiller University of Jena, Humboldtstrasse 10, Jena, 07743 Germany — The adsorption of a series of cationically derivatized dextran polyelectrolytes onto anionic nanocrystalline cellulose (ANC) has been studied using quartz crystal microbalance with dissipation monitoring (QCM-D) and surface plasmon resonance (SPR). Samples of dimethylaminoethyl-dextran (DMAE-Dex), diethylaminoethyl-dextran (DEAE-Dex), and diisopropylaminoethyl-dextran (DIAE-Dex) had degrees of substitution (DS) ranging from 0.06-0.90. DMAE-Dex, DEAE-Dex, and DIAE-Dex all showed decreasing adsorption onto ANC and decreasing water content of the adsorbed film with increasing DS. Additionally, DEAE-Dex films adsorbed onto ANC had lower water contents than DMAE-Dex films with the same DS. Interestingly, QCM-D results for DIAE-Dex with high DS revealed mass loss, while SPR results clearly showed DIAE-Dex adsorbed onto ANC. These observations were consistent with dehydration of the ANC substrate. This study indicates that by controlling the DS and hydrophobic content of the polyelectrolyte, the water content of the film can be tailored.

C1.00224 ABSTRACT WITHDRAWN —

C1.00225 Engineering Novel Thermoreversible Hydrogels with Applications in Regenerative Medicine and Delivery Systems, DIVYA BHATNAGAR, State University of New York at Stony Brook, NIKHIL MEHANDRU, Harvard University, JAPBANI NANDA, W. Tresper Clarke High School, YICHENG SUN, Mission San Jose High School, MIRIAM RAFAILOVCH, State University of New York at Stony Brook — A major concern in regenerative medicine is the increasing need for effective biomaterials for scaffolds, cell delivery vehicles, and drug delivery systems. In this study, we engineered a thermo reversible composite hydrogel of hard, medium and soft stiffness by blending Pluronic F127 (F127) with biocompatible hyaluronic acid (HA) and bioadhesive gelatin. Rheological analysis demonstrated that hard gel produced the highest elastic modulus in both HA-F127 and Gelatin-F127 hydrogels. It was found that increasing the concentration of HA and gelatin increased the critical solution temperature (CST) at which the solution gels. Glucose and sodium chloride, additives commonly found within the body, were analyzed to have minimal effect on the mechanical properties but caused a decrease in CST. Adult human dermal fibroblasts were plated on the composite hydrogels to demonstrate scaffolding and cell delivery. The highest growth was observed in hard Gelatin-F127 hydrogels. Cells also showed the best response to hard Gelatin-F127 gels in shear modulation force microscopy and were found to be homogeneously distributed in the three-dimensional matrix of the gels. Our novel composite hydrogel displayed synergistic properties of its individual components and had the necessary characteristics for effective use in the medical setting: mechanical strength, cell adhesion and viability.

C1.00226 Synchrotron SAXS and WAXD Studies of Cellulose Nascent Crystals: Experiment and Structure Analysis, YING SU, CHRISTIAN BURGER, BENJAMIN S. HSIAO, BENJAMIN CHU, Stony Brook University, STONY BROOK UNIVERSITY TEAM — Cellulose nascent crystals extracted from biomass (wood pulp, jute and cotton) by combined chemical and mechanical treatments are low cost, environmentally friendly and high performance materials to form the barrier layer in ultrafiltration membranes. This research project is aimed at using the synchrotron X-ray scattering methods to characterize the nascent crystalline nanofibers in different formats. The SAXS (Small Angle X-ray Scattering) data of cellulose nanofiber suspensions was analyzed and the polydisperse ribbon model with rectangular cross section fit the data well. The 2D and 3D simulations of WAXD (Wide Angle X-ray Diffraction) pattern of jute cellulose fibers solved the contents ratio of cellulose I-alpha and I-beta and Hermans' orientation parameter P2.
